Lightning charge moment changes deduced from highly sensitive ELF magnetic field observations in Southeast Asia

*Yasuhide Hobara[1], Amir Izzani Mohamed[2], Chandima Gomes[3], Wan Ismail Bin Ibrahim[2], Zulkurnain Abdul-Malek[4], Syahrun Nizam[5], Michael Stock[6], Kazuo Shiokawa[7], Hiroshi Kikuchi[1], Takuo T. Tsuda[1]

1. Graduate School of Information and Engineering Department of Communication Engineering and Informatics, The University of Electro-Communications, 2. University of Malaysia Pahang Pekan, Malaysia, 3. University of the Witwatersrand Johannesburg, South Africa, 4. Universiti Teknologi Malaysia Johor Bahru, Malaysia, 5. University Malaysia Perlis Perlis, Malaysia, 6. EarthNetworks, Inc. Germantown, USA, 7. Nagoya University, Nagoya, Japan

In 2018 we established the new permanent observation site in Pahang, Malaysia and started continuous recording of horizontal magnetic waveforms in the Extremely Low Frequency (ELF) band by using high sensitivity search coils. We carried out test measurements at four different locations in Malay peninsula and found out that Pahang is the most electromagnetically quiet place for measurement. Initial results indicate a very good performance registering clear waveforms from lightning discharges. We successfully estimated individual lightning charge moment changes (CMCs) with a small lower bound (~few Ckm) with a lightning location data from total lightning network indicative of deducing spatial and temporal dependence of lightning with CMC over Southeast Asia region.

[M-IS27] Atmospheric electricity: Applications toward natural disaster mitigation

convener:Yasuhide Hobara(Graduate School of Information and Engineering Department of Communication Engineering and Informatics, The University of Electro-Communications), Masashi Kamogawa(Department of Physics, Tokyo Gakugei University), Chairperson:Yasuhide Hobara

In recent years, various types of natural disasters caused by climate change, earthquake, etc. occur frequently in the world. In 2018 heavy precipitation in various regions of Japan and the earthquakes in Hokkaido and Indonesiaproduced/greater human and economic/damage.
In 2019JpGU Atmospheric Electricity (AE) session, invited experts are going to introduce their scientific challenges in order to monitor, predict and mitigate natural disasters by using knowledge of the atmospheric electricity. For example, monitoring and prediction of extreme weather by the latest weather radar system and lightning observations, electromagnetic phenomena prior to earthquakes, etc. will be included. We certainly welcome contributed papers regarding all topics on atmospheric electricityincluding global circuit, ion and fair weather electricity, thunderstorm electrification, lightning physics, lightning and meteorology, electrical effects of thunderstorms on the middle and upper atmosphere such as transient luminous events and high energy phenomena, lightning protection, terrestrial electromagnetic environment and so on.

Discussion

Earthquake precursory electromagnetic phenoma : Summary and prospective

*Masashi Hayakawa[1]

1. Hayakawa Institute of Seismo Electromagnetics.Co. LTD. University of Electro-Communications venture company

This paper describes the overview of electromagnetic phenomena mainly prior to an earthquake (EQ)(so-colled Seismo Electromagnetics). Initially this paper will report on the history of seismo-electromagnetics, findings for the 1995 Kobe EQ and the 2011 Tohoku EQ, recent statistical results, latest achievement (lithosphere-atomosphere-ionosphere coupling), prospective, etc.

Detection of lower ionospheric anomaly preceding earthquake using nonlinear autoregressive neural network

*Kakeru Matsuki[1], Hayato Iibuchi[1], Hendy Santosa[3], Yasuhide Hobara[1], Michael A Balikhin[2]

1. The University of Electro-Communications , 2. University of Sheffield, 3. University of Bengkulu

It is possible to monitor the state of the lower ionosphere by observing the VLF (Very Low Frequency) transmitter radio waves with a frequency band of 10 to 50 kHz propagating between the Earth and the ionosphere. In recent years, NARX - NN (Nonlinear Auto Regressive with eXogenous Input - Neural Network) has been applied as a highly accurate modeling and prediction method of temporal variation of VLF band transmitter radio wave amplitude. As a result, we obtain the extremely high prediction accuracy of cross correlation coefficient 0.9 or more between predicted and observed amplitude. Meanwhile, anomalies in the VLF band transmitter radio wave amplitude have been reported indicating the disturbance of the lower ionosphere at night from a week to few days before large earthquakes. Since the accuracy of anomaly detection is not high yet, this study aims to improve the detection accuracy of the lower ionospheric disturbance by analyzing the nighttime amplitude of the VLF band transmission wave using NARX - NN. By specifying the external factors that affect the lower ionospheric disturbance preceding the earthquakes and statistically investigating the difference between observed and predicted values of the VLF amplitude, we contribute to understand occurrence mechaism of lower seismo ionospheric anomalies.

Analysis of multipoint measurements of plasma turbulence

*Michael A Balikhin[1], Simon N Walker[1]

1. University of Sheffield

The presentation is devoted to the review of advanced methods for the analysis of multipoint measurements of plasma turbulence. Both time and frequency domain methods are reviewed. Using examples of in situ spacecraft observations of plasma turbulence it is shown how the system science based approaches can be used to identify linear and nonlinear dynamical processes within the turbulence.

In strong electric fields of thunderclouds and lightning, electrons are accelerated to relativistic energy, and emit bremsstrahlung gamma rays which are observed by space bourne, airbourne, and on-ground experiments. To reveal the mechanism and condition where the electron acceleration takes place, we have been performing the Gamma-Ray Observation of Winter Thunderclouds (GROWTH) experiments in coastal areas of Japan Sea since 2007. In 2015, we started multi-point observation campaigns with portable radiation detectors in Ishikawa and Niigata Prefectures. So far, we have revealed characteristics of long-lasting gamma-ray bursts from thunderclouds (long bursts: Tsuchiya et al. 2007), and photonuclear reacitons in the atmosphere triggered by terrestrial gamma-ray flashes coincident with lightning discharges (short bursts: Enoto et al. 2017). We are expanding the number of detectors to observe more events of such long and short bursts with multiple detectors. in the 2018-2019 winter season, we operated more than 20 radiation detectors. We are also promoting joint-observation campaigns with low-frequency radio and atmospheric electric-field measurements (Wada et al. 2018). We succeeded in the first simultaneous detection of long and short burst events in Kanazawa. Because the short-burst-triggering LF pulse took place within 1 km from the position where the long burst ceased, it is suggested that the strong electric field responsible for the long burst assisted the short burst. We will report the progress of the GROWTH project and this simultaneous detection event.

Electromagnetic and stroke current observations on rocket-triggered lightning

*Takeshi Morimoto[1], Shinya Kurokawa[1], Yoshitaka Nakamura[2], Kazuo Yamamoto[3]

1. Kindai University, 2. Kobe City College of Technology, 3. Chubu University

Rocket-triggered lightning is the most effective technique for artificial triggering lightning. It involves launching a small rocket trailing a thin grounded wire toward an overhead charged cloud. This technique is incredibly favorable for various lightning observations for example earth currents, leader developments, related electromagnetic and high-energy radiations etc. because a lightning strike is induced at the desired location. In Japan, a number of rocket-triggered lightning experiments were succeeded in winter thunderstorm seasons.

During the winter of 2017-18, the authors conducted a rocket-triggered lightning experiment in Noto Peninsula, facing to the Sea of Japan in Ishikawa Prefecture. A conductive wire was connected to the rocket and launched at faster than 100 m/s. A rope was also connected to prevent the rocket from rising above an altitude of 200 m. The rod-type ground electrode with a diameter of 1 cm was buried at a depth of 1 m.

We were successful in triggering lightning stroke at 1352:28h December 29, 2017. The two types of Rogowski coils to measure lightning current, hi-speed video cameras, RF antennas in VHF and LF bands were equipped around the striking point. The corona current and e-field were measured at about the distance of 50 m from the point. The measured lightning current was reached to -12 kA and continued for 290 ms. The recorded images with high time resolutions against recoded RF radiations and the current will be demonstrated in this talk.

[M-GI34] Marine Manganese Minerals

convener:Akira Usui(Marine Core Research Center, Kochi University), Yoshio Takahashi(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Katsuhiko Suzuki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Takashi Ito(Faculty of Education, Ibaraki University), Chairperson:takashi ito(Ibaraki Univ.), Yoshio Takahashi(東京大学), Katsuhiko Suzuki(JAMSTEC)

Marine manganese deposits include nodules and crusts of massive iron-manganese oxide aggregates associated with useful metals. The deposits are known as potential resources of cobalt, copper, nickel, rare earth elements, platinum, and tellurium. However, the controlling parameters on the regional and temporal variations in chemical and mineralogical composition have not been clarified yet. In this session, various factors in the growth of manganese oxides, enrichment and circulation of metals, paleoenvironment, and formation age of manganese deposits will be discussed from viewpoints of geology, mineralogy, paleocean sciences, geochemistry, microbiology, and sea floor engineering.

We attempted to apply the method of Shima-Shima-gaku (lamina stratigraphy named by prof. S. Kawakami) on the secular variations in growth structure, chemical and mineralogical properties between the growth columns of the hydrogenetic ferromanganese deposit. The critera for describing each bands or zones based on the macroscopic (=physical) properties are not always consistant with chronological correlations or may not match with mineral/chemical composition. Our microscopic characterization using optical microscope, XRF mapping, XRD, acid-leach, micro-focus X-ray CT proved a possibility of separating local and regional sources of each mineral particle or element which is closely associated the environments of eposition.

Manganese is the third most abundant metallic element, after iron and titanium, in the Earth’ s crust, and ferromanganese minerals are sensitive to changes in redox condition. Assessing the formation and preservation of ferromanganese minerals is important for understanding the global marine cycles of manganese and numerous associated trace elements. The most extensive manganese mineral deposits occur on abyssal plains, including those below open-ocean gyres. However, the extent of ferromanganese minerals buried in subseafloor sediments remains unclear. During the Integrated Ocean Drilling Program (IODP) Expedition 329, we drilled the entire sedimentary sequence at 6 sites in the ultra-oligotrophic region of the South Pacific Gyre (SPG), where dissolved O_2 and aerobic microbial communities are present from the seafloor to the sediment-basement interface [1]. By using high-resolution imaging techniques, we found abundant (10^8-10^9 particles cm^{-3}) micrometer-scale ferromanganese mineral particles (Mn-microparticles) in the oxic pelagic clays of the South Pacific Gyre [2]. Furthermore, we established microparticle separation technique by the combined use of density concentration and flowcytometer/particles sorting techniques. Major and trace element compositional analyses revealed that iron and manganese were the major components of Mn-microparticles, while they also contained rare-earth elements. From the number of Mn-microparticles per unit volume of sediment and the global distribution of oxic pelagic clays, we estimated the number of Mn-microparticles to be 1.5-8.8 $\times 10^{28}$ particles, which accounted for 1.28-7.62 Tt of manganese. This estimate is at least 2 orders of magnitude larger than the manganese budget for manganese nodules and manganese crusts on the seafloor. Along with the examination of manganese input, formation, and preservation, this study provides new insights into the global budget of metallic elements in the abundant Mn-microparticles present in deep subseafloor environments.

Nuclear Science and Engineering Center, Japan Atomic Energy Agency, 6. Graduate School of Science, The University of Tokyo

Ferromanganese crusts (FMCs) are abyssal benthic chemical sediments that consist mainly of Fe and Mn oxide and hydroxide minerals, enriched with trace and precious metals. Due to their similar physicochemical properties, the elements zirconium (Zr) and hafnium (Hf), which are concentrated in FMCs, have a theoretically uniform ratio (Zr/Hf), which ratio is found in numerous systems. However, recent advances in analytical techniques have allowed observation of significant differences in the fractionation of these elements between seawater (Zr/Hf~45-350; Firdaus et al. 2011) and FMCs (Zr/Hf~57-88; Schmidt et al., 2014). In this study, we conducted adsorption experiments and XAFS analyses to clarify the concentrations and fractionation mechanisms of Zr-Hf in FMCs using synthesized minerals (Ferrihydrite and δ-MnO_2), radio-Zr and Hf tracers, and natural samples.

Six FMCs were collected from the Takuyo-Daigo and Ryusei seamounts, at water depths of from 950 m to 3000 m, using a ROV equipped with a live video camera and manipulators. The near surface layers (less than 1 mm) of all the FMCs were analyzed with XAFS and ICP-MS for Zr, Hf and other elements, and with XRD for mineral composition. Radiotracers were produced using the RIKEN AVF cyclotron for adsorption and co-precipitation experiments. Appropriate amounts of these tracers were added to 0.7 M NaCl solutions containing desferrioxamine B (DFOB) to obtain some Zr and Hf concentrations of solutions. The speciations of these elements in said solutions were confirmed by ESI-TOF-MS. Synthesized Ferrihydrite or δ-MnO_2 was added to the solutions and stirred for three hours at a pH of 8. In addition, Ferrihydrite or δ-MnO_2 was synthesized in said solutions. The activities of radio tracers in the filtered solutions were measured using a Ge detector. The adsorption/co-precipitation amounts to the solid phase were calculated using the differences in the radioactivity of the solution before and after filtration.

The major mineral composition of Fe and Mn in the FMCs did not vary significantly with the water depth of these seamounts. The concentrations of Zr and Hf increased with depth, and their ratios were totally fractionated from those of the seawater (Firdaus et al., 2011). Hf was more enriched in all FMCs than was Zr. The observed Zr chemical states in the FMCs were mainly coprecipitation with Ferrihydrite and coprecipitation with d-MnO2. In our adsorption experiments, the largest adsorption rate was observed in Hf to δ-MnO_2, followed in order by Zr to δ-MnO_2, Hf to Ferrihydrite and Zr to Ferrihydrite. The partition coefficients (K_D values) were calculated using the concentration ranges of Zr and Hf in seawater, where it was clear that Hf adsorbed more on both. Even though complexation rates estimated by RI-TLC were considered, there was no change in the adsorption behaviors in these experiments. For these samples, we found that the bond lengths between Zr-O and Hf-O in the first shells were shortened when they were incorporated into the oxides, with Hf-O becoming more shortened compared to Zr-O. The DFT calculations showed that Zr and Hf adsorbs on Fe and Mn oxides as bidentate-mono nuclear and bidentate-binuclear structures. The calculation results for the binding energies and bond orders of Zr and Hf to minerals gave a reasonable explanation of the fractionation mechanism for Zr-Hf pairs in FMCs.

Isotope fractionation of Mo-like elements during adsorption to ferromanganese oxides

*Masato Tanaka[1], Yoshio Takahashi[1]

1. Graduate School of Science, The University of Tokyo

A large mass-dependent isotope fractionation between seawater and ferromanganese oxides was observed, where lighter isotopes of Mo were preferentially incorporated into ferromanganese oxides. The large isotopic fractionation of molybdenum (Mo) is most likely caused by geometrical change from tetrahedral (Td) to distorted octahedral (Oh) during adsorption on manganese oxides based on X-ray absorption fine structure (XAFS) spectroscopy. The coordination number relates to its ionic radius. Thus, the elements which have similar ionic radius to Mo are expected to show the similar phenomena to Mo, i.e. the large isotope fractionation. Germanium (Ge) and Vanadium (V) can be candidate of such elements because they have similar ionic radius to Mo (Ge(IV): r= 0.53 Å, V(V): r=0.54 Å, and Mo(VI): r=0.59 Åfor 6-hold coordination). In this study, we examine the adsorption structure of Ge and V on Fe-/Mn-(oxyhydr)oxides by XAFS spectroscopy. Furthermore, the isotope fractionation during adsorption on the minerals is estimated by quantum chemical calculations.

XAFS analysis indicated that the adsorbed species of Ge on Fe- and Mn-(oxyhydr)oxides have Td geometry. On the other hand, the adsorbed structure of V on ferrihydrite is Td whereas that on δ-MnO_2 is distorted Oh. This trend of V in adsorbed species is similar to that of Mo. The geometries of hydrated species of Ge and V are Td. Thus, it is expected that a large V isotope fractionation occur during adsorption on Mn oxide, but a small fractionation in the case of Ge. In fact, a large isotope fractionation for V and a small isotope fractionation for Ge were estimated by quantum chemical calculations. This finding indicates that the requirement to show a Mo like large isotope fractionation during adsorption is not only an appropriate ionic radius. Recently, we found that two elemental properties of Mo(VI), namely d^0 electronic configuration and appropriate ionic radius, lead to the large isotope fractionation. In fact, V(V) possesses d^0 electronic configuration, but Ge(IV) does not. Tungsten (W)(VI) also satisfies the two properties and shows a large isotope fractionation during adsorption on Fe-/Mn-(oxyhydr)oxides. Thus, the elements which have the two elemental properties (Mo-like elements) can exhibit a Mo like large isotope fractionation during ferromanganese oxides.

Distinct distribution trends of arsenate and molybdate in marine ferromanganese nodules

*Shitong Yang[1], Soichiro Uesugi[1], Haibo Qin[1], Akira Usui[2], Yoshio Takahashi[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2. Geology Department, Kochi University

Marine ferromanganese nodules or crusts with the hydrogenetic (HG), diagenetic (DG) and hydrothermal (HT) origins, are important sedimentary substrates for various elements such as lead (Pb), zinc (Zn), cobalt (Co), cerium (Ce), molybdenum (Mo), tungsten (W), arsenic (As), antimony (Sb), tellurium (Te), and etc. However, the distribution behaviors and host phases of tetrahedral arsenate (AsO_4^{3-}) and molybdate (MoO_4^{2-}) oxyanions in the ferromanganese oxides are far from understood. Herein, we combine sequential extraction approach and spectroscopic analyses to explore the mineralogical components of HG ferromanganese nodules collected from the Pacific Ocean and the speciation of arsenate and molybdate therein.

X-ray diffraction (XRD), X-ray absorption near-edge structure (XANES) and extended X-ray absorption fine structure (EXAFS) spectroscopy analyses indicate that the predominant manganese and iron phases were vernadite (δ-MnO_2) and ferrihydrite, respectively. According to the sequential extraction examination, both As and Mo are associated with the iron (oxyhydr)oxide phases. As K-edge EXAFS analyses indicate the immobilization of arsenate by ferrihydrite via forming inner-sphere complexes in double corner-shared form. This result is consistent with the sequential extraction data. However, Mo L_3-edge XANES analyses suggest the adsorption of molybdate on vernadite surfaces via the edge-shared complexation, being contrary to the conclusion derived from the sequential extraction results. This inconsistency reveals the unreliability of sequential extraction approach to verify the host phase of trace elements in complicated natural samples due to the potential occurrence of re-adsorption risk.

According to the spectroscopic analyses, chemical binding (ΔG_{chem}) rather than the previously proposed coulombic interaction (ΔG_{coul}) is the predominant driving force for the retention of arsenate and molybdate by HG ferromanganese nodules. The disparate distribution trends of arsenate and molybdate are attributed to their different intrinsic properties (e.g., averaged dissociation constants of conjugate acids) and the diverse properties (e.g., surface site densify, adsorption equilibrium constant and crystalline structure) of ferrihydrite and vernadite. These research findings will help assess the geochemical behaviors and environmental fate of trace elements in marine environment.

Ferromanganese nodules are spherical material mainly composed of manganese, iron, and other transition metal (oxyhydro)oxides, which are widely distributed on the deep seafloor around the world [1]. It has been widely accepted that ferromanganese nodules can be classified into three types: hydrogenetic, diagenetic and hydrothermal types [1]. Among them, hydrogenetic nodules are composed of Fe–Mn (oxyhydr)oxides that precipitated from seawater and thus, this type of nodules can be expected to provide proxy paleoceanographic records [2, 3, 4, 5].
In this study, we investigated mineralogy and geochemistry of ferromanganese nodules sampled from the Minamitorishima EEZ for the purpose of elucidating formation environment of the nodules. Both the ferromanganese mineral phase and bulk chemical compositions clearly show that these nodules are hydrogenetic in origin. Based on X-ray CT and micro X-ray mapping analyses, oxide layer of the nodules can be subdivided into five layers [6. 7]. Although ferromanganese mineral is common to all the oxide layers, we found that Mn/Fe and Ni content systematically changed from inner layer to outer layer. The result implies that bottom water of the Minamitorishima EEZ has gradually been oxygenated toward the present.

[M-GI35] Development of computational sciences on planetary formation, evolution and surface environment

convener:Yoshi-Yuki Hayashi(Department of Planetology/CPS, Graduate School of Science, Kobe University), Masaki Ogawa(Division of General Systems Studies, Graduate School of Arts and Sciences, University of Tokyo), Shigeru Ida(Earth-Life Science Institute, Tokyo Institute of Technology), Kanya Kusano(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Hiroki Kashimura

Computer simulations have been recognized as one of the fundamental tools in understanding planetary formation, evolution and diversity of surface environment. However, is may be notified that the continuous development of computational abilities in recent years does not seem to be well utilized in improving numerical simulations in those fields; computational efficiency has been improved by 6 orders of magnitude compared from the early 90's, many of our simulations do not seem to catch up qualitatively and quantitatively such improvement. We propose here in this session to ask those who are interested in computational sciences of various fields not only of planetary formation and evolution but also of earth and planetary sciences in general to join. The aim is to discuss various scientific and technical aspects of our numerical simulations to improve our skills to fully utilize those development of computational resources that is realized or will be realized in near future as "K" to "post-K".

Discussion

Simulation Studies of Solar Activities as a Cause of Solar-Terrestrial Environment Variation

*Kanya Kusano[1], Hideyuki Hotta[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Faculty of Science and Engineering, Chiba University

Solar activity is the main driver of disturbance of solar-terrestrial environment, and an extreme space weather disaster caused by a giant solar eruption is a potential risk to modern society. The prediction is just a way to mitigate the space weather disaster. In this study, in order to improve our understanding and predictability of the solar-terrestrial environmental variation, we are developing the various types of simulations of solar activities. In this paper, we will report the recent progress of the following two topics. The first topic is for the comprehensive simulation of the whole solar convection zone. Since comprehensive calculation covering whole convection zone has not been carried out ever due to significant temporal and spatial differences between deep and surface layers, our understanding for connection between the solar surface and the deep solar interior has been limited. Here we succeed in carrying out such a calculation for the first time. The results show that the surface region has an unexpectedly small effect on the deep convection zone. The second topic is for the physics-based prediction of imminent giant solar flares. The results indicate that the non-linear force-free modeling based on the vector magnetic field data can be a powerful tool to predict when, where and how large giant solar flares will occur.

Development of a global non-hydrostatic Martian atmospheric model and its high-resolution simulation

*Hiroki Kashimura[1], Hisashi Yashiro[2], Seiya Nishizawa[2], Hirofumi Tomita[2], Kensuke Nakajima[3], Masaki Ishiwatari[4], Yoshiyuki O. Takahashi[1], Yoshi-Yuki Hayashi[1]

1. Kobe University/Center for Planetary Science, 2. RIKEN Center for Computational Science, 3. Kyushu University, 4. Hokkaido University

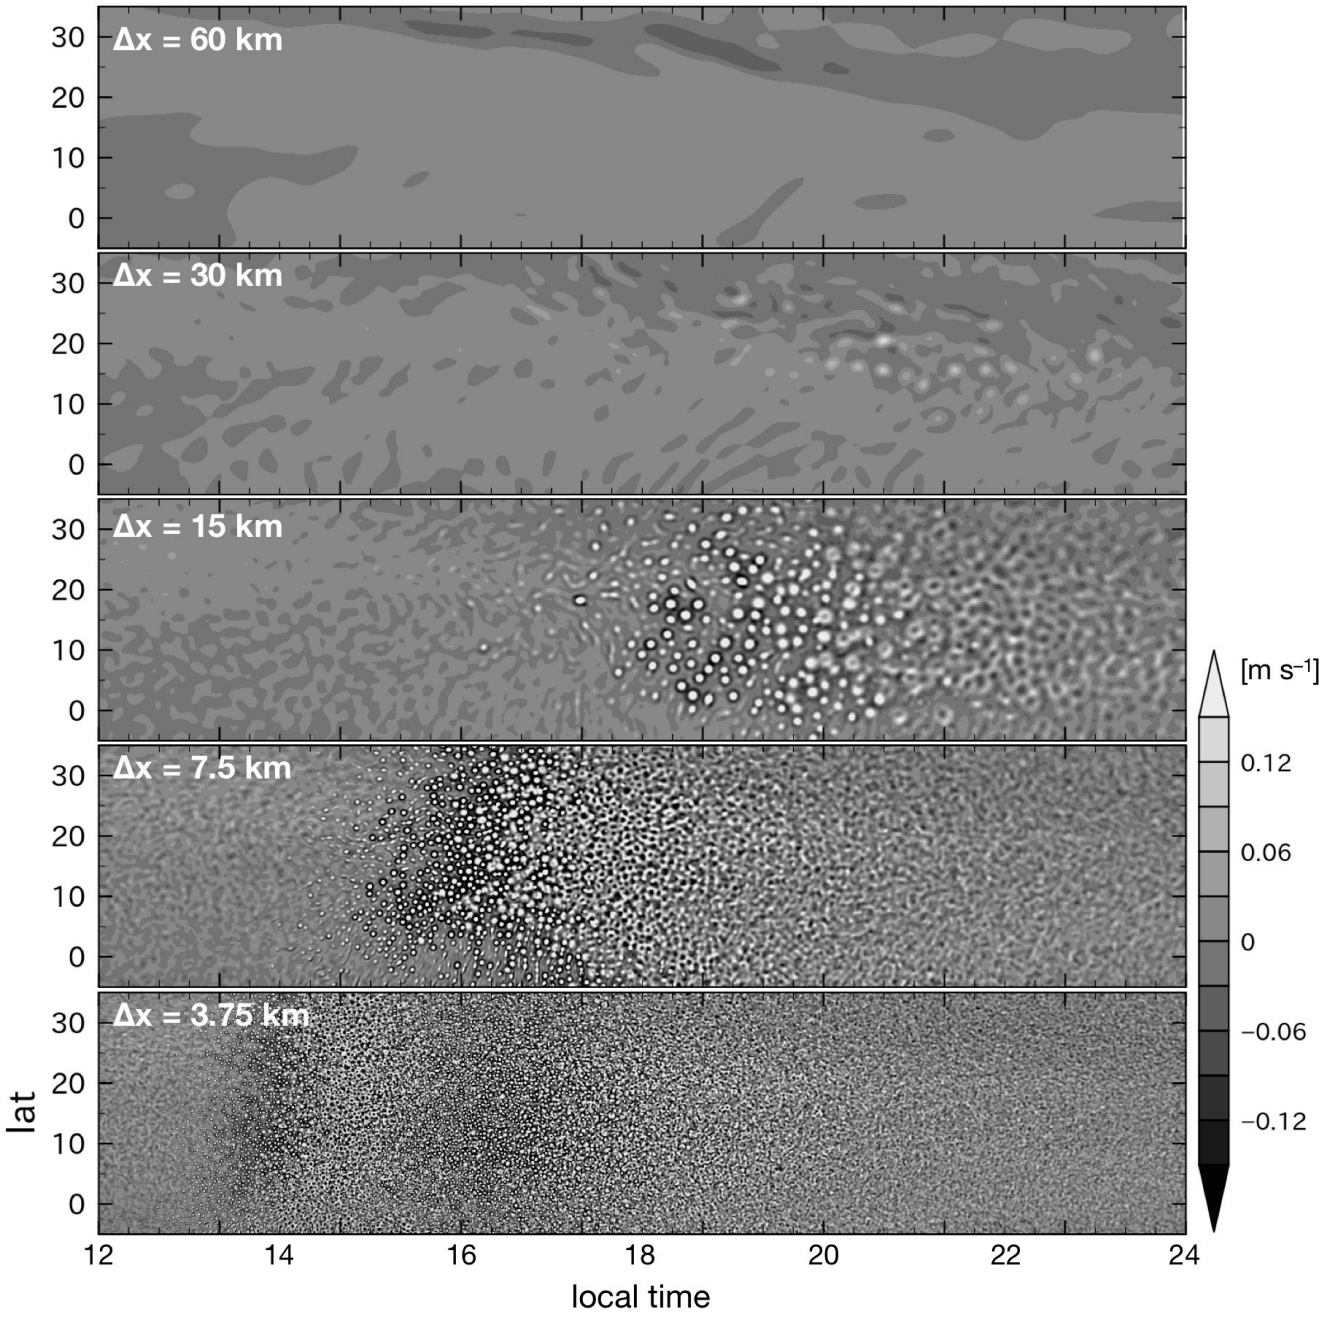
Scales of atmospheric motions in Earth range from a few meter scale to the planetary scale, and multi-scale phenomena interact with each other. This is a reason for promoting an atmospheric simulation with higher resolution. The situation must be the same in other planets such as Mars. In the Martian atmosphere, dust storms in various scales—from dust devils of tens to hundreds of meter scales, to local dust storm of several tens of kilometer scale, and to global dust storm—have been observed. However, interactions between these scales are unknown. In addition, since Mars has a thin atmosphere and no ocean, the temperature difference between day and night is large and vertical convection should play an essential role in the Martian meteorology, but it is also unknown. To investigate these mysteries, global atmospheric simulations with horizontal resolution as high as few kilometers are required. Additionally, in order to explicitly simulate vertical convection, it is necessary to solve the governing equations without assuming the hydrostatic balance.

We are developing a non-hydrostatic global Martian atmospheric model (Martian SCALE-GM) which is suitable for large-scale parallel computation, targeting to perform high-resolution simulations described above on the post-K computer. SCALE-GM (http://scale.aics.riken.jp/) is being developed by using the dynamical core of NICAM (Tomita and Satoh, 2005; Satoh et al., 2008; Satoh et al., 2014), a non-hydrostatic model using a finite volume method in the icosahedral grid systems (Tomita et al., 2001, 2002), that has been used for simulations of Earth atmosphere and climate, and by aiming at sharing of physical process modules with the regional model (SCALE-RM) and application to other planetary atmospheres. We are developing Martian SCALE-GM by incorporating constants and physical process modules of the Martian atmosphere. The Martian physical modules are taken from DCPAM (https://www.gfd-dennou.org/library/dcpam/), an existing pan-planetary atmospheric general circulation model (GCM). DCPAM is a traditional, hydrostatic GCM using a spectral method for horizontal discretization.

In this study, we ported a Martian atmospheric radiation model (Forget et al., 1999) and a soil model from DCPAM to SCALE-GM and performed a test of temperature evolution in a vertical 1D-atmosphere and soil. The atmosphere model has 100 layers (Δz = 1 km), and distribution of dust is fixed with 0.2 optical depth. The soil model has 18 layers. Soil's heat capacity and thermal conductivity are set to 9.7×10^5 [J K^{-1} kg^{-1}] and 0.076 [W m^{-1} K^{-1}], respectively. Surface albedo is fixed at 0.2. For the calculation of surface fluxes and vertical diffusion, BH91B95 (Beljaars & Holstang, 1991; Beljaars, 1995) and MY2.5 (Mellor & Yamada, 1982) are used, respectively. The initial condition is the 200 K constant temperature atmosphere and soil. We have confirmed that both models (SCALE-GM and DCPAM) show almost the same temperature evolution.

Next, we performed 3D calculations under a Mars-like condition in 7 different horizontal resolutions and checked the dependence of the numerical solutions on the horizontal resolution. Horizontal grid intervals are $240\times(1/2)^n$ [km] (n = 0, 1, 2, 3, 4, 5, 6); i.e., 3.75 km at minimum. The horizontal diffusion

©2019. Japan Geoscience Union. All Right Reserved.



representing turbulent mixing in sub-grid scales is given in the 3rd order Laplacian with the relaxation time for the shortest scale given by $100\times(1/2)^n$ [s]. The atmosphere is divided into 36 layers, which are concentrated near the surface. To avoid wave reflections at the model top, a sponge layer represented by 1st order Laplacian is set above 40 km altitude; the relaxation time for the shortest scale is given by $3600\times(1/4)^n$ [s] except for the case of $\Delta x = 3.75$ km, in which 3 s is used. The 4th order Runge-Kutta method is used for time-integration with a time step of $360\times(1/2)^n$ [s]. The surface albedo is set to 0.5. Neither topography nor condensation processes are included.

Numerical solutions showed that vertical convections due to diurnal solar heating did not appear clearly in the cases with Δx larger than 15 km, whereas they appeared in higher resolution cases. Furthermore, it was confirmed that the horizontal scale and occurrence local-time of the vertical convection are highly dependent on the horizontal resolution at least in this range.

(Figure: Horizontal resolution dependence of vertical wind. Snapshots at 2 km altitude after 30 days from the spring equinox of the Northern hemisphere.)

Numerical simulations on the collision, adhesion, and growth of dust particles in turbulent gas in a protoplanetary disk

*Takashi Ishihara[1], Kohei Hamabata[2], Yoshiki Sakurai[2], Masayuki Umemura[3]

1. Graduate School of Environmental and Life Science, Okayama University, 2. Graduate School of Engineering, Nagoya University, 3. Center for Computational Sciences, University of Tsukuba

In a protoplanetary disk, dust grains, which are icy or rocky microscopic particles, are present at about one percent of gas mass. The dust grains collide and adhere with each other to grow in size repeatedly in turbulent gas of a protoplanetary disk. Planetesimals are widely believed to form as a consequence of this hierarchical coagulation from submicron-size dust particles to kilometer-size bodies in a protoplanetary disk. However, it has been argued that there are several physical barriers such as bouncing and radial drift barriers in the planetesimal formation process, and these remain unresolved, especially for silicate dust. In recent years, as a possible solution to these problems, the effect of turbulent clustering of dust grains has been attracting attentions.

In previous studies, it was pointed out that the clustering of particles by turbulence promotes adhesion growth (Pan et al, ApJ2011), and the statistics such as the collision velocity of dust particles in turbulent flow were investigated by a direct numerical simulation (DNS) of turbulence, solving the Navier–Stokes equations (Pan and Padoan, ApJ 2015). Recently, a series of large-scale DNSs of turbulence was conducted to study the velocity distribution of colliding particles in the turbulent flow and the dependence on flow nonlinearity (Reynolds number) (Ishihara et al, ApJ2018). However, numerical simulations on the coagulation process of dust particles were not performed. Therefore, whether dust grains grow hierarchically has not been clarified.

In this study, we developed a parallel code (using MPI and OpenMP) to simulate the collisional adhesion process of dust particles, in which the critical collision velocity (Wada et al, A & A, 2013) is taken into account, and investigated the adhesion processes of 512^3 dust particles using a large-scale DNS of turbulence.
As a result, we have found the following by the analyses of the obtained data:
(1) Dust particles collides with each other within the critical collision velocity preferentially at positions with smaller enstrophy (intensity of vorticity), while dust particles collide with the critical or higher collision velocity at positions with larger enstrophy.
(2) Even if the average collision speed exceeds the critical collision velocity, the collisions within the critical collision velocity can occur repeatedly, and thus rapidly growing dust grains do exist.
(3) The sticking probability of dust particles directly obtained by our simulations is larger than that estimated by the previous DNS data analysis (Ishihara et al ApJ 2018).
(4) The Reynolds number dependence of the dust motion for grains with long stopping time (the response time to flow change) is very weak. Hence, even in protoplanetary disk turbulence with much larger Reynolds number, the same growth process as in this study is expected.

The reasons and implication of the above results will be discussed by conducting the additional data analysis.

Development of N-body Simulation Code for Planetary System Formation With Particle-Particle Particle-Tree Scheme

*Yota Ishigaki[1,4], Junko Kominami[2], Junichiro Makino[3], Masaki Fujimoto[4]

1. University of Tokyo, 2. Tokyo Institute of Technology, 3. RIKEN AICS, 4. Institite of Space and Astronautical Science, Japan Aerospace Exploration Agency

In general, the planetary system is thought to be formed from protoplanetary disks surrounding the central star. In particular, it is accepted that terrestrial planets and the cores of gas giant planets are formed by accretion of km size objects (planetesimals) in the protoplanetary disk. The accretion process of the planets has been mainly discussed using the gravitational multi-body simulations (N-body simulations) of planetesimal systems. Various unresolved problems have been pointed out in the conventional standard planetary system formation theory.In recent years, new planetary system formation models have been proposed to solve these problems.However, there is no model with no problem even in these new models. Since N-body simulations with sufficient number of particles has not been performed, the generalized planetary system formation theory has not been constructed yet.

We have developed a new N-body simulation code with particle-particle particle-tree (P^3T) scheme for planetary system formation, GPLUM. The code GPLUM uses a fourth-order Hermite scheme to calculate gravitational interactions between particles within a cut-off radius and a Barnes-Hut tree scheme for gravitational interactions from particles beyond. The conventional simulation codes with P^3T scheme has the bottleneck that the calculation speed decreases when the mass ratio among the particles becomes large. We have solved it by implementing an algorithm which determines the cut-off radius based on mass and orbital semi-major axis of particles individually for each particle. The performance of GPLUM is significantly improved for the simulations of particle systems with mass distribution.

By improving the performance of the N-body simulation code, we made it possible to carry out numerous global simulation with various parameters. GPLUM allows us to perform N-body simulations with ~10^6-10^7 particles. By using GPLUM, we will perform N-body simulations with wide range and high resolution and investigate various parameters by perform parameter studies with N-body simulations.

Current status of post-K Exploratory Challenge, computational planetary science

*Junichiro Makino[1,2]

1. Kobe Univ, 2. RIKEN R-CCS

In FY 2016, as one of research project for post-K supercomputer, "Exploratory Challenge 3 Elucidation of the Birth of Exoplanets and the Environmental Variations of Planets in the Solar System" has been started. This FY is the last year for the two-year production phase, even though the post-K computer will not be ready until FY 2021. In this talk, I'll overview this project (we call this project computational planetary science project for short).

The development of post-K supercomputer was started in 2014, and its planed completion year is around 2021, with up to 100 times faster speed on real applications compared to K computer. As one of four "Exploratory Challenges", computational planetary science has been selected, and it is assigned to Kobe University, with other eight research institutes.

The computational planetary science project consists of four sub topics: planetary formation, dynamics and evolution of planets, solar activities and environmental change, and the origin of life. In this talk, I'll overview these topics, computational challenges, and products so far and future prospects.

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute), Chairperson:Takashi Yoshino(Okayama University), Yoshio Kono(愛媛大学地球深部ダイナミクスセンター), Yoshinori Tange

Phenomena such as destruction, eruption and collision are catastrophic phenomena, which is different from geological phenomena like mantle convection. However, global phenomena such as meteorite collisions characterised by extinction of dinosaurs were caused not only by long-term fluctuations but also by such a dramatic high-speed phenomenon. It is also important to understand the high-speed dynamics in order to consider evolution of the Earth and disaster prevention. Now it has become possible to capture fast phenomena from femtosecond to several minutes scale under the extreme condition with progress of synchrotron radiation technology. The purpose of this session is that comprehensively understand high-speed dynamics from many methods such as material science / observation / numerical model.

Toward organization of a new field on fast process in Earth and planetary science

*Takashi Yoshino[1]

1. Institute for Planetary Materials, Okayama University

In the evolution of the Earth and the planet, it is necessary to consider that the event occurred on a short scale, which is different from the evolution on the geological time scale, gives a global impact on the evolution of the planetary scale and its surface environment.In order to understand such events, it is indispensable to understand high-speed processes such as destructive processes as typified by seismic activity, eruption processes in volcanic activities, and huge meteorite collision processes. Since these phenomena are events that can occur anytime even now, it is also an important research topic in terms of disaster prevention. In this presentation, we propose to combine the research on the elementary processes of these phenomena and the research on the influence of these phenomena from various types of research fields, and aim to construct an interdisciplinary research organization.
In recent years, with the progress of measurement experiment technology in large synchrotron radiation facility and X-ray free electron laser facility, It has been possible to detect the short time scale catastrophic phenomenon occurring in extreme environments in a wide range time interval extending from several minutes (> 10^2 s) to femtosecond (10^{-15} s). Studies combining synchrotron radiation with high pressure experiments is shifting from the observation of static processes to monitoring of dynamic processes such as deformation, attenuation, and destruction. It is becoming possible to capture phenomena on the millisecond scale.Situations are being developed that can detect the high-speed process. In studies using X-ray free electron laser, a situation where the collision process can be tracked in detail at 100 picosecond scale has been realized during impact compression experiment using high intensity laser. Furthermore, in the field of computer science using supercomputers, the progress of high-speed process reproduction experiments has been remarkable, and it is time to be able to oversee seamless research on capturing high-speed processes from atomic scale to huge meteorite collision.Research on high-speed processes has been studied independently in each event, but there are many aspects that common phenomena in the method of grasping the high-speed process and its elementary process are common. This session was planned with the goal of forming a research network that can efficiently operate "knowledge" by incorporating numerous methods such as material science, geophysical observation and numerical model. By establishing and utilizing this network, it is expected that we will comprehensively understand the high speed dynamics in Earth and planetary science, and at the same time obtain new knowledge about the impact on the global scale and cause a new paradigm shift.

Fractal particle size distribution of pulverized fault rocks and dynamic fragmentation of rocks

*Jun Muto[1], Osamu Nishikawa[2], Hiroyuki Nagahama[1]

1. Department of Earth Sciences, Tohoku University, 2. Graduate School of Engineering and Resource Sciences, Akita University

Earthquake is a catastrophic phenomenon caused by the rapid slip on fault. Development of high-speed rotary shear apparatus enables us to conduct friction experiments of various rocks at seismic slip rates to investigate dynamic fault behaviors [1]. The nominal strain rate at the seismic slip reaches 100 /s under the slip rate of 1 m/s occurring across the 1 cm width of the slip zone. On the other hand, the field observations along large-scale strike-slip faults reported the peculiar fault rocks with in-situ shattered microstructures [2]. The rocks are called pulverized fault rocks and characterized by a lack of shear deformation and intense fragmentation. These intensive damage zones have been suggested to form dynamically during earthquake rupture propagation. Theoretical calculation of the rupture propagation predicts much higher strain-rate deformation exceeding 10000 /s near the rupture tip [3]. However, because such high strain rate can be achieved only along the very close to the tip, several models have also been proposed to explain the wide distribution (~ 100 m from the fault core) of the pulverized rocks along the fault [2,4,5]. From the microstructural analysis of pulverized rocks, we reported the measurements of size distributions of fractured particles [6]. Fragments in those rocks in both fault zones show a fractal size (power-law) distribution down to the micron scale. Fractal dimensions of fragments, dependent on mineral types, reaches 2.92 near the fault cores. The value exceeds a theoretical upper fractal limit of confined comminution (~2.58 [7]) and experimentally created gouges by high-speed friction experiment (~2.6 [8]). Fractal dimensions close to 3.0 have been reported in high-speed impact loading experiments. The observed fractal properties imply that pulverization is likely to have occurred by a dynamic stress pulse with instantaneous volumetric expansion, possibly during seismic rupture propagation similar to impact loading. The obtained results from fractal properties of the pulverized rocks are consistent with laboratory experiments for dynamic fragmentation of rocks using Split-Hopkinson Pressure Bar (SHPB or Kolsky Bar) apparatus [5, 9]. SHPB is a loading apparatus that transmits planar elastic compressive waves into a sample under strain rates of 10 ~ 1000/s. Using the apparatus, Doan and Gary [5] clearly showed that the high strain rate exceeds 150 /s is required to cause pulverization of granite. Moreover, from the analysis of grain size distribution of fragments created by SHPB experiments of fine-grained novaculite, Barber and Griffith [9] showed that energy dissipation by fragmentation is not trivial than previously considered (10 % to as much as 40 %). According to dynamic fragmentation model by Hild [10], strength of rocks in multiple fragmentation regime dramatically increases with strain rate. This implies that the significant strain-rate hardening accompanying pulverization may be the responsible for the significant energy sink of the earthquake [9]. In the presentation, we review the dynamic fragmentation phenomena based on field evidence, theoretical models and laboratory experiments using SHPB apparatus to shed light on the dynamic fault behavior.

Universal aspects of acceleration process toward unstable fast rupture

*Takahiro Hatano[1]

1. Earthquake Research Institute, University of Tokyo

In this talk, we will elaborate the acceleration process of unstable slip on a model of earthquake fault. based on an empirical friction law that has been verified in the lab scale, it is shown that slip velocity increases in a power law manner resembling the inverse Omori law. This acceleration process has been known empirically, and is derivable theoretically for a class of simple systems. We will show that this power-law acceleration is realized in a wider class of systems including non-planer faults and random brittle media. Analysis on a mean-field model indicates saddle node bifurcation is responsible for the power law behavior.

The mechanism of intraslab earthquakes (> 40 km depth) is fundamentally different from those of shallower ones. This is because the frictional strength is much higher and fracture process associates ductile flow (i.e., semi-brittle flow) at deeper parts. The location of the double seismic zone in the subducting Pacific slab corresponds to the main dehydration field in the pressure-temperature diagram of the hydrous peridotite (Omori et al., 2002). The cause of intraslab seismicity at intermediate depths has been attributed to breakdown of hydrous minerals such as serpentinite (e.g., Ferrand et al., 2017) and lawsonite (Okazaki et al., 2016) because it causes unstable fault slip or shear localization. However, the role of aqueous fluid in fracturing at high pressures is still unclear.

To evaluate the effect of water on semi-brittle behavior of dunite and harzburgite, we conducted in-situ uniaxial deformation experiments on as-is/water-saturated dunite and harzburgite at pressures 1-3 GPa and temperatures 670-1250 K with a constant displacement rate using a deformation-DIA apparatus. Pressure, stress, and strain were measured in situ by using x-ray diffraction patterns and radiographs. Radiographs were taken at each several minutes in most of deformation experiments, though radiographs were continuously taken (each 5 seconds) during a deformation run (at 2 GPa and 860 K). Acoustic emissions (AEs) were also recorded continuously on six sensors, and three-dimensional AE source location were determined.

Formation of throughgoing faults was observed in water-saturated dunite and harzburgite at 860 K and lower temperatures. Fault slip rate is between 3E-5 and 4E-4 s^{-1} which are comparable to the background strain rate just before a faulting (1E-5 and 3E-4 s^{-1}), showing that shear localization is ineffective under water-saturated conditions. Addition of the aqueous fluid resulted in the reduction in the number of AE events in the faulted sample (i.e., aseismic faulting). A high time-resolution strain monitoring revealed that fault slip rate fluctuate within several ten seconds (i.e., stick-slip phenomena). Because the high time-resolution strain monitoring is a preliminary experiment, the relationship between stick-slip phenomena and aqueous fluid is unclear. We will investigate that point in near future.

A mechanism of magma fracturing revealed by in-situ X-ray imaging and diffraction

*Satoshi Okumura[1], Kentaro Uesugi[2], Tatsuya Sakamaki[1], Akio Goto[3]

1. Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University, 2. SPring-8/JASRI, 3. Center for Northeast Asian Studies, Tohoku University

Explosive volcanism is one of the most spectacular phenomena on Earth. Explosive volcanism is characterized by the vigorous release of magma fragments and volcanic gases to the surface. In such cases, the magma is the continuum in the crust but becomes fragmented during its ascent. In particular, brittle fragmentation of silicic (relatively SiO2-rich) magma results in explosive eruptions. Therefore, the cause of brittle fragmentation of magma determines whether the eruption will be explosive or effusive.

The viscoelasticity of magma and the relaxation timescale of its structure are currently thought to control fragmentation (Dingwell, 1996 Science). Under rapid deformation rates, magma exhibits elastic behaviour, while viscous magma behaviour is dominant when the deformation rate is slow. Fiber elongation experiments for magmas clearly demonstrate the transition from viscous elongation to brittle fracturing with increased elongation rates. This transition is empirically formulated and can be applied to the modelling of volcanic eruptions (Gonnermann and Manga, 2003 Nature). In contrast, the atomic- to nano-scale structure of melt across this transition is poorly understood. For example, magma exhibits shear thinning (viscosity decreases as shear rate increases) behaviour when the shear rate is close to the conditions at which magma fracturing occurs. No explanation for the relationship between shear thinning and brittle fracturing has yet been proposed. Understanding the atomic- to nano-scale structures across viscous to brittle transition will provide important information for clarifying the mechanism of magma fragmentation. We have investigated magma fracturing by using in-situ X-ray imaging and diffraction techniques. Some preliminary results of our work will be introduced in this presentation.

Estimation of physical parameters of volcanic eruptions based on analysis of eruptive products –Toward understanding of eruption dynamics–

*Fukashi Maeno[1]

1. Earthquake Research Institute, University of Tokyo

'Volume' and 'mass discharge rate' of volcanic eruptions are fundamental parameters in understanding the spatiotemporal scale of magma accumulation and migration in the shallow crust and the type and nature of the surface phenomena accompanying the eruption. 'Volume' of one volcanic eruption is the most fundamental physical parameter for determining the scale of the eruption. Its mid- to long-term transition is related to the accumulation process of magma and the frequency of the eruption, as well as the entire volcanic activity. On the other hand, 'discharge rate' of magma is closely related to magma ascending process, and it is a parameter that controls diversity and transition of eruption styles, eruption intensity, and plume height, etc. The elucidation of 'volume' and 'discharge rate' of magma (physical parameter of eruption) is a key in understanding various volcanic phenomena occurring in the crust and the earth surface as the magma rises. The improvement of the estimation accuracy is indispensable to promote the understanding of the causes of diversity of volcanic activities and eruption phenomena, and the magma reservoir-conduit system. Also the magma discharge rate, which is one of the factors that dominates the diversity of the eruption, greatly influences the characteristics of the eruptive products caused by magma ascent and decompression such as the microstructure and texture, and the chemical composition heterogeneity. The elucidation of the relationship between such physical parameters of eruption and the characteristics of the products may enhance the understanding of volcanic eruptions. On the other hand, in recent eruptions, by comparing ejecta/deposit data with various remote observation data from the ground and satellites, it is possible to grasp the process from magma extrusion to deposition at high resolution. The knowledge obtained therefrom is expected to be an important constraint in the reconstruction of past volcanic events. Estimation of the eruption physical parameters is important not only for understanding the dynamics of volcanic eruption but also for predicting volcanic disasters and future eruptions. In this presentation, we will introduce the estimation of physical parameters of eruption in recent volcanic eruptions and the past gigantic caldera-forming eruptions and also describe the issues.

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute), Chairperson:Takashi Yoshino(Okayama University), Yoshio Kono(愛媛大学地球深部ダイナミクスセンター), Yoshinori Tange

Phenomena such as destruction, eruption and collision are catastrophic phenomena, which is different from geological phenomena like mantle convection. However, global phenomena such as meteorite collisions characterised by extinction of dinosaurs were caused not only by long-term fluctuations but also by such a dramatic high-speed phenomenon. It is also important to understand the high-speed dynamics in order to consider evolution of the Earth and disaster prevention. Now it has become possible to capture fast phenomena from femtosecond to several minutes scale under the extreme condition with progress of synchrotron radiation technology. The purpose of this session is that comprehensively understand high-speed dynamics from many methods such as material science / observation / numerical model.

Discussion

Chemical reaction processes bridge between asteroid Ryugu and early evolution of Earth

*Seiji Sugita[1,3], Hideharu Kuwahara[2], Kosuke Kurosawa[3]

1. Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo, 2. Ehime University, 3. Chiba Institute of Technology

JAXA's Hayabusa2 has arrived at asteroid Ryugu and is uncovering many new aspects of the primitive asteroid, such as extremly low albedo (4.5+/- 0.1%), flat spectra (Cb type), young resurfacing age (<10^6 yr for the top 1 m layer), high boulder number dentity (x2 of Itokawa) and low abundance of hydrated minerals. These pieces of information is very importance for understanding the early evolution of inner solar system and Earth's surface environment. In particular, what happens upon hypervelocity impacts of such bodies is important for understading the atmospheric chemistry of early Earth. In this study, we review atmospheric entry processes, high-temperature chemistry processes, and discuss the implications of recent results on asteroid missions, such as Hayabusa2 and OSIRIS-REx, for Earth's early evolution.

Time-resolved synchrotron X-ray observations of mineral transformations under static pressures: applications to non-equilibrium behaviors in shocked meteorites

*Tomoaki Kubo[1], Masaaki Miyahara[2]

1. Kyushu University, 2. Hiroshima University

High-pressure transformations occur on timescales of ~0.01 to a few seconds in shocked meteorites. Reactions in such short timescales often remain incomplete and/or metastable state, which is usually problematic for the interpretation, but can be good information for shock durations if the kinetics is experimentally known. Here we present some experimental results on curious kinetic behaviors in seifertite and lingunite, those presences in shocked meteorites have been difficult to explain based on phase equilibrium. A conventional method combining multi-anvil high-pressure apparatus with synchrotron white X-ray was routinely used to observe non-equilibrium behaviors and their kinetics in minerals at pressures up to ~30 GPa by collecting time-resolved X-ray diffraction data every 10 sec with energy dispersive method. By using this system, we found that seifertite and lingunite are metastably formed at high pressures from silica and plagioclase, respectively. The problematic presence of these phases in shocked meteorites can be reasonably explained as metastable phases. Extrapolations of kinetic data obtained to shorter timescales at higher temperatures of shock events uniquely constrain the critical shock durations and the size of the impactor. Similar strategy has also been applied to the back-transformation recorded in shocked meteorites. Time-resolved X-ray observations have revealed that some high-pressure phases such as bridgmanite and lingunite do not directly transform to their low-pressure phases, but through the amorphous state. This may explain the presence of amorphous phases with enstatite and plagioclase compositions in shocked meteorites. Our studies demonstrate that the conventional 10-second time-resolved synchrotron X-ray observations under static pressures capture the critical processes of solid-state reactions during shock events. On the other hand, crystallization of high-pressure phases from shock-induced melt is another important process to be solved. Improvement of the system with better time resolution and grain observations by 2D detector are required to detect the rapid melt crystallization processes.

Ultrafast pump-probe experiemnts for planetary materials using high-power lasers and XFEL

*Norimasa Ozaki[1]

1. Osaka University

Materials at high pressures and temperatures are of great current interest for warm dense matter (WDM) physics, planetary sciences, and inertial fusion energy research. At the high-energy density (HED) conditions, the micro-structures of material significantly influence the behavior and properties. Ultra-short X-ray pulse, *i.e.*, X-ray free electron laser (XFEL), is a unique and powerful tool to directly observe a structure and to reveal the time scale of the structural change under the dynamic high pressures. Here we present recent experimental results on shock-compressed planetary materials using high-power laser and XFEL.

Tracking dynamical phenomena with X-ray free-electron lasers

*Tetsuo Katayama[1]

1. Japan Synchrotron Radiation Research Institute

X-ray free-electron lasers (XFELs) provide brilliant X-ray pulses with femtosecond duration and are utilized to track dynamics, which is difficult to capture using synchrotron radiation. In the femtosecond time domain, one can achieve "molecular movie"[1-3] with an atomic spatio-temporal resolution by combining XFEL and synchronized optical laser pulses. On the other hand, in the nanosecond time domain, XFELs are utilized to observe irreversible dynamic processes[4,5] with the single-shot measurement scheme that can not be performed with synchrotron radiation.
In this presentation, I will talk XFEL properties and research examples at SACLA to discuss the XFEL potentials in Earth and planetary science.

High speed measurement with synchrotron radiation X-ray.

*Kentaro Uesugi[1]

1. Japan Synchrotron Radiation Research Institute

X-ray is suitable for a probe for investigation of materials inside because of its deep penetration depth. For examples, X-ray transmission images show the internal structure of materials, the X-ray energy spectrums show the chemical characteristics and mineral phase of the materials can be obtained from X-ray diffraction.

Synchrotron radiation X-ray has continuum spectrum and is highly collimated basically. Therefore, the X-ray condition such as energy, beam size and intensity could be tuned for the purpose of the measurement and materials. A lot of insertion devices such as in-vacuum type undulator have been installed in a storage ring of third-generation synchrotron radiation facility to obtain ultra-high flux density (photons / sec / mm^2) or brilliance (photons / sec / mm^2 / $(mrad)^2$ / 0.1%b.w.) X-ray at the sample. The highest brilliance of X-ray is about 10^9 time higher than the laboratory-based X-ray source. The high brilliant X-ray enable us to do ultra-high speed, spatial resolution and energy resolution measurement comparing to laboratory-based system.
At the SPring-8 the following experiments could be possible, X-ray imaging with more than 1kHz frame rate (liquid flow), X-ray diffraction with several kHz (insect flapping) and dispersive XAFS with 100Hz. These are essential technique for capturing various non-equilibrium or dynamic phenomena. At the conference, some examples of high speed measurement will be shown.

Recent advances in high-pressure synchrotron X-ray experiments on magmas under pressure at the beamline 16-BM-B in Advanced Photon Source

*Yoshio Kono[1]

1. Geodynamics Research Center, Ehime University

High-pressure synchrotron X-ray experiments using large volume press is one of the most useful tools to investigate structure and properties of Earth’ s materials under high pressure and high temperature conditions. However, in contrast to extensive studies on high-pressure mineralogy and mineral physics, experimental investigation of structure and properties of magmas under pressure has been limited, due to experimental difficulties. In the past decade, new developments in high-pressure experiments, particularly combined with synchrotron X-ray techniques, have advanced the study of magmas under pressure. The new experiments have revealed significant changes to the structure and physical properties of magmas under pressure. In this talk, I will introduce recent advances in high-pressure synchrotron X-ray experiments for studying magmas at high pressures, developed at the beamline 16-BM-B, HPCAT in Advanced Photon Source, USA.

Keywords: High pressure, Magma, Synchrotron X-ray

[U-07] How JpGU will manage environment and disaster from the impacts of unforeseen geo-hazards

convener:Koji Okumura(Graduate School of Letters, Hiroshima University), Jun Matsumoto(Deaprtment of Geography, Tokyo Metropolitan University), Daisaku Kawabata(Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Masaki Matsushima(Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology), Chairperson:Daisaku Kawabata, Koji Okumura(Hiroshima University)

Japan Geoscience Union has established the Environment and Disaster Coping Committee in 2008 to cope with various environmental and natural hazard issues. Those issues are among the most urgent and important geoscientific issues for the society. The enormous extent and severity of the disasters caused by the 2011 Tohoku earthquake and tsunamis urged collaboration of many scientific associations to know the effects of the extreme natural hazards. A number of severe meteorological, volcanic, and earthquake hazards demanded interdisciplinary collaboration to respond to the emergencies. The occurrence and consequence of severe disasters were clearly controlled by the combined effect of environments and hazards. In this session, we share our activities related with recent unforseen disasters, and discuss how Japan Geoscience Union sets up the framework to enhance the real cooperation among scientific associations to prepare the impacts of unexpected hazards.

Discussion

Seismotectonic environments and landscape as keys to mitigate the impacts from unexpected hazards

*Koji Okumura[1]

1. Graduate School of Letters, Hiroshima University

Even if we know little about the hazards that may occur at certain location, the geologic envieonments and landscape may tell us the risks. They are seismotectonic enveironments and landscapes. Since people contact with geologic and geomorphic environments and landscapes very often, they will be useful keys to understand the risks from natural hazards in that location. The environments and landscapes of the 2018 June 16 Osaka-hokub earthquakes and 2018 September 6 Hokkaido Iburi Tobu earthquakes will be discussed.

Activities related with the eruption at Kusatsu-Shiranesan (Motoshiranesan) volcano on 23 Jan,2018 - Focusing on JMA’s activities -

*Junichi Miyamura[1]

1. Japan Meteorological Agency

Japan is one of the world's leading volcanic country with 111 active volcanoes, and so many volcanic disasters have been repeated. But after the early 20th century, no large eruptions occurred and volcanic activity in Japan has been quiet.
On the other hand, the eruption at Ontakesan volcano on 2014 sacrificed many mountaineers who were near the crater and caused the greatest volcanic disaster after the war. One of the features of eruptive disasters is that even a small eruption could lead to a great disaster if encountered near the crater. In the latest case, the eruption at Kusatsu-Shiranesan volcano on January 23, 2018 suddenly occurred at Motoshiranesan where there was no record of historical eruption and caused human damage at the ski resort near the eruption point.
The Volcanological Society of Japan was established as the world's first academic conference on volcanoes in 1932 and re-established as a specified nonprofit corporation in 2002 for the purpose of advance and disseminate volcanology and related science. The institution to which the member belongs is not only universities and research institutes, but also local municipalities, disaster prevention organizations, high schools and geological consultants. Recently, in order to lead to the reduction of volcanic disaster by volcanology research, we also focus on public awareness raising, such as opening lectures and symposiums targeting the general public.
In this presentation, we will introduce the activities related with the 2018 Motoshiranesan eruption by each institution, mainly on the correspondence of Japan Meteorological Agency.

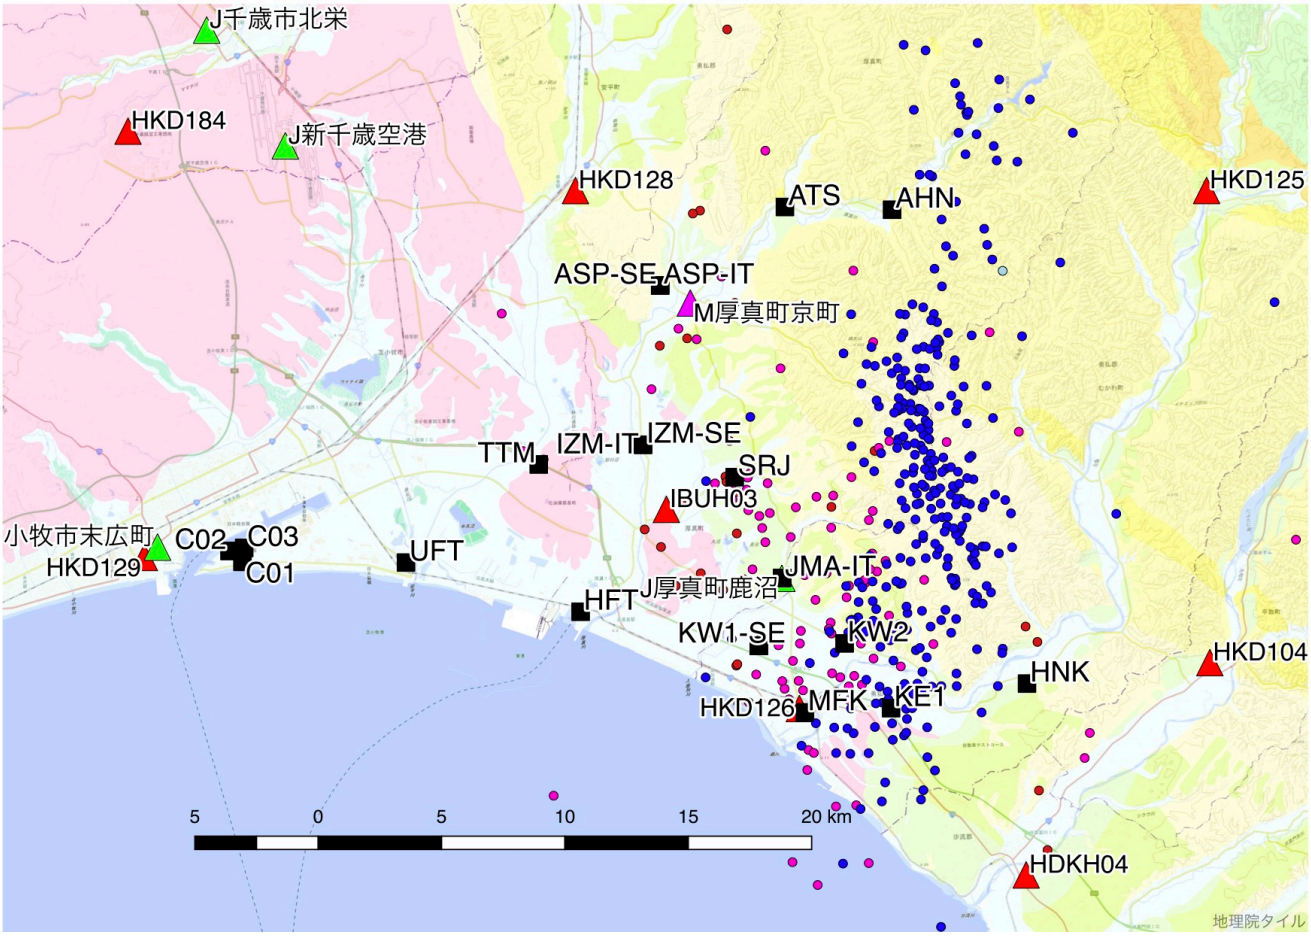
Aftershock and microtremor array observation around the source area of the 2018 Hokkaido Eastern Iburi earthquake

*Masayuki Yoshimi[1], Kahori Iiyama[2], Hitoshi Morikawa[2], Hiroyuki Goto[3]



1. Geological Survey of Japan, AIST, 2. Tokyo Institute of Technology, 3. DPRI, Kyoto Univ.

The 2018 Hokkaido Eastern Iburi earthquake (Mw 6.6, depth=37 km) is a shallow to moderate depth earthquake. Strong ground motions were widely observed around the source area and in the Ishikari-Yufutsu sedimentary basin, culminated with the maximum seismic intensity VII of the JMA scale at JMA Atsuma seismic station. Waveforms with clear velocity pulse, having 1 to 3 dominant period, were observed along the west of the source area: K-NET Mukawa (HKD126), JMA Atsuma, KiK-net Atsuma (IBUH03), and Atsuma city hall. Velocity response spectra of these pulse waveforms are comparable to that of the Takatori station record, located close to the heavy damage area, during the 1995 Kobe earthquake. Therefore, we need to resolve the reason why such strong ground motions were developed during the 2018 earthquake although the magnitude was moderate (Mw 6.6) and focal depth was not shallow.

Four seismic station, where the strong pulse waveform was observed, are commonly located along the basin edge of the Yufutsu sedimentary basin. The subsurface velocity structure around the source area is considered to responsible for producing the ground motions. Thus, we conducted temporal observation of aftershocks and microtremor array measurements around the source area to investigate spatial variation of the site amplification and subsurface velocity structure. We deployed 14 temporal seismic station during 16th-21st Sep., 2018 to record around 20 aftershocks with magnitude larger than M2. We also conducted microtremor array survey at 13 locations with array aperture of several to 30 meters. Site amplification and subsurface velocity structures will be shown.

Effect of non-linear site response on earthquake hazard map

*Takao Kagawa[1]

1. Tottori University Graduate School of Engineering

Various earthquake hazard maps are published by country and municipalities in Japan. It is better to consider non-linear site response for the hazard maps, however, simple frequency independent amplification of ground motion is frequently adopted. The site responses are generally evaluated from the data of microtremor or stationary earthquake observations; i.e. weak motion, therefore rigidity reduction and damping increase under strong ground motion are not considered in the responses. It is suspected that prolonged predominant period by non-linear site response and synchronized prolongation of residential natural period cause heavy building damages by the 2016 Kumamoto earthquake. It is also suspected that non-linear site response was one of triggers of slope failures and fill ground disaster through the 2018 Hokkaido eastern Iburi earthquake. The non-linear site response is an important issue to consider earthquake disaster by strong ground motion and also ground disaster.

Seismological community has noticed the effect from 1990s, however, evaluation methodology; i.e. program SHAKE, has been proposed in 1970s in engineering community. Latest methodologies have been introduced for modeling subsurface structures in seismological community such as microtremor survey, seismic interferometry, diffuse wave field theory and so on. Joint study across research fields beyond earth and planetary science is required for providing further realistic earthquake hazard map.

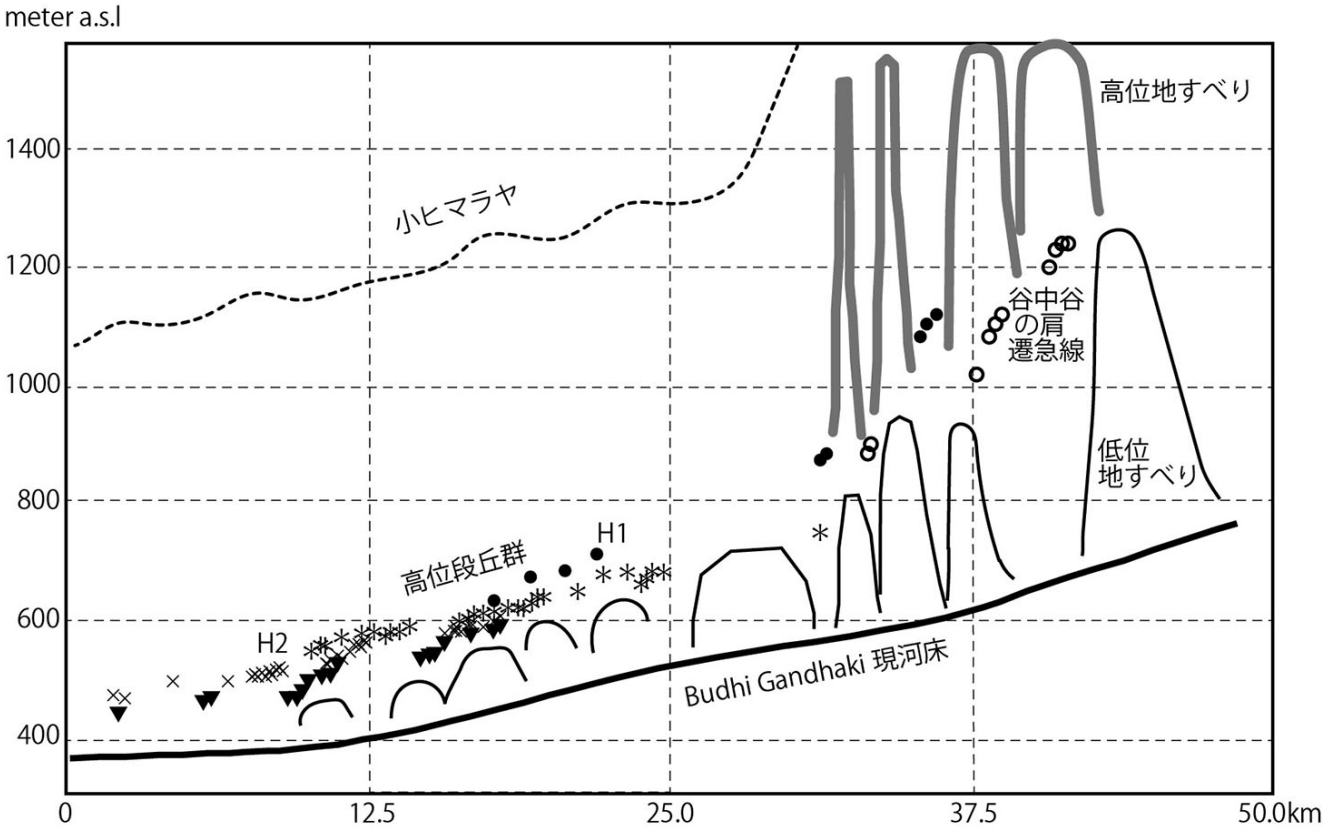
Evolution of catastrofic landslides due to rapid valley incision and filling since Last Glacial Age in central Nepal Himalayas



*Hiroshi YAGI[1]

1. Faculty of Art, Science and Education, Yamagata University

There remain higher landslides located on the upper slope of inner gorge, that was formed due to sever valley incision before 20k in the Last Glacial Age.

Sever valley incision caused destabilization of valley slope and the consequent valley filling stabilized the valley slope again. Present landslides are caused by re-incision of the filling of the Last Glacial Age.

Keywords: Nepal Lessor Himalaya, rapid valley incision & valley filling, destabilization of valley slope, inner gorge, last glacial age

The model study of ionospheric variations during the solar eclipse event by assimulating the GNSS TEC observations

*Chia-Hung Chen[1], Charles Lin[1], Tomoko Matsuo[2]

1. Department of Earth Sciences, National Cheng Kung University, 2. Department of Aerospace Engineering Sciences, University of Colorado at Boulder, CO

Using the physics-based thermosphere-ionosphere model (NCAR-TIEGCM) with an ensemble Kalman filter, this study reports the first data assimilative analysis of the ionosphere responses to the solar eclipse on 21 August 2017. The system, using a 2-minute assimilation cycle of data from ground-based GNSS observations, show dynamic variations of the equatorial ionization anomaly (EIA) due to the electrodynamic effects of the solar eclipse. Two major ionospheric responses are captured: (1) an early appearance of EIA at the westward boundary of moon shadow and (2) an enhanced EIA at lower latitudes and suppressed EIA at the higher latitudes. These eclipse-induced conjugate EIA variations are produced by an eastward electric field perturbation around magnetic equator and a westward electric field perturbation at the higher latitudes.

Characteristics of mesoscale thermospheric-ionospheric dynamics associated with heating in the auroral region

*Tomokazu Oigawa[1], Hiroyuki Shinagawa[2], Satoshi Taguchi[1]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology

The thermosphere and ionosphere in the polar region have been studied for a long time. Recent results of the ground and satellite measurements have suggested that polar thermospheric and ionospheric dynamics are extremely complicated. In particular, in the auroral region, various processes, such as ion-neutral drag, Joule heating, heating and ionization by particle precipitation, chemical processes, diffusion, and atmospheric gravity waves, are strongly coupled. Previous observations have shown some characteristic mesoscale phenomena such as large vertical winds and significant increasing of mass density in the auroral region. It is considered that local heating plays an important role in such phenomena. However, we still have not quantitatively understood how such large vertical winds and significant increasing of mass density occur. In order to study the mesoscale thermospheric and ionospheric dynamics in the auroral region, a high-resolution numerical model including various physical and chemical processes is required. We will report on how the thermospheric and ionospheric dynamics change depending on the magnitude of the heating and the spatial structure of the heating region using a two-dimensional numerical model. In addition, interaction between the thermosphere and the ionosphere will be discussed.

Understanding the flow of energy and mass throughout the magnetosphere-ionosphere-thermosphere coupled system is a fundamental goal of solar-terrestrial physics. Since substantial energy accumulated in the substorm growth phase in the magnetospheric tail flows into the polar ionosphere immediately after the substorm onset, investigating the energy dissipation process at high latitudes around the time of substorm onset can contribute significantly to achieving that objective. The energy dissipation generates acceleration and heating of the ionosphere and thermosphere, but this might occur not only near aurora but also far from it by hundreds kilometers equatorward. We analyzed ionospheric and thermospheric measurements in the northern Scandinavian area (65-80 N) during periods of considerably low geomagnetic activity but with some aurorae above Svalbard (75-80 N). Thermospheric winds measured with a Fabry-Perot interferometer (FPI; 630.0 nm) at Tromsø, Norway (69.6 N) showed westward accelerations coinciding with auroral brightening at the Svalbard area at the dusk sector though the relative distance from Tromsø to the aurora was 200-500 km in some cases. Moving into the dawn sector with the earth’ s rotation, the acceleration direction turned to southeastward through stagnation area or period seen at magnetic local midnight. The acceleration pattern well represents thermospheric responses to the ionospheric convection, but of particular interest is its location, in which the thermospheric wind have been obtained at the sub-auroral region far from the main auroral oval. In this analysis, we cannot infer to horizontal patterns of the wind acceleration because we have only a point measurement from the Tromsø FPI. While this result suggests the importance of two-dimensional measurements of ionosphere and the thermosphere, we need a new configuration of the observation network to infer horizontal winds and accelerations. In this presentation, we will introduce “SDI-3D” project, which aims at developing 3 Scanning Doppler Imagers (SDIs) and deploying them at the same area as for the EISCAT_3D, which may start in operation in 2022.

Analysis of the thermospheric neutral wind vector using observed images of *Trimethylaluminium* (*C6H18Al2*) released from sounding rocket in the upper atmosphere

*Yuki Otsuka[1], Masa-yuki Yamamoto[1], Hiroaki Saito[1]

1. Kochi University of Technology

Altitude profiles such as neutral atmospheric density and ionized atmospheric density in the thermosphere/ionosphere fluctuate by solar activity, season, day and night changes. These fluctuations with affecting on ground, communication with artificial satellites, and make affecting there orbits, but the detailed mechanism of occurrence has not been well understood. We have been conducting collaborative experiments with JAXA, NASA, etc. on inverstigating neutral atmospheric wind in the thermosphere/ionosphere, which is thought to play an important role in this mechanism.
In this research, the main objective is to calculate the neutral wind velocity in the thermosphere from the images of TMA observed in rocket experiment by JAXA conducted in July 2013.
JAXA conducted a rocket experiment in July 2013 to clarify the full picture of electromagnetic interaction and ionized/neutral atmosphere interaction acting on mid-latitude ionosphere. S-310-42 and S-520-27 sounding rocket were launched from Uchinoura Space Center(USC). Trimethylaluminum(TMA)was released in the former and lithium(Li) was released from the latter rocket into the upper atmosphere. Sequential optical observation of changes in these luminescent clouds was operated at each observation point and aircraft. Figure.1 shows the flight path of the aircraft/rockets in the experiment, the observation point, the emission region of TMA and Li, etc.
To calculate the wind speed, we use the images of TMA observed in July 2013 rocket experiment. I analyze the image sequence taken from the aircraft(Figure 2) and those images at USC(Figure 3)as a combination in which the TMA clouds are clearly seen and a long-time optical observations were performed. We use the method of Yokoyama(2011)and Kihara(2015)for caluculating of newtral wind speed.

Method by Yokoyama(2011)[1]
1 From the observed image, the central position of the cloud(TMA gas) is obtained from luminance information. Thereafter, the central axis of the TMA gas is obtained.
2 Choose one of the stars in the observed image as the center star. Also select ten stars around that.
3 Correct the distortion of the lens by using the X,Y coordinates of the stars(right ascension , declination) on the image.
4 Convert the coordinates of the obtained central axis are into celestial spherical coordinates. After that, it converts to earth coordinates using observation point information.
5 From the data of each observation point obtained by the above procedure, wind speed is calculated by using triangulation method.

Method by Kihara(2015)[2]
1 From the observed image, the central position of the cloud(TMA gas) is obtained from luminance information. Thereafter, the central axis of the TMA gas is obtained.
2 Correct distortion of the camera lens. After that, convert the coordinates on the image into the elevation and the azimuth angles.

©2019. Japan Geoscience Union. All Right Reserved.

3 After applying the correction, the difference information is obtained from two images of the same point at different times. Then, the wind speed is calculated from the difference information.

We carried ou extraction of central axis of a TMA cloud, extraction of stars on the images, conversion to elevation and azimuth angles, then derived an approximate wind speed profile. However, it is thought te error at the time of detecting the center axis of the TMA cloud and the conversion error at azimuth/elevation angles are influenced. In the future, it is also necessary to correct lens distortion, tilt of camera, and aircraft velocity and altitude changes.
In this presentation, we would like to introduce more precise caluculation method of neutral wind speed.

Establishment of real-time analysis method in a new HRO interferometer system and operation test of comprehensive meteor observation

*Takumi Sato[1], Seiya Takeda[2], Masa-yuki Yamamoto[1]

1. KOCHI UNIVERSITY OF TECHNOLOGY, 2. Inc.Bascule

Meteors are natural phenomenon that dusts is space with several millimeters to several centimeters in diameter in outer space jump into and collide with upper atmosphere of the earth, vaporizing and getting hot because of adiabatic compression by aerodynamic heating with emitting light at the same time. At the moment, thermal energy by aerodynamic heating make molecules in the atmosphere ionize, with generating a large amount of plasma. This plasma makes a elongated dense-ionized column along the meteoric trajectory. Meteor radio observation is an observation method using scattered radio waves by free electrons in the ionized column. In this research, at Kochi University of Technology (KUT), we conducted Ham-band radio meteor observation (HRO) in forward scattering method using the 53.755 MHz VHF (amateur band) wave that is transmitted stably from Fukui Prefectural University.
The objective of this research is that we apply a new observation method and analyzing algorithm to KUT 5ch meteor radio interferometer and develop meteor research using 5 antennas of the meteor radio interferometer [1]. Because of the limited radio meteor observation in Japan, if we share accurate observation method and observation result with the other observers, we can contribute to the development of study on meteor science.
In this research, we conducted three methods (comprehensive meteor observation [1]) of the new HRO interferometer system (HRO interferometer system), optical observation, and infrasound observation.
In the HRO interferometer system, after the signal received at the antennas was demodulated in their receivers, with making input to an observation PC through an AD board, real-time processing by analysing software on the PC was performed. A group of data set triggered only when exceeding a threshold set in advance on the software are saved as a meteor echo. In the analysis of meteor plasma direction of each meteor with considering intrinsic phase difference, we calculated each phase difference in north-south and east-west directions with baseline length of 0.5 λ and 2.5 λ (λ is observation wavelength), after processing interference calculation among signals of multiple antennas using 5ch meteor radio interferometer [1].
In the optical observation, we used existing high sensitivity B/W CCD camera (WAT-100N) and color 4K camera (Sony, α6300) newly installed with a combination of UFOCaptureV2 and HD2 that are motion capture software. The observation data was analyzed from the information recorded by cameras by analyzing position, velocity, linearity of motion, etc. by using UFOAnalyzerV2 for data stored through UFOCaptureV2 and HD2.
In the infrasound observation, we conducted a unique meteor observation for such as large fireballs by using a group of infrasound sensors that can observe very low frequency sound of less than 20 Hz caused by large scale natural phenomena. It is possible to estimate energy scale of the meteor entry from obtained amplitude and period of the sound wave.
In order to determine the intrinsic phase shift, we searched for the observability of the same phenomenon for the comprehensive meteor observation data.
In this research, we obtained 2 meteor shower data from August 2018 to January 2019. Especially, in 2019 at Quadrantids, three candidates of the intrinsic phase shift was obtained by analysis of comprehensive meteor observation data, but we could not confirm the intrinsic phase shift.

©2019. Japan Geoscience Union. All Right Reserved.

As a result of this research, we obtained the candidate values necessary for accurate calculation of meteor plasma direction by the interferometer data processing. Due to lack of the observation data, we could not confirm the intrinsic phase shift, thus after checking the analyzing process, we will continue to use the system and obtain more data to establish the intrinsic phase shift and ensure the accuracy and reliability of the observation method.
We applied the new trial called real-time analyzing to KUT 5ch radio meteor interferometer with confirming the validity of the new receiver system, and obtained the candidate values of the intrinsic phase shift necessary for our future research. We shared a part of accurately obtained data on the web and a mailing lists, so as to contribute to the development of meteor science.

Solar flare effects of the D-region ionosphere using daytime tweek atmospherics

*Kodai Yamanobe[1], Hiroyo Ohya[2], Hiroyuki Nakata[2], Toshiaki Takano[2], Kazuo Shiokawa[3]

1. Graduate School of Science and Engineering, Chiba University , 2. Graduate School of Science and Engineering, Chiba University, 3. Institute for Space-Earth Environmental Research, Nagoya University

It has been known that intensity and phase of very low frequency (VLF, 3-30 kHz)/low frequency (LF, 30-300 kHz) transmitter signals significantly change due to intense ionization by solar flares [e.g., Mitra, 1974; Thomson et al., 2005]. Santolik and Kolmasova [2017] showed daytime tweek atmospherics (1.5-10.0 kHz) did not become observal for two hours just after a solar flare of M2.2 class, which suggests large absorption due to the solar flare. However, there are little studies for tweeks during solar flares. In this study, we investigate solar flare effects of the D-region ionosphere using tweek atmospherics. We analyzed the daytime tweek atmospherics observed at Kagoshima (31.48N, 130.72E) and Moshiri (44.37N, 142.27E), Japan, during January-July, 2013. The sampling frequency is 20 kHz, and the VLF data were recorded for each two minuteat 20-22 and 50-52 minutes every hour. For two M1.4-class flares, the daytime tweeks were received about 30-40 minutes after the solar flares. For a M5.6-class flare, the daytime tweeks were not observed for about 4 hours after the solar flare. The tweek reflection height had a weak negative correlation (-0.38) with X-ray flux observed by the GOES-13/15 satellites, suggesting that electron density in the D-region ionosphere increased with increasing the X-ray flux.In the presentation, we will discuss the D-region ionization and propagation mechanism of the tweeks during solar flares in more detail.

This session covers a broad scope of studies of physics and chemistry in the atmosphere and the ionosphere. Coupling processes between plasma and neutral species, and upward and downward coupling among lower/upper atmosphere, and ionosphere/mesosphere/thermosphere including magnetosphere are discussed. We solicit papers based on experiments with ground-based and/or space-borne instruments, theoretical studies, numerical simulations, and development of new observation techniques.

Toward a detection of sporadic-E episodes by ALOS2 ScaSAR InSAR

*Masato Furuya[1], Jun Maeda[2], Kosuke Heki[1]

1. Department of Earth and Planetary Sciences Hokkaido University, 2. Hokkaido University Library

Maeda et al. (2016) and Furuya et al. (2017) reported their detections of sporadic-E (Es) episodes in Japan, using L-band interferometric synthetic aperture radar (InSAR). The SAR data images are acquired by Advanced Land Observation Satellite (ALOS) 1/2 launched by JAXA in 2006 and 2014, respectively. The high spatial resolution of InSAR data allow us to examine the detailed structure of Es episode, which will complement the high temporal resolution of GNSS TEC data. The previous two studies are based on stripmap-mode SAR images, which have higher spatial resolution but are limitted in terms of the observation swath-width (Maeda et al., 2016; Furuya et al., 2017). Although the stripmap-mode is the most standard SAR imaging mode, ScanSAR mode is also nearly operational nowadays, and can image the Earth with much wider swath-width by as much as 350 km; the standard stripmap-mode of SM1 for ALOS2 covers only 50 km. Although the ScanSAR mode is a bit worse in terms of the spatial resolution along radar range direction than the stripmap mode image, ScanSAR InSAR image can dramatically improve the observation coverage, and thus help detect both small-scale and large-scale structure of Es. We first check the data availability of ScanSAR images in Japan at any specific areas, and then check if any significant anomalies in either TEC or ROTI are observed via the database provided by NICT. We will report our preliminary results of ScanSAR InSAR imaging of Es in Japan.

Vertical fine structure and time evolution of plasma irregularities in the E_s layer, observed by a high resolution Ca^+ lidar

*Mitsumu K. Ejiri[1,2], Takuji Nakamura[1,2], Takuo T. Tsuda[3], Takanori Nishiyama[1,2], Makoto Abo[4], Toru Takahashi[1], Katsuhiko Tsuno[5], Takuya Kawahara[6], Takayo Ogawa[5], Satoshi Wada[5]

1. National Institute of Polar Research, 2. SOKENDAI (Department of Polar Science, The Graduate University for Advanced Studies), 3. The University of Electro-Communications, 4. Tokyo Metropolitan University, 5. RIKEN, RAP, 6. Shinshu University Faculty of Engineering

The vertical fine structures and the time evolution of plasma irregularities in the sporadic E (E_s) layer were observed via calcium ion (Ca^+) density measurements using a resonance scattering lidar with a high time-height resolution (5 s and 15 m) at Tachikawa (35.7˚N, 139.4˚E) on December 24, 2014. The observation successfully provided clearer fine structures of plasma irregularities, such as quasi-sinusoidal variation, localized clumps, “cats-eye” structures, and twist structures, in the sporadic Ca^+ (Ca^+_s) layers at around 100 km altitude. These fine structures suggested that the Kelvin-Helmholtz (K-H) instabilities occurred in the neutral atmosphere whose density changed temporarily or spatially. The maximum Ca^+ density in the Ca^+_s layer was two orders of magnitude smaller than the maximum electron density estimated from the critical frequency (f_oE_s) observed by the ionosonde at Kokubunji (35.7˚N, 139.5˚E) simultaneously. The correlation showed a strong positive correlation with a coefficient of 0.91. These results suggest that Ca^+ contributes forming the E_s layer as well as major metallic ions Fe^+ and Mg^+ in the lower thermosphere. Moreover, the formation of a new Ca^+_s layer at 110 km and the upward motions of the Ca^+_s layers at 100 km and 110 km were observed just after the sunrise time at the conjugation point and before the local sunrise. Although the presence or absence of a causal relationship with the sunrise time was not clear, a possible explanation for the formation and the upward motions of the Ca^+_s layers was the occurrence of strong eastward winds at around 100 km, rather than the enhancement of the eastward electric field.

Study of Effects of Stratospheric Sudden Warming on Medium-Scale Traveling Ionospheric Disturbances Using Total Electron Content Data Obtained from World-Wide GPS Receiver Networks

*Yuichi Otsuka[1], Atsuki Shinbori[1], Prayitno Abadi[2], Takuya Tsugawa[3], Michi Nishioka[3]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. LAPAN, 3. National Institute of Information and Communications Technology

Medium-Scale Traveling Ionospheric Disturbances (MSTIDs) are wavy structures of the ionospheric plasma density with horizontal scale-size of hundreds of kilometers. In order to investigate effects of Stratosphere sudden warming (SSW) on MSTIDs, we have analyzed total electron content (TEC) data obtained from GPS receivers at different four longitudinal sectors (east Asia, Europe, and western and eastern America) before and after SSW that occurred on January 2009 and 2013. To obtain perturbation component of TEC, which could be caused by MSTID, we have subtracted 1-hour running average from the original TEC time series for each pair of satellites and receivers, and converted the slant to vertical TEC. We have defined MSTID activity as dI/I, where dI is the standard deviation of the perturbation component within 1 hour, and I is 1-hour average absolute vertical TEC. In this study, we applied the same method to the GPS-TEC data at mid-latitudes before and after major Stratospheric Sudden Warming (SSW) events that occurred on January 2009 and 2013. We have found that MSTID activity during daytime is high before SSW events and low after SSW events. On the other hand, the nighttime MSTID activity does not show such a difference between before and after SSW events. These results suggest difference of mechanisms generating MSTIDs between daytime and nighttime. The daytime MSTIDs could be caused by gravity waves propagating upward from below into the thermosphere. Recent simulations suggest that these gravity waves are secondary waves generated from dissipation of the primary waves in the MLT region. Miyoshi et al. (JGR, 2015) have reported that the generation of secondary gravity waves is more active when the strato-mesospheric jet is strong, and that the generation of secondary waves is inactive when the strato-mesospheric jet is attenuated or becomes westward. Consequently, low MSTID activity after January 24 could be caused by weaker generation of secondary gravity wave during weaker or westward strato-mesospheric jet. On the other hand, gravity waves propagating from below does not contribute to generation of MSTIDs during nighttime.

Tsunami-generated ionospheric currents inferred from geomagnetic observations at ground level: Case for the 2011 Tohoku Earthquake

*Takuto Minami[1], Masashi Kamogawa[2], Tsutomu Ogawa[1], Makoto Uyeshima[1], Toru Mogi[3], Hiroshi Ichihara[4]

1. Earthquake Research Institute,The University of Tokyo, 2. Department of Physics, Tokyo Gakugei University, 3. Graduate School of Engineering, Hokkaido University, 4. Graduate School of Environmental Studies, Nagoya University

It is known that large earthquakes cause atmospheric gravity/acoustic waves reaching the ionosphere and drive ionospheric dynamo currents at the altitude (e.g. Iyemori et al. 2005). Related phenomena were detected by observations of total electron content (TEC) (e.g. Tsugawa et al. 2011) and reported by numerical simulations (e.g. Kherani et al. 2013). However, the form of electric currents due to the coseismic ionospheric dynamo has never been revealed from the perspective of geomagnetic observations at ground level.

We investigated 1-min sampling magnetic data at nineteen on-land stations on the Japan Arc and at one ocean-bottom magnetometer ~200 km off the Tohoku, to reveal the form of coseismic electric currents in the ionosphere during the 2011 Tohoku earthquake (Mw 9.0). First, we subtracted the effects of non-seismic components of ionospheric and magnetospheric origins from the geomagnetic data, using magnetic transfer functions between the stations of interest along the Japan Arc and a reference site in China, Changchun. Second, we subtracted the oceanic dynamo effects due to the tsunami by a time-domain finite element simulation in the same manner as Minami et al. (2017). By rotating the coordinate system at each station to that consisting of radial and transverse axes in terms of the tsunami centre, we recognized a clear concentric propagation of a trough in the radial magnetic component with a phase velocity of ~ 1 km/sec and a trough amplitude of ~ 7 nT. This propagation happens in all the directions and the propagation velocity is almost the same as that of the slow coseismic ionospheric disturbances (CID) observed by TEC observations (e.g. Kakinami et al., 2013). The radial propagation of a trough in the radial component indicates presence of anti-clockwise electric currents in the ionosphere.

In the presentation, we report our analysis of the geomagnetic data at ground level and the inferred characteristics of the coseismic electric currents in the ionosphere. We also plan to show some results of spectral analyses of the propagation features involved in the geomagnetic data.

Relationship between the magnitude of Sakurajima eruptions and the disturbance of GPS-TEC

*Kiyoto Shoji[1], Hiroyuki Nakata[1], Toshiaki Takano[1], Hiroyo Ohya[1], Takuya Tsugawa[2], Michi Nishioka[2]

1. Graduate School of Science and Engineering, Chiba University, 2. National Institute of Information and Communications Technology

It is reported that ionospheric disturbances are caused by ground and atmospheric perturbations, e.g. earthquakes, typhoons and volcanic eruptions. Even though the volcanic eruptions excite the atmospheric waves, there is little reports of ionospheric disturbances caused by volcanic eruptions. Therefore, in this study, we analyzed the ionospheric disturbances caused by volcanic eruption using Total Electron Content (TEC) determined by GNSS system.
We analyzed TEC data observed in GNSS Earth Observation Network (GEONET) which is maintained by Geospatial Information Authority of Japan. We assumed that the ionospheric pierce points (IPP) are located at the altitude of 300 km. The 30-second TEC data are obtained in about 1200 points of GEONET. The mask angle is 30 degrees. We analyzed four events of Sakurajima eruptions (7:45 UT on Oct.-3-2009, 1:07 UT on Sep.-19-2012, 20:25 UT on Dec.-9-2012 and 20:21 UT on Feb.-12-2014). The magnitudes of the eruptions are estimated by the infrasound meter located at Higawa-Korimoto.
The TEC disturbances are larger in the larger magnitude of the events.
It is expected that the TEC disturbance is inversely correlated with the distance from the crater as the energy of the atmospheric wave spreads according to the distance from the crater. Examining the relationship between TEC disturbances and the distances of IPPs from the crater. There was an inverse correlation with the distance in one events out of four events. However, no correlation was found in the other three events. This may be due to the directions of the magnetic field and the wave normal of the disturbance to the GPS satellite-receiver. In order to correct these effect, we calculated two coupling coefficients of the directions of the atmospheric wave from the calculation results of the acoustic ray tracing the one is related to the direction of the magnetic field, and the other is to the direction between the transmitters (satellites) and GNSS receivers. After this connection, an inverse correlation between TEC disturbances and the distance from the crater was appeared in three events.
However, some data showed higher values than the expected values. In the IPPs where the corrected values are high, the correction coefficients are very small. Therefore, the cause of the high values is too effective correction.

Water vapor estimation using digital terrestriall broadcasting waves - Simultaneous observation with microwave radiometer -

*Hiroshi HANADO[1], Seiji Kawamura[1], Hironori Iwai[1], Shinsuke Satoh[1], Katsuhiro Nakagawa[1], Takuya Tajiri[2], Narihiro Orikasa[2], Yoshinori Shoji[2], Kentaro Araki[2], Hiromu Seko[2]

1. National Institute of Information and Communications Technology, 2. Meteorological Research Institute

1. Introduction

NICT is developing a method that can observe water vapor in a wide area and efficiently. Water vapor is an important quantity along with wind velocity and temperature in the weather prediction. Solid / liquid phase water in the atmosphere can be observed with weather radars, but water vapor, water in gas phase, can not be observed with radars. Water vapor observation methods in a wide area are limited. Currently, GPS / GNSS precipitable water observation which is used as water vapor data in a weather numerical model uses the delay amount of the L-band radio waves from the GPS / GNSS satellites. NICT have demonstrated that similar measurements are possible with the terrestrial digital broadcast wave in UHF [1]. The method is that using delay profile decorded from scattered pilot signals embedded in the terrestrial digital broadcast wave, the reflected wave scattered from the surrounding reflector, building or towers, is separated from the direct wave. By using phase difference between the reflected wave and direct one, the influence of the phase noise of the reference signal at the broadcast station / reception point is canceled, and the propagation delay of the UHF band radio wave is measured with accuracy of picosecond level.

2. Simultaneous observation with microwave radiometer

We installed a microwave radiometer and terrestrial digital broadcasting wave receiver on the roof of the Meteorological Research Institute, Tsukuba, in February 2017, and we are continuing long-term observation. The microwave radiometer is an instrument capable of observing the amount of water vapor accumulated in the vertical direction above the measurement point. On the other hand, water vapor observation by the terrestrial digital broadcast wave means the amount of water vapor along the horizontal direction near surface. These observation volumes are different in size and shape. Therefore, by combining the two sensors, complementary observation of the water vapor amount is expected. In terms of time resolution, the microwave radiometer is not so good as it directs the antenna beams in a plurality of directions and estimates from the received thermal noise powers. In the water vapor estimation by terrestrial digital reception, more than 50 samples are measured per second, and it has a rather high temporal resolution. In this presentation, we will compare the variation of water vapor observed by microwave radiometer and terrestrial digital broadcasting wave for about one and a half years, and introduce the analysis results focusing on the difference in characteristics.

[P-EM18] Heliosphere and Interplanetary Space

convener:Ken Tsubouchi(University of Electro-Communications), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Kazumasa Iwai(Institute for Space?Earth Environmental Research (ISEE), Nagoya University), Chairperson:Yasuhiro Nariyuki, Kazumasa Iwai

This session aims to secure comprehensive insights into physical processes of plasmas and fields in the heliosphere. Presentations of the recent studies from any approaches (integrated observations/theoretical modeling/massive numerical simulation) are welcomed. Topics are not restricted to any specific issues: phenomenological studies on solar flares/CME/solar wind, and related fundamental physics problems such as shocks/waves/turbulence/particle transport and acceleration can be the main target, including heliospheric high-energy phenomena and their impact on the Earth's environment.

The interplanetary magnetic flux ropes (IFRs) are ejected from the Sun to interplanetary space in association with the coronal mass ejections (CMEs). Their magnetic structure is an important research subject which provides information on the mechanism of CMEs. On the other hand, The IFRs often cause strong geomagnetic storms because of intense southward magnetic fields carried from the solar atmosphere. Thus, the IFRs have long been studied since they were discovered more than 30 years ago. It is the first step for such studies to determine the 3-D geometries and internal magnetic field structures of IFRs. We need to assume a physical model of the IFR and compare the model structure with observations. There are 2 representative analysis methods which are currently used along the line. They are: (1) a fitting method to models of force-free magnetic field configurations, and (2) a reconstruction method of magnetic field structures based on the Grad-Shafranov (GS) equation. Recently, Al-Haddad et al. (Solar Phys. 2018) examined the mutual agreement between the results from the two methods for 13 well-determined IFRs carefully selected. They found that the agreement is relatively good in only 6 cases, and thus concluded that the compatibility of different models with specific IFR structures must be taken into account.

The present study is an extension of the work by Al-Haddad et al. In the GS method, 2-D structure (essentially a cylindrical structure) is assumed, and the axis orientation is determined so that the symmetry condition is satisfied between inbound and outbound crossings of the IFR. If the IFR fields satisfy the force-free condition, the internal structures obtained by the 2 methods agree with each other. Actually, however, the GS method includes the effect of plasma pressure while the force-free model neglects the plasma pressure. This can cause the discrepancy between the two. With this idea in mind, we started to examine how the axis orientations deviate from each other. However, we encounter an unexpected problem, that is, it is not easy to point start and end times of an IFR from the observed data. Especially in the GS method, the selection of the IFR interval is strongly affected by the symmetry condition. In this presentation we show results of our trial to determine the axis orientation for many possible IFR intervals.

Validation of estimated interplanetary flux rope axial direction using internal plasma motions: benchmark test

*Nobuhiko Nishimura[1], Munetoshi Tokumaru[1], Katsuhide Marubashi[2]

1. Institute for Space Earth Environmental Research, 2. National Institute of Information and Communications Technology

Interplanetary flux rope (IFR) is a structure with helical magnetic field lines wrapping around a central axis to form a flux rope structure. Accurate estimation of this structure is important for improving the space weather forecasting and understanding the evolution of IFR. Local structures of IFRs have been investigated by many model fittings and reconstruction method. However, the outputs of these model fittings and reconstruction method are often different. The chirality and magnetic flux of corresponding flux rope at the Sun are often compared with those of IFR to check the validity of estimation of IFR properties, but it is questionable whether this consistency check guarantees the validity of IFR axis direction which is one of the important properties of IFR. In this study, we propose a method that validates IFR axial direction based on plasma motion. It is known that the radius of IFRs often expand or sometimes contract during the passage of IFR through a spacecraft and if the expansion or contraction exist, the direction of plasma motion in IFR may be perpendicular to IFR axis in the frame comoving with the IFR. This suggests that plasma velocity in IFR reflects the axial direction of IFR. We test the method for a well-investigated IFR event on May 21-22, 2007. The magnetic field structure of this event has already been investigated by Liu et al. (2008) using multi-spacecraft measurements at STEREO-B, ACE, Wind, and STEREO-A and other researches (e.g. Kilpua et al. 2009) which report similar axial directions to that of Liu et al. (2008). Herein, We consider that the axial direction determined by them is correct since Liu et al. (2008) found that output from reconstruction at STEREO-B agrees fairly well with the observations at ACE and Wind. We fit the cylindrical and toroidal IFR models (Marubashi et al. 2007) to this event and then apply our validation method proposed in this study to the outputs from the fittings. We checked whether the outputs with the correct axial direction are judged to be valid and vice versa. We find that the fitting result with correct axial direction is judged valid. However, our validation method also judged some fitting results with wrong axial direction to be valid. We need to improve our validation method to make it work well.

Effect of line-of-sight integration on locations of coronal mass ejection in the sky projection map of interplanetary scintillation observations

*Munetoshi Tokumaru[1], Ken'ichi Fujiki[1], Kazumasa Iwai[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

The g-value derived from interplanetary scintillation (IPS) observations abruptly enhances when a high density (i.e. shocked) plasma associated with a coronal mass ejection (CME) intersects the line-of-sight (LOS). The plane-of-sky location of the line-of-sight, which shows the g-value enhancement, provide information of the radial distance of the CME-driven shock, and enables determination of the shock transit speed in the solar wind between the Sun and the Earth. It should be noted here that IPS measurements include an effect of the LOS integration, and the plane-of-sky location of g-value enhancements is affected significantly by this effect for some cases. The most significant bias is expected for an Earth-directed event. In this study, we investigated the dependence of the LOS integration effect on the radial distance, the angular width, and the non-uniform expansion for an Earth-directed CME. We made calculations of the sky projection map of g-value using the CME model (Tokumaru et al., 2003). As the result, we found that the plane-of-sky location of g-value enhancements tends to underestimate the actual distance of CME, and that this tendency is distinct in the region near the Sun, being less as the CME moves further from the Sun. This means that apparent acceleration is observed for an Earth directed CME propagating with a constant speed. The degree of this tendency is significant for a case with a small angular extent of CME and also for a case with the non-uniform expansion. Such apparent acceleration of CME near the Sun has seldom reported from IPS measurements for Earth-directed CMEs. This fact may suggest that the CME detected by IPS has a sufficiently large angular width, and hence that the acceleration effect is counterbalanced or overwhelmed by intrinsic deceleration of CME during propagation.

Estimation of spatial structure of whistler mode wave packets in Earth’s bow shock by multiple spacecraft analysis

*Chika Umegaki[1], Takanobu Amano[1], Naritoshi Kitamura[1]

1. The university of tokyo

There have been a lot of unresolved issues in the generation mechanism of nonthermal charged particles observed ubiquitously in space plasmas. The Fermi acceleration at a shock wave is one of the leading mechanisms for the nonthermal particle acceleration. In this mechanism, it is necessary to confine charged particles in the vicinity of the shock wave while charged particles are being accelerated, which requires pitch angle scattering due to wave-particle interactions. In the case of electrons, whistler mode waves are considered to play a major role in the pitch angle scattering. Whistler mode waves are electromagnetic waves that are right-hand circularly polarized with respect to the background magnetic field. They are thought to contribute to the scattering of electrons by interacting with counter-streaming electrons. In fact, there have been reports of coherent whistler mode waves propagating parallel to the magnetic field in the vicinity of the shock wave (Hull et al., 2012). Recently, it was found that such whistler mode waves are indeed resonantly interacting with suprathermal electrons (Oka et al., 2017). However, it has been known that the acceleration of electrons at the shock is rare, and the relation between whistler mode waves and electron scattering (or acceleration) efficiency has not yet been clarified. The applicability of the standard quasi-linear theory for the electron scattering efficiency by coherent whistler mode waves seen in the shock transition region is not understood very well. For this purpose, one has to identify the spatio-temporal scale of coherent whistler wave packets.
In this study, we aim to estimate the spatial scale of the coherent whistler mode waves around bow shock. For instance, by estimating the scale size of whistler mode wave packets in the direction perpendicular to the magnetic field, we may impose a limit for the energy of electrons being scattered by the wave. This is because gyroradii of electrons must be sufficiently smaller than the perpendicular size of wave packets otherwise the conventional cyclotron resonance theory should not be applicable. For this purpose, simultaneous observations by multiple spacecraft are necessary. In this study, we performed an analysis for high-frequency (~100 Hz) electromagnetic waves observed during bow shock crossings with enhanced energetic electron flux observed by NASA's MMS (Magnetospheric MultiScale) spacecraft.
In particular, we report results for the following two bow shock crossing events: 11:44 UT on October 7, 2015 (Event 1), and 10:29 UT on December 6, 2016 (Event 2). The spacecraft separation was 20 km and 7 km for the Event 1 and Event 2, and comparison between the two may enable us to estimate the scale size of whistler mode wave packets. We applied a band pass filter with for the frequency range 100-250 Hz (fce > 1 kHz) for Event 1, and 50-150 Hz (fce ~ 300 Hz) for Event 2 where prominent peaks were observed in the magnetic field power spectra. We confirmed that whistler mode waves appeared sporadically as wave packets with a short duration (50 - 100 ms). We used MVA (Minimum Variance Analysis) for determining the wave propagation direction. Note that we eliminated the 180-degree ambiguity by referring the Poynting vector direction. Also, we estimated the wavelength from the wave electric-to-magnetic field amplitude ratio using Faraday’s law. The obtained wavelengths of the whistler mode waves were roughly 10 km. This indicates that the spacecraft separations were larger (smaller) than the wavelength for the Event 1 (2). By doing the same analysis for each spacecraft, we found that wave packets observed during Event 1 were almost always uncorrelated. On the other hand, both correlated and uncorrelated wave packets were found for Event 2. This suggests that the whistler mode wave packets have spatial scale of a few km. In this report, we will estimate the spatial scale sizes of wave packets in parallel and perpendicular to the magnetic field direction.

Experimental Test for Stochastic Shock Drift Acceleration Theory

*Takanobu Amano[1], Takuma Katou[1], Naritoshi Kitamura[1], Mitsuo Oka[2], Yosuke Matsumoto[3], Masahiro Hoshino[1]

1. Department of Earth and Planetary Science, University of Tokyo, 2. Space Sciences Laboratory, University of California, Berkeley, 3. Department of Physics, Chiba University

High-energy charged particles are ubiquitous in space. They have energies orders of magnitude higher than the thermal energy and often exhibit a power-law distribution in a wide energy range. The collisionless shock is one of the leading mechanisms that may produce such high-energy non-thermal particles. Indeed, radio, X-ray, and gamma-ray observations strongly suggest that shock waves associated with supernova remnants, pulsar winds, relativistic jets in active galactic nuclei and gamma-ray burst are accelerating relativistic electrons. On the other hand, in-situ observations in the heliosphere (at planetary bow shocks, or interplanetary shocks driven by coronal mass ejections) have shown that the acceleration of electrons is, in general, weak or even absent in many of the shock crossings.

We have recently proposed a theory for electron acceleration at shocks that may resolve the observational controversy. The theory referred to as stochastic shock drift acceleration (SSDA) assumes stochastic pitch-angle scattering during electrons are interacting with a collisionless shock. The energy gain comes from the gradient-B drift (due to the magnetic field compression in the shock transition layer) in the direction anti-parallel to the convection electric field and is not associated with the assumed scattering. The scattering is, however, essential to confine the accelerated electrons in the shock transition layer for a long time, because, otherwise they would quickly escape from the system. In other words, the theory assumes that the electron transport obeys the diffusion-convection equation with an energy gain term determined only by the magnetic field gradient. It successfully explains the formation of a power-law energy spectrum, with a maximum energy cut-off determined by the rate of pitch-angle scattering. We here present the result of an experimental test using NASA's MMS (Magnetospheric MultiScale) spacecraft observation of an Earth's bow shock crossing event on December 9, 2016.

In particular, we have checked the following points that are predicted by the theory: (1) exponential increase in energetic particle intensity toward downstream within the shock transition layer, (2) nearly isotropic pitch-angle distribution. We find that both are reasonably satisfied in a thin layer (~7 sec. or ~350 km assuming a shock propagation speed of ~50 km/s) within the shock transition region. The result is then used to estimate the rate of pitch-angle scattering as a function of energy. We find that the pitch-angle scattering rate increases as increasing the particle energy from just above the thermal energy up to a few keV, beyond which it saturates to a nearly constant value. We find that the observed maximum energy cut-off (~30 keV) in the electron energy spectrum is consistent with that predicted by the theory based on the observed pitch-angle scattering rate. All of these results strongly indicate that the observed non-thermal electrons are accelerated by the SSDA.

Radial structure of heliospheric boundary region

*Shuichi Matsukiyo[1], Gary P. Zank[2], Haruichi Washimi[3], Tohru Hada[1]

1. Faculty of Engineering Sciences, Kyushu University, 2. The Center for Space Plasma and Aeronomic Research, University of Alabama in Huntsville, 3. International Center for Space Weather Science and Education, Kyushu University

The kinetic structure of the heliospheric boundaries is investigated using one-dimensional full PIC (Particle-In-Cell) simulations. Both the termination shock and the heliopause are simultaneously reproduced in the simulation. The spatial scale of the heliopause increases as the angle between the heliopause normal and local magnetic field (referred to as the normal angle, hereafter) becomes increasingly oblique. The VLISM region, out side the heliopause, contains compressible flucturations in both magnetic field and plasma density. The fluctuations are originated from the inner heliosheath, the region between the termination shock and the heliopause, pass the heliopause, and propagate away from it. The total pressure, including the plasma pressure and magnetic pressure, at the heliopause is not constant when the normal angle is oblique in contrast to predictions based on MHD theory. In the oblique case, the solar wind plasma and interstellar plasma are able to inter-penetrate by moving along the local magnetic field. Since their bulk velocities along the magnetic field differ from each other, the distributions overlap in phase space so that the effective local plasma pressure parallel to the magnetic field is enhanced. This results in an increase that resembles a hump in the density and parallel pressure of the local plasma, which is not seen in magnetic field.

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan), Chairperson:Takayuki Muto

The Atacama Large Millimeter/Submillimeter Array (ALMA) starated its science operation in 2011, and long-baseline observations have become available since 2014. With its high sensitivity and resolution, ALMA has provided us with qualitatively new information on star and planet formation and small bodies in our Solar System. For example, in the observations of protoplanetary disks, ring-like structures have been commonly found and the structures with the scale of several-AU are discovered in several systems. In our solar system, 60km pixel-scale non-uniform brightness distribution and the rotation of the asteroid Juno are detected. Spatially-resolved thermal mapping of Europa icy surface enables us to search for thermal anomaly in possible plume source regions. As of Cycle 4, Solar observations are available, enabling us, for example, to determine the physical parameters of plasmoid quantitatively. In this session, we overview the latest results of ALMA observations in the field of planetary sciences. We also accept any theoretical and experimental works that are closely related to the observations and discuss the impact on the planetary science community.

ALMA started solar observations with Bands 3 and 6 from Cycle 4. Millimeter waves at 100 GHz (band 3) and 240 GHz (band6) are radiated by free-free emission in the chromosphere, and brightness temperatures are directly related with electron temperatures by the Planck function. Before ALMA, observations of the chromosphere are mainly performed by absorption lines from UV to near IR. These lines are formed under non-local thermodynamically equilibrium, and it is difficult to interpret brightness temperatures directly with electron temperatures. Thus, ALMA opens a new window for temperature diagnostics in the solar atmosphere.

Although intensities in millimeter wave in a quiet sun are directly related with electron temperatures, where these emissions come from is not well understood. Numerical and observational comparisons between millimeter waves and UV lines are performed in the past. However, temperature structures in the solar atmosphere are complex and full of varieties. We cannot simply estimate the formation region of millimeter waves from the case studies. In order to understand temperature structures in solar atmosphere by ALMA, it is crucial not only to compare between multiwavelength observations but also to understand radiative processes of millimeter waves and chromospheric lines in multiple regions in the solar atmosphere.

We analyze ALMA data of a plage region observed in Cycle 4. We compare the ALMA data with vector magnetic field in the photosphere by Hinode/SP, transition-region images and spectra by IRIS, and chromospheric and coronal images by SDO/AIA. As a result, velocities of a moving feature in a stripe structure in ALMA data correspond to sound speeds in the chromosphere, and it is reasonable to interpret that millimeter waves are emitted from the mid-chromosphere. However, we do not find the same structures between millimeter waves and chromospheric images. In this presentation, we review the preceding studies on the formation region of millimeter waves in the solar atmosphere, introduce the plage observation, compare with numerical simulation of radiative transfer of millimeter wave and chromospheric lines, and discuss what ALMA is looking in the solar atmosphere.

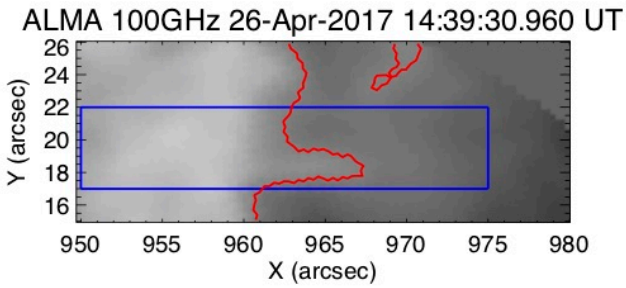
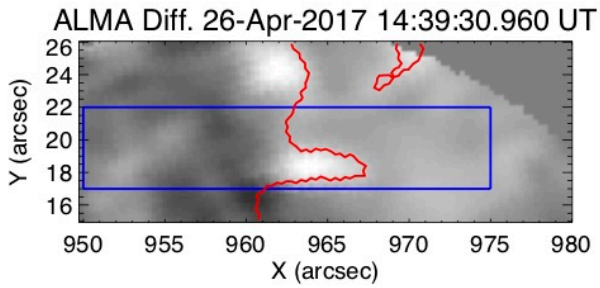
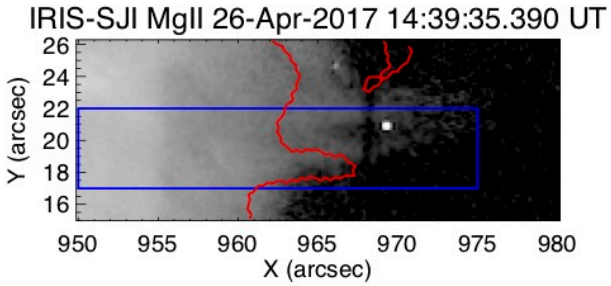
Multi-thermal structures in a spicule observed with ALMA, IRIS, and AIA/SDO



*Masumi Shimojo[1], Tomoko Kawate[2], Takenori Okamoto[1], Takaaki Yokoyama[3]



1. National Astronomical Observatory of Japan, 2. Institute of Space and Astronautical Science , 3. University of Tokyo



A spicule is a key phenomenon for understanding the solar atmosphere. We succeeded in observing a large spicule with ALMA, IRIS, and AIA/SDO simultaneously, and report the details of the spicule in the paper. While an eruption of a blob-like structure shown in the 100 GHz images started just before appearing a spicule in the He II and Mg II images, a spicule seen in 100 GHz image itself began about one minute after beginning the spicule in the He II and Mg II images. The spicule in the 100 GHz images can be seen as an absorbing structure in the Fe XII images. The maximum height and width of the Mg II/He II spicule are larger than those of the 100 GHz/Fe XII spicule. The 100 GHz/Fe XII spicule is included in the Mg II/He II spicule and is located at the southern edge of the Mg II/He II spicule. The rising velocities of the spicule in the Mg II and He II image, and the erupted blob in the 100 GHz images are ~70 km/s. On the other hand, the rising velocity of the spicule in the 100 GHz and Fe XII images is ~40 km/s. Considering of the differences of the structures shown in the Mg II/He II and 100 GHz/Fe XII images, and the typical formation temperature of each band, the 100 GHz and Fe XII images show a cold and dense component of the spicule. The conclusion is consistent with the recently radiative MHD simulations, and we can explain why the 100 GHz spicule is delayed, shorter, and slower than the Mg II/He II spicule. The solar limb observations with ALMA are very few. Hence, it would be not accidentally that the blob-like eruptions are associated with both two large spicules observed with ALMA. The fact might suggest that large spicules included a cold and dense component is produced by magnetic reconnection that is induced by a plasmoid eruption, like a corona jet.

Istituto di Astrofisica e Planetologia Spaziali, Italy

One of the most striking features in Martian atmosphere is a very large (planet-encircling) storm, "global dust storm". The storm lifts the dust particles from the surface into the air, where the dust particles block sunlight from reaching the surface. This brings a decrease of the surface temperature. In contrast, the thickened dust layer absorbs the radiation, and directly leads to heating the atmosphere. Such a drastic change in the thermal structure in the atmosphere induces significant modulation in the dynamics as well as in the composition.

Starting from the middle of June 2018, a global dust storm has occurred on Mars for the first time in the past 11 years. Taking this unique opportunity, we observed Mars with ALMA on 30 June 2018 and 16 July 2018 that correspond to active periods of the global dust storm.

Observing with submillimeter wavelength has a good advantage compared to other optical and infrared wavelengths, since the dust opacity becomes transparent at the submillimeter wave and the emission from deep inside the global dust storm can be detected. We used Band 5 (183 GHz) and 6 (220 and 230 GHz) on 30 June, and only Band 6 on 16 July. Band 6 measurements allow us to investigate maps of temperature vertical profiles and wind fields from the CO lines. Band 5 measurements enable us to investigate maps of water vapor vertical profiles. The preliminary results from these ALMA observations will be discussed in the presentation.

Atmospheric observation of submillimeter wave and the thermal evolution of ice giants

*Kenji Kurosaki[1], Masahiro Ikoma[2]

1. Department of Physics, Nagoya University , 2. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Our solar system has two ice giants: Uranus and Neptune. Voyager II explored Uranus in 1986 and Neptune in 1989 and observed the effective temperature and the gravitational moments that are important to understand the atmospheric and interior structure. Recently by use of ground telescope submillimeter absorption features are observed. Submillimeter observations showed that Uranus did not have remarkable feature while Neptune had absorption features of HCN and CO. That is, atmospheric structures are different between Uranus and Neptune. Since the amount of CO is related to the atmospheric O/H, the observation is expected to restrict the metal enrichment of ice giants. Moreover, the atmospheric structure affects the thermal evolution of the ice giants. In this talk, we focus on ice giants in our solar system.

Planetary-system formation revealed with ALMA

*Misato Fukagawa[1]

1. National Astronomical Observatory of Japan

I review the current understanding of planetary-system formation that has primarily been obtained from observations of protoplanetary disks, the birthplaces of planets, with the radio astronomical telescope, Atacama Large Millimeter/submillimeter Array (ALMA). High angular resolution is one of the most important observing capabilities to address planetary-system formation, given the spatial scale of the planetary systems including the Solar system (30 au to Neptune), and considering the distance to the nearest star forming regions (>100 pc) where we can observe young planet-forming disks. The resolution of ~5 au at least would be necessary to obtain the spatial distribution of disk material (various gas species, dust grains) which are ingredients of planets. ALMA is the interferometer consisting of multiple antennas, providing us the resolution of about 5 au recently. ALMA has provided at least 43 12-m antennas for recent observations, providing also high sensitivity and good image quality.

The ALMA observations have so far shown that (1) rings are common for protoplanetary disk and (2) the diversity in disk structure is still seen including spiral arms and strong non-axisymmetry. Rings and other disk structures often interpreted as the sign of planet-forming activity and these observations have stimulated theoretical study on how planetesimals (km-sized bodies) form and how planet formation proceeds in an entire region of the disk. The detection of various rare molecules including organic ones is another highlight. The emission from such molecules is quite faint and the detections were owing to the ALMA's high sensitivity. Other ALMA results include finding the possible new tool to probe grain growth using polarization, and detections of tenuous gas that may be produced by collisions of cometary or planetary bodies in more evolved debris disks. Those results also give us an insight on the fruitful future in comparative study with the distribution of various material in the Solar system.

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan), Chairperson:Munetake MOMOSE(Ibaraki University)

The Atacama Large Millimeter/Submillimeter Array (ALMA) starated its science operation in 2011, and long-baseline observations have become available since 2014. With its high sensitivity and resolution, ALMA has provided us with qualitatively new information on star and planet formation and small bodies in our Solar System. For example, in the observations of protoplanetary disks, ring-like structures have been commonly found and the structures with the scale of several-AU are discovered in several systems. In our solar system, 60km pixel-scale non-uniform brightness distribution and the rotation of the asteroid Juno are detected. Spatially-resolved thermal mapping of Europa icy surface enables us to search for thermal anomaly in possible plume source regions. As of Cycle 4, Solar observations are available, enabling us, for example, to determine the physical parameters of plasmoid quantitatively. In this session, we overview the latest results of ALMA observations in the field of planetary sciences. We also accept any theoretical and experimental works that are closely related to the observations and discuss the impact on the planetary science community.

Probing dust aggregate structure in protoplanetary disks by millimeter-wave polarization

*Ryo Tazaki[1], Hidekazu Tanaka[1], Takayuki Muto[2], Akimasa Kataoka[3], Satoshi Okuzumi[4]

1. Tohoku University, 2. Kogakuin University, 3. NAOJ, 4. Tokyo Institute of Technology

Dust coagulation in protoplanetary disks is the first step of planetesimal formation and a pathway from dust aggregates to planetesimals remains unclear. Both laboratory and numerical studies have so far shown that the structure of a dust aggregate plays important roles in planetesimal formation. However, the aggregate structure has been poorly constrained by disk observations. Recently, ALMA opens a new window to observe (sub-)millimeter-wave polarization of disks, which is expected to provide additional constraints on dust aggregate properties. In this study, we perform 3D radiative transfer simulations in order to study how the structure of dust aggregates affects millimeter-wave polarization from disks. As a result, it is found that relatively compact particles are favorable to explain observed millimeter-wave scattering polarization of disks, whereas highly porous and fractal particles fail to explain the observations.

A CONSTRAINT ON THE AMOUNT OF HYDROGEN FROM THE CO CHEMISTRY IN DEBRIS DISKS

*Hiroshi Kobayashi[1], Kazunari Iwasaki[2,4], Aya Higuchi[3]

1. Department of Physics, Nagoya University, 2. NAOJ, 3. RIKEN, 4. Osaka University

The faint CO gases in debris disks are easily dissolved into C by UV irradiation so that the ratio of C to CO may show the reformation rate of CO depending on the amount of underlying hydrogen molecules. We conduct radiative transfer calculations with chemical reactions for debris disks. We find the C/CO ratio is proportional to the far UV flux and the hydrogen nucleus number density. Using the deriving formula for the C/CO ratio, we give a constraint on the amount of hydrogen for debris disks around 49 Ceti with age ~ 40 Myr; the hydrogen nucleus density ~ 2x10^{-8} cm^{-3}. That implies that the debris disk contains tenuous gases caused by the depletion of a protoplanetary disk.

Structure of the protoplanetary disk around V1094 Sco obtained from dust continuum emission and SED

*Sanemichi Takahashi[1,2], Takayuki Muto[1], Takashi Tsukagoshi[2], Jun Hashimoto[2]

1. Kogakuin University, 2. NAOJ

Understanding the structure of protoplanetary disks is important for revealing the environment of planet formation. Recent ALMA observations have found that detailed structures are formed in protoplanetary disks. In this work, we investigate the structure of the protoplanetary disk around V1094 Sco. We performed numerical calculations of radiative transfer and compared the results with dust continuum emission obtained from ALMA Band 8 observations and SED. According to the dust continuum emission, we found that the disk consists of two regions, inner optically thick region (< 100 au) and outer optically thin region (> 100 au) . We also found that the results can reproduce the SED observations well when (1) disk inner edge is puffed up and the shadow is formed behind it and (2) the small grain (< 1 um) is depleted in the inner region.

The Synthetic ALMA Multiband Analysis of the Dust Properties of the TW Hya Protoplanetary Disk

*Seongjoong Kim[1], Hideko Nomura[1], Takashi Tsukagoshi[2], Ryohei Kawabe[2,3,4], Takayuki Muto[5]

Department of Astronomy, School of Science, University of Tokyo, 5. Division of Liberal Arts, Kogakuin University

Analyzing multiband observations of dust continuum emission is one of the useful tools to constrain dust properties which help us to understand the physical properties of the disks. We perform the synthetic ALMA multiband analysis to find the best ALMA band set for constraining the dust properties of the TW Hya protoplanetary disk. We find that the Band [10,6,3] set is the best set among the possible combinations of ALMA Band [3,4,5,6,7,8,9,10]. We also find two conditions for the good ALMA band sets providing narrow constraint ranges on dust properties; (1) Band 9 or 10 is included in the band set and (2) Enough frequency intervals between the bands. These are related with the conditions which give good constraints on dust properties: the combination of optically thick and thin bands are required, and large β (β is the power-law index of dust opacity, $\kappa_\nu \propto \nu^\beta$) and low dust temperature are preferable. To examine our synthetic analysis results, we apply the multiband analysis to ALMA archival data of the TW Hya disk at Band 4, 6, 7, and 9. Band [9,6,4] set provides the dust properties close to the model profile, while Band [7,6,4] set gives the dust properties deviating from the model at all radii with too broad constraint range to specify the accurate values of dust temperature, optical depth, and β. Since these features are expected by the synthetic multiband analysis, we confirm that the synthetic multiband analysis is well consistent with the results derived from real data.

Dust evolution in the protoplanetary disk around TW Hya

*Takayuki Matsuura[1], Satoshi Okuzumi[1]

1. Tokyo Institute of Technology

Protoplanetary disks are places of planet formation. Therefore, researching construction and evolution of protoplanetary disks is important when we discuss planet formation. In particular, TW Hya is one of the best interesting stars to understand dust evolution in protoplanetary disks. It is a young star with a protoplanetary disk, and the disk has been observed at various wavelengths due to the good observation condition. Particularly, the latest high resolution imaging observation by ALMA revealed that the disk around TW Hya has gaps at 22 au and 37 au.
Various mechanisms of gap formation have been proposed. One of them is due to gravitational interaction between a planet and a disk. Accordingly, considering existence of planets, simulations on disk evolution are carried out. Those simulations show that dust is depleted and a gap forms at planetary orbit. However, the results of the simulations have different tendencies compared with the observation by ALMA, such as dust inside a gap is less than outside, and much dust accumulates on an outer edge of a gap.
Therefore, in this study, we aim to clarify what kind of physical characteristics the disk around TW Hya has in order to reproduce the dust distribution of TW Hya. For that, we simulate dust evolution in a disk and search for parameter ranges that reproduce the radial distribution of brightness temperature and spectral index obtained by ALMA. We assume that planets exist at 22 au and 37 au. We set the planet masses and the fragmentation velocity of dust to free parameters.
As the result, when the planet masses are 4—10 earth masses and the fragmentation velocity is 0.5 m s^{-1} , the simulation result reproduces observation by ALMA roughly. When we assume faster fragmentation velocity than the value that reproduce observation, dust is depleted inner the gap and more dust accumulates on the outer edge of the gap. When we assume heavier planets, more dust accumulates on the outer edge of the gaps and the contrasts of the gaps grow in excess. Thereby the observation is not reproduced.
The fragmentation velocity obtained in this study is slower than the value that has considered from a conventional growth theory of dust in disk. That suggests a possibility that monomers composing dust are large size of 10 μm or more(Wada et al.,2013), or monomers are covered by CO_2 ice(Musiolik et al.,2016). Additionally, the result suggests a possibility that planetesimals formed with the assumption different form scenario that dust coalesces into planetesimals.

Planets are formed from dust and gas in circumstellar disks around young stars.
Observations of dust and gas in circumstellar disks can provide fundamental information on planet formation processes, and high-resolution (sub-)millimeter imaging is now revealing the dust substructure likely generated by forming planets in disks.
Here we report the detection of an excess in dust continuum emission at 233 GHz (1.3 mm in wavelength) in the circumstellar disk around TW Hya, the closest such system to Earth, revealed through high-sensitivity observations with the Atacama Large Millimeter/submillimeter Array (ALMA).

We have carried out 3 au resolution continuum observations at 233 GHz (Band6) toward the protoplanetary disk (PPD) around TW Hya using ALMA in 2016 and 2017.
The sensitivity has been improved by a factor of 3 than that of our previous cycle 3 observations.
The overall structure is axisymmetric, and there are apparent gaps at 25 and 41 au as previously reported.
The most remarkable new finding is a few au scale excess emission at the south-west part of the PPD.
The excess emission is located at 52 au from the disk center and is 1.5 times brighter than the surrounding PPD.
The extracted emission after subtracting the axisymmetric PPD emission has a size of 4.4x1.0 au and a total flux density of 250 micro-Jy, corresponding to a dust mass of 0.03 earth masses.
Since the excess emission can also be marginally identified in the Band 7 image at almost the same position, the blob is unlikely a background source.
The excess emission can be explained by a massive CPD around a Neptune mass forming-planet or a dust clump accumulated in a small elongated vortex.

Ice cores can reconstruct past atmospheric environment. One of advantages for ice core archive is to reconstruct past gas and aerosols, which are important factors for evaluation of global warming. Antarctica and Greenland ice sheets have some ice domes (summit), where are useful sites for ice core drilling due to high elevation. Highland in the ice sheets can reconstruct wider emission area around the drilling sites.

At first, we will review some famous papers how reconstruct past aerosols from Antarctic dome ice cores. Antarctic dome cores can reconstruct recent 800 kyr BP, and aerosol fluctuation preserves in the cores along eight glacial-interglacial periods. Ice core community turns for obtain old ice archive in inland Antarctica (oldest ice project), so that Antarctic deep ice cores are one of topics for the ice core community.

Then, we will talk about our present project of Greenland SouthEastern Dome shallow ice core project (SE-Dome project). The SE-Dome has a huge accumulation rate (about 1.0 m water equivalent per year), where is about 4 time compared to ordinal Greenlandic dome ice cores, and 30 times to Antarctic ice cores. High accumulation dome has an advantage to reconstruct high-time resolution (e.g. seasonal scale) of recent epoch such as Anthropocene (AD 1750 to present). We obtained a 90 m ice core from the SE-Dome site in 2015, and then reconstructed aerosol fluctuations with seasonal scale from 1960 to 2014. As a result, sulfate flux responds to the decreasing trend of SOx emissions, but the nitrate flux does not follow the decrease in NOx. We have a plan in 2020 for next drilling of about 300 m ice core to reconstruct aerosol fluctuation with seasonal scale over the Anthropocene. We are looking for new joint studies using the ice core with members in the community of atmospheric chemistry.

The atmospheric sulfate is important for both climate change and air quality; it influences radiation forcing and cloud's lifetime, and accounts for major components in fine particulate matter mass in urban regions with affecting visibility and public health. The emitted SO_2 is oxidized by OH radicals in the gas-phase, but modeling studies suggest that the large proportions (~80%) of global sulfate production were occurred in the aqueous-phase. However, the treatment of aqueous-phase in cloud pH set in atmospheric chemistry-transport models had the largest impact for atmospheric sulfate concentrations. Due to the lack of critical understanding for the chemical processes responsible for sulfate production, it is difficult to predict future changes in [SO_4^{2-}] and its effects on climate and air quality.

To help address this, here we use mass-independent oxygen isotopic composition ($\Delta^{17}O$) of sulfate providing insight into past oxidation pathways responsible for sulfate formation. We present $\Delta^{17}O$ of SO_4^{2-} obtained from a 90.45 m depth ice core drilled at a high-elevation dome site in southeast Greenland called SE-Dome, covering the last 60 years. We found that $\Delta^{17}O$ of SO_4^{2-} with low during the 1960s-1970s and high in after the 2000s. This increase in $\Delta^{17}O$ of SO_4^{2-} indicates that sulfate formation pathways responsible for sulfate changed after 1960 to the present along with declining SO_2 emission. In the presentation, we will discuss the enhanced role of a oxidation processes contributing to increase $\Delta^{17}O$ of SO_4^{2-}, and its implication to the changes in atmospheric chemistry though the changes in anthropogenic activities. This provides insight into direct and indirect effects of anthropogenic activities to the air quality by changing sulfate formation pathways. These functions, so called "chemical feedback", should be considered for making efficient mitigation policy for climate change and air quality by controlling emission of anthropogenic pollutants.

Estimation of high sulfate aerosol sources in 2012 spring at Cape Hedo, Okinawa

*Syuichi Itahashi[1], Shiro Hatakeyama[2], Kojiro Shimada[3], Akinori Takami[4]

1. Central Research Institute of Electric Power Industry, 2. Center for Environmental Science in SaitamaCenter for Environmental Science in Saitama, 3. School of Creative Science and Engineering, Waseda University, 4. National Institute for Environmental Studies

Air quality in Asia can cause regional-to-global environmental issues. Intensive observation campaigns approximately 1 week long have been conducted periodically from March 2010 to November 2015 at Cape Hedo, Okinawa, Japan. The period-averaged sulfate aerosol (SO_4^{2-}) concentrations for each campaign ranged from 0.34 to 6.97 $\mu g\ m^{-3}$, and the average concentration of all observations was 3.13 $\mu g\ m^{-3}$. The maximum daily mean concentrations surpassed 15 $\mu g\ m^{-3}$ in springtime 2012. The sources of this high SO_4^{2-} concentrations were estimated by using the air quality model with the tagged tracer method in this study. The main source of the high SO_4^{2-} concentrations in March was volcanoes and that in April was anthropogenic emissions from China. In March, the prevailing northerly wind transported a volcanic SO_2 plume with a low conversion ratio to Cape Hedo. The impacts of 15 volcanoes in Japan were estimated in this study, and a substantial impact of Sakurajima, which accounted for more SO_2 than anthropogenic emissions from Japan, was found. Throughout April, source apportionments from anthropogenic emissions from China were found; hence, the source was further divided into 31 provincial scales. Shandong and Jiangsu provinces, which are the first and seventh largest emission sources in China, were identified as important sources at Cape Hedo. These sources showed day-to-day variation, and the highest contribution from Shandong province was on April 23, whereas that from Jiangsu province was on April 22.

Isotopic constrains on sources and formation pathways of atmospheric nitrate in Mt. Everest

*Kun Wang[1,2,4], Shohei Hattori[2], Shichang Kang[1,3,4], Mang Lin[2], Naohiro Yoshida[2,5]

1. Northwest Institute of Eco-Environment and Resources, Chinese Academy of Sciences , 2. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 3. CAS Center for Excellence in Tibetan Plateau Earth Sciences, 4. University of Chinese Academy of Sciences, 5. Earth-Life Science Institute, Tokyo Institute of Technology

Studies on the sources and formation pathways of nitrate is crucial to better understand nitrogen cycle and atmospheric oxidation capacity. Tibetan Plateau (TP) and surroundings, referred to as the Third Pole and “Asia water tower”, contain the largest number of glaciers outside the polar regions and are largely experiencing shrinkage. A complete understanding on the source and formation mechanisms of atmospheric nitrate in the TP is important to indicate the impact of human activities on the environment and also crucial to investigate nitrogen cycle in glacier-hydrology systems of this region. Besides, it can supply information on interpreting ice core records to understand the past atmosphere chemistry. Here we collected aerosol samples from the Everest through pre-monsoon (April-May) and monsoon season (June-August) in 2018, and measured for the first time the isotopic compositions ($\delta^{15}N$, $\delta^{18}O$ and $\Delta^{17}O$) of nitrate in this region, allowing insights into their sources and potential formation mechanism. The results show that the seasonal variations in both $\delta^{15}N$ and $\Delta^{17}O$ values have a similar trends with maximum during pre-monsoon season and minimum during monsoon season. The relatively high values of $\delta^{15}N$ in pre-monsoon seasons, maybe indicate the enhanced contribution from fossil fuel combustions in South Asia which can be transported to our sampling sites across the Himalayas by the mountain/valley wind system. The $\Delta^{17}O$ (NO_3^-) value, which is dependent on both the $\Delta^{17}O$ (NO_2) value and the oxidation pathways (O_3 and OH) of NO_2 to NO_3^-, show that the O_3 oxidation pathway is dominant during pre-monsoon season, resulting in higher values of both $\delta^{18}O$ and $\Delta^{17}O$. In contrast, during monsoon season, formation involving HO_2/RO_2 radicals becomes important, producing lower values of $\delta^{18}O$ and $\Delta^{17}O$. To better understand the oxidation process of past atmosphere in the Everest region, observations of oxygen-17 excess of nitrate and sulfate in ice cores collected from this region in the future are recommended.

Development of a large volume sampling system for measuring stable isotope analysis of carbonyl sulfide and field observation

*Kazuki Kamezaki[1], Shohei Hattori[1], Naohiro Yoshida[1,2]

1. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 4259 Nagatsuta-cho, Midori-ku, Yokohama, Kanagawa 226-8502, Japan, 2. Earth-Life Science Institute, Tokyo Institute of Technology, 2-12-1-IE-1 Ookayama, Meguro-ku, Tokyo 152-8550, Japan

Carbonyl sulfide (OCS) is the most abundant sulfur-containing gas in the ambient atmosphere, with an average mixing ratio of 500 parts per trillion (ppt) by volume in the troposphere. OCS is suggested as a sulfur source of the stratospheric sulfate aerosols (SSA) which plays an important role for Earth of radiation budget and for ozone depletion. Moreover, since leaves consume OCS whenever they are assimilating CO_2 with same process but plant does not emit OCS to atmosphere by respiration, OCS provides a means to partition net ecosystem exchange into gross primary production (GPP) and respiration on land. Nevertheless, current figures for tropospheric OCS sources and sinks carry large uncertainties.

Isotope analysis is a useful tool to trace sources and transformations of trace gases. Very recently, Angert et al. (2019 Sci. Rep.) reported $d^{34}S$ value at Israel and Canary Island for tropospheric OCS using a gas chromatograph (GC)/multi collector-inductively coupled plasma mass spectrometer (MC-ICP-MS). For the measurement of sulfur isotope ratios of OCS in our laboratory, an online method measuring on a GC/isotope ratio (IR)-MS using S^+ fragmentation ions had been developed (Hattori et al., 2015). This method supports simple analysis of sulfur isotopic compositions of OCS over 8 nmol. However, application this method for atmospheric samples has yet to be done by this GC/IR-MS method, because of the large sample amounts that are necessary (i.e. 500 L of 500 pmol mol^{-1} OCS). Therefore, we developed a large volume air sampling system to apply S^+ IR-MS method for atmospheric samples and we observed $d^{34}S$ value in Suzukakedai campus at Yokohama (Kamezaki et al., 2019 Atmos. Meas. Tech.).

We will discuss the difference between the result of Angert et al. (2019) and our observation. Additionally, we also report the result in field campaign using our developed method.

Observations of aerosol optical properties by sky radiometers at SKYNET Southeast and South Asian sites

*Al Mashroor Fatmi[1], Hitoshi Irie[1], Hossain Mohammed Syedul Hoque[1], Alessandro Damiani[1], Pradeep Khatri[2], Tamio Takamura[1], Thanawat Jurupongsaku[3], Govindan Pandithurai[4]

1. Center for Environmental Remote Sensing Chiba University , 2. Tohoku University, 3. Chulalongkorn University, 4. Indian Institute of Tropical Metereology

Direct and scattered sunlight measurements using sky radiometers were performed at two SKYNET sites –Phimai (15.18˚N, 102.56˚E) in Thailand and New Delhi (28.63˚N, 77.17˚E) in India. Phimai is a rural site and during the dry season (January to April), the site is affected by biomass burning. New Delhi is an urban site and expected to be influenced by vehicular and industrial emissions and agricultural waste burning. Depending on the data availability, aerosol optical properties during the year 2012 and 2016 were analyzed for New Delhi and Phimai, respectively. During the dry season in 2016 at Phimai, enhanced aerosol absorption optical depth (AAOD) was observed corresponding to the influence of biomass burning. The wavelength dependence of AAOD was quantified using the absorption Ångström exponent (AAE). The mean AAE at Phimai during the dry season in 2016 was 1.5±0.2, indicating the presence of organic brown carbon aerosols. This was consistent with coincident multi-axis differential absorption spectroscopy measurements showing higher concentration of organic compounds (formaldehyde and glyoxal) during the dry season, corresponding to biomass burning. At New Delhi, the mean AAE values during winter (December ~ February) and monsoon season (June ~ August) were 1.51±0.23 and 0.88± 0.24, respectively. The higher AAE during winter indicates the significant injection of organic brown carbon, probably due to transportation of carbonaceous materials from agricultural waste burning from Northern India. Thus, deduction of AAE, retrieved through sky radiometers observations, is expected to be useful for better understanding the physical and optical properties of light absorbing organic aerosols.

Analysis of factors causing variations in the absorption Ångström exponent of aerosols in Japan using skyradiometers

*Kodai Yamaguchi[1], Hitoshi Irie[1], Pradeep Khatri[2], Toshihiko Takemura[3], Hirokazu Yamamoto[4]

1. Chiba University, 2. Tohoku University, 3. Kyushu University, 4. National Institute of Advanced Industrial Science and Technology

Aerosols have brought the most significant uncertainty in predicting future climate change. To reduce the uncertainty, it is essential to better understand the optical properties of aerosols. Organic aerosols and mineral dust, which are the main aerosols, have been considered to cause only a weak light absorption, and their radiative forcing has been negative in most climate models. However, recent laboratory experiments and observations indicated that there should be aerosols (such as brown carbon) causing a strong light absorption in particular in the ultraviolet-to-visible wavelength regions. Although the Absorption Ångström exponent (AAE) was used as a useful index for representing the wavelength dependence of such light absorption, its observation has been limited. Under this circumstance, we made long-term observations using skyradiometers of SKYNET at 6 sites in Japan (Chiba, Fukue, Kasuga, Miyakojima, Sendai, and Takayama). Using our newly developed analysis algorithm package (SR-CEReS), we retrieved AAE values for the 6 sites to investigate factors causing their variations. While the theoretical AAE value of black carbon is considered to be unity, our analysis shows that the annual averages of AAE were in the range from 1.15 to 1.51, indicating the presence of aerosols having strong light absorption in the ultraviolet-to-visible wavelength regions at all the 6 sites. Moreover, urban sites tended to show higher AAE values. We additionally analyzed nitrogen dioxide and sulfur dioxide concentration data taken by the Multi-Axis Differential Optical Absorption Spectroscopy (MAX-DOAS) observations, which were conducted simultaneously with the skyradiometer. Then, it was suggested that the AAE could be enhanced by emissions from ships, factories, or steelworks.

Sources of atmospheric black carbon and related carbonaceous components at Rishiri Island, Japan

*Chunmao Zhu[1], Yugo Kanaya[1], Hisayuki Yoshikawa[2], Tomohisa Irino[2], Osamu Seki[2], Yasunori Tohjima[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. Hokkaido University, 3. National Institute for Environmental Studies

A field study was conducted to clarify sourcesof atmospheric black carbon and related carbonaceous components at Rishiri Island, Japan. We quantified equivalent black carbon (eBC) particle mass and the absorption Ångström exponent (AAE), atmospheric CO and CH_4, in addition to levoglucosan in total suspended particles, a typical tracer of biomass burning. Sixteen high eBC events were identified attributable to either anthropogenic sources or biomass burning in Siberia/China. These events were often accompanied by increases of co-emitted gases such as $CH_4$and CO. Specifically, we observed pollution events with elevated eBC, AAE, levoglucosan, and CH_4–CO slope in late July 2014, which were attributed to forest fires in Siberia by reference to the FLEXPART model footprint and fire hotspots. In autumn, drastic increases of eBC, AAE, and levoglucosan were observed, accompanied by an eBC–CO slope of >15 ng m^{-3}/ppb, resulting from long-range transport of emissions from extensive burning of crop residue on the Northeast China Plain. Other than the sources of fossil fuel combustion in China and forest fires in Siberia, we also report that pollution events in northern Japan are caused by crop residue burning in China. This study elucidated valuable information that will improve understanding of the effects of biomass burning in East Asia on atmospheric carbonaceous components.

Black carbon (BC) deposited on snow lowers snow albedo, potentially contributing to the warming in the Arctic. The distributions of inorganic aerosols (ions), which contribute to direct and indirect aerosol effects, are also greatly influenced by deposition. It is critically important to measure the spatial distributions of BC and ions in snowpack in different regions of the Arctic to quantify these effects. Because accurate measurements of BC and ions in snowpack are very limited, we measured the mass concentrations of size-resolved BC (C_{MBC}) and ions in snowpack over Finland, Alaska, Siberia, Greenland, and Spitzbergen in early spring during the period of 2012 –2016 by using a single-particle soot photometer and ion chromatography, respectively. BC deposition amounts (DEP_{MBC}) during snow accumulation periods were derived from C_{MBC} and snow water equivalent (SWE). Detailed analyses have shown that the spatial distributions of the anthropogenic BC flux and topography strongly influenced the latitudinal variations of C_{MBC} and BC size distributions. The average size distributions of BC in snowpack shifted to smaller sizes with the decrease in C_{MBC}, likely due to an increase in the removal efficiency of BC with the increase in BC diameter during transport from major BC sources. The present C_{MBC} were much lower than previous C_{MBC} measured by using an Integrating Sphere/Integrating Sandwich spectrophotometer by a factor of about 13. The present accurate data of C_{MBC}, SWE, and DEP_{MBC} are very useful in constraining climate model to estimate the effect of BC on the climate of the Arctic.

The single-particle extinction and scattering method for online characterization of submicron particles: Principles and applications to aerosol research

*Nobuhiro Moteki[1]

1. The Univerisity of Tokyo

We will introduce the single-particle extinction and scattering (SPES) method as a new fundamental tool for online measurements of submicron particles and its applications to aerosol research. The SPES method accurately determines the amplitude and phase of the forward-scattered wave from a single particle on the basis of the interference patterns between the scattered and the incident fields when the particle traverses a tightly-focused laser beam. The complex refractive index and volume of the detected particle can be estimated from the SPES data using our original data-processing algorithm. In the presentation, we will talk about the measurement principle, the theoretical framework of data analysis including the potential effects of particle shape, the performance tests, and some applications to black carbon and mineral particles.

High spatial resolution vehicular emissions inventory for China using VEIN model

*Sergio Ibarra Espinosa[1], Xuelei Zhang[1], Aijun Xiu[1], Edmilson Dias de Freitas[2]

1. Research Group of Regional Atmospheric Environment, Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, P. R. China, 2. Department of Atmospheric Sciences, University of São Paulo, Brazil.

Vehicular emissions are an important source of pollution in China. These and other anthropocentric emissions, with poor meteorological conditions enhance critic episodes of high concentrations of air pollutants (Wang S. and Hao J., 2012). Environmental policies seeks to improve air quality by diminishing and cutting emissions, making the emissions characterization of crucial importance. Even more, air quality modelers needs emissions inventories as inputs, which usually suffer of limited temporal and spatial representation and over simplification. Under these circumstances, it is not expected good air quality simulations. I other words, garbage-in, garbage-out.

This study aims to improve the temporal and spatial representation of vehicular emissions. This will be achieve using the VEIN model (Ibarra-Espinosa *et al.,* 2017), initially with a top-down approach. The method and data is described as follows: stock vehicles will be obtained for 31 provinces (National Bureau of Statistics (NBS), 2016) considering vehicle survival pattern and average age of use of the fleet (HAO *et al*, 2011; Wang H. *et al*, 2012). NBS data is aggregated without discriminating taxis and motorcycles, therefore, the vehicular composition and activity will be obtained with the percentages of Wang H. *et* al, (2008): Passenger Cars (PC), Taxi, Motorcycle, Moped, Bus, Small Trucks, Medium Trucks and Heavy Trucks by type of fuel. Furthermore, we will divide traffic at peak and off peak hours and by Freeways, Arterial and residential roads, shown on Fig.1, in each province to obtain the representative speed in each case, based on the driving cycles obtained by Wang Q. *et al*, (2008). We will use Copert (Ntziachristos and Samaras, 2016) emissions factors inside VEIN correcting by chemical composition of fuel and deterioration factors. Cold starts and evaporative emissions will be obviously included. To ensure consistency with the emissions and fuel consumed on each province, activity will be calibrated in order that fuel consumption estimation or CO_2 estimations matches with statistics of automotive fuel sales or CO_2 emissions, depending on the availability of data. Top-down emissions will be spatially dis-aggregated by length of type of road from OpenStreetMap in each province as shown by Andrade *et al*, (2015).

[AAS04-15] Seasonal and interannual variations of the Atmospheric Potential Oxygen over the Western North Pacific observed by using a cargo aircraft C-130H

*Shigeyuki Ishidoya[1], Kazuhiro Tsuboi[2], Yosuke Niwa[3], Shohei Murayama[1], Hidekazu Matsueda[2], Yousuke Sawa[2], Nobuyuki Aoki[1], Kentaro Ishijima[2], Kentaro Kozumi[4], Genta Umezawa[4], Kazuya Yukita[4], Shigeharu Nishida[4], Megumi Yamamoto[4] (1.National Institute of Advanced Industrial Science and Technology (AIST), 2.Meteorological Research Institute, 3.National Institute for Environmental Studies, 4.Japan Meteorological Agency)

Effect of land use change on GHG fluxes of tropical peat forests in Borneo island

*Ryuichi Hirata[1], Habura Borjigin[1], Tomohiro Shiraishi[1], Takashi Hirano[2], Lulie Melling[3]

1. National Institute for Environmental Studies, 2. Hokkaido University, 3. Sarawak Tropical Peat Research Institute

Borneo island, which is located in southeast Asia, has a rich forest and it store a huge carbon in biomass and soil. It is well known that peat, which is large carbon reservoir, widely spreads in the island. While tropical peat forest occupies only 0.25% of surface area on globe, it accounts 3% of soil organic carbon on earth. Tropical peat forest, in which forest grows on peat which depth from 1 to 10 m. Recently, the area of tropical peat forest is rapidly decreasing because of fire or plantation and has resulted in large carbon lost. Therefore, carbon management and control for tropical peat forest is very important with the objective of development, conservation and disaster prevention. In this study, we will introduce the studies to evaluate the effects of land use change on greenhouse gas fluxes of tropical peat lands from site scale to regional scale various methods i.e. flux observation of eddy covariance and chamber methods, remote sensing and numerical simulation under several projects.

Remote sensing of carbon assimilation function of terrestrial ecosystem by Earth-observation satellite

*Hibiki M Noda[1], Yukio Yoshida[1], Haruki Oshio[1], Tomoki Kiyono[1], Tatsuya Miyauchi[1], Tsuneo Matsunaga[1]

1. NIES National Institute of Environmental Studies

Since industrial evolution, global warming has progressed owing to increase of CO_2 emitted by human activities. To deal effectively with this issue by mitigation and adaptation, it is necessary to monitor emission and sequestration of GHGs with their underlying mechanisms including biogeochemical processes. Plant photosynthesis is one of the important factors to drive carbon cycling between atmosphere and biosphere. The terrestrial ecosystems assimilate about 30 % of anthropogenic CO_2 through photosynthesis. Since the photosynthetic process is quite sensitive to climatic conditions such as temperature, radiation and precipitation, there are still uncertainty in the estimation of photosynthetic production of regional to global scale. This uncertainty would be lager under climate change condition in near future. Thus, it is necessary to obtain the temporal dynamics of the photosynthetic production in large area.
Satellite remote sensing has been used to monitor the spatial and temporal dynamics of terrestrial ecosystems that are responsible for such photosynthetic CO_2 absorption. Such observation provides us with geographical information on the potential distribution of carbon sequestration by the aid of ecosystem models. In these years, advent of the spectroradiometer, which has high wavelength resolution, such as TANSO FTS on Greenhouse Gases Observing Satellite (GOSAT) enable us to observe solar-induced chlorophyll fluorescence (SIF) emitted from the terrestrial ecosystems. Since the chlorophyll fluorescence is emitted from photosynthetic process itself, SIF remote sensing is drawn considerable attention as a new technique to observe the photosynthetic activity of the vegetation. SIF has been measured by gas-measurement satellites, such as GOSAT, GOSAT-2, OCO-2 and GOME2 on MetOp A and B.
In this talk, we will introduce our previous and on-going studies about estimation of photosynthetic production of the terrestrial ecosystem. We also discuss about future perspective about SIF studies in GOSAT and GOSAT-2 projects.

Analysis of the carbon dioxide in the upper troposphere and lower stratosphere by the data from GOSAT TANSO-FTS TIR

*Nawo Eguchi[1], Akihiro Honda[1], Naoko Saitoh[2], Yosuke Niwa[3]

1. Kyushu University, 2. Chiba University, 3. National Institute for Environmental Studies

Stratospheric cooling was reported, it could be caused by increasing the carbon dioxide (CO_2), which is a major greenhouse gas. While, the concentration of CO_2 in the stratosphere is not well understood, nor are the exchange processes between the upper troposphere and lower stratosphere (UT/LS ; 250-100hPa). The present study investigated the intra-seasonal, seasonal and inter-annual variations of CO_2 to understand the CO_2 concentration at UT/LS and the Stratosphere and Troposphere exchange process.

We used the vertical profile data (Level 2) of CO_2 derived from thermal infrared (TIR) region (Band 4: 5.5 - 14.3 μm) of the Thermal And Near-infrared Sensor for carbon Observation (TANSO) - Fourier Transform spectrometer (FTS) on board Greenhouse gas Observing SATellite (GOSAT). The analysis period is four years from January 2010 to December 2013. We adapted the bias correction values derived from Saitoh et al. [AMT, 2016] which validated the TIR CO_2 profiles at UT/LS region with the Comprehensive Observation Network for TRace gases by AIrLiner (CONTRAIL). For reference, the atmospheric transport model, NIES-TM (ver.5) and the Nonhydrostatic Icosahedral Atmospheric Model (NICAM)–based Transport Model (TM) were used [Niwa et al., 2011; 2017].

The growth rate of CO_2 concentration at UT/LS were approximately 2 ppmv/year, which one at southern hemisphere were relatively larger than one at northern hemisphere. The seasonal variation of CO_2 concentration, showed that the maximum peak existed after a few month with respect to the peak at the middle or lower troposphere. The inter-annual variations were affected by the ENSO cycle; the higher (lower) CO_2 concentration at UT were seen during La Nina (Normal / El Nino) period. Finally, the intra-seasonal variation CO_2 concentration at UT/LS were associated with both the vertical and horizontal transportation due to the deep convection and the Asian monsoon anticyclonic circulation, respectively. To clarify the dynamics of CO_2 concentration on the time scale within the area and season within which we could not observe by aircraft observation or balloon observation, the results are used for verification of physicochemical process of global model and also for their development can do.

Seasonal and interannual variations of the Atmospheric Potential Oxygen over the Western North Pacific observed by using a cargo aircraft C-130H

*Shigeyuki Ishidoya[1], Kazuhiro Tsuboi[2], Yosuke Niwa[3], Shohei Murayama[1], Hidekazu Matsueda[2], Yousuke Sawa[2], Nobuyuki Aoki[1], Kentaro Ishijima[2], Kentaro Kozumi[4], Genta Umezawa[4], Kazuya Yukita[4], Shigeharu Nishida[4], Megumi Yamamoto[4]

1. National Institute of Advanced Industrial Science and Technology (AIST), 2. Meteorological Research Institute, 3. National Institute for Environmental Studies, 4. Japan Meteorological Agency

The cargo aircraft C-130H flies once per month from Atsugi Base (35.45˚N, 139.45˚E), Kanagawa, Japan, to Minamitorishima (MNM; 24.28˚N, 153.98˚E), and air samples are collected during the level flight (~6 km) and the descent portion at MNM. The air samples have been analyzed for $O_2/N_2$and Ar/N_2ratios and stable isotopic ratios of N_2, $O_2$and Ar since May 2012. The analysis indicated a significant artificial fractionation due to thermal diffusion during the air sample collection. Nevertheless we succeeded to correct the effects of the fractionation on the observed O_2/N_2ratio precisely by using the observed Ar/N_2 ratio (Ishidoya et al., 2014). The corrected O_2/N_2ratio showed a secular decrease accompanied by a prominent seasonal cycle. The average secular change rate of the mid-tropospheric corrected O_2/N_2ratio was found to be -25.2±0.5 per meg $yr^{-1}$for the period 2012 –2018, which agreed well with that observed at La Jolla, USA by Scripps O_2program (Keeling and Manning, 2014). As the uncertainty of the change rate, we considered the spatial difference of the rates and the stability of the O_2/N_2ratio of standard air.

The Atmospheric Potential Oxygen ($APO=O_2+1.1xCO_2$), calculated by using the corrected O_2/N_2ratio, also showed prominent seasonal cycles, and the amplitude of the mid-tropospheric seasonal APO cycle observed at 25.5˚N was found to be 55 and 31 % of those observed at 33.5˚N and the surface MNM (Ishidoya et al., 2017), respectively. On the other hand, the corresponding seasonal amplitude of CO_2at 25.5˚N was found to be 72 and 93 % of those at 33.5˚N and the surface MNM, respectively. An atmospheric transport model (Niwa et al., 2017) reproduced general features of the observed seasonal APO and CO_2cycles, and its tagged simulation suggested that the mid-tropospheric seasonal APO cycle in the northern low latitudes was reduced significantly by the anti-phase seasonal APO cycle from the southern hemisphere. The observed APO showed interannual variations superimposed on secular downward trends, and the temporal change rates take maxima from the end of 2014 to the beginning of the 2015 at the surface MNM and in the mid-troposphere at 29 –34 ˚N. A comparison between the observed and simulated interannual variations of APO suggested that an interannual variation of the atmospheric transport contributed about 30 % of the observed variation.

Acknowledgments

We thank the staff of Japan Meteorological Agency for their work to collect the air samples onboard a cargo aircraft C-130H. This study was partly supported by the JSPS KAKENHI Grant Number 15H02814, and the Global Environment Research Coordination System from the Ministry of the Environment, Japan.

Discussion

Turbulent kinetic energy dissipation rates depending on the polar vortex and on synoptic-scale disturbances in the UTLS region in the Antarctic

*Masashi Kohma[1], Kaoru Sato[1], Koji Nishimura[2], Masaki Tsutsumi[2]

1. Department of Earth and Planet Science, Graduate School of Science, The University of Tokyo, 2. National Institute of Polar Research and The Graduate University for Advanced Studies (SOKENDAI)

The turbulence kinetic energy dissipation rate (TKEDR) is a fundamental parameter describing atmospheric turbulence. Our previous study reported the first estimation of the TKEDR in the free atmosphere in the Antarctic from atmospheric radar measurements at Syowa Station, and showed that the TKEDR in the 10–15 km height range became large in May through October. This fact suggests that the seasonal evolution of polar vortex has impact on the TKEDR in the upper troposphere and lower stratosphere (UTLS). The present study investigates the dependence of the TKEDR on the relative location to the polar vortex and on each phase of synoptic scale disturbances during austral winter in the UTLS region using the radar measurements at Syowa Station. First, the TKEDR is obtained as a function of the relative distance from the edge of the polar vortex. The edge of the polar vortex was determined from Ertel’ s potential vorticity on 475-K isentropic surface (Nash et al., 1996). The result showed that the TKEDR is significantly large near the polar vortex edge compared to that outside and deep inside the polar vortex. Furthermore, it is clarified that the TKEDR largely depends on synoptic-scale PV perturbation around the tropopause (300-K isentropic surface).

Momentum budget of semiannual oscillation around the tropical stratopause

*Yoshihiro Tomikawa[1,2], V. Lynn Harvey[3], John A. Knox[4], Masatomo Fujiwara[5]

1. National Institute of Polar Research, 2. SOKENDAI, 3. University of Colorado Boulder, 4. University of Georgia, 5. Hokkaido University

Meteorological reanalysis data have been updated and improved in the past decade, which are pretty useful for climate and meteorological studies. Their comprehensive evaluation is going underway as the SPARC Reanalysis Intercomparison Project (S-RIP). This study reports the momentum budget of semiannual oscillation around the tropical stratopause for four kinds of the latest reanalysis data (i.e., MERRA, MERRA2, ERA-Interim, and JRA55) as a part of S-RIP. They showed that, while the westerly acceleration is primarily due to unresolved wave drag (i.e. gravity wave drag), the easterly acceleration is induced by momentum transport due to meridional circulation and resolved wave drag. This feature is consistent with previous studies based on simulation and observation. However, the contribution of unresolved wave drag is maximized in MERRA/MERRA2 later than in ERA-Interim/JRA55. We discuss the difference between the latest reanalyses and its impact on the tropical dynamics.

A study on sources of gravity waves that reach the summer stratosphere and mesosphere based on high-resolution radiosonde data

*Haruka Okui[1], Masashi Kohma[1], Kaoru Sato[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Gravity waves (GWs) are mainly generated in the troposphere and play a crucial role in the momentum transport in the stratosphere and mesosphere. Several possible main sources of GWs are suggested by theoretical, numerical and observational studies; topography and jet-front systems in winter, and strong convection in summer (e.g. Sato *et al.*, 2009). In addition, theoretical work by Bühler *et al.* (1999) indicated that the Kelvin-Helmholtz (KH) shear instability can cause significant emission of GWs in summer. Having critical layers in the lower stratosphere, orographic waves hardly propagate into the summer stratosphere and mesosphere. On the other hand, most GWs emitted from the KH instability above the tropopausal jet do not encounter their critical layer and can reach the stratosphere and mesosphere. However, observational studies from this view point are insufficient. In this study, using high-resolution radiosonde data from 9 stations in Japan, the generation and propagation of GWs with short vertical wave length ($\leq$ 4 km) in the troposphere and lower stratosphere are investigated. The parameters describing the wave structure are estimated by a hodograph analysis. Drawing a comparison with GWs observed in winter, source and propagation characteristics of GWs in summer are highlighted. The latitude-height distribution of wave amplitudes and phase velocity characteristics suggests that orographic waves are not dominant in summer in contrast with those in winter. The vertical direction of wave energy propagation shows that summer GWs propagate upward and downward from the 10-15 km height region, where the occurrence frequency of the events with Richardson number (Ri) less than 0.25 (which is a necessary condition for the KH instability) is high. In addition, wave amplitudes in the lower stratosphere are relatively large above the peak of the occurrence frequency of $Ri < 0.25$, which is located around the latitude and height region of 30°N-35°N, 12-15 km. These results suggest that the KH instability is one of major sources of GWs in the summer stratosphere. The KH instability tends to occur when the vertical wind shear is large and the static stability is low. In summer, the vertical shear associated with the jet is stronger at higher latitudes and the static stability is lower at lower latitudes. The peak of occurrence frequency of $Ri < 0.25$ as mentioned above is situated at the middle latitudes inbetween. Therefore, it can be inferred that this region is climatologically important for shear-generated GWs which can reach the summer stratosphere.

Stratospheric initial conditions provide seasonal predictability of the North Atlantic and Arctic Oscillations

*Yu Nie[1], Adam Scaife[2,3], Hong-Li Ren[1,4], Ruth Comer[2], Martin Andrews[2]

1. Laboratory for Climate Studies, National Climate Center, China Meteorological Administration, Beijing, China, 2. Met Office Hadley Centre, Exeter, UK, 3. College of Engineering, Mathematics and Physical Sciences, University of Exeter, Exeter, UK, 4. Department of Atmospheric Science, School of Environmental Studies, China University of Geoscience, Wuhan, China

The North Atlantic Oscillation (NAO), the regional manifestation of the Arctic Oscillation (AO), dominates winter climate variability in Europe and North America. Skilful seasonal forecasting of the winter NAO/AO has been demonstrated recently by dynamical prediction systems. However, the role of initial conditions in this predictability remains unknown. Using a latest generation seasonal forecasting system and reanalysis data, we show that the initial upper stratospheric zonal wind anomaly contributes to winter NAO/AO predictability through downward propagation of initial conditions. An initial polar westerly/easterly anomaly in the upper stratosphere propagates down to the troposphere in early winter, favoring a poleward/equatorward shift of the tropospheric mid-latitude jet. This tropospheric anomaly persists well into the late winter and induces the positive/negative phase of NAO/AO in the troposphere. Our results imply that good representation of stratospheric initial condition and stratosphere-troposphere coupling in models is important for winter climate prediction.

To investigate the seasonal characteristics of chemical tracer distributions in the extratropical upper troposphere and lower stratosphere (ExUTLS) as well as stratosphere–troposphere exchange processes, origin fractions of air masses originating in the stratosphere, tropical troposphere, mid-latitude lower troposphere (LT), and high-latitude LT in the ExUTLS are estimated using 10-year backward trajectories calculated with European Centre For Medium-Range Weather Forecasts (ECMWF) ERA-Interim data as the meteorological input. Time-series of chemical tracers obtained from ground-based and airborne observations are incorporated into the trajectories, thus reconstructing spatiotemporal distributions of chemical tracers in the ExUTLS. The reconstructed tracer distributions are analysed with the origin fractions and the stratospheric age of air (AoA) estimated using the same backward trajectory. The reconstructed distributions of CO and CO_2 in the ExUTLS are affected primarily by tropospheric air masses because of the short chemical lifetime of the former and large seasonal variations in the troposphere of the latter. Distributions of CH_4, N_2O, and SF_6 are controlled primarily by seasonally varying air masses transported from the stratosphere. For CH_4 and N_2O distributions, their seasonally varying photochemical decay along the average pathway from the source region are particularly important. This study developed and demonstrated a unique and effective method to exploit the advantages of observational data in combination with trajectory analysis. This method provides a means to understand both air mass transport and chemical decay for photochemical active substances from a new perspective.

Possible impacts of stratospheric ozone on circulation changes in the tropical troppposphere following a stratospheric sudden warming event

*Makoto Deushi[1]

1. Department of Atmospheric Environment and Applied Meteorology, Meteorological Research Institute

Many studies have shown that there are significant impacts of the stratospheric ozone on dynamical coupling between the stratosphere and troposphere (S-T) at middle and high latitudes, especially in the Southern hemisphere (e.g. Marshall *et al.*, JC, 2006; Thompson *et al.*, Nature Geo, 2011). In contrast, little attention has been given to role of the stratospheric ozone in modulating S-T dynamical coupling in the tropics (and sub-tropics) so far. Recently, there has been an increasing interest in the S-T dynamical coupling in the tropics because it has been recognized that this coupling has significant influences on moist convection and organized convective systems in the tropics (e.g. Son *et al.*, JC, 2017; Nishimoto and Yoden, JAS, 2017).
In this study, possible impacts of the stratospheric ozone on tropospheric circulation and precipitation in the tropical and sub-tropical regions were examined, focusing on a period of several months following a major stratospheric sudden warming (SSW) event. As a case study, the major SSW occurred in the winter of 2003/2004 was investigated. A set of ensemble re-forecasts was performed by using a chemistry-climate model (CCM) and an atmospheric general circulation model (AGCM) to elucidate radiative effects of the stratospheric ozone anomalies induced by the major SSW on the troposphere at low latitudes. The ensemble re-forecasts were conducted using the Lagged Averaged Forecasting (LAF) method with 60 ensemble members, where the initial-times were set just before the occurrence of the major SSW. The CCM resolves well full stratospheric and tropospheric chemistry processes, and considers online radiative feedbacks from the simulated atmospheric ozone. The CCM ensemble re-forecast was compared to the AGCM ensemble re-forecast in which climatological monthly mean ozone was forced. The CCM ensemble re-forecast reproduced well significant ozone decrease in the lower tropical stratosphere due to rapidly enhanced upward Brewer-Dobson circulation there after the major SSW. About two weeks after the occurrence of the major SSW, systematic differences with statistical significance between the two ensemble re-forecasts were simulated in the tropospheric circulation and precipitation especially in the northern tropics and sub-tropics. The northern cell of the Hadley circulation became stronger in the CCM ensemble re-forecast than in the AGCM one, with the larger amount of precipitation over the Intertropical Convergence Zone (ITCZ). To confirm these impacts of the stratospheric ozone on the (sub-) tropical troposphere, other major SSW events are also investigated.

Stratosphere-troposphere exchange of ozone and carbon monoxide over the northern Pacific Ocean in northern winter using two chemical reanalysis data sets

*Haosen Xi[1], Masatomo Fujiwara[1], Kazuyuki Miyazaki[2]

1. Graduate School of Environmental Science, Hokkaido University, 2. NASA Jet Propulsion Laboratory, California Institute of Technology, USA

Stratosphere-troposphere exchange (STE) is one of the important factors that determine the distribution of constituents in the troposphere and stratosphere. Two-way airmass exchange between the lower stratosphere and the troposphere occurs in association with mid-latitude weather disturbances, with the net transport from the stratosphere to troposphere. In this study, we analyze the STE over the northern hemisphere Pacific Ocean in northern winter, focusing on transport of ozone and carbon monoxide (CO) using two chemical reanalysis data sets, the Tropospheric Chemical Reanalysis version 1 (TCR-1; Miyazaki et al., 2015) and the Monitoring Atmospheric Composition and Climate (MACC; Inness et al., 2013). The TCR-1 is a 10-year chemical reanalysis data set for the period from 2005 to 2014, while the MACC is for 2003 to 2012. Both reanalyses assimilate major satellite chemistry data during the respective periods. We calculate the amount of CO transported from the troposphere to stratosphere (TST) and ozone transported from the stratosphere to troposphere (STT) on the 350-K isentropic surface, by using 4 PVU potential vorticity to evaluate irreversible transport across the tropopause (e.g., Homeyer and Bowman, 2013). Results from the analysis of TCR-1 data are as follows. The amount of ozone transport per case maximizes in November and minimizes in February, and that in years 2005-2008 is significantly smaller than that in years 2009-2014 with the maximum in the 2010 winter (i.e., from November 2010 to March 2011). The amount of CO transport per case maximizes in March and minimizes in November, and that in years 2005-2009 is significantly larger than that in years 2010-2014 with the maximum in the 2009 winter. Results from MACC data are qualitatively similar. In the presentation we will also show the results with additional criteria for irreversibility by using trajectory calculations.

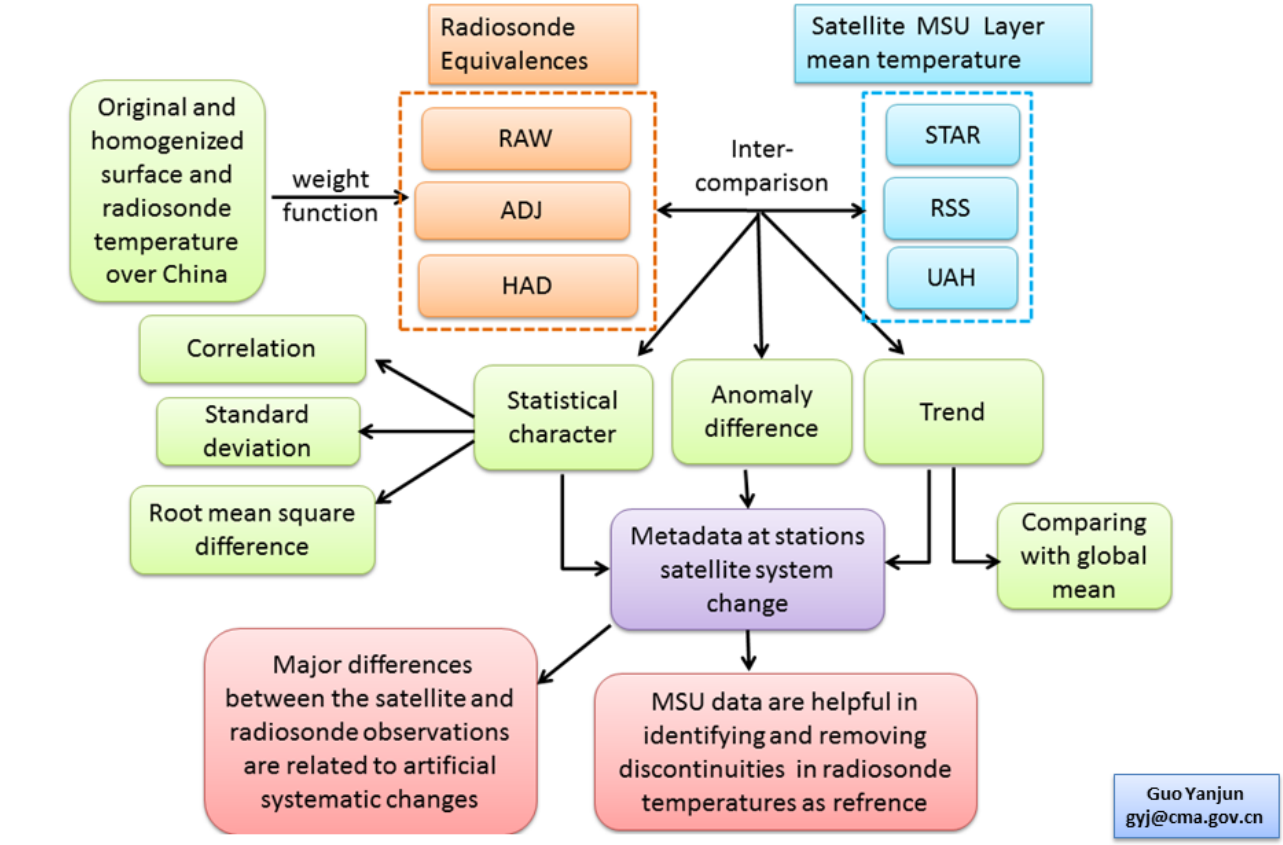
Inter-comparison of Upper Air Temperature in China between Satellite MSU and Radiosonde Datasts

*Yanjun GUO[1], Cheng-zhi Zou[2], Panmao Zhai[3], Guofu Wang[1]



1. National Climate Center(NCC), China Meteorological Administration(CMA) , 2. Center for Satellite Applications and Research, NOAA/NESDIS, 3. Chinese Academy of Meteorolgical Sciences (CAMS), China Meteorological Administration (CMA)

Reconciling upper-air temperature trends derived from radiosonde and satellite observations is a necessary step to confidently determine the global warming rate. This study examines the raw and homogenized radiosonde observations over China and compares them with layer-mean atmospheric temperatures derived from satellite microwave observations for the lower-troposphere (TLT), mid-troposphere (TMT), upper troposphere (TUT), and lower stratosphere (TLS) by three research groups. The comparisons are for averages over China, excluding Tibetan Plateau, and at individual stations where metadata contain information on radiosonde instrument changes. It is found that major differences between the satellite and radiosonde observations are related to artificial systematic changes. The radiosonde system updates in early 2000s over China caused significant discontinuities and led the radiosonde temperature trends to exhibit less warming in the middle and upper troposphere and more cooling in the lower stratosphere than the satellite temperatures. Homogenized radiosonde data have been further adjusted using shift-point adjustment approaches to match with satellite products for China average. The obtained trends during 1979-2015 from the re-adjusted radiosonde observation are respectively 0.203±0.066, 0.128±0.044, 0.034±0.039, and -0.329±0.135 K Decade^{-1} for TLT, TMT, TUT, and TLS equivalents. Compared to satellite trends, the re-adjusted radiosonde trends are within 0.01 K Decade^{-1} for TMT and TUT, and 0.054 K Decade^{-1} warmer for TLT and 0.051 K Decade^{-1} cooler for TLS. The results suggest that the use of satellite data as a reference are helpful in identifying and removing inhomogeneities of radiosonde temperatures over China and reconciling their trends to satellite microwave observations. Future efforts are to homogenize radiosonde temperatures at individual stations over China using similar approaches.

Environmental Characterization of the Atmosphere Using WACCM-X

*Rose Tseng[1], Michelle Kanipe[1], Brian Urbancic[1], Robert Tournay[1], Omar Nava[1], Daniel Emmons[1], Robert Loper[1], Charlton Lewis[1]

1. Air Force Institute of Technology

Researching the characteristics of the whole atmosphere can yield a variety of weather and climate understanding for the terrestrial and space environments. Of particular interest are the neutral species, wind, and temperature distributions from the surface to the middle atmosphere and across multiple latitudes. This is accomplished using data from the Whole Atmosphere Community Climate Model-Extended (WACCM-X) with the ionosphere, a model developed by inter-divisional collaboration at the University Corporation for Atmospheric Research. Presented here are the vertical profiles of neutral species, wind speed, and temperature of the troposphere and middle atmosphere up to 80 km. Preliminary results from a 10-year period show all three parameters vary temporally and spatially, particularly across latitudes and seasons. Ongoing work includes rigorous analysis, utilizing all years of WACCM-X data available.

[A-AS05] Stratosphere-troposphere Processes And their Role in Climate

convener:Yoshio Kawatani(Japan Agency for Marine-Earth Science and Technology), Shingo Watanabe(Japan Agency for Marine-Earth Science and Technology), Takashi Sekiya(Japan Agency for Marine-Earth Science and Technology), Kaoru Sato(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Chairperson:Yoshio Kawatani

The Stratosphere-troposphere Processes And their Role in Climate (SPARC) is one of the major projects of the World Climate Research Programme (WCRP), and is characterized by its focus on chemical and dynamical coupling in the stratosphere and troposphere. In this session, we welcome presentations on various processes in the stratosphere and tro posphere.

Observational features of atmospheric fields during a zonal wavenumber two (WN2) type major sudden stratospheric warming (MSSW) event that occurred in February 2018 (MSSW18) are analyzed using the Japanese 55-year Reanalysis, satellite measurements by a microwave limb sounder, and a new three-dimensional wave activity flux. MSSW18 was characterized by a clear polar vortex split, continuance of easterlies with remarkable double peaks, clear planetary-wave propagation in the easterly region of the upper stratosphere and extraordinary upward propagation of WN2 planetary waves from the upper troposphere whose peak was comparable to that during an MSSW event that occurred in January 2009 (MSSW09), although MSSW18 showed relatively modest warming, unclear disappearance of the stratopause and weak stratopause elevation compared to those during MSSW09. Further analyses revealed that wave packets propagated upward simultaneously in both the Eastern and Western Hemispheres. Those observed in the Eastern Hemisphere converged strongly at the western edge of the Aleutian High and most of them did not propagate into the upper stratosphere. The wave packets observed in the Western Hemisphere locally propagated into the upper stratosphere over North America despite the fact that easterlies were predominant there in the mature stage of MSSW18. Furthermore, our results revealed that the regions and levels of wave-packet attenuation corresponded well to the area of weak eastward phase tilt or the quasi-barotropic condition of smaller-scale waves during MSSW18, whereas during MSSW09 the westward phase tilts of smaller-scale waves were clearly visible in the upper stratosphere.

Response of the Southern Hemisphere atmosphere to the QBO from winter to early summer

*Yousuke Yamashita[1], Hiroaki Naoe[2], Makoto Inoue[3], Masaaki Takahashi[4]

1. Japan Agency for Marine-Earth Science and Technology, 2. Meteorological Research Institute, 3. Akita Prefectural University, 4. National Institute for Environmental Studies

The equatorial quasi-biennial oscillation (QBO) is dominant variability in the tropical stratosphere and is characterized by the oscillation of downward propagating easterly and westerly wind regimes. Several studies have examined possible linkages between the QBO and atmospheric circulations, such as the meridional circulation around tropics and the polar vortex intensity in the Northern Hemisphere (NH), which are related to the changes of waves and circulations in the stratosphere (e.g., Plumb and Bell 1982, Holton and Tan 1980). On the other hand, the mechanism by which the QBO modulates extratropical circulation over the Southern Hemisphere (SH) is poorly understood, as the various studies employed different height levels and metrics to define the phase of the QBO (e.g., Garcia and Solomon 1987; Baldwin and Dunkerton 1998; Naito 2002; Hitchman and Huesmann 2009). Previous studies employed composite analysis that possibly includes signals other than the response to the stratospheric QBO, such as the responses to solar cycle and El Niño-Southern Oscillation (ENSO). In this study, we examined the response of atmospheric circulation over the SH to the stratospheric QBO, using multiple linear regression analysis for the long-term Japanese 55-year Reanalysis (JRA-55) dataset to separate the influences of the QBO and other factors on the SH polar vortex. In addition to the terms of middle- and lower-stratospheric QBO, the multiple linear regression includes equivalent effective stratospheric chlorine (EESC), solar cycle, ENSO, and volcanic aerosol terms as explanatory variables. Analyses of the regression coefficients associated with both middle- and lower-stratospheric QBO suggest an influence on the SH polar vortex from SH winter through early summer in the seasonal evolution. One possible pathway is that the middle-stratospheric QBO results in the SH low latitudes stratospheric response through the QBO-induced mean meridional circulation, leading to a high-latitude response. This favors delayed downward evolution of the axis of SH polar vortex at high latitudes (around 60˚S) from August to November during the westerly phase of the QBO. Although this pathway is inconsistent with weakening of the SH polar vortex in August, the other possible pathway is unveiled from the detailed analysis. The other possible pathway involves the response to lower stratospheric QBO that induces the increase in upward propagation of planetary waves from the SH extratropical troposphere to stratosphere in August. This pathway is consistent with weakening of the SH polar vortex in August.

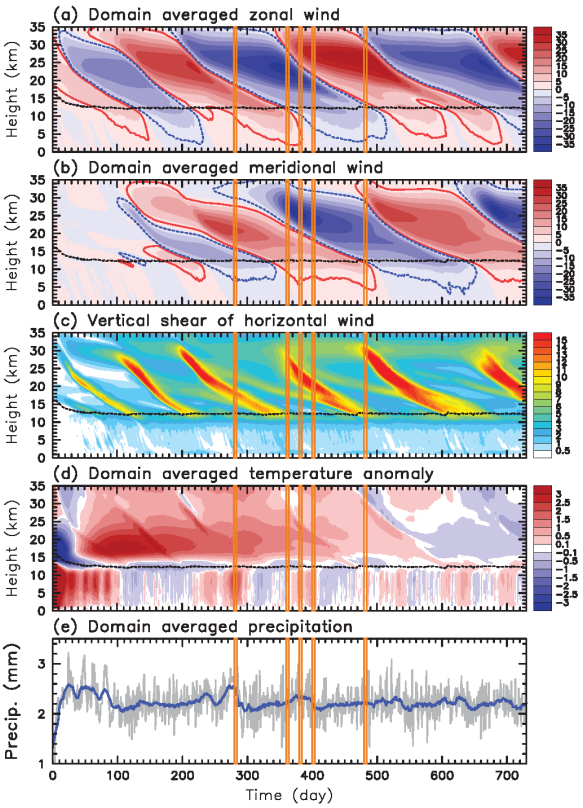
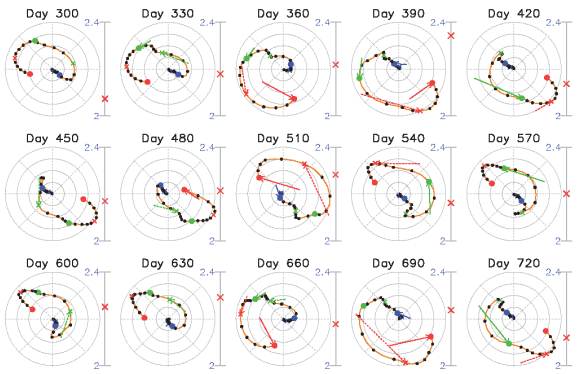
Influence of QBO-like Oscillation on Tropical Convective Systems in a Three-Dimensional Minimal Model Framework of the Stratosphere-Troposphere Coupled System

*Shigeo Yoden[1], Hai Bui[2], Takahiro Banno[1]

1. Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2. Geophysical Institute, University of Bergen



We report on the three-dimensional minimal model of the stratosphere-troposphere coupled system that produces a self-sustained oscillation reminiscent of the quasi-biennial oscillation (QBO) in a radiative-moist convective quasi-equilibrium state. The computational domain is rectangular (640 km x 160 km, 5 km grid size; Bui et al., 2019), or square (100 km x 100 km, 1 km grid size), without Coriolis effects under doubly periodic boundary conditions. After initial transient time, a QBO-like oscillation with a period of about 300 days emerges in the stratosphere, both in the domain-averaged zonal wind and meridional wind (Figure-left). Synchronization of the zonal and meridional winds is characterized as an anti-clockwise rotation of a skewed spiral feature with height in the horizontal wind hodograph (Figure-right).



The QBO-like wind oscillation penetrates into the troposphere with large reduction of oscillation amplitude, and influences tropospheric temperature anomalies and precipitation with an irregular period of about 100 days. Heavy precipitation is associated with positive temperature anomalies. The simulation reveals three types of precipitation patterns; isolated quasi-stationary type clusters, fast-moving back-building type and squall-line type patterns. The quasi-stationary type is newly identified in the present three-dimensional model, and the zonal-height cross sections of the meridionally averaged clouds and relative humidity for this pattern show clear-sky areas without shallow clouds and with low humidity, whereas shallow clouds exist over the entire domain including non-precipitating areas with high humidity for the fast-moving back-building type or squall-line type patterns. Intermittent self-organization of convective systems into quasi-stationary type and transition back to the fast-moving back-building type or squall-line type are fundamental characteristics of self-aggregation in the three-dimensional minimal model framework.

Downward Propagation of Planetary Wave Packets from the Stratosphere to the Troposphere During Northern Hemisphere Winter

*Matsuyama Yuya[1], Toshihiko Hirooka[2]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University

Downward propagation of planetary wave packets from the stratosphere to the troposphere is often observed during Northern Hemisphere winter and their influence on the tropospheric circulation has been also reported by various authors. Recent observational studies show that the downward propagation into the troposphere frequently occurs over the North America centered around 90W. Hence, we investigate the frequency distribution of downward propagation events of planetary wave packets and its relationship to the background field using the Japanese 55-year Reanalysis (JRA-55) data. We calculate Plumb’ s (1985) wave activity flux (WAF) and extract the downward propagation events over the analysis period (1958-2016) based on a specified criterion value for the vertical component of WAF at 30 hPa. Next, we investigate the longitudinal location of each downward propagation event and classify it into eight sectors of 45 degrees along the longitudinal circle to make a composite analysis of the classified events. Resultantly, around 500 events are extracted during the analysis period and it is found that about more than 80% of the events occurred in three sectors between 135W to 0E; these events are shown to be intimately related to the development of the Aleutian High in the stratosphere, which is located in the west of the downward propagation region. As for the other events, a developed anticyclone was also observed in the west of each downward propagation region.

[A-OS14] Coastal physical processes associated with mixing, eddies, internal waves

convener:Eiji Masunaga(Ibaraki University), Taira Nagai(Graduate School of Science, The University of Tokyo), TSUTSUMI EISUKE(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Eiji Masunaga, Eisuke Tsutsumi

Recently developed observational and numerical approaches have revealed details of physical processes in coastal regions, which is a key to understanding global ocean circulations and ecosystems. This session aims to provide discussions of mixing, eddies, nonlinear internal waves in coastal and marginal oceans, estuaries and lakes. Observations, numerical modeling and laboratory experiments associated with these phenomena are encouraged to submit an abstract to this session. In addition, studies that consider linkages between coastal physical processes and large scale open ocean processes, e.g., the Kuroshio, global ocean circulations.

The cooling of sea surface temperature in the southern Indonesian Seas due to a combination of the Ekman transport and tidal mixing in narrow straits

*Taira Nagai[1], Toshiyuki Hibiya[1]

1. Graduate School of Science, The University of Tokyo

The Indonesian archipelago is characterized by the warmest sea surface temperatures (SSTs) in the world and is a key region of the world climate system. Kida and Wijffels (2012) reported that SST cooling around the Nusa Tenggara Islands (NTIs) located at the southern Indonesia plays a crucial role in the seasonal variation of SST over a large area in the Indonesian Seas. Although they suggested that both the monsoonal winds and tidal mixing might significantly impact such SST cooling, their numerical model settings were somewhat idealized.

In this study, to investigate the mechanisms of SST cooling around the NTIs, we carry out a numerical simulation using a regional ocean model where the realistic distribution of vertical diffusivity estimated from a high resolution baroclinic tide model is incorporated. The simulated results show that significant mixing in the narrow tidal straits between the NTIs creates well-mixed waters, which spread out northward (southward) during Austral summer (winter) and finally causes significant SST cooling over a large area of southern Indonesian Seas.

We therefore carry out numerical experiments where either of the monsoonal wind or localized tidal mixing in the narrow straits is switched off. These numerical experiments show that well-mixed waters in the narrow straits are continuously advected by the northward (southward) flow driven by the western (eastern) monsoonal wind during Austral summer (winter) until the Indonesian Throughflow spreads them out over a large area of southern Indonesian Seas, demonstrating the importance of the combined effect of the Ekman transport and tidal mixing.

A reanalysis of regional circulations in the Southern South China Sea using a HYCOM-ROMS downscaling ocean model

*Naru Takaura[1], Yusuke Uchiyama[1], Nizamani Zafarullah[2], Akihiko Nakayama[2]

1. Kobe Univ, 2. Tunku Abdul Rahman University

A high-resolution, high-precision downscaling oceanic circulation model for the Southern China Sea (SCS) was developed based on the Regional Oceanic Modeling System (ROMS) at a lateral resolution of 5 km, initialized and forced by the Hybrid Coordinate Ocean Model (HYCOM) global reanalysis product. A multi-year reanalysis was conducted for the four-year period from 2012 to 2015 with the HYCOM-ROMS system that properly accounts for wind stress and heat budget at surface, freshwater influences from the atmosphere and major rivers, and tidal variability.
The model results were confirmed to agree well with satellite and in situ measurement, and generally consistent with the findings in previous studies. For instance, prevailing strong meridional currents are provoked along the continental shelves between China and the southern Vietnam, which are driven by seasonally varying monsoons dominated in the winter and summer, followed by current separation to the east off the southern Vietnam occurred in summer.
Prospective applications of the system include assessments of oceanic dispersal of wastewater, quantification of marine ecosystem network, analyses of micro plastic transport, its coastal accumulation and maintenance of offshore structure. In the present study, we utilized the model outcome to evaluate external forcing conditions on offshore oil platforms along the coast of the Malay Peninsular and Borneo Island by using extreme value statistics for surface currents and wind. The maximum surface velocity was found to occur off the coast of Borneo Island, which is influenced by the Mindanao Current. It was suggested that water mass exchange between the Pacific and the SCS is extremely significant as it subsequently controls regional circulations in the coastal margins in the SCS.

Nutrient and phytoplankton dynamics in the continental slope region of the East China Sea associated with the Kuroshio frontal eddy

*Naoki Yoshie[1], Anri Kabe[1], Kazuki Ohgi[1], Eisuke Tsutsumi[2], Shigenobu Takeda[3], Joji Ishizaka[4], Xinyu Guo[1]

1. Center for Marine Environmental Studies, Ehime University, 2. Research Institute for Applied Mechanics, Kyushu University, 3. Faculty of Fisheries, Nagasaki University, 4. Institute for Space-Earth Environmental Research, Nagoya University

The lower-trophic level ecosystem in the continental slope region of the East China Sea (ECS) during summer generally shows typical subtropical features, i.e., small size pico-phytoplankton such as cyanobacteria dominates in the euphotic layer under the oligotrophic condition due to the stable stratification. It is also known that such stable physical and chemical conditions are often disturbed by the Kuroshio frontal eddy. In this study, we investigated the phytoplankton dynamics associated with the passing of Kuroshio frontal eddies. We conducted comprehensive observations with the high horizontal resolution (7km) around the continental slope region in the ECS in the late-July, 2018. We observed drastic changes in the depth of subsurface chlorophyll maximum (SCM) and nitrate concentrations around the SCM, and micro-phytoplankton such as diatom mainly changed around SCM. We found cyclonic frontal eddies with 15-35 km diameter around the 40-80 m depth near the drastic change of the SCM. These changes were caused by the horizontal advection of nutrient-rich shelf water associated with the passing of the cyclonic frontal eddies.

Dissipation and transport due to internal tides generated by multiple submarine canyons

*Qiang Li[1], Xianzhong Mao[1], Ran Liao[1]

1. Tsinghua University

Rough seafloor is a major source to generate internal waves in the ocean. High-resolution multibeam survey reveals detailed seafloor with complicated features, however, some are not shown in commonly used topography datasets, such as Smith and Sandwell (1997). A group of canyons on the continental shelf of the northern South China Sea were recently discovered during a geographic survey. Interaction between barotropic tides and concave-shape canyons generates internal tides, showing complex interference patterns. A linear model, based on normal-mode decomposition, reveals complex beam generation and interaction inside and between the canyons. Then, a very high resolution and three dimensional numerical model is employed to validate the linear model result and estimate local energy dissipation for internal wave generation by a group of canyons. Instead of complicated turbulence models, constant viscosity coefficients are used. Nonlinear interaction or shear instability during internal tide generation and propagation causes local diapycnal mixing, which is one of the key processes to drive material transport in continental shelf. Transport due to internal tides in the canyon region is also calculated and its relationship with local internal tide generation and propagation is discussed.

Measurement of Physical structure in Kasumigaura using high resolution tow-yo instrument

*Daiki Asaoka[1], Eiji Masunaga[1], Shunsuke Komuro[2], Shunichi Matsumoto[2], Masahiko Ono[3], Hiroaki Banba[3]

1. Ibaraki University, 2. Ibaraki Kasumigaura Environmental Science Center, 3. Ministry of Land, Infrastructure, Transport and Tourism

This study shows physical processes in Lake Kitaura, Kasumigaura, using field observations by YODA Profiler and Mooring system. Hypoxia and eutrophication have a bad influence on ecosystems in the study area. Understanding physical processes is essential to understand ecosystems in lakes and oceans. Lake Kitaura is a long lake in the north-south direction with 25 km and 4 km in the east-west. The stratified layer is generated due to strong incoming heat flux during the summer season. Mooring observation results show that the thin mixed layer was gradually thickened due to the wind stress and disappeared within several hours. Details of this mixing processes were further investigated by making use of a high-resolution tow-yo instrument, the YODA Profiler. The warm surface water was transported toward on the downwind side due to the wind stress. Small scale K-H instability like motions were observed during this event. According to the data from the YODA Profiler, the Wedderburn number can roughly explain the baroclinic and mixing structures in the east-west direction. However, the Wedderburn number is not able to be used for explaining quantitative vertical displacements of the thermocline, because the complexity of the observed density distribution. The vertical isotherm displacements can be simply explained by wind stress. Time series of the mixed layer depth were calculated to evaluate mixing in the lake. The mixed layer reached the bottom when the daily-averaged wind speed exceeded 8 m/s, resulting in complete vertical mixing. Results from the north-south long transect survey show wavy like baroclinic (or stripe-shaped) temperature distribution with a horizontal scale of several km. In addition, three dimensional numerical simulations were conducted using the SUNTANS. Model results also show a wavy like baroclinic structure in the north-south direction caused by the complicated coastal shape and east-west wind stress. The wavy like baroclinic structure is generated by convergence of warm water into bay-shaped areas.

Mixing and baroclinic structure in a stratified shallow lake, Lake Kasumigaura, Japan

*Eiji Masunaga[1], Daiki Asaoka[1], Shunsuke Komuro[2], Shunichi Matsumoto[2], Masahiko Ono[3], Hiroaki Banba[3]

1. Ibaraki University, 2. Ibaraki Kasumigaura Environmental Science Center, 3. Ministry of Land, Infrastructure, Transport and Tourism

This study presents mixing and baroclinic structure associated with hypoxia in a shallow lake, Lake Kasumigaura, using field observations and numerical simulations. Hypoxia in stratified lakes is one of the pressing issues for maintaining water environment and ecosystems. Mooring observations show that hypoxia events occur when the stratification is enhanced by the surface heat flux. The stratification (N^2) is controlled by the ratio between the surface wind stress and surface heat (buoyanvy) flux. The strength of the stratification/mixing can be simply explained by the Monin-Obukov length scale, L_{MO}. N^2 is linearly related with L_{MO} in a log scale with a correlation coefficient of approximately 0.7. According to the heat budget analysis, the bottom sediment heat flux toward the bottom significantly contribute to the heat content as well as the surface heat flux. The heat flux toward the bottom is roughly an order of 100 W m^{-2} during the summer season, which suppresses mixing near the bottom. The internal wave-like baroclinic structure was observed by high resolution survey using the YODA Profiler. Baroclinic motions are enhanced by the surface wind stress, and they transport the hypoxic water, suspended sediments and phytoplanktons. In addition to field surveys, three-dimensional simulations were conducted with SUNTANS to further investigate physical processes in the lake. Numerical results well agree to observational results and show that baroclinic motions influence in the whole of the lake basin. The wind-induced baroclinic energy is generated in the middle of the lake basin and propagate to the onshore. This study suggests that mixing and baroclinic motions due to buoyancy and wind effects play an important role in the oxygen distribution in Lake Kasumigaura.

Discussion

Turbulent mixing and vertical nitrate flux in the Bungo Channel, Japan

*TSUTSUMI EISUKE[1], Naoki Yoshie[2], Takashi Mano[3], Kanda Taisei[3], Naoki Fujii[4], Xinyu Guo[2]

1. Research Institute for Applied Mechanics, Kyushu University, 2. Center for Marine Environmental Studies, Ehime Univeristy, 3. Graduate School for Science and Engineering, Ehime University, 4. Faculty of Agriculture, Saga Univerisity

Turbulent mixing plays a key role in primary production in coastal seas through supplying nutrients to the euphotic zone from deeper layers and to the ocean from rivers. Understanding of turbulent dynamics in coastal seas is therefore essential for prediction, conservation and management of coastal ecosystems. Here, we studied turbulent mixing and the associated vertical nitrate transport in a tidally-energetic channel between the Kuroshio region and the Seto Inland Sea (Bungo Channel, Japan). Takeoka [1993] hypothesized that strong vertical mixing and the associated secondary circulation in the channel maintains primary production through supplying large amount of nutrients coming from the Kuroshio region. We conducted simultaneous measurements of turbulence and nitrate concentration along a section in the Bungo Channel using a microstructure turbulence profiler (TurboMAP-5, JFE Advantech) and optical nitrate sensor (SUNA-V2, Sea-Bird Scientific) on 27 August, 2017. We found nitrate-rich cold waters in the bottom of the southern part of the section, which coincide with a typical bottom intrusion from the Kuroshio region. Largest vertical eddy diffusivity of O(10^{-2}) m^2 s^{-1} and the associated upward nitrate flux of O(10) mmol m^{-2} day^{-1} were obtained at 20-30 m depth south of deep and narrow strait (Hoyo Strait). Also, subsurface maximum in chlorophyll fluorescence is observed just above the strong turbulence layer, possibly suggesting phytoplankton blooms in response to the high turbulent nitrate flux. The strong vertical turbulent diffusion was associated with density overturns and elevated vertical shear, indicating internal wave breaking. We hypothesis that internal tides generated in the Hoyo Strait is one of the key processes in enhancement of turbulent mixing and nutrient transport in the Bungo Channel.

Numerical Analysis of Submerged Turbulent Buoyant Jet in River Mouth

*Yen-Chen Mou[1], Gene You[1], Chih-Chieh Young[2]

1. National Taiwan University, 2. National Taiwan Ocean University

The purpose of this study is to investigate the characteristics of submerged turbulent buoyant jet in river mouth by simulating basic fluid mechanisms. The numerical model composes two-dimensional continuity equation, momentum equation, and advective diffusion equation. Since our model is building on basic fluid mechanics formulas, we can test the movement of buoyant jet in the river mouth depends on different parameters, such as environmental and geometrical factors. One of our focuses will be how the phenomena be influenced by inflow hydrograph and sediment concentration, as well as real events and analyze their effect submerged turbulent buoyant jet motion pattern.

Our model will be applied to simulated several characteristic behaviors that are consistent with prior knowledge, including: (1) the inflow concentration is higher at the fixed inflow rate and calculation time, the formed buoyant jet has a large influence range and higher concentration; (2) when the inflow rate is high in a fixed flow concentration and calculation time, the generated buoyant jet has a large influence range and that shape more bulging. Moreover, we will adjust the downstream boundary conditions. When the downstream water level is high, the range and the duration time of the buoyant jet are great. As expected, the concentration of the same location is also higher than other situation that has a lower downstream water level. So far, this model will progress to the extent that it can capture the overall trend of buoyant jet movements, and this simulation is based only on the physical mechanism of the sand-containing fluid itself.

Implementing regional downscaling capability in the STEAMER radionuclide dispersion prediction system based on multi-nested ROMS model

*Kamidaira Yuki[1], Hideyuki Kawamura[1], Takuya Kobayashi[1], Yusuke Uchiyama[2]

1. Japan Atomic Energy Agency, 2. Kobe University

Oceanic regional downscaling capability was implemented into Short-Term Emergency Assessment system of Marine Environmental Radioactivity (STEAMER) developed by Japan Atomic Energy Agency (JAEA) to enable us to predict more realistically the oceanic dispersion of radionuclides at higher spatiotemporal resolutions for broader applications. The system consisted of double-nested Regional Ocean Modeling System (ROMS) with tidal forcing embedded in the Multivariate Ocean Variational Estimation system for the Western North Pacific (MOVE-WNP), assimilative reanalysis/forecast product and an oceanic radionuclide dispersion model SEA-GEARN developed by JAEA. Surface wind stress was provided by the Grid Point Value of the Global Spectral Model (GPV-GSM) atmospheric reanalysis/forecast while surface heat and freshwater fluxes are from the Comprehensive Ocean-Atmosphere Data Set (COADS) monthly climatology. Ten principal tidal constituents from the TPXO 7.0 global tidal reanalysis were additionally imposed on the sea surface height as boundary condition along the perimeter to include barotropic tides and the resultant intrinsic baroclinic tides. The horizontal grid spacing was decreased from ~10 km in the outermost MOVE-WNP, to 3 km in the intermediate ROMS-L1 model, and further down to 1 km in the innermost ROMS-L2 model. The model results showed reasonable agreement with tidal observations. The system was used to comparatively examine downscaling and tidal effects on the dispersion of radionuclides hypothetically released from the Fukushima Daiichi Nuclear Power Plant. The simulated dissolved ^{137}Cs distribution had seasonal variability and was different from that obtained using coarser-resolution models because downscaling enhanced both horizontal and vertical mixing. Temporal ^{137}Cs fluctuations were slightly amplified as a result of the suppression of horizontal mixing and enhancement of vertical mixing by tides. In addition, the submesoscale effects strengthened the three-dimensional ^{137}Cs fluctuations by <10 times, while the tidal effects promoted slightly increased the intensity of three-dimensional ^{137}Cs fluctuations by approximately 3-30%. This indicated that the submesoscale effects substantially surpassed tidal forcing in oceanic mixing in the coastal margin off Fukushima.

Transport processes around the Izu-chain islands investigated with a Lagrangian particle tracking model

*Waku Kimura[1], Eiji Masunaga[1], Taichi Kosako[2], Yusuke Uchiyama[3]

1. Ibaraki University, 2. Port and Airport Research Institute, 3. Kobe University

This study investigated mass transport and dispersion around Izu-chain islands off the Japan mainland using with 3-D Lagrangian particle tracking simulations modeled in a high-resolution reginal ocean modeling system (ROMS). The Kuroshio and eddies, tides largely influence physical processes in the study area. Details of transport processes involving the Kuroshio, eddies and tides have not been understood well. However, these processes are important for understanding oceanic environments and ecosystems in the North Pacific Ocean. Particles were released from three regions: around the Izu-chain islands (north of the Kuroshio), in the Kuroshio, south of the Kuroshio. Model results show that the particle trajectory is different depends on the initial location of particles. Approximately 60% particles released from the Izu-chain islands were transported outside the model domain in 30 days. On the other hands, more than 90% particles released from the Kuroshio and south of the Kuroshio flew out from the domain in 30 days. The vorticity is enhanced by the tidal forcing in the whole study area. The tidal forcing enhances the horizontal diffusion of particles within 2 days scale. By contrast, in the longer time scale longer than 5 days, the dispersion of particles is suppressed by the tidal forcing, because large scale motions are suppressed by tides. The frequency spectrum of the particle velocity shows semi-diurnal peaks and high frequency (low frequency) is enhanced (decreased) by the tidal forcing.

Fates and dynamical roles of pinch-off mesoscale eddies originated from the Kuroshio Extension Jet

*Yusuke Uchiyama[1], Nobue Okada[1], Changming Dong[2]

1. Graduate School of Engineering, Kobe University, 2. Nanjing University of Information Science & Technology

Mesoscale eddies are ubiquitous in the world ocean that frequently collide with currents, leading to substantial alteration of the associated dynamics. For instance, the Kuroshio plays a major role in preconditioning the coastal environment around Japan through poleward heat and material transport from the subtropics, while its path is known to meander occasionally by eddy collisions. Pinch-off mesoscale eddies that detach intermittently from the Kuroshio tend to travel westward as Rossby waves and have been found to collide with the Kuroshio again to alter oceanic and coastal environment through alteration of the Kuroshio path.

For realization of such processes, we applied the eddy detection algorithm used in Liu et al. (2012) to ARMOR3D. The ARMOR3D dataset is a 3D global currents and density data set that is reconstructed from a combination of extensive satellite data and in situ observations based on the geostrophic thermal wind relation and statistical methods as described in Guinehut et al. (2012). By conducting several sensitivity tests, we introduced constraints on vorticity magnitude of detected mesoscale eddies and their relative positions to the Kuroshio path to determine pinch-off eddies near the Kuroshio Extension (KE) region. It was found that the constraint on vorticity magnitude of the detected individual eddies greater than $0.15f$, where f is the local Coriolis frequency, throughout eddy lifetime is significant to successfully isolate pinch-off eddies.

With this constraint, we discovered that most of the detected pinch-off eddies are cyclonic on the south side of the KE region, while anticyclonic eddies are predominant on the north side. The former occurred 2.5–3 times as often as the latter, although in the entire North Pacific, cyclonic eddies occurred only 12.1% more frequently than anticyclonic eddies. Hence, it is considered that this cyclone dominance in the pinch-off eddies from the Kuroshio is a unique feature. We also succeeded to determine pinch-off eddies that collide again with the Kuroshio by introducing another constraint, which is the threshold distance between the Kuroshio path and terminal positions of pinch-off eddies traveled westward. In several selected cases with these constraints, comparisons of the surface temperature and salinity before and after the eddy collisions clearly exhibit that the alteration of the Kuroshio path due to eddy collisions is quite influential in modifying the oceanic structures. It was also found that the pinch-off eddies occasionally interact with other mesoscale eddies to modify the upper-ocean structure pronouncedly.

The Kuroshio path in the KE region is known to vary on annual to decadal time scales, where it was rather stable for 1993-1995 and 2002-2005, whereas largely meandered unstably for 1996–2001 and 2006–2009. During the first unstable periods, the number of cyclonic pinch-off eddies were significantly increased in the area between 144 °E and 150 °E for 1996–2001. However, no significant increase was observed during the other unstable period for 2006–2009. More than 70% of the pinch-off eddies that collided with the Kuroshio appeared during the unstable periods, suggesting that the stability of the Kuroshio path in the KE region is a key influencer on vigorous generation of such colliding pinch-off eddies.

The cryosphere is a fundamental component of the earth system. It is a region where snow and ice exist in the form of glacier/ice sheet, snow cover and snowfall, frozen ground, sea ice and fresh water ice, and they play a critical role in the global environment under the interactions with atmosphere, ocean, ecosystem and others. In this session, research results on physical and chemical characteristics of snow and ice, variations and dynamics of cryospheric environment, roles of the cryosphere on the earth and other planets will be discussed broadly, regardless of the research method.

Japan Aerospace Exploration Agency (JAXA) polar-orbit satellite, Global Change Observation Mission for Climate (GCOM-C) has been launched on 23 December 2017. The Second-generation Global Imager (SGLI) which is carried on GCOM-C observes various geophysical variables in the Atmosphere, Ocean, Land and Cryosphere for long-term monitoring of earth environment using multi wavelength, high resolution and multi angles. When focusing on the cryosphere: snow, sea-ice, glacier and ice sheet, their high albedo affect the cooling mechanism of the radiative balance. The GCOM-C/SGLI regularly creates cryosphere standard products including C1: snow, ice and cloud classification product and C2: snow grain size and snow surface temperature product. We validated these products by comparison with other satellite products and in-situ observation data. C1 product was validated by comparing other similar satellite product (e.g. Terra/MODIS) focusing on the snow and ice extent. C2 product was validated by match-up comparison with in-situ data and satellite retrieval results. Snow grain size of shallow layer was measured at the in-situ observation carried out at the East GRIP site on the North-eastern Greenland Ice Sheet in July 2018. Snow and ice surface temperature was derived from automatic weather station (AWS). From these validation results, all standard product was achieved the release threshold and JAXA decided to release the GCOM-C/SGLI product. In the presentation, some examples and case study of the GCOM-C/SGLI observation results will be shown.

Overview of the cryospheric variables derived from GCOM-C/SGLI observations: The first-year results

*Masahiro Hori[1], Teruo Aoki[2,4], Knut Stamnes[3], Wei Li[3], Nan Chen[3], Rigen Shimada[1], Tomonori Tanikawa[4], Masashi Niwano[4]

1. Earth Observation Reseacrh Center, Japan Aerospace Exploration Agency, 2. Okayama University, 3. Stevens Institute of Technology, 4. Meteorological Research Institute

The “Global Change Observation Mission-Climate” (GCOM-C) is an Earth observing satellite of Japan Aerospace Exploration Agency (JAXA) for the global observation of the Earth environment. GCOM-C carries a multi-spectral optical radiometer named Second Generation Global Imager (SGLI), which has special features of wide spectral coverage from 380 nm to 12 μm, a high spatial resolution of 250 m, a field of view exceeding 1000 km, two-direction simultaneous observation, and polarization observation. The GCOM-C satellite was successfully launched from the Tanegashima Space Center in Japan on December 23, 2017 and SGLI started the Earth observations on January 1st, 2018. From the SGLI observations snow-related variables such as snow and ice cover extent, snow grain size, and snow surface temperature are being retrieved and the products of those variables have been released to the public from the JAXA’s satellite data providing service “G-Portal” (https://gportal.jaxa.jp/gpr/index/index) since December 20th 2018. These snow physical variables are important for determining spectral albedo and radiation budget at the snow surface. In this presentation, the first-year results of SGLI snow observations are presented as well as the introduction of the SGLI products with the special attention to the thermal infrared observations at 250-m spatial resolution.

Relationships between PASAR-2 backscatter amplitude changes and snow depths

*Hiroto Nagai[1], Satoru Yamaguchi[2], Katsuya Yamashita[2], Mayumi Kashima[3]

1. Waseda University, School of Education, 2. National Research Institute for Earth Science and Disaster Resilience, 3. Esri Japan Corporation

For local governments heavy snowfall gives a very big economic burden. A large amount of tax will be put into operation of the snow removal vehicle, for example. The snow removal expenses of Niigata prefecture approaches 10 billion yen annually, but the operation plan (route selection and operation count) of the snow removal vehicle is not based on objective awareness of snow depth which can vary year by year.
In order to solve this problem, it is important to grasp the snow depth deep space distribution. The estimation of snow accumulation by the conventional satellite-mounted synthetic aperture radar (SAR) was mostly based on the C-band, and adaptation to the snow layer including liquid moisture have difficulty due to the short wavelength (Bernier et al., 1999; Li et al., 2017; Rignot et al., 2001; Shi et al., 1993; Shi and Dozier, 1995). However, in the L-band SAR, the correlation between the snow depth and the backscattering intensity was confirmed to be wet snow, which was a negative correlation (the snow is deeper the reflected intensity decreases) in the night observation assumed to be dry snow It was shown that positive correlation was obtained by day observation (Nagai et al., 2018a, 2018b).
In this research, we examined the image processing algorithm suitable for snow depth estimation for PALSAR-2 which is the L-band SAR equipped with "Daichi-2". First of all, the night observation data was used to minimize the influence of liquid moisture. Obtain data of the observation as 2015/11/22, 2016/11/20 as the no-snow period and 2018/01/28 as the snowy season, convert the backscattering intensity (dB). A series of moving average filter of 0, 5, 10, 15...55 pixels were carried out for each. Then statistical comparison of the ground measurement value compiled by Niigata University (Iyobe and Kawashima, 2016) and the SAR-derived backscatter amplitude changes was carried out.
As a result, the moving average filter with 10 pixels or more shows a negative correlation of $r < -0.3$, $p < 0.1\%$ in all cases, and the correlation coefficient decreased as the number of pixels of the filter increased. There was no significant difference between the November average image and the single scene image. For the linear approximation between the intensity difference and the measured value, the slope was almost constant with the moving average filter of 10 pixels or more.
By using data at night during the winter season, we can estimate snow depth from SAR with high negative correlation. In order to create a snow depth map with a better correlation coefficient, it is necessary to apply a stronger moving average filter, but since it becomes a coarse and smooth snow depth map according to it, it is necessary to consider a filter according to the application.
In addition to this, statistical analysis is also presented in this presentation on other seasons as the standard as well as for snow melting daytime observations presumed to contain a large amount of snow in the snow, and a snow depth estimation method using SAR deepens in the discussion.

On 25 April 2015, an earthquake (M7.8) occurred at Gurkha region located northwest of Kathmandu, the capital of Nepal. On 12 May, an earthquake of M 7.3 occurred at 80 km northeast from Kathmandu. Due to this series of large earthquakes, slope failure events (ice avalanche, snow avalanche, snow-rock avalanche, rock avalanche) occurred frequently in snow mountain area of the Himalaya. In Langtang valley, a huge snow-rock avalanche caused more than 100 victims in Langtang village. We investigated the characteristics of bereaking-off from hunging glaciers around Mt. Langtang-Lirung using satellite data and digital aerial images in 2015 and 2018.

School of Science, Kathmandu University

Glaciers in High Mountain Asia are valuable indicator of climate change, and its melt water have an important role for the regional water resources (e.g. Immerzeel et al., 2010). We thus need to estimate Himalayan glacier melting amount. However, the lower part of large Himalayan glaciers is generally covered with debris mantle, which makes the melting process complicated. Several previous works pointed out a role of ice cliffs that promote local enhancement of the ice melting (e.g. Brun et al., 2018). In previous studies, digital elevation models (DEMs) based on satellite imageries have been analyzed to estimate glacier mass change. However, it is difficult to extract ice cliffs due to their low resolution. Recently, Structure from Motion (SfM), image analysis technology, has been dramatically developed. This method enables to obtain high resolution glacial terrain data and identify the small features on glacier surface such as ice cliffs.
In this study, we generated high resolution DEMs and orthomosaic images from aerial photographs taken at three different times at the Trakarding glacier, Rolwaling region, Nepal Himalaya in order to evaluate area and aspect of ice cliffs, and analyzed the relation between cliff distribution and glacier surface elevation change. We carried out field observations and conducted aerial photogrammetry by fixed wing UAV in 2017 and helicopter in 2018 at the entire debris-covered area (3.1 km^2). We also analyzed photographs taken in 2007, and then created high resolution (0.2~2.0 m/pix) DEMs and orthomosaic images, from which about 500 ice cliffs were extracted.
DEMs shows that the surface elevation of the Trakarding Glacier declined between 2007 and 2017 by -1.65 m w.e. yr^{-1} while it lifted up between 2017 and 2018 by +1.25 m w.e. yr^{-1}. We find that the surface elevation changes are spatially heterogeneous. The more significant surface lowering happens, the higher cliff density is observed, suggesting that the ice cliff locally enhances glacier melting. In addition, the ice cliff length density was 7.9×10^{-3} m m^{-2} in 2017, which remarks the highest density comparing to a previous study in the Khumbu region (Watson et al., 2017). Further, we find significant correlation between ice cliff length and its slope area, which means that it is possible to estimate the slope area of cliff from the cliff length, which can be obtained from satellite images.

Quantify the range of projections of future changes in glacier mass caused by differences among observed past climate datasets

*Megumi Watanabe[1], Aki Yanagawa[2], Yukiko Hirabayashi[3], Satoshi Watanabe[4], Shinjiro Kanae[1]

1. Tokyo Institute of Technology, 2. Meisei University, 3. Shibaura Institute of Technology, 4. The University of Tokyo

Observed climate data used as input in glacier models are expected to differ among datasets particularly at high elevations. Differences among datasets have not yet been described as a cause of uncertainty in projections of future changes in glacier mass, although uncertainty caused by varying future climate projections among general circulation models (GCMs) has often been discussed. Differences among climate datasets are expected to propagate as uncertainty in future changes in glacier mass due to bias correction of GCMs and calibration of glacier models. We project ensemble future changes in the mass of glaciers in Asia through the year 2100 using a glacier model. A set of 18 combinations of inputs, including two observed past air temperature datasets, three observed past precipitation datasets, and future air temperature and precipitation projections from three GCMs were used. The uncertainty in projected changes in glacier mass was partitioned into three distinct sources: GCM uncertainty, observed past air temperature uncertainty, and observed past precipitation uncertainty. Our findings indicate that, in addition to the differences in climate projections among GCMs, differences among climate datasets can propagate uncertainty into projected changes in glacier mass. Significant differences in observed precipitation did not cause major uncertainty in projected changes in glacier mass.

[A-CC27] Glaciology

convener:Takayuki Nuimura(Tokyo Denki University), Ishikawa Mamoru(Hokkaido University), Kzutaka Tateyama(National University Corporation Kitami Institute of Technology), Hiroto Nagai(Waseda Univ., School of Education), Chairperson:Takayuki Nuimura(Chiba Institute of Science)

The cryosphere is a fundamental component of the earth system. It is a region where snow and ice exist in the form of glacier/ice sheet, snow cover and snowfall, frozen ground, sea ice and fresh water ice, and they play a critical role in the global environment under the interactions with atmosphere, ocean, ecosystem and others. In this session, research results on physical and chemical characteristics of snow and ice, variations and dynamics of cryospheric environment, roles of the cryosphere on the earth and other planets will be discussed broadly, regardless of the research method.

Snow grain size is one of the most important factors as a snow physical parameter expressing the snow metamorphism as well as controlling the albedo. As snow grains are generally non-spherical and complicated shapes, the optically-equivalent grain size is not a common glaciological grain size[1)]. Thus, various techniques to measure the specific surface area (SSA) as an optically-equivalent grain size have been developed[2-5)]. It is known from intercomparisons of those techniques so far that one of the most accurate field instruments is IceCube (A2 Photonics Sensor, France)[2)]. The IceCube measures a reflectance of snow sample at the wavelength of 1,310 nm using an integrating sphere and a laser light source. The value of SSA is transformed from the reflectance. A weight of the IceCube is as much as about 20 kg and the snow sampling into a sampling case is needed. These impose not only a workload to the observer but also a certain observation time. We therefore developed a small and light-weight (1/10) instrument, the Handheld Integrating Sphere Snow Grain Sizer (HISSGraS), which operates on the same principle as the IceCube and can measure snow pit face or snow surface directly. This direct measurement enables us to measure the SSA of snow of natural condition in a short time. We measured the SSAs with HISSGraS and IceCube for several snow samples in a cold laboratory and for natural snow pit face in Japan and Greenland. When the SSAs were measured for the same snow samples with both HISSGraS and IceCube, the those SSAs agreed well with each other. When HISSGraS measured snow pit face directly and IceCube measured snow samples collected from the same snow pit, the SSAs by HISSGraS were somewhat larger than those by IceCube. This is because the snow crystals in a sampling case would be compressed at the sampling and the snow grain size could differ from that under natural snow condition.

Experimental study on compaction process of highly porous ice: Implications for density change of icy regolith layer on icy bodies

Minami Yabe[1], *Minami Yasui[1], Masahiko Arakawa[1]

1. Department of Planetology, Graduate School of Science, Kobe University

Ice sheets are found on the polar regions of Earth and Mars. Ice sheets were formed as snow was piled up and compacted into ice. Icy satellites are covered with ice regolith layer which is generated from impact craters by collisions of small bodies. It is supposed that this regolith layer is compacted by self-gravity, but the gravity of small icy satellites is very small and also the surface temperature is quite low, compared with that on the surfaces of Earth and Mars, so the compaction rate of ice regolith layer could be very low, then the deep icy regolith layer might be kept at high porosity on their surfaces. This icy regolith layer could be attributed to the evolution of the surface geology on icy satellites such as topographic relaxation and impact cratering. In this study, we focused on the compaction process of icy regolith layer on icy satellites and conducted compression experiments for highly porous ice under low stresses to examine the relationship between the compaction rate and the porosity.

Snow samples were prepared by filling ice particles with the diameter of ~20 μm into the cylinder mold and by compressing them by a piston into the cylinder with the diameter of 20 mm and the height of 40 mm. The initial porosity was 0.5-0.65. In order to examine the effect of sintering among ice particles on the compression rate, the sintering duration was changed from 0 to 200 hours. We conducted creep tests under constant stresses from 21 to 42 kPa. The displacement of the sample height was measured by a laser or a contact-typed displacement sensors while the diameter change was measured by using images take by a time lapse camera. The temperature was set to be -9and -11 ˚C.

First, we examined the relationship between the strain in a height direction, dh/h, and that in a horizontal direction (diameter change), dr/r, and found to be (dr/r)=-0.11(dh/h). Thus, the compaction rate, $(1/\rho \cdot d\rho/dt)$, was found to be obtained to be -0.78 times the strain rate in a height direction (we call this rate as “compression rate” hereafter), $1/h \cdot dh/h$.

Next, we examined the effect of sintering duration on the compression rate. Under same stress condition, the compression rate was smaller as the sintering duration was longer. However, when the sintering duration passed the critical period, the compression rate was nearly constant even if the sintering duration passed longer. This critical period became shorter as the initial porosity was larger. In this study, to exclude the effect of sintering duration on the compression rate, we examined the effects of porosity, stress, and temperature on the compression rate that was expected for the sample sintering at the period loger than the critical period.

We examined the relationship between the compression rate and the porosity, ϕ, and found that the compression rate could be fitted by the following power equation under a constant stress, irrespective of the initial porosity, $1/h \cdot dh/dt = B\exp(C\phi)$, where B and C are constants. The constant increased exponentially with the increase of the stress, σ, that is, $B \propto \sigma^n$, where n is constant. The constants, C, and n, did not depend on the stress and obtained to be C=24, and n=1.8.

Finally, we evaluated the compaction processes due to self-gravity on the Antarctica and a saturnian icy satellite, Enceladus, by using our obtained empirical equation. We calculated the density and the elevation change of the snow layer on the Antarctica and the icy regolith layer on Enceladus. In this calculation, we assumed that the initial density was homogeneous, 180 kg/m^3, in the whole layer and the stress on the ground surface was 100 kPa. In the case of the Antarctica (a layer thickness of 10 m), the density just above the ground surface increased about three times and the thickness was changed to be a half after 100 years. In the case of Enceladus (a layer thickness of 5 km), the thickness was changed to be

©2019. Japan Geoscience Union. All Right Reserved.

a half after 100 years, as same as the case of the Antarctica, but the density just above the ground surface increased about only twice and the density in the layer on Enceladus was smaller than that on the Antarctica on the whole.

Effect of snow impurities on the radiation budget and snow melting observed at Sapporo during 10 winter seasons

*Yoichiro Hirozawa[1], Teruo Aoki[1,2], Masashi Niwano[2], Sumito Matoba[3], Yuji Kodama[4], Tomonori Tanikawa[2]

1. Okayama University, Graduate School of Natural Science and Technology, 2. Meteorological Research Institute, 3. Institute of Low Temperature Science, Hokkaido University, 4. National Institute of Polar Research

Snow impurities originated from light-absorbing aerosols in the atmosphere have an effect to accelerate the cryospheric warming by reducing the albedo. According to IPCC AR5, black carbon (BC) on snow and ice was assessed to have a global and annual mean radiative forcing (RF) of +0.04 Wm^{-2}. However, the larger effect on the radiation budget and snow melting could be expected in urban area where the snow impurity concentrations are high. In this study, we investigated the effect of snow impurity (BC and mineral dust) concentration on albedo and snow melting from snow and meteorological data observed at Sapporo using physical based snow albedo model (PBSAM) (Aoki et al., 2011). The observation site is the meteorological observation field (43° 04' 56"N, 141° 20' 30"E, 15 m a.s.l) of the Institute of Low Temperature Science of Hokkaido University and the observation period analyzed is 10 winter seasons from 2007 to 2017. The observed broadband albedos were compared with the theoretical values calculated with the PBSAM to which the observed data of snow grain size, impurity concentrations, and downward radiation were input. In addition, we conducted numerical sensitivity experiments on the albedo change due to snow impurities and calculated their RFs. We also estimated a contribution of snow impurities to snow melting from the energy balance analysis.
Comparing the time series of the observed broadband albedos with the theoretically calculated values, the calculated albedo variations due to the change in snow grain size and impurity concentration agreed well with the observations in each year of the analysis period. The determination coefficient (R^2) and the root mean square error (RMSE) for the whole period obtained from the albedo comparison in the shortwave (SW) spectral region were 0.847 and 0.046, respectively, confirming the high accuracy of PBSAM. Next, sensitivity experiments were conducted on the albedo changes in the visible (VIS), near-infrared (NIR), and SW regions depending on the presence and absence of snow impurities. The albedo change and RF due to snow impurities (BC + mineral dust) in the whole period were -0.053 and +6.7 Wm^{-2}, respectively for the SW region. In addition, we estimated total snowmelt amount from the surface energy balance calculation and measured energy flux between the bottom of the snowpack and the underlying ground. The total estimated amount of snow melt for the whole period was 398 mm w. e..The contributions from surface melting and melting at the ground were 76% and 24%, respectively. The melting energy due to snow impurity-induced albedo reduction is equivalent to 28% of total amount of snow melting, which is larger than the melting at the ground and is not negligible. Furthermore, the contributions from BC and dust to this value are 21% and 7%, respectively.

[A-CG42] Biogeochemical linkages between the surface ocean and atmosphere

convener:Yuzo Miyazaki(Institute of Low Temperature Science, Hokkaido University), Jun Nishioka(Hokkaido University, Institute of low temperature sciences), Koji Suzuki(Hokkaido University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Chairperson:Yuzo Miyazaki(Institute of low temperature science, Hokkaido University), Jun Nishioka(Institute of low temperature science, Hokkaido University)

Multi-scale vertical and horizontal ocean mixing processes can strongly influence the distribution of dissolved and suspended substances including macro- and micro-nutrients, and may impact on phytoplankton bloom formation. The changes in nutrient dynamics generally affect the abundance, composition and metabolic activity of marine organisms such as phytoplankton and bacteria during the bloom. Marine phytoplankton can produce volatile organic compounds (VOCs) and marine atmospheric aerosols, which strongly influence on atmospheric chemistry. Primary and secondary organic and inorganic components produced via marine phytoplankton activity can contribute to the Earth's radiative forcing, and in turn marine ecosystems including biogeochemical processes directly or indirectly. Therefore, the biogeochemical cycles have a tight linkage between the ocean and the atmosphere. In order to understand physical, chemical and biological processes relevant to phytoplankton bloom formation in the ocean, dynamics of VOCs and marine aerosols in the atmosphere, and the biogeochemical linkage between the ocean and the atmosphere, we welcome new interdisciplinary presentations and active discussions on physical, chemical, and biological sciences both from ocean and atmospheric fields in this session. Studies linked to the Surface Ocean-Lower Atmosphere Study (SOLAS) project are good examples, but other related studies are also invited.

Bromoform ($CHBr_3$) is one of the important bromine containing volatile halocarbons that are involved in ozone depletion in the atmosphere. Although the possible source of reactive bromine species from snow and sea ice has been discussed, mechanisms that control $CHBr_3$ production within sea ice and emission to the atmosphere remain unclear. Here, we show evidence of massive $CHBr_3$ production at sea ice surface-snow interfaces and its strong emission to the atmosphere from five field-campaigns to the Arctic Ocean, the Southern Ocean, and the Sea of Okhotsk in the winter and spring, in addition to supporting laboratory experiments. We found that the ice-related strong $CHBr_3$ emission was linked to the production of the $CHBr_3$ at the snow-sea ice interface through the haloform reaction. Our results suggest that sea ice acts as a strong $CHBr_3$ source for the atmosphere, indicating a significant contribution to the atmospheric bromine cycle.

Accumulation processes of trace metals into arctic sea ice: distribution of Fe, Mn and Cd associated with ice structure

*La Kenya Evans[1], Jun Nishioka[1]

1. Institute of Low Temperature Sciences, Hokkaido University

Increased loss of Arctic summer sea ice can influence the cycling of biogeochemical materials (trace metals, nutrients, etc.), affecting seawater’ s biology and chemistry. Sea ice is important for the supply of biogeochemical materials, especially trace metals, to the surface waters of the polar oceans; but its role is not clear. Understanding the accumulation and release mechanisms into Arctic sea ice will clarify the geochemical behaviour of trace metals. This study compared dissolved (D) and labile particulate (LP) Fe, Mn, and Cd to the observed sea ice structure from a single Arctic sea ice core. The structure of sea ice reflects the process of ice formation, which may aid in the determination of accumulation processes. Using photographic analysis for the percentage of pore microstructure and $\delta^{18}O$ analysis, sea ice structure was observed as: snow, granular (frazil), mixed (granular and columnar) and columnar ice. Salinity and nutrients were low, indicating brine drainage and multi-year ice. High trace metal concentrations in snow ice indicated meteoric snow as a source and accumulation during snow ice formation. High concentrations of LPFe in granular ice indicated accumulation via suspension freezing by frazil ice followed by entrainment. Dissolved Mn and Cd accumulated in snow and granular ice through chemical transformation processes. Elevated DMn and DCd in granular ice resulted from the reduction and release from accumulated Fe and Mn oxides. Elevated DMn and DCd in snow ice may have been due to the photochemical reduction of LPFe and LPMn. Low trace metal concentrations in mixed and columnar ice indicated trace metal release due to brine drainage. Our study clearly indicated that the differences observed in trace metals, within sea ice structure, showed that sea ice formation, chemical reduction and brine release were the processes behind trace metal accumulation and release in this Arctic sea ice.

Is halogen chemistry responsible for low ozone levels observed over western Pacific equatorial region? - From observations on R/V Mirai

*Yugo Kanaya[1], Kazuyuki Miyazaki[1], Fumikazu Taketani[1], Takuma Miyakawa[1], Hisahiro Takashima[1,2], Yuichi Komazaki[1], Xiaole PAN[3,1], Saki Kato[2], Kengo Sudo[4,1]

Constraints from ozone (O_3) observations over oceans are needed in addition to those from terrestrial regions to fully understand global tropospheric chemistry and its impact on the climate. Here, we provide a large data set of ozone and carbon monoxide (CO) levels observed (for 11666 and 10681 h, respectively) over oceans. The data set is derived from observations made during 24 research cruise legs of R/V *Mirai* during 2012 to 2017, in the Southern, Indian, Pacific, and Arctic Oceans, covering the region from 67˚S to 75˚N. The data are suitable for critical evaluation of the over-ocean distribution of ozone derived from chemical transport models. We first give an overview of the statistics in the data set and highlight key features in terms of geographical distribution and air mass type. We then use the data set to evaluate ozone concentration fields from Tropospheric Chemistry Reanalysis version 2 (TCR-2), produced by assimilating a suite of satellite observations of multiple species into a chemical transport model, namely CHASER. Over the western Pacific equatorial region (125-165˚E, 10˚S to 25˚N), the observed O_3 level frequently decreased to less than 10 ppb in comparison to that obtained with TCR-2, and also those obtained in most of the Atmospheric Chemistry Climate Model Intercomparison Project (ACCMIP) model runs for the decade from 2000. These results imply loss processes that are unaccounted for in the models. We found that the model's positive bias positively correlated with the daytime residence times of air masses over a particular grid, namely 165-180˚E and 15-30˚N; an additional loss rate of 0.25 ppb h^{-1} in the grid best explained the gap. Halogen chemistry, which is commonly omitted from currently used models, might be active in this region and could have contributed to additional losses. Our open data set covering wide ocean regions is complementary to the Tropospheric Ozone Assessment Report data set, which basically comprises ground-based observations, and enables a fully global study of the behavior of O_3.

Very low $\delta^{15}N$ of atmospheric nitrate found in the earstern equatorial Pacific and its implication to dynamic nitrogen recycle between ocean and lower atmosphere

*Shohei Hattori[1], Kazuki Kamezaki[1], Yoko Iwamoto[2], Sakiko Ishino[1], Mitsuo Uematsu[3], Kazuhiko Miura[4], Naohiro Yoshida[1]

1. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 2. Hiroshima University, 3. University of Tokyo, 4. Tokyo University of Science

Atmospheric nitrogen sources in the marine boundary layer of the remote ocean have been known to include long-range transport (LRT) of anthropogenic pollutants, and the LRT of anthropogenic atmospheric particulate nitrate ($p\text{-}NO_3^-$) within the free troposphere has been observed in regions influenced by westerlies from the Asian continent over Pacific Ocean. This traditional paradigm that the ocean is considered a passive recipient of anthropogenic N deposition can be applied western north Pacific regions. However, for the equatorial Pacific under the influence of pristine air, the sources of such $p\text{-}NO_3^-$ remain unresolved. To address this, we present $\delta^{15}N$ of $p\text{-}NO_3^-$ collected over the Pacific Ocean between 40˚S and 68˚N on two cruises, carried out by the Research Vessel *Hakuho Maru*, and estimated $\delta^{15}N$ of source NO_x of each sample. We categorized six marine regions within the Pacific Ocean, based on backward trajectory analysis to determine their source regions and various ion concentrations to assess whether anthropogenic or non-anthropogenic sources were dominant.

We found remarkably low $\delta^{15}N(NO_x)$ values for the equatorial Pacific regions compared to those in other regions over Pacific Ocean. These low source $\delta^{15}N(NO_x)$ values cannot be explained using conventional NO_x apportionment. Given that the eastern equatorial Pacific is one of the biologically active ocean regions resulted from upwelling water, here we postulate the alternative biogenic nitrogen source (NH_3 or alkyl nitrate) in this region. In the presentation, we will discuss important feature of self-recycle process of nitrogen between ocean and lower atmosphere in the eastern equatorial Pacific. We will also discuss its implication to nitrogen deposition for this region, which may contribute to new marine biological production and/or nitrous oxide emissions.

Origin of water-soluble organic nitrogen in marine atmospheric aerosols in the subtropical North Pacific

*Tsukasa Dobashi[1,2], Yuzo Miyazaki[1], Eri Tachibana[1], Yoko Iwamoto[3], Kazutaka Takahashi[4], Sachiko Horii[4], Shu-Kuan Wong[5], Koji Hamasaki[5]

1. Institute of Low Temperature Science, Hokkaido Univ., 2. Graduate School of Env. Sci., Hokkaido Univ., 3. Graduate School of Biosphere Science, Hiroshima Univ., 4. Graduate School of Agricultural and Life Sciences, Univ. of Tokyo, 5. Atmosphere and Ocean Research Institute, Univ. of Tokyo

Marine atmospheric aerosol is one of the most important factors that determine the climate change, because it absorbs and reflects the sunlight which affects radiative balance of the atmosphere. In particular, water-soluble organic nitrogen (WSON) in aerosol affect physicochemical properties of aerosol such as water-solubility characteristics, acidity, light-absorption properties of the particles. However, little is known about the origin of WSON in marine atmospheric aerosols. The purpose of this study is to elucidate the origin of WSON by cruise observation in subtropical North Pacific where very limited data are available.

Size-segregated aerosol samples were collected on board the R/V *Hakuho Maru* (KH-17-4) over the subtropical North Pacific, mainly along 23ºN, during August–October in 2017. Water-soluble organic carbon (WSOC) and water-soluble total nitrogen (WSTN) were measured by a total organic carbon analyzer with a TN unit. The concentrations of inorganic nitrogen (IN) were measured by ion chromatograph. The WSON concentration was derived from the difference between WSTN and IN. The stable carbon isotope ratio ($\delta^{13}C$) was measured by elemental analyzer-isotope ratio mass spectrometer (EA-IRMS). Longitudinal distributions of WSON at 23ºN showed that the submicrometer WSON concentration (av. 5.9 ±6.0 ng N m^{-3}) to the east of 160ºW was significantly larger than that to the west (av. 2.2 ±2.0 ng N m^{-3}). Additionally, the mass fraction of WSON to WSTN in the eastern oceanic region reached as large as 40% with an average of 14.1%, suggesting the importance of WSON in this oceanic region. Backward trajectory, the chlorophyll *a* concentration in seawater, and the $\delta^{13}C$ value suggested that the majority of the observed WSON was derived from microbial activity in the sea surface. WSON did not show any significant correlation with a tracer of primary emission (i.e., Na^{+}), indicating that the majority of WSON were not directly emitted as aerosol particles from the ocean surface, but were produced from N-containing gas species released into the atmosphere. Furthermore, a significant correlation between the concentrations of WSON and the nitrogen fixation rate in the sea surface indicates that reactive nitrogen, produced by nitrogen fixing organisms (e.g., cyanobacteria), are emitted from sea surface to the atmosphere, which significantly contributed to the formation of aerosol WSON.

Atmospheric NH_3 plays a vital role not only in the environmental ecosystem but also in atmosphere chemistry. To fully understand the effects of NH_3 on the formation of haze pollution in Beijing, ambient NH_3 and related species were measured at high resolutions during the wintertime Air Pollution and Human Health-Beijing (APHH-Beijing) campaign in 2016. Simulations were made to gain insights into impacts of NH_3 on the formation of secondary inorganic aerosols (SIAs) and regional fine particle pollution. We found that the total NH_x (gaseous NH_3+particle NH_4^+) was mostly in excess of the SO_4^{2-}-NO_3^--NH_4^+-water equilibrium system during our campaign. This NH_x excess made medium aerosol acidity, with the median pH value being 3.6 and 4.5 for polluted and non-polluted conditions, respectively, and enhanced the formation of particle phase nitrate. During polluted periods, SIAs contributed most to $PM_{2.5}$ and were highly correlated with aerosol water content (AWC), indicating the importance of heterogeneous reactions in haze formation. Our analysis suggests that NH_4NO_3 is the most important factor driving the formation of AWC, with NO_3^- controlling the prior pollution stage and NH_4^+ the most polluted stage. Increased formation of NH_4NO_3 under excess NH_x, especially during the nighttime, may trigger the decreasing of aerosol DRH and hence lead to hygroscopic growth even under lower RH conditions and the wet aerosol particles become better medium for rapid heterogeneous reactions. A further increase of RH promotes the positive feedback "AWC-heterogeneous reactions" and ultimately leads to the formation of severe haze. Both our observational and modelling results suggest that the control of NH_3 may be more effective in reducing $PM_{2.5}$ under current emissions conditions in the North China Plain (NCP).

Discussion

Salt weathering in humidity-change environments: a laboratory experiment

*Masato Sato[1], Tsuyoshi Hattanji[2]

1. Graduate School of Life and environmental Sciences, University of Tsukuba, 2. Faculty of Life and Environmental Sciences, University of Tsukuba

A laboratory weathering experiment simulating under changing humidity conditions were carried out using five types of rocks (porous tuff, porous sandstone, dense sandstone, and two porous mudstones) with three types of salts (sodium chloride, sodium sulfate, or magnesium sulfate). The rock specimens were subjected to humidity oscillations in a climatic cabinet where air humidity ranged from 20%RH to 98%RH during 6-hour periods 20˚C. Prior to the weathering experiment, the specimens were oven-dried, and the water supply was restricted only from air humidity during the experiment.
Humidity oscillation induced cycles of repeated of salt deliquescence-recrystallization and hydration-dehydration. Salts on rock surface deliquesced and hydrated in a high-humidity period, while they crystallized in a low-humidity period. The degrees of damage were correlated with moisture amounts absorbed to the rock specimens in the high-humidity period.
Sodium chloride which deliquesces at humidity of more than 80%RH caused the most intensive weathering. Porous sandstone with sodium chloride was completely broken down after 100 cycles of humidity changes. Dense sandstone and porous tuff showed flaking or swelling on their surfaces. Equotip surface hardness of dense sandstone with sodium chloride decreased with increasing number of humidity cycles. Sodium chloride can easily induce salt weathering by salt deliquesce and recrystallize in environment where air humidity fluctuates in a short time interval, such as the surfaces of rock cliff in coastal spray zones.
Magnesium sulfate induced a weight loss in porous sandstone, through flaking from the surface of porous tuff, and through swelling and cracking on the surface of dense sandstone. Sodium sulfate was not effective in the humidity-change experiment, although salt efflorescence was extensively produced. Slow hydration rate of sodium sulfate can cause the ineffectiveness of sodium sulfate. In addition, volumetric expansion with hydration of sodium sulfate may result in pore clogging, and hinder infiltration of moisture into the rock specimens. The restricted activity of sodium sulfate suggests that sodium sulfate rarely induces salt weathering by daily humidity fluctuation. Magnesium sulfate might influence rock decay more than sodium sulfate when air humidity fluctuates in a short period.

Verification a new control device of blown sand transport rate by wind tunnel experiments

*Yoshinori Kodama[1], Riko Saikusa[2]

1. Faculty of Agriculture, 2. Faculty of Regional Sciences

A new water-pool device for reducing blown sand transport rate was proposed from a view point of saltating particle motion. Wind duct experiments were conducted to check sediment trap efficiencies of a proposed device. In our experimental conditions, maximum wind velocity: 12.9 m/s, it worked well: reducing blown sand transport rate less than 6 % within 4.55 m distance. We estimated that the least length of the device is 11.3 m at 18.0 m/s wind condition, which is almost maximum in Tottori Sand Dunes.

Bedrock landslides, river blockage, and barrier-lake outburst as general geomorphic processes in high-relief mountainous landscape: an example from the Marshyangdi River, central Nepal

*Yuki Matsushi[1], Hiroshi YAGI[2], Hiroyuki Matsuzaki[3]

1. Disaster Prevention Research Institute, Kyoto University, 2. Department of Education, Art and Science, Yamagata University, 3. icro Analysis Laboratory, Tandem Accelerator, The University of Tokyo

This study demonstrates generality of large-scale bedrock landslides, river blockage by the slid mass, and debris flow by the barrier-lake outburst in landscape evolution of high-relief mountainous watersheds. We focused on the Marshyangdi River, south-eastern range of the Annapurna massif, central Nepal, to conduct ground-based surveys and geo-spatial analyses. Geology along the river consists mainly of Paleozoic and Mesozoic sedimentary rocks, gneiss, phyllite, schist, and shale from the upper to lower reach. Deeply-incised gorge develops in the area of massive gneiss, while fill terraces occupy the wide area of valley floor downstream from the Main Central Thrust. The lower- to mid-level terraces exhibit characteristic morphology with hummocky mounds with gneiss boulders settled on the surface, indicating their origin that may be relevant to large scale debris flow events by deep-seated bedrock landslide and subsequent barrier lake breach. Exposure ages of the boulders ranges from 2 to 4 ka, indicating repeated occurrence of such events under the Holocene climate. On the upstream area, several sets of lacustrine deposits remain along the main channel. The sequence and distribution indicate that the paleo landslide-dammed lakes expanded few-kilometers in length and few hundreds meters in depth before breaching. The debris flow ran through the river for tens of kilometers, spreading out over the downstream valley. Results of evidence mapping and topographic analysis indicate that these kind of large-scale sequential phenomena play a general function in landscape evolution of a high-relief steep mountainous watershed in tectonically-active settings. Disaster mitigation for such possible event requires enhancement of preparedness through prediction and risk assessment for conceivable hillslope and/or fluvial processes.

Influence of lithology on production and transport of soils on hillslopes underlain by granite and hornfels

*Takuma Watakabe[1], Yuki Matsushi[2], Hiroyuki Matsuzaki[3]

1. Graduate School of Science, Kyoto University, 2. Disaster Prevention Research Institute, Kyoto University, 3. The University Museum, The University of Tokyo

We measured rates of soil production and transport using cosmogenic ^{10}Be and measured characteristics of soil properties in hillslopes underlain by granite and hornfels in Shirakawa watershed, eastern Kyoto City. Rates of soil production and transport of the granite hillslope were faster than those of the hornfels hillslope. Soil on the granite hillslope was incohesive sand with large saturated hydraulic conductivity and low water retention ability. In contrast, soil on the hornfels hillslope was cohesive sand with low saturated hydraulic conductivity and high water retention ability. Characteristics of the granite soil promote wet–dry weathering effect in the shallow subsurface materials of the granite hillslope. Thus, physical, mechanical, and hydrological properties of soils on each bedrock control the rates of soil production and transport.

Characterization of the vertical unsaturated flow for an integrated prediction of the storm runoff response and landslide initiation on a hillslope

*Makoto Tani[1], Yuki Matsushi[2], Takahiro Sayama[2], Nagahiro Kojima[3]

1. University of Human Environments, 2. Disaster Prevention Research Institute, Kyoto University, 3. Lake Biwa Environmental Research Institute

Studies on hillslope hydrology have demonstrated storm runoff responses are generated mainly through subsurface flow instead of overland flow, and studies on erosion control have empirically revealed landslides usually occur at the time of intense rainfall after a large cumulative rainfall. based on these findings, we have to explain with consistency that the flow generation mechanism for large magnitude storms on hillslope can produce both hydrograph responses below a threshold condition of rainfall and a landslide initiation above the threshold. Recent observational studies have shown vertical unsaturated flow within a hillslope soil layer may dominantly control the responses of ephemeral groundwater table to storm rainfall through the pressure-head propagation and that the responses are rather transmitted to the stream runoff with little modification. The present study discusses the reason why the vertical unsaturated flow can produce the runoff responses during large magnitude storms and provides a perspective on an integrative prediction of the storm runoff response and landslide initiation

Discussion

The landform and flood characteristics of the Iron Gate on the ancient road from Samarkand to Bamian, south Uzbekistan

*Hiroshi Shimazu[1]

1. Department of Geography, Faculty of Geo-Environmental Science, Rissho University

“The Iron Gate” is located on the ancient road from Samarkand, which has been one of the largest cities in the central Asia from ancient times, via Termes, where is the crossing point of the Amudarya, to Bamian, which has been one of the important cities as Buddhism. The Iron Gate is a narrow gorge located several kilometers east of the main mountain ridge of the Hissar Mountains. Its length is 2 kilometers and its width of the narrowest part is 10 meters. Both valley side slopes are very steep and their relative height is about 200 meters. Genjo, who is one of the most famous Buddhism priest of 7th century walked through the gorge on the way to India.

Debris flow deposits, whose maximum diameter in b-axis is over 50cm, and sorted and clear laminated flood sediments, which are more rounded and smaller sandy gravels are distributed in the canyon. The relative height between these surface top and valley bottom is several meters. Present valley floor is buried valley bottom, whose surface is flat or covered with lobate large gravel deposits. Although there is poor vegetation on the both valley side slopes and surface of the sediments, only sporadic shrubs are on the valley bottom and both side of the eroded cliff of the sediments Heavy flood event frequent occurred in this region and debris flow and sediment flow buried the Iron Gate canyon section. After the event the buried valley bottom was dissected by water flow. Sediment transport events repeated more than once in a year and heavy flood event repeated once in several years. Samarkand and Termes have precipitation between October and April. The temperature in cold season of the city is below zero and this region has some snow. Snow melt is accelerated by rain in March and April and flood events are caused in this region.

The reason why this important road was constructed in the area of such higher risk of flood is that this place was the important checkpoint of this road. The forts of this region, located the ridge of hill, were favorable to watch passers pass through the canyon road, where sometimes closed by flood.

OSL dating of sediment core in Olgoi lake, Mongolia

*Yudai Igarashi[1], Noriko Hasebe[1], Nagayoshi Katsuta[2], Hitoshi Hasegawa[3], Davaadorj Davaasuren[4], Yukiya Tanaka[5], Uyangaa Udaanjargal[1], Keisuke Fukushi[1], Ichinnorov Niiden[6]

1. Kanazawa University, 2. Gihu University, 3. Kochi University, 4. National University of Mongolia, 5. Kyunghee University, 6. Mongolian Academy of Science

In the southern part of Mongolia, there are many lakes in the basin between mountain ranges, which is called “Valley of the Lakes”. These lakes experienced lake level fluctuations during the Quaternary period. This lake level variation is considered important information to understand climate change. The influx from the Khangai Mountains is a major source of water for the Valley of the Gobi lakes, a large southern basin. Olgoi lake is the research target of this study and locates closer to the summit of the Khangai mountain range than other lakes of Valley of the Gobi lakes, so it is highly likely that it reflects influx sensitively. A sediment core was collected from Olgoi lake to investigate the environmental change of the region. In this study, OSL dating of quartz was carried out to date core samples from Olgoi lake. This Core sample showed the age value of 0.7 to 10 ka covering the Holocene. In addition, it is suggested that the sedimentation of gravels, which is the most characteristic feature of the lower part of the Olgoi lake core sample, was related to the Holocene rapid temperature change events. There is a large gap in age values in this core sample at 7.5-9.0m. There is a high possibility that it reflects past sedimentary environment and even the climate, but I could not reach the final argument by the ages obtained in this research. To understand the complex transition of sedimentary environment of Olgoi lake, high resolution analyses of sediment characteristics and precise age control would be necessary.

Paleo Lake level change in southern part of Mongolia

*Noriko Hasebe[1], Makoto Sambo[2], Uyangaa Udaanjargal[2,3], Shuukaaz Ganbat[3], Keisuke Fukushi[1], Yukiya Tanaka[4], Davaadorj Davaasuren[3]

1. Institute of Nature and Environmental Technology, Kanazawa University, 2. Department of Earth Sciences, Kanazawa University, 3. National University of Mongolia, 4. Kyunghee University

Lake Boontsagaan, Orog and Olgoy are located in the Valley of the Lakes, Gobi-Altai transition zone, which stretches from central to western Mongolia. This area suffers desertification probably due to the ongoing global worming and dried up lake sediments are worried as a source of contaminated sand storm. The flat surface in Valley of Lakes is covered with Quaternary lake sediments. Paleoshorelines are identified near the lakes. This study observed the sedimentary structures of the outcrops on the paleoshoreline and samples were collected to estimate the time when lake level was high by Quartz OSL dating method. The outcrop near the Ology, Boontsagaan, and Orog lakes are higher than the present lake level by 8 m, 15 m and 3 m, respectively.
The history of lake level change is proposed based on the age, altitude of the localities, and sedimentary structure of the outcrops. Data from Boontsagaan lake, for which coarse grains were analysed, scatter, therefore the youngest age component is extracted by plotting the data on the radial plot (Galbraith, 1988, Vermeesch, 2009). Ages from Boontsagaan Lake are around ~4-9 ka, while ages from Olgoy and Orog lakes are around ~1-2 ka. Because Boontsagaan Lake is larger and deeper than other lakes, its lake level change would be less active. Besides, relative height of the locality to the current lake level is higher then other two lakes. Therefore, the lake level was very high before ~5 ka, and relatively high at ~1-2 ka. The obtained results are consistent with previously reported data from the nearby sites (Lehmkuhl et al., 2018).

Coral reefs commonly act as natural barrier against swell wave impact. Conventionally, reefs efficiently attenuate storm waves. However, recent studies have indicated that during energetic typhoon swells, generation of infragravity waves can lead to hazardous conditions where the reef does not act like a protecting barrier anymore. In order to know the wave behavior near and over the reef, high-resolution 3D topographic data is required for the numerical calculation. However, most of the previous studies result from one- or two-dimensional numerical calculations based on low-resolution topographic data. This is mainly due to the challenging environment for conducting bathymetry/topography surveys in the vicinity of the reef. Hence, it was difficult to discuss the wave processes under the influence of the microtopography. In this study, we developed high resolution and complete set of the 3D topographic data (girid size: 1 m) from land to about 95 m water depth at the east coast of Kudaka Island, Okinawa Prefecture (an area of approximately 3 ×5 km) by UAV topographic and multibeam bathymetric surveys. Based on the terrain data with 5 m mesh size, we conducted two-dimensional wave-by-wave calculations with the Boussinesq-type wave model, BOSZ. The results show that the deformation and propagation mechanisms of the waves near the reef are highly controlled by microtopography features such as the differences in slope angles and the presence of spurs and grooves.

The coastal seafloor at depths shallower than ~130 m was subjected to alternating subaerial erosion and sedimentation during Quaternary sea-level change. However, the coastal seafloor is rarely discussed in conventional geomorphology. Recently, the development of exploration technology such as multibeam echo sounder survey enables us to observe the accurate and detailed coastal seafloor geomorphology. In this presentation, we discuss the novelty and possibilities of coastal seafloor geomorphology based on case studies from around the world and research materials of our group.

[H-SC07] CCUS (Carbon Dioxide Capture, Utilization, and Storage) for Climate Mitigation

convener:Masao Sorai(Institute for Geo-Resources and Environment, National Institute of Advanced Industrial Science and Technology), Ziqiu Xue(Research Institute of Innovative Tech for the Earth), Masaatsu Aichi(Graduate School of Frontier Sciences, University of Tokyo), Chairperson:Masao Sorai(National Institute of Advanced Industrial Science and Technology)

The prevention of the global warming, which is the urgent challenge facing the world, requires the full-out efforts of science and technology. This session focuses on the CCUS (Carbon Dioxide Capture, Utilization, and Storage) as one of the useful countermeasures for the CO2 emission reduction. It not only targets various scientific phenomenon caused by the capture and storage of CO2, CO2 utilization, and CO2-EOR/EGR, but also discusses the latest R&D developments of each method for the environmental impact assessment, safety assessment, the measuring, monitoring and verification (MMV), and public acceptance. The main theme is the recognition of key issues toward the practical use of CCUS, in addition to the deepening of our knowledge about the CO2 behavior on the underground.

Numerical simulation of variational pore pressure response to ocean tidal loading during CO2 injection

*Toshifumi Akaki[1], Hajime Yamamoto[1]

1. Taisei Corporation

As a promising measure against global warming, CCS (Carbon dioxide capture and storage) has been extensively studied over recent decades and some large-scale projects are currently in operation worldwide. Carbon dioxide is captured from flue gases emitted from large sources such as coal-fired power plant, and injected and kept stored in a deep geologic formation for long-term. In the geologic CO2 storage, reliable and cost-effective monitoring techniques of the injected CO2 need to be established. It is well known that the pore-pressure of groundwater is affected by the earth and ocean tides. Recently, at a geologic CO2 storage project, it has been reported that the pore-pressure fluctuation at a monitoring well is explained by diurnal earth tides, and the amplitude of the pressure fluctuation significantly attenuated when the carbon dioxide arrived at the well due to the changes in compressibility of pore fluid around the well (i.e. the compressibility of CO2 is much smaller than that of water). This suggests a potential low-cost CO2 monitoring technique through monitoring and analyzing tidal responses of pore pressure during geologic CO2 storage. The tidal response of pressure is understood as a hydro-geomechanical coupled phenomena in deformable porous media containing water and CO2. Previous studies indicated that the changes in amplitude of pore-pressure before and after CO2 arrival at a monitoring well can be simply explained by poroelasticity theory. However, numerical simulations are required to further quantitatively investigate the tidal effects on pressure fluctuation at monitoring wells during CO2 injection. For example, the pressure response is possibly affected by many geometrical and geological settings in three-dimensional space, such as distance between the monitoring wells and CO2 plume, geometry of CO2 plume, and pressure dissipation induced by fluid flow. In this study, we developed a numerical simulator in the framework of poromechanics to simulate three-dimensional deformations and stress changes of geological formations under two-phase flow conditions of water-CO2, which was enhanced to be adoptive to cyclic loading by diurnal and semi-diurnal tide. Using this simulator, we investigate variation of responses of pore water pressure to the ocean tide loading during CO2 injection. Amplitude of the response at injection well decrease during CO2 injection, and somewhat recovered due to upward movement of CO2 plume after injection. The final amplitude in this simulation is smaller than initial amplitude under water saturated condition due to an effect of CO2 plume staying top of the reservoir.

Relationship between rock deformation and permeability evolution during fracturing in rocks for CCUS technology

*Takashi Fujii[1], Xinglin Lei[1], Masao Sorai[1]

1. National Institute of Advanced Industrial Science and Technology

An understanding of relationship between fluid flow transport and geo-mechanical response within geological reservoirs is of a fundamental concept for a suitable utilization of deep underground repositories (e.g., Carbon Capture and Storage (CCS), Carbon Capture Utilization and Storage (CCUS), shale gas exploration). Particularly, fracture permeability within caprocks plays an important role in producing hydrocarbon during the trapping of buoyant gas fluids in reservoirs for CCUS projects. Wide variations of permeability value depending on rock deformation (including fracturing process) for several types of rocks has been determined using the coupled fluid flow transport (TOUGH2) and geo-mechanical response (FLAC3D) simulator (e.g., Rutqvist et al., 2002) so far. However, the evolution of permeability during fracturing in such rocks is very complex, and there now are being reported few constitute law for the linked deformation and fracture permeability. Furthermore, few laboratory studies have experimentally been conducted so as to replicate this process by simultaneously fracturing specimens and measuring permeability at in situ fracturing stress states (Carey et al., 2015; Fujii et al., 2015; Frash et al., 2016).
The purpose of this study is to investigate experimentally permeability change during fracturing in (i) caprocks (shale, mudstone, slate) and (ii) reservoir rock (sandstone, tuff), the conditions of which assumes that CO_2 is injected into geological media. We attempt to fit a model to obtained experimental data (i.e., permeability: K, volumetric strain: e_v) in order to develop suitable constitute law for the optimize use of coupled geo-mechanics and fluid flow simulator.
Our results demonstrate that there could mainly be classified into the two patterns of relationship between e_v and K of all materials tested. Particularly, it is apparent that the permeability behavior throughout fracturing and slipping processes are quite different between rock groups of (i) and (ii). Caprocks have a sharp-jumped increase of permeability during fracturing in the rock matrix, but reservoir rocks have significantly smaller permeability change, compared to the caprocks in post-failure regime. Furthermore, model fitting results suggest that the relationship between e_v and K of all materials tested could be explained fully by modification of conventional model (e.g., Cappa et al., 2009)
In light of findings of our study, it can be concluded that the propsed constitute law might be contributed to the simplification and optimization of the coupled fluid flow and geomechanical simulator.

Comparison of Optical Fiber Sensing Technique and Strain Gauge in a Measurement of Rock Deformation Caused by Chemical Osmosis

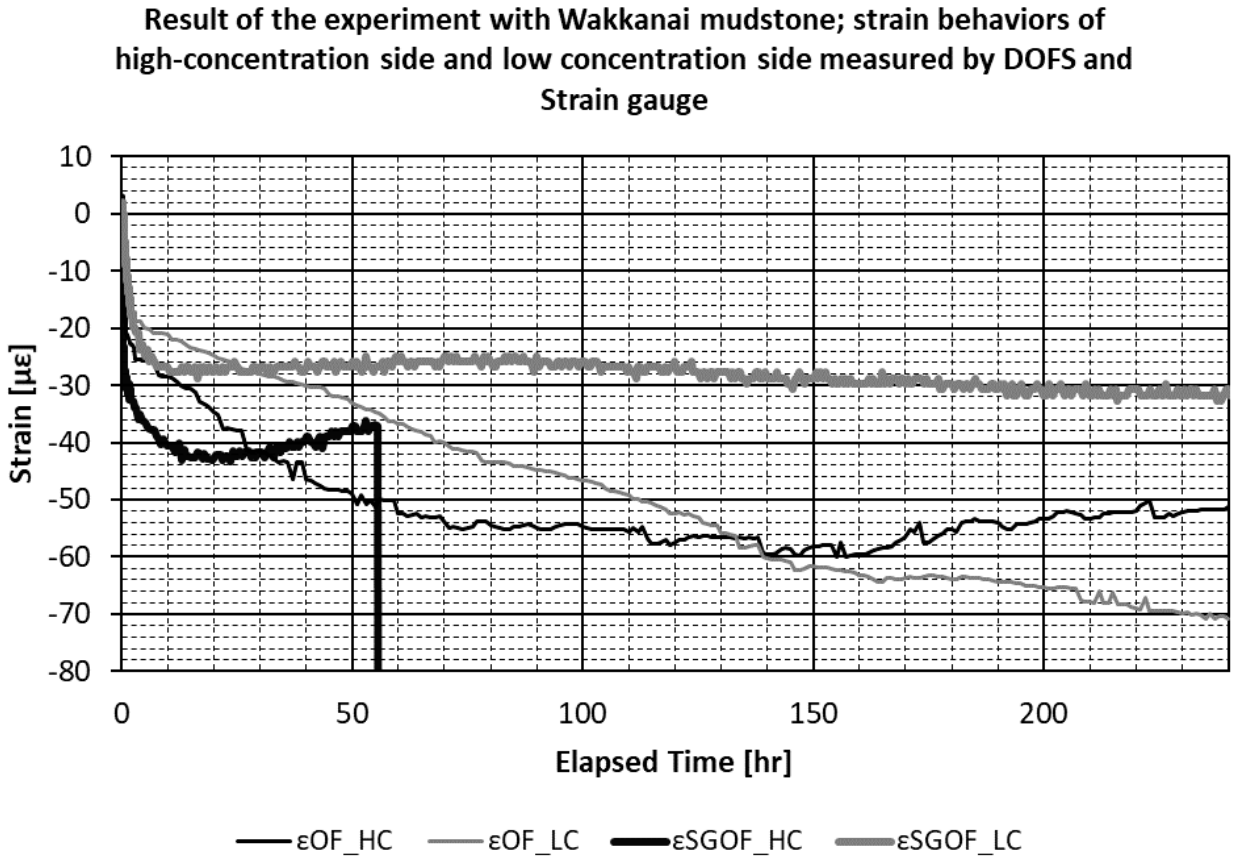
*Shogo Hirota[1], Tomochika Tokunaga[1], Ziqiu Xue[2], Hyuck Park[2]

1. Department of Environmental Systems, Graduate School of Frontier Science, the University of Tokyo, 2. Research Institute of Innovative Technology for the Earth

Mass transport and water flow in subsurface are generally considered to be much smaller than those on surface environment. Stability of subsurface environment is useful to isolate specific substances (e.g. CO_2 or high-level radioactive wastes) from human societies for a long time. For these purposes, argillaceous formations perform as effective seal layer because of its low permeability and smaller diffusion coefficient.

It is known that some argillaceous rocks show semipermeable membrane behavior, i.e., the process called chemical osmosis. Chemical osmosis causes water flow across semipermeable membrane driven by the gradient of osmotic pressure between two solutions (Marine and Fritz, 1981). Previous research showed that the pressure change caused by chemical osmosis can reach to about 20 MPa (Neuzil, 2000). Osmosis-induced pore pressure change can cause deformation of porous medium (Greenberg et al., 1973: Noy et al., 2004), however, the detailed discussion on the osmosis-induced deformation behavior of argillaceous rocks is still premature because of the difficulty for measuring multiple strain in the sample.

Generally, normal strain gauges by measuring the changes of the electrical resistance are used for laboratory-scale rock deformation experiments. Experiments for measuring deformation caused by chemical osmosis take a long time and drifts caused by water intrusion and/or delayed heat dissipation is considered to be the issue for the accurate measurements. Distributed optical fiber sensing (DOFS) is a technique for possibly avoiding the measurement drift. In DOFS measurement, the backscattering light is used to measure strains along the fiber, and DOFS can use entire optical fiber as a sensor, thus, strain behavior at multiple points along the optical fiber can be obtained.



The purpose of this study is to investigate the applicability of both strain gauges and DOFS to the laboratory-scale chemical osmosis experiments through the comparison of both results, and to discuss the strain behavior of argillaceous rocks by chemical osmosis. In this experiment, core samples with the height of about 30mm and diameter of about 50mm made from mudstones collected from the Wakkanai Formation in Hokkaido prefecture and the Oganocho Formation in the Chichibu Basin, Saitama prefecture, were used. Strain gauges were attached to the sample, and axial and circumstantial strains near the both edges were measured. Optical fiber was attached helically to the sample, and the strains along the direction of the fiber were measured. The lateral and top surfaces of the specimen were sealed by silicon rubber to prevent water flow through these surfaces. In the experiment, the bottom surface of the sample was contacted to NaCl solution with 10g/L higher concentration than that of pore water, and osmotic flow was induced by the concentration gradient. The strains of the specimen caused by osmotic flow were measured by both DOFS and strain gauges. Temperature was kept almost constant throughout 240 hours by putting the apparatus into a box made with heat insulating material and the experimental room was controlled by air conditioner.

In the initial phase of the experiments, the strain behaviors measured by both strain gauges and DOFS showed a good agreement. Initial strain behavior characteristic to the poroelastic effect was found only in the measurement by strain gauges because of the much shorter sampling interval compared with that in

©2019. Japan Geoscience Union. All Right Reserved.

DOFS. On the other hand, after 20 hours, strains measured by the strain gauges near the bottom of the sample, i.e., high-concentration side, started to increase while those measured by DOFS not. It is considered to be caused by the unstable behavior of strain gauges.

Experiment of precipitation of salt for dry-out condition caused by CO_2 storage in saline aquifer

*Hayato Morigaki[1,2], Masaatsu Aichi[1]

1. University of Tokyo, 2. Toshiba Energy Systems & Solution Corporation

Since CO_2 is transported in dry condition to prevent corrosion of the press-in pipe, CO_2 injected into the saline aquifer may evaporate water and dry the formation. In this case, there is concern that the porosity and permeability of the reservoir will decrease due to salt precipitation and clogging. On the other hand, the influence of cap rock on the sealing ability has not been considered sufficiently.
In this study, in order to observe the state of salt precipitation while controlling the degree of drying, the experiment was carried out with humidity control to generate a suction of about 100 MPa using a thermo-hygrostat. In the experiment, the core sample with the side sealed and the brine reservoir attached at the bottom was placed in the humidity control space, and the water evaporation from the top of the core sample was measured and the precipitation of salt was observed. In addition, in the comparison between before and after this experiment, we also tried to evaluate the influence of semipermeable membrane performance of mudstone on the presence or absence of precipitation and change in salt concentration of brine in the reservoir. The salt concentration of the reservoir, which was assumed to be the saline aquifer, was set at 0.6 mol / L as seawater, and when experiments were conducted assuming that the brine saturated rock was exposed to dryness, it was confirmed that the flux of moisture did not change remarkably before and after salt precipitation on the muddy sandstone of the Otadai Formation, the mudstone of the Otadai Formation and the mudstone of Wakkanai Formation. Also, the salt transport inhibition due to the semipermeable membrane effect was not noticeable. This suggests it is not necessarily expected that the precipitation of salt by drying improves CO_2 shielding performance of cap rock.

Thermodynamic Approach to Wettability of CO_2/Brine/Mineral System by Augmented Young Laplace Equation

*Masashige Shiga[1,2], Masao Sorai[1], Masaatsu Aichi[2], Hiromi Honda[2]

1. AIST, 2. The University of Tokyo

CO_2 Geo-Sequestration (CGS)has been regarded as one of the most significant technologies to reduce the amount of CO_2 emissions into the atmosphere.

Sealing performance of the caprock in the geological formation is largely influenced by wettability which is evaluated by the contact angle of the CO_2/Brine/Mineral system.

A lot of researchers have measured the angles in various conditions (e.g. pressure, temperature, salinity, or types of minerals) by various methods.

However, the value and the trend of the contact angle have not been confirmed yet.

This is mainly because there are a lot of inconsistencies in the experimental data due to the difficulties of controlling the surface roughness or impurities.

In order to tackle this problem,we calculated the contact angle and studied the key factor to affect its value by using augmented Young Laplace equation in which a thickness of the film on the mineral substrate is considered as a thermodynamic variable.

Parameters of the interfacial properties were calculated by PhreeqC, which is a simulator performing a wide variety of aqueous geochemical calculations.

A proposal of CO2 underground storage using hydrate

*Takaomi Tobase[1]

1. Electric Power Development Co., Ltd.

There is a fact that methane exists naturally and stably in the form of hydrate (solid).
As natural analog with methane hydrate, form CO2 hydrate using gas hydrate mechanism based on temperature and pressure, propose that could also be applied to underground storage of CO2. The concepts of the CO2 hydrate storage are as follows.
(1) Injection liquid or supercritical CO2 in the storage layer.
(2) Injected CO2 moves above by a density difference, when temperature and pressure condition reached the domain that formed hydrate, make clogging in a pore (come to have seal function).
(3) CO2 becomes able to storage under layer of CO2 hydrate having seal function. (not need the cap rock as geological structure)
As a result of investigating the temperature in the surrounding sea area of Japan, we confirm that temperature and pressure condition to form CO2 hydrate in the underground of sea bottom. It is thought that very likely to be the CO2 hydrate storage.
Aquifer storage (including CO2-EOR) to have the cap rock as a method of the CO2 storage is popular. But if CO2 hydrate storage is realized, we can hope that contribute to right lot expansion of the CO2 storage.

Carbon Capture and Storage (CCS) is expected as a mitigation measure of climate change and global warming causing by the rise in atmospheric carbon dioxide (CO_2) concentration. CCS is a technology that can reduce the amount of CO_2 emissions from large point sources, such as electricity power plant, by separating and recovering CO_2 from atmosphere-releasing gas and storing it in the basement. Main items of reservoir evaluation are (1) evaluation of injection performance and (2) evaluation of storage capacity. In this research, the above two evaluation items were investigated by numerical analysis. Analysis module, TOUGH2-ECO2N which deals with multicomponent and multiphase fluid was used.

(1) Evaluation of injection performance
The influence of basic physical parameter (permeability and porosity) on the CO_2 injection performance of the reservoir layer was investigated. As a result, it has been found that permeability affects whole pressure level of the reservoir layer and porosity affects the slope of pressure rise. Furthermore, their influence on the long-term distribution range of pressure and CO_2 plume has been revealed clearly.

(2) Evaluation of storage capacity
The basic physical parameter of analysis model for the evaluation of the storage capacity was determined with history matching based on the monitoring and the prediction simulation of the pressure, which was conducted in the CCS project in Canada Quest. In order to reveal the factors affecting the storage capacity evaluation were carried out, case studies such as changing placement of injection wells, etc. It is expected that the findings from this study can contribute to the evaluation of the storage capacity, such as predicting pressure rise in the reservoir layer and distribution of CO_2 plume, and the helpful for enabling "reservoir management", such as arrangement of injection wells, number of wells, injection rate and time, and installation of a pressure relief well.

Monitoring hydromechanical responses in aquifer by distributed fiber-optic strain sensing: From lab to field

*Yi Zhang[1,2], Ziqiu Xue[1,2], Tsutomu Hashimoto[1,2], Hyuck Park[1,2]

1. Geological Carbon dioxide Storage Technology Research Association, 2. Research Institute of Innovative Tech for the Earth

Pore fluids control deformation of porous media by the fluid-to-solid hydromechanical (HM) coupling in which a change in fluid pressure can modify the effective stress and deform the porous medium (Wang, 2000). The HM coupling mechanism provides a possibility that to understand aquifer characteristics and fluid activities during fluid extraction and/or injection operations, e.g., in geological CO_2 storage (GCS), by monitoring rock strain changes. We successfully measured such HM deformations using a high-resolution distributed fiber optic strain sensing (DFOSS) tool in both laboratory and field scale studies. From the DFOSS-obtained HM information, we are able to track the pressure impact zone, understand the permeability structure of the aquifer formation and identify the preferential flow layers. Moreover, we can track the fluid migration front during CO_2 displacing water and the mechanical response of CO_2 breaking through to a low-permeability layer or caprock. The application of DFOSS would be beneficial to guide the aquifer pressure management for safe GCS with prior or simultaneous water extraction (Buscheck et al., 2012).

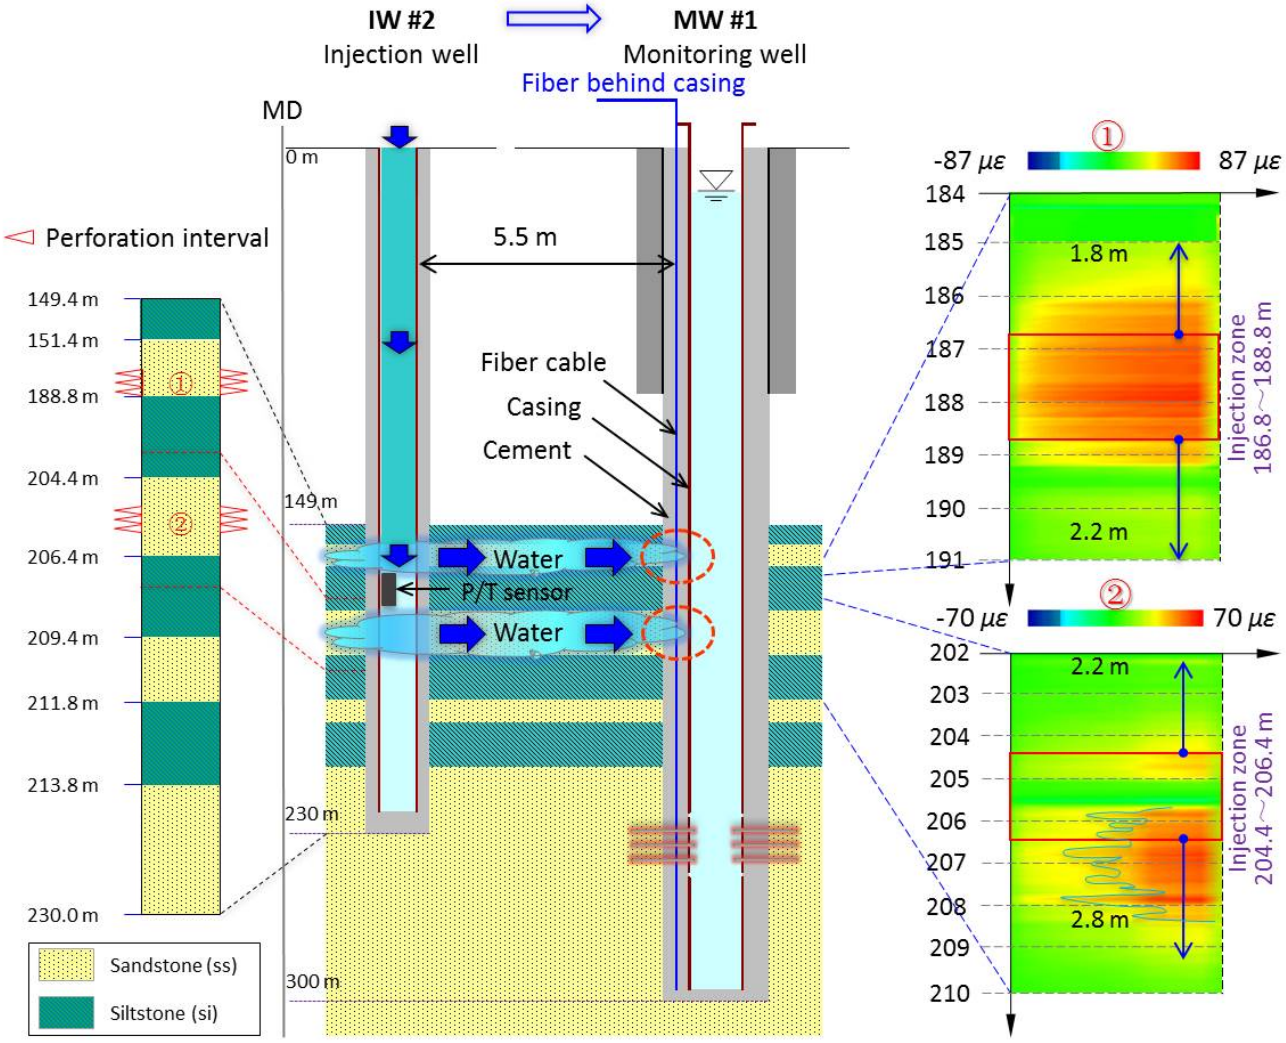
Field Testing of Hybrid Brillouin-Rayleigh Distributed Sensing System for Subsurface Water Injection Monitoring

*Yankun Sun[1,2], Ziqiu Xue[1,2], Tsutomu Hashimoto[1,2], Xinglin Lei[3], Yi Zhang[1,2]

1. Geological Carbon Dioxide Storage Technology Research Association, 2. Research Institute of Innovative Technology for the Earth, 3. National Institute of Advanced Industrial Science and Technology

Massive fluid injections into underground formations inevitably alter stress state and even induce damaging earthquakes, so robust high-resolution monitoring technologies are urgent to track geomechanical behaviors of injected fluids. Here we present one of the first case studies demonstrating the use of distributed fiber optic sensing (DFOS) technique based on hybrid Brillouin-Rayleigh backscattering for well-based monitoring of geomechanical deformations induced by field water injection. Injection tests were conducted with different injection scenarios between injection well (230 m, IW #2) and 5.5 m away from fibered monitoring well (300 m, MW #1) deployed cable behind casing in Mobara, Japan. Geomechanical responses were real- time recorded using DFOS approach; the resulting strain profiles were used to capture fluid evolution behaviors; thus evidencing that induced strains significantly depend on injection rate, injection pressure and lithological heterogeneity using this approach. Concurrent borehole logging was utilized to detect injection-induced variation of near- wellbore formations, which results agreed reasonably well with DFOS readings. This field application of hybrid DFOS technology conclusively enables speedy improvement of finely monitoring subsurface geoscience engineering activities, such as CO_2 storage.



Based on this methodology, some conclusions in this study can be drawn below:
1. An advanced DFOS system based hybrid Brillouin-Rayleigh backscattering is successfully applied to real-time monitor water injection tests between two adjacent wells. Two different injection formations ① and ② are investigated.
2. Field testing demonstrates that induced geomechanical deformation (i.e., strain) is mainly dependent on injection volume rather than injection temperature, which has no significant effect on the strain changes.
3. Geomechanical deformations harmoniously emerge and eliminate with injection schemes, although the effect of packers on the strain profile results in slight emergency of strain leaps. The impacted zones expand along vertical direction beyond corresponding injection sections.
4. Formation heterogeneity results in lateral transport of injected water and its pressure propagation in the pore space. Compared with *V*sh -GR and BH, the lower *V*sh related to formation is easier for strain accumulation. In addition, although the impact acting on clay-rich formations is relatively small, the existence of shale just weakens the induced deformation intensity rather than completely stops the strain expansion.
5. According to open-hole resistively logs of IW and MW, simplified simulation result further confirms strong small-scale formation heterogeneity and discontinuities of shale-sand distribution in the injection formations.
6. Testing results also reveal that there are two main reasons accounting for vertical expansion of impacted zones during water injections. First reason is formation heterogeneity, which is quantified by open-hole resistivity logging and GR data, largely affecting fluid behaviors, including migration, evolution and diffusion in subsurface. Second reason is that due to poroelastic deformation, different injection scenarios can generate different injection pressure, which will ultimately lead to different geomechanical deformation responses and first-arrival pressure front patterns of injected water propagating to the

Monitoring the distribution and migration of CO_2 injected into geological formations is needed for management of geological storage of CO_2. Superconducting gravimeters (SG’s) potentially enable monitoring of offshore CO_2 storage at ground-based stations because of its high precision. We conducted continuous gravity observations using SG’s near the seashore at the Tomakomai CCS (carbon dioxide capture and storage) demonstration site, Japan to study variation in the observed gravity near the seashore. The gravity data after correcting for tides, polar motion, and barometric pressure changes was strongly affected by shallow groundwater level changes but it was corrected by expressing their effects as a summation of linear functions of groundwater level changes. The standard deviation of the gravity residuals was reduced to less than 1 μGal after correcting for the groundwater effects. The small variation in the observed gravity residuals suggests that the ground-based gravity monitoring using SG's can be useful in long-term monitoring of offshore CO_2 storage.

Pilot test for microbubble CO_2 injection to reservoir in oil field - Test planning and preparation -

*Kazunori Nakagawa[1], Ryo Ueda[1], Masanori Nakano[1], Ziqiu Xue[2]

1. Japan Petroleum Exploration Co., Ltd., 2. Research Institute of Innovative Technology for the Earth

In this study we have studied to evaluate the effect of microbubble CO_2 injection to CO_2 storage by core flooding test in laboratory and develop the tools for microbubble CO_2 injection in reservoir and we reached at the step which we plan to conduct the field pilot test in 2019.

We provide an introduction to the planning and preparation to the field pilot test for microbubble injection technology.
Summary of the pilot test
We plan to conduct this test at a part of oil field in Japan. This oil reservoir is consisted of the alternate layers of sand and mud and has high hetrogeneity which the advantage in the microbubble injection technology is expected. Huff' n Puff method will be applied in this test and pressure and flow rate at CO_2 injection and reproduction (flow back) from reservoir after CO_2 injection are measured as field test data. Two CO_2 injection tests, microbubble and normal injection are planned to estimate the effect of microbubble injection technology and behavior. Injected CO_2 volume is 100t at each test, microbubble and normal injection. Moreover, we construct the flow simulation model and estimate the microbubble CO_2 injection before and after field test.
preparation
We produced the tools for microbubble CO_2 injection in well based on prototype tools developed in this study and constructed facility which consisted of CO2 storage tank, CO2 injection pump and warming apparatus in test field.

Acknowledgements

This presentation is based on results obtained from a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO) and the New Energy the Ministry of Economy, Trade and Industry (METI) and attributed to basic study for micro bubble CO_2 injection technology by Tokyo-gas Co., Ltd. and RITE. We deeply appreciate them.

Mechanisms inducing anomalously high pCO_2 without CO_2 leakage in coastal environment

*Yuji Watanabe[1,2], Keisuke Uchimoto[1,2], Makoto Nishimura[1,2], Saeko Mito[1,2], Ziqiu Xue[1,2]

1. Geological CO2 Storage Technology Research Association, 2. RITE

When CO_2 is stored in sub-seabed geological formations in Japan, marine monitoring is mandatory to detect CO_2 leakage as soon as possible should it occur. In the Tomakomai CCS Demonstration Project, a threshold line based on a negative correlation between partial pressure of CO_2 (pCO_2) and dissolved Oxygen saturation in seawater is used to detect an anomalously high value of pCO_2, which is suspected to be a sign of CO_2 leakage. Although CO_2 leakage has never occurred in Tomakomai, pCO_2 values obtained in the monitoring have frequently exceeded the threshold line; that is, many false-positives have been produced. It is important to consider what can be causes of the false-positives. To discuss the causes, we analyzed data observed in the marine monitoring of the Tomakomai project, and meteorological data at Tomakomai. It is implied that weather conditions, such as wind speeds and precipitation, were related with false-positives. Also, we found that total alkalinity was remarkably low at a monitoring survey where many false-positives were observed. The low values of total alkalinity make pCO_2 values higher than usual, and consequently they might produce many false-positives. Based on the results, we are going to present how to avoid or reduce false-positives.

Functions of Real-time Tsunami Inundation Forecast System Using S-net Pressure Data

*Wataru Suzuki[1], Naotaka YAMAMOTO CHIKASADA[1], Takayuki Miyoshi[1], Shin Aoi[1]

1. National Research Institute for Earth Science and Disaster Resilience

We have developed real-time tsunami inundation forecast system using S-net ocean bottom pressure data (Aoi et al., 2019, JDR). The forecast methodology of the system is mainly based on the multi-index method (Yamamoto et al., 2016, EPS) coupled with tsunami scenario bank (Chikasada et al., 2019, Technical Note NIED). In addition, the system has many functions to perform appropriate forecast considering a nature of the observed S-net pressure data, additional seismological data, regression targeted for specific region and alerting for tsunami without search for tsunami scenario bank. In this presentation, we introduce the developed forecast system focusing on these various functions.

The system has a redundancy and robustness in processing the observed S-net data by receiving the data from dual receiver with quality check. The pressure data are corrected for offset, band-pass filtered to extract the tsunami components. It was found that high waves due to typhoon or storm cause noises even in the ocean bottom pressure data and scenarios are selected by multi-index method. Therefore, the system does not make forecast information if no stations have larger amplitude than criterion value.

Forecast information, i.e., coastal tsunami heights and inundation depth distribution, is produced from the selected scenarios from the multi-index method by taking the maximum and average value of the selected scenarios. The scenario with the largest variance reduction between the observed and scenario data can be forecast information too. Standard deviation can be used to present the scattering of the forecast. As additional information, the system imposes the consistency with the hypocenter information on the selected scenarios by the multi-index method. This works well for the tsunamis generated at the edge or outside of S-net region. Moreover, most possible tsunami scenario for specific region can be derived from the selected scenarios in comparison with the forecast tsunami inundation depth at representative points based on neural network regression. The system also has functions to alert the tsunami by detecting the large pressure changes as well as using the tsunami warnings issued by the Japan Meteorological Agency. Detailed information based on the tsunami simulation based on 10-m mesh topography model is output for Kujukuri-Sotobo region of Chiba prefecture and rough and limited information is output from Ibaraki prefecture to Pacific coast of Hokkaido.

Improvement of Real-time Tsunami Forecast System for Outer-rise Earthquake

*Naotaka YAMAMOTO CHIKASADA[1], Toshitaka Baba[2]

1. NIED, 2. Tokushima University

The outer-rise earthquakes often induce the behavior of the unusual tsunamis. For example, it induces an abnormally larger tsunami than expected from its seismic ground motion, called tsunami earthquake and/or contains short wavelength components produced by sea floor displacements caused by shallow depth fault slip. Additionally, the depressed wave usually arrives preceding the first elevated wave for the normal fault earthquake tsunamis. National Research Institute for Earth Science and Disaster Resilience (NIED) has developed real-time tsunami inundation forecasting method using real-time ocean bottom pressure data taken by the dense offshore observation network such as the Seafloor observation network for earthquakes and tsunamis (S-net) that has been constructed along the Japan Trench (Chikasada et al., 2019, Technical Report of NIED; Yamamoto et al., 2016, EPS). They calculated synthetic tsunami waveforms at the observation locations by solving nonlinear long-wave equations using a staggered leapfrog finite-difference scheme. A run-up boundary condition was applied to the coastal regions and an open boundary condition was applied to the rims of calculation region. But they did not consider about dispersive wave (Baba et al., 2017, Ocean Modeling) neither the attenuation effect of ocean bottom pressure changes (Chikasada et al., 2018, AGU).
Therefore, we reconsidered the effects of the dispersion term and the attenuation for a few thousands tsunami scenarios stored in the Tsunami Scenario Bank (TSB). As a result, we confirmed that these two effects possibly cause underestimation in real-time tsunami forecast. Therefore, we need to update waveforms calculated and registered for outer-rise earthquake into the TSB with a dispersion term. However, it is quite time-consuming task to solve non-linear long-wave equations with Boussinesq terms. In order to reduce calculation time, the linear long-wave equations with Boussinesq terms could be used to generate offshore synthetic waveforms. We considered the attenuation effect as well.
This work was partially supported by JSPS KAKENHI Grant Number JP15H05718 and JP18K04674.

Maximum tsunami height prediction using Ocean-Bottom Pressure Values based on Gaussian Process Regression

*Kotaro Takahashi[1], Kenjiro Kashiwabara[1], Yasuhiko Igarashi[1,2], Toshitaka Baba[3], Takane Hori[4], Masato Okada[1]

1. Graduate School of Frontier Sciences, The University of Tokyo, 2. Japan Science and Technology Agency PRESTO, 3. Institute of Technology and Science, The University of Tokushima, 4. Research and Development Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology

Tsunami early warning systems using water pressure gauges operate around the world to cope with human damage caused by tsunami waves. The systems use a correlation between observed pressure gauges value around coast and tsunami height at prediction points near shore, based on prior insights such that tsunami height highly depends on the topography (bathymetry) during its propagation.

In predicting the tsunami height, it is important both to avoid underestimation for minimizing the damage and to increase accuracy for minimizing the evacuation cost. Takahashi et al. [2018] proposed a method making use of a database of the tsunami height and the observed pressure-gauge-values. While it is good at avoiding underestimation, it puts the prediction accuracy second; its prediction is likely to be highly overestimated. To improve the accuracy, Igarashi et al. [2016] proposed a method based on Gaussian Process regression, but it does not avoid underestimation. In this work, we extend the method by Igarashi et al. [2016], and proposed a prediction method with less underestimation and higher accuracy. We used pressure gauges data from the Dense Ocean-floor Network System for Earthquakes and Tsunamis (DONET) in the Nankai trough to investigate the prediction accuracy and the possibility of underestimation by our proposed method. Compared to the method by Takahashi et al. [2018], our method dropped the average prediction error from 4.44m to 1.61m, at the cost of an increase in the average underestimation rate of only 3.5%. Likewise, compared to the method by Igarashi et al. [2016],

our method dropped the average underestimation rate from 43.2% to 4.38%, at the cost of an increase in the average prediction error of only 0.84m. These facts prove the effectiveness of our method, which is good at making predictions with both little underestimation and high accuracy.

Improvement for Finite-Difference Formula of Non-Linear Longwave Equations to Express Tsunami Decay

*Masaaki MINAMI[1]

1. Meteorological Research Institute

In the current, we can not correctly express the decay process of the tsunami by numerical calculation. In the meantime, social demands for accurately expressing the tsunami decay are strengthening, for judging the timing of cancellation of the tsunami warning and information on the outlook of the tsunami. Therefore, at the Meteorological Research Institute, we are conducting research to improve the accuracy of the subsequent wave and decay process of the far-field tsunami and modeling of the decay process using observation waveforms (Hayashi et al., 2010, JSCE papers B2 (coastal engineering) etc.). We are conducting large-scale and highly accurate tsunami calculations using supercomputer using nonlinear longwave equations, which is a conventional tsunami numerical calculation method. (Minami et al., 2018, Japan Seismological Society Autumn Meeting etc.) Nevertheless, the decay process of the tsunami was not correctly expressed like the results of various calculations so far.

In this paper, we focused on bottom friction of tsunamis, which is an important factor in decay, and improved the differential formula of nonlinear longwave equations. First, in the friction term in the equation, the position difference of the total water depth (D) for calculating the friction term has been calculated as the arithmetic mean of the two adjacent meshes (central difference). If you use arithmetic averaging, there is a possibility that non-negligible errors may occur compared to when solving continuously. This is because D changes in the friction term on the order of -1/3. Therefore, the positional difference was improved to the one using the average value theorem (fig1). Furthermore, with regard to the time difference, assuming that dt is dt/n within one calculation step dt seconds and assuming that the calculation is repeated n times, it is possible to take the limit at $n \rightarrow \infty$, and the difference expression can be transformed as shown in fig 2.

Using these improved difference formula and appropriate coefficients, we calculated in the case of the 2010 Chile earthquake tsunami (Mw 8.8), and as a result its deay is larger than the conventional formula. In the example of fig3, the total energy amount of the later part, which became larger than the observation amount, decreased by about 4% and approached the observation amount. As a calculation condition of the tsunami, all areas including the entire Pacific Ocean (E100° to W90°) are assumed to be 30 seconds mesh (GEBCO 30 sec-grid), and in the area surrounding Hokkaido, Honshu, Shikoku and Kyushu, nesting is performed with a 10 second mesh, and we calculated for a long time (72 hours) in order to see the decay process. For the calculation we use JAGURS (Baba et al., 2015) , considering the elastic loading of the crust and the density effect of seawater, and using the result of the fault parameter (Fujii & Satake, 2013).

By using this formula, the decay of the tsunami becomes larger than the conventional formula by about 5%, and it is 10% or more in large case when the total depth D is small (generally less than 1 m) such as run-up and exposure. Also, by improving the time difference, it is possible to take longer time steps and it is possible to shorten the calculation time.

Although the decay process of the tsunami was not correctly expressed by the previous numerical calculation, it became possible to express the decay process more correctly by this method. In the future,

©2019. Japan Geoscience Union. All Right Reserved.

we will continue to study this method and apply this method to various cases to improve the accuracy of the tsunami decay process.

Real time tsunami inundation forecast method developed for Central America Region

*Yuichiro Tanioka[1], Ulbert Gleb Grillo[2], Greyving Jose Argrello[2], Amilcar Cabrera[2]

1. Hokkaido University, Institute of Seismology and Volcanology, 2. Nicaraguan Institute of Territorial Studies, Nicaragua

In 1992, the Nicaragua tsunami earthquake generated a large tsunami which caused a significant disaster along the coast. In Central America, it has been an issue to develop a tsunami warning system which can manage a tsunami earthquake such as the 1992 Nicaragua earthquake. Recently, the Intergovernmental Oceanographic Commission of UNESCO (IOC/USESCO) decided to make the Central America Tsunami Advisory Center (CATAC) in Nicaragua. Therefore, Japan International Cooperation Agency (JICA) with Japan Meteorological Agency (JMA) run a technical program to support the establishment of CATAC. In this paper, we develop a tsunami inundation forecast method for CATAC which can manage a tsunami earthquake.

First, we previously developed the method to appropriately estimate the source model (Tanioka et al., 2017). The technique was tested for four large earthquakes, the 1992 Nicaragua tsunami earthquake (Mw7.7), the 2001 El Salvador earthquake (Mw7.7), the 2004 El Astillero earthquake (Mw7.0), and the 2012 El Salvador-Nicaragua earthquake (Mw7.3), which occurred off Central America. At first, fault parameters were estimated from the W-phase inversion. Then the fault length and width were determined from scaling relationships. To estimate a slip amount, we constructed a depth dependent rigidity curve, similar to that suggested by Bilek and Lay (1999). The curve with a central depth estimated by the W-phase inversion was used to calculate the slip amount of the fault model. Using that slip amount, the tsunami numerical simulation with inundations was carried out. The result indicated that the observed tsunami heights, run-up heights, and inundation areas for the 1992 Nicaragua tsunami earthquake were well explained by the computed one. The other tsunamis from the other large earthquakes were also reasonably well explained by the computed ones.

In this paper, we applied the near-field tsunami forecast method (NearTIF) using a data base (Gusman et al., 2014) by computing a tsunami from the appropriate fault model which estimated in the above. First, we built a data-base which contained tsunami waveforms at several reference points for each region and inundation results at 6 regions, Gulf of Fonseca, Corinto, Puerto Sandino, El Transito, Masachapa,El Astillero, along the Pacific coast of the Central America. We put source models of Mw7.0, 7.2, 7.4, 7.6, 7.8, 8.0, 8.2 along the subduction interface. Totally, 135 source models are in the data base. The best tsunami inundation distribution for the forecast will be chosen by comparing the tsunami waveforms at the reference points computed in a real time with the tsunami waveforms at those points in the data base. Nest, the method is applied for the 1992 Nicaragua tsunami earthquake case. The source model for the 1992 Nicaragua earthquake was previously estimated from the W-phase inversion with the scaling relationship. The slip amount is estimated using the depth dependent rigidity curve. The tsunami forecast result shows that the observed tsunami heights, run-up heights, and inundation areas are reasonably well explained by the tsunami forecasted inundation map. The method developed in this paper should be useful for the tsunami early warning system at CATAC.

Near-fault observations of an offshore earthquake by DONET: Comparison of ocean bottom pressure gauges and strong-motion accelerometers

*Ayumu Mizutani[1], Kiyoshi Yomogida[1]

1. Natural History Science, Graduate School of Science, Hokkaido University, Earth and Planetary Dynamics

New ocean-bottom networks for earthquakes and tsunami such as S-net and DONET have been recently deployed in the offshore Japan. One important feature of these networks is that seismometers and ocean bottom pressure (OBP) gauges are installed at the same sites. Tsunamis are designed to be recorded in terms of water pressure changes. During an earthquake, the water pressure near its fault area changes not only by tsunamis (i.e., sea surface heights) but also by water depth change of instruments themselves, vertical accelerations of a seafloor itself (i.e., reaction force from water column), and the seismic waves radiated (including ocean acoustic waves) (e.g. Saito and Tsushima, 2016).

In this study, we analyzed the OBP and strong-motion accelerogram records provided by DONET1 that associated with the 2016 Off-Mie earthquake (Mw 6). First, we compared the pressure records in the forms of acceleration, velocity and displacement recorded in strong-motion accelerograms. Velocity and displacement records were calculated by integrations of accelerometer seismograms. Because a simple integration leads to unreasonable results, we conducted the baseline correction by the method based on Iwan et al. (1985). Second, we estimated tsunami heights at stations near the fault in near real-time basis, using the records of OBPs and accelerograms combined.

We obtained the following results by these comparisons: (1) the pressure change proportional to ocean-bottom velocity especially for each first motion, (2) in contrast, at around 0.1Hz, the pressure proportional to ocean-bottom acceleration at some stations, and (3) during the coseismic period, the effect of displacement not contributing to the pressure change at the same site. (1) and (2) are consistent with the numerical simulations by Saito (2017).

Next, we removed the effect of accelerations using 0.05-0.1Hz band-pass filter from the OBP records that were processed by 0.1Hz low-pass filtering, enabling us to extract tsunami and displacement signals at 10s intervals. The resulted waveforms are matched well with 0.01Hz low-pass filtered OBP records, suggesting that this method would be useful for tsunami early warning with near-fault combined records of OBP and accelerograms.

Many researchers have developed numerical models based on the nonlinear shallow water equations to estimate the propagation and inundation of tsunamis. Several models have been distributed as the software packages including source code, thus tsunami inundation simulation can be performed easily with bathymetric and topographic data available free. However, the tsunami modelling researchers also empirically understand that no tsunami simulation results agree perfectly with that of other research institutes even if the same numerical model is used. The maximum inundation depth, flow velocity and inundated area are different to a certain extent. To clarify the variation in tsunami simulation is very important to establish the standard method that confirm the reliability of tsunami inundation models and it will be useful for the tsunami countermeasure/mitigation planning.

The present study aims to evaluate magnitude of the variation in tsunami inundation simulation quantitatively. We conducted tsunami simulations under the same input data: the initial source model of tsunami, bathymetry, topography and land-use model provided by Cabinet Office, Government of Japan are adopted. A total of eight research institutes participated this project using four kinds of numerical models that are widely employed for the tsunami hazard/risk assessment. Comparison of the time history of water surface elevation and flow velocity at the specific points indicated that a significant difference was confirmed among the model results to the maximum value of physical quantities. The spatial distribution maps of the maximum inundation depth also showed that large variation occurs around the front of tsunami run-up. In order to explain the variation in tsunami inundation model quantitatively, the total flooded volume and the total momentum flux were newly defined. By statistical procedures using these variables, we were able to show the mean value, confidence interval and coefficient of variation of the tsunami inundation models.

Numerical Modeling of Tsunami Inundation in Urban Area using Sub-Grid Scale Drag Force Model

*Nobuki Fukui[1], Nobuhito Mori[2]

1. Graduate School of Engineering, Kyoto University, 2. Disaster Prevention Research Institute, Kyoto University

Numerical simulation of tsunami inundation using high-resolution topography (resolution is less than 1m) needs to consider the effect of structures on wave run-up. However, numerical simulation with medium resolution (resolution over 50m to 100m) is still important for practical use due to computational cost. This study developed Drag Force Model (DFM) and individual Drag Force Model (iDFM) as an urban roughness parameterization to obtain acceptable accuracy in medium resolution tsunami inundation model based on physical modeling. The model treats the effect of structures as grid-averaged drag force and projected area in x and y-direction in Cartesian coordinate and characteristic structure height are used as parameters representing the sub-grid scale structure. Furthermore, iDFM considers the number of structures and structure height in the area of interests individually. The edge detection technology for image processing tool is used to count the number of structures. Moreover, various mesh size 10cm to 40cm (25m to 100m in real scale) are used to check mesh size dependency. The validation DFM and iDFM is conducted using numerical simulation and physical modeling of tsunami inundation targeting available tsunami inundation experiments.

Numerical experiment of tsunami deposits related to fault parameters by sediment transport model

*Ako YAMAMOTO[1], Tomoyuki Takahashi[2], Kenji Harada[3]

1. Forest of Research and Management Organization Forestry and Forest Products Research Institute, 2. Kansai University, 3. Shizuoka University

Large tsunamis cause extensive damage to coastal areas. Underestimation of the tsunami risk can increase the extent of damage and delay reconstruction. To improve tsunami estimation requires review of many records of tsunami cycles and sources (i.e., geologic faults). Sand deposits from tsunamis provide many paleo tsunami records; however, the relationship between tsunami sand deposits and the magnitude of tsunamis is not understood. Takahashi et al. (1999) proposed a sediment transport model for tsunamis. This model was adapted using data from the 1960 Chilean tsunami in Kesennuma Bay, although the amount of sand transportation was underestimated due to the local topography. Takahashi et al. (2011) improved the model based on a hydraulic experiment using three types of sand grains, although verification using other grain sizes and mixed sand compositions has not been conducted. Furthermore, numerical analysis focusing on tsunami sand deposits in inundation areas has fewer verification examples. Yamamoto et al. (2017, 2018) carried out a hydraulic experiment to validate the sediment transport model. This experiment used three types of sand grains, which had sizes different from those used by Takahashi et al. (2011). The model of Takahashi et al. (2011) was confirmed to be very accurate for medium sand. However, the relationship between the tsunami sand deposits and fault parameters has not been verified.

To clarify the relation between tsunami sand deposits and fault parameters, we carried out numerical experiments of sediment transport in a simple topography. The numerical experiments consisted of two steps. The first step investigated the influence of fault conditions on the tsunami waveform. The fault condition was changed according to fault width, length, slip, and position. The waveform observed in this experiment was used as the boundary condition for the second step of the experiment. The second step investigated the effect of the tsunami waveform on the sand deposits in the land area. The topography conditions were changed by changing the slope of the sea area and land area. Furthermore, we investigated the effect of setting a structure in the land area on the sand deposits. Numerical experiments confirmed the points at which the nature of sediment deposits changes according to fault and topography conditions.

Evaluation of potential impact of tsunami-induced sediment transport in Kochi Prefecture during the Nankai Trough megathrust earthquake and tsunami

*Kei Yamashita[1], Daisuke Sugawara[2], Shuji Seto[1], Taro Arikawa[3], Tomoyuki Takahashi[4], Fumihiko Imamura[1]

Introduction

Strong flows due to giant tsunamis may cause large-scale sediment erosion, deposition and resulting morphological changes in coastal areas, in which sometimes alter the nature and size of tsunami hazards (e.g., Sugawara, 2017). The tsunamis flow loaded with a large amount of sediments possesses an increased hydrodynamic force, which causes not only loss of lives and properties but also incidental injuries to human healths, such as “Tsunami lung”. Flush-out of coastal sediments into deeper sea often cause irreversible changes in sandy beaches, on which post-tsunami natural coastal processes may form an altered beach morphology. Sediment deposition on lands and shallow waters hampers not only emergent rescue and support, but also post-disaster recovery and reconstruction. Environmental pollutions due to chemical elements in sludge deposits are additional consequences of the tsunami-induced sediment transport.

In 2012, the Cabinet Office of Japan updated the tsunami risk assessment of the Nankai Trough earthquake and tsunami. However, influences of the sediment transport have not been included quantitatively in the tsunami scenarios. In this study, numerical simulations of tsunami sediment transport caused by the Nankai Trough earthquake have been performed to investigate the potential impacts of sediment erosion, deposition and morphological change in Tosa Bay, Kochi Prefecture, where severest damages are presumed by the Case 4 of the assessment of the Nankai Trough earthquake.

Numerical Calculation Methods

The tsunami sediment transport model (STM) proposed by Takahashi et al. (1999) was used. The STM takes into account exchange of bed- and suspended loads, in which parameters of the transport formula depend on the grain size of the sediment. Computational region covers a wide area of Tosa Bay including Kure Bay in Takaoka-gun to Hane Cape in Muroto City. To assess the uncertainties due to the grain size, three types of median size d_{50} were assumed, i.e., d_{50} = 0.127, 0.267 and 0.394 mm.

Results and Discussion

The numerical simulations demonstrated that in the mouths of class A (Niyodo and Mononobe) and B

©2019. Japan Geoscience Union. All Right Reserved.

(Shinjo, Aki, Ioki and Nahari) rivers, strong flows caused severe erosion greater than 10 m in depth, regardless of the choice of the grain size. A large amount of the sediments were flushed out to the offshore zone deeper than the wave base. In addition, extensive sediment deposition occurred on the lands neighborhood of the class A rivers. For example, deposit thickness near Niyodo River was as large as 1 m. Note that thickness of known paleotsunami deposits in this area is much smaller than the simulations. Further comparison of the field data and modeling results is needed to examine the assumptions of the size of the Nankai Trough earthquake. Based on the findings from the 2011 Tohoku tsunami, averaged deposit thickness is estimated at 4-5 cm. Choice of the grain size caused variations of the averaged deposit thickness ranging from 4.2 to 11.3 cm.

Sediment erosion and deposition were significant around harbors and bays along the coast. Bottom sediments of the mouth and inner part of Susaki Bay were eroded and that the sediments were deposited over a wide area of Susaki City. However, the simulated thickness of the deposit on Ikenouchi area including Tadasu-ike was quite thin compared to the paleotsunami deposits (Okamura and Matsuoka, 2012). Coastal defenses and changes in the land use might have affected to the difference between the deposits. In the mouth of Usa and Urado Bays, the simulations showed that part of the sediments were transported to the land near the source meanwhile most sediments were deposited on the seaward the bay mouth and the head of the bay.

The simulated morphological changes became larger with decreasing grain size. Increase in the maximum inundation heights was 2 and 1 m for d_{50} = 0.127 and 0.394 mm, respectively. In some of the investigated areas (i.e., Geisei-mura), effect of the morphological change to the inundation height was totally different. These results imply importance of sediment transport modeling for regional tsunami hazard assessments.

Conclusions

In Kochi Prefecture, tsunami-induced sediment transport may cause not only large-scale morphological changes of the coasts but also increase in tsunami hazards. Note that the influences of the sediment transport depend significantly on uncertainties in bed materials. Acquisition of detailed sedimentary data will benefit improved assessment of impacts from tsunamis. Further discussions are needed regarding countermeasures to tsunami hazards considering the regional characteristics of tsunami-induced sediment transport.

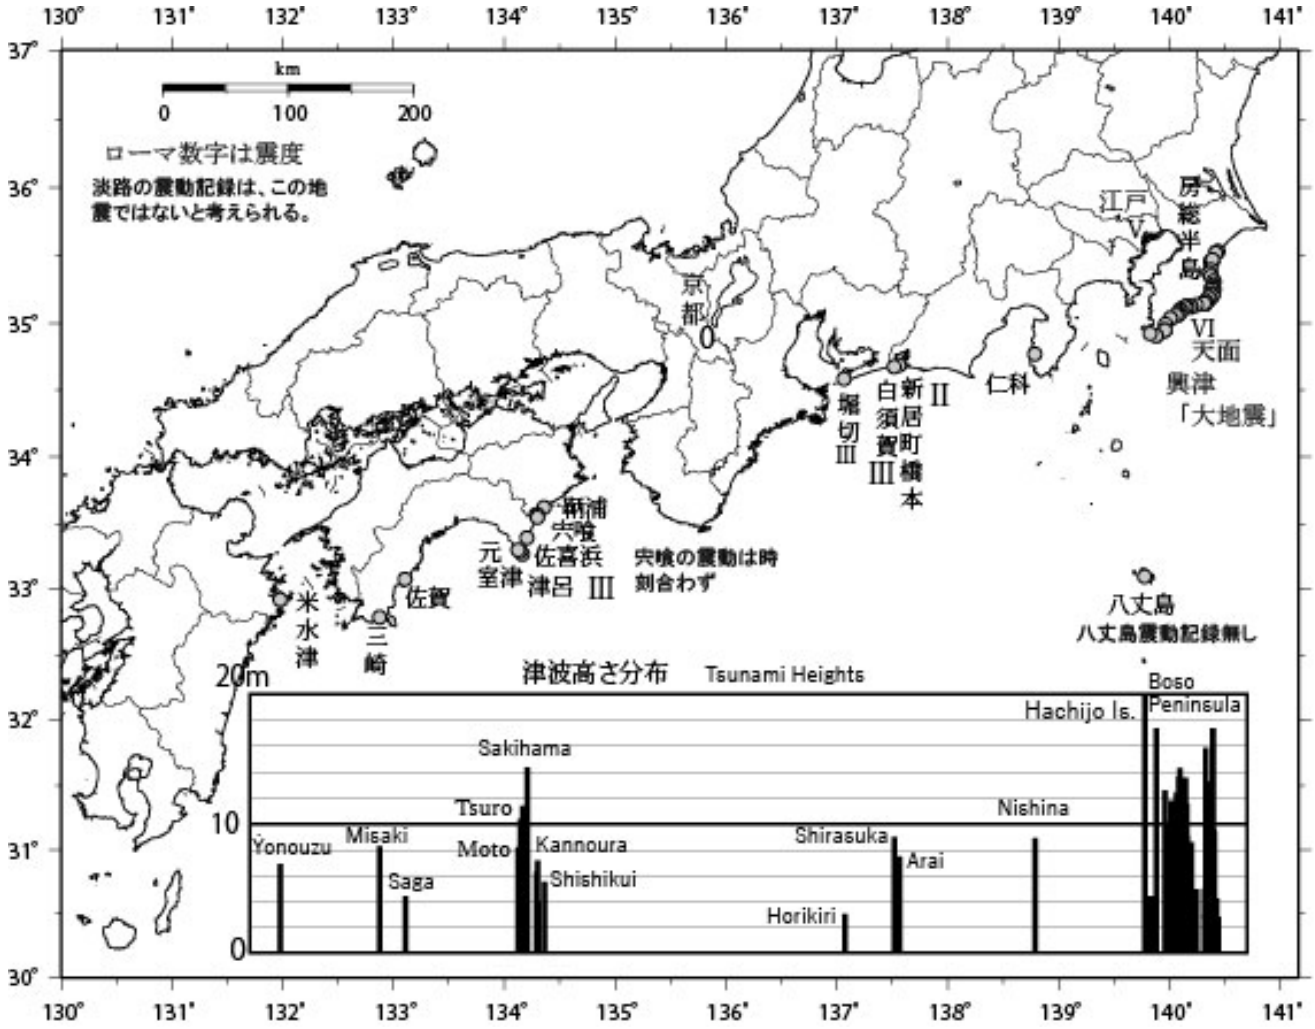
Tsunami damage of the Keicho Earthquake of February 3rd, 1605 on the coasts of Tokai, Shikoku, and Kyushu Districts



*Yoshinobu Tsuji[1], Kentaro Imai[2], Yuuichi Ebina[3], Hiroyuki Iwase[4], Ryoko Oobayashi[2]

1. Shimanto City, 2. JAMSTEC, 3. IRIDeS, 4. Ecoh co. LTD

We conducted field survey of the tsunami damaged coast of the Keicho 9 earthquake of February 3rd, 1605 on the coasts of Tokai, Shikoku And Kyushu and tsunami inundation or run-up heights were measured newly at 17 points by using GPS. Tsunami height distribution along Boso Peninsula had been clarified by Tsuji et al(2018). At Nishina, Nishiizu Town, Shizuoka prefecture, sea water went upstream along Nishina River about 1.4 km from the river mouth and run up height was estimated at 8.9 meters above mean sea level. At Hashimoto in Arai Town, Kosai City, Shizuoka prefecture, 80 houses out of 100 houses were swept away, and tsunami height was 8.2 meters. At Shirasuka, a post town of Tokaido houses were swept away and severel people, horses, and cows were killed, and tsunami height was 9.4 meters. At Horikiri village, Tahara city, near the to of Atsumi Peninsula, Aichi preffecture, all fishing ships were wrecked but no house and human damage took place, and height was estimeted at 3 meters. At Sakihama, Muroto city, Kochi prefecture, sea water rose up to the entrance step stone of the main building of Dainichiji temple, and tsunami height was 14.4 meters. Coastal villages near cape Muroto, about 400 people were killed due to the tsunami. At Saga, Kuroshio Town, documents given by Lord Motochika Chosokabe was lost in Sakamoto's house, where tsunami height was estimated at 6.2 meters. At Misaki, in Tosashimizu city, 153 peoples were killed due to the tsunami, and tsunami height was estimated at 8.1 meters. Tsunami height distribution is illustrated in the figure.
This research was supported by MEXT (“Research project for compound disaster mitigation on the great earthquakes and tsunamis around the Nankai Trough region”).

Re-examination of tsunami heights distribution during the 1854 Ansei Tokai Earthquake

*Kentaro Imai[1], ebina yuichi[2], Yoshinobu Tsuji[3], Hiroyuki Iwase[4], Takane Hori[1], Narumi Takahashi[1,5], Takashi Furumura[6]

1. Japan Agency for Marine-Earth Science and Technology, 2. International Research Institute of Disaster Science, 3. Shimanto City, 4. ECOH CORPORATION, 5. National Research Institute for Earth Science and Disaster Resilience, 6. Earthquake Research Institute The University of Tokyo

The great Nankai Trough earthquake has been accepted for the recurrence on the characteristic earthquake based on the plate tectonic interpretation. On the other hand, Seno (2012) pointed out the possibility that overlapping regions are few and complementary in the seismic zone of the Ansei Tokai Earthquake and the Showa Tonankai Earthquake. It is necessary to similar reinterpretation of the tsunami source. In this research, we reexamined the historical documents related to the Ansei Tokai earthquake Tsunami, along the coast of the Izu Peninsula from the coast of the Kii Peninsula, close to the source area of the Ansei Tokai earthquake. Furthermore, field survey for tsunami trace height based on historical documents conducted to clarify the characteristics of the tsunami height distributions.

We extracted historical materials on the 1854 Ansei Tokai Earthquake published in the Japan Earthquake reference material as “Zotei Dai Nippon Jishin shiryo”, “Shinshu Nihon Jishin Shiryo” and so on. 801 documents stored in these collections were selected and checked for newly found documents that have not been used in previous research. We conducted a field survey on tsunami trace height information obtained through historical document. We reviewed carefully these selected historical documents, and evaluation for tsunami trace height on the field was carried out by GNSS and laser range finder measurement. For the comprehensive tsunami trace height distribution, the data evaluated by previous research [Hatori (1977); Tsuji et al. (1991); Namegaya & Tsuji (2005); Tsuji et al. (2013); Tsuji & Saito (2014); Imai et al. (2017)] were partially used.
There are two peaks of the tsunami height during the tsunami trace height distributions on the Ansei Tokai earthquake tsunami, the one as the tsunami trace height was reached 22 m at Kuzaki the east of the Shima Peninsula. the other one as the tsunami trace height was exceeding 15 m at Iruma the south east of Izu Peninsula. This information are extremely important clues to re-examine for the tsunami source of the Ansei Tokai earthquake. We examine the tsunami source that explains such tsunami trace height distribution in this presentation.

Acknowledgments: This research was supported by MEXT (“Research project for compound disaster mitigation on the great earthquakes and tsunamis around the Nankai Trough region”).

The role of water in the concentration of Cr

*Shoji Arai[1]

1. Department of Earth Sciences, Faculty of Science, Kanazawa University

The role of water in the formation of chromitites, which have been designated as a typical orthomagmatic ores, has been long controversial. Johan et al. (1983, 2017), for example, concluded that chromites are precipitated from water-rich fluids at relatively low temperatures (< 1000 ºC) to form podiform chromitites in the mantle. Those arguments are mainly based on two observations; (1) podiform chromitites and surrounding peridotites have been preferentially hydrated, which may mean the initial water enrichment, and (2) chromite grains contain fluid and hydrous mineral inclusions of apparently primary origin. I criticize the related interpretations based on those observations. The selective hydration in and around chromitite pods is due to the Mg-rich character of olivines, which has been obtained during a subsolidus cooling stage (Arai, 1978), and does not definitely show the involvement of water-rich fluid in chromitite formation. The origin of the chromite-hosted hydrous mineral inclusions has not been left unclear. Many authors a priori interpreted the inclusions as being representative of the trapped melts or fluids that precipitated the host chromites. This is, however, highly questionable. The inclusions are most probably formed during a stage of peridotite-melt reaction within a complicated igneous stage of podiform chromitite generation in the mantle. Hydrothermal fluids can transport Cr and precipitate chromite, but may not form most of the podifrom chromitites.

Mineralogical Features of Silver-Bearing Minerals in Chimney Ore from Myojinsho Caldera, Myojin Knoll and Bayonnaise Knoll Seafloor Hydrothermal Area, Izu-Bonin Arc

Shinji Kawaguchi[1], *Kotaro Yonezu[1], Thomas Tindell[1], Jun-ichiro Ishibashi[2], Tatsuo Nozaki[3], Yoko Ohtomo[4], Koichiro Watanabe[1]

1. Deaprtment of Earth Resources Engineering, Faculty of Engineering, Kyushu University, 2. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 3. Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology, 4. Faculty of Engineering, Hokkaido University

Submarine hydrothermal deposits in western Pacific is characterized as volcanic massive sulfide deposits mainly consisting of Cu-Pb-Zn (± Au ±Ag). Recent explorations have resulted in discoveries of submarine mineral resources in the exclusive economic zones around Japan. The previous study reported chimney ores collected from Izu-Bonin arc are of high grade (Au; 24.1 ppm, Ag; 1275 ppm, Cu: 1.14%, Pb: 5.57%, Zn: 35.03%), (Tanahashi et al, 2004). According to this study, chimney ores were characterized by porous constituents and concentric ring structures, white colored barite layer and sulfide mineral layer mainly composed of sphalerite and galena are recognized from the outer surface to the center part. This concentric ring structures may be attributed to order of precipitations during formation of the chimney ores, however only few studies have discussed mineralization of the chimney along the growth axis (e.g., Watanabe & Hayashi, 2014). Purpose of our research is to clarify mineralogical features of silver minerals in chimney ore by identifying the precipitation conditions of hydrothermal fluids in the Izu-Bonin arc. We studied chimney ores collected during the NT13-09 scientific cruise and NT14-06 scientific cruise.The chimney ores collected from Izu-Bonin arc have quite similar mineralogical features. They have a tubular structure and can be divided into three groups along growth axis from outside to inside of chimney; G1: composed of barite; G2: mainly composed of barite and the principal sulfide minerals of submarine hydrothermal ore deposit (sphalerite, pyrite, chalcopyrite and galena); and G3: composed of main sulfides. According to EPMA analysis, barite is observed in G1 and G2 in addition to pore filling barite in G3. These barite formations are considered to mixing of the hydrothermal fluid with ambient seawater and formation temperature estimated for the initial barite mineralization recognized in G1 and G2 as 190-215℃, and for the second barite mineralization in G3 is as 150-195℃, suggesting temperature decrease of the hydrothermal fluid during the formation of chimney ores (Iizasa, et al. 1997). Based on these results, we propose following formation stages. First, G1 are formed by mixing of the hydrothermal fluid with seawater. Subsequently, porous G2 is formed by a change in the mixing ratio of seawater and hydrothermal fluid. Finally, the hydrothermal contribution becomes greater, so that exclusively sulfide mineral can be precipitated in G3. In addition, as shown in barite observed in G3, after the hydrothermal activity stopped, the second barite is precipitated in the void of the porous chimney ore by mixing ambient seawater and hydrothermal fluid. We noticed that the silver-bearing minerals can be observed in G2 and G3 as tetrahedrite-tennantite series minerals (Ave (wt.%): Ag; 2.9, Cu: 11.1, Zn: 7.0, Pb: 46.6, Sb: 4.0, As: 3.0 and S: 10.9) of 1-20 μm. Silver bearing minerals are associated with sphalerite and galena. According to Ag vs. Sb/(Sb+As) diagram, relatively silver-rich hydrothermal fluids contributed to form the chimney ore in Izu-Bonin arc as compared to that of typical with Kuroko type deposits. Especially from the chimney ore of the Bayonaissea knoll, 1-10 μm of tetrahedrite-tennantite series containing a high content of silver (Ave (wt.%): Ag: 52.9, Cu: 9.6, Zn: 1.6, Pb: 37.5 and S: 13.8) are observed at the rims of galena in the boundary between G1 and G2. Silver mineralization may be explained as follows. Firstly, silver present in galena formed during the principal sulfide mineralization moves by equilibrium equation,

©2019. Japan Geoscience Union. All Right Reserved.

$2Pb^{2+} = Ag^{+} + Sb^{3+}$ (Karup-Moller, 1971 and Foord, 1989) towards the right side by decreasing in temperature. As a result, tetrahedrite-tennantite series minerals are precipitated at G2 and G3. After hydrothermal active vent stopped, further temperature drop was introduced and furutobeite is formed from tetrahedrite-tennantite series minerals.

Organic matters and acid-sulfate alteration in Itomuka Mine, Hokkaido, Japan: implications for the transportation and deposition mechanisms of mercury

*Takuya Echigo[1], Mitsuyoshi Kimata[2], Masahiro Shimizu[2]

1. Graduate School of International Resource Sciences, Akita University, 2. Graduate School of Life and Environmental Sciences, University of Tsukuba

We investigated the ore and hydrothermal alteration minerals and solid organic matters from Itomuka mercury mine which is located in the eastern part of central Hokkaido to examine the transportation and deposition mechanisms of mercury. In addition to the ore minerals, native mercury and cinnabar, powder X-ray diffraction (XRD) analysis showed that the mercury ore consist of quartz, marcasite, alunite, kaolinite and minor amounts of pyrite and smectite. This mineral assemblage suggests that mercury deposition occurred with the advanced argillic alteration under low temperature and low pH condition. Two types of solid organic matter were recognized in quartz vein by yellow-green fluorescence under the ultraviolet radiation: (1) film-shaped organic matter occurring on the surface of quartz vein and (2) globule-shaped organic matter filling pores of quartz vein. Both of these organic matters occur with mercury minerals, cinnabar, native mercury and calomel (Hg_2Cl_2). These organic matters were analyzed with SEM-EDS, micro-X-ray diffraction and micro-FTIR. SEM-EDS analysis showed that film-shaped organic matter is closely associated with mercury and silica minerals though globule-shaped organic matter is not associated with such minerals. Micro-FTIR spectra of both organic matters are similar and suggested that these contain aromatic rings, carboxyl group (-COOH) and adamantine ($C_{16}H_{10}$). Micro-XRD showed that film-shaped organic matter consists quartz, opal- and adamantine crystals and globule-shaped organic matter consists of quartz and amorphous organic matter, respectively. The occurrence of these organic matters suggests that hydrothermal fluid which transported mercury was highly reduced. Because the solubility of Hg in acidic fluid is low, neutral to alkaline fluid seems to have leached mercury from the basement sedimentary rocks of Hidaka formation. The mercury-bearing fluid ascended along the faults in Itomuka formation and oxidized at near the surface. Reduced sulfur (HS^-) in the fluid oxidized into sulfate (SO_4^{2-}) and reduced pH, which resulted in mercury deposition and advanced argillic alteration. Probably, rapid oxidation of ore-forming fluid promoted the precipitation of marcasite, a metastable phase of iron sulfide. The dominance of native mercury over cinnabar indicates that mercury was transported by biphase (liquid+vapor) hydrothermal fluid.

Significances of 12 Ma manganese ores in the Hokuroku district, Akita: unique Mn accumulation and interaction with organic matter during submarine hydrothermal activities

*Yuya Tsukamoto[1], Takeshi Kakegawa[1]

1. Tohoku Univ.

Various Mn ores are found in the Hokuroku district in Akita through the course of the present study. Stratified and veined Mn ores, which lengths are up to 10 cm, are formed during volcanic recession periods (less than 1 Ma) with associated with carbonaceous sediments and local hydrothermal systems. Such short-term precipitation of “pure” Mn ores is unusual, compared to normal Fe-Mn nodules or crusts. In order to understand detailed mechanisms, in particular, role of organic matter, of Mn ore formations, we performed standard mineralogical characterization, magnetic field analyses and oxygen isotope analyses on Mn ores. The first type of Mn ores appear on mudstone and veins in hydrothermally altered hyaloclastite of rhyolite lavas. Detailed geological and geochemical studies revealed that local submarine hydrothermal processes mobilized Mn and Fe in host rocks, Fe-oxides were precipitated first and then discharged Mn were precipitated as oxides (rhodonite and todorokite) on mudstone. $\delta^{18}O_{SMOW}$ value of Mn oxide is + 7.7‰ showing the precipitation temperature less than 112 C. Mn carbonate (rhodochlosite and kutnohorite) also appears in the same region. $\delta^{13}C_{PDB}$values of Mn carbonate were -21‰ (PDB), suggesting interaction with organic matters during intrusive activities of later rhyolite. The second type of Mn ores appear as veins in rhyolitic tuff or stratified lenticular forms with mud/tuffs. Ca. 30 μm colloform structures consisted of organic matter and Mn oxides can be observed. Major Mn mineral in these second type is todorokite. $\delta^{18}O_{SMOW}$value of second types of Mn ores is + 8.5‰ indicating low temperature precipitation of Mn oxides less than 101 C. Magnetic field was detected on Mn oxides in colloform structure by magnetic field microscopy (MFM). Such magnetic fields indicate high cation vacancies and abundance of Mn^{4+}, which are common in biogenic Mn oxides. Formational processes of both Mn ores provide new insight of the unique formational process of Mn ores, especially geological separation from $Fe^{2+}$and interaction with organic matter, in hydrothermal systems at the subseafloor on felsic volcanic setting. Further, this study indicates that low temperature (<100 C) hydrothermal activities can form the Mn ores with high precipitation rates.

Microbial communities around ca. 2.7 Ga submarine hydrothermal fields at the Potterdoal deposit in Abitibi Greenstone Belt, Canada

*Takeru Osato[1], Akizumi Ishida[1], Takeshi Kakegawa[1]

1. Tohoku University

The Archean submarine hydrothermal environment is often considered as a cradle of early life. Large uncertainties still exist as to which microorganisms were active around Archean submarine hydrothermal systems and if hydrothermal communities could be the primary producers for the global biosphere. To approach this problem, we studied ca. 2.7 Ga volcanogenic massive sulfides (VMSs) and associated sedimentary rocks at the Potterdoal deposit in Abitibi Greenstone Belt, Canada. Purposes of the present study are (1) to evaluate which type of microorganisms were active in 2.7 Ga submarine hydrothermal environments, and (2) to find new biosignature in nanoscale analysis of organic matter (OM).
VMS ores were mainly composed of chalcopyrite, sphalerite, pyrrhotite and pyrite, mostly showing layered and sorting textures. They often contained brecciated shale or actinolite or chlorite. Chert and sandstone appeared in the distal area from the VMSs. Most examined VMSs did not have OM, but some samples had up to 0.5 wt.% of carbon concentration. Those OM were found together with actinolite or chlorite or shale fragments trapped in VMSs. Carbon concentration in sedimentary rocks were moderate in general, ranging from 0.0 to 0.9 wt.%C. The thermal alteration temperature was estimated as below 300 ˚C based on the full widths of half maximum of the D1 band in the Raman spectra of kerogen, indicating that less altered features. Overall carbon isotope compositions of kerogen were ranging from -44.6 to -23.6 ‰ (PDB). These values suggest that the presence of contrast microbial ecosystems at this region, utilizing either hydrothermal CH_4 or atmospheric CO_2. Transmitted electron microscope analysis revealed that examined kerogen were mainly composed of immature OM with minor graphene layers. Novel nanostructures of Mo-sulfides stacked with graphene or Fe-sulfides were newly found in immature kerogen structures.These nano-sulfides associated with kerogen may suggest incorporation of biological sulfides in OM during the early diagenesis, possibly giving new evidence of sulfur metabolisms for the early life.

Involvement of difference academic fields in earth sciences including geology, petrology, geochemistry, mineralogy, and microbiology is required to understand the genesis of ore deposits. The field of resource geology is essential not only for efficient exploration and development of ore deposits but also for better understanding and assessment of hazardous elements that may be caused by the resource development. This session widely covers various topics of field investigation and observation, laboratory experiments, theoretical calculation, development of analytical methods and others related to the supracrustal migration and concentration of elements.

In order to explore accessible and profitable natural resources, scientific elucidation of their origin and evolution are an essential issue. The natural resources often have fine-grained textures and minute mineral/fluid inclusions in the host minerals. Therefore, microanalysis is required to clarify their mineralogical and geochemical characteristics in detail. Focused-ion beam (FIB) microfabrication and transmission electron microscopy (TEM) are potentially effective techniques for this purpose. FIB allows to precisely extract portions of interest in sub-micron scale from various types of samples. Using TEM, microtextural, chemical, and crystallographic information can be obtained in nano-scale spatial resolution from ultrathin-film (100–200 nm) samples. With taking these technical advantages, state-of-the-art FIB and TEM at JAMSTEC KOCHI have been applied to a variety of geosciences including clay mineralogy [1], biomineralization [2], mantle rheology [3], and meteoritics [4].

One of uniqueness of the FIB/TEM laboratory at KOCHI is a combined FIB-FESEM instrument equipped with an energy dispersive spectrometer (EDS) and a cryo-holder system [5]. We are currently developing a FIB-fabrication scheme of fluid inclusions in minerals such as olivine and halite, so that those fluids are exposed in frozen state for their in-situ chemical analysis including X-ray elemental mapping using EDS [6]. 3D tomography by micro X-ray CT is effective to visualize distribution of fluid inclusions especially in nontransparent minerals prior to nanofabrication and analysis by the FIB-FESEM system.

The nanoscale occurrence of fluid (as voids) and mineral inclusions can be further characterized by high-resolution TEM. This technique would be useful for mineralogical analysis of fine-grained resource materials such as deep-sea mud containing abundant rare-earth elements [7] and manganese deposits. As a typical example, we have mineralogically characterized several-micron-sized Mn-rich microparticles recently discovered in seafloor sediments, and found vernadite-like mineral therein based on their electron diffraction patterns and elemental mappings [8]. We are further developing the linkage fabrication/analysis scheme to extend toward more comprehensive sample analysis including trace elemental and isotopic analyses using NanoSIMS [9]. These microanalysis techniques would play a key role for our better understanding of environments for the formation of resource materials.

Microscopic study on rare earth elements in ion-adsorption type ore of China

*Hiroki Mukai[1], Yoshiaki Kon[1], Kenzo Sanematsu[1], Yoshio Takahashi[2], Motoo Ito[3]

1. National Institute of Advanced Industrial Science and Technology, 2. Graduate School of Science, the University of Tokyo, 3. Kochi Institute for Core Sample Research JAMSTEC

At present, China constitutes more than 80 % of the rare earth elements (REE) production in the world. Among REE ores, ion-adsorption type ones existing mainly in southern China are a major supply source of heavy REE (HREE) which are especially valuable. The ion-adsorption type ore is formed under weathering of the underlying parent granite rocks. This ore typically contains more than 50 % of ion-exchangeable REE that can be extractable with electrolyte solution such as ammonium sulfate $(NH_4)_2SO_4$ solution. It has been estimated that permanent negative charge on clay minerals, such as kaolinite, leads to surface adsorption of REE in the ore. However, the direct observations or analyses for the individual minerals have been rarely conducted due to the relatively low concentrations of REE (<2000 ppm). In the present study, we analyzed weathered granite collected from an ion-adsorption ore in Dingnan County, Jiangxi Province, China on a submicroscopic scale by using various experimental apparatuses.
XRD measurements indicated that the weathered granite is mainly composed of quartz, K-feldspar and kaolinite. The results of SEM-EDS and LA-ICP-MS measurements showed that “kaolinitic particle” is abundant with REE compared to the other minerals. These results suggest that the kaolinitic particles are major reservoir of REE in the ore. The elemental mapping for a kaolinitic particle by LA-ICP-MS showed that each element is distributed heterogeneously in the particle. The SEM-EDS analyses also suggested that the kaolinitic particle is composed of several minerals. For further micro-analyses, cross sections were processed from the kaolinitic particles by FIB. XAFS study on the cross sections suggested that REE are basically hydrated in the particle. STEM-EDS analyses revealed that the kaolinitic particle contains illite and hematite in addition to kaolinite. Considering general weathering process, it can be assumed that K-feldspar was altered into illite and further into kaolinite during chemical weathering. Elemental mapping with high spatial resolution by NanoSIMS clarified that REE are distributed in kaolinite and illite.

The occurrence of gold in ore is one of the most important information in gold deposit research. This information allows us to optimize beneficiation and smelting processes, as well as providing valuable insights into the mineralization mechanism, which can improve exploration strategies (e.g., [1]).

In hydrothermal gold deposits, gold is not always visible as native gold, electrum, caraverite (AuTe2) or other gold minerals. In many cases, it also exists as submicrometer-size inclusions and solid solution in other minerals, which is so-called “*invisible gold*” [2]. Pyrite is the most ubiquitous and well-known host mineral for this invisible gold, and its trace element geochemistry has been increasingly recognized as a useful tool to understand the mineralization processes (e.g., [3]).

In this study, we report the geochemical features of invisible gold in pyrites collected from the Akeshi and Kasuga deposits. These deposits, located in the southern part of the Kagoshima Prefecture, Japan, are currently under operation, and are classified as high-sulfidation gold deposits. In both Akeshi and Kasuga, gold minerals are only reported from high-grade ores, and other hosts of gold in lower-grade ores remain still uncertain [4]. Pyrite is the most common sulfide mineral in these deposits. Here, we report the results of EPMA (Electron Probe Micro Analyzer) and LA-ICP-MS (Laser Ablation Inductively Coupled Plasma Mass Spectrometry) trace element analyses of pyrite, in order to determine their mineralization processes.

Hydrothermal Mineral Assemblage of the Southwest Prospect, in the Vicinity Sto. Tomas II (Philex) Porphyry Cu-Au Deposit, Baguio District, Philippines

*Avriel Venis Literal Cirineo[1], Akira Imai[2], Ryohei Takahashi[1], Noel C. Oliveros[3], Redempta P. Baluda[3], Victor B. Maglambayan[3], Roy Ronald C. Luis[3], Maria Lourdes M. Faustino[3]

1. Graduate School of International Resource Sciences, Akita University, 2. Faculty of Engineering, Kyushu University, 3. Philex Mining Corporation

Overprinting relationship between intrusive rocks, diatreme-breccias and mineralized porphyry-type veinlets are documented in the Southwest prospect was recently discovered along the contact of the basement Pugo metavolcanics and conglomerates of the Zigzag formation, overlain by dacitic tuff termed as the Keratophyre (KTP). The prospect is located at the southwestern periphery of the Sto. Tomas II orebody, a 60-year old porphyry Cu-Au mine being operated by Philex Mining Corporation (PMC).
At least four intrusive rocks were recognized. In chronological order, they are the: (1) coarse-grained biotite quartz diorite (ODP –Old Diorite Porphyry), (2) fine-grained quartz diorite porphyry (EMD -Early Mineralization Diorite), (3) medium-grained porphyritic hornblende quartz diorite (LD –Late Diorite) and (4) hornblende andesite porphyry (DP –Diorite Porphyry). Meanwhile, at least five breccia facies were identified: (1) Phreatomagmatic Breccia facies 1 or PMBx1, (2) Phreatomagmatic facies 2a or PMBx2a, (3) Phreatomagmatic Breccia facies 2b or PMBx2b, (4) Early Mineralization Diorite Breccia or EMDBx and (5) Diorite Porphyry Breccia or DPBx. The PMBx facies are polymictic breccias with chaotic mixture of clasts set in a matrix composed of rock flour of earlier formed rocks and juvenile tuffaceous matrix. They are sub-vertical pipes that flare upwards and may represent diatreme breccias (Sillitoe, 1985, Baker et al., 1986, Lawless and White, 1990). On the other hand, EMDBx and DPBx are intrusion breccias that were formed during the emplacement of their intrusive equivalents (Sillitoe, 1985). Porphyry-type veinlets are observed overprinting ODP, EMD and PMBx1, while at the same time, quartz vein fragments are included in the latter. These veinlets are also commonly found along the contacts between LD and the PMBx1. PMBx2a and PMBx2b crosscut all the earlier intrusions and breccias. Spatial and temporal associations suggest syn-mineralization timing of the EMD, PMBx1 during porphyry-type quartz veining, while LD and some of the porphyry-type veinlets associated with the LD suggest a late-mineralization timing.
Intense potassic alteration is characterized by secondary biotite-quartz-magnetite-anhydrite-chalcopyrite-bornite. It is exhibited by EMD and andesitic clasts of Pugo Metavolcanics occurring as clasts in the diatreme breccias. It is also well-developed in the EMD at the deeper central portion of the prospect, in the matrix of the adjacent EMDBx and PMBx1. Secondary biotite is present as fine disseminations in the groundmass and as polygrain aggregates completely altering former ferromagnesian minerals, such as hornblende. It is often accompanied with quartz, anhydrite, magnetite and copper iron sulfides. Occasional K-feldspar, chlorite, illite and epidote are present in the assemblage. Associated sheeted quartz and granular quartz veinlets indicated a wide range of liquid-vapor homogenization temperature (T_h(L-V)) from 436˚C to 578˚C and 461˚C to >720˚C, respectively, and salinities from 41 to 43 wt% $NaCl_{equivalent}$ and 37 to 43 wt% $NaCl_{equiv.}$ This alteration is overprinted by illite-chlorite-carbonate-magnetite±K-feldspar alteration with abundant chalcopyrite and bornite. It pervasively overprinted the quartz stockwork zone hosted in the PMBx1 adjacent to the EMD at the central deeper portion of the prospect. Associated banded quartz veinlets indicated Th(L-V) >720˚C and salinities ranging from 55 to 70 wt% $NaCl_{equiv.}$ The shallower portions dominated by the later breccias were altered by chlorite-illite-pyrite±chalcopryite with associated quartz-gypsum cement. Lastly, propylitic

©2019. Japan Geoscience Union. All Right Reserved.

alteration is exhibited by LD. It is characterized by chlorite-epidote-calcite±illite. Associated crystalline quartz-chlorite veinlets indicated lower Th(L-V) 246˚C and lower salinity of 40 wt% $NaCl_{equivalent.}$
K-Ar ages determined on the secondary biotite of the EMD sample that exhibited intense hydrothermal biotitization typical at the potassic core in Southwest and on the hornblende grains of LD that showed no hydrothermal alteration are both 3.5Ma. This indicates that the hydrothermal biotitization prevalent in the potassic alteration in EMD and the emplacement of the LD could have happened in a single magmatic-hydrothermal event. This may also indicate that the timing between the potassic alteration and intrusion are close in Southwest, and also constrained an older age than the mineralization at the Sto. Tomas II orebody (Imai, 2001, Waters et al., 2011).

Characteristics and genesis of weathering REE deposits

*Kenzo Sanematsu[1]

1. Mineral Resource Research Group, Institute for Geo-Resources and Environment, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

The world rare earth deposits can be classified into carbonatite, alkaline-rocks related, placer and ion-adsorption types. Rare earth elements (REE) which are present as trace elements in the mantle and crusts can be geologically condensed by either or both of the formation of alkaline magma and weathering. This talk reviews on the characteristics and genesis of weathering REE deposits consisting of weathered carbonatites, placer and ion-adsorption type deposits.

Weathered carbonatite deposits are characterized by high REE grades. Carbonatites are high in REE (>1%, approximately) and these elements are condensed by dissolution of carbonate minerals during chemical weathering. The dominant REE minerals are primary and secondary phosphate minerals including monazite. The ores are rich in LREE (light REE) and Th and poor in HREE (heavy REE), reflecting compositions of the unweathered carbonatites. REE minerals are generally fine-grained compared to unweathered carbonatites and this may influence the recovery of REE during mineral processing.

Placer deposits are formed by weathering and erosion of igneous and metamorphic rocks and deposition of heavy minerals in alluvium and beach sands. Placer ore minerals are mainly Ti minerals (ilmenite and rutile), zircon and cassiterite. REE-bearing placer deposits contain monazite and lesser amount of xenotime. Although the bulk REE grade is low, the ore consisting of sand and gravels can be mined and heavy minerals are processed easily. This deposit type was the leading world REE producer in the world until 1965. Since monazite is the dominant REE mineral, placer deposits are rich in LREE and Th and poor in HREE. Zircon is the common HREE-bearing mineral in placer deposits, however they are not economically extractable.

Contrasting to the two types of residual deposits mentioned above, ion-adsorption type deposits are characterized by REE adsorbed electrostatically on the surface of clays (not in the crystal structure of minerals) and they are extractable by ion exchange from the REE ores. The ores, called ion-adsorption ores, are formed mainly from granite by chemical weathering. Although these deposits are generally low in REE, they can be rich HREE. Parent granites contain weatherable REE bearing minerals such as fluorocarbonates (e.g., bastnaesite, synchysite) and REE-bearing silicates (e.g., allanite, titanite) and LREE/HREE ratios of these minerals constrain those of ion-adsorption ores. In contrast, parent granite rich in phosphate minerals (e.g., monazite and apatite) tends to form weathered granites with low ion-exchangeable REE because most REE are incorporated in phosphate minerals which resistant to chemical weathering. Kaolinite, halloysite, illite and vermiculite appear to have ion-exchangeable REE. Since the ores and extracted solutions are generally low in Th, ion-adsorption type deposits are poor in Th compared with the other REE deposits.

Objective evaluationof precursory seismic quiescence and activation phenomenon in wide area

*Sumio Yoshikawa[1]

1. Meteorological Research Institute

The 1995 Kobe earthquake of M7.3 is an earthquake known to have observed abnormal changes in seismic activity accompanied by various changes such as crustal deformation, groundwater and electromagnetism before the main shock. Especially Mogi (1995) pointed out the seismicity gap and the quiescent phenomenon of the seismic activity with a long-term and wide-area perspective. Yoshida (1995) pointed out the wide range of the preceding phenomena of seismic activity and showed that the area wider than the epicenter area is involved in the earthquake occurrence process. Therefore, if any prediction method is supposed, it is a problem how much accuracy it is possible to know based on such a preceding phenomenon in wide area.

eMAP is a tool to evaluate the appearance probability of seismic activity by Poisson's probability (Yoshikawa et al., 2017). In this method a region is set for each individual epicenter and the degree of abnormality is displayed in all regions. In order to consider the above problem, we examined the possibility of diagnosis of wide area seismic activity by this method.

By analysis of the quiescence and activation phenomenon in wide area during the Kobe earthquake, mainly in the Kinki, Chugoku and Shikoku districts, the following features were found. At that time, in the JMA seismic catalog before the unification, the magnitude threshold is considered to be around M 2.0 since 1988. The spatial distribution of the seismic activity has changed in a relatively short time scale and a stable pattern is not seen until 5 to 6 years before the main shock, but about 2 years before, a quiet phenomenon is confirmed in the area with the range of 50 km in the eastern part of Hyogo Prefecture. About a year before to the main shock, we can see activation in the epicenter area and a wide area surrounding it. This seems to be due to the small foreshock activity occurred along various active faults and geological lineaments. Based on this seismic sequence, it is possible to suppose a forecasting tactics as follows. First of all, by grasping the location and extent of the quiescence phenomenon, we assume the location and the scale of the main shock (Yoshikawa, 2015), and then estimate the urgency of earthquake occurrence by detecting the simultaneity of temporal changes.

Long-term Probability of a Great Earthquake along the Kurile Trench, Hokkaido Japan (2)

*Masajiro Imoto[1], Morilkawa Nobuyuki[1], Fujiwara Hiroyuki[1]

1. National Research Institute for Earth Science and Disaster Resilience

Great earthquakes (M8 and larger) repeatedly occur along the Kurile Trench off Hokkaido. A much larger one in the 17-th century (17-th type earthquake) is indicated by studies of tsunami deposits, which is considered as representing the simultaneous of Tokachi-oki and Nemuro-oki earthquakes. The Earthquake Research Committee, the Government of Japan has reported the long-term probability of the 17-th type earthquake. We discuss the uncertainty of the long-term probability of the 17-th type earthquake, applying the method by Parsons (2008) to compare the likelihood of both the Brownian Passage Time distribution and the Poisson distribution for recurrent earthquakes. We adopted the seven probable ranges of origin times observed at Mochirippu-toh, and the five ranges at Kiritappu Marsh (Table 7 in the ERC report). Considering two probable ranges of 68% and 95% listed, two different functions of a origin time are adopted as weights; a modified Gaussian function and a step-function. The latter function is fixed so as to reserve the 68% and 95% probabilities in their ranges.
The likelihood ratios of the BPT model to the Poisson one are 0.70-0.79 for the Mochirippu-toh and 1.9-2.0 for the Kiritappu Marsh. The mean of the 17-th type earthquake probability in the next 30 years over the model parameters is about 11% for the Mochirippu-toh and around 21% for the Kiritappu Marsh. Only slight differences of both likelihood ratios and the thirty year probabilities among the three weight functions are observed.

Parallel and Focused Increase Trends in Time Series (M-T Diagram) of Earthquake Occurrences

*Satoshi Hashimoto[1]

1. none

Usually time sequence of earthquakes is not used as continuous variations because of special property of its occurrences. A few cases such as aftershocks and repeated earthquakes are attributed to continuous series. However, in a time series downloaded from HP of earthquake catalog continuous increase variations are seen clearly in almost all M-T diagrams, here M and T mean magnitude and occurrence time of earthquakes, respectively.

For example, since 2000 a time series of earthquake is shown under the conditions that M > 5.5, D (depth) < 50km, and main 4 islands of Japan with sea areas. In this series clear increase trend consisted from 13 earthquakes (M > 6) can be recognized on a time period from 2002 to 2005. Note that 3 points deviated largely from the straight line are excluded. Surprisingly the straight line connects roughly to the M9 of 2011/3/11 Tohoku-oki Earthquake. If we focus our attention to the increase trend, several lines with similar slope can be seen in other time durations since 2000. These lines are parallel with each other and interrupted at some value of M.

One more important character is seen in the M-T diagram since 2000. Before 2011/3/11 extrapolated more lines gather to the value M9 of Tohoku-oki Earthquake in detailed observations. These are called focused lines. Focused lines are coexisted with the parallel series. Both series are exhibited in whole time span of about 100 years of the catalog. The excluded points described above are probably included by other parallel or focused lines. In short, almost all earthquakes are included in many increase trends of earthquake time sequences.

Little work has be done to the regularity shown above. If several focused time series are found for a few and several years at present, extrapolation of the series will cross in near future. Just the crossing point is the predicted point.

In order to obtain further information about two kinds of the time series, several blocks of Japanese islands are analyzed together with sea areas. From the results two kinds of the time series can be seen in the all blocks. In a small region, increase trend of M~7 does not appear, but in a case of M~6, focused trends are also seen. This fact means that possibility of the prediction is successfully performed to M~6.

Appearance of two kinds of time series is not understood at present. Statistical rule of earthquake occurrences called G-R (Gutenberg-Richter) law is well known. This is one of the power laws, in which number of very large earthquakes are very small, and number of small earthquakes are order of magnitude greater than that of large earthquakes. Comparison of this law with the present results can give us important suggestion. This law does not include the factor of time. Present results shows linear increase trends are very simple but real time series are very complex. Time plays main role in the time series. G-R law is obtained from just after many earthquake occurrences. Present results do not show the individual earthquakes, but show continuous processes in earthquake preparation time span.

At the first stage of this study, present trends are presumably attributed to the constant rate of strain

©2019. Japan Geoscience Union. All Right Reserved.

energy accumulation. However, this idea does not interpret the both parallel and focused trend in the time series. Namely mechanism that long time of several years are spent for accumulating the energy is not adequate in the present results. Perhaps critical state of the crust on the earth did exist hundreds of millions of years ago. At present the state can occur the earthquake both at all time and all places, crust give rise to the earthquake occurrences depending on the time durations. Trial of the prediction is now under planning, but origin of the mechanism is an important problem to be solved.

Revisiting a simple method for short-term earthquake probabilities derived from past Seismicity

*Mamoru Kato[1]

1. Graduate School of Human and Environmental Studies Kyoto University

We revisit the method of Kato (2016, doi:10.4294/zisin.68.163) to estimate the probability that random earthquake predictions would hit using the seismicity data after 2011. When the seismicity rate is high, a random earthquake prediction without scientific evidence often becomes successful. Accidental, occasional hits will not guarantee that such methods of earthquake prediction are worthy of trust, and we should have a measure to judge whether the method is reliable. Kato (2016) proposed a method to roughly compute the probability that a random earthquake prediction accidentally hits. In this method, assuming that the rate of background seismicity is nearly constant in any period. This presentation is a follow-up to this study, and we reevaluate the method of Kato using the other seismicity data in Japan. We also revisit two probabilities of Utsu (1977) and argue how to make apparently successful earthquake predictions

Recent anomalous groundwater temperature and water level changes at the frontier land zone of Nanki region for impending great earthquakes at the Nankai trough

*Tameshige Tsukuda[1]

1. none

Earthquakes are generated by the anisotropic principal stress regime in the rock medium. In the preparing process of a large earthquake, the medium would be deformed generating regions of contraction and dilatation around the nucleus of the shearing stresses. According to a hydraulic model, pore fluid flow is driven upward to the ground surface through crack systems serving as flowing pipes by high pressure pumps at a deep spot. The change in the quantity of the upwelling hot water from deep underground causes a change of groundwater temperature(Tsukuda et al., 2005).
We have 16 groundwater observation stations for temperature, and 3 stations for water level in the Tokai and Nanki regions, central and southwest Japan, respectively, where are close to the source regions of the great Nakai-trough earthquakes. This paper reports the seismological meaning of the data from Nanki region.
At stations HA and WA in Shionomisaki, Nanki region, Wakayama Prefecture, the long-term trend of the water level is rising, corresponding to the ground subsidence found by levelling and GNSS data (Kobayashi, 2013). The trend of temperature is similarly rising, suggesting contraction of the rock medium under Shionomisaki, the southernmost end of Honshu. At KZ(Kozagawa)about 15km northeast of HA or WA in the Nanki region, the temperature is monotonously falling since the observation started in 2002. However, the decreasing temperature changed to severely increase in the middle of 2015, and changed to decrease again in 2017.
As mentioned above, the deformations of the rock medium are accelerated under the regions close to the source regions of the great erthquakes at the Nankai trough. For prediction studies for the impending great erthquakes, we should start to conduct detailed and multidisciplinary observations.

Keywords: dilatation, contraction , groundwater temperature, water level, precursor, earthquake prediction

What happen on the East Japan Megaquake; answer to sufferers

*Nobuaki Niitsuma[1]

1. Institute of Geosciences,Shizuoka University

Significant change on stress field was appeared on Northeast Japan. The difference on stress field can be identified by Euler rotation of principal stress axes (Niitsuma, JpGU2015, s-ss27), and the stress fields rotated toward trench side in southeastern part of Northeast Japan but not in northwestern, comparing to stress field of Megaquake. The foci of Megaquake was located on the boundary of the rotation, which indicate the rotation was caused by Megaquake.

Hida area in the central Japan sits on the southwest extinction of the rotation boundary. Hida area had earthquakes from 6 February 2011, 10 days before foreshocks of Megaquake. The activity was complementary with the foreshocks, and the polarities of the stress field (Niitsuma, JpGU2017, sss05-P01) were normal, except the last of 6th March with reversed polarity, comparing with stress field of Megaquake. The maximum foreshock happened 3 days and mainshock of Megaquake 4 days later the polarity reversal, which means Hida area was a part of the constitution to block subduction of Pacific Plate along Japan Trench. The southwestern extinction of Hida area consistent of continental crust, connecting to Korean Peninsula, and the strain for Megaquake had been accumulated in the longest continental crust in Japan and Pacific Plate.

The activity of earthquakes can be converted to Plate relative motion, using area of earthquake fault S from the magnitude M based on log S =1.2M −9.9 (Matsuda,1975). The total area of earthquake faults in North East Japan from 1923/9/2 (just after Kanto Earthquake) to 2011/3/10 (just before East Japan Megaquake) is stepwise increasing on Benioff Chart and reaches to area of M9.0 as same for East Japan Megaquake. The area of relative Plate motion along the Japan Trench for the time interval is 9% less than the earthquake faults, which means the strain for East Japan Megaquake could not be accumulated after Kanto Earthquake, but before.

The area of earthquake faults in North East Japan reached to area for M9.0 before Kanto Earthquake 1923 from 1793, for which area of relative Plate motion was 1.34 of M9.0 and could accumulate strain of 0.34 for M9.0. The Plate motion is not enough for the strain of M9.0 which should be accumulated before 1793.

Because records on historical earthquakes in Northeast Japan are poor comparing with Southwest Japan, the ratio 1.65 on areas of historical earthquake faults in Northeast to Southwest Japan from 1793 to 1923 for calculation on corrected area of earthquake faults in Northeast Japan before 1793.

The corrected area of earthquake faults in Northeast Japan is 0.73 of M9.0 from 1611 to 1793, whose area of Plate motion is 2.06 in which 1.33 could be accumulated enough for the Megaquake. The history of strain accumulation indicates that the Megaquake strain could be kept after filled up with spending for usual earthquake.

Before Megaquake, the focal distribution around non seismic Megaquake foci indicates that rupture was reaching to Megaquake foci. The difference in magnitude of CMT to initial moment in CMT solutions for Hida-side were small than 0.4, which means the main moments were smaller than one forth of estimated

©2019. Japan Geoscience Union. All Right Reserved.

moment from initial moment. Such magnitude differences were identified on the foreshock of Kumamoto Earthquake in April 2016.

[S-SS14] Fault Rheology and Earthquake Physics

convener:Keishi Okazaki(Japan Agency for Marine-Earth Science and Technology), Hideki Mukoyoshi(Department of Geoscience Interdisciplinary Graduate School of Science and Engineering, Shimane University), Hiroyuki Noda(Kyoto University, Disaster Prevention Research Institute), Keisuke Yoshida(Tohoku University), Chairperson:Hideki Mukoyoshi, Shunya Kaneki(Osaka University)

The goal of this session is to integrate theoretical, experimental, observational, and numerical perspectives from various fields such as seismology, geodesy, geology, mineralogy, and so on, to define what is known about earthquake source processes and the physical and chemical elementary processes of faulting. This session welcomes studies that address such issues as pre-, co-, and post-seismic processes, the rheology of seismogenic faults and fault rocks, laboratory experiments on elementary processes, numerical models based on frictional laws, and estimates of the stress field in the seismogenic zones. We also welcome studies on fault-zone drilling projects and in situ stress measurements.

Effect of slickenside on the crustal strength

*Jun-ichi Ando[1], Takayoshi Nagaoka[1], Naotaka Tomioka[2], Hiroyuki Kagi[3], Kaushik Das[1]

1. Department of Earth and Planetary Systems Science, Hiroshima University, 2. Kochi Institute for core sample research, Japan Agency for Marine-Earth Science and Technology, 3. Geochemical Research Center, Graduate School of Science, University of Tokyo

Slickenside is a glossy and smoothly surface developed on the fault slip plane. Although the slickenside is a common and well-known microstructure, its microstructural characterization and effect on the fault behaviour have not fully studied so far. To understand these points, we characterized the microstructures of natural samples and conducted the frictional experiments. The recovery samples from the experiments were also characterized.

Samples and experiment: The natural samples we characterized were slickensides found on the following rocks collected from several localities. 4-Cherts, 3-Limestones, 1-Amphibolite, 1-Serpentinite, 1-Chromitite, 1-Sandstone, 2-Mudstones, 1-Coaly mudstone and 1-Tuff breccia. The frictional experiments were conducted using limestone and gabbro blocks, and calcite powder with 45 to 75 μm in grain size, with a biaxial friction apparatus. The experimental conditions were 3 - 80 MPa of normal stress, 0.1 m/s and 30 μm/s of slip velocity. The characterization methods of samples were optical microscopy, SEM, TEM, AFM and XANES measurements.
Results and conclusion: The present characterization of natural samples demonstrates that the slickenside is composed of nano-size grains, whose aspect ratio (h/d) of height (h) and diameter (d) is constant at about 0.02 –0.05 for each sample. These nano-size grains can be identified as same minerals, not amorphous, composed of the parent rocks with some minor exceptions. This fact indicates that the nano-size grains were created during fault slip only by grinding of parent rocks without any reaction including the heating-induced reaction. Therefore, our first conclusion is that the slickenside is a product of aseismic faulting. The slickensides were created by all frictional experiments. The characteristics of these slickensides are same as those of natural samples described above. The interesting results are that the aspect ratio (h/d) of nano-size grains is constant for each experiment and tends to decrease with increasing normal stress from ca. 0.23 to ca. 0.07. The h/d values of nano-size grains composed of natural samples are much smaller than those of the recovered samples, which suggests that the studied natural slickensides were created by faulting at the higher normal stress conditions than at least 80 MPa, and preserved during exhumation from original depth to earth’ s surface. This consideration indicates that the fault having slickenside exists at depth corresponding to at least 80 MPa normal stress, ca. 3 km and more. The experimental results using limestone block having pre-existing mirror polished slip plane show that the static and dynamic friction coefficients are very low, ca. 0.3 and 0.2, respectively. In general, it is believed that the frictional sliding on pre-existing fault governs the crustal strength. Therefore, our second conclusion is that the slip behaviour of fault having slickenside might governs the crustal strength. However, the experiments using gabbro block did not show the low static and dynamic friction coefficients. Hence the further detail experiments using simulated slickenside are needed to understand the crustal strength.

Dehydroxylation kinetics of clay minerals and its application to friction heating along an imbricate thrust in an accretionary prism

*Hirokazu Masumoto[1], Jun Kameda[1]

1. Faculty of Science, Hokkaido University

Dehydroxylation of clay minerals within fault gouges is significant for assessing transient thermogenesis due to high-velocity, frictional slip along fault zones. The clay minerals kaolinite and chlorite are common in fault zones hosted in sedimentary rocks at subduction margins. To better understand the dehydroxylation processes of these clay minerals, high-temperature X-ray diffraction (XRD) analyses were carried out by using a 1:1 mixture of kaolinite and chlorite standard samples. We evaluated the kinetic parameters of each dehydroxylation reaction by thermogravimetric analysis Thermal models of frictional heating employing this calibration show that the frictional heating can explain the reported clay mineralogy in a fossil imbricate thrust from a shallow part in an ancient accretionary prism (Shirako Fault, Japan). This result supports the previous assertion, and the observed temperature anomaly appears to demonstrate the frictional heating caused by coseismic slip on this fault.

Origin of frictional melt in the Jurassic accretionary complex of the Mino Belt on the basis of trace element and isotope analysis

*Chizuru Ozawa[1], Tsuyoshi Ishikawa[2], Kohtaro Ujiie[1]

1. University of Tsukuba, 2. JAMSTEC

Pseudotachylytes (solidified frictional melts) in exhumed accretionary complexes have great significance for understanding the dynamics of earthquake faulting in subduction zones. However, they are rarely preserved in a recognizable form mainly due to subsequent hydrothermal alteration. Recently, a pseudotachylyte was found in the Jurassic accretionary complex of the Mino Belt, central Japan. The pseudotachylyte is ~2 mm-thick and separates gray chert above from cataclasite below. Although the pseudotachylyte has been hydrothermally altered, its microstructures are characterized by presence of fault and injection veins, intensely cracked gray chert fragments incorporated from wall rocks, and locally embayed and rounded wall rocks, suggesting thermal cracking and thermal erosion associated with increased heating. Here, we analyzed major and trace elements and Sr and Pb isotopes of the milligram-level samples taken by micro-milling technique along the structures of the pseudotachylyte, cataclasite and gray chert, as well as the black chert and black carbonaceous mudstone near the pseudotachylyte. The pseudochylyte exhibits remarkably high trace element concentrations compared to those of gray chert. The trace element composition of the pseudotachylyte requires the involvement of black carbonaceous mudstone as well as gray chert, suggesting that the frictional melt originated from the mixture of gray chert and black carbonaceous mudstone. Based on major and trace element chemistry, the mixing ratio is estimated to be ~50–60% of gray chert and ~40–50% of black carbonaceous mudstone, and the ratio is consistent with the Sr and Pb isotope compositions. Despite the hydrothermally alteration, the chemistry of the pseudotachylyte well preserves melt-derived characteristics, thus provides useful information for understanding the frictional melting on faults and its source materials.

Geochemical constraint on the origin of albite-bearing black fault rocks in the Kodiak accretionary complex

*Tsuyoshi Ishikawa[1], Asuka Yamaguchi[2]

1. Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2. AORI, The University of Tokyo

The Pasagshak Point thrust in the Kodiak accretionary complex is considered to represent the paleo-plate-boundary décollement at seismogenic depths. The fault rocks in this thrust consist of cataclasites and ultrafine-grained black fault rocks (BFRs), and the latter makes up the principal shear zones (Rowe et al., 2005; Meneghini et al., 2010). The BFRs contain crystalline microlayers characterized by the presence of fine-grained albitic plagioclase (Meneghini et al., 2010). Previously Yamaguchi et al. (2014) showed that the trace element characteristics of BFRs are consistent with the occurrence of fluid-rock interactions at >350 deg. C. Here we present further trace element and isotope analyses on the same samples, and re-examine the data in detail. Plagioclase abundances (albite + anorthite) calculated from major element compositions are distinctly higher in BFRs than in host rocks and cataclasites. Distinctly high Sr concentrations and low 87Sr/86Sr ratios observed in BFRs are well correlated with the plagioclase abundances. This indicates that the petrogenesis of BFRs requires additions of Na and Sr derived from external sources, possibly migrating saline fluids. The 87Sr/86Sr ratio estimated for end-component fluid is as low as 0.705, strongly suggesting the involvement of fluids from basaltic source. Li isotope ratios of BFRs are also consistent with equilibration with basalt-derived fluids. Thus, it is likely that saline fluids largely derived from basaltic oceanic crust of the lower plate migrated through the plate boundary décollement, and frictional heating combined with comminution induced high-temperature fluid-rock interactions at >350 deg. C to produce the unique geochemical characteristics observed for BFRs.

Importance of initial maturity and reaction kinetics on maturation of carbonaceous material and its implications for thermal maturity as a proxy for temperature in estimation of coseismic slip parameters

*Shunya Kaneki[1], Ichiba Tatsuya[1], Shuhei Yamashita[1], Tetsuro Hirono[1]

1. Graduate School of Science, Osaka University

Most of total seismic energy during earthquake slip is considered to convert into frictional heat, which activates many physicochemical reactions in faults. Various thermal indicators for detecting frictional heat recorded in fault rocks have been suggested, such as formation of pseudotachylyte and thermal transformation of fault-forming minerals. Among these reactions, thermal maturation of carbonaceous materials (CM) has been received a considerable attention, because CM changes its maturity in response to ambient temperature even with short-term heating duration.

On the basis of these backgrounds, CM maturity has been applied to estimate maximum temperature and coseismic slip parameters experienced by various faults during earthquakes (e.g., Hirono et al., 2015; Kaneki et a., 2016). These studies, however, may contain several concerns when evaluating amount of frictional heat from CM maturity: (1) mechanochemical effect, (2) kinetic effect of heating rate, (3) effect of initial maturity, and (4) cumulative effect of repeated earthquakes. Recently, Kaneki et al. (2018) and Kaneki and Hirono (2018) experimentally investigated the impacts of (1) and (2), and suggested that kinetic effects of both shear-induced mechanochemistry and heating rate can strongly dominate maturation process of CM, indicating that such kinetic effects should be considered to establish CM as a more rigorous fault geo-thermometer. However, the impacts of (3) and (4) on CM maturation process still remain unknown, leading to uncertainties in estimation of maximum temperatures from CM maturity.

In this study, we aim to understand the impact of (3) on CM maturation process and its implication for CM-based fault geo-thermometer. We adopted four grades of CM for our starting materials (lignite, bituminous coal, anthracite, and graphite), and performed low-velocity friction experiments with slip rate of 1 mm $s^{-1}$and normal stresses of 1 and 3 MPa under dry condition, to reproduce coseismic shear damage on CM samples without frictional heating. We then conducted heating experiments on both intact and sheared CM samples with targeted temperatures of 100, 200, 300, ..., 1300 ˚C (100 ˚C interval) and heating rates of approximately 1 and several hundreds of ˚C s^{-1}. We finally carried out infrared and Raman spectroscopies to evaluate maturity of both intact CM samples and products after friction and heating experiments. The results show that mechanochemical effect can enhance maturation process of lignite by ~100 ˚C whereas no significant difference between maturities of intact and sheared CM samples are present in bituminous coal, anthracite, and graphite. All CM samples, except for graphite that showed no significant change in maturity with heating, show higher reaction temperature by ~500 ˚C in heating experiments with higher heating rate. These results indicate that kinetic effects of both mechanochemistry and heating rate affect CM maturation process and the effects depends on initial maturity of CM. Thus, by taking consideration into initial maturity and kinetic effects, thermal maturation of CM could be an universal proxy for temperature in estimation of coseismic slip parameters.

Experimental investigation of cumulative effect on thermal maturation of carbonaceous material as a proxy for earthquake slip

*Tetsuro Hirono[1], Yuhtaro Shimamura[1], Shunya Kaneki[2]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University, 2. Disaster Prevention Research Institute, Kyoto University

Estimation of the maximum temperature recorded in fault rocks gives us important information about earthquake enegetics and fault slip behavior, because the frictional heat is directly related to dynamic parameters and to fault-weakening mechanisms. The thermal maturity of carbonaceous material (CM) has received considerable attention as a new temperature proxy because the organochemical characteristics of CM change irreversibly with increasing temperature. Various approaches by using infrared and Raman spectroscopies, elemental composition analyzer, biomarker method, and vitrinite reflectance measurement have been performed. However, for more accurate estimation of frictional heat, not only shear-enhanced mechanochemical effects but also chemical kinetics should be considered. In particular, cumulative effect by repeated earthquake events, related to the kinetics of the maturation, has not well understood. Here we demonstrated repeated heating events on bituminous coal and anthracite by using a tube furnace. We heated the samples 1, 10, and 100 times under conditions of 100, 300, 500, 700, 900, 1100, and 1300 degree C and 40-s heating duration, and conducted infrared and Raman spectroscopic analyses on the samples after heating. The disappearance of aliphatic C-H at 500 degree C were observed on all samples, and the intensity ratio of D and G bands on the Raman spectra of all samples increased beyond 700 degree C. Thus, we could conclude no significant cumulative effect on the thermal maturation of CM under rapid heating, indicating that the detected temperature on a fault corresponds to the largest earthquake slip event.

Fault rheology at the depth limits of the seismogenic zone

*Berend Antonie Verberne[1]

1. Geological Survey of Japan, National Institute of Industrial Science and Technology

The limits of the seismogenic zone demarcate changes in fault behaviour with increasing depth in Earth’ s crust, from aseismic, velocity (*v*-)strengthening to seismogenic, *v*-weakening, and vice versa. Significantly, the *v*-dependence of fault strength is a material property of the sliding medium present in the core of fault, or the fault gouge. I conducted shear tests using simulated fault gouge composed of calcite ($CaCO_3$) at an effective normal stress of 50 MPa, at temperatures of 20 to 600ºC, employing sliding velocities (*v*) of 0.03 to 300 μm/s –sufficient to span the brittle-plastic transition in this material. Mechanical results showed (unstable) *v*-weakening behaviour from ~80-100ºC to ~550ºC, but stable *v*-strengthening for <80-100ºC and >550ºC. All gouges sheared at temperatures <=550˚C showed localization into nanocrystalline principal slip zones, while samples sheared at >550˚C were characterized by distributed deformation. Using the post-test micro- and nanostructures observed in calcite gouge as a basis, plus a previously established microphysical model, I argue that transitions in fault stability are caused by changes in the (nano)granular flow processes accommodating shear. Specifically, the rate of intergranular compaction by Arrhenius-type processes such as diffusion or crystal plasticity, is key to thermally-activated transitions in the velocity dependence of gouge-filled faults. At the low-temperature transition from *v*-strengthening to *v*-weakening, at shallow crustal levels representing the upper-limit of the seismogenic zone, diffusion creep (e.g. pressure solution) may be dramatically accelerated due to the nanogranular nature of the fault rock that forms. At higher temperatures, towards the base of the seismogenic zone, a transition occurs from nanogranular flow in localized faults to distributed, fully creep-controlled flow in ductile shear zones.

Fault models revisited based on friction to flow law

*Toshihiko Shimamoto[1]

1. State Key Laboratory of Earthquake Dynamics, Institute of Geology, China Earthquake Administration

Friction to flow law (Shimamoto and Noda, 2014, JGR) can describe a transition from friction to flow using only friction and flow parameters, and shear zone width *w*. Friction and flow laws are described in terms of velocity and displacement, and shear strain rate and shear strain, respectively, and *w* is needed to relate velocity and shear strain rate to merge the two laws. The friction to flow law is a mixing law connecting friction and flow laws smoothly, and no other parameters are required probably because no new deformation mechanisms operate in the intermediate regime. In JpGU last year, Shimamoto and Noda argued (i) that the velocity dependency of shear resistance is by far the most heterogeneous in the intermediate regime between friction and flow, and (ii) that frictional patches can be surrounded by viscous matrix in the middle part of lithosphere because temperature for the onset of flow depends on rock types. This presentation will discuss (1) how fault models change in view of the friction to flow law, (2) how to construct realistic mechanical models of faults and plate boundaries that are usable in modelling earthquake generation, and (3) how to reproduce friction to flow transition for important rocks in laboratory.

Shimamoto and Noda (cited above) already discussed a revised fault model using results from earthquake modelling based on friction to flow law. A new problem addressed here is a question which of power law (dislocation creep) and grain-size sensitive flow law (diffusion creep or superplasticity) should be used as a flow law to describe fault properties. The latter law has often be favoured because the cores of deep shear zones are often composed of very fine-grained ultramylonites, grain size being on the order of microns or even smaller. Both flow laws are determined for calcite and plagioclase (Heard and Raleigh, 1972, GSA Bull.; Schmit et al., 1977, Tectonophysics; Rybacki and Dresen, 2000, JGR). Thus, strength profiles were constructed with the friction to flow law, assuming $w = 0.1 \sim 10$ m and velocity = 10 mm/yr. Results clearly show that diffusion creep occurs at lower stresses for both minerals (although this is not the case in laboratory experiments). Power-law creep is expected in the middle and lower parts of lithospheres, whereas diffusion creep is expected to be dominant in fault and plate-boundary zones. Thus, frictional patches can be surrounded by linear or nearly linear viscous flow matrix at some depths, and this can be quite important in analysing low-frequency earthquakes and slow slips.

Traditional fault models, started from Sibson (1977, J. Geol. Soc. London), have proposed how materials controlling friction and flow properties, types of fault rocks reflecting deformation mechanisms, and fault geometry such as fault and shear zone widths changes with increasing depth. Such models are bases for constructing realistic mechanical models for faults and plate boundaries. However, the models alone are not usable in modelling earthquakes and plate-boundary behaviours. Friction to flow law captures essential changes in fault properties with depth in a very simplified manner. Both transient and steady-state properties are included and the law can be used in earthquake modelling. However, the law for single material can never describe complex and variable properties of faults and plate boundaries. I want to discuss what has to be done to connect fault and earthquake studies, as much as possible in my presentation. Here I point out the importance of three problems; (I) to check if the friction to flow laws holds for important rocks or not in laboratory experiments, (II) to determine flow laws for important rocks constituting fault and plate-boundary zones, and (III) to determine transient flow properties in flow laws (see Noda and Shimamoto, 2010, GRL). I will give apparatus capabilities required for (I). Unfortunately,

Timing of Earthquakes on Intraplate Active Faults Subjected to Stress Perturbation by Megathrust Earthquakes: Insights from Earthquake Sequence Simulation

*Hiroyuki Noda[1]

1. Kyoto University, Disaster Prevention Research Institute

Estimation of likelyhood of occurrence of intraplate large earthquakes is crutially important because of expected large amplitude of ground motion in nearby cities and short distance between source and human society which makes earthquake early warning difficult. Currently issued National Seismic Hazard Maps for Japan [2018, the Headquarter for Earthquake Research Promotion] adopts assumptions of Poisson process or Brownian passage time distribution depending on available information for each active fault. They yield rather wide distribution of temporal probability density for a timescale of the reccurence interval or the estimation error of history of events. The timelscale is typicaly much longer than recurrence intervals of megathrust earthquakes T_{cyc} which causes semi-periodic stress perturbation to intraplate faults. In the present study, effects of the semi-periodic stress perturbation to an intraplate active fault having a ductile shear zone beneath the seismogenic part [e.g., Shimamoto and Noda, 2014] are investigated by means of dynamic earthquake sequence simulation using a spectral boundary integral method [e.g., Lapusta et al., 2000].

Utsu [1974] pointed out that historical earthquakes in Southwest Japan are concentrated in -50 and +10 years from Nankai trough megathrust earthquakes. Such active periods of intraplate earthquakes may be due to semi-periodic stress perturbation by the megathrust earthquakes [e.g., Hori and Oike, 1996; Shikakura et al., 2014]. An important question is how its duration is scaled for different tectonic settings. T_{cyc} of megathrust earthquakes in Japan trench subduction zone is 500-800 years [e.g., Sawai et al., 2015] and much longer than in Nanka trough. Parameter studies on T_{cyc} and amplitude of the stress perturbation have been conducted to elucidate what controls the timing of intraplate earthquakes.

A 2D numerical simulation of a strike-slip fault [e.g., Lapusta et al., 2000] with ductile shear zone was considered as a model for an intraplate fault, accounting for a friction-to-flow fault constitutive law [Shimamoto and Noda, 2014] composed of the aging law and a quartzite flow law [Hirth et al., 2001], and effective normal stress distribution with maximum value of 50 MPa. The model was drived by far-field shear stress which was perturbed as a sawtooth wave function of variable amplitude about 1 MPa and T_{cyc} from 100 to 1000 years. If the perturbation was perfectly periodic, the system synchronized with the perturbation and the intraplate earthquakes ocurr at a specific phase in the cycle of megathrust earthquakes. If the interval was randomized by Gaussian distribution of 10% standard deviation, then the timing of the intraplate earthquakes distributed more widely, and concentrate in the latter half of the cycle, consistently with the notion of the active period. The shape of the distribution can be explained by a seismicity model based on ΔCFF [e.g., Shikakura et al., 2014], not by a rate-and-state spring-slider model [Dieterich, 1994; Ader et al., 2014]. The result of the parameter study suggests that not only the history of the activity of the fault, but also stress change on it due to recurring megathrust earthquakes or other events may be useful in constrainig the likelihood of intraplate earthquakes.

Physics of earthquake triggering: effect of stress perturbation to slip acceleration

*Takahiro Hatano[1]

1. Earthquake Research Institute, University of Tokyo

Recent observation studies have revealed that the occurrence of tremors is sensitive to faint stress changes such as ocean tides. This might not be surprising in light of the low stress drop caused by tremors. Interestingly, however, ordinary earthquakes too may be sensitive to weak stress perturbations, although it is not so common as for tremors. Dynamic triggering should be the most prominent illustration of such sensitivity, but the occurrence of ordinary earthquakes could be also correlated to ocean tides, snowfalls, and rainfalls.

To understand such sensitivities to stress perturbation in a unified point of view, here we analyze the rupture nucleation process on a fault subject to weak periodic stress modulation. Assuming the rate- and state-dependent friction law with one state variable, we calculate the threshold amplitude above which the rupture initiation exhibits correlation with the perturbation phase. It is found that the crack-like nucleation is more sensitive to the perturbations than the patch-like nucleation. The estimated threshold amplitude for the crack-like nucleation is significantly lower than the tidal stress change. Time-to-failure for the both nucleation types in the presence of perturbation is estimated, and it is not significantly affected by the stress perturbation. We also discuss the optimum frequency at which the correlation is enhanced.

Foreshock activities controlled by slip rate on a 4-meter-long laboratory fault

*Futoshi Yamashita[1], Eiichi Fukuyama[1], Shiqing Xu[1]

1. National Research Institute for Earth Science and Disaster Resilience

We report foreshock activities associated with evolving local slow slip events preceding the main rupture on a laboratory fault. To investigate the preparation process of laboratory earthquake with enough spatial resolution, we used a large-scale friction apparatus newly developed and installed at National Research Institute for Earth Science and Disaster Resilience (NIED) as shown in Figure 1. We used two rectangular metagabbro blocks as experimental specimens, whose nominal contacting area was 4.0 m long and 0.1 m wide. Height of each specimen was 0.2 m. Normal load was applied by eight flat jacks on the top surface of the upper specimen, and the associated pressures were kept at around 6 MPa during the experiments. After applying normal load, we applied shear load to the side surface of the lower specimen by manually pumping up a hydraulic jack, which was fixed at the western end of the apparatus. To monitor local phenomena on the fault, we installed 16 AE sensors, 40 triaxial rosette strain gauges, and 10 eddy current displacement sensors along the fault. We conducted experiments with relatively high shear loading rate (67-185 kPa/s) and low shear loading rate (2-7 kPa/s). In each experiment, displacement data showed that both the eastern and western edges of the fault kept slipping during the shear loading, though the slip rate was very low (< ~20 μm/s). It is consistent with FEM calculation that fault should start to slip at both edges in this configuration. This steady slip was significant during the experiments with low loading rate, in both quantity and area. However, such steady slip did not immediately trigger seismic events. Most of seismic events occurred just before the main rupture, and therefore should better be termed foreshocks. To understand what controls the occurrence of foreshocks, we first investigated the amount of stable slow slip accumulated after the previous main rupture. We found that foreshocks were not activated at around both fault edges even after the accumulated slip attained around 10 μm there (Figure 2a). On the other hand, foreshocks occurred around the central locked area with only a small amount of slip. We next compared the spatiotemporal distribution of foreshocks with that of slip rate. Displacement and strain data indicated that precursory slow slip began at the central locked area and then propagated outward over the fault area preceding the main rupture. We found that this slow slip had caused high slip rate (several hundreds of μm/s), which coincided with the occurrence of foreshocks (Figure 2b). These observations suggest that the key factor controlling the occurrence of foreshocks in this experiment is not the amount of accumulated slip but that of slip rate. The mechanism may be associated with the unstable fault slip triggered by fast loading in the laboratory (McLaskey and Yamashita, 2017, JGR; Xu et al., 2018, Tectonophysics), and the seismicity episodically activated in nature such as emergence of repeating earthquakes due to increased loading rate by afterslip of the 2011 *M*9.0 Tohoku-oki earthquake (Hatakeyama et al., 2017, JGR).

Supersonic propagation of slow slip rupture during rock friction experiments

*Eiichi Fukuyama[1], Futoshi Yamashita[1], Shiqing Xu[1]

1. National Research Institute for Earth Science and Disaster Resilience

Rupture propagation speed on the fault has been considered to be slower than elastic wave velocities of the material. Exceptions were when extremely high energy is imposed, much higher than the fracture energy needed for the rupture to advance. The rupture propagating faster than the elastic velocities is called supersonic rupture. We observed such supersonic rupture propagation of slow slip events during large scale rock on rock friction experiments on a 1.5×0.1 m^2 fault using Indian metagabbro rock specimens. Such slow slip events were accompanied by low frequency vibrations whose onsets were synchronized with those of slow slip events; they also propagated faster than the elastic wave velocities of the rock. Since typical precursory slow slip and coseismic slip events have been observed on the same fault in a sequence of the friction experiment, the slow slip events with supersonic rupture might share the same friction environment as that for the typical preslip-mainshock type events. We interpret this phenomenon as an occurrence of non-linear deformation of a very thin layer on the fault surface. For linear deformation case, the limitation of propagation velocity comes from the elastic property of rock specimens, but non-linear deformation can propagate independently of the material elastic constants but the propagation velocity tend to be proportional to the strain rate. In addition, because there are several similarities between the present observation and the slow slip events observed in the subduction zone worldwide, it may provide a clue to understand these phenomena.

[S-SS14] Fault Rheology and Earthquake Physics

convener:Keishi Okazaki(Japan Agency for Marine-Earth Science and Technology), Hideki Mukoyoshi(Department of Geoscience Interdisciplinary Graduate School of Science and Engineering, Shimane University), Hiroyuki Noda(Kyoto University, Disaster Prevention Research Institute), Keisuke Yoshida(Tohoku University), Chairperson:Hiroyuki Noda(DPRI, Kyoto University), Keisuke Yoshida(東北大学大学院理学研究科 地球物理学専攻)

The goal of this session is to integrate theoretical, experimental, observational, and numerical perspectives from various fields such as seismology, geodesy, geology, mineralogy, and so on, to define what is known about earthquake source processes and the physical and chemical elementary processes of faulting. This session welcomes studies that address such issues as pre-, co-, and post-seismic processes, the rheology of seismogenic faults and fault rocks, laboratory experiments on elementary processes, numerical models based on frictional laws, and estimates of the stress field in the seismogenic zones. We also welcome studies on fault-zone drilling projects and in situ stress measurements.

The powerful M 7.2 earthquake that shock the Sulawesi island of Indonesia on September 28, 2018, was a seismic standout for many reasons, not the least of which is that it triggers tsunami and landslides and causes major life and economic loss in the city of Palu. In this study, integrated geophysical observations of the 2018 Mw 7.5 Palu, Indonesia earthquake, provide robust evidence of an early and persistent supershear rupture speed. Slowness-enhanced back-projection (SEBP) of teleseismic data provides a sharp image of the rupture process, consistently across multiple arrays. The inferred rupture path agrees with the surface rupture trace inferred from the net surface displacement field derived by sub-pixel InSAR image correlation. The SEBP results indicate a sustained rupture velocity of 4.1 km/s from the rupture initiation to the end, despite large fault bends. The persistent supershear speed is further validated by evidence of far-field Rayleigh Mach waves in regional seismograms. Supershear earthquakes with rupture velocity exceeding shear-wave speeds, previously observed in laboratory experiments and large strike-slip events, often have an initial sub-shear stage before they transition to supershear. The rupture speed of the 2018 Palu earthquake is supershear from very early on. The short or absent supershear transition distance can be caused by high initial shear stress or short critical slip-weakening distance, and promoted by fault roughness near the hypocenter. Steady rupture propagation at a supershear speed considered to be unstable, lower than the Eshelby speed, could result from the presence of a damaged fault zone.

The role of curvature in earthquake mechanics

*Pierre Romanet[1], Daisuke Sato[2], Ryosuke Ando[1]

1. Earth and Planetary Science Department, University of Tokyo, 2. Disaster Prevention Research Institute, Kyoto University

In recent years, many studies have tried to catch the influence of geometry in earthquake mechanics. In this paper, we suggest a new interpretation of the effect of geometry on the stress on a fault, as a direct effect of local curvature and torsion of line field of slip along the surface of the fault. Within this framework, it is possible to unify the understanding of bends, kinks and roughness, as an effect of local parameters along the fault. Starting from the representation theorem, that links the displacement in a medium to the slip distribution on his boundary, and assuming homogeneous infinite medium, we first derive a new regularized boundary element method. Using this equation, we were able to separate the influence of geometry, express by curvature and torsion of the fault surface geometry and the slip direction, from the effect of the gradient of slip. This allows us to shed a new light on the mechanical effects of geometrical complexities on fault surface. We used that new discovery to solve a paradox between smooth and abrupt kink [Tada and Fukuyama 1996] as well as re-interpret the effect of roughness on the fault: It can be shown that the effect of drag stress [Fang and Dunham 2013] along the fault it actually exactly equal to the effect of curvature along the fault.

Heterogeneous source modelling by the fully dynamic simulations of earthquake cycles on a strike-slip fault and scaling relations.

*Percy Galvez[1,5], Anatoly Petukhin[2], Paul Somerville[3], Ken Miyakoshi[2], Kojiro Irikura[4]

Numerical modeling is a necessary tool for the assessment of variability strong ground motions in potential devastating large earthquakes. In a simulation-based seismic hazard analysis, it is critical to be able to generate a large number of physically self-consistent source models whose rupture process captures the main physics of earthquake rupture and is consistent with the spatio-temporal heterogeneity of past earthquakes. An inherent difficulty in such efforts is that, from a mechanical point of view, stress and strength heterogeneities cannot be prescribed arbitrarily as was done in earlier work. Their interdependence must be consistent with a mechanical model of deformation and stress evolution over the longer time scale of the earthquake cycle.

In this work, a set of spontaneous source models have been generated in a wide magnitude range (*Mw* 5.5-7.5) by using multicycle simulations under the rate-and-state friction law with the goal of studying the characteristics of source scaling relations and strong ground motions. To get realistic irregular seismic sequence, several realizations of 2D correlated heterogeneous random distributions of characteristic weakening distance "*Dc*" in rate and state friction are tested. A mesh grid size of 125 meters has been used to resolve properly the nucleation and cohesive zone of the seismic events. The fault is 128 km in length and 30km in width, the seismogenic width is 18km. The quasi-dynamic solver QDYN (Luo, et al., 2017) has been used to nucleate the seismic events and SPECFEM3D (Galvez et al, 2014; 2016) to resolve the rupture process. Other important parameters are the normal stress, which controls the stress drop and rupture velocity during an earthquake, and the maximum value of *Dc* distribution, that controls rupture velocity but not stress drop. Following these ideas, we perform dynamic rupture modeling to take into account the free surface effects and perform a parametrization study; parameters of our final friction model are shown in Fig.1.

In order to validate source models we compare the source scaling relations vs. seismic moment *Mo* for the modeled rupture area *S*(*Mo*), average slip of the ruptures *Dave*(*Mo*) and the slip asperity area *Sa*(*Mo*), with similar scaling relations from the source inversions. Fig. 2 shows result for *S*(*Mo*). The seismogenic zone width plays a fundamental role in the *S* vs *Mo* scaling. In fact, Luo et al. (2017) reported that events which break the whole seismogenic width and reach the free surface are exposed to an attraction effect from the free surface. This attraction effect may explain the transition regime from Stage 1 (self-similar rupture, $Mw < 6.5$) to Stage 2 ($6.5 < Mw < 7.4$). Ground motions have been also computed from our models. Their peak ground velocities (*PGV*) agree well with the GMPE values.

Acknowledgements. This study is based on the 2018 research project 'Examination for uncertainty of strong ground motion prediction for inland crustal earthquakes' by the Secretariat of Nuclear Regulation Authority (NRA), Japan. The Super Computer Shaheen II at KAUST University has been used to run the models presented in this study.

Strain energy released by an earthquake: Contributions of random slip fluctuations

*Tatsuhiko Saito[1], Akemi Noda[1]

1. National Research Institute for Earth Science and Disaster Resilience

Strain energy in the lithosphere is the source of earthquake generation. For example, the shear strain energy change caused by the interplate coupling along the Nankai Trough, Japan affects the seismicity in the inland area (Saito et al. 2018 JGR). The aftershocks of the 2016 Kumamoto earthquakes were activated by the shear strain energy brought by the mainshocks (Noda et al. 2018 ACES; Tanaka et al. 2018 JpGU). The strain energy change caused by an earthquake is one of the most fundamental quantity for earthquake mechanics. When the stress change occurs uniformly on the earthquake fault (constant stress drop), a simple theoretical equation gives the relation between the seismic moment, initial stress, stress drop, and the strain energy liberated by the earthquake (e.g., Aki and Richards 2002). This relation leads that the strain energy released by an earthquake is proportional to the seismic moment. However, for actual earthquakes, the stress change on the fault is considerably heterogeneous.

The present study theoretically investigates the relation between the strain energy released by an earthquake and the seismic moment when the stress change is not uniform on the fault plane due to heterogeneous slip distribution. We assume that the initial stress is homogeneous in space and suppose that the heterogeneous slip distribution is given by the sum of the reference slip distribution causing the constant stress drop and the randomly fluctuating slip distribution. We adopt a stochastic approach using an ensemble of the slip fluctuations characterized by the power spectral density functions such as Gaussian and von Karman type function. The derived theoretical relation gives a scaling law of the strain energy with the power spectral density function of the slip fluctuation. This deduces the following results. (1) When an earthquake contains randomly fluctuating slip distribution, the liberated strain energy is smaller than that of the constant stress-drop earthquake. (2) This indicates that a representative value of stress drop becomes large due to the randomly fluctuating slip distribution in the view point of the energy partition. This study refers to this stress drop as effective stress drop. This was also reported by some studies such as Noda et al (2003 GJI) and Hirano and Yagi (2017 GJI). This study derived a theoretical equation of the effective stress drop with the power spectral density function of the random slip fluctuation. (3) When the stress change is not constant on the fault, the strain energy is not proportional to the seismic moment unless the correlation distance of the slip fluctuation is proportional to cube root of the seismic moment. (4) The energy balance gives a value of the initial stress that is required for the earthquake generation. In order to generate an earthquake, the initial stress needs to be larger than the sum of the half of the effective stress drop and the apparent stress (the apparent stress is given by rigidity, radiation energy, and seismic moment (Wyss and Brune 1968,1971)).

The change in the elastic strain energy due to the 1992 Landers earthquake and triggering mechanisms of aftershock activity

*Toshiko Terakawa[1], Mitsuhiro Matsu'ura[2], Akemi Noda[3]

1. Graduate School of Environmental Studies, Nagoya University, 2. Institute of Statistical Mathematics, 3. National Research Institute for Earth Science and Disaster Resilience

Earthquakes are physical processes to release elastic strain energy stored in the Earth’s crust by shear faulting. This quantity is essentially important for understanding earthquake generation. However, we have little knowledge on the quantity, because it is difficult to measure stress in-situ. Recently, Terakawa and Hauksson (2018) developed a method to model and estimate the 3-D absolute stress field from earthquake focal mechanism data, using the reference pore pressure as a single parameter (the reference pore pressure). In this study, we directly investigated changes in elastic strain energy, based on 3-D abosolute stress fields modeled by Terakawa and Hauksson (2018). Then, we tried to propose a new criterion to understand aftershock activity following large earthquakes instead of the change in Coulomb Failure Function (CFF), based on elastic strain energy.

First, we investigated partitioning of changes in shear and volumetric strain energies due to the 1992 Landers earthquake (M_W 7.3). Changes in volumetric strain energy did not depend on the reference pore pressure, or the level of deviatoric stress field. On the other hand, those in shear strain energy was closely related to the parameter. More shear strain energy were released when the background deviatoric stress magnitudes were higher. The elastic strain energy released by the mainshock is consumed as radiated, fracture and thermal energies. The amount of change (decrease) in the elastic stain energy must be at leaset larger than radiatied energy, which can be estimated (e.g., Kostrov, 1974; Ide, 2002). Therefore, the change in shear strain energy plays a crucial role to constrain the the most plausible reference pore pressure and eventually the level of the (absolute) deviatoric stress field.

When a stress field is compressed due to the mainshock, frictional strength as well as volumetric strain energy in the region will increase after the mainshock. This means that an increase in elastic strain energy do not necessarily mean activation of seismicity. The shear and volumetric strain energy are closely related to the average shear and normal stresses acting on faults randomly and isotropically distributed in the crust (e.g., Saito et al., 2018; Matsu’ura et al., under review). Increases in shear and volumetric strain energies have positive and negative effects on triggering aftershocks following the mainshock. In order to understand aftershock activity, we need to correctly consider both effects of the two kinds of strain energies into account. As the elastic strain energy is scalar quantity, we do not have to set any receiver faults, unlike using the change in CFF. In the source region of the Big Bear earthquake (M_W 6.5), which is the largest aftershock following the Landers mainshock, the shear strain energy increased, but the volumetric strain energy decreased. Both changes would have promoted this event. In the region just south of the hypocenter of the mainshock, the total effect from the two kinds of strain energies suggest that seismicity would have become inactive, contrary to the actual activation. Focal mechanism solutions of some of these events were normal faulting with NW-SE tension. We can understand that these events would have reactivated by decrease in fault strength under the stress field characterized by strike-slip faulting with NE-SW compression and NW-SE tension. This suggest that many aftershocks in the region may have been triggered by overpressurized fluids.

Toward understanding generation mechanism of crustal earthquakes based on accumulation/release of elastic strain energy

*Akemi Noda[1]

1. National Research Institute for Earth Science and Disaster Resilience

Although the physical process of interplate earthquakes has been modeled from the viewpoint of accumulation and release of shear stress on plate boundaries, it is difficult to apply the framework directly to cycles of crustal (inland) earthquakes. It is necessary to assume a fault plane to obtain shear stress in a stress field, but the faults in the crust are not a continuous and unique plane of weakness like plate boundaries. Furthermore, there are many unknown faults covered by sedimentary layers.

The shear strain energy is a scalar quantity appropriate for evaluating the potential of earthquake occurrence in the case that the fault plane cannot be specified. The scalar quantity corresponds to the average value of the shear stress acting on randomly distributed cracks in the crust (Saito et al., 2018). In other words, an increase and decrease in the shear strain energy correspond to the accumulation and release of crustal stress, respectively. In addition, since the work done for shear faulting is related to the release of elastic strain energy in the surrounding region (Aki & Richards, 1980; Matsu'ura et al., 2019), the strain energy can be thought of as an essential physical quantity for earthquake generation. Evaluating the accumulate and release of the shear strain energy in the crust, therefore, would help to understand the generation mechanism of crustal earthquakes.

To evaluate the shear strain energy changes, we must have not only stress changes but also background stress fields. However, it is difficult to know the absolute value of the background stress. Under the assumption that the absolute level of the background stress is much greater than the stress changes, Saito et al. (2018) derived an expression of shear strain energy changes normalized by the differential stress of the background stress using the spatial pattern of background stress orientation and the stress changes. Then, they calculated the normalized shear strain energy changes in the inland seismogenic layer caused by interplate coupling along the Nankai Trough, and found the correlation between the shear strain energy changes and seismicity in the southwestern Japan.

In order to apply this framework to tectonic zones in the crust, Noda et al. (2018 AGU) developed a method to evaluate the shear strain energy changes using elastic/inelastic strain analysis method (Noda & Matsu'ura, 2010). Firstly, we inverted the 3-D moment tensor density distribution in the crust as the source of crustal deformation from GNSS displacement data. The 3-D elastic/inelastic strain distribution in the crust was obtained from the estimated moment tensor density distribution. The stress changes were calculated by multiplying the elastic strain distribution by assumed elastic constants. Secondly, given a background stress field, the 3-D shear strain energy changes in the crust was evaluated from the calculated stress changes.
This method was applied to coseismic and preseismic GNSS data associated with the 2016 Kumamoto earthquake. For the background stress, we used the 3-D tectonic stress field estimated by CMT data inversion (Terakawa & Matsu'ura, 2010). The coseismic shear strain energy changes were estimated from the coseismic GNSS displacement data and showed its correlation with the spatial pattern of aftershock activity. Next, we evaluated preseismic changes in shear strain energy from GNSS displacement rate data (2005~2011), and found an increase (accumulation) in a part of the Futagawa fault, which is one of the main faults coseismically slipped during the earthquake, and a large decrease (release) in the

©2019. Japan Geoscience Union. All Right Reserved.

northeastern end of the fault, where the coseismic slip terminated. The shear strain energy change was caused by a large inelastic deformation (brittle fracture/plastic deformation) in the shallow crust along the Aso-Kuju volcanoes.

Paleoseismological survey on the Shibetsu fault zone in the eastern part of Hokkaido, Japan

*Takashi Azuma[1], Daisuke Hirouchi[2], Koji Okumura[3], Kaoru Taniguchi[4], Masashi Omata[4], Yorihide Kohriya[4]

1. National Institute of Advanced Industrial Science and Technology, 2. Shinshu University, 3. Hiroshima University, 4. Pasco CORPORATION

We conducted a paleoseimological survey on the Shibetsu fault zone in the eastern part of Hokkaido in 2018.
This fault zone has a length more than 52 km but no data was obtained about slip-rate and history of fault activeity in previous study (Hokkaido, 2004 and 2005). On a detailed topographic map with an air-borne LiDAR data, we found a new fault scarp with height of 2-5 m on fan produced the lastglacial age at Kotanuka site, and excurvated a trench (25 m in length, 8 m in width, 4 m in depth) and 4 drilling surveys (5 m in depth). We observed a high-angle fault cutting a tephra layer (Ma-l: ca.12,000 yrBP) and black soil with 40 cm on the trench wall. Based on drilling survey, the fan gravel layers, which covered with sandy sediment containing humic silt with 14C ages of 22,140-21,690 cal.BC and 20,587-20,343 cal.BC, is offset ca.3 m in vertical. We discuss the fault event and slip-rate of this fault with careful, because there are deformation of strata not only faulting but also periglacial process in the trench walls.

Deformation of marine terrace surfaces associated with active Rokkasho fault in southern Shimokita peninsula, northern Japan

*Mitsuhisa Watanabe[1]

1. Faculty of Sociology, Toyo University

The marine terrace surfaces formed in MIS 5e and MIS 5c have successively deformed, resulting in a 1 km wide flexural scarp tilting to the east. These surfaces dipping to the same direction converged upon in the scarp. The flexure is consistent with the prevailing Neogene structure. Some bedding reverse faults are observed, which indicates that the structure is an active one. The marine terrace surfaces and the Tertiary system have been folded convincingly owing to the activity of west-dipping blind active thrust (the active Rokkasho fault), merging into the extensive submarine fault along shelf edge in the north.

Keywords: marine terrace, flexural scarp, bedding reverse fault, active fault

Vertical crustal movement during the past 600 years in the Kikai Island, deduced from the height distribution and ages of coral microatolls

*Masanobu Shishikura[1], Hideaki Maemoku[2], Tomoo Echigo[3], Yuichi Namegaya[1], Tatsuya Ishiyama[4], Ryo Kinjo[2], Naoto Inoue[3]

1. Institute of Earthquake and Volcano Geology, National Institute of Advanced Industrial Science and Technology, 2. Hosei University, 3. Geo-Reserch Institute, 4. Earthquake Research Institute, University of Tokyo

The Kikai Island is known as a tectonically active region due to the MIS 5e coral terrace reaching over 200 m in altitude. Holocene marine terraces divided into four levels suggest that 1-2 m of uplift has intermittently occurred every 1500-2000 years (Sugihara et al., 2003). However, recently simulation results propose that the main factor of terrace formation is a combination of steady uplift and erosive action triggered by relatively small coseismic uplift (Shikakura, 2014). According to the geodetic observation, GNSS data shows uplifting at about 2 mm/year, but it is contradictory that the leveling survey results (comparison between Sep. 1997 and Apr. 2014) indicate subsiding at approximately 1 mm/year (Ito et al., 2015).

As described above, there are various views and observation results on the crustal vertical movement pattern of the Kikai Island. Therefore, we focused on coral microatoll which is a natural tide gauge and reconstructed the long-term crustal vertical deformation based on its distribution and age.

Since the microatoll formed by *Polites sp.*, grows on the basis of the low tide level, and records sea level change annually, it is good paleoshoreline indicator to reconstruct past crustal vertical deformation. We found a total of 25 living microatolls at three areas in the northern part, eastern part and southern part of the Kikai Island and one emerged microatoll. We obtained detailed cross-sections of five living micro-atolls and sliced samples of emerged microatoll to take a CT-scan image, and also obtained some samples for 14C age which were calibrated of marine reservoir effect based on data of Hirabayashi et al. (2017).

In the northern area (Onozu), the height of the top surface of all living microatolls was almost flat at -1.01 - 1.07 m (TP), and the maximum was 78.8 cm in radius. Emerged microatoll found in this area is 270 cm in radius. Its shape of the top surface is almost flat but the altitude is decreasing gently from the center (-0.80 m TP) to the edge (-0.87 m TP) and is 20 cm higher than the living microatolls. From the CT scan image, 237 lines of annual band can be counted in the range of 260 cm showing clearly growing in the horizontal direction. Therefore, the mean horizontal growth rate is estimated to 1.1 cm/year. It is consistent with 14C age data which shows AD 1305-1425 in the center and AD 1489-1650 in the margin. Based on the growth rate obtained from analysis of emerged microatoll, the age of growth of the living microatoll in this region can be estimated to about 72 years ago.

The largest one of the living microatolls confirmed in the eastern area (Kadon) has a radius of 145.6 cm and can be estimated to about 132 years ago, which is no contradiction to the 14C age of the center (AD 1680-1880). The shape of the top surface is roughly horizontal throughout the growth period, but the altitude is slightly uneven between -1.06 m (TP) and -1.20 m (TP).

©2019. Japan Geoscience Union. All Right Reserved.

Based on the above results, the relative sea level change of the Kikai Island slowly decreased by 7 + α cm within 300 years from the 14th to the 17th century, and rapidly fall by 20 - α cm at the 17th century or in the period until the 19th century. Also, since at least 137 years ago, the sea level is almost stable while fluctuating about 10 cm at the maximum. Although it is difficult to distinguish the crustal deformation and the eustatic sea level change, if it is regarded that all of the change was the tectonic influence, it can be denied the steady uplift at a constant rate for the past 600 years. The rapid sea level fall during the 17th century or until the 19th century may have been an intermittent coseismic uplift.

Variation of coseismic fault displacements on multiple seismic cycles at a site: An example from the Kamishiro fault, Itoigawa-Shizuoka Tectonic Line active fault system, central Japan

*Naoya Takahashi[1], Shinji Toda[2]

1. Graduate school of Science, Department of Earth Science, Tohoku University, 2. International Research Institute of Disaster Science, Tohoku University

Predicting coseismic fault slip at a site on an active fault is crucial from the view point of fault displacement hazard assessment. The characteristic earthquake model, where an amount of coseismic slip at a point on a fault is roughly consistent through seismic cycles (Schwartz & Coppersmith, 1984), has been widely accepted and applied for hazard assessment. However, recent paleoseismic studies, high-resolution topographic data and quantitative more precise dating techniques have revealed that many faults do not repeat persistently their characteristic displacements (e.g., Zielke, 2018).To further discuss this issue, however, more case studies in particular on a dip-slip fault are required.
We estimated co-seismic slips of paleo-earthquakes at Oide site (36.7˚N, 137.87˚E) on the Kamishiro fault and evaluated variability in co-seismic slips through seismic cycles. The Kamishiro fault is a reverse fault which is located at the northernmost part of the Itoigawa-Shizuoka Tectonic Line active fault system in Japan. Advantages of this fault are that the co-seismic slip distribution of the most recent event, the 2014 Nagano-ken-hokubu earthquake (Mw 6.2), is precisely measured by field observation and differential LiDAR analysis, and that there is a flight of displaced terraces that record slips of recent earthquakes. Several paleoseismic studies share the evidence for the penultimate and the antepenultimate events that occurred in AD 1714 and ~1.2 ka (AD 841 or AD 762) respectively, whereas the event ages older than 1.2 ka are not well constrained. Here we mapped five displaced terraces (T1-T5, from the older) at Oide using aerial photographs taken by the US Armed Forces in the 1940s. Then, we estimated cumulative net slip of T1, T2 and T5 terraces using a tool developed by Wolfe et al. (2018) which incorporates topographic and fault properties with uncertainties and enables us to objectively estimate a plausible cumulative net slip. We made 30 topographic profiles for each terrace, and sought the mean and standard deviation of the cumulative net slip. We also constrained terrace ages based on radio carbon dating. As a result, we estimated coseismic slips of the penultimate and the antepenultimate events, 1.5±0.2 m and 2.7±0.4 m, respectively. Next, we performed a Monte Carlo simulation to estimate slips of events before the antepenultimate earthquake and then explore a possible range of CV (Coefficient of Variation) for co-seismic slips. CV is a ratio of a data set’ s standard deviation to mean and used to assess variability. Low CV indicates co-seismic slips are nearly the among seismic cycles, and high CV (close to 1) means slips are variable. Because previous paleoseismic studies found one to three earthquakes occurred between T1 formation (5-2.7 ka) and 1.2 ka, we iteratively computed one to three co-seismic slips before 1.2 ka so that the simulated slip sequences can reproduce the cumulative terrace offsets. This approach enabled us to calculate CV that ranged from 0.3 to 0.5 (1 σ), which indicates that a recent sequence of co-seismic slips at Oide does not follow the characteristic earthquake model but varies in a narrow range.

High-resolution shear-wave seismic reflection surveys across the Kamishiro fault, Itoigawa-Shizuoka Tectonic Line active fault system, central Japan

*Naoki IKEGUCHI[1], Nobuhisa Matsuta[2], Kyoko Kagohara[3], Shinsuke Okada[4], Daisuke Hirouchi[5], Tatsuya Ishiyama[1], Katsuya Noda[6], Hiroshi Sato[1]

1. Earthquake Resarch Institute University of Tokyo, 2. Graduate School of Education, Okayama University, 3. Faculty of Education, Yamaguchi University, 4. Graduate school of Science, Tohoku University, 5. Faculty of Education, Shinshu University, 6. GEOSYS Inc.

Coseismic net fault slip based on very shallow fault trajectories offers insights to understand properties of source faults for assessing seismic risk from crustal earthquakes in the overriding plate. To illuminate very shallow fault geometries, we carried out new shear-wave very shallow seismic reflection profiling across coseismic surface ruptures emerged along the Kamishiro fault, a northernmost segment of the Itoigawa-Shizuoka tectonic line (ISTL) active fault system, during the 2014 Nagano-ken-hokubu earthquake (Mw = 6.2) (c.f., Hirouchi et al., 2015; Ishimura et al., 2015; Katsube et al., 2017; Okada et al., 2015).

We collected seismic data along six seismic lines (Shiojima, North-Oide, South-Oide, Wing-21, Iimori, Horinouchi, respectively) in 2017 and 2018 by using Electrodynamic Vibrator System (ELVIS; GEOSYM) as an SH seismic source, a land streamer composed of 96 channels, and recording system GEODE (GeoMetrics). Acquisition parameters are: sweep length, 10 sec: sweep frequency, 20-120 Hz: source intervals, 1 m (2 m only in the Wing 21 seismic line); receiver intervals: 0.5 m; sampling rate: 1 msec.

By correlation of processed depth sections based on standard CMP stacking with surface geology and drill-hole data, the seismic sections up to a depth of approximately 100 m resolve thrust geometries extending from the 2014 coseismic surface ruptures that are mostly consistent with previous results in field mapping (e.g., Togo and Hasegawa, 2015; Lin et al., 2015; Okada et al., 2015), ground-penetrating radar (Kimura and Taniguchi, 2015; Nakano and Une, 2015). Our new seismic sections also successfully illuminate previously unrecognized blind thrust faults deforming Quaternary sediments which were not activated during the 2015 event. Our results show that shear-wave seismic reflection surveys using Electrodynamic Vibrator System and a land streamer are very effective to obtain detailed subsurface images of not only active faults but also unrecognized blind thrust structures.

Discussion

Paleoseismic investigations on the un-ruptured section during the 2014 earthquake along the Kamishiro fault, ISTL active fault zone, Central Japan

*Hisao Kondo[1], Hideki Kurosawa[2], Yoko Hirakura[2], Keita Takada[3], Kohei Abe[2], Miwako Ito[2], Atsuo Igarashi[3], Tetsuya Ikeda[3], Atsushi Miwa[2]

1. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 2. OYO Cooperation, 3. Fukken Co., Ltd

We perfomed paleoseismological invetigations on the un-ruptured fault section along the Kamishiro fault, ISTL active fault zone, central Japan. The un-ruptured section extends for about 15 km, consisting of the southernmost section of the Kamishiro fault. The northern most section have activated during the 2014 Nagano-ken Hokubu earthquake, Mj 6.7. Near Lake Nakatsuna, the Kamishiro fault forms tentonic geomorphic features such as fault scarp on the lucustrin terrace and fluvial terrace, monoclinal scarp on the lowland. Beside the eastern side of Lake Nakatsuna, we obtained two bore holes in order to estimate vertical slip rate based on lucustrin terrace deposite at hanging-wall side and fine sediments at foot-wall side. We estimated about 1.0 mm/yr of vertical slip rate as the minimum value. The fault exposure at the depth of -29 m in the borehole core at the foot-wall side implies that thrust front is located at the west of the borehole site. It indicates that the slip rate at present is the minimum estimatation. 350 meter south of this site, we obtained several Geoslicer across the fault scarp. The scarp hight is about 2 m. Based on geomorphic and geologica section, we identified two paleoseismic events after the depositon of alluvial fun deposite. At this moment, we estimated that the most recent event occurred after 664 A.D. More carbon dating samples will allow us to constrain teh timing of paleoseismic events. Near the sourthern most termination of the Kamishiro fault, south of Lake Kizaki, we re-investigated timing and slip per event during 5-6 paleoseismic events. Here, 2-3 events has been identified based on the shallow geologic section up to 6 m deep revealed by Geoslicer technique. We added four borehole cores to identify thrust structures and older events. At present, fine sediments and carbon dating results yeild 1.0 mm/yr of vertical slip rate after 1.2 ka. More dating results will provide high-resolution chronology of past events and slip per events, that will help us to discuss the occurrence of past multi-segment earthquakes.

History of interplate earthquakes along the Sagami Trough from uplifted coasts in the Boso Peninsula

*Junki Komori[1], Masanobu Shishikura[2], Ryosuke Ando[1]

1. The University of Tokyo, 2. The National Institute of Advanced Industrial Science and Technology

We surveyed tectonically uplifted coast, Heisa-ura, in the southernmost part of the Boso Peninsula, central Japan, for the estimation of the recurrence history of subduction earthquakes. The megathrust earthquakes along the Sagami Trough, located to the south of Tokyo, are known to repeatedly occur as represented by the 1703 M8.2 Genroku Kanto Earthquake. The interval time of these earthquakes is previously believed to be longer than 2,000 years from the investigations of the marine terraces in the Boso Peninsula (e.g. Nakata+, 1980). However, the recent dating survey indicated that their interval time might be 500–800 years at the shortest (Komori+, 2017) and required more detailed investigation. The Heisa-ura coast, we surveyed in this study, has not been investigated well before because no significant landform such as marine terraces are developed there. This region is, however, considered to suffer the fastest averaged uplift rate in the surrounding area from the recent study of the marine terrace distribution. Thus the buried sedimentary structure in Heisa-ura possibly records the emergence history of this coast. Here we show the result of the detailed geological survey using Geoslicer done in Heisa-ura for the first time. We obtained 8 sedimentary structure ~2 m deep along a survey line perpendicular to the coast. This investigation revealed that shoreface deposit contains shell fragments is placed deeper than 0.5–1.0 m beneath the surface. Additionally, the sedimentary structure is different between the survey points above and below the estimated elevation of the paleo-shoreline angle. These results indicate that the sedimentary structure beneath the Heisa-ura coast might records the chronicle of crustal deformations which has not been explored. This survey would give us several important factors for the discussion of the mechanisms of the subduction earthquakes along the Sagami Trough and the future hazard assessment of them.

Inferring location and activity of the Iriyamase fault, the Fujikawa-kako fault zone, based on boring core sample analyses and physical fault model

*Namiki Ryo[1], Ryosuke Ando[1], Masanobu Shishikura[2]

1. The University of Toyko, 2. National Institute of Advanced Industrial Science and Technology

The Fujikawa-kako (estuary) fault zone, located in the northern end of the Suruga-Nankai-trough, is claimed to be possible to be activated with the Nankai megathrust earthquakes, resulting in fatal damage in this region. However, it is difficult to accurately estimate the activity of the Iriyamase fault, which is considered as one of the most active faults in this fault zone, because no clear tectonic landform is found on the alluvial fan developed in the Fujikawa estuary area. Recently, three boring cores drilled in the Fujikawa estuary area are preliminarily analyzed by Shisikura et al. (2018). The KNB core is taken at the west side of the Fuji river as well as the hanging wall side of the Iriyamase fault, whose location is estimated by AIST (2016); The SKB core is at the west side of the Fuji river and the footwall side; the FGB core is at the east side of the river and the footwall side.

Based on the result of these analyses, it is estimated that the average displacement rate of Iriyamase fault is about 1~3 m / ky, which is smaller than the previous estimates (Yamazaki, 1992). Moreover, it is also pointed out that the both hanging wall and footwall sides of Iriyamase fault has been subsiding in the long term because Late Holocene terrestrial sediments are buried at the depth beneath the present sea level even in the KNB core located at the hanging side. According to the depth of layers deposited in the peak of the postglacial transgression, this subsiding rate is estimated to be at the 3m/ky.

In this presentation, we show the result of radiocarbon dating and a diatom analysis in these three cores based on more detail analyses of the core samples. Furthermore, we construct physical models based on these results to consider the underlying tectonic conditions.

The diatom analysis of the SKB core shows that diatoms are rarely found at depths shallower than 56 m, and the shallower strata are found to be terrestrial sediments. This result agrees with the long-term subsidence suggested by Shisikura et al. (2018). Moreover, the average displacement rate of Iriyamase fault is estimated about 2 m / ky by comparing the results of the diatom analyses of two cores (KNB and SKB). In order to understand the tectonic origin of the long-term subsidence in the Fujikawa estuary area, we construct the two physics-based models, called the Fuji volcano model and the fault model. In the Fuji volcano model, we calculated the amount of the subsidence caused by the isostasy effects due to the development of the Fuji volcano; the amount of subsidence is calculated to be about 0.7m by the volume increase of Fuji volcano in the past 17 thousand years, 41.37 km^3 (Miyazi, 2007). Thus, this result is far smaller than the amount of the long-term subsidence based on the boring core analysis. In the fault model, we calculate the average displacement rate of the Iriyamase fault, assuming faults as the finite rectangles in the semi-infinite elastic medium based on Okada (1992). We assume two faults to explain both the subsidence at the KNB core and the vertical offset between KNB and SKB; fault A is located between KNB and SKB and Fault B is located in the western side of KNB. The result shows that the average displacement rate of fault B is required to be much larger than that of fault A, because subsidence due to fault B in its footwall side must overcome the uplift due to fault A in the hanging side of fault A.

Coastal submergence events identified by fossil diatoms and plant macrofossils at Ukishima-ga-hara adjacent to the Suruga Trough (eastern Nankai Trough), central Japan

*Yuki Sawai[1], Arata Momohara[2], DAN MATSUMOTO[1], Yumi Shimada[1,3]

1. Geological Survey of Japan, AIST, 2. Chiba University, 3. University of Tsukuba

We identified eight episodic submergence events based on paleontological analyses on peaty sediment samples at Ukishima-ga-hara lowland in Shizuoka Prefecture, central Japan. Lithostratigraphy of sediment samples from Ukushima-ga-hara has no clear changes in facies, but changes in compositions of diatom assemblages and plant macrofossils suggest episodic submergence events. For example, at about 2.3 m and 3.1 m below the ground surface, while aerophilic diatoms (such as *Diadesmis contenta*) dominate underlying peaty layer, freshwater and brackish planktonic taxa (*Aulacoseira* and *Thalassiosira*) abound in overlying layer. Radiocarbon ages of plant macrofossils taken from samples just above and below the event horizons were used to constrain event ages. As the results of applying Bayesian estimation, the youngest one may be correlated with either 1707 or 1498 earthquake. The second one was with either 1361 or 1498 earthquake. The third one covers ages of 1096 and 887 earthquakes. These submergence events may be generated with coastal deformation associated with subduction zone earthquake along Suruga Trough and/or active fault earthquake at Fujikawa-kako-fault zone.

Active structures of central Hokkaido are characterized by north-striking active thrusts along the western flanks of the Hidaka Mountains and eastern flanks of the Kabato Mountains. Whereas structural styles and positions of active thrusts along the Umaoi and Kurisawa Hills are clearly related to frontal Hidaka fold-and-thrust belt, structural relations between east-facing folded fluvial terraces along the eastern flanks of the Kabato Mountains and pre-Neogene basement-cored folds remain poorly understood. In addition, geomorphic expression of active faults/folds along the northern Yubari Mountains is quite insufficiently recognized in contrast to both their northern southern extension. To define these unsolved questions, we collected new seismic reflection data from the eastern flank of the Kabato Mountains, through alluvial plain of the Ishikari River to the western flank of the northern Yubari Mountains, by use of both ca. 14.5 km long array of seismic recorders at 20 m intervals and a vibroseis truck as seismic sources at 10 m intervals. Our processed seismic profile based on standard CMP stacking and its preliminary interpretation suggest the eastern flank of the Kabato Mountains is underlain by a tight, east-vergent, asymmetric anticline that deforms Paleogene to Pliocene sediments. Synclinal and anticlinal axial surfaces newly identified on folded, middle to late Pleistocene fluvial terraces on the eastern flank of the Kabato Mountains are apparently consistent with those recognized in the seismic section. This may suggest recent growth of the fault-related anticline and activities of underling west-dipping blind thrusts imaged in this experiment. In contrast to the east-vergent asymmetric anticline beneath the eastern flank of the Kabato Mountains, structural styles beneath the western flank of the northern Yubari Mountains in the eastern half of the section include more gentle westerly dipping Pliocene-Pleistocene (?) sedimentary units with steeper dip panels, possibly suggesting an east-dipping blind thrust fault. Previously unrecognized, very subtle, west facing scarps on alluvial plain and late Pleistocene fluvial terraces are consistent with these underlying thrusts and may indicate their recent fault activities.

Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University, 7. Sedimentary Environments Research

In the 2016 Kumamoto earthquake, surface ruptures appeared not only on the Futagawa fault, source fault of this event but also on the other active faults. Especially, on the Idenokuchi fault located about 2 km south of and subparallel to the Futagawa fault, normal fault scarps (10 km length and Max. 2 m vertical offset) appeared (Toda et al., 2016). Toda et al. (2016) presented that the slip-partition occurred using the Futagawa (strike-slip fault) and Idenokuchi (normal fault) faults, indicating the structural relationship between both faults. Additionally, in considering the 2016 event, there is one question whether the activity of Idenokuchi fault coincides that of the Futagawa fault or not. Recent paleoseismological survey (Kumahara et al., 2017; Iwasa et al., 2018; Shirahama et al., 2018; Toda et al., 2018; Tsutsumi et al., 2018; Ueta et al., 2018) revealed that 3 or 4 events including the 2016 event were estimated since Kikai-Akahoya (K-Ah) tephra (7.3 ka; Machida and Arai, 2003) fall. Thus, if the Idenokuchi fault ruptures together with the Futagawa fault, we would find multi-events on the Idenokuchi fault during the last seven thousand years.

We excavated a 14-m-long, 6-m-wide, 3-m-deep trench on the antithetic fault of the Idenokuchi fault, where we found 30-60 cm vertical offset associated with the 2016 event. In the laboratory, we conducted tephra analysis and radiocarbon dating. Now, we are measuring radiocarbon dates, and thus will estimate depositional and event ages in our presentation.

On the trench walls, we recognized clear, but complex normal and reverse faults. A main normal fault with a high dip angle bounded basement rocks and soil just below the 2016 surface rupture. On the hanging wall side, we found many antithetic normal faults and reverse faults. In the soil sediments, we identified K-Ah tephra (thickness of 40 cm) based on volcanic glass morphology and refractive index. Soil sequence on the hanging wall side is shown from the surface: surface soil, brown soil, black soil (paleosol1), brown soil, K-Ah, black soil (paleosol2) and yellowish soil.
At present, we identified at least four events including the 2016 event since paleosol2. Especially, after K-Ah deposition, we confidently three events including the 2016 event, corresponding with the frequency of the Futagawa fault activity (Kumahara et al., 2017; Toda et al., 2018; Tsutsumi et al., 2018; Ueta et al., 2018). This preliminary result suggests that the Idenokuchi fault ruptured with the Futagawa fault. Additionally, we also identified a few probable events and will discuss this with radiocarbon dates in the presentation.

We conducted paleoseismic investigations such as drilling and trenching surveys across the Hinagu segment of the Hinagu fault zone, Kumamoto, Japan. The result based on the careful trench wall observation and preliminary radiocarbon dating of sediments show that paleoearthquake cycle of the Hinagu segment is shorter than previous evaluation of the fault.

Seismic trenching on offshore part of the Hinagu Fault Zone, Kyushu, Japan −3D structure and paleo-seismicity of offshore dextral strike-slip fault

*Takashi OGAMI[1], Shintaro Abe[2], Kenjiro Mukaiyama[3], Shigeyuki Suda[4]

1. Geological Survey of Japan, AIST, 2. ADEP, 3. Kawasaki Geological Engineering Co. Ltd., 4. JGI Inc.

As a part of "Comprehensive research project for the major active faults related to the 2016 Kumamoto earthquake" of MEXT, we conducted offshore-fault surveys at the offshore part of the Hinagu-Fault-Zone, Kyushu, Japan. We have obtained ultra-high-resolution 3D-seismic data and two offshore drilling cores, and integrated them to clarify detailed geological structure and paleo-seismicity of the fault zone since the Last glacial maximum (LGM).

We chose coastal area of the Yatsushiro Sea, off the Tsunagi town, Kumamoto Prefecture, as study area. The sedimentary body of the postglacial period is formed thicker than 10 m at the area. Inside a rectangle area of 1 km by 2 km, we obtained ultra-high-resolution 3D-seismic data using the boomer source. Two drilling cores are obtained at both sides of the target fault.

3D geological structure and shape of the fault are figured out based on the 3D-seismic data. We distinguished extensional duplex structure at right-stepover section along the fault, which strongly suggest dextral strike-slip faulting. The structural depression associated with the extensional duplex would emphasize vertical faulting, which would provide clues to clarify the paleo-seismic events based on sedimentary analysis.

Two drilling cores penetrates the sedimentary body of the postglacial period, and are classified into Facies B, A4, A3, A2 and A1, in ascending order. Our interpretion of them are followings. Facies B: Sediment before LGM. Facies A4: Terrestrial sediment after LGM. Facies A3: Muddy bay sediment of transgressive stage. Facies A2: Sandy sediment overlapping ravinement surface. Facies A1: Sandy and muddy bay sediment of highstand. Based on 3D-seismic data, we classified strata of facies A4, A3, A2 and A1 into 7 seismic units (U7-U1, in ascending order) . The seismic units of U7-U3 are composed of facies A4 and A3. The seismic unit of U2 and U1 correspond with facies A2 and A1, respectively. The basement of seismic unit of U7 corresponds to the boundary of facies B/A4, and is interpreted as an erosional surface during lowstand of LGM around 18 ka.
Thickness of the seismic unit of U7, U5, U3, U2 and U1 changes abruptly at the fault, which should have result of 5 faulting events of E5-E1, in ascending order. Based on age-depth curve at drilling site on the downthrown side of the fault, faulting events of E5-E3 could be estimated as followings. E5: 18 ka-12.01 cal kBP, E4: 9.96-9.50 cal kBP, E3: 8.86-8.62 cal kBP. E2 should occurred during formation of seismic unit U2, which corresponds to the sediment of facies A2 (8.31-1.65 cal kBP). E1 displaces top of seismic unit U2, and we don’ t recognize displacement inside U1 and sea floor. Therefore, E1 should have occurred just before U1 deposition. Facies A1 corresponds to U1 and its deposition started after 1.59 cal kBP. Therefore, E1 should have occurred just before 1.59 cal kBP.
This study successfully demonstrated "3D-seismic trenching", which comprises ultra-high-resolution 3D seismic survey and offshore drilling surveys, can figure out detailed geological structure and paleo-seismicity of strike-slip fault.

Conductivity Structure models of large and small slip regions at the 2016 Kumamoto earthquake sequence

*Satoru Yamaguchi[1], Yuto Yamanaka[2], Akira Mimura[1], Kazuki Fkue[1], Daigo Furukawa[1], Tada-nori Goto[3], Hisatoshi Koji[3], Sota Kawaguchi[3], Koki Aizawa[4], Shinichi Takakura[5]

Department of Urban Management, Graduate School of Engineering, Kyoto University, 4. Institute of Seismology and Volcanology, Kyushu University, 5. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

The 2016 Kumamoto earthquake sequence in Japan started with M_{JMA} 6.5 foreshock and the M_{JMA} 7.3 mainshock occurred 28 hours after the foreshock. The events occurred mainly within the Hinagu and Futagawa fault zone, which are known to be active faults.
Asano and Iwata (2016), Kubo *et al.* (2016), and Kobayashi *et al.* (2017) analyzed the detailed source rupture process of the foreshock, mainshock, and another notable event and proposed the source rupture models. It is important and interesting to reveal conductivity structure of the fault and compare it the source rupture models above mentioned because resistivity structure is one of the crucial elements to reveal subsurface structure of the fault.
We made magnetotelluric (MT) surveys using an audio- frequency MT (AMT) method, which is suitable for revealing shallow part (0 -2 km in depth) with high spatial resolution, along two lines (MSK and NSH lines) of ~2 km across the Futagawa Fault. The MKS line crosses the large slipped region and along the line, we made measurements at 11 stations. The NSH line crosses the small slipped region and along the line, we made measurements at 14 stations. We obtained two-dimensional resistivity models between depths 0 - ~1.0 km along the two lines, we call them MSK model and NSH model, respectively.
We recognize two common conducive regions in both models. One is highly and near vertical conductor below the surface fault traces of the Futagawa Fault. The conductor is located just beneath the surface fault trace in the MSK model and is shifted south in the NSH model. Another is deep and wider conductor which includes deep part of the conductor mentioned above. This conductor of the MSK model is wider and shallower than that of the NSH model. These features are consistent with that of source rupture models, further we can say that our conductivity models figured out more detailed subsurface structure of the Futagawa Fault.

The Timing and Extent of the Last Surface Rupture Event on the Himalayan Frontal Thrust in Central Nepal around Butwal

*Koji Okumura[1], Soma Nath Sapkota[2], Prakash Pokhrel[2], Hisao Kondo[4], Takuya Furuhashi[3]

1. Graduate School of Letters, Hiroshima University, 2. Department of Mines and Geology, 3. Taiheiyo Cement Corporation, 4. Geological Survey of Japan, AIST

The 2015 Gorkha earthquake ruptured only the deeper northern part of the thrust during the Mw 7.8 earthquake, but did not rupture the surface and shallow portion of the Himalayan Frontal Thrust (HFT) in south. Since then, the evaluation of the potential of the future surface rupture event on the HFT in central Nepal in south of 2015 rupture became an important task for paleoseismology. Mishra et al. (2016), Bollinger et al. (2016), and Wesnousky et al. (2017) proposed respective 1100 CE, 1344 CE and/or 1408 CE, and 1221 CE to 1262 CE (possibly 1255 CE) for the timing of the last surface-rupture event. Each report eliminates the timing of earthquake proposed by the other authors. Therefore, it is necessary to think over the possibility of multiple events in short (less than 100 km) segments or of misleading radiocarbon dates. Also, the existence and the east termination of 1505 CE Indian central seismic gap event (Malik et al., 2017) are not certain yet. In order to solve the rupture history and rupture extents in central and western Nepal, we excavated two trenches across the HFT around the city of Butwal. One is at 12 km west of Butwal at Sorauli (27.70˚N 83.36˚E) and another is at 60 km ESE of Butwal at Susto (27.48˚ N 83.86˚E). Around the Sorauli trench site there is no clear continuous scarp along the Siwalik hill front, but ~100 m wide zone of alluvial surface adjacent to the foot of the hills tilt toward south and juxtaposed to flat alluvial surface. The boundary between the tilted surface and the flat plain is continuous and looks like the active front of a flexure scarp. The trench across a small scarp on the tilted surface did not expose any fault, but a fine sand layer was tilted towards the boundary. An Baesian model of radiocarbon dates indicates the timing of tilting is between 1328 CE and 1435 CE. This period coincides with the 1344 CE earthquake (Bollinger et al., 2016). The Susto trench in the east of Butwal was dug into the foot of ~20 m high fault/flexure scarp below an uplifted terrace surface. In this trench also, 13˚ south-dipping fine sand layers appeared but the fault was below the water table and not exposed. The timing of the tilt in Susuto trench as well as results from investigation in further west in the boundary area between 1344 CE and 1505 CE event will be reported.

Discussion

Linear surface ruptures detected by SAR -- *the Kumamoto earthquake, the Northern Osaka earthquake and the Hokkaido Eastern Iburi earthquake*

*Satoshi Fujiwara[1], Hiroshi Une[1], Takayuki Nakano[1], Hiroshi Yarai[1], Tomokazu Kobayashi[1], Yu Morishita[1]

1. GSI of Japan

1. Introduction

The radar interferogram of ALOS-2 for the 2016 Kumamoto earthquake (M7.3) generally shows elastic deformation caused by the main earthquakes but many other linear discontinuities showing displacement are also found (Fujiwara et al., 2016).

We also found similar linear surface ruptures of the Northern Osaka earthquake on June 18, 2018 (M6.1) and the 2018 Hokkaido Eastern Iburi earthquake (M6.7).

In this presentation, we will show the characteristics of these linear surface ruptures.

2.General characteristics of the linear surface ruptures

The linear surface ruptures are those that Sangawa *et al.* (1985) presented about active faults in the southern part of Suruga Bay West Coast, and did not cause a large earthquake independently and the faults moved as a result of other large earthquakes.

The followings are the common features of the linear surface ruptures:

(1) The standard length of them is several kilometers, with linear or gentle curvilinear shape. The displacement is on the order of a few centimeters to several tens of centimeters.
(2) They are far from the seismogenic fault, and it is unlikely that they are the main seismic fault itself or the branch faults.
(3) There is no evidence that they generated large earthquake ground motions at the time of the main earthquake.
(4) They were likely moved passively, and it is considered to be the resultant faults, not the cause of the main big earthquake.
(5) Since there is a correlation between the topography and the displacement, some of them are recognized as "active faults" from their topographical features. Therefore, there is a possibility that similar fault movements have been accumulating from the past.
(6) The direction of strike and the displacement pattern of them are consistent with the surrounding stress field.

3. Characteristics for each earthquake

3-1) 2016 Kumamoto Earthquake
(1) About 230 linear surface ruptures have been confirmed.

©2019. Japan Geoscience Union. All Right Reserved.

(2) The form of displacement accounts for most of the normal fault.
(3) The interval, depth and displacement of them are almost constant and uniform for each area, and they form several groups of the linear surface faults.
(4) There are fault groups of similar shape from Beppu Bay to Unzen in the central part of Kyushu, Japan. This implies a possibility that there is a common form of them in central Kyushu.
(5) ΔCFF based on the fault model of the Futagawa fault zone and the Hinagu fault zone for the Kumamoto earthquake can not explain the cause of the displacement of them.

3-2) Northern Osaka earthquake on June 18, 2018
(1) The linear surface rupture was recognized at a place coincident with one of the faults of the Arima–Takatsuki fault zone (Makami fault). Makami fault has been confirmed that it moved at the time of the 1596 Keicho–Fushimi earthquake (M 7.5).
(2) Although the right–lateral fault component is dominant, the rupture does not reach the surface of the ground, but the displacement of the deviation component spreads by a width of about several hundred meters.
(3) On the linear surface rupture, vertical displacement of the south side down is found.
(4) According to the long-term observation before the earthquake, a wide belt around the linear surface rupture has continuously sunk.
(5) The general crustal deformation due to the main shock is small, and it is about several cm at the maximum.

3-3) 2018 Hokkaido Eastern Iburi earthquake
(1) The displacement shows east–west shortening, and there are almost no vertical components. Then, they can be described as reverse fault motion with very low dip angle.
(2) The trace on the ground surface is not a straight line but a somewhat complicated curve that follows the terrain.
(3) The traces of them have not been recognized as active faults.
(4) In the seismic exploration (Yokokura et al., 2014), deviations in the basement are recognized just under them and they may be a hidden fault.

Acquisition of micro-landforms in the forest using small UAV-LiDAR: An example from surface rupture of the 2008 Iwate-Miyagi Nairiku, Japan, earthquake

*Asaka Konno[1], Taro Suzuki[2], Shinji Toda[1]

1. International Research Institute of Disaster Science, Tohoku University, 2. Waseda University

For active fault research, photogrammetry (e.g., Photoscan) with UAV (Unmanned Aerial Vehicle) has been introduced to map surface ruptures for the recent earthquakes. However, this method has mainly two drawbacks: it is necessary to set reference points (GCP: Ground Control Point), and it cannot be applied to ground in the dense forest. A small LiDAR equipment attached to the UAV laser is expected to overcome these issues. Although this approach is considered to be effective for detailed mapping of earthquake surface ruptures, none of the papers has been published such an application in the forest. Here we investigate the effectiveness of UAV laser surveying under the forest comparing to the topographical data acquired by terrestrial laser survey (Maruyama et al., 2008; Yoshimi et al., 2010) for the surface rupture that appeared at the 2008 Iwate Miyagi Nairiku earthquake.

Our study field is along the ~0.7-km-long surface rupture located in the north-east of the Aratozawa Dam. The heights of the free faces was several tens of cm to 2 m. We conducted the UAV flights at an altitude of 50-70 m on November 15, 2018. The area is densely covered with cedar plantations and broad-leaved trees, and thus surface rupture is almost invisible from aerial photographs. For the UAV aviation laser surveying, DJI Matrice 600 Pro owned by Waseda University was used. Six GNSS receivers mounted on the UAV allows us to precisely calculate the UAV location only with the errors of the attitude (0.1 °) and the position (1 cm). Based on the precise position information of the UAV, we attached the LiDAR equipment Velodyne's VLP-32C to the UAV to acquire detailed topographical data in the forest. We filtered the point cloud data using Landforms of ISP's software, and then extracted only the ground surface removing the points reflected from vegetation. The swath of ~0.16 km^2 along the surface rupture, measured in about 15 minutes of flight, enable us to provide about 69-million-point cloud data. Among them, the ground point data of ~200,000 points were only screened (~0.3%). Even though it is much fewer than the 8 million points obtained by terrestrial laser surveying of Mariuyama et al. (2008), the points are more homogeneously distributed and data loss is small. Since the terrestrial laser irradiates the beam to the horizontal direction from the installed machine, the data could not be acquired from a blind spot behind trees. In terms of data precision, we confirmed the DEM model from UAV LiDAR is comparable with the terrestrial LiDAR DEM with centimeter-order accuracy. An absolute advantage of the UAV LiDAR is overwhelmingly short operation that allows us to perform not only urgent post-earthquake survey but also repeating measurements to follow degradation process of fault scarps.

Bayesian Inference and Forecast on Renewal Processes for Recurrent Earthquakes with Uncertain Occurrence Times

*Shunichi Nomura[1], Yosihiko Ogata[1]

1. The Institute of Statistical Mathematics

We discuss parameter inference and forecast in renewal processes for recurrent earthquakes suffering from uncertainties in their occurrence times. Exact likelihood and hazard evaluation in point process theory involves multiple integral with respect to uncertain occurrence dates and are often difficult to calculate even numerically. Alternatively, Monte Carlo simulation of the uncertain occurrence histories can be used for the evaluation by calculating the integrated functions for respective simulated histories and simply averaging them. We apply a renewal model with the Brownian Passage Time (BPT) distribution to Japanese paleoseismic catalog in which at least 2 latest events are specified for each fault segment. It is shown that the Monte Carlo method yields almost the same results as numerical integration. In parameter inference, we assume a common coefficient of variation (COV) parameter for recurrence intervals of Japanese paleoearthquakes due to scarcity of their histories. From datasets in 73 inland paleoseismic sites in Japan, we obtain a Bayes estimate of the common COV at 0.50, which is significantly larger than the COV estimate at 0.24 currently applied in the long-term forecast held by the Headquarters for Earthquake Research Promotion (HERP) of Japan. The difference in COV’ s estimates makes critical influences on long-term probability forecast in several fault segments. We also show numeric experiments of parameter inference and forecast for virtual active fault and compare Bayesian inference and forecast to plug-in methods with maximum likelihood estimates.

Slip rate of the Chaman fault: estimates based on ^{10}Be exposure dating for offset geomorphic surfaces in Afghanistan

*Zakeria Shnizai[1], Yuki Matsushi[2], Hiroyuki Tsutsumi[1]

1. Doshisha University, 2. Kyoto University

Afghanistan is located in a tectonically active part of the world near the collision boundary between the Eurasian and Indian plates. The Chaman fault traverses the eastern part of the country and is a major left-lateral strike-slip fault that accommodates much of the differential movement between the Indian and Eurasian plates. The fault starts from Makaran coast and extends to northeast through the Chaman City, Pakistan. Then it extends to north-northeast into Afghanistan and runs in west of Kabul and finally merges with the Pamir faults system. It is ~1000 km long and strikes from N10˚E to N35˚E. High slip-rates of the fault are known by previous works in the Pakistan side. In Afghanistan no research has been done, therefore we prepared a detailed fault map based on visual images interpretation and previous literatures. The fault offset older and younger alluvial fans and stream deposits of late Pleistocene and Holocene age. Along the fault, relative ages of geomorphic surfaces are known but their absolute ages are unknown. In the absence of absolute ages for faulted deposits, it is not possible to determine the fault slip-rate. Therefore we have conducted cosmogenic dating as was done in Pakistan side to provide age controls for fluvial deposits in the study area. Terrestrial Cosmogenic Nuclide (TCN) uses the interactions between cosmic rays and nuclides in transported boulders, and therefore is an excellent method to directly date alluvial deposits. TCN is particularly useful in Afghanistan due to lack of terrestrial organic materials for radiocarbon dating. Our study focuses on three different areas located at Wardak Province. One of the sites is Ghat Bandakul south of Kabul where the distal part of alluvial fan deposited at the mouth of a stream channel is offset left-laterally. The fan slopes 3-5˚ westward for ~1 km from the foot of the Syah-Tapa Mountain. The deposits are composed of clay, sandstone and granitic clasts originating from bedrocks. Analysis of ALOS images and field work indicate that younger and older terrace risers are displaced left-laterally along the fault for 165 m and 235 m respectively. We collected 6 samples from the top 1-3 cm of each desired sandstone boulders that were >1m in diameter and well-embedded in surface to ensure their long-term stability. The sandstone has large amounts of quartz mineral, which yields ^{10}Be TCN nuclide ideal for dating deposits over Quaternary timescale. Samples were processed at the laboratories of DPRI, Kyoto University and MALT, University of Tokyo.
Based on ~165 m displaced alluvial fan with a ^{10}Be exposure age of ~46 kyr, we obtained the first geomorphologically determined slip-rate of 3.5 mm/yr along the Chaman fault. This slip-rate is considerably smaller than the geologically and geomorphologically defined slip-rates of 19–24 mm/yr and 33 mm/yr along the fault in the border region of Afghanistan and Pakistan. Along the southern section at Ghazni and Zabul Provinces, we mapped east-dipping thrust faults as well as the multiple fault splays indicating a complex interplay between left-lateral faulting and northwest compression, which may cause slower slip-rate at the northern end of the fault. We plan to date two other alluvial surfaces in the southern part of the study area to determine exact slip-rate of the fault in Afghanistan.

[S-SS17] Seismic evidence of volcanic roots

convener:Naofumi Aso(Tokyo Institute of Technology), Yohei Yukutake(Hot Springs Research Institute of Kanagawa Prefecture), Chairperson:Naofumi Aso, Yohei Yukutake

Magma transport system beneath volcanoes is a key to understand long-term geodynamics and the evolution of the Earth. Especially, deep long-period earthquakes around the Moho beneath active volcanoes are supposed to relate to the magma transport system, although their activities and mechanisms are not understood well. Revealing the role of deep long-period earthquakes in the magma transport system is a key to understand deep volcanic roots around the lower crust, including deep magma chambers. It is therefore essential to estimate complete seismicity with a high-resolution hypocenter distribution and focal mechanisms of deep long-period earthquakes, based on innovative techniques including template matching, relocation methods using waveform cross-correlations, and waveform inversions. Also, high-resolution seismic imaging using advanced tomography techniques, including tomography using ambient noise interferometry, with a dense seismic network is essential to visualize the magma transport system. We welcome studies to understand volcanic roots from a variety of seismological approaches including but not limited to the methods mentioned above.

Spectral characteristics of deep low frequency earthquakes at Mount Fuji

*Motoo Ukawa[1]

1. Nihon University

Source processes of deep low frequency (DLF) earthquakes beneath volcanoes have poorly understood, mainly because of the small magnitudes of the earthquakes. In this study, we investigate spectral characteristics of the DLF earthquakes beneath Mount Fuji, focusing 11 events with long durations of 5 to 20 minutes including relatively large maximum earthquakes of M0.9 to M1.8. Spectral characteristics of earthquakes, as well as the amplitudes of seismic waves, provide us constraints for their source models. In the present spectral analysis, wavelet analysis with Morlet analyzing wavelet is applied to the DLF events. The results show following characteristics of the DLF earthquakes. The predominant frequencies of the 11 events range relatively narrow frequency band of 1 to 2 Hz. High frequency components of mainly 5-10 Hz are superposed onto the main low frequency waves in the events with large amplitudes. One event shows gradual change of the predominant frequency from 1.5 Hz to 1.0 Hz during 5 minutes. Source models of DLF earthquakes should explain the above spectral characteristics.

Deep low-frequency earthquakes corresponding to the 2011 and 2018 eruptions in Kirishima volcano

*Ryo Kurihara[1], Kazushige Obara[1], Akiko Takeo[1], Yusaku Tanaka[1]

1. Earthquake Research Institute, The University of Tokyo

Deep low-frequency earthquakes (LFEs), or sometimes called as deep long-period earthquakes (DLPs), are earthquakes whose dominant frequencies are lower than those of regular earthquakes of the same magnitudes. Deep LFEs occur beneath Kirishima volcano in southwest Japan at the depths of about 10-15 km and 20-25 km according to the catalog of Japan meteorology agency (JMA), while deep LFEs at most volcanoes in Japan occur at the depth of about 30 km.The LFEs near volcanoes can be a key to reveal physical processes of volcanic activities including eruptions because deep LFE activities are supposed to correlate with eruptions. For example, White (1996) showed that the deep long-period earthquakes (DLPs), so-called LFEs, occurred before the 1991 eruption of Pinatubo volcano, Philippine. Shapiro et al. (2017) showed the relationship between DLPs and long period earthquake near the surface beneath the Klyuchevskoy volcano group at Kamchatka, Russia. However, the relationships are still unknown in many volcanoes in Japan. Takahashi and Miyamura (2009) analyzed deep LFEs all over Japan using the catalog of JMA and concluded that they could not find deep LFEs corresponding with the surface volcanic activity such as eruptions. In fact, LFEs were constantly observed in Kirishima volcano in the JMA catalog. In this study, in order to reveal the relationships between activities of volcano such as eruptions and activities of deep LFEs, we first investigated spatial distribution of LFEs by relocation of the hypocenters of LFEs occurred from April 2004 to December 2015 in the JMA catalog using Network correlation coefficient method (Ohta and Ide, 2011). We then obtained time-series change of LFEs by comprehensive detection of deep LFEs based on matched filter technique (Gibbons and Ringdal, 2006; Shelly et al., 2007) from April 2004 to March 2018.

In results of relocation, hypocenters of the deep LFEs are concentrated in small clusters at the depth of 13 km and 22 km, especially many LFEs are located at the depth of about 22 km. On the other hand, result of the matched filter technique shows that deep LFEs at the depth of 23-25 km are activated for about two years including 2011 subplinian eruptions of Shinmoe-dake in Kirishima volcano group. The period of activation corresponds to the period of crustal deformation due to the volume change of the magma reservoir located beneath Ebino plateau at the depth of about 8 km (Nakao et al., 2013). From both results, we find that deep LFEs activated in the two years are located at the depth of 23-25 km, deeper than the locations of deep LFEs which constantly occurred from 2004 to 2018. Waveforms of deep LFEs activated around the 2011 eruptions have different characteristics such as lower frequencies and weak P wave onsets. The locations of activated deep LFEs migrated from shallow part to deep part of the small cluster at the depth of about 23-25 km during the two years of activation. In addition, there are some characteristic deep LFEs which were intensively observed in the periods of phreatic eruptions from March 2010 to July 2010 and phreatomagmatic eruptions from June 2011 to September 2011.Activation of deep LFEs was also observed in the period of eruptions in 2018, however, the depth and waveforms of the deep LFEs are same as those of deep LFEs which constantly occur at the depth of 20-23 km.
These results suggest that the deep LFEs occurring at the depths of 20-25 km are triggered by fluid flow. The difference of deep LFEs in 2011 and 2018 suggest that the fluid paths of the 2011 eruptions and 2018 eruptions are different. Activation of deep LFEs was not observed at the depth of 13 km in the periods of both eruptions, therefore, this deep LFEs may correspond to Ohachi volcano which did not erupt in the periods.

Origin of long-duration of deep low-frequency earthquakes and activity of shallow low-frequency earthquakes beneath northeastern Japan

*Masahiro Kosuga[1], Taichi Haruyama[1], Yuki Matsuno[2], Iori Narita[2], Takuto Maeda[1]

1. Graduate School of Science and Technology, Hirosaki University, 2. Faculty of Science and Technology, Hirosaki University

We investigated the origin of long duration of deep low-frequency (DLF) earthquakes and the activity of shallow low-frequency (SLF) earthquakes beneath northeastern Japan. Source mechanism of DLF events has attracted attention because the events are anomalous with very low predominant frequencies and with a very deep hypocentral location, suggesting a possible link to a magma transport system. Previous studies have shown that the source mechanisms are variable, double couple, CLVD, and single force, among the events. However, the other aspect of the characteristics of DLF events, long duration of the seismic signal, has not been well studied. We firstly searched for typical DLF events with low frequency and long duration. ThenWe we evaluatedthe frequency content by employing frequency index (FI) defined by the logarithm of the amplitude ratio of spectra between high- low-frequency ranges. We specify specified the range as 2–4 Hz and 10–20 Hz for low- and high-frequency ranges, respectively. These ranges correspond to the predominant frequencies of DLF and shallow ordinary earthquakes. We specified determined the location of typical DLF eventsbased on the FI and durationmeasurements. For the case of Hijiori in Yamagata prefecture, long-lasting (> 10 s) monochromatic vibration is was in phase among the stations, which suggests that the source effect is the origin of extended coda is a source origin rather than some path effects. Spectrogram of this event shows no hint of overtones expected from a resonance mechanism. We next numericallysimulated seismograms from several source models by the OpenSWPC code for seismic wave propagation in 2D/3D media. Simulation indicates that the resonance of seismic waves in a low-velocity body could produce monochromatic vibration, but under an exceptional condition of the size and physical properties of the resonant body, and restricted location of the initial source that trigger the resonance. We are conducting the following simulation for a moving source through multiple channels of the fluid transport system.

Event detection using FI is effective for SLF earthquakes that have no low-frequency flag in the JMA earthquake catalog. We searched for the SLF events in the Hakkoda area in Aomori prefecture and the Hakodate area in southern Hokkaido. SLF events in Hakkoda exhibit a cylindrical distribution beneath the Odake volcano in a depth range from the surface to about 5 km, clearly separated from the distribution of VT earthquakes around the volcano. Since the activity of SLF events are restricted in time when the expansion of volcanic body was suggested by GNSS observation, the SLF activity probably related to a magmatic activity of the volcano. In Hakodate area, the SLF earthquakes are located apart from the active volcano, Esan, and with focal depths shallower than 10 km. We confirmed the depth of several SLF earthquakes by adding travel time data from our two temporary seismic stations just above the SLF sources. Thus, the SLF events in this area are collocated with ordinary high-frequency events. Investigation of the generation mechanism of SLF earthquakes in the brittle regime is also important to comparably understand the mechanism of DLF earthquakes in the ductile regime.

Deep low-frequency earthquakes, tomography and magmatic system beneath active volcanoes

*Dapeng Zhao[1]

1. Department of Geophysics, Tohoku University

We made a systematic study of deep low-frequency earthquakes, high-resolution tomography and magmatic system beneath active volcanoes on the Japan Islands. Low-frequency earthquakes (LFEs) in the lower crust and uppermost mantle are widely observed, and they occur not only along the subducting Philippine Sea (PHS) slab interface but also beneath active arc volcanoes. The volcanic LFEs are still not well understood because of their limited quantities and less reliable hypocenter locations. We used seismic tomography to determine detailed three-dimensional (3-D) P and S-wave velocity (Vp and Vs) models of the crust and upper mantle beneath the Japan Islands, and used the obtained 3-D Vp and Vs models to relocate the volcanic LFEs precisely (Niu et al., 2008; Yu et al., 2018). Our results show that the volcanic LFEs can be classified into two types: pipe-like and swarm-like LFEs, and both of them are located in or around zones of low-velocity (low-V) and high-Poisson's ratio (high-σ) in the crust and uppermost mantle beneath the active volcanoes. The pipe-like LFEs may be related to fluid migration from the lower crust or the uppermost mantle, whereas the swarm-like LFEs may be related to local magmatic activities or small magma chambers. The number of LFEs sometimes increases sharply before or after a nearby large crustal earthquake that may cause cracks and fluid migration. The spatiotemporal distribution of the LFEs may indicate the track of migrating fluids. As compared with the tectonic LFEs along the PHS slab interface, the volcanic LFEs are more sensitive to fluid migration and local magmatic activities. High pore pressures play an important role in triggering both types of LFEs.

We also investigated the 3-D seismic structure of source areas of the 6 October 2000 Western Tottori earthquake (M 7.3) and the 21 October 2016 Central Tottori earthquake (M 6.6) that occurred near the Daisen volcano in SW Japan (Zhao et al., 2018a). The two large events took place in a high-velocity (high-V) zone in the upper crust, whereas low-V and high-σ anomalies are revealed in the lower crust and upper mantle. LFEs (M 0.0–2.1) occurred in or around the low-V and high-σ zones, which reflect upward migration of magmatic fluids from the upper mantle to the crust under the Daisen volcano. The nucleation of the Tottori earthquakes may be affected by the ascending fluids. The flat subducting PHS slab has a younger lithosphere age and so a higher temperature beneath the Daisen and Tottori area, facilitating the PHS slab melting. It is also possible that a PHS slab window has formed along the extinct Shikoku Basin spreading ridge beneath SW Japan, and mantle materials below the PHS slab may ascend to the shallow area through the slab window. These results suggest that the Daisen adakite magma was affected by the PHS slab melting and upwelling flow in the upper mantle above the subducting Pacific slab.

Detailed 3-D Vp, Vs and σ images of the crust and upper mantle beneath Kyushu are determined, with a focus on the source area of the 2016 Kumamoto earthquake (M 7.3) that occurred in the Beppu-Shimabara graben (BSG) where four active volcanoes and many active faults exist (Zhao et al., 2018b). The 2016 Kumamoto earthquake took place in a high-V and low-σ zone in the upper crust, which is surrounded and underlain by low-V and high-σ anomalies in the upper mantle. This result suggests that, in and around the source zone of the 2016 Kumamoto earthquake, strong structural heterogeneities relating to active volcanoes and magmatic fluids exist, which may affect the seismogenesis. Along the BSG, low-V and high-σ anomalies do not exist everywhere in the upper mantle but mainly beneath the active volcanoes, suggesting that hot mantle upwelling is not the only cause of the

©2019. Japan Geoscience Union. All Right Reserved.

graben. The BSG was most likely formed by joint effects of northward extension of the Okinawa Trough, westward extension of the Median Tectonic Line, and hot upwelling flow in the mantle wedge beneath the active volcanoes.

Seismic imaging of deep structure beneath active volcanoes

*Junichi Nakajima[1]

1. Department of Earth and Planetary Sciences, Tokyo Institute of Technology

Seismological observations clearly show that flux melting in the mantle wedge is a deep source of magmatism in subduction zones and generated melts are transported to the continental crust through a mantle upwelling flow. However, physical processes of magmatism beneath deep crust are poorly understood. Here I review seismological structures (seismic velocity and attenuation, S-wave reflectors, and low-frequency earthquakes) beneath active volcanoes in Japan, focusing on deep magma chambers and possible pathways of magmatic fluids to the upper crustal levels.

Deep low-frequency volcanic earthquakes and their implication for deep crustal processes in the magmatic arc

*Haruhisa Nakamichi[1]

1. Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University

Under temperatures and pressures of the lower crust and the upper mantle, rocks typically deform in a ductile manner, and it is unlikely that a sufficient deviatoric stress accumulates to generate brittle failure. However, earthquakes do occur in the upper mantle and in the lower crust beneath active volcanoes, and they are known as volcanic deep low-frequency earthquakes (VDLFs). They release energy mostly in the low-frequency range (<5 Hz), and are characterized by emergent arrivals and long-duration codas. VDLF activity observed at depths of 10-50 km in Japan, the Philippines, Alaska, and the Western US (Power et al., 2004; Ukawa, 2005; Nichols et al. 20011) has generally been attributed to magma transport in the mid-to-lower crustal and uppermost mantle regions. However, because VDLF seismicity is infrequent, with relatively weak and emergent signals, the relationship between deep magma transport and seismic radiation remains poorly understood. Dense seismic observation systems in boreholes, such as the high-sensitivity seismograph network “Hi-net” in Japan (Obara et al. 2005), are effective at detecting not only non-VDLFs (Obara, 2002) but also VDLFs. Since 1997, the Japan Meteorological Agency has routinely detected and located DLFs using the Hi-net dataset, and have identified DLFs in and around most quaternary volcanoes in Japan (Takahashi and Miyamura, 2009). Several studies have attempted to estimate source mechanisms of VDLFs in Japan. The first attempt, carried out by Ukawa and Ohtake (1987), provided a single force as the source mechanism of a VDLF beneath Izu-Ohshima by using the particle motion directions of *S*-waves. More recently, strike-slip type and non-double-couple source mechanisms were obtained using waveform inversions for VDLFs in Northeast Japan (Nishidomi and Takeo 1996; Okada and Hasegawa, 2000). Nakamichi et al. (2003; 2004) estimated the source mechanisms of Mts. Iwate and Fuji through the moment tensor inversion of spectral ratios of body waves, using data from a dense seismic network. The authors explained the source mechanisms as the motion of a tensile crack coupled either with a shear crack or with a chamber. No significant common features have been found in these estimated source mechanisms of VDLFs in Japan. The depths of VDLFs correspond to the depth interval where CO_2-rich fluids are expected to be liberated from ascending basaltic magmas, suggesting that such fluids play an important role in facilitating earthquake instabilities in the presence of tectonic stresses. The striking temporal correlation between VDLF activity and CO_2 gas emissions has been pointed out by Mammoth Mountain (Hill, 1996) and Izu-Ohshima (Watanabe, 2013). However, a temporal correlation between the VDLF activity and surficial geological and shallow geophysical activity is currently debated. The intrusion of basaltic magma before the eruption of Mt. Pinatubo in 1991 was correlated with VDLFs (White, 1996), and temporal correlations are clear for the 1998-1999 unrest of Mt. Iwate, where VDLF seismicity started 5 days before the initiation of the volcano tectonic (VT) seismicity (Nakamichi et al., 2003). We are currently investigating this correlation for the volcanic activity of Sakurajima, which is located in the southern part of the Aira caldera. There is a correlation between VT and VDLF seismicity in the Aira caldera since 2000. For example, both VT and VDLF increased in number between 2017 and 2018. On the other hand, no clear correlation between the VDLF seismicity and the eruption activity of Sakurajima volcano has been identified thus far.

Argon release mechanism of deformed phengite

*Tetsumaru Itaya[1]

1. Engineering Geology Center, Hiruzen Institute for Geology and Chronology

The author has proposed the argon release from phengites in HP-UHP metamorphic rocks by their ductile deformation in the exhumation and cooling of the metamorphic sequences to explain the relationships between K-Ar phengite ages and the metamorphic grade since Itaya and Takasugi (1988). This argon release hypothesis has not been accepted for 20 years until Nuong et al. (2008) described the age (K-Ar phengite)-temperature-structure relations in the Ishigaki high-pressure schist belt, southern Ryukyu Arc, Japan. Its main reason would be that the argon release mechanism is vague. Recently, the author made its mechanism clear in the literature that is in submission to journal. This paper will focus on the argon release mechanism of deformed phengites.

Cosca et al. (2011) described the effect of deformation on radiogenic argon retentivity from high pressure experiments (10kb and 600 ˚C over a period of 29 hours, giving ca. 10% shortening) performed on rock samples of peraluminous granite containing euhedral muscovite and biotite. Intragrain in-situ $^{40}Ar/^{39}Ar$ analyses for deformed muscovite provided 309 to 264 Ma, consistent with 0-16 % argon loss relative to the undeformed muscovite (311 Ma). They interpreted that the reduction in the effective diffusion length scale in naturally deformed rocks occurs most probably through productions of mesoscopic and submicroscopic defects such as stacking faults. The extreme size reduction of phengite observed at domains close to the rigid garnet in pelitic schists of the Sanbagawa belt are identical to the reduction in the effective diffusion length scale described by Cosca et al. (2011), likely enhancing the argon release. The Sanbagawa pelitic schists suffered extremely long deformation (longer than 31 million years) during the exhumation and had the extremely slow exhumation rate (slower than 0.7 mm/y). In this case, the phengite could grow up with “Ostwald ripening phenomenon” consuming the extremely fine-grained phengite close to the rigid garnet. The size reduction and “Ostwald ripening” growth would continue to become final stage of static phengite crystal size (0.02-0.06 mm in width and 0.4-1.0 mm in length) observed in matrix. During these processes phengite could experience chemical change depending on local bulk chemistry under the P/T conditions changing from moment to moment during the exhumation, making heterogeneous chemistry. On the other hand, Lago di Cignana UHP unit in western Alps suffered relatively quick deformation (shorter than 5 million years) during the exhumation and had the extremely fast exhumation rate (15 - 26 mm/y). In this case, the phengite crystals could record heterogeneously deformed domains in a crystal as well as among the grains, resulting in heterogeneous argon release. In fact, the laser step heating $^{40}Ar/^{39}Ar$ analyses of single phengite crystal in the UHP schists of Lago di Cignana provided significantly irregular age spectrum in comparison with the phengite from the Sanbagawa schists of which the age spectra show the perfect plateau for both the phengite separates and a phengite crystal.

A muscovite in metagranitoid from Grand Paradiso Massif in western Alps yielded heterogeneous age values, giving 54 to 218 Ma (Beltrando et al., 2013). The dated points by the crystal edge are significantly younger than the ages in the part far from the edge. These features suggest that the submicrosopic defects occurring preferentially near the crystal edges are affected by the rubbing with other phases, enhancing preferentially the argon release.

Detrital zircons from a traverse along the Asemi River (Sanbagawa Metamorphic Belt, Shikoku, Japan): U-Pb geochronology and Hf isotopic composition

*Ulrich Knittel[1], Shigeyuki Suzuki[2], Monika Walia[3], Juan-Hsi Lee[4], Hao-Yang Lee[5]

Sanbagawa Belt is a classic high-P/low-T metamorphic belt that is exposed over a distance of about 1000 km on Kyushu, Shikoku and Honshu Islands in Japan. The age of this belt has been the focus of many studies in recent years since the discovery of young detrital zircon grains (80 - 95 Ma), younger than the presumed age of peak metamorphism.

Samples for this study come from a traverse along the Asemi River in central Shikoku. Dating of single zircon grains using the LA–ICP–MS U–Pb dating method shows that zircons from all sites investigated are younger than 90 Ma and thus the protoliths are younger than the previously accepted age of metamorphism for this part of the Sanbagawa Belt at ca. 116 Ma. Our sampling sites include the site sampled by Minamishin et al. (1979) which is the reference for metamorphism at ca. 116 Ma in this part of the belt. We therefore conclude that the linear arrays found by Minamishin et al. are mixing lines rather than isochrones. Another sample was taken within the area recently delineated as having experienced eclogite facies metamorphism prior to overprinting in the epidote-amphibolite facies(Taguchi et al., 2018). This implies that the eclogite facies metamorphim took place after 90 Ma, the maximum deposition age of the protolith.

Within the detrital zircon populations contained in the Sanbagawa meta-sediments several age groups are recognized that are also known from SE China. However, compared to those from mainland China, zircons from the Sanbagawa meta-sediments are usually characterized by higher eHf(T) values suggesting higher input of material derived from the depleted mantle. For example, eHf(T) values of zircons of the age group 82-116 Ma range from -2.4 to +9.6 and those of the 127–146 Ma group have altogether positive eHf(T) values of +11.5 to +19.0 indicating depleted mantle sources. We envisage these zircons to have been derived from the ocean side of a magmatic arc. All grains in the range 215-250 Ma are characterized by negative eHf(T) ranging from -2.3 to -15.2, suggesting re-melting of already existing crust.

Tectonic process of the Sanbagawa eclogite: zircon U–Pb and REE composition analyses

*Shogo Aoki[1], Kazumasa Aoki[2], Tatsuki Tsujimori[3], Yuta Tsuchiya[1], Daichi Kato[2]

1. Department of Biosphere-Geosphere Science, Okayama University of Science, 2. Department of Applied Science, Okayama University of Science, 3. Center for Northeast Asian Studies, Tohoku University

High-pressure and low-temperature (HP) metamorphic rocks in the Pacific-type orogeny are relicts of deeply-subducted accretionary prisms along the past subduction zones. The geochronological data of the HP rocks provide us with the time-scale information involved in material cycle from surface to deep mantle.
The Sanbagawa metamorphic belt in SW Japan is one of well-studied HP metamorphic belts in the world. However, the timing of the prograde metamorphism, especially of the eclogite-facies metamorphism has been controversial (e.g. Okamoto et al., 2004; Wallis et al., 2009).In order to solve this issue, we applied in-situ zircon U–Pb age and rare earth element (REE) composition analyses to the Sanbagawa eclogite in central Shikoku.
Igneous core and metamorphic rim domains of the separated zircons can be recognized, based on their cathodoluminescence images and Th/U ratios. The U–Pb datings of those domains clearly show existence of two different metamorphic units in the Sanbagawa metamorphic belt; i.e., one is ca. 120-100 Ma older metamorphic unit and the other is ca. 90 Ma younger one. Chondrite-normalized REE patterns obtained from the metamorphic rims in both units show no Eu anomaly and HREE depletion. These characteristics suggest that each unit suffered the eclogite-facies metamorphism at ca. 120-100 Ma and ca. 90 Ma, respectively.
Our new data combined with the mode of occurrence of the Sanbagawa eclogite in Shikoku are suggestive of the following tectonic scenario:
1. The highest-grade part of the older unit was subducted to the depth over 15 kbar at ca. 120 Ma, and stagnated there until ca. 90Ma.
2. The highest-grade part of the younger unit underwent the eclogite-facies metamorphism at ca. 90 Ma, and was juxtaposed with the eclogite of the older unit at the depth.
3. Both units were exhumed at the same time after the juxtaposition.

Petrological implications of a new occurrence of retrogressed eclogite from the Sanbagawa belt of southwest Japan

*Tomoki Taguchi[1], Shunsuke Endo[2], Yohei Igami[1,3], Akira Miyake[1]

1. Graduate School of Science, Kyoto University, 2. Interdisciplinary Faculty of Science and Engineering, Shimane University, 3. Institute of Materials and Systems for Sustainability, Nagoya University

The Sanbagawa belt is one of the most famous subduction-related high-pressure (HP) metamorphic belts in the world, and the metamorphic facies series of the belt reaches the eclogite facies. Sanbagawa eclogites are found within coarse-grained mafic-ultramafic masses (Iratsu type) and their surrounding fine-grained mafic, pelitic, and siliceous schists (Seba type) in central and eastern Shikoku, southwest, Japan (Aoya & Endo, 2017 JGSJ). However, the regional extent of the eclogite facies region (eclogite unit) has not yet been established because most were overprinted by lower-pressure assemblages during the exhumation stage. In order to document the eclogite facies metamorphic features of the belt, we recently conducted comprehensive petrological studies of the pelitic schists in the Asemi-gawa region of central Shikoku (Taguchi & Enami, 2014a, 2014b JMPS; Taguchi et al., 2019 JMG). Our previous studies have revealed that a new eclogite unit exists in a limited high-grade area of this region and is composed primarily of pelitic schists. A number of petrological studies have been conducted on the mafic lithology of this region (e.g. Otsuki & Banno, 1990 JMG; Aoki et al. 2009 Lithos; Uno et al., 2015 CMP). However, none of these works recognize the presence of a definitive eclogitic indicator (omphacite, jadeite) within the mafic lithologies, which contrasts with the other eclogite units of Shikoku. This hinders the reliable reconstruction of the extent of the eclogite facies metamorphism in the Sanbagawa belt. Based on an integrated petrological and mineralogical approach, this study reports that mafic schist with garnet + omphacite + quartz paragenesis was first discovered in the Asemi-gawa region. The mafic schist occurs as thin layers within pelitic schist of the albite–biotite zone. This rock includes abundant garnet porphyroblasts up to 5 mm in diameter and shows prograde-type compositional zoning with no textural or compositional break. Omphacite in the mafic schist only occurs as inclusions in garnet, and albite is the major Na phase in the matrix, suggesting that the mafic schist represents highly retrogressed eclogite. The omphacite in the sample displays a strong Raman peak at 678 cm^{-1}, and concomitant Raman peaks are all consistent with those of the reference omphacite Raman spectrum. Transmission electron microscopy (TEM) observations showed that the selected area electron diffraction pattern of the omphacite is compatible with the common *P*2/*n* omphacite structure. The combination of Raman geothermobarometries and conventional thermodynamic calculations gives peak (pressure–temperature) *P*–*T* conditions of 1.7–2.0 GPa and 440–540 ˚C for the mafic schist. The peak *P*–*T* values are comparable to those of the schistose eclogitic rocks (Seba type) in other Sanbagawa eclogite units of Shikoku. These findings suggest that most of the schistose eclogites and associated metasedimentary rocks along the Sanbagawa subduction zone probably share similar simple *P*–*T* histories.

P-T estimations of Kashio mylonite in Oshika, Nagano, Japan: Constraints on the amalgamation of Ryoke and Sambagawa belts

*Yoshihiro Nakamura[1], Yutaka Takahasi[1], Tohru Danhara[2], Hideki Iwano[2], Takehumi Hirata[3]

1. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 2. Kyoto Fission-Track Co., Ltd., 3. Geochemical Research Center, The University of Tokyo

Sambagawa (*LTHP*-type) and Ryoke (*HTLP*-type) metamorphic belts are classically termed as a “paired metamorphic belt” and closely related to the island arc magmatism and regional metamorphism in subduction zone (e.g., Brown, 2010). Although almost all Ryoke metamorphic belt in SW Japan are not directly in contact with Sambagawa metamorphic belt, Oshika area in Nagano prefecture, Japan, is one of the few examples of the geological field where can be directly observed the amalgamation of Ryoke and Sambagawa belts along the Median Tectonic Line (MTL). Hence, it is the best place for discussing the relationship between metamorphism and deformation related to the tectonic evolution of MTL. Our detailed investigations of both metamorphic rocks lead to be constraints on the exhumation tectonics of *HPLT*-type metamorphic rocks and tectonic evolution from ductile to brittle deformations in subduction zone.

In this area, it is well known that the medium-*T* mylonite (so called “Kashio mylonite”) is widely exposed along the MTL (Takagi, 1986). We newly found that the low-*T* mylonites, as indicated by the Z-maximum *c* -axis lattice preferred orientations (LPOs) of recrystallized quartz, were also distributed. Both Ryoke and Sambagawa metamorphic rocks were deformed by low-*T* mylonitization within ~500m of the MTL. The mineral stretching with a gentle plunge to the NNE or SSW, suggesting the sinistral shearing, are well developed on the mylonite foliation. In the low-*T* mylonite zone, garnet porphyroclasts showed a significant chemical zoning of the grossular (X_{Grs}) from core to rim. The mylonite foliation was composed of white mica (Si in apfu = 3.38-3.49) and chlorite (X_{Mg} = 0.39-0.41). Based on the chemical analyses of recrystallized minerals, we attempted to apply the geothermometry and barometry. The *P-T* conditions of the low-*T* mylonites were estimated at 420~450 ˚C /0.5-0.6 GPa. A part of the Ryoke pelitic gneiss origin mylonites was estimated at ~540 ˚C /0.9 GPa. These *P-T* conditions of the mylonites are consistent of peak *P-T* conditions during Sambagawa metamorphism (e.g., Enami et al., 1994), suggesting the amalgamation of Ryoke and Sambagawa metamorphic belt during mylonitization.

In addition, U-Pb ages of zircons in the Kashio mylonite of Ryoke metamorphic belt were analysed by LA-ICPMS. The prominent age spectra of the mylonite showed 69.0 +/- 0.6 Ma (*n*=10), suggesting the solidification age of host Ryoke granite. Our data on protolith demonstrate a younger age than previously reported ages during mylonitization (>83 Ma, Kubota and Takeshita, 2008; or 95~85 Ma, Takagi, 1997). This suggests that the host Ryoke granite and Sambagawa metamorphic rocks were deformed by low-*T* mylonitization during 58-69 Ma. After the mylonitization and amalgamation of both metamorphic rocks, the exhumation of Ryoke and Sambagawa belts might be occurred owing to the change in plate motion at around 55 Ma (Seton et al. 2015).

Static phenomena retained by garnet during exhumation of metamorphic rocks

*Masaki Enami[1], Yui Kouketsu[2]

1. Institute for Space–Earth Environmental Research, Nagoya University, 2. Nagoya University

Electron back scatter diffraction (EBSD) method was employed for the analysis of crystallographic orientations of garnet grains to discuss tectonic behavior of various types of metamorphic rocks during exhumation. Selected metamorphic rocks were coesite-eclogite from the Sulu belt, China, granulite in the Mogok belt, Myanmar, and epidote-amphibolite and quartz schist of eclogite and non-eclogite units, respectively, in the Sanbagawa belt, Japan. The garnet grains are grouped into segmentation and honeycomb types. The segments forming an aggregate, which formed by hydration reaction during the exhumation stage, share similar crystallographic orientations, with misorientations of less than 3—4°. This suggests that the segmentation textures were not formed by deformational crush and the grains recorded a static environment during exhumation. The Sulu and Mogok garnet grains segmented under granulite-upper amphibolite facies conditions have been continually exhumed to the earth's surface without incurring specific deformation and/or rotation. The garnet grains in the epidote-amphibolite from the Sanbagawa eclogite unit were once fragmented by hydration reactions during exhumation and have subsequently become unified by hydration reactions during prograde epidote-amphibolite facies metamorphism. This fact indicates that the Sanbagawa garnet grains in the eclogite unit have recorded static conditions during the hydration and dehydration stages. Honeycomb garnet in a quartz schist from the Sanbagawa non-eclogite unit, which formed during prograde stage under the lower epidote-amphibolite facies, also shows no evidence suggesting deformation processes. This sample might not have undergone significant deformation during exhumation from depths of 25—30 km (0.8—0.9 GPa) to the earth's surface. Such undeformed phenomena recorded in these metamorphic garnet grains during exhumation might have been promoted by episodic exhumation, buoyancy-driven and static exhumation of the metamorphic belt, or local concentration of tectonic stress and heterogeneities of deformation impacts caused by the contrast of lithologic competency and tectonic discontinuity development.

Garnet zoning suggesting the correlation between the Higo and Abukuma metamorphic rocks

*Tadao Nishiyama[1], Yuto Wakida[1]

1. Department of Earth and Environmental Sciences, School of Science, Graduate School of Science and Technology, Kumamoto University

The Higo and Abukuma metamorphic rocks are both Cretaceous low P/T metamorphic rocks, located in central Kyushu (the former) and in northeast Japan (the latter), respectively. The correlation between the two metamorphic rocks has been discussed in terms of SHRIMP U-Pb ages of plutonism, metamorphism and sedimentation (Sakashima et al., 2003), although they are separated by more than 1,000 km. This paper presents new evidence for this hypothesis by reporting garnet zoning in the Higo metamorphic rock (HMR) which is very similar to that in the Abukuma metamorphic rock (AMR).

Pelitic and psammitic gneisses in the garnet-cordierite zone in the HMR contains commonly garnet crystals, which are subhedral to euhedral grains of several millimeters in size. We examined chemical zoning of these garnets from 41 samples of pelitic gneiss in the Kousadake area, Kousa and Tomochi Towns, Kumamoto Prefecture. Typical mineral assemblage of the pelitic gneiss is garnet + biotite + K-spar + plagioclase + quartz ± cordierite ± sillimanite. Ilmenite, titanite, and rutile (less common) occur as inclusions in garnet. Garnet zoning can be classified into three types: flat, simple and complex types. The flat type shows no concentration gradient of any component from the core to the rim. The composition ranges from Prp9Alm68Sps3Grs20 to Prp20Alm73Sps3Grs4, depending on the bulk composition of the sample. The simple type shows a gradual change in composition from the core richer in Sps and Grs components (Prp15Alm51Sps26Grs8) to the rim richer in Alm component (Prp15Alm61Sps19Grs3). The complex type has several variations in the zoning, however, all the variations show discontinuous or rapid changes in composition. The complex A type consists of the plateau-like core richer in Sps and Grs components (Prp2Alm36Sps33Grs29) and the rim richer in Alm and Prp components (Prp23Alm67Sps7Grs3). The complex B type shows a core-mantle-rim structure. The core is nearly constant composition with Prp6Alm61Sps14Grs19, followed by a rapid increment of Grs component up to 28 mol % associated with counterpart decrement of Alm and Sps components in the mantle (Prp6Alm58Sps8Grs28). In the rim, Grs and Sps components gradually decrease with counterpart increment of Prp and Alm components to Prp12Alm73Sps5Grs10. The Grs contents in the core of the complex A type and also in the mantle of the complex B type are much higher than those of the simple and flat types, indicating higher pressure condition for the formation. Garnets with these three types of zoning occur randomly in the garnet-cordierite zone of the studied area, suggesting the different nucleation timing of these garnets rather than diffusive homogenization of zoning in higher grade rocks (Yoshimura,1995).

The complex A and B types of zoning are quite similar to those of sector-zoned garnets from the AMR reported by Hiroi et al. (1998), who suggested the followings. These zonings may indicate three stages of garnet growth at different pressures: the earliest stage characterized by relatively low T (~650 C) and medium P (~0.6 GPa), the second stage with much higher pressure up to 1.2 GPa, and the third stage with higher T (~800 C) and lower P (~0.5 GPa). Thus, the HMR may have experienced the P-T path similar to that of the AMR. This similarity of the P-T path together with the consistency of the age of plutonism, metamorphism and sedimentation (Sakashima et a., 2003) strongly suggests that the HMR and AMR may have formed the same geological terrane. The tectonics leading to the large-sale displacement between

©2019. Japan Geoscience Union. All Right Reserved.

the HMR and AMR can be either a nappe tectonics or strike-slip tectonics, although this study cannot provide any information on the tectonics.

$FeAlO_3$ phase at ultrahigh-temperature metamorphic conditions: Evidences from the sillimanite—Fe_2O_3 and sillimanite—Fe_3O_4 systems at 9 kbar and 1050 ℃

*Toshisuke Kawasaki[1], Tatsuro Adachi[2], Hiroaki Ohfuji[1], Yasuhito Osanai[2]

1. Ehime University, 2. Kyushu University

Two high pressure experiments at 9 kbar and 1050 ℃ under moisture condition reveal $FeAlO_3$ phase is stable under ultrahigh-temperature metamorphic conditions. $FeAlO_3$ and corundum newly crystallised accompanying SiO_2-rich melt and vapour among sillimanite crystals from the mixture of Rundvågshetta sillimanite and reagent-grade Fe_2O_3 (weight ratio of 95:5) within Pt capsule. We found no hematite in the charge. In contrast, we found $FeAlO_3$ phase, SiO_2-rich melt and vapour among sillimanite from the mixture of Rundvågshetta sillimanite and reagent-grade Fe_3O_4 at (weight ratio of 86:14) within AuPd capsule. We found a domain composed by $FeAlO_3$, corundum, magnetite—hercynite spinel and ulvöspinel at the bottom part of the charge. The domain was contact with melt among sillimanite. The present results suggest the possibility that $FeAlO_3$ phase would be an index mineral of ultrahigh-temperature metamorphism for the partially melted Fe—Al-rich granulites under hydrous and oxidised environments.

Keywords: FeAlO3 phase, sillimanite, corundum, spinel, ultrahigh-temperature granulies

Halogens in nanogranitoids entrapped during granulite facies to ultrahigh-temperature metamorphism in the lower crust

*Fumiko Higashino[1], Tetsuo Kawakami[2]

1. Graduate School of Environmental Studies, Tohoku University, 2. Graduate School of Science, Kyoto University

Granulite facies to ultrahigh-temperature (UHT) metamorphic terranes in the deep crust are considered as a potential source region of granitoid melts that eventually form plutons (e.g., Sawyer et al., 2011; Brown et al., 2011). Melt inclusions such as “nanogranitoids” and “felsite inclusions” recently found from such granulite facies and UHT metamorphic terranes are the explicit evidence of partial melting (Cesare et al., 2009; 2015; Hiroi et al., 2014). Such inclusions enable us to estimate the melt composition formed by partial melting (Cesare et al., 2015) and to estimate the timing of partial melting when combined with pressure-temperature-time (*P-T-t*) paths (Kawakami et al., 2013; 2016).
In determining the melt compositions using nanogranitoids, re-melting and re-homogenization of nanogranitoid inclusions using piston cylinder is often performed, and nanogranitoids with decrepitation texture are avoided from such experiments (Cesare et al., 2015). However, nanogranitoids that has decrepitation texture are common in high-*T* pelitic gneisses (e.g., Hiroi et al., 2014; Cesare et al., 2015; Kawakami et al., 2016) and if development of such texture is related to the *P-T* path of the host rock as in the case of fluid inclusions (Vityk and Bodnar, 1995), neglecting the decrepitated nanogranitoids might mean neglecting of specific metamorphic history. Therefore, efforts in determining chemical compositions of melt inclusions of decrepitated nanogranitoid inclusions is also valuable. Among various chemical aspects, information on major halogens (F and Cl) in lower crustal nanogranitoids is extremely poor (e.g., Cesare et al., 2015; Acosta-Vigil et al., 2016; Ferrero et al., 2018). This study aims to provide some new data on the halogen contents in nanogranitoids to better understand the partial melting in the granulite facies active lower crust using fully crystallized nanogranitoids.
Nanogranitoid inclusions are found as inclusions in garnet from granulite facies mafic and pelitic gneisses from Balchenfjella (Sør Rondane Mountains, East Antarctica). Mineral assemblages of the large-sized (>100 μm) nanogranitoid inclusions are Bt + Pl + Qtz in mafic gneiss, and Bt + Pl + Qtz + And + Sil in pelitic gneiss. Mesoperthite in the nanogranitoid inclusion and in the matrix of the pelitic gneiss gave temperature of >900 ºC based on ternary feldspar thermometry. These observation evidences that Balchenfjella experienced UHT metamorphism and the nanogranitoid inclusions represent the UHT melt. The re-integrated composition of nanogranitoids range from granodioritic in the mafic gneiss to granitic in the pelitic gneiss, and mostly peraluminous. The peraluminous melt compositions might be a result of post-entrapment interaction between the melt and host garnet. F/Cl ratio of biotite in the nanogranitoids can be an indicator of F/Cl of the nanogranitoid melts, and low F/Cl ratio observed in this study contrasts with high values observed in peraluminous silicic melts from intrusive and extrusive igneous rocks. This suggests that F/Cl ratio in shallower level silicic igneous rocks is mainly controlled by the magmatic processes in the shallow crust, and chemical characteristics of source rocks or F/Cl ratio of the original melts in the source region is of secondary importance.

Significance of high-Ti biotite and anatectic conditions of paragneiss in the Oki-Dogo Island, Japan

Hiroshi Yoshida[1], *Shunsuke Endo[1], Mai Fujiwara[1], Atsushi Kamei[1]

1. Department of Earth Science, Interdisciplinary Faculty of Science and Engineering, Shimane University

The Oki Gneiss exposed on the eastern side of the Oki-Dogo Island in SW Japan consists mainly of paragneiss and subordinate orthogneiss. These lithologies were originated from Paleoproterozoic (~1800 Ma) clastic rocks and granitoids, and subjected to low-P/T type metamorphism associated with anatexis at around 240 Ma (Tsutsumi et al., 2006; Cho et al., 2012). The Oki Gneiss must be a key to understand the correlation with Precambrian basements in the Korean Peninsula and Permo-Triassic tectonic framework of East Asia. In the present study, we conducted field survey in the entire areas of the Oki Gneiss and examined the spatial extent and P–T conditions of high-grade metamorphism and anatexis. Although structures of the Oki Gneiss were affected by intensive Cenozoic volcanic activities, the main foliation (gneissosity) largely strikes E–W and dips to the south or north. Migmatitic gneiss shows complex ptigmatic folding, but outcrops showing polyphase deformation are uncommon and the main foliation probably represents a single deformation phase. Migmatitic pelitic gneiss consists of biotite- and sillimanite-rich melanosome and plagioclase- and quartz-rich leucosome parallel to the main foliation, and is commonly cut by discordant leucogranite dikes. The peak mineral assemblage of aluminous pelitic gneiss is garnet + biotite + sillimanite + cordierite + plagioclase + quartz + spinel (hercynite-gahnite) + ilmenite + rutile + graphite or its partial assemblages. Spinel only occurs in southern areas. Occasionally, euhedral andalusite enclosing sillimanite occurs in the leucosome, and they might be cotectic minerals crystallized during cooling. Garnet grains are chemically homogeneous except for the reverse-zoned (i.e., increase in Mn and decrease in Mg) grain margins. However, some garnet in northern localities faintly preserves growth zoning characterized by high Mn, Ca and Y contents at the core of garnet grains. To estimate peak-T conditions, we used Ti-in-biotite and Zr-in-rutile geothermometers for biotite and rutile in equilibrium with quartz and zircon. High-Ti biotite (up to 5.9 wt% TiO_2) is found as inclusions in garnet and tiny rounded grains completely enclosed within single crystals of matrix quartz or plagioclase. These high-Ti biotite grains imply high-T metamorphism (up to 760˚C), but high-Ti biotite in garnet shows significantly higher Mg#, suggesting Fe-Mg exchange with the host garnet during cooling. Coarse-grained platy biotite aligned in the gneissosity shows low Ti and is associated with low-Zr rutile and sillimanite, suggesting re-equilibration (~550–650˚C) and pervasive ductile deformation during an early retrograde stage. High-Zr rutile (1200–1700 ppm Zr) only occurs as inclusions in garnet with no any associated cracks, and implies high-T conditions of ~750–780˚C. Presuming high-Ti biotite in quartz/plagioclase and homogenous core of garnet are in equilibrium at the thermal peak, combination of conventional geothermobarometers gives peak P–T conditions of ~0.42–0.60 GPa and 760–780˚C for samples from widely-spaced localities. Samples from southern localities tend to show lower P conditions. Calculated phase equilibria verify the coexistence of cordierite, garnet and spinel during anatexis at the estimated peak conditions for the southern samples. The ubiquitous occurrence of high-Ti biotite implies the Oki Gneiss entirely underwent high-grade metamorphism (transitional upper amphibolite to granulite facies). Taken together, the Oki Gneiss represents a Paleoproterozoic basement that was overprinted by a 240 Ma thermal event associated with ductile flow, low-P/T metamorphism and anatexis at mid-crustal levels (~15–20 km).

Eclogite-to-granulite transition in the Ufipa Complex (Tanzania): the time-lag between collision and the granulitization

*Morita Isamu[1], Tatsuki Tsujimori[1], Nelson Boniface[2], Shogo Aoki[3], Kazumasa Aoki[3]

1. Tohoku University, 2. University of Dar es Salaam, 3. Okayama University of Science

Eclogite-to-granulite transition found in the collisional tectonic regime can provide not only regional tectonic history but also basic principles underlying crustal thickening attributed to the continent-continent collision at convergent plate boundary. In order to understand the dynamics and timescale of collision-induced crustal thickening, we conducted petrological and geochronological research for partially granulitized eclogite and associated metamorphic rocks of the Ufipa Complex (Tanzania).

The Ufipa Complex is a newly confirmed Neoproterozoic metamorphic complex that is equivalent to the Mozambique Belt formed during 'Pan-African orogeny'. Granulitized eclogite is a coarse-grained kyanite-bearing retrograde eclogite with the major mineral assemblage of garnet + omphacite + kyanite + rutile; kyanite contains both omphacite and clinozoisite. Kyanite-free eclogite is medium-grained less-retrograded, bimineralic eclogite. Garnet–omphacite–kyanite–quartz geothermobarometry yielded a P = ~1.9–2.1 GPa and T = ~920–960°C for eclogite stage and P = ~1.3–1.6 GPa and T = ~900–940℃ for high-pressure granulite stage.

LA-ICPQMS zircon U–Pb geochronology for the eclogites revealed that time-lag Δt between collision at ~588 Ma and granulite-facies recrystallization at ~559 Ma was ~30 m.y. Zircon growth during eclogite-facies was confirmed by both mineral inclusions and trace-element abundances. In-situ zircon dating using petrographic thin-sections also confirmed the timing of granulitization. The inferred Δt of ~30 m.y. is consistent with other continental collision zones even in Cenozoic orogens in the literatures.

Switching of metamorphic growth kinetics due to volume fraction of metamorphic fluid

*Kazuhiro Miyazaki[1]

1. Orogenic Processes Research Group, Institute of Geology and Geoinformation, Geological Survey of Japan/National Institute of Advanced Industrial Science and Technology

In general, it is predicted that the growth kinetics should switch from interface-controlled to diffusion-controlled kinetics with increasing grain size. Rate constant and diffusion coefficient are required for estimate the critical grain size for the switching. It is assumed that the effective diffusivity is a product among diffusivity of solute in water, volume fraction of metamorphic fluid and tortuosity. Using rate constant of silicate in aqueous fluid and diffusion coefficient of solutes in aqueous fluids, the switching will occur around 1 mm in diameter at 500 degree C and 1 G Pa with 0.02 volume % of metamorphic fluid. The switching will occur around 1 cm with 0.2 volume % of metamorphic fluid, and will occur around 10 cm with 2 % volume of metamorphic fluid, respectively. Accompanying the switching with diffusional instability, growth kinetics can be predicted by degree of supersaturation. Recently, degree of supersaturation or reaction affinity, which is a function of degree of supersaturation, were reported from different metamorphic belts (e.g. Miyazaki, 2015; Spear and Pattison, 2017). Typical value for reaction affinity of the nucleation of a porphyroblast, such as garnet, is 300 J/mol oxygen (Spear and Pattison, 2017). Using this value, diffusional instability will occur above 1 μm. Therefore, garnet should grow unstable and result in highly irregular morphology after the switching. However, such garnet is rare in general regional metamorphic belt. In other word, existence of euhedral to subhedral garnet larger than cm-scale implies interface-controlled growth under sufficient metamorphic fluid condition at deep crustal depths. Unlike in the case of garnet porphyroblast, matrix mineral, such as phengite, probably grew by interface-controlled dissolution-precipitation with non-hydrostatic condition, because supersaturation of the dissolution-precipitation is perhaps much lower than that of net-transfer reaction and size of phengite is usually less than 1 mm.

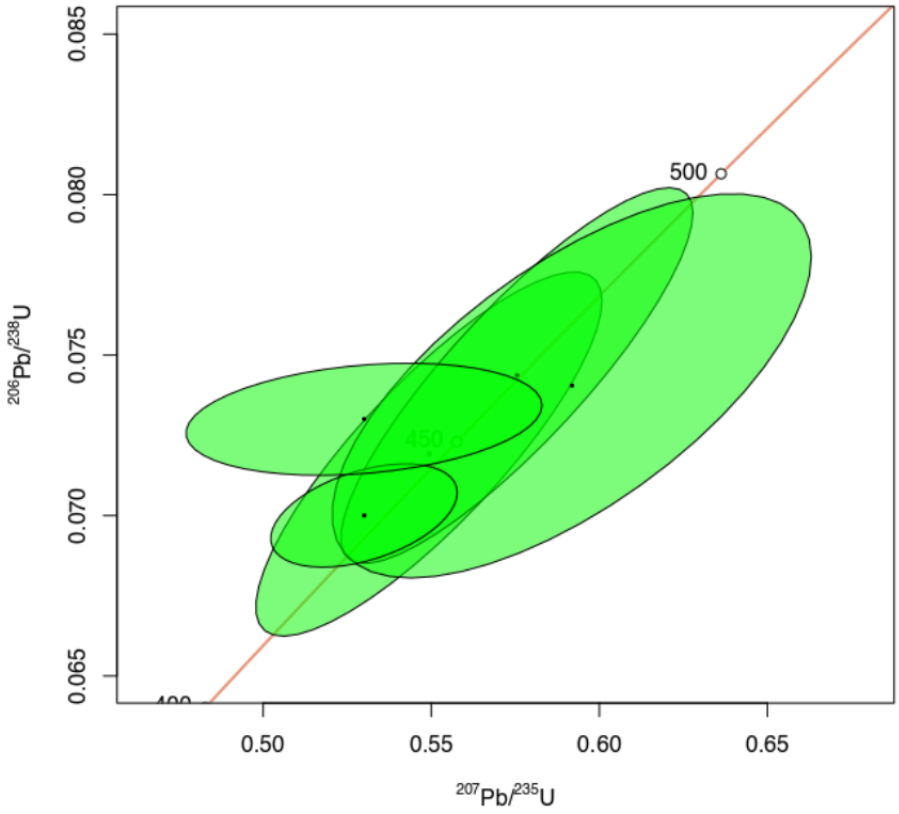
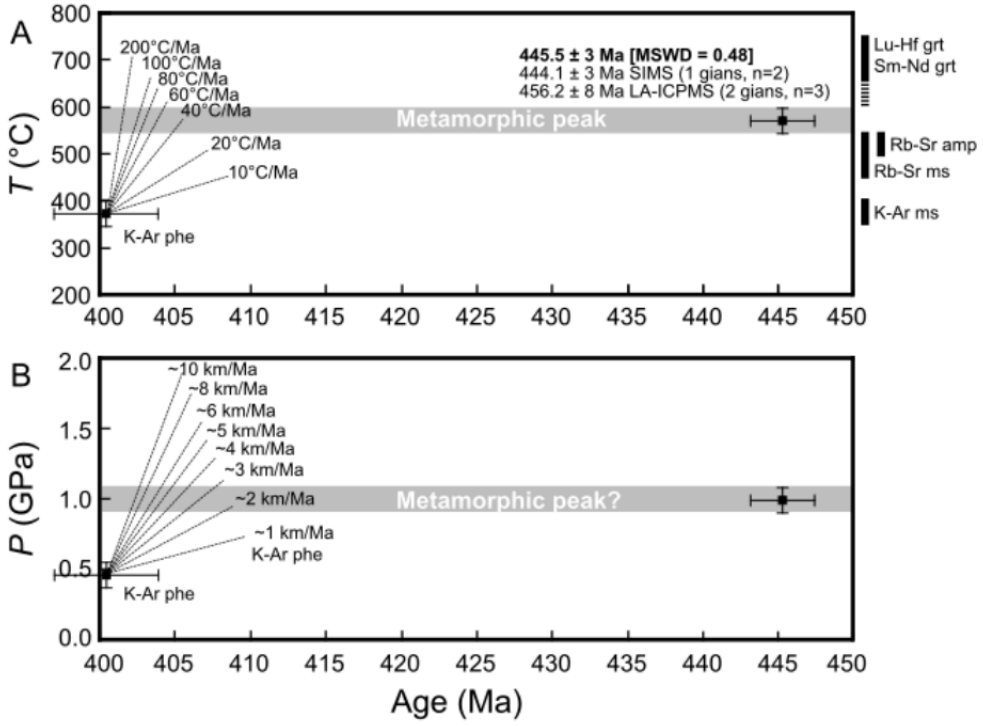
Early Paleozoic subduction-zone metamorphism in Japan: A geochronological reappraisal of Kitomyo Schists



*Shota Matsunaga [1], Tatsuki Tsujimori[1], Atsushi MIYASHITA[2], Shogo Aoki[3], Kazumasa Aoki[3]

1. Tohoku University, 2. Seikei University, 3. Okayama University of Science



Early Paleozoic subduction-related high-pressure metamorphic rocks have been reported from the Kitomyo Schists of the Kurosegawa Belt (Maruyama and Ueda 1975 [doi: 10.2465/ganko1941.70.47]) and the Fuko Pass Metacumulates (FPMC) of the Oeyama Belt (Tsujimori and Liou 2004 [doi: 10.1111/j.1525-1314.2004.00515.x]). In order better to understand the earliest subduction zone record of the ‘proto-Japan’, we revisited the Kitomyo Schists petrologically and gecohronologically. The metasedimentary sample is a well-deformed, quartzo-feldspathic mica schist, with the mineral assemblage of garnet + clinozoisite + phengite (Si p.f.u. = 3.3–3.5) + quartz + albite. Euhedral grains show distinct prograde chemical zoning in spessartine decrease toward the rims. The lack of biotite, oligoclase and paragonite indicate that the schist underwent a HP intermediate type metamorphism. The metabasaltic rock is a well-deformed, amphibolite. Although the amphibolite was overprinted severely at a greenschist-facies condition, relict barroisitic amphibole [B]Na (Na in the B-site) = ~0.69 and rutile, indicating HP metamorphism. LA-ICPQMS and HR-SIMS zircon geochronology yielded 445.5 ±3 Ma for the timing of HP intermediate type metamorphism of the Kitomyo Schists. Metamorphic zircon in metasedimentary sample is characterized by lower U (117–132 μg/g) and lower Th (34–143 μg/g) than detrital magmatic zircons. Our reapproval suggests that the Kitomyo Schists formed in an Early Paleozoic subduction zone with geothermal gradient in the order of ~15°C/km. Such a relatively high geothermal gradient in the subduction zone has produced the HP intermediate type metamorphism. The earliest subduction record in the ‘proto-Japan’ was not ‘cool’ enough to produce blueschist.

Dating a 'princess': U–Pb age determination of 'nunakawaite' (strontio-orthojoaquinite)

*Tatsuki Tsujimori[1], Tomomi Hara[1], Yuzuki Shinji[1], Tomohiro Ishizaka[1], Hiroshi Miyajima[2], Jun-Ichi Kimura[3], Shogo Aoki[4], Kazumasa Aoki[4]

1. Tohoku University, 2. Fossa Magna Museum, 3. JAMSTEC, 4. Okayama University of Science

'Nunakawaite' (strontiojoaquinite) is an orthorhombic variety of strontiojoaquinite [$Sr_2Ba_2(Na,Fe)_2Ti_2[Si_4O_{12}]_2O_2(O,OH)_2 \cdot H_2O$]; it is a rare joaquinite group mineral that is only found in a riebeckite-bearing albitite in the serpentinite-matrix mélange of the Itoigawa–Omi area. The mineral was originally named after 'Princess Nunakawa' (*nunakawa hime*) in the Japanese Shinto mythology '*Kojiki*'.

'Nunakawaite' is characterized by remarkably high Ba, Zr, Nb, Zn, LREEs, MREEs, and enriched in U (35.8–721 $\mu g \cdot g^{-1}$), Pb (2.2–31 $\mu g \cdot g^{-1}$), and Th (7.42–2365 $\mu g \cdot g^{-1}$). LA-ICPMS analyses show highly variable U/Pb ($^{238}U/^{206}Pb$ = 9.245–68.98) and Pb ($^{207}Pb/^{206}Pb$ = 0.0758–0.756) isotope ratios, and the scattered trend define an isochron line with a lower intercept at 89.19 ±1.07 Ma. The 'nunakawaite' U–Pb age confirms that the 'nunakawaite'-hosted riebeckite-bearing albitite formed at late Cretaceous. This implies that the serpentinite-matrix mélange unit with early Paleozoic jadeitites and late Paleozoic blueschist, eclogite and amphibolite was reactivated by a significantly younger tectonic event.

In-situ Sr-Pb isotope analyses show two different isotope trends between Sr-rich accessory minerals in riebeckite-bearing albitite ('nunakawaite' and ohmilite) and those in jadeitite (itoigawaite, stronalsite, vesvianite, Sr-rich epidote). The Sr-Pb isotopes also support the idea that the riebeckite-bearing albitite formed by a fluid-induced metasomatic event different from the jadeitite-forming metasomatism at early Paleozoic. The formation of riebeckite-bearing albitite at ~90 Ma is coeval with late Cretaceous granitic intrusion of the Omi area (youngest zircon U–Pb: 90.8 ±1.1 Ma: Nagamori et al. 2018). The granitic intrusion might have acted an important role in the formation of 'nunakawaite'. In other words, reactivation of metasomatic mineralization in the Paleozoic serpentinite mélange is recorded in the Cretaceous riebeckite-bearing albitite.

Modeling of the progressive evolution of subducting slab composition by sparse modeling

*Kenta Yoshida[1], Tatsu Kuwatani[1,2], Kenta Ueki[1], Ryosuke Oyanagi[1], Shotaro Akaho[3]

1. Japan Agency for Marine-earth Science and Technology (JAMSTEC), 2. PRESTO, Japan Science and Technology Agency, 3. National Institute of Advanced Industrial Science and Technology (AIST)

The progressive evolution of subducting rocks under intermediate high-*P/T* type metamorphism is modelled by using thermodynamic calculation combined with mass-transfer calculation. On the basis of non-negative matrix factorization analysis, Yoshida et al. (2018 J. Metamorph. Geol.) pointed out the evolutional change of the composition of metapelites collected from the Sanbagawa metamorphic belt. The evolutional change can be approximated as the increase of stoichiometric garnet, which may have resulted from the fixation of garnet and the effusion of other components by high-temperature aqueous fluids. To model this progressive compositional evolution more quantitatively, we performed mass-transfer calculation to determine a specific reference frame of the evolutionally-changing whole-rock compositions. Generally, mass-transfer calculation defines one or multiple immobile elements on the basis of petrographic observation, common knowledge of mobility of elements, deviation of the concentration among the dataset used, and so on (e.g., Baumgartner and Olsen, 1995; Ague 2011). The Data-driven Isocon analysis, newly proposed method applying a sparse modeling approach, is designed to determine reference frame of mass-transfer being mostly free from the arbitrariness to choose immobile element(s), and also applicable for the case where no elements can be assumed as a completely immobile element (Kuwatani et al., 2019 in this meeting M-GI33). This new method defines a reference frame of a series of dataset on the basis of the data structure, finding a least-mobile (not necessary to be “immobile”) element. To figure out the mass gain/loss behavior of the subducting metapelites, applying the Data-driven Isocon analysis is suitable because (1) the dataset show weak but mostly monotonous compositional trend (Yoshida et al., 2018); (2) it is difficult to assume a specific immobile element on the basis of the petrographic observation provided previously. We performed the Data-driven Isocon analysis to the major component dataset of the metapelites collected from the Sanbagawa metamorphic belt of the central Shikoku (Goto et al., 1996). The Isocon analysis indicated a total of 6% of mass loss during the progressive metamorphism, which is characterized by the decrease of Na and Si and the increase of divalent cations assuming Al as the least-mobile element. This result indicated that the evolutional change of the Sanbagawa metapelites is characterized not only by mass loss possibly because of the high-temperature fluid, but also some addition of mafic components. Among the high metamorphic grade zone (> garnet zone) of the relevant area, common existence of the ultramafic blocks are observed, suggesting the previous contact with the wedge mantle (Aoya et al., 2013). The addition of the mafic components may have originated from the material transfer from the ultramafic bodies. On the basis of actual mass loss obtained from the Isocon analysis and the thermodynamic modelling, the water production rate can be calculated (e.g., Dragovic et al., 2018). From the chlorite zone (approximately 350 degC, 0.5 GPa) to the oligoclase-biotite zone (approximately 610 degC, 1.0 GPa), water production rate of 64 kg/m3/Myr, being consistent with the previously indicated values (6-90 kg/m3/Myr: Peacock, 1989; 5-20 kg/m3/Myr: Lyubetskaya and Ague, 2009), was obtained.

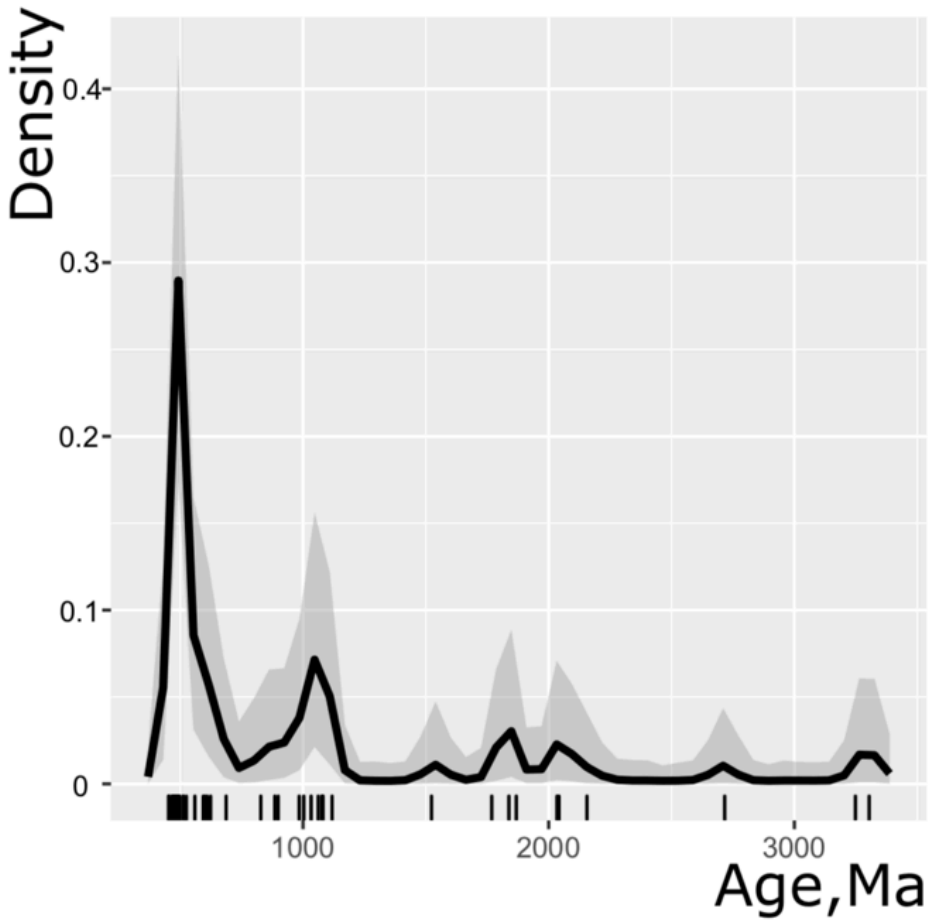
Bayesian statistical evaluation method for detrital zircon geochronology: Applications

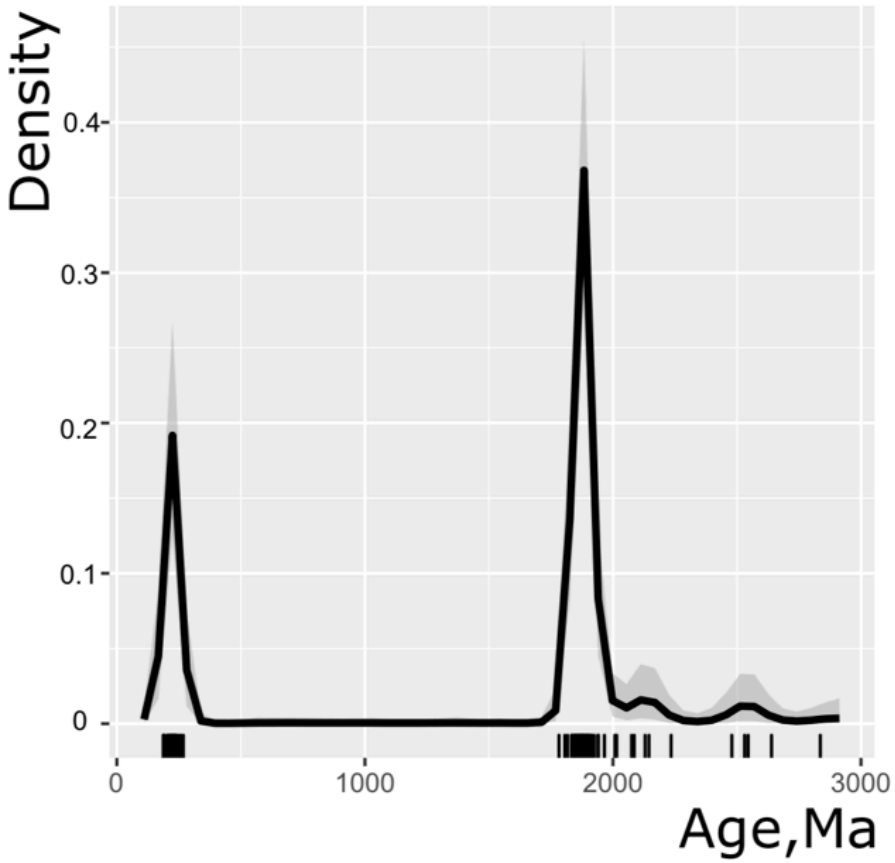
*Tan Furukawa[1], Tatsuki Tsujimori[2], Shogo Aoki[3], Kazumasa Aoki[4]

1. Tohoku University, Department of Earth Science, 2. Tohoku University, 3. Faculty of Biosphere-Geosphere Science, Okayama University of Science, 4. Department of Applied Science Okayama University of Science



Detrital zircon geochoronology is an essential method for determining the provenance and maximum depositional age of sedimentary and metamorphic strata. The age distribution is conventionally evaluated by using histograms. However the lack of the statistical verification of the histograms can cause misunderstanding of data. In order to overcome the raised statistical issues, we established new statistical evaluation method to evaluate distribution for detrital zircon ages, based on Bayesian Statistics (Furukawa and Tsujimori, 2019 JpGU, session M-GI33). As the application of our new statistical evaluation method, LA-ICPMS U-Pb dating for detrital zircon separates from the Carboniferous lawsonite-bearing metagreywacke of the Osayama serpentinite mélange (OSM) and the Cretaceous arkose sandstone of the Akaiwa Formation (AFS), Tetori Group was conducted.

The OSM of the Renge Belt tectonically overlies the pre-Triassic geotectonic units of the Chugoku Mountains (e.g., Tsujimori 1997 Min. Mag.; Tsujimori and Itaya 1999 IAR). The geological and lithological features are similar to those of late Paleozoic blueschist-bearing serpentinite mélange units of the Kurosegawa Belt in Shikoku, Kyushu and Kii Peninsula. Our new data shows that the OSM zircons show at least bimodal age distributions at ~500 Ma and ~1,100 Ma with 95% certainty; the group of the oldest concordant ages reaches 3,300 Ma and the youngest concordant age was 412 Ma.Comparison with existing data in the literatures (e.g. metasediments in the Kii Peninsula: Yoshimoto et al. 2013 JMPS), our Bayesian-based statistical evaluation shows a strong similarity.



We also applied our new evaluation method to the Tetori Group sandstones. The youngest grain yields 187 Ma, and the oldest concordant age was 2,940 Ma. Our evaluation found statistical 'discrepancy' with more than 90% certainty between our AFS data and the existing data of the Itsuki Formation (Kawagoe et al., 2012 Mem. FPDM), which stratigraphically occupy higher portion of the AFS and unconformably overlies the AFS. Throughout the two applications, we introduce how our new statistical evaluation works and its advantages in geological sciences.

3D structural analysis using X-ray Computed Tomography technique: a case study for fault rocks from the Nojima Fault, southwest Japan

*Takafumi Nishiwaki[1], Aiming Lin[1], Bingcheng Liu[1]

1. Kyoto University

Fault rock structures in active fault shear zone can contain important information of seismic slip mechanism (e.g. Lin et al, 2013; Lin and Nishiwaki, 2019). The micro- to macro-structural characteristics of fault rocks formed pass entirely throughout faulting periods, resulting in a broad suite of deformation processes being recorded by deformation structures and textures in spatial within the fault zone (Lin, 2008). Therefore, to understand the spatial variation of meso- and microstructures of fault shear zones, it is important to analyze the three dimensional (3D) images of fault rocks.
In this study, we conducted the 3D structural analysis using X-ray computed tomography (XCT) technique for the cataclastic rock samples including fault gouge obtained from the scientific drilling project "Drilling into Fault Damage Zone (DFDZ)" penetrated throughout the Nojima Fault (NF) Zone that triggered the 1995 M_w 6.9 Kobe earthquake. XCT technique is a non-destructive imaging analysis using CT-value, a function of density and chemical composition. Drilling investigations and 3D structural analyses of drill cores reveal that a ~60 m wide fault damage zone containing a 10–30 cm thick fault gouge zone developed along NF (Nishiwaki et al., 2018; Lin and Nishiwaki, 2019). The fault gouge zone consists of many different color gouge layers 1-2 mm to ~10 cm thick in both sides of the fault plane. In the gouge layer, there is foliations oriented parallel or sub-parallel to the boundaries of each gouge layer. XCT analysis shows the 3D structural features as followings: 1) the main fault plane shows a sharp boundary between two fault gouge layers and cut or offset all other fault gouge layers and fragments, 2) foliations developed within individual fault gouge layers defining the composite planer structures on the X-Z section which show a right-lateral shear sense as that inferred from the topographical and geological evidence, and 3) fine-grained materials were injected into the cataclastic rocks and formed veinlet network structures with complicated spatial variation. These results indicate that the XCT imaging technique is a powerful tool to study 3D deformational structures and textures of fault rocks combining with conventional structural analysis.

High- and low-stress subduction zones recognized in the rock record

*Kazuhiko Ishii[1], Simon Richard Wallis[2]

1. Department of Physical Science, Graduate School of Sciences, Osaka Prefecture University, 2. Department of Earth and Planetary Science, Faculty of Science, The University of Tokyo

Knowledge of the frictional strength along subduction plate boundaries is an essential part of understanding the conditions necessary for plate tectonics, the processes leading to great earthquakes occur along subduction megathrusts and the thermal structure of subduction zones. The frictional strength of faults increases with depth until ductile deformation becomes dominant and is usually expressed as the ratio of shear to normal stress known as the coefficient of friction, mu or the apparent coefficient, mu', when the effects of fluid pressure are taken into account. Lamb (2006) uses force balance for forearc domains to infer mu' = 0.03-0.09 along subduction boundaries. Gao and Wang (2014) infer mu' = 0.02-0.13 based on the comparison between heat flow data and numerical modeling, while England (2018) estimates relatively uniform values mu' = 0.05-0.07 from analytical modeling of heat flow data. In addition, a global 3D thermo-mechanical model presented by Osei Tutu et al. (2018) suggests the average mu' along plate boundaries is required to be <= 0.05 to match the observed present-day plate motion and net rotation.

The published estimates of mu' for subduction boundaries are significantly lower than Byerlee's Law (mu' ~ 0.4, assuming hydrostatic fluid pressure) and closer to values published for seismic slip rates with mu' ~ 0.1 (Di Toro et al., 2011). However, estimates for different subduction zones or obtained by different methods show variations over an order of magnitude. It is desirable to obtain direct estimates of shear stresses from ancient subduction zones both as an independent test of the suggested values and because if high- and low-stress subduction zones can be identified in the ancient record then observations of the associated geology can help identify those characteristics that are responsible for differences in shear strength along subduction zone boundaries.

Thermal modelling shows that high- and low-stress subduction zones can potentially be recognized in the ancient record based on the shape of the prograde P-T path in the forearc region. For all but very young and very slowly subducting slabs, high-stress subduction can be distinguished by curved P–T paths with higher P/T gradients at greater depths. Low-stress subduction over the same domain results in straight paths.

The Cretaceous Sanbagawa belt of SW Japan records metamorphism developed as a result of rapid (20-24 cm/yr) subduction of the Izanagi plate with a slab age of around 60 Ma. The prograde P-T paths show the characteristics predicted for high-stress subduction. Comparisons with thermal modelling suggest an apparent coefficient of friction, mu', of > 0.11, and the corresponding peak shear stresses are ~60 MPa.

Prograde P–T paths and geochronological information from high grade blocks of the Franciscan Complex, USA, indicate rapid cooling during the initial 10-20 Myr subduction with low mu' <= 0.02.

P–T paths in subduction-type metamorphic belts have the potential to be used as paleo stress indicators. Examining differences between high- and low-stress subduction-type metamorphic belts can help determine what controls the strength of different subduction boundaries and assess the potential for

great earthquakes in modern settings.

High-temperature Raman spectroscopic study of CO_2-containing melanophlogite

*Masami Kanzaki[1]

1. Institute for Planetary Matereials, Okayama University

Introduction: Melanophlogite is one of natural silica minerals with a clathrate structure. The structure has two kinds of cages which can host small guest molecules such as CH_4, CO_2, N_2 and H_2S. These are M^{12} and M^{14} cages correspond to pentagondodecahedral [5^{12}] and tetrakaidecahedral [$5^{12}6^2$] units made of 5- and 6-membered SiO_4 rings, respectively. Previous crystal structural studies suggested that CO_2 is mostly locating in larger M^{14} cage. A few years ago, we found a very intense and broad peak below 100 cm^{-1} in CO_2-containing melanophlogite. To clarify the origin of this peak in relation with CO_2 guest molecule, heat treatment experiments and in-situ high-temperature Raman spectroscopy measurements were conducted up to 1100 ^{o}C.
Experimental: Micro-Raman spectra were obtained using a home-built Raman system made of single-monochromator, CCD detector and Ondax SureBlock filters for low frequency measurement. The heat treatment was conducted using a muffle furnace, and the in-situ study was conducted with a wire-heater cell. Natural shperical single crystals from Fortunillo, Italy were crushed and small fragments were used for the experiments.
Results and discussion (origin of low-freq. peak): For the heat treatment experiments, nearly CO_2-free melanophlogite was obtained at 950 ^{o}C for 6 h, judging from intensities of CO_2 vibrational peaks (Fermi diad). Simultaneously, the low-frequency peak nearly disappeared. For shorter time durations or lower treatment temperatures, CO_2 vibrational peaks and low-frequency peak were still visible. We found that CO_2 vibrational peaks of the heat treated samples were split.
For the in-situ study, integrated total intensity of CO_2 vibrational peaks started to drop at around 450 ^{o}C, and simultaneously the low-frequency peak intensity decreased. These peaks completely disappeared at 1100 ^{o}C, while melanophlogite itself remained intact. Thus, it was concluded that the low-frequency peak is originated from CO_2 molecules, not from melanophlogite structure. Librational and translational modes of CO_2 molecules in the cages of melanophlogite would be responsible for the low-frequency peak. Thus, degassing behavior can be studied by monitoring both the low frequency band and the vibrational peaks.
(vibrational peak splitting): At about 450 ^{o}C, we noted that the vibrational CO_2 peak started to split (or more precisely, new peak appeared at slightly higher frequency and grew with temperature while the original peak became weaker). This splitting is partly quenchable, as demonstrated in the heat treated sample mentioned above. Vibrational peak splitting has been reported for CH_4 and H_2S in melanophlogites, and has interpreted as occupancy of those molecules in both M^{14} and M^{12} cages. Thus, peak splitting observed in our study can be interpreted similarly. No splitting of CO_2 has been reported before, except one report at very low temperature. From those observations, we speculated that at above 450 ^{o}C, CO_2 molecule is able to migrate from original M^{14} cage to next M^{14} or M^{12} cages. Because M^{14} cages make an infinite chain by sharing 6-membered rings, migration of CO_2 from M^{14} to M^{14} cages through the 6-membered ring will contribute to long-range diffusion (i.e., degassing). On the other hand, migration of CO_2 from M^{14} to next M^{12} through 5-membered ring will contribute to disordered distribution of CO_2 in M^{12} and M^{14} cages, which caused vibrational peak splittings. Thus, high-temperature Raman spectroscopic study could provide us more insight of diffusion behavior of CO_2 and possibly other gas molecules in melanophlogite structure.

Synthesis of barium carbonate with calcite structure and rotational disorder of carbonate ions

*Hiroyuki Kagi[1], Ayaka Saito[1], Kazuki Komatsu[1], Jun Kawano[2]

1. Geochemical Research Center, Graduate School of Science, University of Tokyo, 2. Fuculty of Science, Hokkaido University

Structures of divalent metal carbonate is constrained by the ionic radii of cations. Cations larger than Ca^{2+} take the aragonite structure and cations smaller than Ca^{2+} take the aragonite structure. Barium carbonate (witherite) takes the aragonite structure and Ba2+ is incompatible to calcite. We have reported that large incompatible cations can be introduced to calcite through amorphous calcium carbonate (ACC). In this study, we synthesized $Ba_{0.7}Ca0.3CO_3$ with the calcite structure by heating treatment on ACC containing Ba^{2+}. The obtained crystal can be interpreted as Ca-containing barium carbonate with the calcite structure, which cannot be found in nature or synthesized from a direct precipitation from the supersaturated solutions.

X-ray diffraction (XRD) patterns of Ba-doped calcite measured at 300 K shows the extinction of 113 reflection with increasing Ba concentration (see Figure 1). The extinction of the 113 reflection was reported on pure calcite at temperatures higher than 1240 K (Ishizawa et al., 2013). The change was attributed to the rotational disorder of CO_3^{2-} ions. In contrast, we have observed the extinction of 113 reflection on the Ba-doped calcite at 300 K.

To investigate the behavior of CO_3^{2-} ions at an atomistic level, molecular dynamics (MD) simulation of Ba-doped calcite was conductedusing the MD program, MXDTRICL (Kawamura 1997). Intensity ratio of reflections 113 to 104 (I_{113}/I_{104}) was measured from XRD patterns obtained from experimental study and MD simulation. $I_{113}/I_{104}$from experiment dropped to 0 at Ba/(Ba + Ca) = 26.8 ±1.6 mol% while that of MD-simulated Ba-doped calcite gradually weakened and did not fall to zero. MD simulations of 25.5% and 50.9% Ba-doped calcite at high temperature were also conducted. In 25.5% Ba-doped calcite, I_{113}/I_{104} remarkably dropped at around 1050 K with the structure of rotationally disordered CO_3^{2-} ions. The transition temperature to the rotational disorder was at around 850 K for 50.9% Ba-doped calcite. These simulated temperatures are much lower than the transition temperature (1250 K) obtained from MD simulation on pure calcite (Kawano et al., 2009). The simulated results showed that the transition temperature to the rotational disordered phase dramatically decreased with increasing Ba/(Ba + Ca) in calcite.

In-situ Raman spectroscopy of ε-FeOOH under high pressures

*Osamu Ikeda[1], Tatsuya Sakamaki[1], Akio Suzuki[1]

1. Department of Earth Science, Graduate School of Science, Tohoku University

ε-FeOOH is one of crucial high-pressure hydrous phases in the Earth's mantle, and is isostructural to δ-AlOOH. A first principles calculation (Gleason et al., 2013) has indicated pressure-induced hydrogen bond symmetrization at 43 GPa, and spin transition of iron at 65 GPa. These transitions cause changes in physical properties, and knowledge of the transition changes can help us to understand the behaviors of hydrous phases under high pressure.

We present a first study of Raman spectroscopy of ε-FeOOH at high pressure and room temperature. The measured sample was polycrystalline ε-FeOOH, which was synthesized in advance from a powder of reagent grade 99 % α-FeOOH at the pressure-temperature condition of 8 GPa and 480 ℃ for 2 hour. Micro-Raman spectrometer NRS-4100TOR (JASCO Corporation), which has a laser with the wavelength 532 nm and power 50 mW installed in Tohoku University, was used to obtain Raman spectra. Symmetric diamond anvil cell with 300 μm culet size was used to generate high pressure. The sample was loaded in the sample chamber of tungsten gasket with NaCl pressure medium. The pressure in the chamber was calculated by means of the ruby luminescence pressure scale (Dewaele et al., 2004).

Along compression, the frequencies of most of peak tops have positive pressure dependences but some peaks (298, 386, 698, and 1099 cm^{-1} at 15 GPa) changed the dependences to negative around 14 GPa. Above 15 GPa some peaks (197, 298, and 443 cm^{-1} at 15 GPa) disappeared and the others (364, 386, 549, 646, 698, and 1099 cm^{-1} at 15 GPa) jumped by frequency 10–30 cm^{-1}. This change around 15 GPa may correspond to the replacement of vibrational modes in Raman spectra of δ-AlOOH at the pressure of 5.6 GPa (Mashino et al., 2016), which indicates a hydrogen-bond related space-group transition from $P2_1nm$ to *Pnnm* (Tsuchiya et al., 2008).

Strong hydrogen-bond generation in dense hydrous magnesium silicate phase E observed by single-crystal neutron diffraction

*Narangoo Purevjav[1], Takuo Okuchi[1], Christina Hoffmann[2]

1. Institute for Planetary Materials, Okayama University, 2. Neutron Scattering Division, Neutron Sciences Directorate, Oak Ridge National Laboratory

Dense hydrous magnesium silicates (DHMS) are considered as the most major water transporters in cold subducting slabs, which are descending into the deep mantle. Phase E [$Mg_2SiH_4O_6$ –ideal] is one of the most important DHMS phases which is stable at conditions between 13 –17 GPa and 800 –1200 ˚C [1]. Besides its stability at such high temperatures, it stores up to 18 wt.% of water within its crystal structure, which is one of the largest among DHMS phases. Thus phase E is one of the most important carriers and transporter of water in the subducting slabs. The crystal structure of phase E was first investigated by single crystal x-ray diffraction except for its hydrogen position [2]. Its structure has brucite-like layers of MgO6 octahedra which are crosslinked by SiO4 tetrahedra [2]. The hydrogen atoms were expected to be located between these MgO6 octahedra layers like those in brucite, $Mg(OH)_2$. The previous expectation on the structure of phase E was recently confirmed by our powder neutron diffraction study [3]. In contrast, present single-crystal neutron diffraction is conducted to investigate hydrogen bonding geometry in phase E structure, including the Debye-Waller factor of the hydrogen, for which we utilize much higher spatial resolution of the single crystal method. The method has been well confirmed to be very sensitive for investigating such properties of the hydrogen atoms within a series of hydrous minerals [4, 5].
We expect that such information is helpful to understand the reason of stability of phase E at the high-temperature condition. A deuterated phase E single crystal was measured by neutron time-of-flight single-crystal Laue diffraction at Spallation Neutron Source, Oak Ridge National Laboratory. From preliminary structure refinement results, we found that the covalent bond O-D was inclined and displaced from the three-fold axis. Such O-D inclination should occur due to interlayer strong hydrogen-bond generation in the phase E structure. The details of the results will be given in the presentation.

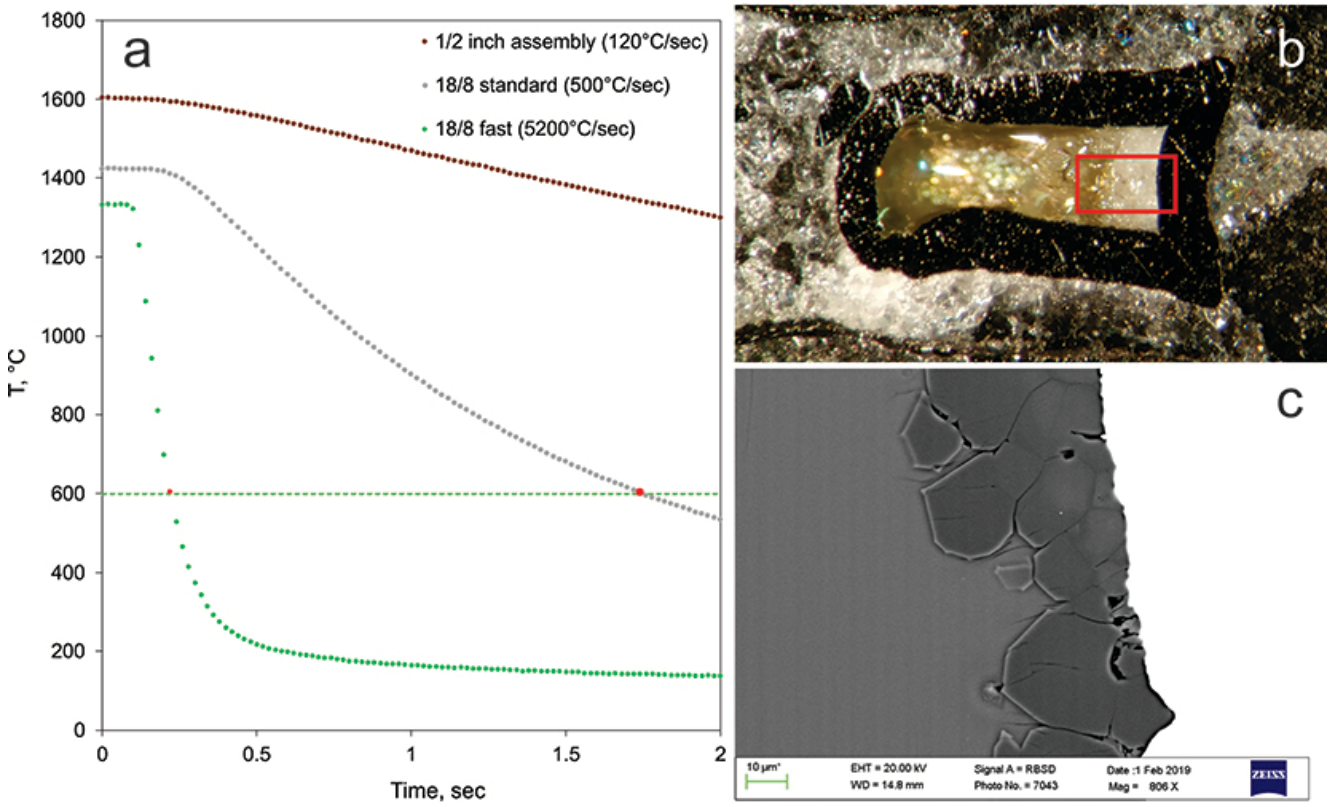
Water partitioning between upper mantle minerals and melts



*Dmitry Bondar[1], Hongzhan Fei[1], Tony Withers[1], Tomoo Katsura[1]

1. Bayerisches Geoinstitut, University of Bayreuth, 95440 Bayreuth, Germany

Water in the Earth's upper mantle is predominantly stored in nominally anhydrous minerals (NAMs) such as olivine, orthopyroxene, clinopyroxene and garnet. Since incorporated water has a strong influence on mantle properties, namely melting temperature, rheology, electrical conductivity and seismic velocity, it is important to know the distribution of water among phases. Knowledge of how water partitions between upper mantle minerals and melts is essential for estimation of water content in incipient melts at different depths, water transport by these melts, and total amount of water in the upper mantle.
There are quite a few studies providing data on water partitioning between NAMs and melts. The most challenging part of these studies is to quench melt coexisting with mineral phases to form glass at elevated pressures (>2 GPa), which is necessary to measure water partitioning with high accuracy. It also becomes more difficult to quench melt with higher Mg/Si ratio into glass, which is necessary in order to crystallize olivine from the melt. Previous studies produced mantle minerals coexisting with quenched melt up to only 5 GPa, namely olivine up to 3 GPa, orthopyroxene up to 4 GPa, clinopyroxene and garnet up to 5 GPa. As a result, there is no systematic pressure, temperature and water content dependence of water partitioning from the data scattered over the narrow pressure range. Many authors also reported that glasses in some run products were not transparent, which implies micro-crystals may have crystallized in those studies.
The difficulty of quenching melt into glass lies in the insufficient cooling rate. The cooling rates of regular piston-cylinder and multi-anvil experiments used for these purposes are 120˚/sec and 500˚/sec, respectively. Quenching glass at elevated pressures and at various compositions is important not only for measuring water partitioning, but also for a number of other tasks, such as melt structure studies and partitioning of other components and elements.
The purposes of the present study are (1) to develop a multi-anvil technique allowing much faster cooling rate than conventional ones and (2) to measure water partitioning between upper mantle minerals and melts for a pressure range from 1 to 13 GPa, which covers the whole upper mantle. Our design for a fast-cooling multi-anvil technique has already been shown to produce a very high quenching rate (5200˚/sec) in comparison with those of regular piston cylinder and multi-anvil apparatus (120˚C/sec and 500˚C/sec, respectively) (Fig. 1a). Using this technique, completely transparent glass coexisting with garnet was successfully quenched at 6 GPa (Fig.1b,c). We plan to improve the fast quenching technique to allow quenching melts under even wider conditions.
Fig 1. (a) Comparison of cooling rate among different assemblies. 1/2 and 18/8 are piston-cylinder and multi-anvil assemblies, respectively. Cooling rate was calculated for the temperature range between target temperature and 600˚C; (b) Glass coexisting with garnet at 6 GPa; (c) BSE image of the area in the red box from picture b.

Drop-solution enthalpy measurement of $MgSiO_3$ majorite

*Hiroshi Kojitani[1], Masamichi Noda[2], Toru Inoue[2,3], Masaki Akaogi[1]

1. Department of Chemistry, Faculty of Science, Gakushuin University, 2. GRC, Ehime University, 3. Dept. of Earth and Planetary systems Science, Hiroshima University

Silicate garnet is one of the major Earth's mantle constituent minerals. With increasing depth, pyroxene components dissolve into the silicate garnet. $MgSiO_3$ majorite (Mj) is an important endmember to express such the pyroxene component dissolving in the silicate garnet solid solution. Recently, we experimentally determined isobaric heat capacity and entropy of $MgSiO_3$ Mj. The stability field of $MgSiO_3$ Mj in the $MgSiO_3$ system thermodynamically calculated using these new thermodynamic data of $MgSiO_3$ Mj together with its enthalpy data measured by Yusa et al. (1993) and Saikia (2008) is not consistent with that determined by previous high-pressure phase relation experiments. In this study, the standard enthalpy of $MgSiO_3$ Mj was determined by drop-solution enthalpy measurement and the obtained enthalpy value was applied to examine the phase stability field of $MgSiO_3$ Mj by thermodynamic calculation.

$MgSiO_3$ Mj samples for the drop-solution calorimetry was the same as those used in the heat capacity measurement, which were synthesized at 19 GPa and 2173 K using a high-pressure apparatus at Ehime University, GRC. The sintered polycrystalline samples were crushed into powder. The drop-solution calorimetry was performed using a Calvet-type high-temperature calorimeter (SETARAM, HT-1000). The powdered sample with weight of about 4 mg was compressed into a pellet and it was dropped into the lead borate solvent ($2PbO{\cdot}B_2O_3$) placed in the calorimeter which was kept at 978 K. The summation of heat content from room temperature to 978 K and solution enthalpy at 978 K, namely drop-solution enthalpy ($\Delta H_{d\text{-}s}$), was measured. To hasten the solution of the samples, the solvent was stirred by bubbling with Ar gas.

$\Delta H_{d\text{-}s}$ ($MgSiO_3$ Mj) was determined to be 69.57±0.77 kJ/mol from the average of five data. This value is the middle between 80.0±2.5 kJ/mol (Yusa et al., 1993) and 59.5±3.2 kJ/mol (Saikia, 2008). From the difference between $\Delta H_{d\text{-}s}$ (MgO) (33.74±0.99 kJ/mol, Kojitani et al. 2012) + $\Delta H_{d\text{-}s}$ (SiO_2 quartz) (40.05± 0.36 kJ/mol, Akaogi et al. 1995) and our $\Delta H_{d\text{-}s}$ ($MgSiO_3$ Mj), the formation enthalpy from the oxides was obtained as 4.2±1.3 kJ/mol. The thermodynamic calculation of the *P-T* phase diagram by adopting the present enthalpy value suggests that the stability field of $MgSiO_3$ Mj would expand to lower temperature region than that determined by previous high-pressure high-temperature experiments and thermodynamic calculations.

High-pressure phase transitions of minerals in the system MgO-TiO_2

*Masaki Akaogi[1], Tetsuya Fujimura[1], Shunto Arai[1], Masaki Okano[1], Hiroshi Kojitani[1]

1. Department of Chemistry, Faculty of Science, Gakushuin University

Mg_2TiO_4, $MgTiO_3$ and $MgTi_2O_5$ form spinel(Sp)-, ilmenite(Ilm)-, and pseudobrookite(Pbr)-type solid solutions, respectively, with other endmembers such as Fe_2TiO_4, $FeTiO_3$ and $FeTi_2O_5$. These phases occur as minor minerals in various igneous and metamorphic rocks. Previous studies on stability relations of Mg_2TiO_4, $MgTiO_3$ and $MgTi_2O_5$ at high pressure were limited below about 3 GPa, except for that the transitions in $MgTiO_3$ were examined up to about 18 GPa. In this study, we have examined the phase transitions of these magnesium titanates up to 28 GPa and 1800 ˚C.

We have determined the high-pressure phase relations in Mg_2TiO_4, $MgTiO_3$ and $MgTi_2O_5$ at 4-28 GPa and 1000-1800 ˚C using multianvil apparatus with the quench method. $MgTiO_3$ ilm transformed to the $LiNbO_3$ (Ln)-type high-pressure phase at 16-20 GPa and 1200-1600 ˚C. The Ln phase was interpreted as the retrograde transformation product from perovskite(Pv)-type $MgTiO_3$ stable at high pressure and high temperature (Linton et al., 1999). Above 21-25 GPa, the recovered phases were MgO and a-PbO_2-type TiO_2, the latter of which was interpreted to be converted from baddeleyite(Bd)-type TiO_2. The transition boundary from Pv to MgO + TiO_2(Bd) has a positive Clapeyron slope. Mg_2TiO_4 Sp dissociates to MgO + $MgTiO_3$ Ilm at about 1 GPa, and at higher pressure they changes to MgO + $MgTiO_3$ Pv and subsequently to 2MgO + TiO_2(Bd). $MgTi_2O_5$ Pbr decomposes at 1-2 GPa to $MgTiO_3$ Ilm + TiO_2 rutile(Ru), the latter of which transforms to a-PbO_2-type TiO_2. At higher pressure, the assemblage changes to $MgTiO_3$ Pv + a-PbO_2-type TiO_2, and subsequently to MgO + 2TiO_2(Bd). These results show that the mixtures of MgO and TiO_2 (Bd) are stable above 20-25 GPa in the three magnesium titanates. We also performed Rietveld structure refinement of Ln-type $MgTiO_3$ using synchrotron powder X-ray diffraction data, and confirmed that Ti^{4+} and Mg^{2+} ions are slightly deviated from the centrosymmetric positions in the octahedra which gives polarity of the $MgTiO_3$ Ln-phase.

The high-pressure transition behaviors of Mg_2TiO_4, $MgTiO_3$ and $MgTi_2O_5$ are similar to those of Fe_2TiO_4, $FeTiO_3$ and $FeTi_2O_5$, respectively, up to moderate pressures, where the phases transform to the assemblages involving $MTiO_3$ Ilm and Pv (M = Mg, Fe). However, the transition behaviors are different at higher pressures: Fe_2TiO_4 transforms to $CaTi_2O_4$(CT)-type phase, and $FeTiO_3$ dissociates to Fe_2TiO_4 CT + a dense orthorhombic $FeTi_2O_5$ phase (Akaogi et al., 2017).

Phase change process of iron sulfide nanoparticle from amorphous to crystalline with grain growth

*Yoshinari Sano[1], Atsushi Kyono[2], Yasuhiro Yoneda[3], Gen-ichiro Yamamoto[1]

1. Graduate School of Life and Environmental Sciences, University of Tsukuba, 2. Faculty of Life and Environmental Sciences, University of Tsukuba, 3. Japan Atomic Energy Agency

1. Introduction

In anaerobic marine sediments, sulfate-reducing bacteria (SRB) acquires metabolic energy by reducing sulfate ions (SO_4^{2-}) to sulfide ions (S^{2-}). Sulfide ions are, furthermore, oxidized from sulfur (S^0) to sulfate ions by the metabolic activity of sulfur bacteria (SB). These series of reaction are called geochemical sulfur cycle and considered as one of the most important elemental cycle. In the reaction, a part of the sulfide ions is readily reacted with ferrous ions (Fe^{2+}) to produce iron sulfide nanoparticle (FeS), and which grows to more stable mackinawite (FeS). In the previous study, it was reported that the crystal growth from iron sulfide nanoparticle to mackinawite occurred in hydrothermal aging experiment at 120°C (Csákberé nyi-Malasics et al., 2012). Despite its importance as a precursor of mackinawite, phase change process of the iron sulfide nanoparticle from amorphous to crystalline has not been elucidated yet. In this study, synchrotron X-ray total scattering measurement and atomic Pair Distribution Function (PDF) analysis were performed to clarify the crystal structure change of iron sulfide nanoparticle with grain growth.

2. Experimental method

At first, iron sulfide nanoparticle suspension was synthesized by the mixing 10 mL of 0.2 M $(NH_4)_2Fe(SO_4)_2 \cdot 6H_2O$ solution with 10 mL of 0.4 M $Na_2S \cdot 9H_2O$ solution in N_2 gas atmosphere. The synthesized suspensions were heated in a Teflon container at 120°C for 2, 4, 6, 8 and 12 hours, respectively. After the end of heating experiments, the solid phases were dried by blowing N_2 gas and stored in vacuum. Synchrotron X-ray total scattering measurements were performed at beamline BL14B1 in SPring-8. The incident beam was monochromatized to a wavelength of 0.20606 Å. X-ray total scattering data at 20 K and 300 K were collected in the Q range between 0 and 25 $Å^{-1}$. Atomic Pair Distribution Function (PDF) analysis was applied to X-ray total scattering data.

3. Results and discussion

The PDF pattern of iron sulfide nanoparticle synthesized in the study almost disappeared at about 2 nm. Those of samples heated for 2, 4, 6, 8, 12 h are, on the other hand, were continuously observed up to 4 nm. This result showed that the particle size of iron sulfide nanoparticle was grown to 4 nm by the heating at 120°C. The Fe-S and Fe-Fe distances obtained by the PDF analysis are 2.25 and 2.65 Å, respectively, which suggests that the local atomic structure around Fe, ie FeS_4 tetrahedra, in iron sulfide nanoparticle almost remains unchanged by particle growth. Compared with the structure model of mackinawite, the iron sulfide nanoparticle would consist of disordered arrangement of FeS_4 tetrahedra. This is consistent with the structure model of iron sulfide nanoparticle proposed by the previous study (Wolthers et al., 2003; Ohfuji and Rickard, 2006; Jeong et al., 2008). In the presentation, we will discuss structure change associated with medium-range atomic order and propose phase change process from amorphous to crystalline by particle growth.

Texture formation in quenching of Fe-S-O micro melt spherules

*Hiroshi Isobe[1]

1. Department of Earth and Environmental Sciences, Faculty of Advanced Science and Technology, Kumamoto University

Microtexture of minerals records physical, chemical and kinetic conditions at crystal growth. Local processes at crystal growth and migration of elements have important role in the rapid crystal growth. Especially, Fe and S-bearing systems are oxidation and evaporation sensitive. And fine particles can be quenched very quickly from high temperature, quench crystals show characteristic textures of crystals. In this study, quick heating and cooling experiments of powdered iron sulfide particles were carried out with a fine particles free falling apparatus with controlled gas flow (Isobe and Gondo, 2013). Oxygen fugacity was controlled to FMQ -0.5, +0.9 or +2.4 log unit. Particles can be heated to the maximum temperatures of approximately 1600˚C within two seconds, are kept approximately one second and quenched within a second.

Run products particles were completely melted and show rounded shape with smooth surface or characteristic texture. Spherical products were initially well homogenized from inhomogeneous starting materials by complete melting. Then, spherules are oxidized and show growth of secondary crystals with rapid cooling.

FeS dendritic crystals occur in sulfur-rich spherules with low fO2 condition. In the higher fO2 experiments, rapid growth of magnetite in Fe-O melt produces iron metal phase from an excess iron in melt phase relative to magnetite.

Compositions of iron sulfide melt in fine spherules are initially close to FeS and are losing S with oxidation following Fe-S-O phase relations depending on oxygen fugacity even in a few seconds. Crystallization of FeS crystals can reduce sulfur content in melt, then evaporation of sulfur can be suppressed. Evaporation of sulfur may be promoted by oxidation of iron sulfide melt to occur magnetite as liquidus phase.

Development of a software for electron diffraction simulation based on dynamical theory and its application to mineralogy

*Yusuke Seto[1], Masahiro Ohtuka[3], Akira Miyake[2]

1. Graduate School of Science, Kobe University, 2. Graduate School of Science, Kyoto University, 3. Graduate School of Technology, Nagoya University

Electron diffraction technique is widely used for the phase identification and crystal structure determination of Earth and planetary materials. Electrons are scattered by the positive potential inside the electron cloud, resulting that the interaction of electrons with matter is much stronger (10^6-10^7) than that of X-rays. This has the advantage that the diffracted electron beams have a high intensity and the patterns can directly be observed on the viewing screen of the electron microscope. The strong interaction, however, easily causes multiple scattering, and thereby the intensities of the reflections are much influenced by the dynamical effects. This makes structure determinations from electron diffraction more difficult and less reliable than that from XRD data. In order to treat the dynamical effects, a lot of computer resources of Fourier transform and/or eigenvalue problem are required, and consequently, such a dynamical analysis was limited to simple structured materials. However, that situation has been changing. In recent years, many-core CPUs can make a lot of computation possible. Moreover, with the rapid spread of field emission transmission electron microscopes (TEM) and sensitive detectors (CCD or CMOS), the quantitative analyses of electron intensities become available even from nanometer-sized minerals.

In the present study, the authors developed a GUI-based software, ReciPro, that simulates electron diffraction patterns using one of the dynamical theories, called the Bethe method (or Bloch wave eigenvalue method), in which the three dimensional eigenvalues of the electron wave function in a crystalline specimen are solved with the appropriate boundary conditions on the entrance and exit face of the crystal. By this method, the diffraction patterns (SAED and CBED) can be obtained with a good accuracy and speed regardless of the specimen thickness. Moreover, ReciPro provides following features: i) Loading any crystal structure including AMCSD (American Mineralogist Crystal Structure Database) database or COD (Crystallography Open Database). ii) Changing a specimen orientation and TEM conditions freely by a mouse operation. iii) Displaying Digital Micrograph file, the de facto standard of TEM image file format developed by Gatan inc., can be read and displayed. iv) Fitting diffraction spots by two dimensional pseudo-Voigt functions. v) Quantitative comparison of simulated and experimental diffraction patterns, and many more features. In the presentation, the authors will report examples of reproducibility of simulated diffraction patterns (SAED and CBED) for several minerals, and future prospects of this approach.

Site occupation analysis for cation in minerals by analytical electron microscopy: application of TEM-ALCHEMI for earth and planetary science

*Yohei Igami[1], Shunsuke Muto[1], Masahiro Ohtsuka[3], Akira Miyake[2], Takahiro Kuribayashi[4], Shoichi Toh[5]

1. Institute of Materials and Systems for Sustainability, Nagoya University, 2. Graduate School of Science, Kyoto University, 3. Graduate School of Engineering, Nagoya University, 4. Graduate School of Science, Tohoku University, 5. Faculty of Science, Fukuoka University

Cation site occupation in natural minerals is very important for earth and planetary science, because it should reflect thermal histories such as peak temperatures and cooling rates. However, natural minerals generally have various complex micro-textures. Therefore, determination of cation site occupation from micrometric regions has been required.
Spence and Taftø [1] developed the ALCHEMI (Atom Location by CHanneling-Enhanced MIcroanalysis) method in which transmission electron microscope with energy dispersive X-ray spectrometer (TEM-EDS) is used to determine the crystallographic sites of impurity elements from micrometric regions in crystals on the basis of channeling-enhanced X-ray emissions. Subsequent improvements in the ALCHEMI have led to more statistical method called HARECXS (High Angular Resolution Electron Channeling X-ray Spectroscopy) or St-ALCHEMI (statistical ALCHEMI). This method is widely applicable including minerals with low symmetric structures (reviewed by [2]). Recently, we successfully determined the order parameter of Al and Si in the tetrahedral sites in sillimanite (Al_2SiO_5) at the areas free from precipitates of mullite ($3Al_2O_3$ $2SiO_2$) and glasses [3]. In this study, we carried out the ALCHEMI/HARECXS method for major rock forming minerals to extend its applicability in earth and planetary science.
Sample minerals are olivine ($[Mg, Fe]_2SiO_4$), diopside ($Ca[Mg, Fe]Si_2O_6$) and sillimanite. The samples were prepared by a focused ion beam system (FIB, FEI Quanta 200 3DS or Helios NanoLab G3 CX), and examined by using TEM-EDS (JEOL JEM-2100F, JED-2300T). X-ray signals generated under illumination of 200 keV electrons were collected as a function of electron beam direction. The homogeneous areas free from dislocations or inclusions were selected as regions of interest.
The one-dimensional tilting ALCHEMI datasets under the condition exciting the particular systematic reflection row (HARECXS profiles) were successfully obtained from regions ~1 μm in diameter by automated control of beam tilting and X-ray detection following Muto and Ohtsuka [2]. For determination of cation site occupation, we performed theoretical calculations of HARECXS profiles using ICSC code [4] and evaluated sample thicknesses by convergent-beam electron diffraction. The experimentally obtained HARECXS profiles were fitted by linear combinations of calculated profiles, and the site occupations of constituent cations were quantitatively determined. Obtained results were almost consistent with the results determined by single crystal X-ray diffraction experiments. Moreover, the cation distributions in annealed samples showed continuous disordering with increasing temperature. This study suggests that the ALCHEMI/HARECXS method is one of the most promising candidates for accurate analysis of minerals in particular the samples having heterogeneous textures.

Molecular Dynamics Study of Soret Effect in Silicate Liquids

*Fumiya Noritake[1]

1. Graduate Faculty of interdisciplinary Research, University of Yamanashi

There are various transportation phenomena driven a potential gradient. The Soret effect is diffusion driven by a temperature gradient (Soret, 1879; Ludwig, 1856). The inverse effect is known as Dufour effect. The Soret effect is sometime used in explanation of fractionation phenomena in geology (Lesher, 1986; Dominguez et al., 2011). Recently Kishi et al. (2018) reports a distribution anomaly of composition in calcium aluminosilicate glass made by migration of high-temperature metal sphere induced by laser irradiation (Hidai et al., 2016). The rate of fractionation by temperature gradient is determined by both thermal diffusivity (D_T) and mass diffusivities (D) because the total net flux must be zero in a steady state. Consequently, understanding the Soret coefficient (D_T/D, or $\partial \log \rho / \partial T$) is difficult because the coefficient might be affected by not only atomic mass and inter-atomic interaction that affect activation energy but also geometric/structural factor.
I applied the molecular dynamics (MD) simulations for pseudo binary and aluminosilicate liquids to investigate the mechanism of fractionation by temperature gradient. The MD simulation appropriate method for this study because it gives trajectories of each atoms in the simulation cells and potentials of each atom at any point in simulation time. MD simulations of sodium/calcium-silicate/aluminosilicate liquids were performed using MXDORTO code (Sakuma & Kawamura, 2009). The simulation conditions are as follows: The inter-atomic potential model was taken from Feuston & Garofalini (1988). Systems of approximately 30000 particles in rod-shaped (approximately 5 x 5 x 17 nm) simulation cell in periodic boundary condition were firstly annealed for 2 ns at 2000 K from randomly generated structure. Then we started the simulations in temperature gradient. The temperatures in sliced region (approximately 0.35 nm thickness) perpendicular to the longest axis at the end and the center of simulation cell were maintained 2000 and 3500 K using the scaling procedure. After several tens nano-second simulations, we confirmed the changes in distribution of composition. The concentration of SiO_2 in the high-temperature center part slightly increases as simulation proceeds. In contrast the concentration of CaO and Na_2O in that part slightly decreases. Soret coefficients for each cation has linear relation with the half width of potential energy distribution in binary silicates. The existence of Al_2O_3 content impedes fractionation in sodium-aluminosilicate whereas it enhances in calcium-aluminosilicate. This behavior might be caused by the charge compensation of 4-fold aluminum cation.

Seebeck coefficient of olivine: Implausible Mercury's thermoelectric dynamo

*Hitoshi Gomi[1], Takashi Yoshino[1], Akira Yoneda[1]

1. Okayama University

The Mercury's magnetic fields are known to be weaker than that predicted by conventional dynamo models. In order to explain the Mercury's weak magnetic field, several models are proposed (Stanley and Glatzmaier, 2010). One of them is the thermoelectric dynamo, which drive the dynamo via the thermoelectric force (Stevenson, 1987). The field strength is proportional to the relative Seebeck coefficient between the core and the mantle. Because the Seebeck coefficient of insulators is more than one order larger than that of metals, the Seebeck coefficient of Mercury's mantle is the central parameter. Therefore, we investigated the Seebeck coefficient of mantle minerals from the first-principles calculations. The structure relaxation and band structure calculations were conducted by using the Quantum ESPRESSO package. The bandgap energy was calibrated by means of the quasiparticles self-consistent GW (QSGW) approximation adopted in the ecalj package. The Seebeck coefficient was calculated via the Boltzmann equation implemented in the BoltzTraP package. The results indicate that the Seebeck coefficient of forsterite with a small amount of dopant exhibit comparable to that previously thought (|S| ~ 1000 mV/K). This value may constrain the upper limit. The Mercury's mantle may contain ~3wt% FeO (Robinson and Taylor, 2001). The Fe substitution and O vacancy act as donor, which is predicted to reduce the Seebeck coefficient, significantly. The field strength also depends on the electrical conductivity of the mangle. Recent high pressure experiments suggest that the electrical conductivity of the Earth's mantle is ~ 10^{-2} Sm. Considering the both of the Seebeck coefficient and the electrical conductivity of mantle material, the field strength is calculated to be ~ 0.1 nT, which is significantly weaker than the observed value of 300 nT. Therefore, we conclude that the thermoelectric dynamo cannot generate the Mercury's magnetic fields.

Density measurement of liquid gallium using externally heated diamond anvil cell

*Ryo Tsuruoka[1], Hidenori Terasaki[1], Seiji Kamada[2], Iori Yamada[1], Fumiya Maeda[3], Tadashi Kondo[1], Satoru Urakawa[4], Naohisa Hirao[5], Akihiko Machida[6]

Japan Synchrotron Radiation Research Institute, 6. National Institutes for Quantum and Radiological Science and Technology

Density of a liquid metal at high pressure and high temperature is fundamental information to determine its equation of state (EOS). Gallium (Ga) which has a low melting temperature at ambient pressure has been reported to have complex liquid structures. The densities of Ga at high pressures have been reported based on the measurement of volume changes (Lyapin et al. 2008), that of liquid structures (Yu et al. 2012), and that of sound velocity (Ayrinhac et al. 2015). However, these densities were not consistent each other. In this study, we measured densities of liquid Ga at high pressure using an X-ray absorption method with an externally heated diamond anvil cell (EHDAC).

Ga sample and reference materials (KBr, RbBr) were loaded into each hole drilled on a pre-indented Re gasket. The reference materials were used for estimation of sample thickness and for determination of experimental pressures (Takubo et al. 2018). The Re gasket was coated with Al_2O_3 to avoid a reaction between the Ga sample and the gasket. High pressure was generated using a symmetric DAC with a lever-arm frame. The culet size of the diamond anvils used was 600 μm. High temperature was generated using external heaters composed of Pt-Rh wires with a ZrO_2 insulator. X-ray absorption measurements were conducted with monochromatic X-ray of 30 keV at BL10XU and BL22XU beamlines in SPring-8. Intensities of incident and transmitted X-rays were detected using a photo-diode or ion chambers. Experimental pressures were determined based on EOSs of KBr and RbBr using their volumes from XRD patterns collected using a flat panel detector.

The densities of liquid Ga were measured up to 9.4 GPa and 500 K. The densities of liquid Ga obtained at 4–9 GPa range 6.53(7)–7.25(14) g/cm^3. The measured density at 4 GPa is consistent with the density calculated from sound velocity data reported by Ayrinhac et al. (2015).

Density measurements of crystalline Fe and amorphous materials at high pressure

*Seiji Kamada[1,2], Hidenori Terasaki[3], Yusaku Takubo[3], Ryo Tsuruoka[3], Fumiya Maeda[2], Rui Yamada[1], Saori Kawaguchi[4], Naohisa Hirao[4], Akihiko Machida[5]

1. Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, 2. Department of Earth Science, Graduate School of Science, Tohoku University, 3. Department of Earth and Space Science, Graduate School of Science, Osaka University, 4. JASRI, 5. QST

Terrestrial planets, such as Earth, Venus, Mars, and Mercury, have metallic liquid and/or solid cores. The cores consistent of mainly Fe and Ni with small amounts of light elements. Chemical compositions of solid state cores have been estimated by density measurements of crystalline core materials in a number of previous studies. On the other hand, there are a few previous studies on density measurements of liquid samples because of technical difficulties. Although Morard et al. (2008, 2013) obtained densities of liquid Fe with light elements by structure analyses from XRD patterns, accuracy of the densities was under debate because they used XRD patterns with narrow reciprocal lattice spaces. In this study, we have measured densities of crystalline Fe and amorphous materials using an X-ray absorption method in order to avoid problems of small diffraction angles due to a diamond anvil cell (DAC).
High pressure measurements were performed using a DAC with a gasket having 3 sample chambers. Fe or amorphous samples were loaded in a sample chamber for density measurements. Powders of KCl, KBr, or RbBr as references for thickness were also loaded in the other sample chambers. After XRD patterns were taken from all samples and references, absorption profiles were also measured. Experimental pressures were determined using pressure averages between KCl and KBr, or KBr and RbBr. Densities based on the X-ray absorption method were obtained using the Lambert Beer law with mass absorption coefficients from NIST data base. Densities of crystalline Fe were obtained up to 20 GPa and density differences between XRD and the absorption method were less than 2%. This technique was applied to densities of amorphous materials as well. We will report the densities based on the X-ray absorption method.

DAC-GHz ultrasonic P wave velocity measurement on KCl and natural olivine

*Akira Yoneda[1], Shinichiro Kobayashi[2], Seiji Kamada[3]

1. Institute for planetary materials, Okayama University, 2. Department of Earth Science, Graduate school of Science, Tohoku Univ., 3. Frontier Research Institute for Interdisciplinary Sciences, Tohoku Univ.

GHz ultrasonic velocity measurements has been developed up to 14 GPa in diamond anvil cell (DAC). In order for GHz ultrasonic measurement, both P and S wave buffer rods were manufactured through sputtering ZnO piezoelectric film on single crystal rods, such as sapphire, rutile, and YAG. Several technical breakthroughs were achieved before observing stable signals from the specimen squeezed in DAC: (1) Wiping by aqueous ammonia on the contact surfaces enhances transmissibility of GHz wave from buffer rod to diamond. (2) Cleaning by lathery detergent and water jet is effective to remove sticky staff on rear surface of diamond. (3) Steel ball supporter provides easier adjustment of contact between buffer rod and diamond. Consequently, we succeeded to demonstrate performance of DAC-GHz system through KCl and natural olivine samples.

Kikai submarine caldera to the south of the Kyushu Island, SW Japan, had at least three eruptions at 140, 95 and 7.3 ka, and its collapse occurred at 7.3 ka during the latest supereruption (>500 $km^3$of magma) in the Japanese Archipelago. We have conducted series of research cruises using the T/S Fukae-maru in this caldera to understand the melt supply system for the supereruption through tracing past supereruptions, identifying current volcanic activities, and imaging current structure.

The surveys to trace past supereruptions include multi-channel seismic reflection (MCS) surveys, visual observation and sediments sampling using remotely operated vehicle (ROV; SHINDAI-2K), and land observation. The MCS surveys provide high resolution marine seismic reflection images, which are classified into seven seismic units characterized by distinctive seismic facies. We interpreted that the upper most seismic unit should be a candidate layer for Koya ignimbrite due to 7.3 ka Akahoya eruption, because the deposit from the Kagoshima mainland with regressive surface erosion on progradational HST (highstand system tract) locates beneath this seismic unit and the deposit probably corresponds to the last glacial period (18 ka) (Shimizu et al., this meeting). This interpretation is supported by the chemical composition of glass shard samples on the sea floor near the caldera wall, which were obtained by ROV divings. The chemical composition of the glass shards indicates characteristic bimodal SiO_2 contents, which consistent with unique characteristic for the Akahoya eruption (Nakaoka et al., this meeting). This seismic unit distributes around the caldera and its whole volume will be calculated to estimate reliable magma volume during the Akahoya eruption. Further, visual observation of the ocean bottom by ROV (Kiyosugi et al., this meeting) and land observation (Suzuki-Kamata et al., this meeting) suggest eruption styles of submarine volcanoes and ignimbrite deposition modes.

Current volcanic activities and structures are obtained using geophysical approaches. High volcanic activities are identified by five months of seismicity data using five ocean bottom seismometers (OBSs): 1100 volcanic tremor events with its fundamental frequency of 2 Hz, high frequency seismic events with obvious P and S arrival, and monochromatic variation events are detected beneath and/or around the caldera (Seto et al., this meeting). Imaging current structures are provided by multi-beam echosounder mapping with backscatter imaging, gravity analysis, and marine electromagnetic experiment. All these structures outside of the caldera wallshows asymmetric features between the trench side and the back-arc side. The backscatter images show rough morphological features in the back-arc side, suggesting recent local eruptions, in contrast with smooth morphology in the trench side. The gravity analysis indicates that thinner upper crust in the back-arc side than that in the trench side (Morita, 2019). The

electromagnetic field variation data obtained by 10 ocean-bottom electro-magnetometers (OBEMs) observation allowed us to image a 3-D electrical resistivity structure, which also shows asymmetric feature at <5-10 km depths (Matsuno et al., this meeting). These asymmetric features between the trench side and the back-arc side suggest that Kikai submarine caldera formation is basically controlled by the subducting slab.

Kikai caldera, most of which is submerged in the seawater of the south of the Kyusyu Island, southwest Japan, is the Quaternary active caldera volcano. Latest eruption accompanied by caldera collapse taken place in 7.3 ka is the biggest Holocene eruption in Japan Archipelago. The ash-fall known as Akahoya was spread to entire southwest Japan and the pyroclastic flow thought as a low-aspect ratio ignimbrite is distributed in subaerial parts of the surrounding islands 40-80 km away from the source. Such submarine caldera must supplied the products not only in air, but largely in the water which has not been identified yet.

In order to understand the distribution of the pyroclastic-flow deposits beneath the sea around Kikai caldera, we conducted high resolution marine seismic studies from 2016 to 2018 by T/V Fukae-maru. We identified the uppermost unit widely recognized around Kikai caldera as the pyroclastic-flow deposit associated with 7.3-ka Akahoya eruption from the seismic sequence stratigraphic analysis and glass composition of sediments. The uppermost unit, characterized by subparallel to hummocky configurations of high amplitude reflections, covers the slope fan and progradational deposits of shelf edge developed between the Kyusyu Island and Kikai caldera. These secondary deposits under the uppermost unit are interpreted to deposit around the last glacial by reason of the erosion structure seen on the top-lap surface of regressive clinoform at 120 m below current sea level. Since uppermost unit is deposited after the last glacial (18 ka) and shows consistent seismic facies around Kikai caldera, the unit is inferred as products of 7.3-ka eruption. This is supported by analysis of glass composition of the sediments sampled at the seafloors interpreted as the above seismic unit, which shows the bimodal geochemical characteristic of high SiO_2 glass shards and lesser amount of low SiO_2 glass shards by which Koya pyroclastic-flow deposits are characterized (Nakaoka et al., this meeting).

This uppermost seismic unit interpreted as pyroclastic-flow deposit represents Akahoya eruption is distributed with a thickness of ~50 m around Kikai caldera. It maintains a certain amount of thickness until it reaches the shelf edge of the Kyusyu and surrounding islands. At least 40 km radius circle around the caldera, this unit is recognizable in most of the area of the seismic profiles. This result shows that a large amount of volcanic materials are ejected not only in air rather in the water at 7.3-ka Akahoya eruption.

Koya pyroclastic flow deposit (PFD) is large scale ignimbrite generated during formation of the Kikai caldera in Kikai-Akahoya eruption at 7.3 ka. Kikai caldera is located ~50 km south of the Satsuma Peninsula and largely presents at the bottom of sea. Koya PFD is thickly distributed on land of Takeshima and Satsuma-Iwojima which represent subaerial part of the northern rim of the Kikai caldera. It is also thinly distributed over distal area, adjacent islands and mainland of south Kyusyu which is 40-60 km away from the source across the sea. This pyroclastic flow deposit has been suggested to exhibit rather low aspect ratio ignimbrite (Ui, 1973). However, on-land survey revealed that the maximum pumice size tends to decrease with increasing the distance across the sea. This may lead to a hypothesis that a significant amount of pyroclastics was lost during traveling over the sea and deposited on the sea floor (Yamane and Suzuki-Kamata, 2017). Our multi-channel seismic (MCS) reflection experiments around the Kikai caldera further suggested several seismic units (Shimizu et al., 2018). We have concluded that the uppermost unit should be a candidate layer for Koya PFD. This layer is recognized extensive distribution around the proximal islands (~30 m thick) and continuous to the Kagoshima bay (~10 m thick). As mentioned above, the Koya PFD is expected to be thickly distributed on the sea floor around the Kikai caldera. However, identification of submarine deposit with the subaerial Koya PFD is not sufficiently. In this study, we measured chemical composition of glass shards on the sea floor obtained by remotely operated vehicle (ROV) and compared with the subaerial Koya PFD.

The ROV conducted four dives to sea floor where MCS data indicate that uppermost unit is distributed near sea floor around the caldera wall and one dive in the south of the Satsuma Peninsula and collected volcanic ash on the sea floor using nozzle. The chemical composition of glass shards (<200 micrometers) from both subaerial and submarine were measured by Electron Probe Micro Analyzer (EPMA).
The glass shards on the sea floor around the caldera wall show bimodal geochemical characteristic which contain a high proportion of high SiO_2 glass shards (SiO_2=72-78 wt.%) and lesser amount of low SiO_2 glass shards (SiO_2=64-68 wt.%). The low SiO_2 glass was reported by Fujihara and Suzuki-Kamata (2013) and confirmed that it is unique characteristic for the Kikai-Akahoya eruption by glass and whole rock composition of other volcanics of the Kikai caldera. This indicate that the sea floor around the Kikai caldera covered by volcanic ash derived from the Koya PFD. Samples from the sea floor in the south of the Satsuma Peninsula were also confirmed that they contain small amount of glass shard corresponding the Koya PFD. These results correspond to the MCS data showing that candidate layer for the Koya PFD is thickly and widely distributed at uppermost part around the Kikai caldera. The vertical variation for contents of low SiO_2 glass on Takeshima Island, which is proximal area of the Koya PHD with a thickness of ~20 m, shows that the content of low SiO_2 glass lacks at the basal level and increases upward and reaches >10% at early stage (~10% level of the total thickness). While, the contents of low SiO_2 glass at distal areas across the sea tend to increase upward to <5%, which are lesser than value of proximal area. The contents of low SiO_2 glass of the sea floor samples around the caldera rim are >10%. Ash size grains are considered to be less under the influence of segregation by difference of density (Nakaoka and

©2019. Japan Geoscience Union. All Right Reserved.

Suzuki-Kamata, 2018). Thus, the Koya pyroclastic flow reached distal area across the sea between the start of eruption and the beginning of containment of low SiO_2 glass and was waning to not reach distal area and deposit on sea floor after the content of low SiO_2 glass increases to >10%.

Submarine volcanoes are one of the frontiers in volcanology: many volcanoes are located under the sea and most of them are not well studied. Since 2016, the Kobe Ocean-Bottom Exploration Center (KOBEC) at Kobe University has investigated a submarine volcano (the Kikai caldera) to understand the structure of the caldera and the style of the caldera forming eruption. The Kikai caldera is located about 45 km off southern Kyushu Island, Japan. Except two islands on the northern part of the caldera rim, most of the caldera structure is under the sea. The caldera has double caldera structure: the outer caldera has width of 19 km and length of 24 km and the inner caldera has width of 15 km and length of 17 km. The formation of, at least, the inner caldera must be related with one of the largest eruption of this volcano occurred about 7300 years ago. In the inner caldera, a giant rhyolite lava dome (~32 km^3) was created after the caldera collapse (Tatsumi et al., 2018).

A remotely operated vehicle (ROV) is a tethered underwater robot connected with a support surface vessel by a cable for power supply and signal transmission. To observe and sample sea floor material, we introduced a ROV (SHINDAI-2K) in 2016. In this presentation, we show preliminary results of 9 dives of the ROV at 8 sites in the following 3 areas in the Kikai caldera.

Outer caldera: We investigated two sites at the northeastern rim of the outer caldera. At one of the sites, we found a massive angular outcrop of dense rock in the caldera wall. This result and andesitic gravel sampled at this site confirmed the presence of igneous rock expected by our prior multi-channel seismic reflection survey. Another site had a sandy seafloor. We sampled the sediments with the ROV and identified volcanic glass fragments ejected by the caldera forming eruption.

Inner caldera: We had two dives around the inner caldera. At the northeast caldera wall of the inner caldera, basement rock appeared as a massive and angular upright outcrop of dense mudstone which had several centimeters wide horizontal banded structure. On the other hand, at the southeastern site in the inner caldera, the sea floor was covered by sandy or muddy sediments. Volcanic glass fragments ejected by the caldera forming eruption were also identified from the sediments. Furthermore, some isolated vesiculated lava blocks were observed at this site. Those blocks had fractured surface, suggesting chilling of hot ejecta due to lava/water interaction.

Lava dome: We had four dives at the lava dome. The outline of the results was already reported by Tatsumi et al (2018). The most surface of the lava dome was covered by meter-scale vesiculated lava blocks (pillow lobes; Tatsumi et al., 2018). These blocks also had water-chilled structures. Relatively dense angular chilled blocks were observed at the east flank of the lava dome where gully-like features had been determined with our prior bathymetry analysis. Furthermore, a small amount of gas emission was observed at the northern flank of the lava dome where water column was expected in our prior

©2019. Japan Geoscience Union. All Right Reserved.

side-scan sonar acoustic images.

Visual observation and sediments sampling using ROV provides valuable information to understand the history and eruption style of submarine volcanoes. Our preliminary observations suggests that (1) the amount and size of vesiculated lava blocks decrease with distance from the lava dome, showing that they were provided from the dome, (2) basement rock of the volcano is exposed at the sea floor in, at least, some areas of the Kikai caldera, (3) as well as old volcanic edifices in the two islands, old submarine volcanic edifices were cut by the caldera collapse and some of them are exposed in the outer caldera wall. These results and further ROV survey will provide new insight into the eruption history of submarine volcanoes.

Seismic activity beneath Kikai Caldera by using Ocean Bottom Observation

*Yasutomo Seto[1], Hiroko Sugioka[2], Yojiro Yamamoto[3], Tsutomu Takahashi[4]

1. Department of Planetology, Graduate School of Science, Kobe University, 2. Department of Planetology, Kobe University, 3. Japan Agency for Marine-Earth Science and Technology, 4. Research and Developement Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology

Kikai submarine caldera located in the southern part of Kagoshima prefecture is located on the volcanic front of the southwestern Japan arc. It was recently revealed that a giant lava dome with a volume of 32km ^{3} is created after super eruption at 7.3 K.a. (Tatsumi et al., 2018). Seismic observation with the T/S Fukae-maru of Kobe University is conducted by five short-period ocean bottom seismographs (OBSs) which were in the deepest part of the caldera from October 19, 2016 to March 14, 2017. As the result, about 1100 volcanic tremors like as swarm with a fundamental frequency of around 2Hz were detected during the period and it was occurred very frequently beneath the caldera. In addition to these low frequency tremors, about 32 high frequency earthquakes with dominant frequency of over 5Hz and many monochromatic tremors were detected, but at the onshore station of Satsuma Iwo-jima no signals corresponding to these volcanic earthquakes have been detected.

In general, volcanoes are strongly inhomogeneous regions compared with ordinary crusts. The seismic waves propagate to stations under the influence of scattering and diffraction due to random inhomogeneities along the seismic ray paths. Actually, the monochromatic tremor observed in the Kikai caldera is detected only at the stations near the place where the hydrothermal activities were observed by the high-performance camera of the remotely operated vehicle (ROV) and multi-beam echosounder mapping, suggesting strong three-dimensional inhomogeneity in the volcanic body. An amplitude envelope method is powerful tool for analyzing seismic waves propagating through such a three-dimensional inhomogeneous medium. In this study, a method based on Takahashi et al. (2007) focusing on peak delay time from direct S-wave onset to the maximum amplitude arrival of its envelope was applied to about 1100 low frequency tremors and about 32 high frequency earthquakes.

For high frequency earthquakes and some low frequency tremors, we picked up the onset times arrival of P- and S-waves recorded clearly to determine the hypocenters. The hypocenters were vertically divided into two parts at a depth of around 10 km, most of which occurred at the shallower parts were laterally expanded within the lava dome. In addition, we measured the peak delay times for S-wave seismograms filtered at four frequency bands of 2-4, 4-8, 8-16 and 16-32 Hz and calculated root mean square envelope for the sum of two components in those bands to investigate a frequency. In this presentation, we will discuss characteristics of the obtained peak delay times.

An investigation of three-dimensional electrical resistivity structure under Kikai Caldera

*Tetsuo Matsuno[1,2], Toki Hirose[2], Yuuki Okizono[3], Nobukazu Seama[2,1], Hiroshi Ichihara[4], Hiroko Sugioka[2,1], Yoshiyuki Tatsumi[1,2]

1. Kobe Ocean Bottom Exploration Center, Kobe University, 2. Department of Planetology, Graduate School of Science, Kobe University, 3. Department of Planetology, Faculty of Science, Kobe University, 4. Graduate school of environmental studies, Nagoya University

We have conducted an electromagnetic experiment to reveal a 3-D electrical resistivity (or conductivity) structure under Kikai Caldera, SW Japan. The electrical resistivity is highly sensitive to thermal structure and the presence of partial melt or magma and fluid in the crust and in the upper mantle. Imaging an electrical resistivity structure provides key constraints on the distribution of magma reservoirs in the crust and in the upper mantle and volcanic structures and activities of this submarine caldera. Our electromagnetic experiment is one part of an integrated marine investigation of Kikai Caldera since October 2016 with T/S Fukae-maru, Kobe University. By semiannual research cruises to the Kikai Caldera region, we have repeatedly deployed and recovered ocean-bottom electro-magnetometers (OBEMs) by changing their locations to obtain a data set that is useful for imaging a 3-D electrical resistivity structure. We set 13 observational sites so far, and we have 10-sites data available for analysis. The 10 sites cover an area of 13 km ×16 km within the submarine double caldera with site-distances of ~5-10 km. The OBEMs measured time variations of electromagnetic fields at sampling rates of 8 Hz and 60 s with instrumental tilts and temperature at seafloor. Data suggested instrumental vibrations during observations, likely because of strong ocean current near the Kuroshio Current or between islands, and unstable positions of OBEMs on very rugged seafloor of lavas in this volcanic area. We carefully checked the time-series data and selected available data terms. We finally obtained magnetotelluric (MT) response functions at the 10 sites at a period range from 21 s to 8192 s, using the BIRRP program [Chave and Thomson, 2004]. For imaging a 3-D electrical resistivity structure, we carried out a 3-D inversion of the MT response functions using an inversion program of Usui et al. [2018]. Undulating seafloor in the study area, which can severely distort the MT responses, was incorporated into a 3-D inversion model with tetrahedron meshes. A preliminary 3-D inversion model (RMS misfit = ~1.7) shows a shallow conductive area of 3-10 Ω-m at <5-10 km depths, which is thin to the west and is thick to the east, and an underlying deep resistive area of 30-300 Ω-m at 10-30 km depths.

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Takeshi Ohba, Akihiko Terada

This session discusses various aspects of active volcanisms including, but not limited to, recent and historical eruptions, various phenomena associated with the volcanic activities, underground structures of the volcanoes, and developments of new instruments based on geophysical, geochemical, geological, and multidiscipline approaches. We also welcome studies on understanding and predicting the transitions of the eruptive activities from observational, theoretical, and experimental approaches.

A geochemical observation method that analyzes substances released from magma and hydrothermal systems such as volcanic gas, hot spring water, volcanic ash, etc. is a potentially effective means for predicting steam eruption and elucidating the structure of hydrothermal system. In Hakone volcano, an earthquake swarm began in late April 2015, and a small steam explosion occurred at the end of June. Prior to the earthquake swarm, the stable isotopic ratio of H2O in the volcanic gas declined and fluctuations in the CO2/H20 ratio synchronized with the increase and decrease in the number of earthquakes were observed. Analyzing the volcanic ash released at the end of June 2015 and using the constituent mineral species and the Cl/S ratio of the component adhered on ash surface, it was presumed that the source depth of the volcanic ash was shallower than about 350-500m. Hakone volcano repeats earthquake swarm and the associated volcanic gas anomalies every few years, and it is expected that means to predict the transition of earthquake swarm can be established by ongoing volcanic gas geochemical observation.

We collected and analyzed monthly fumarolic gases T and S, respectively, that are releasing naturally in Owakudani and Kamiyuba, which are geothermal zones developed in the central volcanic cone of Hakone volcano, and obtained the following results. The CO2/H2S ratio of T reached its maximum value around October 2017, and then showed a tendency to gradually decrease toward to January 2019. At T, a similar tendency was also observed for He/CH4 ratio. The CO2/H2S ratio of S remained nearly constant from February 2018 to February 2019, but decreased once in November 2018. The He/CH4 ratio of S showed a declining trend in 2018 like T, but the rate of decline was slower than T. CO2 and He are derived from magma that degas, H2S and CH4 are derived from hydrothermal system. Therefore the declining trend of CO2/H2S ratio and He/CH4 ratio observed in 2018 indicates that the flux of magmatic gas to shallow hydrothermal system was decreasing. The cause of the decreasing trend may be due to the development of the sealing zone surrounding the magma. The declining trend of the CO2/H2S ratio and the He/CH4 ratio in 2018 looks to disappear in 2019. The CO2/H2S ratio of T and S rose slightly from January 2019 to February. Corresponding to the rise, a minor swarm earthquake was observed on Hakone volcano on January 24, 2019 (based on Hot Springs Research Institute of Kanagawa prefecture HP). The N2/He ratio of T and S remained low from 2018 to 2019, but T was exceptionally high in January 2019. N2 is a component derived from the atmosphere, and an increase in N2 in T indicates that the fluid pressure in the shallow part hydrothermal system decreased and a part of atmospheric contamination occurred. The apparent equilibrium temperature (AETD) can be calculated by combining the hydrogen isotope ratios of H2O and H2 contained in T and S. A decline phenomenon preceding the earthquake swarm were observed in 2014 and 2017. From early 2018 to the October, AETD is declining especially for S. The decrease may be a preceding sign of earthquake swarm.

Chemical and isotopic composition of volcanic gases at Mt Kirishima Iwoyama, Japan

*Takeshi Ohba[1], Muga Yaguchi[2], Kotaro Toyama[3], Hirochika Sumino[3], Urumu Tsunogai[4], Masanori Ito[4], Ryo Shingubara[4]

1. Department of chemistry, School of Science, Tokia University, 2. Meteorological Research Institute, 3. The University of Tokyo Graduate School of Arts and Sciences Department of Basic Science, 4. Nagoya University Graduate School of Environmental Studies

INTRODUCTION

At Mt Kirishima Iwoyama, several fumarolic gases appeared in the vicinity of the summit in December 2015, and the discharge of fumarolic gas was enhanced in May 2017. In addition, a small steam eruption occurred in April 2018. Volcanic gas contains components degassed from magma and is useful for evaluating volcanic activity. In this study, from December 2015 to January 2019, fumarolic gases were repeatedly collected and analyzed at Mt Kirishima Iwoyama. We consider the relationship between the variation of the chemical composition and stable isotope ratio of these samples and the recent volcanic activity.

SAMPLING OF FUMAROLIC GAS

Fumarolic gases a, b, c were collected near the summit of Mt. Kirishima Iwoyama. The location of fumarole-a is the place where fumarolic gas first appeared in Dec. 2015. The fumarole-b is located about 40 m south of fumarole-a. The fumarole-c is about 200 m away from the fumarole-a in the south-southwest direction. The outlet temperature of the fumaroles was all close to the boiling point of water and the discharge pressure of fumarolic gases was low.

RESULTS AND DISCUSSIONS

The SO2/H2S ratio of fumarolic gas-a fell sharply from May to October 2018, but again rose in January 2019. The ratio at fumarolic gas-b also rose from October 2018 to January 2019. The Oxygen isotope ratios of H2O rose at three fumarolic gases from October 2018 to January 2019. At all three fumarolic gases, the CO2/H2O and the H2S/H2O ratio fell from October 2018 to January 2019.

In general, CO2 is a component originating in magma, H2S is a component originating in hydrothermal system, and the CO2/H2S ratio rises as the flux of magmatic gas to a shallow hydrothermal system increases. In Mt Kusatsu Shirane and Mt Hakone, the H2S/H2O ratio of the fumaroles is stable in time, and the CO2/H2S ratio could be a good indicator of the magmatic gas flow rate for the shallow hydrothermal system. The H2S/H2O ratio of Mt Kirishima Iwoyama is variable, and the situation is different from Mt Kusatsu Shirane and Mt Hakone. For example, from January to March 2018, the H2S/H2O ratio of fumarolic gas-a changed little, but fumaroles b and c greatly decreased. From March to May 2018 the H2S/H2O ratio dropped greatly in fumarolic gas-a, but in fumarolic gas-c it increased in reverse. Thus, the change in H2S/H2O ratio was not coordinated between fumaroles, and the cause of H2S/H2O ratio change is estimtated to be local. For this reason, it is not appropriate to use the CO2/H2S ratio of fumarolic as an indicator of the flux of magmatic CO2 to the shallow hydrothermal system at Mt Kirishima Iwoyama. The reason why the H2S/H2O ratio of fumarolic gases greatly fluctuates may be

©2019. Japan Geoscience Union. All Right Reserved.

attributed to the insufficient development of shallow hydrothermal system.

The SO2/H2S ratio of fumarolic gas gas was low in January 2018, but it rapidly rose in March 2018 just before the steam eruption. In addition, the increase in SO2/H2S ratio occurred simultaneously in three fumarolic gases. At this time, the apparent equilibrium temperature (AETD) calculated by combining the hydrogen isotopic ratios of H2O and H2 sharply increased to values close to the magmatic temperature at the fumaroles-a and b. A similar increases in SO2/H2S ratio and AETD also occurred in May 2017, when the discharge of fumarolic gas was enhanced. The H2O oxygen isotopic ratios of the three fumaroles have been similarly fluctuated. The oxygen isotopic ratio reached the maximum value in fumaroles a and b in March 2018 just before the eruption in April. Considering the SO2/H2S ratio and the high oxygen isotope ratio in May 2017, it is highly likely that so-called the attempted eruption occurred.

Temporal and spatial variations of helium isotope ratios in volcanic gases in Kirishima volcanic group, Japan

*Kotaro Toyama[1], Hirochika Sumino[1], Kaori Kawana[1], Takeshi Ohba[2], Muga Yaguchi[3], Yoshihide Akiyama[1], Koki Aizawa[4], Kaori Tsukamoto[4]

1. Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo, 2. Department of chemistry, School of Science, Tokia University, 3. Meteorological Research Institute, 4. Institute of Seismology and Volcanology, Faculty of Science, Kyushu University

In Kirishima volcanic group in Kyushu, Southwest Japan, Shinmoe-dake is an active volcano and erupted in 2008, 2011, 2017 and 2018, and Iwo-yama also erupted in 2018. For the volcanic disaster preservation, forecasting the timing of the volcanic eruption is required. It is known that the temporal variations in chemical and isotopic compositions of volcanic gases are useful to evaluate the present state of volcanic activity [1]. Especially, helium isotope ratio ($^3He/^4He$) exhibits unique values corresponding to the origin (e.g., 7-8 Ra in the mantle and about 0.02 Ra in the crust, where 1 Ra denotes atmospheric $^3He/^4He$ ratio of 1.4×10^{-6} [2]). Some studies have reported pre-eruptive $^3He/^4He$ anomalies, suggesting the increase of the magmatic helium supply into the hydrothermal system preceding eruption [1, 3, 4].

We report spatial and temporal variations of $^3He/^4He$ ratios of fumaroles and hot spring gases collected from 10 sites in Kirishima volcanic group during 2016 to 2018. The measured $^3He/^4He$ ratios were corrected for atmospheric contamination based on $^4He/^{20}Ne$ ratios. The air-corrected $^3He/^4He$ ratios (6.8 to 7.7 Ra) of the central craters in the active volcanos (i.e., Iwo-yama and Shinmoe-dake) are higher than those (4.3 to 5.3 Ra) of the other sites. These $^3He/^4He$ ratios decrease with the increase of the distance from the magma reservoir, location of which is estimated as pressure source of crustal deformation associated with the 2011 Shinmoe-dake eruption, to each sampling site. This trend reflects that the contribution of radiogenic ^4He in old groundwater increases with migration distance of the gas from the magma to the site [5].

The $^3He/^4He$ ratios of fumaroles in Iwo-yama slightly increase before Shinmoe-dake eruptions, and decrease after the eruption. This variation cannot be accounted for by the contribution of the radiogenic ^4He relative to total helium in the fumaroles before and after the eruptions, because it is estimated that the amount of radiogenic ^4He which volcanic gas can acquire during its migration from magma to the surface is negligible. Alternatively, the variation results from the change in mixing ratio of gases derived from two reservoirs having high and low $^3He/^4He$ ratios. Assuming that the magma chamber has high $^3He/^4He$ ratio, the increase of $^3He/^4He$ ratios of the fumaroles before the eruption would be resulted from increase of the supply of the gas from the chamber to the Iwo-yama fumaroles. Once an eruption occurs at Shinmoe-dake, magmatic gas is effectively released through the volcanic vent, resulting in decrease of its supply to the Iwo-yama fumaroles. Thus, the temporal variation of $^3He/^4He$ ratios in volcanic gases may reflect the pressure variation of the magma chamber.

Emission regions of gaseous elemental mercury around Yugama crater lake at Kusatsu-Shirane volcano, Japan

*Akihiko Terada[1], Noriaki Mizutani[1]

1. Volcanic Fluid Research Center, Faculty of Science, Tokyo Institute of Technology

Kusatsu-Shirane volcano is one of the most active volcanoes in terms of release of a large amount of heat as volcanic gas and thermal hot waters. In addition to a hot crater lake, locally referred to as Yugama, the Shirane pyroclastic cone exhibits thermal features such as steaming grounds and fumaroles. Because many visitors visit around the Shirane pyroclastic cone for sightseeing, risk evaluations of phreatic eruptions are valuable. Gaseous mercury emissions from ground surface at active volcanoes suggest thermal activities such as shallow hydrothermal system. Mercury contained in geothermal hot water separated from hydrothermal reservoirs as a gas phase and is transported to the surface along relatively high permeable zones. Thus, a spacial distribution of gaseous mercury emission rates from ground surface is one of a clue used to detect fracture zones. Such fracture zones may correspond to areas where explosion vents are formed in future. Furthermore, changes in flux of gaseous mercury may reflect temperature changes in a hydrothermal reservoir although mercury flux from ground surface is affected by environmental factors including air temperature, soil moisture content and organic carbon. Recently, portable apparatuses enabling to measure concentrations of gaseous elementary mercury (GEM) have been developed. To detect fracture zones around the Shirane pyroclastic cone, we applied the portable GEM analyzer which is low power consumption and light weight. On the basis of a simple numerical model which we have developed, we calculated GEM flux from GEM density measured around the soil. As a result, two GEM emission zones, A and B were found at the southern flank of the Shirane pyroclastic cone. The zone A corresponds to a locality of fissure vents formed by phreatic eruptions occurred at the beginning of 20 century. No volcanic vents are observed at ground surface at the zone B while its direction is parallel to an orientation of past fissure vents at the bottom of Yugama crater lake. We believe the zone B is fracture zone which was buried by thick ejecta emitted by following eruptions.

This work is supported by Japan Society for the Promotion of Science under the Grants-in-Aid for Scientific Research of 18H01290.

Magnetotelluric images of Kusatsu-Shirane volcano, revisited by 3-D modeling with tetrahedral elements considered topography effect

*Kuo Hsuan Tseng[1], Yasuo Ogawa[1], Nurhassan .[2], Sabri Bulent Tank[3], Akihiko Terada[1], Wataru Kanda[1], Masato Fukai[1]

1. Tokyo Institute of Technology, 2. Bandung Institute of Technology, Indonesia, 3. Bogazici University, Turkey

Mount Kusatsu-Shirane, Japan, is an active volcano with temporary phreatic eruptions. The distribution of subsurface conductor was previously inferred with 2-D inversion of magnetotelluric data which considered the topography effect. We combine the magnetotelluric data from 94 stations which were investigated in 2001-2002 and 8 stations which were investigated in 2017-2018 for inverse modeling. The stations were located on the volcano, mostly around Yugama crater. We selected the data by 15 frequencies for the 3-D inverse modeling. The model was calculated by FEMTIC (Usui, 2015; Usui et al., 2017), considering the topographic effect.

The final model presents two major electric conductive structures. A 0.5-3 ohm-m conductive structure with 500-1000 meters thickness is located at 300 meters depth, beneath Yugama crater and extend to the east slope of Kusatsu-Shirane volcano until Sesshogahara fumarole field. Another conductor at the west of Yugama crater has 600-1000 meters thickness at 1500-2000 meters depth.

Comparing the final model with microseismic data, most of the hypocenters are under a low conductive (<2 ohm-m) structure beneath Yugama crater. This conductive structure infers a hydrothermal deposit of volcano, which cut-off the seismicity as a cap rock. At the north of Mizugama crater, a high resistivity structure at the edge of conductor infers the path of fumarole. The deep conductor between Kusatsu-Shirane volcano and Manza geothermal field infers the geothermal source of Kusatsu-Shirane volcano system.

Magma conduit and associated hydrothermal systems of Aso volcano as revealed by broadband magnetotelluric data

*Nobuo Matsushima[1], Mitsuru Utsugi[2], Shinichi Takakura[1], Tadashi Yamasaki[1], Maki Hata[3], Takeshi Hashimoto[4], Makoto Uyeshima[3]

1. Geological Survey of Japan,AIST, 2. Kyoto University, 3. The University of Tokyo, 4. Hokkaido University

Aso volcano is one of the most active volcanoes in Japan. The caldera forming eruptions occurred from 210 ka to 90 ka, emitting the volcanic product of 600 m^3 in total. The caldera has a dimension of 25 ×18 km^2. After the caldera forming eruptions, post-caldera cones more than 17 were formed at the center of the caldera. Resent eruptions occurred repeatedly at Naka-dake cone. The count of the eruption events from Naka-dake crater was 73 times from 1901 to 2015. These volcanic activities suggest the stable magma supply from deep seated magma source to the surface. To investigate the magma plumbing system, the resistivity structure under Aso volcano was analyzed using the broadband magnetotelluric (MT) data. The four components of MT impedance and two components of tipper vector were used to obtain the resistivity structure by three-dimension inversion (Siripunvaraporn and Egbert, 2009). Overall structure was obtained using 55 measurement sites in and around of Aso caldera (Hata et al., 2016). We observed additional 9 sites near Naka-dake crater and revised the previous model to examine mainly the shallow structure near the active crater. The resistivity structure represents the low resistivity (< a few Ω•m) body which extends from near surface to a depth of 15 km (bsl) with a columnar shape, dipping northward and roughly directs to the epicenter of deep low-frequency earthquakes. The top of the low resistivity body is just located below the Naka-dake crater at sea level, which corresponds to the upper bound of magma depth estimated by melt inclusion analysis (Saito et al., 2018). From these results, we conclude that the low resistivity body indicates the upper part of the magma plumbing system of Aso volcano from deep seated magma source to the present active crater.

[S-CG57] Structure and evolution of Japanese islands - Formation of island arc systems and earthquake cycles

convener:Hiroshi Sato(Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo), Masanao Shinohara(Earthquake Research Institute, University of Tokyo), Masahiro Ishikawa(Graduate School of Environment and Information Sciences Yokohama National University), Makoto MATSUBARA(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Masanao Shinohara(Earthquake Research Institute, The University of Tokyo), Tatsuya Ishiyama(Earthquake Research Institute, University of Tokyo)

Subduction processes such as accretion, back-arc-spreading, and arc-arc collisions have shaped the Japanese island arc. Recent advances in seismic imaging, both passive and controlled source, have produced new images of the crust-mantle structure under Japan and surrounding regions. Through the influence of pre-existing faults and rheological structures, these crust and mantle structures are exerting strong control on active tectonic processes like seismic activity and crustal deformation in the overriding plate. We seek contributions that document and/or model the deformation of the Japanese islands over a variety of time scales from the earthquake cycle to the tectonic evolution of the Japanese island arc, and from a range of research fields including seismology, geology, geochemistry, tectonic geomorphology, and geodynamics. Multidisciplinary studies are encouraged. We also welcome contributions in numerical or analogue geodynamical modeling that explore deformation processes.

Recent Earthquake Activity in Northern Hokkaido, Japan

*Tetsuo Takanami[1,2]

1. Carnegie Institution for Science, 2. Hokkaido Research Center of Geology

In order to understand the future earthquake potential damage in northern Hokkaido, we examined the current seismic activity from the perspective of plate tectonics. An earthquake swarm, with largest earthquake of M_{JMA} 4.3, starting on July 15, 2012 in the town of Nakagawa in northern Hokkaido, Japan, where residents felt the earthquakes of seismic intensity IV three times in 3 days (The Seismological Bulletin of Japan, JMA, 2012). At the same time, a slow earthquake was also detected nearby during the swarm (M. Ohzono et al., 2015; S. Ikeda, 2016). It is inferred from the results that the source area is associated with almost horizontal E-W compressional tectonics. Den and Hotta (1973) first proposed the paleo-tectonic movement of the Okhotsk plate in the Mesozoic to Paleogene time along western Hokkaido and the island of Sakhalin to the north. Nakagawa is located at the western margin of the Okhotsk paleo-plate. The present tectonic movement of the island of Hokkaido is controlled by the triple interaction among the Pacific, the North American and the Eurasian plates. The current activity of an earthquake swarm and slow earthquake near Nakagawa suggests that the tectonic movement on the remnant boundary zone has not completely vanished. Further, according to the geodetic imaging by Loveless and Meade (2010), the slip rates across the corresponding area were estimated as 13.0±2.1 mm/y ~ 8.4±2.1 mm/y of E-W closing or shortening. In order to shed light on the current earthquake behavior in the western boundary of the Okhotsk paleo-plate, we study seismic activity in northern Hokkaido centered on Nakagawa using earthquakes of magnitude 2 or more in the JMA unified catalog from January 1, 1996 to October 30, 2018. The map of epicenters indicates that almost all are inland earthquakes within a western coastal zone extending 40km east-west and 200km north-south with very few earthquakes located in the east side of the Sea of Okhotsk. Here we focus on the earthquake activity in the northern half of the zone (44.2˚N - 45.5˚N; 141.5˚E - 142.5˚E). The topical earthquake swarm and slow earthquake near Nakagawa occurred when the general earthquake activity was at its highest. We apply the Gutenberg-Richter frequency-magnitude formula (G-R law) to our earthquakes set and obtain a b-value of 0.87 that is somewhat small but almost normal. This current seismic activity is also useful in considering future potential damages in northern Hokkaido. The largest earthquake magnitude from the G-R relation is estimated to be about $M_{JMA}5$ consistent with the fact that few moderate to larger earthquakes with magnitude (M_{JMA}) greater than 5 have occurred in the research region. Our results are limited by the number of earthquakes in the region since the installation of the high density network in late 1990. In 2007, the Headquarters for Earthquake Research Promotion, an office of Japanese government estimated the magnitude of the biggest earthquake of $M_{JMA =}$ 7.6 if the Sarobetsu fault zone in northern Hokkaido fails over its entire zone. Since we have a catalog for a certain time interval (2.7 years) the straight line projection to higher magnitudes gives an estimate of the probability of having a larger earthquake. Projecting the line to say M_{max} =7.6 expected gives a value of 0.0055, implying that we could expect one M_{max} =7.6 in 183 years. We are aware that such a long term projection based on a relatively short data interval is subject to significant error. As earthquake data are added in the future, this aspect should be reexamined.

Seismic constraints on the crustal structure off the southwestern coast of Hokkaido, Japan Sea

*Tetsuo No[1], Takeshi Sato[1], Shuichi Kodaira[1], Hiroshi Sato[2], Tatsuya Ishiyama[2]

1. JAMSTEC, 2. ERI, University of Tokyo

Offshore crustal structure studies have been conducted around Japan, with a primary focus on the Pacific side such as the Nankai Trough and Japan Trench via multichannel seismic reflection (MCS) and ocean bottom seismograph (OBS) surveying since the 1990s (e.g. Kodaira, 2009); moreover, seismic surveys have been conducted in the Japan Sea since the 2000s (e.g. Sato et al., 2018a). In 2018, we conducted a MCS and OBS survey off the southwestern coast of Hokkaido, which was one of the unsurveyed areas in the Japan Sea. Our survey area included the source region of the 1993 Hokkaido Nansei-Oki Earthquake, which is the largest earthquake among the shallow earthquakes that occurred in the Japan Sea since the Meiji period. Therefore, as our survey lines were oriented traverse the source region of the 1993 Hokkaido Nansei-Oki earthquake to the east and west, our data provided very important information for studying the relation between this earthquake source fault and its surrounding crustal structure. Furthermore, we targeted the Japan Basin, which is located to the west of the Hokkaido Nansei-Oki Earthquake source region. The Japan Basin is the widest basin in the Japan Sea, with previous studies estimating that it possesses a standard oceanic crustal structure and thickness (e.g. No et al., 2014; Sato et al., 2018b). Our survey area provides another key piece of information for comparison with a previous geomagnetic study because it overlaps with an area that has been defined by a striped pattern of geomagnetic anomalies (e.g. Kinoshita et al., 1995).

We conducted the seismic survey using the JAMSTEC R/V *KAIREI*. The survey area extends from the Okushiri Basin and Shiribeshi Trough to the Okushiri Ridge, the Japan Basin, and comprises nine MCS lines and one seismic refraction line using OBSs. Furthermore, the seismic refraction survey line was extended onshore to link with a land seismic survey in Oshima Peninsula, which was simultaneously conducted by the Earthquake Research Institute, University of Tokyo.

According to the provisional data processing results, clear shortening structures are imaged in the MCS data that cover the Okushiri Basin, Shiribeshi Trough, and the source region of the Hokkaido Nansei-Oki earthquake. However, a sedimentary layer with a thickness of approximately 2 km is observed in the Japan Basin, and clear reflectors, dense normal faults are observed throughout this sedimentary layer. Furthermore, a strong reflector is identified at approximately 7 km under the sedimentary layer, which we presumed to be the Moho. We image clear reflectors in the crust and uppermost mantle. Furthermore, the Moho reflector is poorly defined in the eastern margin of the Japan Basin, with a shortened structure and clear east-dipping crustal reflector imaged in this region.

The results of data analysis of seismic survey using OBSs indicate that the Japan Basin is a relatively homogeneous structure that possesses a standard oceanic crustal structure. However, the P-wave velocity structure indicates a thicker crust to the east of the region where the MCS data confirmed a shortened structure. Additionally, it is suggested that the crust thickens rapidly across the Okushiri Ridge.

Deep seismic reflection profiling across the Oshima Peninsula, SW Hokkaido, Japan

*Hiroshi Sato[1], Tatsuya Ishiyama[1], Naoko Kato[1], Hidehiko Shimizu[2], Takeshi Sato[3], Shinji Kawasaki[2], Tetsuo No[3], Shuichi Kodaira[3], Seiichi Miura[3]

1. Earthquake Research Institute, The University of Tokyo, 2. JGI Inc, 3. Japan Agency for Marine-Earth Acience and Technology

An onshore-offshore seismic data set was collected across the Oshima peninsula, SW Hokkaido to the Japan basin, off SW-Hokkaido to determine the geometry of seismogenic source faults and basic structure of backarc of NE Honshu arc (Sato, T. et al., 2019 JpGU; No et al., 2019, JpGU). Here, we present the result of deep seismic reflection profiling across the Oshima peninsula, high-reslolution seismic reflection survey across the western boundary fault of Hakodate plain and P-wave velocity structure obtained from onshore-offshore integrated seismic processing.

The deep seismic data set was collected across the Oshima peninsula in May, 2018. Vertical land seismometers (GSR) were deployed with a spacing 50 to 200 m along the 54-km-long seismic line using fixed 1119 channel. The seismic source was four to five vibroseis trucks with standard 150 m shot spacing. As high energy shot, 50 stationary sweep were carried out every 5 km along the seismic line. Sweep frequency was 6 to 60 Hz and sweep length was 16 to 20 sec. The obtained seismic data were processed according to a standard common-midpoint (CMP) stacking and a post stack time migration. We used refraction tomography to determine the P-wave velocity structure, that revealed down to 8 km in depth beneath the western part of the seismic line. Obtained P-wave velocity profile demonstrates the geometry of the top surface of pre-Tertiary rocks. The Kamiiso massif and Esashi range marked by high Vp (> 5 km/s) and 2 km of sediment cover are distributed in the Tate and Hakodate Basins. With a pattern of seismic reflection, main geologic structure is interpreted a series of westward dipping Miocene normal faults. The NS-trending Kamiiso massif is an uplifted zone bounded by a high-angle reverse fault, which formed as a normal fault. The high-resolution seismic reflection profiling was performed across the western boundary fault of the Hakodate plain. Seismic source was a viborseis truck and the seismic signal was recorded fixed 845 channel offline recorders (GSR). Shot and receiver intervals are 10 m. The 8-km-long seismic section portrays the geometry of active fault down to 2 km in depth. The fault dips 45 degrees westward in more than one km depth. Judging from the stratigraphy, it is interpreted as a reactivation of normal fault as reverse fault. On the contrary, the shallower part of active fault forms thin-skinned type of deformation associated with wedge-thrust, fault-related fold and flat-ramp structure. The obtained shallow structure is very concordant with the feature of tectonic geomorphology and frontal part of active thrust is presented as a blind thrust. The air-gun shots along the offshore of Oshima peninsula were recorded by fixed recorders on land and integrated P-wave velocity was obtained covering 310 km seismic line. The basic feature is very similar to the velocity model proposed by Sato, T. et al. (2019) JpGU. The velocity structure portrays the detailed structure produced by Miocene backarc extension and formation of the Sea of Japan crust. In spite of the later shortening deformation, basic structure has extensional tectonic features. There no evidence of the subduction of the Sea of Japan crust beneath the Hokkaido continental crust.

Crustal deformation and stress accumulation on source faults around Hokkaido, Japan, due to coupling at the Kuril trench

*Akinori Hashima[1], Hiroshi Sato[1], Tatsuya Ishiyama[1], Andrew M. Freed[2]

1. Earthquake Research Institute, The University of Tokyo, 2. Purdue University

2018 Mw6.7 Hokkaido-Iburi earthquake, Japan, brought about disastrous landslides near epicenter, and a power blackout on the whole Hokkaido island. In order to assess activity of such an intra-plate earthquake, we need to know not only the geometry of local source faults but also stress on them. The geometry model for the source faults over Japan was already published by the Headquarters for Earthquake Research Promotion of the Japanese government. We are now revising the model and adding new source faults in the offshore areas. Stress in the plate interior is essentially formed due to the interplate interaction at plate boundaries. The Kuril trench near Hokkaido has hosted a massive megathrust rupture. GPS observation shows widespread locking region southeast off Hokkaido. Similarities to the preseismic state around the 2011 Mw9.0 Tohoku-oki earthquakes along the Japan trench are pointed out such as decades of subsidence along the southeast Hokkaido and decrease in seismicity in recent years in this region. In order to quantitatively estimate the effect of these plate boundary process, we construct a finite element model (FEM) to estimate regional deformation and stress accumulation rate on source fault around Hokkaido due to the locking along the Kuril trench.

Our model contains the region of 3700 km x 4600 km including the Kuril–Japan trench. The bottom of the model is taken at the depth of 700 km to consider the whole upper mantle. The geometries of the Pacific and Philippine sea slabs under the Northeast Japan –Izu Bonin arcs, and the Southwest Japan –Ryukyu arcs, respectively, are incorporated following the previous studies. The model region is divided into 1000,000 tetrahedral elements. The size of the elements is set 5 km around the slip region and gradually larger close to the boundaries. Fault slip can be modeled by giving constraint equation of displacement discontinuity. Slip region is taken on the upper surface of the Pacific plate shallower than the depth of 80 km. We simply set the Pacific and Philippine sea slabs as the 70-km thick elastic plates over viscoelastic asthenosphere. The continental side is assumed to be elastic-viscoelastic stratified structure. Elastic thickness is tested for the case of 30 and 50 km. Since the interseismic deformation includes the effect of the concurrent viscous relaxation in the asthenosphere, we used response after complete relaxation.

In order to understand the basic feature of crustal deformation around Hokkaido, we compute response to locking of two offshore regions inferred from the past earthquake occurrence: Tokachi and Nemuro. Crustal deformation in Hokkaido obtained from GPS observation shows ~5 cm/yr northwestward movements on the Southeast coast, which decay toward the North and West, except the effect of the 2003 Mw8.0 Tokachi-oki and 2011 Mw9.0 Tohoku-oki earthquakes. This basic feature can be realized in the case of elastic thickness of 50 km and locking rate of 4 cm/yr in Tokachi and 8 cm/yr in Nemuro, respectively. These locking rates form compressive stress fields over the Hokkaido region. The compressive axes are NW-SE in the eastern Hokkaido and E-W in the western Hokkaido. The calculated stress field in the western Hokkaido is consistent with the occurrence of the 2018 Hokkaido-Iburi earthquake. In this study, we also apply the calculated stress field to source fault model around Hokkaido and calculate Coulomb stress to examine the earthquake activities.

Structural Heterogeneity in and around the Source Region of the 2018 Hokkaido Eastern Iburi Earthquake, Central Hokkaido, Japan

*Takaya Iwasaki[1], Noriko Tsumura[2], Tanio Ito[3], Kazunori Arita[4], Makoto Matsubara[5], Hiroshi Sato[1], Eiji Kurashimo[1], Naoshi Hirata[1], Susumu Abe[6], Katsuya Noda[7], Akira Fujiwara[8], Shinsuke Kikuchi[9], Kazuko Suzuki[10]

1. Eathquake Research Institute, the University of Tokyo, 2. Graduate School of Science, Chiba University, 3. Association for the Development of Earthquake Prediction, 4. Hokkaido Research Center of Geology, 5. National Research Institute for Earth Science and Disaster Resilience, 6. JAPEX, 7. GEOSYS Inc., 8. JOGMEC, 9. JGI Inc., 10. Schlumberger Ltd.

Central Hokkaido, Japan, has complicated tectonic history of subduction, accretion and collision processes from Late Jurassic to the present. Since Paleogene or Early Miocene, compressional stress regime has been dominated by the dextral oblique collision between the Eurasia and North America (Okhotsk) Plates and the subsequent westward movement of the Kuril Arc due to the oblique subduction of the Pacific Plate. The latter event was responsible for the formation of the Hidaka Collision Zone (HCZ) and the foreland fold-and-thrust belt with a very thick (>10 km) sedimentary package. The 2018 Hokkaido Eastern Iburi Earthquake (M=6.7) took place at a very deep depth of 37 km under this foreland fold-and thrust belt. To understand the mechanism on the occurrence of such a deep earthquake from the surrounding structural heterogeneity, we reanalyzed controlled source seismic data from the 1998-2000 Hokkaido Transect Project by applying advanced processing techniques including CRS/MDRS stacking methods and integrated refraction/wide-angle reflection analyses.

The seismic reflection processing imaged for the first time the NE Japan Arc underthrust eastward beneath the thick sedimentary package. The refraction/wide-angle reflection data were re-interpreted by tomography and ray-tracing methods. The latter analysis with aid of the new structural information from the reflection processing indicate that the crust is very thin (15-23 km) and the Moho depth is 22-30 km. The Pn velocity is a normal value of around 8 km/s. These structural features are well consistent with those in the offshore area of NE Japan, which belongs to the same geological unit. Based on the structural information mentioned above, the aftershock distribution was carefully investigated. Aftershocks relocated by the 3D structure model (Matsubara, 2017) with appropriate station corrections are distributed in a depth range of 7-45 km showing a steep geometry facing to the east. We cannot find any evidence that the aftershock distribution is related with shallow west-verging active faults developed in the fold-and-thrust belt. We think that the high-angle fault of this earthquake was formed by a certain tectonic event before the collision, maybe in Late Oligocene to Middle Miocene. The relocated aftershocks are separated into the upper (7-20 km) and lower (22-45 km) groups. The seismicity gap between them corresponds to the lower crust of our velocity model, probably representing its ductile property. According to our results, more than 80 % of relocated events occurred within the uppermost mantle of our structure model. Possible explanation for this high seismic activity is the cold crust delaminated from the Kuril Arc side, whose existence was is confirmed by a series of seismic reflection profiling in the southern part of the HCZ (Arita et al., 1998; Tsumura et al., 1999; Ito, 2000, 2002) and seismic tomography by Matsubara et al. (2017). This delaminated crustal body prevents the thermal circulation and upward migration of dehydrated fluid to cool the forearc mantle and generate more favorable environment for the brittle failure.

Electrical resistivity distribution around the middle axis of Hokkaido Island: constraint for tectonics of ultra-mafic rocks

*Hiroshi Ichihara[1], Toru Mogi[1], Yusuke Yamaya[2]

1. Earthquake and Volcano Research Center, Nagoya University, 2. AIST

Middle axis of Hokkaido Island is located on a tectonic boundaries between NE Japan arc and Kurile arc. In the south part of the boundary, collision due to migration of fore-arc aliver is known (Hidaka Collision zone). Huge serpentine rock bodies are exposed in the high P/T metamorphic belt (kamui-kotan belt) located on the NE Japan arc side near the boundary. In addition, a fresh peridotite rock body (Horoman periodotite) is also distributed in the south part around the boundary. However, tectonic process to bring the surface has not been understood although it is the key to understand the tectonics. In this study, we discuss the crustal structure beneath the arc-arc boundary especially for ultra-mafic rock area based on electrical resistivity distribution obtained in following three areas: (1) middle part of Hidaka collision zone where serpentine is exposed, (2) north part of Kamui-kotan belt where serpentine is exposed but the collision is not occurred, and (3) south part of Hidaka collision zone where the Horoman peridotite is distributed. In the area (1) and (2), very low resistivity (1-10 ohm-m) anomalies area found in the depth around 10-40 km beneath the surface serpentine body but they are not significant beneath out of the serpentine area. We interpreted them as high fraction of aqueous fluid area related to serpentine forming and bring them to the surface. In the area (3), we found thin sheet-like high resistivity body near the surface embedded to low resistivity body (Ichihara et al., G3). The surface high resistivity correspond to the peridotite because unaltered igneous rocks are basically resistive. The underlying conductive area possibly reflect cretaceous sedimentary rock based on integrated interpretation of geomagnetic anomaly, gravity anomaly and the resistivity distribution. If these interpretations in the area (3) are true, the Horoman peridotite covers over the sedimentary rock, implying the unknown tectonics processes occurred on the south part of Hidaka collision zone.

[S-CG57] Structure and evolution of Japanese islands - Formation of island arc systems and earthquake cycles

convener:Hiroshi Sato(Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo), Masanao Shinohara(Earthquake Research Institute, University of Tokyo), Masahiro Ishikawa(Graduate School of Environment and Information Sciences Yokohama National University), Makoto MATSUBARA(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Hiroshi Sato(Earthquake Research Institute, Tokyo University), Masahiro Ishikawa(Yokohama National University)

Subduction processes such as accretion, back-arc-spreading, and arc-arc collisions have shaped the Japanese island arc. Recent advances in seismic imaging, both passive and controlled source, have produced new images of the crust-mantle structure under Japan and surrounding regions. Through the influence of pre-existing faults and rheological structures, these crust and mantle structures are exerting strong control on active tectonic processes like seismic activity and crustal deformation in the overriding plate. We seek contributions that document and/or model the deformation of the Japanese islands over a variety of time scales from the earthquake cycle to the tectonic evolution of the Japanese island arc, and from a range of research fields including seismology, geology, geochemistry, tectonic geomorphology, and geodynamics. Multidisciplinary studies are encouraged. We also welcome contributions in numerical or analogue geodynamical modeling that explore deformation processes.

Three-dimensional seismic velocity structure beneath and around Japanese Islands including beneath the Pacific Ocean using NIED S-net data

*Makoto MATSUBARA[1], Hiroshi Sato[2], Kenji Uehira[1], Masashi Mochizuki[4], Toshihiko Kanazawa[5], Narumi Takahashi[1], Kensuke Suzuki[3], Shinichiro Kamiya[1]

Ministry of Education, Culture, Sports, Science and Technology, Japan , 5. Association for the Development of Earthquake Prediction

1. Introduction
We investigate the 3D seismic velocity structure beneath and around Japanese Islands including beneath the Sea of Japan and Pacific Ocean with seismic tomographic method. National Research Institute for Earth Science and Disaster Resilience (NIED) constructed the High-sensitivity seismograph network (Hi-net) after the 1995 Kobe earthquake, the Seafloor observation network for earthquake and tsunamis along the Japan Trench (S-net) after the 2011 Tohoku-oki earthquake on March 11, and the Dense Oceanfloor Network System for Earthquakes and Tsunamis (DONET) constructed by Japan Agency for Marine-earth Science and Technology (JAMSTEC) was transfered to NIED on April 1, 2016. We used arrival time data detected by these networks operated by NIED as well as other organizations and apply the seismic tomography for these data.

2. Data and method
The target region, 20–48°N and 120–148°E, covers the Japanese Islands. In addition to the arrival time data used by Matsubara et al. (2017), we used P- and S-wave arrival times for 32952 earthquakes recorded at approximately 1500 stations including the NIED S-net and DONET from April 2016 to June 2018. We also added the arrival time data detected at the stations operated by universities near the coast of the Sea of Japan from 2000 to 2004. Totally 6356481 P arrival data and 3534482 S arrival data from 112631 events are available. The inversion reduces the RMS of the P-wave traveltime residual from 0.245 s to 0.189 s and that of the S-wave data from 0.287 s to 0.236 s after 11 iterations.

3. Result and discussion
We clarified the seismic velocity structure beneath the Sea of Japan at depths of 10-20 km from off Hokkaido to Wakasa Bay. Vp beneath the Okushiri and Sado Islands is low at a depth of 10 km however, Vp beneath the Sea of Japan is high at depths of 10-35 km. Vp along the coast of Sea of Japan in western Japan is moderate. The lithospheric velocity structure in this region is strongly affected by the mid-Tertiary break up and formation of the Sea of Japan. Through the reactivation of the younger compression, tsunamigenic source faults has been developed. The information of the lithospheric structure provides the essential information to the structure of faults.
Due to the contribution of S-net, the velocity structure of the overlying plate beneath Pacific Ocean has been improved. One important feature is the probable Mesozoic rift structure trending NS from the coast of Tohoku to the west of Hidaka collision zone. Recent the 2018 Hokkaido Eastern Iburi Earthquake (M6.7) may related to the reactivation of the rift related structure in the upper mantle to the lower crust, where marked by high-Vp.

Spatio-temporal extent of Cretaceous fore-arc basin in Japan

*Yukio Isozaki[1], Ryo Hasegawa[1], Yukiyasu Tsutsumi[1]

1. Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo

Recent analyses on detrital zircon ages in sandstones calrified various new aspects on characteristics and secular changes in provenance for the fore-arc domain of Cretaceous Japan. The shallow marine to fluvial Cretaceous strata are disrtibuted in multiple zones running almost parallel to the coeval arc-trench system in SW Japan, which is represented by the paired granitoid (Ryoke) and blueschist (Sanbagawa) belts. For example, the Upper Cretaceous Izumi Group in Shikoku and Kii peninsula has been regarded as a typical fore-arc sedimentary package deposited between the coeval grnaitoid and blueschist belts. Much emphasis was given to its origin in a pull-apart setting along an imaginary large strike-slip movement of the Median Textonic Line. Nonetheless, the lastest zircon analyses documented that its spatio-temporal dimentsion was much greater than previously believed, e.g., more than 1000 km along-arc, and nearly 100 km wide across-arc in sapce, and extended up into the Paleocene in age. The Izumi Group likely represnt a remnant of much large sedimentary basin, and its current restircted occurrence, ca. ca. 300 km along arc and ca. 20 km across-arc, was made by large-scale removal of fore-arc crust, probably relevant to the back-arc rifting to open the Japan Sea. The missing fore-arc crust can be properly reconstructed by checking ancient provenance through zircon dating in Kyushu and southern Tohoku district.

Geotectonic identities of dismembered ancient fore-arc clastics: U-Pb dating of detrital zircons in Cretaceous-Paleogene shallow marine/fluvial sandstones sporadically found in Kanto, central Japan

*Ryo Hasegawa[1], Yukio Isozaki[1], Yukiyasu Tsutsumi[2]

1. Department of Earth Science and Astronomy, The University of Tokyo, 2. Department of Geology and Paleontology, National Museum of Nature and Science

For reconstructing the fore-arc basin of Cretaceous arc-trench system in Japan, provenance analysis for sandstones has been carried out by U-Pb dating of detrital zircons, particularly for the “Cretaceous-Paleogene” sandstone-bearing units sporadically occurred in 5 distinct areas in the Kanto Mountains and northern Kanto/southern Tohoku region, i.e. the Shoya Formation in Saku, the Kanohara conglomerate in Shimonita, the Yorii Formation in Yorii (Kanto Mountains), the Nakaminato Group (northern Kanto), and the Futaba Group (southern Tohoku), of which geotectonic identities are ambiguous. The U-Pb dating of detrital zircons from these units constrained the depositional ages of 10 sandstone samples to the Late Cretaceous and early Paleocene, and also their provenance. These results confirmed that 1) the Shoya Fm and the lower-middle Nakaminato Gr are of the Maastrichtian age, which are correlated with the Izumi Group on the Late Cretaceous Ryoke ganitoids in SW Japan, 2) the Kanohara conglomerate, Yorii Fm, and Oarai Fm are of the Danian (early Paleogene) age, which were deposited on the Ryoke belt as well as the Izumi Gr., 3) the Futaba Gr is of the Coniasian age, which is correlated not with the Izumi Gr. but with the coeval units in western Kyushu, i.e., basal Himenoura Group, Kumamoto Gr, and upper Mifune Gr, which were deposited unconformably on a slightly older (Early Cretaceous) granitoids in the same fore-arc domain. These new age data provide new clues in reconstructing paleogegraphy of Cretaceous arc-trench system in Japan, before the Miocene opening of the Japan Sea. The expected discontinutity between pre-Miocene SW and NE Japan crusts in central Japan is currently buried beneath thick Quaternary sediments of the Kanto plain; nonetheless, the present data suggests two candidates, i.e., the seismologically detected major break of the pre-Cenozoic basement along the River Tone and the conventional Tanagura tectonic line to the north.

Laboratory Measurements of Vp, Vs and Vp/Vs for polycrystalline labradorite up to 800˚C and 1GPa

*Satoko Honda[1], Masahiro Ishikawa[1]

1. Graduate School of Environment and Information Sciences, Yokohama National University

In order to estimate the elastic properties of crustal rock-forming minerals at mid-to-lower crustal P-T conditions, we performed simultaneous measurements of compressional-wave (Vp) and shear-wave (Vs) velocities of the labradorite. In this presentation, we report temperature-pressure dependence of the elastic wave velocity for labradorite, intermediate member of plagioclase feldspars, at crustal P-T condition.

The fine-grained pollycrystalline labradorite was fabricated from the nano-sized powders of crushed natural labradorite crystal ($An_{61}Ab_{37}Or_2$, $An_{65}Ab_{34}Or_1$), and was used for the measurements. After milling and forming mineral powders, sintering was carried out at a temperature of 1180–1210˚C with controlled time. Ultrasonic measurements on these samples were conducted up to 1.0 GPa in a temperature range of 25-800˚C with a piston cylinder high pressure apparatus.

The Vp increase rapidly with pressure increase up to 0.40 GPa at room temperature, while it is moderately increasing between 0.40 and 1.00 GPa. At 1.00GPa up to 800 ˚C, the elastic wave velocities decrease with increasing temperature blow 600 ˚C, δVp/δT and δVs/δT of the labradorite sample (An65Ab34Or1) is -1.6×10^{-4} km/s/˚C, -1.0×10^{-4}km/s/˚C . In contrast, above 600 ˚C , the elastic wave velocities show an increasing trend in the range of 600–800 ˚C . At cooling stage, Vp and Vs show an decreasing trend with decreasing temperature above 400˚C.
Previous studies report that elastic wave velocities of polycrystalline anorthite show an increasing trend in the range of 240–640 ˚C (Matsukage et al 2015) and that a polycrystalline plagioclase ($An_{51\pm1}$) at 1.0 GPa show marked increase in Vp and Vs between 700 and 800 ˚C (Kono et al 2008). They suggest that these discontinuous velocity changes in temperature dependence of Vp and Vs would be associated with phase transformation in plagioclase. However, it is unclear whether our measurements results between 650 and 800˚C is phase transformation, because the phase transformation was not determined on our sample using X-ray diffraction analisys. In addition, the temperature conditions of the discontinuous in Vp and Vs at high temperature is not consistent with the phase boundary previously reported. Phase transformation, therefore, would have been only temporary during the experiment.

Shallow to deeper structures of the Median Tectonic Line active fault system in Shikoku illuminated by new hi-resolution seismic reflection profiling, southwest Japan

*Tatsuya Ishiyama[1], Naoko Kato[1], Shin Koshiya[2], Hiroshi Sato[1], Makoto MATSUBARA[3], Tomoko Elizabeth Yano[3], Taro Koike[4], Katsuya Noda[4]

1. Earthquake Research Institute, University of Tokyo, 2. Department of Civil and Environmental Engineering, Faculty of Science and Engineering, Iwate University, 3. National Research Institute for Earth Science and Disaster Resilience, 4. Geosys, Inc.

Median Tectonic Line (MTL) active fault system is one of the most pronounced, trench-parallel active dextral slip faults in SWJapan, extending for approx. 300 km (Okada, 1992). With ubiquitous proximity to the north dipping terrane boundary MTL between Samgawa metamorphic rocks (Sm) and Ryoke granitic rocks to the north, their structural links with active strands of the MTL have been widely discussed. Seismic experiments in Kinki (Wakayama) clearly illuminate that near-surface steeply dipping fault plane appears merge into underlying more shallowly dipping reflectors correlated with top Sm (Sato et al., 2015). In Shikoku, however, previous seismic sections have not fully resolved such structural linkages of the major fault strands of the MTL, whereas pioneering deep seismic experiments successfully imaged northerly dipping MTL (Ito et al., 1995). To define structural characters of the shallow to deeper subsurface geometry, we collected new seismic reflection profiles across MTL active fault system in Shikoku island. Our new, processed seismic profile across the Okamura Fault, Komatsu Fault (Goto and Nakata, 1998), and the MTL and its preliminary interpretation suggest northerly dipping Sambagawa metamorphic rocks beneath the northern flank of the Ishizuchi Mountains and Niihama plain to the north. As is the case with previous seismic results, downward extensions of the MTL apparently dips northward, in contrast to near-surface steep fault planes identified in outcrop and trench exposures. In addition, northerly dipping clouds of microseismicity also suggest its deeper extension. Similarly, in our new seismic profile in Wakimachi, Tokushima, Chichio fault (Okada and Tsutsumi, 1997), active dextral slip fault that dips vertically at ground surface, is apparently underlain by very strong and continuous north dipping reflectors from the top of Sm. This observation also suggests that the Chichio fault may merge into, rather than cut across these Sm reflectors. We will mainly discuss on (1) detailed structural characters identified in the new seismic data, (2) their structural linkages with near-surface structures of the active strands, and (3) implications for overall shallow to deeper geometry of the MTL based on both new and previous seismic data, regional seismicity based on JUICE catalogue (Yano et al., 2017), and crustal structures estimated from seismic tomography (Matsubara et al., 2017).

Cenozoic evolution of the Tsushima Strait and the Fukue Basin, southern Sea of Japan: an interplay of tectonics, palaeo-environment, and volcanism

*Johan S. Claringbould[1], Hiroshi Sato[1], Tatsuya Ishiyama[1], Anne Van Horne[1,2], Shinji Kawasaki[3], Susume Abe[4]

1. Earthquake Research Institute, The University of Tokyo, 2. Department of Geology and Geophysics, University of Wyoming, 3. JGI, Inc., 4. JAPEX

The Japanese island arc is tectonically active with earthquake and tsunami hazard along both the Pacific and Sea of Japan coasts. Following the tsunami disaster from the 2001 Off-Tohoku (M9) earthquake, the Japanese government initiated an extensive evaluation of tsunami hazard around Japan. Since records of prior tsunamis along the southern Japan Sea margin are rare, we here investigate the geologic evolution of the SW Japan back-arc basin to identify and analyse potential tsunami source-faults.

Located between SW Japan and the Korean Peninsula, and connecting the Japan Sea and East China Sea, the Tsushima Strait and the Fukue Basin represent a structurally complex region that formed over the last ~25 Ma as a result of several tectonic phases: (i) back-arc rifting and rotation, (ii) post-rift compression, (iii) weak thrusting, and (iv) subsidence and strike-slip deformation. Syn-depositional volcanism and changes in regional palaeo-environment are known from previous studies surrounding this connecting region, but how these factors fit together in the regional tectonic framework is not well understood. In addition to analysing recent seismic reflection data and detailed gravity data, we here re-evaluate extensive seismic reflection profiles and well data of ten boreholes offshore the SW Japan arc. We observe large basement blocks and igneous bodies, and inverted and cross-cut half grabens filled with syn-kinematic deposits. Clear stratal terminations suggest multiple transitions in regional stress regime. The gravity data allow us to link the syn-depositional igneous bodies to previously-dated volcanism onshore. Additionally, planktonic and calcareous nanno-fossils from the well data provide control on absolute timing of different kinematic stages, while benthic foraminifers and pollen show changes in palaeo-water depth, coeval with local, relative palaeo-climate reversals, respectively.

From ~25 Ma pollen data show warming of the local climate in southern Japan Sea side of the Tsushima Strait, while on the East China Sea side in the Fukue Basin relative cooling is observed. This is related to initial rifting, opening up back-arc basin allowing relative warm water to flow through the Tsushima Strait into the Japan Sea warming the local climate, and relative cold water flowing back cooling the local environment in the Fukue Basin on the opposite side of the Tsushima Strait. Subsequently, negative flower structures and large half-grabens filled with over 5400 m of synrift sediments developed between ~18-16 Ma, containing benthic foraminifera suggesting a deepening marine environment. This is linked to the rapid, clock-wise rotation of SW Japan, which pivot point migrates along a dextral oblique normal fault west of Tsushima. At ~15 Ma rift structures are abruptly inverted or cross-cut by thrust faults and wedge thrusts, with microfossils and pollen on the Japan Sea side suggesting shallowing of the palaeo-waterdepth and cooling of the local climate, respectively. Contrary, in the Fukue Basin, the local climate shows relative warming. We suggest that during this compressional tectonic event a topographic sill developed in the Tsushima Strait that cut off water flow between the cooler Japan Sea and the subtropic East China Sea. From ~6 Ma, the local climate on the Japan Sea side warms again contemporarily with deepening of the marine palaeo-environment and deposition of sub-horizontal

Pliocene sediments, implying a weakening of the compressional stress and renewed water flow through the Tsushima Strait. These observations along with previously published data of the surrounding areas enable us to better understand the connection between the Cenozoic structural development of the SW Japan arc, and the related the palaeo-environment changes and volcanism. As a result, we are better able to identify potential tsunami-source faults along the southern Japan Sea margin based on our understanding of the structural evolution.

Association of drastic climate change and biological evolution during Neoproterozoic is one of the most enigmatic features of the Earth history. The If the Earth’ s surface has been hardly covered with thick ice-cover during the 58-myr-long Sturtian glaciation, the evolution of organisms was mostly reset. However, there is glowing evidence of protozoan fossils immediately after the Sturtian and Marinoan glaciations. This requires the argument that liquid environments as refugia for protozoans must have occurred in tropical zones or around volcanos.
Moroccan Anti-Atlas exposes several Proterozoic inliers surrounded with Ediacaran, Paleeozoic and Mesozoic strata. Accumulated age data of zircon U-Pb indicate that active tectonics had been sustained here during Cryogenian and Ediacaran. Paleogeographic interpretation based on paleomagnetism reconstructed a high latitude of Anti-Atlas. Neoproterozoic sedimentary sequence here is dominated by volcanics and siliciclastics, and carbonate is developed as lentic bodies on granodiorite rock.
This study focuses on two carbonate bodies near Bleida and Ouarzazate in Anti-Atlas. The Blida section exposes a 25-m-thick sequence of bedded and fine-grained dolostone of red color. This overlies 586Ma volcanic rock, and apparently underlies possible diamictite with a fault contact. Dolostone of the lower part of the section contains relics of iron-oxidizing bacteria. Carbon isotope of the dolostone is low as -6‰, but the stratigraphic position negates the correlation to the Shuram negative excursion of late Ediacaran. The low d13C value likely inherited endogenic carbon, and this interpretation is supported by low d18O indicating high water temperature (around 40-50ºC). While, the 30-m-thick carbonate sequence near Ouarzazate consists of red-colored limestone alternated with volcanoclastic sandstone and siltstone. It rests on 580Ma volcanics. The carbonate sequence exhibit stromatolites at least four stratigraphic levels. The higher d13C value (around -1.5‰) was likely reflected from CO2 degassing or gas exchange with the atmosphere. These stromatolites show regular lamination of ~1 mm interval and appears color changes reflected from a redox gradient within a biofilm.
These carbonate sequences in Anti-Atlas are not directly associated with the Snowball glaciations. However, active volcanism that had sustained latest Neoproterozoic might had provided liquid water environments, as biologic refugia during the Marinoan Snowball Earth.
N.B.Funding was provided by the Academy Hassan II of Science and Technology of Morocco AcadHIIST/SDU/2016-02 (grant to Abderrazzak El Albani and Nasrrddine Youbi and others)and Managem-ONA Group.

1. Tokyo Institute of Technology, 2. The University of Tokyo

The large fluctuations of δ13C_carb in the Paleoproterozoic are important in terms of the speculation on the atmospheric oxygen level and the global stratigraphic correlations. The interval characterized by the generally high values of δ13C_carb up to +10 ‰is called Lomagundi-Jatuli Event (LJE; ca. 2.2-2.0 Ga) and interpreted as reflecting high rates of oxygen production (e.g. Karhu & Holland, 1996; Martin et al., 2011). The drop of δ13C_carb and δ13C_org at the end of LJE are reported from Shunga in Fennoscandia, and the negative shift of δ13C_org is correlated with that of Franceville in Gabon (Kump et al., 2011); however, the δ13C_carb data in Gabon is still missing because of the scarcity of the carbonate rocks. The Paleoproterozoic Francevillian Group in Gabon consists of FA (fluvial sandstones), FB (black shales/carbonates), FC (cherts), FD (black shales), and FE (sandstones) in ascending order. The lithostratigraphic correlation between the Franceville, Lastoursville, and Okondja basins suggests that the FA-FB-FC units are in different depositional settings and the FD-FE units are in common facies, which indicates the final opening of the intracratonic basins. In order to explore the global correlation of δ13C_carb, the analyses in the FD-FE units are required. In this study, we conducted two drillings in the Lastoursville and Okondja basins to obtain the fresh core-samples of FD. The lithological observations clarified that numbers of carbonate layers are intercalated in black shales in the FD unit in the both areas. We analyzed δ13C_carb of these carbonate layers, and filled in the stratigraphic blanks in the FD unit. In this presentation, we will discuss the propriety of the δ13C_carb stratigraphic correlations.

The redox condition of late Paleoproterozoic shallow marine environment: The Cape Smith Belt, Canada

*Kento Motomura[1], Shoichi Kiyokawa[1], Minoru Ikehara[2], Takashi Sano[4], Kentaro Tanaka[3], Tsubasa Miki[3], Yuji Sano[3]

1. Kyushu University, 2. Kochi University, 3. University of Tokyo, 4. National Museum of Nature and Science

The oceanic redox condition strongly affects the chemical compositions of seawater, especially, redox-sensitive elements such as Fe and Mo. Although it is suggested that bio availability of these bio-essential elements have restricted the biological development through Precambrian ocean, the redox conditions and the trigger of its transition at late Paleoproterozoic era are poorly constrained.

In this study, we reconstructed 50 m lithostratigraphy and chemostratigraphy including major and trace element compositions and C-N-S isotopes ($\delta^{13}C_{org}$, $\delta^{15}N$, $\delta^{34}S$) in order to clarify the sedimentary environment and the trigger of its change.

A part of the drilled hole from the Northern Povungnituk Group, Cape Smith belt of Canada is used for geochemical analyses. The sequence consists of the alteration of sandstone and black shale deposited at northern margin of the Superior province at ~1.9 Ga. Two lithological units, lower and upper units, are identified based on sedimentary sequence. The lower unit is characterized by the transition from coarse sandstone dominant to black shale dominant sequence, while, the upper is fine sandstone dominant sequence.

Vanadium concentrations normalized by total organic carbon (TOC) shows clear evidence for the transition of the redox condition. Although V/TOC at the bottom of the sequence (<~50 ppm/%) is lower than that of black shale from the Bravo Lake Formation of Buffin island in which a previous work cleared the black shale deposited under euxinic condition (H_2S-rich), the value increased and reaches the mean of the black shale (~105ppm/%) from the Formation at lower coarse sandstone dominant portion. These increase of V/TOC suggests ocean redox conditions changed from anoxic (weak-reducing) to euxinic (strongly-reducing). This inference is consistent with redox-sensitive element behavior confirmed from the correlation between the V concentration and TOC.

$\delta^{15}N$ of the sequences (~+7 –+9 ‰) are comparable with that of the modern ocean and that indicates nitrification, denitrification and NH_3assimilation keep $\delta^{15}N$ of dissolved N species high. $\delta^{13}C_{org}$and $\delta^{34}S$ change at the same interval ($\delta^{13}C_{org}$: -30.6 –-33.2 ‰, $\delta^{34}S$: +11.9 –-4.1 ‰) and that suggests some trigger which affects $\delta^{13}C_{org}$and $\delta^{34}S$ caused development of strongly-reducing condition. $\delta^{13}C_{org}$and $\delta^{34}S$ transition are likely to represent input of isotopically light $HCO_3^-$and SO_4^{2-}. The activity of large igneous provinces and oxidative weathering of black shale which relates regression suggested by the change of lithofacies are plausible for these isotope change.

Paleovegetation changes reconstructed by terrestrial plant biomarker analyses in the sediments deposited across the Cenomanian/Turonian boundary in the Tomamae area, Hokkaido, Japan

*Masashi A. Ikeda[1], Ken Sawada[2], Takuto Ando[3], Hideto Nakamura[4], Reishi Takashima[5], Hiroshi Nishi[5]

Faculty of Science, Osaka City University, 5. The Center for Academic Resources and Archives, The Tohoku University Museum, Tohoku University

The Cretaceous is known as the extreme greenhouse period attributed to the elevated atmospheric CO_2 concentration triggered by the superplume activity. In particular, the Oceanic Anoxic Events (OAEs) caused by the occurrences of the Large Igneous Plateaus (LIPs) in several times during the mid-Cretaceous. Global environmental disturbance events have been extensively investigated in the ocean, but there have been few reports for terrestrial environmental variation during the OAE periods (e.g. Kuypers et al., 2002). In the present study, we analyzed biomarkers of terrestrial plants including lichen and fungi in the sediments deposited across the Cenomanian/Turonian boundary (CTB) from the northern Hokkaido, Japan to reconstruct paleovegetation changes and to evaluate paleoecology of individual plants during environmental disturbance event.

We analyzed sedimentary rocks across the CTB in the Saku Formation,Yezo Group, were collected from the Omagari-zawa sections of the Tomamae area, northern Hokkaido, Japan. The sediments used correspond to the OAE2 intervals (1st build-up, Trough, 2nd build-up and Plateau phases), determined by $\delta^{13}C$ stratigraphy (Omatsu et al., 2014). For the biomarker analysis, the extractions of freeze-dried sediments were fractionated using silica-gel column and analyzed by GC-MS.

By sterane and hopane ratios, we confirmed the high contribution of terrigenous matter input and low maturity of organic matter (vitrinite reflectance ca. 0.4% level; lignite to subbituminous coal rank) in the Omagari-zawa section. These results agree with those reported by Ando et al. (2017). Higher Plant Parameter (HPP) as the vegetation index of higher plants increased in the 1st build-up and 2nd build-up stages, and declined in the Trough and Plateau stages. We interpret that the coniferous vegetation has expanded under arid condition. Moreover, we analyzed the proportion of 1-methyl dibenzofuran in total methyl dibenzofurans as a lichen indicator (1- MDBF ratio), and perylene/ pyrene ratio as a fungal assemblage index. Variations in lichen and fungi vegetation tend to decrease from the 1st build-up to the 2nd build-up stage, which are resemble to those of coniferous vegetation. Thus, it is considered that the vegetation overall declined against the mid-Cretaceous environmental disturbance, especially affected by arid/humid fluctuation.

Deep-sea mud enriched in rare-earth elements and yttrium (REY), termed as REY-rich mud, has been expected as a novel mineral resource for the industrially critical elements [1]. Targeting the Japanese exclusive economic zone around Minamitorishima Island, where highly promising REY-rich mud (total REY content > 5,000 ppm) lies at very shallow depth (2 to 4 m) below the seafloor [2], we have conducted a variety of researches on the mud from both scientific and engineering perspectives.

In the presentation, we report a general overview of the research progress on REY-rich mud, and discuss the importance of the mud from viewpoints of the Japan’s resource security and a new strategy for economic growth.

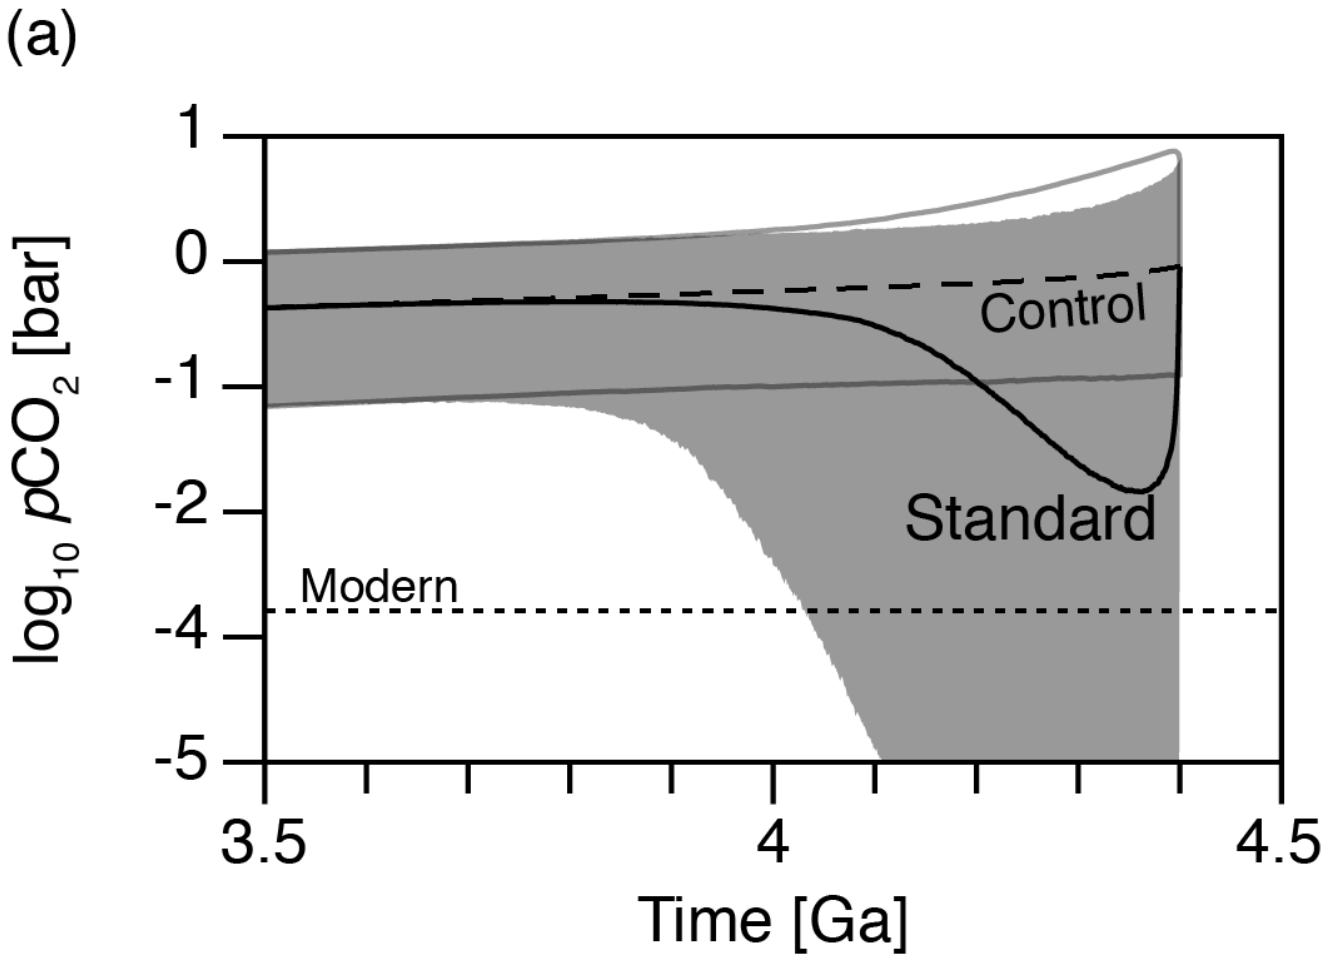
A cold and alkaline Hadean ocean caused by impact ejecta weathering

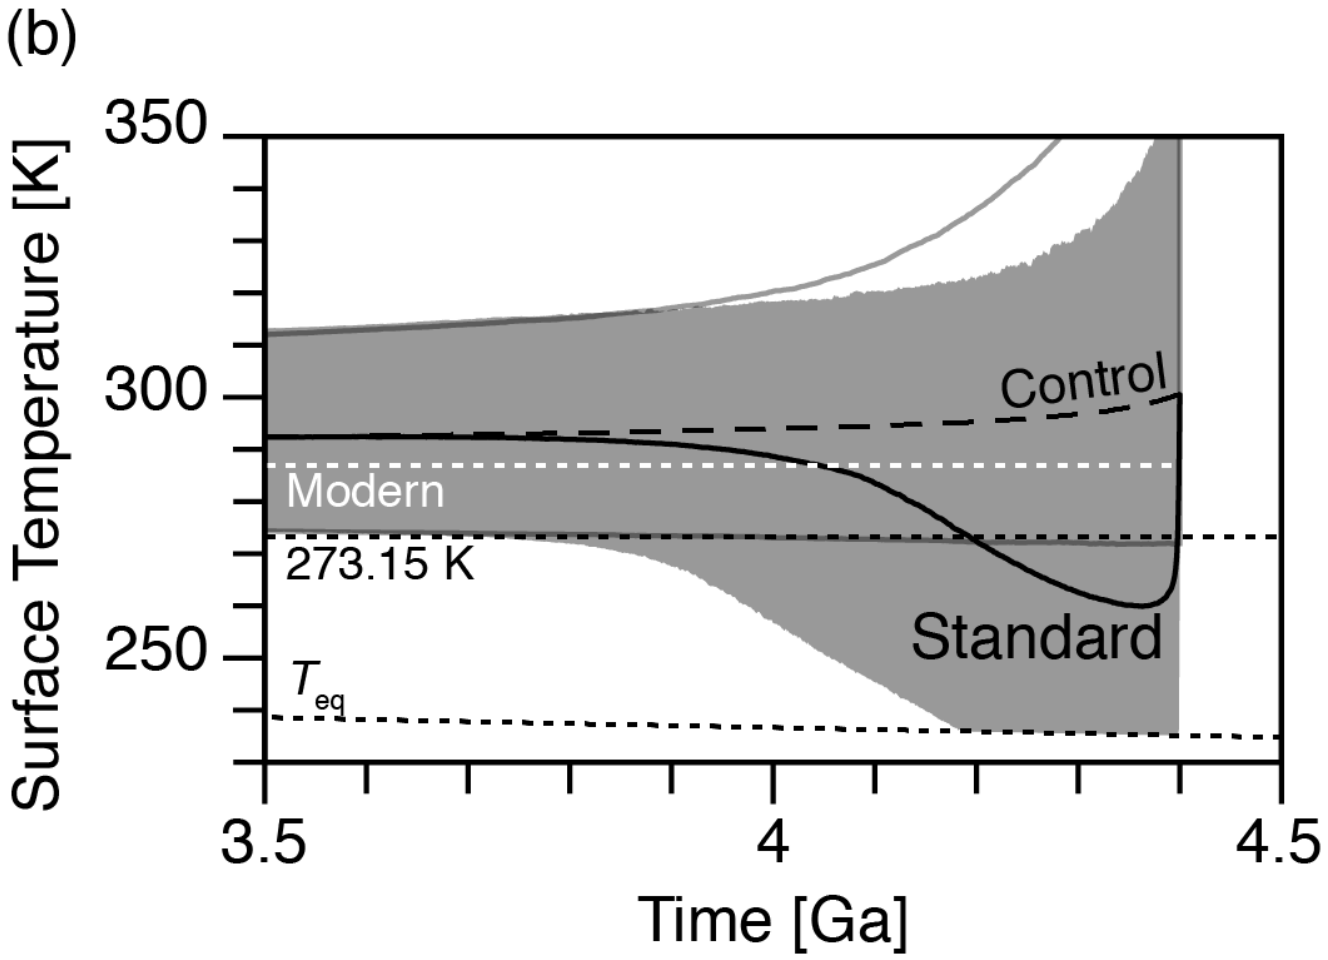
*Shintaro Kadoya[1], David C Catling[1]

1. University of Washington

Life probably arose in the Hadean (either on land or in the sea) and then would have spread through the early ocean. Hence, determining constraints on the early marine environment is essential for understanding conditions for the spread of early life, in addition to the history of the Earth itself. In this study, we modelled the evolution of the surface environment of the Earth, including the surface temperature, pCO_2, and oceanic pH.



As revealed by previous works (e.g., Krissansen-Totton et al., 2018, PNAS), Earth's long-term surface environment is controlled by the carbonate-silicate geochemical cycle. This negative feedback has moderated the surface temperature, resulting in the continuous existence of surface liquid water, even when the solar luminosity was smaller in the past than today. To compensate for the faint Sun, the feedback sets a high pCO_2 in the past, which would result in a more acidic ocean. The same mechanism can be applied for modelling the Hadean eon. However, we have to add another factor: impact ejecta weathering. As indicated by impact craters on the Moon, the Earth would also undergo intense meteorite impacts during the Hadean. Since the impact ejecta are easily weathered, they provided an additional sink of CO_2. Hence, previous works (e.g., Sleep & Zahnle et al., 2001, JGR) suggested that the surface temperature and pCO_2 would actually be low, i.e., a cold Hadean Earth –an idea that has been controversial.



In this study, we calculated the evolution of the surface environment by varying parameters in a geologic carbon cycle model within their ranges of uncertainty. Since the ejecta weathering is a source of carbonate alkalinity (i.e., a sink of CO_2), the pCO_2 and surface temperature of cases with ejecta weathering (hereafter, standard cases) are lower than those of cases without ejecta weathering (hereafter, control cases), as shown in Figure 1a and 1b. The surface temperatures of some standard cases are even lower than 273.15 K (Figure 1a). The coldness does not always mean that the Earth was in a snowball state during the early Hadean; instead, it just indicates a high likelihood of a cold climate. The low pCO_2 of standard cases also results in high ocean pH (Figure 1c). In addition, because the high pH results in a high precipitation rate of carbonate, the carbonate alkalinity of standard cases tends to be lower than that of control cases.

For the standard case, such a relatively cold surface and alkaline ocean are confined to the early Hadean, in which the impact flux (i.e., ejecta production rate) is high. However, the impact craters on the Moon also indicate the possibility of an enhanced impact flux around 4 Ga (i.e., the late heavy bombardment; LHB). The estimated impact flux for the LHB is also high enough to result in a cold surface and alkaline ocean. Hence, we should consider the possibility that life existed in a cold and alkaline early ocean.
Fig. 1. Results with control (without ejecta weathering) and standard cases (with ejecta weathering) for the geologic carbon cycle model for (a) atmospheric partial pressure of CO_2, pCO_2, (b) global mean surface temperature, and (c) ocean pH.

At the JpGU Meeting 2017, we reported the discovery of numerous fragments (<~3 mm in size) of stony meteorites and impact spherules of basalt in the lowest (i.e., the earliest) ~70 m section of the submarine Apex Basalt that overlies the ~110 m-thick Marble Bar Chert Member (MBCM; ca. 3.46 Ga in age) in the ABDP #1 drill core, which was recovered in 2003 at Marble Bar, Pilbara, Western Australia. We suggested that the asteroid body that produced the meteorite fragments was >10 km in diameter, impacted at ~40 km E of Marble Bar, terminated the deposition of the MBCM, and created a crater (“The Apex Impact Crater”) more than ~100 km in diameter. To test this hypothesis, in the summer of 2018 we conducted a geological survey of the proposed “Apex Impact Crater” utilizing a drone equipped with a high-resolution (4K) camera.

Our survey has revealed the presence of “impact tsunami deposits” at the boundary of the MBCM and the Apex Basalt. They are ~1-40 m thick, extending at least 20 km along the strike in the Marble Bar area. They contain numerous fragments (<5 mm size) of stony meteorites, together with various-sized (<1 mm to ~10 m), generally angular-shaped, fragments and blocks of the MBCM. We have also discovered ~15-40 m thick “impact tsunami deposits” underlying the Apex Basalt at ~80 km SE of Marble Bar. Numerous fractures (mostly perpendicular to the bedding planes, and many extending to 100s of meter into the underlying Duffer Formation), the dislocations and rotations of the MBCM in ~cm to ~100 m scales, as well as the “impact tsunami deposits”, were most likely created by an asteroid impact. Our survey has provided evidence that the ~3km-thick Apex Basalt represents the crater-filing komatiite/basalt lavas that were generated by the sudden decompression-melting of the mantle peridotites, triggered by a giant impact, and that the Mt. Edgar Batholiths (~3.46-3.43 Ga in ages), which intruded in the crater, probably represent the rebound of the older continental crust and the products of partial melting of the mantle peridotite and oceanic crust.

Our investigations suggest that the greenstone-granite complexes (“granite dome complexes”) that characterize the geology of the East Pilbara district may represent 8 or more craters created by impacts of asteroid bodies 10-30 km in diameter during the Archean. Consequently, the magmatism and tectonics of early Earth may have been dictated by gigantic asteroid impacts, rather than by the plume- and/or plate tectonics.

An evaluation of impact dating for shocked zircons with planar features (PFs) in the Vredefort dome by LA-ICP-MS multi-spot analysis

*Shinji Yamamoto[1], Taiga Kato[1]

1. Graduate School of Environment and Information Sciences, Yohohama National University

Shock-metamorphosed zircons, as an indicator mineral of meteorite impact, have often been utilized for impact dating (e.g. Kamo et al., 2009). Mechanical and thermal effect by impact are thought to lead Pb-loss of shocked zircon, resulting in partly and fully age resetting. The 2.02 Ga Vredefort dome, largest and oldest impact crater, crop out highly-shock metamorphosed basement rocks which include shocked zircons with various shock features such as planar features and granular textures. Previous studies demonstrate that shocked zircons with planar features in the Vredefort show various metamorphic ages from 731 to 3104 Ma, and these ages are interpreted to be correspond to age resetting of regional metamorphism and impact metamorphism. Recent analysis using EBSD, SL and SRIMP for shocked zircon by Moser et al. (2011) reveal that shocked zircons with curvi-planar features have a potential for impact dating in the Vredefort (2.02 Ga), and EBSD misorientation map suggest that deformation of zircon by impact event enhances the age resetting. However, impact dating using shocked zircons with planar features has not been established. Erickson et al. (2013) reported SHRIMP U-Pb ages of detrital shocked zircon with PFs recovered from downriver of the Vredefort dome, and conclude that predominant impact age were identified and that most of shocked zircons record regional metamorphic events. Here we report impact resseting ages from detrital shocked zircons with PFs at the Vaal River sand, cutting along the Vredefort Dome, and identified zircon deformation texture revealed by EBSD misorientation maps. Such deformation in shocked zircon supposed to be formed by impact, and their deformation texture (PFs and EBSD map) may help to identify the ancient impact record.

Application of acid-washing to trace element and tungsten isotope analyses of Eoarchean rocks from the Isua Supracrustal Belt

*Hatsuki Enomoto[1], Tsuyoshi Iizuka[1], Yoshitaka Homma[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

The short-lived ^{182}Hf–^{182}W decay system has been widely used to understand early Earth chemical evolution. Recently, ^{182}W anomalies have been found from many Archean terranes (e.g., Willbold et al., 2011; Touboul et al., 2012). These W isotope variations should be produced by the chemical fractionation of Hf/W on the Earth while ^{182}Hf was extant, or contribution of extraterrestrial materials having different W isotope compositions after core formation. While the W isotopic anomalies potentially provide valuable insights into processes on the early Earth, the exact cause of the isotopic anomalies is not yet clearly understood. As the possible causes, early silicate differentiation, early metal-silicate equilibrium at various conditions, and late veneer have been proposed, but these hypotheses respectively are inconsistent with the lack of correlations with Nd, Os isotopic data, and highly siderophile elements abundances (e.g., Rizo et al., 2016b; Puchtel et al., 2018; Touboul et al., 2012). Alternatively, the apparent lack of the correlations may be attributed to secondary disturbance in the W isotope compositions of the Archean rocks, given that W is highly fluid-mobile during metasomatism (e.g., Bali et al., 2012).

In this study, we applied an acid-washing method to Eoarchean metamorphosed rocks from the Isua Supracrustal Belt, with the aims to evaluate the possible effect of metasomatism on the W isotope systems, and to obtain their original W isotope compositions. We measured trace element compositions and W isotope ratios of acid-washes and residues of the metamorphosed basalts using ICP–MS.

The acid-washes show enrichments in light REE, whereas the residues exhibit enrichments in heavy REE. This suggests that acid-washing selectively removed a secondary component gained during metasomatism, given that light REE are relatively fluid-mobile as compared to heavy REE. Negative ^{182}W anomalies were found in the washes showing light REE enrichments. By contrast, non-resolvable ^{182}W anomaly was obtained for the residues displaying heavy REE enrichments. These findings suggest that the Isua metamorphosed basalts have a W isotope heterogeneity even in a single rock sample. Moreover, our results imply that the W isotope compositions of Isua supracrustal rocks could have been modified secondarily as a result of metasomatism. This can account for the lack of correlation between W isotopic data and other geochemical or isotopic data.

Limited primary production in the early Archean oceans and its biogeochemical consequenses

*Kazumi Ozaki[1]

1. Toho University

The activity level of the biosphere is a critical factor controlling the chemical composition of the atmosphere. The modern Earth's biosphere is powered by the oxygenic photosynthesis, which utilizes ubiquitous water as their electron donor, with the result that Earth's surface environment is extremely well oxygenated. Before the advent of the oxygenic photosynthesis, in contrast, primary production would have been limited by the geophysical input rate of critical electron donors (e.g., H_2 and Fe^{2+}) from the Earth's interior to the exogenic system. Here, we revisit previous modelling of the global biogeochemical cycles of H, C, and Fe in order to more precisely reconstruct global net primary production (NPP) during an interval of early Archean time before the advent of oxygenic photosynthesis. The biogeochemical model includes a series of metabolic reactions in the primitive anoxic biosphere (e.g., anoxygenic photosynthesis, methanogens, and fermenters) and takes redox (H) balance in the ocean-atmosphere system into account. I explore the effect of a variety of combination of key parameters (e.g., atmospheric CO_2 levels, geophysical input flux of Fe^{2+}, and volcanic outgassing flux of H_2) with a stochastic approach in order to search the possible solutions which allow for creating a warm climate state (>288 K) during the Archean. The results suggest that NPP by anaerobic metabolisms has been a few percent of the modern value. The H-based producers, photoferrotrophs, and CO-consuming acetogens contribute ~80%, ~18%, and ~2% of total NPP, respectively. The estimated extremely low NPP implies the geological fluxes of H_2 and Fe^{2+} as a limiting factor for biological productivity. The results also show that the atmospheric CO_2 levels are needed to be >~70 PAL (present atmospheric level) for maintaining warm climate state and that atmospheric CH_4 levels would have been >100 ppm despite the limited activity of the biosphere.

Behaviors of carbon cycle system and inevitability of the hot climate in the Archean Earth

*Yasuto Watanabe[1], Eiichi Tajika[1], Kazumi Ozaki[2], Peng Hong[3]

1. The University of Tokyo, 2. Toho University, 3. Chiba Institute of Technology

Although the luminosity of the Sun in the Archean (from 4.0 Ga to 2.5 Ga) was dimmer than that of today, geological records of $d^{30}Si$ and $d^{18}O$ from marine cherts suggests that the terrestrial surface environment may have been warm or even hot (328-358 K). Recently, along with these geological records, thermostability of reconstructed ancestral enzymes of cyanobacteria, which reflects the temperature of marine photic zone, also supports the hot surface environment.

To achieve such hot environment under the dimmer Sun, greenhouse effect of carbon dioxide and methane is considered to be necessary. Previous study using a coupled model of atmospheric photochemistry and ocean microbial ecosystem showed that the warm climate can be achieved by non-linearly amplified flux of methane to the atmosphere from the marine ecosystem only when H_2-using photosynthetic bacteria and Fe-using photosynthetic bacteria coexisted in the Archean marine ecosystem. This means that the photochemical processes and the marine microbial processes would have been important in realizing the hot environment under low pO_2 condition in the Archean. However, few studies investigated how these processes affected the global carbon cycle in the Archean.

Here we developed a coupled atmosphere photochemistry-marine microbial ecosystem-global carbon cycle model and assessed how the hot climate suggested from the geologic records can be achieved in the Archean. We found that, there are high pCO_2 (hot climate) stable solutions and low pCO_2 (warm climate) unstable solutions against the range of CO_2 degassing rate similar to that of today. In the low pCO_2 solutions (<~100 PAL), CO_2 is removed from the atmosphere-ocean system as the haze particle, hence such a condition is unstable in the Archean carbon cycle system. This finding strongly supports the results of the hot terrestrial environment in the Archean as suggested from many previous studies. The hot climate may be an inevitable result in the Archean carbon cycle system.

Occurrence and chemical composition of metamorphic carbonate rocks in the Isua supracrustal belt, West Greenland: Implications for the origin of carbonate rocks and compositions of the Eoarchean seawater.

*Yoshida Satoshi[1], Kazutaka Yasukawa[2], Yasuhiro Kato[2], Yusuke Sawaki[3], Tsuyoshi Komiya[3]

1. Department of Earth & Planetary Science, Graduate School of Science, The University of Tokyo, 2. Department of Systems Innovation, Graduate School of Engineering, University of Tokyo, 3. Department of Earth Science & Astronomy Graduate School of Arts and Sciences, The University of Tokyo

The Earth is a unique planet where liquid water and life exist through the geologic time. Therefore, reconstruction of the surface environment of the early Earth is an important issue to consider early life. However, we know little about the early Earth, because the first 500 million years record of the Earth was almost lost.

In recent decades, many studies has been done on the reconstruction of surface environment of the early Earth and early life (c.f. Schidlowski et al., 1979; Ueno et al., 2002; Tashiro et al. 2017). Especially, research on the origin of metamorphic rocks derived from banded iron formation (BIF), carbonate rock and chert in the 3.81 Ga Isua supracrustal belt (ISB), southern West Greenland has been actively carried out in order to reconstruct the surface environment of the early Earth (c.f. Rose et al., 1999; Bolhar et al., 2004; Friend et al., 2008; Nutman et al., 2010).

Recent geochemical studies suggested that the meta-carbonate rock in the ISB originated from a chemical sedimentary rock based on their Post-Archean Average Shale (PAAS)-normalized rare earth element (REE) patterns (Friend et al., 2008; Nutman et al., 2010). They argued that the meta-carbonate rocks have positive La ($[La/La^*]_{PAAS}$; $La^* = 2\,Ce - 2\,Pr$), Eu ($[Eu/Eu^*]_{PAAS}$; $Eu^* = 0.5\,Sm + 0.5\,Gd$) and Y (Y/Ho) anomaly. In the ISB, the carbonate rocks occur with one of three types following rocks: meta-chert, meta-conglomerate and meta-basalt. However, the relationship between the occurrence and the chemical compositons of meta-carbonate rocks is still ambiguous.

We estimated origin of the meta-carbonate rocks with different occurrence, and reconstructed chemical composition of the Eoarchean seawater from geochemistry of the meta-carbonate rocks in the northern part of the ISB. The meta-carbonate layers accompanying the meta-chert are several centimeters thick, and interlayered with meta-chert layer. The meta-carbonate rocks accompanying the meta-conglomerate rock occur as matrix of meta-conglomerate or layer formed centimeter thick. Previous workers considered that those meta-carbonate rocks originated from shallow water sediments (e.g. Dimorth, 1982; Nutman et al., 1984), whereas others interpreted that they formed through metasomatic alteration (e.g. Appel et al., 1998); thus the origin of the meta-carbonate rock are still controversial. The meta-carbonate rocks accompanying meta-basalt occur as veins in the meta-basalt and their thickness are centimeter to tens of centimeters. Those differences in the occurrence are related to their origin.

We analyzed major and trace element (e.g. REE and Zr) contents of the whole rocks of the carbonate rocks with X-ray Fluorescence (XRF) for major elements and High-Resolution Inductively Coupled Plasma Mass Spectrometry (HR-ICP-MS) for trace elements at the University of Tokyo, respectively. Some carbonate rocks have high SiO_2, TiO_2, Al_2O_3, and Zr contents, possibly due to involvement of detrital and

©2019. Japan Geoscience Union. All Right Reserved.

volcanic materials with/without silicification. We selected the carbonate rocks with low SiO_2, TiO_2, Al_2O_3, and Zr contents in order to remove influence of the silicification and contamination of the detrital materials.

The PAAS-normalized REE patterns of meta-carbonate rocks interlayered with the meta-chert show LREE-depleted patterns with positive La (La/La*: 1.18-1.40), Eu (Eu/Eu*: 1.80-5.50) and Y (Y/Ho: 34.9-45.3) anomaly and without Ce anomaly. The meta-carbonate rocks accompanying with meta-conglomerate rocks show LREE-depleted patterns with positive Eu (Eu/Eu*: 1.43-1.91) anomaly, and lack La, Ce and Y anomaly. The meta-carbonate rocks accompanying with the meta-basalt possess LREE-depleted pattern with Eu (Eu/Eu*: 1.35-1.91) anomaly, and lack La, Ce and Y anomaly.

The positive La and Y anomaly indicates that the meta-carbonate rocks were originate from chemical sediments precipitated from seawater (e.g. Webb and Kamber, 1999; Bolhar et al., 2004), and the lack of the Ce anomaly indicates that the Eoarchean seawater was anoxic as many previous works suggested. In addition, the positive Eu anomaly suggests that the meta-carbonate rocks was precipitated from seawater, influenced by hydrothermal activity.
We classified the meta-carbonate rocks in the ISB into two groups based on the occurrence and REE patterns: chemical sedimentary rock and metasomatized rock. The former includes the meta-carbonate rocks interlayered with meta-chert, whereas the latter comprises those accompanied with meta-conglomerate and meta-basalt.

[M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Yusuke Okazaki

Past environmental changes and events at multi-decadal to tectonic timescale toward an understanding of Earth climate system by an integration of terrestrial and marine proxy studies and numerical modeling will be discussed. At JpGU2019, a series of presentations on present and future climate and environmental changes from paleo-perspective will be held. We welcome a variety of paleo-environmental studies from a wide range of background. We hope that this session will provide an opportunity to promote communication between participants from multidisciplinary field.

Development of Longitudinal dunes under the Pangean atmospheric circulation

*Hiroki Shozaki[1], Hitoshi Hasegawa[2]

1. Faculty of Science, Kochi University, 2. Faculty of Science and Technology, Kochi University

From the Permian into the Early Jurassic, the supercontinent Pangea dominated our planets. Because of its largest landmass in the Earth’ s history, atmospheric circulation at this period is thought to be significantly different from today. Modelling experiments have suggested cross-equatorial Hadley circulation and its seasonal overturning. However, there are large discrepancy between model-generated surface wind pattern and geological evidence of paleo-wind pattern recorded by eolian sandstones in the central-western U.S.A. Previous study suggested that its discrepancy can be caused by the wrong interpretation of how winds shaped the dune in Pangea. Here, we re-examined Lower Jurassic eolian sandstone records in U.S.A. and reconstructed paleo-wind pattern with focusing on its dune morphology and orientation. Based on the recently revised paleomagnetic reconstructions, sand dune sea was widespread at about 24˚–33˚N. Spatial pattern of paleo-wind directions suggests influence of multi-directed paleo-winds, with dominant westerly winds in northern area and northeasterly winds in southern area. The reconstructed paleo-wind pattern appears to be consistent with the modelling results of paleo-location of subtropical high-pressure belt in the boreal winter of the Early Jurassic. In addition, spatial pattern of eolian slipface orientations suggest that dunes are mainly consists of longitudinal dunes with NNW–SSE orientation in Pangean time, which are markedly different from orientation direction of longitudinal dunes in present desert. We proposed that the development of NNW-SSE oriented longitudinal dunes could be formed by orbitally-induced latitudinal shifts of subtropical high-pressure belt in Pangea supercontinent. Modeling experiments also generated large modulation of strength and location of subtropical high-pressure belt in response to orbital-scale insolation changes. Reconstructed surface wind pattern and different directions of longitudinal dune orientation recorded in Jurassic eolian sandstone records therefore represent a distinct pattern of Pangean atmospheric circulation.

Response of primary producers in the ocean anoxic events during the Cretaceous

*Haga Mayuko[1], Eiichi Tajika[1], Kazumi Ozaki[2]

1. The University of Tokyo, 2. Toho University

In the Cretaceous, it is known that the “Ocean Anoxic Events (OAEs)” occurred repeatedly. In the OAEs, marine biogeochemical cycles, biological activity, and process of sedimentation may have been different from those under the oxic condition like today. In fact, biomarkers of cyanobacteria and green sulfur bacteria have been found from the sediments during the OAEs. It is therefore suggested that the redox condition and the primary procedures were quite different at the time of the OAEs. If we regard OAE as a disturbance to the marine biogeochemical cycle system, it is important to understand the response of photosynthetic ecosystem that plays a key role in controlling the ocean redox condition during OAEs.

In the Cretaceous, the climate was warmer and the sea level were higher than today because seafloor spreading rate were very high, hence the shallow water area expanded due to the transgression. Under such conditions, the ocean tends to be oligotrophic and oxic because vast shelf area is locus for the deposition of organic matters and traps large amounts of phosphate and nitrogen (Ozaki et al, 2013). We, however, do not know the marine biogeochemical cycles of nutrients and the behaviors of primary procedures under such a condition in the Cretaceous. We therefore developed a marine biogeochemical cycle model coupled with a marine ecosystem model and investigated the condition of OAEs ,marine biogeochemical cycles of nutrients and the behaviors of primary producers in the Cretaceous.

We found that algae is the dominant primary procedure under the “normal” Cretaceous condition, but once the global surface temperature rises owing to, such as activities of large igneous provinces (LIPs), concentration of phosphate in the ocean increases owing to enhanced chemical weathering of land surface. This leads to increase in the marine primary production which, in turn, promotes anoxic conditions in the ocean because dissolved oxygen is consumed by organic matter decomposition, initiating OAE. In the anoxic ocean, nitrogen is limited because nitrate is consumed by organic matter decomposition and thiodenitrification, inhibiting photosynthetic activity of algae. Cyanobacteria becomes dominant primary procedure because some of them can fix nitrogen. In the upwelling regions, green sulfur bacteria becomes dominant because hydrogen sulfide produced by sulfate reducing bacteria upwells to the euphotic zone.

The linkage between desertification and tectonism inferred from the provenance change of the terrestrial sediments in the Tarim basin

*Aki Sakuma[1], Ryuji Tada[1], Tomohiro Yoshida[1], Hitoshi Hasegawa[2], Naomi Sugiura[1], Akinori Karasuda[1], Ke WANG[1], Hongbo Zheng[3]

1. Department of Earth and Planetary Science, School of Science, the University of Tokyo, 2. Faculty of Science and Technology, Kochi University, 3. School of Resource Environment and Earth Science, Yunnan University

The Tarim basin, which locates to the northwest from the Tibetan Plateau, is the area where the most significant aridification was expected as a result of the uplift of the Himalaya and the Tibetan plateau due to the collision between the Indian subcontinent and the Eurasia continent during Cenozoic (e.g. Kitoh, 2005). However, the geological evidence supporting the relationship between the aridification of the Tarim basin and the tectonism in its surrounding areas is not obtained sufficiently. The reason why the difficulty in examining the relationship between the timing of tectonism and aridification arises is that the timing of the onset of aeolian dune deposition in the Tarim basin, which is the good evidence of the aridification, depends on age models and, thus, there is uncertainty in the timing of the desertification. To solve this problem, it is effective to compare the timing of both tectonic and climatic events on the same section.

In this study, the provenance change of the upper Eocene to the middle Miocene fluvial sandstone deposited in the Aertashi section in the southwestern edge of the Tarim basin was examined using the Electron Spin Resonance (ESR) signal intensity and Crystallinity Index (CI) analyses of quartz in the 64-500 μm fraction and the thin section observation. The timing of the tectonic movement in the Pamir estimated from the provenance change is compared with the timing of the desertification implied by the lithology to examine the relationship between the tectonism and the desertification.

The result of the ESR signal intensity and the CI analyses indicates that the provenance changes of the fluvial sandstone in the Aertashi section are divided into six stages and the boundary between stages are ca. 35Ma, ca. 33Ma, ca. 26Ma, ca. 21Ma, and ca. 17Ma, respectively. Thin section observation shows that the composition of the fluvial sandstone changes significantly at ca. 17Ma with higher content of lithic fragments with wide variety of the types, and the relatively high content of biotite and mafic minerals after ca. 17Ma.
The significant provenance changes at ca. 33Ma, ca. 26Ma, and ca. 17Ma showen by the ESR signal and the CI data imply that the tectonic movement in the Pamir possibly occurred around these times. Since the onset of desertification in the Tarim basin is estimated around 35Ma based on the lithology, the uplift of the Pamir does not seem to have been the cause of the initial aridification in the Tarim basin.

Paleoceanographic reconstruction in the northwestern Pacific during MIS 19 using ultra-high temporal resolution oxygen isotope profiles and planktonic foraminiferal assemblage

*Yuki Haneda[1], Nanako Yokokawa[1], Makoto Okada[1], Hiroki Hayashi[2], Yoshimi Kubota[3], Yusuke Suganuma[4]

1. College of Science, Ibaraki University, 2. Interdisciplinary Factulty of Science and Engineering, Shimane University, 3. National Museum of Nature and Science, 4. National Institute of Polar Research

The orbital configuration during Marine Isotope Stage (MIS) 19 are characterized by a weak eccentricity-precession forcing and an obliquity maximum associated with a precession minimum as well as MIS 1, although the both absolute values of obliquity are different. Thus, MIS 19c, one of the sub-stages during MIS 19, is assumed as the best analogue for the present interglacial suggesting the timing of the next glacial inception in the future when the anthropogenic influences are excluded.

The Chiba composite section (CbCS) at east-central Japanese island faces the northwestern Pacific containing the Kuroshio Extension Front (KEF) which is north limit of the Kuroshio Current transporting amount of heat and water from the Equatorial to mid-latitude. Modern observation, climate model, and geologic records reveal that variations of the oceanic fronts in the northwestern Pacific (surface temperature and latitudinal position) and atmospheric circulation in the North Pacific interact. However, response of the KEF to external and internal forcings under the modern orbital configuration remain unclear.

Here, we reconstruct detailed paleoceanographic variations in the northwestern Pacific during MIS 19 using stable oxygen isotope ($\delta^{18}O$) and planktonic foraminiferal assemblage records form the CbCS. Spectral and wavelet analyses were conducted in order to assess periodicity of our new $\delta^{18}O$ records. Vertical water temperature structure and their gradient (ΔT), and relative abundance variation of warm-water species exhibit latitudinal displacements of the KEF on multi-millennial scale across the MIS 20–19 transition and during late MIS 19 (MIS 19b to 19a). Results of the spectral and wavelet analyses for the $\delta^{18}O$ records show periodicities of 2,300–6,000 year during late MIS 19. Similarities of timing and periodicity between paleoceanographic records from the CbCS and North Atlantic indicate that disruption of the Atlantic meridional overturning circulation due to freshwater discharge into the North Atlantic caused the southward displacements of the KEF via atmospheric dynamic. A power of the 9,700 year-periodicity in surface planktonic $\delta^{18}O$ and ΔT is stronger during MIS 19c, which probably originates from tropics caused by equatorial insolation at equinoxes with the orbital perihelion. This result indicates the seasonality of the insolation at low-latitudes paced the sea surface condition at the CbCS throughout MIS 19 and this low-latitude influence became larger especially when the North Atlantic forcing by freshwater discharges and AMOC variability was low. Our result suggests that millennial-scale stability and variation of oceanographic condition along the KEF under this orbital configuration depend on North Atlantic climate variability.

Paleoclimate reconstruction using fossil pollen analyses from a sedimentary sequence around the Matuyama-Brunhes polarity transition in the Chiba composite section

*Makoto Okada[1], Hitomi Takizawa[1], Yuki Haneda[2], Yusuke Suganuma[3,4], Quentin Simon[5]

1. Department of Earth Sciences, College of Science, Ibaraki University, 2. Graduate school of Science and Technology, Ibaraki University, 3. National Institute of Polar Research, 4. Graduate University for Advanced Studies, 5. Aix-Marseille University

To examine the “Svensmark effect”, linking climate cooling and geomagnetic field strength decrease, during the time of geomagnetic reversal, we have conducted a pollen analysis in the Chiba Composite Section including the Matuyama-Brunhes polarity reversal boundary, and correlated the quantitative paleoclimatic variation deduced by the modern analog method with the paleomagnetic and ^{10}Be records. The samples used in this study are from 33 horizons in a stratigraphic interval between 4-31 m above the Byk-E tephra bed where the sample density of pollen fossil data used in the previous study (Suganuma et al., 2018) is low. Samples were subjected to KOH-acetolysis treatment (Moore et al., 1991) and hydrofluoric acid treatment as pretreatment to extract pollen fossils. As a result of microscopic examination with an optical microscope, we identified 27 genera in total of 3 families, 24 genera of woody pollen, 2 genus pollen grasses and 2 spores. The abundant pollen fossils are Pinus, and some other genera distributed in the subarctic to cool temperate zones such as Picea, Tsuga, Fagus, etc.
Applying the modern analog method (Nakagawa et al., 2002) to the pollen assemblage data, the reconstructed paleoclimatic parameters show lower overall temperatures than the current study area. Comparing various climatic parameters from the modern analog method with the oxygen isotope records, insolation, ^{10}Be showing the penetration of galactic cosmic ray into the atmosphere and relative paleointensity, the reconstructed climatic parameters showed a variation consistent with paleoceanographic temperatures deduced from oxygen isotopes of planktonic foraminifera. Moreover, we do not recognize any trend of decreasing in air temperature corresponding to geomagnetic field strength collapse at the M-B boundary as reported by Kitaba et al. (2017).

Reconstruction of vertical thermal structure in the western Pacific warm pool over the last 1 Myr

*Fumito Mizuno[1], Takuya Sagawa[2], Keisuke Mukaida[3], Yoshimi Kubota[4], Toshitsugu Yamazaki[5], Junichiro Kuroda[5]

1. Graduate School of Natural Science and Technology. Kanazawa University, 2. Institute of Science & Engineering. Kanazawa University, 3. Collage of Science & Engineering. Kanazawa University, 4. National Museum of Nature & Science, 5. Atmosphere and Ocean Research Institute. The University of Tokyo

The zonal atmospheric circulation in the tropical Pacific, the Walker circulation, is closely related to the zonal gradients of sea surface temperature (SST) and thermocline through the ocean-atmosphere interaction. Variability of such an interaction in a couple of years timescale is known as El Niño Southern Oscillation (ENSO), which has a great influence on climate not only in the tropics but also in wide areas on the globe. Proxy SST records revealed that the zonal SST gradient has changed in various timescales, and it is interpreted that the ENSO-like ocean-atmosphere interaction also worked on the longer timescale. However, there is no definitive evidence that the change in the zonal SST gradient was accompanied by change of the Walker circulation. Here we reconstruct thermocline temperature variability, which is sensitive to the strength of the Walker circulation. By comparing the variations of zonal and vertical temperature gradients, we examined whether the ENSO-like ocean-atmosphere interaction was functioning on the tens of thousands to hundreds of thousands of years timescale. The sample used in this study is a piston core MR14-02 PC4 collected on the Ontong-Java Plateau located in the western Pacific warm pool (WPWP). Surface and thermocline temperatures were reconstructed by Mg/Ca analyses of planktonic foraminifera, *Globigerinoides ruber* and *Pulleniatina obliquiloculata*, respectively, for the last million years. We compared the vertical temperature gradient (difference between surface and thermocline temperature: ΔT_{WPWP}) and the zonal temperature gradient (difference between *G. ruber* SST in this study and alkenone SST in the East Equatorial Pacific ODP Site 846 : ΔSST_{W-E}). As a result, the relationship between ΔT_{WPWP} and ΔSST_{W-E} in the past was not similar to that of the modern ENSO variability. This result suggests that the change of temperature structure in longer timescale was caused by a mechanism different from today. Also, ΔT_{WPWP} and ΔSST_{W-E} showed a longer time scale change than the glacial-interglacial cycles, and the cycle is approximately 400 kyr. This implies that the thermocline variability in the equatorial Pacific might be related to the Milankovitch cycle. The results of this study suggest that it is necessary to discuss vertical and meridional thermal structures in addition to the zonal SST gradient in order to understand the dynamics of past ocean-atmosphere interaction.

[M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Michinobu Kuwae(愛媛大学沿岸環境科学研究センター)

Past environmental changes and events at multi-decadal to tectonic timescale toward an understanding of Earth climate system by an integration of terrestrial and marine proxy studies and numerical modeling will be discussed. At JpGU2019, a series of presentations on present and future climate and environmental changes from paleo-perspective will be held. We welcome a variety of paleo-environmental studies from a wide range of background. We hope that this session will provide an opportunity to promote communication between participants from multidisciplinary field.

Future perspective on the response of marine calcifiers to “evil twins” of climate change due to increased PCO2

*Hodaka Kawahata[1]

1. Atmosphere Ocean Research Institute, the University of Tokyo

This talk is developed from our comprehensive review paper of PEPS: Kawahata, H., Fujita, K., Iguchi, A, Inoue, M., Iwasaki, S., Kuroyanagi, A., Maeda, A., Manaka, T., Moriya, K., Takagi, H., Toyofuku, T., Yoshimura, T., Suzuki, A. (2019) Perspective on the response of marine calcifiers to global warming and ocean acidification –Behavior of corals and foraminifera in a high CO2 world “hot house”. Progress in Earth and Planetary Science 6: 5 (p.1-37).

Our planet will experience global warming and ocean acidification due to increased partial pressure of CO2 in the atmosphere. They are often referred to as the “evil twins” of climate change, potentially inducing severe threats in the near future.

Generally, majority of marine calcifying organisms show decreases in calcification rates in response to acidified seawater by increased pCO2. However, the response often differs depending on situations, species, and life-cycle stage. Calcification of Calcarina gaudichaudii, generally increased with increased pCO2. As one possible cause of these different sensitivities, Calcarina hosts diatoms as its symbiotic algae. High-CO2 seawater is favorable to diatom growth.

X-ray micro-computed tomography will provide valuable information regarding biomineralization including calcification of planktic and benthic foraminifera in response to ocean acidification as well as regarding carbonate dissolution.

Based upon the analysis of the biogeochemical cycle (today, at P/E boundary and in Cretaceous), “high speed” and “high level” pCO2 are the primary and secondary factors, respectively, leading to acidification in the Earth surface’s system. Over the long-term, it is well known that alkalinity has fluctuated largely in the Earth’s surface environment. Therefore, it is important to quantitatively reconstruct alkalinity, which is another key factor determining the saturation state of carbonate minerals.

Reconstruction of seawater pH and atmospheric CO_2 concentration based on boron isotopic composition of biogenic calcium carbonate

*Kaoru Kubota[1]

1. Kochi Institute for Core Sample Research, JAMSTEC

A lot variety of environmental information is recorded in marine biogenic calcium carbonate that is represented by reef building coral skeletons and foraminifera shells. Among these, **boron isotope ($\delta^{11}B$)** proxy is of great importance in the realm of paleoclimatology and paleoceanography, since it can record seawater pH and CO_2 concentration of the overlying atmosphere. Along with the growing interest to recent environmental problems such as global warming and ocean acidification due to anthropogenic CO_2 emission, past carbon cycle research has been actively conducted, and boron isotope proxy is priceless tool to study it. In 1980s, applicability of this proxy was foreseen, but high precision boron isotope measurement with small sample requirement was difficult at that time. As boron exist abundantly around us (the most representative one is borosilicate grass), analytical technique has evolved as the boron-free clean environment improved. Thermal ionization mass spectrometry (**TIMS**) was first developed, and nowadays multi-collector inductively coupled plasma mass spectrometry (**MC-ICPMS**), secondary ionization mass spectrometry (SIMS), and laser-ablation inductively coupled plasma mass spectrometry (LA-ICPMS) (and others) is now available. Measurable minimum sample amount, achievable analytical precision, and spatial resolution of the analysis are largely different among methods, and efforts to measure boron isotope composition more precisely with smaller amount of samples has continued at research institutes around the world. In **Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology**, boron isotope measurements by using TIMS and MC-ICPMS are available: the former realizes the most precise measurement in the world, and the latter realizes analytical precision and required sample amount that is comparable with major overseas laboratory. In this presentation, I will explain theoretical background why boron isotope of marine biogenic calcium carbonate becomes seawater pH proxy and characteristics of two different mass spectrometry, and then overview already-done research and ongoing research topics. Recent development of visualization technology of pH of calcifying fluid of reef building coral and foraminifera has enabled deeper understandings of boron incorporation systematics. On the one hand, boron isotopes of reef building coral is most-likely a direct indicator of pH of calcifying fluid; on the other hand, those of foraminifera is likely influenced by microenvironment pH gradient surrounding foraminifera. Whatever the mechanism is, a clear relationship between boron isotopes and seawater pH is observed in various samples such as cultured, recently live-collected, and fossil samples, thus many studies use this proxy in paleoclimatology and paleoceanography by understanding empirical relationship collectly ("calibration").

A 70 years changes of the Java Sea surface condition based on geochemical analyses of a coral core

*Ai Genda[1], Atsushi Suzuki[2], Toyoho Ishimura[3], Minoru Ikehara[4], Mayuri Inoue[1]

1. Graduate School of National Science and Technology, Okayama University, 2. Geological Survey of Japan Natinal Institute of Advanced Industrial Science and Technology, 3. National Institute of Technology, Ibaraki College, 4. Center for Advanced Marine Core Research, Kochi University

At Indonesian Archipelago, observed and instrumental records have not been well recorded because of complex terrain. In this study, we have reconstructed sea surface condition of the Java Sea for past 70 years based on $\delta^{13}C$, Sr/Ca and U/Ca ratios in the coral skeleton.
A coral core (*Porites* sp.) was collected from the the Seribu Islands located at the Java Sea, Indonesia. Measurements of Sr/Ca, U/Ca ratios and $\delta^{13}C$ were performed by inductively coupled plasma (ICP)-optical emission spectrometer, ICP-mass spectrometer and stable isotope ratio mass spectrometer with about 2-month time resolution.
Although it has been reported that both coral Sr/Ca and U/Ca ratios can be used as paleothermometer [Beck et al., 1992; Min et al., 1995], coral U/Ca ratios also depends on seawater pH [Inoue et al., 2011] and carbonate ion concentration ($[CO_3^{2-}]$) [Anagnostou et al., 2011]. Furthermore, since coral $\delta^{13}C$ reflects DIC of ambient seawater, we will discuss about marine environments such as water temperature and seawater pH at the Java Sea for 70 years.

Reconstruction of paleoenvironments in the western Pacific for the last 220 years

Mutsumi Chihara[1], Ayaka Fukushima[2], Minoru Ikehara[3], Hodaka Kawahata[2], Atsushi Suzuki[4], *Mayuri Inoue[1]

1. Department of Earth Sciences, Okayama University, 2. Atmosphere and Ocean Research Institute, the University of Tokyo, 3. Center for Advanced Marine Core Research, Kochi University, 4. Geological Survey of Japan, AIST

In the tropics, *Porites* corals are recognized as the excellent archives of past climate and environmental and oceanic conditions because coral skeletal geochemistry, such as oxygen and carbon isotopes and Sr/Ca ratios, provides quantitative information on sea surface temperature (SST) and salinity. However, continuous long records more than 200 years based on coral records have been limited.

Here, we present a 224-year SST record with high time resolution (~2 month) derived from Sr/Ca ratios and stable isotopes ($\delta^{18}O$ and $\delta^{13}C$) from Philippines (13°N, 124°E), which located on the northern edge of the western pacific warm pool (WPWP).

Coral Sr/Ca was measured by an inductively coupled plasma optical/atomic emission spectrometer (ICP-OES/AES) with a precision was better than 0.6 % which is equivalent to 0.5 ℃. Analyses of $\delta^{18}O$ and $\delta^{13}C$ were measured by isotope ratio mass spectrometer (IR-MS). Precision was better than 0.05 ‰for $\delta^{13}C$ and 0.10 ‰for $\delta^{18}O$. In this study, spectral analysis was performed by using the kSpectra. Reconstructed SST varies from 25 to 32 ℃ and shows that there were multiple cold events during the last 224 years in the western tropical Pacific. A decreasing trend in $\delta^{13}C$ for the last 50 years was found which may reflect accelerated increase in the amount of anthropogenic CO_2 (Suess effect).The result of $\delta^{18}O$ analyses implies western pacific climate was cooler and drier in the early 19th century which is almost consistent with other coral records. In contrast, warmer and wetter conditions persist since 1950s.The spectral analysis of the annual SST and $\delta^{18}O$ anomaly for 224 years shows significant peaks at 3-8 years. These frequencies are considered to be related to the ENSO variability.

Ocean deoxygenation from the Last Glacial Maximum to the future global warming: inshight from model simulations

*Akitomo Yamamoto[1], Ayako Abe-Ouchi[2,1], Rumi Ohgaito[1], Akinori Ito[1], Masahito Shigemitsu[1], Yasuhiro Yamanaka[3], Akira Oka[2]

1. Japan Agency for Marine-Earth Science and TechnologyAtmosphere and Ocean Research Institute, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Faculty of Environmental Earth Science, Hokkaido University

Global warming is expected to decrease ocean oxygen concentration by less solubility of surface ocean, reduced ventilation and enhanced stratification. The associated expansion of the oxygen minimum zone would have adverse impact on marine organisms and ocean biogeochemical cycles. Earth system models show a consistent deoxygenation trend over the twenty-first century; however, longer-term changes in ocean oxygen are still unclear due to the uncertain response of deep ocean circulation.

During the Last glacial maximum, recent proxy data show that, despite greater oxygen solubility due to sea surface cooling, the oxygen concentrations throughout the deep ocean were generally lower. These records provide the response of oxygen content to climate forcing that are comparable in magnitude to the expected future changes. Therefore, the understanding of glacial deoxygenation will help us to better understand and predict future oxygen changes. In addition, glacial deep-water deoxygenation is crucial to understand glacial-interglacial CO_2 change, since glacial deoxygenation reflects increased accumulation of respired carbon in the glacial deep ocean. However, the mechanisms of deep-water deoxygenation and contribution form the biological pump to glacial CO_2 drawdown are poorly understood due to the difficulties in reproducing glacial deoxygenation.

In this study, we report the importance of glaciogenic dust for the glacial deep-water deoxygenation from our numerical simulation which successfully reproduces the magnitude and large-scale pattern of the observed oxygen changes from the present to Last Glacial Maximum. Sensitivity experiments reveal that physical changes (e.g., more sluggish ocean circulation) contribute to only half of all glacial deep deoxygenation, whereas the other half is driven by enhanced efficiency of the biological pump. We found that iron input from the glaciogenic dust with higher iron solubility is the most significant factor for enhancement of the biological pump and global deep-water deoxygenation. The model-proxy agreement of oxygen change supports the simulated contribution of the enhanced biological pump to the decrease of more than 30 ppm of glacial CO_2.

On the other hand, our model underestimates deoxygenation in the deep Southern Ocean due to enhanced ventilation in the Southern Ocean. Our results suggest that the stratified Southern Ocean is required for reproducing glacial deoxygenation in the Southern Ocean. However, present climate models cannot reproduce the stratified Southern Ocean. A possible reason is that climate models are too coarse to capture the process of dense water formation on the Antarctic shelf and tend to underestimate the strength of stratified Southern Ocean. Similar to glacial oxygen changes, our global warming simulation show that changes in ocean circulation in the Southern Ocean are crucial for long-term projecting future oxygen changes associated with global warming. Therefore, the understanding of glacial oxygen changes will help us to better understand and predict future oxygen changes.

Extraction of high-quality ^{14}C data from terrestrial sediments containing pollen fossils

*Takayuki Omori[1], Keitaro Yamada[2], Ikuko Kitaba[2], Takeshi Nakagawa[2]

1. The University Museum, The University of Tokyo, 2. Research Centre for Palaeoclimatology, Ritsumeikan University

Fossil pollen grains, which are commonly found in various types of sediments, have great potential for radiocarbon chronological research. If measurable amounts of fossil pollen grains can be extracted readily from sediment matrices, then ^{14}C age determination could be performed at any depositional depth, regardless of with or without plant macrofossils, and the quality of the deposition age model can be considerably increased. Thus far, several lake sediments have been tested for pollen ^{14}C. However, technical issues such as complex preparation procedures, collection rate, and purity of concentrated sample persisted and pollen ^{14}C analysis has not been applied routinely. A novel pollen concentration method is developed herein using a next-generation cell sorter to quickly prepare pure concentrates of fossil pollen grains suitable for ^{14}C dating, with a relatively simple preparation procedure.
Cell sorter was originally developed for biomedical researches to instantaneously identify and separate cells of specific fluorescence and shape. Some of the latest model machines can perform machine tuning and sample preparation semi-automatically, and it is designed to solve most issues via the exchange of replacement parts. In the proposed method of pollen purification, pollen-enriched suspension is introduced into cell sorter, which can separate more than a million grains of fossil pollen in half a day. The pollen ^{14}C analysis was conducted using a SG06 sediment core from Lake Suigetsu, which has one of the most reliable age models that we can use as reference. Pollen fossil samples equivalent to 50–100 μgC were extracted from ca. 25-30 g of wet sediment and were measured using a compact AMS system (NEC 0.5 MV 1.5SDH-1) of LRD.UMUT. The ^{14}C data of the pure pollen samples agreed well with the Suigetsu's ^{14}C dataset on terrestrial plant leaf fossils. This result shows that accurate ^{14}C data can be obtained from any depth of the core, even at depths at which plant remains are not present. Using the proposed method, the Suigetsu's ^{14}C data can be enhanced for data density and evenness of the data intervals, both of which would directly contribute to the accuracy of the age model. We also believe that the proposed method can be applied to various sediment types from both marine and terrestrial realms, and will assist high-precision chronological study as well as quantification of marine reservoir age.

Oxygen isotope fluctuations of pollen fossils from Lake Suigetsu, Japan

*Keitaro Yamada[1], Takayuki Omori[2], Ikuko Kitaba[1], Takeshi Nakagawa[1]

1. Research Organization of Science and Technology, Ritsumeikan University, 2. The University museum, The University of Tokyo

Interactions of atmospheric, marine, terrestrial, and cryospheric realms are important factors in considering mechanisms of climate change (Lowe et al., 2008). Pollen analysis widely used methods to reconstruct past climate changes. However, comparing pollen data with other geochemical proxies, especially stable isotope signals, is not straightforward due to the non-linearity included in the conventional pollen composition signals. On the other hand, pollen grains are composed of sporopollenin and potentially provide isotopic signals which can be more directly compared with key palaeoclimatic records from across the world (Loader and Hemming, 2004). In this study, we first established a method to extract fossil pollen grains from sediment matrix by “cell sorter”. Then we applied that new method to the varved sediments obtained from Lake Suigetsu, Japan (in particular, transition from the Lateglacial to the early Holocene) in order to test if the isotopic signals of pollen grains are keeping meaningful palaeoclimatic information or not.

Lake Suigetsu (35˚35'N, 135˚53'E, 0 m a.s.l.), Fukui prefecture, is one of the Mikata Five lakes, which measures 3 km east-west by 3 km north-south, with the maximum water depth of ca. 34 m. Lake Suigetsu preserves annually laminated sediments over the last ca.70 kyr with a significant number of event layers that allows precise correlation among parallel cores. Two long cores (SG93, SG06) have previously been recovered from the centre of the lake. An exceptionally precise age model has been established for the cores through a combination of over 800 radiocarbon (^{14}C) dates and high precision varve count (Staff et al., 2011; Marshall et al., 2012; Schlolaut et al., 2012; Bronk Ramsey et al., 2012). In this study, we used well-dated SG06 cores and extracted pollen fossils using cell sorter.

Cell sorter is able to characterise particles using optical parameters (mainly fluorescence), and separate specific particles using electrostatic deflection. Pollen fossils can be isolated by cell sorter without fluorescent dyes using cell sorter because sporopollenin constituting pollen grains is naturally auto-fluorescent (Tennant et al., 2013). After chemical and physical pre-treatments, pollen-enriched suspension was introduced into the cell sorter and extracted half a million pollen fossils from each sample. After drying and weighing, δ^{18}O value of the high-purity pollen pellets were determined using High Temperature Conversion Elemental Analyzer (TC/EA, Thermo Scientific) in the University of Tokyo.

The oscillation of the δ^{18}O value of the extracted pollen pellets roughly mirrored that of the NGRIP, showing typical climatic transitions that characterise the Late glacial period. Our results strongly imply that the stable isotope signal of fossil pollen grains is keeping record of past climate changes.

Reconstruction of lake-level changes during the last glaciation based on fossil diatom record in Lake Biwa

*Takashi Suzuki[1], Yoshio Inouchi[2], Keisuke Otsuka[1], Kaoru Kawakami[3]

1. Graduate School of Human Science, Waseda University, 2. Faculty of Human Sciences, Waseda University, 3. Graduate School of Environmental Science, Hokkaido University

This is a report of a research for reconstruction of lake-level change history of Lake Biwa based on the transfer function of diatom assemblage into water depth. We have analyzed diatom assemblages, sand content, and C/N ratio in drilling core sample from the lake bottom of 23.45 m in depth and surface sediment samples from the lake bottom from 5 m to 30 m in depth off estuary of Echi River, Lake Biwa. The relative abundance of planktonic species in diatom assemblage from surface sediments can be changed into water depth. The transfer function applied to fossil diatom record in drilling core sample into lake-level change history during the last 50 ka.
We compared the record with Sanbao & Hulu cave stalagmites $\delta^{18}O$ records in China and NGRIP $\delta^{18}O$ record in Greenland from 50 ka to 10 ka. The result shows that the lake-level change history in Lake Biwa reflects East Asian winter monsoon intensity. Lake-level rose under relatively cold conditions or abrupt cooling like Heinrich Events and lake-level fell under relatively warm conditions. The lake-level response to climate conditions suggests that snowfall in winter depending on East Asian winter monsoon intensity mainly contributed to water balance of Lake Biwa during the last glacial period.

An estimation of microplatcis sedimentation flux in a coastal sea

*Hirofumi Hinata[1], Michinobu Kuwae[1], Issei Masumoto[1], Hayato Kawamata[1]

1. Ehime University

Plastics production has been increasing each year. It is estimated that 4.8-12.7 million tons of plastics flowed out into the ocean in 2010. The plastics weathers due to UV degradation and fragmented into small pieces. Generally, the plastic particles of the 0.3-5mm in size are called microplastics. They are likely to be incorporated into the ecosystem and there is concern about bad influence on ecosystem. Recent studies have found that microplastics sink to the sea bottom. However, the sedimentation flux has not been clarified yet. In this study, the sedimentation flux of microplastics was estimated. We collected and analyzed the sediment cores from the bottom of Beppu Bay. Beppu Bay is suitable for the core sampling, because sediments have not been vertically disturbed.Five cores were taken using Gravity Corer. Four sediment cores were for microplastic analysis, and one for dating sediment layers. The sedimentary age was determined using the Pb-210 method. Microplastics extracted from the four core samples were analyzed by FT-IR to determine the polymer type. A total of 142 pieces of microplastic were detected. The most common polymer type among plastics was polyethylenewhich accounted for 55% of the total in number. The average sedimentary flux from 1998 to 2017 was calculated as 217 [pieces/m^2·y)].

Beppu Bay sediments: Potential palaeoenvironmental archives for a candidate auxiliary stratotype for Anthropocene-Holocene boundary

*Michinobu Kuwae[1], Yoshiaki Suzuki[2]

1. Center for Marine Environmental Studies, Ehime Univ., 2. Department of Eearth Scieces, Fuculty of Education and Integrated Arts and Sciences, Waseda Univ.

A markedly increasing influence of human activity on the Earth system since 1950s has gained attention as one of the notable turning points of Earth's history, which is noteworthy to propose the 'Anthropocene' as a potential new unit of the International Chronostratigraphic Chart which serves as the basis of the Geological Time Scale. Now is ongoing the definition and selection of the Global Boundary Stratotype Section and Point (GSSP) mainly by the Anthropocene Working Group (AWG), a working group of the Subcommission on Quaternary Stratigraphy (SQS) of the International Commission on Stratigraphy (ICS). There are several candidates of a suitable stratotype for hosting an Anthropocene GSSP, including ice core, tree-ring, and coral that record an increasing fallout signal of ^{14}C and ^{239}Pu as well as a rapid decrease in $\delta^{13}C$ during 1950s. However, since (1) radionuclide fallout did not have major biological or other widespread physical repercussions, (2) ice might disappear itself due to global warming, and (3) ^{14}C signal won't detect in 100, 000 years or more, other stable auxiliary stratotypes and markers may be needed for the establishment of GSSP.

GSSPs previously ratified have often been established in marine sediments; anoxic marine sediments emerges as one of the candidates for Anthropocene auxiliary stratotypes (Waters et al., 2018). In anoxic marine sediments, there are the potential Anthropocene boundary markers, including microplastics, diatom and foraminifer assemblages, metals, organic contaminations, and spheroidal carbonaceous particles, which can be used to correlate globally. Several marine anoxic basins have been addressed for a candidate of auxiliary stratotype, such as Santa Barbara Basin, etc., but, an existence of a Japanese marine anoxic basin has not been well-known. Here we introduce laminated sediments in the anoxic Beppu Bay basin for a potential auxiliary stratotype of Anthropocene and discuss its recent progress of stratigraphy and advantage to propose the candidate, and future tasks to acquire a comprehensive dataset for establishment of the boundary.

[M-IS22] Electromagnetic phenomena associated with seismic and volcanic activities

convener:Tetsuya Kodama(Research Unit I, Research and Development Directorate, Japan Space Exploration Agency), Toshiyasu Nagao(Institute of Oceanic Research and development, Tokai University), Chairperson:Tetsuya Kodama, Toshiyasu Nagao

This session deals with reviews and contributions on the recent studies of electromagnetic (EM) phenomena associated with earthquakes and volcanic eruptions. One of the main targets of the session is to clarify the mechanism of seismo-EM emission and Lithosphere-Atmosphere-Ionosphere (LAI) coupling. Recently, some scientists claim that seismic activities are the critical phenomena. These kinds of approach are also welcome.

Stress-induced charges in gabbro at high temperature

*Chihiro Yamanaka[1], Daiki Maezono[1]

1. Graduate School of Science, Osaka University

Preseismic ionospheric disturbance just before large earthquakes was found at the 2011 off the Pacific coast of Tohoku Earthquake (Heki,2011). Similar phenomena up to 18 cases (Heki's TEC anomaly) were found in earthquakes of M 7-9 since 1994. It should be noted all the earthquakes larger than M 8.5 during that duration were 5 times and Heki's TEC anomaly was observed for all of them.
Assuming the phenomena were drived by surface electromagnetic field due to stress induced charges distributed thinly around focal or nucleation zone, we have been studying stress-induced charges from silicate rocks. A dried gabbro sample (10×10×3 cm) was heated up to 350℃, then stress-induced current under uniaxial stress of 10 MPa was observed with the variation of temperature.
Experimental results showed that stress-induced charges increased from room temperature to 200℃ but then decreased at higher temperature. We would like to discuss the mechanism of Heki's TEC anomaly based on the experimental results and computer simulation.

Evaluation of ULF seismo-magnetic precursor phenomena at Kakioka, Japan over 1983 –2018 by using SEA and Molchan’ s error diagram

*Katsumi Hattori[1], Kei Takahashi[2], Peng Han[3]

1. Department of Earth Sciences, Graduate School of Science, Chiba University, 2. Department of Earth Sciences, Faculty of Science, Chiba University, 3. Southern University of Science and Technology, China

To clarify and verify the ultralow frequency (ULF) seismo-magnetic phenomena, we have performed statistical studies on the geomagnetic data observed at the Kakioka (KAK) station, Japan, during 1983-2017. We investigated the energy of ULF geomagnetic signals of the frequency around 0.01 Hz using wavelet transform analysis. To minimize the influences of artificial noises and global magnetic perturbations, we used only the geomagnetic data observed at midnight time (LT 2:30 AM to 4:00 AM).We define the geomagnetic anomalies when the Z components of geomagnetic data exceeds median +1.5 IQR, where IQR is the interquartile range. Considering that ionospheric disturbances may also lead to enhancements in the Z component, we exclude the anomaly when the energy of H component exceeds median +3.0 IQR. Statistical analysis of superposed epoch analysis have indicated that ULF magnetic anomalies are more likely to appear before sizable isolated earthquake events rather than after them, especially 6-10 days before the events. Finally, we have evaluated the precursory information of ULF geomagnetic signals for local sizable earthquakes using Molchan’ s error diagram. The results show that the ULF seismo-magnetic phenomena at Kakioka clearly contain precursory information and have a possibility of improving forecasting of large earthquakes. The details will be given in the presentation.

On the tsunami and electromagnetic pulses appeared abound 10min. after the 2011 Tohoku earthquake

*Yuji Enomoto[1], Tsuneaki Yamabe[1], Shigeki Sugiura[2], Hitoshi Kondo[2]

1. Shinshu Univeristy, Ueda Campus Fii, 2. Genesis Reserach Institute, Inc.

Tsunami and electromagnetic pulses have appeared about 10 min. after the 2011 Tohoku-Oki earthquake(Heki, GRL, 2011; Utada et al. EPS Lett., 2011; Tsunagawa et al. EPS Lett., 2011). The disturbance to the ionosphere is thought to have been influenced by the atmospheric gravity wave caused by the tsunami. But this model could not explain the variation of geomagnetism, observed at Esahi site. In order to explain geomagnetic variation, we present a model that positively charged mists flied up with the atmospheric gravity wave along with the atmospheric electric field as the tsunami pulse was generated.

Reinvestigation of correlation between groundwater anomalies and earthquakes carried out by an amateur network in Japan

*Yoshiaki Orihara[1], Masashi Kamogawa[2], Toshiyasu Nagao[1]

1. Institute of Oceanic Research and Development, Tokai University, 2. Dpt. of Phys., Tokyo Gakugei Univ.

An amateur volunteer group for an earthquake prediction, “the catfish club”, had monitored groundwater levels and the temperature of thermal water to detect earthquake precursor signals since 1976. More than 200 participants in Kanagawa, Tokyo, Shizuoka, and some prefectures monitored them. Their sampled data are sent to the office of the catfish club, and the summarized reports were published every month. Oki and Hiraga (1988) reported the probably predicted events such as the 1978 Izu-Ohshima kinkai earthquake (M 7.0) and the 1978 Miyagiken-Oki earthquake (M 7.4). In this study, we statistically evaluate the anomaly appearance rate, the earthquake occurrence rate, and the probability gain using the data from 1977 to 1987.

Acknowledgment: This study was supported by the Earthquake Research Institute The University of Tokyo Joint Usage/Research Program.

The future direction of EMSEV, IUGG International Working Group

*Toshiyasu Nagao[1]

1. Institute of Oceanic Research and development, Tokai University

EMSEV (Electromagnetic Studies of Earthquakes and Volcanoes) was established in 2001 as a mother foundation of IAGA, IAVCEI, and IASPEI under IUGG (International Union of Geodesy and Geophysics). At that time, many studies of electromagnetic precursory phenomena were reported in earthquake prediction research but never seemed to be recognized by the traditional seismology community. For this reason, the grassroots movement had been expanded for the necessity of promoting international research.

Therefore we urged the establishment of an organization to study earthquake prediction and volcanic eruption prediction based on the electromagnetics in IUGG. It was officially launched in 2001 and the first meeting was made during the IUGG Sapporo in 2003.

Professor emeritus of the University of Tokyo, Seiya Uyeda served as the first chair of EMSEV, then Dr. Jacques Zlotnicki of the French National Science Research Center took the chair till 2018. EMSEV meeting was held, which organizes every two years, in Potenza in Italy in 2018. During the meeting, Professor Toshiyasu Nagao was proposed to serve as the next chair. This proposal was approved through the discussion of the mailing list.

In the future EMSEV, we must show the statistical correlation between the ionospheric anomaly and the earthquake first, then we have to prove why the earthquake precursors phenomena appear in the ionosphere based on the lithosphere - atmosphere - ionosphere coupling hypothesis. In particular, from satellite observations, France launched the DEMETER satellite in 2004, showing the statistical significance of VLF band anomalies just before the earthquake. Inspired by this result, China launched the CSES (Chinese Seismo-Electromagnetic Satellite) in 2018.

We decided that the next meeting of EMSEV will be held in Taiwan in the fall of 2020.

Discussion

Experimental platform for design and advance evaluation of frequent satellite observations to innovate weather, ocean and land surface predictions

*Takemasa Miyoshi[1], Shunji Kotsuki[1], Koji Terasaki[1], Shigenori Otsuka[1], Takumi Honda[1], Atsushi Okazaki[1], Kohei Takatama[1]

1. RIKEN

We propose to develop a unique platform with an advanced data assimilation technology, realizing numerical simulation experiments for advance evaluation of future satellite missions in their design phase. This will provide a scientific, objective approach to an effective design of future satellite missions to maximize the benefit to practical applications such as hydrometeorological prediction and resource control of fisheries. The authors have been leading data assimilation research to explore the best mix of computer model simulations and real-world data for weather forecasting, taking advantage of new-generation technologies such as the K computer and Himawari-8 satellite. The authors' previous research revealed that every-10-minute Himawari-8 observations could lead to a large improvement of typhoon and heavy rainfall predictions, though every-30-minute observation was insufficient. We would expect that frequent observations would also be beneficial for ocean and land surface prediction. Therefore, we aim to develop a platform for numerical experimentation to evaluate potential future satellite missions such as quasi-zenith orbiters and small cube-sat constellations for frequent observation over Japan and its surrounding area. This platform will be useful for designing future satellite missions with high cost-benefit performance.

Technology demonstration mission for next generation precipitation observation radars

*Tomoo Ushio[1], Toshio Iguchi[2], Kenji Nakamura[4], Kinji Furukawa[3], Riko Oki[3], Daisuke Jodoi[3]

1. Tokyo Metropolitan University, 2. NICT, 3. JAXA, 4. Dokkyo University

We have studied doppler velocity measurement for precipitation particles using a precipitation observation radar in a low Earth orbit as a post-mission of Dual-frequency Precipitation Radar (DPR) on the Global Precipitation Measurement (GPM) core satellite. Also, we have studied Geostationary Precipitation Radar (GPR) which can observe precipitation continuously and flexibly from a geostationary orbit as a future mission. In this study, we have studied the method which can separate precipitation echoes from ground/sea clutters by the doppler velocities in order to observe high latitude areas. Therefore, we need to verify the feasibility of the doppler velocity measurement for precipitation particles. Additionally, we need to improve antenna performance drastically in order to observe precipitation from a geostationary orbit which is far away from a low Earth orbit. Therefore, we need to verify the feasibility of upsizing an antenna for the GPR.

Based on the above background, the purpose of the proposed mission is to demonstrate that it is possible to measure the doppler velocity of precipitation particles from an orbit by a pulse compression radar using a planar antenna and to operate antenna deployment and connection mechanisms normally in an orbit. Also, we aim to get data regarding antenna deployment behavior and structural characteristics.

We consider the value of the proposed mission as follows. Firstly, the value of the doppler velocity measurement demonstration is as follows.
This demonstration contributes to realize post-GPM/DPR mission. If the doppler velocity measurement becomes possible in the mission, it is expected to understand the mechanical structure of a precipitation system globally and to improve the accuracy of weather and flood forecasts. This demonstration contributes to realize the GPR mission. If the GPR becomes possible, it is expected to identify the forming process of a typhoon and to improve the accuracy of weather and flood forecasts.
Next, the value of the antenna deployment and connection demonstration is as follows.
This demonstration contributes to improve the performance of satellite antennas for earth observation, communication, radio astronomy, disaster monitoring, national security, etc. because the deployment and connection mechanisms make it possible to enlarge planar antennas. This demonstration contributes to realize innovative missions like the GPR because the deployment and connection mechanisms make it possible to construct a 30-m-class large planar antenna. The deployment and connection mechanisms have the potential to construct super large space structures like Space Solar Power Systems (SSPS).
We consider the feasibility of the proposed mission as follows. When we assume that the size of a demonstration system is 1.2m x 2.2m x 0.7m in storage state and 1.2m x 2.2m x 4.4m in deployment state, we expect that the system meets the installation condition for HTV-X which has been developed as a post-KOUNOTORI (HTV) by JAXA. Also, as a result of thermal analysis for the system, we expect that the system meets the thermal condition for HTV-X. Furthermore, we demonstrated that it is possible to operate the half size deployment and connection mechanisms of the system normally by a ground experiment in FY2017.
As future works, we will study the feasibility of the doppler velocity measurement from the aspect of HTV-X attitude control performance. Also, we will improve the function and performance of the deployment and connection mechanisms.

Mission of creating base maps as public infrastructures for disaster and monitoring

*ISHITSUKA Naoki[1]

1. The Remote Sensing Society of Japan

As a satellite earth observation mission to be realized as Japan, we propose a mission of creating base maps as public infrastructures for disaster and monitoring.

The purpose of the proposed mission, is the observation and the base map prepared, as well as the monitoring and elucidation of global resources from long-term and continuous quantitative monitoring of large-scale disasters. Optical and SAR sensors, which are the genealogy of ALOS, observe with high spatial resolution, so that it can be applied to basic information (land cover, topography), disaster prevention / reduction (change detection, flooding, illegal dumping) Actual utilization such as agriculture(precision farming, food security), forestry, fishery, energy (geology, reserves, resource management, pollution monitoring), climate change (glacier, drift ice, flood), environment (coastal environment, carbon stock) , To earth science, and so on.

High resolution earth observation data with a wide swath is necessary for detailed map creation which is limited in medium resolution satellite. The high-resolution base map created from the satellite data covering the whole earth will be developed as public infrastructures and become a data access hub and can contribute to social implementation of satellite images such as disaster and agriculture. Then, it will serve as a basis for use in policies to solve international and regional issues, and for use in providing services enriching our lives. In particular, agriculture, forestry and fisheries industry and land management, disaster prevention, social infrastructure is a leading application area. For example, it is difficult to predict when and where a disaster occurs, so it is necessary to maintain wide-area high-resolution images as a base map. In SIP the second phase by the Japanese Cabinet Office, "strengthening national resilience (disaster prevention and reduction)" is started, high-resolution satellite as public infrastructure, supposed to be the supply of data and information There. Also, for use in the map creation field, there are cases where ALOS data was used for updating maps at the Geographical Survey Institute, etc. and for field polygon production work at Ministry of Agriculture and Fisheries. Underlying data of these G space is necessary essential to the realization of data society called “Society 5.0” promoted by the government. In SAR, it is required to make observation of the ground change due to forest monitoring and interferometric SAR, making full use of the achievement of Japan 's L band. In addition, there is great expectation for high resolution monitoring of polar sea ice and glacier utilizing observational weatherability. It is desirable for both sensors to operate at the same time, since various effects such as complementation and improvement in accuracy can be obtained by using the optical sensor and the SAR sensor in an integrated fashion.

Thus, for optical, it is necessary capability to observe a wide range of several tens of km high resolution image having m ~ sub meter. In addition, it is regrettable that ALOS-3 could not install the all-time stereoscopic observation that was an advantage over other countries in ALOS, and it is desirable to have a resurrection by successor satellite. With regard to SAR, it is considered to adopt a new method by DBF in ALOS - 4, and it is considered that wide range high resolution observation such as several hundred kilometers at several m resolution by DBF technology can be continued for succeeding machines depending on the result.

©2019. Japan Geoscience Union. All Right Reserved.

However, since the data becomes extremely large in both optical and SAR, the part of downlinking this data becomes a bottleneck. It is important to continue to cooperate with the development of other data downlink environments including data transmission speed, data on board processing, data relay satellite, ground station and communication, basic research on data compression technology.

In addition, the observed frequency secure has become a real operational issues, this is a need for a solution to break, the number of satellites increases or the constellation, a wide swath, the study of technologies, such as the attitude maneuver. In addition, as an innovative solution, it is necessary to consider the high resolution observation from the geostationary orbiting satellite, etc.

Environmental changes caused by global warming, earth resources from the viewpoint of long-term monitoring of (mineral resources, biological resources, water resources, etc.), and continues without interrupted the ALOS Series with high resolution sensor is desired. We believe it will lead to a worldwide presence improvement of the ALOS series.

Aerosol monitoring, forecasting and estimate of its impacts with multispectral imager data

*Keiya Yumimoto[1,2], Takashi Maki[2], Taichu Y Tanaka[2], Thomas Sekiyama[2], Toshihiko Takemura[1]

1. Kyushu University, 2. Meteorological Research Institute

Airborne aerosols are tiny particles that are globally distributed in the atmosphere from the troposphere to the stratosphere and that affect various aspects of human society and health and the Earth system including ocean biogeochemistry and climate. Our understanding of the aerosol lifecycle and aerosol impacts has been advanced by the following activities: (1) aerosol monitoring: observations of distributions of aerosol components and their radiative impacts, (2) assimilation/forecasting: aerosol (PM2.5) numerical prediction and early warning system to reduce effects on human society and health, and (3) climate data: long-term records including aerosol reanalysis product contributing climate and epidemiology studies. Multispectral imagers (from near UV to near infrared) onboard polar-orbiting and geostationary satellites have been providing essential data to those activities. In this presentation, we will make a brief review of those activities to show how multispectral imagers play the important role in aerosol studies and to provide an opportunity to consider their future plan.

Global aerosol and cloud observation by space-borne multi-wavelength polarization high-spectral-resolution lidar

*Tomoaki Nishizawa[1], Hajime Okamoto[2], Syoken Ishii[3], Yoshitaka Jin[1]

1. National Institute for Environmental Studies, 2. Kyushu University, 3. National Institute of Information and Communication Technology

We propose global satellite measurements of vertical distributions of aerosols and clouds (particles) by multi-wavelength polarization high-spectral-resolution lidar (HSRL) using both HSRL and polarization measurement techniques. This proposal realizes polarization HSRL measurements in ultraviolet, visible, and near-infrared spectral regions (355, 532, and 1064nm) and conducts multi-wavelength and multi-parameter measurements of particles simultaneously.
The proposed lidar, which has twice or larger measurement channels than the previous space lidars, measures global, three-dimensional (vertical and horizontal) distributions of particles; this enables to observe various optical and microphysical properties (e.g., extinction, size distribution, chemical components) simultaneously and to obtain more reliable particle information in quantitative and qualitative than the past. Observational studies using both these global, three-dimensional data of particles and numerical models (e.g., aerosol chemical transport model, and cloud resolving model) will lead to understating preprocess on aerosol-cloud interaction better, reducing uncertainties on evaluation the particle effects on climate change, and improving prediction accuracy of the climate change. Furthermore, this space lidar observation can be used to monitor and forecast transport and diffusion of aerosols getting air quality worse (e.g., volcanic ash, mineral dust, smoke, and air pollution) and to evaluate the aerosol effects on atmospheric environment (e.g., human health, vegetation, and air quality). These improvements of the scientific knowledges contribute to internationally consensus building to solve global warming issues and improving environmental measures both within and outside Japan.
The proposed lidar should have a role to be a succession sensor of space lidar mission to observe global particle distributions such as CALIPSO satellite lidar (CALIOP) launched in 2006 and EarthCARE satellite lidar (ATLID) launched in 2021 and lead internationally particle observation mission by space lidar after EarthCARE mission. More advanced techniques on laser and lidar in space by improving the laser and lidar techniques established in vegetation lidar mission MOLI as well as HSRL techniques developed for ground-based lidars are established in this proposal. The developed techniques are also key techniques for lidars to measure meteorological parameters such as temperature, wind speed, and water vapor. Thus, this proposal is also a bridge for the technical development of the space lidar to measure meteorological parameters.

Discussion

Dual-Doppler-velocity-mission using cloud radar and lidar

*Okamoto Hajime[1], Kentaroh Suzuki[2], Tomoaki Nishizawa[3], Shoken Ishii[4]

1. Kyushu University, 2. The university of Tokyo, 3. National Instuitute for Environmental Studies, 4. National Institute of Information and Communications Technology

Dual-Doppler velocity measuring mission from space-borne cloud radar and lidar is proposed. 94GHz cloud radar and lidar with Doppler function will measure three-dimensional air motion in clouds as well as in clear sky, respectively. High spectral resolution functions at 355nm and 532nm with polarization are planned to distinguish cloud particle type and aerosols. The lidar will have multiple field of views in order to penetrate relatively thick clouds. Since the radar will have capability to observe clouds and lidar will measure aerosols, it will be a successor mission to CloudSat and CALIPSO launched in 2006 and EarthCARE satellite in 2021. The mission will also serve to construct continuous records of clouds and aerosols for climate change studies.

Wind is one of key meteorological elements describing the atmospheric state as well as pressure, temperature, and humidity. Global wind profile observation is important to significantly improve the initial conditions essential for numerical weather prediction (NWP) and other meteorological studies. Although space-based observation system is a very important role in NWP, current space-based wind observing system has a problem that it is biased to observation related to temperature and water vapor compared with wind observation. The World Meteorological Organization wants to develop a global wind profiling system. Space-based Doppler Wind Lidar (DWL) can provide global wind profiles, which is a promising technique to fill the current gap. Under the circumstance, ESA launched the first space-based DWL Aeolus in August 2018. Since target mission period of Aeolus is three years, many NWP and science communities want continuous global wind profile observation. The working group on Japanese space-based DWL has made feasibility study for the space-based DWL for future global wind profiling since 2011. In 2017, ANA Holdings Inc. proposed to apply for optimizing aviation route using wind data improved by the future space-based DWL wind measurement at the space business promotion event S-Booster 2017. The proposal won the grand prize at S-Booster 2017, and the space-based DWL for the space business has been spotlighted since the event. The proposal is based on the global wind profile observation with the space-based DWL. The purposes of the global wind profile observation are to improve the precision of NWP and to contribute to understandings of mechanism of natural disasters and climate change and to new applications of wind data use.

Technology demonstration of space-borne water vapor DIAL

*Makoto Abo[1], Chikao Nagasawa[1], Yasukuni Shibata[1], Osamu Uchino[2], Takashi Shibata[3]

1. Graduate School of System Design, Tokyo Metropolitan University, 2. National Institute for Environmental Studies, 3. Nagoya University

We propose technology demonstration of space-borne water vapor differential absorption lidar (DIAL) for global high-resolution water vapor observations in the troposphere and lower stratosphere, to improve the understanding about the role of water in the global water and energy cycles and main physical processes (e.g., convection, emission, rainfall, the troposphere-stratosphere exchange of chemical species).

[M-SD44] Future Missions of Satellite Earth Observation

convener:Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Shinichi Sobue(Japan Aerospace Exploration Agency), Yuki Kaneko(Japan Aerospace Exploration Agency), Chairperson:Riko Oki(宇宙航空研究開発機構)

Satellite observation can be an effective tool in science and can be applied to the rapid global environmental change. Monitoring for a long term, advancing new ideas and developing technologies to support them are needed to solve social and scientific problems.
The Task Force on Future Space R&D System of the Subcommittee on Remote Sensing (TF) supported by 25 academic societies and affiliated organizations has formulated the ''Grand Design of Earth Observation'' in FY2017. From the academic point of view, it suggests earth observation missions that Japan should conduct within a decade. From September 2018 to December 2018, the TF calls for proposals of earth observation missions as a trial that aims to discover new ideas from the scientific and practical domains and refine those ideas through multidisciplinary discussion. The adopted proposals will be mentioned in the revised Grand Design, and the TF will work with the government on using it as a reference in updating the Implementation Plan of the Committee on National Space Policy. This session consists of oral presentations of the proposals that passed the preliminary examination of documents and active discussions to expand and deepen the study. We welcome attendees from various backgrounds who are interested in earth observation.

Impact assessment of hyperspectral infrared sounders toward Himawari-8/9 follow-on satellites

*Kozo OKAMOTO[1], Hiromi Owada[2], Masahiro Kazumori[2], Michiko Otsuka[1], Yoshifumi Ota[2], Naotaka Uekiyo[1], Hiromu Seko[1], Akiyoshi Ando[2], Ryo Yoshida[2], Hiroshi Ishimoto[1], Masahiro Hayashi[1], Haruma Ishida[3], Yoshiaki Sato[2], Hiroshi Kunimatsu[2], Kotaro Bessho[2], Hironobu Yokota[2]

1. Meteorological Research Institute, 2. Japan Meteolological Agency, 3. Meteorological Satellite Center

Japan Meteorological Agency has started the discussion on Himawari-8/9 follow-on satellites to be launched in 2028. We are investigating impacts on numerical weather prediction of a hyperspectral infrared sounder on the follow-on satellites using an observing system simulation experiment (OSSE) approach. We will present preliminary results of simulation and global and regional data assimilation experiments of the sounder.

Keywords: Himawari follow-on satellite, data assimilation, OSSE , hyperspectral infrared sounder

Observation system simulation experiments for a hyperspectral infrared sounder onboard geostationary satellite

*HIROMI OWADA[1], Kozo OKAMOTO[2], Masahiro Kazumori[1], NAOTAKA UEKIYO[2], Hiroshi Ishimoto[2], Masahiro Hayashi[2]

1. Japan Meteorological Agency, 2. Meteorological Research Institute

At the Japan Meteorological Agency, we started preparation for the Himawari-8/9 follow-on satellites. Hyperspectral infrared sounder (HSS) is one of the instruments to consider to be installed in the follow-on satellites. By installing HSS on a new geostationary satellite, it is possible to acquire information on highly accurate profiles of temperature and water vapor at high frequency, and it is expected that accuracy of numerical weather prediction is greatly improved by using this new data in data assimilation system. In order to confirm this assumption, we evaluate the impact on numerical weather prediction when we install HSS on the follow-on satellites and assimilate their data with observation system simulation experiment (OSSE).

In this presentation, we report on the generation of HSS pseudo observation data and the initial results of OSSE in JMA's current global data assimilation system.

Realization of pseudo high frequency high resolution observation by geostationary satellite and orbiting satellite combined observation

*Yoshiaki HONDA[1]

1. Center for Environmental Remote Sensing, Chiba University

Observation data of the earth observation optical sensor data from both the earth science and the actual utilization is required more frequently and higher resolution. However, in order to realize this high frequency observation and high resolution observation at the same time, it is impossible with one satellite, and it is being realized by many operations of micro satellite. However, in general, micro satellites have problems such as short design life and no calibration system. On the other hand, satellites of medium size or more including geostationary satellites have a long design life and have a calibration system. However, in order to realize high frequency and high resolution with satellites of medium size or larger, if we try to secure the number of satellites, its budget is enormous and not realistic. This proposal is based on high frequency observation of geosynchronous satellites with relatively low resolution among satellites launched by Japan (assumed to be successors such as Himawari, GCOM - C, ALOS etc), and high resolution but low frequency orbiting satellite observations We aim to manufacture pseudo high frequency high resolution observation data through a model that adjusts part of sensor specifications of each satellite and adjusts the difference between observation geometries, and provides such a high quality long-term framework . This aims to expand the use of satellite optical sensor data in earth science and practical use fields, and to expand scientific progress and practical use. This framework is a planned budget size, one step to get bigger results, and expansion of the actual field of use will also contribute to the continuity of the Earth observation in Japan. Furthermore, by incorporating newly planned satellites of other countries into this framework, we aim to increase the presence of our Earth observation in the field of earth science and practical use.

Geostationary Optical Earth Observation Satellite

*Kazuo Oki[1], Toshiyoshi Kimura[2], Tadahito Mizutani[2], Takeo Tadono[2]

1. The University of Tokyo, 2. JAXA

Geostationary satellite is the most practical Earth Observation for its instantaneous observation and ability to choose target area on demand. Some kind of users, especially disaster monitoring, agriculture and national security users are demanding such unique character crucially. However, technical difficulties prevent from realization of the system, so far. Practical observation needs a certain fine ground resolution. But it means necessity for huge main mirror for the satellite optics. For an example, 5~7m resolution at Nadir position needs 3.6m diameter mirror. So far, 1~2m diameter one-piece mirrors were studied, in contrast. Recent optical technologies make it possible to have an extra large telescope using segmented mirrors for astronomical telescope on the ground, like Keck astronomy or TMT project. Using such technologies, we studied geostationary satellite telescope system with 3.6m diameter segmented telescope to materialize 7m ground resolution at Nadir position. Observation bands should have good correlation with ALOS-3 satellite on low Earth orbit, i.e. panchromatic, RGB, NIR and additional bands. To ensure the night observation, IR band is under consideration in addition. Such new Earth observation scheme improves time resolution dramatically, and it will make possible to observe movement of target like video camera. It will reveal many motile phenomena including Tsunami, Typhoon and human activities like car traffics. Also, it is expected that various social services unprecedented in cities, forests, agriculture, water (rivers and oceans), etc. are expected to be offered, and we believe that many users will appear in the field of science and practical use. The study started in 2018 and will end in 2020 to confirm the technical readiness level of required technologies, observation plan and algorithms for new earth observation data products.

[U-06] Japan's contribution to IUGG celebrating 100th anniversary

convener:Setsuya Nakada(National Research Institute for Earth Science and Disaster Resilience), Kenji Satake(Earthquake Research Institute, University of Tokyo), Kumiko Goto-Azuma(National Institute of Polar Research), Chairperson:Kumiko Goto-Azuma(National Institute of Polar Research), Setsuya Nakada(NIED)

International Union of Geodesy and Geophysics (IUGG) is one of the 40 unions in the International Science Council (ISC), celebrating its 100th anniversary in 2019. IUGG promotes and coordinates research on the interior and the periphery of the Earth. The IUGG has associations of eight research fields (IACS, IAG, IAGA, IAHS, IAMAS, IAPSO, IASPEI, and IAVCEI), which carry out semi-autonomously activities in cooperation with each other. In addition, IUGG encourages research to respond to social needs such as reduction of natural disasters and environmental conservation. The IUGG Subcommittee at the Japan Science Council's Earth and Planetary Science Committee and the eight association-committees under the former serve as representatives of Japan for the IUGG and 8 Associations.
 In this session, as IUGG celebrates its 100th anniversary, researchers related to each association exchange the ideas on the role of IUGG in earth science and the contribution that Japanese researchers should make to IUGG.

Centennial of the International Cooperation in Earth and Space Sciences

*Alik Ismail-Zadeh[1,2,3]

1. Karlsruhe Institute of Technology, 2. International Union of Geodesy and Geophysics, 3. International Science Council

The International Union of Geodesy and Geophysics (IUGG) was established in 1919 under the umbrella of the International Research Council (later ICSU, and now the International Science Council) as one of the unions to promote activities of existing associations dealing with geodesy, terrestrial magnetism and electricity, hydrology, meteorology, physical oceanography, seismology, volcanology. This presentation describes the origin and the development of the Union for the last century and until today. During the initial period (1919-1939), the number of member countries increased from nine founding Member countries to 35 Member countries; general assemblies were held every three years, each in a different international venue, and the number of delegates attending the assemblies increased from a few dozen to several hundred scientists. The World War II (WWII) interrupted the cooperation, and international scientific activities were resumed in 1946. The Union continued cooperation with many international scientific organizations of ICSU, and began cooperation with new intergovernmental organizations such as UNESCO and the World Meteorological Organization, and their programs. The technologies developed during the WWII were brought to bear in the extraordinary global scientific effort that was the International Geophysical Year (1957-1958). Changes in the geopolitical landscape brought about changes in the IUGG’ s structure. International campaigns encompassing multiple disciplines became commonplace, and international scientific bodies were organized. At the beginning of the 21st century IUGG added an eighth association on cryospheric sciences, developed new grants, science education, and recognition programs, and added new commissions on geophysical risk & sustainability, climatic & environmental change, data & information, and planetary sciences to existing commissions on mathematical geophysics and study of the Earth’ s deep interior. IUGG has been initiating, developing, and implementing international cooperative programs, setting scientific standards, developing research tools, educating and building capacity, and contributing to science for policy. Today, IUGG is a vibrant modern scientific union of 72 nations and scientists from all over the world promoting research, linking scientific knowledge to societal needs, and working toward a sustainable Earth.

IUGG and Japan: the past, the present, and the way to go from now

*Masaru Kono[1]

1. Tokyo Institute of Technology

International Union of Geodesy and Geophysics (IUGG) was formed in 1919 and held its first General Assembly in 1922. A hundred years has passed since then. Japan was one of the seven member countries which joined IUGG at the inauguration. Prof. A. Tanakadate of Tokyo University represented Japan at that time, and he was elected as one of three Vice-Presidents for 1919-1922. Since then, except the period that Japan was vetoed to take part in the Assemblies after Japan was defeated in 1945, Japan has consistently been a strong supporter of the IUGG activities.

Because of the "cold war" after the end of the world war, there were very few chances that east and west scientists meet at the same place, IUGG and other international scientific organizations were playing an important role in providing such opportunities. In particular the International Geophysical Year (IGY) of 1957-1958 was a splendid opportunity for cooperation between east and west countries. Japan took part in this project in many subject including the rocket observation, but among them, the start of the antarctic research which was carried out with the concent of the international community, was a highlight of this project.

Several decades have passed since then. In these years, the status of IUGG became quite low. IUGG holds it General Assembly every four years, collecting 3000 to 4000 scientists, but AGU Fall meeting is held every year, and nowadays they receive about 30,000 participants while keeping the scientific standards quite high. Nowadays, there are EGU, JpGU, and others which collect more than 10,000 participants. These societies also have well-cited jounals to output scientific results in printed form. It looks that there is little possibility that IUGG can compete with these societies in the scientific merit.

With these situations in mind, which way should IUGG go in the future? One possibility is to work in problems which concerns the whole Earth, and thus it is impossible to find the solution in a single country. A clear example of such a problem is the Global Warming. The international scientific organization which deals with this is IPCC, but the scientists working in IPCC have strong ties with some of the Associations in IUGG (eg., IAMAS, IAPSO, IAHS). Another possibility is to look for a scientifically important probem, which usually has small number of scientists engaged in the problem. A good example in IUGG is SEDI which works in the deep interior of the Earth. It is also an interdisciplinary science including seismology, geomagnetism and others. SEDI seems to prosper by providing an interdisciplinary platform for these hundred or so very high-level scientists.

Contributions from the Science Council of Japan to international cooperation in the field of Earth and planetary science

*Hisashi Nakamura[1]

1. Research Center for Advanced Science and Technology, University of Tokyo

Since its establishment in 1949, the Science Council of Japan (SCJ) has made a variety of contributions to international academic cooperation in every field of natural and social sciences as an official member of the International Science Council (ICSU: currently InterAcademy Council). The budget for international commitment has been stable in spite of continuous decline of the entire budget of SCJ. Recognizing that international cooperation is essential for research activities in the field of Earth and planetary science, ICSU has promoted the International Geophysical Year (IGY: 1957-58) and the 4th International Polar Year (IPY: 2007-08), while offering its membership to 12 international unions/associations in our field, including the International Union of Geodesy and Geophysics (IUGG). Under this international framework, the Japanese government has been offering financial support to those unions/associations through SCJ, in which 12 branch committees are organized under the Earth and Planetary Science Committee to appoint some members as delegates to executive meetings of those unions/associations and promote related domestic activities. In addition, SCJ co-hosts a general assembly of an international union/association held in Japan under the approval of the SCJ International Affairs Committee, as exemplified by the 2017 IAG-IASPEI Joint Scientific Assembly in Kobe. This presentation offers an overview of specific contributions from SCJ to international cooperation in the field of Earth and planetary science.

History and Japanese contribution to the International Association of Cryospheric Sciences IACS

*Ralf Greve[1]

1. Institute of Low Temperature Science, Hokkaido University

The International Association of Cryospheric Sciences, or IACS, is the eighth association of the International Union of Geodesy and Geophysics (IUGG), launched by the IUGG Council on 2007-07-04. Despite being the latest of the IUGG associations, IACS looks back on a history of 125 years, starting with the International Commission on Glaciers (Commission Internationale des Glaciers) founded in 1894. It then evolved via the International Commission of Snow and Ice (ICSI) of the International Association of Hydrological Sciences (IAHS) and the transitional Union Commission for the Cryospheric Sciences (UCCS) into its current constitution as an independent IUGG association, recognizing the increased importance of cryospheric sciences within the context of Global Change. In this presentation, we will outline the history of IACS and its precursor organizations, describe the current activities of IACS and highlight the Japanese links with IACS in the form of contributions to its governance, divisions and research activities.

*Toshihiko Iyemori[1]

1. Kyoto University

During the last 20 years, the size of international meeting such as AGU, EGU and AOGS has been getting larger and larger, and they are now the major place for the researchers in geoscience and space science to show their results and collect new information. This tendency is the same also for the scientists in our country, and the role of IAGA need to change its role. In this presentation, IAGA activities and our contribution in the last 20 years will be presented.

The role of IAHS in education, research, social issues concerning water and future perspective

*Maki Tsujimura[1]

1. Faculty of Life and Environmental Sciences, University of Tsukuba

IAHS (International Association of Hydrological Sciences) was launched in 1922, and now have approximately 5500 individuals, 10 commissions and 3 working groups. The Scientific Assembly is held every 4 years and held in Yokohama, Japan 1993. Professor in Emeritus Dr. Kuniyoshi Takeuchi, Yamanashi University has served as a president of IAHS from 2001 through 2005, thus Japan has taken an important role in IAHS.

The commission consists of Continental Erosion, Coupled Land-Atmosphere Systems, Groundwater, Remote Sensing, Statistical Hydrology, Snow and Ice Hydrology, Surface Water, Tracers, Water Quality, Water Resources Systems, and it covers a variety of field in hydrology. Also, a working group “PANTA RHEI –Change in Hydrology and Society” has been launched in 2013 focusing on changing hydrological cycle system with changing human system.

The Japan National Committee of IAHS in cooperation with Japan National Committee of IHP (International Hydrology Programme) hold a symposium “Japan Water 2012: International Contribution from Japan in education/ research of water science and technology”. Also, Japan Association of Hydrology and Water Resources, Japanese Association of Hydrological Sciences, Japanese Association of Groundwater Hydrology and Japan Society of Physical Hydrology collaborated to publish Hydrological Research Letters (HRL) since 2017. Additionally, IAEA (International Atomic Energy Agency) Regional Training Course on Isotopic Data Processing and Interpretation –Hands on Exercises is held in March 2019, Tsukuba, Japan supported by Japan National Committee of IAHS and Japan National Committee of IHP.
On the other hand, the changing environment in hydrology and water resources in Japan and the world requires the change of the role in IAHS. We need to promote a collaboration between IAHS and IHP, early career support and career paths developments in future.

Centenary of the atmospheric sciences: Its progress and future issues

*Teruyuki Nakajima[1]

1. Japan Aerospace Exploration Agency

IAMAS (International Association of Meteorology and Atmospheric Sciences), one of associations of IUGG (International Union of Geodesy and Geophysics), celebrates in 2019 its centenary after establishment with IUGG. Held are commemorative projects and memorial events at the IUGG general meeting in Montreal in this July. Atmospheric science has long been developed as a science related to various weather phenomena related to the lives of mankind. As a result, there are many important issues related to society. Especially over the past 100 years, there are major developments such as establishment of weather prediction infrastructure, researches to global warming problem and environmental problems such as ozone hole etc. An overview of these progresses will be important for us to think about what we should do next. In particular, in this era, as climate and environment changes have become apparent and disasters increase, observation and understanding of the phenomena is increasingly necessary through collaborations with other areas such as the social science etc. I like to discuss that point.

Contributuins of Japan to IAPSO

*Yukio Masumoto[1]

1. Graduate School of Science, The University of Tokyo

The International Association for the Physical Sciences of the Oceans (IAPSO) is one of eight associations of the International Union of Geodesy and Geophysics (IUGG). IAPSO is promoting the study of scientific problems relating to the oceans and the interactions taking places at the sea floor, coastal, and atmospheric boundaries insofar as such research is conducted by the use of mathematics, physics, and chemistry. IAPSO has addressed this goal through four fundamental objectives: (1) Organize, sponsor, and co-sponsor formal and informal international forums permitting ready means of communication amongst ocean scientists throughout the world; (2) Establish commissions, sub-committees, and organize commensurate workshops to encourage, stimulate, and coordinate new and advanced international research activities; (3) Provide basic services significant to the conduct of physical oceanography, and (4) Publish proceedings of symposia, meetings, and workshops, and fundamental references on the current state-of-the art and knowledge of physical oceanography.
The Japanese ocean research communities have been contributing to IAPSO mainly through their research activities at the IAPSO assemblies and through administrative works by taking a position of the exective committee member for about 20 years, with the president position by Prof. Imawaki for four years from 2003. This presentation summarizes the Japanese contributions to IAPSO and discuss on future relation between the Japanese research communities and IAPSO.

IASPEI- activities, history and Japan’s contribution

*Kenji Satake[1], Thorne Lay[2], Johannes Schweitzer[3]

1. Earthquake Research Institute, University of Tokyo, 2. IASPEI President , 3. IASPEI Secretary General

IASPEI (International Association of Seismology and Physics of the Earth’s Interior) is one of the eight associations of IUGG, and promotes the study of earthquakes and other seismic sources, the propagation of seismic waves, and the Earth's internal structure, properties, and processes. IASPEI has seven commissions on seismological observation and interpretation, on tectonophysics and crustal structure, on earthquake generation process - physics, modelling, and monitoring for forecast, on earth structure and geodynamics, on earthquake hazard, risk and strong ground motion, on earthquake source mechanics, and on education and outreach. Besides these topical commissions, IASPEI has their regional commissions in Europe (since 1951), Asia (since 1996), Africa (since 2011) and Latin America (since 2013). These regional commissions meet bi-annually, typically with training courses, to promote seismology in each region.

Seismology started as national scale for describing the earthquake phenomena and their effects. First seismological societies were established in Switzerland (1878), in Italy (1879) and in Japan (1880). After the first teleseismic recording in Germany from an earthquake in Japan (1889), seismology became an international science, and Frist International Seismological Conference was held in Strasbourg in 1901, representing 8 countries including Japan. In 1904, International Seismological Society was established. In 1922, it became a part of IUGG (established in 1919), with changing name to IAS in 1930 and IASPEI in 1951.

IASPEI plays important roles in unifying seismological observations, such as naming seismic phases, defining measurement procedures, or improving the network of seismic stations, and published Manuals of Seismological Observatory Practice (the latest version in 2012). IASPEI has a close relation with International Seismological Centre, which has produced seismological bulletins based on the IASPEI standard. IASPEI also provided standard seismic velocity structure models of the earth, such as iasp91 or ak135. Global distribution of earthquakes in the earth and the reference earth models have been important basic data for developing the science such as plate tectonics, or structure and dynamics of the earth’s interior. IASPEI also conducted peer reviews and evaluated the published precursory phenomena for earthquakes. IASPEI developed and distributed seismological software, and International Handbook of Earthquake and Engineering Seismology.

IASPEI supports FDSN (International Federation of Digital Seismograph Networks) which is composed of groups responsible for installation and maintenance of seismological networks, and activities of CTBTO (Comprehensive Test-Ban Treaty Organization) which uses seismic data to detect nuclear explosions. IASPEI also supports joint commissions with other associations of IUGG, such as ILP (International Lithosphere Project), on tsunamis, volcanology or on space geodesy.

The IASPEI commission of Seismological Society of Japan practically acts as the national committee of IASPEI, and disseminates IASPEI information to Japanese seismological community, nominates officers and award candidates. SSJ has made financial supports to ASC (Asian Seismological Commission) and IASPEI, for travel support of participants and for management of the ASC meetings. Several members of executive committees and chairs of commission are elected from Japan. The last scientific assembly of

©2019. Japan Geoscience Union. All Right Reserved.

IASPEI, joint with IAG, was held in Kobe, Japan, in 2017 with great success.

Keywords: IASPEI, Seismology, IUGG

Recent history of IAVCEI in Japan and young researchers' response to IUGG and IAVCEI

*Setsuya Nakada[1]

1. National Research Institute for Earth Science and Disaster Resilience

Japanese volcano researchers, especially young scientists, do not recognize well the relationship of IAVCEI with IUGG. IUGG is less visible than IAVCEI to them. The latter used to be introduced first as the international conference that they can challenge. IAVCEI is visible also in the Volcanological Society of Japan (VSJ) of which they are members. Japanese researchers served as the executive board members of IAVCEI, such as its presidents by Hisashi Kuno, Shigeo Aramaki, and Setsuya Nakada for these 100 years. Scientific Assemblies of IAVCEI were held in Japan in 1962, 1981, and 2013. The Cities on Volcanoes (COV) is the second largest international conference of IAVCEI, held every two years between the years of IAVCEI Scientific Assembly and IUGG General Assembly since 1998. COV conference originates from the International Volcano Conference, which was held in the Kagoshima City in 1988, as a forum between scientists and non-scientists for mitigating volcanic disasters. The fifth COV conference was held in the Shimabara City in 2007.

In spite of the fact that IUGG General Assembly was held in Sapporo in 2003, it seems that IUGG has not become well known among young, possibly middle-aged volcano researchers. For example, recent IAVCEI Science Assembly gathers over 1000 participants, while there are only about 300 participants at General Assemble of IAVCEI when IUGG. The latter number is much smaller than around 1000 participants of recent COV. Though one of the reasons may be few excursions for volcanologists, organized in IUGG conferences, it is likely that a simple reason is the size of fields covered by the conferences. Each association itself is wide in fields enough and the assemble of 8 associations will be too wide for young researchers to attend. They may feel not comfortable like business even in AGU and EGU, contrasting to comfort in own associational conference.

This may be similar to the relationship between JpGU and individual national societies. We have to confirm and share the merit of assemblage of large international associations having fields related to but different from each other. In addition, roles of government-contributing organization like IUGG and International Science Council (ISC) should be confirmed among us. In this case, increasing the number of participants to the conference is not the first priority. Global climate change and regional geological hazards such as large earthquakes and volcanic eruptions have become worldwide high priority issues to reduce the risks. Under this situation, the United Nation clarified the sustainable development goals (SDGs) until 2030, therefore, the missions by IUGG and ISC, which are guaranteed by governments, have expanded to solve these issues.

[U-08] Opinions and recommendations from meeting participants to the future of the Japan Geoscience Union

convener:Yozo Hamano(KOBE Ocean-Bottom Exploration Center, Kobe University), Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita(Geosciences and Civil Engineering, Institute of Science and Engineering, Kanazawa University), Chairperson:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita

The JpGU meeting 2019 will be the 30th since the start of the Joint Meeting of the Earth and Planetary Science societies, and 15th after the foundation of the Japan Geoscience Union (JpGU).Today, JpGU is becoming indispensable for the Earth and Planetary Science community due to the significant increase in the number of participants and the progress towards one of the International Organization of Geosciences. However, since the voluntary group that originally started aggregating the individual's intentions of the community, grew to a huge organization of about 10,000 members, it becomes rather difficult to reflect requests and opinions as individuals. In addition, by becoming a public interest corporation, it is rather difficult to operate as an academic organization under the constraints of the public interest corporation law. In aiming for further development of JpGU in the future, we would like to invite all the participants of the meeting to express their strict opinion and constructive proposal for the future of JpGU. The opinions of participants will be valuable materials for considering the direction of JpGU after 2020. We would like to invite many participants to present opinions and recommendations from various viewpoints, returning to the bottom-up spirit which is the basic philosophy of the science community.

Request and proposal from the Committee on Earth and Planetary Sciences of the Science Council of Japan to JpGU

*Ryoichi Fujii[1]

1. Research Organization of Information and Systems

Japan Geoscience Union (JpGU) and the Committee on Earth and Planetary Sciences (EPS) of the Science Council of Japan (SCJ) has long been collaborating closely for the wide developments of earth and planetary sciences. Recent collaborations are being done, e.g., for the revision of the dream roadmap and the proposal of the large-scale research programs.
In this presentation we would like to present our request and proposal to JpGU and to discuss in depth the future, closer collaborations between the two organizations.

Geography in JpGU: current status and future perspectives

*Takashi Oguchi[1], Ikuho Yamada[2], Yuichi S. Hayakawa[3], Daichi Kohmoto[4], Hitoshi Saito[5]

1. Center for Spatial Information Science, The University of Tokyo, 2. Faculty of Science and Engineering, Chuo University, 3. Graduate School of Env.Science, Hokkaido University , 4. Nara University of Education, 5. College of Economics, Kanto Gakuin University

Although some geographers and geographical societies have been members of JpGU, the majority of geographers in Japan seldom contribute to JpGU activities. One reason for this is that more than half of Japanese geographers are specialized in human geography, whereas JpGU focuses on physical sciences. However, interdisciplinary studies integrating arts and sciences are becoming all the more important, and modern geography linked to natural hazards and global environmental issues requires knowledge of earth sciences. Therefore, geography in JpGU should play an increasing role. This presentation aims to discuss how to strengthen collaborative relationships between JpGU and geographers.

Biogeoscineces will connect everthing together

*Takeshi Kakegawa[1]

1. Graduate School of Science, Tohoku University

Biogeosciences Section is unique compared to other sections at JPGU. Other sections have strong affiliation with big national projects, such as wide-sale observation of earthquake, space mission, climate change observation, etc. As a result, Biogeosciences Section has difficulty to establish main or leading subjects in JPGU. Scientific subjects and themes are often overlapped between Biogeosciences Section and other sections. This makes presence of Biogeosciences Section unclear at JPGU. In order to promote Biogeosciences Sections, I am going to suggest some points. It will be important to establish strategic collaborations with other sections of JPGU and other communities, such as microbiology, ecology, agriculture, and /or bio-engineering fields. I think that organizing temporal sections with other communities or having invite speaker from other community will be effective. Biogeosciences Sections should have more functions as an interface with others.

Coverage of JpGU

*Yukihiro Takahashi[1]

1. Department of Cosmosciences, Graduate School of Science, Hokkaido University

Geoscience unions originally started from classical several categories, namely, solid earth, atmosphere, land and ocean water, upper atmosphere and space, and plant. However, in AGU or EGU, adding to those conventional fields, many new science targets or methodologies are becoming important player in the union. Especially, biology including agriculture and natural hazard became one of the largest communities. On the other hand, such movement in JpGU is going at very slow speed. Here we discuss the strategy about this matter.

Is he a bit overkill for English?

*Yoshi-Yuki Hayashi[1]

1. Department of Planetology/CPS, Graduate School of Science, Kobe University

English is taught in English or a special subject is also taught in English, indeed, English has been introduced to elementary school, and English examination of college entrance examination has become to be said to be four skill test today, lead this The importance of "international" importance of the leadership including not only the Keidanren that causes it but also the academic community, the direction of individuals' shooting spirit towards these, ... that socioeconomic and cultural academic background I do not know that the various aspects of JpGU are no exception.

However, has not underestimated the influence of stopping recharging of the Japanese space which I have been working diligently since the Meiji era so that education and practice up to the research level can be conducted in my mother tongue almost exclusively in European languages? Do you think that a Japanese language space and its operation ability are natural there and there is nothing to think that it is acquired naturally? As a mother tongue is being trained, we have a wide width and deep depth Although I am able to acquire imagination comprehension ability with, but because it is too "nature" its cost and power can not be forecasted easily, but I am worried that the power is rapidly declining.The language is recharged It goes without saying that training is necessary in order to master this.

I can not predict how far the convergence of language (Englishization) will proceed.The leap in China may brake somebody, but if it keeps it as it is, it will be several generations and Japanese will become a daily word It is a momentum to degenerate into a language that can only be used for the languages of European languages Unlike the multilingualization of the European languages group, it is not easy for the language system to respond at a high level to multilingualization between different languages If you try to secure the breadth and depth of thinking you will have to concentrate on a specific language system and you may be made to choose to switch at the language selection stage. I do not like being there, so I wonder if there can be an avalanche decline.
Advanced knowledge is accumulated in the English space Today, it is desirable to improve the management system to ensure that it contributes to the participation in the Japanese-English system, and it is also wonderful to build an operational system that can accept English sessions. I would like to have English, I would like to forcibrate that the material must be in English, eliminate Japanese sessions that emphasize Japanese language spaces and emphasize provision of knowledge to those with their native language. I would like to be able to accept it rather than it.

By the way I put a raw google translation in English abstract AI seems to need a little time to engage in this issue.

Globalization of Japan Geoscience Union

*Hirokuni Oda[1]

1. Institute of Geology and Geoinformation, Geological Survey of Japan, AIST

In the presentation, globalization of Japan Geoscience Union (JpGU) is going to be discussed as a member. Although activities of JpGU is broad, JpGU annual meeting and academic publishing are considered as the key pillars. Also, the necessity of globalization on these two have been emphasized. On academic publishing, journal PEPS has been started on 2014 supported by Grant-in-Aid for Publication of Scientific Research Results "Enchancement of International Dissemination of Information" of JSPS. In addition, Impact Factor 2017 has been given to the journal and its future is promising. JpGU meeting was jointly organized successfully with AGU in 2017 and the next JpGU-AGU meeting will be held in 2020. Although globalization of JpGU meeting has been promoted, Japanese language is also considered as important. The burden on the participants and organizers of the meeting by the requirements both in English and Japanese cannot be ignored. Also, there seems to be a barrier in inviting researchers to JpGU meeting from abroad, where number of international sessions and attendees are limited. Number of international meetings on geosciences has been increasing and relative importance of JpGU meeting in the world is decreasing. Thus, the meaning of globalization for JpGU and significant increase of the number of English sessions (or significant decrease of the number of Japanese sessions) of JpGU meeting will be discussed.

A proposal for JpGU based on the questionaires to SSJ members

*Koshun Yamaoka[1]

1. Earthquake and Volcano Research Center, Graduate School of Environmental Studies, Nagoya University

The Seismological Society of Japan (hereafter, SSJ) is one of the original members of the group which is ancestral of present JpGU. The group consists of several societies including SSJ organized a joint meeting instead of independent meetings which were usually held in early April every year. In this historical circumstances SSJ expects JpGU meeting as one of the regular meetings of SSJ in addition to the SSJ fall meeting. In this regard, sessions that are equivalent to those in the SSJ fall meeting are proposed for JpGU meeting every year.
Academic society exists because members expect benefits in participating the society. Similarly member societies such as SSJ also expect benefits in participating JpGU. JpGU is expected to represent academic community of earth and planetary science, which is sometimes called geoscience, of Japan to raise visibility and recognition in Japan’ s society. Visibility of geoscience, especially in high school education, is still low in spite of Japan’ s geological unstableness. This is one reason that Japan has underestimated the risk of geohazards. Academic characteristics of geoscience which inevitably need tackle the complexity, irreversibility and unrepeatability of earth’ s process is sometimes unreasonably degraded relative to other fields. JpGU also works for encouraging collaboratory researches beyond conventional discipline and national boundaries.
The results of such function of JpGU are sometimes opposed to by members. One member of SSJ make an opposition of the management of JpGU meeting, saying that JpGU meeting is too long, too expensive and too much obsequious to English language. The first issue come from the recent condition of universities, in which academic schedule is getting more and more tight. SSJ send questionnaires asking for such an opinion is common or not. Half of the answers favor the opinion although 2/3 of the answers express the satisfaction in participating JpGU meeting. More effort should be made on the session scheduling by considering the participants’ needs. 90% of the answer favors variety of JpGU sessions which cannot be enjoyed in the independent society meeting. I am personally happy to be able to have sessions in English in regular scientific meetings in Japan because English is de facto common language in science community, and because it is what I dreamed when joint meeting started when I was young.
Another function to be expected to JpGU is providing inter-society communication opportunity. Recently many societies suffer gradual decline of members, especially of young generation. Sharing administration may be one of the measures against financial decline. Merging of societies can also be a solution. We need to look for a relation between JpGU and each societies for the development of science.

Discussion

Opinions and recommendations to the Japan Geoscience Union from Society of Geomagnetism and Earth, Planetary and Space Sciences

Yoshiharu Omura[2], Shigeto Watanabe[3], *Yuto Katoh[1], Takuya Tsugawa[4], Yuichi Otsuka[5], SGEPSS steering committee

1. Graduate School of Science, Tohoku University, 2. Research Institute for Sustainable Humanosphere, Kyoto University, 3. Hokkaido Information University, 4. National Institute of Information and Communications Technology, 5. Institute for Space–Earth Environmental Research, Nagoya University

We present opinions and recommendations to the future of the Japan Geoscience Union (JpGU) from members of Society of Geomagnetism and Earth, Planetary and Space Sciences (SGEPSS). The opinions and recommendations are categorized into (1) opinions for the future perspective of JpGU and (2) comments and requests to the organization of the JpGU meeting.

- Future perspective of JpGU as an international meeting and the relation with AOGS

- Increase the number of sessions jointly organized by multiple societies

- Official channel of opinions/suggestions from participants/conveners to JpGU

In this presentation, we summarize the opinions and recommendations from the members of SGEPSS.

A proposal from a representative of General Geoscience Sector on a possible direction to future JpGU: actions for domestic activities could be weighted

*Hidenori Kumagai[1]

1. Japan Agency for Marine-Earth Science and Technology

As one of the representative of General Geoscience Sector, here I pointed following items as to be discussed in order to strengthen foundations of JpGU through activation and diversification of domestic earth science community: 1) too much internationalization is to be suppressed, 2) accessibility for the members outside the metropolitan area or the member societies, 3) support for member societies and 4) enhance the function as the "Union." Details described in Japanese (see abstract written in Japanese).

Fifteen years of Japan Geoscience Letters and its future

*Shogo Tachibana[1], Eiichi Tajika[2]

1. UTokyo Organization for Planetary and Space Science, University of Tokyo , 2. Dept. Earth and Planetary Science, University of Tokyo

It has been 15 years since the first issue of Japan Geoscience Letters (JGL), which is a newsletter of JpGU. Fifty-five issues have been published with 157 articles on hot topics in the Earth and planetary science field. The JGL has been a window into various disciplines in Earth and planetary science and is potentially be a good outreach tool to the society. There are many things to do to make the JGL better as the newsletter of JpGU that has been expanding as the largest geoscience community in Japan. However, it is not possible to make them a reality because of limited human resources. In this talk, we will discuss the 15-year publication activity of JGL and its future.

[P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University), Chairperson:Satoshi Tanaka, Masaki Nishino(名古屋大学宇宙地球環境研究所)

Scientific data sets acquired by not only Japanese lunar mission SELENE (Kaguya), but also other countries' missions, have become new standard for lunar science. Analyses of these data have been providing several new knowledge and changing some hypotheses into the truth of the Moon. In concurrence with these studies, some countries including Japan are planning future lunar missions. In this session, we will discuss scientific results based on newly acquired lunar data, strategy for future missions including SLIM, and theoretical and experimental studies for lunar science.

Over the past 50 years, the lunar interior has been investigated by analyzing the Apollo lunar seismic data (e.g. [1]-[3]). However, currently proposed models of the internal structure are not in accordance with each other although each model can explain the Apollo seismic data. This means there still exists a large uncertainty in the lunar internal structure because the Apollo data does not have enough quality to determine the inner structure precisely. Since the internal structure is a significant factor to elucidate the origin of the Moon, it is essential to obtain new seismic data in order to improve our knowledge of the lunar internal structure.

In particular, the lunar crustal structure (e.g. elastic velocity, density, layer-thickness) is significant when discussing the thermal environment at the initial stage of the lunar formation. From the observation results of KAGUYA (SELENE), it is suggested that the lunar crust consists of very pure anorthosite, which means the refractory element Al concentrates within the crust (e.g. [4][5]). Since the bulk amount of refractory elements gives a strong constraint on the thermal condition of the lunar formation, revealing the lunar crustal structure will lead to better understanding of the history of the Moon.

When determining the lunar crustal structure, impact-induced seismic waves are usually used [6]. Generally, at least 3 seismic stations are required to determine seismic source locations. In the case of the Apollo, although 4 seismic stations were placed and made a network on the nearside of the Moon, it was difficult to determine the impact locations (seismic source locations) precisely due to uncertain arrival time readings and unknown origin times. In future seismic explorations, it is required to carry out seismic observations even at a single point since it is difficult to deploy multi-seismic stations at once. In this situation, the precise determination of origin times and impact locations will play an important role in order to improve the crustal structure. However, as described above, it is considered that a single seismic station is not adequate for the precise determination of origin times and impact locations. This is one of the serious problems when performing a future seismic exploration.

In order to overcome this problem, it has been proposed to apply ground observation data of lunar impact flashes to seismic observations on the Moon [7][8]. Since the basic recording system of the impact flash observation allows us to determine impact times and locations more precisely compared to seismological approaches, it will enable to realize seismic observation at single point. However, these fields of study (lunar impact flash and lunar seismology) have been carried out independently in the past. In this study, we bring these two field together by performing observing simulations of impact-induced seismic waves by combining a seismological simulation with the lunar impact flash observation data as a first step for the consideration of a future seismic exploration.

New Results from Restored Apollo Magnetic Field Records

*Peter J Chi[1]

1. University of California Los Angeles

Three Apollo missions collected digital magnetic field measurements by the Lunar Surface Magnetometers on the surface (Apollo 12, 15, and 16) and by Subsatellite Biaxial Magnetometers in orbit surrounding the Moon (Apollo 15 and 16). After approximately a half century, the Apollo 15 and 16 missions are still the only lunar missions conducting simultaneous surface and orbital magnetic field experiments. The Apollo magnetic field experiments enabled many first discoveries, such as the lunar magnetic anomalies and the electrical conductivity of the Moon.

A recent effort has restored all the Apollo magnetic field records from the archaic data format originally archived. The restored LSM data have revealed many narrowband ion cyclotron waves in the Earth’s magnetotail that were not investigated during Apollo years. The restored data also allow re-analyses for the Moon-solar wind interaction and magnetic sounding of the lunar interior. We find that the observed transfer function responses in both tangential and radial components on the lunar surface are consistent with theoretical expectations at least for frequencies greater than 10^{-4} Hz. The comparison between SBM and LSM data indicates that, when the Moon is in the solar wind, the surface magnetic field is slightly enhanced on the sunward side. This paper summarizes the recent findings from the restored Apollo magnetic field data and discusses the unexplored topics for future magnetic field measurements on the lunar surface.

Analysis of the High Latitude Region of the Moon with Spectral Profiler Data: Possible Presence of Water Ice

Haramitsu Kyoda[3], *Satoshi Tanaka[1], Makiko Ohtake[1], Hiroshi Nagaoka[2], Yusuke Nakauchi[2], Keisuke Onodera[4]

1. Department of Solid Planetary Sciences Institute of Space and Astronautical Science, 2. Japan Aerospace Exploration Agency, 3. Department of Complexity Science and Enginnering, the University of Tokyo, 4. Department of Space and Astronautical Science, SOKENDAI

Recently, space agencies such as NASA and JAXA are actively planning to explore the polar region of the Moon since its usability as lunar base and possible existence of volatile elements([1],[2]). Landing site selection should be taken into consideration of the sunshine rate, existence of volatile materials in the vicinity [3], and so on. Therefore, geological and geomorphological studies in the polar region of the Moon have become more important. In this paper, we focused on detecting of water ice in the polar region using Spectral Proler(SP) data obtained by KAGUYA. Li et al.,(2018)[4] reported exposed water in the permanently shaded area by M^3 data. It is possible to detect more distinct feature of water absorption by the SP data with high S/N ratio. Data analysis by the SP data in the polar region is still difficult due to the large solar incidence angle, however, we reported that the data could be handled with high-accuracy by estimation of insolation area for each spectrum using deep learning method [5]. Based on the SP data in the fully shaded area classied by the method above, we investigated the spectrum having absorption at 1260 nm and 1500 nm both of which are featured by ice and frost of water. As a result, we found about 300 spectrum data having distinct water absorption. One of the data with this absorption obtained in the middle of April, 2009 was located at around (lat. , lon.)=(-85, 50) at where Li et al., (2018) indicated the presence of water ice, but most of the data locations are not overlapped. Moreover, the solar incident angles of all selected data are too high to detect the direct nor the secondary reflected light from the surface of the target area. It is possible that the floating dust at a distance of several tens of kilometers the Moon originated from the impacts or levitation may have been detected[6].

Detection of Dark Regions on the Lunar Surface with Shadow Masked Multiband Imager Data

*Riho Ito[1], Hiroka Inoue[2], Makiko Ohtake[2], Hisashi Otake[2], Ryosuke Nakamura[1]

1. National Institute of Advanced Industrial Science and Technology, 2. Japan Aerospace Exploration Agency

The lunar low-reflectance regions, such as Dark Mantle Deposits (DMDs), iron or titanium rich regions, or weathered older mare, have important information for clarifying the process of lunar evolution. To locate the global distribution of the low-reflectance (dark) region is one of important studies for lunar geological science. Since even small dark regions can be detected based on high-resolution lunar images such as Kaguya's Multiband Imager (MI) images, a goal of this research is to identify candidates of the darkest region with various spatial scale on the global lunar surface. However, a simple automatic identification of small dark regions from Kaguya's MI images, such as using a threshold value, may be hindered by shadows. Therefore, in this research, dark regions other than shadows were identified after removing the shadow regions from the MI images.

The areas that have relatively lower reflectance than the surrounding area due to the difference in the local solar incidence angle are treated as same as actual shadows cast by being hidden from sunshine because the areas often show abnormal spectrum patterns. In the first step, to detect shadow regions, we employed conditional generative adversarial networks (cGAN) which is deep learning method. The cGAN is composed of the generator neatwork and the discriminator network. The Generator is trained to generate realistic fake images that cannot be distinguished from real images by the Discriminator, whereas the Discriminator is trained to detect the fake images generated by the Generator. We prepared supervised data which are pair of MI images and correct shadow masks for training the cGAN networks. In this step, Generator was trained for generating a realistic shadow mask as much as possible according to an input MI image. After the training, our Generator successfully provide a shadow mask in which we can detect high contrast shadows and shadows by craters or other land features. On the other hand, we found that our network had low accuracy for smaller shadows and surround regions of invalid values, and these detected shadow masks included many noises.

In the next step, we employed simple thresholding to detect candidates of DMD from the MI images with shadow masks generated by the trained Generator. Since the results of shadow detection are not stable when an image has many invalid values., regions higher than ±60 ˚including relatively many invalid values were excluded from target regions. The threshold value was determined from a histogram of the reflectance which calculated from the band 2 (750 nm) of the MI image after the shadow removal, and regions where the reflectance was lower than the threshold were detected as candidate of the dark region. In this study, because dark regions with a small size in the detected candidates may be mis-detection of the small shadow regions that could not be distinguished and removed by the trained network, dark regions which area are smaller than 900 pixels (0.36 km^2) were excluded from candidates. Though this process may exclude candidates for actual small dark regions that are not shadows, we decided to focus on locating candidates that can be more reliably determined as dark regions. As threshold processing and noise removal method are important factors greatly affecting the detection of the final candidate points, we will consider the improvements for detecting smaller dark regions in the future work.

In the result of applying this method, although some noise remained, some known DMDs, in the Sinus Aestuum, Taurus-Littrow, Sulpicius-Gallus and Mare Vaporum, were detected as candidates of dark regions. Most of the other detected points were also located in the region of high titanium. In this work, analysis results of detected dark regions and utility of the detection methods will be reported and

Estimation of Moho depth under lunar basins by using only the GRAIL gravity data

*Gaku Nishiyama[1], Noriyuki Namiki[2]

1. Department of Earth and Planetary Science, The University of Tokyo, 2. RISE Project, National Astronomical Observatory of Japan

In order to unravel the formation of solar-system, the subsurface structure of planets and moons will be a key to constrain early differentiation and subsequent thermal evolution. In particular, lunar crustal thickness is of importance for understanding the volume of the ancient magma ocean. Conventionally planetary crustal thickness is estimated by analyzing gravity anomaly data derived from tracking data of spacecrafts using downward continuation filter. In this method, the relief of crust-mantle interface (Moho) are calculated as a variation of surface density anomalies under the condition that a mean crustal thickness or crustal thickness at a specific location has been already known from seismic observation. In this study, however, we demonstrate that the calculation is theoretically incorrect in the point that the Moho relief is imposed on the surface density at certain depth. Downward continuation filter is mathematical trick to stabilize the previous calculation, but it indeed violating gravity theory.

In this study, we show a new method which doesn't require ad hoc assumptions of crustal thickness nor downward continuation filter, but assumes the simple shape of Moho uplift. Under the assumption that the Moho is uplifted like an axisymmetric cylinder beneath Crisium basins , the observed Bouguer gravity anomalies can be expanded in the Bessel-Fourier coefficients . Then we find the best fit parameters such as radius, height and depth of cylinder. Thus, the depth of surrounding crust is estimated to be 37.9±7.7 km. Our estimate is consistent with that of the analysis result of moonquake data measured at Apollo 12 & 14 landing sites. This result indicates that the new method can estimate crustal thicknessby gravity data alone and independently from seismic data. Here we assumed a simple morphology of mass anomalies beneath Crisium basin, however, the top surface of the cylinder as well as surrounding Moho boundary shall be laterally variable. In further research we evaluate an influence of the shape, crustal flexure, and other effects.

Ejecta Thickness Distribution of Lunar Schrödinger Basin

*Luyuan Xu[1], Minggang Xie[1]

1. State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology

A hypervelocity impact on a target with solid surface forms an impact crater, and a fraction of debris is ejected and emplaced ballistically from the crater. The thickness distribution of primary ejecta gives insight into the processes of impact cratering, the stratigraphy of planetary crust, the evolution of planetary surface, and the source of lunar samples. However, the widely used empirical ejecta thickness distribution model of McGetchin et al. (1973) is inconsistent with recent observations of complex craters and the Orientale basin.

As a typical case to address this problem, here we conducted detailed measurements of ejecta thickness distribution for Schrödinger Basin, which is a large impact basin located near the lunar south pole, the best-preserved peak-ring basin, and the second youngest one on the Moon.

Based on LROC WAC, Kaguya TC, and LOLA DTM data, the thickness of primary ejecta is estimated indirectly from the measurements of partially filled pre-basin craters using crater morphometry and the effect of crater degradation is taken into considerations. The results show that the ejecta thickness distribution of Schrödinger Basin is more consistent with Pike (1974)’s model rather than McGetchin et al. (1973)’s, the excavation of Schrödinger basin-forming impact does not penetrate through lunar crust, and the rim relief of Schrödinger Basin consists mostly of rim uplift rather than the primary ejecta.

Possible evolution paths of the lunar orbit based on tidal response in the global ocean model of the early Earth

*Mai Motoyama[1], Hideo Tsunakawa[1], Futoshi Takahashi[2]

1. Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology, 2. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University

The Moon's orbital evolution has been affected by the Earth's ocean tide as well as the solid Earth's tide (e.g. MacDonald, 1964, Kaula, 1964). Many previous studies pointed out that the continental crusts would be few amounts in the early Earth (e.g. Stein & Ben-Avraham, 2007, Rino et. al., 2004), possibly with larger seawater volume than the present day (e.g. Kurokawa et al., 2018, Korenaga et. al., 2017). Thus the early Earth is considered to have been covered by the global ocean for a long time, strongly implying the importance of the ocean tide for the early evolution of the Earth-Moon system. Most of previous studies of the evolution of the Earth-Moon system calculated back to the past with the initial condition of the present state (e.g. Abe et. al., 1997, Rubincam, 2015). The backward calculation is inappropriate to estimate the effects of various parameters concerning the early Earth’s ocean, since there are many uncertain factors such as continental drift. Thus we carried out forward calculation of the lunar orbit from the past for the first 2 billion years to understand characteristic effects of the ocean state in the global ocean model.
Energy dissipation mechanism of the ocean is one of the critical factors in the Moon’s orbital evolution (e.g. Webb, 1982, Lambeck, 1977). Recent studies have revealed that the internal gravity wave, so-called internal tide, is a main mechanism of tidal energy dissipation in the deep ocean (e.g. Taguchi et. al., 2014, Egbert & Ray, 2000). In this study, we considered its effect on the early evolution, assuming the early ocean is as deep as the present abyssal depth.
Our results show that the eigenmode resonance occurs once or more for the first 2 billion years. The Earth-Moon distance rapidly increases with a step-like change at the eigenmode resonance. In the case of the ocean depth decreasing linearly to the time, it is found that the torque due to the oceanic tidal bulge causes continuous increase in the Earth-Moon distance with an especial response of eigenmode oscillation. These acceleration effects could work in the coevolution of the early Earth-Moon system.

Geochemical and Petrological Investigations of Lunar Feldspathic Crust by Lunar Sample Studies and Remote Sensing Data

*Hiroshi Nagaoka[1], Yuzuru Karouji[1], Makiko Ohtake[1]

1. Japan Aerospace Exploration Agency

Feldspathic highland crust deriving from ferroan anorthosite (FAN) have been assumed to be formed by the lunar magma ocean (LMO) model, whose the early crust was accumulated by the crystallization and flotation of plagioclase (Warren, 1985). However, the studies of lunar meteorites which originated from the highlands not covered by the Apollo missions, found more magnesian anorthosites than FAN (e.g., Takeda et al., 2006). Furthermore, Kaguya observation revealed feldspathic crust with higher Mg# (= molar 100 ×Mg/(Mg + Fe)) than FAN (Ohtake et al., 2012).
Furthermore, purest anorthosite (PAN) (>98% plagioclase) lithology was found in central peak of several large craters by Kaguya observation. On the basis of Kaguya results, the massive PAN layer are assumed to be distributed under mafic-rich mixing layer in highlands (Ohtake et al., 2009; Yamamoto et al., 2012).
Like this, lunar meteorite studies and global remote sensing data have provided new global information on geological features of lunar crust.

Feldspathic meteorites from lunar highlands are brecciated by impacts on the lunar surface.
The 10-30% mafic minerals (pyroxene and olivine) are included in the meteorites.
These feldspathic meteorites is similar with the surface composition of mafic-rich mixing layer of feldspathic crust in elemental composition (e.g., FeO, Th).
On the other hand, several highly pure anorthosite (PAN) clasts were found among some of feldspathic lunar meteorites (Nagaoka et al., 2014). They are correspond with PAN lithology observed by Kaguya.

In this work, we have measured and summarized the elemental and mineral composition of feldspahtic lunar meteorites, by bulk chemical analyses, electron micro-probe analyses, and UV-VIS-NIR reflectance spectroscopy. In this presentation, we report and discuss geochemical and petrological features of lunar crust on the basis of recent geochemical and petrological studies combined the above lunar samples analyses data and the recent remote sensing data.

Development of frosting system for lunar simulant and the detectability of ice growing on the simulant by NIR measurement

*Aoi Ogishima[1], Kazuto Saiki[1]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University

In recent years, many remote sensing studies have suggested the existence of lunar water, but it is still an open issue how or how much water is on the Moon. Lunar prospector launched in 1998 found the concentration of proton around lunar poles. In 2009 Lunar Crater Observation and Sensing Satellite (LCROSS) project observed ejecting debris from Cabeus crater and estimated that concentration of water ice is 5.6±2.9 wt%. Chandrayaan-1 data suggested the abundance of water could be as high as 0.077wt%. After these results, Japan’ s space agency JAXA and India’ s space agency ISRO have signed an Implementation Arrangement (IA) for a Joint Lunar Polar Expedition in December 2017. In preparation for this mission, assuming that the grains of lunar regolith are covered by water frost on the lunar permanently shadowed regions, we made minute ice on lunar simulants and measured their Near-Infrared reflectance spectra. As lunar simulant we use olivine (from San Carlos, 125-250um, Fo90) and lunar simulant FJS-1 (Shimizu Corporation). We developed a frosting system. It’ s a kind of cooling stage in which simulant grains cooled with liquid N2 can be mixed with highly humid air and vibrated. In the stage, water frosts condensed and cover the surface of grains. The top of the stage is covered with silica glass plate, so we can observe the spectra without taking out samples from the stage. We observed the reflectance spectra of the frosted simulants with a Near-Infrared imaging spectrometer developed by Saiki at 950-1600 nm, angle of incidence = 30˚, angle of viewing = 0˚. After the measurement, we weighed the mass of frosts. In order to prevent additional frost during weighing, we made a vinyl house and weighed frosted samples in the house purged with dry N2 gas. Then, the samples were heated and the frosts on them evaporated. After heating we weighed the samples again, regarded the decreased mass as the mass of frosts, and calculated mass fraction of frosts. We succeeded in making the minute ice less than 1wt% on the simulant, but it is difficult to make ice homogeneously and to control the amount. In order to address these problems, we developed a new fall-type frosting system. In this system cooled simulant fall down in humid air and covered by minute ice homogeneously.We continue trial and error on falling distance and humid air volume aiming to control the amount of frost on the order of 0.1 wt%. Latest results will be reported.

Scientific approach for the promotion of lunar polar exploration mission

*Masahiro KAYAMA[1], Ko Hashizume[2], Hiroshi Nagaoka[3], Kazuto Saiki[4], Chihiro Yamanaka[4], Makoto Hareyama[5], Makiko Ohtake[3]

1. Tohoku University, 2. Ibaraki University, 3. Japan Aerospace Exploration Agency, 4. Osaka University, 5. St. Marianna University School of Medicine

Remote sensing spacecraft missions (e.g., LCROSS and Deep Impact), lunar sample studies, and theoretical simulations suggest the existence of various water species (e.g., H_2O ice, hydroxyl and molecular water, and aqueous phase) on the lunar surface and in the subsurface. Lunar water is thought to originate from solar wind, meteorite/asteroid/comet collisions, and/or volcanic eruptions and concentrated locally on the lunar surface to subsurface, especially permanently shadowed regions near the lunar poles. These findings indicate the possibility of the presence of available water resources for future human activity on the Moon. Moreover, lunar water is significant because it is closely related to a formation process of the lunar magma ocean and its differentiation to the mantle. Therefore, Lunar Polar Exploration Mission is planned to be launched in the 2020’s to survey lunar water. From the viewpoint of resources, science and engineering, this mission provides new insights into lunar evolutionary history and lunar base construction. Here, we will discuss analytical techniques for in-situ water analyses on the lunar poles and experiments simulating low-temperature and high-vacuum lunar environment.

Feasibility study of detection of the lunar subsurface ice with UHF-band GPR based on FDTD electromagnetic simulation

*Atsushi Kumamoto[1], Hideaki Miyamoto[2], Toshifumi Nishibori[3], Takafumi Niihara[2], Fuminori Tsuchiya[1], Ken Ishiyama[3]

Detectability of the subsurface ice by UHF-band (0.5-3 GHz) ground penetrating radar (GPR) onboard the rover in the lunar polar region was investigated based on electromagnetic simulation using finite-difference time-domain (FDTD) method. The water brought on the lunar surface is lost within 1 day due to photodissociation. However, if a part of water molecules jump to polar region within 1 day, they can be kept in the polar shadowed region [Arnord, 1979]. Some observations such as impact experiment in LCROSS mission [Colaprete et al., 2010] and SAR polarization measurements in Chandrayaan mission [Spudis et al., 2010] suggests the existence of the water in the lunar polar region.

In this study, we used Meep code [Oskooi et al., 2010] for FDTD simulation. The simulation space with a size of 0.25 m x 1.25 m is divided into meshes with a size of 0.3 mm x 0.3 mm. The uppermost part with a height of 0.5 m is filled with vacuum (permittivity: 1). The second part with a thickness of 0.5 m is filled with dry regolith, basalt (permittivity: 7) including voids (vacuum). The lowermost part with a thickness of 0.25 m is filled with several kind of media such as (i) cavity (vacuum), (ii) rocks (basalt without pores), (iii) pure ice (permittivity: 3), and (iv) icy regolith, regolith whose voids are filled ice. The porosity of the dry and icy regolith layers was determined based on the report from Apollo missions on the vertical profile of the bulk density of the lunar subsurface soils up to depth of 3 m [Carrier et al., 1991]. Chirp pulse in a frequency range from 0.5 to 3 GHz was transmitted for 167 ns from 0.4 m above the dry regolith surface. The electromagnetic fields in simulation space were evolved with time step of 0.52 ps. At the transmission point, the waveform of electric field component of the echoes was recorded at an interval of 33 ps.

Calculation results suggests that subsurface echoes from (i) cavity, (iii) rocks, and (iv) icy regolith at a depth of 0.5 m can be detected with enough echo powers while the echo power from (iii) pure ice were as large as volume scatters due to inhomogeneity in the regolith. They are a little different from the results of our previous calculation performed in a frequency range 1-15 GHz with subsurface materials at a depth of 0.1 m: The echo powers from ice and icy regolith were as large as volume scatters. We can consider that the difference is from (a) the decrease of the volume scatters power by changing the operation frequency range, and (b) the depth dependence of permittivity contrast in inhomogeneous regolith.

[P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University), Chairperson:Masahiro Kayama(東北大学), Yusuke Nakauchi(JAXA/ISAS)

Scientific data sets acquired by not only Japanese lunar mission SELENE (Kaguya), but also other countries' missions, have become new standard for lunar science. Analyses of these data have been providing several new knowledge and changing some hypotheses into the truth of the Moon. In concurrence with these studies, some countries including Japan are planning future lunar missions. In this session, we will discuss scientific results based on newly acquired lunar data, strategy for future missions including SLIM, and theoretical and experimental studies for lunar science.

Introduction: Smart Lander for Investigating Moon (SLIM) is a Japanese technology demonstration mission to pinpoint landing within a hundred meters in radius, which will be launched in fiscal year 2021. The lander carries one small instrument (high-resolution Multiband Camera; see Saiki et al. in this conference) to derive the detailed mineralogy of the olivine-rich exposure to investigate a olivine bearing lithology for understanding their origin and investigating the composition of the lunar unsampled mantle or deep crustal material. To directly explore this unexplored lithology, one of the small fresh craters just outside of the Theophilus crater is selected as a landing site for the SLIM mission. In this study, we analyzed geology of Theophilus crater and the selected landing site.

Crater Theophilus (11.4˚S, 26.4˚E) is located in the immediate vicinity (northwest) of the Mare Nectaris on the Moon. It is on the ring of the Nectaris basin. Its diameter is 110 km, and it has a clear central peak at the center of the crater. Previous study revealed the central peak’ s compositional diversity [1][2]. However, the origin of other lithologies and the relation of these rare geologic lithologies in this unique central peak are still not clear. In addition to their geological (mineralogical) diversity.

Data and Results: We used remote sensing reflectance spectra and spectral images obtained by the SELENE (Kaguya) Spectral Profiler (SP) and Multiband Imager (MI). Olivine-dominant lithology at the central peak have clear diagnostic absorption of olivine. Percentage of olivine among olivine and pyroxene of the olivine dominant lithology is estimated to be more than 70. The FeO abundance of the olivine-dominant lithology estimated ranges from 5 to 8 wt.%. Olivine-dominantlithology appears to be present as a basal lithology of the central peak blocks. Olivine dominantlithology is also observed as localized exposures at many small but fresh craters throughout the wall and ejecta region. These fresh craters commonly have a very clear olivine absorption feature, and the FeO abundance of these localized olivine exposures ranges up to 12 wt.%,which corresponds to a nearly pure olivine rock, if Mg# (Mg/(Mg+Fe) in mole per cent) of the olivine is assumed to be similar to the olivine-rich rock types (troctolite and dunite) among the Apollo samples.

Discussion: Based on the modal abundance, FeO abundance, distribution, and morphological information of the observed lithologies, we believe that the central peak of Theophilus crater mainly consists of olivine-dominant lithologies with lesser amounts of purest anorthosite (PAN) and Mg-spinel bearing lithologies. Distribution of Mg-spinel bearing lithology is limited in our datasets and they tend to have a relatively sharp vertical boundary with the adjacent lithology. Therefore, we interpret it is not presented as a laterally extensive unit before the formation of the Theophilus crater as suggested [1]. Observed olivine-rich composition comparable to dunite and a sharp boundary with the adjacent PAN lithology suggest that it is not a part of the continuous crustal material. Instead, it is probably mantle (or the lower part of the crustal) origin, which is excavated by the Nectaris basin forming impact as suggested by the global distribution of the olivine-rich sites [2], well before the formation of the Theophlius.

Observing scenario for the Multi-Band Camera onboard SLIM

*Kazuto Saiki[1], Yuya Igarashi[1], Yusuke Nakauchi[2], Chikatoshi Honda[3], Makiko Ohtake[2], Hiroaki Shiraishi[2], Hiroyuki Satoh[2], Yoshiaki Ishihara[4], Takao Maeda[5], Chihiro Yamanaka[1]

Smart Lander for Investigating Moon (SLIM) is being planned by Japan Aerospace Exploration Agency (JAXA). SLIM aims to research and demonstrate the engineering key issues related to the smart landing on the gravitational planets. They are precise guidance algorithm, vision based navigation, smart landing gear. By doing SLIM mission, we expect to achieve the paradigm shift in the field of celestial body landing from ‘landing where easy to land’ to ‘landing where desire to land’. We proposed Multi-Band Camera (MBC) for SLIM lander. MBC is a compact VIS-NIR camera composed of an imaging sensor (InGaAs), a filter-wheel with 10 band-pass filters, and a movable mirror for panning and tilting. Scientific objectives of MBC are the identification of rocks and rock-forming minerals around the lander and the estimation of Mg#(=Mg/(Mg+Fe)) of olivines that might have come from lunar mantle.

MBC has a telescopic optical system and is a camera with a new concept of spectroscopic observation of rock rather than powder called regolith, so various innovative methods are required for its operation. Among them, we will introduce the methodology of scan operation, on-site calibration, autofocus system, spectroscopic observation of rocks, and Mg # estimation.

Since it is dangerous to land on a place covered with rocks, SLIM landing site was carefully selected. The landing site should be the site where the rock distribution does not become an obstacle to landing and the distribution is as much as rocks can be observed. Since MBC is a telephoto optical system in which the horizontal viewing angle is 4 degrees, rocks would not be observed in random shots. Therefore, it has a function to create a map with a combined low resolution scanned images of around 300 shots that can cover the all observable field of view. After specifying the location of the rock to be observed, we will perform spectroscopic observations efficiently. SLIM, a small unmanned spacecraft, arrives at the moon after a much longer period of time than a manned rocket, so it will be attacked much higher levels of radiation. Because there is a possibility that the background signal of the imaging device increases or the transmittance of the filter changes, we plan to calibrate on the moon. Specifically, MBC has a function to acquire deep space images as dark background data and subtract it from observed image. We also plan to carry out luminance calibration by installing a standard diffuse reflection plate. Since MBC is a telephoto optical system, a focus adjustment mechanism is also indispensable. We realized an automatic focus adjustment function using the fact that the file-size compression rate of the acquired image decreases when approaching the best focus. Although spectroscopic observation of rocks in the near infrared range is thought to be inherently difficult, we are planning to make use of the observable conditions obtained by observation experiments of natural rocks and rock-analogs. In addition, we are planning to spline-fit the data of each band intensity and detect subtle change in wavelength of the absorption peak of Fe^{2+} to estimate Mg # of olivine.

Current status of a Japanese lunar polar exploration mission

*Takeshi Hoshino[1], Makiko Ohtake[1], Yuzuru Karouji[1], Hiroaki Shiraishi[1]

1. Japan Aerospace Exploration Agency

Introduction:

Recently, it has been suggested that water ice might be present in the lunar polar region based on spectral measurements of artificial-impact-induced plumes in the permanently shadowed region, and remote sensing observation of the lunar surface using a neutron spectrometer [1], [2] and visible to infrared spectrometer [3]. In addition to the scientific interest about the origin and concentration mechanism of the water ice, there is strong interest in using water ice (if present) as an in-situ resources. Specifically, using water ice as a propellant will significantly affect future exploration scenarios and activities because the propellant generated from the water can be used for ascent from the lunar surface and can reduce the mass of the launched spacecraft of lunar landing missions.

However, currently it is unclear if water ice is really present in the polar region because of the currently limited available data. Therefore, we need to learn that by directly measuring on the lunar surface. If there is water ice, we also need to know it’ s quantity (how much), quality (is it pure water or does it contain other phases such as CO_2 and CH_4), and usability (how deep do we need to drill or how much energy is required to derive the water) for assessing if we can use it as resources. Therefore, JAXA is studying a lunar polar exploration mission that aims to gain the above information and to establish the technology for planetary surface exploration [4]. JAXA is also studying possibility of implementing it within the framework of international collaboration with Indian Space Research Organisation (ISRO).

Spacecraft configuration:

The spacecraft system comprises a lander system and a rover system. The system does not have a communication relay satellite but is based on direct communication with the Earth. The minimum target for the landing payload mass is several-hundred kilograms. The launch orbit is the lunar transfer orbit (LTO). After the spacecraft reaches the Moon it is inserted into a circular orbit having a 100km altitude via a few orbital changes. During powered-descent phase, the position of the lander is estimated by landmark navigation using shadows created by the terrain. After landing, the rover is deployed on the lunar surface using ramps. The rover then prospects water ice with its observation instruments..

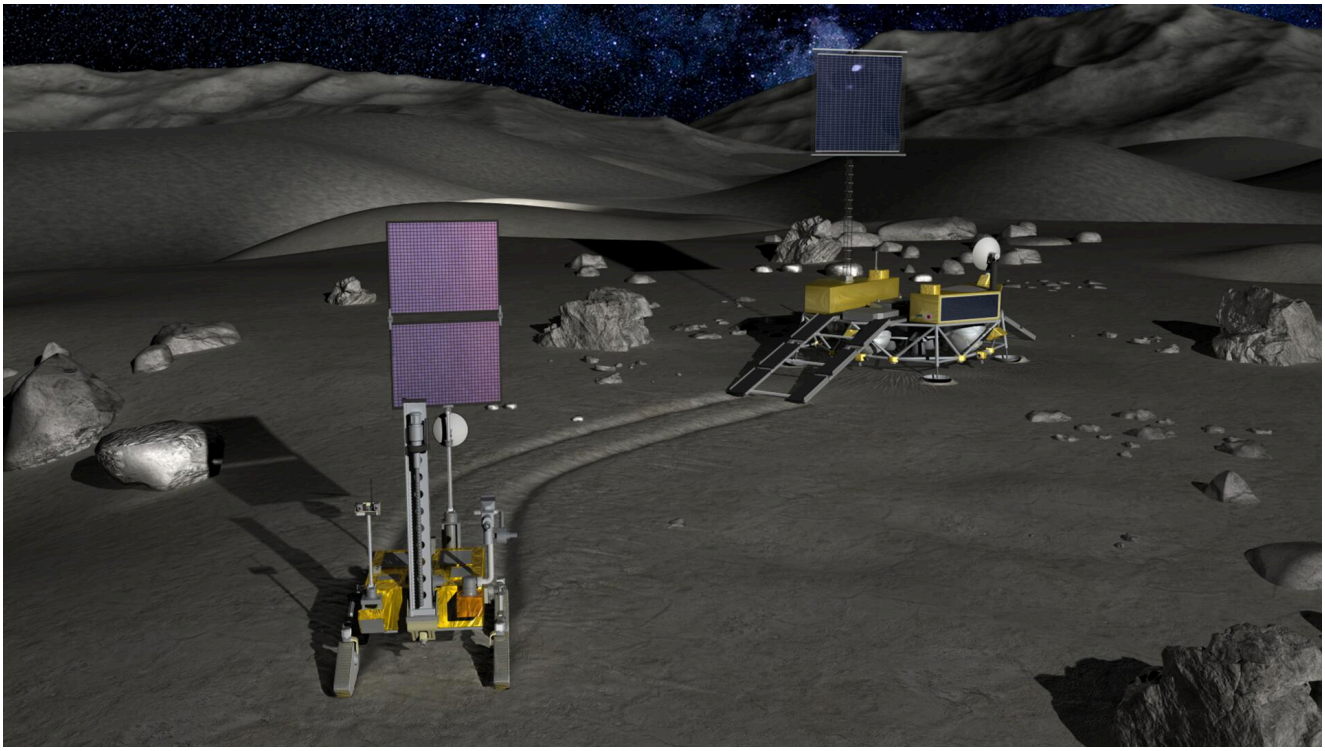
a few orbital changes. During powered-descent phase, the position of the lander is estimated by landmark navigation using shadows created by the terrain. After landing, the rover is deployed on the lunar surface using ramps. The rover then prospects water ice with its observation instruments..

Landing site selection:

Considering the mission objectives and condition of the lunar polar region, we listed the following parameters as constraints.
- Presence of water
- Surface topography
- Communication capability
- Duration of sunshine



As a first trial of the landing site selection, sunshine is simulated using digital elevation models to obtain the sunlight days per year and the number of continuous sunshine periods at each site. Also, slope and the simulated communication visibility map from the Earth are created. These conditions can be superimposed to select the landing site candidate.

Current status:
Recently, we finished joint mission definition review (JMDR) with ISRO, in which JAXA provide a launch rocket and a rover while ISRO provide a lander system. Related to the instruments which will be carried on the rover or the lander, JAXA selected several candidate instrument study teams for accelerating development of these instruments. In this presentation, we are going to introduce current status of the mission planning.

HERACLES mission: Returning to the Moon by an ESA-JAXA-CSA Joint Study

*Yuzuru Karouji[1], Hiroshi Nagaoka[1], Yoshiaki Ishihara[2], Masahiro KAYAMA[3], Satoru Yamamoto[4], Nobuyuki Hasebe[5], Ko Hashizume[6], Yoshiko Ogawa[7], Toru Yada[1], Junichi Haruyama[1], Masanao Abe[1], Makiko Ohtake[1], HERACLES Science Working Group, HERACLES International Science Definition Team

1. Japan Aerospace Exploration Agency, 2. National Institute for Environmental Studies, 3. Faculty of Science, Tohoku University, 4. J-spacesystems, 5. Advanced Research Institute for Science and Engineering, Waseda University, 6. Faculty of Science, Ibaraki University, 7. The University of Aizu

Global Exploration Roadmap published in January 2018 by the International Space Exploration Coordination Group (ISECG) clearly identify the Moon as the next logical destination and defined strategic goals and objectives for its exploration. Returning to the Moon not only yields fundamentally important science opportunities for our understanding of the Solar System but also allows us to test hardware and operational procedures for the exploration and utilization of space beyond Low Earth Orbit (LEO). The Human-Enhanced Robotic Architecture and Capability for Lunar Exploration and Science (HERACLES) is a joint mission under study by European Space Agency (ESA), Japan Aerospace Exploration Agency (JAXA) and Canadian Space Agency (CSA) with NASA and Roscosmos having observer status [e.g., 1]. Thus, HERACLES is an international effort in preparation of returning humans to the Moon and providing opportunities for unprecedented science utilizing the Lunar Orbital Platform-Gateway (Gateway). It is a sub-scale demonstration mission of human lunar exploration aiming for launch in the mid-2020's, and the vehicle is composed to test key components including the three following elements: The Lunar Ascent Element (LAE) will be provided by the ESA, the Lunar Descent Element (LDE) will be provided by the JAXA, and the rover will be provided by the CSA.

The coordination of the planning of science opportunities is performed by the multi-agency HERACLES Science Working Group (SWG). The SWG is also responsible for developing a mission science management plan to describe science themes and science payload instruments selection processes, and data/sample allocation policies. The SWG engaged the science communities of each country and organized the HERACLES international Science Definition Team (iSDT). The iSDT will generate a prioritized list of investigations and will provide input for the landing site selection.

Recently, the iSDT discussed the science scope of the HERACLES mission. The iSDT agreed that the following five non-prioritized topics are the most important lunar science themes that should be addressed by HERACLES; (1) crustal anorthosite composition and crystallization age, (2) mantle composition, (3) improvement of chronology with crater counting of young basalts (<2.5 Ga), (4) internal structure: surface, subsurface, crust, mantle and core, (5) mechanism of material transport (e.g., water) to the Moon. Furthermore, the iSDT has identified several potential landing areas to accomplish these science themes: Jackson crater, Moscoviense basin, Copernicus crater, Schrödinger basin and some young basalts in the Flamsteed region [2, 3].

By the way, the International Space Exploration Program Committee of the Advisory Committee for Space Science and Engineering organized the HERACLES Task Force and independently of SWG, is compiling to recommendations on science and engineering of HERACLES mission. These reports will be submitted at the end of February 2019. These recommentdations will also be taken deeply as opinions of the Japanese scientific community and SWG will discuss how to reflect it in the SWG discussion in the future. In this presentation, we are going to report outcom of previous activities related to the HERACLES SWG and planned discussion within Japanese lunar science community of study in this SWG.

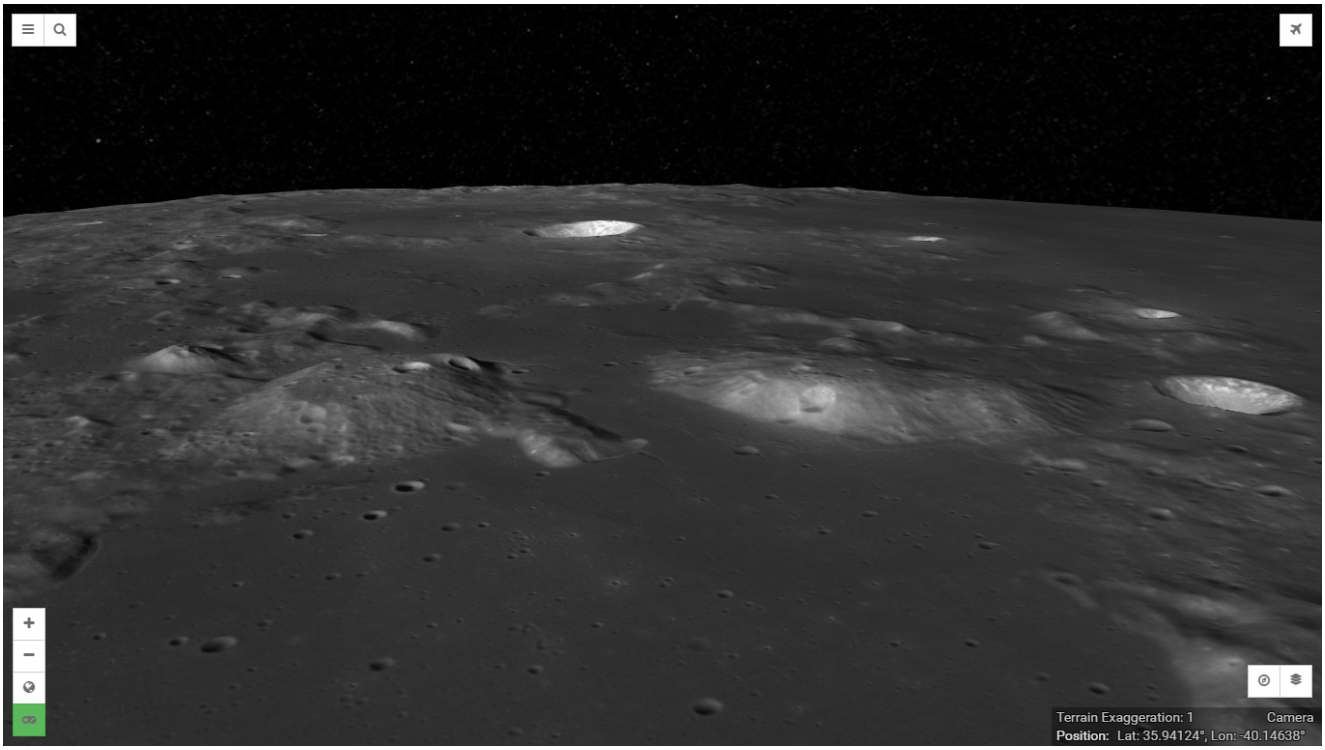
Lunar Science for Landed Missions –High-Priority Landing Sites Visualized with NASA’s Moon Trek

*Brian Hamilton Day[1], Emily Law[2]

1. NASA Solar System Exploration Research Virtual Institute, NASA Ames Research Center, 2. NASA Jet Propulsion Laboratory, California Institute of Technology



The Lunar Science for Landed Missions workshop was held on 10–12 January, 2018 at NASA Ames Research Center and was attended by lunar scientists, representatives from commercial companies, and representative of various international space agencies including the Japan Aerospace Exploration Agency and the European Space Agency. The workshop was cosponsored by the Solar System Exploration Research Virtual Institute (SSERVI) and the Lunar Exploration Analysis Group (LEAG). The primary goal of the workshop was to produce a set of high-priority landing site targets, generated by the lunar science community, for near-term lunar missions. The scope of such missions was aimed primarily, but not exclusively, at commercial exploration companies with interests in pursuing ventures on the surface of the Moon. The results of this workshop were published in a report that summarized the findings of the workshop and provided an analysis of priority landing sites and how missions to these sites would meet key science and exploration goals determined by NASA and the scientific community (Jawin, et al, 2019). This presentation for JpGU will review the landing sites advocated by the workshop, highlight characteristics that make them high-priority sites, and showcase the sites using visualizations generated using NASA’s Moon Trek data visualization and analysis portal (Day and Law, 2017).

NASA SSERVI: Merging Science and Human Exploration

*Brad Eugene Bailey[1], Kristina Gibbs[1], Gregory Schmidt[1]

1. NASA

NASA's Solar System Exploration Research Virtual Institute (SSERVI) represents a close collaboration between science, technology and exploration, and was created to enable a deeper understanding of the Moon and other airless bodies. SSERVI is supported jointly by NASA’ s Science Mission Directorate and Human Exploration and Operations Mission Directorate. The institute currently focuses on the scientific asp ects of exploration as they pertain to the Moon, Near Earth Asteroids (NEAs) and the moons of Mars, but the institute goals may expand, depending on NASA's needs, in the future. The nine initial teams, selected in late 2013 were funded from 2014 - 2019, have expertise across the broad spectrum of lunar, NEA, and Martian moon sciences. An additional four teams were selected in 2017.

The research includes various aspects of the surface, interior, exosphere, near - space environments, and dynamics of these bodies. In addition, SSERVI has ten International Partners which collaborate with US teams NASA anticipates additional team selections in mid 2019 from the 3rd SSERVI Cooperative Agreement Notice call for proposals. Calls for proposals are issued every 2-3 years to allow overlap between generations of institute teams, but the intent for each team is to provide a stable base of funding for a five-year period.

SSERVI's mission includes acting as a bridge between several groups, joining together researchers from:

1) scientific and exploration communities, 2) multiple disciplines across a wide range of planetary sciences, and 3) domestic and international communities and partnerships.

The SSERVI central office is located at NASA Ames Research Center in Mountain View, CA. The administrative staff at the central office forms the organizational hub for the domestic and international teams and enables the virtual collaborative environment. Interactions with geographically dispersed teams across the U.S., and global partners, occur easily and frequently in a collaborative virtual environment. This talk will consist of an overview of SSERVI’ s mission, current US teams and International Partners.

Prediction of the high-resolution numerical flux by using a deep neural network

*Yosuke Matsumoto[1]

1. Graduate School of Science, Chiba University

Magnetohydrodynamic simulations have played important roles for understanding space and astrophysical phenomena. In such circumstances, shock waves and turbulence are inherent properties, and both aspects equally affect evolution of the whole system. Therefore development of numerical algorithms capable of solving both shock waves (discontinuities) and turbulence (waves) with high resolution is a challenging task to tackle violent phenomena in space and astrophysical plasmas.

High-order (greater than the fifth) spatial interpolation coupled with approximate Riemann solvers is a promising solution to such problems (Matsumoto et al., 2016; Minoshima, Miyoshi, Matsumoto, 2019). CANS+ (Matsumoto et al., 2016) employs the fifth order MP5 reconstruction scheme coupled with the HLLD approximate Riemann solver (Miyoshi and Kusano, 2005), and it successfully provided highly resolved solutions for both shock waves and turbulence. A drawback of adopting high-order schemes is its large and complex floating-point operations for obtaining the numerical flux at the cell surface, including minmod (with four arguments) limiters and conversion from the primitive to the characteristic variables. These numerical operations in addition to calculation of the HLLD numerical flux dominated overall computational loads.

In this paper, we propose a different way of calculating the numerical flux by adopting supervised learning algorithms. A deep (multilayer) neural network consists of input and output layers, whose sizes are determined by the problem of interest, and arbitrary numbers and sizes of hidden layers. These layers are connected by linear operations followed by a mapping through nonlinear functions such as a sigmoid function (fully connected networks). Weighting parameters used in the linear operations in each layer are updated repeatedly so that the loss function between the output and the label data (true value) becomes a minimum value. In the present particular problem, we prepared learning data by examining a 1-D shock tube problem which contains rarefaction waves and discontinuities by using CANS+. The input and label data are cell states for all primitive variables in six-point stencils centered on a cell and the numerical flux on the right-hand side of the cell, respectively. We have implemented a multi-layer, fully-connected network by using the Chainer framework for the prepared learning data. With the given data set we successfully obtained a network that can predict the numerical flux with 99% accuracy. In this talk we present detailed algorithms and learning data, and discuss future perspectives including application to multidimensional simulations.

Multiple Boris integrators for particle-in-cell simulation

*Seiji Zenitani[1], Tsunehiko N Kato[2]

1. Kyoto University, 2. National Astronomical Observatory of Japan

We construct Boris-type schemes for integrating the gyration of charged particles in particle-in-cell (PIC) simulation. The new solvers virtually combine the classic 2-step Boris solver arbitrary n times, and then they provide n^2 times smaller errors. We derive a single-step form of the multiple Boris solvers, whose coefficients are given by polynomials. We carry out numerical tests of the new solvers, in comparison with other particle integrators.

Contour Dynamics for Vlasov–Poisson Plasma with the Periodic Boundary

*Hiroki Sato[1], Tomo-Hiko Watanabe[1], Shinya Maeyama[1]

1. Nagoya University

Zabusky, Hughes, and Roberts presented a contour dynamics algorithm for the Euler equations of fluid dynamics in two dimensions [1].On the paper, they succeed in calculating time development of contours of vorticity on the x-y plane with the contour dynamics(CD) algorithm, which is a method by using contours of vorticity, piece-wise constant function, and line integrals of Green’ s function on the contours. The CD method does not use underlying lattice, but uses nodes on the contours, and it can lead to more accurate calculation for complex deformation of vorticity.

This method is also applied to Vlasov–Poisson system. In order to study the CD in the Vlasov–Poisson plasma, we have developed a method to implement the periodic of potential and its derivative are satisfied.To check validity of out method, we test the Linear Landau damping by means of the CD scheme.While discretization of the distribution function might lead to some difference from that with continuous distribution, soundness of our new scheme is confirmed in comparison with analytical solutions.

We are also investigating in behaviors of the CD in the continuous limit, and in the nonlinear Landau damping as well.

Simulation methods and visualization tools for MHD simulations in a sphere

*Akira Kageyama[1], Kumiko Hori[1], Naohisa Sakamoto[1]

1. Graduate School of System Informatics, Kobe University

In recent years, we have been developing a set of simulation and visualization tools for magnetohydrodynamics (MHD) simulations in the spherical geometry. The adopted numerical scheme is a finite-difference method on the Yin-Yang-Zhong grid [1], which is an overset grid system in the spherical geometry.

The codes are written in Fortran 2003 or in eFortran [2], which is a dialect of Fortran 2008 language. The features of eFortran include; the period "." as the member access operator; block comments, addition/subtraction/multiplication assignment, pre-defined and user-defined aliases, automatic check of "implicit none" call, "just once" block, and "skip" block. We have developed a preprocessor to convert the dialect into the legitimate Fortran. It is a simple text converter in Python that keeps the line numbers of the input dialect and the output standard codes.

We have performed MHD simulations of relaxation process in a sphere [5]. Since the spherical geometry is free from the lateral dynamic pressure on the spherical boundary, we can observe MHD relaxation process in which flow and the magnetic field coexist. Intriguing structures of magnetic/flow fields are observed after relaxations.

One of interesting applications of the spherical MHD solver is the spherical shell convection with resistive inner core. Magnetic field generated by dynamo process in the convective spherical layer can diffuse into the inner solid core. We have solved slowly rotating spherical thin shell convection system and confirmed that the resistive inner core plays important roles to keep the dynamo operating in convection rolls in the ring- or spiral-shape.

We have also applied the Yin-Yang-Zhong simulation code to simulate MHD flows in a precessing sphere. We have confirmed that magnetic field is generated in spherical precession flows in some parameter regimes that are reported in previous studies. The structure and the generation mechanism of the magnetic field is analyzed in detail.

For the visualization purposes, we have developed two kinds of visualization tools for simulation data produced on the Yin-Yang or Yin-Yang-Zhong grid : (a) Two dimensional (cross sectional) in-situ visualization library with vector graphics format (EPS) [3], and (b) three dimensional visualization methods based on an advanced visualization framework KVS (Kyoto Visualization System) [4].

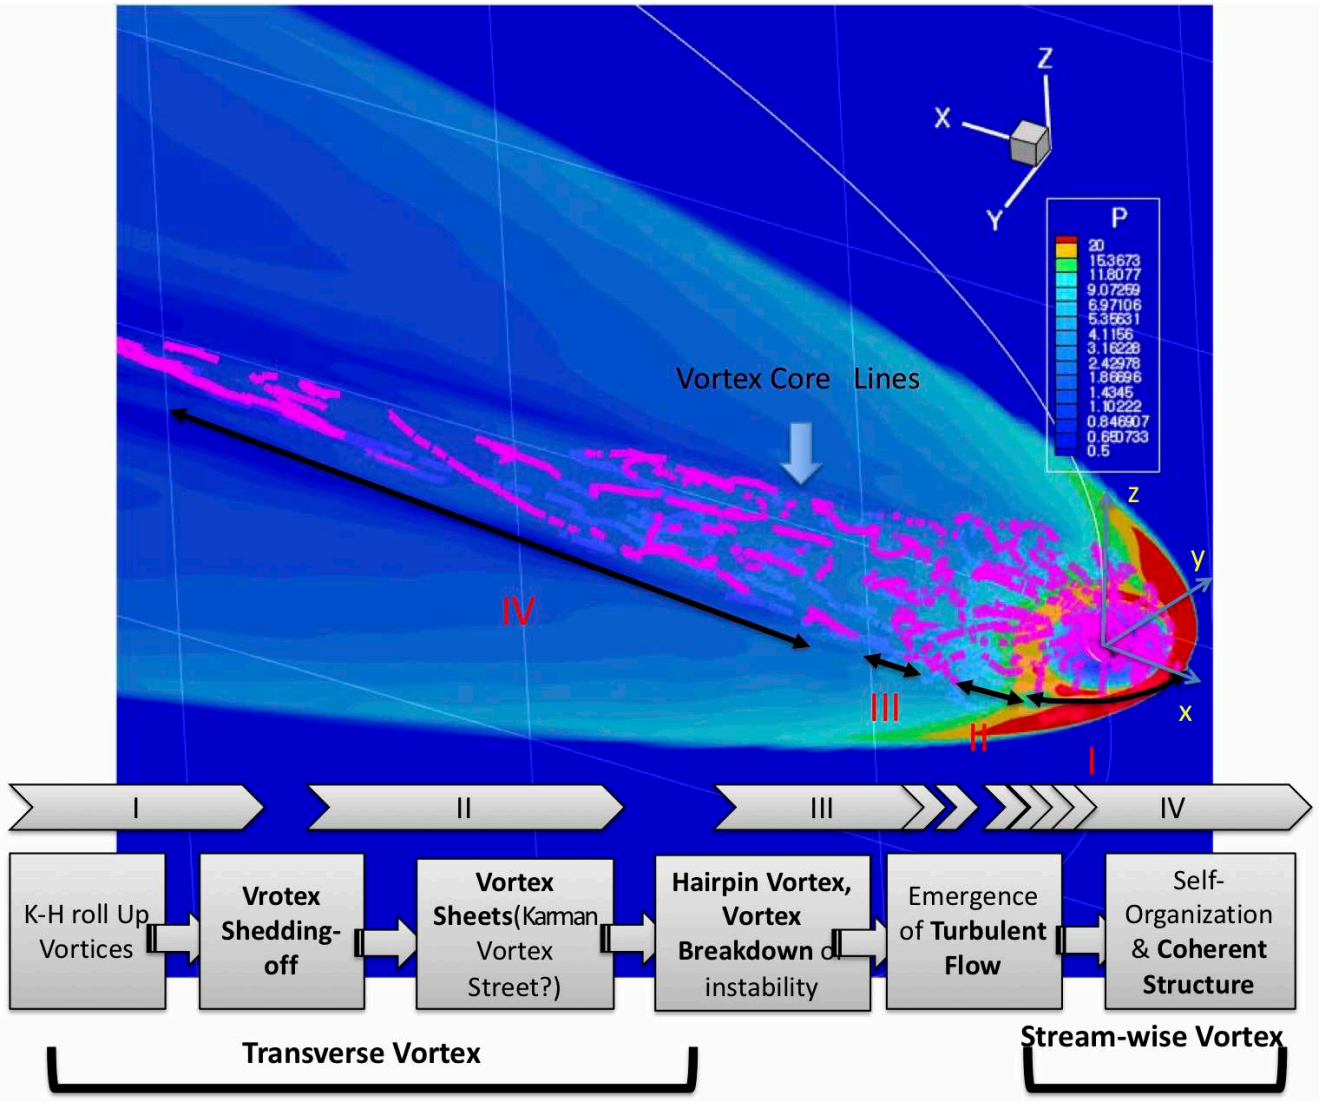
Kármán Vortex Street, Strouhal Number, Hairpin Vortex in 3D global Magnetohydrodynamic MHD simulations in Northward IMF



*DongSheng CAI[1]

1. University of Tsukuba

A Kármán vortex street is a repeating pattern of two rows of paired swirling vortices and appears after some obstacles or stagnation areas in fluid or plasma flows. It is caused by a process known as a vortex shedding where vortices leave the shear layer. Recently, several studies have discussed the Kelvin-Helmholtz (K-H) instability and its related waves and vortex structures by using 2D / 3D global (Magneto Hydro Dynamics) MHD simulations in the northward IMF (Interplanetary Magnetic Field). These found a double-vortex sheet in which a vortex train propagates, respectively, along the inner and outer edges of the magnetopause. In the present paper, we show that these two rows of vortices form the Kármán vortex street, and we discuss its generation mechanism with the help of 3D global MHD simulations. These Kármán vortex stretches and elongates in the night side and becomes to be the so-called the Hairpin vortex that is essential for the coherent structure. We also identify the non-dimensional number vortex so-called the Strouhal number in our simulation. The Stouhal number is ubiquitous and represents one of the most significant features in the Kármán vortex street.

Correlations between plasma density and magnetic field strength in MHD turbulence in space

*Tohru Hada[1], Yasuhito Narita[2], Yasuhiro Nariyuki[3]

1. Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2. Space Research Institute, Austrian Academy of Sciences, 3. Faculty of Human Development, University of Toyama

Large amplitude magnetohydrodynamic (MHD) turbulence is ubiquitous in space plasma, for example, in the solar wind, in the foreshock region (Narita, World Scientific, 2010) and in the sheath region of the earth's bowshock (e.g., Pollock et al., J. Atmosph. Solar Terr. Phys, 2018). Moreover, recent Voyager observations of large amplitude density and magnetic field fluctuations in the heliosheath behind the termination shock arouse a vivid discussion on the compressible nature and the origin of the observed turbulence (Burlaga and Ness, ApJ, 2009; Gutynska et al., ApJ, 2010). An obvious way of generating the density fluctuations is via the presence of compressive wave modes, such as obliquely propagating MHD waves. The density response is linear to the magnetic field perturbations in this case, and it vanishes in the limit of parallel wave propagation. In a finite (large) amplitude Alfvenic turbulence the density perturbation may be mainly generated via the "frozen-in" of the magnetic field to the plasma or the static balance between the plasma pressure and the magnetic field. Both of these processes result in the quadratic response of the density to the magnetic field perturbations, although their correlation is positive for the former and negative for the latter. This simple fluid picture, sometimes referred to as the "quasi-static" approximation, is known to be significantly modified when the ion response to the turbulence is kinetically treated (Mjolhus and Wyller, Phys. Scripta, 1986; Medvedev and Diamond, Phys. Plasmas, 1996). In this presentation, we address this unsolved issue of the correlations between the plasma density and the magnetic field amplitude in the presence of finite amplitude MHD turbulence by performing hybrid simulations (kinetic ions + fluid electrons), and by examining the in situ Cluster spacecraft data of the foreshock plasma (Narita and Hada, Earth, Planets and Space, 2018).

Stochastic models of phase space diffusion via wave-particle interaction with parallel propagating electromagnetic waves

*Yasuhiro Nariyuki[1]

1. Faculty of Human Development, University of Toyama

Particle diffusion due to electromagnetic waves is one of fundamental processes in various phenome in space plasms such as electron acceleration in the outer radiation belt [e.g., Saito et al, JGR, 2016], astrophysical shock [e.g., Yamazaki, JHEA, 2015], and solar wind [e.g., Seough et al, APJ, 2015]. Although quasi-linear theories are widely used as a standard theory of particle scattering, nonlinear wave-particle interactions such as particle trapping also affect particle diffusions in the presence of finite amplitude waves. Saito et al [JGR, 2016] demonstrated that nonlinearity of whistler chorus waves plays a significant role in electron diffusion though nonlinear wave-particle interactions.

In Saito et al [JGR, 2016], the artificial randomization of gyrophases (phase breaking) is incorporated to discuss suppression of coherent wave-particle interactions. Remark that such a randomization corresponds to a noise term in equations of motion of each particles. In this sense, phase breaking causes not only the suppression of coherent processes but also diffusions in phase space. In the present study, we discuss the generalization of phase breaking. It is shown that particle diffusion depends on probability density functions of noises and their parameters. Noise terms in equations of the pitch angle are also necessary to describe diffusion in phase space. Treatment of phase breaking as a stochastic differential equation is also discussed.

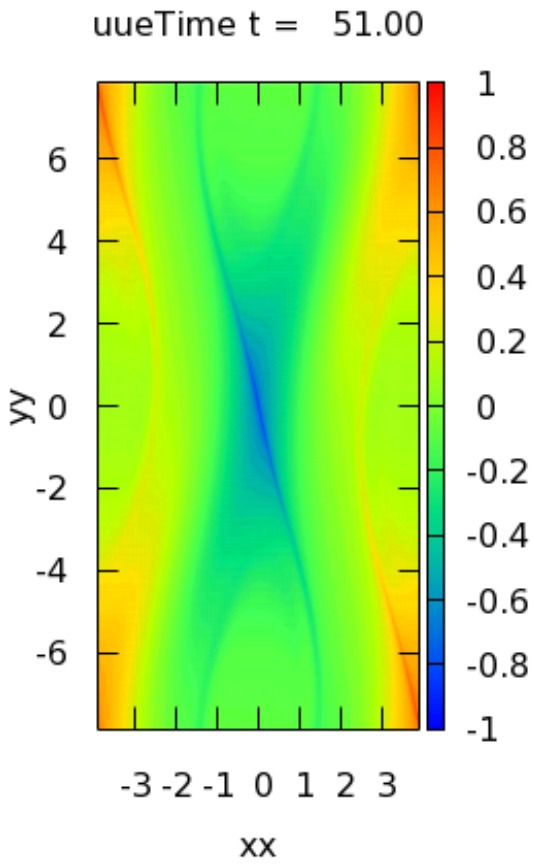
Electron beam instability in collisionless magnetic reconnection with a strong guide field

*Kazuya Shimomura[1], Tomo-Hiko Watanabe[1], Shinya Maeyama[1], Akihiro Ishizawa[2]



1. Nagoya Univertsity, 2. Kyoto University

Magnetic reconnection is a fundamental physics mechanism in magnetized plasma that causes a topological change of magnetic field lines and a conversion of magnetic energy to kinetic energy, leading to a self-organization of plasmas in laboratory and space. It is considered that the two-fluid effects or the kinetic effects facilitate the fast reconnection of magnetic field lines in colllisionless plasmas. Anomalous resistivity (AR) is one of the candidates that contributes to continuously drive the magnetic reconnection. A recent simulation study reports that AR induced by the Buneman instability accelerates the magnetic reconnection [1]. However, it is not clear how the instability causing the AR is spontaneously driven during the reconnection.
In our study so far, we have carried out numerical simulations of the collisionless magnetic reconnection by means of the gyrokinetic model of a slab plasma with a strong guide field [2][3]. During the reconnection, the parallel electric field is induced by the electron inertia at the X-point where electrons are acccelerated along the guide field. A liner analysis by use of the dispersion releation shows that the kinetic Alfvén waves (KAWs) are destabilized when the electron beam velocity exceeds the Alfvén speed, where, we assumed a plane wave in an uniform background profile. Furthermore, in this δf gyrokinetic model, the total distribution function F is approximately described as $F=FM+\delta f=(1+Uv)FM\tilde{}1/2pi\ exp(-(v-U)^2/2)$, where FM, δf and U are the Maxwellian, perturbed distribution function, and a beam velocity component, respectively. In order to analyze a stability of the KAWs in an inhomogeneous background profile during the collisionless magnetic reconnection, we must use the total distribution function rather than δf, since the KAWs are stable for $(1+Uv)FM$, according to the Nyquist criteria. Therefore, in this study, the magnetic reconnection process triggered by the electron inertia is simulated by use of a full-f gyrokinetic model of a slab plasma with the guide field. As a result, the shifted Maxwellian is formed at the X-point self-consistently by the parallel electric field. The attached figure shows distribution of the parallel electron beam on the reconnection plane in the nonlinear phase during the reconnection. It is possible to carry out the stability analysis in an inhomogeneous background by use of this simulation results. Results of the stability analysis will also be discussed at the meeting.

Particle acceleration with precursor wave driven wakefield in relativistic shocks

*Masanori Iwamoto[1], Takanobu Amano[1], Masahiro Hoshino[1], Yosuke Matsumoto[2]

1. Graduate School of Science,The University of Tokyo, 2. Graduate School of Science, Chiba University

The acceleration mechanism for generating ultra-high-energy cosmic rays (UHECRs) with energies above 10^{18}eV is one of the most important unsolved problems in astrophysics. Relativistic shocks in extragalactic astrophysical objects such as jets from active galactic nuclei (AGNs) and gamma-ray bursts (GRBs) are considered as efficient acceleration sites and commonly proposed sources for UHECRs. Observations of anisotropy in the arrival direction of the UHECRs favor the extragalactic origin.

In relativistic shocks, large-amplitude electromagnetic waves are excited by synchrotron maser instability (SMI) in the shock transition and propagate upstream (Hoshino & Arons 1991). The precursor wave emission via the SMI is widely studied by means of 1D particle-in-cell (PIC) simulations. Hoshino (2008) demonstrated that the pump electromagnetic wave decays into a Langmuir wave via parametric decay instability and found that nonthermal particles are generated in the manner analogous to wakefield acceleration (WFA) during the nonlinear process of the Langmuir wave collapse. The WFA is first proposed in laboratory plasmas (Tajima & Dawson 1979) and recently applied for UHECR acceleration (e.g., Chen et al. 2002). The WFA in the context of relativistic shocks is considered a promising candidate for UHECR acceleration.

It was believed that in multidimensional shocks, the intense wave emission via the SMI would cease soon due to inhomogeneity along the shock surface. Recently, however, our high-resolution 2D PIC simulations in pair plasmas showed that the wave emission continues (Iwamoto et al. 2017, 2018). Although our studies give positive results for the WFA in relativistic shocks, we could not directly demonstrate it because finite mass difference of two opposite charges is essential for exciting the wakefield.

In this presentation, by performing 2D PIC simulation of ion-electron shocks, we will demonstrate that the wakefield is indeed induced by the large-amplitude precursor wave. Especially for relatively high magnetization, the precursor wave amplitude is significantly amplified and exceeds that in pair plasmas due to a positive feedback process associated with ion-electron coupling through the wakefield. Nonthermal electrons and ions are generated during the nonlinear process of the wakefield collapse and the particle energy spectrum shows a power-law distribution. We will discuss the particle acceleration mechanism in details.

Stochastic Shock Drift Acceleration in the Shock Transition Region with Finite Pitch-Angle Anisotropy

*Takuma Katou[1], Takanobu Amano[1]

1. The University of Tokyo

The acceleration of non-thermal electrons is one of the important subjects in space physics. The shock accelerated non-thermal electrons have been observed at Earth's bow shocks (Gostling et al. 1989). These electrons are supra-thermal (with energies from 1keV to 100keV), and their distribution is power-law. However, acceleration models proposed in the past could not reproduce such observed spectra. Recent in-situ satellite observations of Earth's bow shock found wave-particle interactions between whistler waves and electrons at the shock transition region (Oka et.al. 2017). These results indicate that whistler waves play an important role for the acceleration of supra-thermal electrons.

We propose the stochastic shock drift acceleration (SSDA) model as a new acceleration mechanism for non-thermal electrons. It takes into account the effect of stochastic pitch-angle scatterings by whistler waves during the course of the Shock Drift Accelerations (SDA), which is a classical acceleration model for supra-thermal electrons at the shock transition region (Wu 1984, Leroy and Mangeney 1984). By introducing stochasticity with pitch-angle scatterings, the acceleration efficiency may be improved. We theoretically analyzed this acceleration model. We showed that the electron energy spectrum becomes a power-law consistent with observations in the limit of strong scatterings. We also found the maximum energy attainable through the proposed model, and it scales linearly with the pitch-angle scattering coefficient which represents the strength of scatterings. In our previous study, we have assumed the electron pitch-angle distribution is isotropic, and an effective shock speed $u/\cos\theta$ (u: shock speed, θ: shock normal angle) is non-relativistic. The SSDA model cannot consider an anisotropy of the electron pitch-angle distribution. It is well known that the shock with a relativistic effective shock speed has a finite pitch-angle anisotropy. Therefore it is difficult to compare the SSDA model with full particle-in-cell (PIC) simulations which can reproduce only the shock with a relativistic effective shock speed because of the limitation of parameters we can take. To fix this problem, we extend the SSDA model so that it can be applied to such a shock. In this presentation, we discuss the consistency between the extended SSDA model and PIC simulation results.

Near-fields and its Applications in Space Plasmas

*Tadas Nakamura[1]

1. Fukui Prefectural University

Solutions to Maxwell's equations consists of two parts: propagating components (electromagnetic waves) and the so-called near-field. Unfortunately, there seems to be considerable confusion on the latter, and the words "near-field" have different meanings depending on authors. For example, Coulomb interaction is often explained as the result of the interchange of virtual photons, however, the Coulomb field is not a photon but a near-field in the sense of this talk. Also, little attention is paid to the difference between propagating plasma waves and plasma near-fields in space physics.

The near-field in the present talk is understood as the off-shell solution to the inhomogeneous linear equations; the term "off-shell" means solutions that do not satisfy the dispersion relation. When the field source is static (Coulomb field or magnetic dipole, for example), it is easy to decompose the field into waves and off-shell near-fields. Here in this talk, the way to do this decomposition for time-dependent field source is explained. When we solve Maxwell's equations, usually we make use of Fourier-Laplace transform to obtain the dispersion relation. The time dependence of the fields is obtained by the inverse Laplace transform using the residue theorem; the wave components are obtained from the residue at the pole of the dispersion relation. One can obtain the near-field component by subtracting this residue contribution from the solution of the inhomogeneous equations.

The author reported the derivation of this result at the fall meeting of SGEPSS last year, and will report its application to space physics this time. The talk at the fall meeting was mainly about the electromagnetic fields in a vacuum; fields in plasmas will be discussed this time. The athematical structure of the fields in plasmas are essentially the same as that in a vaccum, however, currents and charges in plasmas cause a wide variety of phenomena in space. Phenomena such as current generation around small bodies in space plasma flows, the return currents genereted by energetic auroral electrons, and several others will be examined as examples.

Problems of Gravitational Waves and Origin of Gravitational Fields Raised by Studies on Binary Black Hole

*Hiroshi Oya[1]

1. Department of Geophysics Graduate School for Science Tohoku University

1.INTRODUCTION
As results of a study on the observations and analyses of the decameter radio wave pulses from the center of our Galaxy, it has been concluded that the super massive objects at the center of our Galaxy consist of two black holes which are forming a binary system rotating with common period of 2200sec; two black holes called Gaa and Gab, here, are associated with spin with rotation periods of 176.4±1.7 sec and 148.6±1.0 sec with orbiting velocities 18% and 21% of the light velocity, respectively. The radius of the orbits of Gaa and Gab are 0.13 AU and 0.15 AU ; applying Newtonian dynamics with assumption of coincidence of the orbital plane surfaces with the observing direction, it has been concluded that Gaa and Gab have masses of (2.27±0.06)x10∧6 SM and 1.94±0.03)x10∧6 SM with unit of solar mass (SM).
2.THE THEORETICAL INVESTIGATION OF THE GRAVITATIONAL WAVE PROPAGATION
Considering the all parameters deduced for the Gaa and Gab binary system, fast reduction of the radii of the orbits of the binary due to emissions of gravitational waves is inevitable in so far as we follow the traditional theory of the generation of the gravitational wave from the black hole. In the present studies, the propagation of wave general across the event horizon have been theoretically investigated using the spacetime of Minkowski which is realized in the frame that is making free fall in the black hole space time. The results has indicated, both for Shwarzschild and Kerr black holes, that the waves are ceased to propagate at the event horizon. Then we concluded that black hole is not able to be origin of the gravitational wave.
3.DISCUSSION AND CONCLUSION
For the LIGO results that reported observations of the gravitational wave from the stellar mass black hole mergers, an alternative interpretation of the possible origin of the merger is the merger of the compact stars which have no event horizon. By the result of our study, the existence of the graviton which is currently assumed as origin of gravitational force meets problem because the graviton is also a wave in the regime of the quantum mechanics. We suggest the necessity of new concept otherwise than graviton hypothesis for origin of the gravitational fields.

Toward the Reduction of Radiative Forcing of Methane and Tropospheric Ozone: Aiming at the Emission Control of CH_4, $NO_x$and NMVOC in Asia

*Hajime Akimoto[1], Tatsuya NNagashima[1], Hiroshi Tanimoto[1], Zig Klimont[2], Markus Amann[2]

1. National Institute for Environmental Studies, 2. International Institute for Applied Systems Analysis

In order to reduce impacts of climate change, including potential further increase of damages due to extreme events related to global warming, reduction of burdens of $CH_4$and tropospheric ozone in Asia are discussed. In order to mitigate the inevitable further increase of radiative forcing (RF) of ca. 0.8 W $m^{-2}$by 2040 caused by the increase of CO_2in 2040, feasible reduction of the industrial RF of methane (CH_4) and tropospheric ozone (trop-O_3) to the 50% of the values in 2011 are targeted to compensate 50% of the RF increase of CO_2. The remaining RF of $CH_4$and trop-O_3(0.26 and 0.22 W m^{-2}, respectively) correspond to the historical levels in 1960-1970. The necessary reductions of anthropogenic emissions of CH_4, $NO_x$and NMVOC in Asia in 2040 to the level of 1970 from that of 2010 have been estimated to be 35% CH_4, 44% NO_2, and 22% NMVOC from those of 2010 assuming the same necessary reduction ratio as for the global emissions. The estimated reductions have been compared with the reduction amount proposed in the Solution Report prepared under UN Environment Asia Pacific Office in 2018. The presumed reduction of the Asian emissions by 2030 through introducing of proven control measures are 27, 57 and 55% for CH_4 , $NO_x$and NMVOC. Thus, the reduction of RF of more than 50% from the reference year of 2010 is feasible for trop-O_3if the emissions of $NO_x$and NMVOC from other part of the world could be reduced coherently. Further efforts would be necessary for the reduction RF of $CH_4$by more than 50% of the present value.

Determination of atmospheric NO_2 column densities using a Pandora instrument measuring direct-sun spectra at Yokosuka, Japan: Improved validation of TROPOMI satellite observations

*Yugo Kanaya[1], Hisahiro Takashima[2,1], Masato I. Nodzu[3], Takashi Sekiya[7], Kazuyuki Miyazaki[1], Henk Eskes[4], Gaia Pinardi[5], Daniel Santana Diaz[6], Moritz Müller[6], Alexander Cede[6]

1. Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Fukuoka University, 3. Tokyo Metropolitan University, 4. KNMI, 5. BIRA-IASB, 6. LuftBlick, 7. Japan Agency for Marine-Earth Science and Technology (JAMSTEC)

Satellite observations of NO_2, a key atmospheric pollutant, have provided critical information on global distribution of NO_x sources and their temporal changes since 1995, and advanced understanding of atmospheric chemistry. A recent remarkable improvement is with their spatial resolution, reaching 7×3.5 km for TROPOMI (Sentinel-5P), launched in 2017. However, there is still a fundamental issue of low bias in the determined tropospheric NO_2 column densities (e.g., 25-50% for TROPOMI), when evaluated against ground-based spectroscopic observations. Potential causes would be (1) a-priori vertical profile shapes, (2) co-present aerosols and/or surface albedo, and (3) spatial inhomogeneity of NO_2, while (4) uncertainty in the ground-based observations could also be important. At Yokosuka (32.32˚N, 139.65˚E), located on the south edge of Tokyo-Yokohama metropolitan area, we newly started direct-sun Pandora spectrometer observations in November 2018 and strengthened validation capability, where the scattered-sun MAX-DOAS observations (from a JAMSTEC original instrument) had been solely referenced before. Results during winter 2018/2019 showed TROPOMI (within 0.1˚ from Yokosuka) had ~40% low bias against MAX-DOAS. The magnitude of difference was similar to the results from longer comparison during Feb-Sep 2018 for TROPOMI and earlier comparisons for OMI (QA4ECV). Pandora (in direct-sun mode) gave values ~24 % less than MAX-DOAS; the cause of difference was likely spatial inhomogeneity, as pollution levels were higher in the northeast for the sight of MAX-DOAS than in south for Pandora. This was consistent with the fact that TROPOMI gave ~18% higher values, when the averaging area was shifted to northeast by 10 km. As such, the importance of factors (3) and (4) was newly evaluated. By considering MAX-DOAS profile shapes in the recalculation of satellite products, we will discuss on factor (1), and the possibility to derive near-surface NO_2 concentrations from satellite observations.

A high-resolution global data assimilation for air pollution analysis on megacity scale using multi-sensor satellite measurements including TROPOMI NO_2 data

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Henk Eskes[3], Folkert Boersma[3], Koji Ogochi[1], Kengo Sudo[4,1], Masayuki Takigawa[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Jet Propulsion Laboratory/California Institute for Technology, 3. Royal Netherlands Meteorological Institute (KNMI), 4. Graduate School of Environmental Studies, Nagoya University

Intensive human activities lead to high emissions of air pollutants at megacities, causing severe damages to human health. The number of megacities is expected to rise in developing regions in the near future. Thus, it is important to provide information on air pollutants and their emissions on a megacity scale for the globe in a consistent way. In this study, we present the results from global chemical data assimilation of multi-species satellite observations with a resolution of 0.56 degree using an ensemble Kalman filter approach (Miyazaki et al., 2015) and high-resolution global chemical transport model, CHASER (Sekiya et al., 2018). Assimilated data were obtained from the OMI, GOME-2, and SCIAMACHY for tropospheric NO_2 column, the TES for O_3 profile, the MOPITT for total CO column, the MLS for O_3 and HNO_3 profiles, and the OMI for total SO_2 column. Data assimilation at 0.56-degree resolution largely improved agreements with the observed surface NO_2 pollutions on megacity scale, with reductions of the root mean square errors (RMSEs) relative to in-situ measuring networks (AirBase, AQS, Hong Kong EPD, and NIES) by 33% for Europe, by 67% for the U.S., and by 75% for East Asia, compared to the model simulations without data assimilation. With increasing horizontal resolution from 2.8 to 0.56 degree, the global total NO_xemission estimates became lower by 10% mainly because of the effects of non-linear O_3-HO_x-NO_x chemistry, while resolving higher NOx emissions by a factor of 4-5 in most of the megacities than their surrounding areas. Using the high-resolution data assimilation system and applying advanced super-observation approach, we demonstrated that assimilation of tropospheric NO_2 retrievals from TROPOMI improved agreements of tropospheric NO_2 column with the assimilated TROPOMI data itself by 62% and with OMI by 40% (not used for data assimilation) compared to model simulation at 1.1-degree resolution for April 2018. These improvements primarily resulted from substantial emission reductions over the U.S., China and India and increases over rural regions relative to the a priori emissions (HTAP_v2.2+GFED4 +GEIA). These results demonstrated the potentials of the high-resolution global data assimilation with the combined use of advanced satellite observations to provide valuable information on spatial and temporal variations of air pollution on a megacity scale globally.

Recent trends of NO_2, VOC, and tropospheric ozone concentrations observed around Chiba, Japan in 2013-2018

*Daichi Yonekawa[1], Hitoshi Irie[2]

1. Chiba university Graduate school, 2. Chiba university

Tropospheric ozone (O_3) is not only a major photochemical oxidant but also the third important greenhouse gas. In recent years its importance is widely recognized as a short-lived climate pollutant (SLCP). As nitrogen dioxide (NO_2) and volatile organic compounds (VOC) are both important precursors of O_3, they play a central role in photochemical chemistry in the atmosphere. In addition, they have negative direct effects on human health. However, recent trends of O_3, NO_2, and VOC have not been fully understood yet even in Japan.
Using the multi-axis differential optical absorption spectroscopy (MAX-DOAS), we conducted continuous observations of NO_2, formaldehyde (HCHO; as a substitute for VOC) and O_3 concentrations for altitudes of 0-1 km at the SKYNET Chiba site (35.63ºN, 140.10ºE, 21 m asl) for 6 years from 2013 to 2018. Analysis of the data showed that NO_2 and HCHO concentrations decreased by about 30%, but a systematic decrease in O_3 concentration was not observed. Similar trends were seen in tropospheric NO_2 column data obtained by the Ozone Monitoring Instrument (OMI) onboard the Aura satellite of the National Aeronautics and Space Administration (NASA), and concentration data of NO_2, non-methane hydrocarbon (NMHC; as a substitute for VOC), and photochemical oxidant (Ox; as a substitute for O_3) observed by the atmospheric environmental regional observation system (AEROS) called Soramamekun. These results are consistent with previous reports. In this presentation, the observed trends and their causes will also be discussed by utilizing our unique MAX-DOAS system that was directed to 4 different azimuth directions (north, east, west, and south), while traffic is heavy at the north, a residential area is located at the east, there is a sea at the west, and a factory area is located at the south around the SKYNET Chiba site.

Long-term seasonal changes in tropospheric ozone over Japan

*Natsumi Kawano[1], Tatsuya Nagashima[1], Seiji Sugata[1]

1. National Institute for Environmental Studies

Tropospheric O_3 is the primary source of OH radicals in the troposphere that contribute to the oxidation capacity of the atmosphere. According to the seasonal cycles of surface O_3, different behaviors at the remote and metropolitan areas in northern midlatitude have been pointed out (Parrish et al., 2013; Cooper et al., 2014; McGlynn et al., 2018; Jung et al., 2018). For example, European, American and Asian continental remote sites indicated that the seasonal cycle in the present decade had earlier annual maximum peaks than the maximum in the past decades. On the other hand, delayed maximum peaks appeared in urban locations. In spite of lots of monitoring stations, research for changes in seasonal O_3 cycles in Japan is still unclear. In this study, we investigate the seasonal cycle changes by using long-term continuous O_3 monitoring data at 265 ambient sites.
First, to clarify the annual O_3 maximum, sine function fitting examined by Parrish et al. (2013) was applied to monitoring data between the 1980s and 2010s. Regarding the spatial distribution of seasonal shifting between the 1980s and 2010s, most monitoring sites showed changes in a delayed shift. In particular, the stations with more than 0.2 days/decade delay belong to eastern and southwestern parts of Japan. Next, sine function was fitted to 5-years moving average over the entire data record to acquire the long-term trends of seasonal maximum in each region. All monitoring station were classified based on the 35-years averaged NOx concentration: urban, suburban and rural (Kurokawa et al., 2009). Results in all classifications showed delayed trends over analysis periods. In rural sites, O_3 mixing ratio reached the annual maximum in 5-days earlier than urban and suburban sites. In future work, we will conduct long-term air quality simulation and investigate the mechanism of seasonal cycle delaying.

Characteristics of Atmospheric Photochemical Pollution at a Comprehensive Site in Guangzhou, China

*Yu Zou[1]

1. Institute of Tropical and Marine Meteorology, CMA,Guangzhou,China

Guangzhou, one of China’ s megacities, is beset with frequent occurrence of atmospheric photochemistry events. In this study, online instruments were used to simultaneously monitor NMHCs, NO*x* and O_3 at Guangzhou Panyu Atmospheric Composition Station (GPACS) of the China Meteorological Administration (CMA), from June 2011 to May 2012, in order to obtain their characteristics, NMHCs reactivity and the control strategies for atmospheric photochemistry. The results showed that during the observation period, the seasonal variation of O_3 mixing ratio was lower in spring and winter compared to summer and autumn, which was opposite that for NMHCs and NO*x*. O_3 mixing ratio began to show a net increase at 8:00LT, likely due to the breakup of the nocturnal boundary layer and increased photochemistry, while a net decrease in O_3 mixing ratio occurred at about 15:00LT, due to the fact that sunlight and its associated photochemistry begin to decrease, leading to low OH radicals and the titration of O_3 by emissions of NO*x*. In terms of NMHCs, aromatics had the largest O_3 formation potential, among which toluene, xylenes, ethylbenzene, 1,2,4-trimethylbenzene and 1,3,5-trimethybenzene were the most important species, with a total contribution of about 44%. Weekday/weekend O_3 differences in the morning and at midday largely depend on how much the O_3 precursors are affected by the different intensity of anthropogenic activities. Although the increase of biogenic NMHCs emissions at midday reverses the sensitivity of O_3 production from NMHCs-sensitive to NO*x*-sensitive, high-reactive NMHCs and NO*x* control can be effective for reducing peak O_3 mixing ratios in Guangzhou. Further investigation based on numerical models is required to reach more robust conclusions.

Thu. May 30, 2019 10:45 AM - 12:15 PM JST | Thu. May 30, 2019 1:45 AM - 3:15 AM UTC | 102 1F

[A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Fumikazu Taketani(海洋研究開発機構), Michihiro Mochida(名古屋大学)

This session provides a forum for the presentation of the broad spectrum of tropospheric and stratospheric chemistry, including various research topics (e.g., dynamical processes, air quality and climate), approaches (modeling, field measurements, remote sensing, and laboratory studies), and species (gas and aerosol). This session also provides an opportunity for discussing possible future collaboration with other research fields relevant to atmospheric chemistry. We strongly encourage authors to prepare presentation slides and a poster in English.

LC/MS analysis of molecular markers present in biogenic secondary organic aerosols collected during year-round observations at a cool-temperature forest

*Kei Sato[1], Sathiyamurthi Ramasamy[1], Satoshi Inomata[1], Yuzo Miyazaki[2]

1. National Institute for Environmental Studies, 2. Hokkaido University

To understand formation processes for organic nitrogen and dimeric compounds present in forest aerosols, we analyzed molecular markers present in forest aerosols collected during year-round observations using negative/mode electrospray ionization-liquid chromatography-mass spectrometry (ESI-LC/MS). Thirty-seven aerosol filter samples were collected at Tomakomai Experimental Forest between January and December in 2013, and 33 of the collected samples were analyzed in this study. Molecular markers analyzed in this study were cis-pinic acid, 3-methyl-1,2,3-butanetricarboxylic acid (3-MBTCA), α-pinene-derived dimer detected by ESI at m/z 357 (α-pinene dimer), isoprene-derived olganosulfate detected at m/z 215 (isoprene OS), and isoprene-derived nitrooxyorganosulfate detected at m/z 260 (isoprene NOS). Each aerosol filter sample was extracted in methanol; the extract was concentrated under gentle stream of nitrogen; the concentrated extract was dissolved in an analytical solvent to obtain an analytical sample; and the analytical sample was analyzed by an LC/MS instrument (Sato et al., 2007). The seasonal change in the concentration of cis-pinic acid, formed from α-pinene oxidation, was peaked in spring and fall, whereas the seasonal change in the concentration of 3-MBTCA, formed from oxidation of pinonic acid, was peaked in summer. Very similar results were reported in a previous paper on the GC/MS analysis of the same samples (Müller et al., 2017). The seasonal change in the concentration of α-pinene dimer was similar to that of cis-pinic acid, suggesting that a major formation process of the detected dimers was the atmospheric oxidation of α-pinene. The seasonal changes in the concentrations of isoprene OS and isoprene NOS, which are derived from isoprene epoxydiol (IEPOX), were peaked at fall and summer, respectively. The seasonal change in the concentration of isoprene NOS agreed well with that of 2-methyltetrols, molecular markers of isoprene secondary organic aerosol. These results suggest that a major formation process of isoprene NOS is secondary organic aerosol formation from isoprene in the presence of air pollutants.

Surfactant Effects on Acid-Catalyzed Reactions at Aqueous Aerosol Surfaces

*Shinnosuke Ishizuka[1], Tetsuya Hama[2], Shinichi Enami[1]

1. National Institute for Environmental Studies, 2. Institute for Low Temperature Science, Hokkaido University

The outermost layer of atmospheric aqueous aerosol is covered with amphiphilic organic compounds. Volatile organic compounds (VOCs) in the gas phase should encounter them first at the air/aerosol interface, rather than solute molecules homgeneously distributed in the bulk. It may control the whole reactivity of the aqueous aerosol and play key roles in birth, growth and degradation processes of atmospheric aerosols. Here we studied activities of quaternary alkyl trimethyl ammonium cations $CH_3(CH_2)_{n-1}(CH_3)_3N^+$ (n = 1, 4, 8, 10, 12, 14) at the surfaces of water using surface-sensitive spraying ionization mass spectrometry. The longer-chain alkyl ammonium cations are detected more prominently at the water surface of the equimolar solution, expressed as an exponential function of the alkyl chain length. We suggest the occurrence of competitive adsorption among the quaternary ammonium cations at water surface. Then, the surfactant effects on the gaseous uptake and subsequent reactions of VOCs was investigated. When isoprene is exposed to acidified water surfaces, proton transfer reaction from H_3O^+ to isoprene occurs, which is followed by chain-propagation reactions. We found that the longer-chain ammonium cations suppressed isoprene oligomer signals but rarely hindered chain-propagation reactions even at larger concentrations, e.g., the higher surface coverage. It suggests that gaseous isoprene is directly added to the protonated species at water surface. We conclude that competitive adsorption between isoprene oligomers and the ammonium cations suppressed the acid-catalyzed reactions. Driving force leading to the adsorptive competition will be argued based on experiments performed by adding anionic and neutral surfactants.

Roles of heterogeneous reactions in the tropospheric chemistry: a global modeling study

*Phuc Thi Minh Ha[1], Fumikazu Taketani[2], Yugo Kanaya[2], Kengo Sudo[1,2]

1. Graduate School of Environmental Studies, Nagoya University, 2. Research and Development Center for Global Change, JAMSTEC

Heterogeneous reactions in the atmosphere largely affect air quality and climate by changing tropospheric photochemical processes involving gases like O_3, HO_x, NO_x, HNO_3, CO, VOCs, and aerosols. There are many previous studies on the effects of heterogeneous reactions at regional to global scales using direct measurements, remote sensing, and simulation. For the atmospheric chemistry simulation, there is a large uncertainty from the treatment of the heterogeneous reactions in the model due to the still insufficient understanding of the mechanism of heterogeneous reactions.
This study is intended to understand the roles of the heterogeneous reactions in the global tropospheric chemistry using a chemistry-climate model CHASER (MIROCESM) (Sudo et al., 2011) which includes more than 250 chemical reactions in the troposphere and stratosphere with more than 70 chemical species. This model also includes aerosol components (SPRINTARS) for sulfate, nitrate, BC, POA/SOA, dust, and sea-salt; formation of nitrate and SOA, and ageing of BC are calculated tightly linked to the chemistry in CHASER. The present version of CHASER considers heterogeneous reactions of N_2O_5, HO_2, RO_2, and HCHO for surfaces of the individual aerosol components and cloud particles.
The model simulation is validated with the observational data from EANET, EMEP and the ship-based observation. Our performed sensitivity simulations with respect to the heterogeneous reactions show that the impacts of the N_2O_5 heterogeneous reaction may not be as large as previously reported; surface concentrations of NO_x, O_3 and OH are only reduced by 1.6%, 2.2%, 2.6%, respectively, in global mean (in regional, at most, 23%, 5.4%, and 12.8%). Whereas, the HO_2 reaction (to form H_2O_2) can cause a significant effect on distributions of O_3 and related species (NO_x, O_3, OH are changed by 68.7%, -21.5% and -70.1%). In addition to the polluted areas in China and India, we found that in the North Pacific region the heterogeneous reactions can play a critical role in the concentrations of NO_x, O_3, CO, OH, HO_2 (up to 69%, 21%, 7%, 70%, 81%, respectively). The possible large impacts of the heterogeneous reactions are also verified with the ship-based observational data for the North Pacific and Alaska regions.

Sensitivity of regional deposition of inhaled atmospheric aerosols in human respiratory tract to their size distribution and hygroscopicity: A case study

*Minrui Wang[1], Toshiyuki Mihara[2,4], Mizuo Kajino[5], Kaori Kawana[2,6], Michihiro Mochida[1,2,3]

1. Institute for Space Earth Environmental Research, 2. Graduate School of Environmental Studies, Nagoya University, 3. Institute for Advanced Research, Nagoya University, 4. Now at Gifu Prefectural Industrial Research Institute, 5. Meteorological Research Institute, Japan Meteorological Agency, 6. Now at Research and Development Center for Global Change, JAMASTEC

Aerosols, which inhaled to human respiratory tract, can cause various diseases that threaten one's health. In order to estimate aerosol's health risk, it is significant to elucidate the sensitivity of regional deposition of inhaled aerosols.

In this study, by applying size distribution and hygroscopic growth factor data of aerosol (measured by a scanning mobility particle sizer in September 2009 and July-August 2010) to an MPPD (Multiple-Path Particle Dosimetry) model, we calculated the regional deposition differentiated by size diameter/hygroscopicity for a resting/light exercising adult male. As a result, regional deposition ratio in intrathoracic region (both tracheobronchial airway and alveolar interstitium) showed a bimodal distribution among particle size diameter ranging between 24.1~359.0 nm, in which the maximum value was 50.1%/50.0% at 24.1 nm (during light exercise). In general, there was a decreasing trend in deposition ratio when particle size diameter increased. For mode particles (dry diameter $d_{p,dry} < 100$ nm), the regional deposition of particles that have low hygroscopicity parameter (κ) tent to be larger than those with higher κ. However, for larger particles (especially when $d_{p,dry} > 200$ nm), this trend became reversed.

In 2009 the measurement was continuous for 10 days, while daily variation was found in aerosol number-size distribution and regional deposition. Therefore, we analyzed the meteorological data of the measurement period in 2009, comparing daytime (12:00-18:00 LST) and nighttime (00:00-06:00 LST) in order to indicate meteorological matters that affect the temporal variation of regional deposition. The result showed that the relative humidity (RH) during daytime was basically lower than 50% except September 15 and September 22~23 due to continuous rain, and the distribution of regional deposition was maximum for relatively hydrophobic mode particles ($d_{p,dry} < 100$ nm, hygroscopic growth factor g ranges between 1.0~1.2). On the other hand, RH during nighttime was mostly higher than 60%, and a bimodal distribution of both hydrophobic and hydrophilic (g ranges between 1.2~1.4) particles was found. Meanwhile, on September 23 RH was high (over 75%) during whole day, we found a monomodal distribution of regional deposition with a maximum value for hydrophilic particles that last about 6 hours in the afternoon.

According to our results we suggested that along with the temporal variation of artificial emission, changes in ambient humidity could also influence the composition of inhaled aerosol particles to a great extent, and therefore affected the regional deposition.

Biogeochemical cycle between atmosphere and ocean via particulate matters
-Award lecture for JpSAC Young Scientist Award-

*Yoko Iwamoto[1]

1. Graduate School of Biosphere Science, Hiroshima University

The oceans absorbs carbon dioxide which is increasing in the atmosphere and has the ability to mitigate sudden climate change. The biological pump driven by marine phytoplankton play an important role in the global carbon cycle. In order to accurately estimate the carbon absorptive capacity of the oceans, it is important to know the supply amount of nutrient elements that support the growth of phytoplankton. Despite the fact that iron is an essential element for marine phytoplankton, the concentration of dissolved iron in the surface ocean is extremely low. Iron containing aerosols such as mineral dust in the atmosphere could be important as a source of iron to the surface ocean.

In my previous work, the sporadic deposition of atmospheric mineral dust by sea fog over the North Pacific was observed during an Asian dust event. By using bulk and individual particle analyses for suspended particulate matters in seawater, the biogeochemical impact of the dust deposition was investigated. As a result, it was found that the bioavailable iron supply to the surface ocean by an Asian dust event was sufficient to promote the growth of phytoplankton, and it also contribute the carbon absorption to the northern North Pacific. In addition, from a mapping data covering the North Pacific and its marginal seas, it was revealed that mineral particles of atmospheric origin existed ubiquitously in the surface ocean even during summer when the influence of Asian dust event is small.

On the other hand, the growth of marine phytoplankton causes changes in the atmospheric environment through aerosol generation. My current research focuses on oceanic aerosols acting as cloud condensation nuclei. From the continuous observation conducted at Noto ground-based research observatory (NOTOGRO) facing the Sea of Japan, it was found that the growth rate of cloud droplets delayed when the organic mass fraction of the aerosol was high. Currently, researches on the linkage between phytoplankton species and marine biogenic aerosol and the climate effect of aerosol generated by bubble bursting at the air-sea interface are conducted.

Kinetic Studies for Quantitative Elucidation of Heterogeneous Halogen Chemistry in the Troposphere
-JpSAC Early Career Scientist Award Lecure-

*Yosuke Sakamoto[1,2]

1. Graduate School of Global Environmental Studies, Kyoto University , 2. Graduate School of Human and Environmental Studies, Kyoto University

Ozone is one of the most important species in the troposphere since it has health and environmental effects, and relates to atmospheric oxidation capacity and climate change. Halogen species are deeply involved in the tropospheric ozone chemistry by forming catalytic reaction cycles. Observations, model simulations and laboratory experiments have suggested that heterogeneous reactions of gaseous oxidants such as ozone and OH radical with halide ions in sea water/ice and sea salt aerosol are important halogen emission sources. However, quantitatively we still have not had conclusions of their importance in many cases due to experimental difficulties to determine kinetic parameters for the heterogeneous reactions. To obtain quantitative kinetic parameters of gas-liquid heterogeneous oxidation reactions of halide ions which are difficult for conventional methods, this study has developed original approaches using laser spectroscopy or mass spectrometry, and applied them to kinetic studies. This presentation includes results of three reaction systems: 1. gaseous ozone with iodide solution (Sakamoto et al. 2009, 2013), 2. gaseous ozone with bromide solution (Sakamoto et al. 2018a), 3. gaseous OH radical with chloride containing deliquesced aerosol (Sakamoto et al. 2018b), and also discussion on contribution of interfacial process to total reaction rate.

Thu. May 30, 2019 3:30 PM - 5:00 PM JST | Thu. May 30, 2019 6:30 AM - 8:00 AM UTC | 103 1F

[A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Hideaki Nakajima(国立環境研究所)

This session provides a forum for the presentation of the broad spectrum of tropospheric and stratospheric chemistry, including various research topics (e.g., dynamical processes, air quality and climate), approaches (modeling, field measurements, remote sensing, and laboratory studies), and species (gas and aerosol). This session also provides an opportunity for discussing possible future collaboration with other research fields relevant to atmospheric chemistry. We strongly encourage authors to prepare presentation slides and a poster in English.

Planetary atmosphere - Mars and Venus -

*Hiroyuki Maezawa[1]

1. Department of Physical Science Osaka Prefecture University

Recently, research on extraterrestrial planets and protoplanetary disks has been rapidly increasing. Mars and Venus, lacking intrinsic magnetic fields, are valuable research targets for further understanding atmospheric environments, habitability of earth-type planets, and the influence of activity of the central star on planetary atmospheres.

On Mars, methane has been detected and research continues to investigate its originand destruction processes by oxidation reaction networks in the atmosphere and on the surface. For an Earth-type planet with an atmosphere mainly of CO_2, the CO_2 is photo-dissociated into CO and oxygen by UV radiation from the sun. Mars and Venus have small percentages of CO and oxygen, and how they are oxidized back into CO_2 has not yet been fully elucidated. This is known as the “CO_2 stability problem”. Also, in order to understand the evolutionary processes of the Martian atmosphere, detailed and systematic observations of the spatial and temporal fluctuations of H_2O and oxidants, including H_2O_2, O_3, O_2, etc., and their altitudinal distributions are important.

Venus experiences high-speed super-rotation winds at approximately the cloud altitude and day to night circulation at higher altitudes. Recently, for example, it has gradually become clear that the latter convection does not show a similar pattern in the morning and afternoon. In addition, the Akatsuki satellite (JAXA) has captured large-scale, bow-shaped patterns induced by atmospheric gravity waves. It is also important to investigate how the complex dynamics seen in the Venusian atmosphere drive material circulations and oxidation reaction networks including those with respect to minor species such as SO_x, HO_x, CO_x, chloride, aerosol, sulfuric acid, etc. Venus and Mars also provide important insights into how abiotically the biomarkers, O_2 and O_3, are formed in typical terrestrial planets with mainly CO_2 atmospheres.

In this talk, the observations of planetary atmospheres, explored via heterodyne spectroscopy with radio telescopes such as the Atacama Large Millimeter/submillimeter-wave Array (ALMA) interferometer, as well as measurements of various wavelengths with ground-based telescopes and satellites will be also discussed. Since the wavelengths of milli/submillimeter waves are comparatively long, they are less attenuated by absorption and scattering by aerosols/dust. In addition, the Doppler shift of the spectrum obtained with heterodyne spectroscopy provides important information about the velocity fields of the mesosphere and lower thermosphere. Also, regardless of the presence or absence of background light sources such as the sun heterodyne spectroscopy allows us to observe day and night-side atmospheres of planets.

CH_4 is the second greenhouse gas and the concentration near the surface is increasing. But there are many emission sources and the increasing rate is varying year by year. The profile of CH_4 can be observed with a ground-based high-resolution Fourier transform spectrometer using spectral inversion analysis. However, the validation of the retrieved profile doesn't have been performed enough. Then, we compared some retrieval parameters and validated the retrieved tropospheric partial columns using aircraft sampling measurements.
We analyzed the spectra taken at Tsukuba between 2012 and 2017. SFIT4 spectral fitting program was used to derive the profiles from spectra in 3 micrometer region. H_2O as interference species affects the accuracy of the retrieved CH_4 profiles. Two initial profiles of H_2O are provided: monthly mean (v1) and daily analyzed (v5). Two kinds of microwindows for the retrieval are also provided according to Sussmann et al. (2011): 5 microwindows (5MW) and 3 microwindows (3MW). Fitting results were compared based on the root mean square residual (RMS) and degree of freedoms (DOFs). As a result, 5MWv1 is worse for both RNS and DOFs than other 3. Then, we compared the results of 5MWv5, 3MWv1, and 3MWv5 with aircraft sampling.
The monthly mean tropospheric partial columns integrated from 0 to 8 km were compared with those calculated from aircraft sampling observed by the center for atmospheric and oceanic studies, Tohoku University near Sendai from 2012 to 2017. When all derived partial columns were compared with aircraft results, all 3 cases (5MWv5, 3MWv1, and 3MWv5) showed 5 -10 % differences in summer when H_2O concentration is high. But when the derived partial columns for which RMS is less than 0.15 were compared, all 3 cases agreed with aircraft results within the uncertainty besides for the -2.9 % bias.

Retrieval of HFC-23 from FTIR observations at Syowa Station, Rikubetsu and Tsukuba

*Masanori Takeda[1,2], Hideaki Nakajima[2,1], Isao Murata[1], Tomoo Nagahama[3], Isamu Morino[2]

The Montreal Protocol on Substances that Deplete the Ozone Layer has successfully been regulated production and consumption of chlorofluorocarbons (CFCs) and global atmospheric CFCs concentration have kept decreasing. On the other hand, production and consumption of hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs) as alternatives for CFCs are expanding up to the present. Especially, HFC-23 (CHF_3) which has very high global warming potential (100yr-GWP: 12,400) is generated as unavoidable by-product of HCFC-22 ($CHClF_2$) production and their emissions into atmosphere have been increasing relevant to production of HCFC-22. Observations of these gases are possible not only by in-situ gas-chromatogram/mass-spectroscopy systems, but also by infrared spectroscopic measurements. Ground-based Fourier Transform Infrared spectrometer (FTIR) has a capability to monitor multiple gas species simultaneously. In this study, we retrieved total column abundances and vertical profiles of HFC-23 from ground-based FTIR observations with the SFIT4 version 0.9.4.4 based on the optimal estimate method (Rodgers, 2000).
We operated atmospheric solar absorption measurements using ground-based FTIR instrument at Antarctic Syowa Station (69.0ºS, 39.6ºE) in 2007, 2011 and 2016. We used two micro-windows (MWs) of 1138.5-1148.0 cm^{-1}(MW1) and 1154.0-1160.0 cm^{-1}(MW2) in this study. As the spectroscopic parameters of HFC-23, the pseudo line lists produced by G. C. Toon (NASA/JPL) were used. For other interfering species, the line parameters from HITRAN2008 were used. Temperature and pressure vertical information from surface to 40 km a.s.l. were taken by the daily temperature and pressure profiles from NCEP (National Centers for Environmental Prediction) Reanalysis-1 dataset. Meteorological information above 40 km a.s.l. were adopted from the monthly climatological profiles from the COSPAR International Reference Atmosphere (CIRA-86) dataset. The HFC-23 a priori profile was taken fromthe simulated profile by Naik et al. (2000), but that was scaled to make the concentration of the lowest level equal to 20 pptv which is the approximate value of surface concentration in southern hemisphere in 2007. For H_2O and its isotopologues, the a priori profiles were taken from independent preliminarily profile retrievals for each observed spectra. For other interfering species, 40 years (1980-2020) mean profiles of the monthly profiles provided from WACCM (Whole Atmosphere Community Climate Model) version 6 were used as a priori profiles. Figure 1 shows the timeseries of the FTIR-retrieved total columns of HFC-23. According to the error analysis, mean systematic and random errors on the HFC-23 retrievals were ~40% and ~10% to retrieved HFC-23 total column, respectively. The FTIR observation is practicable to estimate the trend of atmospheric HFC-23, because the random uncertainty is relatively small.
In addition, we performed retrievals of HFC-23 from FTIR spectra at Rikubetsu (43.46ºN, 143.77ºE) and Tsukuba (36.05ºN, 140.12ºE) in Japan in the same way as the retrieval strategy at Syowa Station. In the presentation, we will discuss on the differences of HFC-23 trends among these three FTIR sites, along with the trends of HCFC-22 from FTIR observations.

Roles of cloud distribution in global atmospheric photochemistry

*Ryoki Matsuda[1], Kengo Sudo[1,2]

1. Graduate School of Environmental Studies, Nagoya University , 2. Japan Marine-Earth Science and Technology

Chemical reactions in the atmosphere directly affect formation and loss of ozone, methane, nitrogen oxides, sulfur oxides and aerosols, and have a great influence on the atmospheric environment and climate change. Since these reactions are driven by photodissociation of ozone and related species caused by ultraviolet radiation, they can be largely modulated by distribution of clouds. This study quantitatively investigates the photolytic impacts of clouds on atmospheric chemistry by using a global chemical transport model (chemical climate model) and observational (satellite and aircraft) data.
First, verification with satellite data (ISCCP D2) shows that the model (CHASER) reproduced well the global distribution of cloud amount as in the satellite data.
Sensitivity experiments were also performed to estimate clouds impacts on the photolytic processes and global photochemical field in the atmosphere. As a result, it was shown that OH radical (OH) concentrations decrease by 10 to 20% near the surface and increase by 10 to 20% in the upper troposphere. The changes basically reflect scattering and reflection of solar UV radiation by low-middle clouds, which is consistent with the previous studies. The global mean OH concentration, proxy of the oxidizing capacity of the atmosphere, increased by about 12% due to clouds while the global mean tropospheric ozone (O_3) concentration increased by about 0.7%.
The above results for clouds impacts on the atmospheric chemical field calculated in the model were verified by using aircraft observation (NASA ATOM-1). The result shows that the observed OH and O_3 concentrations are reproduced more accurately when clouds are properly considered in the model.
These results indicate that clouds have significant influences on the global atmospheric chemistry (especially on the OH concentration field). Since OH determines the concentrations of chemical species such as methane, carbon monoxide (CO), fluorocarbons (CFCs), etc. which are important for climate and stratospheric ozone, this study suggests that the variation and trends in clouds can largely affect the chemical species, which may give an additional influence on climate and atmospheric environment.

Evaluating global distribution and interannual variation of stratosphere-troposphere exchange of ozone: impacts of climate variabilities

*Kengo Sudo[1,2], Xin Li[1]

1. Graduate School of Environmental Studies, Nagoya University, 2. Research and Development Center for Global Change, JAMSTEC

The stratosphere-troposphere exchange (STE) of ozone (O_3) can have significant impacts on the interannual variability and long-term trend of global tropospheric ozone and radiation budget. This study investigates global STE of O_3 particularly focusing on the roles of major climate variabilities such as ENSO, PDO, and QBO and climate trend (surface temperature). Using a chemistry coupled climate model, this study estimates temporal variation in the vertical and meridional STE O_3 fluxes during the years of 2000-2016. For the major climate variabilities of ENSO and PDO, associated STE changes are assessed in detail using a composite analysis. The model validation shows that the model well captures the OMI-observed tropospheric column ozone (TCO) abundances (r~0.55), especially around the tropical Pacific (r~0.8). It is shown that in the tropics there is upward O_3 transport to the stratosphere (troposphere to stratosphere transport, TST) while in the extratropics, O_3 transport is downward (stratosphere to troposphere transport, STT), consistent with the Brewer-Dobson circulation in the stratosphere. Although geographical distributions of vertical and meridional STE fluxes are not changed largely by ENSO or PDO, the STE fluxes are significantly amplified by the ENSO events. Horizontal patterns of STE flux anomaly are found to be similar with respect to the El Niño episodes and the PDO warm phases (STT increased by 21% and 10%, respectively, in the northwest Pacific). These anomalies are reversed during the La Niña and PDO cold phases (STT decreased by 16% and 3%, respectively, in northeast Pacific). The anomaly of global net STE O_3 flux is interpreted as several key factors using a multiple-regression analysis. The result shows that the STE anomaly is explained largely by the combination of ONI, PDO, QBO, and global mean surface temperature (R^2~43%). Contributions of ONI and PDO to STE anomaly are estimated to be 22.3% and 23.1%, respectively. This study quantitatively reveals the possible connection between climate condition and STE.

[A-CG36] Earth & Environmental Sciences and Artificial Intelligence

convener:Tomohiko Tomita(Faculty of Advanced Science and Technology, Kumamoto University), Ken-ichi Fukui(Osaka University), Daisuke Matsuoka(Japan Agency for Marine-Earth Science and Technology), Satoshi Ono(Kagoshima University), Chairperson:Tomohiko Tomita(Kumamoto University, Faculty of Advanced Science and Technology)

In recent years, we have been required to explore the gigantic environmental data leading global environmental studies of modern meteorology, oceanography, and hydrology to accomplish Society 5.0 and Sustainable Development Goals (SDGs). Such environmental data, which are typical "big data," include the reliable long-term observatory data, ground radar data, satellite observation, oceanographic observation, global objective analysis data, and so on. However, it is hard to say that such big data are fully utilized, or nobody may have examined many of them. Therefore, to examine the global environment more faithfully, we need to apply the techniques of artificial intelligence/machine learning on such big data, that is, spatiotemporal data modeling of artificial intelligence, prediction and detection by machine learning, techniques of automated data mining, and so forth. Only cross-cutting diagnosis of the gigantic environmental data could resolve a wide variety of environmental problems including measures against global warming. In addition, the application of artificial intelligence/machine learning on the big data would raise us to the 4th paradigm of science (the 1st paradigm, observation/experiment; 2nd, theory; 3rd, simulation; 4th, data driven). This session sincerely invites various research initiatives that accelerate the application of artificial intelligence/machine learning on such gigantic environmental data.

Discussion

Recent Progress in Deep Neural Network Architectures and their Applications

*Shinichi Shirakawa[1]

1. Yokohama National University

A deep neural network (DNN) is a powerful machine learning model that shows remarkable performance in various artificial intelligence domains such as computer vision and natural language processing. A DNN is composed of a number of non-linear, differentiable units that have tunable parameters. In the training phase, DNN parameters (called connection weights) are trained so as to minimize training loss. After training the DNN, we expect it to be able to produce the generalized rule for the target task, i.e., the trained DNN is expected to return the ideal outputs from inputs for unknown data.

Researchers in the deep learning community are actively proposing a novel DNN architecture (i.e., the network structure of DNNs) to improve the performance and applicability of DNNs. For instance, a convolutional neural network (CNN) is frequently used as the network model for computer vision tasks, and the recurrent connection and long short-term memory (LSTM) cell is suitable for treating time series and sequential data. Besides these network structures, many extended network modules and architectures have been developed.

In this talk, we provide an overview of the recent progress in deep neural network architectures and their amazing applications. We also overview how to handle multimodal data in DNNs and present several studies on modality translation such as image-to-text (image captioning) and text-to-speech.

Although a lot of DNN architectures have been proposed so far, the selection and design of the architectures are still the users' task. Such a task is not trivial because the appropriate architecture heavily depends on the target problem and dataset, meaning that trial and error and expert knowledge are required for users. The second topic of this talk is the automatic design of DNN architectures, called neural architecture search (NAS). Recent studies show that NAS can improve the performance of DNNs depending on the dataset. Particularly, we present the computationally efficient NAS methods that can work on a single GPU with reasonable computational time.

At the end of this talk, we would like to discuss the applicability of deep neural networks to the field of global environmental science.

Improving performance of oxidant prediction using machine learning by optimizing input data based on atmospheric science knowledge

*Tomohiro Sato[1], Peijiang Zhao[1], Koji Zettsu[1]

1. National Institute of Information and Communications Technology

[Background] Air pollution was the cause of 3.7 million premature deaths globally in 2012 (WHO, 2014). In Japan, the amount of oxidant (Ox) keeps high level or has been still increasing, although other air pollutants, such as NO_2 and $PM_{2.5}$. has been decreasing. High level of Ox affects human health and crop yields (e.g., Zheng et al., 2018). There are many factors for Ox generation, such as precursors especially NO_2 and VOC, sunlight and wind. They are non-linearly connected, thus, modeling of physical and chemical processes for Ox amount prediction is difficult and requires large calculation costs. There are many studies for Ox prediction using machine learning (ML) as an alternative of traditional modeling. Keller et al., (2017) showed that the random forest demonstrated the GEOS-Chem model calculation of ozone (O_3), major component of Ox, within an error less than 10% during the first 10 days with a 1/100 calculation cost. Other ML methods have been tested for O_3 prediction, Multi Linear Regression, Artificial Neural Network (Pires and Martins, 2011), Gene Expression Programming (Samadianfard et al., 2013).

[Aim] Previous studies of air pollution prediction by ML have well developed the model algorithm. Guennec et al., (2016) reported that improvement of input data, such as data augmentation, also increased the prediction performance. In this study, we approached to improve the Ox prediction using ML technique by optimizing the input data.

[Dataset and Method] Ox, especially O_3, is formed via photo-chemical reaction. The O_3 amount increases after the sunrise (e.g., $NO_2 + hn \rightarrow NO + O$, $O + O_2 + M \rightarrow O_3 + M$), takes a maximum during the day, and decreases during the night due to collision with surface and other species. This O_3 trend is observed throughout a year with a variation depending on whether, season and human activity. In this study, we compared the predicted results of Ox amount using two types of input data; in case 1, the Ox amount data itself (V_{obs}) and case 2, difference ($DeltaV = V_{obs} - V_{diurnal}$) from the reference diurnal variation ($V_{diurnal}$). We used data of amounts of major air pollutants (such as Ox, NO_2, SPM, $PM_{2.5}$, SO_2, CO), temperature, humidity, and wind at 16 points in Fukuoka city in 2014 to 2016 (Atmospheric Environmental Regional Observation System). The reference diurnal variation $V_{diurnal}$ was mean in each local hour and year. The ML model that we employed was a Convolutional Recurrent Neural Network (CRNN) based on a Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) (Zhao and Zettsu, 2018). The value of measurement at each point was translated into 2-D map based on the longitude and latitude in the CNN part and the spatial features was extracted. A short-term prediction was performed by the LSTM part. We used the data for the last 24 hours as an input. The output was mean value of Ox amount in all points after six hours.

[Results and Discussion] We demonstrated the Ox prediction using the CRNN model with two types of input data (V_{obs} for Case 1 and DeltaV for Case 2). Root mean squared error and accuracy for the two predictions were compared; Case 1: 10.3 ppb/75.4%, Case 2: 6.7ppb/84.7% (in 2014), Case 1: 11.0 ppb/72.7%, Case 2: 8.3ppb/79.6% (in 2015), Case 1: 9.4 ppb/76.7%, Case 2: 8.6ppb/79.4% (in 2016). Using DeltaV, the accuracy was increased at most 10%. We also compared the predictions in terms of time in a day. In case 1, the model overestimated the Ox amount during the night and underestimated during the day. This bias was significantly improved in case 2 for all years.

©2019. Japan Geoscience Union. All Right Reserved.

[Conclusion and remarks] We demonstrated an optimization of input data for Ox prediction using the CRNN model. Our approach showed the accuracy of the Ox prediction was improved at most 10% using a difference from the reference diurnal variation instead of using a raw data. This study indicates an importance to optimize input data based on atmospheric science knowledge for air pollution prediction by ML.

Spatiotemporal Climate Forecasting with ConvLSTM

*Ekasit Phermphoonphiphat[1], Tomohiko Tomita[3], Masayuki Numao[2], Ken-ichi Fukui[2]

1. Graduate School of Information Science and Technology, Osaka University, 2. The Institute of Scientific and Industrial Research, Osaka University, 3. Faculty of Advanced Science and Technology, Kumamoto University

Recent years, climate forecasting techniques with machine learning have been developing to get high accuracy result, unlike physical simulation that uses the techniques of ensemble mean and has already been employed by JMA (Japan Meteorological Agency) which cannot perform well for long term prediction because climate data is a very high non-linear relationship. Machine learning techniques can build a forecasting model by learning patterns from prior data while maintaining the spatial correlation that very important for climate data because the variable from one area could affect other areas. In this paper, we studied the spatial-temporal pattern of machine learning techniques can improve the forecasting result. The experiment compares 3 forecasting models. Linear regression model is a simple forecasting linear model that try to produce linear formula from the training dataset, we use this model with non-spatial correlation setup. CNN (Convolutional Neural Network) is a class of deep learning, the key idea is convolutional layer that is able to maintain spatial correlation through the network. ConvLSTM (Convolutional Long Short-Term Memory) is the improvement version of Fully Connected Long Short-Term Memory that combines convolution operator inside every gate (the control unit that measures how much information will pass through) in the memory cell; therefore, spatial correlation is preferably maintained on the arbitrary of times. We run the experiment to forecast temperature at 2 meter height of the Japan area, we used the monthly mean data of ERA-Interim dataset that started from 1979 to the present. The result has shown that ConvLSTM performs the best accuracy compares to CNN and non-spatial correlation setup linear regression model.

Deep-Learning Based Short-Term Prediction Method for Sea Ice Concentration Using Explanatory Variables

*Issei Kawashima[1], Toru Kouyama[1], Ryu Sugimoto[1], Ryosuke Nakamura[1]

1. National Institute of Advanced Industrial Science and Technology

Importance of short-term future and middle-term future prediction techniques of sea ice concentration (SIC) has been significantly increasing for navigation of vessels which uses the Northern Sea Route. High frequent updating of the short-term prediction for adopting to SIC is required and thus its calculation load is an important issue same as the accuracy of the prediction. We have been developing a deep-learning based sea ice prediction method and adopting it to Sea of Okhotsk where sea ice coverage dramatically changes during a season. The proposed method can predict SIC immediately once we have sufficient observation or simulation data and the calculation time is very short. In addition, we have confirmed that the predicted SIC has basically good correlation with actual SIC, even though this method only uses previous and current observed SIC by AMSR2. However, considering actual applications, such as navigation for vessels, it is necessary to improve the accuracy of the proposed method as much as possible.

In this study, we proposed a new short-term prediction method for temporal variation of SIC. The new method uses not only SIC but also other variables which can be obtained from observations and/or simulations. The new method can improve the prediction accuracy than that in the previous method.

[A-CG36] Earth & Environmental Sciences and Artificial Intelligence

convener:Tomohiko Tomita(Faculty of Advanced Science and Technology, Kumamoto University), Kenichi Fukui(Osaka University), Daisuke Matsuoka(Japan Agency for Marine-Earth Science and Technology), Satoshi Ono(Kagoshima University), Chairperson:Tomohiko Tomita(Kumamoto University, Faculty of Advanced Science and Technology)

In recent years, we have been required to explore the gigantic environmental data leading global environmental studies of modern meteorology, oceanography, and hydrology to accomplish Society 5.0 and Sustainable Development Goals (SDGs). Such environmental data, which are typical "big data," include the reliable long-term observatory data, ground radar data, satellite observation, oceanographic observation, global objective analysis data, and so on. However, it is hard to say that such big data are fully utilized, or nobody may have examined many of them. Therefore, to examine the global environment more faithfully, we need to apply the techniques of artificial intelligence/machine learning on such big data, that is, spatiotemporal data modeling of artificial intelligence, prediction and detection by machine learning, techniques of automated data mining, and so forth. Only cross-cutting diagnosis of the gigantic environmental data could resolve a wide variety of environmental problems including measures against global warming. In addition, the application of artificial intelligence/machine learning on the big data would raise us to the 4th paradigm of science (the 1st paradigm, observation/experiment; 2nd, theory; 3rd, simulation; 4th, data driven). This session sincerely invites various research initiatives that accelerate the application of artificial intelligence/machine learning on such gigantic environmental data.

Discussion

Remote sensing of cloud using the deep learning based on three-dimensional radiative transfer

*Hironobu Iwabuchi[1], Ryosuke Masuda[1], K. Sebastian Schmidt[2,3], Alessandro Damiani[4], Rei Kudo[5]

1. Graduate School of Science, Tohoku University, 2. Department of Atmospheric and Oceanic Sciences, University of Colorado, 3. Laboratory for Atmospheric and Space Physics, University of Colorado, 4. Center for Environmental Remote Sensing, Chiba University, 5. Meteorological Research Institute, Japan Meteorological Agency

Remote sensing is a field of active research to which the machine learning techniques are applied. Machine learning models can be trained to detect characteristics and estimate properties of spatial and temporal variations of geophysical features. The deep learning uses a deep neural network and is rapidly developing in wide areas of industrial applications and scientific research. The deep neural network generally offers high capabilities of automatic feature extraction from multi-variate, multi-modal data and a good approximation of non-linear functions. If a deep learning model is trained well, its advantages are high accuracy with reasonable speed of calculation, which is suitable for practical applications to processing a large amount of data.

We will present a few applications of the deep learning to remote sensing of cloud from satellite- and ground-based optical measurements. In optical remote sensing of clouds, three-dimensional (3-D) radiative transfer effects are a major source of retrieval errors. Radiative interactions operate across spatial elements of the cloudy atmosphere at a wide range of spatial scales. Radiance measured at each pixel of an image taken by a satellite-based imager or ground-based camera is influenced by not only cloud density and microphysical properties along the line of sight but also the spatial distribution of clouds in a wide domain surrounding the line of sight. Although the retrieval of cloud properties is usually based on the independent pixel approximation assuming a plane-parallel, homogeneous cloud for each image pixel, the 3-D radiative interaction makes it difficult to retrieve cloud properties at pixel level if one uses single-pixel radiances solely. Thus, use of multiple pixels looks attractive, offering a great potential to accurately retrieve cloud properties from an image. Convolutional neural networks (CNNs) naturally traces the 3-D radiative effects that appear across image pixels, which traditional single-pixel approaches cannot capture. We have thus developed deep learning models to estimate the spatial distribution of cloud properties from multi-spectral, multi-pixel cloud retrieval from satellite imagery and images taken by a ground-based digital camera. Training data of pseudo-observation radiances are made from simulations using a Monte Carlo 3-D radiative transfer model for cloud fields simulated by a large eddy simulation model with high spatial resolution. In this case, the deep learning model is trained to learn the multi-scale spatial structure of clouds in addition to the complicated relationships between cloud properties and radiances. Deep CNNs show high retrieval accuracy for cloud properties such as cloud optical thickness and effective droplet radius from multi-spectral images of visible, near-infrared, and shortwave infrared channels, efficiently deriving the spatial distribution of cloud properties at multiple pixels all at once from radiances at multiple pixels. By using multi-scale features in the images, it is possible to recover the information lost in 3-D radiative transfer. Results show significantly better accuracy compared with traditional approaches.

Time series of cloud cover during the night derived from an omnidirectional camera

*Karin miyabe[1], Kazunori Ogohara[1]

1. University of Shiga Prefecture

Surrounding atmospheric environment have a big influence on our lives. For example, fog causes various accidents due to poor isibility. Leisure facilities must be stopped when wind speed is high. Meteoropathy tends to increase depending on perature or weather. Therefore, environmental prediction with higher temporal and spatial resolution than that of daily ather forecast is needed. Cloud cover (CC) will have a large impact on prediction of environmental changes in other tities (e.g. temperature, humidity, wind speed and direction). The method for deriving CC from RGB images taken by an omnidirectional camera has been investigated so far. However, it was not applicable to nighttime images, which is usually grayscale images, due to low SN and low brightness. Therefore, we develop a method for deriving CC from grayscale images taken by an omnidirectional camera during the night using deep learning. Also, we investigate he distortion of the whole-sky images because CC measured in the celestial sphere has a different value from that measured in whole-sky images.We separate cloud areas from sky areas in the whole-sky images using a deep learning technique for semantic segmentation, U-net. U-net is a encoder-decoder type of convolutional neural network. Area under an ROC curve (AUC), which is an evaluation index commonly used in the discipline of machine learning, for nighttime images is 0.985 and that for rainy images during the night is 0.984. However, that for evening and morning images is lower than them, 0.952. Therefore, the proposed method may not be applicable to evening and morning images.

Time series prediction of cloud cover using whole-sky images and meteorological elements

*Kazunori Ogohara[1], Teppei Sonoda[2]

1. School of Engineering, University of Shiga Prefecture, 2. Graduate School of Engineering, University of Shiga Prefecture

Prediction of the sky conditions is becoming important in several sectors of society. The most typical codition of the sky is cloud cover (CC). CC should have a correlation to air temperature, ground temperature, humidity, and solar radiation, etc. Therefore, prediction of CC is highly significant from the perspective of social application and should have a large impact on accuracy of time-series prediction of other variables.
We have developed a novel method for segmentation of cloud areas in whole-sky images using an encoder-decoder based convolutional neural network to derive CC from images observed by an omnidirectional camera. F-measure for cloud obtained by 10-fold cross validatoin was 0.86. We could generate time series of daytime CC for 1.5 years using the proposed method.
We have tried to predict CC after one hour based on time series of CC itself and solar radiation using recurrent neural network. RMSE of CC between the observed and predicted time series is 0.022 and the predicted time series of CC is more accurate than the persistence model. However, predicted CC tends to get close to 0.4-0.5 and the phase shift like the persistence model is partially seen.

Fundamental investigation about the inductive prediction of precipitation based on the time series data

*Naoki Matsumoto[1], Tomohiko Tomita[1], Kenichi Fukui[2]

1. Kumamoto Univ., 2. Osaka Univ.

This work applied the artificial neural network (ANN) to observatory data and conducted a fundamental investigation about improving the prediction accuracy in precipitation. Especially, this work focused on the improvement of training data for the short-term prediction in precipitation.
The used data were precipitation, temperature, pressure, vapor pressure, wind speed, and wind direction with hourly interval edited by the Japan Meteorological Agency, and the ANN prediction model was constructed based on multilayer perceptron. Using these data and the ANN prediction model, this work tentatively predicted the time variation of hourly precipitation at Kumamoto, Japan. Then, through systematic changes of the training data, this work investigated how the accuracy of short-term predicton was improved. Especially, the contributions of each observation parameter and of increase of observatories were investigated. For the evaluation of prediction, this work emploied the verification by comparing the peak values between prediction and observation and the appearance time of the peak that are both important for heavy rainfall prediction, and the sum of squared errors between predicted and real values.
This work found that setting the data to the west into the training data is effective for predicting Kumamoto's hourly precipitation. This work also found that the peak value in prediction was greatly improved from 30% to 80% by deleting the data at the time when no precipitation occurs in the training data. Then, the contribution of vapor pressure increases. We will continue to investigate how the precipitation prediction can be improved through the changes of parameters, observatories, and forecast lead times in the training data.
The results of this work will contribute to the construction of a simple precipitation prediction scheme at the location where sophisticated observation data can not be obtained.

Identification of ships image on SAR data using machine learning

*Takashi Sonoke[1], Hirohide Demura[1]

1. University of Aizu

SAR(Synthetic Aperture Radar) has been popular in Earth remote sensing because this is available for all-weather and night time, unlike optical sensors. The identification of ships has been remarked from viewpoints of coast guard such as finding and monitoring marine accidents and poaching boats without Automatic Identification System (AIS). Current monitoring such situations still has been a visual inspection. This brings some difficulties such as too huge area, too time-consuming processes and so on to monitor them. So, screening candidates of ships have been required for helping the watchers. Machine learning is one of the best solutions because usual visual inspections have been substituted by the recent AI trend.
This research adopts the Convolutional Neural Network (CNN) because this is the most popular approach in image analysis. We have many uses with CNN in image recognition. This research verifies whether a ship image on SAR can be identified by CNN. This research used SAR images of PALSAR2/ALOS2 with a resolution of 10 m/pixel, polarization is HV (horizontal transmitting, vertical receiving) for the identification of ships. This machine learning needs a set of labeled data with positive/negative. The label is given to ship image on SAR using AIS. Results with PALSAR 2 data with a resolution of 10 m / pixel showed high accuracy of 95%. This research showed the availability of a method to discover ships from SAR images using CNN. In the future, this research will classification of ships not only identification. This research will examine how the change of SAR image due to marine weather affect machine learning. I would like to discuss with marine weather experts at JpGU.

[A-CG37] Science in the Arctic Region

convener:NAOYA KANNA(Arctic Research Center, Hokkaido University), Masashi Niwano(Meteorological Research Institute), Tetsu Nakamura(Faculty of Environmental Earth Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University), Chairperson:Tetsu Nakamura(Faculty of Earth Environmental Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University)

The Arctic and circumpolar region is the key area for the study of global change because the anthropogenic impact is projected to be the largest in this area due to the complicated feedback processes of the nature. A number of international and interdisciplinary research projects have been conducted for the studies on the land-atmosphere-ocean system. In order to understand the feedback processes occurring in the Arctic and to project the global warming in the future, we need to establish the intense observational network and to exchange the knowledge and information by combining the different scientific communities under the common interest of the Arctic. The objectives of this session are 1) to exchange our knowledge on the observational facts and integrated modelling and 2) to deepen our understanding on wide range of natural sciences related to the Arctic and the circumpolar region. Studies on humanities, social sciences, and interdisciplinary fields are also welcomed.

Arctic midlatitude linkage modulated by the QBO

*Jinro Ukita[1], Kazuhiro Hoshi[1], Meiji Honda[1], Tetsu Nakamura[2], Koji Yamazaki[2]

1. Niigata University, 2. Hokkaido University

We examined an observed relationship between the BKS sea ice variability and the midlatitudes cold anomaly and found that this relationship is highly dependent on the QBO phase, easerly (QBO-E) or westerly (QBO-W). For the QBO-E winters midlatitude cold (warm) anomalies appear significantly under the low (high) sea ice condition. On the other hand, such a relationship is not found in the QBO-W winters. This dependence is a robust feature. Atmospheric circulation anomalies related to the high and low sea ice conditions are also different between the two QBO phases. In the troposphere, stationary Rossby wave propagation from the BKS region and the negative NAO appear in QBO-E, along with weakened stratospheric polar vortex and downward propagation of the signals. For QBO-W, such tropospheric and stratospheric signals are mainly absent. Our results may provide an explanation for why some simulations suggest the presence of Arctic sea ice impacts on midlatitude surface temperature while others do not. The most important implication is that in the Arctic-midlatitudes climate linkage tropics also plays a key role.

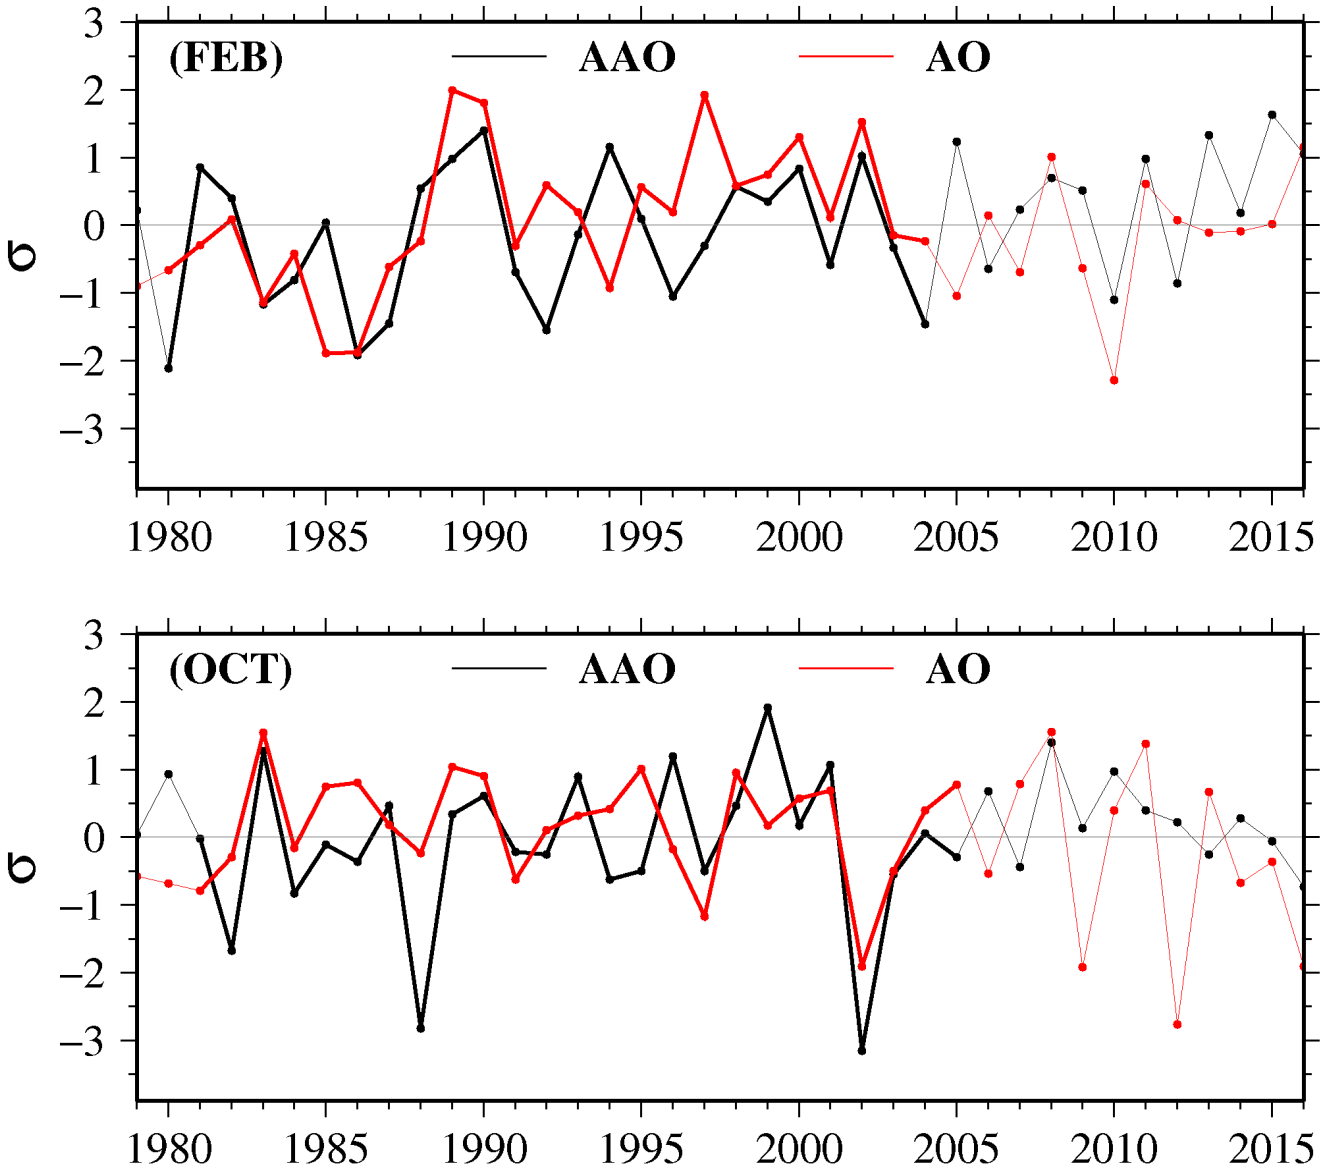
Abstract



Teleconnections between lower and higher latitude regions are widely known in both the Northern and Southern Hemispheres. To broaden our view of these teleconnections, we searched a reanalysis dataset for evidence of a teleconnection between the Arctic Oscillation (AO) and the Antarctic Oscillation (AAO), two widely separated circumpolar phenomena. Statistical analysis of the Japanese 55-year reanalysis dataset showed significant in-phase synchronization between the AO and AAO, particularly in October and February, with a vertical structure extending from the troposphere to the stratosphere. This vertical structure may suggest a stratospheric control, and we did not find a significant signature indicating a tropical ocean control. We also observed decadal-scale modulation of the synchronicity. Observational evidence implies that the stratospheric meridional circulation may be responsible for AO–AAO synchronization. This paper was published in ***GRL,*** 45, DOI:10.1029/2018GL081002 by Tachibana et al., 2018.

Plain Language summary

The Arctic Oscillation (AO) and the Antarctic Oscillation (AAO) are dominant atmospheric variability patterns in the Northern and Southern hemispheres, respectively. Each is a pressure seesaw between the pole and the midlatitudes that remotely affects weather, climate, and environment around the world. We showed interhemispheric in-phase synchronization between the AO and AAO in October and February, and we also found decadal-scale variation of the synchronicity. Because the vertical structure of the AO–AAO synchronization extends from the troposphere to the stratosphere, stratospheric variations may be responsible for the synchronization. This finding of AO–AAO synchronization points the way to a better understanding of past, present, and future pole-to-pole climatic relationships and improvements in long-term weather forecasts.

Marginal ice zone sea ice observations in the refreezing Chukchi Sea

*Takehiko Nose[1], Tsubasa Kodaira[1], Takuji Waseda[1], Jun Inoue[2]

1. The university of Tokyo, 2. National Institute of Polar Research

Regions in the Arctic Ocean that were inaccessible in November are now open for navigation, even for non-icebreakers, and R/V Mirai, a Polar Class 6 vessel, carried out a late autumn voyage in 2018. It conducted a 12-day sea ice observation campaign during the 9th–20th of November along a fixed Marginal Ice Zone (MIZ) transect in the eastern Chukchi Sea and obtained first-hand observations at a time when research vessels are rarely in the sea. Satellite sea ice data were compared with the shipboard observations and compared relatively well. A sequence of events to describe the observations are grouped and described in four phases: 9th–13th, “Sea ice growth under relatively calm wind conditions”; 14th–16th, “the on-ice wave event, sea ice break up, and subsequent sea ice advance”; 17th–18th, “sea ice retreat or a mass shift under moderate easterly winds”; and 19th–20th, “warming sea surface temperature (SST) under strengthening cold off-ice winds and air temperatures below -10 ˚C”. Shipboard and ERA5 reanalysis data were analysed to identify physical processes that affect the Chukchi Sea refreezing process. Sea ice conditions during the first two phases appear to be influenced primarily by surface winds whereas the analysis suggests a driver of sea ice conditions in the latter phases were due to ocean interior processes. The MIZ transect waters became heavily ice covered within five days after R/V Mirai began its return voyage, so the observation period covered most of the refreezing process along the transect water.

Prediction of wildfire and air pollution with machine learning over the five domains of Eastern Eurasia

*Teppei J Yasunari[1,2], Ichigaku Takigawa[3], Kyu-Myong Kim[4], Arlindo M da Silva[4]

1. Faculty of Engineering, Hokkaido University, 2. Arctic Research Center, Hokkaido University, 3. Graduate School of Information Science and Technology, Hokkaido University, 4. NASA Goddard Space Flight Center

Under the ongoing global warming, necessity of better forecasting on wildfires and its air pollutions is increasing. In the last year, we carried out a preliminary wildfire prediction using the areal-averaged monthly mean data over a large Siberian domain (Yasunari et al., 2018, presented at AGU Fall Meeting 2018: http://bit.ly/2PG1bmK). Here we extend our previous analysis of machine learning and prediction into the five separated domains over the Arctic and sub-Arctic regions over Eastern Eurasia including Siberia, East Asia, Far East, etc. We use the same monthly mean dataset during 2003-2017 as we did in the last year above (i.e., NASA's FEER fire data, MODIS Snow Cover Fraction, SCF, Modern-Era Retrospective analysis for Research and Applications, Version 2, MERRA-2). The time periods of 2003–2014 and 2015–2017 focus on learning and prediction. Areal averaged data for objective (i.e., wildfire and air pollution variables) and explanatory variables (i.e., snow, temperature, wind, surface soil wetness, precipitation, geopotential height, etc.) over the defined five domains over Eastern Eurasia (Domain 1: 57°–70°N, 60°–90°E; Domain 2: 57°–70°N, 90°–140°E; Domain 3: 60°–70°N, 140°–180°E; Domain 4: 42.5°–57°N, 60°–90°E; Domain 5: 42.5°–57°N, 90°–140°E) are calculated, together with producing monthly time-lagged data for explanatory variables up to six months (i.e., total 174-month data available during 2003 and 2017). In addition, we made different areal-averaged fire pixel count data in which some smaller fires were removed with defined thresholds to remove expected human-made fires such as bonfires (i.e., assumed natural fire cases). If the areal-averaged fire data under the thresholds on a specific month showed no fire, we replaced that data to zero (i.e., used for our analyses but treated as zero fire data on that month).
Using Random Forest Regression, for example, in the machine learning, except for Domain 5, all the fire-included case showed the worse prediction score than those of the assumed natural fire cases. This implies that smaller fire cases, which were likely ignited by human activities or others, would be one of the causes for making wildfire predictions worse. However, over Domain 5, all the fire-included case showed the best probably because the assumed natural fire case was probably affected by the unusual large-scale wildfire events (i.e., outliers). These significantly large-scale wildfire cases also likely to make predictions worse because of not enough such cases existing in the training data (i.e., not frequent). In addition, these outliers might happen under unusual climatic and environmental conditions. How to include more large-scale fire cases in training data would be one of the important future targets on wildfire prediction with machine learning. On the day of the presentation, we'll also show the results for air pollution prediction.

Hydrological Changes in the Four Largest Siberian Arctic River Basins

*Kazuyoshi Suzuki[1], Tetsuya Hiyama[2], Kazuhito Ichii[3], Yoshihiro Iijima[4], Koji Matsuo[5], Dai Yamazaki[6,1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Chiba University, 4. Graduate School of Bioresources, Mie University, 5. Geospatial Information Authority of Japan, 6. Institute of Industrial Sciences, The University of Tokyo

The Arctic freshwater budget affects global climate and is critical for understanding the climate in polar regions. However, the hydrology of the largest Eurasian Arctic rivers is still not understood well. In this paper, we analyze spatiotemporal variations in hydro-climatological factors related to four of the largest Siberian Arctic river basins (Ob, Yenisey, Lena, and Kolyma). To examine recent hydro-climatological changes in these river basins, we utilize monthly observation-based gridded meteorological and evapotranspiration data, Moderate Resolution Imaging Spectroradiometer (MODIS)-based products such as the snow area fraction (SAF) and normalized vegetation index (NDVI), global land data assimilation system products, and Gravity Recovery and Climate Experiment (GRACE) data from 2000 to 2016. Combining these with river runoff data, we identify how river runoff shifted from June to May during the study period. River runoff in May significantly increased although there was no clear trend in annual discharge. In addition, SAF decreased drastically in April and this is evidence that spring snow coverage in Siberian basins is shrinking and snowmelt is shifting toward earlier. On the other hand, we found the positive trend in summer NDVI. Focusing on permafrost distribution, this paper will discuss the correlation in the temporal lag between the water cycle and vegetation activity.

Mapping thermokarst subsidence in Central Yakutia using L-band SAR interferometry

*Takahiro Abe[1], Go Iwahana[2,3], Takeo Tadono[1]

1. Earth Observation Research Center, Japan Aerospace Exploration Agency, 2. International Arctic Research Center, University of Alaska, Fairbanks, 3. Arctic Research Center, Hokkaido University

Thermokarst is an irreversible phenomenon with geomorphological change, resulted from the thawing of ice-rich permafrost or the melting of massive ice. The formation of large depressions in the ground surface by thermokarst processes results in surface inundation, and causes damages on infrastructure. Central Yakutia in Eastern Siberia is one of the regions where ice-rich permafrost is broadly distributed. The remarkable surface subsidence due to thermokarst has been observed in recent years, which could cause destruction of building and infrastructure in this area (Shiklomanov et al., 2017; Hjort et al., 2018). The thermokarst settlement are frequently observed in continuous permafrost zones in arctic regions, especially in Alaska and the Northeastern Siberia. However, it is so difficult to know where and how surface deforms in vast permafrost zones.

Remote sensing technique, especially Interferometric Synthetic Aperture Radar (InSAR), has a great potential to monitor the thermokarst subsidence, and seasonal permafrost melting and heaving. SAR sends microwave toward ground, and receive the reflected and scatter signals under all-weather and day-and-night condition without any instrument on ground. Thus, InSAR can provide essential information to understand thawing process of ice-rich permafrost and to predict the future stage over arctic permafrost region. Many studies about permafrost dynamics using SAR images have been reported so far (e.g., Liu et al., 2010; Iwahana et al., 2016; Antonova et al., 2018; Strozzi et al., 2018), but there is no study using SAR in Central Yakutia.

In this study, we used ALOS/PALSAR (2007-2010) and ALOS-2/PALSAR-2 (2014-2018) images to examine ground subsidence caused by thermokarst development. GAMMA software was used to generate Single Look Complex data from Lv1.0 data in ALOS/PALSAR and Lv1.1 data in ALOS-2/PALSAR-2. ALOS world DEM derived from ALOS/PRISM was used to simulate and remove topographic effect. We generated many interferograms, selected some of them, and applied stacking procedure weighted on period between two SAR data acquisition time, estimating the mean change rate along line of sight (LOS). Assuming ground displacement is only vertical component, the LOS change was converted to vertical displacement using incidence angle.

At the last JpGU, we reported ground subsidence in Mayya, on the right bank of Rena River, Central Yakutia, derived from ALOS/ALOS-2 InSAR stacking. To validate the InSAR signals, we carried out the ground observation in Mayya at the end of September, 2018. As a result, the subsidence rate of 2-3 cm/yr was obtained at the two measurement points in 2017-2018. The result of ground observation is consistent with that of InSAR result from ALOS-2. We also went to some places where there are subsidence signals in the ALOS-2 results. As a consequence, the two large subsidence signals were found in alasses. Alas is considered as a final geomorphological stage of old thermokarst development. Significant amount of the subsidence may be due to consolidation settlement associated with soil desiccation under recent dry climate conditions. However, judging from new developments of polygonal subsidence in the bottom areas of alasses, ground ice still remains under the alasses, which may cause further thermokarst progress.

©2019. Japan Geoscience Union. All Right Reserved.

Moreover, we extended our target to other cities, Amga, and Churapcha, where thermokarst has been also developing (e.g., Saito et al. 2018). The similar subsidence signals were obtained in the two cities, where it is in area of many polygons. It suggests that the signals be presumably due to thermokarst development.

Spatiotemporal variation of thaw subsidence and frost heave of permafrost caused by wildfire around Batagay, East Siberia

*Kazuki Yanagiya[1], Masato Furuya[2]

1. Graduate School of Science, Hokkiado University, 2. Faculty of Science, Hokkaido University

Thawing permafrost release soil organic carbon as a greenhouse gases, and it can be positive feedback on global warming (Shuur et al. 2015). To estimate terrestrial carbon budget precisely, permafrost degradation should be observed in the entire circumpolar region. However, it is impractical to perform field observation over all the permafrost areas in northern hemisphere. Especially in Siberia, observation sites by the international network (e.g. GTN-P, CALM) is very few despite the largest area in terms of permafrost distribution. Therefore, remote sensing techniques to cover wide areas are indispensable. Observing ground deformation by InSAR (Interferometric Synthetic Aperture Radar) can tell us the state of permafrost with high spatiotemporal resolution. Some previous studies are conducted in a part of Alaska, Canada and Siberia that can be easy to compare with field work (Liu et al. 2010; Short et al. 2011; Antonova et al. 2018).

We focused on East Siberia, where no previous studies by InSAR are conducted. Study area is around Batagay town (67’ 39N, 134’ 39E). At ~10 km southeast of Batagay, there is a well-known and one of the largest slump terrains caused by thawing of permafrost (Murton et al. 2017). Processing ALOS and ALOS2 InSAR images, we found the deformation signal due to wildfire at the hill to the 20 km northwest of Batagay. Loss of surficial vegetation layer by wildfire accelerates permafrost thawing, and the degradation continues for several years to decades after a fire (Yoshikawa et al. 2002). Furthermore, given the fact that the frequency and intensity of wildfires are increasing in the Arctic region with global warming (Alexander et al. 2018; Gibson et al. 2018; Masrur et al. 2018), it is important to reveal the spatiotemporal variation of the ground deformation in the post-wildfire area.

Here, we report our detection of the post-wildfire ground deformation in the place where the fire occurred in 2014. We used SAR images obtained from ALOS 2 (L-band) and Sentinel-1 (C-band) satellites from 2014 to 2018. Secular deformation is detected by ALOS2 data. The results indicated that thawing subsidence up to 10cm in the satellite line of sight direction continued after 2-3 years after the fire. Seasonal deformation from 2017 to 2018 is detected and compared with both satellites data. The magnitude and spatial patterns of subsidence and uplift was consistent in both satellites. Especially, short-term InSAR images with Sentinel-1 data revealed detailed temporal variation from the start to the end of thawing and freezing. Estimation of permafrost thawing amount from ground deformation amount detected by InSAR can contribute to reducing uncertainty of terrestrial carbon budget. Those physical models are under discussion (Liu et al. 2014; Hu et al. 2018; Molan et al. 2018). In this study, we verified the Molan model in our study area, and developed it taking into account the deformation in the slope direction.

Recent years of increasing air temperature in the Arctic have known to lead a significant increase in the retreat speed of permafrost coast, which has threatened livelihoods and infrastructure along the coasts. The Kara Sea hosts more than 25% of the total length of Arctic coasts. Despite many works for more than six decades, little is known about how the Kara Sea coasts, affected by permafrost and sea-ice, may have changed through time and what the climatic and environmental drivers are. To understand the dominant climatic factors influencing the dynamic processes along the permafrost and sea-ice affected coastline, we study dynamics of permafrost coast along the Baydaratskaya Bay of Kara Sea, Western Siberia, during the rapidly retreated period 2005–2016, by handheld differential GPS mapping, satellite imagery, measurements of ground temperature and subsurface resistivity, and meteorological data. These multidisciplinary data reveal that the activity of wind-driven ocean wave during the sea ice-free (open water) days influences the magnitude of coastal retreat in the study area, while that recent temperature rise less contributes to enhancing coastal retreat during the study period. This suggests that the magnitude of wave activity over the sea ice-free days controls the quantities of the eroded sediment and the associated release of nutrient to the nearshore zone, which might result in influencing infrastructure along the permafrost coast and marine ecosystem in the proximal ocean.

Ice front variations of Heilprin Glacier in northwestern Greenland controlled by the ocean and glacier bed geometries

*Izumi Asaji[1,2], Daiki Sakakibara[3], Takuto Ando[3], Shin Sugiyama[1]

1. Institute of Low Temperature Science, Hokkaido University, 2. Graduate School of Environmental Science, Hokkaido University, 3. Arctic Research Center, Hokkaido University

The Greenland ice sheet is losing mass under the influence of increasing surface melting and ice discharge from marine-terminating outlet glaciers. Better understanding of mechanisms controlling ice dynamics of marine-terminating glaciers is crucial for predicting future mass loss from the ice sheet. However, processes controlling rapid retreat of the glaciers are not well explained. As many Greenlandic glaciers thinned recent years, ice thickness near the current front position is possibly close to the hydrostatic equilibrium condition. Therefore, we hypothesize that a possible cause of recent rapid retreat of marine-terminating glaciers is surface lowering below the flotation level (ice surface elevation at which buoyancy and gravitational forces balance). Validation of this hypothesis requires detailed ice surface and bed elevation data near the calving front.

In this study, we measured bed topography and surface elevation of Heilprin Glacier in northwestern Greenland. Heilprin Glacier has a 6 km-wide terminus, which is currently separated to three calving fronts. The front position advanced by 800 m from 1990 to 2000, and retreated by 1 km from 2000 to 2009. We measured the ocean bed topography near the one of the calving front situated in the north, using a sonar fixed on a boat from 13 to 15 August, 2018. The surface elevation change from 2001 to 2012 was analyzed by using digital elevation models generated from satellite images acquired by an optical sensor ASTER (Advanced Spaceborne Thermal Emission and Reflection Radiometer) mounted on the Terra satellite. We computed the flotation level from the bed elevation, and compared it with glacier surface elevation before and after the rapid retreat.

Near the studied glacier front, the fjord is deeper in the northern side of the glacier, and the maximum water depth in the region was 340 m. The glacier retreated by 1 km over this deepest area from 1998 to 2008. Analysis of the data showed that the glacier surface near the front in 2000 was 10 m below the flotation level, suggesting significant ice thinning prior to the rapid retreat. It is likely that the retreat of northern front of Heilprin Glacier was driven by thinning and ice flotation at the deepest area of the fjord.

Meltwater discharge and flooding of the outlet stream of Qaanaaq Glacier, northwestern Greenland

*Ken Kondo[1,2], Daiki Sakakibara[3,2], Shungo Fukumoto[1,2], Shin Sugiyama[2]

1. Graduate School of Environmental Science, Hokkaido University, 2. Institute of Low Temperature Science, Hokkaido University, 3. Arctic Research Center, Hokkaido University

Glacial meltwater discharge is increasing in Greenalnd under recent warming climate. As a consequence, floods and damages on infrastructures are reported at outlet streams of land terminating glaciers. For instance, discharge from Qaanaaq Glacier in northwestern Greenland rapidly increased on 21 July 2015 and 2 August 2016, leading to floods of a proglacial stream and destruction of a road between a settlement and Qaanaaq Airport. To better understand the mechanisms of the flood events at Qaanaaq Glacier, we investigated meteorological conditions during the 2015 and 2016 events by using AWS operated on the ice cap at 944 m a.s.l. (SIGMA-B) (Aoki et al., 2014). We performed field measurements in the summer 2017 and 2018 to investigate melting process of Qaanaaq Glacier and the response of the outlet discharge. These data were combined with surface mass balance of Qaanaaq Glacier observed from 2012 to 2018 to analyse the cause of floods in 2015 and 2016.

Surface mass balance was significantly more negative in 2015 and 2016 as compared to the other years. Glacier wide mass balance was −0.76±0.13 m w.e. in 2014/2015 and -0.28±0.7 m w.e. in 2015/2016. Before the floods, daily mean temperature rose above 5 ˚C for 5 days in 2015 and above freezing for almost a month in 2016 at SIGMA-B. Such warm conditions caused intensive melting over the entire glacier, resulting in saturation and disappearance of snowpack from the glacier below 950 m a.s.l. In addition to large exposure of ice surface, heavy rainfall (90 mm d^{-1}) occurred on the date of the flood in 2016. we assume that the exposed ice surface helped immediate runoff of a large amount of rainwater. These analyses suggested the loss of snow cover played a key role in the flood events in 2015 and 2016.

We measured discharge from Qaanaaq Glacier from 21 July to 3 August 2017. Stream discharge rapidly increased on 28 July 2017, leading to a peak value of 8.11 m^3 s^{-1}. From 21 to 28 July, snowline elevation rose from 500 to 650 m a.s.l. after intensive melting. Runoff measured before the peak discharge accounted for only 60 % of the estimated total glacier melt, indicating the rest of meltwater remained in snowpack on the glacier. These data suggested snowpack was saturated with meltwater, and rapidly released water during the period of rapid melting and upglacier snowline migration. Together with data obtained by similar measurements in 2018, we conclude that saturation and disappearance of snowpack are the key to predict rapid increase in stream discharge and flooding.

Occurrence frequency of lee-side downslope winds near Siorapaluk in northwest Greenland

*Akihiro Hashimoto[1], Tetsuhide Yamasaki[2], Teruo Aoki[3,1], Masashi Niwano[1], Satoru Yamaguchi[4]

1. Meteorological Research Institute, 2. Avangnaq, 3. The Graduate School of Natural Science and Technology, Okayama University, 4. Snow and Ice Research Center, National Research Institute for Earth Science and Disaster Resilience

In early April 2018, Niwano et al. (2018) conducted the scientific traverse expedition “Snow impurity and glacial microbe effect on the abrupt warming in the Arctic (SIGMA) Traverse 2018”. The expedition crews had initially planned to depart Siorapaluk on April 2, 2018. However, their departure was delayed by four days because of strong winds and snow blocking the way. Numerical experiment showed that the strong wind had characteristics of a lee-side downslope wind (Hashimoto et al., 2018). Matoba and Yamasaki (2018) reported a sea ice outflow event and its damage to fishery along the coast of Qaanaaq (50-km southeast of Siorapaluk) in early December 2016, which was the first time experience for residents of Qaanaaq over the last 30 years. They assumed that northeasterly winds of more than 30 ms^{-1} on 6-hour average dispersed sea ice from the coast, based on observation data at Qaanaaq airport.

These strong wind events seriously affected the scientific activity and residents’ living, which motivate the authors to study occurrence characteristics of strong winds in the northwest Greenland. According to observation performed during 2016-2017 and 2017-2018 winter seasons in Siorapaluk, strong winds more than 15 ms^{-1} occur in several times. These winds are always from the north-northeast to the observation point, which means that these winds blow beyond the ridgeline in the north of Siorapaluk. Year-round observation in Qaanaaq shows that strong winds appear also in summer as well as in winter. Some strong wind events are found to occur simultaneously in Siorapaluk and Qaanaaq. Numerical simulations are conducted for the period from May 2017 to April 2018 by using the Japan Meteorological Agency’s non-hydrostatic model (JMA-NHM) with the 1-km horizontal resolution to reveal temporal and spatial distributions of strong winds and mechanisms causing them. Statistical features of strong winds and dynamical connections between synoptic and local wind systems will be presented in the meeting.

Impacts of clouds on the Greenland ice sheet surface melt and mass balance

*Masashi Niwano[1], Akihiro Hashimoto[1], Teruo Aoki[2]

1. Meteorological Research Institute, 2. Graduate School of Natural Science and Technology, Okayama University

Clouds have been recognized to enhance surface melt on the Greenland Ice Sheet (GrIS). However, quantitative estimates of the effects of clouds on the GrIS melt area enhancement and resultant ice-sheet-wide surface mass balance modulations are still lacking. Here we assessed the effects of clouds with the state-of-the-art regional climate model NHM-SMAP (Niwano et al., 2018), conducting a numerical sensitivity test in which clear-sky downward radiations and adiabatic atmospheric conditions were assumed, although the precipitation rate was the same as in the control all-sky simulation. By including or excluding cloud effects, we quantified time-integrated feedbacks for the first time. We found that the surface melt area extent increased by 3.1%, 0.3%, and 0.7% (of the total GrIS area) by the presence of clouds during summer (June to August) in 2012, 2013, and 2014, respectively. During the same periods, clouds reduced solar heating and thus daily runoff by 1.6, 0.8, and 1.0 Gt day^{-1}, respectively: clouds did not enhance the GrIS surface mass loss. In the ablation area, the presence of clouds results in a reduction of downward latent heat flux at the snow/ice surface so that much less energy is available for the surface melt, which highlights the importance of indirect effects of clouds.

Introduction of the IASC project "T-MOSAiC"

Masaki Uchida[1], *Tetsuo Sueyoshi[1]

1. National Institute of Polar Research

Terrestrial Multidisciplinary distributed Observatories for the Study of Arctic Connections (T-MOSAiC) is one of the IASC (International Arctic Science Committee) projects. T-MOSAiC has been formulated as a research and synthesis project to provide an integrated, cross-disciplinary evaluation of how the changing Arctic Ocean affects terrestrial environments, from the coastal zone to the continental interior. The project will focus on connecting studies which take place throughout the Arctic and across disciplines in order to generate new findings into Arctic geosystems, ecosystems and human systems. There are key aspects to be addressed include connectivity, gradients, discontinuities, thresholds, extreme events and emergent properties, with specific questions that bridge sites and disciplines. Data sets will be available via open access repositories. T-MOSAiC will run in parallel to the ocean-based project Multidisciplinary drifting Observatory for the Study of Arctic Climate (MOSAiC), with temporal overlap in 2019-2020 and exchange of data sets such as climate observations from land and ocean stations.

Participating in T-MOSAiC has several advantages to your research. Join an international project across disciplines that targets key physical, ecological and societal issues affecting the Arctic and the world, at this critical time of rapid change and international decision-making. Contribute to fill key observational data in gaps identified by the T-MOSAiC Science Plan. Assure laboratory and project visibility at the international level. Benefit from T-MOSAiC and IASC grants for early career researchers for networking. Link with large T-MOSAiC partners such as MOSAiC (https://www.mosaic-expedition.org/), INTERACT (https://eu-interact.org/), Sentinel North (https://sentinelnorth.ulaval.ca/en), Nunataryuk (https://nunataryuk.org/) and others. Develop new collaborations, including across disciplines. Please visit the T-MOSAiC web site and get more information (https://www.t-mosaic.com/).

Estimation of ice thickness and volume in the Sea of Okhotsk using ICESat and CryoSat-2 data

*Sohey Nihashi[1], Nathan T. Kurtz[2], Takenobu Toyota[3]

1. National Institute of Technology, Tomakomai College, 2. NASA GSFC, 3. Institute of Low Temperature Science, Hokkaido University

Sea-ice thickness in the Sea of Okhotsk is estimated from freeboard derived from satellite altimeter data. Ice thickness is estimated by assuming densities of sea ice, snow, and seawater based on in-situ observations (Toyota et al., 2007; Ohshima et al., 2001). Snow depth is assumed 10% of ice thickness by referring to in-situ observation (Toyota et al., 2007). Ice freeboard (thickness) derived from a laser altimeter GLAS on ICESat is used for 2004-08 (Nihashi et al., 2018). After 2011 to 2018, data from radar altimeter SIRAL-2 on CryoSat-2 is used. CryoSat-2 freeboard is obtained by a method of Kurtz et al. (2014). Comparison with ice thickness observed hourly aboard icebreaker Soya by visual observation suggests that ice thickness derived from ICESat and CryoSat-2 are almost consistent. Total ice thickness (ice thickness including snow depth) in February and March, when the sea-ice area is maximum, averaged over the entire sea-ice zone ranges from 77.5 cm (2008) to 123.0 cm (2017). The mode of total ice thickness ranges from 50-60 cm (2007; 2008; 2017) to 90-100 cm (2013). Ice volume in the Sea of Okhotsk is estimated from the total ice thickness and ice concentration derived from AMSR-E (2004-11), SSMI (2012), and AMSR2 (2013-18). Ice volume is estimated by interpolating these sea-ice datasets onto an NSIDC polar stereographic grid at a spatial resolution of about 12 km. The maximum ice volume is 8.3×10^{11} m^3 (2016), while the minimum is 5.4×10^{11} m^3 (2015). The interannual variability is shown to be mainly determined by the sea-ice area, although ice thickness seemed to be effective in 2008. It has been shown that the maximum sea-ice area and ice production in the Sea of Okhotsk can be explained from atmospheric and oceanographic conditions (e.g., Ohshima et al., 2006; Nakanowatari et al., 2010; Kashiwase et al., 2014). Based on these studies, we compare the ice volume with the atmospheric and oceanographic data. And then we find that the ice volume can be explained to some extent by the air temperature in the northwest and north of the sea just before the freezing season (November-December), the air temperature in the northwest of the sea during active freezing period (February-March), and the wind toward the offshore during the ice advance season (January-March). Multiple regression analysis is performed on the ice volume using these atmospheric conditions. And we try to reproduce the ice volume in the Sea of Okhotsk since the 1950s when the satellite data does not exist from the atmospheric data by using the regression line.

Arctic Sea Ice Changes in the DAMIP experiments using the MRI Earth System Model

*Takuro Aizawa[1], Masayoshi Ishii[2], Naga Oshima[2], Seiji Yukimoto[2], Hiroyasu Hasumi[1]

1. Atmosphere and Ocean Reseaerch Institute, The University of Tokyo, 2. Meteorological Reseaerch Institute

Arctic sea ice decreases rapidly with a temperature rise by Arctic amplification which is caused by an increase of the greenhouse gases. According to some studies, the Arctic Ocean is projected to become ice-free Ocean in the nature future. As sea ice melts due to the effect of sensible heat, it has a close relationship with air temperature. Although the historical temperature in the Arctic is well known by the previous observational studies, the historical sea ice variability hasn’ t still understood sufficiently because of the lack of observations in pre-satellite era. Therefore, the modeling study will greatly contribute to the understanding of the Arctic climate change.

Meteorological Research Institute (MRI) has developed a new version of MRI Earth System Model (MRI-ESM2) for participating in the various Model Intercomparison Project (MIP), especially CMIP6 (Coupled Model Intercomparison Project Phase 6). We conducted the CMIP6 historical experiment (1850-2014) and the DAMIP (Detection and Attribution MIP) experiments by MRI-ESM2. The DAMIP experiments consist of hist-GHG (Well-mixed greenhouse-gas-only historical simulations), hist-aer (Anthropogenic-aerosol-only historical simulations) and hist-nat (Natural-only historical simulations). The DAMIP experiments make it possible to the clarify the impacts of anthropogenic and natural forcing on the global warming. And the experiment will be able to estimate how the sea ice variability was influenced by the external anthropogenic and the natural forcing. The decadal to multi-decadal variability of the Arctic sea ice is seen in all experiments, but each experiment indicates some characteristic changes. The hist-GHG experiment shows a strongly decrease in the sea ice extent due to the rapid increase of the greenhouse gases. The hist-aer experiment indicates an expansion in the summer sea ice extent over the period to 1980 when the concentration of sulphate aerosols is peak out, which lead to the global and Arctic cooling. But over the period from 1980 to now, the summer sea ice extent shows a decrease. The hist-nat experiment shows a weakly decrease in the summer sea ice extent over the period from 1880 to 1940, since then the summer sea ice extent remains at the same level. Thus, our simulations show the historical summer Arctic sea ice extent and the contributions of the external anthropogenic and the natural forcing to the sea ice changes.

Oceanographic Observation in the Refreezing Warm Chukchi Sea during 2018 Mirai Cruise

*Tsubasa Kodaira[1], Takehiko Nose[1], Takuji Waseda[1], Jun Inoue[2]

1. The University of Tokyo, 2. National Institute of Polar Research

In November 2018, R/V Mirai entered Chukchi Sea to conduct observations with special attention to the Marginal Ice Zone (MIZ). Based on satellite SST measurements over Chukchi Sea, it is found that Chukchi Sea has a clear warming trend in the last decade. The warm Chukchi Sea enabled R/V Mirai to conduct rare observations in November to measure the refreezing ocean. The preliminary results of the hydrographic and velocity observation are presented. The repeated measurements along an observation line toward MIZ north of Hana Shoal showed temperature and salinity changes largely over the Chukchi slope compared to the shallow shelf.

Observed Waves in the refreezing eastern Chukchi Sea during 2018 Mirai Cruise

*Takuji Waseda[1], Takehiko Nose[1], Tsubasa Kodaira[1], Alison Kohout[2], Johannes Gemmrich[3], Hui Shen[4], Jun Inoue[5]

1. The University of Tokyo, 2. National Institute of Water and Atmospheric Research, 3. University of Victoria, 4. Bedford Institute of Oceanography, 5. National Institute for Polar Research

The sea ice in the Pacific side of the Arctic Ocean starts to melt in August, retreats the most in September, and advances again in October. In November, in typical years, most of the Chukchi Sea is covered by ice. Waves generated in the open waters is largest in October. During the R/V Mirai (JAMSTEC) expedition in November 2018 (MR18–05C, PI J. Inoue), anomalously warm surface waters delayed freezing of Chukchi Sea providing a unique opportunity to observe ocean waves in the freezing period. A drifting wave buoy, ship-borne wave gauge, and satellite synthetic aperture radar data were analyzed to characterize the waves during that period. The drifting wave buoy was deployed at the edge of the Marginal Ice Zone, gradually migrated to the west, and eventually got trapped in the sea ice. During this period, the largest significant wave height observed by a buoy was 2.6 m. Once trapped in ice, the buoy-detected wave energy significantly reduced from the open water wave height detected by ship-borne wave gauge. The possible generation, decay, and propagation of waves in the ice-covered sea for on-ice and off-ice conditions will be discussed in conjunction with the obtained satellite SAR images.

Mooring measurement near a marine-terminating glacier in Bowdoin Fjord in northwestern Greenland

*Yoshiki Fujishi[1,2], Yasushi Fukamachi[1,3], NAOYA KANNA[3], Shin Sugiyama[1,3]

1. Institute of Low Temperature Science, Hokkaido University, 2. Graduate School of Environmental Science, Hokkaido University , 3. Arctic Research Center, Hokkaido University

Submarine melting of calving glaciers is considered as an important process in the mass loss of the Greenland ice sheet (Straneo et al., 2013). Moreover, freshwater runoff has been increasing in recent years and its impact on marine ecosystem is recognized. Bowdoin Glacier, a marine-terminating outlet glacier in northwestern Greenland, has experienced rapid retreat since 2008 (Sakakibara et al., 2018). However, oceanographic observations are sparse in Greenlandic fjords, especially near the calving front of glaciers. The lack of a long-term in-situ data makes it difficult to quantify submarine melting. To better understand seasonal variability in current, temperature, and salinity in this proglacial fjord, mooring measurement was performed in Bowdoin Fjord, a 20-km-long fjord in front of Bowdoin Glacier.
Two moorings were deployed in Bowdoin Fjord, one at 17 km from the glacier front (BF17) and another at approximately 1 km from the glacier front (BF01), respectively. The ocean depth was 540 m at BF17 and 186 m at BF01. The moorings were equipped with a pressure sensor (DEFI2-D50HG, JFE Advantech), thermistors (NWT-SN, Nichiyu Giken and SBE56, Seabird), current meters (INFINITY-EM, JFE Advantech) and conductivity-temperature sensors (SBE-37SM, Seabird). At BF17, a current meter and a conductivity-temperature sensor were at the depths 527 m and 530 m, respectively. A pressure sensor and seven thermistors were at 220 m and 222, 246, 268, 318, 368, 418, and 468 m, respectively. At BF01, a current meter and a conductivity-temperature sensor were at the depths of 167 m and 170 m, respectively. The instruments were operated from August 2016 to July 2018 at BF17 and from July 2017 to July 2018 at BF01.
At BF17, temperature near the bottom was lower during northward current (towards the glacier). Temperature variations corresponded well with that of salinity throughout the year, i.e. temperature increased when salinity decreased. From August to October, we observed fortnightly temperature variations suggesting the influence of tide on water exchange in the fjord. In early August, water near the bottom at BF01 flowed towards the glacier and temperature near the bottom rapidly decreased. This event occurred when the daily mean air temperature measured at Qaanaaq Airport exceeded 0 ˚C, indicating the initiation of subglacial discharge. Temperature variations near the bottom at BF01 correlated with salinity, i.e. temperature and salinity increased at similar timings. Both at BF17 and BF01, temperature variations were small in winter and spring, which we attribute to sea ice cover usually observed in Bowdoin Fjord from November to June. Our data suggested that tide plays a key role in water exchange in the fjord, whereas water property near the glacier front was strongly influenced by meltwater discharge. In the presentation, water property variations and fjord circulation are discussed with weather conditions, and the data obtained at BF17 are compared with those at BF01.

ACKNOWLEDGEMENTS
This research was funded by the Arctic research project Arctic Challenge for Sustainability (ArCS).

[H-DS15] Human environment and disaster risk

convener:Tatsuto Aoki(School of Regional Development Studies, Kanazawa University), Hisao Kondo(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Tatsuto Aoki(金沢大学地域創造学類)

This session discusses disaster risks being inherent in the natural and human environment, which sometimes happen to appear at a disaster, from the viewpoint of not only natural sciences but also social and human sciences. Examples of discussion subjects are as follows: uncertainty of forecasting disaster and problems of huge disaster with low frequency that raised from the 2011 Tohoku earthquake, the methodology for improving hazard maps, national recovery plans considering probable changes or sustainability of the society, international cooperation for disaster mitigation, problems of active faults or liquefaction, adjusting disaster mitigation plan to the regional characteristics, technical development for supporting disaster prevention, education for the disaster mitigation.

*Tomio INAZAKI[1], Takanori Ogahara[1]

1. Public Works Research Institute, Tsukuba Central Institute

We reanalyzed the comprehensive geoscientific investigation data obtained at a site where outstanding liquefaction took place just after the 2011 off the Pacific coast of Tohoku earthquake. The studied site, Makuhari-Kaihin Park, Chiba Prefecture, faces the Tokyo Bay and is situated on a reclaimed land constructed through 1973 to 1987. The field surveys were composed of high-resolution seismic surveys along two short lines, core boring at 4 points, suspension PS logging, CPTs at 7 points, and dynamic cone penetration tests. Core descriptions and detailed grain size analyses were quite helpful to discriminate man-made strata from natural layers and classify them into wet deposits, dry soils and surface cover soils. A time series of aerial photos of the site was interpreted to reconstruct the reclamation process of the site. Our interpretation is as follows; 1) Northern block was first reclaimed since 1973 and the southern block was followed since 1976. Reclamation was completed till 1987 and then the surface was covered with improved soils to form a loan park surrounded by a planted zone. The boundary between the reclamation blocks was buried in the northern part of the park. Aerial photos clearly recorded dendritic sand dunes in the southern block spread by using aligned sand pipes. Wet deposits were overlain with 1 to 2 m thick dry soils toward the offshore.
Based on the time and spatial history of the reclamation process at the site, we implemented a geoscientific interpretation of liquefaction process of the site. 1) The cover soils acted as a cap layer which controlled the mode of occurrence of the surface fissures and sand boil chains caused by liquefaction. 2) Sand dominant parts in the wet deposits first liquefied during the earthquake, and it caused segmentation of man-made strata into several fragments and differential oscillations during the earthquake. Liquefaction resulted in fluidization of fine-grained parts in the wet deposits. No trace of liquefaction was recognized in the underlying natural layers. In contrast, characteristic structure associated with liquefaction and fluidization was obvious in the wet deposits in the whole points of the site. It means that the surface fissures and sand boil chains were inappropriate to explain liquefaction process because liquefaction inherently takes place in the subsurface.

Distribution morphology of deformed reclaimed valley associated with the 2018 Hokkaido Eastern Iburi Earthquake

*Takayuki Nakano[1], Satoshi Fujiwara[1], Hiroshi Une[1]

1. GSI of Japan

1. Introduction

In the 2018 Hokkaido Eastern Iburi Earthquake (M6.7) that occurred on September 6, 2018 (Japan Society of Erosion Control Engineering, 2018 etc.), the fluidization phenomenon of filled land caused by liquefaction etc. in reclaimed valley on Kiyota Ward, Sapporo City seriously damaged residential land and social infrastructures (Japanese Geotechnical Society and Japan Society of Civil Engineers, 2018 etc.). In order to discuss this fluidization phenomenon of reclaimed valley, it is necessary to know the reclaimed valley distribution morphology. Therefore, we disclosed the distribution morphology of the reclaimed valley created by the difference between the pseudo DEM generated from aerial photos using the SfM-MVS technique and the post-construction DEM. Also, we extracted the surface deformation in this area from SAR interferogram and compared it with reclaimed valley distribution.

2. Target area and study method

Reclaimed valley distribution maps were created in Kiyota Ward, Sapporo City (Kiyota site) and Atsuma Town (Atsuma site). Pre-construction DSMs were generated from 44 aerial photos of the 1960s and 1970s taken by the GSI of Japan, respectively. The DSMs were generated by using the SfM-MVS technique and the DSMs were converted to a pseudo DEM by filtering (Nakano, 2017). On the SfM analysis, we established 35 and 20 ground control points (GCPs) respectively. A 5-m grid DEM of the fundamental geospatial data was used for the post-construction DEM. The used SAR interferogram is an image by a pair of August 23, 2018 and September 6, 2018 analyzed by the GSI of Japan using the ALOS-2 data of JAXA.

3. Result & Discussion

We acquired the reclaimed valley distribution map more detail than the past distribution map in the Kiyota site. The reclaimed thickness at the Satozuka district where ground damage was serious in the Kiyota site was ca. 15 m at the maximum. Since the RMSE of vertical residual of GCPs on the SfM analysis was ca. 1.2 m, the value of reclaimed thickness has an error equivalent to that. Comparing this reclaimed valley distribution map with the SAR interferogram, we could identify surface deformations moving away from the satellite or non-interference areas in the reclaimed valley area. This non-interference areas correspond the serious damage areas and the surface deformations area has the potential to show the subsidence or sliding-like deformation of reclaimed valley.

In the Atsuma site, we confirmed small reclaimed valley which the thickness is less than 10 m. The RMSE of vertical residual of GCPs on the SfM analysis was ca. 0.8 m. Surface fissures in this site were discovered on site (Iiba and Nagai, 2018 etc.), and it is estimated that the sliding-like deformation of reclaimed valley occurred.

4. Challenges

We identified the reclaimed valley distribution morphology easily and quickly by using SfM-MVS and filtering analysis with aerial photo. Also, InSAR indicated the possibility of quickly detecting the surface deformation immediately after the disaster. However, we should be careful since the pseudo DEM created from DSM generated by the SfM analysis will have large errors when the area was forest land before construction. It is necessary to examine a more effective and prompt filtering method. Finally, I would like

to offer my sincere sympathy to the people living in the damaged regions by the earthquake.

Liquefaction risk evaluation using relative height data of natural levee

*Mamoru Koarai[1], Kouta Uchiyama[1], Takayuki Nakano[2]

1. Earth Science course, College of Science, Ibaraki University, 2. Geospatial Information Authority of Japan

The liquefaction risk evaluation of the natural levee has been divided in two by a border of relative height 5m in the liquefaction evaluation standard of Nakano et.al. (2015).But it is necessary to reconsider evaluation division, because almost no natural levee with over 5m relative height exists in the Naka River low land and the Tone River downstream.
In this study, land condition map, 5m grid DEM and liquefaction occurrence area by The 2011 off the Pacific coast of Tohoku Earthquake in downstream of the Tone River were overlaid by GIS. The relative height of natural levee was calculated from an elevation of the natural levee liquefaction generated and an elevation of other neighbor landform such as back marsh, coastal plain and delta.
After the liquefaction occurrence rate of the natural levee was calculated every relative height difference of the 0.5m unit, the liquefaction occurrence rate decreased suddenly between 1.5 m-2.5 m of relative height or the liquefaction occurrence rate gradually decreased over 1.5 m-2.5m of relative height. It is appropriate to establish a border of relative elevation of a natural levee by 2m or 3m.

Spatial Analysis of Social Vulnerability to large-scale flood: a case study on the Katsushika Ward, Tokyo

*LIAN XIAO[1]

1. University of Tsukuba

Due to global climate change, the scalability and frequency of flooding is increasing. On the other hand, population aging and family structural changes, as well as the lack of adaptation measures, accelerate vulnerability to flooding. It is necessary to reduce the vulnerability to floods and to accelerate adaptive capacity. Therefore, assessing social vulnerability to flooding disasters is an important step in reducing flooding vulnerability and accelerating resilience.

In this study, we refer to the MOVE framework (a disaster vulnerability assessment framework) and analyze social vulnerability from three perspectives: exposure to a flood, susceptibility, and resilience. We subsequently develop an index system to evaluate the social vulnerability using 14 indicators. Spatial distribution of the social vulnerability of floods in the Katsushika Ward, Tokyo, is revealed based on the collected data using the information entropy method and geographic information system (GIS).

Importance and method of visualization of future occurrence possibilities of giant earthquakes along the Nankai trough

*Yo Fukushima[1]

1. International Research Institute of Disaster Science, Tohoku University

Earthquakes occur in a diverse fashon and we can only make probabilistic forecasts on their occurrence. In a future, we might be able to make deterministic forecasts for certain earthquakes, but at the current status we do not foresee a realization of such a type of forecast.

Currently, discussion on how to take countermeasures on the anticipated giant Nankai trough earthquakes based on forecast information is going on in Japan, led by a Japanese governmental working group. On the giant Nankai trough earthquakes, it has been known mainly from historic documents and seismological observations that 1) the mean recurrence interval of giant Nankai trough earthquakes is 100–150 years, 2) there are two segments, west and east of the Kii peninsula, and they tend to generate earthquakes one after another with a short time interval (within a few years) or rupture simultaneously, 3) normally there are few interplate earthquakes along the Nankai subduction.

Based on such current knowledge, the report by the governmental working group issued in December 2018 emphasizes on the case where a magnitude ~8 earthquake rupturing only one side (west or east) and another earthquake is strongly anticipated on the other side. The report also mentions the cases where a smaller earthquake (magnitude ~7) or an unusual slow slip occur, but with conservative descriptions on the countermeasures for such cases. In short, the report focuses on relatively certain and presumably impending case of what to do in case of the “half-rupture”.

While, at the standpoint of the national government, the framework of the report is appropriate, there seems to be potential motivation on local government, public organizations and private companies to make own flexible decisions depending on their circumstances. There may be cases where some anomalous geophysical phenomenon, even without an eventual occurrence of a giant earthquake, would lead to social reactions and the organizations should take some countermeasures. It seems thus useful for the organizations to understand the possibilities of anomalous natural phenomena that might lead to an earthquake (and social phenomena that follows). Event tree diagrams used in volcanology and other fields can be useful for that purpose. It would be important that experts collaborate with the stakeholders (potential users) and know their needs and opinions in developing them.

Investigation of efficient tsunami evacuation using real-time disaster information

*Yusuke Oishi[1,2,3], Takashi Furumura[2], Fumihiko Imamura[3], Yoshiteru Mihara[4], Fumiyasu Makinoshima[3], Yamashita Kei[3], Takao Higashiyama[5], Tomonori Goto[5], Makoto Oomura[4], Mitsuyuki Nagayama[4]

1. Fujitsu Laboratories Ltd., 2. Earthquake Research Institute, the University of Tokyo, 3. IRIDeS, Tohoku University, 4. Kawasaki City, 5. Fujitsu Ltd.

1. Introduction

In recent years, due to the expansion of the offshore tsunami observation network in Japan and the development of high-speed analysis techniques to utilize the observed data, it is becoming possible to transmit more detailed real-time disaster prediction information. Just after the 2011 Tohoku-Oki Earthquake occurred, while the majority of voice calls were regulated, packet communication continued to be relatively connected and smartphones played an important role in information sharing. Therefore, it is expected that real-time disaster information obtained through smartphones can realize safer evacuation in the near future. In this study, in order to evaluate the effect and the challenge of providing real-time disaster information through smartphone in tsunami evacuation, a demonstration experiment was carried out.

2. Tsunami evacuation demonstration experiment

In the demonstration experiment conducted in the opportunity of the Kawasaki city’s annual tsunami evacuation drill on December 9, 2018, we set up points where passing through was not permitted due to assumed damages caused by strong shake of earthquake, e.g., building collapse, fire, liquefaction, etc., and staff members were located with panels that said “impassable”. When participants of the demonstration experiment encountered the impassable points, they posted the location of these points through a smartphone application, and the posted information was shared in real time on the application screen of other participants. The smartphone application was developed for this experiment and was distributed before the experiment. The number of participants who used the provided smartphone application was 84.

Evacuation behaviors were measured as time series data of position information by the position measurement function of smartphones. In the experiment, in order to evaluate the effect of real-time disaster information about the locations of above-mentioned impassable points on evacuation behaviors, 24 participants from the organizations conducting the demonstration experiment were divided into two groups. One of the two groups were not provided the posted information. As a result, in the group with disaster information, multiple evacuees succeeded in choosing an efficient evacuation route by reducing the number of encounters to the impassable points, and the effectiveness of the real-time disaster information was confirmed. However, when comparing the average value for each group, although the evacuation distance was slightly shorten in the group with the information, it did not lead to reduction in evacuation time, because the average walking speed was slower than the group without the information. The average walking speed that takes the standstill time into account was 4.9 km/h for the group without the real-time disaster information and was 4.7 km/h for the group with the information.

©2019. Japan Geoscience Union. All Right Reserved.

One of the estimated factors that lower the average walking speed is the standstill time to consider evacuation routes using the smartphone application at the branching points and at the places near the impassable points, or the action to post the impossible points. In the group with the real-time disaster information, among twelve people, nine people stopped for more than 10 seconds during the evacuation action.

3. Future work

One of the reasons why the average evacuation speed was decreased in the group with the real-time information is that the accuracy of the posted information was rather low and the standstill time to consider evacuation route was prolonged. In the questionnaire conducted after the evacuation drill, there were multiple opinions such as "With the wrong information, there were no passible road leading to the evacuation site". Among the 74 postings about the impassable points, 40 posts (54.8% of the whole) were accurate with an error of 20 m or less. In order to realize evacuation effectively utilizing real-time disaster information, it is important to evaluate the quality of information and consider information providing means that are easy-to-understand and lead to immediate determination of the next action.

An analysis of the year-round distribution of $PM_{2.5}$ and Oxidant by (Web)GIS and R

*Junji Yamakawa[1]

1. Graduate School of Natural Science and Technology, Okayama University

The year-round concentration distribution of $PM_{2.5}$ and Oxidant in Okayama City, Okayama Prefecture, Japan were estimated by using the geostatistics method and expressed by the (Web)GIS.

The observed concentration data of those environmental substances were obtained from the Website of the National Institute for Environmental Studies. The target year of $PM_{2.5}$ was 2015, and the year of the oxidant was 2006. GNU R (R core team, 2018) was used for geostatistics analysis. The JPGIS (Geographical Survey Institute, 2018), which is government-based open data, was used for geostatistics analysis. The On-premise type GIS and the WebGIS were used in the research. The QGIS (QGIS Development Team, FOSS4G, 2018), and the jSTAT MAP (Statistics Bureau, Ministry of Internal Affairs and Communications, 2019) were used for the each type of the GIS.

First, the variogram of the observed concentration data of the environmental substances, were calculated for the estimation of the spatial dependence, then the prediction of the concentration distribution on the target area were carried out by using the Kriging method. The estimated concentration data were examined together with other geographic information data using (Web)GIS. The expression scheme of the accuracy of the estimation were investigated on the QGIS. Furthermore, transformation of the coordinates that was required on the using of the jSTAT MAP was also investigated.

The year-round mean concentration distribution of $PM_{2.5}$ and oxidant in Okayama city were estimated with certain accuracy. It was also possible to qualitative analysis of the coefficient of variation of estimated distributions of $PM_{2.5}$ and oxidant by GIS and WebGIS. The minor error on the conversion from the rectangular coordinate system to the regional mesh code requires further consideration.

GIS is effective for analysis and mapping of the global environmental data and geographic information data. WebGIS is also becoming capable of executing these analysis with only by the Web browser. Further utilization is expected in the study field of the Earth and planetary science.

Keywords: GIS, jSTAT MAP, Kriging, FOSS4G, PM2.5, Oxidant

Development Process and Spatial Structure of Urban Villages in Shenzhen City China

*YARONG LUAN

During the 30 years of the reform and opening-up policy, economically developed cities and regions have expanded rapidly in China. Villages which originally surrounded the city before their expansion were rapidly submerged by the expanded city areas and surrounded by high-rise buildings. They are turned into the "urban villages". In the rapidly urbanized regions, urban villages are common phenomena. This problem becomes extremely serious in the Pearl River Delta region in China.

In the present study, Shenzhen City was selected as the research area. Field work was performed on the 18 sample urban villages selected from total 320 urban villages of Shenzhen City. Based on the changes in their internal spatial structures, the development of the urban villages is divided into three stages, e.g., embryonic stage, growth stage, reformed stage. After analyzing the spatial structures, different characteristic features were found in each stage. And the main factors of the spatial structural changes arising from different stages were summarized.

It was found that the traffic condition was the key factor for the embryonic stage; rental price was the key factor for the growth stage and the regulatory power of the government was the key factor for the reformed stage.

An analysis on the location characteristic of alley spaces in Tokyo

*Ryo Taniguchi[1], Go Ishikawa[1], Mayumi Oka[2]

1. Tokyo Map Research Inc., 2. Research Organization of Information and Systems The Institute of Statistical Mathematics

The number of alley spaces in urban areas is rapidly decreasing due to road transportation plans centered on automobiles and large-scale development. In recent years, however, aspects of the alley as a common space are being reconsidered, and town planning with the alley was also promoted throughout the country. The alley is considered to be an important factor characterizing urban spaces, but it is difficult to grasp its location as special information. So than before, we devised "Alley Estimation Logic" which extracts block areas where the existence of allays is presumed by using GIS, and have checked the accuracy of logic through field survey in Tokyo and Tokushima prefectures.
In this study, we conducted "Alley Estimation Logic" for Tokyo and estimated the alley location. For the analysis, we used “Foundation Geographical Data” (scale level 2500) made by Geographical Survey Institute and “ArcGIS Pro 2.2” by Esri. Furthermore, we calculated "Alley Ratio" from the estimation result and considered the location characteristics of the alley through comparison with the number of wooden buildings and the use district etc. In addition, we estimate the "Alley Ratio" of municipalities in Mie prefecture as a whole, and we will verify regional differences due to differences in prefectures.

Image analysis of night scape using lyrics

*Hiroki Komai[1], Kazunari Tanaka[1]

1. Osaka Institute of Technology

Night scape has a beauty that attracts people. In recent years, due to the spread of cameras and SNS, there are many new trends and new popular spots. As a byproduct, this seems to attract tourist. In this research, the characteristics of the night scape were analyzed using the photos and post contents from SNS. As a result, by the analysis to evaluate a part of the values, the examples: the perseverance, the painfulness and the merriment are appeared of the night scape.

On the Method to Evaluate Signboards based on the Relationship with the Surrounding Space

*Akihiro Kishikawa[1], Kazunari Tanaka[1]

1. Osaka Institute of Technology

The street space in the city is an important space to impress visitors with the image of the city.

However, in recent years, miscellaneous and townscapes are being formed due to the enlargement of buildings and the diversification of size, forms and colors of signboards.

The signboard design combines size, color, and letters together to create a signboard.

In this research, we aim at grasping the degree of group signs by checking the placement and colors appropriate to the characteristics of the place for Kyoto city.

Based on these relationships, we try to design a signboard suitable for the street.

ON THE LANDSCAPES ELEMENTS FROM A BIRD’S-EYE VIEW SCAPE

*Nobuaki Tanaka[1], kazunari Tanaka[1]

1. Osaka Institute of Technology

When it comes to landscapes, beautiful landscapes are formed from local climates such as history and customs by elements such as varying nature and demographic structures. A feature that creates these beautiful landscapes is the linear landscape element. This linear element is characterized as being beautiful because landscape elements that can be continuously viewed form a beautiful landscape such as a building that looks continuous due to the shape and color, in addition to linear landscape elements such as rivers and roads. Hypotheses concerning continuity and image are present not only in urban landscapes, but also in the landscape of rural areas and mountainous regions. Therefore, in this research, focusing on a bird's eye view from high vantage points, we aim to examine urban landscapes by analyzing their elements, shape, view and area. As for the examination method, analyzed and expressed the continuity of streets, rivers, green roads etc, using image analysis and GIS. From the results, extract and consider the relationship between the position and shape of elements with regards to continuity and the beauty of urban landscapes.

[H-CG31] Nuclear Energy and Geoscience

convener:Eiji Sasao(Tono Geoscience Center, Japan Atomic Energy Agency), Ryuta Hataya(Central Research Institute of Electric Power Industry), Shinji Takeuchi(Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University), Chairperson:Tadafumi Niizato

Handling of geological hazard assessments represent a major environmental concern in the modern society due to constructing nuclear facilities and their radioactive wastes, and also related to the management of contaminated biosphere after nuclear disasters of Fukushima-Daiichi Nuclear Power Plant. The session rational is to provide a forum to deal with various aspects of scientific and engineering aspects of nuclear power. The session in this year focuses on radioactive waste disposal and covers not only scientific aspect such as characterization of geological environment but also engineering aspects such as microbe-nuclide, mineral-water, and cement-water interactions. In addition to this, themes on seismic hazards at nuclear facilities, environmental behavior of radionuclides emitted from disabled nuclear plants, and volume reduction and reuse of cesium contaminated soils are welcomed. Through these presentations, we aim to promote intercultural communication and collaboration between science, engineering and social science.

Uplift estimation in coastal sea area by extrapolation of the land area model and its uncertainty

*Ryuta Hataya[1], Takaomi Hamada[1], Yohei Shimizu[1]

1. Central Research Institute of Electric Power Industry

1. Introduction

The research meeting of the METI in 2015-2016 discussed research issues of geological disposal in the coastal area [1]. After that, we began this study in August 2016[2]. In this study, finally, we’ d like to estimate the downward erosion under the coastal seafloor.

2. Method

We use the conventional method considering the future preliminary investigation for geological disposal siting [2, 3, 4, 5 etc.]. We drew the distribution map of the late Pleistocene uplift in the land using these data. Then, we construct a model of uplift motion after late Pleistocene in three dimensions on the basis of the uplift distribution and extrapolate it to the sea. Next, we have verified the model by discussing the uplift history from the tertiary to the recent. Furthermore, we’ ve discussed uncertainty of the extrapolation of uplift late from the land to the sea by the sensitivity analysis.

3. Case study

We have conducted the case study on the Miyazaki plain, which is known to have terraces widely distributed and the amount of uplift after the late Pleistocene is relatively large.

(1) Basic uplift model

Our basic model of the uplift in the case study area is a flat plate approximation model, which means monotonous tilting in one direction [2].

(2) Verification of uplift model by discussing the uplift history

The geological structure of the Neogene system shows tilting movement in the ESE direction [6]. The geomorphology and geological distribution of Pleistocene suggest tilting movement in the ENE direction. In addition, it is now rotating counterclockwise in North Kyusu district [7]. From these, the tilting direction in the late Pleistocene is considered to be in the ENE direction.

(3) Discussed uncertainty of the extrapolation of uplift late from the land to the sea

In addition to the basic data set, we have created multiple possible data sets reflecting the uncertainty of the survey. These are saved data of some areas from the basic data set, and some data are replaced based on working hypotheses of terrace chronology. We constructed models from each data set and compare the average uplift rate distribution models of the late Pleistocene of coastal sea area. In this examination, the difference in uplift estimation due to the amount of data was larger than the difference of terrace chronology.

4. Summary and future tasks

©2019. Japan Geoscience Union. All Right Reserved.

Needless to say, the uplift model in the land depends on the data set of the uplift, and discussion on geological history is useful for verification of the model. Also, in this presentation, we showed how to evaluate the effect of uncertainty deriving from data set and models (working hypothesis). We would like to continue case studies.

Acknowledgments:
This study was conducted as a project of the Ministry of Economy, Trade and Industry. Tono Geoscience Centre of Japan Atomic Energy Agency, DIA Consultant and Kawasaki Geological Engineering greatly helped us. For the survey of the sea area, we used the sea acoustic wave exploration records disclosed by the National Institute of Advanced Industrial Science and Technology. We express our deep thanks to their participants.

Deep groundwater mobility at costal area estimated by groundwater dating

*Takuma HASEGAWA[1], Kotaro NAKATA[1], Yuichi Tomioka[1], Tomoko Ota[1], Atsunao Marui[2], Isao Machida[2], Reo Ikawa[2], Masahiko Ono[2], Shinji Matsumoto[2]

1. Central Research Institute of Electric Power Industry, 2. The National Institute of Advanced Industrial Science and Technology

On high-level radioactive waste disposal, “Nationwide map of Scientific Features for Geological Disposal” was published and costal area is the favorable from transportation point of view. To evaluate deep groundwater mobility at coastal area, groundwater was sampled from deep borehole at the order of 1000 m in depth. Major ions, tritium, carbon-14, chorine-36 were measured. Based on these results, the groundwaters were categorized into four groups, which are modern meteoric water, modern seawater, glacial meteoric water, fossil sea water. Meteoric water and seawater was divided by 1900 mg/l of Cl concentration. Modern and old groundwater was divided by 10 pMC of ^{14}C concentration. The type of seawaters was well categorized into modern seawater and fossil seawater by ^{14}C concentration because residence times of modern seawater and fossil seawater are quite different. $^{36}Cl/Cl$ of Modern sea water is equivalent to that of present seawater ($\fallingdotseq 0.7\times10^{-15}$), and that of fossil sea water is higher than that of present seawater. It indicates that $^{36}C/Cl$ of fossil seawater influenced by in-situ production, which takes at least a few ten thousand years. Thus, the category of modern seawater and fossil seawater was validated by not only ^{14}C but also ^{36}Cl. Due to the lack of information, which are shallow groundwater and surface investigation, it could not be confirmed that modern meteoric water and glacial meteoric water was categorized by water isotopes and noble gas temperature. However, it is deduced the origin of Cl of meteoric water is from modern seawater and that of glacial meteoric water is from fossil sea water. It is though that the age of mixing water reflects the groundwater age.

As a result, the deep groundwaters at costal area were categorized into modern meteoric water and modern seawater about 40%, glacial and fossil seawater about 60%.

This study was performed under contracts “Development and Improvement on waste disposal system at coastal area” awarded by the Japanese Ministry of Economy, Trade and Industry.

Attempt to Estimate permeability of rock mass based on elasticity and resistivity measurement in underground tunnel

*Sota Kawaguchi[1], Tada-nori Goto[1], Koki Kashiwaya[1]

1. Graduate School of Engineering, Kyoto University

Fracture distribution in the rock has a great influence on the groundwater flow. So, it is necessary to grasp its characteristics for resource exploration and geological disposal of radioactive waste. Previous studies have been attempting to grasp the hydraulic characteristics on a local scale using boreholes and the like, but it is considered difficult to grasp the hydraulic characteristics in undrilled areas. In this study, we tried to estimate the permeability of rocks in deep underground from physical property values like resistivity and Young's modulus in order to grasp macroscopic hydraulic characteristics of rock including fracture. The validity of the present estimation method was examined, by comparing this estimated value with the measured value.

The survey area is the research tunnel exposed bedrock (depth 300 m, 500 m) of the Mizunami underground research labolatory of the Japan Atomic Energy Agency, located in Mizunami-city, Gifu Prefecture. In this area, a lot of logging data is published and the fracture distribution in the gallery is also examined in detail.(eg. Ishibashi et al.,2016) Furthermore, permeability of the same rock is measured in 2015 (Sato, 2015). In this study, we measured resistivity using a small electric surveying device (4 pole method with electrode interval of about 10 cm) in addition to these. Young's modulus was measured using a Schmidt-lock hammer.

In this study, the permeability was estimated using a rock physics model. The resistivity was expressed as follows using modified archie’ s law (Katsube and Hume,1983)(1).

$\sigma_{eff}=a\,\sigma_w\,\Phi^m+\sigma_c c$(1)

Where σ_{eff} is electrical conductivity of rock, $a$is toriosity, σ_w is relectrical conductivity of pore water, $\Phi$is porosity, m is cementation factor, σ_c is clay reistivity.The elasticity of rock, was expressed as follows using Gassmann’ s Relation (Gassmann, 1951) added clay effect (2).

$1/K=1/K_m+\Phi/K_w+c/K_c$(2)

Where K is bulk module of rock, K_m is bulk module of mineral, $\Phi$is porosity, K_w is bulk module of pore water, c is clay content, K_c is bulk module of clay. Where K is bulk module of rock, Km is bulk module of mineral, $\Phi$is porosity, Kw is bulk module of pore water, c is clay content, Kc is bulk module of clay. The porosity and the clay content rate were two unknown parameter, and these were determined from the measured values of resistivity and bulk modulus by Nelder-Mead method. Permeability was estimated from Kozeny-Carman's equation (Carman, 1961) for plane crack (3).

$k=\Phi t^2/8\,\tau^2$

k is permeability, $\Phi$is porosity, t is opening width, τ is tortuosity.

Estimated value of pemeability and measured value are consistent with estimated value and error of about one digit in many rock parts.

We will use other rock physics models like unsaturated pore and data obtained from laboratory experiments and loggingdate to further improve the estimation accuracy of permeability.

Study on relationship between pathway of groundwater and mass transport, and cooling process of granitic rock

*Eiji Sasao[1], Takashi Yuguchi[2], Masayuki Ishibashi[1]

1. Tono Geoscience Center, Japan Atomic Energy Agency, 2. Faculty of Science, Yamagata University

Fractures in the crystalline rock (e.g. granite) can act as the pathways for groundwater flow and mass transport. Therefore, understanding of the fracture distribution is an important subject for the disposal of high-level nuclear waste. The authors studied the relation between the formation of fracture and infilling mineral, and geological history from the emplacement to present in the Toki granite, Tono district, central Japan (Sasao et al., 2015). Ishibashi et al. (2016a) found that the micropores are selectively formed in plagioclases due to deuteric alteration and that those have the potential of acting as matrix diffusion paths. These results suggest that the magma cooling process played a significant role for the formation and development of the pathways for groundwater flow and mass transport.

The authors studied cooling process of granitic magma in the Toki granite, distributed in the southwestern part of Gifu Prefecture, central Japan, based on petrological, mineralogical and themochronological methodologies. We also discussed the relationship between magma cooling process, and fracture distribution and alteration of biotite and plagioclase (Yuguchi et al., 2019a, 2019b, 2015, 2012, Ishibashi et al., 2016a, 2016b, 2014). In this study, We present the relationship between formation of the pathway of groundwater and mass transport, and cooling process of granitic rock.

Fracture characterization in the accretionary complex from the view point of mass transfer

*Shinji Takeuchi[1], Chikara Kurata[1], Masakazu Niwa[2], Tadamasa Ueki[2]

1. Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University, 2. Japan Atomic Energy Agency

Introduction
As most of the basement rock of Japan is thought to be composed of accretionary complexes (Kano et al., 1998), accretionary prisms should not be ignored for the site selection of geological disposal of high-level radioactive waste. Because of many discontinuous structures such as faults and fractures formed due to the subduction of the plate in the accretionary complex, radioactive materials may migrate in the discontinuous structure together with the groundwater flow. Therefore, it is important to understand the characteristics of the mass transfer in along the discontinuous structure in the accretionary complex. In this study, we have carried out geological observation, permeability test in the laboratory, etc. using the samples containing discontinuous structures in the Neogene and Pre-Neogene accretionary complex (Takeuchi et al. 2018).

The study areas are Chichibu Belt (Akiruno City, Tokyo) for the Pre-Neogene accretionary complex, and Miura Group Misaki Formation (Miura City, Kanagawa Prefecture) for the Neogene accretionary complex. In the Misaki Formation, plain-less fault (Ijiri et al., 1955) in the mudstone are widely distributed. On the other hand, argillaceous matrix rock in the mélange which characterizes the accretionary complex are widely distributed. An optical microscope, scanning electron microscope (SEM) observation, X-ray fluorescence micro-scanner (XGT) analysis, permeability test, etc. have been were carried out using those samples.

2. Neogene accretionary complex

In the Miura Group Misaki Formation exposed to the southern tip of Miura Peninsula, plain-less faults are widely distributed. It was confirmed by SEM observation and XGT observation that there has been no change in the element distribution, although the host rock was granulated due to a cataclastic fracturing in the fault zone (Takeuchi et al. 2018). The porosity of the host rock and faults has been measured using SEM images. As a result of measurement, the porosity in the fault zone is about 1.2%, and that of the host rock is about 2.7%. In addition, hydraulic conductivity of the host rock without plain-less fault and the specimen perpendicular to the plain-less fault is estimated by the permeability test. As a result, the former is about 6 E - 9 (m / s), and in the latter is about 2E - 8 (m / s). This suggests hydraulic anisotropy in the formation with plain-less fault. From the above results, it is expected that a barrier effect on the mass transfer within the area surrounded by the plain-less fault.

3. Pre-Neogene accretionary complex

As a result of observation of thin sections, scaly cleavage due to shear deformation can be observed in the mudstone. In addition, concentrations of Fe have been confirmed along the cleavage from the XGT analysis. The concentration of Fe (the count number of XGT analysis) perpendicular to the cleavage shows almost restricted to the cleavage part, and diffusion has not been observed in the adjacent area. As a result of permeability test in the laboratory, the hydraulic conductivity parallel to the cleavage is estimated

©2019. Japan Geoscience Union. All Right Reserved.

about 4E - 8 (m / s), on the other hand, that perpendicular to the cleavage is about 2.5 E-8 (m / s). From the result above, it is assumed that faint hydraulic anisotropy exists in the mudstone matrix part. The reason for the small difference in hydraulic conductivity is thought to be connectivity of the curvature scaly cleavage or the weathering at the surface.

From the above results, it is considered that cleavage planes in the mudstone matrix can be selective migration pathways for mass transfer.

4. Summary

From this study, we have constructed a conceptual model showing the characteristics of material transfer in discontinuous structures in Neogene and Pre-Neogene accretionary complex. In the future, we have to improve the conceptual model from the mass transfer point of view properly by using deeper samples.

Retardation of Cs and Sr leachings by geopolymer matrices with zeolte and titanate adsorbent

*Kazuma Kuroda[1], Soonthornwiphat Natatsawas[1], Chaerun Raudhatul Islam[1], Hnin Wint Wint Two[1], Kanako Toda[1], Yutaro Kobayashi[1], Tsutomu Sato[2], Tsubasa Otake[2]

1. Graduate school of Engineering, Hokkaido University, 2. Faculty of Engineering, Hokkaido University

After the accident at the Fukushima Daiichi Nuclear Power Station (FDNPS) that occurred due to the Tohoku big earthquake in 2011, contaminated water with radioactive nuclides such as cesium (Cs) and strontium (Sr) have been continuously generated due to cooling of fuel debris by water. Zeolite or titanate adsorbents have been used for removing Cs or Sr from the contaminated water. The spent adsorbents would probably be solidified for the safety storage and disposal. Glass and cement have been proposed for solidifying binder. However, they have some disadvantages such as generation of secondary radioactive waste during vitrification and large amount of waste volume limited by bigger free water volume. Recently, geopolymer is considered as new binder which has potential to solve the above disadvantages for safety disposal of the spent adsorbent. Geopolymer has the potential to decrease total volume of solidified substances comparing cement because amount of containing free water is less than that containing cement. Primary phases of geopolymer such as calcium silicate hydrate (C-S-H) or potassium alumino silicate hydrate (K-A-S-H) may have property for sorbing radioactive nuclides. Furthermore, it is possible to obtain the desirable phases by changing the type and ratio of the starting materials. So, the appropriate primary phases could be designed depending on the type of the radioactive nuclide in disposed radioactive waste. However, there are few data about leaching behavior of radioactive nuclides from geopolymer in real disposal condition. In this context, this study was conducted leaching and sorption experiments to understand the leaching behavior from geopolymer with zeolite or titanate containing Cs or Sr.

In this study, geopolymer samples from mixing of KOH, metakaoline and water glass were investigated in leaching experiments. From the leaching experiments of Cs and Sr from geopolymer with titanate, most of Sr was tightly remained after 90 days even without titanate. This means that K-A-S-H matrix formed after the mixing has high capacity for Sr storage. On the other hand, small part of Cs (around 4%) was leached out after 90 days. However, although it is well known that Cs and Sr are easily leached out from cement matrix (A. El-Kamash, et al., 2006, and M. Takaoka, et al., 2015), K-A-S-H matrix is better in terms of Cs and Ss storage. From sorption experiments of Cs and Sr by using powder C-S-H and K-A-S-H samples as matrix components of cement and geopolymer, it is cleared that K-A-S-H has higher sorption capacity than that of C-S-H. From desorption experiment of Cs and Sr using deionized water from the C-S-H and K-A-S-H, it is cleared that almost of Cs was desorbed from C-S-H even for one day, while 90% of Cs was remained in K-A-S-H under the same condition. Consequently, K-A-S-H matrix in geopolymer has higher retention capacity than that of C-S-H matrix in cement. We conducted safety assessment for geopolymer and cement waste form in pit type disposal system using leaching ratio obtained in this study. From results of the assessment, K-geopolymer would be applicable for safety encapsulation and disposal of Cs and Sr as waste form.

[H-CG31] Nuclear Energy and Geoscience

convener:Eiji Sasao(Tono Geoscience Center, Japan Atomic Energy Agency), Ryuta Hataya(Central Research Institute of Electric Power Industry), Shinji Takeuchi(Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University), Chairperson:Shinji Takeuchi

Handling of geological hazard assessments represent a major environmental concern in the modern society due to constructing nuclear facilities and their radioactive wastes, and also related to the management of contaminated biosphere after nuclear disasters of Fukushima-Daiichi Nuclear Power Plant. The session rational is to provide a forum to deal with various aspects of scientific and engineering aspects of nuclear power. The session in this year focuses on radioactive waste disposal and covers not only scientific aspect such as characterization of geological environment but also engineering aspects such as microbe-nuclide, mineral-water, and cement-water interactions. In addition to this, themes on seismic hazards at nuclear facilities, environmental behavior of radionuclides emitted from disabled nuclear plants, and volume reduction and reuse of cesium contaminated soils are welcomed. Through these presentations, we aim to promote intercultural communication and collaboration between science, engineering and social science.

Discussion

Focus points of post-closure monitoring in geological disposal

*Hiroaki Murakami[1], Yusuke Watanabe[1], Kenji Fukuda[1], Teruki Iwatsuki[1]

1. Japan Atomic Energy Agency

To understand geological-environment stability at the deep underground, it is important to understand the hydrochemical disturbance process and its recovery process due to construction, operation and closure of the underground facility. Monitoring after closure of underground facility is effective method to understand the EdZ recovery process, however few studies have been reported on post-closure monitoring. We considered about focus points of post-closure monitoring by using hydrochemical data of groundwater in/around Mizunami Underground Research Laboratory.

As the groundwater level declined due to the construction and operation of the Mizunami URL, mixing of deep high-salinity groundwater and shallow low-salinity groundwater occurred in the monitoring section of conglomerate layer. In this section, groundwater flow will change again as water pressure recovers after closure of the Mizunami URL. Therefore, we should extract hydrogeologically important sections such as the conglomerate layer and select it as the observation section of post-closure monitoring.

5 years monitoring results for the environmental dynamics of radiocesium in mountainous forest of the Abukuma Mountains, Fukushima

*Tadafumi Niizato[1], Takayoshi Watanabe[1], Yoshito Sasaki[1], Katsuaki Mitachi[2], Satomi Ito[1], Hironobu Abe[1]

1. Japan Atomic Energy Agency, 2. ATOM TRANSPORT SERVICE CO., LTD

An understanding of long-term environmental dynamics of radiocesium, which is released by the TEPCO’s Fukushima Dai-ichi Nuclear Power Plant accident, is a key issue for predicting the future radiocesium distribution and forest products radioactivity in a forested environment, especially ^{137}Cs with half-life of 30 years. We compiled the five-years monitoring results of radiocesium input-output budgets in broad-leaved deciduous forests and Japanese cedar evergreen forests of the Abukuma Mountains, Fukushima, Japan. The input-output rates were a few percent of the radiocesium inventory of the monitoring site. In addition, both rates have been decreasing with time. Belowground radiocesium occupied 90% of the total inventory in the Japanese cedar forest on October 2015. The belowground radiocesium was distributed mainly in the topsoil of 0-6 cm depth, approximately 70-80% of the underground inventory on August 2016. These results indicate that the distribution of radiocesium in the forest is similar to the distribution of tree rootlet responsible for absorption of inorganic elements, nutrients, and water. This means long residence time of radiocesium in rooting zone. In the condition of the limited amount of radiocesium input-output rates in the forest, estimation of the migration flux of radiocesium from forest floor to the forest products are considered to be most important issues in the present.

Problems of geological disposal based on the contaminated water issues at Fukushima Daiichi NPS

*Naoaki Shibasaki[1]

1. Fukushima University

The contaminated water issues at the Fukushima Daiichi Nuclear Power Station (NPS) have not been solved yet even after 8 years since the severe nuclear accident. Many countermeasures against the issues have been implemented, however, the groundwater bypass and frozen soil wall are not effective as expected. This is due to lack of investigations and understanding on the complex geology and hydrogeology at the site. Based on the experience, the author examined the Nationwide Map of Scientific Features for Geological Disposal published in July 2017 by the Ministry of Economy, Trade and Industry, Japan. The map does not show detailed information on groundwater and hydrogeology. The author presents crucial points for geological disposal from the viewpoints of hydrogeology and groundwater flow system.

Keywords: Fukushima Daiichi NPS, contaminated water issues, groundwater, geological disposal, Nationwide Map of Scientific Features for Geological Disposal

Problems of the "Nationwide Map of Scientific Features for Geological Disposal" in Saitama prefecture and storage method of High-level Radioactive Waste (HLW)

*Kazuaki SEKINE[1], Kazuyuki SUENAGA[2], Tadao KOBAYASHI

1. Saitama Prefectural Chichibu High School, 2. SUENAGA Environmental Geology

The "Nationwide Map of Scientific Features for Geological Disposal" was announced by the Agency for Natural Resources and Energy in 2017. Candidate sites for suitable places and inappropriate places for geological disposal are shown by each color. In Saitama prefecture, the linear yellow part extending from the northwest end to the southeast direction is the most prominent unsuitable place. Other areas are mostly suitable.

In the northern part of Saitama Prefecture, there is the Kanto Plain Northwest Rim Fault Zone. The main one is the fault zone represented by the Fukaya fault and the fault zone represented by the Ayasegawa fault. This fault zone is evaluated as follows. The dip is southwest inclination of 50 ˚to 70 ˚(depth less than 500 m) , the width is about 20 to 25 km, the average slip speed is 20 to 40cm / 1,000 years, The latest activity period is after 6,200 years ago, before about 2,500 years ago. When this fault caused an earthquake, the predicted seismic intensity is the maximum magnitude 8.0 (The Headquarters for Earthquake Research Promotion Committee,2005).

The length of the Fukaya fault system is about 80 km (Sugiyama, 2000). According to the criteria of the "Nationwide Map of Scientific Features for Geological Disposal", since the inappropriate place related to the active fault is one hundredth of the length of the fault, the width of the inappropriate area of the Fukaya fault system is about 800 m. Since there is a possibility that the dip of the fault plane is 50 ˚, considering the horizontal spread, there is no sufficient basis for the width of the inappropriate area.

The depth of the epicenter of the earthquake caused by the Fukaya fault and the Ayasegawa fault is estimated to be 17 to 19 km and the magnitude of the earthquake is to be the maximum magnitude of 8.0. The area with seismic intensity of 7 is distributed in Honjo City, Yoshimi Town, etc. Also the intensity 6 is expected to be distributed in wide area in the prefecture. These areas are much wider than the areas that are regarded as inappropriate in the "Nationwide Map of Scientific Features for Geological Disposal". Since the depth of the epicenter is expected to be 17 to 19 km, there is a high possibility that a wide area suffers a strong shake.

Since the geological disposal site could be kept for more than tens of thousands of years, there is a possibility that a new active fault will destroy the site. As a result, the radioactive material leaks out and it is possible that it can be carried to the ground by groundwater. It is pointed out that groundwater flow is the most important requirement for geological disposal of radioactive waste (IAEA, 1977) , but the matter of groundwater flow is not reflected in the " Nationwide Map of Scientific Features for Geological Disposal ". Since the behavior of groundwater is not well understood in deep underground, classification of suitable sites by the "Nationwide Map of Scientific Features for Geological Disposal" requires detailed study of groundwater.

As the "Nationwide Map of Scientific Features for Geological Disposal" has many problems, construction

©2019. Japan Geoscience Union. All Right Reserved.

of the geological disposal site is not carried out until sufficient safety and understanding of the people are obtained, and it is appropriate to temporarily keep the radioactive waste on the ground etc. (Science Council of Japan, 2012). It seems necessary to seriously consider options other than geological disposal.

Discussion

Education and research for rehabilitation of agriculture against harmful rumors in nuclear disaster areas

*Masaru Mizoguchi[1]

1. Graduate school of Agricultural and Life Sciences, The University of Tokyo

Since the eastern Japan earthquake of 2011, various universities are carrying out educational programs that take students to the field and let the students recognize the importance of picking up on-site needs from the real field. This session convener also went to Iitate Village in Fukushima Prefecture three months after the nuclear accident, developed a unique agricultural land decontamination method in cooperation with NPO corporations and farmers, and has been experimentally cultivating crops. Also, since 2012, we have held students' field tours and have witnessed changes in student's awareness before and after the local visit. Through these experiences, we have come to the idea that it is necessary to nurture young people who will challenge the creation of a new Japanese type agriculture in Fukushima. "Educational research program for revitalizing agriculture and elimination of bad rumor in Iitate village" is being carried out at the Ministry of Education, Culture, Sports, Science and Technology's "Fukushima Innovation Coast Concept Promotion Project. In this session, members of the Japanese Society of Soil Physics will report changes in student’s consciousness observed through on-site education and field research, and discuss social value of university.

Towards the reborn of Iitate village 'Agriculture'

Makoto Sugisoka[2], *Masaru Mizoguchi[1]

1. Graduate school of Agricultural and Life Sciences, The University of Tokyo, 2. Division of Reconstruction Measures, Iitate Village

In Iitate Village where all villagers were evacuated due to the accident of TEPCO Fukushima Daiichi Nuclear Power Plant, evacuation order were canceled in March 2017 except for some areas. Because of lack of living environment and anxiety about radioactivity in the environment, the number of people who actually settle in Iitate village is less than 10%. However, the Iitate Village Office has proposed four agricultural plans (For protecting agricultural lands, For fun-to -live, For livelihood, For challenging new agriculture) according to the wishes of farmers, and is striving for the revival of "agriculture". In this presentation, I will introduce such efforts.

Keywords: Iitate Village, agriculture, reborn

Difference among crop species by radiocesium absorption from different soil fractions

*Nihei Naoto[1], Yoshimi Ohmae[1], Makoto Furukawa[1], Syuichiro Yoshida[1]

1. The University of Tokyo, Graduate School of Agricultural and Life Sciences

Radioactive cesium (137 Cs) contaminated widely due to Fukushima Daiichi Nuclear Power Plant accident. The presence form of 137 Cs in soil can be divided into a fraction (adsorbed to ion exchange state or organic matter, defined as f 1 fraction) which crops are considered to be easy to absorb and utilize, and the another fraction (strong acid extraction and total decomposition component by hydrofluoric acid, defined as f2 fraction) which crops are considered to be difficult to absorb and utilize.

If we know how much 137 Cs will be absorbed from which soil fraction, we can grasp the Cs absorption characteristics of a crop. However, there has been no research report on a method showing 137 Cs absorption from each soil fraction. In this study, to grasp the soil fraction absorbing 137 Cs of the crop, the transfer factor (defined as TFf 1 and TFf 2) from each soil fraction were investigated by using the naturally occurring stable isotope cesium (133 Cs) . In addition, absorption ratios (defined as λ 1 and λ 2) in crops derived from each soil fraction were calculated.

Soybean, buckwheat and rice were cultivated for 30 days in a pot, and the 133 Cs and 137 Cs concentrations in the aerial part were measured. Contaminated soil (137 Cs approx 22 kBq / kg, 133 Cs approx. 3.4 mg / kg) obtained by topsoil stripping due to decontamination in Fukushima prefecture was used for soil. The soil after cultivation was successively extracted (ammonium acetate extraction, hydrogen peroxide decomposition, nitric acid decomposition, total decomposition by hydrofluoric acid), and the concentrations of 133 Cs and 137 Cs contained in each fraction were measured. In order to simplify the calculation, the soil fraction was set to two fractions of f1 (ammonium acetate extraction, hydrogen peroxide decomposition) and f2 (nitric acid decomposition, total decomposition by hydrofluoric acid). Measurement of 133 Cs was measured by ICP mass spectrometer (Perkin Elmer, Nex ION 350 S), measurement of 137 Cs by NaI scintillation counter (Perkin Elmer, Wizard). Judgment of each soil fraction absorbed by crops was calculated by 133 Cf 1 ×TFf 1 + 133 Cf 2 ×TFf 2 = 133 Ccrops, 137 Cf 1 ×TFf 1 + 137 Cf 2 ×TF f 2 = 137 Ccrops.

Cf1 or Cf2 is the Cs concentration of the soil in f1 or f2 fraction, TFf1 or TFf2 is Cs transfer factor from f1 fraction or f2 fractionation soil to crop, and Ccrop shows Cs concentration of crop.

TFf 1 and TFf 2 were different depending on the crop, soybean had higher absorption from f 2 fraction than buckwheat. Absorption from f1 fraction in 137 Cs of crops was 66% for soybean, 89% for buckwheat, 76% for rice, confirming the difference between crops. Furthermore, the effect of suppressing Cs absorption by potassium fertilization was shown to be different for each crop. By devising and defining these indices, it was possible to grasp the absorption capacity of crops.

Wild vegetables and mushrooms retrieving agriculter in Iitate Village, Fukushima Prefecture

*Kosuke Noborio[1], Yudai Fukuyama[2], Satoko Fujita[1], Hiroaki Sugino[2], Masaru Mizoguchi[2]

1. Meiji University, 2. the Univewrsity of Tokyo

Wild vegetables and mushroom at mountaineous slopes could be key agricultural products in Iitate Village in the future. Radiocesium fallout from the Fukushima Daiichi Nuclear Powerplant contaminated surface soils in its vicinities. Removal of contaminated surface soils was recently completed in agricultural fields, but not in forest areas where wild vegetables and mushrooms were grown. Pine mushroom is one of the precious wild mushrooms in Japan because it has not been successfully grown under controlled environments. We thought pine mushroom could be a key agricultural product for retrieving agriculture in Iitate Villege. Soil and air temperatures in a litter layer were measured to know environmental condidition of growing pine mushroom. We report the preliminary results of the environmental conditions.

Effect of Study Tour toward Participants' Attachment on the Study Site - Case Study of University Student Tour to Iitate Village, Fukushiima Prefecture -

*Natsumi Ebitani[1], Masaru Mizoguchi[1], Hiroaki Sugino[1]

1. Graduate school of Agricultural and Life Sciences, The University of Tokyo

Reconstruction in the affected areas of the Great East Japan Earthquake is progressing, but now there have been many people who feel less interested in understanding of the current situation and remained damage. In order to advance the further development after the basic reconstruction with lessons learned from the disaster, it is necessary to communicate the charm of the area to people outside of the affected area and make opportunities for rural exchange. Therefore, the authors are considering regularly holding study tours to the affected area. This presentation introduces a one-night two-day study tour as a case study for Iitate Village in Fukushima Prefecture held three times from October to November 2018. Before and after the tour, we conducted a questionnaire survey on a total of 44 participants (university students) who are mainly majoring in agriculture, and analyzed the obtained data by co-occurrence network analysis and factor analysis. In the end, this study discusses the effect of the tour on students' attachment to the tour site, and examined how future study tours should be.

Shrinking and draining continental lower crust: its binary effects of stress and fluid on crustal activities

*Takehito Koyama[1]

1. Institute of Industrial Science, the University of Tokyo

Basically, the continental crust itself is presumed to be static passive polycrystalline rocks with its ductility in the aseismic deep. However, this ductility seems difficult to explain crustal activities still debated: not only the long-standing stability (the resistivity to the isostatic decay) but also the short-term activities, e.g., inland horizontal compressive state (Zoback, et al. (1989)), intracrustal seismicity (Calais, et al. (2016)), and rare lower crustal earthquakes (Simpson (1999)).

Then, can we rethink the crust, especially its controversial lower? Actually, I presented a possibility of the shrinking and draining of the continental crust through “phase separation or phase demixing” at JpGU in 2012. Thus, I will propose a new lower crust causing the deformation, qualitatively but comprehensively discussing the activities.

As basic components of the lower crust, I consider SiO_2 and H_2O (with other elements and volatiles). Their melt mixtures cause phase separation under lower crustal temperatures and pressures (Kawamoto (2006), Hack, et al. (2007)). Furthermore, melt SiO_2 forms 3-dimensional macromolecular network (Stebbins (2016)). Thus, I regard this process as the volume shrinking of this elastic SiO_2 network separating from an aqueous fluid (Tanaka (2012), Koyama, et al. (2009), Koyama and Tanaka (2018); also the shrinking SiO_2 in Tognonvi, et al. (2011)): This network macroscopically behaves as a phase-separating glass (before crystallization) or an elastically hard self-squeezing wet sponge.

Then, the new lower crust, constructed by the shrinking SiO_2 network draining the H_2O fluid, combines and interacts with the usual upper crust (Figure): The elastic shrinking laterally compress the upper crust from below, bringing the long-term stability and intermittent drained-fluid injections triggering the intra-upper-crustal earthquakes. Importantly, this lower crust, aiming at shrinking, must follow some degree of external compression: the aseismicity or the apparent ductility. However, when the elastic SiO_2 network suffers a large local differential stresses under the stress/fluid interlayer interactions, the brittleness should arise as lower crustal seismicity.

Therefore, assuming the lower crust to be not monistic solid but dualistic solid/fluid coexisting during their phase separation, we can qualitatively explain the crustal movements using the actively shrinkable/drainable lower crust mechanically/materially interacting with the upper crust.

Keywords: Continental crust, Stability, Stress, Seismicity, Phase separation

Seismic velocity structure in southern Hokkaido deduced from ocean-bottom seismographic and land observations

*Yoshio Murai[1], Kei Katsumata[1], Tetsuo Takanami[2], Tomoki Watanabe[3], Tadashi Yamashina[4], Ikuo Cho[5], Masayuki Tanaka[6], Ryosuke Azuma[7]

1. Institute of Seismology and Volcanology, Faculty of Science, Hokkaido University, 2. Department of Terrestrial Magnetism, Carnegie Institution of Washington, 3. Marine Works Japan LTD, 4. Kochi University, 5. National Institute of Advanced Industrial Science and Technology, 6. Meteorological Research Institute, 7. Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University

The Kuril arc collides with the northeast Japan arc in the southern part of Hokkaido, Japan. Such a collision results in building the Hidaka Mountains and is related to the seismic activity and large earthquake occurrence such as the Urakawa-Oki earthquake (Ms 6.8) on March 21, 1982. It is important to image the three-dimensional crustal structure in order to clarify the collision tectonics and understand the patterns of earthquake occurrence and the mechanism of large earthquake occurrence. A group of seismologists from eleven universities operated a dense temporary network of land stations from 1999 to 2001 in and around the Hidaka Collision Zone [Katsumata *et al.* (2002, Bull. Earthq. Res. Inst., **77**)]. In addition, we conducted ocean-bottom seismographic observations in 1999 and 2000 in the south off Hokkaido region. Murai *et al.* (2003, GRL **30**) estimated P-wave velocity (Vp) structure by the 3-D tomographic inversion [Zhao *et al.* (1992, JGR **97**)] of seismic travel time data obtained from networks of ocean-bottom seismographs (OBSs) and land stations in 1999. However, their spatial resolution was poor for the deep crustal structure and they could not obtain S-wave velocity (Vs) structure because of limitation of the number of data. Murai *et al.* (2016, JpGU) estimated structure of both Vp and Vs by the tomographic inversion of travel time data from OBSs and land stations in 1999 and 2000. We found a problem in the reduction of the travel time residuals due to errors of station corrections in their analysis. Here we estimate Vp and Vs structure again after correcting their errors.

The results from the tomographic analysis are as follows.

1. A high-velocity body seems to be obducted toward the crest of the Hidaka Mountains from east beneath the land area, which is interpreted as the obducted lower crust of the Kuril arc. The high-velocity region extends to the east of the Hidaka Mountains at depths of 15-35 km. A low-velocity region is located to the west of the Hidaka Mountains so as to contact with the high-velocity region at the Hidaka main thrust. It is interpreted as the northeast Japan arc. These results are consistent with those obtained by previous tomographic studies.

2. We found a distinct low velocity region dipping southwestward from beneath the Hidaka Mountains to the source area of the 1982 Urakawa-oki earthquake at depths of 35-45 km which was imaged only by the tomographic analysis using the data from OBSs. It is interpreted as the lower part of the delaminated Kuril arc lower crust, which has an area of about 50 km wide by 50 km long.

3. The colliding low-velocity crustal material disappears in the southeast of Cape Erimo. Moreover many microearthquakes occurred in the low-velocity region whereas the seismic activity was low outside it. These results suggest the effect of arc-arc collision is reduced abruptly in the offshore area as the southeastward extension of the Hidaka Mountains.

©2019. Japan Geoscience Union. All Right Reserved.

4. The hypocenter of the 1970 Hidaka earthquake (M 6.7) is located at the boundary between the high and low velocity regions. The fault plane of the 1982 Urakawa-oki earthquake is located at the western boundary of the high Vp anomaly faster than 8.0 km/s. Thus these M7 class inland earthquakes occurred at material boundaries, which is consistent with Kita *et al.* (2012, JGR **117**).

5. The overriding plate above the seismogenic asperity of the 2003 Tokachi-oki earthquake (M 8.0) is characterized by high Vp/Vs on the northeast side of Cape Erimo. This result is consistent with Machida *et al.* (2009, Tectonophysics **465**).

Acknowledgments
We thank the crew of the R/V Kofu Maru of the former Hakodate Marine Observatory for their cooperation during deployment of OBSs. We thank D. Zhao for permitting us to use his computer program for 3-D tomographic inversion.

Structural Complexity Associated with Arc-Arc Collision in Hokkaido Island, Japan - Review on Controlled-Source Seismic Researches in Western and Central Hokkaido -

*Takaya Iwasaki[1], Noriko Tsumura[2], Tanio Ito[3], Kazunori Arita[4], Hiroshi Sato[1]

1. Eathquake Research Institute, the University of Tokyo, 2. Graduate School of Science, Chiba University, 3. Association for the Development of Earthquake Prediction, 4. Hokkaido Research Center of Geology

Hokkaido Island has a complicated crustal structure reflecting subduction, accretion and collision processes from Late Jurassic to the present (e.g. Niida and Kito, 1986; Kimura, 1986; Ueda 2016). Central Hokkaido is composed of almost N-S trending geological units of the Sorachi-Yezo Belt (SYB), Hidaka Belt (HB) and Tokoro Belt (TB) from west to east. This region has been highly deformed under the dextral oblique collision between the Eurasia and North America (Okhotsk) Plates and the following westward movement of the Kuril Arc due to the oblique subduction of the Pacific Plate. The latter event has formed the Hidaka Collision Zone (HCZ) with the uplift of the Hidaka metamorphic rocks along the Hidaka Main Thrust (HMT) and the development of the west-verging fold-and-thrust belt with thick sedimentary package on the SYB.

In this paper, we review the previous controlled-source seismic studies in western and central Hokkaido, focusing the structural complexity formed by the arc-arc collision. The first seismic refraction study was undertaken in western Hokkaido in 1968-1969 (Okada et al., 1973). The crust obtained is 20-30 km thick, consisting of 5.9 and 6.6 km/s layers overlying the uppermost mantle of 7.5 km/s. Seismic refraction studies in 1984 and 1992 revealed the complicated structure in central Hokkaido (Iwasaki et al., 1998). The result from the 1984 profile along the Pacific coast is characterized by a rather thick (> 7 km) sedimentary package with a velocity of 2.5-5.5 km/s in SYB. The 1992 refraction/wide-angle reflection profile, which was extended from the western SYB to the eastern TB with SW-NE direction, also show a thick (~8 km) sedimentary package with a velocity of 2.6-5.8 km/s in the southwestern part of SYB, The upper crustal velocity show significant increase from 5.6 km in HB to 5.7-6.15 km in TB.

In 1990’s, several seismic reflection and refraction/wide-angle refraction experiments were undertaken in the southern HCZ (Arita et al., 1998; Tsumura et al., 1999; Ito et al., 2000) and the northern HCZ (Iwasaki et al., 2004, 2016). In the southern HCZ, the crustal delamination by the collision was clearly imaged from the reflection data by applying an advanced method of CRS/MDRS stacking (Tsumura et al., 2014). Namely, the upper 22-23 km crust in the Kuril Arc side is obducted along the HMT, while the lower part of the crust is descending almost to reach the Pacific plate. In the northern part of the HCZ, the detailed structure was obtained along the 227-km profile with E-W direction. In the fold-and-thrust belt of SYB, there exists a very thick (> 10-12 km) sediments including two or three velocity reversals. East of this package, several west-verging events are recognized down to a depth of 7-8 km, probably corresponding to the faults and structural boundaries formed by the collision process. The HMT was well imaged both by seismic reflection processing and refraction/wide-angle reflection analysis, along which the crystalline basement is almost outcropped. Beneath these complicated structures, we succeeded in imaging the NE Japan Arc crust which descends eastward to a depth of about 40 km under the hinterland side.

In the northern HCZ, the clear crustal delamination is not seen. The obduction of the upper Kuril crust starts at a deeper crustal level of at least 27-30 km and more easterly (~20 km) of the HMT as compared

©2019. Japan Geoscience Union. All Right Reserved.

with the case in the southern HCZ. If the metamorphic rocks outcropped east of the HMT are the same crustal materials at depths shallower than 23 km as in the case of the southern HCZ, the deeper crustal portion originally situated at 23-27~30 km depth must exist in the western side of the present HMT. The very strong and deep reflectors found west of the HMT might result from the mixture of upper crustal (low velocity) materials of the NE Japan Arc and middle/lower crustal (high velocity) materials of the Kuril Arc.

Seismic imaging of the eastern Japan forearc region using S-net data

*Genti Toyokuni[1], Dapeng Zhao[1], Naoki Uchida[1], Takashi NAKAYAMA[1]

1. RCPEVE, Tohoku Univ.

The great 2011 Tohoku-oki earthquake (Mw 9.0) occurred off the Pacific coast of Northeast Japan, where the Pacific plate is subducting beneath the Okhotsk plate. The S-net (the Seafloor observation network for earthquakes and tsunamis along the Japan Trench), initiated in 2016, is a large-scale, permanent, ocean-floor seismograph network with cabled 150 stations, which covers a wide oceanic region off Northeast Japan (Kanazawa, 2013). In this study, we aim to reveal the 3-D seismic velocity structure beneath the forearc region covered by the S-net.

We carefully picked 3754 first P-wave arrival times of 63 local earthquakes (M3.5–6.2) in the Tohoku forearc region from the continuous S-net records. Then, the newly picked data are integrated with the existing arrival-time data (Zhao et al., 2012) of 360 teleseismic and 1,180 local earthquakes recorded at 3,205 Hi-net stations on the Japanese land areas. These combined data are inverted to obtain a new 3-D P-wave velocity (Vp) model beneath the entire Northeast Japan arc by using the seismic tomography method of Zhao et al. (2012).

In this work we focus on the obtained 3-D images at depths < 40 km below the region covered by the S-net. The major results are summarized as follows.
(1) Prominent low-Vp anomalies are revealed in the off-Iwate and off-Fukushima areas. These features are consistent with those revealed by previous works (e.g., Zhao et al., 2011; Huang & Zhao, 2013; Liu and Zhao, 2018), indicating that our hand-picked arrival-time data are quite accurate and robust.
(2) A significant high-Vp anomaly is revealed along the Japan Trench especially beneath the off-Miyagi region where the 2011 Tohoku-oki earthquake (Mw 9.0) occurred, which may reflect that the sedimentary layer is very thin above the subducting Pacific plate.

The relationship between the location of the mid crustal reflector and seismicity in Iwaki area, northeastern Japan

*Takashi Iidaka[1], Shin'ichi Sakai[1], Toshihiro Igarashi[1], Kazushige Obara[1], Aitaro Kato[1], Tetsuya Takeda[2], Shigeki Nakagawa[1]

1. Earthquake Research Institute, University of Tokyo, 2. National Research Institute for Earth Science and Disaster Resilience

The Tohoku-Oki earthquake occurred on March 11, 2011. After the 2011 Tohoku-Oki earthquake, the seismicity in Japan changed. The seismicity increased in some areas. The seismicity decreased areas also exist. It has been considered that the change of the seismicity is related to the change of the stress field caused by the large slip at the plate boundary. The Iwaki area, northeastern part of Japan, is one of the areas that the seismicity changed. The seismicity in this area increased drastically. Before the 2011 Tohoku-Oki earthquake, the seismicity was very low. But, the seismicity increased after the Tohoku-Oki earthquake. The cause of the changes of seismicity was not clear. It is very important to survey the crustal structure in order to understand the mechanism of the seismicity in this region. The characteristics of the seismicity of the area are following. The earthquakes were occurred within a triangle area. The size of the one side of the triangle was around 50 km. The crustal seismicity in the area divided into two depth range. The seismicity in the shallower area is less than 15 km. The depth range of the other group is 15–25 km.

A temporary dense seismic array (63 seismometers) has been deployed to know the seismicity and mechanism in this area. Usuda (Master thesis 2018) studied the crustal structure using this data. The crustal structure was studied with a reversed VSP (Vertical Seismic Profile) method. The clear two later phases were detected. One of the later phases was the reflected wave at the Moho boundary. The other phase was the reflected phase at the middle of crust. The location of the boundary of the middle of the crust was consistent with that of seismic activity area inside the crust. The amplitude of the reflected wave was very large. It was expected that the reflected wave was caused by the reflector with fluid.

We researched that the relationship between the seismicity in this area and location of the mid-crustal reflector. In this area, the seismicity increases from March, 11, 2011. The seismicity started at the southern part the reflector. The seismicity increased in and around reflector area from Mar., 11 to Apr. 10, 2011. At the northern part of the reflector, a relatively low-seismicity area appeared. On the Apr., 11, 2011, the Hamadori earthquake occurred in the low-seismicity area. We suppose that there is some relationship between the seismicity of the area and reflector. If the reflector is caused by the crustal fluid, the increase of the seismicity in Iwaki area might be related to the crustal fluid.
The outline of reflector obtained by Usuda (Master thesis 2018) is related to the location of the temporally seismic stations. In Iwaki region, the earthquakes are located at the north of the reflector. We want to know the true size of the reflector. We researched the waveforms of the seismic stations located in the north of the reflector area. Hi-net and F-net stations were used. The later phase with large amplitude was found at the seismic stations. We found the reflector at the north of the reflector of Usuda (2018).

Abnormal Seismic Anisotropy beneath the Tokyo Metropolitan Area (1) Mantle of the Philippine Sea Slab

*Motoko Ishise[1], Shin'ichi Sakai[1], Aitaro Kato[1], Shin Aoi[2], Makoto MATSUBARA[2]

1. Earthquake Reseach Institute, University of Tokyo, 2. National Research Institute for EarthScience and Disaster Resillience

1. Introduction

The Tokyo metropolitan area is located on a unique convergence zone associated with the North American (NA) plate: beneath the metropolitan area, dual subduction system was formed by the Pacific (PAC) and Philippine Sea (PHS) plates. Furthermore, subduction of the PHS slab brings a collision zone between the NA plate and the Izu-Ogasawara islands arc, which is on the PHS slab, in the vicinity of the metropolitan area. Therefore, the metropolitan area is seismically active and has various types of earthquakes. However, the relationship between the configuration of plates (the NA, PAC, and PHS plates) and the seismicity remains unknown, although seismo-tectonics of the region has been studied from the various points of view, such as earthquake mechanism, hypocenter distribution, and seismic velocity structure. Thus, we focus on seismic anisotropy that could provide useful information on dynamics and tectonic. In this study, we investigate the three-dimensional (3D) structure of P-wave azimuthal anisotropy beneath the Tokyo metropolitan area.

2. Data and Method

The modeling space is the Tokyo metropolitan area (34.7 - 36.8˚N, 138.5 - 141.5˚E, 0 - 150 km). In order to determine 3D P-wave azimuthal anisotropy velocity structure, seismic anisotropy tomography method of Ishise and Oda [2008] was applied to 442960 P wave arrival time data from 1859 local earthquakes recorded at 500 seismic stations, including 296 Meso-net stations. Initial source parameters (location and origin time of earthquake) used in this analysis were determined independently by NIED. The 3D velocity structure in the modeling space is described by velocity parameters assigned to a 3D grid structure. The grid structure was composed of 0.1˚ - 0.2˚ grid spacing in the latitude and longitude directions. In the vertical direction, grid nodes were spaced at 5 - 20 km.

3. Results

As a result of the tomographic analysis, we found a unique anisotropy region in the lower edge of the PHS slab mantle, or rather the contact zone between the PHS and PAC slabs. The region has strong anisotropy, and the fast axes are uniformly oriented in the N-S trending direction. Generally, anisotropy in the slab can be explained by lattice preferred orientation of mantle minerals or alignments of cracks and faults. However, any mechanism cannot explain the N-S trending anisotropy in the PHS slab beneath the study area. It might suggest that the modeling under the assumption of azimuthal anisotropy would be inappropriate for the study area. Alternatively, it is possible that we have to change our basic idea of the subduction zone.

Acknowledgments: We used Hi-net seismological data. This study was supported by the Tokyo metropolitan project.

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

Thu. May 30, 2019 3:30 PM - 5:00 PM JST | Thu. May 30, 2019 6:30 AM - 8:00 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[S-SS12] Crustal Structure

convener:Kazuo Nakahigashi(Tokyo University of Marine Science and Technology), Chairperson:Tsuruga Kayoko(Tokyo University of Marine Science and Technology), Yojiro Yamamoto(Japan Agency for Marine-Earth Science and Technology)

The aim of this session is to cover seismological and geophysical studies on the Earth's crust. Contribution on seismological and geophysical structure of the crust, processes that develop in the crust which include earthquakes, volcanoes and geological descriptions of the crust are welcomed. We also welcome theoretical and methodological studies that will serve as basics in such explorations.

An onshore-offshore seismic data set was collected across the Suruga bay in 2018 to determine the deep structure of the subducting Philippine Sea plate (PHS), whose upper surface is estimated to be a seismogenic source fault of the Fujikawa fault system. Three-component of land seismometers (GSX) were deployed with a spacing 100 –200 m from the southern range of Akaishi Mountains to Yui and western part of Izu Peninsula along the seismic lines using total 300 seismometers along the 40-km-long seismic lines. Three-component of ocean bottom seismometers (OBSs) were deployed with spacing of 1 km on the sea bottom deeper than 500 m along the 18 km-long marine part. Five shallow marine ocean bottom seismometers (OBXs) were deployed at the shallow marine western part of Suruga Bay along the 2-km-long interval. They recorded seismic shots generated from four, 200 kg dynamite shots and air gun array with a total volume of 1950 cu. inch. Total number of shots by air gun array was 1479 and shot spacing was 25 m. Data quality is good, allowing the identification of clear refraction by air gun array in the integrated shot gathers. Multi-channel seismic data were also collected towing a 600-m-long streamer cable with 96-ch hydrophones (Tsuruga et al., 2019 JpGU). The redatumed seismic data were produced using interferometric OBS imaging method (Shiraishi et al., 2016). All seismic data were processed according to a standard common-midpoint (CMP) stacking and a post stack time migration. We used refraction tomography to determine the P-wave velocity structure, that revealed down to 10 km in depth beneath the central part of the seismic line. Obtained post-migrated time section portrays the west-dipping reflectors from 3.5 sec (TWT) to 7 sec beneath the eastern part of the Suruga bay, from 5 to 11 sec beneath thesouthern range of Akaishi Mountains. The migrated time section was depth converted using the velocity structure obtained by earthquake tomography based on Hi-net data. On the depth section the depth to an estimated upper surface of PHS is 7 km beneath Yui, western coast of Suruga bay, and 15 km in beneath the central part of land seismic line in the Shizuoka side. The p-wave velocity structure deduced by refraction tomography reveal the wedge-shaped low-velocity area beneath the western part of Suruga bay. The velocity structure accords well to the subduction of PHS and distribution of hypocenters.

The onshore-offshore seismic survey was performed under the Integrated Research Project on the Fujikawa-kako fault zone funded by MEXT. This survey also supported by the research fund of ERI, Univ. Tokyo.

Multi-channel seismic profiling in the northern part of Suruga bay using the Shiyomaru-vessel of Tokyo University of Marine Science and Technology (Preliminary report)

*Kayoko Tsuruga[1], Hiroshi Sato[2], Hisatoshi Baba[3], Yoshihiro Sekino[1], Toshifumi Hayashi[1], Hayato Kondotec[1], Chiharu Aoyama[1], Tetsutaro Aikawa[1], Tatsuya Ishiyama[2], Masanao Shinohara[2], Shinji Kawasaki[4], Yasuhisa Tanaka[4]

1. Tokyo University of Marine Science and Technology, 2. University of Tokyo, 3. Tokai University, 4. JGI, Inc.

There is few detail observations and studies about the subduction structure in Suruga trough area as a plate boundary between the Philippine sea plate and Eurasia plate. It is very important to understand the detail structure of Fujigawa fault system to prevent and reduce earthquake disaster by future Tokai earthquake. We have been trying to clarify a shallow structure in this important area by means of both seismic reflection and refraction surveys since 2016 and 2017 (Tsuruga *et al.*, 2016, 2017, 2018). In this report, we show the preliminary results of the seismic reflection and refraction surveys in Suruga Bay, Central Japan, conducted by Shiyomaru-vessel of Tokyo University of Marine Science and Technology (TUMSAT) cooperated with University of Tokyo and Tokai University.

We conducted the 2-D seismic reflection and refraction survey with air-guns and streamer cable system in Suruga Bay, from Oct. 1 to 9, 2018, along three surrey lines (*i.e.*, H30-L00/R00, H30-L01 and H30-L02 lines) which were located in the northern part of Suruga bay with the length of 19.5 km, 20.0 km and 16.1 km, respectively. We used two Bolt air-gun source systems of 'Tri-Gun' 1500LL (350 cu.in x 3) and 1500LL (300cu.in x 3) with a total air volume of 1,950 cu.in for H30-L00/R00 and H30-L02 survey lines with a shot interval of 50 m while we used Tri-Gun 1500LL (350cu.in x 3) with a volume of 1050cu.in with a shot interval of 25 m along H30-L01 line. Total shot number was 2717. Hydrophone receivers array consisted of Hydroscience digital streamer cable including 96 channel sensors with an interval of 6.25 m inside a cable of 600 m long, and a small tailbouy. TUMSAT research vessel 'Shinyomaru' has the following principle specifications: length, beam, and gross tonnage are 65 m, 12.5m, and 986 tons, respectively. Details of the refraction survey across a land area and oceanic area will be shown by Sato *et al.* and Baba *et al.* (in this meeting, 2019).

Preliminary results show some important features as follows: Reflection section of H30-L00 indicates a continuous west-tilting reflection phase which may be located around an upper boundary of the sedimentary layers over the subducting oceanic plate toward west. These reflection phases might be continued to the those along H29-L02 located in the northern area and H30-L02 and H28-L03 located in the southern area. We have not found the dominant characteristics of subduction boundary in these observations. Along H30-L01 we might find an interesting feature as a boundary between Honshu block and Izu peninsula. The details of our result will be shown in the presentation.

This study was supported by fond from the Ministry of Education, Culture, Sports, Science and Technology. We appreciate the big cooperation by Shizuoka prefecture Federation of Fisheries Cooperative Associations and many Fishery Cooperatives around Suruga Bay to understand our study. We thank Tokai University for helping us in an ocean by a vessel 'Hokuto'. Finally, we greatly thank Shinyomaru's crews and many staffs of our university for their encouragement and helps.

Crustal structure refraction survey using Airgun-OBS in the northern part of Suruga Bay -Fujikawa fault zone- (Preliminary Report)

*Hisatoshi Baba[1], Kayoko Tsuruga[2], Hiroshi Sato[3], Tatsuya Ishiyama[3], Masanao Shinohara[3], Takahito Nishimiya[4], Shintaro Abe[5]

1. Department of Marine and Earth Science, Tokai University, 2. Tokyo University of Marine Science and Technology, 3. Earthquake Research Institute, University of Tokyo, 4. Meteorological Research Institute, Japan Meteorological Agency, 5. Association for the Development of Earthquake Prediction

As part of the exploration of the crustal structure of the Ministry of Education, Culture, Sports, Science and Technology "Priority investigation observation in the Fujikawa fault zone" (Sato et al., 2019 (the present Society); Tsuruga et al., 2019 (the present Society)), in Suruga Bay Reflection and refraction seismic survey by the Tokyo University of Marine Science and Technology, practice ship "Shinyo Maru (986 tons)" was carried out at a survey line of about 19 km (H30 - L00 main line) traversing north to east and west. In this our presentation, we present a preliminary report on the outline of Airgun-OBS structure exploration (refraction seismic survey) and the results obtained.

The H30 - L00 main line starts at the water depth of 485 m in Shizuoka, Shimizu, Okitsu City coastal area, the deepest part is 1320 m in the vicinity of the central part of Suruga Trough and the eastern end is over 500 m in the coastal area of Numazu, Heda City. It is a survey line of trough topography sandwiched by slopes. Since the distance between east and west distances in the northern part of Suruga Bay is short and the coastal area is also a fishing ground, the length of the survey line is limited to about 19 km.

For the refraction seismic survey in the main line, two sets of Tri-Gun by Bolt Co., Ltd. (total capacity 1950 in^3) were towed, and at about 50 m intervals (since the shooting points were adjusted so as to be interposed between practically approximately blast occurred at intervals of 25 m), 18 sets OBS were deployed at about 980 m intervals. Typhoon 24 passed around Suruga Bay on the day of the exploration, so six of the 18 OBSs caused abnormal floating and so on, and they stranded to the coast (Nakao et al., 2019 (the present Society)), so data could not be obtained near the Suruga trough central axis. However, good records were obtained with 12 OBS.

Analysis is ongoing. Looking at the state of each Record Section obtained, the first arrival data can be clearly confirmed throughout the survey line, but a complex structure is presumed because it is also a line surrounding the plate boundary. The earliest layer of apparent velocity is about 6.8 km / sec, and the velocity structure model is estimated to be roughly 5-layer structure. The sedimentary layer of the first, the second and the third layer (acoustic basement layer) are inclined to the west side towards the Suruga Bay central axis, and the reflection cross section (Tsuruga et al., 2019 (the present Society)) and Match. Detailed structure model results will be reported in this presentation.

We have greatly cooperated and inconvenienced the Yui Port Fishery Cooperative Association, Shimizu Fisher Cooperative Cooperative Association and Toda Fisher Cooperative Cooperative Association for the establishment of OBS.

3D seismic attenuation profiling for imaging an active fault in Uchiura wan

*Tetsuro Tsuru[1], Shio Shimizu[1], Mayu Ogawa[1], Jin-Oh Park[2], Seishiro Furuyama[1], Kosaku Arai[3], Takahiko Inoue[3], Chen Guo[2]

1. Tokyo University of Marine Science and Technology, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. National Institute of Advanced Industrial Science and Technology

We tested seismic attenuation profiling (SAP) to image active faults on a mini-3D seismic reflection dataset observed at Uchiura wan in 2018. Seismic reflection surveys are often conducted to investigate not only geological structures but also development of faults in sedimentary basins, because the past activities of faults are recorded as offsets of geological formations at their locations. However, it is sometimes difficult to specify the existence of faults within highly faulted/fractured areas because seismic reflections are inherently invisible there. SAP has been, therefore, applied to image faults as well as fractures and investigate their activities in poorly reflective areas: the igneous oceanic crust and volcanic areas.

SAP is a method to map seismic attenuation property using seismic reflection data. The authors use the spectral ratio method to estimate Q from seismic reflection data in frequency domain, because the method can be robustly applied in poorly reflective area. Reversely, Q-estimation methods in time domain are not stable in such areas because no reliable amplitude information is available there. However, SAP using the spectral ratio method has not been applied to image faults and fractures developed in sedimentary units (e.g. Tsuru et al, 2017; 2018), because the accuracy in Q-estimation decreases due to spectrum distortions. The spectrum distortions are mostly caused by interruption between primary reflections and interbed multiples within the sedimentary layers. Shimizu (2019) investigated the influences of several Q-estimation methods to interbed multiples by numerical experiments and then improved some processing parameters in the estimation of Q in the frequency domain. As a result, the authors successfully imaged a trend of an active fault on SAP time-slices (Q-slices) from a mini-3D seismic reflection dataset.

A high-resolution mini-3D seismic survey was conducted at Uciura wan in Suruga Bay on August 7th in 2018, by chartering R/V Daini Ikoi Maru of Oki Seatec Co., Ltd. During the survey, twenty of seismic lines were collected with sampling rate of 1 ms. An underwater speaker was adopted as an energy source in consideration of mitigating impact on marine ecosystem. Shot records were collected every 10 s (equivalent to about 10 m with the vessel speed of 2 knots) with a streamer cable of 16 channels. The source and the streamer cable were towed at 0.5 and about 1 m depths, respectively.

As a result of seismic data processing, including band-pass filter, NMO corrections and stacking with one velocity of 1500 m/s, a 3D seismic cube was created. The seismic cube was used for input data of SAP analysis. The data processing was conducted by MATLAB. On the other hand, as a result of the SAP analysis, a 3D cube of average Q was created. An active fault, which cuts seafloor, was clearly demonstrated over several seismic reflection profiles. However, its trend was not clear on seismic time-slices. Reversely, the trend of active fault was clearly figured out on several Q-slices as high attenuation anomalies. In this paper, we would like to show the results of SAP analysis from the mini 3D seismic reflection data observed in Uchiura wan.

Gravity survey at the extension of the Takahama fault and the Yokosuka fault in Nishio City, Aichi Prefecture

*Tokunosuke Tatsuzawa[1,2], Tatsuya Sumita[2], Shinobu Ito[2], Tomoya Abe[2]

1. Department of Earth Sciences, Resources and Environmental Engineering, Creative Science and Engineering, Faculty of Science and Engineering, Waseda University, 2. National Institute of Advanced Industrial Science and Technology

We conducted a gravity survey in Nishio city, Aichi Prefecture to clarify the subsurface structure related to the Takahama fault and the Yokosuka fault (Fig.1). Seismic reflection survey was held in that area in September 2018 (Ito, 2019) and the velocity structure was also obtained by refraction analysis. Then, we consider that we can clarify more detailed subsurface structure by conducting gravity survey on the seismic survey lines and their extensions (Line1 and Line2) and also by comparing gravity survey results with the seismic survey results. We also conducted gravity survey along the Yahagi Furukawa river (Line 3) that is supposed to cross the northern extension of the Yokosuka fault in the active fault map “Gamagori” (Okada et al., 2004) issued by Geospatial Information Authority of Japan and that is also crossing the concealed fault inferred by Sugito and Okada(2004).
In this survey, a total of 150 points of relative gravity was measured by the Lacoste D-type gravimeter (D68) and the Lacoste G-type gravimeter (G304). Measurement distance intervals were about 50m or 100m on Line1 and Line 2, about 30m or 50m on Line 3. The location coordinates of each gravity measurement point were mainly measured by GNSS(network type RTK-VRS), while some points were also measured by Total Station. Gravity anomaly was calculated by the standard procedure SPECG1988 (GSJ Gravity Survey Group, 1989). We performed terrain correction with 50m mesh DEM (Murata et al., 1996) for the Bouguer anomaly calculation. The contribution of terrain on gravity anomaly is small because the surveyed area is nearly flat. In fact, the maximum difference between simple Bouguer anomaly and the Bouguer anomaly calculated with 50m mesh DEM is 0.074mGal, and the pattern of the anomaly profile does not differ greatly between them.
As a result of gravity survey, the pattern of the Bouguer anomaly profile on Line1 and Line 2 is well related to the contour line of 3000m/s in P wave velocity section by the refraction analysis. On Line3, the Bouguer anomaly shows significant change around the point where the presence of the concealed fault of the Yokosuka fault was estimated (Sugito and Okada, 2004; Imaizumi et al., 2018). In addition, the Bouguer anomaly shows complex change on the eastern part of Line 2, where the P wave velocity is also lower than surrounding area by the result of the refraction analysis. In the coming months, we are going to make the density structure model by using the reflection boundary of the seismic profile and the gravity anomaly to reveal the details.

Subduction geometry and seismicity around northern Ryukyu subduction zone

*Yojiro Yamamoto[1], Tsutomu Takahashi[1], Yasushi Ishihara[1], Koichiro Obana[1], Seiichi Miura[1], Shuichi Kodaira[1], Yoshiyuki Kaneda[2]

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Kagawa University

At the Ryukyu subduction zone, located forearc region of Japan’ s Southwest Islands, the Philippine Sea plate is subducting beneath the Eurasian plate toward northwest direction. Due to the subduction, not only active seismicity but also short-term slow slip event (SSE) (Nishimura, 2014) and low frequency tremor (LFT) activity (Yamashita et al., 2015) were observed in the forearc region of Ryukyu arc. However, the subduction geometry is still unclear since seismic and geodetic stations are limited to the sparsely distributed islands. To know the seismicity, lithospheric structures and subduction geometry, Japan Agency for Marine-Earth Science and Technology (JAMSTEC) launched a series of seismic observations and active-source seismic surveys at the Ryukyu arc from 2013, as a part of research project funded by Ministry of Education, Culture, Sports, Science and Technology, Japan. In FY2016, we have conducted a passive source observation in the northern Ryukyu forearc region. We have deployed 47 seismic stations including 43 ocean bottom seismographs (OBS) and 4 onshore stations at Tanegashima (two stations), Nakano-shima, and Akuseki-jima. The observation period of OBS is about 4 months, from September to December 2016.

In this study, we conduct double-difference seismic tomography (Zhang and Thurber, 2006) to obtain both precious hypocenter location and structural information around plate boundary. We combine 1,303 events detect from our observation data with 454 events from Japan Meteorological Agency (JMA) with our data set. To improve the spatial resolution and ray coverage, we also used the arrival time data at 33 permanent stations from JMA seismic catalogue and dataset of a part of previous OBS observation in Hyuga-nada (Yamamoto et al., 2013; 161 events and 27 OBSs). After the tomographic inversion, we estimate the focal mechanisms by using P-wave first arrival polarity data. Then, we establish the subduction geometry model with reference to the velocity model, distribution of low-angle thrust type earthquakes, previous geometry model based on active source surveys (Nishizawa et al., 2009, 2017; Nakanishi et al., 2018).

Estimated subduction geometry indicates that there is no obvious roughness in this study area. Interplate earthquake, defined as earthquakes within 5 km from plate boundary of this study, is active at depth between 15 and 30 km especially in the southern part. The down-dip limit of interplate earthquakes is corresponding to the high Vp/Vs just above the plate boundary, suggesting that the existence of serpentinized mantle wedge. In addition, LFT, SSE, and interplate earthquake seem to be separately occurred along the plate boundary. Intraslab earthquake is also active. Some of them occurred in the seaward of trench axis. The separation between intraslab earthquakes and plate boundary is larger (25 ~ 30 km) in northern part than that in southern part (15 ~ 20 km). This regionality might be relate to the subduction of Amami Plateau.

Terrestrial cosmogenic nuclides as a dating tool of landforms and near-surface materials: applicability and limitations

*Yuki Matsushi[1]

1. Disaster Prevention Research Institute, Kyoto University

This study overviews methodology for application of terrestrial cosmogenic nuclides for dating of diverse types of landforms and near-surface materials. Accumulation of the nuclides in the bedrock or sediment on land surfaces enables us to determine exposure ages of the landform. This methodology targets reconstruction of environmental changes in mountainous areas due to climatic transition, timings of large landslide occurrence, and formation ages of fluvial or marine terraces. In this application, post-event erosion or sedimentation, and/or pre-event irradiation of cosmic rays enlarge uncertainty in the model ages. The nuclide concentration in an eroding bedrock or current sediment reflects residence time of the material near the land surface, which then can be converted to denudation rates of the landform. This application has revealed rates of carbonate denudation as a function of climatic conditions of the sites, soil production and catchment-wide denudation rates in silicate areas, which corresponds to topography of the terrain. For samples of deeply-buried sediments, ratio of paired nuclides in identical mineral grains indicates ages of burying of the debris. The pair of ^{10}Be and ^{26}Al in quartz has been used for dating sediments in caves, for a timescale of 10^6 years. Analysis of such samples provides also a clue to reconstruct paleo denudation rates of the source areas of the debris. In this presentation, applicability and limitations of this method will be discussed with several actual data and outputs from various models of nuclide accumulation.

Uplift rate in an inland region and coastal region in the past 10^4 to 10^5 years can be estimated based on the elevation and emergent age of marine terraces (e.g., Ota and Omura, 1991). Marine depositional terraces in Japan have been dated by using radioactive carbon dating, tephrochronology, and recently developed optically stimulated luminescence dating (especially pIRIR dating for feldspar; e.g., Ito et al., 2015). On the other hand, it is difficult to date marine erosional terraces which lack sedimentary layers on the surfaces to apply these dating methods.

This study attempted to date marine erosional terraces by using terrestrial cosmogenic nuclide (TCN) dating methods, especially ^{10}Be and ^{26}Al methods. The ^{10}Be and ^{26}Al methods can reconstruct an exposure age and/or erosion rate of a rock based on the contents of ^{10}Be and ^{26}Al which are produced by irradiations of cosmic rays to oxygen and silicon in the rock (Wakasa et al., 2004; Matsushi et al., 2007). The production rates of ^{10}Be and ^{26}Al at the surface or at a certain depth depend on the cosmic-ray intensity (related to the latitude and altitude), density of the covering materials, and depth of the rock. The cosmic-ray intensity is computed theoretically, and the density of the covering materials can be also measured or assumed. Therefore, time-depth process of the rock, namely erosion and deposition history at the site, can be constrained by measuring the ^{10}Be and ^{26}Al contents.

We studied marine erosional terraces in Hyuga City, Miyazaki Prefecture, southwest Japan. Three groups of marine terraces were identified in this region, which are hereinafter named M1, M2 and L surfaces, respectively. The elevations of the surfaces are 30-50 m for M1 surface, 19-30 m for M2 surfaces, and sea-level to ~8 m for L surface. Considering the elevation, M1 and M2 surfaces can be correlated to the Sanzaibaru surface and Nyutabaru surface (Nagaoka et al., 2010), respectively, whereas L surface is thought to be the Holocene terraces. We collected rock samples for TCN dating by excavating three pits on M2 surface. The cross-sections of the pits consist of the basement rock, angular to subangular gravel layer interpreted as *in-situ* weathered basement rock, and soil from the base to the top. Rock samples were collected from the top of the gravel layer (depth: ~50 cm to 1 m) which is thought to be the surface of the former wave-cut benches. The lithology of the samples is the granite porphyry of the Osuzuyama acidic rocks formed in the middle Miocene (Nakata, 1978). The samples were processed by following the procedures of Kohl and Nishizumi (1992) and the ^{10}Be and ^{26}Al contents were measured using JAEA-AMS-TONO, an accelerator mass spectrometer at the Tono Geoscience Center, Japan Atomic Energy Agency (Saito-Kokubu et al., 2013).

The ^{26}Al contents measured were rejected because these values were lower than the theoretical values. The ^{10}Be contents yielded ~100 to 70 ka of the minimum exposure ages. More realistic erosion/deposition scenarios were adopted for better dating of the terrace surfaces, in which sedimentary layers were assumed to be deposited at a constant rate after the emergent of the surface. Consequently, M2 surface is thought to be emerged in MIS 5a although the correlated Nyutabaru surface emerged in

©2019. Japan Geoscience Union. All Right Reserved.

MIS 5c. We are planning to determine more accurate age of the surfaces by tuning model parameters and by obtaining depth profiles of TCN contents.

Estimation of thermal history of Toki granite over 0.1Myr timescale by Multi-OSL-thermochronometry

*Manabu Ogata[1], Georgina E King[2], Frédéric Herman[2], Shigeru Sueoka[1]

1. Tono Geoscience Center, Japan Atomic Energy Agency, 2. University of Lausanne

Estimation of denudation history is important for geological disposal of high-level radioactive waste because denudation influences underground water flow and distance between the surface and underground facility. Terrestrial cosmogenic nuclide (^{10}Be, ^{26}Al) dating is used to evaluate denudation rate in a few meters, whereas low-temperature thermochronology, such as fission-track and (U-Th)/He methods, is applied to estimate denudation histories for a few to several kilometers in the last 10^6-10^8 years. However, the middle-term (10^4-10^5 years) denudation history over several hundred meters is more important for geological disposal because it takes tens of thousands of years to reduce the radioactivity of radioactive waste to the level of that of natural uranium ore.
Recently, multi- OSL-thermochronometry has been proposed as a tool that offers the potential for tight constraint of cooling histories in the low-temperature domain (< 75℃) over recent (0.1-0.2 Myr) timescales. This method determines the timing and rate at which electrons are trapped and thermally released in minerals, in response to in situ radiation and rock cooling. The technique of OSL thermochronometry is able to be used to unravel denudation histories.
Application of OSL thermochronometry is currently limited to regions that have experienced denudation rates higher than 3 mm/year, assuming a general geothermal gradient and surface temperature; luminescence signals saturate before the rocks are exhumed to the surface in a slowly-denuded region. Given such limitations on the cooling/denudation rate, previous researches on OSL themochronometry has focused on tectonically active mountain ranges, such as the Himalayas, the Southern Alps of New Zealand and Hida range in Japan.
We attempt to apply multi-OSL-thermochronometry to the tectonics that have experienced slowly denudation rate using long borehole. We used the borehole MIZ-1 which was drilled at Mino plateau, Gifu, Japan. The denudation rate in this area is expected to be around 0.1 mm/year or less from the denudation rate since ~40 Ma estimated by the apatite fission track method and uplift rate between MIS6 and MIS2 based on elevations and emergent ages of the fluvial terraces. This borehole consists mainly of the Cretaceous Toki granite pluton which is located at the Sanyo Belt in the Inner zone of the South west Japan Arc. The total length of MIZ-1 is about 1,300 mabh (meter along borehole) and Toki granite ranges from 110 to 1,300 mabh. We collected the samples at 159, 449, 751 mabh for multi-OSL-thermochronometry.
Cooling histories of all samples are similar. Their temperatures decreased to the present ambient temperature at each depth before 0.1 Ma and have then been stable. These results correspond to the expected slow denudation rate. Our results indicate that, by using long borehole, multi-OSL-thermochronometry can be applied to slowly-denuded regions.
This study was carried out under a contract with METI (Ministry of Economy, Trade and Industry) as part of its R&D supporting program for advanced research on long-term stability of geological environment.

Depth condition under which OSL signal of quartz gouge experiences coseismic zeroing

*Yuki Minomo[1], Kiyokazu Oohashi[1], Noriko Hasebe[2], Kazumasa Miura[3]

1. Graduate School of science and Technology for Innovation, Yamaguchi University , 2. Institute of Nature and Environmental Technology, Kanazawa University, 3. Kanazawa University

Attempts to determine the age of faulting recorded on a fault rock have been made using methods such as the K-Ar dating, FT dating, and ESR dating (e.g., Murakami & Tagami, 2004, GRL). Among the proposed methods, the luminescence dating method has an applicable time range of few decades to few hundred thousand years ago, and hence it is suitable for dating an active fault. Early trial demonstrated a successful determination of the latest earthquake event along the active fault in central Japan (Ganzawa et al., 2013, JGSJ). The slip rate dependence of the condition that optically-stimulated luminescence (OSL) signal of quartz gouge resets was experimentally verified, so that the signal start to decrease from the slip rate of 0.25 m/s and becomes zero at slip rate ≧ 0.65 m/s (Minomo et al., 2018, JPGU). Here we show the clear reduction (zeroing) of OSL signal of quartz gouge after the laboratory experiments and estimate depth condition required to occur age resetting in natural fault zones. In the experiments, we used quartz powder with a particle size of <150 μm which is extracted from Tsushigawa granite, located in Awaji island, Hyogo Prefecture. We irradiated 400 Gy of gamma-ray for the quartz powder before the experiments to simulate natural radiation damage. Friction experiments were conducted under the following conditions in darkroom environment using a rotary-shear, high-velocity friction apparatus in Yamaguchi University; normal stress of 0.5–5.0 MPa and slip rate of 0.65 m/s (constant from starts to finish). To eliminate the effect of crushing on OSL signal, we measured coarse grains (75–150 μm) extracted from recovered sample.As a result of the measurement, OSL signal intensity start to decrease from the normal stress of 0.5 MPa. We found “partial resetting” which is characterized by coexistence of both particles with signal and without signal at normal stress of 0.5 and 1.0 MPa, and then frequency of the signal intensity for each aliquot is bimodal distribution.On the other hand, complete resetting of the signal was observed in all particles at normal stress ≧ 2.0 MPa.. Assuming a coseismic fault slip rate of 0.6 m/s, depth conditions required for operating partial and complete resetting of OSL age expected to be 18~36 m and 72 m respectively.

Result of age determination of samples from Hokuriku Group

*Noriko Hasebe[1], Ryo Kamiguchi[2]

1. Institute of Nature and Environmental Technology, Kanazawa University, 2. Department of Earth Sciences, Kanazawa University

The Hokuriku Group is distributed from the southern part of Ishikawa Prefecture to the eastern part of Toyama prefecture and deposited in the Neogene period (about 25 Ma to 2.5 Ma). This study reports zircon fission track (ZFT) and U-Pb ages from several volcanic rocks distributed in the Tsurugi district, the southern part of Ishikawa Prefecture, Kanazawa University district, and Uozu area in Toyama prefecture. The Iozen Formation in Tsurugi district show ZFT ages between 12.2 ±1.9 to 15.7 ±2.8 Ma (error, 2 sigma) and U-Pb ages between 17.2 ±0.5 to 21.0 ±0.9 Ma. U-Pb ages coincide with the Japan Sea opening event, and eruption age by ZFT is about 5 mys after zircon crystallization. One sample from Otogawa Formation shows an equivalent age with the Iozen Formation, suggesting a rapid volcanic sedimentation for both formations. The sample from a quarry, which we thought is from TR1 (Ohkubo, 1999), therefore estimated age is about 4.4 Ma (Tamura and Yamazaki, 2004) by the correlation, shows much older age of ZFT 33.2 ±4.6 Ma and U-Pb 65.3 ±2.0 Ma, and further investigation, especially on the sample identification, is necessary. For Uozu area, ZFT ages of 3.4 ±0.7 to 9.7 ±1.4 Ma and U-Pb ages of 2.9 ±0.8 to 71.7 ±2.8 Ma are obtained, and eruption ages are equivalent to tephra found in Yatsuo district (Sumii, 1986)

Geochemical origin/cycle analysis with isotopologues and isotopomers

*Naohiro Yoshida[1]

1. Department of Chemical Science and Engineering, Earth-Life Science Institute, Tokyo Institute of Technology

Since the 1950's, the stable isotope composition of natural samples has proved to be a unique tool for the study of geological and biological processes, their evolution and effect on Earth's surface environment. However, due to technical and conceptual limitations, the complete set of information potentially contained in the different modes of isotopic substitution remains largely unexplored. In this study, using new methodological developments that allow analysis of more isotopically substituted molecules, we are developing new tracers in 3 modes of isotopic substitution, fully integrated in the study of geological, biological and anthropogenic processes which affect the origin and evolution of the Earth's surface environment.

3 modes of substitution of stable isotopes in a single molecular species are;

1) Position specific isotope abundance (PSIA): Our group has pioneered PSIA of N_2O[1,2] and organic molecules using classic isotope mass spectrometry[3] and nuclear magnetic resonance[4,5]. We have shown that PSIA of hydrocarbons and organic acids allows to distinguish between biological and non-biological processes[4,6].

2) Mass-independent fractionation (MIF): The discovery of MIF of sulfur and oxygen in terrestrial samples has revolutionized environmental geochemistry and our understanding of the evolutionary history of the Earth's environment and life[7-9].

3) Clumped isotopes (i.e. isotopologues and isotopomers with 2 minor isotopes) provide unique information about the temperature history of molecules such as carbonates[10] or organic compounds[11-13].

We are currently developing new and improved tracers of environmental and biogeochemical processes and applying them to the environmental diagnosis. We are establishing and standardizing new methods for the analyses of every 3 complex modes of isotopic substitution, and unifying them to develop ultimate environmental diagnosis.

The development and application of these new isotopic tools to the environment evolution, in modern and more ancient eras, represents an important conceptual advance in Earth and life sciences. This will open new areas of research about, for example, the geological production of some atmospheric gases, metabolic processes and the biological fixation of atmospheric CO_2, the production and cycling of pollutant gas by industrial processes. As a whole, these new tracers will be integrated together for diagnosis of the Earth's environment.

Estimation of Paleoenvironment by sedimentary rocks in Labrador, Cacada

*katsutaka sudo[1], Yuji Sano[1], Tsuyoshi Komiya[1], Bakert David[2], Michael Broadley[2], Bernard Marty[2]

1. University of Tokyo, 2. CRPG-CNRS, Université de Lorraine

In the previous research, we reported isotopic compositions of graphite and carbonate in the 3.95Ga metasedimentary rocks from northern Labrador, Canada (Tashiro et al., 2017). Based on the isotopic shift of 20-30‰, we claimed a carbonate fixation by the Earth’ s earliest life. In this work, we picked up graphite from the very old rocks collected in Labrador and Nuvvuagittuq, and measured volatile isotope compositions by the step-wise heating method. We analyzed nitrogen isotopes to investigate whether the organic carbon was producted by cyanobacteria or methanobacteria, and noble gas (argon, krypton, xenon) isotopes to determine the age of rocks. We have used two types of gas mass spectrometer; VG3600 for nitrogen, Helix-MC for noble gases. The obtained data together with experimental method will be given in the presentation.

Hf-W dating of zircons from mesosiderites with high-pressure sintered sample

*Yuta Koyama[1], Naoto Takahata[1], Yuji Sano[1], Naoji Sugiura[1], Mizuho Koike[2], Makiko K. Haba[3], Sakata Shuhei[4], Hideharu Kuwahara[5], Tetsuo Irifune[5]

Hf-W dating is a chronometer based on the decay of ^{182}Hf to stable ^{182}W with a half-life of 8.9 Myr (Vockenhuber et al., 2004). This radiometric dating method is important for discussing the timing of core formation in protoplanets and meteorites' parent bodies because hafnium is a lithophile element while tungsten is a siderophile one. In-situ analysis of Hf/W ratio on zircon ($ZrSiO_4$) mineral shows several difficulties, whereas meteoritic zircons have been often used to acquire the information of the early solar system due to their high resistance to thermal metamorphism and great aptitude for U-Th-Pb chronology. Generally, in-situ analysis needs standard materials which have well documented concentrations of target elements and the same matrix as the sample in order to avoid the change of sensitivity depending on major components (matrix effects) during an analysis using a secondary ion mass spectrometer (SIMS). There are no available standard zircons which include abundant and homogeneous tungsten because of its incompatibility with zircon crystal. Therefore, the previous studies determining the relative sensitivity factor (RSF) of Hf and W (Hf/W) for Hf-W dating of zircons using SIMS have been based on several assumptions (e.g., Ireland & Bukovanská,2003; Koike et al., 2017). These methods for measuring Hf/W ratios are indirect ways in terms of lacking standard zircons with known amount of W. In this study, we created new standard zircons which have abundant Hf and W concentrations. High purity zircon powder was mixed with hafnium and tungsten oxide. They were well crushed and mixed by a high energy ball mill and solidified by high-pressure sintering method with multi-anvil apparatus (ORANGE-3000, Geodynamics Research Center, Ehime University) in order to establish the direct way to determine the RSF of Hf/W ratio on zircons for in-situ analyses. Moreover, we applied these standards to Hf-W dating of zircons from a couple of mesosiderites with NanoSIMS (Atmosphere and Ocean Research Institute, the University of Tokyo) at approximately 30 μm scale. As a result of these analyses, we obtained the Hf-W age consistent with Koike et al. (2017) for the mesosiderite Asuka 882023.

Radiometric ages *vs.* astrophysical ages -with regard to the numerical age in the International Stratigraphic Chart

*Ichiro Kaneoka[1]

1. Earthquake Research Institute, University of Tokyo

In July, 2018, ICS(International Stratigraphy Commission) of IUGS published the new International Stratigraphic Chart (ISC: v.2018/07). The author drew an attention to the public about some issues to be cautioned on the usage of numerical ages in the ISC based on the 2009 version(v.2009/08) at the JpGU before (Kaneoka, 2016). The essential points do not change between the two versions of ISC, but there are some differences in the representation of numerical ages in the new ISC. Here, the author comments some points about them and discuss issues of astrophysical and radiometric ages used in the ISC.

Thermal interaction of the lithosphere and asthenosphere revealed from internal variations of pressure-temperature history in orogenic peridotite complexes

*Kazuhito Ozawa[1], Carlos J. Garrido[2], Karoly Hidas[2], Jean-Louis Bodinier[3]

1. Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo, 2. Instituto Andaluz de Ciencias de la Tierra (IACT), CSIC –UGR, Armilla, Granada, Spain, 3. Geosciences Montpellier, Montpellier, France

Dynamics of interaction between lithosphere and asthenosphere in their boundary zones (LABZ) plays an important role in transferring heat, material, and momentum from the earth’ s interior to the surface. Orogenic peridotites provide direct and high-resolution information for better understanding mantle processes taking place in the boundary zone. However, their exhumation obscure the information on dynamics operating in LABZ, while they could be driven and affected by processes taking place in and beneath the LABZ. This issue leads to ambiguity in the link between magmatism, relevant to whole-rock chemical characteristics, and exhumation of peridotite complexes, relevant to deformation and subsolidus reactions. Bodinier et al. (2008) actually pointed out two possible formation scenarios for plagioclase peridotites in orogenic peridotite complexes: subsolidus reaction from spinel peridotites and open magmatic processes in the plagioclase peridotite facies in the shallow mantle. In the context of lithosphere-asthenosphere interaction, it is crucial to discriminate these two possibilities. Spatial and temporal changes of pressure and temperature within an orogenic peridotite complex can be used to better constrain its history of decompression and magmatism. By exploiting the advantage of size of orogenic peridotite complexes, these data may provide valuable constraints on the LABZ dynamics.

Here, we examine internal variations of thermal and decompression history of three orogenic peridotite complexes: Ronda, Pyrénées, and Horoman. They exhibit diverse geological and petrologic characteristics providing an excellent chance of comparative study. The common feature of these orogenic peridotites is decompression from the garnet peridotite facies deeper than ~50km. In this study, we focus on garnet-related reaction microstructures, which are powerful tools to resolve pressure-temperature history because of their high hysteresis as compared with suppressed hysteresis of chemical zoning in minerals. Garnet and its breakdown products show contrasting features among the three. (1) Garnet was completely decomposed in both peridotite and pyroxenite lithologies in Horoman with formation of symplectite in slightly depleted peridotites; garnet rarely remains in both peridotite and pyroxenite lithologies with extensive formation of symplectite and kelyphite in Ronda; and garnet is completely decomposed into two-pyroxene spinel symplectite in peridotites but well preserved with partial formation of kelyphite rim and veinlets in pyroxenites in Pyrénées. (2) Coarse-grained granular olivine-plagioclase assemblage in both fertile peridotite and pyroxenites is common in Horoman; formation of olivine-plagioclase assemblage forming fine-grained intergrowth in fertile peridotites and pyroxenites is common with its extent being spatially variable in Ronda; and formation of olivine-plagioclase assemblage rarely in pyroxenites and very rarely in fertile peridotites in Pyrénées. These contrasts suggest: (1) high-temperature decompression path all through its ascent in Horoman; (2) low-temperature in deeper levels but relatively high-temperature decompression path in shallower levels in Ronda; and (3) high-temperature decompression path in deeper levels followed by rapid cooling in shallower levels in Pyrénées. Combined with pressure-temperature path deduced from chemical zoning and microstructure related to exsolution and dissolution in pyroxenes, we propose that the shallow high-temperature decompression of Ronda was caused by heating in the plagioclase peridotite facies and that the

©2019. Japan Geoscience Union. All Right Reserved.

high-temperature decompression of Horoman by heating over a wide depth range deeper than the plagioclase peridotite facies. Pyrénées is probably intermediate of these two cases. The contrasting modes of thermal perturbation may imply different mechanisms of lithosphere-asthenosphere interaction, such as active upwelling vs. passive upwelling.

Hydration and Ca-metasomatism in Mantle Wedge: An evidence from the Alag Khadny Accretionary Wedge, Western Mongolia

*OTGONBAYAR DANDAR[1], Atsushi Okamoto[1], Masaoki Uno[1], Noriyoshi Tsuchiya[1]

1. Graduate School of Environmental Studies, Tohoku University

Hydration and metasomatic reactions of mantle wedge play important roles on global material circulation and changes in physical properties along the plate interface within the subduction zone. Metasomatism is caused by specific components of fluids such as silica; however, our understanding on the relationship between hydration and metasomatism in mantle wedge is still limited. In this study, we report outstanding alteration textures of orthopyroxene as an evidence for significant Ca metasomatism within the mantle wedge, and its relation to the hydration processes.

The Alag Khadny accretionary wedge is located in the Chandman area, western Mongolia, Central Asian Orogenic Belt. The accretionary wedge is subdivided into northern and southern belts. The northern belt is consisted of orthogneiss bodies with layers of mica schists and paragneisses, including amphibolized eclogite, marble, and serpentinite bodies. The southern belt is composed mainly of serpentinized peridotite with minor ophicarbonates and limestone layer including lenses of epidote amphibolites. The ultramafic body mainly consists of harzburgite and lherzolite with minor dunite and its origin is interpreted as mantle wedge.

We collected 17 samples from the ultramafic body in southern belt of the Alag Khadny accretionary wedge in the Chandman area. The peridotites contain primary olivine (Ol), orthopyroxene (Opx), clinopyroxene (Cpx), and spinel. The peridotites were suffered from various extents of metasomatism and hydration. P-Olivine was replaced by antigorite with various extent, whereas primary Cpx was preserved without reactions. One of the notable features that is common in the peridotite is intense replacement of orthopyroxene (>60 vol.% was replaced). The mineralogy of the orthopyroxene replacement is divided into three types: secondary Cpx (S-Cpx) + tremolite (Tr), S-Cpx + tremolite (Tr) + S-olivine, S-Cpx. S-olivine shows lower Mg# (0.85-0.91) than the primary ones (Mg#=0.90-0.91), and S-Cpx shows the lower Al content and higher Mg# than the primary Cpx. Mass-balance calculation for the Opx pseudomorph showed the gains of Ca and water, and losses of silica, Mg and Fe. Due to the lack of Ca source in the primary minerals, significant amount of Ca metasomatism occurred induced by infiltration of the external fluids. The products of Ca metasomatism (S-Cpx, Tr) are commonly cut by antigorite veins, indicating that main hydration (antigorite formation) occurred after Ca metasomatism. The stability field of mineral assemblage of the Opx replacement was consistent with the P-T conditions of eclogite bodies in the Chandman area (T= 590-630 ˚C and P=11-16 kbar), implying that the hydration and metasomatism were caused by mantle wedge due to a supply of fluids derived from dehydration of the subducting slab.

Attenuated Total Reflection Infrared (ATR-IR) Spectroscopy of Antigorite, Chrysotile and Lizardite

*Ilona Talvikki Sakaguchi[1]

1. Nagoya University

Ilona Sakaguchi[1], Yui Kouketsu[1], Katsuyoshi Michibayashi[1], Simon Wallis[2]

[1]Graduate School of Environmental Studies, Nagoya University, [2]Department of Earth and Planetary Science, The University of Tokyo

Distinguishing serpentine minerals antigorite, chrysotile and lizardite from a thin section can be challenging due to the similarity of their optical properties and chemical composition. Infrared spectroscopy (IR) is a method based on the characteristic absorption of infrared radiation by different chemical bonds. Since each serpentine mineral has a distinct crystal structure, infrared spectroscopy can be applied in serpentine mineral identification. Infrared radiation is also particularly strong in polar bonds making IR spectroscopy a powerful tool in studying serpentine mineral hydroxyl groups. Transmission infrared spectroscopy is the most widely used IR method but it requires time-consuming and arduous sample preparation. Using a newer method known as attenuated total reflection infrared spectroscopy (ATR-IR) can significantly reduce the sample preparation time since the measurements can be made directly from the surface of a normal thin section.

We applied the ATR-IR method to characterize antigorite, chrysotile and lizardite from samples from Mt. Shiraga serpentinite body, located in central Shikoku, SW Japan. The ATR-IR method proved to be a reliable and simple method to measure the infrared spectrum of serpentine minerals as there were clear differences in the absorbance band positions of the three serpentine minerals. However, we observed notable differences in the absorbance band positions and absorbance intensities of serpentine minerals between the ATR-IR measurements and transmission IR measurements published in previous studies. These results reflect the fact that the ATR-IR method is susceptible to spectral distortions that are caused by the dependence of absorbance intensity to wavelength and by anomalous dispersion of infrared radiation. On the other hand, spectral mapping is much more convenient in the ATR-IR method as measurements can be done from normal thin sections. We also used the ATR-IR method to map a sample with three co-existing serpentine minerals with interesting reaction textures.

ATR-IR spectroscopy, and especially ATR-IR mapping, has a lot of potential in the field of mineral spectroscopy and it could be applied in the study of a wide variety of serpentinite microstructures, such as veining and faulting. One possible research avenue would be to combine ATR-IR mapping of serpentinite microstructures to quantitative analysis of serpentine mineral hydroxyl group absorbance intensities.

Fabric and petrological characteristics of sheared peridotites in Marion transform fault, Southwest Indian Ridge

*Kakihata Yuki[1], Katsuyoshi Michibayashi[2], Henry Dick[3]

1. Shizuoka University Graduate School of Science, 2. Nagoya University Graduate School of Environmental Studies, 3. Woods Hole Oceanographic Institution

The ultraslow spreading (14 mm/yr) Southwest Indian Ridge (SWIR) lies between the Bouvet and Rodriguez Triple Junctions. The SWIR is volcanically inactive, possibly reflecting poor advection of heat and intensive conductive cooling. Accordingly, there are only partly thin basaltic crusts, and peridotites exposed to the sea floor. Dredge surveys have been performed along the SWIR, and basalt, gabbro and peridotite specimens have been derived since 1980s.

In this study, we studied the microstructural development of 7 peridotite samples obtained from Marion Fracture Zone of the SWIR by the PROTEA cruise Leg.5 in 1983. The peridotites consisted of olivine, orthopyroxene and clinopyroxene with amphibole, plagioclase and chlorite, as well as secondary minerals such as serpentine and magnetite. The peridotites were classified into two groups based on their microstructures: 2 ultramylonites consisting of extremely fine grains (3-5 μm) with several porphyroclasts (~15 μm) and 5 heterogeneous tectonites consisting of deformed coarse-granular textures with subsequently developed fine-grained textures. In both types of peridotites, some of olivine grains had subgrain boundaries, whereas phase mixing occurred. These textural features suggest that heterogeneous textures of tectonites had been developed as lowering temperature and decreasing grain size, and subsequently became to ultramylonites.

Major element compositions of olivine and spinel indicated that these peridotites had fertile to moderately depleted mantle composition. Amphibole grains have the chemical compositions of tremolite, magnesio-hornblende and pargasite.

The ultramylonites have intensely deformed amphibole grains, whereas the heterogeneous tectonites have amphibole ranging from undeformed to highly deformed grains, indicating that amphibole formed before and/or during intensive shearing in the mantle. Moreover, olivine crystal-fabrics within the deformed amphibole bearing peridotites have B and E types developed under hydrous conditions. Consequently, the petrophysical characteristics of peridotites indicate that the uppermost mantle below the Marion transform fault has been hydrated during shearing.

Fine olivine grains in heterogeneous tectonites showed weak crystallographic preferred orientation (CPO) patterns. In contrast, those in the ultramylonites exhibited strongly concentrated CPOs. Furthermore, olivine grains were distorted more strongly in the ultramylonites than in the tectonites. These textural characteristics imply that fine-grained textures within the tectonites were deformed by mainly grain boundary sliding/diffusion creep under relatively low differential stress, whereas the ultramylonites were mainly deformed by dislocation creep under high differential stress.

Structure and formation mechanism of lithosphere-asthenosphere boundary decoded from Ichinomegata peridotite xenoliths

*Yuto Sato[1], Kazuhito Ozawa[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Lithosphere-asthenosphere boundary (LAB) is one of the largest discontinuities in mantle where heat transfer mechanisms change from conduction to convection (Sleep, 2005, 2006). Various formation mechanisms of LAB have been proposed and still controversial (Green et al., 2010; Hirschmann, 2010; Hirth & Kohlstedt, 1996; Karato, 2010, 2012; O' Reilly & Griffin, 2006). Mantle xenoliths are fragments of mantle material (Nixon, 1987) and could have derived from the LAB zone and are useful to reconstruct its internal structure and to understand the ultimate cause of LAB zone and dynamic processes operated there. We have examined spinel peridotite xenoliths from Ichinomegata maar located in the back-arc side of NE Japan to address this issue (Sato & Ozawa, submitting to Ame. Min.; Sato & Ozawa, 2017, 2018, JpGU meeting; Sato & Ozawa, 2016, 2017, AGU fall meeting). We succeeded in reconstructing the structures and clarifying the formation mechanism of the LAB zone beneath Ichinomegata.

Ichinomegata maar is a latest Pleistocene andesitic-dacitic volcano yielding spinel peridotite xenoliths (Katsui et al., 1979). Diversities of thermal, chemical, rheological, and petrological features of the xenoliths have been documented by previous studies (e.g., Kuno, 1967; Kuno & Aoki, 1970; Takahashi 1980, 1986; Koyaguchi, 1986; Tanaka & Aoki, 1981; Abe et al., 1992, 1998; Abe & Yamamoto, 1999; Satsukawa & Michibayashi, 2014; Satsukawa et al., 2017). Despite the numerous data, the derivation depths of the xenoliths have never been seriously examined. We devoted our effort to geothermobarometry of spinel peridotite xenoliths, and successfully estimated derivation pressures and temperatures ranging 0.7-1.6 GPa and 828-1081 ˚C for 8 of the 9 examined xenoliths by examining the time scale of development of every chemical zoning to identify minerals, mineral portions, and chemical species attaining equilibrium as close as possible just before the xenolith extraction.

Various depth variations were clarified. The shallow mantle, ranging from 28 to 32 km, is characterized by low temperature, granular, and plagioclase- and amphibole-bearing mantle, and the deep mantle, from 41 to 55 km, by high temperature, porphyroclastic, and plagioclase- and amphibole-free and melt-bearing mantle. It is notable that the sample-derived solidus condition coincides with the depth of change of deformation microstructures. This indicates that the wet solidus controls rheological LAB zone beneath Ichinomegata. We infer that the shallow zone corresponds to lithospheric mantle and the deep zone to LAB zone.

Intimate correlations between the depth variations of absence or presence of plagioclase and amphibole and geochemical data obtained by previous studies (e.g., Tanaka & Aoki, 1981; Abe et al., 1998) enable us to reconstruct geochemical depth variation; clinopyroxene and whole-rock of plagioclase- and amphibole-bearing shallower peridotites are characterized by light rare earth element (LREE) depleted patterns, low $^{87}Sr/^{86}Sr$ ratios (~0.7027-0.7030), and high $^{143}Nd/^{144}Nd$ ratios (~0.5133-0.5134); in contrast, those of plagioclase- and amphibole-free and melt-bearing deeper peridotites by LREE enriched patterns, high $^{87}Sr/^{86}Sr$ ratios (~0.7033-0.7047), and low $^{143}Nd/^{144}Nd$ ratios (~0.5125-0.5130).

Previous studies attributed geochemical diversity to local magma-related processes beneath MOHO (e.g., Takahashi, 1980; Abe et al., 1992). However, the systematic depth variations of geochemistry indicate a

©2019. Japan Geoscience Union. All Right Reserved.

larger-scale stratification of the upper mantle beneath Ichinomegata. We infer that the shallower geochemically depleted mantle represents oceanic lithosphere formed during Japan Sea opening and that the deeper enriched mantle represents LAB zone which formed recently through lithosphere thinning by asthenospheric upwelling. A similar scenario was proposed by Ohki et al. (1994) on the basis of temporal variations of Nd-Sr isotopes from Middle Miocene.

Metasomatic banding and deformation instability in the metamorphic rocks

*mitsuhiro toriumi[1]

1. Japan agency of marine science and technology

Low grade metamorphic rocks formed in the plate boundary commonly show mineral bands composed of albite, amphiboles, chlorite and epidote in basic schists, and of chlorite, albite and quartz in pelitic schists. These bands are almost monomineralic and bimineralic and parallel to subparallel against schistosity plane. Judging from the orientation of bands nearly normal to the maximum stress direction, it seems that the banding is derived from compaction banding/porosity banding induced from the non-linearity of microcrack plasticity (Toriumi and Hara, 1995), elastic modulus (Fortin et al., 2009) and preferred orientation growth of chlorite and actinolite.
In this model, the low grade metamorphic rocks deform accompanied with progressive banding of low porosity and with migration of water vertical to the banding, and it induces stability change of solution and metamorphic minerals. Chlorite may favor the compaction bands but albite does porous bands. This type of yielding shoud lower the yield stress and then the deformation instability may occur in the metasomatic process in the plate boundary rocks.
Toriumi, M., and Hara, E., 1995, Tectonophysics, 245,249-261

[S-VC37] Dynamics of volcanic eruptions and their physical and chemical processes

convener:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo), Chairperson:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo), Hiroyuki Shimizu(Earthquake Research Institute, The University of Tokyo)

This session discusses the dynamics of volcanic and igneous activities such as magma accumulation, magma ascent in volcanic conduits, and dispersion of volcanic products. In order to understand such multi-scale phenomena, the researches of microscopic and macroscopic scales and the techniques that combine the different scales are required. We aim to discuss the latest approaches based on the recent observations, laboratory experiments and numerical simulations, from the viewpoint of cross-cutting research.

The existence of a causal link between large earthquakes and volcanic unrest is widely accepted. Recent observations have also revealed counterintuitive negative responses of volcanoes to large earthquakes, including decreased gas emissions and subsidence in volcanic areas. In order to explore the mechanisms that could simultaneously explain both the positive and negative responses of volcanic activity to earthquakes, we here focus on the role played by topography. In the laboratory, we shook a volcanic edifice analogue, made of gel, previously injected with a buoyant fluid. We find that shaking triggers rapid migration of the buoyant fluid upward, downward, or laterally, depending on the fluid’ s buoyancy and storage depth; bubbly fluids stored at shallow depth ascend, while low-buoyancy fluids descend or migrate laterally. The migration of fluids induced by shaking is two orders of magnitude faster than without shaking. Downward or lateral fluid migration may decrease volcanic gas emissions and cause subsidence as a negative response, while upward migration is consistent both with an increase in volcanic activity and immediate unrest (deformation and seismicity) after large earthquakes. The fluid migration is more efficient when the oscillation frequency is close to the resonance frequency of the edifice. The resonance frequency for a 30-km-wide volcanic mountain range, such as those where subsidence was observed, is ~0.07 Hz. Only large earthquakes are able to cause oscillation at such low frequencies.

Groundmass crystallization experiments of an andesitic pumice under low vapor pressure.

Recently, nanoscale crystals (ultrananolite and nanolite) have been found in groundmass glasses of volcanic rocks. These crystals are thought to crystallize at very shallow part of conduit or inside lava dome. It is suggested that nanoscale crystals recorded information about eruption style transition in shallow conduit. In addition, the eruption style is assumed to be change with viscosity increase due to crystallization of nanoscale crystals. Therefore, it is imoprtant to clarify the nucleation and growth condition of nanoscale crystals for understanding volcanic eruption dynamics . Kinetics of nanoscale crystallization is, however, poorly understood compared to that of microlites. In this study, we performed the series of crystallization experiments that simulate dehydration-induced crystallization in shallow conduit and near surface conditions and investigated the crystallization condition of ultrananolite and nanolite.

As a starting material for the experiments, we used almost microlite-free andesitic pumice clasts from the 1914 (Taisho) Plinian eruption of Sakurajima volcano. The water content in the groundmass glass is approximately 0.5 wt.%. The samples were sealed in a silica glass tube and heated instantaneously to temperatures of 800, 900, 930, and 1000˚C for 3 and 30 minutes, and 2, 8 and 32 hours. When the silica glass tube was evaluated and welded shut, vapor pressure produced via degassing of the starting material is calculated to be of 0.07 (Low Vapor Pressure runs: LVPs). The higher vapor pressures were conducted at 2, 4, and 6 MPa by dehydration of brucite powder.

The mineral assemblage of the crystallized nanolite includes magnetite and pyroxene. The crystallization mode of the groundmass crystals is mostly classified into 5 types; 1) homogeneous nucleation of pyroxene in whole the sample and following growth to the size up to nanolite and occasionally microlite, 2) homogeneous nucleation of ultrananolite in whole the sample, 3) homogeneous nucleation of pyroxene and magnetite crystallization in the vicinity of plagioclase, 4) heterogeneous nucleation of pyroxene on the surface of plagioclase phenocrysts and microlites, and 5) heterogeneous crystallization of pyroxene and magnetite on the bubble surface. Appearance of these types was dependent on the experimental conditions. Magnetite nanolite crystallized under relatively high supercooling, i.e. at low H_2O vapor pressure. Pyroxene nanolite crystallized under wide temperature and pressure conditions. Ultrananolite crystallized in all the runs at 800˚C and at LVP. This indicates that ultrananolite appears under high supercooling. These results on nanoscale crystallization can be used to constrain the pressure-temperature-time paths of volcanic pyroclasts in a shallow conduit.

Decoding pre-eruptive magma evolution and water behavior from plagioclase phenocrysts: Application to the Hoei eruption of Mt. Fuji

*Tsuyoshi Iizuka[1], Chiyo Harada[1], Kenji Shimizu[2], Takayuki Ushikubo[2], Morihisa Hamada[2], Mitsuhiro Yoshimoto[3]

Explosive eruptions are often accompanied by signs of mixing of felsic and mafic magmas in their eruptive products, suggesting the potential link between explosive eruptions and magma mixing. Yet, the underlying mechanism of such eruptions remains elusive. The key to this debate is understanding pre-eruptive magma evolution including water behavior in the magma and the time lag between the magma mixing and eruption.

Water behavior in pre-eruptive magma has been widely studied using melt-inclusions in phenocrysts. More recently, it has been shown that hydrogen concentration in plagioclase phenocryst can be used as a hygrometer of pre-eruptive magma (Hamada et al., 2013). Furthermore, zoning of hydrogen content in the phenocryst can be used as a high-resolution chronometer, as hydrogen diffusion in plagioclase is sufficiently fast.

Here we report the first study that combines in-situ measurements of the contents of major and trace elements, including hydrogen, in plagioclase phenocrysts using the EPMA, LA-ICP-QMS, and SIMS, respectively. These analyses were carried out on sequential eruptive products of the 1707 Hoei eruption at Mt. Fuji. The Hoei eruption is characterized by its explosivity and wide chemical variation in the eruptive products (e.g., SiO_2=50~70 wt%), and the interaction of mafic and felsic magmas has been considered as playing a role in triggering the explosive eruption (Fujii et al., 2002).

We found that the light REE concentrations of plagioclase phenocrysts split in two clusters. These results suggest that there were at least two magma reservoirs underneath Fuji volcano in which magma differentiation had individually proceeded before the Hoei eruption, and also that plagioclase phenocrysts crystallized from these individual magmas were partly mixed before or during the eruption.

Our results further reveal that most melt inclusions have lower water contents than those estimated from hydrogen contents of the host plagioclase phenocrysts and the plagioclase-melt hydrogen partitioning. This suggests that water in melt inclusion could be more easly lost by secondary events than hydrogen in plagioclase phenocryst. Measured hydrogen contents in plagioclase phenocrysts suggest that the early-erupted felsic magma contained water up to 17wt%, whereas the late-erupted mafic magma had lower contents of ~5 wt%. Moreover, the combination of REE and hydrogen contents in the plagioclase phenocrysts (Figure) revealed that the higher water contents, Ce contents, and lower Anorthite contents in the evolved magma can be attributed to fractional crystallization. Moreover, intra-grain chemical variations suggest that rapid crystallization of plagioclase likely driven by decompression accompanied by the exsolution of water occurred in the felsic magma several hours before the explosive eruption. The decompression and water exsolution may result from the convection of the felsic magma caused by the injection of the hot and water-poor mafic magma.

Probing magmatic processes just prior to historic eruptions at Sakurajima volcano: Toward understanding “magma pre-charge”

*Naoki Araya[1], Michihiko Nakamura[1], Satoshi Okumura[1]

1. Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku UniversityUniversity

Based on the pressure at which volatiles within phenocryst-hosted melt inclusions and plagioclase rims were finally equilibrated, Araya et al. (2019, Scientific Reports) reported that the magma storage depths immediately prior to the historic Plinian eruptions at the Sakurajima volcano (AD 1471, 1779, 1914) were much shallower (0.9–3.2 km) than those of the present magma reservoirs beneath Aira Caldera (~10 km) and Sakurajima (~4–6 km). They proposed that the Plinian eruptions were fed from a thick shallow conduit pre-charged from the magma reservoirs. How this process, “magma pre-charge”, has occurred is poorly understood because the Sakurajima case is the first report. As magma pre-charge is assumed to have occurred at least a few tens of days before each eruption, probing magmatic processes just prior to the eruptions is a key to prepare for the possible future eruption.

Magnetite is a mineral suitable for investigating short-timescale pre-eruptive processes because of its fast element diffusion (i.e., high time resolution) compared to common phenocrystic silicates. We have analysed chemical compositions of more than 300 magnetite phenocrysts in pumices and lavas from the historic eruptions. The magnetite phenocrysts showed scarce zoning in each crystal (mostly within 1 Usp mol%), while their compositional range is wide (e.g., 27–45 Usp mol% for the 1914–1915 eruption). This indicates that the eruptions had initiated from a magma reservoir heterogeneous in at least either temperature, melt composition, or oxygen fugacity, and that this heterogeneity had not been perturbed prior to the eruptions. Therefore, widely accepted models for eruption trigger, such as new magma injection and overturn of stratified magma reservoir are not likely to apply to these historic Plinian eruptions.

We analyzed water contents of phenocryst melt inclusions (= MIs) in the erupted materials of Vulcanian explosions from Sakurajima volcano in a period from October 30, 1975 to February 18, 2015. The 11 typical and characteristic Vulcanian explosions were selected with respect to the seismic and geodetic behaviors prior to the explosions. The water contents of 153 MIs were analyzed with FT-IR micro-reflectance spectroscopy (Yasuda, 2014). We then observed the texture of MIs and analyzed the major chemical element compositions with EMPA.

Most of the MI s have dacitic to rhyolitic compositions. The MIs in lava-type pyroclasts have lower water contents (0–1.9wt.%) than those in the scoria type (0–4.1 wt.%). This is consistent with a general view that the lava-type pyroclasts are derived from degassed and compacted magmas in a very shallow conduit. The MIs with high water contents were quenched and fragmented at deeper parts of the conduit or within short time insufficient for water re-equilibrium with surrounding melt in the shallow conduit.

The MIs in pyroclasts from the Minamidake crater have higher water contents than those from the Showa crater. The average water content of MIs in the samples from the Showa crater is 1.4 wt.%, while that from the Minamidake crater is 0.6 wt.%. This shows that the magma was ejected from the shallower part of conduit or their residence time in the shallow conduit was longer during the activity of the Showa crater, being consistent with the fact that Vulcanian explosions from the Minamidake crater were more vigorous than those from the Showa crater.

The water contents of MIs contained in the pyroclasts erupted on August 24, 1995 from the Minamidake crater were 1.9–4.3 wt.% (2.5 wt.% on average). This range of water contents is similar to those of the three historical Plinian eruptions of Sakurajima (Araya et al., 2019). This indicates that the magma ascended nearly as fast as in the Plinian eruptions, and that magma ascent rate does not solely determine the difference between Vulcanian and Plinian eruptions.

The eruption on August 24, 1995 occurred after approximately 3 months low-activity period. As a precursory phenomenon of the explosion, raid and large intrusion of magma was detected through inflation of the volcanic edifice observed with an extensometer. Five hours after the expansion started (at the time the tiltmeter scaled-out), the eruption began concurrently with the beginning of the BL swarm. In the early stage, the eruption was not accompanied by air shocks, and a fire fountain 100–200 m in height was observed, then later the activity shifted to the Vulcanian explosions with repeated air shocks. The volume of magma intruded prior to the eruption was estimated from the amount of crustal inflation to be more than 5 times as much as that of the average value for the explosions at Minamidake crater. Such a sub-Plinian-like eruption sequence on August 24, 1995 seems to be consistent with the result that the magma ascent rate was close to those of the Plinian eruptions.

Cyclic degassing behavior accompanying dome-forming lava effusion at Shinmoedake volcano in the 2018 eruption

*Taishi Yamada[1], Hideki Ueda[1], Toshiya Mori[2], Toshikazu Tanada[1]

1. National Research Institute for Earth Science and Disaster Resilience, 2. Geochemical Research Center, Graduate School of Science, The University of Tokyo

Shinmoedake volcano, one of the most active volcanoes in the Kirishima complex in Japan, had a series of eruption in 2018. At the beginning of the eruption sequence in March 2018, Shinmoedake had a dome-forming effusive eruption. Observation networks of the National Institute for Earth Science and Disaster Resilience (NIED, V-net), the Japan Meteorological Agency (JMA), and the Geospatial Information Authority of Japan (GSJ, GEONET) around the Kirishima area detected significant ground deformation accompanying the lava effusion. The deformation can be explained by assuming a pressure source located at the same position (7 km NW from Shinmoedake, depth of 10 km) that is adopted to explain syn-eruptive ground deformation in the 2011 eruption (Ueda, 2018, VSJ). The time series of the magma chamber contraction obtained by geodetic observations provides remarkable insight to constrain the macroscopic behavior of the eruption mechanism. Here, we examine characteristics of volcanic earthquake catalogue, seismic, acoustic, tilt, SO2 gas flux measurement, and visual observation data obtained by observation networks of NIED, JMA, and University of Tokyo, to constrain detail aspects of the effusive eruption such as the magma flow regimes inside the conduit.

Hypocenters of low-frequency earthquakes accompanying the lava effusion are distributed almost vertically in the range of 0.1–3.2 km from the surface. Therefore, we assume vertical elongated conduit geometry. Syn-eruptive seismic waveforms record cyclic tremor signals with a peak frequency of about 0.8 Hz, with a duration of 5–20 minutes as well as repose time. The tremor is accompanied with explosive degassing from the crater, which is recorded by infrasound, SO2 gas flux measurement, and visual camera data. Tilt data with a bandpass filter of 250–2000 s show inflation-deflation cycles of the Shinmoedake edifice accompanying the cyclic degassing. Both inflation and deflation of the filtered tilt data correspond to the repose time and amplitude increasing of the tremor.

Some features of the cyclic degassing at Shinmoedake from our data set are summarized as follows: (1) Inflation of the volcano edifice (2) Beginning of degassing and deflation of the volcano edifice (3) End of degassing and repose time until next inflation. Such an inflation-deflation cycle is reported by Takeo et al. (2013) from observation data of lava effusion in the 2011 eruption. Dome-forming lava effusion at Santiaguito also produces such a cyclic degassing and related ground deformation (Johnson et al., 2014). The inflation prior to the degassing may have similar source physics to that related Strombolian and Vulcanian eruptions. Next our challenge is to quantify the source of those signals to estimate the amount of relating gas or magma, and relationship with the time series of the magma chamber contraction.

Acknowledgement: We appreciate the JMA to provide observation data at Kirishima area.

Estimation of the amplitude of infrasoundsignal based on sound diffraction

*Kyoka Ishii[1], Akihiko Yokoo[1]

1. Graduate School of Science, Kyoto University

Observation of infrasound signals generated from volcano eruptions provides us with important information directly reflecting explosion processes at the source. How to determine the locations of stations for acquiring clear signals has been one of the most fundamental problems for researchers. The best way to solve this problem should be a numerical simulation of infrasound wave propagation considering the propagation effect of topography (e.g., Kim & Lees, 2011; Lacanna & Ripepe, 2013). However, we have to take time and cost money to perform numerical simulations. In this study, we attempt to estimate the amplitude of infrasound signal by an easier method applying the sound diffraction theory. We replaced the cross-section of topography from the source to the station by an equivalent single screen and calculated the attenuation of the amplitude due to diffraction by the thin screen based on Macdonald's exact solution (1915). Then, our results were compared with the calculated amplitudes from 3D-FDTD simulation (Kim et al., 2015) and the observed amplitudes of 31 explosive events occurring at Showa crater, Sakurajima in September 2017. For comparison, the amplitude value was converted to the amplitude ratio with respect to the amplitude of the KUR station in the line-of-sight with the source. As a result, the amplitude ratios estimated by our method were determined at an accuracy of ±30% of the amplitude from the FDTD simulation at all stations. The amplitude ratio of our method was included in the range of the observed amplitude ratio at five stations. On the other hand, at one station, where the azimuth and distance from the source is almost similar to those of the KUR station, observation results cannot agree with the result of our method. This discrepancy suggests that the infrasound signal is affected by other effects than diffraction, such as reflection at the ground, and further study is required in the future.

Mechanism and frequency change of pressure oscillation in the laboratory geyser system

*Noriko Teshima[1], Atsushi Toramaru[2]

1. Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University

Geysers are hydrothermal activities seen in volcanic areas, which have the similarities with volcanos in seismicity. It is known that the pressure pulses occurring inside geyser's conduit excite tremors, but the source and mechanism of the pressure pulses are still unclear. Because phenomena of natural geysers are complex due to additional factors such as the influence of atmospheric conditions, and because their interiors are hardly observed directly, simplified laboratory experiments which allow us to directly observe what are happening in the interior may be useful. In this study, we tried to reveal the mechanism of the pressure oscillation and factors controlling its dominant frequency using our fluid oscillation model and pressure and temperature data measured in our laboratory experiments.

We designed an experimental setup which reproduces cyclic eruptions of natural geysers. The setup mainly consisted of a flask and a glass tube, which correspond to natural hot water chamber and conduit, respectively. Heating the flask by the hotplate, we measured pressure and temperature in the flask, and erupted mass of each eruption. We also took video images of flask interior and water surface in the conduit with normal-speed and high-speed video cameras. From the movies of the water surface, we digitalized the vertical water column movement in the conduit using a video analysis software. We examined the effects of experimental conditions on characteristics of pressure oscillation by varying three geometric parameters of the experimental system: (i) inner flask volume, (ii) initial water level in the conduit, and (iii) cross-sectional area of the conduit.

In interpreting experimental results, we used the model proposed by Toramaru et al. (Volcanological Society of Japan 2010 Fall Meeting), in which the frequency of pressure oscillation is represented in terms of geometric parameters of the experimental system and the effective bulk modulus K* of fluid in the flask. In our experiments, it was difficult to determine correctly the effective bulk modulus K* from the movie analysis or another measurement, so we calculated the values of K* using a model to relate the pressure variation in the flask ΔP and water level in the conduit ΔL, by $AK^*/Vo = \Delta P/\Delta L$, where, A is cross-sectional area of glass tube, Vo is inner flask volume, respectively. The values other than K* were obtained from our experimental measurements. From these expressions, we calculated theoretical values of the resonance frequency and compared it with the measured values of dominant frequency of pressure oscillation.

The results showed that the measured pressure oscillation in the flask consisted of high-frequency pulses and subsequent low-frequency damped oscillation. The damped pressure oscillation had a strong inverse correlation with vertical water column movement in the conduit. From the observation of video images synchronized with pressure record, we found that the bubble formations in the flask bottom caused the pressure pulses. From an eruption to the next eruption, the dominant frequency of pressure oscillation decreased systematically. This monotonic decrease in the dominant frequency was explained by the reduction of K*, as a result of increase in the gas volume in the flask by heating. We found that the dominant frequency of pressure oscillation varied depending on experimental conditions. The variations in temporal behavior of dominant frequency could be interpreted by differences in the setting of

©2019. Japan Geoscience Union. All Right Reserved.

geometric parameters and in the initial values of K* just after eruptions due to various erupted masses of the preceding eruptions.

In conclusion, the pressure oscillation in the experimental geyser system is caused by bubble formations in the flask and vertical water column movement in the conduit. The dominant frequency of pressure oscillation is controlled by the geometric parameters of the experimental system and the erupted mass of the preceding eruption.

Effects of temperature on the run-out distance of large-scale pyroclastic density currents: Numerical simulation of a two-layer depth-averaged model

*Hiroyuki A. Shimizu[1], Takehiro Koyaguchi[1], Yujiro J. Suzuki[1]

1. Earthquake Research Institute, The University of Tokyo

During large-scale explosive volcanic eruptions, a mixture of volcanic particles and gas is continuously ejected from the volcanic vent and can flow along the ground surface as a pyroclastic density current (PDC). Understanding the relationship between the run-out distance of PDC (i.e., the extent of PDC deposits) and the eruption conditions (e.g., the magma discharge rate and the temperature of erupted mixture) is desired to mitigate volcanic hazard associated with explosive eruptions. This study aims to clarify the effect of temperature on the run-out distance of large-scale PDCs on the basis of numerical simulations. The effect of temperature is a key issue, because it closely relates to the eruption style; the temperature ranges from less than 500 K for phreatomagmatic eruptions to more than 1000 K for magmatic eruptions.

Generally, the run-out distance of PDC is affected by the vertical stratification of particle concentration in PDC; it is determined by lift-off of the upper dilute part (particle concentrations < 1 vol.%) or deposition of the lower dense part (~ 10—50 vol.%). To reproduce the run-out distance of a density current with a strong density stratification, we have developed a new two-layer depth-averaged model. In order to evaluate the effects of temperature on the PDC dynamics, our model considers entrainment of ambient air into the upper dilute current, and thermal expansion of the entrained air. We assumed that a homogeneous dilute current is steadily supplied during time > 0 from the source vent on a horizontal ground surface. We performed a parametric study for various temperatures of the dilute current at the source (400—1200 K).

The numerical results show that, as a dilute current spreads radially from the source, the current density decreases through particle settling, air entrainment, and thermal expansion of the entrained air. When the frontal region of the dilute current becomes lighter than the ambient air to reverse buoyancy and lift off, the dilute current stops forward propagation and converges to a steady state (the distance between whose front position and the source position is referred to as $r_{\infty U}$). Particles settling from the base of the dilute current form a thin dense current, which also spreads radially. As the radial mass flux of the dense current at the front balances the basal deposition rate, the dense current stops forward propagation and converges to a steady state (the distance between whose front position and the source position is referred to as $r_{\infty L}$). The result of the parametric study shows that the relative magnitude between $r_{\infty U}$ and $r_{\infty L}$ depends on the temperature: $r_{\infty U}$ is shorter than $r_{\infty L}$ in high-temperature cases (> 600 K) whereas $r_{\infty U}$ is longer than $r_{\infty L}$ in low-temperature cases (< 600 K). This variation comes from the fact that the lift-off distance of the dilute current (i.e., $r_{\infty U}$) significantly increases as the temperature decreases, because thermal expansion of entrained air is suppressed with the decreasing temperature. The results of the low-temperature cases (i.e., $r_{\infty U} > r_{\infty L}$) explain the observation that stratified surge deposits originated from dilute PDCs are widely observed in the deposits of phreatomagmatic eruptions.

Total grain-size distribution of pumice fallout deposits (Kj-P1) from 54 ka plinian eruption at Kuju Volcano

*Tomohiro Tsuji[1], Kishimoto Hiroshi[2], Fujita Kouji[2], Chisato Nakamura[3], Nagata Tomohiro[3], Kimura Kazunari[3], Michiharu Ikeda[1], Naoki Nishizaka[4], Kozo Onishi[4]

1. Shikoku Research Institute Inc., 2. Asia Air Survey Co. Ltd., 3. Naiba, 4. Shikoku Electric Power Co. Inc.

Constraining physical parameters (e.g. Total grain-size distribution; TGSD) of tephra dispersion and deposition from explosive volcanic eruptions have been studied using observation and analyses of deposits of recent eruptions. However, TGSD of old tephra deposit is a significant challenge and has been rarely studied, because of the difficulty of measuring grain size of altered pumice particles and lack of observation. In this study, to estimate TGSD of VEI5 dacitic plinian explosive eruption occurred at 54 ka at Kuju volcano, we conducted geological survey and grain size analyses for the Kj-P1 pumice fall deposit.

Based on grain-size distribution, maximum pumice size and components, Kj-P1 pumice fall deposit is divided into finer lower and coarser upper layer. We analyzed each grain-size distribution for the lower and upper layers.

Generally, sieving and laser-diffraction analysis have been used for measuring grain-size of tephra and we also used these methods. However, because the upper layer of Kj-P1 has been altered and lumped, it can be hardly separated. In addition, because the altered pumice particle could be broken into finer particles under water, we cannot measure accurate grain sizes. Then, we challenged a new method, image analysis, outlining pumice particles on photographs of outcrops and measure the sizes and area ratio of each pumice particles. We combined the results of the image analyses, sieving and laser-diffraction analyses at 15 and 20 localities for the lower and the upper layers. Using volonoi distribution, Md phi and sigma phi are calculated to be -1.5 and 2.5 for the upper layer and 0.5 and 2.6 for the lower layer. The result fit the observation of altered pumice particles at the outcrops better than the result without the image analyses. To verify this method, analytical methods such as numerical simulation are needed.

Estimating ashfall volumes for the 2018 Shinmoedake eruptions using the Ellipse Approximated Isopach (EAI) method - How to quantify ashfall volumes from limited ashfall observation locations

*Yasuhisa Tajima[1], Setsuya Nakada[2], Masashi NAGAI[2], Fukashi Maeno[3], Jun Oikawa[3], Teruki Oikawa[4], Yasuo Miyabuchi[5], Toshiaki Hasenaka[5], Masataka Kawaguchi[5]

1. NIPPON KOEI CO.,LTD., 2. NIED, 3. ERI, the Univ. Tokyo, 4. Geological Survey of Japan, AIST, 5. Kumamoto Univ.

A volcanic ash eruption began on March 3, 2018 at the Shinmoedake Volcano, in the Kirishima Volcanoes Group. Eruption activity increased to March 5, and lava flow was observed on March 6. Eruptions continued until June 27. We observed volcanic ashfall amounts around the Shinmoedake Volcano and analyzed volcanic ashfall volumes for each eruption using the EAI method (EAI ashfall volume) proposed by Tajima et al. (2013). The EAI method can be used in four different ways. Firstly, ashfall volume is estimated based on one ashfall deposit data point. Second, the estimation is undertaken using two ashfall deposit data points. Third, the estimation is based on three ashfall deposit data points. Fourth, the estimation is based over four ashfall deposit data points.

Tajima et al. (2013) suggest that if an accurate calculation axis and an accurate aspect ratio of a distribution are determined, we can calculate the total volume of ashfall deposit using the EAI method using only one ashfall deposit data point. The calculation axis for the ellipse must be accurate, but it is difficult to determine an accurate calculation axis from the observation. Tajima et al. (2013) determined the lower threshold of detectable ashfall as 0.1 g/m^2 for an eruption of the Sakurajima Volcano. This lower threshold of detectable ashfall value is used in this calculation. The EAI method is used based on one data point calculation, and we have taken a suitable aspect ratio of the ellipse which is fitted between the EAI isopach from 0.1 g/m^2 and a limit location of detectable ashfall. We calculated ashfall deposit volumes for the period of eruption from 11 am on March 1 to 7 am on March 2.

Next, we demonstrate a calculation using two data points. Tajima et al. (2013) suggest, if an accurate axis of the ellipse distribution is determined, we can calculate an EAI ashfall volume of the deposit using two ashfall data points. In this case, we would need a limit location of a detectable ashfall deposit, because it is difficult to determine an accurate calculation axis. In this case we select two ashfall deposit data points for the EAI calculation, then we determine a suitable axis which is fitted between the EAI isopach as 0.1 g/m^2 and a limit location of visible ashfall. In this way, we estimated the EAI ashfall volume of the eruption at 15:58 pm on March 9. For comparison, we observed a limit location of visible ashfall on a car.

We show a calculation procedure for three ashfall deposit data points. This is a normal calculation case shown by Tajima et al (2013). We select two ashfall deposit data values for the EAI calculation, and determine a suitable axis to fit the observation points and the calculated distribution. However, sometimes it is take the over or under estimated volume from the calculation, because estimation of EAI ashfall volume can be influenced by environmental variables, such as wind direction changes, depositional conditions of ash-fall, and other research conditions. Lastly, we demonstrate the estimation of ashfall deposit volumes using four ashfall deposit data points. In this case, we select two ash-fall values for the EAI calculation. We determined a suitable axis which best fits the observation points and the calculated distribution. Using four ashfall deposit data points improves accuracy.

©2019. Japan Geoscience Union. All Right Reserved.

It is determined the EAI ashfall volumes of over 10 eruptions of the 2018 Shinmoedake eruptions. We assume that the eruption rate of each volumes per an hour increased before the lava flow producing. We will discuss the accuracy of the EAI method and the practical applications of this method.

National Research Institute for Earth Science and Disaster Resilience, 4. Research and Education Center for Natural Hazards, Kagoshima University

A tephra fallout process during a volcanic eruption has mainly been investigated by geological method such as based on measurement of mass and grain size distribution on tephra deposits. Recently, a combination of the tephra fallout deposit data with numerical simulations of tephra dispersal and fallout contributes to understanding the detail of the eruption dynamics. In order to further promote the combination between the simulations and the observations, we need multi-parameter observations of the eruptive phenomena with high-time resolution which is comparable with the timescale of the eruption. One of the methods for the high-resolution observations is to apply techniques already used in other fields, such as precipitation measurements by weather radar and disdrometer in meteorology. In this study, we investigated the main characteristics of tephra fall from the eruptions at Sakurajima volcano in southern Kyushu, Japan by using a laser based optical disdrometer, Parsivel.

The disdrometer measurements were carried out for two years at one station located 2.5 km south of Showa crater of Sakurajima volcano, and made it possible to detect 76 tephra fall events, in which particle size and fall velocity were simultaneously measured with one-minute sampling interval. We found that the tephra fall can be easily distinguished from precipitation because of a notable feature of the tephra fall that both the particle size and the fall velocity gradually decrease with time during each event. The detected events were compared with the information about the direction of eruption cloud which is reported in eruption list by JMA, and it was found that the detection rate of the tephra fall during the eruptions with south-directed eruption cloud is about 7 times higher than that with other directions. Furthermore, the feature of the temporal changes in the size and the velocity was also most obvious in the case of south-directed eruption cloud. These indicate that the disdrometer can successfully measure the tephra fall directly reaching from the crater location to the station, and that the disdrometer measurements at multiple stations covering all directions may provide valuable information about the tephra dispersion and eruption cloud dynamics.

By using the tephra fall events, we obtained a quantitative relationship between the particle size and fall velocity. The cumulative weight of the tephra fall during one event was also measured by digital electric scale set close to the disdrometer, which enabled us to calculate the density of the particles. On the basis of the size-velocity relationship and the particle density data, we can estimate morphological parameters of volcanic particles in models of terminal fall velocity in previous studies. Furthermore, the tephra size and fall velocity data enabled us to calculate a particle size distribution per unit volume and size class, and we found that this distribution is well explained by exponential distribution. In the case of precipitation, the value of exponent is modeled as a function of the amount of rain fall. When we estimate the exponent as a function of the amount of the tephra fall using the same manner as precipitation, it was found that the exponent is smaller than that for precipitation. Because the size-velocity relationship and the particle size distribution are important parameters for radar analysis, the formulation and parametrization for its relationship and distribution in this study can be utilized for eruption cloud observations by weather radar.

[S-TT43] seismic monitoring and processing system

convener:Takahiro Maeda(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Masanao Shinohara(Earthquake Research Institute, The University of Tokyo)

This session covers scientific and technical issues in seismic monitoring or data processing systems for earthquakes or explosions observation. This includes development or improvement of seismic observation networks, innovative techniques in observation and monitoring, cutting-edge data acquisition and processing techniques in geophysical explorations. Other topics related to geophysical observation are also welcome.

Summary and Considerations about Borehole Stress Meter for Continuous Observation

We will explain the following items
1. Stress Meter can Observe both Stress and Strain
2. Stress unlike Strain can be Derived without Knowing an Elastic Constant
3. Why is Observed Elastic Invariants Similar with Vertical Component ?
4. How High Resolution Does a Stress Meter Have ?
5.How Wide Observation Range Does a Stress Meter Have ?

Seismic monitoring by an autonomous robotic float equipped with a hydrophone: MERMAID

*Masayuki Obayashi[1], Hiroko Sugioka[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Department of Planetology, Kobe University

Seismic monitoring in the oceans has been limited to rather localized experiments such as ocean bottom seismometers (OBSs) and moored hydrophones. Because about 70% of the Earth is covered by water, advances in seismic monitoring depend on the development of radically new instruments, capable of providing seismic data all over the ocean. Recently a new instrument, named MERMAID (Mobile Earthquake Recording in Marine Areas by Independent Divers), was developed to measure acoustic signals converted from seismic waves at the seafloor. The MERMAID is an autonomous robotic float equipped with a hydrophone and drifts passively at 1,500 −2,000 m depth until an earthquake signal is detected. If this is identified as a strong P wave, the MERMAID ascends at speed of 10 cm/s for transmission of the recorded waveform within time window of a hundred seconds before and after the P wave arrival as well as its global positioning system coordinates at the surface. After transmitting the data via satellite links, the MERMAID descends at speed of 5 cm/s to monitor earthquake signals at 1,500 −2,000 m depth again. Therefore we are able to obtain seismograms from the ocean in quasi-real time. Under an international project collaborated among Japan, France, United States and China, we planed to deploy more than 40 drifting buoys with hydrophone to image the detail of the South Pacific mantle plume that is one of two huge mantle plumes from the base of the mantle. As part of this project, we deployed drifting floats in the South Pacific during the 1st leg of MR18-06 cruise. We will show the obtained seismograms and discuss their quality.

Earthquake observation in a borehole over 250 ˚C using high temperature optical fiber and DAS technology

*Tsunehisa KIMURA[1]

1. Schlumberger

DAS (Distributed Acoustic Sensing) technology has been used to meet the demands of pipeline monitoring and intrusion detection in Oil & Gas business since 2011. The latest optical fiber sensing technology using differential phase data called “hDVS” (heterodyne Distributed Vibration Sensing), now enables DAS to record seismic signal including VSP (Vertical Seismic Profiling)[1)]. Three-dimensional imaging can also be performed by a 3DVSP method[2)]. We have introduced the observation of natural earthquakes and waves, targeting the tsunami detection, using the hDVS device at recent meetings of JpGU and the seismological society of Japan (SSJ)[3)].

Late 2018, we conducted an experiment of natural earthquake observation using the hDVS system at the geothermal well in Japan. A high temperature optical fiber logging cable with 300 ˚C rating was run in a deviated well having a maximum depth of about 1,600 m and connected the third generation hDVS acquisition system to the optical fiber (single mode fiber) and recorded natural earthquake events for 5 days. The maximum temperature recorded at a depth of about 900 m was more than 250 ˚C. Under such a high temperature environment, almost all electronic, electric and magnetic sensors including seismometers cannot operate for a long time. Even with the use of DAS equipment, there is no precedent as far as I know, at least it is the first attempt in Japan.

A weight of 2 m length and 25 kg weight was attached to the high temperature optical fiber logging cable, and the observation was started by lowering the weight to the depth of 977 m inside the casing in order to avoid the weight becoming stuck in the open hole section of the well. With continuous recording with 60 seconds as one file, data of 975 m section from the surface was recorded for 5 days. In this paper, we report on the result of verifying how much observation of natural earthquake waves can be performed by using continuous measurement data.

During the observation period, we succeeded in capturing six natural earthquake events. Two of them were medium-scale earthquakes published in the earthquake information of the Japan Meteorological Agency (JMA). An example of this was recorded as follows.

(21st of November, 2018 04:09:49.9 Latitude 30˚24.0'N Longitude 130˚9.0'E 123km depth M5.2)

Earthquake data recorded by hDVS is shown in Fig. 1.

The arrival time of the P-wave analyzed from the waveform is 4:10:12.2 JST on 21st of November at the deepest part of the borehole and 4:10:12.5 JST near surface. Measurement parameters were gauge length 4 m, spatial sampling 1 m, and sampling period 1 msec. We also conducted reprocessing to change the gauge length and confirmed that data with higher S/N can be obtained. Reprocessing the raw data for an optimized gauge length is a capability that is unique to hDVS amongst the available DAS techniques.

We also compared it with continuous seismometer records by NIED (Hi-net). The nearest Hi-net station

©2019. Japan Geoscience Union. All Right Reserved.

from the wellsite (just about 4km away), is compared with the recorded hDVS data, and it was found that they match well. For small earthquake events, S/N was higher in the measurement data of hDVS in some cases, which will be shown during the presentation.

It was confirmed that hDVS/DAS system can be used to monitor natural earthquake events while monitoring the reservoir or other purpose under very high-temperature condition such as geothermal well or very deep well that reaches a mantle, if the condition of the optical fiber is good.

Acknowledgements: JMA and NIRD data are used as a reference earthquake data for comparison. We thank these organizations.

Distributed Acoustic Sensing measurement by using seafloor optical fiber cable system off Sanriku for dense seismic observation

*Masanao Shinohara[1], Tomoaki Yamada[1], Takeshi Akuhara[1], Kimihiro Mochizuki[1], Takeo Kasajima[2], Takahiro Arioka[2], Masayuki Hamakawa[3], Shunsuke Kubota[4]

1. Earthquake Research Institute, University of Tokyo, 2. Fujitsu Laboratories Ltd., 3. Fujitsu Limited, 4. YK Giken Co., Ltd.

Recently Distributed Acoustic Sensing (DAS) measurement which utilizes an optical fiber itself as a sensor becomes popular for security surveillance, monitoring of oil pipe line system. etc. In addition, DAS measurement begins to be applied to seismic prospecting such as vertical seismic profiling for an exploration of energy resources. As DAS measurement is thought to be useful for earthquake observation, there is a trial to observe an earthquake using a seafloor optical fiber. DAS measurement is one of optical fiber sensing technologies. A coherent laser pulse with short duration is transmitted continuously to a single mode optical fiber, and backscattered light is observed. When a small deformation of a fiber occurs by a vibration near fiber, a pattern change of the backscattered light is observed. Travel time of light and pulse length correspond to distance of measurement point and spatially resolution, respectively. Spatially resolution is 1 - 20 m in the highest case. From these characteristics, DAS measurement enables a linear array seismic observation. A length of the array with short sensor interval corresponds to that of a deployed optical fiber. Using the present technology, the maximum length of a DAS measurement reaches more than 70 km. On the other hand, development of data processing is needed because the principle of measurement by the DAS differs from that of conventional seismic measurement using a pendulum. In 1996, a seafloor seismic tsunami observation system using an optical fiber cable was deployed off Sanriku by Earthquake Research Institute, the University of Tokyo. The system still continues the observations experiencing an interruption by a damage of the 2011 Tohoku-oki earthquake. The system has six spare (dark) optical fibers for future extension. The length of dark fibers is about 120 km without a repeater. The dark fibers are suitable for DAS measurement due to dispersion shifted single mode fiber. Therefore we start development of a seafloor seismic observation system by the DAS technology with Sanriku cable observation system as a next generation of marine seismic observation system. The observation system using the DAS measurement can increase spatial resolution on seafloor seismic observation. In February 2019, we made a pilot observation of DAS measurement using a dark fiber of Sanriku seafloor observation system. An interrogator was installed in the landing station temporarily, data were recorded continuously for 100 km length with spatial resolution of 10 m or 40 m and sampling frequency of about 500 Hz. As a result, earthquakes including small local earthquakes occurring near the cable system, deep earthquakes were recorded. We will develop data processing using the obtained data.

Hydrothermal fluids and seawater are often entrapped in minerals as fluid inclusions in crustal/mantle materials, marine halites and even in rare meteorites [1, 2, 3, 4]. The chemical compositions of fluid inclusions and mineral inclusion therein are keys to decipher their origins and evolution of the geofulids. A laser-ablation inductively-coupled-plasma mass-spectrometry (LA-ICP-MS), a Raman spectrometry and an environmental SEM (cryo-SEM with EDS) are methods for chemical analysis of fluid inclusions, entrapped tiny minerals and gasses. For example, Kawamoto and coworkers recently determined Na/K ratio of fluid inclusions in olivine crystals from mantle xenoliths from the Pinatubo volcano by LA-ICP-MS in 20-μm spatial resolution [1]. The attempt successfully provided new insight on the fate of seawater subducting into the mantle in a plate convergent region. Lowenstein et al. investigated major chemistry of fluid inclusions from marine halites by a cryo-SEM with EDS system, and found systematic and oscillating changes in Phanerozoic seawater chemistry (Na^+ vs. Cl^- and Mg^{2+} vs. Cl^-) [3].

As unique sample preparation and analytical approach to a fluid inclusion, combined instrument of focused ion beam system and scanning electron microscope with a cryo sample stage (cryo-FIB-SEM) is recently utilized (e.g., Yoshida et al., 2018 [2]). Fluid inclusions can be exposed as ices in the vacuum sample chamber of cryo-FIB-SEM, and then the frozen fluids can be directly analyzed by EDS attached to SEM. Advantages of this approach are a direct access to fluid inclusions by precise sample milling with FIB, and simultaneous analysis for major elements with a relatively high spatial resolution (~5 μm). The method has been first applied to fluid inclusions in quartz [2].

A cryo-FIB-SEM approach is, however, time-consuming: entire processing and analysis with cryo-FIB-SEM requires several to few tens of hours for a several tens micrometer-sized sample. Descriptions of exact locations and spatial distribution of each fluid inclusion in host minerals will help to minimize a processing time with FIB. We, therefore, used a laboratory-based micro-focus XCT apparatus (μXCT) at the Center for Advanced Marine Core Research, Kochi University for acquiring an accurate three-dimensional characterization of fluid inclusions in minerals with a spatial resolution of 0.5 to 2.5 μm depending on sample size. In the present study, we aim to improve the throughput of the fluid inclusion analysis using cryo-FIB-SEM and establish a reasonable analytical flow. We have obtained spatial distributions of fluids in olivine from the Pinatubo xenoliths and those in halite in Sicilian rock by μXCT. Pretreatments for the samples have been carried out by micro-sampling system, and then microfabrication and chemical analysis of frozen fluids in the samples have been carried

out by cryo-FIB-SEM.

In this talk, we will present the effectiveness of coordinated sample preparation utilizing cryo-FIB-SEM and μXCT, and a comprehensive microanalysis of fluid inclusions in addition to cryo-FIB-SEM. For instance, residues of fluid inclusions and associated minute minerals in FIB-processed samples can be further characterized in a higher spatial resolution by an analytical transmission electron microscope (TEM) and a secondary ion mass spectrometer (SIMS).

Feasibility Study for Precise Particle Characterization of Fine Clay Particle Using An Automated Particle Image Analysis and Nanotrakcking Analysis.

*Daisuke Sasakura[1], Aiko Hayauchi[1], Sho Kimura[2]

1. MalvernPanalytical Japan ,Div of Spectris Co.Ltd,., 2. Faculty of Agriculture, University of the Ryukyu

Introduction

Clay minerals are very common in soils, in fine-grained sedimentary rocks such as shale, mudstone, and siltstone and in fine-grained metamorphic slate and phyllite. Typical mechanism to generation of clay is alteration of the surface on mineral rock due to affected by transfer of water on the earth surface. Behavior of generation of clay is controlled by surface of minerals be forced to transform to other mineral component due to the moment contact with water. Particle size of clay minerals are usually ultrafine-grained, such as normally considered to be less than 2 micrometers in size on standard particle size distributions. Notable properties of clay are high-affinities with water, minerals due to unique properties of possible to make intercalation in crystal structure, and possibly disperse to anywhere with moving of water on earth surface due to fine particle size range. Therefore, to understand characteristics of clay is possible to consider as a maker index parameter of material transportation on the surface of earth. Especially particle characterization of clay is promising as fundamental parameter. Existing approaches to characterize of particle are such as an electron microscope (Scanning type: SEM, Transmission type :TEM) , an optical microscope (OM) , a laser diffraction (LD), an electro zone methods (coulter counter) and a dynamic light scattering (DLS) . However, drawbacks of these methods were such as indirect method, limited work on concentration determination, time consuming to measure over than several thousand particles and requirement to highly concentration (over than 3wt%) of ionized water. Complementally analytical approach using an automated particle image analysis (APIA) and Nanotracking analysis (NTA) are promising tools to as new flamework. In this report will be discuss for feasibility and technical discussion to applicable for fine clay using this flamework.

Material and Methods.

As model samples for clay mineral, purchased Kaolin was used. To investigate purity and chemical components using crystal structure , XRD (Aereris , MalvernPanalytical , Almero, Netherlands) was used. Profile of XRD chart suggested diffraction peaks on 9.6, 19.3, 19.9, and 29.1 degrees. These peaks were significantly suggested as Pyrophyllite using library search.To characterize micrometer particles range, APIA analyses were conducted on a Morphologi G3SE as automated image analysis system (MalvernPanalytical Instruments, Worcestershire, UK). To characterize nanometer range, NTA analyses were conducted on a NS300 as nanotracking analyzing systems (MalvernPanalytical Instruments, Worcestershire, UK) with particle concentration.

Crystal structure and local structures of natural perovskite-type (Na,REE,Ca)(Ti, Nb)O_3 loparite by single crystal diffraction and XAFS analyses

*Ginga Kitahara[1], Akira Yoshiasa[1], Makoto Tokuda[1], Kazumasa Sugiyama[2]

1. Kumamoto University, 2. Tohoku University

The perovskite type compound ABX_3 expresses various physical properties such as ferroelectricity and piezoelectricity, symmetry changes according to composition, pressure and temperature, and various deformations of framework constituted by BX_6 octahedral occur. Even in a solid solution, ferroelectricity, para electricity, superionic conductivity and the like are developed. Recently, it has attracted attention as a material for solar cells.

The perovskite-type minerals, which exist in the Earth’ s mantle, are one of the major host mineral of trace elements such as Th and REE. However, there are few detailed studies on rare earth elements and various heavy metals contained in naturally occurring perovskite-type minerals. In this study, we report on structural properties of solid solution, local structural characteristics of contained elements and irregularities due to radioactive elements, etc.

Analysis of chemical composition using SEM JSM-7001F manufactured by JEOL and EDS INCA SYSTEM manufactured by Oxford, and BL-9C and NW10A of KEK were used analysis of local structures and oxidation states by XAFS analysis and refinement of single crystal structure using Rigaku XtaLAB Super Nova.

The mineral produced from, Mt. Khibiny, Kola, Russia, which we treat as samples, is the solid solution with Lueshite $Na^{+}Nb^{5+}O_3$, Loparite $Na^{+}REE^{3+}Ti^{4+}{}_2O_6$, Perovskite $Ca^{2+}Ti^{4+}O_3$, Tausonite $Sr^{2+}Ti^{4+}O_3$ as end members. (Mitchell and Chakhmouradian 2000) SEM-EDS analysis reveal that there are albites mainly composed of $NaAlSi_3O_8$ at the rim. Therefore, we performed single crystal X-ray diffraction experiment with untwinned crystals picked up from the center.

Many discussions have been made on the crystal structure of Loparite. (Haggerty and Mariano 1983, Vlasov 1966, Mitchell 1996, Zubkova et al. 1998, Chakhmouradian et al. 1999, Mitchell et al. 2000) We attempted to analyze rhombohedral, tetragonal and tetragonal crystals which have been mentioned in previous research using this sample. Rhombohedral crystal: space group *R-3c*, a = 5.5077(2), c = 13.4906(5), Tetragonal crystal: space group *I4/mcm*, a = 5.5166(6), c = 7.7814(10), Ortho crystal Space group *Pbnm*, a = 5.5142(5), b = 5.5085(7), c = 7.7961(8) From more precise structural analysis, we will discuss the phase transition of Loparite structure etc.

From the shape of the XANES spectrum of Fe by spectral analysis, it turned out that the oxidation state of Fe contained is divalent, similar to the Ce-perovskite we investigated last time. In the Ti K-edge spectrum, it can be seen that the local distortion around Ti is considerably large from the peak intensity of pre-edge. With the substitution of Nb, the local strain of Ti at the octahedral site in the solid solution is larger than the $CaTiO_3$ end component, and the electron transition probability from 1s to 3d orbital is increasing. In the Th L3-edge spectrum, XANES is remarkable, and it can be interpreted that the actinoid element Th changes to U by causing radioactive decay, and irregularization corresponding to local metamictization

Crystal Size Distributions based on crystal habit of groundmass pyroxene crystals in the ejecta of the Shinmoedake 2011 eruption

*Shota Okumura[1], Mayumi Mujin[2], Akira Tsuchiyama[1], Norimasa Shimobayashi[1], Akira Miyake[1]

1. Department of Geology and Mineralogy, Graduate School of Science, Kyoto University, 2. Division of Earth and Planetary Materials Science, Department of Earth Science, Tohoku University

The 2011 eruption of Shinmoedake, Kirishima volcano, Japan, is characterized by the transition of eruption styles and was preceded by magma mixing (e.g., Suzuki et al., 2013). However, the condition in the volcano has not fully clarified yet, thus clarification of the transition processes needs more information about the magma ascent process from the chamber to the shallow conduit. Meanwhile, Marsh (1988) has proposed that Crystal Size Distributions (CSDs) reflect the kinetic and physical processes affecting crystallization. Mujin and Nakamura (2014) and Mujin et al. (2017) have studied the CSDs of the groundmass crystals in the products of the eruption, and found that the CSD plots exhibit kinks which divide the groundmass crystals into two groups; the coarser ones with the gentler slope and the finer ones with the steeper slope. They proposed that the CSDs reflect the difference of the physicochemical conditions of magma depending on eruption styles. In this study, we focused on pyroxene crystals in groundmass to obtain the information about the physicochemical conditions during ascent in the conduit.

The samples used were the gray pumice of sub-Plinian eruptions and Vulcanian explosions of Shinmoedake 2011 eruption. We determined the miller indices of the pyroxene groundmass crystals by X-ray CT at SPring-8 (BL47XU) and an electron backscatter diffraction (EBSD), analyzed the size and shape of them with a field emission scanning electron microscope (FE-SEM), observed their microtextures with a transmission electron microscope (TEM), and performed composition analysis by a scanning TEM with an energy dispersive X-ray spectrometer (STEM-EDS).

We found that many of the crystals were in a hexagonal or octagonal prism. The former consisted of {010} and {110} prismatic faces and the latter had {100} faces. There were more hexagonal crystals than octagonal ones in the sub-Plinian pumice. In the Vulcanian pumice, by contrast, octagonal ones were dominant and there were only a few of hexagonal ones. In both eruption styles, the hexagonal ones were distributed in finer part than the octagonal ones. The slopes of the CSD also differed according to the habits; that is, the slopes of the hexagonal ones were steeper than that of the octagonal ones. The TEM observation showed that these pyroxene crystals in groundmass were composite crystals composed of orthopyroxene (Opx) and clinopyroxene (Cpx) which was attached to both {100} faces of the Opx, and that the Cpx parts on the both sides were occasionally in twin orientation relationship each other. Their microtextures were symmetric with respect to *c*-axis, which indicated the concentric spreads of the textures.

We found that the size distributions and slopes of the hexagonal and octagonal ones were similar to those of the finer group and the coarser group in Mujin and Nakamura (2014), respectively. Marsh (1988) proposed that CSD slope is a measure of the product of growth rate and residence time. Assuming that the growth rates were almost the same regardless of habits, residence times could be estimated from the CSD slopes as similar durations to the magma ascent durations in the conduit estimated from geophysical data (Kozono et al., 2013, Sato et al., 2013). In particular, the estimated residence time of the hexagonal ones in sub-Plinian pumice was similar to the ascend duration in sub-Plinian eruption. Hence, the hexagonal habit is assumed to reflect the relatively rapid magma ascent rate, which indicates that the

©2019. Japan Geoscience Union. All Right Reserved.

habits of pyroxene groundmass crystals may reflect the ascent rates in the conduits. Moreover, the TEM observation suggests that microtextures of the crystals may record the temporal change of conditions during the ascent, which indicates the possibility that pyroxene groundmass crystals contribute to reveal the behavior of magma.

Petrochemistry and zircon U-Pb age of ``lateritic'' metamorphic rocks from the Kitakami Mountains

*Nobutaka Tsuchiya[1], Yamato Kumagai[1], Tatsuro Adachi[2], Nobuhiko Nakano[2], Yasuhito Osanai[2]

1. Department of Geology, Faculty of Education, Iwate University, 2. Department of Earth Sciences, Faculty of Social and Cultural Studies, Kyushu University

Fe- and Al-rich metamorphic rocks were discovered from the Shinkama, Ofunato City, Kitakami Mountains, Japan. These metamorphic rocks underwent contact metamorphism during the intrusion of the lower Cretaceous Goyosan granitic rocks. The rocks from Shinkama are mainly composed of Pl, Bt, Ms, Grt, Crd(+/-), Kfs, Spl(+/-), Ilm, Ap. On the other hand, the rocks from Shinkama east are Pl, Bt, Ms, Grt(+/-), Crd, Kfs, Spl, And(+/-), Sil(+/-), Crn(+/-), Ilm, Ap. These rocks are characterized by low SiO2 contents (20--47%), high FeO* contents (12--33%) and high Al2O3 contents (18--38%). Bulk rock chemistry of the metamorphic rocks are resemble those from ``lateritic'' rocks from the Abukuma Metamorphic Belt. ``Lateritic'' rocks from the Abukuma Metamorphic Belt characteristically contains staurolite, however, metamorphic rocks from Shinkama does not include staurolite. This indicates the possibility that the metamorphic rocks in the Shinkama were probalbly metamorphosed under low pressure conditions than those from the Abukuma Metamorphic Belt.

U-Pb dating of zircons were carried out using Agilent 7500cx quadrupole inductively coupled plasma mass spectrometer (ICP-MS) with a New Wave Research UP-213 Nd-YAG UV (213 nm) laser ablation system (LA) installed at the Kyushu University. The operating parameters of analyses with LA-ICP-MS system are after Adachi et al. (2012). Zircon grains from the Shinkama metamorphic rocks are euhedral crystal (ca. 0.05mm) with remarkable oscillatory zoning, and define a concordant age of 126+/- 3Ma. On the other hand, zircon grains of subhedral crystal (larger than 0.1mm) with no oscillatory zoning, and define a concordant age of 326+/- 3Ma. The former age correspond to the contact metamorphism of Early Cretaceous, on the other hand, the latter corresopond to the hydrothermal alteration event of Carboniferous.

How to make 'syn-plutonic dike' --- Another story from the Ryoke granitic province, Southwest Japan

*Takashi Nakajima[1], Hiroyuki Kamiyama[2], Ian S. Williams[3]

1. Geological Survey of Japan, 2. Ueyama-Shisui, Co. Ltd., 3. Australian National University

Syn-plutonic dike is interpreted to express a magma chamber process with intermingling silicic and mafic magmas in fluidal state.

In the Ryoke granitoids in Southwest Japan, mafic rocks often occur in so-called syn-plutonic dikes. They are pillow-like balls in the silicic matrix (pillow-type), and dikes intruding silicic matrix with silicic back-veins into them (dike-type). We found the 14-20Ma time discrepancies between mafic and silicic rocks in above both two types of syn-plutonic dikes in the Ryoke granitoids, 90-94Ma of silicic rocks and 70-75Ma of mafic rocks in zircon U-Pb ages. The time duration of 14-20Ma seems too long to imagine that these two components of the syn-plutonic dike was generated during a lifetime of a single magma chamber.

In a silicic rock of those syn-plutonic dike, we found a partly dissolved and re-grown intrastructure of a zircon grain in the CL image, with the ages of cc.70Ma in the re-grown part and cc.90Ma in the undissolved core. The mafic rocks of the syn-plutonic dike nearby gives cc.70Ma and the host Ryoke granitoids around them give 90-96Ma. So it could be interpreted that the syn-plutonic dike was formed with injection of the mafic magma at cc.70Ma into the already solidified 90-96Ma granitoids and partially melted them, which led the physical interaction of local silicic mushy melt and mafic magma. The partly dissolved and re-grown zircon described above could tell that story of forming syn-plutonic dike.

As this type of the “syn-plutonic dikes” occur widespread in a km-sized area in the Ryoke granitoids, that process may be regarded as local and partial revival of granitic magma chamber.

[S-CG53] Environment formed and maintained by active faults

convener:Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Makoto Yamano(Earthquake Research Institute, the University of Tokyo), Takafumi Kasaya(Japan Agency for Marine-Earth Science and Technology), Hideki Hamamoto(Center for Environmental Science in Saitama), Chairperson:NAOJI KOIZUMI, TADANORI GOTO(Graduate School of Engineering, Kyoto University)

An active fault causes a large earthquake at a very low frequency such as once every several thousand to tens of thousands years and destroys the surrounding environment. On the other hand, during the period when the large earthquake or the fault movement does not occur, the unique environments such as mountains, basins, structural lakes, hot springs and mineral deposits are formed and maintained by the topography and hydrogeological structure made by the accumulation of the fault movement. In general, the presence of active faults is recognized as a factor of environmental destruction, but it is also necessary to understand the active faults as a factor of environmental formation and maintenance. In this session, we welcome wide-ranging topics on the role of active faults as a factor for the formation and maintenance of the environment and how to investigate it.

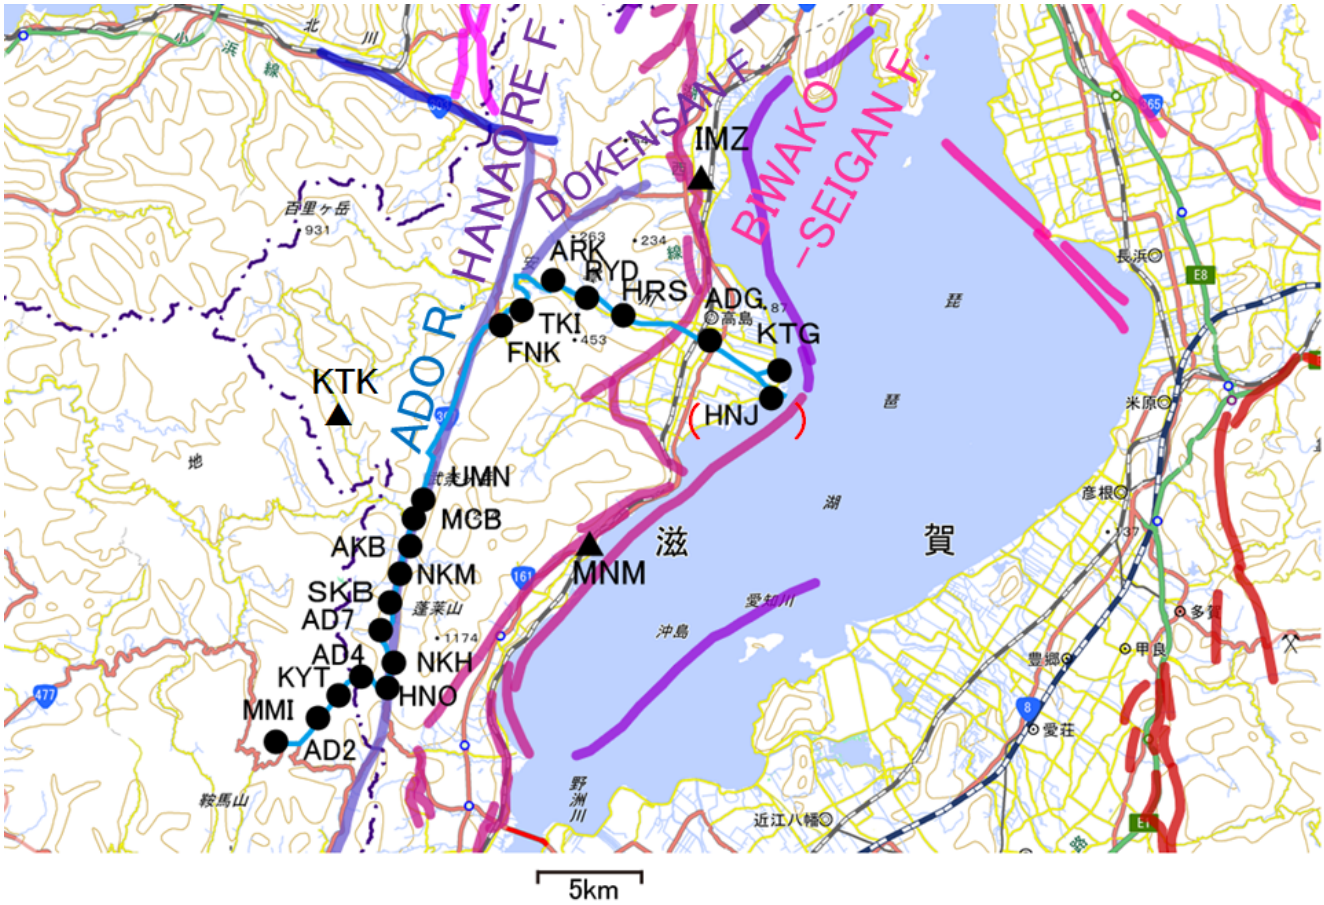
Effect of the Hanaore fault and Biwako-seigan fault on the water quality of the Ado river in Shiga Prefecture

*Naoji Koizumi[1], Masahiro Ueda[1], Shinsuke Minote[1], Tatsuya Tanaka[1], Masahiro Maruo[1], Kanto Mitani[2]

1. School of Environmental Science,the University of Shiga Prefecture, 2. Daikokuten Bussan Co., Ltd.

1.Introduction
Along a fault plain, there is a fractured damage zone, which has high permeability. This zone is often become groundwater path from deep to shallow (Faulkner et al., 2010). As a result, the fault-related groundwater stably supplies heat and chemical materials including water itself, which make some effect on the environment in and around the fault zone. For example, hot and mineral springs tends to distribute in and around fault zones. This fault-related groundwater should also have some effect on the river in the case that the river runs along or across the fault.

The Ado river, which is located in the western part of Shiga Prefecture, is the second longest in the rivers which flow into Lake Biwa, which is the largest lake in Japan. The catchment area of the Ado river is also the largest in the rivers which flow into Lake Biwa. In the part of the upstream and most of the midstream, the Ado river runs along the Hanaore fault. In the downstream the Ado river cross the Biwako-seigan fault (Fig.1). Both of the faults are the main active faults in the western part of the Shiga Prefecture. Therefore the Ado river is suitable for investigating the effect of active faults on the river water quality.



2.Observation
We surveyed the Ado river during the period from August 12 to August 14 in 2018 (Fig.1) , which is named the spatial survey. Before this period there had been no precipitation for thirteen days at IMZ and MNM. Therefore it is considered that the river water was mainly composed of the base flow, which supplies from groundwater to river. We also surveyed the Ado river at RYD, HRS, ADG and KTG about once a month from April, 2018, which is named the temporal survey.

3.Result
In the spatial survey the water quality type was Ca-HCO3 at all the sampling points. The ion concentrations were gradually increased from AD7 to TKI although there were no systematic change in the ion concentrations at the other sampling points. Between HRS and ADG, where the Ado river crosses the Biwako-seigan fault, there was no change in the ion concentrations. In the temporal survey, there was also no no change in the ion concentrations between HRS and ADG. This shows that the Hanaore fault has some effect on the water quality of the Ado river although the Biwako-seigan fault has little effect on it.

Fig.1 The solid circles show the sampling points of the Ado river during the period from August 12 to August 14 in 2018. The solid triangles denote meteorological observation points of Japan Meteorologidal Agency. This is modified from the figure of the active fault database of Japan (Geological Survey of Japan, AIST, 2019). The background map is from Geographycal Information Authority of Japan (2019).

Hydrothermal vents in the deep basin of Lake Biwa

*Michio Kumagai[1]

1. Ritsumeikan University

The autonomous underwater vehicle (AUV) “Tantan” was constructed and first deployed in the year 2000, as the world’s first AUV conceived for lake ecosystem exploration and monitoring. Tantan (meaning “freshwater surveillance” in Japanese) was designed to move along bottom slopes keeping a constant distance above the sediments, with a payload that includes two high-definition video cameras, a digital camera, a submersible microscope and various sensors. In December 2009, Tantan identified turbid water ebullition on the deep area in the North Basin of Lake Biwa, which is a larger basin with maximum depth 104 m and 99% water volume, and follow-up investigations were conducted in April, December 2010 and January 2012. This study confirmed the existence of hydrothermal vents, and provided the evidence that their vent numbers per unit area on the lake bottom have increased from 1.0 km^{-2} vent in 2009 to 54.0 vents km^{-2} in 2012. We also found that those discovered vents located along the ridge of sunken mountains which form the basement of Lake Biwa with covered sediments. Some back-up investigations have been performed with a remotely operated vehicle (ROV) and several kinds of sonar devices, and all of the outputs support the existence of vents found by Tantan.

Heat flow anomalies observed on the seafloor in the vicinity of faults: indication of fluid flow

*Makoto Yamano[1], Shusaku Goto[2], Yoshifumi Kawada[3], Hideki Hamamoto[4]

1. Earthq. Res. Inst., Univ. Tokyo, 2. Geol. Surv. Japan, AIST, 3. IRIDeS, Tohoku Univ., 4. Center Environ. Sci. Saitama

Active fluid flow along faults may yield temperature or surface heat flow anomalies because advective heat transport by fluid flow is much more efficient than conductive transport. On land, it is rather difficult to observe such anomalies as temperature profile measurement in deep boreholes is required. On the other hand, we can conduct dense heat flow measurements on seafloor if surface sediment is soft enough to allow penetration of temperature probes. Heat flow and/or temperature anomalies in the vicinity of faults have been reported in some accretionary prisms, e.g., Cascadia and Barbados subduction zones. In this presentation, we show examples of heat flow anomalies associated with faults on the seafloor in the Nankai Trough area.

Accretionary prism developed landward of the Nankai Trough is extensively faulted in a compressional stress field due to subduction of the Philippine Sea plate. At the toe of the prism off Muroto, eastern Shikoku, closely-spaced heat flow measurements were made with a ROV and conspicuous high anomalies were found around the second frontal thrust, indicating that pore fluid flows upward along the fault (Kawada et al., 2014). Off the Kii peninsula, a large thrust fault system termed the megasplay cuts through the entire prism and its branches reach the seafloor. Yamano et al. (2014) conducted heat flow measurements with a surface ship across a branch of the megasplay and observed high heat flow values on the lower part of a fault scarp. Goto et al. (2008) made measurements with a submersible around biological communities along another branch of the megasplay and showed a sharp heat flow variation in a scale of several meters. These observations demonstrate that fluid flow along faults in various spatial scales can be detected by surface heat flow measurements.

The velocity or flux of vertical fluid flow may be estimated through long-term monitoring of temperature distribution in surface sediment. Temporal variation of the bottom water temperature propagates downward through sediment by thermal diffusion. Since this propagation process is affected by vertical fluid flow, analysis of long-term record of temperatures at multiple depths allows us to estimate fluid flow velocity (Goto et al., 2005). This method was applied to temperature records obtained in and around a biological community located a tip of the megasplay branch fault and the result indicates the existence of upward fluid flow (Kawada et al., 2013).

How can we quantify the hydraulic permeability of fault based on geophysical survey?

*Tada-nori Goto[1], Sota Kawaguchi[1]

1. Graduate School of Engineering, Kyoto University

For understanding impacts of faults/fractures to the Earth's environment, evaluation of hydraulic permeability along fault and fractures are required because they hydrogeologically play a role of pathway of deep groundwater and gas. Previous studies have obtained the hydraulic characteristics using boreholes and rock samples. However, such information is only valid in a local scale, and it is basically considered to be difficult to estimate the hydraulic permeability at several-hundred meter scales or more. In this study, we try to estimate the permeability in and around fractures in typical bedrocks (e.g., granitic rocks) based on the geophysical explorations: resistivity, seismic velocity and so on. The geophysical logging experiment (e.g., cross-hole tomography) can indicate both local and larger scale geophysical information. More large-scaled information can be obtained by land-surface geophysical surveys. For evaluation of permeability of large-scale fault, a rock physical modeling will be helpful since it can connect geophysical property to the hydraulic property theoretically or numerically.
Prior to the challenge of large-scale permeability estimation, we applied the rock physical modeling to the small-scale geophysical measurements. We measured DC resistivity and elastic properties (Young modulus) on the exposed fresh granite at the Mizunami Underground Research Laboratory, Japan Atomic Energy Agency. Based on the simple rock physical model, we estimated the permeability of granite with less fracturing. The in-situ permeability measurements confirmed that the estimated values are enough close to the measured ones (within the difference of half of order). The technique is also valid to the permeability measurements by pumping test at wells. We succeeded that the observed permeability obtained at Mizunami can be reproduced by only using geophysical logging data such as resistivity and seismic P-wave velocity.
Then, we applied this rock physical model to the large-scale geophysical images based on the magnetotellurics and seismic tomography. Although it is a preliminary result, the estimated permeability structure by our method is not realistic one unfortunately. In this study, we discuss on the additional information and technique how the accuracy of estimated permeability is improved.

Healing process of the Nojima Fault zone after 1995 Hyogo-ken Nanbu earthquake

*Hideki Murakami[1], Naoto Oshiman[2], Ryokei Yoshimura[2], Tsutomu Miura[2], Masato Kamo[2]

1. Research and Education Faculty,Kochi University, 2. Disaster Prevention Research Institute,Kyoto University

Two faults of the Nojima Fault and the Higashiura Fault exist in the northeastern part of Awaji Island. Repeated activities of these faults have formed the topography of Awaji Island. In this study, we report the result of the Nojima water injection experiment of 2018 and the healing process of the Nojima Fault zone estimated from self-potential variations associated with water injection experiments. The water injection experiments were conducted 8 times between 1997 and 2018 in an 1800 m long borehole near the Nojima Fault, which is the surface earthquake fault of 1995 Hyogo-ken Nanbu earthquake, to investigate the recovery process of the fault zone after the large earthquake. We have estimated the time evolution of hydraulic parameters from self-potential variations associated with water injection. It is expected that hydraulic parameters will decrease as the healing process of the fault zone progresses. Though the Nojima Fault has repeatedly moved at a recurrence interval of ca. 2,000 years during the Late Quaternary, it is estimated from the experiment results that the healing process of the fault zone is progressing in several years after the earthquake shorter than the recurrence interval.

Thu. May 30, 2019 9:00 AM - 10:30 AM JST | Thu. May 30, 2019 12:00 AM - 1:30 AM UTC | A11 TOKYO BAY MAKUHARI HALL

[S-CG55] Crustal fluids and deformation

convener:Yuichi Kitagawa(Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Koji Umeda(Hirosaki University), Fumiaki Tsunomori(Geochemical Research Center, Graduate School of Science, University of Tokyo), Chairperson:Yuichi Kitagawa(産業技術総合研究所地質調査総合センター地震地下水研究グループ), Fumiaki Tsunomori(東京大学大学院理学系研究科地殻化学実験施設)

We will provide an opportunity to discuss about observation and modeling of crustal fluids. Topics of interests include, but not limited to (1) a field of physics and chemistry of fault fluids, which is related to earthquake occurrences and researches physical and chemical changes of the fluids caused by crustal deformation including earthquakes, (2) a field of earthquake hydrology, which estimates crustal deformation from level, pressure and chemistry of groundwater using poroelastic theory, and (3) a field of chemistry of crustal fluids, which concerns chemical and isotopic features of the crustal fluids and try to estimate the flux of them.

Discussion

Estimation of fault models of the short-term SSE using groundwater pressures at the Hokusei observation site

*Yuichi Kitagawa[1], Norio Matsumoto[1]

1. Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

One of the problems is the lack of high quality crustal deformation/groundwater observation sites in the western part of Aichi prefecture and the northern part of Mie prefecture around Ise Bay, in terms of the estimation of short-term slow slip events (SSEs) occurring at the plate boundary of the Nankai Trough. One of the causes is that unconsolidated sedimentary layers such as the Tokai Group are thickly deposited in this area. In May 2016, the inner pipe of the observation well at the Hokusei observation site located in the northern part of Mie prefecture was sealed with a packer in order to improve the response of groundwater level to crustal deformation. Because the permeability of the target aquifer at this site is low, the groundwater level before the sealing was poor in response to crustal strain changes before the sealing. The groundwater pressure is observed after sealing, then tidal fluctuation clearly appeared in the groundwater pressure, therefore we found the response of the groundwater pressure to crustal deformation to be clearly improved. The response of the groundwater pressure to crustal strain after sealing improved about 10 times than that of the groundwater level before the sealing. By eliminating the tidal component, barometric pressure response, and rain response from the groundwater pressure data, short-term SSEs were detected by the changes in groundwater pressure in July 2016, November 2017 and April 2018. And then slips of the short-term SSEs were estimated to be spread to Northern Ise Bay by the data of strain, tilt and groundwater pressure. In the area around Northern Ise Bay where deep low frequency tremors are not active, it is shown that short-term SSEs repeatedly occurred. In soft sedimentary layer which is unsuitable for observation of crustal deformation by strain meter and tilt meter, it is showed that the measurement of groundwater level (pressure) is a powerful means of crustal deformation observation.

Groundwater level changes during the 2018 Hokkaido Eastern Iburi earthquake

*Tomo Shibata[1], Ryo Takahashi[2], Hiroaki Takahashi[3], Takanori Kagoshima[4], Yuji Sano[4], Daniele Pinti[5]

1. Graduate School of Science, Kyoto University, 2. Geological Survey of Hokkaido, Hokkaido Research Organization, 3. Graduate School of Science, Hokkaido University, 4. Atmosphere and Ocean Research Institute, The University of Tokyo, 5. GEOTOP, Université du Québec

Groundwater table level in wells can fluctuate under stress provoked by earthquakes located even thousands of kilometers away. The mechanisms of changes in groundwater level can be explained by hydrological changes such as pore-pressure response to coseismic static elastic strain, permeability changes caused by seismic waves and fluid migration along seismogenic dilatant cracks or crustal ruptures. The Geological Survey of Hokkaido, Hokkaido Research Organization (HRO), has been monitoring groundwater tables in several wells after the 2018 Hokkaido Eastern Iburi earthquake. The wells were drilled for exploiting hot spring water but have not been used in the last 20 years. The groundwater level was measured by pressure gauges with resolution about 5-10 mm in 10-minute intervals in each monitored well. After the Hokkaido Eastern Iburi earthquake, we were able to find a step-like decrease in groundwater levels in three wells. These wells are located within the region where tensile changes of the quake-induced volumetric strain can be calculated by using the fault model, suggesting that the changes in groundwater levels are qualitatively consistent with those in volumetric strain. The observed groundwater level changes are also affected by tidal and barometric effects, and we can estimate the response of groundwater level for tidal components. The tidal responses in all the wells have not changed before and after the earthquake.

Postseismic streamflow changes after the 2016 Kumamoto earthquake

*Naoji Koizumi[1], Shinsuke Minote[1], Tatusya Tanaka[1]

1. School of Environmental Science,the University of Shiga Prefecture

It has been well known that large earthquakes sometimes cause hydrological changes widely in and around the region of strong ground motion. In several cases of those changes, stream flow and spring flow increases in lowland and water table drops in highland. It has often been explained by permeability enhancement in the region of strong ground motion (Rojstaczer et al. ,1995; Wang and Manga, 2004). Since Japan is relatively rich in water resources, people may have not paid much attention to these earthquake-related hydrological changes. But those hydrological changes are clearly one of the seismic risks and should also be examined in Japan because those changes sometimes continue for a period of several months to years (Rojstaczer et al. ,1995) .

The 2016 Kumamoto Earthquake, which occurred mainly in Kumamoto Prefecture, Japan in April 2016, caused severe damages in and around Kumamoto Prefecture. It also caused many changes in stream water and groundwater (Ichiyanagi and Ando, 2017; Sato et al., 2017). The region of strong ground motion of the main shock spreads from the coastal plain to the Aso caldera.

We analyzed the data of streamflow at fourteen flow rate observation stations of three major rivers in Kumamoto prefecture during the period from 1990s to 2017. After the 2016 Kumamoto earthquake, streamflow was increased at four of the fourteen observation stations, where the rivers flow from the Aso caldera or the foot of Mt.Aso. However the streamflow was not increased just after the 2016 Kumamoto earthquake. It was increased 2 months after the Kumamoto earthquake, when a heavy rainfall occurred. In addition it is found that (flood frow rate/precipitation amount) ratio tends to be increased when the precipitation amount is large after the 2016 Kumamoto earthquake. This can be explained not by permeability enhancement but by decrease of the soil moisture retention capacity. In and around the region of the strong ground motion of the 2016 Kumamoto earthquake there were many mudslides and landslides, which could reduce the soil moisture retention capacity. The earthquake-related decrease of the soil moisture retention capacity could have caused the streamflow increase in and around the region of the strong ground motion of the 2016 Kumamoto earthquake.

Faculty of Information Science and Technology, Osaka Institute of Technology, 6. Chiyoda Technol corp., 7. Union Material Inc., 8. Office for University-Industry Collaboration, Osaka University, 9. Institute of Nuclear Physics, Almaty, Republic of Kazakhstan

We have developed a radium concentration monitoring system in order to analyze a radium concentration in soil samples based on a gamma-ray spectrum. A gamma-ray spectrum of a soil sample was measured by a SrI_2 solid scintillator equipped by a multi-pixel photon counter (hereinafter a detector). The detector was shielded by 5cm-thick lead brocks, because 214-bismuth, which is a daughter elements of radium contained in cement materials, emits strong gamma-ray. We have achieved 80% background reduction. We prepared a calibration curve in order to determine a soil radium concentration by a peak area of 214-bismuth in a gamma-ray spectrum of JG-1 geochemical reference sample (AIST, GSJ). We are going to have a discussion to improve problems of this system.

^{222}Rn concentration distribution in Yatsushiro Sea

*Kuniyo Kawabata[1], Fumiaki Tsunomori[2], Yujin Kitamura[1], Hakuho-Maru K18-3 scientists

1. Graduate School of Science and Engineering, KAGOSHIMA UNIVERSITY, 2. Geochemical Research Center, Graduate School of Science, University of Tokyo

Radon concentrations in Yatsushiro sea were surveyed to examine relationship with the submarine sediments and geological structure such as submarine active faults.

^{222}Rn is a radioactive noble gas and occurs naturally in earth’ s crust as an intermediate step in the normal radioactive decay chain of uranium series. Radon shows high solubility for water and thus high mobility through groundwater and fluids in earth’ s crust. Concentration of radon in crustal fluid and groundwater can provide a clue to understand geology of the aquifer and state of crustal deformation as crack formation and change in strain state, because its release rate depends mainly on rock surface area. Recently location of active faults and its activity have been examined by using the method (e.g. Malgrange and Gleeson, 2014, Tsunomori et al., 2017).

A bunch of submarine active faults underlies in Yatsushiro area sea. These faults compose the Futagawa-Hinagu Fault zone which was activated at the 2016 Kumamoto earthquake. To evaluate records of submarine landslides and changes in submarine circumstances due to historical earthquakes, R/V Hakuho-Maru sailed for research expedition (KH-1803) in Yatsushiro sea from 27th to 30th July, 2018. We collected bottom water from obtained multiple cores and piston cores, and pore waters from piston cores for the measurement of the radon concentration in the sample water on board.
The results of radon concentration distribution from multiple cores, (MC 1-12), show that higher concentration along the Line Y18a. The radon concentrations from bottom water of piston cores (PC 1-11) also show similar results while the values are larger than the results from multiple cores. A higher radon concentration is attributed to difference in (1) Radium concentration in sediments, and/or (2) properties of sediments such as porosity and/or surface area of grains which are caused by difference in types of sediment or fault activity in sediments. The Line Y18a extends across a major submarine active fault (FA1, Tanoura-Tsunagi-oki-faults) (Kagohara et al., 2011). Such a geological setting suggests that the radon concentration distribution in Yatsushiro sea might reflect the current fault activity. We discuss the contributing factor of the higher radon concentration by comparison with Ra concentration in sediment, sediment properties in each site and geological structure in Yatsushiro sea.

[S-CG58] Brittle-Ductile Transition and Supercritical Geofluids for Crustal Energy in Island Arc

convener:Noriyoshi Tsuchiya(Graduate School of Environmental Studies, Tohoku University), Hiroshi Asanuma(AIST), Yasuo Ogawa(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Shigemi Naganawa(Akita University), Chairperson:Noriyoshi Tsuchiya, Atsushi Okamoto

Nature of rock mass below the brittle-ductile transition (BDT) is of great scientific interest to understand various phenomenon in the Earth's crust. We will review and discuss current understanding of characteristics the rock mass below the BDT, including composites, stress, failure mechanism induced by liquid injection and associates earthquake generation mechanism, and water rock interaction, considering engineered geothermal development in the BDT. Discussions on the possible phenomena in the geothermal development in the BDT will be followed in this session.
New drilling technology is key of issues. This session will cover advanced drilling technology under high temperature conditions for energy extraction.

Supercritical Geothermal Resources as a Function of Mass and Energy Transport in Subduction Zone

*Noriyoshi Tsuchiya[1]

1. Graduate School of Environmental Studies, Tohoku University

Our research group is conducting fundamental and engineering studies of “Supercritical Geothermal Development”. Fracture networks and their formation mechanisms would be studied by using petrological and fluid inclusion studies in order to understand the geological model of a supercritical geothermal reservoir. The granite-porphyry system provides useful information for understanding supercritical geothermal reservoirs and EGS technology as novel energy system in subduction zone. Hydrothermal experiments under supercritical conditions were performed by using tri-axial machine. Fracture cloud could be formed and permeability was enhanced in supercritical conditions.

Mineral precipitation/dissolution from water and brine with decreasing temperatures along hydrostatic pressures

*Kenichi Hoshino[1]

1. Department of Earth and Planetary Systems Science, Hiroshima University

Mineral-fluid interactions with decreasing temperatures along hydrostatic pressures, from 15.84 MPa - 500°C to 6.64 MPa - 200°C, have been simulated for 0.01 molal and 1 molal NaCl solutions. The dielectric constants of the former were taken from SUPCRT92 (Johnson et al., 1992), while those of the latter has been proposed from quartz solubility data in brine as:

$$\varepsilon_b / \varepsilon_w = a / (2\pi b)^{0.5} \exp(-(T - c)^2 / (2b)) + d,$$

where, ε_b is the constant of the 1 molal NaCl solution, ε_w is that of water derived by SUPCRT92, π represents the ratio of the circumference of a circle to its diameter, T is a temperature in Celsius, the parameter a depends on a pressure (P in MPa) as a = -0.9 * P + 420, and b, c and d are the constants as 13000, 300 and 0.8, respectively.

On the other hand, a difference in chemical potentials of a jth solute ($\Delta\mu^\circ_j$) in the solution and water may be expressed as:

$$\Delta\mu^\circ_j = \omega_j(1/\varepsilon_b - 1/\varepsilon_w),$$

where, ω_j is the Born coefficient of the solute. Since the coefficients of the most charged species as well as $SiO_{2(aq)}$ are positive and ε_b is larger than ε_w in the simulated conditions, the chemical potentials of the above solutes in brine are smaller than those in water. This causes great differences between mineral solubilities in water (0.01M NaCl) and in brine (1M NaCl) as below.

Quartz

Since quartz solubility decreases with decreasing temperatures in water and brine, quartz precipitates from the both solvents with decreasing temperatures. However, because a decreasing rate of solubility in brine is smaller at higher temperatures and larger at lower temperatures, the precipitation amount shows a maximum at around 350 - 400°C. On the other hand, the amount decreases monotonically with decreasing temperatures in water.

Feldspar

Aluminum is dissolved mostly as AlO_2^- (= $Al(OH)_4^-$) in the both solvents. Equilibrium constants of dissolution reactions of K-feldspar, albite and anorthite with the above Al species decrease with decreasing temperatures. Therefore, the precipitation amounts of those feldspar from water solvent decrease monotonically with decreasing temperatures. On the other hand, it is quite interesting that they dissolve in brine at higher temperatures, while precipitate at lower.

Pyroxene and Al-free amphibole

Most pyroxene and amphibole show similar tendencies as feldspar. They gradually precipitate or dissolve small amounts with decreasing temperatures in water, while they dissolve in brine at higher temperatures and precipitate at lower.

One of the conceivable causes of the above temperature dependencies of the silicate precipitation/dissolution in brine is a great difference in activity coefficients of charged species. For

©2019. Japan Geoscience Union. All Right Reserved.

example, the activity coefficients (Debye-Hückel terms) for a divalent element in 0.01M NaCl solutions at 450°C and 300°C are 0.34 and 0.47, respectively, while they differ largely in 1M solutions as 0.023 and 0.20, respectively.
Carbonate
$CO_{2(aq)}$ is the major dissolved species above 250°C in the both solvents. Since the equilibrium constants of dissolution reactions of calcite, dolomite and magnesite with $CO_{2(aq)}$ decrease with decreasing temperatures, they precipitate from water gradually with decreasing temperatures, while they dissolve in brine at higher temperatures and precipitate at lower as feldspar, pyroxene and amphibole.

It should be emphasized that the temperatures of brine at which the above all silicate and carbonate minerals change their modes from dissolution to precipitation are around 400°C - 300°C.

Precipitation/dissolution of solid solutions of the above minerals and alteration (hydration) of some of the above minerals will also be discussed in the presentation.

Keywords: dielectric constant, brine, mineral, precipitation, dissolution

Thermodynamic data of aqueous species for supercritical water–rock interaction: dissolution experiments and density-based extrapolation

*Atsushi Okamoto[1], Hajime Ishii[1], Ryosuke Oyanagi[2], Noriyoshi Tsuchiya[1]

1. Graduate School of Environmental Studies, 2. JAMSTEC

Geothermal reservoirs under the supercritical conditions (supercritical geothermal reservoirs) have been taken grater attentions as the potential renewable energy in volcanic areas in the world. The chemical and physical processes of such supercritical regions are of special importance for various geological processes including understanding the formation of hydrothermal ore deposits, hydrological properties around brittle-ductile transitions of the crusts, and metamorphic and metasomatic processes. The thermodynamic data of the aqueous species at elevated temperatures and pressures has been constructed based on the Helgeson-Kirham-Flowers (HKF) model, where molar Gibbs energy is defined as a function of dielectric constant of water and species-specific Born parameter (e.g., Tanger and Helgeson, 1988), and the most common data is available through a software SUPCRT92. However, a large issue for understanding the supercritical water-rock interaction is a lack of thermodynamic data of charged aqueous species (ions and complexes) for the region near critical point of water and low water-density region (<0.35 g/cm3). In contrast to the electrostatic model like HKF model, the empirical density model has been proposed based on the fact that the log of molar Gibbs free energy of aqueous species shows a linear relationship with log of water density. Based on this model, Caciagli and Manning (2003) proposed the extrapolation of SUPCRT log K data to the high pressure regions; however, the effectiveness of this method to the low density region is not clear. In addition, the experiments for dissolution experiments are lacking for the low-density region.

In the present study, we tried the expansion of log K data set of the speciation and mineral dissolution into the vapor-like supercritical region (400, 420 degreeC, 20-35 MPa). We also conducted the new experiments for the mineral solubility measurements. The apparatus consist of 60 ml vessel with Ti inner wall, and pressure was controlled by syringe pump. We conducted the dissolution experiments with albite power and mix powders of albite-K-feldspar-quartz. Then, for evaluating the validity of the extrapolated data, we compared the extrapolated logK of mineral dissolution equilibrium and the ion products (log Q) obtained from the solution chemistry of the experiments and extrapolated log K data set of aqueous species. The deviation of log K from log Q is systematic and less than 2 in log unit, indicating the effectiveness of this method as the first approximation.

Nitrogen isotope ratios of ammonium in hypersaline hot spring waters distributed along Arima-Takatsuki fault zone.

*Kazuhiro Amita[1], Takashi Nakamura[2], Shinji Ohsawa[3]

1. Faculty of Engineering Science, Akita University, 2. International Research Center for River Basin Environment, University of YAMANASHI, 3. Institute for Geothermal Sciences, Graduate School of Science, Kyoto University

Recently, there has been a lot of research on the relationship between hot springs and deep thermal fluids (Slab dehydrated fluids) which are thought to be released from subducting oceanic plate (eg, Kazahaya et al., 2014; Kusuda et al., 2014). These researches shown that the water of slab dehydrated fluid is a high salinity of Na-Cl type and rich in the CO2, and that the isotope ratios of helium and carbon had the similar values as that of the mantle. On the other hand, although nitrogen (ammonium ion) is a component contained in most deep fluids, it is not clear properties and behaviors. Studies on nitrogen in rocks have been conducted since the 1960's that have been obtained many knowledge on their concentrations and isotope ratios. Haendel (1986) pointed out that the concentration and isotope ratios of ammonia nitrogen in rock, change systematically with the progression of a series of metamorphism from sediment to rock. In this relation, the nitrogen concentration decreased as the degree of metamorphism progressed, and conversely the nitrogen isotopic ratio increased. Similar trends have also been confirmed in subsequent studies (eg, Gray and Marilyn, 1991, Yiefei, 2006). On the other hand, Amita et al. (2014) pointed out the possibility that metamorphism is involved in the made of deep thermal fluids. Therefore, it is expected that we can obtain knowledge about the behavior of nitrogen in deep under the earth's surface by clarifying the relationship between the nitrogen isotope ratios of rocks and deep fluids. Therefore, as a preliminary approach to the measurement of the nitrogen isotope ratios of ammonium ion contained in the hypersaline hot spring, two hot springs distributed along the Arima-Takatsuki fault zone are selected and performed sampling survey and nitrogen isotope ratios of ammonium ion were measured. Two sampling points are part of the hot springs that the authors have performed research in the past (Osawa et al., 2015) and are well-understood hot springs whose chemical and isotopic properties. Therefore, as a preliminary approach to the measurement of the nitrogen isotope ratios of ammonium ion contained in the hypersaline hot spring, two hot springs distributed along the Arima-Takatsuki fault zone are selected and performed sampling survey and nitrogen isotope ratios of ammonium ion were measured. The hot spring water samples collected at the sampling site were immediately cooled and frozen immediately to suppress biological activity and kept until just before the isotope analysis. Pretreatment for measurement of nitrogen stable isotope ratio of ammonium ion was carried out by ammonia gas diffusion method which can suppress measurement inhibition due to decomposition of dissolved organic nitrogen. The water samples were made alkaline in a sealing vial, ammonium ion was scattered as ammonia gas, and catched to a filter paper acidified with diluted sulfuric acid, and the object was analyzed using an isotope ratio mass spectrometer (ANCA-GSL with Hydra 20-20, Sercon Ltd.). As a result of the analysis, we obtained results of +13.3 (‰) and +12.8 (‰) as nitrogen isotope ratios of two hot spring water samples. Since these results are values before data correction, careful consideration is required at the evaluation. Although, it was confirmed that the measurement of nitrogen isotopic ratios can be performed even for hyper saline hot springs where the total dissolved solids exceeds tens of thousands ppm.

Crustal fluid pressure gradients and permeability estimated from fluid-rock reaction zones

*Masaoki Uno[1], Diana Mindaleva[1], Noriyoshi Tsuchiya[1]

1. Graduate School of Environmental Studies, Tohoku University

High pore fluid pressure has been recognized by geophysical observations and is generally considered as triggers of earthquakes and slow–earthquakes (e.g., Audet and Bürgmann, 2014). Although such high pore fluid pressure is recognized as mineral filled fractures in geologic observations, the actual fluid pressure gradients in the crustal rock have not been evaluated quantitatively and remain largely unknown. Here we propose a new methodology estimating the fluid pressure gradients recorded in fluid-rock reaction zones, by utilizing thermodynamic analyses in conjunction with trace element profiles along the reaction zones. With numerical analysis of reactive advection-diffusion transport profiles of Cl and F in the fluid-rock reaction zones, we constrain the duration, fluid velocity and permeability of the fluid-rock reaction zones. We have analyzed amphibolite and granulite hosted fluid–rock reaction zones at Sør Rodane mountains, East Antarctica. The analyses of decimeter scale granitic dyke–crust reaction zone at 0.5 GPa, 700˚C (Uno et al., 2017) show fluid pressure gradients of ~100 MPa/10 cm or ~1 MPa/mm. mm-sized hydration reaction zones around single fracture at ~0.5 GPa, 450˚C (Mindaleva et al., in prep.) also suggest fluid pressure gradients of ~1 MPa/mm. These extremely high fluid pressure gradients represent the low permeability of the intact amphibolite and granulite host rocks without fractures. The estimated permeabilities are ~10^{-20} m^2 for the granulite–granitic dyke reaction zones and amphibolite–fluid reaction zones, and are several orders smaller than the widely accepted crustal permeability model (~10^{-18} m^2; e.g., Ingebritsen and Manning, 2010). On the other hand, permeability along the fractures are estimated as high as $10^{-14–15}$ m^2 for the granulite and amphibolite-hosted fractures, which is analogous to the permeability estimated for the hypocenter migration for the inland earthquake swarms (~10^{-15} m^2; e.g., Okada et al., 2014). These results show the importance of low permeability of intact amphibolite/granulite-facies metamorphic rocks in conjunction with episodic high permeability of brittle fractures even at high temperature conditions of 450–700˚C, both of which affect the regional scale permeability in the deep crust.

[S-CG58] Brittle-Ductile Transition and Supercritical Geofluids for Crustal Energy in Island Arc

convener:Noriyoshi Tsuchiya(Graduate School of Environmental Studies, Tohoku University), Hiroshi Asanuma(AIST), Yasuo Ogawa(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Shigemi Naganawa(Akita University), Chairperson:Noriyoshi Tsuchiya

Nature of rock mass below the brittle-ductile transition (BDT) is of great scientific interest to understand various phenomenon in the Earth's crust. We will review and discuss current understanding of characteristics the rock mass below the BDT, including composites, stress, failure mechanism induced by liquid injection and associates earthquake generation mechanism, and water rock interaction, considering engineered geothermal development in the BDT. Discussions on the possible phenomena in the geothermal development in the BDT will be followed in this session.
 New drilling technology is key of issues. This session will cover advanced drilling technology under high temperature conditions for energy extraction.

EGS (Engineered / Enhanced Geothermal System) is expected to generate significant energy and reduce CO2 emission. Although EGS could be effective in Japan where many volcanoes exist, there are still many problems to solve to run the power plant using EGS. The supercritical fluid which can exist below the brittle-ductile transition (BDT) is essential to develop the EGS. However, structures and physical properties around and below BDT are still unclear. Since the development of EGS needs long time before operation and requires high cost, it is important to evaluate the suitable area for EGS. Therefore, estimating the structure in high spatial resolution from surface to around BDT is important to develop EGS and reduce risks.

In recent years, surface-wave analysis has been widely applied to estimate underground structure from ambient noise. In this analysis, surface-wave phase velocity can be estimated from ambient noise, and S-wave velocity structures can be estimated from surface-wave phase velocity because phase velocity strongly depends on S-wave velocity. Surface-wave analysis using ambient noise does not require active sources. Therefore, this is effective to survey steep area where it is difficult to enter such as geothermal area. In addition, this method is also effective to monitor change in subsurface for a long period because we can obtain seismic ambient noise continuously only using seismometers.

We used continuous seismic data recorded by a high-sensitivity seismograph network (Hi-net) for a year. We computed cross spectra of ambient noise data between the station pairs, and extracted phase velocity dispersion curves using the frequency domain method. Since the frequency domain method can overcome the limitation of interstation distance (far-field approximation) occurred in the time domain method, we can extract phase velocity at short-interstation pairs which reflect local structures. We then estimated the 3D S-wave velocity structure by applying a direct surface-wave inversion method. Our results show the low velocity structures beneath active volcanoes such as Mt. Asama, and Mt. Nasu, that could reflect volcanic fluid. If we apply this method to dense seismometers around the geothermal fields or volcanic area, we could obtain S-wave velocity in higher spatial resolution and use the information to identify suitable reservoir for EGS.

Resistivity-Based Temperature and Permeability Estimation of the Kakkonda Geothermal Field, Japan, Using a Neural Network

*Ugou Tsubasa[1], Kazuya Ishitsuka[2], Toru Mogi[3]

1. Department of Socio-Environmental Engineering Scool of Engineering Hokkaido University, 2. Division of Urban Management, Grduate School of Engineering, Kyoto University, 3. Division of Sustinable Resources Enginieering, Faculty of Engineering, Hokkaido University

Estimation of temperature distribution around a geothermal field is important to understand a geothermal system. Previously, temperature distributions were successfully estimated by a neural network based on temperature logs and magnetotelluric (MT) data (Ishitsuka et al., 2018). This method firstly learns the relationship between three-dimensional locations, resistivities and temperatures by a neural network or neural kriging. Then, the optimized neural network is used to estimate temperature distribution based on a resistivity structure obtained by the MT method. On the other hand, not only temperature but also permeability are important physical parameters to evaluate a geothermal system. In this study, we developed a method to estimate permeability distribution as well as temperature distribution by a neural network and neural kriging. The methodology was applied to the Kakkonda geothermal field, Japan.
Permeability along a well is not generally measured. Therefore, to create a training data of permeability, we estimated permeability along a well based on porosity deduced from resistivity log using Archie’s law. Temperature-dependence of the resistivity of water was corrected at the processing. In addition, we assumed that the salt concentration at each depth was equal to the salt concentration of the collected fluid inclusion. Subsequently, the porosity was converted into the permeability by the Kozeny-Carman equation.
We then estimated temperature and permeability distribution around the Kakkonda geothermal field. For training data, we used temperature logs and the estimated permeability logs using resistivity profiles at the 7 wells (Hanano and Kajiwara, 1999). To estimate temperature distribution, we used the resistivity structure by Yamaya et al. (2017) using the MT method.
As for the result, the temperature rising was estimated in the deep part, and the point where the high-temperature fluid is considered to be rising from the geothermal reservoir was estimated. The permeability showed a high value, especially in the low resistivity part. The accuracy of the estimated temperature and permeability distribution was evaluated by comparing temperature data measured beneath a depth of 3100 m of WD-1 well. As a result of accuracy verification, neural networks showed the smallest temperature error when the number of the intermediate layers was 2, and the permeability error was the smallest when the number of the intermediate layers was 9. Both the temperature and the permeability of neural kriging were smaller than those of neural networks. Although further development of the methodology to increase the accuracy of the estimation is required, our results demonstrated the effectiveness of our neural network approach to estimate permeability as well as temperature distribution around a geothermal field.
This study is supported by a NEDO project.

Inner part of Sanzugawa caldera, NE Japan, is one of the promising geothermal areas that had been found by many geological and geophysical surveys after 1970’ s. In this area, one geothermal power plant (Uenotai geothermal power plant) is currently in operation, and additional one (Wasabizawa geothermal power plant) is being constructed now.

There are a number of high-temperature hot springs along Akayumatasawa river that flows through the center of Sanzugawa caldera. This study reports the resistivity and geological structures based on MT surveys and field surveys around Akayumatasawa. In addition to these structures, the gravity structure, distribution of hot springs, and hypocenter clusters under Akayumatasawa indicate existence of geothermal fluid that is ascending from deep subsurface.

Characterization of hydraulic fracturing phenomena in supercritical geothermal environments revealed by elastic wave measurements

*Miura Takahiro[1], Noriaki Watanabe[1], Kiyotoshi Sakaguchi[1], Ryota Goto, Kota Yamane, Takeshi Komai[1], Youqing CHEN[2], Takuya ISHIBASHI[3], Noriyoshi Tsuchiya[1]

Supercritical geothermal resources above the critical temperature of water (374℃) are expected as potential novel geothermal resources [Watanabe et al., 2017, Nat. Geosci.]. Although granitic rocks under temperature and depth conditions where supercritical geothermal resources are present are considered ductile against compression, they may be brittle against tensile, so that it is suggested that the reservoir layer may be formed. In fact, we carried out hydraulic fracturing experiments on cylindrical granite with a borehole in σ_1 direction placed under 450℃ and confining pressure triaxial stress (greatest principal stress σ_1:90MPa, intermediate principal stress σ_2 / least principal stress σ_3:40 MPa), and then three-dimensional isotropic reticulated fractures are formed with a smaller water pressure than hydraulic fracturing at low temperature, and it is found that the permeability increases by about 1000 times [Watanabe et al., 2017, Geophys. Res. Lett.]. Based on this previous study, we are currently working on clarifying the phenomenon of hydraulic fracturing under supercritical geothermal environments using a hydraulic fracturing experiment system under high stress and true triaxial stress conditions.

We have carried out hydraulic fracturing experiments on cubic granite with vertically downward borehole at 400℃ or 450℃ and true triaxial stress (σ_1:40 MPa, σ_2:15 MPa, σ_3:5 MPa), and AE (Acoustic Emission) measurement during the experiment and P-wave velocity measurement before and after the experiment have been conducted. As a result, irrespective of temperature and stress field, the P wave velocity of the rock after the experiment decreased isotropically, and it was suggested that the formation of reticulated fractures found in the previous study is mainly due to pressurization of existing microcracks which are isotropically distributed in rocks by low viscosity water. Furthermore, as a result of AE measurement during the experiment, the peak of AE occurrence was present not only at the time when the borehole pressure reached the maximum value (breakdown pressure) but also after the breakdown. Considering the deformation behavior of the rock during the experiment and the observation result of the thin sections after the experiment, it is suggested that the first peak is due to the occurrence of hydraulic fracturing but the second peak is due to the occurrence of small scale shear deformation and fracture depending on the stress field of the rock where strength has decreased by hydraulic fracturing. As a result, the possibility that the rock behavior after the breakdown also affects the ultimate fracture pattern and the change of permeability was newly found.

Experimental measurements of transport pore radius of thermally cracked granite and the relationship of pore structure to permeability

*Sueyoshi Kazumasa[1], Tadashi Yokoyama[2], Ikuo Katayama[1]

1. Department of Earth and Planetary Systems Science, Hiroshima University, 2. Graduate School of Integrated Arts and Sciences, Hiroshima University

Fluid flow in rocks plays a key role in many geological processes such as geothermal reservoirs. Permeability is known to be dependent on porosity and pore radius (Walsh and Brace, 1984), while direct determination of pore radius is usually more difficult than determination of permeability. Water expulsion method (Yokoyama and Takeuchi, 2009) is a way to determine the radius of transport pore from gas pressure at which gas breaks through a water-saturated sample (ΔP_{break}). Although several previous studies investigated the relationship between permeability and ΔP_{break} of impermeable rock such as mudstone, those of granite have not been reported. In this study, we develop the water expulsion method under confining pressure and aim to evaluate the relationship between permeability and pore characteristics such as porosity and transport pore radius under high pressure up to 30 MPa.

Thermally-cracked Aji granites were prepared to cylindrical shape (20 mm long and 20 mm in diameter). Thermal cracking was introduced by heating up to 600 ℃ and porosity of a heat-treated sample was about 2.4 % . The transport pore radius was determined by a manner similar to those reported in Yokoyama and Takeuchi (2009), which is an experimental method measuring gas pressure ΔP_{break} (Pa) at which gas breaks through a water-saturated sample. From ΔP_{break} and interfacial tension γ (N m^{-1}), transport pore radius r (m) can be estimated as follows: $r = 2\gamma / \Delta P_{break}$. Permeability was determined from the flow rate at a constant pore pressure (P_p = 0.5 - 3 MPa). The flow rate was measured by a flow method using water as a pore fluid and permeability was calculated following Darcy’ s law. Porosity was estimated using the gas porosimeter, where the grain volume and pore volume of a sample were determined by using Boyle’ s law. Experiments were performed under confining pressure ranging 5 to 30 MPa at room temperature.

Transport pore radius and permeability of thermally-cracked Aji granite were 0.74 μm and 5.5×10^{-17} m^2 under confining pressure of 5 MPa. These values decreased with increase in confining pressure and were 0.14 μm and 2.0×10^{-18} m^2 under confining pressure of 30 MPa. Permeability k (m^2) of granite can be approximated by pore radius r and porosity ϕ according to the relation: $k = 5.32\times10^{-3}\,\phi\, r^2$. This indicates that permeability is primarily dependent on transport pore radius. These results are consistent with the conventional permeability model (Simpson et al., 2003) and estimation of transport pore radius is important for understanding permeability of granite.

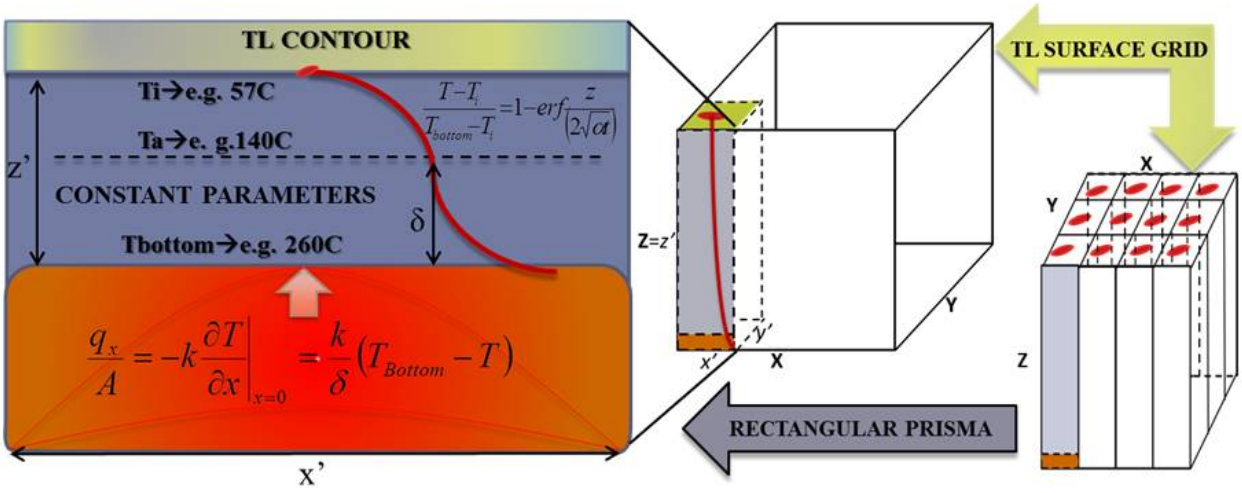
Geothermal reservoir evaluation by using TL of Quartz and Fluid Flow Simulation Model of the Kakkonda system in Japan



*Alvaro Josue Amaya[1], Nobuo Hirano[1], Noriyoshi Tsuchiya[1]

1. Tohoku University. Graduate School of Environmental Studies

Thermoluminescence (TL) of quartz is used in many geoscientist applications: Radiation measurements, geological dating and recently in geothermal activity prospection. After kinetic understanding, a new geothermal reservoir model has been developed based on the analysis of geological thermoluminescence surface samples and cuttings of borehole quartz samples combined with the system behavior equations. This novel methodology has been designed especially for an early stage of geothermal exploration condition and has been validated in the Kakkonda geothermal field in its initial exploration state. The system was simulated from surface to 5 Km on depth. In order to obtain the geothermal model that uses TL as a heat sensor, the sensitivity of the mineral property to natural heat has been monitored and evaluated through kinetic TL quartz decay experiments using aliquots of a standard sample rooted from same geothermal origin and subjected to different controlled conditions of temperatures taken at different time and deconvoluted by keeping constant 4 peak positions for all database; this has allowed the development of novel TL equations that have been coupled in this proposed reservoir model, which, is based on the description of the system through 3 governing equations for a specific control volume: the geothermal potential system balance, the Fourier equation, and the non-steady state heat conduction equation. Coupled with reservoir model and thermoluminescence model, we can obtain a numerical model of three-dimensional geothermal prospecting temperatures at any position (X, Y, Z) got through geoprocessing GIS tools. Finally, the 3D thermal model was used to parameterize a fluid flow simulation that considers the supercritical condition of the system at 5 Km as a heat source model and by using Hydrotherm software many scenarios of natural system evolution were gotten and a novel sustainable application for operation of the geothermal production operation in the Kakkonda Geothermal Power Plant was proposed.

[S-CG59] Reducing risks from earthquakes, tsunamis & volcanoes: new applications of realtime geophysical data

convener:Masashi Ogiso(Meteorological Research Institute, Japan Meteorological Agency), Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Satoshi Kawamoto(Geospatial Information Authority of Japan), Mitsuyuki Hoshiba(Meteorological Research Institute), Chairperson:Mitsuyuki Hoshiba(Meteorological Res. Inst., JMA, Japan), Satoshi Kawamoto(Geospatial Information Authority of Japan)

As the number of population centers grows in regions with earthquake, tsunami and volcano hazards, the importance of improving methods for rapid, realtime estimates of activity increases. Realtime monitoring, analysis, and prediction of seismic ground motion, crustal movement and tsunami will be powerful tools to contribute to earthquake and tsunami disaster preparedness/mitigation. Tsunami and Earthquake Early Warning systems exist today in many locations around the world. Now JMA has started to promptly provide Eruption Notices to inform people of impending and beginning volcanic eruptions. Large events like the 2011 Tohoku Earthquake (Mw9.0) have demonstrated some of the shortcomings of existing techniques. In this session, we invite presentations on new ideas, methods and applications of (near) realtime analysis of seismic, geodetic and tsunami data, to the problem of realtime prediction aimed at improving disaster preparedness/mitigation in the fields of earthquake, tsunami and volcano observation. Presentation is encouraged to bring together scientists, engineers, and practitioners from a broad range of backgrounds from around the world, and to promote collaborative communication at the leading edge of the science and technologies.

Earthquake early warning in the United States and beyond

*Richard M Allen[1]

1. University of California Berkeley

The ShakeAlert earthquake early warning (EEW) system is now delivering alerts up and down the west-coast of the United States (California, Oregon and Washington). The warnings are being used by targeted groups including transportation, schools, hospitals and other infrastructure operators. Alert are also available to the public in some regions through smartphone apps, and there is an expectation that they will be more widely available in the coming months. The system is operated by the US Geological Survey in cooperation with UC Berkeley, Caltech, the University of Oregon and the University of Washington.

The ShakeAlerts are currently generated by seismic-only algorithms, specifically the EPIC point-source algorithm and the FINDER finite-source algorithm. A great deal of research effort is underway to determine the accuracy and reliability of the current system, and to determine what additional information could be provided by new algorithms. In particular, the use of geodetic observations to improve magnitude estimates and estimate fault finiteness for the largest events is being explored, as is the addition of the PLUM ground motion model approach.

Looking beyond traditional seismic and geodetic networks, the use of smartphones to detect earthquakes and characterize their likely impact for EEW is also being explored. The MyShake global smartphone seismic network is currently recording ground shaking using the 40,000 Android phones that have the app installed. More than 800 earthquakes around the globe have been detected, and research is underway to use these detections to generate alerts and also to improve the quality of alerts from traditional networks.

Study on the relationship between seismometer site environment and earthquake early warning seismic parameter estimation accuracy

*Katsutomo Niwa[1], Naoyasu Iwata[1], Shunroku Yamamoto[1]

1. Railway Technical Research Institute

When earthquakes that threaten the safety of railway facilities and running trains occur, earthquake early warning systems aim to stop the trains as soon as possible. The seismometers installed for these systems automatically detect the P-wave arrival, then using information from the initial few seconds of the P-wave estimate seismic parameters such as epicentral distance, epicentral back-azimuth and magnitude, in order to quickly issue an alarm if necessary.

In this research, in order to improve the accuracy of the seismic parameters estimation, we examined the influence of the seismometers installation environment on the accuracy. We defined as characteristics representing the site environment: the ambient noise level of the observation site, determined from 2 seconds of the waveform recorded before P-wave arrival; and the hardness of the subsurface ground, indicated by the average S-wave velocity from the depth of 30m to the surface, henceforth referred to as AVS30.

Firstly, we calculated the RMS pf the 2 seconds of data before the P-wave arrival as the noise level, and checked the relationship between the noise level and the estimation error of the seismic parameters. When the noise level is small, the error of the P-wave detection time tends to become small. When the noise level is large, the automatic P-wave detection time tends to be earlier than would be chosen manually. The epicentral distance tends to be underestimated as the noise level is larger. The estimation error of the epicentral back-azimuth tends to decrease the estimation error as the noise level decreases. However, the magnitude based on the calculated displacement is hardly affected by the noise level, because the magnitude is determined by the maximum value of the observed amplitude.

Following this, we checked the relationship between AVS30 and the estimation error of the seismic parameters. The AVS30 is calculated from the K-NET PS logging result according to a method proposed by Shi and Midorikawa (1999). Since the variation of AVS30 showed little correlation with the estimation error, it can be thought that P-wave detection is hardly affected by the hardness of the subsurface ground. Though the epicentral distance tends to be underestimated as AVS30 gets smaller, this is only to a small extent. The epicentral back-azimuth tends to be smaller as the AVS30 is larger. The magnitude estimation is not correlated with the AVS30.

According to the results outlined above, the accuracy of the seismic parameters estimation will be improved in a quiet environment where the ambient vibration is small, and the subsurface ground is relatively hard. When we select the installation site of seismometers for earthquake early warning, we should therefore give priority to site environments with these characteristics.

Prediction of surface ground motion using underground seismic records based on data assimilation (2)

*Masaya Ishihara[1], Hisashi Nakahara[1]

1. Solid Earth Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University

Introduction

To improve Earthquake early warning (EEW), methods using data assimilation have been proposed for seismic wave field prediction (e.g. Hoshiba et al., 2015) and tsunami prediction (Maeda et al., 2015). Hoshiba et al. (2015) used radiative transfer theory to predict the spatial distribution of seismic intensity. Maeda et al. (2015) used wave equation for tsunami prediction. Recently, Furumura et al. (2018 SSJ) used wave equation for the prediction of long-period seismic ground motion. However, data assimilation based on wave equation has probably not yet used for short-period seismic waves due to restrictions on the density of observation stations, computational costs, and so on. In order to predict short period seismic waves, therefore, we started to apply data assimilation based on wave equation to one-dimensional problems for vertical boreholes such as KiK-net (Ishihara and Nakahara, 2018 SSJ). If we can reproduce surface seismic records quickly and precisely from subsurface seismic records, we will be able to speed up the issuing of alarms more quickly than with surface earthquake records alone. This research is regarded as a basic research towards the advancement of the onsite type EEW for local earthquakes.

Data, Method

In this study, we used NIED KiK-net CHBH10 (Chiba) station. At this observation site, strong motion seismometers are installed on the surface and at a depth of 2000m. We analyzed 60 earthquakes of over M5 occurring around Chiba prefecture. In the simulation, we used the method of Tanaka & Takenaka (2004) which can solve the oblique incidence of plane waves in horizontally stratified structure efficiently by the finite difference method. We calculated the direction of arrival and the incident angle of seismic waves from the particle trajectory of the 1-second-long initial P waves on subsurface records. We simulated the wavefield based on the finite difference method using seismic velocity structure estimated from the logging information. Using the calculated incident angles and subsurface records, we simulated waveforms on the ground surface and compared them with observed waveforms.

Results and discussion

Ishihara and Nakahara (2018 SSJ) found out two problems in this analysis. First, the degree of the fit between observed and calculated waveforms becomes worse with the lapse time. This is caused by artificial upgoing waves which occur when observed waveforms (upgoing wave + downgoing wave) and calculated waveforms (falling wave) do not match at a subsurface station. Another big problem is that the degree of the fit is deteriorated as the angle of incidence becomes larger. This is because artificial SV waves are generated due to the absence of information about stress when inputting observation values (particle velocity) of P waves at the subsurface observation station.

In this study, we calculated the ratio of artificial SV to P waves assuming only P wave input (stress input is zero) to evaluate this effect. The incident angle was varied from 0 ˚to 45 ˚with a step of 1 ˚. As a result, artificial SV waves are generated with an amplitude of about 4% of the P-wave maximum amplitude for an incident angle of 10 ˚, about 10% for 20 ˚, about 25% for 30 ˚and 50% for 45 ˚. In addition, in order to

©2019. Japan Geoscience Union. All Right Reserved.

reduce this effect, we are repeating simulations by adding virtual stress conditions and subsurface observation stations.
In the future, we will compare our result with the wavefield calculation of Haskell (1962). In order to solve these problems and to improve the prediction accuracy, we will consider optimum arrangements of subsurface observation stations and suitable settings of appropriate stress conditions.

Current technology seems to be hard to predict an occurrence of earthquakes, but is capable to deliver realtime earthquake information just after the occurrence. For railway systems, the earthquake early warning (EEW) system for Shinkansen was utilized in 1990s. For nationwide warning and alerts, Japan Meteorological Agency (JMA) has operated the EEW system since 2007, and realtime information of ground motion plays an important role in society.

On the other hand, the JMA EEW provides only seismic intensities, and not yet to alert broader ground motion information such as long-period ground motions. Long-period ground motions generated during large earthquakes shake skyscrapers in urban area and cause furniture overturning and damage of elevators in them. Recently, JMA issues the long-period ground motion levels based on 5%-damped absolute velocity response spectra in the period range of 1.6 to 7.8 s to respond beyond the seismic intensity measures. Dhakal et al. [2015] constructed a ground motion prediction equation (GMPE) for absolute velocity response spectra in the period range of 1 to 10 s using 36 earthquakes and 12,401 strong motion recordings observed at K-NET and KiK-net stations. The GMPE can provide accurate predictions with correction factors that use depths of the Vs 1.4 km/s layer beneath the sites from the subsurface velocity model provided by the Japan Seismic Hazard Information Station (J-SHIS). The GMPE has an advantage to use the JMA magnitude Mj that is available immediately after the earthquake, not moment magnitude Mw. We developed realtlime long-period ground-motion prediction system using the GMPE of Dhakal et al. [2015] and hypocenter locations and earthquake magnitudes provided by the JMA EEW.

JMA plans to deliver alerts of EEW for long-period ground motions that are similar to the current EEW for seismic intensities. A working group to investigate prediction information for various needs has been established at JMA to activate the plan. Realtime prediction information for ground motions is not allowed to open to the public based on the weather service law. Therefore, NIED collaborates with JMA, and performs demonstration experiments to deliver prediction information of long-period ground motions where NIED acts as a virtual business predictor. The demonstration experiments consist of two types. One is an experiment to use automatic processed prediction information. The other is an experiment to use spatial distribution of prediction information.

In this presentation, we introduce demonstration experiments, results, and future perspectives to deliver observation and realtime prediction information to users using long-period ground-motion prediction system and API and long-period ground-motion monitor.

Real-time forecasting of long-period ground motions for the Nankai Trough earthquake: The effectivity of the Green function-based data assimilation method

*Atsuki Oba[1], Takashi Furumura[1], Takuto Maeda[2]

1. Earthquake Research Institute, University of Tokyo, 2. Graduate School of Science and Technology, Hirosaki University

In this study, we considered the possibility of more efficient data assimilation method in order to realize real-time forecasting of Long-Period (LP) ground motions based on the assimilation of strong-motion records and simulation of seismic wave propagation.

Furumura et al. (2019) conducted the real-time forecasting experiment of LP ground motions in the metropolitan area for the 2007 Off Niigata and the 2011 Off Tohoku earthquakes based on the data assimilation of the K-NET and KiK-net records and seismic wave propagation simulation using 3-D FDM. They used optimum interpolation technique, which was also used for real-time forecasting of seismic intensity (Hoshiba and Aoki, 2015) and tsunami (Maeda et al., 2015; Gusman et al., 2016). Since the performance of the supercomputers has improved a lot for recent years, simulation for the Japanese islands scale can be done several times faster than the propagation speed of the seismic wave. However, more effort is necessary to reduce the computational time in order to attain longer lead time before the shaking.

In this study, we considered the applicability of Green's function-based data assimilation. This method is proposed by Wang et al. (2017) as Green'sFunction Tsunami Data Assimilation (GFTDA). GFTDA is the method developed for efficient data assimilation and forecast of tsunami using offshore tsunami network. The Green's functions between the target point and each station are calculated beforehand. The tsunami waveform at the target point is calculated instantaneously by convoluting these Green's functions and the residuals between observation and forecast calculated for each station. This method is proved to be mathematically equivalent to the previous data assimilation method in Wang et al. (2017).

To validate the use of this Green's function-based method for the forecast of LP ground motions, we first conducted the numerical experiment for the 2004 off the Kii Peninsula earthquake (M7.4) and forecasted the LP ground motions at Shinjuku (K-NET TKY007) using the strong-motion records observed in this event. Green's functions are calculated efficiently using reciprocity. The results showed that instant forecast can be available with its accuracy equivalent to that of the previous method. LP ground motions in the distant target point can be forecasted immediately after the assimilation of the observed data near the source, which leads to much longer lead time. Moreover, more accurate forecast and longer lead time were obtained by using offshore stations in DONET, a dense oceanfloor network system for earthquake and tsunamis.

Next, we conducted the forecast experiment for the Nankai Trough earthquake using this method. The target points were Konohana (KiK-net OSKH02), Tsushima (K-NET AIC003) and Shinjuku (K-NET TKY007) stations. For the source model, we used the 1944 Tonankai earthquake, the 1946 Nankai earthquake and the largest event expected (M9) suggested by the Cabinet Office, Japan (2016). For each event, LP ground motions were calculated by 3-D FDM and were used as the observation data. In addition to

©2019. Japan Geoscience Union. All Right Reserved.

aforementioned networks, stations in the JMA submarine cable network and hypothetical stations of N-net, a newly-planned ocean bottom seismograph/tsunameter network off Hyuganada, were also used. The intensity of strong ground motions was evaluated by GMRotD50 (the median value of the geometric means of the response spectra for two horizontal components when rotating from 0 to 90 degree; Boore et al., 2006). For the evaluation of the duration of LP ground motions, cumulative displacement was calculated. The accuracy of the forecast improved with the assimilation time. In the experiment for the 1946 Nankai earthquake, for example, when the rupture started form the east side, the forecast at Shinjuku with velocity response spectrum and cumulative displacement 70% of the actual observation was obtained about 80 s before the large amplitude LP ground motions started. It required 70 s assimilation after the rupture started. In the case that the rupture started from the west side, the longer lead time (~120 s) was secured when the accuracy reached the same level due to the farther distance between the target point and the rupture initiation point. However, because LP ground motions developed as the fault rupture approached the metropolitan area, longer assimilation time (~100 s) was necessary. From these results, it will be suggested that assimilation should be done while the fault rupture extends and the forecasts should be updated constantly as well as the importance of the strong-motion records near the source region in order to the realize both accurate forecast and longer lead time.

Development of EEW system exchanging real-time seismic intensity and seismic waveform

*Shigeki Horiuchi[1], Yuko Sato[1], Taku Urabe[2], Yamaimaiti Nizhamudong[3], Kazuo Sasaki[3]

1. Home Seismometer Corporation, 2. telemetra , 3. Challenge

1. Introduction JMA started to issue PLUM telegram in EEW system, which delivers values of real-time intensity measured at all JMA seismic stations in addition to the values of hypocenter parameters. Since the magnitude saturates when a catastrophic earthquake occurs, JMA recommends to use the PLUM method, which uses the maximum value of intensity within 30 km from user location for the intensity estimation. Horiuchi et al. (2011) proposed a method to estimate the fault area of a catastrophic event in real time by using the spatial distribution of real-time seismic intensities. In this report, we developed a system that estimates the location of fault area, displays it on the screen of user’ s PC, and outputs the sound alarm. This system collects continuous waveform from seismic stations using MEMS sensor and delivers waveform data at a time of earthquake occurrence to users PC.

2. Method of real-time estimation of the fault area of a catastrophic event In the case JMA issues EEW with magnitude 7.7 or more, the present system starts to determine fault area by using the method of Horiuchi et al. (2011) with data of real-time shaking intensities. When values of observed seismic intensity is larger than the estimated values from the empirical attenuation equation by Shi and Midorikawa (1999), their method determines distances from these stations to the edge of the fault and determine the location of fault area from the distribution of the edge locations.

3. System overview The present system consists of center server and seismic observation stations equipped with MEMS sensor and Raspberry pi. The roles of center server are (1) receives the plum telegrams from JMA, (2) accepts user registration, (3) acquires continuous waveforms for observation stations, (4) transmits followings to the windows PC of users, 1) hypocenter parameters from JMA, 2) Real-time seismic intensities from JMA and from observation stations of Raspberry Pi, 3) Waveform data at a time of earthquake occurrence. It is required for the user to register user information such as the coordinates of the user location from the Web screen. When the EEW is delivered, the predicted seismic intensity is outputted on the screen. There is a function to issue EEW for the training. In a case a user generates an earthquake in the web site of center server, the center server sends hypocenter parameters and values of shaking intensity to him. If the testing earthquake is a catastrophic event, his PC computes and displays the spread of the fault area for the testing event.

4. result

(1) Since the present PC software provides shaking intensity data and the real-time waveform from the neighboring observation station, these data may be effectively used for the accurate damage prediction by a strong earthquake.

(2) We checked with using observed shaking intensity data whether the spread of the fault area are correctly obtained by the present system. We use shaking intensity data obtained by K-NET from the 17 major earthquakes for the checking. As a result, it was shown that a nearly correct fault area was estimated.

[S-CG59] Reducing risks from earthquakes, tsunamis & volcanoes: new applications of realtime geophysical data

convener:Masashi Ogiso(Meteorological Research Institute, Japan Meteorological Agency), Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Satoshi Kawamoto(Geospatial Information Authority of Japan), Mitsuyuki Hoshiba(Meteorological Research Institute), Chairperson:Naotaka Chikasada(National Res. Inst. for Earth Science and Disaster Resilience), Masashi Ogiso(Meteorological Research Institute, JMA)

As the number of population centers grows in regions with earthquake, tsunami and volcano hazards, the importance of improving methods for rapid, realtime estimates of activity increases. Realtime monitoring, analysis, and prediction of seismic ground motion, crustal movement and tsunami will be powerful tools to contribute to earthquake and tsunami disaster preparedness/mitigation. Tsunami and Earthquake Early Warning systems exist today in many locations around the world. Now JMA has started to promptly provide Eruption Notices to inform people of impending and beginning volcanic eruptions. Large events like the 2011 Tohoku Earthquake (Mw9.0) have demonstrated some of the shortcomings of existing techniques. In this session, we invite presentations on new ideas, methods and applications of (near) realtime analysis of seismic, geodetic and tsunami data, to the problem of realtime prediction aimed at improving disaster preparedness/mitigation in the fields of earthquake, tsunami and volcano observation. Presentation is encouraged to bring together scientists, engineers, and practitioners from a broad range of backgrounds from around the world, and to promote collaborative communication at the leading edge of the science and technologies.

Enhancements of real time seismic intensity estimation using seismic intensity meters maintained by a local government –Case study on Tottori prefecture -

*Takao Kagawa[1]

1. Tottori University Graduate School of Engineering

Enhancements of real time seismic intensity estimation using seismic intensity meters maintained by a local government is demonstrated. Dense observation network is desirable for upgrading accuracy and quality of Earthquake Early Warning System. Seismic intensity meters installed in all municipalities are the most suitable equipment for the purpose. The seismic intensity meters in Tottori prefecture are improved to broadcast packets with peak ground acceleration and JMA seismic intensity at every one second. The data are received at Tottori University and PLUM method is applied to the data for estimating JMA seismic intensity distribution at 1km grid points. In this study, two additional methodologies are introduced on the system. One is attenuation of seismic intensities from observed sites and propagation from every grids for estimation. Another is introduction of P wave amplitudes for seismic intensity estimation. Using the methodologies, we can obtain rapid and detailed seismic intensity distribution than before.

Earthquake damage can be caused from a small-sized earthquake (magnitude class 4.5) occurs in inland areas to a large-sized earthquake such as the 2011 Tohoku earthquake (Mw 9.1). In recent years, it is possible to estimate the amount of detailed displacement of the destruction zone from the inversion analysis of observed data. Moreover, ground motion prediction equations (GMPEs) and earthquake prediction recipes have been proposed. Those developments contributed to the earthquake disaster mitigation measures. Earthquake early warning system (EEW) of Japan has been in operation since 2007, it is very useful to issue information that have a great impact on disaster mitigation, however, some problems still exist with the information issued by EEW. For instance, the warnings are sometimes issued after S-wave arrivals, which leaves an area without alarm known as a blind zone area.

In this study, we used a dense seismic network dataset recorded during the 2016 Kumamoto (Mw 7.0), and the 2019 January 3rd (Mw 5.1) earthquakes, maximum JMA intensity of 7 and 6 upper, respectively. In spite of the difference of magnitudes and source size area the two earthquakes had close maximum intensity values. It noted that the average spacing distribution of seismic instrument in that regions is ~ 4-5 km. We here obtain the maximum peak ground acceleration (PGA) on free surface on each observed point, we then corrected PGA to engineering basement, using site effect information from J-SHIS (NIED), spaced by 1×1 km^2. Using PGA on engineering bedrock, we estimate the PGA on free surface by multiplying with surface amplification factor at each grid point of 1×1 km^2, we then evaluate the seismic intensity at each grid. We repeat this process for each observed point considering the inter-station distance and finally produce the intensity map.

Our method gives a quick information about earthquake location (close or far), hypocentral depth (shallow or deep) inferred from apparent velocity distribution maps. It also recognizes the earthquake source size (small or large) inferred from the spatial distribution of PGA. We also attempted scaling by so-called P wave detection and maximum seismic intensity distribution prediction using theoretical amplitude ratio (5 times) of S wave / P wave at the seismic source.

It is a very important issue to observe the strong-ground motion in real-time to improve the performance of EEW. We strongly recommend local government to have their own high density network, which gives a quick earthquake disaster information. The Japan Meteorological Agency will aim for speeding up and improving the precision of emergency earthquakes (eliminating the blind zone) by integrating server information of each local government (with small budget without directly telemetering observation point data covering several thousands of points).

Improvements of the GEONET real-time analysis system (REGARD) for more reliable operation

*Kazuyuki Ohashi[1], Satoshi Abe[1], Yasuaki Kakiage[1], Satoshi Kawamoto[1], Hiroshi Munekane[1]

1. GSI of Japan

The displacement data produced by GNSS observations never saturate for large earthquakes in contrast to seismometer data that has a limitation of instrument saturation. Geospatial Information Authority of Japan has launched a real-time GNSS analysis system named “REGARD” which estimates finite fault models based on the Japanese nationwide GNSS network GEONET. The REGARD system has been in operation since April, 2016. The system experienced 2016 Kumamoto earthquake, and provided a single rectangular fault model with very high variance reduction (VR) of 96%. The REGARD system has been become increasingly important for rapid response to major earthquakes for providing coseismic displacements, finite model estimate, and moment magnitude rapidly. Therefore, the system must be more stable. So we try to implement other positioning procedure to REGARD system.

The REGARD system conduct relative positioning by using reference station data and rover station data. If reference station data lacked, we can’t obtain the coordinates of all other station. So we focus on Precise Point Positioning(PPP). Real-time PPP analysis needs correction data of Ionospheric delay, Tropospheric delay, satellite clock and so on. We implement as follow system. (1) Collect real time observation data from about 100 worldwide GNSS station. (2) Estimate ephemeris and collection data by using MADOCA(Multi-GNSS Advanced Demonstration tool for Orbit and Clock Analysis) developed by JAXA. (3) Conduct real time PPP analysis.

As a results of accuracy evaluation of real time PPP analysis, the accuracy is less than REGARD system. If we subtract one station results from other station(PPP-differential), the accuracy is improvement as well as REGRAD system. Therefore, real time PPP analysis system is expected to be useful for improving redundancy and robustness of REGARD system.

Development of “real-time” uncertainty evaluation algorithm for the estimated coseismic fault model using MCMC approach

*Keitaro Ohno[1], Yusaku Ohta[1]

1. Recerch Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University

Rapid understanding of the magnitude of large earthquakes and their associated fault dimensions are extremely important. Since September 2012, Geospatial Information Authority of Japan (GSI) and Tohoku University are jointly developing the GEONET real-time analysis system (REGARD). REGARD system rapidly estimates two types of coseismic fault models, which are slip distribution along the plate interface and single rectangular fault model, using permanent displacement field based on the real-time GNSS tine series. Currently, REGARD adopted the maximum likelihood approach to estimate the optimum model. The system has two points to be improved. As first point, it is difficult to estimate the quantitative uncertainty estimation of the obtained result because of the estimated result should contain both of the observation error of the real time GNSS and modeling error caused by the model settings. Understanding of such uncertainties quantitatively based on the data is important for evaluation of the result for disaster response. Second point, the problem is non-linear to estimate the single rectangular fault model in REGARD. Thus, the result strongly may depend on the initial values of the fault parameters. It is necessary to find the global minimum quickly for real-time use.

Based on these backgrounds, we are developing coseismic fault model estimation system using MCMC (Markov Chain Monte Carlo methods), which is probabilistic approach based on Bayesian statistics. MCMC does not specify one maximum likelihood value, but estimates the posterior probability density function (PDF). In addition, dependency on the initial value is relatively small by searching unknown parameters over a wide range randomly. In this study, we focus on the development the algorithm to estimate the single rectangular fault model deduced from permanent coseismic displacement field in real-time. We adopted basic Metropolis Hasting method as sampler and utilized parallel tempering approach to improve the sampling efficiency. One of the challenges for using MCMC in real time is how to make search settings, such as initial value, walk distance, variance of likelihood function, and Burn-in, which are generally decided by the try and error. We suggest a method of deciding these values automatically using scaling law and original sampling flow. Other challenging issue is calculation time. In generally, the calculation cost of MCMC is problem for the real-time purpose. To improve the performance of the MCMC we adopted OpenMP for the parallelization of the computing.

We applied this approach to the 2011 Tohoku-Oki earthquake, 2016 Kumamoto earthquake, and 2016 Fukushima-Oki earthquake using the actual permanent displacement time series from REGARD. In each estimations, we got 1×10^6 samples and obtained posterior PDF within 30 seconds. To emphasize, this algorithm could estimate the magnitude as distributions based on the data. Especially in Tohoku-Oki earthquake, obtained results clearly shows the tradeoff between the fault area and the slip amount. This result suggests that the onshore GNSS data cannot constrain them, which are extremely important factors for precise near-field tsunami forecasting.
In our presentation, we will show the more detail characteristic of the algorithm. We are working on development of it for single rectangular fault model aiming at actual operation. Furthermore, we will expand this approach to not only the single rectangular fault but also the slip distribution along the plate interface.

Drifting float measurement of pressure change by tsunami

*Masayuki Obayashi[1], Shingo Watada[2], Hiroko Sugioka[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. Earthquake Research Institute, University of Tokyo, 3. Department of Planetology, Kobe University

Recently a new instrument, named MERMAID (Mobile Earthquake Recording in Marine Areas by Independent Divers), was developed to measure acoustic signals converted from seismic waves at the seafloor. The MERMAID is a Lagrangian drifter equipped with a hydrophone and drifts passively at 1,500 –2,000 m depth until an earthquake signal is detected. If this is identified as a strong P wave, the MERMAID ascends at speed of 10 cm/s for transmission of the recorded waveform within time window of a hundred seconds before and after the P wave arrival as well as its global positioning system (GPS) coordinates at the surface. After transmitting the data via satellite links, the MERMAID descends at speed of 5 cm/s to monitor earthquake signals at 1,500 –2,000 m depth again.
It was reported that tsunamis were recorded by hydrophones (e.g. Okal et al., 2007), notably in frequency bands extending outside the range of the Shallow Water Approximation. If MERMAID floats can cover the oceans as dense as the Argo project of which almost 4000 floats are now drifting to measure temperature and salinity in the oceans, we acquire valuable tsunami data. Here we estimate what signals are observed by a MERMAID, by comparing to the pressure change of the 2010 Chile Tsunami measured by a differential pressure gauge (DPG) at about 4800 m deep seafloor.
We assume linearized water wave with period T, amplitude H, and phase velocity c as shown in Figure 1. Phase velocity c is given by $c = (g \tanh(kD) / k)^{1/2}$, where k is horizontal wavenumber $k = \omega / c$, $\omega = 2\pi / T$ is angular frequency and g is gravity. The wavenumber $k(\omega, D)$ of the water waves in a constant depth ocean as a function of a wave period is obtained by the recursion equation. The water wave height $W(x, t)$ as the function of time t and horizontal position x is expressed as
$W(x,t) = H e^{i(kx-\omega t)}$
The MERMAID is Lagrangian float drifting at a depth of z ($0 > z > -D$) and measures Lagrangian pressure of water, where D is water depth.
Lagrangian pressure $\delta p(x, z, t)$ is given by
$\delta p(x, z, t) = -\{H \rho_o g \sinh(kz) / (\sinh(kD) \cosh(kD))\} e^{i(kx-\omega t)}$
Eulerian pressure is given by
$p'(x, z, t) = \{H \rho_o g \cosh(k(D+z)) / \cosh(kD)\} e^{i(kx-\omega t)}$
Therefore, pressure measured by a DPG at seafloor is expressed as
$p'(x,-D, t) = \{H \rho_o g / \cosh(kD)\} e^{i(kx-\omega t)}$
and the pressure $\delta p(z)$ measured by a MERMAID at z depth can be related
with the DPG pressure $p'(D)$ by
$\delta p(z) = R\, p'(-D)$, $R = -\sinh(kz) / \sinh(kD)$
If T is large enough that k is close to 0, R becomes close to z/D. Figure 2 shows the R as the function of T for floats at 1000 (blue) and 2000 (red) m depth, suggesting the R acts as a low-pass filter. Figure 3 shows the predicted pressure changes observed floats drifting at 1000 (blue) and 2000 (red) m depth. In the presentation, we will discuss availability of tsunami measurement by a float.

Development of the Real-time Forecasting for Meteorite Impact Tsunami

*Naotaka YAMAMOTO CHIKASADA[1], Toshitaka Baba[2], Tetsuharu Fuse[3]

1. NIED, 2. Tokushima University, 3. NICT

Tsunami induced by earthquakes, submarine landslides, volcanic eruption in submarine and coastal area and meteorological phenomena is one of the most devastating natural disasters. A meteorite impact into the oceans spawn large tsunami depending on the size and velocity of the meteorite and the sea depth at the location of the impact as well. However, we do not have a numerical model to reproduce both of meteorite impacts and tsunami propagations. We have started to develop a new numerical model to simulate tsunamis generated by the meteorite impact combining iSALE (Wünnemann et al., 2006) for simulating impact phenomena and JAGURS (Baba et al., 2017) for simulating tsunami. The iSALE is a multi-material and multi-rheology shock physics code for simulating impact phenomena. JAGURS is a parallelized tsunami simulation code to solve two-dimensional non-linear long-wave equation with Boussinesq terms for representing observed tsunami waveforms, tsunami height and inundation. We set sea-floor deformation, sea-surface disturbance and velocity of gravity wave which is the output from iSALE to the input of JAGURS. We then calculate tsunami height along the coastlines in any place using ASTER GDEM version 2 (Fujisada et al., 2012) and GEBCO_2014 Grid. ASTER GDEM has one arcsecond (about 30 m) spatial resolution and covers land between 56S and 60N latitude as a topographic data. GEBCO’s gridded bathymetric data has thirty arcseconds (about 1 km) spatial resolution for the worldwide.
We first investigate the tsunami generation using iSALE code for creating tsunami source model depending on the meteor size, the velocity of impact, the size of cavity, the width and depth of crater and tsunami propagation speed. We also investigate probabilistic hazard of meteorite impact tsunami using simplified cavity curves with developed JAGURS built-in. Finally, we construct a new numerical model of meteorite impact tsunami combining iSALE and JAGURS. Additionally, we consider the way of automatic detection of meteorite impact using the recode of the highly sensitive seismograph network in real-time.
We gratefully acknowledge the developers of iSALE, including Gareth Collins, Kai Wünnemann, Boris Ivanov, H. Jay Melosh and Dirk Elbeshausen. Data analysis and visualizations of iSALE were carried out on PC cluster and computers at Center for Computational Astrophysics, National Astronomical Observatory of Japan. This work was partially supported by JSPS KAKENHI Grant Number JP18K04674.

[B-PT05] Biotic History

convener:Isao Motoyama(Department of Earth and Environmental Sciences, Yamagata University), Takao Ubukata(Division of Geology & Mineralogy, Department of Earth & Planetary Sciences, Kyoto University), Kazuyoshi Moriya(Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University), Chairperson:Isao Motoyama, Takao Ubukata, Kazuyoshi Moriya

The Biotic History session covers all aspects of ancient life and the history of biosphere through the geologic time. The study of ancient life is essential for unveiling mysteries of our planet earth. It also provides evidence for evolution of oceans, continents and island arcs. Modern progress in this field has been enhanced by interdisciplinary collaboration with allied sciences, such as paleoceanography and evolutionary biology. Our session intends to be a hub of communication amongst all earth scientists studying the biosphere; we welcome biological and biogeochemical approaches toward the understanding of the history of life.

Cause of accelerated evolution of Earth’s life; four-layered underground robust bio-communities played a critical role for the accelerated genome evolution as a response of mass extinction

*Shigenori Maruyama[1], Akio Kanai[2], Issay Narumi[3]

1. Earth-Life Science Institute, Tokyo Institute of Technology, 2. keio University, 3. Toyo University

It has long been recognized the concept of five kingdom or six kingdom model which shows the life with difference of function and size. If believing Darwinian Evolution, how can we interpret the diversified distribution with primitive small microbes to the most evolved types of large life. If we consider the most evolved metazoans such as human being to be the result of increased free oxygen in atmosphere, why do the anoxic microbes remain on the surface.
We have engaged in the decoding Earth history Program over 30 years, and obtained the following six results, (1)Since the birth of life until 4.0Ga, three times of Great Evolution of Life (GEL) occurred, (2)Those evolutions were predominantly controlled by the pO_2 increase in the environments, (3)Underground bio-communities are present forming 4-layers with boundary layers, (4)Each layer corresponds to different pO_2 levels; the older the lower pO_2 , (5)In between the two, where two-way genome biomes are present, although speculative, and (6)These four layers could have been formed during the 3 GEL times, accompanying many mass extinctions. Those were remained as fossil environments where evolution stopped, because of no significant environmental changes, in spite of extremely severe surface environments with frequent mass extinction and resultant accelerated evolution of life.
The result corresponds to the concept of 5-6 Kingdom which suggests the preservation of biological communities with different level of pO_2 in environments. Through the Earth history, new GEC occurred with great change of pO_2 , the advanced life on the surface suffered mass extinctions due to exponentially decreased pO_2, instead the underground microbes invaded to the surface, and evolved there again. This is the entity of evolution of life on the earth. Therefore, the presence of robust 4 layered underground biological communities must have contributed to evolving life on this planet, in spite of severe environmental change of planets over 4.0 billion of years in the Universe, not by death, but evolved thorough GEL at 4.0Ga, 2.2Ga and 0.6Ga.

Amino acid composition in molluscan shells and its relation to taxa and shell microstructure ~ Toward reconstruction of ancient trophic level using compound specific isotope analysis of amino acids ~

*Naoki Yugami[1], Akiko Goto[2], Robert Jenkins[2]

1. Graduate School of Natural Science & Technology. Kanazawa Univercity, 2. Institute of Science & Engineering . Kanazawa Univercity

We may clarify the trophic level of fossils applying “trophic level estimation method using compound specific isotope analysis of amino acids” (Chikaraishi et al., 2009). When applying the method to fossils, we must pay attention to whether amino acids in fossils are original or not, so screening of fossil samples is important. We can apply "amino acid composition conforming to shell microstructure" to the screening of fossi samples. This depends on a study showing the amino acid composition is different for each shell microstructure in the present bivalve (Kobayashi and Samata, 2006). We may determine whether amino acids present in the fossil shell are original or not by confirming “whether there is an amino acid composition specific to the shell microstructure observed in the fossil”. However, Kobayashi and Samata (2006) showed only the difference in amino acid composition each shell microstructures in the bivalvia, and not showed stability in the lineage relationship of the same microstructure. Moreover, there are problems such as the fraction of the amino acid composition, the method used, and the equipment to be used are different for each article, so it is difficult to compare for each article easily. In addition, there are no papers showing amino acid composition of Protbranchia of bivalvia. From the above, the stability of the amino acid composition for each shell microstructures in the lineage is unknown. Therefore, we set the pupose of this research that clarifying the stability of the amino acid composition of each shell microstructure in molluscan from the present raw sample. In this study, we focus on nacreous structure because this structure contain a lot of organic matter and it is primitive structure. We will clarify the stability of the amino acid composition of each taxa and shell microstructure, comparing within each taxa and lineage of bivalve, gastropod, and cephalopod.

As a result of cluster analysis, we found that the amino acid composition can be roughly divided into two groups, "primitive group" and "derivative group", in both the gastropoda and bivalvia. The amino acid composition of *Turbo sazae, Turbo mamoratus* and *Lunella coreensis* of gastropoda belonging to the same family were stable. Moreover, in the bivalvia, the amino acid composition is stable in the Pteriomorpha and Palaeoheterodonta, and in the Protobranchia, respectively. We could find the differences in the amount of alanine etc. in the Pteriomorpha- Palaeoheterodonta lineage and Protobranchia lineage. From this, it can be said that the amino acid composition of the nacreous structure is stable in family in gastropoda and stable in subclass in bivalvia. Cluster analysis showed that "gastropoda group" and "bivalvia group" have relatively close relationships, and their amino acid composition is similar in that alanine and glycine are abundantly included. However, it has been suggested that proteins used for shell formation in bivalvia and gastropoda may have been obtained independently in the process of evolution (Mann et al., 2018). Since amino acids which are likely to be included depending on the function of the protein are determined, it is thought that the amino acid composition converges evolutionarily and is similar even if it has different proteins.

Through this study, both bivalvia and gastropoda are roughly divided into two groups, "primitive group" and "derivative group", and furthermore, we could set the amino acid compositions used for screening of

fossil samples of nacreous structure to five, "Nautilus", "primitive of Vetigastropoda", "derivative of Vetigastropoda", "primitive of Bivalvia (Protobranchia)", "derivative of Bivalvia (Pteriomorpha, Palaeoheterodonta)". Therefore, we will be able to screen fossil samples of nacreous structure more precisely by using "amino acid composition conforming to lineage-shell microstructure" for trophic level estimation.

Relation of shell form to rocking motion in planispiral cephalopods

*Takao Ubukata[1]

1. Division of Geology & Mineralogy, Department of Earth & Planetary Sciences, Kyoto University

In Recent *Nautilus*, thrust force produced by the hyponomic jet acts to rotate the shell resulting in a rocking motion during swimming. This instability is a potential problem for any other ectoconchleate cephalopods with planispiral conchs when they swim. A smaller distance between the center of gravity and center of buoyancy tends to cause a large rotation of the shell. For this reason, it has long been imagined that ammonoids with long body chambers are less stable than *Nautilus* during swimming. In contrast, it has also been considered that a long body chamber places the aperture higher and positions the hyponome at the same level of the center of gravity so that the hyponomic jet can act directly through the center of gravity. Previous discussions on static stability of ectoconchleate cephalopods largely focused on indirect assessment based on the aperture orientation and the position of the center of gravity and center of buoyancy. The present study assessed the angle of rocking motion for various shell forms of planispiral cephalopods to generalize the relationship between conch geometry and static stability. The angle of rocking motion was computed for theoretical morphologic models based on force and moment balance presuming a neutrally buoyant condition. The thrust force of hyponomic jet was assumed to be expelled from the ventral edge of the aperture and to generate a moment which is opposed by the restorative moment produced by inclination of segment between the center of gravity and center of buoyancy. Form drag and shear stress acting on the shell moving with respect to surrounding water were ignored in calculating the opposing moment. The inclination angle of the segment between the center of gravity and center of buoyancy was regarded as the angle of rocking motion and was computed for each theoretical model with given values of whorl expansion rate, relative umbilical width, and relative whorl breadth. The result revealed following: (1) The angle of rocking motion fluctuates with changes in the whorl expansion rate (*W*) if the value of *W* is small enough so that the body chamber is more than one whorl in length. In this condition, the rocking angle varies sensitively to the change in *W*. (2) The rocking angle is large when the shell is slender. (3) The rocking angle does not highly depend on the relative umbilical width. These results indicate that the long body chamber resulting from a small *W* does not always allow the animal stable swimming and a slight intraspecific or ontogenetic variation in *W* may cause drastic change in static stability in such form. The result suggests that such static instability limits swimming ability in some ammonoids with tightly coiled conchs.

Paleoenvironment aross the Meddle Eocene Climatic Optimum

Hiroki Masui[1], *Kazuyoshi Moriya[1]

1. Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University

The Middle Eocene Climatic Optimum (MECO) is an abrupt short-term global warming event that occurred about 40 Ma. Although this event is now reported from all across the world, the environmental impacts and biotic responses accompanying the event are still poorly understood. Since we are now faced with the threat of global warming, deeper understanding of past global warming events like the MECO is critical.

We present bulk carbonate stable isotope data, coarse fraction accumulation rates (CFAR), and planktic foraminiferal assemblage data spanning the MECO interval from International Ocean Discovery Program (IODP) Site U1408 in the Northwest Atlantic to assess environmental changes and biotic responses across the event. A negative shift in bulk $d^{18}O$ was observed from 40.6 Ma (the MECO onset) to 40.0 Ma (the peak MECO), followed by a sudden return to the background level by 39.9 Ma (the termination). A significant decline of CFAR was observed near the peak of the MECO (40.3 Ma–40.0 Ma). This may reflect a decline in planktic foraminiferal production due to starving caused by elevated metabolism coupled by limited availability of nutrients. In contrast, a sudden increase in bulk $d^{13}C$, CFAR, and eutrophic planktic foraminiferal genus, *Pseudohastigerina*, was observed immediately after the peak of the MECO (40.0-39.9Ma). This may indicate a sudden switch to the eutrophic environment and an increase in primary and planktic foraminiferal production. The termination of the warming might have caused continental aridification and resulted in an increased input of aeolian dust to the ocean. In addition, the relative abundance of photosymbiotic planktic foraminiferal genus, *Acarinina*, declined toward the peak of the MECO, while the relative abundance of another photosymbiotic genus, *Globigerinatheka* remained almost constant throughout the MECO. This may indicate the loss of photosymbiotic algae exclusively affected *Acarinina* during the event.

Reconstruction of the North Pacific subtropical gyre from the Middle to Late Miocene as inferred from radiolarian assemblages

*Shin-ichi Kamikuri[1], Isao Motoyama[2], Taiki Sawada[3]

1. Faculty of Education, Ibaraki University, 2. Faculty of Science, Yamagata University, 3. Japan Petroleum Exploration Co.,Ltd.

A major objective of the present study is to reconstruct gyral circulation patterns of the subtropical North Pacific from the middle to late Miocene based on the radiolarian assemblages. We collected the mudstones from ODP Site 1021 of the California margin in the northern area of the California Current, and from outcrops of the Boso Peninsula (Japan) in the northern area of the Kuroshio.
The middle Miocene subtropical Pacific was dominated by warm-water taxa, and similar taxa in the eastern and western areas. The distribution pattern of radiolarian faunas in the subtropical North Pacific was due to be similar in the surface water structure and temperature, and indicates that the general gyral circulation system was only weakly developed in the middle Miocene. During the late Miocene the cool-water taxa increased and the warm-water taxa declined overall in the subtropical Pacific. At the same time the east-west faunal provincialism increased. This faunal change has been associated with the resultant strengthening of the general gyral circulation in the subtropical Pacific due to the significant high latitude cooling and the closing of the Indo-Pacific Seaway at that time.

Fossilization processes of Pliocene tree fossils from the Yasu River, Shiga Prefecture, Japan: Organic geochemical approach

*Jinya Nakamura[1], Ken Sawada[2], Masashi A Ikeda[1], Hideto Nakamura[3], Minoru Tsukagoshi[4]

1. Graduate School of Science, Hokkaido University, 2. Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 3. Faculty of Science, Osaka City Univerisity, 4. Osaka Museum of Natural History

The Pliocene fossil forest (ca. 2.7 Ma) is known to be distributed in the Yasu River, Shiga Prefecture, Japan. The tree fossils in the forest are characterized by blackish coal-like tissues in the surface but living tree-like fresh lignite in their inner part. In the present study, we investigate by organic geochemical analyses to identify the taxonomy and to examine fossilization, diagenesis, and taphonomy of the tree fossil.

The tree fossils used was separated to three parts; surface (outer), intermediate, and inner parts. The outer part is blackish coal-like tissue, but inner part is brownish lignite. The intermediate part is dark brownish lignite-like tissue. Lipids were extracted with dichloromethane/methanol, and separated to aliphatic, aromatic and polar fractions. Lipids were identified and quantified by GC-MS. The residues after extraction were used for pyrolysis and thermochemolysis by GC-MS equipped a Curie-point pyrolyzer. Thermochemolysis was performed with tetramethylammonium hydroxide (TMAH)

By the thermochemolysis, vanillic phenols are predominantly detected in all parts of the tree fossils. Phyllocladane and cuparane were identified as major plant-derived terpenoids in fee (extractable) components of the fossil samples. The phyllocladane is conifer-derived diterpenoid, and cuparane is a specific sesquiterpenoid produced by subfamily Cupressaceae. In addition, sugiol, which originated from family Taxodiaceae, were not detected in the fossil samples. Thus, the tree fossil can be presumably identified as subfamily Cupressaceae.

Polyaromatic hydrocarbon (PAH), which are generated by combustion at high temperature, were hardly detected in the blackish outer sample. Thus, the fossil did not experience burning by wild fire etc. The relative abundances of aldehyde-type lignin phenols are clearly lower in the outer sample, implying that degradation of woody tissues took place in the outer parts of fossil. Interestingly, aromatic and A-ring degraded (des-A) terpenoids were identified as free compounds in the outer sample. The aromatic and des-A terpenoids were reported to be compounds generated by microbial degradation during early diagenesis. The facts indicate that the woody tissues might be degraded by microbial activity in the outer part of the tree fossil. Moreover, the relative abundances of methoxy phenols decrease in the outer part, so that gelification of the degraded woody tissues occurred in the parts.

[M-IS09] dust

convener:Ishizuka Masahide(Kagawa University), Yasunori Kurosaki(Arid Land Research Center, Tottori University), Thomas Sekiyama(Meteorological Research Institute), Kana Nagashima(Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change), Chairperson:Tsuyoshi Sekiyama

Mineral dust is generated from the ground surface by strong winds, and it transports long distance over the earth. In the process, cloud formation and absorption and scattering of solar radiation cause weather and climate changes. Also, when deposited in the ocean, feeding nutrients to phytoplankton, promoting photosynthesis, and when deposited on snow and ice causes albedo change. This is known as the yellow dust (Asian dust) phenomenon in Asia region including Japan. In order to understand this, integration in a wide range of academic areas is necessary.
 In the emission process, the amount of dust changes greatly depending on the surface condition in dryland area, and in order to know the conditions, it deals with areas such as soil, topography, vegetation, precipitation, desert and soil deterioration. In the transport process, we deal with areas such as weather, atmospheric aerosol, radiation. In the deposition process, we deal with areas such as ocean, snow ice, health to people and livestock. Drying and changes in vegetation also have social scientific aspects such as national policies, management of livestock, and population increase. Dust and sand dunes are common phenomena not only to the Earth but also to other planets such as Mars and Saturn. In this way, it is impossible to understand the dust phenomenon only in one field, it is important for researchers in many areas to discuss and share information through this session, and advance exchange of researchers.

Global modeling study of atmospheric supply of lithogenic and pyrogenic Fe-containing aerosols to the ocean

*Akinori Ito[1], Akitomo Yamamoto[1], Michio Watanabe[1], Maki Noguchi Aita[1], Ying Ye[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Alfred Wegener Institute for Polar and Marine Research

Atmospheric supply of iron (Fe) to the ocean has been suggested to increase the marine primary productivity in large parts of the ocean. However, there are still large uncertainties regarding the effects of atmospheric aerosols on Fe dissolved in the surface ocean and marine productivity. Here, we use an atmospheric chemistry model and two ocean biogeochemistry models to explore the sensitivity to the atmospheric input of dissolved Fe.

The atmospheric model considered the deposition of both lithogenic and pyrogenic Fe-containing aerosols and their chemical transformation due to reactions with gaseous species. Sensitivity simulations are carried out with the deposition of lithogenic Fe only, and both Fe content in mineral dust of 3.5% and solubility of 2% are prescribed in the ocean models.

The results from the sensitivity simulations show that additional sources of dust and combustion aerosols increased the marine phytoplankton biomass in the subarctic north Pacific. The two ocean biogeochemistry models show similar spatial patterns but substantially different magnitude of responses to the atmospheric input of dissolved Fe. Moreover, the atmospheric model underestimated dissolved Fe concentration in aerosols over the North Pacific, although more observations are needed before drawing any firm conclusions on the model performance over the Pacific. Thus, further investigations of processes in emission of Fe from East Asia and transformation of dissolved Fe in the atmosphere and the ocean are needed.

Regional variations in the elemental and mineral compositions of solid particles in rainwater in Iran

*Yoriko Yokoo[1], Chihiro Sakamoto[1], Atsushi Kitamura[1], Ryo Anma[2], Shiva Mehrabani[3]

1. Faculty of Science and Engineering, Doshisha University, 2. Tokushima University, 3. Kurdistan University

We collected monthly solid particles (air dust; > 0.2 μm) in rainwater samples in four western cities (Hamedan, Ilam, Shiraz, Ahvaz) from October 2014 to July 2015 and three eastern cities (Mashhad, Birjand, Zahedan) from January 2016 to January 2017 in Iran, and determined their elemental and mineral compositions in order to elucidate the regional variation and to consider their provenance. In no-rainfall months, we rinsed the sampler with ultrapure water and collected the trapped air dust. Mineral composition of the collected dust was determined using an XRD. We dissolved the same dust samples using mixed-acids and measured elemental compositions using an ICP-MS.
The amount of dust in eastern cities were higher than those in western cities, especially the samples collected in Birjand. Samples from Mashhad and Zahedan had high amount of dust during dry season. These results suggest that aeolian dust from surrounding deserts such as Dasht-e Kavir and Dasht-e Lut affected atmospheric deposition in eastern Iran.
All of dust samples contained quartz and feldspar. Most of the dust samples in western cities also contained calcite. The concentrations of Ca, Na and K in the dust of western cities were 0.45-29.33%, 0.24-0.82% and 0.49-1.94%, respectively. Those in the dust of eastern cities were 0.97-6.23%, 0.59-2.74% and 0.88-3.15%, respectively. The concentration of Ca in the dust of western cities were higher, and Na and K concentrations were lower than those of eastern cities. High calcite contents were observed in western cities and Birjand : thus, high-Ca in the dust is attributed to calcite originated from the arid area. A part of Ca in the dust of eastern cities could also be attributed to feldspars.
Cd, Sb, Pb and As in the dust of western cities and Ni, Zn, As, Cd and Sb in those of eastern cities had the maximum values of the enrichment factor (EF): $(X/Al)_{sample}/(X/Al)_{crust}$ over ten. These results suggest a part of the dust were originated from anthropogenic substances such as road dust and petroleum industry. The EF values of Pb and As of dust samples in western cities showed higher than those in eastern cities, suggesting that the atmospheric deposition were influenced by anthropogenic substances from petroleum industry, which is generally high in Pb and As.

Comparison of airborne microbial variations in air samples from Asian-dust source and arrival regions

*Teruya Maki[1], Tatsuyuki Fujita[1], Yuuma Mastuba[1], Yasunori Kurosaki[2], Masahide Ishizuka[3], Kei Kawai[4], Yasunobu Iwasaka[5]

1. College of Science and Engineering, Kanazawa University, 2. Arid Land Research Center, Tottori University, Tottori University, 3. Faculty of Engineering, Kagawa University, 4. Graduate School of Environmental Studies, Nagoya Universit, 5. Center for Environmental Creative Studies

Aerosol dust is emerging as a significant vehicle for long-range transport of microorganisms. Nonetheless, many factors relating to this highly influential dispersal mechanisms remain unresolved, including the variation in dispersal bacterial communities during stochastic desert dust events, and the effect of aerosol transit over continental and oceanic surfaces to these communities. Here we elucidated bacterial 16S rRNA gene and fungal ITS-defined changes in airborne microbial communities at Asian-dust source regions (Gobi) and arrival regions (Japan) both lying along the trajectory for dust-event transport. Aerosols collected in the both regions generally reflected local origin from freshwater, marine, plant, or animal sources. In particular, dust events in the Gobi Desert increased these microbial cells and mineral particles to more than ten folds of concentrations. After dust-events occurrences in desert areas, the spore-forming microorganisms (bacteria: Bacillaceae, fungi: Davidiellaceae) and organic-aggregating bacteria (Cytophagaceae) showed high relative abundances, suggesting the survival of some microbes against strict atmospheric stressors over desert. These stress-resistance microbial populations were frequently dominated during Asian-dust evens over Japan, which are located cross China industrial area and Japan Sea. Presumably, atmospheric stressors over desert transit over deserts, anthropogenic polluted areas and oceanic waters strongly selects for airborne microbial populations through atmospheric stressors.

Health effects of cross-border air pollutants and Asian dust are of significant concern in Japan. Currently, models predicting the arrival of aerosols have not investigated the association between arrival predictions and health effects. We investigated the association between subjective health symptoms and unreleased aerosol data from the Model of Aerosol Species in the Global Atmosphere (MASINGAR) acquired from the Japan meteorological agency, with the objective of ascertaining if these data could be applied to predicting health effects.
Subjective symptom scores were collected via self-administered questionnaires and, along with modeled surface aerosol concentration data, were used to conduct a risk evaluation using generalized estimating equations between October and November 2011.
Altogether, 29 individuals provided 1670 responses. Spearman's correlation coefficients were determined for the relationship between the proportion of the participants reporting the maximum score of two or more for each symptom and the surface concentrations for each considered aerosol species calculated using MASINGAR; the coefficients showed significant intermediate correlations between surface sulfate aerosol concentration and respiratory, throat, and fever symptoms (R=0.557, 0.454, and 0.470, respectively; $p < 0.01$). In the general estimation equation (logit link) analyses, a significant linear association of surface sulfate aerosol concentration, with an endpoint determined by reported respiratory symptom scores of two or more,was observed (P trend=0.001, odds ratio [OR] of the highest quartile [Q4] vs. the lowest[Q1]=5.31, 95% CI=2.18 to 12.96), with adjustment for potential confounding. The surface sulfate aerosol concentration was also associated with throat and fever symptoms. Association of surface dust aerosol concentration and respiratory symptom were odds ratio [OR] of the highest quartile [Q4] vs. the lowest[Q1]=3.32, 95% CI=0.90 to 12.27).
In conclusion, our findings suggest that modeled data are potentially useful for predicting health risks of cross-border aerosol arrivals.

Dust layer captured by an inversion layer over the Gobi Desert on 29–30 April 2015

*Kei Kawai[1], Yuta Nishio[2], Kenji Kai[1,3], Jun Noda[4], Erdenebadrakh Munkhjargal[1,5], Masato Shinoda[1], Nobuo Sugimoto[6], Atsushi Shimizu[6], Enkhbaatar Davaanyam[5,7], Dashdondog Batdorj[8]

Asian dust originates in arid and semi-arid regions of East Asia, such as the Gobi Desert and the Taklimakan Desert. If the dust emitted from the ground surface reaches the free troposphere, it can be transported toward the Pacific Ocean over a long range by the westerlies. Therefore, the vertical distribution of dust over the source region is a key factor of the long-range transport of dust. In the Gobi Desert, a ceilometer (compact lidar) observation has been conducted at Dalanzadgad, Mongolia, since the end of April 2013. The ceilometer observed a developed dust storm over the ground and a dust layer at a height of 1.2–1.8 km on 29–30 April 2015. According to SYNOP reports, this dust storm had already developed in the upwind region before arriving at Dalanzadgad. This feature was consistent with the sudden increase of the ceilometer observation values. Then, the dust was lifted to a height of 1.2–1.8 km, and the dust layer was observed at almost the same height for 12 hours by the ceilometer. During this dust event, radiosonde observation at Dalanzadgad showed an inversion layer at a height of 1.2–1.5 km over cold air. These results suggest that the dust layer was captured by the inversion layer, which prevented the dust from reaching the free troposphere and restrained the long-range transport of the dust by the westerlies. This study was supported by Research Fellowships of Japan Society for the Promotion of Science (JSPS) for Young Scientists and by Grants-in-Aid for Scientific Research from the JSPS (16H02703, 17H01616, and 18J12795).

[M-IS09] dust

convener:Ishizuka Masahide(Kagawa University), Yasunori Kurosaki(Arid Land Research Center, Tottori University), Thomas Sekiyama(Meteorological Research Institute), Kana Nagashima(Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change), Chairperson:Kana Nagashima

Mineral dust is generated from the ground surface by strong winds, and it transports long distance over the earth. In the process, cloud formation and absorption and scattering of solar radiation cause weather and climate changes. Also, when deposited in the ocean, feeding nutrients to phytoplankton, promoting photosynthesis, and when deposited on snow and ice causes albedo change. This is known as the yellow dust (Asian dust) phenomenon in Asia region including Japan. In order to understand this, integration in a wide range of academic areas is necessary.
In the emission process, the amount of dust changes greatly depending on the surface condition in dryland area, and in order to know the conditions, it deals with areas such as soil, topography, vegetation, precipitation, desert and soil deterioration. In the transport process, we deal with areas such as weather, atmospheric aerosol, radiation. In the deposition process, we deal with areas such as ocean, snow ice, health to people and livestock. Drying and changes in vegetation also have social scientific aspects such as national policies, management of livestock, and population increase. Dust and sand dunes are common phenomena not only to the Earth but also to other planets such as Mars and Saturn. In this way, it is impossible to understand the dust phenomenon only in one field, it is important for researchers in many areas to discuss and share information through this session, and advance exchange of researchers.

Favorable regions for dust haze transport revealed by ensemble simulations

*Kazunori Ogohara[1], Shogo Isoda[1]

1. School of Engineering, University of Shiga Prefecture

Dust is the major source of the solar heating in the Martian atmosphere and then drives the circulation of dust itself. Dust events (dust storms, dust devils and dust haze) are disasters in the Mars atmosphere near the surface because they can generate strong winds and block sunlight almost completely. Statistics of dust events have been studied by analyzing atmospheric temperature, dust optical depth and visible images observed by successive orbiters, landers and rovers. Active areas of local dust storms, including curvilinear and textured storms have been identified observationally. The tendency of such small scale dust events should be affected by the large scale atmospheric conditions such as thermal or dynamical stabilities. Activity of regional dust storms has been investigated using the vast number of images observed by Mars Orbiter Camera onboard Mars Global Surveyor (MGS/MOC) and MARs Color Imager onboard Mars Reconnaissance Orbiter (MRO/MARCI). They tend to break out near the storm zones in the northern mid-latitudes and are probably very linked to baroclinic instability and the fronts. Although mechanisms of the growth, maintenance and decay of global dust storms have not been well investigated, most of global dust storms started in the southern spring to summer seasons as regional storms were merging with each other.
Questions about the mechanisms of dust storms and haze are as follow:
- Why does a dust storm/haze break out?
- Why does the dust storm/haze expand?
Mechanisms of initiation and maintenance of local dust storms will be understood and categorized into a few types in the near future by statistical studies. They can be also inferred from observations and theories of terrestrial dust storms. However, there are local dust storms also in the northern mid-latitudes. Why do not the local storms grow into regional dust storms? Why do not all regional dust storms merge with each other? Ogohara and Satomura (2011) found five favorable regions for expansion of local dust haze (FRs) and revealed what kind of the atmospheric phenomena controls the dust haze transport around such regions. However, it still remains unclear whether these five FRs are also favorable for dust haze transport climatologically because they performed just a single year calculation. Thus, we identify the climatologically robust FRs in this study by ensemble simulations. If such FRs were found, atmospheric phenomena characteristic of the FRs would govern the dust transport around there.
Each ensemble simulation is performed in the same manner as that by Ogohara and Satomura (2011). Although they could not separate injected dust from the background dust due to the model architecture, wee modify the model in this study so that I can treat the injected and background dust separately. The first spin-up run started from an isothermal (220 K) condition with constant surface pressure (6.4 hPa) and no wind over the entire planet. Fifty kinds of small disturbances are added to the temperature output data of the first spin-up run. The small disturbances of temperature at each sigma level are normal random numbers. The standard deviation of the distribution function is 0.01 times of the standard deviation of temperature at the sigma level of the first spin-up result. The second spin-up runs are performed for 1 MY from L_s=180 independently using the 50 kinds of the output data of the first spin-up run with small disturbances as the initial data. After these spin-up runs, fifty global maps of dust haze expansion potential are made using the output data from the 50 kinds of the second spin-up runs as the initial data. The maps of dust haze expansion potential clearly show that there are a few robust FRs in the northern fall season. Also, it turns out that standard deviations of dust haze expansion are significantly

©2019. Japan Geoscience Union. All Right Reserved.

higher in the northern high latitudes than in the low latitudes. The reasons why dust tends to expand around the robust FRs are the same as those explained by Ogohara and Satomura (2011). However, high ensemble standard deviation in dust haze expansion is clearly shown at the first time by this study. In the presentation, we will show when dust haze tends to spread extensively and when it does not.

Measurement of adhesion force of individual aerosol particles by atomic force microscopy

*Kohei Ono[1], Yuki Mizushima[4], Ayumi Iwata[3], Furuya Masaki[1], Nozomu Tsuchiya[1], Atsushi Matsuki[2]

1. Graduate School of Natural Science and Technology, Kanazawa University, 2. Institute of Nature and Environmental Technology, Kanazawa University, 3. Faculty of Science and Technology, Keio University, 4. College of Science and Technology, Kanazawa University

A new method was developed to quantitatively evaluate the adhesion force of individual aerosol particles. The method involves force-curve-mapping by atomic force microscopy. Firstly, adhesion force of particle surrogates (PSL, ammonium sulfate, quartz) were measured to evaluate the applicability of the new method on individual particles. Spatial distribution and representative adhesion force was successfully obtained. The force-curve-mapping method was then applied on actual ambient samples. The aged Asian dust particles following long-range transport were collected within Kanazawa University campus. The same dust particles were identified under both AFM and SEM-EDX and analyzed for their morphology, adhesion force distribution and elemental composition. It was found that the adhesion force of aged silicate Asian dust was greater than that of fresh dust collected near the source in China. It was suggested that the adhesion force of aged silicate dust increases and becomes comparable to those of inorganic salts (i.e. ammonium sulfate and sea salt particles). Ca-rich Asian dust exhibited even stronger adhesion force. The result revealed difference of adhesion forces between silicate and Ca-rich Asian dust following atmospheric processing during long-range transport. This study also spotted few carbonaceous particles with exceptionally high adhesion force, suggesting certain organic aerosols may be particularly adhesive. This work successfully demonstrated the importance of adhesion force measurement on individual particle basis, and applicability of force-curve-mapping method for characterizing adhesivity of internally mixed particles.

Occurrence of micro-meso scale dust storms and its relationship to the vegetation and topography in Mongolian grassland and Gobi Desert

*Kenji Kai[1], Kei Kawai[2], Teruya Maki[3], Jun Noda[4]

1. College of Education, Ibaraki University , 2. Nagoya University, 3. Kanazawa University, 4. Rakuno-Gakuen University

Gobi Desert and Mongolian grassland are one of the main sources of the Asian dust. In order to investigate the occurrence of micro-meso scale dust storms and its relationship to the vegetation and topography, we conducted moving observations running across the Gobi Desert from Ulaanbaatar to Dalanzadgad in springs of 2015-2017. An optical particle counter (OPC: Aerotrak 9306-V2), a sunphotometer (Microtops II) and meteorological instrument were installed in a car.

The vegetation had a suppression effect on the dust emission. Number concentrations of coarse particles (1-10 μm) decreased from the desert to the grassland. They had significant negative correlations with the vegetation (NDVI) from 3 μm to 10 μm, but the number concentration at 0.3 –0.5 μm had little correlation to the vegetation.

During the moving observations, we found a hotspot of dust storms in the Gobi Desert. An analysis of Himawari-8 Dust RGB clearly shows that the hotspot appeared at a jointing point of two valleys, a bottleneck and an exit of a valley.

In summary, the horizontal distribution of number concentrations of aerosol particles reflected the surface vegetation. Locations of the hotspot were determined by a local topography such a jointing point of two valleys.

Mineral dust particles are blown up into the free atmosphere by sand-dust storm (SDS) in drylands, and they are broadly distributed by wind in the upper atmosphere. SDS is a type of disaster in drylands, which sometimes kills people and animal, destroys infrastructure, reduces merchandise value of livestock etc. In downwind regions like Japan, there is reports on its health effect. In the global scale, there are many reports about their effects on climate via direct and indirect effects of radiation. Many researchers have developed numerical dust model to avoid such damages, but their accuracy is still low, especially in its emission phase (Uno et al. 2006; Carmichael et al. 2008).

We can divide causes of dust emission (in other words, wind erosion) into erosivity (i.e., ability of wind to cause erosion) and erodibility (i.e., susceptibility of soil and land surface to wind erosion represented by the threshold wind speed for dust emission). Erosivity can be expressed by one parameter, which is wind speed and accuracy for its observation and its forecast is relatively reliable. On the other hand, erodibility has many parameters relating with soil and land surface such as soil particle size, soil wetness, crust, soil freeze, snow cover, vegetation cover, and we have a very big hurdles for monitoring all with high accuracy. This can be a big reason of low accuracy of dust emission modeling.

Tottori University set up a dust monitoring system at Tsogt-Ovoo, Mongolia, which is located in a northern part of the Gobi Desert. We have clarified that effects of soil crust (Ishizuka et al. 2012 SOLA), vegetation cover in topographic depression (Gantsetseg et al. 2017 J. of Arid Land), stone (Buyantogtokh et al. 2019 in preparation), dead leaves on erodibility. We also have conducted analyses of wind and present weather data included in synoptic report to elucidate dust emission conditions, which differs place by place. Kurosaki et al. (2011 GRL) clarified that dust emission frequencies increased at many synoptic meteorological observatories in East Asia from 1990s to 2000s and the major causes are in increased erodibility, which can be shown by reductions of threshold wind speed. Wu et al. (2016 SOLA) clarified that the major causes for dust emission are different station by station in East Asia. Wu et al. (2019 in preparation) clarified that effect of livestock number at Abaga Qi, which is located at Xilingol Grassland, China.

Keywords: drylands, aeolian dust, wind erosion, erosivity, erodibility

Monitoring and assessing aeolian desertification processes based on a dust erodibility index –A case study in the Xilingol grassland, China

*Jing Wu[1], Yasunori Kurosaki[1], Chunling Du[2], Tao Wang[3]

1. Arid Land Research Center, Tottori University, 2. School of Economics and Management, Inner Mongolia Agricultural University, 3. Northwest Institute of Eco-Environment and Resources, Chinese Academy of Sciences

Aeolian desertification is land degradation characterized by wind erosion, which is dependent on erosivity and erodibility. Progressive aeolian desertification causes dust to occur frequently, which has negative impacts on the environment and human health. To effectively prevent the expansion of aeolian desertification, it is crucial to monitor the processes of aeolian desertification and understand its mechanism(s). However, due to its complexity, it is difficult to apply a common indicator for monitoring desertification status.
In this study, we assessed aeolian desertification by using a dust erodibility index as an indicator that reflects the vulnerability of the land surface to wind erosion. We used dust occurrence ratio (DOR), which was calculated as the ratio of the frequency of dust occurrence to the frequency of strong winds, to represent the status of aeolian desertification. We evaluted aeolian desertification procesess at one site (Abaga-Qi) in the Xilingol grassland during the period 1974–2013. DOR values during 2001–2013 were notably higher than those in 1974–2000, indicating that land surface conditions became vulnerable to wind erosion in recent years. However, the DOR values trended lower from 2001 to 2013, corresponding to periods in which restoration projects were implemented aimed at combating desertification in China. To understand the mechanism(s) underlying aeolian desertification after the implementation of restoration projects, we conducted multiple regression analysis of climatic variables (precipitation and temperature) and an anthropogenic variable (livestock number) on recent variations (2001–2013) in aeolian desertification. Stepwise multiple regression results indicate that the recent decline in DOR values was associated with abundant precipitation and low temperature during summer of the previous year and a small livestock population at the end of the previous year. Livestock reduction made the greatest contribution. Our results suggest that aeolian desertification can be effectively reversed by reducing the number of livestock in the Xilingol grassland.

Influences of land surface conditions and human activities on dust events in Inner Mongolian grasslands, China

*Mei Yong[1], Masato Shinoda[2], Nandintsetseg Banzragch[2]

1. Inner Mongolia normal university, 2. Nagoya university

Aeolian processes in temperate grasslands (TGs) are unique in that the plant growth–decay cycle, soil moisture, and land-use interactivity affect seasonal and interannual variations of dust events. When compared with Mongolian TGs, Inner Mongolian TGs are characterized by unique land-uses (settle grazing and grass mowing). Since 2003, to prevent desertification and dust storms, land-uses have been controlled by the grassland protection law. We used process-based ecosystem (DAYCENT) and statistical models as well as dust event observations during March–June 1981–2015 to (1) identify critical land surface factors that control dust emission (soil moisture and vegetation components; live grasses, standing dead grasses and litter) in Inner Mongolian steppe and desert steppe sites, and (2) estimate the impacts of the controlled land-use law on dust events. The DAYCENT model realistically simulated dynamics of the vegetation components and soil moisture that were captured by observations (2005–2015). Results showed that at both sites, the spring dust events had a similar amplitude of significant correlation with wind speed and a combination of all the surface factors that retained anomalies (memory) of the preceding year. Among the surface factors, vegetation was a critical dust suppressing factor in Inner Mongolian TGs, similar to Mongolian TGs. Importantly, in the desert steppe, the standing dead grasses had the strongest memory and simultaneous significant correlation with the dust events, while no significant correlations were found in the steppe. This suggests that in the steppe, intensive grazing and mowing resulted in smaller dead grasses and a negligible effect on dust events. Moreover, simulations of dust events under controlled land-use (light grazing) and uncontrolled conditions (heavy grazing) showed that since 2003, the grassland protection law resulted in reduced dust events by 25% and 40% in the steppe and desert steppe, respectively.

[M-IS12] tsunami deposit

convener:Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics (CRiED), University of Tsukuba), Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University), Chairperson:Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University)

The 2011 off the Pacific coast of Tohoku Earthquake and tsunami have an influence on the development of tsunami deposit research. After the tsunami, a lot of findings have been reported on various research fields. However, identification criteria of the tsunami deposit are not yet established. Moreover, it is still uncertain how to use the tsunami deposit in the risk assessment. In this session, we welcome researches from all aspect of sedimentary records of modern and paleo tsunamis both onshore and offshore, and numerical and experimental modeling studies for risk assessment. In addition, we also welcome other event deposits, such as flooding and storm surge, that they are considered to be important for discrimination of tsunami deposit.

Geological Record of Tsunamis and Storms Influenced by Relative Sea-Level Change, Southern Hidaka Coast, Hokkaido, Japan.

*RYO NAKANISHI[1], Satoshi Okamura[1,2], Tsumoru Sagayama[3], Yusuke Yokoyama[4], Yosuke Miyairi[4]

1. Hokkaido Edu. Univ., 2. Hokkaido Soil Res. Co-op., 3. HRCG, 4. Univ. Tokyo

In the last a few hundred years, southern Hidaka coast in Hokkaido was suffered from large tsunamis by subduction of the Pacific Plate along the southern Kuril Trench. 2003 Tokachi-oki earthquake left traces at maximum altitude 4 m in Hyakunin Hama in the eastern part of Cape Erimo, also maximum altitude 3 m in western part of Cape Erimo. It was caused by the edge wave propagating from Cape Erimo along the west coast of the Hidaka area (Tanioka et al., 2004) . On the other hand, geological studies in eastern part of Hokkaido revealed that intervals of outsized tsunamis by Kuril subduction inferred average nearly 400 years but range widely from about 100 to about 800 years (Sawai et al., 2009), and these probably reached western part of Cape Erimo. However, the only 17th century tsunami deposits reported in the western part of Cape Erimo are said to be unknown the trigger. Thus, This study conducted Simple boring survey to reveal tsunamis cycle and age of emergence in Northern Hidaka coast. Consequently, we compared western part and eastern part of Cape Erimo about scale of tsunamis, also examined the relationship with the paleo environment.

As a result of boring survey by a geoslicer in the peat swamp behind the beach, we found three volcanic ash layers and nine event sand layers in the humus and the peat. In order from the top, it was AD 1663 Us-b tephra, AD946 B-Tm tephra, two sand layer (Us1, U1), 2700-2500BP Ta-c2 tephra, seven sand layer (U2-8). Peat layers change to remarkably undegraded humus from the U4 layer downward. The number of sand layers decreased landward, finally being zero at about 500 m from coastline. U1-8 sand layers were similar in particle size and gray color to beach sands, and sorting very well. These common characteristics were from inverse to normal grading and contain rip-up clasts. Also, grain size and thickness were inverse correlation with distance from coastline, but no correlation with distance from river. Because the diatom assemblages from event sand layers contained marine, brackish and terrestrial species in contrast peat occupied by freshwater species, these turn out to derive from seaward. Conversely, the Us1 layer had limited distribution several tens meter from paleo beach ridge, the thickness changed from 20 cm to very thin at only 20m landward. Grain size of the Us1 layer was fine - very coarse, including Φ1cm flat gravel. The Us1 layer can be supposedly distinguished from U1-8 layers from these features similar to storm deposits. A result of measuring ages for the time of sand deposition by AMS radiocarbon dating, we obtained the age of about 5500BP from under the U8 layer, about 2000BP from above the U1 layer. The average recurrence intervals of event is nearly 400 years, the interval is sometime shorter (50 years) or longer (550 years) than the average, so the U1-8 event layers are probably tsunami deposits by subduction earthquakes like seen in eastern Hokkaido.

The U7 layer is the thickest in all sand layers, thickness of event layers tend to become thinner as the upper stratigraphy. The U7 layer is most widely distributed inland, it deposited in about 4900BP, when high-standard period in eastern Hokkaido (Dura et al., 2016). It was found from the result of continuous chemical analysis of peat samples in the vertical direction that Fe and S increased as deeper at the depth deeper than the U5 layer (about 3800BP). In this site, considering the humus layer shows undegraded under the U4 layer, this chemical characteristic imply that the peat was reductive and the sea-level was high at that time. We inferred that tsunamis inundated over the sand ridge in this area only for 5500BP to

©2019. Japan Geoscience Union. All Right Reserved.

2000BP, because didn’ t find tsunami deposits from the stratigraphy since 2000BP. In conclusion, when restoration of paleo tsunami record, it necessary to consider that changing sea-level and associated topographic change.

Before and after relationship between the seismic uplift and the large tsunami due to the seventeenth-century giant earthquake observed in the seismic barrier systems around the Kuril subduction zone

*Futoshi Nanayama[1,5], Kazuaki Watanabe[1], Keita Fukatsu[2], Takeshi Hasegawa[4], Kiyoyuki Shigeno[3], Masayuki Ishii[6], Kazuhito Ishiwata[7], Shigeto Inokuma[8]

The Kuril subduction zone is one of the most frequent earthquakes in Japan. There are many undeveloped plains in this area, unspoiled nature is left, and many barrier coasts and tsunami deposits due to the giant earthquake (17th century type) repeatedly generated at 400 to 500 years intervals can be widely observed around this area. However, the relationship between the timing of both is not clear yet. Especially two tsunami deposits, which are occurred in the 17th century, can be observed in many places around the eastern Pacific coast of Hokkaido. On the other hand, there are many active barrier systems around the coast of Nemuro Strait and Konsen ~ Tokachi coast, and it has recently become evident that a 17th century giant earthquake occurred as a trigger. Our research group examined the relationship between the occurence timing of these uprifting barrier systems and the 17th century tsunami in several areas in detail, and some interesting facts have been found, so we will report the outline in this meeting.

This work was supported by JSPS KAKENHI Grant Number 18K03767.

Coastal landform changes and Washover deposits due to high waves generated by anatmospheric low-pressure system in June 2016 at Horokayanto, Hokkaido, Japan

*Takashi Chiba[1], Yuichi Nishimura[2]

1. Faculty of Bioresource Sciences, Akita Prefectural University, 2. Graduate School of Science, Hokkaido University

The lake bottom of Horokayanto, one of the lagoons in eastern Hokkaido, Japan, was partly exposed as a result of sandbar breaching during severe weather in June 2016. The mean lake level fell from approximately 3.1 to 1.2 m above TP, which is equivalent to the height of the MHHTL in the Tokachi area by the breached sandbar. Some erosion forms were recognized in the southwestern breached point of the sandbar. However, the washover fan formed by the high waves from the seaward to the lakeward sides was recognized in the northeastern part of the sandbar. Moreover, characteristic diatom assemblages resulting from coastal environmental changes were also recognized around the lake. The high-tide-level indicator *Pseudopodosira kosugii* was recognized in the emerged lake bottom assemblage together with freshwater–brackish and brackish–marine species. Water pressure or moisture changes caused by either the emergence, the changes in light quantum density and ultraviolet rays, the changes in water quality such as salinity and pH, or a mixture of these factors, may have influenced the increase in *P. kosugii*. Reworked Neogene marine diatoms such as *Denticulopsis* spp. that were presumably derived from nearby Neogene basement rocks were also detected–albeit infrequently–in the modern assemblages. The fossil diatoms were eroded by current inflows into the lake during the severe weather. During the period of emergence, seawater may have been transported into Horokayanto Lagoon by high waves generated by an atmospheric low-pressure system. However, the height of the waves was below that of the central part of the sandbar.

Institute of Marine Geology and Geophysics, Russian Academy of Sciences, 9. Japan Meteorological Agency, 10. Geospatial Information Authority of Japan, 11. Ministry of Education, Culture, Sports, Science and Technology

Historical and prehistorical tsunami deposits in Kunashir Island, the Northern Territories, were studied as parts of visa-free exchange programs of Japan and Russia. The reconnaissance survey was conducted for 30 days for 4 years from 2015 to 2018, and 105 sites in the ca. 50 km area along the Pacific coastline was examined. As a result, it was confirmed that the sand layer, which can be regarded as a trace of the 1994 Hokkaido Toho-Oki tsunami is well preserved near the surface layer in the eastern lowland from Furukamappu to Ruyobetsu. The 1994 tsunami run-up, estimated from the distribution of the deposits, is 50-150 m from the coast and 3-4 m in height. Furthermore, the chemical composition of the volcanic glass was analyzed for as many as 30 volcanic tephras. Examining the results together with the stratigraphy, it was found that known tephra from volcanoes of Hokkaido, such as Ko-c1 (1856), Ta-a (1739), Ko-c2 (1694), Ta-b (1667), Ma-b (10th Century) and Ta-c (2,700 BP) are deposited at multiple sites on the island. With these volcanic deposits as the key layer, we could estimate the age of the candidates of tsunami deposits. For example, in the wetland of Furukamappu, there is one event in the 17th and 10th centuries, and two in the 10th century and 2700 years ago. It is inferred that the large tsunami that would leave the deposit in Kunashiri occurred at a frequency of once in 1000 years.

Deposit-based assessment of tsunami size: example from Nankai-Trough earthquakes

*Daisuke Sugawara[1], Kentaro Imai[2], Shinsuke Okada[3], Takuto Maeda[4]

1. Museum of Natural and Environmental History, Shizuoka, 2. JAMSTEC, 3. Tohoku University, 4. Hirosaki University

Researches on historical documents and geological records, such as tsunami deposits, have clarified the recurrence of the Nankai-Trough earthquakes and tsunamis during the past 6000 years. Magnitudes and source parameters of some historical tsunamigenic earthquakes, such as the 1707 Hoei and 1854 Ansei events, have been examined based on numerical modeling of coseismic crustal deformation and tsunami propagation and inundation. For example, the extent of the rupture area of the Hoei earthquake was revised based on the numerical modeling of tsunami inundation, considering tsunami heights from historical records and tsunami deposits in the Ryujin-ike pond in the eastern coast of Kyushu island (Furumura et al., 2011). The revised rupture area of the Hoei earthquake was extended to the Hyuga-nada, 70 km beyond the previously estimated rupture area.

The magnitude of the presumed largest (Mw=9.0) earthquake which may occur in the Nankai Trough (Disaster Management of Cabinet Office, 2012) is much greater than the size of known historical events. To validate the assumptions of the largest earthquake, information from tsunami deposits, which may record tsunamigenic earthquakes in longer time span, will play an important role. However, most tsunami deposits in the Nankai Trough region have been found from coastal lakes and narrow lowlands. In this region, spatial distribution of tsunami deposits cannot be a good indicator of tsunami inundation. Explorations are needed to correlate spatially-limited data of tsunami deposit with the magnitude information and source parameters of earthquake and tsunami.

In this presentation, deposit-based assessment of the size of earthquake and tsunami will be discussed based on numerical modeling of tsunami and sediment transport in the Ryujin-ike pond. Main interest of the research is that whether or not we can correlate the formation processes, distribution and thickness of tsunami deposit with the source parameters of the tsunami. In addition, results of the modeling will be compared with field observations of the deposits, to discuss the relationship with the historical earthquakes.

Flume experiments for understanding variety of tsunami deposit

*Naofumi Yamaguchi[1]

1. Center for Water Environment Studies, Ibaraki University

Flume experiments, in which sedimentary conditions can be easily controlled, are expected to provide insights into the sedimentary process under tsunami flow. The previous studies using flume experiments have contributed to improvement of numerical models of tsunami sediment transport. By contrast, there is not enough experimental studies to examine sedimentary process in order to improve the identification and interpretation of (paleo) tsunami deposits in geological record. In this presentation, I will summarize previous studies of tsunami deposit using flume experiment, and show the potential for better understanding of sedimentary process of tsunami deposits.

[M-IS12] tsunami deposit

convener:Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics (CRiED), University of Tsukuba), Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University), Chairperson:Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics, University of Tsukuba)

The 2011 off the Pacific coast of Tohoku Earthquake and tsunami have an influence on the development of tsunami deposit research. After the tsunami, a lot of findings have been reported on various research fields. However, identification criteria of the tsunami deposit are not yet established. Moreover, it is still uncertain how to use the tsunami deposit in the risk assessment. In this session, we welcome researches from all aspect of sedimentary records of modern and paleo tsunamis both onshore and offshore, and numerical and experimental modeling studies for risk assessment. In addition, we also welcome other event deposits, such as flooding and storm surge, that they are considered to be important for discrimination of tsunami deposit.

Inverse modeling of Tsunami deposit using Deep Learning Neural Network

*Rimali Mitra[1], Hajime Naruse[1]

1. Kyoto University, Graduate School of Science

Tsunami is one of the most catastrophic disasters along coastal zones, and tsunami deposits are layers of sediment formed by hydrodynamic activities of tsunami. These event deposits provide clues to estimate the recurrence intervals and relative magnitude of prehistoric tsunamis that serve as a tool for future tsunami hazard evaluation. Towards the quantitative assessment of hydraulic conditions of tsunamis from deposits, this study applies the inverse model using deep learning neural network (DNN) for tsunami deposit. In order to conduct machine learning of DNN, forward model calculation was repeated at random initial flow conditions (e.g. maximum inundation height, flow velocity, concentration, etc.) to produce artificial training data sets which represent depositional characteristics such as thickness and grain-size distribution. The model serves as the modified version of previously proposed FITTNUSS model, which incorporates nonuniform and unsteady transport of suspended sediment and also turbulent mixing. Then, DNN was trained for establishing the inverse model on the basis of artificial data sets. SGD (Stochastic gradient descent) is used as an optimizer for this DNN model. Tests using artificial data sets successfully indicated that the established DNN can reconstruct the original flow conditions from the characteristics of deposits. Finally, the model was applied to natural data sets taken from the 2011 Tohoku-Oki Tsunami deposit. The deep learning neural network showed promising result for natural data sets. Comparing to existing inverse models, deep learning neural network enables the inversion to employ a forward model that requires higher computational costs, and to avoid a local optimum. The further applicability and validation of this method will be checked with other parameters, and natural data set from different field visits in future endeavour.

Numerical estimation of tsunami size using boulders deposited by the 2011 Tohoku-oki tsunami at Settai, Miyako city, Japan

*Tatsuya Takei[1,4], Kazuhisa Goto[2], Masaki Yamada[3]

1. Department of Earth Sciences, Graduate School of Science, Tohoku University, 2. International Research Institute of Disaster Science (IRIDeS), Tohoku University, 3. Earthquake Research Institute, University of Tokyo, 4. Department of Complexity Science and Engineering, Graduate School of Frontier Sciences, Tokyo University

Tsunami boulders are important geological evidence to understand paleotsunami activity. Previous studies have intended to extract the information about tsunami size from the distribution of tsunami boulders. However, although several numerical methods have been proposed to estimate tsunami size using tsunami boulders, there have been no studies validating the estimated tsunami size by comparing with the actual tsunami size. Also, it is important to consider the methodology of the estimation of tsunami size using boulders. In this study, we estimated local size of the 2011 Tohoku-oki tsunami at Settai, Miyako City, Japan based on the numerical modeling of boulder transport. We seaerch an incident wave condition of sin waves which could explain the distribution of boulders well. We then compared the estimated results with the tsunami size calculated by existing well-validated tsunami source model. As a result of the simulation, we estimated that the tsunami size was ranging from 9 m to 21 m in wave height and from 60 s to 300 s in period at the point of 5200 m offshore of Settai.This range covers the actual tsunami size; so the tsunami size can be estimated from the boulders in Settai. According to the above results, the method that we proposed was effective. On the other hand, we found that assumption of the initial position of boulders are critically important and it should be constrained by multiple information such as topographic condition and composition of the boulders.

Constraint of the ages of historical tsunami deposits on the Ishinomaki Plain

*Hiroshi Tetsuka[1], Kazuhisa Goto[2], Takashi Ishizawa[1], Daisuke Sugawara[3], Yusuke Yokoyama[4], Yosuke Miyairi[4]

1. Department of Earth Science, Tohoku University, 2. International Research Institute of Disaster Science, Tohoku University, 3. Museum of Natural and Environmental History, Shizuoka, 4. Atmosphere and Ocean Research Institute, University of Tokyo

The research of tsunami deposit has an important role for understanding the paleo-tsunami history. On the Ishinomaki Plain, where the AD 2011 Tohoku-Oki tsunami inundated widely, at least six paleo-event deposits were found by previous studies (Shishikura et al., 2007; Sawai et al., 2012; Takeda et al., 2017). Sawai et al. (2012) correlate the latest three event deposits (Sand K, A, and B) with the tsunamis generated by the AD 1611 Keicho Ohsyu earthquake, the AD 1454 Kyotoku earthquake, and the AD 869 Jogan earthquake, respectively. Among them, the event age of Sand B is well constrained by the To-a tephra of AD 915 and radiocarbon ages, which ensure the validity of correlation with the historical record. However, the event ages of Sands K and A were not well constrained because accurate estimation of these event ages by radiocarbon dating is theoretically difficult. There remains a need to improve the accuracy of these event ages for understanding recurrence interval of tsunamis and comparing with the age of tsunami events in other sites. Therefore, we conducted multi-proxy analyses including radiocarbon dating, and analyses of diatom and pollens for the samples taken from the Ishinomaki Plain and then discuss the age of event deposits formed during the last 700 years.

The field survey was carried out on the coast area of Higashi-Matsushima City, Miyagi Prefecture. Cultivated soil, silt, and peat layers were found in the core samples. In some sites, one or two medium sand layers were found. Diatom analysis, pollen analysis, X-ray CT scan, and radiocarbon dating were conducted for the clearly identified two sand layers. The radiocarbon dating results were calibrated by OxCal Ver. 4.3.2 (Bronk Ramsey, 2009) with IntCal13 (Reimer et al., 2013) and constrained by stratigraphy (Bronk Ramsey, 2008).
Two sand layers (hereafter we call, Sands 1 and 2 for the upper and lower sand layers, respectively) are closely spaced with sandy silt layer of approximately 1–3 cm between them. Two hypotheses can be considered for the formation of these sand layers; they were deposited by different events, or a single event. Eyewitness observation and X-ray CT scan analysis imply that the sandy silt deposits in between these two sand layers contain many sand grains, and clearly different from the peat layer below Sand 2. The radiocarbon dating revealed that the age of sandy silt layer is intermediate between silt above Sand 1 and peat below Sand 2. In addition, sandy silt includes many freshwater diatoms but does not include marine and marine-brackish diatoms; diatom assemblage is clearly different from peat below Sand 2 that contains marine-brackish diatoms but few freshwater diatoms. Thus, sandy silt between Sands 1 and 2 is probably deposited as normal sediment so that Sands 1 and 2 should have been formed by different events.

The ages of Sands 1 and 2 can be constrained as 11 to 408 cal BP and 357 to 538 cal BP (2σ), respectively. These event ages are consistent with the AD 1611 Keicho Ohsyu earthquake and the AD 1454 Kyotoku earthquake, as interpreted by Sawai et al. (2012). The pollen analysis further shows the extensive increase of *Pinus sp.* and *Cryptomeria sp.* in the sediment above Sand 1. This result can be correlated with the afforestation policy by Sendai Domain after mid-17th century as planting Japanese

©2019. Japan Geoscience Union. All Right Reserved.

pine and cedar was encouraged by the AD 1621 Sendai domain’ s law (Hanso Date Masamune kensho-kai, 1938). Therefore, Sand 1 has most likely been formed by the AD 1611 tsunami.

Non-destructive analyzes of sediments to discern tsunami-related mud cap and overlying muds to improve age determination of tsunami deposits

*Takashi Ishizawa[1], Kazuhisa Goto[2], Yusuke Yokoyama[3], Yosuke Miyairi[3]

1. Department of Earth Science, Tohoku University, 2. International Research Institute of Disaster Science, Tohoku University, 3. Atmosphere and Ocean Research Institute, The University of Tokyo

Age of tsunami deposit is usually determined from dating results of sediments above and below the tsunami derived layers. However, determining the upper boundary of tsunami deposit is often difficult, because the top of tsunami deposit is sometimes comprised of mud-dominated sediment (mud cap) which can be indistinguishable from overlying muddy sediment deposited under normal sedimentary condition. This ambiguity may cause serious problem determining true tsunami ages.

Here we present an examples of non-destructive and destructive analyses of core sample taken from Okirai, Iwate prefecture. Our results indicated that X-CT (X-ray Computed Tomography), XRF (X-ray Fluorescence), and grain size analyses were useful to identify tsunami-related mud cap from overlying muds deposited after tsunami events. Since X-CT and XRF analyses are non-destructive analyses, it is highly recommended to conduct these analyses before subsampling of the sediments for further analyses including radiocarbon dating. Such careful sampling for dating will contribute to improve age estimation of tsunami deposits.

Sedimentological and paleontological studies of storm surge deposits in intertidal mud floor -case study of Ena Bay on Miura Peninsula, Central Japan.

*Akihisa Kitamura[1], yamamoto yuka[1], Takashi Toyofuku[2]

1. Institute of Geosciences, Faculty of Science, Shizuoka University, 2. Japan Agency for Marine-Earth Science and Technology (JAMSTEC)

Storm surges and tsunamis deposits provide essential information for disaster assessments of coastal lowlands in low- and middle-latitude regions and active margins. However, studying these coastal lowland strata is becoming increasingly difficult, particularly in residential regions, due to extensive anthropogenic disturbances. Consequently, the focus of research has had to extend to shallow marine deposits such as bay sediments, although few studies have examined storm surge deposits related to recent storm events. This study identified storm surge deposits within tidal flat sediments in Ena bay, located in the southern coastal area of metropolitan Tokyo, Central Japan. Identification of the deposits was based on a comparison of surveys undertaken before and after Typhoon Lan (lowest pressure of 915 hPa), which struck the area on 23 October 2017. The results indicate that the storm surge deposits are limited to the supratidal and intertidal zones, demonstrating that the distal extent of sand beds deposited by storm surges is less than that of sand beds typically deposited by larger tsunamis.

Shallow marine tsunami deposits and bioturbation

*Koji Seike[1]

1. Geological Survey of Japan, AIST

The huge tsunami waves induced by the 2011 off the Pacific coast of Tohoku Earthquake severely affected shallow marine ecosystems along the Pacific coast of northeastern Japan. Among shallow marine settings, subtidal seafloor ecosystems composed of fine-grained sediments are the most heavily disturbed by tsunami waves as they are greatly altered by rapid erosion and deposition processes (Seike et al., 2013). In order to discuss preservation potential of the tsunami deposits in relation to sediment mixing by recolonizing benthic animals, we have monitored temporal changes in the sedimentary structures of the tsunami affected area (Seike et al., 2016, 2017a). Tsunami deposits also provide useful information on the nature of bioturbation because there are no pre-existing burrows in the sediments. We revealed the nature of bioturbation such as burrowing depth, substrate-softening effect by echinoid bioturbation on the basis of observations on the 2011 tsunami deposit (Seike et al., 2017b, 2018).

[M-IS16] Dynamics of eruption cloud and cumulonimbus; modelling and observation

convener:Eiichi Sato(Meteorological Research Institute), Fukashi Maeno(Earthquake Research Institute, University of Tokyo), Takeshi Maesaka(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Eiichi Sato(Meteorological Research Institute)

Volcanic eruption clouds (eruption column, pyroclastic flow, and umbrella cloud) and cumulonimbus are similar phenomena in the atmosphere. Models that can precisely reproduce the physical processes in such phenomena, and accurate observations have been required. Recently, the development of remote sensing techniques such as weather radar and weather satellite are remarkable, and they are being adopted for volcanic eruption monitoring. However, it is indispensable to verify the results of modeling and remote sensing using in-situ observations. In this session, we will discuss the modelling and the observations of eruption clouds and cumulonimbus from the viewpoint of meteorology, volcanology, geology, and other related fields. The related phenomena such as ashfall, rainfall, snowfall, hail and volcanic block will also be discussed.

The present paper describes the results of observational studies of volcanic ash columns using different types of weather radars: X-band marine radar, bi-static Ku-band radar, Ka-band Doppler radar, and operational X-band polarimetric radar. In order to observe eruption columns with extremely fine temporal resolution, an X-band marine radar was set up during three months in 2018 at the Kurokami observatory of Kyoto University located about 4km from the vent of Sakurajima volcano. The marine radar has a slot antenna that has the PPI scanning speed of 48 rpm, with a vertical beam width of 22˚ and a horizontal beam width of 1.2˚, and a range resolution of 8m. We carried out observations by physically changing the rotational axis of the slot antenna from vertical (PPI) to horizontal (RHI) to achieve an elevation angle resolution of 1.2˚. The MRI Ku-band radar and Kagoshima University Ku- band radar set up in 2017 in Sakurajima have Luneberg antenna with a horizontal and vertical beam width of 3˚. The antenna rotates spirally from an elevation angle of 0˚ to 90˚ to obtain hemispherical volume data in one minute. The Ka-band Doppler radar of NIED was operating at the Kurokami observatory during 3 months in 2015 to investigate the inner structure with the RHI antenna scanning. The MLIT operational X-band polarimetric radar located approximately 11km from the vent of the Sakurajima volcano can measure volcanic ash columns three-dimensionally at 5-minute intervals, even though it is an operational radar aiming to measure heavy rainfalls in Sakurajima.

Utilizing these different types of radar data, we perform detailed analysis of eruption columns. The marine radar succeeded in detecting eruptions and at the same time detecting falling pyroclastic particles (Fig. 1). The radar also reveals the fine structure of an ascending eruption column at 1.25-second intervals. While the marine radar observes volcanic ash columns with the wider azimuth angel resolution 22˚ due to its fan beam antenna, Ka-band Doppler radar can observe the targets with finer azimuthal resolution using RHI scanning of the parabolic antenna. The Ka-band radar RHI observations also reveal the upward speed of the ash echo top at 2-minute intervals. While both the marine radar and the Ku-band Doppler radar measure eruption column vertically at a fixed azimuthal direction, the Ku-band Doppler radar measures all azimuth and elevation angles every 1 minute. Using this scanning strategy, we can clarify the temporal change of the eruption column during its downwind movement: the radar reflectivity factor of the upper part of the eruption column becomes high 5-minute after the eruption, which is probably due to the aggregation process in water clouds (Fig. 2). The operational X-band MP radar collects 20 tilts PPI scan data at 5-minute interval. We can construct three-dimensional data of ash clouds with time and spatial interpolation method. Then we can obtain the wide-area ash fall distributions.

In conclusion, as mentioned above, different types of weather radars are now available for studying volcanic eruption columns and their applications to disaster prevention are promising.

We report the comparison between results by radar and lidar observations of Minamidake eruption on June 16, 2018, at Sakurajima, and the radar observation results of Kuchinoerabujima eruptions since December 2018. The radar reflectivity factor data distribution showed that the plume reached 3,300 m height within 1 min after the onset of the Minamidake eruption and increased to be 5,000 m height, after 3 min from the onset of the eruption. At the same time, it was confirmed from the radar reflectivity factor data that the eruption column shifted 1 km to the west direction. The radar reflectivity factor reincreased vertically above the crater at about 3,000 m height, 5 min after the starting of the eruption, which is corresponding to the second eruption. In the lidar observation, changes corresponding to the movement in the west direction of the eruption column were observed from 3 min after the start of the eruption to 8 min afterward, and the scattering peak corresponded well with the enhancement of the radar reflectivity factor. After 15 min from the onset of the eruption, there was no change in the radar reflectivity factor corresponding to the ash plume, but the significant scattering intensity of the lidar was found at a distance less than 2 km and continued for more than 20 minutes. It reflects that the lidar outperforms the radar in terms of detecting the finer particles exist in the atmosphere. The lidar observation showed that volcanic ash was diffused and moved by the wind. Next, we observed the increase in the radar reflectivity factor corresponding to the eruption columns of the eruptions on December 18, 2018, and January 17 and 29, 2019 at Kuchinoerabujima. One minute after the eruption on December 28, the radar reflectivity factor showed a rise to 3,000 m of ash plume and reached the maximum height at about 5,000 m, 3 min after the onset of the eruption. It was found from the radar reflectivity factor that the maximum height of the plume was 4,000 m, 2 min after the onset of the eruption on January 17. Five minutes after the onset of eruption, the reflectivity factor of the plume reached 4,000 m and did not raise any further. From these facts, we can suggest that by grasping the temporal change of the plume height given by the temporal changes in radar reflectivity factor, we can extract the information of the eruption intensity.

2018-2019 Kuchinoerabu-jima eruption plume/cloud echoes observed by JMA weather radar network

*Eiichi Sato[1], Keiichi Fukui[2], Toshiki Shimbori[1]

1. Meteorological Research Institute, 2. Japan Meteorological Agency

At Shindake crater of Kuchinoerabu-jima volcano, a very small eruption occurred on October 21, 2018, and then continued intermittently until December 13. After that, three eruptions accompanied by pyroclastic flow occurred on December 18, 2018, January 17 and 29, 2019. Although Japan Meteorological Agency (JMA) failed to visually confirm the top of the former two eruption plumes, they were observed by Himawari-8, a meteorological satellite of JMA, and X-band MP radar of Disaster Prevention Research Institute (DPRI), Kyoto University. Meanwhile, the eruptions were also observed by JMA's weather radar network. In this presentation, we will report on the analyses using them.
Eruption plume/cloud echo associated with the eruption on January 17, 2019 was observed by Tanegashima radar and Naze radar. The plume echo height observed by Tanegashima radar was about 6.7 km above sea level (ASL), and about 6.5 km ASL by Naze radar. These are consistent with about 6 km above the crater edge (about 6.6km ASL), the result of the analysis with Himawari 8. On the other hand, the eruption plume echo height observed by the DPRI radar was about 4 km above the sea level. This may be due to the vertical wind shear. In other words, the authors think that the 125-degree RHI observation, i.e., vertical cross section observation by DPRI radar, did not capture the top of the plume, because the wind direction observed by the JMA wind profiler at Yakushima was northwesterly or north-northwesterly in the lower troposphere (2km or less), however, the wind was westerly in the middle troposphere (about 3-6km).
Meanwhile, in other cases including eruption cases on December 18, 2018 and January 29, 2019, the JMA radar network did not properly capture the eruption plume/cloud echoes. It is considered that the volcanic ash density especially near the top of the plume was low, and the mismatch occurred between the scan sequence of the radar and the rising process of the plume.
As a result of analysis by weather radar, we captured some of the eruption activity, however, there were many cases that could not be properly caught. We will show the limits of the observation method with weather radar, and show some possible countermeasures.

Numerical Study on the Ejection Conditions of Ash Clouds during Recent Eruptions of Kuchinoerabujima Volcano

*Yasuhiro Ishimine[1], Teruki Oikawa[2], Nobuo Geshi[2]

1. Research and Education Center for Natural Hazards, Kagoshima University, 2. Geological Survey of Japan, AIST

Kuchinoerabujima Volcano in Kyushu, Japan have erupted in 2014 and 2015. The volcanic activities intensified again since October 2018 and generated explosive eruptions accompanying pyroclastic density currents on 18 December 2018, 17 and 29 January 2019. The pyroclastic density currents are so hazardous that it is crucial to assess the risk that residential area near the volcano could be affected by the currents.

We performed a series of numerical simulations on the ejection of volcanic ash clods and subsequent density currents with the parameter settings, which were based on the observational data acquired during the explosive eruptions of Kuchinoerabujima volcano from 2014 to 2018. The supercomputer system HOKUSAI, RIKEN was used (Project number: Q18431).

We assumed that the initial temperature, density and ejection speed of ash clouds significantly affect the dynamics of the ash clouds, and thus, we searched plausible combinations of the parameter set of the thee variables by conducting a series of numerical simulations. Some of the simulations yielded the results that are comparable with the observed eruptions accompanying pyroclastic density currents. In particular, the results implies that the pyroclastic density currents are prone to occur when the initial temperature of the ejected ash clouds is lower than 800K.

In addition, the numerical simulations exhibited that the small north-south trending ridge on the east of the volcanic vent of Kuchinoerabujima volcano had the main part of the pyroclastic density currents spread over the western flank of the volcanic edifice. This is consistent with our observation at Kuchinoerabujma volcano.

Image analysis of volcanic clouds during the 2011 Kirishima Shinmoedake eruption

*Takehiko KOBORI[1], Kisei KINOSHITA[1], Naoko IINO[2], Masayuki MAKI[1], Seiji FUKUSHIMA[1]

1. Kagoshima University, 2. Kumamoto University

We report the development and spatial scale of the sub-plinian eruption of Kirishima Shinmoedake in January 26-27, 2011. In addition to the multipoint image observation and the cloud diffusion analysis of satellite images in the previous reports [1-3], we analyze Ohnami-ike volcano monitoring camera images [4] and the photographs published.
For the image analysis of the plume, we improved the photo analysis program [5] and developed a method fitting the skyline created from the elevation tile [6] to the image. By considering the curvature of the earth when creating skyline, accurate altitude estimation became possible.
Since 2008, fumes and white vaporous clouds were often observed at Shinmoedake. Then, volcanic ash containing fresh magma was confirmed at the small eruption on January 19, 2011 at 01:27 [7]. After that, it changed to continuous discharge of ash cloud as observed on January 22 and 25. The plume flowed and rose to about 5-7 km downstream, with its top reaching 1700 to 2200 m above sea level, and flowed horizontally. Discharge of the plume continued until around 14:00 on January 26, and reached the highest point of 1700-1900 m above sea level at the downstream 3-4 km. Despite poor visibility due to atmospheric turbidity on January 26th, near-infrared video images and photographs from the observation point of 50 km south-southwest of Shinmoedake, captured the whole plume shape and developmental process of the sub-plinian eruption started at 15:29 on January 26th. The upper part of the large-scale ash cloud was also observed from a southern point of Kagoshima City located in 58 km southwest of Shinmoedake, and the visible web camera in the Hitoyoshi Basin located in 38 km north of Shinmoedake. By sharpening and analyzing these images, the plume height was obtained. On January 26, the plume rose to 7-8 km downstream, the altitude above sea level was 5000-6000 m, rarely 7000 m. This is close to sea level altitude 7000 m (accuracy 1 km) [8] obtained from radar analysis of the Tanegashima and Fukuoka data. On January 27, continuous magmatic clouds were observed since the morning. At the explosion at 15:30 and 15:41, sub-plinian type eruption restarted, and heavy ash cloud reaching 7000-8000 m above sea level was seen from each observation point.

Cloud Radar Network for Early Detection of Cumulonimbus Generation

*Takeshi Maesaka[1], Tadayasu Ohigashi[1], Koyuru Iwanami[1], Shin-Ichi Suzuki[1], Yukari Shusse[1], Namiko Sakurai[1]

1. National Research Institute for Earth Science and Disaster Resilience

Recently municipal engineers point out that urban city is vulnerable for localized heavy rainfall, and that rainfall monitoring and forecasting are important for water management. A weather radar is a powerful tool for that purpose; however it is only precipitation particles (hydrometeors excluding cloud particles) that current operational radars (S-, C- and X-band) can detect. This means that when the radar catches the echo, the rainfall may have already started. Meanwhile, the heavy rainfall is caused by a mature cumulonimbus which develops from a cumulus. So the detection of the cumulous is expected to make the lead time of heavy rainfall forecasting longer. But the current radar cannot observe the cumulus which consists of the cloud particles. For an early warning of heavy rainfall, we developed the cloud radar network around Tokyo metropolitan area.
The network consists of five Ka-band (35 GHz) radars whose specifications are as follows: azimuth-/elevation-scanning Cassegrain antenna with a diameter of 2 m, 3 kW Extended Interaction Klystron (EIK) as a microwave amplifier, pulse compression by linear frequency modulation, and dual polarimetric capability (simultaneous transmission and reception of H and V; only three of the five radars). The minimum sensitivity we need is -17 dBZ (-20 dBZ) at 20 km range for dual (single) polarimetric type, respectively, because our target is the detection of a conversion from cloud droplets to raindrops. These radars were just deployed in February 2015. We would like to present preliminary results of our cloud radar and to discuss the availability to the early monitoring of cumulonimbus generation.

[M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Hitoshi Hasegawa

Past environmental changes and events at multi-decadal to tectonic timescale toward an understanding of Earth climate system by an integration of terrestrial and marine proxy studies and numerical modeling will be discussed. At JpGU2019, a series of presentations on present and future climate and environmental changes from paleo-perspective will be held. We welcome a variety of paleo-environmental studies from a wide range of background. We hope that this session will provide an opportunity to promote communication between participants from multidisciplinary field.

Paleotemperature and precipitation history (18.1–4.5 ka) in stalagmite bulk and clumped isotopes from Hiroshima, Japan

*Hirokazu Kato[1], Shota Amekawa[1], Akihiro Kano[1]

1. Department of Earth and Planetary Science, The University of Tokyo

Variation in stalagmite $\delta^{18}O$ is basically controlled by two major factors, temperature and isotopic composition of cave dripwater derived from the local precipitation. It is however not easy to separate relative impacts from these two fundamental controls by conventional oxygen isotope alone.
A possible solution is applying carbonate clumped isotope thermometry that can reconstruct the temperature without information of the isotopic compositions of the environmental water. The principle of the clumped isotope thermometry is based on the temperature-dependency of the abundance anomaly of $^{13}C^{18}O^{16}O$ (Δ_{47}) from acid digestion of carbonate.
In this study, carbonate clumped isotope (Δ_{47}) was measured from 50 layers of Hiro-1 stalagmite from Hiroshima Prefecture by purification line and MAT 253 settled at Kyushu University. The growth interval of the stalagmite is from 18.1 to 4.5 ka and includes two hiatuses in 10.8–7.7 ka and 12.8–11.4 ka.
The Δ_{47} values of 50 layers in Hiro-1 range from 0.683 to 0.741‰, which correspond to 3.2–23.4 ºC by temperature calibration on the basis of tufa measurements (Kato *et al.*, 2019).The temperature range of each time-series is 5.2–12.5 ºC (7.4 ºC in average; 18.0–16.0 ka), 10.4–12.8 ºC (11.9 ºC in average; 15.9–14.5 ka), 3.2–9.4 ºC (6.1 ºC in average; 14.2–12.6 ka), 6.8–12.4ºC (9.2 ºC in average; 11.0–10.7 ka), 7.6–23.4 ºC (15.7 ºC in average; 7.7–4.9 ka) and 3.9–9.7 ºC (8.2 ºC in average; 4.9–4.5 ka).
The Δ_{47} temperature record from Hiro-1 is broadly consistent with already-known climatic stages. For instance, the temperature recovery from LGM, lowering around Younger-Dryas, increase into Holocene and the peak of warming around Hypsithermal. Temperature difference between LGM (18.0–16.0 ka) and mid-Holocene (7.7–4.9 ka) is 8.3 ºC. Isotopic data in the period of 15.9–14.5 ka, and also at 10.7 ka has the features from the kinetic effect, i.e., high $\delta^{18}O$ values and low Δ_{47} values comparing to the data of adjacent intervals. These intervals are characteristic in high prior calcite precipitation (PCP) of Hiro-1 stalagmite as suggested by Hori *et al.* (2013) and this shift was likely caused by some disequilibrium effect.
The $\delta^{18}O_{Hiro\text{-}1}$ profile can be corrected by subtraction of temperature effect and $\delta^{18}O_{MW}$ which represents isotopic composition of past meteoric water was obtained. The reconstructed $\delta^{18}O_{MW}$ value shows 1–2‰ rising from the last glacial period to Holocene. The shift has probably reflected an increase of summer precipitation by strengthened EASM in Holocene and the lowering of continentality by advance of Seto Island Sea.

Terrestrial paleoclimate since 80 ka recorded in stable and clumped isotopes of two stalagmites obtained from the Pacific side of the Japanese islands

*Shota Amekawa[1], Hirokazu Kato[1], Akihiro Kano[1], Kenji Kashiwagi[2], Taiki Mori[3], Ryoko Senda[3], Chuan-Chou Shen[4]

Terrestrial paleoclimate during late Quaternary has been broadly reconstructed by oxygen isotope ($\delta^{18}O$) of stalagmites. Previous studies have pointed out that stalagmite $\delta^{18}O$ is largely associated with change in $\delta^{18}O$ of meteoric water due to amount effect and shift of vapor sources, but also can be influenced by temperature change. One of solutions for evaluating the temperature effect is carbonate clumped isotope thermometer. Clumped isotopes are isotopologues in which rare isotopes are doubly or multiply substituted. In case of CO_2 generated from reaction of carbonate and phosphoric acis, the measuring target is $^{13}C^{18}O^{16}O$ (mass of 47). Previous studies have shown that measured abundance of clumped isotopes is slightly more than the stochastic abundance and its excess or "clumping" (Δ_{47}) comes from thermodynamic stability, which allows us to reconstruct temperature during carbonate precipitation only by Δ_{47} of the generated CO_2. In this study, Δ_{47} and stable isotopes are applied to two stalagmites from the Pacific side of the Japanese islands, which should not be affected by vapor from Indian Ocean and Japan Sea.
Two analyzed stalagmites (KA01 and 03) were obtained from Taiki town, Mie prefecture, Japan. 32 U-Th age points determined at National Taiwan University reveal that KA01 was dated from ca. 14 ka to ca. 1 ka and KA03 (Mori et al., 2018) was from ca. 80 ka to ca. 20 ka as well as the Holocene. $\delta^{18}O$ changes of KA01 and KA03 show similar trends with the cave records in south Chinese (e.g. Hulu cave), but the amplitude of the $\delta^{18}O$ changes was reduced in half.
Results of our Δ_{47} values require reconsideration of the previous interpretation for the Chinese stalagmite $\delta^{18}O$, dominant control by $\delta^{18}O$ of meteoric water. A reconstructed temperature at the top of KA01 is consistent with modern temperature at the cave. The whole trend of reconstructed temperature combined with $\delta^{18}O$ of modern rainfall indicates that $\delta^{18}O$ changes of KA01 are mainly controlled by temperature changes instead of rainfall $\delta^{18}O$. Δ_{47} of KA03 yields higher temperature during cool periods of Heinrich events (HE), which apparently contradicts with previous studies. Before and after HEs, the carbon isotopic value increases by 0.5–1 ‰, indicating degassing of ^{13}C-depleted CO_2 from dripwater and carbonate precipitation in the conduit of the host rock because of reduced water supply. Drying during HEs could have made the surface of the stalagmite dry and resulted in apparent contradictory temperature. This study verifies that $\delta^{18}O$ change should be used together with Δ_{47} for robust interpretation of the stalagmite records.

Seasonal changes in Li/Ca ratio and inferred phytoplankton abundance as analyzed by daily growth increments of *Pecten albicans* (Bivalvia)

*Kondo Yasuo[1], Hondo Shutaro, Hasegawa Hitoshi[1], Nshio Yoshiro[1], Hirota Takayoshi

1. National University Corporation Kochi University

To evaluate the potentials of scallop shells as paleoenvironmental archives, Li/Ca ratio and other geochemical data were obtained using LA-ICP-MS for the *Pecten albicans* specimen (KSG-th001) collected alive on April 29, 2011, from Tosa Bay, and was analyzed in relation to the seasonal changes of environmental parameters including water temperature and Chlorophyll *a* (Hirota and Ichikawa, 2012). In the analysis, fine striae on the left valve of *P. albicans*, were used as daily growth marker.
As a result, the analyzed specimen displayed overall higher rate of shell growth from spring to summer, while shell growth slowed down in fall and winter in 2010. A white band (annual ring) on the generally brown left valve corresponds to the lower rate interval of shell growth. However, another lower shell growth interval is recognized between spring (ca. 50 days) and late summer (ca. 20 days). This corresponds to the lower water temperature interval in late June and early July at 100 m depth in Tosa Bay, which is interpreted as representing upwelling associated with anticlockwise rotational current in Tosa Bay when the Kuroshio current became close to the shore.
These microgrowth patterns of the shell of *Pecten albicans* displayed a close similarity to the Li/Ca profile. Li enrichment in scallop shells is considered to have originated from the frustules of edible species in the digestive tract of scallops, and Li/Ca ratio of *P. maximus* in a bay in France was proposed as a proxy of timing and magnitude of diatom bloom (Thébault and Chauvaud, 2013). Our study confirms the validity of Li/Ca in scallop shells as a proxy of diatom bloom for different scallop species in a distant biogeographic province.
This study was performed under the cooperative research program of Center for Advanced Marine Core Research (CMCR), Kochi University Accept No.18B060 .

Geological reconstruction of Antarctic Ice Sheet deglaciation on Soya Coast, East Antarctica since the Last Glacial Maximum

*Moto Kawamata[1], Yusuke Suganuma[2,1], Koichiro Doi[2,1], Takanobu Sawagaki[3], Akihisa Hattori[1]

1. Department of Polar Science, School of Multidisciplinary Science, SOKENDAI (The Graduate Unversity for Advanced Studies), 2. National Institute of Polar Research, 3. Hosei University

A robust understanding of the history of ice retreat in East Antarctica since the Last Glacial Maximum (LGM) is important in order to validate ice sheet and glacial-isostatic adjustment models and to anticipate their contribution to global sea-level rise. Geomorphological studies and surface exposure dating (SED) will provide direct evidence of the timing and the history of ice retreat on coastal oases and nunatak regions in East Antarctica. Recent studies have reported retreat ages based on surface exposure dating (SED) in Skarvsnes, southern part of Soya Coast, East Antarctica. However, the history of ice retreat remains unclear, because a limited number of surface exposure ages were reported by a previous study, and the results were not interpreted based on field-based geomorphological survey In this study, we reconstruct the last history of ice retreat of the Skarvsnes based on the field-based geomorphological survey and newly obtained SED samples. As results of the field survey, we distinguish three Phase of the ice sheet retreat at the Skarvsnes. The basement rocks at the highest peak (ca. 400 masl) to ca. 250 masl area of the Skarvsnes was weathered extensively, whereas weathering of the basement rocks below ca. 250 masl was relatively weak. The extensively weathered basement rock feature is quite similar to that of the northern part of Soya Coast, where ^{14}C dating of fossil shells in the raised beaches suggests that the area had remained ice-free throughout the LGM. Therefore, the differences in weathering feature are thought to indicate the upper limit of ice sheet height at LGM at the Skarvsnes (Phase 1). In the other area of Skarvsnes, glacial striations including cross-cutting set were clearly observed. That is, the ice sheet flow direction was changed with ice sheet thickness thinning under the influence of the basement topography after the LGM (Phase 2). Eventually, the ice sheet was flowing down divided in North and South obstructed by the 362 masl mountain (Shirasuso-Yama) near the current ice sheet margin (Phase 3). Several surface exposure ages were obtained from rocks sampled at sites of different altitudes and distances from the current ice margin. These ages are consistent with the above geomorphological interpretation and it suggests that near current ice sheet margin has been exposed from ice about 9 ka. These data are almost consistent with retreat ages at Mac. Robertson Land in East Antarctica.

Department of Solid Earth Geochemistry, Japan Agency for Marine-Earth Science and Technology

Silicate weathering on land has been considered to play an important role in controlling global climate change through the consumption of atmospheric CO_2 on long timescales (>10^6 yr). This process has been working as a negative feedback mechanism, which has prevented the Earth system from runaway warming or cooling. However, whether this system works on even shorter-term global climate changes on the timescale of 10^4–10^5 yr such as Quaternary glacial-interglacial cycles is still controversial. In order to constrain the response time of the solid earth to global climate change, we employed the marine Os isotopic ratios ($^{187}Os/^{188}Os$) as a proxy of continental weathering. The marine Os isotopic ratio reflects the relative intensity of two dominant influxes to the ocean; radiogenic continental-derived materials ($^{187}Os/^{188}Os$ = 1.0–1.4) and unradiogenic mantle-like materials (i.e. hydrothermal fluids and cosmic dust) ($^{187}Os/^{188}Os$ = ~0.12). Owing to the contrasting $^{187}Os/^{188}Os$ values between these two influxes, and short residence time of Os in the ocean (~10^4 yr), the variability in $^{187}Os/^{188}Os$ of seawater constitutes a sensitive tracer for mantle and continental input into the marine environment. By assuming that the fluxes of mantle-derived materials into the ocean were constant during the Quaternary, we can obtain the fluctuation in the intensity of continental silicate weathering on glacial-interglacial timescales from the marine Os isotope record. Here, we report the marine Os isotopic variations during the glacial-interglacial cycles derived from the pelagic sediment in the Lau Basin, western South Pacific Ocean. In the present work, we targeted metalliferous carbonate as the most suitable media preserving marine Os isotope records at the timing of deposition. This sediment is enriched in hydrothermal Fe-oxyhydroxides that absorb Os in seawater efficiently and deposits rapidly without significant contamination of detrital materials from continents. As the result, we observed a clear fluctuation of the marine $^{187}Os/^{188}Os$ value along with the glacial–interglacial cycles. Based on the marine $^{187}Os/^{188}Os$ record, we also present the fluctuation of riverine Os flux calculated by simple 1-box mass-balance modeling, and its implications for the Quaternary climate change.

Studying changes in rates and magnitudes of glaciations/deglaciations during the past is a key to understand global climate system. The Last Glacial Maximum (LGM), centered around 20,000 years ago, as well as period after the LGM, therefore, represents key period to investigate. Sea level observations from sites far from the former ice sheets (far-field) are well suited due to the relatively small influence of surface deformation caused by glacio-hydro-isostatic adjustments (GIA). Australian coastlines are located in such regions and were targeted in this study of sea level changes over the past 30,000 years. The sites are situated off the North Eastern and North Western coasts of Australia respectively the Great Barrier Reef (GBR) and Bonaparte Gulf. Over thirty fossil reef cores were obtained from GBR shelf edge and two transects in northern and southern sites and >1,000 radiometric dating were conducted, in combination with detailed sedimentogic and biologic studies (Yokoyama et al., 2018). GIA modeling was also conducted to deduce global mean sea level (GMSL) from relative sea level records obtained from these regions. The results show that the LGM started when GMSL abruptly dropped by about 40 metres at around 31,000 years ago. The sea level at the shelf edge of the Great Barrier Reef then dropped by around 20 metres between 22,000 and 21,500 years ago, to -118 metres below the present and similar changes are observed in Bonaparte Gulf samples. Sea level began to rise just after the full extent of the LGM, consistent with previous studies. The LGM GMSL obtained from our study is about -125 to -130 metres. Sea level records from the North Australian coasts suggest that glaciers may have behaved more dynamically during the LGM than previously thought. The GBR had been existed despite from severe environmental changes during the last 30,000 years (Webster et al., 2018).

[M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Yusuke Okazaki

Past environmental changes and events at multi-decadal to tectonic timescale toward an understanding of Earth climate system by an integration of terrestrial and marine proxy studies and numerical modeling will be discussed. At JpGU2019, a series of presentations on present and future climate and environmental changes from paleo-perspective will be held. We welcome a variety of paleo-environmental studies from a wide range of background. We hope that this session will provide an opportunity to promote communication between participants from multidisciplinary field.

Long-chain alkenediones found from marine sediments and their unsaturation ratios: key compounds to study the evolution of alkenone biosynthetic pathway?

*Satoshi Furota[1], Hideto Nakamura[2], Ken Sawada[3]

1. Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Faculty of Science, Osaka City University, 3. Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University

Long-chain alkenones (C_{37} to C_{39} alkenones) are characteristic compounds produced by haptophyte, and their unsaturation ratios in marine sediments have been used as a proxy for sea surface temperature (SST). Paleocenographic studies using the alkenone proxies are based on the physiological features of the modern alkenone producers such as *Emiliania huxleyi* and *Gephyrocapsa oceanica*. However, these species firstly occurred at ca. 0.29 Ma and ca. 1.85 Ma, respectively, and thus, understandings of the evolutional variations in the alkenone biosynthetic pathway is important to apply the alkenone proxies to the older age. In our recent study, $C_{38:2}$ alkenedione was found in the Miocene to Pliocene marine sediments (Furota et al., 2016). This compound was interpreted to be produced by ancient alkenone producers, because (1) the molecular structure resembles to those of the alkenones, (2) it has not been detected from the extant alkenone producers and sediments, and (3) the relative abundance of the alkenedione to alkenones were significantly higher in the older sediments. Therefore, the alkenedione presumably is a key compound to study the evolutional changes in the biosynthetic pathway of alkenones.
We analyzed the alkenones and alkenediones in the hemipelagic sediments recovered from the NE Atlantic during the IODP exp. 339 to evaluate the variations in their compositions at 100,000-year scale from the late Miocene to Pleistocene. We measured using gas chromatography–flame ionization detector (GC–FID) and GC–mass spectrometry (GC–MS) equipping with a mid-polarity capillary column (VF-200 ms). The GC analysis using the mid-polarity column makes the peak shapes sharp and achieves the well chromatographic separations in the analyses of long-chain alkenones, and thus, several recent studies applied this technique (Longo et al., 2013; Furota et al., 2016).
The long-chain alkenones and the C_{38} alkenediones were detected from all the study samples. Interestingly, the carbon numbers of the alkenediones are only C_{38} in contrast to the alkenones. Mass fragmentogram shows that the C_{38} alkenedione has a methyl-ketone and ethyl-ketone groups at the each terminals of the carbon chain. In addition to $C_{38:2}$ alkenedione as reported previously, we firstly identified tri-unsaturated ($C_{38:3}$) alkenedione in the late Pliocene–Pleistocene sediments.
The relative abundances of the C_{38} alkenediones to alkenones were significantly higher in older sediments, and gradually decreased from the Miocene to Pleistocene. These results support the interpretation that the alkenediones could be produced by the ancient alkenone producers, and imply that those producers decreased from the Miocene to Pleistocene. The unsaturation ratios of C_{38} alkenediones, defines as $C_{38:2}/(C_{38:2} + C_{38:3})$, highly correlate with the unsaturation ratios of the C_{37} alkenones ($U^{K'}_{37}$) ($R^2 = 0.85$). This fact strongly suggests that the alkenediones had a similar biological function and biosynthetic pathway related to the alkenones. Furthermore, the carbon number of alkenediones (C_{38}) is averaged one for those of alkenones (C_{37}–C_{39}), and the positions of ketone groups are equal to those of alkenones. From these results, we conclude that the C_{38} alkenedione had the similar functions with the alkenones, and might be produced by primitive alkenone biosynthetic pathway.

Geomorphic and pedogenic forcing on the distribution of organic matter from vegetation to soil- a concern for paleoenvironment studies

*Biswajit Roy[1], Kanva Goyal[1], Prasanta Sanyal[1]

1. Indian Institute of Science Education Research Kolkata

The $\delta^{13}C$ values of soil organic matter (SOM) have been used to reconstruct the abundance of C_3 and C_4 plants. However, the intimate connection of distribution of vegetation with geomorphic processes and landforms may impart different $\delta^{13}C$ value in the contemporaneous vegetation. Such variation would also get registered in the organic matter composition of the soil, with an erroneous assumption of a significant change in C_3 and C_4 abundance. Therefore, it is important to understand the effect of lateral variation in riverine geomorphic architecture and its impact on the $\delta^{13}C$ value of vegetation and soil. In this study, a lateral transect (6 km) of an undulatory geomorphic surface of north-south trending lateritic alluvium of South Bengal (India) was considered to unveil the effect of topography, and active channel distance on the contemporaneous vegetation and soil. A variation of ca. 50‰ is observed in the n-alkane H-isotopic composition (δD_{C31}) of the dominating tropical deciduous species (Sal- *Shorearo busta*). The $\delta^{18}O$ value of the groundwater and the river water was analysed to understand the source of water for the tropical trees. The D/H ratio suggests that the vegetation near the active channel was mostly influenced by the river water (enriched) and in distal areas by the groundwater (depleted). Preliminary study on the $\delta^{13}C$ values of the Sal species suggests an enrichment of ca. 7‰ away from the active river channel. The difference is attributed to the change in water-availability, canopy, topography, and vegetation density that varied along the transect. Disparity in the efficiency of water use was observed in the long chain n-alkane average chain length (ACL) and carbon preference index (CPI) distribution. The higher ACL (>29) and CPI (>2) values are mostly associated with the badlands or upland soil environment with very low moisture availability. Preservation of the contemporaneous vegetation signals in the litter layer was regulated by the geomorphology, vegetation density, and the soil texture. The upland, and the distal areas with sparse vegetation tend to preserve more positive $^{13}C/^{12}C$ ratio (−24‰) compared to the lowland with well-developed soils (−28‰). The upland and distal soils, with a coarser texture, suggests faster decomposition of OM (TOC% <0.2) due to higher percolation and soil aeration; whereas in fine-textured lowland soils depleted (−4‰) and high TOC% (>0.5) is observed. Further, due to continuous abrasion by the riverine process, the TOC is also low in the soils adjacent to the active river. The nitrogen isotopic composition ($\delta^{15}N_{SOM}$) increases as alteration/decay or leaching of SOM proceeds. The faster decomposition and microbial processing of SOM in upland and distal area soils registered higher $\delta^{15}N$ (+4‰) values whereas lower values are registered in low-lying areas. This geomorphic and pedogenic effect on the plant-soil system may result in ambiguous interpretation about the past vegetation and thus warrants detail vegetation, geomorphic and physical or chemical characterisation of the soil before employing it as a paleo-record archive.

Sea surface salinity of the Kuroshio Current along the Nansei Islands in the mid-Holocene inferred from fossil corals

*Kohki Sowa[1], Chuki Hongo[2], Kentaro Tanaka[3], Takuma Fujii[4], Saburo Sakai[1], Kosei E. Yamaguchi[6,5]

1. Japan Agency for Marine-Earth Science and Technology, 2. Ryukyu University, 3. The University of Tokyo , 4. Kagoshima University, 5. Toho University, 6. NASA Astrobiology Institute

Sea surface salinity (SSS), which is the parameters of water mass properties, is one of the crucial tracers for reconstructing water motion and climate system. After the mid-Holocene, a period roughly from 7000 to 5000 years ago, freshening of seawater in the Western Pacific has been reported, and the cause of the salinity variation is under discussion (e.g. Stott *et al.*, 2004). The distribution of annual-mean salinity in the Northwest Pacific is space-dependent on factors such as depth, longitude, and latitude. Therefore, to understand the cause of the freshening, more constraining salinity conditions in time and space are needed. However, most research was limited to tropical areas.

The Kuroshio Current comes from the North Equatorial Current and cultivates the coral ecosystems of the subtropical, temperate area along the Nansei Islands (N24°-31°). Therefore, the Nansei Islands provide a latitudinal constraint to the paleo SSS variation. The $\delta^{18}O_{seawater}$ estimated from $\delta^{18}O$ and Sr/Ca in coral skeletons enables reconstruction of the seasonal SSS for shallow areas. Previous studies reconstruct SSS at Kuroshio Current only for Kikai Island (28°N, 130°E), which is off the main Kuroshio Current. To discuss spatial distribution of SSS during the mid-Holocene, further SSS data at different latitudes along the main Kuroshio Current area of the Nansei Islands are useful.

This study shows SSS for Okinawa Island (26°N, 128°E) and Takara Island (29°N, 129°E) during the mid-Holocene using modern and fossil coral cores. The ^{14}C age is 5400±140 cal. yr BP (Okinawa Island) from fossil *Porites* coral and 6180±180 cal. yr BP (Takara Island) from *Acropora* coral, which was collected near the coring site of the fossil *Porites* coral. For Okinawa Island, the seasonal $\delta^{18}O$ of fossil *Porites* coral (~26-year, N=1) averages -4.36‰, which is ~0.54‰ higher than that of modern coral (~5-year, N=2). XRD analysis and SEM observation imply good preservation of coral skeletons. The average extension rate > 6 mm suggests minor kinetic isotopic effect related to skeletal growth. Previous studies suggested that sea surface temperatures of the Kuroshio Current have been consistent during the past 7500 years, inferred from research on sediment cores (e.g. Lo *et al.* 2013). These imply that SSS was slightly higher in the mid-Holocene than today, at Okinawa Island. In this presentation, we will discuss SSS along the Nansei Island in the mid-Holocene using additional $\delta^{18}O$ and Sr/Ca analyses at Okinawa and Takara Island.

An ocean-dynamic model for the periodic inflow of Tsushima Current in the early Holocene

*Atsuhiko Isobe[1]

1. Research Institute for Applied Mechanics, Kyushu University

In the early Holocene, the Tsushima Current was a periodic inflow into the Sea of Japan opened to the North Pacific, and thereafter became a steady throughflow after 8,000 years from the present (Oba et al., 1991, Oba, 2006). However, we met some resistance to accept this periodic-inflow idea from ocean dynamics, because the Tsushima Current has been recognized as a linear bypass flow which separates from the subtropical gyre (Minato & Kimura, 1980). Thus, the Tsushima Current could not be a periodic flow unless the subtropical gyre had fluctuated, or unless the Tsushima Strait was periodically opened and closed to the North Pacific. We here proposed an ocean dynamic model in which a periodic inflow generated from the steady subtropical gyre by using a non-linear model based on an island rule in Kida & Qiu (2013). We demonstrate that the volume transport of the Tsushima Current has two solutions which were alternatively revealed in line with the transition of the environment which might appear around the shallow Tsushima Strait in the early Holocene.

Centennial to millennial scale variability of the Aleutian Low and Westerly Jet during the Holocene

*Kana Nagashima[1], Naomi Harada[1]

1. Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change

The Aleutian Low (AL), the semi-permanent low-pressure system located over the Gulf of Alaska, is critically linked to environmental change in the North Pacific and surrounding continental areas. At timescales that exceed the recent instrumental record of the last 100 years, the AL intensity has been reported to vary on centennial to millennial scales from various proxy records (e.g., Anderson et al., 2005, 2016; Fisher et al., 2008; Jones et al., 2014). However, the ultimate trigger of these intensity changes has not been systematically studied.

Recent meteorological records showed that the Westerly Jet (WJ) over East Asia and the North Pacific links strongly to the AL intensity and position through changes in cyclogenesis, monsoon, and storm track activity (e.g. Lau, 1998; Nakamura et al., 2002; Nakamura and Shimpo, 2004). According to Lau (1988), southward displacement of the WJ axis and associated storm track path over the North Pacific results in a southeastward shift and intensification of the AL. At longer timescales, however, the interactions between the AL and the WJ are virtually unknown. This study examines millennial- and centennial-scale linkages between the AL and WJ during the Holocene to better understand the long-term nature of their interaction. We also introduce WJ records from the Southern Hemisphere, because the WJ path in both the Northern and Southern Hemispheres trace the expansion and shrinkage of the Hadley Cell circulation, which helps to understand changes in North Pacific atmospheric circulation.

The proxy records of the AL and WJ revealed millennial-scale coupling of the AL-WJ path with weakened AL and poleward WJ shifts in both hemispheres during 7–5.2 and 2.8–1.2 ka, and an intensified AL and equatorward shift of the WJ path during 5.2–2.8 ka and 1.2 ka onward (Nagashima et al., submitted to Quaternary Research). Centennial scale AL intensification and equatorward shifts of the WJ path in both hemispheres also appeared in the proxy records. Periods of centennial and millennial-scale AL maxima and equatorward shifts of the WJ correlate well with periods of solar activity minima, suggesting solar activity has played a primary role in the generation of the atmospheric circulation changes, possibly through dynamic Hadley cell changes (Nagashima et al., submitted to Quaternary Research).

Monsoon-related errors in paleotemperature estimation based on leaf margin analysis in central Japan

*Yuqing Wang[1], Arata Momohara[1], Yongjiang Huang[2]

1. Graduate School of Horticulture, Chiba University, 2. Key Laboratory for Plant Diversity and Biogeography of East Asia, Kunming Institute of Botany, CAS

Paleotemperature reconstruction has important implications for a better understanding of present climate change. Among various paleotemperature estimation methods, Leaf Margin Analysis is a method that has been widely used by paleobotanist. In the modern flora, former researchers found that the percentage of the species with untoothed leaf margin in total woody dicot species of a flora (untoothed%) is strongly correlated to mean annual temperature (MAT). Based on this phenomenon, equations showing relationships between untoothed% and MAT have been used in paleotemperature estimation proposed as the Leaf Margin Analysis. However, untoothed%-MAT relationships are inconsistent among different regions according to previous studies. To date, eight different untoothed%-MAT equations have been proposed for different regions, although several samples from Japan are included, these sites were only obtained from limited areas close to the Pacific Ocean. However, considering various local climate conditions caused by the complex topography in Japan along with the different influence of summer and winter monsoon, the untoothed%-MAT relationship may vary among different areas in Japan, which cannot be reflected in the formerly published equations.

In this study, we aim to detect the untoothed%-MAT relationship in woody floras of central Japan. Two research areas with different climate conditions were chosen: The Pacific Ocean coastal areas and the Sea of Japan coastal areas. Based on the climate data, the Pacific Ocean coastal areas are characterized by less snow condition and higher summer precipitation affected by the activity of the East Asian Summer Monsoon. While the Sea of Japan coastal areas are characterized by heavy snow in winter, which is formed under the influence of Tsushima warm current in the Sea of Japan with East Asian Winter Monsoon, and grown season precipitation in this zone is much lower than the Pacific Ocean coastal areas.

We found that the untoothed%-MAT relationships of the two research areas are obviously different. In the Pacific Ocean coastal areas, a significant positive untoothed%-MAT relationship was detected. Compare to the other regions of the world, floras from central Japan include more species characterized by toothed-margin leaf at a given mean annual temperature. While in deep snow areas along the Sea of Japan, the untoothed%-MAT relationship becomes unclear with the effect of deep snow cover.

According to our results, paleotemperature estimated by the Leaf Margin Analysis of Japanese fossil floras may include inadequacy. The heavy snow condition along the Sea of Japan began since the middle Early Pleistocene, thus fossil floras of interglacial stages younger than that of these areas is not suitable to do the Leaf Margin Analysis. For Japanese fossil localities from areas without thick snow cover, because the untoothed%-MAT relationship of Japanese flora deviates from other regions of the world, applying these fossil floras into the formerly published untoothed%-MAT relationships will receive inaccurate paleotemperature data.

[M-IS26] Arctic and Antarctic Science and Future Plan

convener:Yoshifumi Nogi(National Institute of Polar Research), Takuji Nakamura(National Institute of Polar Research), Atsuko Sugimoto(Arctic Research Center, Hokkaido University), Shin Sugiyama(Institute of Low Temperature Science, Hokkaido University), Chairperson:Tetsuo Sueyoshi(National Institute of Polar Research), Yoshifumi Nogi(National Institute of Polar Research)

This session will be a forum to discuss the scientific program and the framework of the future integrated multidisciplinary study focused on the polar regions, and to consider how a large-scale science plan for Polar Science should be formulated. One of the focus of the discussion will be on the importance in the Master Plan 2020, which will be announced by the Science Council of Japan.
The changes in the polar regions are essential for future projection of the Earth system. The Antarctic and Greenland ice sheet holds most of the ice and is the largest freshwater reservoir on the Earth, which is equivalent to about 70 m height of sea level. Moreover, dense seawater is produced in the polar regions and formed bottom water that drives the thermohaline circulation. Changes in the thermohaline circulation are considered to be a large impact on the global environment. Therefore, the polar regions are the key components that control global climate and sea level changes. However, the polar regions are still poorly unknown components in the Earth system and the systematic various field of scientific observations is required. From such background, the convener believes that polar science is one of the important topics which should be proposed to the Master Plan 2020.

Constraining how fast sea levels will rise around the globe in the coming decade requires a vastly improved interdisciplinary understanding of how the heat from the warming circumpolar ocean waters will cause rapid change in the Antarctic ice sheets. Advancing our knowledge of the rates of change requires improved observations of the ice, the ocean and the solid earth and bringing together scientists from these disciplines to address the key questions: (i) How much ice passes over the Antarctic grounding line each year? (ii) How does ocean circulation influence ice flow over the grounding line, and how will it change? And (iii) How will changes in ice mass affect sea level around the world? Like many major problems facing humans, the constraining the future rate of change of the Antarctic ice sheets is a problem that must be addressed through shared resources and coordinated science –across nations and across disciplines.

Here we present the vision of the Antarctic Circumpolar Interdisciplinary Survey that will allow us to better project future sea level rise from Antarctica. To address the questions requires data from all around the Antarctic ice sheet on the thickness of the ice entering the global oceans across the grounding line, the bathymetry surrounding the ice sheets and the dynamics of the warming ocean. Key observations cannot be obtained from space and require collaborative work on the ice sheet and the circumpolar Antarctic ocean. Together the international community has the capacity to address this question. Ongoing international efforts and technological advances have developed a wide range of capabilities for direct and remote sensing of the ice, ocean and rock around Antarctica. Understanding how much ice is flowing across the grounding line can be measured with using small aircraft based at permanent bases or field camps around the continent, long range aircraft based off continent and from drones launched form ships. The water depth close to the ice sheet can be obtained with ground-based explorations, airborne observation submersibles or gliders. Salinity and temperature are measured from a broad span of instruments, with additional sensors measuring current velocity, tidal variation and biogeochemical markers also deployed. Most oceanographic work operates from ships, but coastal sites also provide platforms for ocean observations, and profiling floats can successfully be deployed from aircraft. Like the International Polar Years and other large collaborative project this effort can serve as a future focal point for Antarctic Science through SCAR and other international programs.

Proposal of Polar Science to Master Plan 2020

*Takuji Nakamura[1], Atsuko Sugimoto[2], Shin Sugiyama[2], Yoshifumi Nogi[1], Tetsuo Sueyoshi[1]

1. National Institute of Polar Research, 2. Hokkaido University

The academic large-scale research master plan of the Science Council of Japan is a collection of large-scale research plans that should be tackled in about 10 years, regardless of the field. After the discussion during past two years, we submitted in March 2019 as a proposal to Master Plan 2020 "Prediction of sea level fluctuation caused by ice sheet fluctuation" on behalf of the polar science field.

In the "Frontier of Polar Regions Science" for masterplan 2017, we have proposed a comprehensive and interdisciplinary research plan covering important processes and data acquisition of polar regions, which records the past global environmental changes with high accuracy, having multiple tipping points and great impact on the global environment. There were some critical comments that the focus was not clear enough, and also about stractural issue whether it should be a mission of the National Institute of Polar Research or a national academic projects.

In the master plan of 2020, we have restructured the proposal from a differentiated view point from the recent Arctic environmental research and Antarctic observation projects, as a comprehensive study of the ice sheet change, by setting the future sea level change for the main outcome of the project.

In this presentation we will introduce the situation of large-scale research projects, review the efforts for masterplan of polar science so far, explain the background of examination of this proposal. The aim is to stimulate the discussion at the session and future studies. The Antarctic / Arctic is an important research field that various topics such as space and planetary science, atmospheric and ocean science, solid earth science etc. should collaborate. It is also essential to obtain public understanding on its importance by stakeholders.

Towards the understanding of mass balance variation of Arctic and Antarctic ice sheets

Teruo Aoki[1,2,4], Masashi Niwano[4], *Tetsuo Sueyoshi[2,3]

1. Okayama Univ., 2. National Institute of Polar Research, 3. Japan Agency for Marine-Earth Science and Technology, 4. Meteorological Research Institute

Greenland and East- and West- Antarctic ice sheets are the largest storage of fresh water on earth. The variation of these ice sheets can effect not only the sea level, but also on global climate through the modulation of the deep water formation in the ocean. The study on ice sheets have therefore a significant importance on studies and projections of global environental change.

In the Arctic, most significant signal of global warming appears by polar amplification, which results in the rapid mass loss of the Greenland ice sheet. The extreme melt event across the entire ice sheet was also observed first time ever in 2012. The cause of mass loss can be attributed to the temperature increase, albedo decrease by snow impurities, and also to the ocean wariming which induces the enhanced melt at the marginal glaciers (Box, 2013; Fettweis et al., 2013). In the Antarctic, while the West Antarctic Ice Sheet is losing its mass rapidly, the signal in the East Antarctic Ice Sheet is not yet clear (Steig et al., 2009, etc.) .

Considering such backgrounds, the following studies are needed to make a breakthrough on our understanding of the surface process of the ice sheets (Aoki, 2015): Expanding and maintenance of the AWS network, Process study by in-situ observations, Modelling efforts of physical processes such as near-surface radiation or snow metamorphose, and Development of the regional polar system model including these processes. Validation of the model performance using satellite observation is further needed. As Japanese research community already has activities on these topics, such studies on snow and ice sheets should be an effective orientation taking an advantage of ongoing research.

Ice sheet volume changes are the largest potential source of sea level change in the past and future. Since ice sheets are vulnerable under climate changes, it is important to carefully understand its dynamics and identify its irreversible behaveour, and critical threshold under climate change. Here I show modeling studies that simulate the past ice sheet change as well as climate change and discuss the implication for the studies needed to understand the tipping points both in past and future.

Prediction of sea level rise caused by ice sheet melt

*Takeshi Tamura[1], Junichi Okuno[1], Yusuke Suganuma[1], Tetsuo Sueyoshi[1], Yoshifumi Nogi[1], Takuji Nakamura[1]

1. NIPR National Institute of Polar Research

The polar climate system, consisting of atmosphere, ocean, and cryosphere, plays important roles in shaping the global environments through its vast exchange and storage of heat and freshwater. The accelerating ice mass loss in the Greenland and West Antarctica is a significant process affecting the global climate and the understanding of the ice-ocean interaction there is of primary importance. In contrast, the status of ice mass change in East Antarctica is still in debates. Recent studies show some fingerprints of huge mass loss in the past warming world and the ice mass loss from the glaciers including Totten Glacier in East Antarctica is increasing. However, the processes of heat supply and sequent ice-ocean interaction are poorly known for both continental ice sheets.
Now, we need to understand their individual processes in polar regions through observation and modeling, and to investigate the actual states and mechanisms of various interactions. In addition, integrated researches need to be conducted, contributing to the future projection of the global environmental change driven by the polar oceans and continental ice sheets. Toward these goals, we need to clarify the state and interactions between the ocean, ice sheet, crust, ecological system, greenhouse gases, etc. and their variations from the past to the future through the field observations and analyses of samples and conduct various kinds of modeling in cooperation with the observations.

Future Research Plan in the Polar region

*Yoshifumi Nogi[1], Tetsuo Sueyoshi[1], Takuji Nakamura[1]

1. National Institute of Polar Research

The changes in the polar regions most likely indicate the precursor and driving force of the global environmental changes, and these changes are essential for future projection of the Earth system. The Antarctic and Greenland ice sheet that holds most of the ice is the largest freshwater reservoir on the Earth, equivalent to about 70 m height of sea level. On the other hand, dense seawater produced in the polar regions formed bottom water that drives the thermohaline circulation. Changes in the thermohaline circulation are considered to be significant impacts on the global environment. Therefore, the polar regions are the key to global climate and sea level changes. However, the polar regions are still poorly unknown components in the Earth system due to the harsh weather conditions in these areas.
The interaction among the atmosphere, ice sheet, solid earth, and the ocean is vital to understand the system in the polar regions, and the various systematic field of scientific observations is required to elucidate the interaction. The scientific program and the framework of the integrated multidisciplinary study focused on the polar regions must be developed from the viewpoints of the global climate and sea level changes. Present scientific activities and plans in the polar region are summarized, and the future integrated multidisciplinary research plans in the polar region are discussed.

Extraction method of weather informations from camera image using Deep Neural Network

*DAISUKE SUGIYAMA[1], RYO ONISHI[1], HIDENORI FUDEYASU[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Yokohama National University

In order to further improve precision of numerical forecasts, it is expected to utilize high-density weather information by various IoT (Internet of Things) sensor equipment networks capable of real-time acquisition via the Internet. However, the IoT sensors are installed on the ground, so we can not observe weather information in the sky simply by using the IoT sensor normally. In this study, we used artificial intelligence technology for image recognition, and worked on the development of a system that extracts cloud amount and solar radiation from images of inexpensive consumer cameras. Our method becomes possible to operate low-price camera-equipped devices as remote sensing equipment without using expensive observation equipment. The weather information extracted is not only input values for numerical simulation but also expected to be utilized in, for example, agriculture. In addition, the society of security camera network is spreading in China and others. Our method can be a fundamental technology of high-density weather observation in such society.
In this study, we first constructed a 5-layer convolutional neural network (CNN) model that predicts cloud cover amount from the image. As data to train this network, we used data labeled cloud cover on about 2,000 sky images from the Internet. The cloud cover in this study means the rate of the clouds in the sky area shown in the camera image in 11 steps from 0 to 10. On the other hand, the Japan Meteorological Agency defines the rate of the cloud region to the whole sky as the cloud amount. Attention should be paid to difference in this definition. We used the 80% data as the training data, and the remaining 20% was used for cross validation. Finally, we compared to the MSE: mean square error, of our method to the existing method. It became clear that cloud cover can be estimated with the overwhelmingly small MSE of 3.0 for this CNN, more than the existing segmentation method of 12.7.
Secondly, as training data, this model use long-term high-frequency observation data for 1 minute, observed by Yokohama National University. We chose solar radiation amount, fixed camera image in this data. The model extracts the amount of solar radiation from the sky image in the range of several tens of kilometers ahead of the fixed camera's photographing direction. With 6 years of this data, the number of images reaches max about 3 million images in one direction, and this big training data is used to train Deep Neural Network. Now, intuitively, a high brightness image tends to be considered to have a high solar radiation amount. However, consumer cameras usually have automatic brightness and contrast adjustment functions. Also, such as the slightly cloudy days are almost high brightness value. The correlation coefficient of brightness value and solar radiation, is not large. On the other hand, we can calculate the theoretical maximum solar radiation from the latitude, longitude and time of image's shooting position (Nakajima et al. 2000). Focusing on this point, we constructed a new Multimodal Deep Learning model with image + theoretical maximum solar radiation as input layers. This model estimates the attenuation value from theoretical maximum solar radiation with images of training data. It was clarified that the amount of solar radiation can be estimated with high accuracy by training this model from the image, position and time.

Automatic detection of weather front around Japan using deep convolutional neural network

*Daisuke Matsuoka[1,2], Shiori Sugimoto[1], Yujin Nakagawa[1], Fumiaki Araki[1], Shintaro Kawahara[1], Yosuke Onoue[4], Masaaki Iiyama[3], Koji Koyamada[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. Japan Science and Technology Agency, 3. Nihon University, 4. Kyoto University

In this study, we automatically detect stationary front from weather forecast simulation data (GPV/MSM) using U-Net deep convolutional neural network. Our U-Net trains ten years weather data (precipitation, sea level pressure, relative humidity, air temperature, and wind velocity) and the position of weather front as the ground truth. As a result of applying the trained U-Net to the untrained one year data, our approach succeeded in accurately detecting Baiu front and autumn rain front except when Typhoon occurred. Moreover, wind velocity (zonal and meridional component) and relative humidity at 1000 hPa play an important role to obtain high detection performance. Our approach is also able to apply to weather simulation data which the weather front is not associated with.

Detection of multiple earthquakes by using theoretical seismograms as training dataset of machine learning

*Seiji Tsuboi[1], DAISUKE SUGIYAMA[1]

1. JAMSTEC, Center for Earth Information Science and Technology

Earthquake Early Warning (EEW) is now routinely used for hazard mitigation purpose in various countries. One of the causes which results false alarm of EEW is earthquakes which happen concurrently in different location. On January 5th, 2018, two earthquakes with magnitude around 5, which separate about 400 km, happened concurrently in Japan and false EEW was issued by JMA. Here we combine numerically computed theoretical seismograms and deep machine learning to properly identify multiple earthquakes to avoid false alarm. We calculate theoretical seismograms for realistic three-dimensional Earth model and use these seismograms to create snapshots of seismic wave propagation images at the surface of the Earth. Then we use these snapshots as training dataset of convolutional neural network. We build neural networks to identify multiple earthquakes and found that this networks may identify multiple earthquakes with 99% accuracy. Advantage of using this approach to identify multiple earthquakes is that we may include any earthquakes in our training dataset and accuracy of hypocenter parameters can be increased by accumulating theoretical seismograms for various earthquake location and size as learning dataset of deep machine learning. We also apply this technique for determination of hypocentral parameters, such as epicenter, depth, origin time and magnitude. We have applied these networks to actual seismograms to show that this procedure works successfully to locate earthquake and determine magnitude.

Classification with imbalanced cloud data using deep convolutional neural network

*Daisuke Matsuoka[1,2], Masuo Nakano[1], Daisuke Sugiyama[1], Seiichi Uchida[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. Japan Science and Technology Agency, 3. Kyushu University

Image classification using deep convolutional neural network is effective technique to detect extreme phenomenafrom climate data. However, the number of extreme phenomena such as tropical cyclone (TC) is overwhelmingly small compared with others. It is knon that classification performance decline du to this imbalance between positive (TCs) and negative examples (non-TCs). In the present study, we developed a new negative data selection method for binary classification for cloud images. We analyze the relationship between the ease of classification and the characteristics of data, and optimize the training data in order to decrease the false alarm ratio (FAR). As the results, we succeeded in decrease FAR from 32.8–53.4% to 60.0–70.0% in the western North Pacific in the period from July to November.

In advancing the research of marine Earth science, observation and computer simulation is an essential element. In recent years, the performance of the observation apparatus is dramatically improved, along with the means of observation is diversified. It is becoming possible to observe in a resolution, which was not imaginable so far. Such data to be generated from the observation is tremendously large in quantity and its quality is drastically improved. To handle these huge and high quality dataset for data analysis, we need to have a high speed and large memory computer system but such a system now becomes within reach in our hands by the recent dramatic improvement of high performance computer system. On the other hand, researchers who can use this kind of large-scale computer in their studies are still quite limited. In this session, we try to review the situation of observation data that has undergone a dramatic change regarded with both quality and quantity in recent years of marine Earth science research. We also try to review the situation from a professional standpoint of simulation about the status of the high performance computer system to analyze these big data. Also we focus on the state of the art data analysis technique and aim to share the outlook from the professional standpoint of computational science and professional position of observation science about the future direction of the marine Earth informatics research.

Discussion

Farmed fish management: integration of observation and simulation

*Haruka Nishikawa[1]

1. Japan Agency for Marine-Earth Science and Technology

Since the natural fish resource is constantly decreasing, the importance of fish farming further increases. However, the technique is still depending on the skill of artisans. The feed quantity is determined by looking. Is it truly the best feed quantity? I plan to develop a fish growth simulation model based on observation and to estimate the best feed quantity by using its simulation. This technique will reduce labor cost and enhance the new entry. I will discuss the future fish farming system that is developed by an integration of observation and simulation.

Q-factor estimation for Greenland ice sheet using 3-D seismic waveform modeling

1. RCPEVE, Tohoku Univ., 2. Okayama Univ., 3. NIPR, 4. JAMSTEC

In and around Greenland, 33 seismographs are now in operation by the project “GLISN” (Greenland Ice Sheet Monitoring Network) as an international cooperation with 11 countries. Since the initiation of this project in 2009, broadband and continuous seismic waveform data have been accumulating, and data analyses using seismic interferometry have actively been conducted. For example, Toyokuni et al. (2018) detected a Rayleigh-wave phase-velocity changes over 4.5 years beneath 90 station pairs throughout Greenland, and suggested that the thermal condition (freezing or melting) of the ice-sheet base might be detected using the pattern of the velocity changes. However, the seismic interferometry is a method based on the assumption that the cross-correlation of noise waveforms from two stations yields Green’s function between them, when averaged over a long period. However, it is suggested that this assumption sometimes fails due to inhomogeneous distribution of noise sources, etc.

This study first aims to investigate whether this assumption holds for the cross-correlation waveforms from GLISN stations using 3-D seismic waveform modeling. Furthermore, we estimate the seismic Q factors of the ice sheet which explains observations the best, by performing computations several times with different structural parameters.

The scheme we used for the 3-D modeling is “Quasi-Cartesian FDM” proposed by Takenaka et al. (2017). It numerically solves 3-D elastodynamic equation by the finite-difference method (FDM), taking into account the earth's curvature, topography, sea water layer, and 3-D structures of density, seismic wavespeeds, and attenuation. We used realistic ice sheet / basal rock topography data (ETOPO 1) and 3-D crustal / mantle structures (Crist 1.0). We used FX10 Supercomputer System in Univ. Tokyo (216 nodes, 432 processor, 8 threads).

The results are as follows:
(1) The cross-correlation waveforms obtained by the seismic interferometry show good agreement with synthetic Green’s functions for almost all the pairs, showing validity of the seismic interferometry on this region.
(2) Computations with various Q factors of the ice sheet revealed that (Qp, Qs) = (20, 20) explains the cross-correlation waveforms the best. This is the first example that the high attenuation characteristic of the ice sheet is confirmed for long propagation distance (>100 km).

CLCL: CAVELib Compatible Library for Head-mounted Displays

*Shintaro Kawahara[1]

1. Japan Agency for Marine-Earth Science and Technology

Head-mounted displays (HMDs) are becoming a practical platform for three-dimensional scientific visualization. To reuse existing software assets that have been developed for CAVE-type VR systems (CAVEs), I developed a C++ library called "***CLCL*** (CAVELib Compatible Library)" for porting the application software for CAVEs to HMDs. CLCL emulates the function calls of CAVELib, which is a commercial library for developing application software executable on CAVEs, and it enables us to easily port CAVELib application software to HMDs with minor modifications to the original source code. Executable files built using CLCL are able to launch on major HMDs which are Oculus Rift, HTC VIVE and Windows Mixed Reality devices. Sharing the source code also leads to an improvement in the VR software development efficiency, which is executable on both CAVEs and HMDs.

Super-Resolution Simulation for Real-Time Prediction of Urban Micrometeorology

*Ryo Onishi[1], DAISUKE SUGIYAMA[1], Keigo Matsuda[1]

1. Japan Agency for Marine-Earth Science and Technology

We propose a super-resolution (SR) simulation system that consists of a physics-based meteorological simulation and an SR method based on a deep convolutional neural network (CNN). The CNN is trained using pairs of high-resolution (HR) and low-resolution (LR) images created from meteorological simulation results for different resolutions so that it can map LR simulation images to HR ones. The proposed SR simulation system, which performs LR simulations, can provide HR prediction results in much shorter operating cycles than those required for corresponding HR simulation prediction system. We apply the SR simulation system to urban micrometeorology, which is strongly affected by buildings and human activity. Urban micrometeorology simulations that need to resolve urban buildings are computationally costly and thus cannot be used for operational real-time predictions even when run on supercomputers. We performed HR micrometeorology simulations on a supercomputer to obtain datasets for training the CNN in the SR method. It is shown that the proposed SR method can be used with a spatial scaling factor of 4 and that it outperforms conventional interpolation methods by a large margin. It is also shown that the proposed SR simulation system has the potential to be used for operational urban micrometeorology predictions.

[M-TT49] Brand-new scope of coupling geophysics being established by infrasound and associated waves

convener:Masa-yuki Yamamoto(Department of systems engineering, Kochi University of Technology), Mie Ichihara(Earthquake Research Institute, University of Tokyo), Nobuo Arai(Disaster Mitigation Research Center, Nagoya University), Chairperson:Masa-yuki Yamamoto(Kochi University of Technology), Hiroaki Saito(Kochi University of Technology)

Infrasound and associated wave studies are recently focused on coupling waves with long-distance and vertical propagation characteristics. Such kinds of waves, having with coupling process between the atmosphere and the surface of ground and ocean, are linked with elastic waves in lithosphere and oceanic sphere, as well as to atmospheric regions up to the upper atmosphere, playing a role of generating many kinds of wavelike turbulences in thermosphere. Moreover, whole on the globe, these waves excited depending on the latitude regions, as well as on the environmental regions, such as snow ice, desert, rainforest, mountain, ocean, etc., have their own characteristics. These waves can be excited by large-scale geophysical events like volcanic eruptions, tsunami, thunderstorms, etc. as well as artificial explosions, propagating with long distance. In this session, we would like to discuss such "coupling geophysics" by using many new or well-known investigated data and simulations of infrasound and associated low frequency waves. It can combine multiple spheres in geophysics and bring a brand-new scope of geophysics. Your contributions from many regions are welcome!

A two-step amplification mechanism of infrasound waves in the ocean-atmosphere system

*Hiroyuki Shinagawa[1]

1. National Institute of Information and Communications Technology

It is widely recognized that atmospheric acoustic waves (infrasound waves) are generated by seismic waves, propagating upward up to the upper atmosphere. The amplitude of seismically excited acoustic waves in the thermosphere is about 10^4 –10^5 times larger than the amplitude of seismic waves on the ground [Shinagawa et al., 2013; Maruyama and Shinagawa, 2014]. In the ocean, compressibility of water becomes important for seismic waves with a period of 10 seconds or less, and acoustic waves are generated by sudden motion at the sea bottom, propagating upward up to the sea surface. Resonance of the acoustic wave in the vertical direction can occur depending on the period of the acoustic wave, and can result in large oscillations at the sea surface. Previous theoretical studies suggest that the amplitude of sea surface oscillation at resonant frequencies could reach about 100 times larger than the sea bottom oscillation [Williams and Guo, 1991; Izumiya et al., 1996]. The large amplitude oscillation driven by resonant acoustic waves generate atmospheric acoustic waves, which propagate upward into the upper atmosphere, resulting in the amplitude of acoustic waves of about 10^6 –10^7 times larger than the sea bottom oscillation. Therefore, oscillations of micrometer amplitudes at the sea bottom become meter-order oscillations in the thermosphere, and may generate significant variations in the ionosphere. In this talk, I will discuss and present possible effects of the resonant amplification of acoustic waves in the ocean on the upper atmosphere.

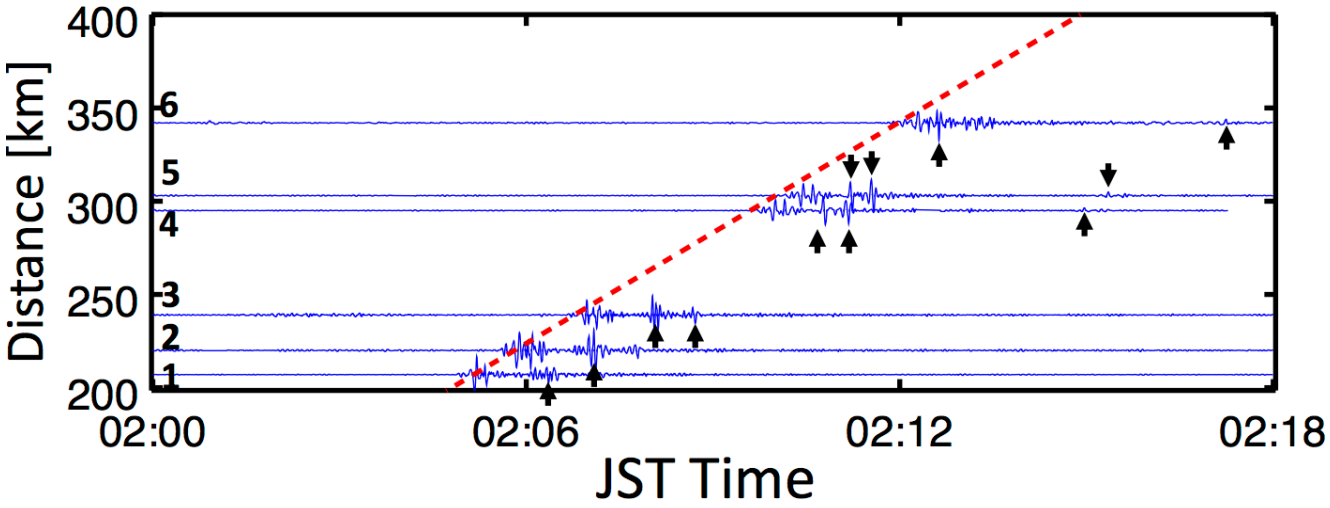
Propagation of infrasound generated by an explosive eruption of Mt. Shinmoedake on 10 March 2018



*Hiroaki Saito[1], Tetsuo Yamamoto[2], Masa-yuki Yamamoto[1]

1. School of Systems Engineering, Kochi University of Technology, 2. Hokkaido University

Mt. Shinmoedake is a part of the Mt. Kirishima cluster of volcanoes in Kyushu Island, Japan. It is located at 31.54 N, 130.53 E and its elevation is 1412 m. Explosive eruptions were observed more than 40 times in March 2018. In these events, air vibrations stronger than 100 Pa were observed several times at an air vibration sensor installed by Japan Meteorological Agency at the site within ~3 km from Mt. Shinmoedake. We focus on the explosive eruption at 1:54 (JST) on 10 March 2018. This event is the most significant air vibration (~272 Pa) observed on 10 March 2018. The infrasound sensors in Shikoku Island deployed by Kochi University of Technology detected the infrasound signals from Mt. Shinmoedake. We detected major signals three times at each of the sites 1 to 3, and four times at each of the sites 4 to 6.

We developed a new formulation for three-dimensional wave propagation in a stratified atmosphere and apply it to the analysis of the detected signals. The present formulation is based on the dispersion relation of the wave, which corresponds to Hamiltonian in particle mechanics, and Hamilton equations describing time variations of group velocity of the wave and wavevector. We adopt the dispersion relation $\omega = c_s k + \boldsymbol{u} \cdot \boldsymbol{k}$, where ω is angular frequency of the wave, c_s is sound speed, $\boldsymbol{k}$ is the wavevector, and $\boldsymbol{u}$ is wind velocity. Using the vertical temperature profiles provided by NRL-MSISE00(Picone et al., 2002) and the zonal and meridional wind profiles by HWM14 (Drob et al., 2015), we made ray tracing of the waves emitted at the explosive eruption observed on 10 March 2018. We show results of the ray tracing calculations and compare them with the signals detected by our infrasound sensors deployed in Shikoku Island(see the figure). Discussion is given on the origin and nature of the observed signals.

Infrasound observations of atmospheric disturbances due to a sequence of 2018 explosive volcano eruptions in Japan.

*Mario Batubara[1], Masa-yuki Yamamoto[1], Saito Hiroaki[1]

1. Kochi University of Technology

In this opportunity, we describe our quantitaive approach for investigating the potential atmospheric effects caused by a sequence of Japanese volcano eruptions in 2018. We used data from a number of infrasound sensors located on Shikoku Island, Japan, to detect the long wave traveling air disturbances likely to have been caused by the explosive eruptions of the volcano. We then identified certain characteristic signatures of the disturbances in individual infrasound pressure records. Based on their arrival times, we have found that the overall propagation speed of the disturbances is in the range of standard sound propagation in the atmospheric boundary layer.

Comparison of seismic waveforms observed by co-located seismometer and barometer installed indoors 2nd report

*Makiko Iwakuni[1], Nobuo Arai[2], Takayuki Otsu[1], Masashi Motohashi[1], Toyomi Sakamoto[1], Takanari Fujii[1], Ryohei Emura[1], Mami Nogami[1], Takahiko Murayama[1], Takuma Oi[3]

1. Japan Weather Association, 2. Disaster Mitigation Research Center, Nagoya University, 3. Toho Mercantile co., Ltd.

Surface vertical vibration due to earthquake is considered to excite sound, and it has been observed by barometer or microphone. Recorded pressure change response to seismic ground motion is considered to be due to difference of gravitational pressure observed by barograph moving up and down, air vibration (compressional wave) excited by earthquake ground motion around barograph, and internal mechanical response to acceleration by earthquake.

We started observation with co-located seismometer and barometer in Isumi, Chiba-prefecture (I30JP in The IMS Infrasound Network of CTBTO). This time one of barometer's port is close. A magnitude 4.5 earthquake occurred off south of Chiba-prefecture at a depth 44km. The seismic intensity scale in Isumi was 2. The port open barometer recorded pressure change due to the earthquake. Whereas, the port close barometer did not record pressure change due to the earthquake. It seems that the gravitational pressure change and barometer's internal mechanical response is very little at the seismic intensity 2 earthquake.

Ionospheric disturbances associated with typhoons and a tornado observed by HF doppler sounding

*Hiroyuki Nakata[1], Ryuichi Mashiko[1], Hiroyo Ohya[1], Toshiaki Takano[1], Keisuke Hosokawa[2], Ichiro Tomizawa[3], Hiromichi Nagao[4]

1. Graduate School of Science and Engineering, Chiba University, 2. Graduate School of Communication Engineering and Informatics, the University of Electro-Communications, 3. Center for Space Science and Radio Engineering, the University of Electro-Communications, 4. Earthquake Research Institute, the University of Tokyo.

It is reported that ionospheric disturbances are excited in association with natural hazards, such as earthquakes, volcanic eruptions, because the atmospheric waves generated by these natural hazards propagate upward to the ionosphere. Although the extreme weather events, such as typhoons and tornados, also excite the strong atmospheric waves, the ionospheric disturbances associated with these extreme events are not fully examined. In this study, therefore, we have examined ionospheric disturbances associated with typhoons and a tornado using HF doppler sounding system (HFD) and wind data observed by AMeDAS data provided by Japan Meteorological Agency.
We have examined the ionospheric disturbance associated with a tornado occurred on May 5, 2012 which is the largest event in Japan. The fluctuations of Doppler shifts were observed and the spectral intensities at the frequencies of 5-20 mHz were enhanced. However, the ionospheric fluctuations continued after the disappearance of the tornado. The enhancement of the doppler shift had a good correlation with a wind speed below the ground of the reflection point.
The ionospheric disturbances associated with typhoons were also correlated with the wind speed on the ground. Examining typhoons that come closer to Japan in 2013-2017, it is found that spectral intensities of the disturbances of HFD data at the frequencies from 5 mHz to 45 mHz were enhanced. The frequencies of the atmospheric disturbances observed on the ground were also the same as those of HFD disturbances. The spectral intensities of HFD and atmospheric disturbances are proportional to each other and the correlation coefficient between them is larger for higher-frequency disturbance.
From these results, the ground weather condition, especially wind data, is very important to examine the mechanism of the ionospheric disturbances associated with these extreme weather events.

Two-year infrasound monitoring by using a prefectural-level sensor network in Kochi

*Masa-yuki Yamamoto[1]

1. Department of systems engineering, Kochi University of Technology

Infrasound, known as pressure waves in atmosphere with its frequency lower than the human audible limit of 20 Hz, can be used as one of the useful remote-sensing methods for atmospheric phenomena especially for large geophysical events such as tsunami, volcanic eruptions, typhoons, etc. In order to construct a dense sensor network in a model region for testing such capabilities and confirming noise level at each site on ground, an infrasound observation network has been installed in Kochi prefecture since 2016, taking account mainly for tsunami disasters. As for the pilot arrangement, we installed 5 sensors in Kuroshio Town in west part of Kochi pref. with a separation of about 2 and 8 km, making two-sized triangle arrays there. Then in 2017, 10 more sensors were added on wider area in whole of prefecture, constructing 25 km scale arrayed deployment in 2 cape areas of Muroto and Ashizuri.
During two years since the sensor network establishment, we have been tested the capability of remote-sensing by using as much as the observed datasets with comparing with the other observations of weather, seismic, optical measurements operated by the other research institutes/agencies.
Tsunami is one of the most dangerous geophysical phenomena for human life and the Japanese originated word of TSUNAMI shows Japan is one of the most dangerous regions for tsunami disasters in the world. Kochi prefecture is located in Shikoku island along its southern coast, namely, in Kochi pref., we have many dangerous sites of tsunami invasion once a huge earthquake happens in Nankai Trough in the pacific ocean. However, in normal situation, no such signals can be detected when we can live there safely from tsunami. We do not need such disaster anymore, but without having phenomena, we cannot check the disaster-mitigation performance in reality.
Thus, we have to investigate the capability of infrasound sensing by using the other geophysical/artificial phenomena such as typhoons, volcanic eruptions, thunders, fireballs (large meteors), and rocket launches. As it is one of the densest infrasound observation networks in prefecture-level area in a nation, we need another analyzing method than that applied for usual arrayed infrasound sensors. Therefore, we tried to develop some methods for getting information from the infrasound datasets, to be useful for future alert system for disaster mitigation.
Recently, multiple typhoon passages, multiple eruption signals from a few volcanoes in Kyushu area, and a bright fireball seen over shikoku island on Jan. 3, 2019 were successfully detected by multiple sensors. In this talk, we will introduce the sensor network in Kochi as a model case and the obtained datasets in consideration of geophysical phenomena.
