Mon. May 27, 2019

[J] Oral | U (Union)：Union

9:30 AM - 10:30 AM JST | 12:30 AM - 1:30 AM UTC | 101 1F

[U-05] Large-scale Research Projects: Master Plan 2020 and its beyond

convener:Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Shigeko Haruyama(Department of Environmental Science, Graduate School of Bioresouces,Mie University), Ryoichi Fujii(Research Organization of Information and Systems), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Chairperson:Eiichi Tajika, Shigeko Haruyama

9:45 AM - 10:08 AM JST | 12:45 AM - 1:08 AM UTC

[U05-01] International Astro-Bioscience Research Center

★Invited Papers

*Yukio Isozaki[1] (1.Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo)

10:08 AM - 10:30 AM JST | 1:08 AM - 1:30 AM UTC

[U05-02] Study of coupling processes in the solar-terrestrial system

★Invited Papers

*Mamoru Yamamoto[1], Hiroyuki Hashiguchi[1], Tatsuhiro Yokoyama[1], Hiroshi Miyaoka[2], Yasunobu Ogawa[2], Kazuo Shiokawa[3], Satonori Nozawa[3], Akimasa Yoshikawa[4], Toshitaka Tsuda[5,1] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.National Institute of Polar Research, 3.Institute for Space-Earth Environmental Laboratory, Nagoya University, 4.International Center for Space Weather Science and Education, Kyushu University, 5.Research Organization of Information and Systems)

[J] Oral | U (Union)：Union

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 101 1F

[U-05] Large-scale Research Projects: Master Plan 2020 and its beyond

convener:Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Shigeko Haruyama(Department of Environmental Science, Graduate School of Bioresouces,Mie University), Ryoichi Fujii(Research Organization of Information and Systems), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Chairperson:Shigeko Haruyama, Hodaka Kawahata

10:45 AM - 11:08 AM JST | 1:45 AM - 2:08 AM UTC

[U05-03] Development of the global earth observation system using satellites

★Invited Papers

*Shinichi Sobue[1], Yoshiaki HONDA[3], Shuichi Rokugawa[2], Akira Iwasaki[2], Nobuhiro Takahashi[4], Yukari Takayabu[2], Riko Oki[1], Toshiyoshi Kimura[1], Teruyuki Nakajima[1], Takeo Tadono[1], Kosuke Yamamoto[1] (1.Japan Aerospace Exploration Agency, 2.University of Tokyo, 3.Chiba University, 4.Nagoya University)

11:08 AM - 11:31 AM JST | 2:08 AM - 2:31 AM UTC

[U05-04] Promotion of Scientific Research on Climate and Earth System Sciences Using Aircrafts

★Invited Papers

*Makoto Koike[1,2] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.The Meteorological Society of Japan)

11:31 AM - 11:54 AM JST | 2:31 AM - 2:54 AM UTC

[U05-05] Global deployment of Deep Argo floats toward accurate prediction of future climate and ecosystem changes

★Invited Papers

*Toshiyuki Hibiya[1] (1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

11:54 AM - 12:15 PM JST | 2:54 AM - 3:15 AM UTC

[U05-06] A new aspect of the polar science: integrated observations of the ice sheet mass loss for better prediction of the sea level rise

★Invited Papers

*Takuji Nakamura[1], Shin Sugiyama[2], Ayako Abe-Ouchi[3], Teruo Aoki[4], Yoshifumi Nogi[1], Takeshi Tamura[1] (1.National Institute of Polar Research, 2.Institute of Low Temperature Science, Hokkaido Univ., 3.Atmosphere and Ocean Research Institute, the University of Tokyo, 4.The Graduate School of Natural Science and Technology, Okayama University)

[J] Oral | U (Union)：Union

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 101 1F

[U-05] Large-scale Research Projects: Master Plan 2020 and its beyond

convener:Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Shigeko Haruyama(Department of Environmental Science, Graduate School of Bioresouces,Mie University), Ryoichi Fujii(Research Organization of Information and Systems), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Chairperson:Hodaka Kawahata, Eiichi Tajika

1:45 PM - 2:08 PM JST | 4:45 AM - 5:08 AM UTC

[U05-07] New frontier of Earth, Space and Life Sciences pioneered by the innovative developments of new-generation mass spectrometry

★Invited Papers

*Kentaro Terada[1] (1.Department of Earth and Space Science, Graduate School of Science, Osaka University)

2:08 PM - 2:31 PM JST | 5:08 AM - 5:31 AM UTC

[U05-08] Building of archive and curating system for astrogeoscience materials

★Invited Papers

*Tsuyoshi Komiya[1] (1.Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo)

2:31 PM - 2:54 PM JST | 5:31 AM - 5:54 AM UTC

[U05-09] Innovative 4D imaging of subduction-zones through real-time observatories, ultra-deep drilling and high-pressure experiments

★Invited Papers

*Masataka Kinoshita[1], Naoshi Hirata[1], Masanao Shinohara[1], Tetsuo Irifune[2], Hiroyuki Kagi[7], Teruyuki Kato[3], Shigeaki Ono[4], Katsuyoshi Michibayashi[6], Natsue Abe[4], Fumio Inagaki[4], Kentaro Omura[5], Kazushige Obara[1] (1.Earthquake Research Institute, University of Tokyo, 2.Ehime University, 3.Hot Springs Research Institute, 4.JAMSTEC, 5.NIED, 6.Nagoya Univ., 7.Geochemical Research Center, Univ. Tokyo)

2:54 PM - 3:15 PM JST | 5:54 AM - 6:15 AM UTC

[U05-10] Construction of the Cooperative Research Infrastructure for Intelligent Muography in Earth and Planetary Sciences, Other Sciences, and Society

★Invited Papers

*Hiroyuki Tanaka[1] (1.Earthquake Research Institute, the University of Tokyo)

[J] Oral | U (Union)：Union

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 101 1F

[U-05] Large-scale Research Projects: Master Plan 2020 and its beyond

convener:Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Shigeko Haruyama(Department of Environmental Science, Graduate School of Bioresouces,Mie University), Ryoichi Fujii(Research Organization of Information and Systems), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Chairperson:Eiichi Tajika, Shigeko Haruyama

3:30 PM - 3:53 PM JST | 6:30 AM - 6:53 AM UTC

[U05-11] Consortium for Planetary Exploration

★Invited Papers

*Yoshi-Yuki Hayashi[1], Shigeto Watanabe[2,5], Taishi Nakamoto[3,4] (1.Department of Planetology/CPS, Graduate School of Science, Kobe University, 2.SGEPSS, 3.The Japanese Society for Planetary Sciences, 4.Dept. of Earth and Planetary Sciences, Tokyo Institute of Technology, 5.Hokkaido Information University)

3:53 PM - 4:16 PM JST | 6:53 AM - 7:16 AM UTC

[U05-12] Japanese contribution to CAESAR: comet astrobiology exploration sample return

★Invited Papers

*Tomoki Nakamura[1], Kazuhiko Yamada[2], Yoshihiro Furukawa[1], Yuki Kimura[3], Aki Takigawa[4], Tomohiro Usui[2], Hitoshi Kuninaka[2], Team CAESAR SRC team (1.Tohoku University, 2.ISAS/JAXA, 3.Hokkaido University, 4.Kyoto University)

4:16 PM - 4:38 PM JST | 7:16 AM - 7:38 AM UTC

[U05-13] Strategic Mars exploration: Orbiter and EDL demonstration mission for space weather, climate, and aquatic environment

★Invited Papers

*Kanako Seki[1], Shigeto Watanabe[2], Taishi Nakamoto[3], Naoki Terada[4], Atsushi Yamazaki[5], Ayako Matsuoka[5], Tomohiro Usui[5], Yasuhito Sekine[3], Kazuhisa Fujita[5], Shoichiro Yokota[6], Satoshi Kasahara[1], Yoshifumi Saito[5], Hiromu Nakagawa[4], Atsushi Kumamoto[4], Hiroyuki Maezawa[7], Mars Orbiter and EDL Technology Demonstration Mission Planning Team (1.Graduate School of Science, University of Tokyo, 2.Department of Cosmosciences, Hokkaido University, 3.Tokyo Institute of Technology, 4.Graduate School of Science, Tohoku University, 5.ISAS, JAXA, 6.Graduate School of Science, Osaka University, 7.Department of Physical Science, Osaka Prefecture University)

[J] Poster | U (Union)：Union

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[U-05] Large-scale Research Projects: Master Plan 2020 and its beyond

convener:Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Shigeko Haruyama(Department of Environmental Science, Graduate School of Bioresouces,Mie University), Ryoichi Fujii(Research Organization of Information and Systems), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo)

[U05-P01] Planetary Exploration Roadmap from Japanese Society for Planetary Sciences

Kiyoshi Kuramoto[1], Hidenori Genda[2], *Naoki Terada[3], Hiroki Senshu[4], Taishi Nakamoto[5], Planetary Exploration Committee JSPS, Working term for revision of reply document for RFI JSPS (1.Graduate School of Sciences, Hokkaido University, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Graduate School of Science, Tohoku University, 4.Planetary Exploration Research Center, Chiba Institute of Technology, 5.Tokyo Institute of Technology)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University), Chairperson:笠羽 康正, Kazuo Yoshioka(The University of Tokyo)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PPS01-01] Circulation of plasma in the Jupiter's inner magnetosphere revealed from time variation in radial profile of plasma temperature and density obtained by Hisaki/EXCEED observation

*Reina Hikida[1], Kazuo Yoshioka[2], Fuminori Tsuchiya[3], Masato Kagitani[3], Go Murakami[4], Tomoki Kimura[5], Atsushi Yamazaki[4], Ichiro Yoshikawa[2] (1.Department of Earth and Planetary Science, Graduate School of Science, the University of Tokyo, 2.Department of Complexity Science and Engineering, Graduate School of Frontier Science, the University of Tokyo, 3.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 4.Institute of Space and Astronautical Science (ISAS), Japan Aerospace Exploration Agency (JAXA) , 5.Frontier Research Institute for Interdisciplinary Sciences, Tohoku University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PPS01-02] Volcanic change of the distribution of Io’s neutral oxygen cloud observed by Hisaki

*Ryoichi Koga[1], Fuminori Tsuchiya[1], Masato Kagitani[1], Takeshi Sakanoi[1], Tomoki Kimura[1], Ichiro Yoshikawa[2], Kazuo Yoshioka[2], Go Murakami[3], Atsushi Yamazaki[3], Howard Todd Smith[4], Fran Bagenal[5] (1.Tohoku University, 2.The University of Tokyo, 3.ISAS/JAXA, 4.Johns Hopkins University, 5.University of Colorado)

4:00 PM - 4:18 PM JST | 7:00 AM - 7:18 AM UTC

[PPS01-03] New pictures of Jovian magnetosphere obtained from the Hisaki satellite observation

★Invited Papers

*Fuminori Tsuchiya[1], Kazuo Yoshioka[2], Tomoki Kimura[1], Chihiro Tao[3], Ichiro Yoshikawa[2], Go Murakami[4], Hajime Kita[4], Ryoichi Koga[1], Hikida Reina[2], Fumiharu Suzuki[2], Sooman Han[2], Masato Kagitani[1], Takeshi Sakanoi[1], Hiroaki Misawa[1], Yasumasa Kasaba[1], Atsushi Yamazaki[4] (1.Tohoku University, 2.The University of Tokyo, 3.NICT, 4.ISAS/JAXA)

4:18 PM - 4:33 PM JST | 7:18 AM - 7:33 AM UTC

[PPS01-04] Axisymmetric conductivities of Jupiter's middle- and low-latitude ionosphere

*Yuki Nakamura[1], Koichiro Terada, Chihiro Tao[2], Naoki Terada[1], Yasumasa Kasaba[3], Hajime Kita[4], Aoi Nakamizo[2], Akimasa Yoshikawa[5], Shinichi Ohtani[6], Fuminori Tsuchiya[3], Masato Kagitani[3], Takeshi Sakanoi[3], Go Murakami[4], Kazuo Yoshioka[7], Tomoki Kimura[1], Atsushi Yamazaki[4], Ichiro Yoshikawa[8] (1.Department of Geophysics, Graduate School of Science, Tohoku University, 2.National Institute of Information and Communications Technology, 3.Planetary Plasma and Atmospheric Research Center, Tohoku University, 4.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 5.Department of Earth and Planetary Sciences, Kyushu University, 6.The Johns Hopkins University Applied Physics Laboratory, 7.Graduate School of frontier Science, The University of Tokyo, 8.The University of Tokyo)

4:33 PM - 4:51 PM JST | 7:33 AM - 7:51 AM UTC

[PPS01-05] The magnetospheres of Saturn and Jupiter as viewed by Cassini and Juno

★Invited Papers

*G Provan[1], Stanley W. H. Cowley[1], Emma Jane Bunce[1] (1.University of Leicester)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder), Chairperson:Takeshi Horinouchi

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PPS05-01] **Super-rotation of Venusian atmosphere in the equatorial region may be caused by the density driven separation**

*Adhithiyan Neduncheran[1], Ugur Guven[1,2], Ananyo Bhattacharya[3] (1.University of Petroleum and Energy Studies, India, 2.United Nations Centre for Space Science and Technology Education in Asia and the Pacific, 3.Sardar Vallabhbhai National Institute of Technology,India)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PPS05-02] Comparison of horizontal distributions of temperature and UV absorbers at the Venus cloud-tops

*Shinichiro Kawase[1], Makoto Taguchi[1], Tetsuya Fukuhara[1], Yeon Joo Lee[2], Atsushi Yamazaki[3,4] (1.Rikkyo University, 2.Max Planck Institute for Solar System Research, 3.Institute of Space and Astronautical Science, 4.Japan Aerospace Exploration Agency)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PPS05-03] Orographic Gravity Waves in the Venus Atmospheric

*Anna Suzuki[1], Masahiro Takagi[1], Yasumitsu Maejima[2], Hiroki Ando[1], Norihiko Sugimoto[3], Yoshihisa Matsuda[4] (1.Kyoto Sangyo University, 2.RIKEN Advanced Institute for Computational Science, 3.Keio University, 4.Tokyo Gakugei University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PPS05-04] Atmospheric structures simulated by T21 and T63 Venus GCMs with radiative transfer

*Masaru Yamamoto[1], Kohei Ikeda[2], Masaaki Takahashi[2] (1.Research Institute for Applied Mechanics, Kyushu University, 2.National Institute for Environmental Studies)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PPS05-05] Thermal-tides structure at the cloud level of Venus derived from Akatsuki/LIR observations

★Invited Papers

*Toru Kouyama[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Takeshi Imamura[3], Masahiko Futaguchi[4], Takeru Yamada[2], Masahiro Akiba[2], Yeon Joo lee, Takao M. Sato[7], Shin-ya Murakami[5], George HASHIMOTO[6], Takehiko Satoh[5], Masato Nakamura[5] (1.AIST, 2.Rikkyo Univ., 3.Tokyo Univ., 4.Toho Univ., 5.JAXA, 6.Okayama Univ., 7.Hokkaido Information Univ.)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PPS05-06] From Venus to Mars: viewpoint of comparative meteorology

★Invited Papers

*Takeshi Imamura[1], Kazunori Ogohara[2], Hiromu Nakagawa[3], Shohei Aoki[3] (1.The University of Tokyo, 2.University of Shiga Prefecture, 3.Tohoku University)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder), Chairperson:Takehiko Satoh

10:45 AM - 11:05 AM JST | 1:45 AM - 2:05 AM UTC

[PPS05-07] A two-stage evolution model of Venus's mantle and its implication for the Earth

★Invited Papers

*Masaki Ogawa[1] (1.Division of General Systems Studies, Graduate School of Arts and Sciences, University of Tokyo)

11:05 AM - 11:20 AM JST | 2:05 AM - 2:20 AM UTC

[PPS05-08] Interaction between the thermosphere and the cloud-level atmosphere of Venus studied with simultaneous observations by Hisaki and Akatsuki

*Yusuke Nara[1], Takeshi Imamura[1], Ichiro Yoshikawa[1], Kazuo Yoshioka[1], Kei Masunaga[2], Atsushi Yamazaki[3], Shigeto Watanabe[4], Manabu Yamada[5], Yeon Joo Lee[1], Naoki Terada[6], Kanako Seki[1] (1.The University of Tokyo, 2.Swedish Institute of Space Physics, 3.ISAS/JAXA, 4.Hokkaido Information University, 5.Chiba Institute of Technology, 6.Tohoku University)

11:20 AM - 11:35 AM JST | 2:20 AM - 2:35 AM UTC

[PPS05-09] Mesoscale Dyanmics in the Venus Atmosphere

*Kevin McGouldrick[1], Javier Peralta[2], Takehiko Satoh[2] (1.University of Colorado Boulder, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

11:35 AM - 11:50 AM JST | 2:35 AM - 2:50 AM UTC

[PPS05-10] Periodicity analysis of Venus' cloud-top temperature measured by Akatsuki LIR

Naoya Kajiwara[1], *Takeshi Imamura[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Toru Kouyama[3] (1.Graduate School of Frontier Sciences, The University of Tokyo, 2.College of Science, Rikkyo University, 3.National Institute of Advanced Industrial Science and Technology)

11:50 AM - 12:10 PM JST | 2:50 AM - 3:10 AM UTC

[PPS05-11] Modeling Venus-like Worlds Through Time: The habitable zone, and the evolution of Venus' atmosphere.

★Invited Papers

*Michael Way[1,2,3], Anthony Del Genio[1] (1.NASA Goddard Institute for Space Studies, 2.GSFC Sellers Exoplanet Environments Collaboration, 3.Department of Physics and Astronomy, Uppsala University, Sweden)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder), Chairperson:Kevin McGouldrick

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PPS05-12] Cloud top structure of Venus retrieved from the Akatsuki IR2 dayside observations

★Invited Papers

*Takao M. Sato[1], Takehiko Satoh[2], Hideo Sagawa[3], Naohiro Manago[2], Yeon Joo Lee, Shin-ya Murakami[2], Kazunori Ogohara[4], George HASHIMOTO[5], Yasumasa Kasaba[6], Atsushi Yamazaki[2], Manabu Yamada[7], Shigeto Watanabe[1], Takeshi Imamura[8], Masato Nakamura[2] (1.Hokkaido Information University, 2.ISAS/JAXA, 3.Kyoto Sangyo University, 4.University of Shiga Prefecture, 5.Okayama University, 6.Tohoku University, 7.Chiba Institute of Technology, 8.The University of Tokyo)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PPS05-13] Formation of superrotation studied by a TEM model

*Takeshi Horinouchi[1] (1.Faculty of Environmental Earth Science, Hokkaido University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PPS05-14] Morphological Feature Extraction from Venus' Cloud Images Using Principal Component Analysis

*Minori Narita[1], Takeshi Imamura[1], Yusuke Nara[1], Yeon Joo Lee, Shigeto Watanabe[2], Atsushi Yamazaki[3], Takehiko Satoh[3], Makoto Taguchi[4], Tetsuya Fukuhara[4], Manabu Yamada[5] (1.The University of Tokyo, 2.Hokkaido Information University, 3.ISAS/JAXA, 4.Rikkyo University, 5.PERC/Chiba Institute of Technology)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PPS05-15] **Principal Components of UV Albedo Variability in Venus' Atmosphere as seen at 283 nm**

*Pushkar Kopparla[1], Yeon Joo Lee[1], Takeshi Imamura[1], Atsushi Yamazaki[2] (1.GSFS, University of Tokyo, 2.ISAS, JAXA)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PPS05-16] Active and inactive behaviors of the planetary-scale waves on Venus cloud top

★Invited Papers

*Masataka Imai[1], Toru Kouyama[1], Yukihiro Takahashi[2], Takeshi Horinouchi[3], Takeshi Imamura[4], Atsushi Yamazaki[5], Shigeto Watanabe[6], Manabu Yamada[7], Masato Nakamura[5], Takehiko Satoh[5] (1.National Institute of Advanced Industrial Science and Technology, 2.Department of Cosmosciences, Graduate School of Science, Hokkaido University, 3.Faculty of Environmental Earth Science, Hokkaido University, 4.Graduate School of Frontier Sciences, University of Tokyo, 5.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 6.Space Information Center, Hokkaido Information University, 7.Planetary Exploration Research Center, Chiba Institute of Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PPS05-17] **Long-term behaviour of the morphology and dynamics of Venus's middle clouds with Akatsuki/IR1.**

★Invited Papers

*Javier Peralta[1], Naomoto Iwagami[2], Sánchez-Lavega Agustín[3], Yeon Joo Lee[4], Ricardo Hueso[3], Minori Narita[4], Takeshi Imamura[4], Phil Miles[5], Anthony Wesley[6], Emmanuel Kardasis[7], Seiko Takagi[8] (1.Institute of Space and Astronautical Science (ISAS), Japan Aerospace Exploration Agency (JAXA), Sagamihara, Japan, 2.Tokyo 156-0044, Japan, 3.Escuela de Ingeniería de Bilbao, University of the Basque Country (UPV/EHU), Bilbao, Spain, 4.Graduate School of Frontier Sciences, The University of Tokyo, Japan, 5.Rubyvale QLD, Australia, 6.Astronomical Society of Australia, Australia, 7.Hellenic Amateur Astronomy Association, Greece, 8.Research and Information Center, Tokai University, Japan)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder)

[PPS05-P01] New thermal infrared camera for fine horizontal brightness temperature structures at the cloud-top level of Venus

*Tetsuya Fukuhara[1], Makoto Taguchi[1], Takeshi Imamura[2], Sanjay S Limaye[3] (1.Rikkyo University, 2.The University of Tokyo, 3.University of Wisconsin)

[PPS05-P02] Temperature and wind variations in Venusian mesosphere and lower thermosphere by mid-infrared heterodyne spectrometer in 2018

*Kosuke Takami[1], Hiromu Nakagawa[1], Hideo Sagawa[2], Isao Murata[1], Yasumasa Kasaba[1] (1.Graduate School of Science, Tohoku University, 2.Division of Science, Kyoto Sangyo University)

[PPS05-P03] Local time dependence of limb darkening seen in the thermal infrared Venus disk

*Masahiro Akiba[1] (1.Rikkyo University)

[PPS05-P04] Stationary wavy features and Banded structures at Venusian cloud top extracted by averaging multiple LIR images

*Kiichi Fukuya[1], Takeshi Imamura[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Toru Kouyama[3] (1.Univ. of Tokyo, 2.Rikkyo Univ., 3.AIST)

[PPS05-P05] Akatsuki's IR2 Nightside Photometry Restoration by Deconvolution

*Choon Wei Vun[1], Takehiko Satoh[2,1], Kevin McGouldrick[3], Takeshi Horinouchi[4], Takao M. Sato[5] (1.SOKENDAI, 2.ISAS/JAXA, 3.University of Colorado Boulder, 4.Hokkaido University, 5.Hokkaido Information University)

[PPS05-P06] Enormous cloud cover as seen by Akatsuki/IR2 on the night-side disk of Venus

*Takehiko Satoh[1,2], Choon Wei Vun[2], Takao M. Sato[3], Takeshi Horinouchi[4], George HASHIMOTO[5], Kevin McGouldrick[6] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Department of Space Science, SOKENDAI, 3.Department of Business and Information Systems, Hokkaido Information University, 4.Faculty of Environmental Earth Science, Hokkaido University, 5.Department of Earth Science, Okayama University, 6.LASP, University of Colorado Boulder)

[PPS05-P07] The global variation of Venus cloud obtained from IR1 camera onboard AKATSUKI

*Seiko Takagi[1], Naomoto Iwagami, Yukihiro Takahashi[1], Mitsuteru Sato[1] (1.Hokkaido University, Graduate School of Science)

[PPS05-P08] Development of a Venus' cloud formation scheme for a convection resolving model

*Ko-ichiro SUGIYAMA[1], Nozomu Fukuhara[1], Masatsugu Odaka[2], Kensuke Nakajima[3], Masaki Ishiwatari[2], Takeshi Imamura[4], Yoshi-Yuki Hayashi[5] (1.National Institute of Technology, Matsue College, 2.Department of Cosmoscience, Graduate School of Science, Hokkaido University, 3.Department of Earth and Planetary Sciences,Flculty of Sciences,Kyushu University, 4.Graduate School of Frontier Sciences, The University of Tokyo, 5.Department of Planetology, Graduate School of Science, Kobe University / Center for Planetary Science (CPS))

[PPS05-P09] Zonal mean structure of Venus atmosphere observed in a Venus general circulation model with explicit radiative transfer

★Invited Papers

*Yoshi-Yuki Hayashi[1], Chisato Shiojiri[1], Hiroki Kashimura[1], Yoshiyuki O. Takahashi[1] (1.Department of Planetology/CPS, Graduate School of Science, Kobe University)

[PPS05-P10] Gravity wave packets detected in radio occultation temperature profiles of the Venus atmosphere

*Ryota Mori[1], Takeshi Imamura[1], Javier Peralta[2] (1.The University of Tokyo, 2.Japan Aerospace Exploration Agency)

[PPS05-P11] Status of lightning hunt in Venus with Akatsuki/LAC and Pirka telescope

*Yukihiro Takahashi[1,2], Mitsuteru Sato[1,2], Masataka Imai[3], Ralph Lorenz[4], Seiko Takagi[1,2], Ono Tatsuharu[1] (1.Graduate School of Science, Hokkaido University, 2.Faculty of Science, Hokkaido University, 3.National Institute of

Advanced Industrial Science and Technology,, 4.Applied Physics Laboratory, Johns Hopkins University)

[PPS05-P12] Possibility of electric discharge in the Venusian atmosphere due to the super-rotation of clouds

*Adhithiyan Neduncheran[1], Ugur Guven[1,2], Ananyo Bhattacharya[3] (1.University of Petroleum and Energy Studies, India, 2.United Nations Centre for Space Science and Technology Education in Asia and the Pacific, 3.Sardar Vallabhbhai National Institute of Technology,India)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder)

[PPS05-P01] New thermal infrared camera for fine horizontal brightness temperature structures at the cloud-top level of Venus

*Tetsuya Fukuhara[1], Makoto Taguchi[1], Takeshi Imamura[2], Sanjay S Limaye[3] (1.Rikkyo University, 2.The University of Tokyo, 3.University of Wisconsin)

[PPS05-P02] Temperature and wind variations in Venusian mesosphere and lower thermosphere by mid-infrared heterodyne spectrometer in 2018

*Kosuke Takami[1], Hiromu Nakagawa[1], Hideo Sagawa[2], Isao Murata[1], Yasumasa Kasaba[1] (1.Graduate School of Science, Tohoku University, 2.Division of Science, Kyoto Sangyo University)

[PPS05-P03] Local time dependence of limb darkening seen in the thermal infrared Venus disk

*Masahiro Akiba[1] (1.Rikkyo University)

[PPS05-P04] Stationary wavy features and Banded structures at Venusian cloud top extracted by averaging multiple LIR images

*Kiichi Fukuya[1], Takeshi Imamura[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Toru Kouyama[3] (1.Univ. of Tokyo, 2.Rikkyo Univ., 3.AIST)

[PPS05-P05] Akatsuki's IR2 Nightside Photometry Restoration by Deconvolution

*Choon Wei Vun[1], Takehiko Satoh[2,1], Kevin McGouldrick[3], Takeshi Horinouchi[4], Takao M. Sato[5] (1.SOKENDAI, 2.ISAS/JAXA, 3.University of Colorado Boulder, 4.Hokkaido University, 5.Hokkaido Information University)

[PPS05-P06] Enormous cloud cover as seen by Akatsuki/IR2 on the night-side disk of Venus

*Takehiko Satoh[1,2], Choon Wei Vun[2], Takao M. Sato[3], Takeshi Horinouchi[4], George HASHIMOTO[5], Kevin McGouldrick[6] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Department of Space Science, SOKENDAI, 3.Department of Business and Information Systems, Hokkaido Information University, 4.Faculty of Environmental Earth Science, Hokkaido University, 5.Department of Earth Science, Okayama University, 6.LASP, University of Colorado Boulder)

[PPS05-P07] The global variation of Venus cloud obtained from IR1 camera onboard AKATSUKI

*Seiko Takagi[1], Naomoto Iwagami, Yukihiro Takahashi[1], Mitsuteru Sato[1] (1.Hokkaido University, Graduate School of Science)

[PPS05-P08] Development of a Venus' cloud formation scheme for a convection resolving model

*Ko-ichiro SUGIYAMA[1], Nozomu Fukuhara[1], Masatsugu Odaka[2], Kensuke Nakajima[3], Masaki Ishiwatari[2], Takeshi Imamura[4], Yoshi-Yuki Hayashi[5] (1.National Institute of Technology, Matsue College, 2.Department of Cosmoscience, Graduate School of Science, Hokkaido University, 3.Department of Earth and Planetary Sciences,Flculty of Sciences,Kyushu University, 4.Graduate School of Frontier Sciences, The University of Tokyo, 5.Department of Planetology, Graduate School of Science, Kobe University / Center for Planetary Science (CPS))

[PPS05-P09] Zonal mean structure of Venus atmosphere observed in a Venus general circulation model with explicit radiative transfer

★Invited Papers

*Yoshi-Yuki Hayashi[1], Chisato Shiojiri[1], Hiroki Kashimura[1], Yoshiyuki O. Takahashi[1] (1.Department of Planetology/CPS, Graduate School of Science, Kobe University)

[PPS05-P10] Gravity wave packets detected in radio occultation temperature profiles of the Venus atmosphere

*Ryota Mori[1], Takeshi Imamura[1], Javier Peralta[2] (1.The University of Tokyo, 2.Japan Aerospace Exploration Agency)

[PPS05-P11] Status of lightning hunt in Venus with Akatsuki/LAC and Pirka telescope

*Yukihiro Takahashi[1,2], Mitsuteru Sato[1,2], Masataka Imai[3], Ralph Lorenz[4], Seiko Takagi[1,2], Ono Tatsuharu[1] (1.Graduate School of Science, Hokkaido University, 2.Faculty of Science, Hokkaido University, 3.National Institute of

Advanced Industrial Science and Technology,, 4.Applied Physics Laboratory, Johns Hopkins University)

[PPS05-P12] **Possibility of electric discharge in the Venusian atmosphere due to the super-rotation of clouds**

*Adhithiyan Neduncheran[1], Ugur Guven[1,2], Ananyo Bhattacharya[3] (1.University of Petroleum and Energy Studies, India, 2.United Nations Centre for Space Science and Technology Education in Asia and the Pacific, 3.Sardar Vallabhbhai National Institute of Technology,India)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS06] Planetary Sciences

convener:Kenji Kurosaki(Department of Physics, Nagoya University), Yusuke Nakauchi(Japan Aerospace Exploration Agency), Chairperson:Kiyoshi Kuramoto(Hokkaido University), Takanori Sasaki(Department of Astronomy, Kyoto University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PPS06-01] Current status of the PLANETS telescope project for planetary and exoplanetary atmospheric monitoring

*Takeshi Sakanoi[1], Masato Kagitani[1], Yasumasa Hirahara[2], Jeffery Kuhn[3], Svetalana Berdyugina[4], Marcelo Emilio[5], Hiromu Nakagawa[6], Mikio Kurita[7], Yasumasa Kasaba[1], Takahiro Obara[1], Shoichi Okano[1] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Graduate School of Environmental Studies, Nagoya University, 3.IfA, University of Hawaii, U.S.A., 4.KIS, Germany, 5.Universidade Estadual de Ponta Grossa, Brazil, 6.Graduate School of Science, Tohoku University, 7.Graduate School of Science, Kyoto University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PPS06-02] Martian Moon eXploration MMX: science objectives and their promotion

*Kiyoshi Kuramoto[1,2], Yasuhiro Kawakatsu[2], Masaki Fujimoto[2], Jean Pierre Bibring[3], David Lawrence[4], Hidenori Genda[5], Naru Hirata[6], Takeshi Imamura[7], Shingo Kameda[8], Koji Matsumoto[9], Hideaki Miyamoto[7], Tomokatsu Morota[10], Hiroshi Nagaoka[2], Hiromu Nakagawa[11], Tomoki Nakamura[11], Kazunori Ogawa[12], Hisashi Otake[2], Masanobu Ozaki[2], Sho Sasaki[13], Hiroki Senshu[14], Shogo Tachibana[7,2], Naoki Terada[11], Tomohiro Usui[2], Koji Wada[14], Sei-ichiro WATANABE[10], MMX study team (1.Hokkaido Univ., 2.JAXA, 3.IAS, 4.APL, 5.ELSI, 6.Aizu Univ., 7.Univ. of Tokyo, 8.Rikkyo Univ., 9.NAOJ, 10.Nagoya Univ., 11.Tohoku Univ., 12.Kobe Univ., 13.Osaka Univ., 14.Chiba Inst. Tech.)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PPS06-03] **Implantation of Martian Materials in the Inner Solar System by a Mega Impact on Mars**

*Ryuki Hyodo[1], Hidenori Genda[1] (1.Tokyo Institute of Technology, Earth Life Science Institute)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PPS06-04] Hydrodynamic escape of a reduced proto-atmosphere on early Mars

*Tatsuya Yoshida[1], Kiyoshi Kuramoto[1] (1.Hokkaido University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PPS06-05] Orbital evolution of Martian moons by rotating Martian proto-atmosphere with low angular momentum

*Ryo Matsuoka[1], Kiyoshi Kuramoto[1] (1.Department of Cosmosciences, Graduateschool of Science, Hokkaido University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PPS06-06] N-body simulations of Moon formation with cooling evolution of the protolunar disk

*Takanori Sasaki[1], Natsuki Hosono[2] (1.Department of Astronomy, Kyoto University, 2.Japan Agency for Marine-Earth Science and Technology)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS06] Planetary Sciences

convener:Kenji Kurosaki(Department of Physics, Nagoya University), Yusuke Nakauchi(Japan Aerospace Exploration Agency), Chairperson:Hiroyuki Kurokawa(東京工業大学 地球生命研究所), Yuki Tanaka(Tokyo Institute of Technology)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PPS06-07] Possibility of giant planet formation by pebble accretion in Class 0/I YSOs

*Yuki Tanaka[1], Yusuke Tsukamoto[2] (1.Tokyo Institute of Technology, 2.Kagoshima University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PPS06-08] The effect of the three-dimensional gas flow around an embedded planet on pebble accretion

*Ayumu Kuwahara[1], Hiroyuki Kurokawa[2] (1.Tokyo Institute of Technology, 2.Earth-Life Science Institute)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PPS06-09] Icy pebble accretion onto terrestrial planets: the effect of gas flow

*Hiroyuki Kurokawa[1], Ayumu Kuwahara[2], Satoshi Okuzumi[2] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.Tokyo Institute of Technology)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PPS06-10] Delivery of ammonia ice to Ceres by pebble accretion

*Yuto Nara[1], Satoshi Okuzumi[1], Hiroyuki Kurokawa[2] (1.Tokyo Institute of Technology, 2.Earth-Life Science Institute, Tokyo Institute of Technology)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PPS06-11] Volatile-driven cryovolcanic eruption on asteroid Ceres as a probe to its interior

*Koki Yumoto[1], Yuichiro Cho[1], Seiji Sugita[1] (1.Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PPS06-12] Ice sheet formation on synchrnously rotating earth-like planets in M-dwarf abitable zones

Soma Arai[1], Kiyoshi Kuramoto[1], *Masaki Ishiwatari[1], Shunichi Kamata[1] (1.Department of Cosmosciences, Graduate school of Science, Hokkaido University)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS06] Planetary Sciences

convener:Kenji Kurosaki(Department of Physics, Nagoya University), Yusuke Nakauchi(Japan Aerospace Exploration Agency), Chairperson:荻原 正博(国立天文台), Yuri Fujii(Nagoya University)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PPS06-13] Three-dimensional linear calculation for non-isothermal type 1 planetary migration

*Kohei Okada[1], Hidekazu Tanaka[1] (1.Tohoku University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PPS06-14] Dependence of Central star mass on Protoplanetary disk evolution

*Ryuunosuke Nakano[1], Takeru Suzuki[1], Masahiro Ogihara[2], Eiichiro Kokubo[2] (1.University of Tokyo, 2.National Astronomical Observatory of Japan)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PPS06-15] Radiation Hydrodynamic Simulations of the Formation of Circumplanetary Disks

*Yuri Fujii[1], Oliver Gressel[2], Kengo Tomida[3], Udo Zieglar[2] (1.Institute for Advanced Research, Nagoya University, 2.Leibniz Institute for Astrophysics Potsdam, 3.Osaka University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PPS06-16] Inefficient Magnetic Accretion Heating in Protoplanetary Disks: Evolution of The Snow Line

*Shoji Mori[1], Xuening Bai[2], Satoshi Okuzumi[3] (1.Department of Astronomy, The University of Tokyo, 2.Tsinghua Center for Astrophysics, Tsinghua University, 3.Department of Earth and Planetary Sciences, Tokyo Institute of Technology)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PPS06-17] Formation of super-Earths and their atmospheres with *N*-body simulations

*Masahiro Ogihara[1], Yasunori Hori[2,1] (1.National Astronomical Observatory of Japan, 2.Astrobiology Center)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PPS06-18] The orbital stability of planets in resonances: the evolution of mass ratio

*Yuji Matsumoto[1], Masahiro Ogihara[2] (1.Academia Sinica Institute of Astronomy and Astrophysics, 2.National Astronomical Observatory of Japan)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS06] Planetary Sciences

convener:Kenji Kurosaki(Department of Physics, Nagoya University), Yusuke Nakauchi(Japan Aerospace Exploration Agency), Chairperson:Kenji Kurosaki(名古屋大学大学院 理学研究科), Yusuke Nakauchi(JAXA/ISAS)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PPS06-19] Experimental study on the structure of shock remnant magnetization

*Shota Kato[1], Masahiko Sato[1], Kosuke Kurosawa[2], Masashi Ushioda[3], Sunao Hasegawa[4] (1.The University of Tokyo, 2.Planetary Exploration Research Center, Chiba Institute of Technology, 3.Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology, 4.Japan Aerospace Exploration Agency)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PPS06-20] Low-dispersion spectra of lunar impact flashes in 2018 Geminids

*Masahisa Yanagisawa[1], Yuki Uchida[1], Seiya Kurihara[1], Shinsuke Abe[2], Ryota Fuse[2], Keisuke Onodera[3,4], Ryuhei Yamada[5] (1.The University of Electro-Communications, 2.Nihon University, 3.SOKENDAI (The Graduate University for Advanced Studies), 4.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 5.The University of Aizu)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PPS06-21] High velocity cratering experiments on sand-gypsum targets simulating asteroids

*Ryo Sugimura[1], Masahiko Arakawa[1], Minami Yasui[1], Takuya Ishiguro[1] (1.Kobe University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PPS06-22] Experimental study on collisional processes of highly porous ice balls simulating Saturn's ring particles

*Yukari Toyoda[1], Minami Yasui[1], Masahiko Arakawa[1] (1.Graduate School of Science, Kobe University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PPS06-23] IN-SITU FORMATION OF THE URANIAN SATELLITES FROM WIDE DEBRIS DISK FORMED BY GIANT IMPACT

*Ishizawa Yuya[1], Takanori Sasaki[1], Natsuki Hosono[2] (1.Department of Astronomy, Kyoto University, 2.JAMSTEC)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PPS06-24] Effect on the obliquity due to a giant impact on a rotating ice giant

*Kenji Kurosaki[1], Shu-ichiro Inutsuka[1] (1.Department of Physics, Nagoya University)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A02 TOKYO BAY MAKUHARI HALL

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University), Chairperson:Wataru Fujiya, Shin Ozawa

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PPS07-07] **Evaluation of shock metamorphism of eucrites by X-ray diffraction analysis**

*Rei Kanemaru[1], Naoya Imae[2,1], Akira Yamaguchi[2,1], Hirotugu Nishido[3] (1.The Graduate University for Advanced Studyies, 2.National Institute of Polar Research, 3.Okayama University of scienece)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PPS07-08] Hf-W dating of main-group pallasites

*Yoshitaka Homma[1], Tsuyoshi Iizuka[1], Akira Ishikawa[2] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Department of Earth and Planetary Sciences, Tokyo Institute of Technology)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PPS07-09] Mineralogical study of TCIs in CM carbonaceous chondrites

*Akane Iemoto[1], Yusuke Seto[1], Akira Miyake[2] (1.Graduate School of Science, Kobe University, 2.Graduate School of Science, Kyoto University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PPS07-10] Importance of 10Be as a key indicator of (solar) cosmic ray irradiation in the early solar system

*Hajime Hiyagon[1], Yuuki Tanimura[1], Tomoya Nakamura[1], Kohei Fukuda[3], Wataru Fujiya[4], Naoji Sugiura[1], Takanori Kagoshima[2], Naoto Takahata[2], Yuji Sano[2] (1.Graduate School of Science, The University of Tokyo, 2.Atmosphere and Ocean Research Institute, the University of Tokyo, 3.Department of Geoscience, University of Wisconsin-Madison, 4.College of Science, Ibaraki University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PPS07-11] **3D microstructure of a cosmic symplectite in primitive carbonaceous chondrite Acfer 094**

*Megumi Matsumoto[1,2], Akira Tsuchiyama[1], Junya Matsuno[1], Aiko Nakato[1,3], Akira Miyake[1], Motoo Ito[4], Naotaka Tomioka[4], Yu Kodama[5], Kentaro Uesugi[6], Akihisa Takeuchi[6], Tsukasa Nakano[7], Epifanio Vaccaro[8] (1.Graduate School of Science, Kyoto Univ., 2.Graduate School of Science, Tohoku Univ., 3.JAXA, ISAS, 4.JAMSTEC, 5.Marine Work Japan LTD., 6.JASRI, 7.AIST, Geological Survey Japan, 8.Natural History Museum, London)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PPS07-12] Chondrule-like objects and refractory inclusions in GEMS-bearing Antarctic micrometeorites and an interplanetary dust particle.

*Takaaki Noguchi[1], Noriaki Ohashi[2], John P. Bradley[3], Daisuke Nakashima[4], Tomoki Nakamura[4], Makoto Kimura[5], Takayuki Ushikubo[6], Noriko T. Kita[7], Naoya Imae[5] (1.Department of Arts and Science, Kyushu University, 2.NEC Networks and System Integration Co., 3.Univ. of Hawaii at Manoa, 4.Tohoku Univ., 5.National Institute of Polar Research, 6.Kochi Institute for Core Sample Research, JAMSTEC, 7.Univ. of Wisconsin-Madison)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A02 TOKYO BAY MAKUHARI HALL

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University), Chairperson:Yoko Kebukawa, Shin Ozawa

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PPS07-13] Spectral and mineralogical properties of naturally-heated carbonaceous chondrites; implication to heating processes on the surface of hydrous asteroids

★Invited Papers

*Moe Matsuoka[1], Tomoki Nakamura[2], Takahiro Hiroi[3], Nobuyoshi Miyajima[4], Naoya Imae[5,6], Akira Yamaguchi[5], Hideyasu Kojima[5,6] (1.Japan Aerospace Exploration Agency(JAXA), 2.Department of Earth and Planetary Materials Sciences, Faculty of Science, Tohoku University, 3.Department of Earth, Environmental and Planetary Sciences, Brown University, 4.Bayerisches Geoinstitut, University of Bayreuth, 5.National Institute of Polar Research, 6.Department of Polar Science, School of Multidisciplinary Science, SOKENDAI)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PPS07-14] Heterogeneity of oxygen and carbon isotopic compositions within carbonate grains in the Yamato 791198 CM chondrite and evolution of isotope ratios during aqueous alteration

*Wataru Fujiya[1], YUTO AOKI[1], Takayuki Ushikubo[2], Ko Hashizume[1] (1.Ibaraki University, College of Science, 2.Kochi Institute for Core Sample research, Japan Agency for Marine-Earth Science and Technology)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PPS07-15] Characteristics of Oxygen isotope ratios of chondrules and isolated olivine grains from Tagish Lake C2 chondrite

*Takayuki Ushikubo[1], Makoto Kimura[2] (1.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2.National Institute for Polar Research)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PPS07-16] Extreme ^{16}O-rich CAIs in Isheyevo chondrite

*Naoya Sakamoto[1], Noriyuki Kawasaki[2] (1.Creative Research Institution, Hokkaido University, 2.Natural History Sciences, Hokkaido University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PPS07-17] Variations in initial ^{26}Al/^{27}Al ratios among fine-grained CAIs in the reduced CV chondrites

*Noriyuki Kawasaki[1], Changkun Park[2], Naoya Sakamoto[1], Hisayoshi Yurimoto[1,3] (1.Hokkaido University, 2.KOPRI, 3.ISAS/JAXA)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PPS07-18] Petrographic study of compact type A CAIs with partial melting process

*Akimasa Suzumura[1], Yusuke Seto[2], Shoichi Itoh[1] (1.Graduate school of Science, Kyoto University, 2.Graduate school of Science, Kobe University)

[J] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University)

[PPS07-P01] Stability of Amino Acid Precursors in Simulated Extraterestrial Environments

*tomohito sato[1], Soushi Kuramoto[1], Takuya Yokoo[1], Yoshida Satoshi[2], Isao Yoda[3], Hitoshi Fukuda[3], Yoshiyuki Oguri[3], MITA Hajime[4], Kazuhiro Kanda[5], Hiromi Shibata[6], Zyunichi Takahashi[1], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.yokohama national univercity, 2.QST, 3.Tokyo Institute of Technology, 4.Fukuoka Institute of Technology, 5.University of Hyogo, 6.Osaka University)

[PPS07-P02] Production of amino acids by gamma rays during aqueous alteration process in meteorite parent body

*Shinya Asano[1], Isao Yoda[2], Yasuji Muramatsu[3], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.Yokohama national university, 2.Tokyo Institute of Technology, 3.University of Hyogo)

[PPS07-P03] **Kinetic approaches for the thermal history of organic matter in meteorites based on Raman spectra**

*Kento Kiryu[1], Yoko Kebukawa[1], Motoko Igisu[2], Takazo Shibuya[2], Kensei Kobayashi[1] (1.Yokohama National Univ., 2.Japan Agency for Marine-Earth Science and Technology)

[PPS07-P04] Relationship between spatial distribution of organic compounds and minerals in the Murchison meteorite

*Taiyo Sengoku[1], Minako Hashiguchi[1], Hiroshi Naraoka[1] (1.Kyushu University)

[PPS07-P05] O and Al-Mg isotope systematics of a hibonite-melilite-rich fine-grained CAI in the reduced CV chondrite NWA8613

*Sohei Wada[1], Noriyuki Kawasaki[1], Hisayoshi Yurimoto[1,2] (1.Hokkaido University, 2.ISAS/JAXA)

[PPS07-P06] Observation of Enstatite Whiskers in Fine-grained Rims in the Carbonaceous Chondrite ALH A77307

*Yasuhisa Shirota[1], Masahiro YASUTAKE[1], Satomi Enju[1], Akira Tsuchiyama[1] (1.Division of Earth and Planet, Science, Kyoto University)

[PPS07-P07] 3D observation of whisker-like material in the porous matrix of the Paris CM chondrite by SR-XCT

*Masahiro YASUTAKE[1], Epifanio Vacarro[2], Kentaro Uesugi[3], Akihisa Takeuchi[3], Tsukasa Nakano[4], Akira Tsuchiyama[1] (1.Division of Earth and Planetary Science, Graduate School of Science, Kyoto University, 2.National History Museum, London, 3.JASRI/SPring8, 4.GSJ/AIST)

[PPS07-P08] Development of cryogenic SIMS technique for isotope analysis of fluid inclusions

*Isono Yuki[1], Naoya Sakamoto[2], Hisayoshi Yurimoto[3] (1.Department of Natural History Sciences, Hokkaido University, 2.Creative Research Institusion, Hokkaido University, 3.Department of Natural History Sciences, Hokkaido University)

[PPS07-P09] X-ray diffraction study using Gandolfi attachment: Implications for small extraterrestrial materials

*Naoya Imae[1,2], Makoto Kimura[1] (1.Antarctic Meteorite Research Center, National Institute of Polar Research, 2.SOKENDAI)

[PPS07-P10] Trace elements analysis and Ar-Ar dating for microgram-scaled extraterrestrial samples

*Ryuji Okazaki[1], Sekimoto Shun[2] (1.Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 2.Institute for Integrated Radiation and Nuclear Science, Kyoto University)

[PPS07-P11] Magnetic separation and identification of low-temperature solid particles using their translation caused by a pair of small permanent magnets

*Chiaki Uyeda[1], Wakana Yamaguchi[1], Keiji Hisayoshi[1], Kentaro Terada[1] (1.Institute of earth and Space Science Graduate School of Science Osaka University)

[PPS07-P12] The metallographic cooling rate of the Tafassasset primitive achondrite

*naoji sugiura[1], Tomoko Arai, takafumi matsui (1.Chiba Institute of Technology)

[PPS07-P13] The systematic investigations of high-pressure minerals in lunar basaltic meteorites

*Masaaki Miyahara[1], Kazunari Kozuma[1], Eiji Ohtani[2], Akira Yamaguchi[3], Takeshi Sakai[4], Hiroaki Ohfuji[4], Naotaka Tomioka[5], Yu Kodama[6] (1.Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2.Department of Earth Sciences, Graduate School of Science, Tohoku University, 3.National Institute of Polar Research, 4.Geodynamics Research Center, Ehime University, 5.5Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 6.Marine Works Japan)

[PPS07-P14] Bulk chemical analysis of iron meteorites by LA-ICP-MS

*Akira Yamaguchi[1], Naoki Shirai[2], Makiko K. Haba[3] (1.National Institute of Polar Research, 2.Tokyo Metropolitan University, 3.Tokyo Institute of Technology)

[J] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University)

[PPS07-P01] Stability of Amino Acid Precursors in Simulated Extraterestrial Environments

*tomohito sato[1], Soushi Kuramoto[1], Takuya Yokoo[1], Yoshida Satoshi[2], Isao Yoda[3], Hitoshi Fukuda[3], Yoshiyuki Oguri[3], MITA Hajime[4], Kazuhiro Kanda[5], Hiromi Shibata[6], Zyunichi Takahashi[1], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.yokohama national univercity, 2.QST, 3.Tokyo Institute of Technology, 4.Fukuoka Institute of Technology, 5.University of Hyogo, 6.Osaka University)

[PPS07-P02] Production of amino acids by gamma rays during aqueous alteration process in meteorite parent body

*Shinya Asano[1], Isao Yoda[2], Yasuji Muramatsu[3], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.Yokohama national university, 2.Tokyo Institute of Technology, 3.University of Hyogo)

[PPS07-P03] Kinetic approaches for the thermal history of organic matter in meteorites based on Raman spectra

*Kento Kiryu[1], Yoko Kebukawa[1], Motoko Igisu[2], Takazo Shibuya[2], Kensei Kobayashi[1] (1.Yokohama National Univ., 2.Japan Agency for Marine-Earth Science and Technology)

[PPS07-P04] Relationship between spatial distribution of organic compounds and minerals in the Murchison meteorite

*Taiyo Sengoku[1], Minako Hashiguchi[1], Hiroshi Naraoka[1] (1.Kyushu University)

[PPS07-P05] O and Al-Mg isotope systematics of a hibonite-melilite-rich fine-grained CAI in the reduced CV chondrite NWA8613

*Sohei Wada[1], Noriyuki Kawasaki[1], Hisayoshi Yurimoto[1,2] (1.Hokkaido University, 2.ISAS/JAXA)

[PPS07-P06] Observation of Enstatite Whiskers in Fine-grained Rims in the Carbonaceous Chondrite ALH A77307

*Yasuhisa Shirota[1], Masahiro YASUTAKE[1], Satomi Enju[1], Akira Tsuchiyama[1] (1.Division of Earth and Planet, Science, Kyoto University)

[PPS07-P07] 3D observation of whisker-like material in the porous matrix of the Paris CM chondrite by SR-XCT

*Masahiro YASUTAKE[1], Epifanio Vacarro[2], Kentaro Uesugi[3], Akihisa Takeuchi[3], Tsukasa Nakano[4], Akira Tsuchiyama[1] (1.Division of Earth and Planetary Science, Graduate School of Science, Kyoto University, 2.National History Museum, London, 3.JASRI/SPring8, 4.GSJ/AIST)

[PPS07-P08] Development of cryogenic SIMS technique for isotope analysis of fluid inclusions

*Isono Yuki[1], Naoya Sakamoto[2], Hisayoshi Yurimoto[3] (1.Department of Natural History Sciences, Hokkaido University, 2.Creative Research Institusion, Hokkaido University, 3.Department of Natural History Sciences, Hokkaido University)

[PPS07-P09] X-ray diffraction study using Gandolfi attachment: Implications for small extraterrestrial materials

*Naoya Imae[1,2], Makoto Kimura[1] (1.Antarctic Meteorite Research Center, National Institute of Polar Research, 2.SOKENDAI)

[PPS07-P10] Trace elements analysis and Ar-Ar dating for microgram-scaled extraterrestrial samples

*Ryuji Okazaki[1], Sekimoto Shun[2] (1.Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 2.Institute for Integrated Radiation and Nuclear Science, Kyoto University)

[PPS07-P11] Magnetic separation and identification of low-temperature solid particles using their translation caused by a pair of small permanent magnets

*Chiaki Uyeda[1], Wakana Yamaguchi[1], Keiji Hisayoshi[1], Kentaro Terada[1] (1.Institute of earth and Space Science Graduate School of Science Osaka University)

[PPS07-P12] The metallographic cooling rate of the Tafassasset primitive achondrite

*naoji sugiura[1], Tomoko Arai, takafumi matsui (1.Chiba Institute of Technology)

[PPS07-P13] The systematic investigations of high-pressure minerals in lunar basaltic meteorites

*Masaaki Miyahara[1], Kazunari Kozuma[1], Eiji Ohtani[2], Akira Yamaguchi[3], Takeshi Sakai[4], Hiroaki Ohfuji[4], Naotaka Tomioka[5], Yu Kodama[6] (1.Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2.Department of Earth Sciences, Graduate School of Science, Tohoku University, 3.National Institute of Polar Research, 4.Geodynamics Research Center, Ehime University, 5.5Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 6.Marine Works Japan)

[PPS07-P14] Bulk chemical analysis of iron meteorites by LA-ICP-MS

*Akira Yamaguchi[1], Naoki Shirai[2], Makiko K. Haba[3] (1.National Institute of Polar Research, 2.Tokyo Metropolitan University, 3.Tokyo Institute of Technology)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-EM10] Multi-scale Coupling in the Magnetosphere-Ionosphere-Thermosphere System

convener:Yue Deng(University of Texas at Arlington), Toshi Nishimura(Boston University), Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Yanshi Huang(Harbin Institute of Technology, Shenzhen)

[PEM10-P01] Atmospheric responses in both hemispheres to relativistic electron precipitation

*Yoshimasa Tanaka[1,13,14], Takanori Nishiyama[1,14], Akira Kadokura[1,13,14], Mitsunori Ozaki[2], Yoshizumi Miyoshi[3], Shin-ichiro Oyama[3,15], Ryuho Kataoka[1,14], Masaki Tsutsumi[1,14], Koji Nishimura[1,13,14], Kaoru Sato[4], Yoshiya Kasahara[2], Atsushi Kumamoto[5], Fuminori Tsuchiya[5], Mizuki Fukizawa[5], Mitsuru Hikishima[6], Shoya Matsuda[6], Ayako Matsuoka[6], Iku Shinohara[6], Masahito Nose[3], Tsutomu Nagatsuma[7], Manabu Shinohara[8], Akiko Fujimoto[9], Mariko Teramoto[3], Reiko Nomura[10], Akira Sessai Yukimatu[1,14], Keisuke Hosokawa[11], Masafumi Shoji[3], Ralph Latteck[12] (1.National Institute of Polar Research, 2.Institute of Science and Engineering, Kanazawa University, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Graduate School of Science, The University of Tokyo, 5.Graduate School of Science, Tohoku University, 6.Japan aerospace exploration agency, Institute of space and astronautical science, 7.National Institute of Information and Communications Technology, 8.Kagoshima National College of Technology, 9.Kyushu Institute of Technology, 10.National Observatory of Japan, 11.Department of Communication Engineering and Informatics, University of Electro-Communications, 12.Leibniz-Institute of Atmospheric Physics e.V. at the University Rostock, Germany, 13.Polar Environment Data Science Center, Joint-Support Center for Data Science Research, Research Organization of Information and Systems, 14.The Graduate University for Advanced Studies (SOKENDAI), 15.University of Oulu, Finland)

[PEM10-P02] Comparison of precipitating particle energy of proton aurora at geomagnetic conjugate points

*Makoto Taguchi[1], Tatsuki Nishijima[1], Akira Kadokura[2] (1.Rikkyo University, 2.Research Organization of Information and Systems)

[PEM10-P03] A regularized deep convolutional general adversarial network (R-DCGAN) for total electron content map completion

*Mingwu Jin[1], Zhou Chen[2,3], Yue Deng[1], Yang Pan[1], Jin-Song Wang[2] (1.University of Texas at Arlington, 2.Institute of Space Science and Technology, Nanchang University, Nanchang, China, 3.Key Laboratory of Space Weather, National Center for Space Weather, China Meteorological Administration, Beijing, China)

[PEM10-P04] A long-lasting auroral bright spot around magnetic north pole: Is it the evidence of stable magnetic reconnection?

*Qing-He Zhang[1], Guo-Cheng Shen[1], Yong-Liang Zhang[2], Kjellmar Oksavik[3], Michael Lockwood[4], Zan-Yang Xing[1], Yu-Zhang Ma[1] (1.Institute of Space Sciences, Shandong University, Weihai, China, 2.The Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, USA, 3.Birkeland Centre for Space Science, University of Bergen, Bergen, Norway, 4.Department of Meteorology, University of Reading, Earley Gate, Post Office Box 243, RG6 6BB, UK.)

[PEM10-P05] Statistical study of the relationship between ion upflow and field-aligned current in the topside ionosphere for both hemispheres during disturbed and quiet times

Shan-Yu Zhou[1], *Qing-He Zhang[1], P. T. Jayachandran[2], Kjellmar Oksavik[3], Larry Lyons[4], Zan-Yang Xing[1], Yu-Zhang Ma[1], Marc Hairston[5], Yong Wang[1] (1.Institute of Space Sciences, Shandong University, Weihai, China, 2.Physics Department, University of New Brunswick, Fredericton, New Brunswick, Canada, 3.Birkeland Centre for Space Science, University of Bergen, Bergen, Norway, 4.Department of Atmospheric and Oceanic Sciences, University of California, Los Angeles, California, USA, 5.William B. Hanson Center for Space Sciences, University of Texas at Dallas, Richardson, Texas, USA)

[PEM10-P06] SAPS in the 2013 March 17 Storm Event: Initial Results from the Coupled Magnetosphere-Ionosphere-Thermosphere Model

*Dong Lin[1,2], Wenbin Wang[2], Wayne Scales[1], Kevin Pham[2], Jing Liu[2], Binzheng Zhang[2], Viacheslav Merkin[3], Xueling Shi[1] (1.Virginia Tech, 2.High Altitude Observatory, NCAR, 3.APL, John Hopkins Univ.)

[PEM10-P07] Westward turning motions of nighttime medium-scale traveling ionospheric disturbances (MSTIDs) at the equatorward side of the dusk side auroral oval associated with auroral brightening

*Sneha Yadav[1,2], Kazuo Shiokawa[1], Shin-ichiro Oyama[1,3,4], Yuichi Otsuka[1] (1.ISEE, Nagoya University, Nagoya, Japan, 2.SPL, VSSC, India, 3.Ionosphere Research Unit, University of Oulu, Oulu, Finland, 4.NIPR, Tachikawa, Japan)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[P-EM10] Multi-scale Coupling in the Magnetosphere-Ionosphere-Thermosphere System

convener:Yue Deng(University of Texas at Arlington), Toshi Nishimura(Boston University), Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Yanshi Huang(Harbin Institute of Technology, Shenzhen)

[PEM10-P01] Atmospheric responses in both hemispheres to relativistic electron precipitation

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[P-EM10] Multi-scale Coupling in the Magnetosphere-Ionosphere-Thermosphere System

convener:Yue Deng(University of Texas at Arlington), Toshi Nishimura(Boston University), Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Yanshi Huang(Harbin Institute of Technology, Shenzhen), Chairperson:Yue Deng(University of Texas at Arlington), Huixin Liu(Kyushu University, Japan), Yanshi Huang(Harbin Institute of Technology, Shenzhen, China), Yukitoshi Nishimura(Boston University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PEM10-01] Auroral fragmentation into patches and pressure balance condition in the source magnetosphere

★Invited Papers

*Kazuo Shiokawa[1], Katsuki Nishi[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PEM10-02] Formation and Evolution of Polar Cap Ionospheric Patches and Their Associated Upflows and Scintillations: A Review

★Invited Papers

*Qing-He Zhang[1], Zan-Yang Xing[1], Yong Wang[1], Yu-Zhang Ma[1] (1.Institute of Space Sciences, Shandong University, Weihai, China)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PEM10-03] Global ionospheric disturbances during the 6-10 September 2017 solar storms

★Invited Papers

*Shunrong Zhang[1] (1.MIT Haystack Observatory)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PEM10-04] Multiscape Coupling of Sub-auroral Polarization Streams

*Nozomu Nishitani[1], Tomoaki Hori[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PEM10-05] Scale sizes of mass density enhancements inferred from accelerometer measurements

*Yanshi Huang[1], Cheryl Huang[2] (1.Harbin Institute of Technology, Shenzhen, China, 2.Space Physics Directoriate, Air Force Research Laboratory, Kirtland AFB, USA)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PEM10-06] **Meso-scale forcing in the upper atmosphere: sources and impacts**

*Yue Deng[1], Qingyu Zhu[1], Cissi Lin[1] (1.University of Texas at Arlington)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM12] Space Weather and Space Climate

convener:Ryuho Kataoka(National Institute of Polar Research), Antti A Pulkkinen(NASA Goddard Space Flight Center), Kanya Kusano(Institute for Space-Earth Environmental Research, Nagoya University), Kaori Sakaguchi(National Institute of Information and Communications Technology), Chairperson:Antti Pulkkinen(NASA/GSFC)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PEM12-01] NASA Heliophysics Division Space Weather Update

★Invited Papers

*Nicola Justine Fox[1] (1.NASA Headquarters)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PEM12-02] NOAA's Current and Future Space Weather Architecture

★Invited Papers

*Elsayed R Talaat[1] (1.NOAA National Environmental Satellite, Data, and Information Service)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PEM12-03] Community Coordinating Modeling Center (CCMC): A hub for collaborative assessment and improvement of space weather capabilities.

★Invited Papers

*Maria M Kuznetsova[1], M. Leila Mays[1], Edward J Semones[2], Peter J Macneice[1], Lutz Rastaetter[1], Ja Soon Shim[1], Yihua Zheng[1], Katherine Garcia-Sage[1], Joycelyn Jones[1], Yaireshka m Collado-Vega[1], Richard E Mullinix[1], Chiu Wiegand[1] (1.NASA Goddard Space Flight Center, 2.NASA Johnson Space Center)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PEM12-04] Different flux evolutions of relativistic electrons of the outer belt associated with high-speed coronal hole streams; Arase and Van Allen Probes observations

*Yoshizumi Miyoshi[1], Satoshi Kurita[1], Ryuho Kataoka[2], Shinji Saito[1], Vania Jordanova[3], Iku Shinohara[4], Takefumi Mitani[4], Takeshi Takashima[4], Nana Higashio[4], Satoshi Kasahara[5], Shoichiro Yokota[6], Tomoaki Hori[1], Kunihiro Keika[5], Yoshiya Kasahara[7], Shoya Matsuda[4], Atsushi Kumamoto[8], Fuminori Tsuchiya[8], Masafumi Shoji[1], Ayako Matsuoka[1], Mariko Teramoto[1], Harlan Spence[9], Geoff Reeves[3], Daniel Baker[10] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.NIPR, 3.Los Alamos National Laboratory, 4.JAXA, 5.University of Tokyo, 6.Osaka University, 7.Kanazawa University, 8.Tohoku University, 9.University of New Hampshire, 10.University of Colorado)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PEM12-05] Study on the predictability of imminent giant solar flares based on the theory of double-arc instability

*Kanya Kusano[1], Tomoya Iju[2], Yumi Bamba[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.NAOJ)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PEM12-06] Update of space weather research and operation activities in NICT

*Mamoru Ishii[1] (1.National Institute of Information and Communications Technology)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM12] Space Weather and Space Climate

convener:Ryuho Kataoka(National Institute of Polar Research), Antti A Pulkkinen(NASA Goddard Space Flight Center), Kanya Kusano(Institute for Space-Earth Environmental Research, Nagoya University), Kaori Sakaguchi(National Institute of Information and Communications Technology), Chairperson:Ryuho Kataoka(National Institute of Polar Research)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PEM12-07] Commercial Space Weather Activities From a USA small Business Perspertive

★Invited Papers

*Chigomezyo Mudala Ngwira[1], Geoff Crowley[1], Chad Fish[1] (1.Atmospheric and Space Technology Research Associates, LLC)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PEM12-08] Development of coronal mass ejection arrival time forecasting system using interplanetary scintillation observations

★Invited Papers

*Kazumasa Iwai[1], Daikou Shiota[2], Munetoshi Tokumaru[1], Ken'ichi Fujiki[1], Mitsue Den[2], Yûki Kubo[2] (1.Institute for Space–Earth Environmental Research (ISEE), Nagoya University, 2.National Institute of Information and Communications)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PEM12-09] Development of real-time prediction system of CME arrival and magnetic field with SUSANOO-CME MHD simulation

*Daikou Shiota[1,2], Seiji Yashiro[3], Kazumasa Iwai[2] (1.National Institute of Information and Communications Technology (NICT), 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Catholic University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PEM12-10] The Role of a Tiny Brightening in a Huge Geo-effective Solar Eruption Leading to the St Patrick's Day Storm

*Yumi Bamba[1,2], Satoshi Inoue[1], Keiji Hayashi[1,3,4] (1.Institute for Space-Earth Environmental Research/Nagoya University, 2.Institute if Space and Astronautical Science/Japan Aerospace Exploration Agency, 3.Key Laboratory of Solar Activity, National Astronomical Observatories, Chinese Academy of Sciences, 4.State Key Laboratory for Space Weather, National Space Science Center, Chinese Academy of Sciences)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PEM12-11] Critical Parameters of Photospheric Magnetic Field to Produce Eruptive Solar Flares and CMEs in Active Regions

*Pei Hsuan Lin[1], Kanya Kusano[1], Daikou Shiota[2], Satoshi Inoue[1], KD Leka[1,3], Yuta Mizuno[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.National Institute of Information and Communications Technology, 3.NorthWest Research Associates)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PEM12-12] Simulation study on internal velocity field variation of eruptive prominence

★Invited Papers

*Takafumi Kaneko[1], Kanya Kusano[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM12] Space Weather and Space Climate

convener:Ryuho Kataoka(National Institute of Polar Research), Antti A Pulkkinen(NASA Goddard Space Flight Center), Kanya Kusano(Institute for Space-Earth Environmental Research, Nagoya University), Kaori Sakaguchi(National Institute of Information and Communications Technology), Chairperson:Antti Pulkkinen(NASA/GSFC)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PEM12-13] Is intensity of auroral electrojet predictable?

★Invited Papers

*Yusuke Ebihara[1], Takashi Tanaka[2], Naoki Kamiyoshikawa[3] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.Kyushu University, 3.Mitsubishi Electric Corporation)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PEM12-14] Geoelectromagnetics with the Geophysical Instrument Combination of Hydro-Québec, AUTUMNX, and USArray Magnetotellurics

★Invited Papers

*Martin G Connors[1], Sébastien Guillon[2], Adam Schultz[3], Naoto Imamura[3] (1.Athabasca University, 2.Hydro-Québec TransÉnergie, 3.Oregon State University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PEM12-15] Quantifying the Latitudinal Extent of the Aurorae During Large Geomagnetic Storms

*Sean Blake[1,2], Antti Pulkkinen[1], Pete Schuck[1] (1.NASA Goddard Space Flight Center, Space Weather Laboratory, Greenbelt, Maryland, USA, 2.Catholic University of America, Department of Physics, Washington DC, USA)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PEM12-16] Simulation of Geomagnetically Induced Current (GIC) Flowing in 500 kV Power Grid in Japan Including a Three-Dimensional Ground Inhomogeneity

*Satoko Nakamura[1], Yusuke Ebihara[1], Shigeru Fujita[2], Tada-nori Goto[3], Shinichi Watari[4] (1.Research Institute for Sustainable Humanosphere, Kyoto University., 2.Meteorological College, Japan Meteorological Agency, 3.Graduate School of Engineering, Kyoto University, 4.National Institute of Information and Communications Technology)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PEM12-17] Reproducibility of the geomagnetically induced currents in Hokkaido with a two-layer conductivity model

*Takashi Kikuchi[1,2], Yusuke Ebihara[2], Kumiko K. Hashimoto[3], Shinichi Watari[4] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Institute for Sustainable Humanosphere, Kyoto University, 3.Kibi International University, 4.National Institute of Information and Communications Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PEM12-18] Fan-shaped aurora as seen from Japan during a great magnetic storm on 11 February 1958

*Ryuho Kataoka[1], Shiori Uchino[1], yasunori Fujiwara[1], Shigeru Fujita[1], Kazuaki Yamamoto[2] (1.National Institute of Polar Research, 2.National Institute of Japanese Literature)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM12] Space Weather and Space Climate

convener:Ryuho Kataoka(National Institute of Polar Research), Antti A Pulkkinen(NASA Goddard Space Flight Center), Kanya Kusano(Institute for Space-Earth Environmental Research, Nagoya University), Kaori Sakaguchi(National Institute of Information and Communications Technology), Chairperson:Kanya Kusano(Nagoya University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PEM12-19] Application Usability Levels: Their evolution and eco-system

★Invited Papers

*Alexa Jean Halford[1], Adam Kellerman[2], Jeff Klenzing[3], Katherine Garcia-Sage[3], Brett A Carter[4], Daniel T Welling[5], Barbara Thompson[3], Antti A Pulkkinen[3] (1.The Aerospace Corporation, 2.UCLA, 3.NASA/GSFC, 4.RMIT, 5.UT Arlington)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PEM12-20] The Operational Space Weather Forecast at NICT, Japan

★Invited Papers

*Kosuke Sakai[1], Kentaro Ukawa[1], Kentaro Kawahara[1], Mamoru Ishii[2], Yuki Kubo[2] (1.Systems Engineering Consultants Co., LTD., 2.National Institute of Information and Communications Technology)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PEM12-21] PROGRESS: An overview of data products

*Michael A Balikhin[1], Simon N Walker[1] (1.University of Sheffield)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PEM12-22] The Probability of Satellite Anomalies by a Disastrous Solar Flare

*Daikichi SEKI[1,2,3] (1.Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University, 2.Centre for the Study of Existential Risk, University of Cambridge, 3.Astronomical Observatory, Kyoto University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PEM12-23] **Operational Forecasting of Solar Flares using Deep Neural Network**

*Naoto Nishizuka[1], Yuki Kubo[1], Komei Sugiura[1], Mitsue Den[1], Mamoru Ishii[1] (1.National Institute of Information and Communications Technology)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PEM12-24] **Spring-Autumnal asymmetry in geomagnetic activity and its origin over last 140 years**

*Hao Luo[1], Xiaoming Sha[1] (1.IGGCAS)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 301B 3F

[A-OS09] Ocean Mixing Processes: Impact on Biogeochemistry, Climate and Ecosystem

convener:Ichiro Yasuda(Atmosphere and Ocean Research Institute, The University of Tokyo), Toshiyuki Hibiya(Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo), Jun Nishioka(Hokkaido University, Institute of low temperature sciences), Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Toshiyuki Hibiya(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[AOS09-18] Searching 18.6 year tidal modulation impact in a global gridded ocean oxygen dataset with its improvements

*Shoshiro Minobe[1] (1.Earth and Planetary Sciences, Faculty of Science, Hokkaido University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AOS09-19] Contribution of tidal energy dissipation to variations of transient climate response and steric sea level rise through ocean heat uptake

*Michio Watanabe[1], Hiroaki Tatebe[1], Tatsuo Suzuki[1], Kaoru Tachiiri[1] (1.Japan Agency for Marine-Earth Science and Technology)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AOS09-20] A Wave Resolving Simulation for Upper Ocean Turbulence Driven by Wave-Current Interaction

*Yutaka Yoshikawa[1], Yasushi Fujiwara[1], Yoshimasa Matsumura[2] (1.Graduate School of Science, Kyoto University, 2. Atmosphere and Ocean Research Institute, The University of Tokyo)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AOS09-21] Revisiting the Characteristics of Mixing Efficiency in the Brazil Basin

*Takashi Ijichi[1], Louis St. Laurent[1], Kurt Polzin[1] (1.Woods Hole Oceanographic Institution)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AOS09-22] Instabilities of finite-amplitude internal wave beams

*Yohei Onuki[1], Yuki Tanaka[2] (1.Research Institute for Applied Mechanics, Kyushu University, 2.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AOS09-23] Evaluation of nutrient flux enhanced by double diffusion in the Kuroshio using glider measurements

*Keunjong Lee[1], Ryo Yamamoto[1], Ichiro Yasuda[1], Takahiro Tanaka[2] (1.Atmosphere and Ocean Research Institute, 2.Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 302 3F

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University), Chairperson:Shin-Ichi Ito(The University of Tokyo)

9:10 AM - 9:30 AM JST | 12:10 AM - 12:30 AM UTC

[AOS12-01] Projected coastal hypoxia in a coupled bio-physical model of the California Current System.

★Invited Papers

*Enrique N Curchitser[1], Raphael Dussin[1,2], Charles Stock[3], Nicoals van Oostende[4] (1.Rutgers University New Brunswick, 2.Lamont-Doherty Earth Observatory of Columbia University, 3.NOAA Geophysical Fluid Dynamics Laboratory, 4.Princeton University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AOS12-02] **Decadal salinity variation in the western North Pacific correlated with the strength of the Oyashio and the Kuroshio Extension**

*Hitoshi Kaneko[1], Takeshi Okunishi[2], Shinya Kouketsu[3], Sachihiko Itoh[1], Takashi Seto[4], Hiroshi Kuroda[5], Yugo Shimizu[4] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 3.Japan Agency for Marine-Earth Science and Technology, 4.National Research Institute of Fisheries Science, Japan Fisheries Research and Education Agency, 5.Hokkaido National Fisheries Research Institute, Japan Fisheries Research and Education Agency)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AOS12-03] **Multiscale routes to supply nutrients through the Kuroshio nutrient stream**

*Takeyoshi Nagai[1], Sophie Clayton[2], Yusuke Uchiyama[3] (1.Department of Ocean Sciences, Tokyo University of Marine Science and Technology, 2.Ocean, Earth & Atmospheric Sciences, Old Dominion University, 3.Kobe University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AOS12-04] **Seasonal variability of upper-ocean primary production around the Kuroshio analyzed using a ROMS-NPZD model**

*Xu Zhang[1], Yusuke Uchiyama[1,2], Yota Suzue[3], Hidekatsu Yamazaki[4] (1.Kobe University, 2.Port and Airport Research Institute, 3.Construction Technique Institute Engineering Co., Ltd., 4.Tokyo University of Marine Science and Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AOS12-05] Nutrient and light conditions at subsurface chlorophyll maximum: physical-biogeochemical observations along a mid-Pacific meridional transect

*Sachihiko Itoh[1], Hitoshi Kaneko[1], Shinya Kouketsu[2], Takeshi Okunishi[3], Hiroshi Ogawa[1], Mitsuhide Sato[4], Hiroaki Saito[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Japan Agency for Marin-Earth Science and Technology, 3.Tohoku National Fisheries Research Institute, Fisheries Research Agency, 4.The Hong Kong University of Science and Technology)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 302 3F

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University), Chairperson:Yoshimasa Matsumura(Atmosphere and Ocean Research Institute, The University of Tokyo)

10:45 AM - 11:05 AM JST | 1:45 AM - 2:05 AM UTC

[AOS12-06] A Lagrangian view of spring phytoplankton blooms

★Invited Papers

*Shinichiro Kida[1], Taka Ito[2] (1.Research Institute for Applied Mechanics, Kyushu University, 2.Georgia Institute of Technology)

11:05 AM - 11:20 AM JST | 2:05 AM - 2:20 AM UTC

[AOS12-07] Significance of acclimation process in simulating chlorophyll distribution in the Arctic Ocean

*Yoshio Masuda[1], Yasuhiro Yamanaka[1], Takafumi Hirata[1], Hideyuki Nakano[2] (1.Graduate School of Environmental Earth Science, Hokkaido University, 2.Meteorological Research Institute)

11:20 AM - 11:35 AM JST | 2:20 AM - 2:35 AM UTC

[AOS12-08] Responses of lower-trophic level ecosystem to nutrient variation in the central part of the Seto Inland Sea

*Naoki Yoshie[1], Hayato Mizuguchi[1], Xinyu Guo[1], Michio Yoneda[2], Katsuyuki Abo[2], Tomoaki Kono[2], Tatsunori Fujita[3] (1.Center for Marine Environmental Studies, Ehime University, 2.Japan Fisheries Research and Education Agency, 3.Kagawa Prefectural Fisheries Research Center)

11:35 AM - 11:50 AM JST | 2:35 AM - 2:50 AM UTC

[AOS12-09] Effects of the temperature and fish size on metabolism and swimming performance of Pacific chub mackerel *Scomber japonicus* in the Northwest Pacific

*Chenying Guo[1], Shin-ichi Ito[1], Michio Yoneda[2], Hajime Kitano[2] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Fisheries Research and Education Agency Japan)

11:50 AM - 12:05 PM JST | 2:50 AM - 3:05 AM UTC

[AOS12-10] Sensitivity analyses of growth and migration of Japanese anchovy (*Engraulis japonicus*) in the East China Sea using a fish growth-migration model.

*Shin-ichi Ito[1], Takashi Setou[2], Michio Yoneda[2], Motomitsu Takahashi[2], Michiya Matsuyama[3], Chenying Guo[1], Takashi Kitagawa[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Fisheries Research and Education Agency Japan, 3.Kyushu University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 302 3F

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University), Chairperson:Enrique Curchitser(Rutgers University)

1:45 PM - 2:05 PM JST | 4:45 AM - 5:05 AM UTC

[AOS12-11] Micro-scale patchiness enhances trophic transfer efficiency and potential plankton biodiversity

★Invited Papers

*Hidekatsu Yamazaki[1], Anupam Priyadarshi[2], Lan Smith[3], Sandip Mandal[4], Mamoru Tanaka[1] (1.Tokyo University of Marine Science and Technology, 2.Banaras Hindu University, 3.Japan Agency for Marine-Earth Science and Technology, 4.Public Health Foundation of India)

2:05 PM - 2:20 PM JST | 5:05 AM - 5:20 AM UTC

[AOS12-12] Long term observations of marine snow, using cabled observatory system

*Marika Takeuchi[1,2], Mark Doubell[3], Jim Mitchell[2], Hidekatsu Yamazaki[1] (1.Tokyo University of Marine Science and Technology, 2.Flinders University, 3.South Australia Research and Development Institute)

2:20 PM - 2:35 PM JST | 5:20 AM - 5:35 AM UTC

[AOS12-13] An insight into the area characteristic of seasonal change in nitrogen isotope ratio based on a marine nitrogen isotope model

*Chisato Yoshikawa[1], Masahito Shigemitsu[1], Akitomo Yamamoto[1], Akira Oka[2], Naohiko Ohkouchi[1] (1.JAMSTEC, 2.AORI)

2:35 PM - 2:50 PM JST | 5:35 AM - 5:50 AM UTC

[AOS12-14] Modeling variability of ^{15}N stable isotope enrichment within the planktonic food chain

*S. Lan Smith[1], Yoshikazu Sasai[1], Chisato Yoshikawa[2] (1.Marine Ecosystem Dynamics Research Group, RCGC, Japan Agency for Marine-Earth Science and Technology, Yokohama, Japan, 2.Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology, Yokosuka, Japan)

2:50 PM - 3:05 PM JST | 5:50 AM - 6:05 AM UTC

[AOS12-15] Discussions

Shin-ichi Ito[2], *Takafumi Hirata[1] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Atmosphere and Ocean Research Institute, The University of Tokyo)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University)

[AOS12-P01] Impact of the nutrient transport through the Tsushima Strait on the ecosystem in the Japan Sea

*Ryota Shibano[1], Akihiko Morimoto[1], Katsumi Takayama[2], Tetsutaro Takikawa[3], Masashi Ito[4] (1.Center for Marine Environmental Studies, Ehime University, 2.Research Institute for Applied Mechanics, Kyushu University, 3.Graduate School of Fisheries and Environmental Sciences, Nagasaki University, 4.Fisheries Oceanography Department, Japan Sea National Fisheries Research Institute)

[AOS12-P02] Revisiting vertical variations in stoichiometry during oceanic organic matter decomposition

*Masahito Shigemitsu[1], Michio Aoyama[1], Toshimasa Doi[1], Taichi Yokokawa[1], Akihiko Murata[1] (1.Japan Agency for Marine-Earth Science and Technology)

[AOS12-P03] Reproduction of iron-rich intermediate water in the Sea of Okhotsk by high resolution biogeochemical model.

*Hatsumi Nishikawa[1], Humio Mitsudera[1], Hiroshi Yoshinari[2], Takuya Nakanowatari[3], Tomohiro Nakamura[1], Keisuke Uchimoto[4], Hiroyasu Hasumi[5] (1.Institute of Low Temperature Science, Hokkaido University, 2.National Institute for Environmental Studies, 3.Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 4.Research Institute of Innovative Technology for the Earth, 5.Atmosphere and Ocean Research Institute, University of Tokyo)

[AOS12-P04] The global oceanic iron distribution estimated by data assimilation approach

*Doi Toshimasa[1], Satoshi Osafune[1], Shuhei Masuda[1], Hajime Obata[2], Kazuhiro Misumi[3], Jun Nishioka[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.The University of Tokyo, 3.Central Research Institute of Electric Power Industry, 4.Hokkaido University)

[AOS12-P05] A high-resolution multi-purpose particle tracking framework for coastal areas near Japan

*Yoshimasa Matsumura[1], Shota Katsura[1], Masao Kurogi[2], Hideyuki Nakano[3], Takateru Yamagishi[4] (1.Atmosphere and Ocean Research Institute, University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology, 3.Meteorological Research Institute, Japan Meteorological Agency , 4.Research organization for Information Science and Technology)

[AOS12-P06] Numerical study on seasonality of ocean litters collected at the Dongsha Island in the northern South China Sea

*Yi-Chia Hsin[1], Chia-Ying Ko[2], Ming-Shiou Jeng[3] (1.Research Center for Environmental Changes, Academia Sinica, 2.Institute of Fisheries Science, National Taiwan University, 3.Biodiversity Research Center, Academia Sinica)

[AOS12-P07] A key spot and timing to monitor chlorophyll-a in the Kuroshio western boundary current

*Takafumi Hirata[1] (1.Faculty of Environmental Earth Science, Hokkaido University)

[AOS12-P08] **Impacts of cyclonic eddies on phytoplankton biomass and phenology in the Kuroshio Extension region**

*Eko Siswanto[1], Yoshikazu Sasai[1] (1.Japan Agency for Marine-Earth Science and Technology)

[AOS12-P09] Diagnostic estimation and uncertainties of nutrient limitation of phytoplankton growth in Michaelis-Menten functional form

*Taketo Hashioka[1], Maki Noguchi Aita[1] (1.Japan Agency for Marine-Science and Technology)

[AOS12-P10] Modeling productivity in lower trophic levels in Otsuchi Bay, northeast of Japan, using a nested OGCM with a biogeochemical component

*Takashi T Sakamoto[1], L. Shogo Urakawa[2], Sachihiko Itoh[1], Hiroyasu Hasumi[1], Kiyoshi Tanaka[1] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Meteorological Research Institute, Japan Meteorologica Agancy)

[AOS12-P11] Change in lower trophic level ecosystems to decadal scale variation of climate system in the North Pacific Ocean

*Maki Noguchi Aita[1], Kazuaki Tadokoro[2], Yoshiki Komuro[3], Taketo Hashioka[1], Naomi Harada[1] (1.Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology, 2.Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 3.Institute of Arctic Climate and Environment Research, Japan Agency for Marine-Earth Science and Technology)

[AOS12-P12] Estimation of experienced environment of jack mackerel in the East China Sea

*Tomihiko Higuchi[1], Motomitsu Takahashi[2], Kotaro Shirai[1], Shin-ichi Ito[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Seikai National Fisheries Research Institute,FRA)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University)

[AOS12-P01] Impact of the nutrient transport through the Tsushima Strait on the ecosystem in the Japan Sea

*Ryota Shibano[1], Akihiko Morimoto[1], Katsumi Takayama[2], Tetsutaro Takikawa[3], Masashi Ito[4] (1.Center for Marine Environmental Studies, Ehime University, 2.Research Institute for Applied Mechanics, Kyushu University, 3.Graduate School of Fisheries and Environmental Sciences, Nagasaki University, 4.Fisheries Oceanography Department, Japan Sea National Fisheries Research Institute)

[AOS12-P02] Revisiting vertical variations in stoichiometry during oceanic organic matter decomposition

*Masahito Shigemitsu[1], Michio Aoyama[1], Toshimasa Doi[1], Taichi Yokokawa[1], Akihiko Murata[1] (1.Japan Agency for Marine-Earth Science and Technology)

[AOS12-P03] Reproduction of iron-rich intermediate water in the Sea of Okhotsk by high resolution biogeochemical model.

*Tomihiko Higuchi[1], Motomitsu Takahashi[2], Kotaro Shirai[1], Shin-ichi Ito[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Seikai National Fisheries Research Institute,FRA)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 102 1F

[A-OS13] Ocean circulation and material cycle in coastal seas

convener:Kiyoshi Tanaka(University of Tokyo), Akihiko Morimoto(Ehime University), Yuichi Hayami(Saga University), Kazuhiko Ichimi(Seto Inland Sea Regional Research Center, Kagawa University), Chairperson:Kiyoshi Tanaka, Akihiko Morimoto

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AOS13-01] On-demand development of bay-scale models using the Japanese Coastal Ocean Monitoring and Forecasting System

*Kei Sakamoto[1], Hideyuki Nakano[1], Shogo Urakawa[1], Takahiro Toyoda[1], Hiroyuki Tsujino[1], Goro Yamanaka[1] (1.Meteorological Research Institute)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AOS13-02] Long term measurement of the current at the bay head in the Suruga Bay, Japan. part 2

*Takaaki Katsumata[1,4], Masato Niki[2], Akihiko Tanaka[1], Hiroyuki Tan[1,3], Kyoko Takashima[2], Takashige Sugimoto (1.Liberal Arts Education Center, Shimizu Campus, Tokai University., 2.School of Marine Science and Technology, Tokai University, 3.Japan Unmanned Vehicle exploration Agency, 4.NPO, the association for the environmental conservation of the ocean)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AOS13-03] Bottom-water intrusion and subsequent water exchange induced by Yamase around Mutsu Bay

*Satomi Fujisaki[1], Atsuhiko Isobe[1], Izumi Ogida[2], Yuki Kosaka[2] (1.Kyushu university, 2.Aomori Prefectural Fisheries Research Institute)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AOS13-04] The Generation Process of the Bottom Intrusion in the Bungo Channel

*Kana Maetani[1], Akihiko Morimoto[2], Xinyu Guo[2], Toru Miyama[3] (1.Graduate School of Science and Engineering, Ehime University, 2.Center for Marine Environmental Studies, Ehime University, 3.Japan Agency for Marine-Earth Science and Technology)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AOS13-05] Characteristics of bottom intrusion in the Bungo Channel

*Akihiko Morimoto[1], Shuya Fujita[1], Hidetaka Takeoka[1], Xinyu Guo[1] (1.Ehime University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AOS13-06] Role of Kuroshio Current in fish resource variability off southwest Japan

*Yushi Morioka[1], Sergey Varlamov[1], Yasumasa Miyazawa[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 102 1F

[A-OS13] Ocean circulation and material cycle in coastal seas

convener:Kiyoshi Tanaka(University of Tokyo), Akihiko Morimoto(Ehime University), Yuichi Hayami(Saga University), Kazuhiko Ichimi(Seto Inland Sea Regional Research Center, Kagawa University), Chairperson:Akihiko Morimoto, Yuichi Hayami

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[AOS13-07] Variation in hypoxic water mass in Ariake Sea -what consumed the dissolved oxygen?-

*Yuichi Hayami[1], Naoki Fujii[1], Hiroyuki Takasu[2], Yu Umezawa[3], Minoru Wada[2] (1.Saga University, 2.Nagasaki University, 3.Tokyo University of Agriculture and Technology)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[AOS13-08] Influence of Nori aquaculture-induced change in light environment on phytoplankton dynamics

*Naoya Minamiura[1], Soichi Yamaguchi[1] (1.Kyushu University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[AOS13-09] **Enhanced West Philippine Sea intrusion diminishes hypoxia conditions in the Pearl River estuary**

*Hon-Kit Lui[1,2], Chen-Tung Arthur Chen[1], Wei-Ping Hou[2], Jian-Ming Liau[2] (1.Department of Oceanography, National Sun Yat-sen University, 2.Taiwan Ocean Research Institute, National Applied Research Laboratories)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[AOS13-10] North Pacific seawater radiocarbon recorded in abalone shells obtained from Otsuchi Bay, Japan

*Ota Kosuke[1], Yusuke Yokoyama[1,2], Yosuke Miyairi[2], Jun Hayakawa[2], Naomi Sato[2], Hideki Fukuda[2], Kiyoshi Tanaka[2] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Atmosphere and Ocean Research Institute, The University of Tokyo)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[AOS13-11] Spreading of Radioactive Cesium off Joban coast through Large River Discharge

*Kiyoshi Tanaka[1], Seiya Nagao[2], Yujiro Kitade[3], Masato Niki[4], Takaaki Katsumata[4], Toru Miyama[5] (1.University of Tokyo, 2.Kanazawa University, 3.Tokyo University of Marine Science and Technology, 4.Tokai University, 5.Japan Agency for Marine-Earth Science and Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[AOS13-12] Development of a river-ocean seamless model for simulating river discharges around Kyushu

*Takahiro Tsutsumi[1], Shinichiro Kida[2], Ryusuke Kuroki[3], Yosuke Alexandre Yamashiki[3] (1.Interdisciplinary Graduate School of Engineering Science, Kyushu University, 2.Research Institute for Applied Mechanics, Kyushu University, 3.Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[A-OS13] Ocean circulation and material cycle in coastal seas

convener:Kiyoshi Tanaka(University of Tokyo), Akihiko Morimoto(Ehime University), Yuichi Hayami(Saga University), Kazuhiko Ichimi(Seto Inland Sea Regional Research Center, Kagawa University)

[AOS13-P01] An experimental study on degradation and fragmentation of marine plastic debris

*YUSEI YAMAGUCHI[1] (1.KYUSHU UNIVERSITY)

[AOS13-P02] Seafloor environment based on grain and concentrations of carbon, nitrogen and sulfur of surface sediment in Ise and Mikawa bays

*Atsuko Amano[1], Koji Seike[1] (1.National institute of Advanced Industrial Science and Technology)

[AOS13-P03] Hydrographic observations of estuarine circulation in Suruga Bay, Japan

*Kiyoshi Tanaka[1], Masato Niki[2], Kunio Kutsuwada[2], Akio Ishida[3], daisuke Takahashi[2], Takaaki Katsumata[2], Kazuyuki Uehara[2] (1.University of Tokyo, 2.Tokai University, 3.Tokoha University)

[AOS13-P04] Residence time of river water in the Jakarta Bay

*Akihiko Morimoto[1], Endro Soeyanto[2], Yuichi Hayami[3], Agus Sudaryanto[2], Suhendar Sachoemar[2] (1.Ehime University, 2.BPPT, Indonesia, 3.Saga University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

[A-OS13] Ocean circulation and material cycle in coastal seas

convener:Kiyoshi Tanaka(University of Tokyo), Akihiko Morimoto(Ehime University), Yuichi Hayami(Saga University), Kazuhiko Ichimi(Seto Inland Sea Regional Research Center, Kagawa University)

[AOS13-P01] An experimental study on degradation and fragmentation of marine plastic debris

*YUSEI YAMAGUCHI[1] (1.KYUSHU UNIVERSITY)

[AOS13-P02] Seafloor environment based on grain and concentrations of carbon, nitrogen and sulfur of surface sediment in Ise and Mikawa bays

*Atsuko Amano[1], Koji Seike[1] (1.National institute of Advanced Industrial Science and Technology)

[AOS13-P03] Hydrographic observations of estuarine circulation in Suruga Bay, Japan

*Kiyoshi Tanaka[1], Masato Niki[2], Kunio Kutsuwada[2], Akio Ishida[3], daisuke Takahashi[2], Takaaki Katsumata[2], Kazuyuki Uehara[2] (1.University of Tokyo, 2.Tokai University, 3.Tokoha University)

[AOS13-P04] Residence time of river water in the Jakarta Bay

*Akihiko Morimoto[1], Endro Soeyanto[2], Yuichi Hayami[3], Agus Sudaryanto[2], Suhendar Sachoemar[2] (1.Ehime University, 2.BPPT, Indonesia, 3.Saga University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 102 1F

[A-OS15] Freshwater discharge through rivers and estuaries to the ocean

convener:Shinichiro Kida(Research Institute for Applied Mechanics, Kyushu University), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Humio Mitsudera(Institute of Low Temperature Science, Hokkaido University), Chairperson:Shinichiro Kida(RIAM, Kyushu University), Humio Mitsudera(Hokkaido University, Institute of Low Temperature Science), Yosuke Yamashiki(GSAIS Kyoto University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[AOS15-01] The forefront research for flow and water quality estimations in coastal area using geo-stationary and polar orbital satellites data

★Invited Papers

*Yuji Sakuno[1] (1.Graduate School of Engineering, Hiroshima University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AOS15-02] Rainfall-Runoff-Inundation Processes and Modeling in a Humid Tropical River Basin

★Invited Papers

*Takahiro Sayama[1], Kodai Yamamoto[2], Ryoko Araki[2], Apip Apip[3], Eva Mia Siska[1], Kaoru Takara[4] (1.Disaster Prevention Research Institute, Kyoto University, 2.Graduate School of Engineering, Kyoto University, 3.LIPI, Indonesia, 4.Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AOS15-03] Role of river inflows from Kamchatka Peninsula in the Okhotsk Sea

*Toru Miyama[1], Humio Mitsudera[2] (1.Application Laboratory, Japan Agency for Marine-Earth Science and Technology, , 2.Institute of Low Temperature Science, Hokkaido University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AOS15-04] CHLOROPHYLL ESTIMATION OF LAKE AND COASTAL WATER USING REMOTE SENSING APPROACH

*Shweta Yadav[1], Yamashiki Yosuke[1], Junichi Susaki[1], Kanako Ishikawa[2], Yoh Yamashita[1] (1.Kyoto University, 2.LBERI)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AOS15-05] Maritime-continent coastal region as land-sea-air triple boundary layer and bio-anthroposphere

*Manabu D. Yamanaka[1] (1.Research Institute for Humanity and Nature / Professor Emeritus of Kobe University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AOS15-06] River-ocean interaction at the Ganges-Brahmaputra river mouth

*Shinichiro Kida[1], Dai Yamazaki[2] (1.Research Institute for Applied Mechanics, Kyushu University, 2.Institute of Industrial Sciences, The University of Tokyo)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

[A-OS15] Freshwater discharge through rivers and estuaries to the ocean

convener:Shinichiro Kida(Research Institute for Applied Mechanics, Kyushu University), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Humio Mitsudera(Institute of Low Temperature Science, Hokkaido University)

[AOS15-P01] MERIT Hydro: Global 90m-resolution hydrography map based on latest topography datasets.

*Dai Yamazaki[1] (1.Institute of Industrial Sciences, The University of Tokyo)

[AOS15-P02] Comparison of model performance between global- and regional-scale river models in simulating compound flooding in coastal deltas in the world's continental rivers

*Hiroaki Ikeuchi[1,2], Dai Yamazaki[2], Yukiko Hirabayashi[3] (1.Graduate School of Engineering, The University of Tokyo, 2.Institute of Industrial Science, The University of Tokyo, 3.Graduate School of Engineering and Science, Shibaura Instittute of Technology)

[AOS15-P03] Observation of a river plume by drone-mounted visible/infrared cameras

*Kenta Araki[1], Shinichiro Kida[2], Atsuhiko Isobe[2] (1.Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2.Research Institute for Applied Mechanics, Kyushu University)

[AOS15-P04] Numerical simulation of typhoon storm surge in the LUOYUAN Bay

*Nan Yuan[1], Humio Mitsudera [1] (1.Hokkaido University, the Institute of Low Temperature Science)

[AOS15-P05] Laboratory and numerical experiments on the ballooning of river-plume bulge

*fujita yusuke[1], Atsuhiko Isobe[2] (1.interdiscipinary graduate school of engineering science, Kyushu Univercity, 2.Research Institude for Applied Mechanics Kyushu Univ)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[A-OS16] Chemical and Biological Oceanography

convener:Namiha Yamada(National Institute of Advanced Industrial Science and Technology), Sayaka Yasunaka(Japan Agency for Marine-Earth Science and Technology), Hiroaki Saito(Atmosphere and Ocean Research Institute, The University of Tokyo)

[AOS16-P01] **Seasonal productions of dinoflagellate cysts in relation to environmental characteristics in Jinhae-Masan Bay, Korea: One year sediment trap observation**

*Hyeon Ho Shin[1] (1.Korea Institute of Ocean Science and Technology)

[AOS16-P02] Pacific anthropogenic carbon between 1991 and 2017

*Akihiko Murata[1], Carter B.R.[2,3], Feely, R.A. Feely, R.A.[3], Wanninkhof, R. Wanninkhof, R.[3], Shinya Kouketsu[1], Sonnerup R.E.[2], Pardo P.C.[4], Sabine C.L.[5], Johnson G. C.[3], Sloyan B.M.[6], Mecking S.[2], Tilbrook B.[6], Speer K.[7], Talley L.D.[8], Millero F.J.[9], Wijffels S.E.[6,10], Macdonald A.M.[10], Gruber N.[11], Bullister J. L.[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.University of Washington, 3.NOAA, 4.University of Tasmania, 5.University of Hawaii Manoa, 6.CSIRO, 7.The Florida State University, 8.University of California, 9.University of Miami, 10.Woods Hole Oceanographic Institution, 11.IBP)

[AOS16-P03] Spatio-temporal variability of surface water pCO2 and nutrients in the tropical Pacific from 1981 to 2015

*Sayaka Yasunaka[1], Shinya Kouketsu[1], P.G. Strutton[2], A.J. Sutton[3], Akihiko Murata[1], Shin-ichiro Nakaoka[4], Yukihiro Nojiri[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.University of Tasmania, 3.NOAA, 4.NIES)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[A-OS16] Chemical and Biological Oceanography

convener:Namiha Yamada(National Institute of Advanced Industrial Science and Technology), Sayaka Yasunaka(Japan Agency for Marine-Earth Science and Technology), Hiroaki Saito(Atmosphere and Ocean Research Institute, The University of Tokyo)

[AOS16-P01] **Seasonal productions of dinoflagellate cysts in relation to environmental characteristics in Jinhae-Masan Bay, Korea: One year sediment trap observation**

*Hyeon Ho Shin[1] (1.Korea Institute of Ocean Science and Technology)

[AOS16-P02] Pacific anthropogenic carbon between 1991 and 2017

*Akihiko Murata[1], Carter B.R.[2,3], Feely, R.A. Feely, R.A.[3], Wanninkhof, R. Wanninkhof, R.[3], Shinya Kouketsu[1], Sonnerup R.E.[2], Pardo P.C.[4], Sabine C.L.[5], Johnson G. C.[3], Sloyan B.M.[6], Mecking S.[2], Tilbrook B.[6], Speer K.[7], Talley L.D.[8], Millero F.J.[9], Wijffels S.E.[6,10], Macdonald A.M.[10], Gruber N.[11], Bullister J. L.[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.University of Washington, 3.NOAA, 4.University of Tasmania, 5.University of Hawaii Manoa, 6.CSIRO, 7.The Florida State University, 8.University of California, 9.University of Miami, 10.Woods Hole Oceanographic Institution, 11.IBP)

[AOS16-P03] Spatio-temporal variability of surface water pCO2 and nutrients in the tropical Pacific from 1981 to 2015

*Sayaka Yasunaka[1], Shinya Kouketsu[1], P.G. Strutton[2], A.J. Sutton[3], Akihiko Murata[1], Shin-ichiro Nakaoka[4], Yukihiro Nojiri[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.University of Tasmania, 3.NOAA, 4.NIES)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 303 3F

[A-OS16] Chemical and Biological Oceanography

convener:Namiha Yamada(National Institute of Advanced Industrial Science and Technology), Sayaka Yasunaka(Japan Agency for Marine-Earth Science and Technology), Hiroaki Saito(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Tsuneo Ono(Japan Fisheries Research and Education Agency), Naohiro Kosugi(気象研究所)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[AOS16-01] Variability of the growth rate for dissolved inorganic carbon in surface seawater along the 165°E line

*Chiho Tanizaki[1], Hisashi Ono[2], Masao Ishii[2], Atsushi Kojima[1], Shinji Masuda[1], Kazutaka Enyo[1], Daisuke Sasano[1], Toshiya NAKANO[1] (1.Japan Meteorological Agency, 2.Meteorological Research Institute, Japan Meteorological Agency)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AOS16-02] Seasonal variations of oceanic CO_2 disequilibrium and anthropogenic CO_2 in the subarctic North Pacific

*Bofeng Li[1], Shukuta Satori[1], Kasai Hiromi[2], Hiroshi Kuroda[2], Taniuchi Yukiko[2], Daisuke Hasegawa[3], Yutaka Watanabe[1] (1.Hokkaido University, 2.Hokkaido National Fisheries Research Institute, Japan Fisheries and Education Research , 3.Tohoku National Fisheries Research Institute, Japan Fisheries and Education Research)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AOS16-03] An evaluation of current and future ocean acidification based on pCO_2 database around Okinawa Island

*Naohiro Kosugi[1], Hiroyuki Tsujino[1], Masao Ishii[1] (1.Meteorological Research Institute)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AOS16-04] Reconstruction of spatiotemporal change of anthropogenic fixed nitrogen in the western North Pacific

*Yutaka Watanabe[1], Kouichi Fujita[1], BOFENG LI[1] (1.Hokkaido University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AOS16-05] On the mechanism of significant increasing trend of silicate in intermediate layer of Oyashio region

*Tsuneo Ono[1] (1.Fisheries Research and Education Agency)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AOS16-06] Systematics of aluminum, manganese, iron, cobalt, and lead in the North Pacific Ocean observed during ocean-section study of GEOTRACES Japan

*Yoshiki Sohrin[1], Linjie Zheng[1] (1.Institute for Chemical Research, Kyoto University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 301A 3F

[A-OS19] Dynamics of oceanic and atmospheric waves, vortices, and circulations

convener:Yuki Tanaka(Graduate School of Science, The University of Tokyo), Ryo Furue(APL/JAMSTEC), Yukiharu Hisaki(University of the Ryukyus), Norihiko Sugimoto(Keio University, Department of Physics), Chairperson:Norihiko Sugimoto, Ryo Furue

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AOS19-01] Instability of Ekman pumping

★Invited Papers

*Yoshiaki Miyamoto[1], Daivd S Nolan[2], Norihiko Sugimoto[3] (1.Faculty of Environment and Information Studies, Keio University, 2.Rosenstiel School of Marine and Atmospheric Science, University of Miami, 3.Keio University, Department of Physics)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AOS19-02] Extratropical Cyclone Structures around Japan -Comparison between Extratropical Cyclones Developing around Japan and those in Northwestern Atlantic Ocean-

*Eigo Tochimoto[1], Hiroshi Niino[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AOS19-03] Application of a new wave energy flux formulation to assessment of tropical wave propagation dynamics: Diagnostics for the tropical synoptic-scale wave disturbances in the Maritime Continent-northern Australian region

*Fukutomi Yoshiki[1], Hidenori Aiki[1] (1.Institute for Space-Earth Environmental Reasearch, Nagoya University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AOS19-04] Direct measurement of turbulent fluxes at sea-air interface by micrometeorological technique

★Invited Papers

*Fumiyoshi Kondo[1], Shujiro Komiya[2], Kosuke Noborio[3], Hidenori Aiki[4], Kunio Kutsuwada[5], Mitsuo Uematsu[6], Osamu Tsukamoto[7] (1.Japan Coast Guard Academy, 2.Max Planck Institute for Biogeochemistry, 3.Meiji University, 4.Nagoya University , 5.Tokai University, 6.The University of Tokyo, 7.Okayama University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AOS19-05] Swell-Dominant Surface Waves Inherent in the Shape of the Rias Coast facing the western North Pacific

*Kosei Komatsu[1,2], Takaki Fujii[1,2], Kiyoshi Tanaka[2] (1.Graduate School of Frontier Sciences, The University of Tokyo, 2.Atmosphere and Ocean Research Institute, The University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AOS19-06] **Variabilities of the Sea Surface Height in the Kuril Basin of the Okhotsk Sea: Coherent shelf-trapped mode and Rossby wave-like mode**

*Vigan Mensah[1], Kay I. Ohshima[1] (1.Institute of Low Temperature Science)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 301A 3F

[A-OS19] Dynamics of oceanic and atmospheric waves, vortices, and circulations

convener:Yuki Tanaka(Graduate School of Science, The University of Tokyo), Ryo Furue(APL/JAMSTEC), Yukiharu Hisaki(University of the Ryukyus), Norihiko Sugimoto(Keio University, Department of Physics), Chairperson:Yukiharu Hisaki(琉球大学理学部), Hidenori AIKI

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AOS19-07] Dynamics of water exchange processes at a deep submarine canyon off the western coast of the Sakhaline which causes the origin of the cold water belt along the Soya Warm Current

★Invited Papers

*Humio Mitsudera[1], Hiroyuki Iida[2] (1.Institute of Low Temperature Science, Hokkaido University, 2.Graduate School of Environmental Science)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AOS19-08] Generation Mechanism of Tropical Instability Waves in the Equatorial Pacific Ocean

*Yuki Tanaka[1], Toshiyuki Hibiya[1] (1.Graduate School of Science, The University of Tokyo)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AOS19-09] Annual Rossby waves below the pycnocline in the Indian Ocean

*Motoki Nagura[1] (1.Japan Agency for Marine-Earth Science and Technology)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AOS19-10] Eddies observed by Argo floats

★Invited Papers

*Katsuro Katsumata[1] (1.JAMSTEC)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AOS19-11] Rhythmic Phenomena in Nonlinear Systems and Oceanic General Circulation

*Shinya Shimokawa[1], Tomonori Matsuura[2] (1.National Research Institute for Earth Science and Disaster Prevention, 2.University of Toyama)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AOS19-12] Control of the ocean circulation by bottom topography and generation of mesoscale disturbances

*Yuri Kase[1], Tomonori Matsuura[1] (1.National university corporation University of Toyama)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[A-OS19] Dynamics of oceanic and atmospheric waves, vortices, and circulations

convener:Yuki Tanaka(Graduate School of Science, The University of Tokyo), Ryo Furue(APL/JAMSTEC), Yukiharu Hisaki(University of the Ryukyus), Norihiko Sugimoto(Keio University, Department of Physics)

[AOS19-P01] **Atmospheric super rotation developed in a GCM (AFES-Venus)**

*Norihiko Sugimoto[1], Masahiro Takagi[2], Yoshihisa Matsuda[3] (1.Keio University, Department of Physics, 2.Kyoto Sangyo University, Department of Physics, 3.Tokyo Gakugei University, Department of Natural Sciences)

[AOS19-P02] Data assimilation of the Venus atmosphere assuming radio occultation measurement by small satellites

*Mirai Abe[1], Norihiko Sugimoto[1], Yukako Kikuchi[2], Asako Hosono[3], Hiroki Ando[4], Masahiro Takagi[4], Itziar Garate Lopez[5], Sebastien Lebonnois[6], Chi Ao[7] (1.Keio University, 2.Yokohama Futaba High School, 3.Toshimagaoka Women High School, 4.Kyoto Sangyo University, 5.Euskal Herriko Unibertsitatea, 6.Sorbonne Universite, 7.Jet Propulsion Laboratory)

[AOS19-P03] Relationship between solar wind and atmospheric circulation

*Paul Prikryl[1] (1.Physics Department University of New Brunswick and Geomagnetic Laboratory Natural Resources Canada)

[AOS19-P04] Contribution of the Atlantic storm track to the Euro-Russian blocking maintenance in summer 2010

*Akira Yamazaki[1] (1.Application Laboratory, Japan Agency for Marine-Earth Science and Technology)

[AOS19-P05] Instabilities in Ekman layer and roll structures in a tropical cyclone boundary layer

*Junshi Ito[1], Hiroshi Niino[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[AOS19-P06] Mathematical description of the internal waves in a proximity of the bottom of the Ocean.

*andrei giniatoulline[1], german tobar[1] (1.Department of Mathematics, Los Andes University, Bogota, Colombia, South America)

[AOS19-P07] How deterministic are the deep zonal jets?

*Ryo Furue[1], Masami Nonaka[1], Hideharu Sasaki[1] (1.APL/JAMSTEC)

[AOS19-P08] The impact of tidal mixing on the Indonesian Throughflow

*Kohki Shiroyama[1], Shinichiro Kida[2], Hideharu Sasaki[3], Ryo Furue[3] (1.Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2.Research Institute for Applied Mechanics Kyushu University, 3.JAMSTEC. APL)

[AOS19-P09] **Verification for subsurface oceanic structure in OFES outputs driven by different wind data sets (NCEP/NCAR and QSCAT)in the tropical Pacific Ocean**

*Hiroshige Fukunaga[1], Kunio Kutsuwada[1], Akira Kakiuchi[1], Yuma Yanagida[1], Hideharu Sasaki[2], Yoshikazu Sasai[2] (1.Tokai University, 2.JAMSTEC)

[AOS19-P10] Inter-comparison of ocean wave data from drifting buoys, moored GPS buoys and reanalysis data

*Yukiharu Hisaki[1] (1.University of the Ryukyus)

[AOS19-P11] Merge and Separation of ocean eddies around the Kuroshio Extension

*koutarou matsuhashi[1], Kazuyuki Uehara[1] (1.The Graduate School of Marine Science Technology)

[AOS19-P12] Influence of eddy-trapped water mass reaching 137E survey line using OGCM and a particle-tracking method

★Invited Papers

*Hideyuki Nakano[1], Hiroyuki Tsujino[1], Kei Sakamoto[1], Shogo Urakawa[1], Takahiro Toyoda[1], Goro Yamanaka[1], Yoshimasa Matsumura[2] (1.Meteorological Research Institute, 2.Atmosphere and ocean research Institute, the University of Tokyo)

[AOS19-P13] A study on the variability of the deep ocean circulation during glacial climate with a climate model of intermediate complexity

*Taigo Ando[1], Akira Oka[1] (1.Atmosphere and Ocean Research Institute, University of Tokyo)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

[A-OS19] Dynamics of oceanic and atmospheric waves, vortices, and circulations

convener:Yuki Tanaka(Graduate School of Science, The University of Tokyo), Ryo Furue(APL/JAMSTEC), Yukiharu Hisaki(University of the Ryukyus), Norihiko Sugimoto(Keio University, Department of Physics)

[AOS19-P01] **Atmospheric super rotation developed in a GCM (AFES-Venus)**

*Hiroshige Fukunaga[1], Kunio Kutsuwada[1], Akira Kakiuchi[1], Yuma Yanagida[1], Hideharu Sasaki[2], Yoshikazu Sasai[2] (1.Tokai University, 2.JAMSTEC)

[AOS19-P10] Inter-comparison of ocean wave data from drifting buoys, moored GPS buoys and reanalysis data

*Yukiharu Hisaki[1] (1.University of the Ryukyus)

[AOS19-P11] Merge and Separation of ocean eddies around the Kuroshio Extension

*koutarou matsuhashi[1], Kazuyuki Uehara[1] (1.The Graduate School of Marine Science Technology)

[AOS19-P12] Influence of eddy-trapped water mass reaching 137E survey line using OGCM and a particle-tracking method

★Invited Papers

*Hideyuki Nakano[1], Hiroyuki Tsujino[1], Kei Sakamoto[1], Shogo Urakawa[1], Takahiro Toyoda[1], Goro Yamanaka[1], Yoshimasa Matsumura[2] (1.Meteorological Research Institute, 2.Atmosphere and ocean research Institute, the University of Tokyo)

[AOS19-P13] A study on the variability of the deep ocean circulation during glacial climate with a climate model of intermediate complexity

*Taigo Ando[1], Akira Oka[1] (1.Atmosphere and Ocean Research Institute, University of Tokyo)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 105 1F

[A-HW24] Isotope Hydrology 2019

convener:Masaya Yasuhara(Rissho Univ.), Kohei Kazahaya(Geological Survey of Japan, AIST), Shinji Ohsawa(Institute for Geothermal Sciences, Graduate School of Science, Kyoto University), Kazuyoshi Asai(Geo Science Laboratory), Chairperson:Masaya Yasuhara(Rissho Univ.), Noritoshi Morikawa(産業技術総合研究所活断層・火山研究部門)

9:00 AM - 9:30 AM JST | 12:00 AM - 12:30 AM UTC

[AHW24-01] The use of natural abundances of stable isotopes to elucidate the nitrogen dynamics in plant-soil systems

★Invited Papers

*Keisuke Koba[1] (1.Center for Ecological Research, Kyoto University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AHW24-02] Reconstruction of local temporal variation on atmospheric sulfur hexafluoride concentration in the Kyoto Basin by multiple environmental tracer and mass transport analyses

*Koki Kashiwaya[1], Taishi Hori[1], Ryuta Hazama[2], Yoichi Sakuma[3], Katsuaki Koike[1] (1.Kyoto University, 2.Osaka Sangyo University, 3.Tokyo Institute of Technology)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AHW24-03] Quantitative reconstruction of the humidity in the moisture source region based on the ^{17}O-excess in precipitation on a subtropical island

Yuina Uechi[1], *Ryu Uemura[1] (1.University of the Ryukyus)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AHW24-04] Identification of deep groundwater recharge system in an intermontane basin

*Takashi Nakamura[1], Kei Nishida[1], Naim Mohamad[2], Bijay Man Shakya[1], Kazuyoshi Asai[4], Sresh Das Shrestha[3] (1.ICRE, University of YAMANASHI, 2.University of Yamanashi, 3.CDG, Tribhuvan University, 4.Geo-Science Laboratory)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 105 1F

[A-HW24] Isotope Hydrology 2019

convener:Masaya Yasuhara(Rissho Univ.), Kohei Kazahaya(Geological Survey of Japan, AIST), Shinji Ohsawa(Institute for Geothermal Sciences, Graduate School of Science, Kyoto University), Kazuyoshi Asai(Geo Science Laboratory), Chairperson:Noritoshi Morikawa(産業技術総合研究所活断層・火山研究部門), Kazuyoshi Asai(Geo-Science Laboratory), Kohei Kazahaya(Geological Survey of Japan, AIST)

10:45 AM - 11:15 AM JST | 1:45 AM - 2:15 AM UTC

[AHW24-05] The discharge rate of the Arima-type deep brine discharge in Ooshika-mura, Nagano Prefecture

★Invited Papers

*Fumitake Kusuhara[1] (1.Central Research Institute of Electric Power Industry)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AHW24-06] Sublacustrine hydrothermal system of the active crater lake, Yudamari of Aso Volcano inferred from Mg budget of the lake

*Shinji Ohsawa[1], Takeshi Saito[2], Kazuhiro Amita[3] (1.Institute for Geothermal Sciences, Graduate School of Science, Kyoto University, 2.Academic Assembly School of Science and Technology, Shinshu University, 3.Graduate School of Engineering Science, Akita University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AHW24-07] Spatial distribution of chemical compositions, hydrogen and oxygen isotopic ratios of stream water of the Shimanto River area, southwestern Japan

*Masaaki Takahashi[1], Hinako Shimizu[1], Kohei Kazahaya[1], Masaya Yasuhara[2,1] (1.The National Institute of Advanced Industrial Science and Technology, 2.Rissho University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AHW24-08] An isotopic study on shallow groundwater origins in a densely-populated area in Shinagawa, central Tokyo, Japan

*Masaya Yasuhara[1], Akihiko Inamura[2], Takashi Nakamura[3], Kazuyoshi Asai[4] (1.Rissho Univ., 2.Geological Survey of Japan, AIST, 3.Yamanashi Univ., 4.Geo Science Laboratory)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

[A-HW24] Isotope Hydrology 2019

convener:Masaya Yasuhara(Rissho Univ.), Kohei Kazahaya(Geological Survey of Japan, AIST), Shinji Ohsawa(Institute for Geothermal Sciences, Graduate School of Science, Kyoto University), Kazuyoshi Asai(Geo Science Laboratory)

[AHW24-P01] Geochemical features for spring at Izu Peninsula

*Kazuyoshi Asai[1], Kazumi Asai[1] (1.Geo Science Laboratory)

[AHW24-P02] Acidification process of shallow groundwater in an alluvial fan in Ueda City, Nagano, Japan

Ran Takahashi[1], *Masaya Yasuhara[2], Seongwon Lee[2], Takashi Nakamura[3], Kazuyoshi Asai[4] (1.Undergraduate student, Rissho Univ., 2.Rissho Univ., 3.Yamanashi Univ., 4.Geo Science Laboratory)

[AHW24-P03] Hydroecological study on fresh water copepod in Chino-ike ('Bloody lake'), an ephemeral lake on the top of Mt. Akagi, central Japan

Hirano Yuri[1], *Masaya Yasuhara[2], Seongwon Lee[2], Yasuhiro Funyu[3], Nozomu Iwasaki[2], Natsumi Shimoda[2] (1. Undergraduate student, Rissho Univ., 2.Rissho Univ., 3.Graduate student, Rissho Univ.)

[AHW24-P04] **Cross-sectional distribution in water chemistry and oxygen and hydrogen isotopic ratios in Fuku River, Saitama, Japan**

*Manatsu Kimura[1], Yasuhara Masaya[2], Seongwon Lee[2] (1.Graduate School of Geo-Environmental Science, Rissho University, 2.Faculty of Geo-Environmental Science, Rissho University)

[AHW24-P05] On concentration and origin of chloride ion in small rivers in Jyoboji area, Fujioka, Gunma, Japan

*Taketoshi Hasegawa[1], Masaya Yasuhara[2], Seongwon Lee[2] (1.Rissho University Graduate School of Geo-environmental Science Environmental Systems Science, 2.Rissho Univ.)

[AHW24-P06] Geochemical characteristics and origin of groundwater in central to eastern Hokkaido

*Yusei Nakagaki[1] (1.Chiba University)

[AHW24-P07] Identification of hydrological characteristics on the groundwater recharge in volcanic and non-volcanic mountains

*sano anna[1], Takashi Nakamura[1], Kei Nishida[1] (1.International Research Center for River Basin Environment, University of YAMANASHI)

[AHW24-P08] Analysis of spring water formation mechanism used by ^{222}Rn concentration at Masutomi-Onsen located in Yamanashi, Japan

*Eiki Mochizuki[1], Takuya Hayakawa[1], Hiroshi Kobayashi[1] (1.Yamanashi Institute of Public Health and Environment)

[AHW24-P09] Migration Behavior of Radiocesium Derived from the Fukushima Dai-Ichi Nuclear Power Plant Accident in Natsui River and Tone River

*Deddy Irawan Permana Putra[1], Shinya Ochiai[2], Seiichi Tomihara[3], Shun Watanabe[4], Kyuma Suzuki[4], Seiya Nagao[2] (1.Kanazawa University, Graduate School of Natural Science and Technology, 2.Low Level Radioactivity Laboratory, Kanazawa University, 3.Aquamarine Fukushima, 4.Gunma Prefectural Fisheries Experiment Station)

[AHW24-P10] Estimation of excess air component in groundwater by using dissolved Argon concentration

*Kazumi Asai[1], Kazuyoshi Asai[1] (1.Chikyukagakukenkyusho inc)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[A-HW24] Isotope Hydrology 2019

convener:Masaya Yasuhara(Rissho Univ.), Kohei Kazahaya(Geological Survey of Japan, AIST), Shinji Ohsawa(Institute for Geothermal Sciences, Graduate School of Science, Kyoto University), Kazuyoshi Asai(Geo Science Laboratory)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 104 1F

[A-CG33] Extratropical oceans and atmosphere

convener:Kazuaki Nishii(Graduate School of Bioresources, Mie University), Yoshi N Sasaki(Hokkaido University), Hatsumi Nishikawa(Institute of Low Temperature Science, Hokkaido University), Shun Ohishi(Division for Land-Ocean Ecosystem Research, Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Kazuaki Nishii(三重大学)

1:45 PM - 2:05 PM JST | 4:45 AM - 5:05 AM UTC

[ACG33-01] Gulf Stream and Kuroshio are synchronized

★Invited Papers

*Tsubasa Kohyama[1], Hiroaki Miura[1], Shoichiro Kido[1] (1.Department of Earth and Planetary Science, The University of Tokyo)

2:05 PM - 2:20 PM JST | 5:05 AM - 5:20 AM UTC

[ACG33-02] A study on mixed layer depth variability in the Kuroshio Extension region based on a frontal Ekman model

*Tomoki Tozuka[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

2:20 PM - 2:35 PM JST | 5:20 AM - 5:35 AM UTC

[ACG33-03] Mechanisms of Reemergence in the North Pacific revealed by Mixed Layer Heat Budget Analysis

*Kazumichi Murata[1], Shoichiro Kido[1], Tomoki Tozuka[1] (1.Department of Earth and Planetary Science, School of Science, The University of Tokyo)

2:35 PM - 2:50 PM JST | 5:35 AM - 5:50 AM UTC

[ACG33-04] Formation mechanism for the North Pacific Transition domain SST and SSS fronts

*Hatsumi Nishikawa[1], Humio Mitsudera[1], Takeshi Okunishi[2], Shin-ichi Ito[3], Taku Wagawa[4], Daisuke Hasegawa[2], Toru Miyama[5], Hitoshi Kaneko[2] (1.Institute of Low Temperature Science, Hokkaido University, 2.Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 3.Atmosphere and Ocean Research Institute, The University of Tokyo, 4.Japan Sea National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 5.Japan Agency for Marine-Earth Science and Technology)

2:50 PM - 3:10 PM JST | 5:50 AM - 6:10 AM UTC

[ACG33-05] Impact of the Kuroshio front on frontal structure of an extratropical cyclone associated with heavy precipitation

★Invited Papers

*Hidetaka Hirata[1], Ryuichi Kawamura[2], Mayumi K Yoshioka[1], Masami Nonaka[3], Kazuhisa Tsuboki[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Department of Earth and Planetary Sciences, Kyushu University, 3.Application Laboratory, Japan Agency for Marine-Earth Science and Technology)

3:10 PM - 3:15 PM JST | 6:10 AM - 6:15 AM UTC

[ACG33-06] Discussion on future studies on the role of midlatitude oceans

*Kazuaki Nishii[1] (1.Graduate School of Bioresources, Mie University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 104 1F

[A-CG33] Extratropical oceans and atmosphere

convener:Kazuaki Nishii(Graduate School of Bioresources, Mie University), Yoshi N Sasaki(Hokkaido University), Hatsumi Nishikawa(Institute of Low Temperature Science, Hokkaido University), Shun Ohishi(Division for Land-Ocean Ecosystem Research, Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Shun Ohishi

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[ACG33-07] Intra-seasonal variability of oceanic low-level cloud in summertime North Pacific and its interaction with sea surface temperature

★Invited Papers

*Naoya Takahashi[1], Tadahiro Hayasaka[1] (1.Center for Atmospheric and Oceanic Studies, Graduate School of Science, Tohoku University,)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[ACG33-08] **Sea surface temperature trend in the East China Sea during the 20th century simulated by a regional ocean model**

*Yoshi N Sasaki[1], Chisato Umeda[1] (1.Hokkaido University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[ACG33-09] Kuroshio Extension and Gulf Stream's influences on the variability of near-surface baroclinicity and the associated atmospheric fields

★Invited Papers

*Bunmei Taguchi[1], Kazuaki Nishii[2], Hisashi Nakamura[1,3] (1.Research Center for Advanced Science and Technology, The University of Tokyo, 2.Graduate School of Bioresources, Mie University, 3. Application Laboratory, Japan Agency of Marine-Earth Science and Technology)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[ACG33-10] Baroclinic Annular Mode in the Southern Hemisphere: Its Reproducibility and Sensitivity to Ocean Fronts assessed in Aqua-Planet Experiments

*Morio Nakayama[1], Masatoshi Mizukoshi[1], Hisashi Nakamura[1], Yu Kosaka[1], Bunmei Taguchi[1], Masato Mori[1], Fumiaki Ogawa[2] (1.RCAST, the University of Tokyo , 2.The University of Bergen)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[ACG33-11] **Hydro-climatic variation in northwestern China and its multi-decadal to multi-centennial teleconnection with the Pacific Ocean**

*Harry F Lee[1] (1.The Chinese University of Hong Kong)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[ACG33-12] Atmospheric zonal-mean meridional circulation and midlatitude oceanic fronts

*Kazuaki Nishii[1], Bunmei Taguchi[2], Hisashi Nakamura[2] (1.Graduate School of Bioresources, Mie University, 2.Research Center for Advanced Science and Technology, The University of Tokyo)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_12

[A-CG33] Extratropical oceans and atmosphere

convener:Kazuaki Nishii(Graduate School of Bioresources, Mie University), Yoshi N Sasaki(Hokkaido University), Hatsumi Nishikawa(Institute of Low Temperature Science, Hokkaido University), Shun Ohishi(Division for Land-Ocean Ecosystem Research, Institute for Space-Earth Environmental Research, Nagoya University)

[ACG33-P01] Analysis of water exchange processes at the Subarctic Boundary of the North Pacific using particle tracking method

*Ashida Hayato[1], Humio Mitsudera[2], Hatsumi Nishikawa[2] (1. Department of Earth and Planetary Sciences, School of Science, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University)

[ACG33-P02] Method to evaluate the effect of obduction on properties in the ocean mixed layer

*Yoshimi Kawai[1] (1.Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology)

[ACG33-P03] Influence of the interannual-scale Bering Sea ice variation on cold air outbreaks

*Mizuki Iida[1], Shusaku Sugimoto[1], Toshio Suga[1] (1.Physical Oceanography Laboratory Department of Geophysics, Graduate School of Science, Tohoku University)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[H-DS11] Subaqueous Landslides and Their Anthropogenic Impact for Coastal Regions

convener:Yujin Kitamura(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS))

[HDS11-P01] Deformed sediment gravity flow deposits associated with bypassing slides:an example from the Miocene Ushikiri Formation, Southwest Japan

*Miki Kobayashi[1], Tetsuya Sakai[2] (1.Nippon Koei, 2.Shimane University)

[HDS11-P02] Submarine Landslide and Resulting Tsunami on the Continental Shelf Slope off Shikoku

*Youdai Gon[1], Toshitaka Baba[1], Tetsuo Matsuno, Mitsuru Hayashi, Hiroshi Ichihara (1.Tokushima University graduate school)

[HDS11-P03] Sedimentary environment estimated from physical properties of sediment core collected during the cruise of Hakuho-maru KH-18-3 in the South Yatsushiro sea, western Kyushu.

*Koki Hori[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Scientists (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University , 2.Department of Earth and Environmental Sciences, Graduate School of Science and Engineering , Kagoshima University)

[HDS11-P04] Variation in vane shear strength and magnetic susceptibility in the cores recovered by Hakuho-maru KH-18-3 cruise in Yatsushiro sea

*Yujin Kitamura[1], Haruka Kageyama[2], Kaede Yamasaki[2], Ryoya Goto[2], Koki Hori[2], Yuta Ikebata[2], Kuniyo Kawabata[1], Daiki Oyama[2], Hakuho-maru KH-18-3 Scientists (1.Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University, 2.Department of Earth and Environmental Sciences, Faculty of Science, Kagoshima University)

[HDS11-P05] Identification of turbidites in the Yatsushiro Sea surface sediment core samples from non-destructive measurements: Hakuho-maru KH-18-3 Cruise, Yatsushiro Sea, Western Kyushu, Japan

*Ryoya Goto[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Cruise Scientist (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Department of Earth and Environmental Sciences, Graduate School of Science, Kagoshima University)

[HDS11-P06] Revised columnar section based on grain size distribution analysis of samples from Hakuho-maru KH-18-3 in Yatsushiro sea

*Yuta Ikebata[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Scientists Family (1.Kyusyu University Graduate School Of Science Earth and Planetary Science, 2.Graduate school of science, Kagoshima University)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

convener:Yujin Kitamura(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS)), Chairperson:Yujin Kitamura(Kagoshima University), Masayuki Utsunomiya(Research Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Yasuhiro Yamada(JAMSTEC)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[HDS11-01] Distribution and sedimentological characteristics of the submarine landslides filling Hidaka Trough, offshore southern Hokkaido, northern Japan with special attention to the uppermost Quaternary submarine landslide bodies

*Hiroyuki Arato[1] (1.Graduate School of International Resource Sciences, Akita University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[HDS11-02] Origin and distribution of mass-transport deposits in the Pleistocene forearc basin, central Japan, deduced from tephro- and biostratigraphy

*Masayuki Utsunomiya[1], Yuzuru Yamamoto[2], Kiyohide Mizuno[1] (1.Geological Survey of Japan, AIST, 2.JAMSTEC)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[HDS11-03] Physico-chemical properties of sediment cores from Yatsushiro Sea, western Kyushu

*Yujin Kitamura[1], Ryoya Goto[2], Koki Hori[2], Yuta Ikebata[2], Haruka Kageyama[2], Kuniyo Kawabata[1], Daiki Oyama[1], Kaede Yamasaki[2], Hakuho-maru KH-18-3 Scientists (1.Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University, 2.Atmosphere and Ocean Research Institute, The University of Tokyo)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[H-DS12] Advanced Remote Sensing toward Mega-Disaster Response

convener:Young-Joo Kwak(ICHARM-UNESCO: International Centre for Water Hazard And Risk Management), Wataru Takeuchi(Institute of Industrial Science, The University of Tokyo)

[HDS12-P01] Satellite-based assessment of electricity restoration efforts in Puerto Rico after Hurricane Maria

*Miguel O Roman[1], Eleanor Stokes[2,3], Zhuosen Wang[2,3], Virginia Kalb[3], Ranjay Shrestha[4,3] (1.Earth from Space Institute, Universities Space Research Association, 2.Earth System Science Interdisciplinary Center, University of Maryland, 3.NASA Goddard Space Flight Center, 4.Science Systems and Applications, Inc)

[HDS12-P02] **Flood inundation forecasting coupled with in-situ water level and satellite data**

*Young-Joo Kwak[1], Jonggeol Park[2], Wataru Takeuchi[3] (1.ICHARM-UNESCO: International Centre for Water Hazard And Risk Management, 2.Tokyo University of Information and Sciences, 3.University of Tokyo)

[HDS12-P03] Long term monitoring of flood damage in the coastal area of Bangladesh

★Invited Papers

*Park Jonggeol[1], Young-Joo Kwak[2] (1.Tokyo University of Information Sciences, 2.ICHARM-UNESCO)

[HDS12-P04] Automatic shoreline detection and coastal change detection using multiple satellite data in Bangladesh

*Young-Joo Kwak[1] (1.ICHARM-UNESCO: International Centre for Water Hazard And Risk Management)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_14

[H-DS12] Advanced Remote Sensing toward Mega-Disaster Response

convener:Young-Joo Kwak(ICHARM-UNESCO: International Centre for Water Hazard And Risk Management), Wataru Takeuchi(Institute of Industrial Science, The University of Tokyo)

[HDS12-P01] Satellite-based assessment of electricity restoration efforts in Puerto Rico after Hurricane Maria

*Miguel O Roman[1], Eleanor Stokes[2,3], Zhuosen Wang[2,3], Virginia Kalb[3], Ranjay Shrestha[4,3] (1.Earth from Space Institute, Universities Space Research Association, 2.Earth System Science Interdisciplinary Center, University of Maryland, 3.NASA Goddard Space Flight Center, 4.Science Systems and Applications, Inc)

[HDS12-P02] Flood inundation forecasting coupled with in-situ water level and satellite data

*Young-Joo Kwak[1], Jonggeol Park[2], Wataru Takeuchi[3] (1.ICHARM-UNESCO: International Centre for Water Hazard And Risk Management, 2.Tokyo University of Information and Sciences, 3.University of Tokyo)

[HDS12-P03] Long term monitoring of flood damage in the coastal area of Bangladesh

★Invited Papers

*Park Jonggeol[1], Young-Joo Kwak[2] (1.Tokyo University of Information Sciences, 2.ICHARM-UNESCO)

[HDS12-P04] Automatic shoreline detection and coastal change detection using multiple satellite data in Bangladesh

*Young-Joo Kwak[1] (1.ICHARM-UNESCO: International Centre for Water Hazard And Risk Management)

[J] Oral | H (Human Geosciences)：H-DS Disaster geosciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 106 1F

[H-DS14] Geohazards in humid, tectonically active countries and their precursors

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Hiroshi YAGI(Faculty of Art, Science and Education, Yamagata University), Satoru Kojima(Department of Civil Engineering, Gifu University), Taro Uchida(National Institute for Land and Infrastructure Management), Chairperson:Satoshi Ishimaru

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[HDS14-01] The sources of landslides occurred by the 2018 Hokkaido Eastern Iburi Earthquake

*Satoshi Ishimaru[1], Wataru Hirose[1], Gentaro Kawakami[1], Ryo Takahashi[1], Yoshihiro Kase[1], Ken'ichi Koshimizu[1], Hiromichi Koyasu[1], Masahiro Chigira[2], Jun Tajika[3] (1.Geological Survey of Hokkaido, 2.Kyoto University, 3.Docon Co., Ltd.)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[HDS14-02] Feature of landslide of pyroclastic fall deposits induced by 2018 Hokkaido Eastern Iburi Earthquake, and its relation with damage

*Jun Tajika[1], Kazuo Amemiya[2], Masahiro Chigira[3], Satoshi Ishimaru[4], Akio Koike[1], Hidetoshi Kon[1], Kenji Kizaki[5], Nobuo Yamane[6] (1.Docon Co.,Ltd., 2.Bousai Chishitsu Kogyo Co.,Ltd., 3.Kyoto University, 4.Geological Survey of Hokkaido, HRO, 5.Kizaki PE Office, 6.Terre Research Co.)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HDS14-03] Influence of slope cutting on failures induced by the July heavy rain, and the Iburi-tobu earthquake, 2018.

*Hidehisa Nagata[1] (1.Fu-Sui-Do Company Limited)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HDS14-04] Slope failures occurred in the southwest part of the Izu-oshima Island in geological time, NE Japan

*Takehiko Suzuki[1], Masahiro Chigira[2] (1.Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, 2.Disaster Prevention Research Institute, Kyoto University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HDS14-05] The strain rate observation by the borehole inclinometer on the bedrock creep slopes in Akadani-west area

*Atsuhiko Kinoshita[1,2], Yasutaka Tanaka[2], Wataru Sakurai[1], Taro Uchida[1], Koichiro Hayashi[3], Yasuuchi Kubota[3], Katsushi Kawato[4] (1.National Institute for Land and Infrastructure Management, 2.Sediment Disaster Prevention Technology Center, Kinki Developing Regional Bureau, Ministry of Land, Infrastructure, Transport and Tourism , 3.OYO Corporation, 4.NIPPON ENGINEERING CONSULTANTS CO., LTD.)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[HDS14-06] Assessing Potential Landslide Areas Due to Earthquake Using Three-Dimensional Resistivity Datasets from Across a Wide Area

*Yusuke Sakai[1], Taro Uchida[1], YASUMASA FUJIWARA[2] (1.National Institute for Land and Infrastructure Management , 2.Eight-Japan Engineering Consultants)

[J] Oral | H (Human Geosciences)：H-DS Disaster geosciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 106 1F

[H-DS14] Geohazards in humid, tectonically active countries and their precursors

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Hiroshi YAGI(Faculty of Art, Science and Education, Yamagata University), Satoru Kojima(Department of Civil Engineering, Gifu University), Taro Uchida(National Institute for Land and Infrastructure Management), Chairperson:Chigira Masahiro, Taro Uchida

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[HDS14-07] Prediction of shallow landslides and debris flow by rainstorm: dynamic hazard mapping toward disaster mitigation

*Yuki Matsushi[1] (1.Disaster Prevention Research Institute, Kyoto University)

2:00 PM - 2:30 PM JST | 5:00 AM - 5:30 AM UTC

[HDS14-08] Land slide warning judgment mesh information of the Meteorological Agency using the Soil Water Index

★Invited Papers

*KENJI OKADA[1] (1.Japan Meteorological Agency)

2:30 PM - 3:00 PM JST | 5:30 AM - 6:00 AM UTC

[HDS14-09] A future direction of remedial measures for sediment disaster reduction from the viewpoint of enhancing a workable early warning system

★Invited Papers

*Masaru Kunitomo[1,2,3,4], Shigetaka Takiguchi[1,2,3,4], Fumiaki Akazawa[1,2,3,4], Kazuyuki Imai[1,2,3,4] (1.Ministry of Land, Infrastructure, Transport and Tourism, 2.Water and Disaster Management Bureau, 3.Sediment and Erosion Control Department, 4.Sediment and Erosion Control Planning Division)

[J] Poster | H (Human Geosciences)：H-DS Disaster geosciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[H-DS14] Geohazards in humid, tectonically active countries and their precursors

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Hiroshi YAGI(Faculty of Art, Science and Education, Yamagata University), Satoru Kojima(Department of Civil Engineering, Gifu University), Taro Uchida(National Institute for Land and Infrastructure Management)

[HDS14-P01] The estimation of frequency for deep-seated landslide with carbon dating in Kii mountain area

★Invited Papers

*Yasutaka Tanaka[1], Toshiaki Kotake[1], Hiroaki Sugawara[1], Atsuhiko Kinoshita[1], Yoshito Ogawauchi[2], Minami Fujiwara[2] (1.Sediment Disaster Prevention Technology Center, Kinki Regional Developing Bureau, Ministry of Land, Infrastructure, Transport and Tourism, 2.Japan Conservation Engineers & CO., LTD.)

[HDS14-P02] Tephra stratigraphy and a slope failure of about 4,000 years ago on the slope of the Late Pleistocene Janoo Volcano in the northwestern of Aso Caldera

*Yasuto Hirata[1], Keiichi Ueta[1], Riichiro Miyawaki[2], Katsutoshi Iemura[2], Toshitaka Yokoyama[2], Akiko Miyawaki[2] (1.Central Research Institute of Electric Power Industry, 2.Hanshin Consultants)

[HDS14-P03] Analysis of causal factors of landslides during 2017 northern Kyusyu torrential rainfall disaster by using decision tree

*Hiromu Daimaru[1], Wataru Murakami[1], Yuki Tsurusaki[2] (1.Forestry and Forest Products Research Institute, 2.Fukuoka Agriculture and Forestry Research Center)

[HDS14-P04] Geologic characteristics of rock mass failures caused by the heavy rain event of July 2018 in Uwajima, Ehime

*Shintaro Yamasaki[1] (1.Disaster Prevention Research Institute, Kyoto University)

[HDS14-P05] On the failure mechanism of embankments in Mabi Town during the Heavy rain of July, 2018, Japan

*Gonghui Wang[1] (1.Disaster Prevention Research Institute, Kyoto University)

[HDS14-P06] Interpretation of landslide surface deformation around the branch basins of Sun Kosi river in Nepal using InSAR images

*Otake Shunpei[1], Hiroshi, P. Sato[1] (1.College of Humanities and Sciences, Nihon University)

[HDS14-P07] The large scale landslides triggered by The 2018 Sulawesi Earthquake, Indonesia

*Masashi Omata[1], Toshiyuki Adachi[2], Takao Yamakoshi[3], Kenichi Matsui[4], Tosho Iwamatsu[1], Susumu Takagishi[1], Chiho Motojima[1], Yuu Okuizumi[1], Umito Wada[1] (1.PASCO CORPORATION, 2.LDP Upper House member, 3.SABO & LANDSLIDE TECNICAL CENTER, 4.Nobuyuki Adzchi Office)

[HDS14-P08] Relationship of the grand deformation and topography in Sapporo City at the 2018 Hokkaido Eastern Iburi Earthquake confirmed by InSAR analysis

*Akihiro Yokota[1], Tomohiro Nishimura[2], Kiyoyuki Shigeno[1], Kenichi Honda[2], Sakae Mukoyama[2] (1.Meiji Consultant Co., Ltd, 2.Kokusai Kogyo Co., Ltd)

[HDS14-P09] Estimation of co-seismic surface displacement and ground deformation associated with the 2018 Hokkaido Eastern Iburi Earthquake, based on differential InSAR and differential LiDAR DEM analysis.

*Kenichi Honda[1], Norichika Asada[1], Naruo Mushiake[1], Tomohiro Nishimura[1], Sakae Mukoyama[1] (1.Kokusai Kogyo Co.,LTD.)

[HDS14-P10] Geological features of landslides of pyroclastic fall deposits induced by the 2018 Eastern Iburi Earthquake and other previous earthquakes

*Masahiro Chigira[1], Jun Tajika[3], Satoshi Ishimaru[2], Takehiko Suzuki[4] (1.Disaster Prevention Research Institute, Kyoto University, 2.Hokkaido Geological Survey, Hokkaido Research Organization, 3.Docon Co. Ltd, 4.Tokyo Metropolitan University)

[HDS14-P11] Earthquake ground motion properties of mountainous district in Totsukawa village, Nara pref. based on the seismic observation – A fundamental study of landslides caused by earthquake –

*Tomoyuki Iida[1], Ryuji Yamada[1], Shigeki Senna[1], Hidemitsu Tokui[2], Tetsuya Onodera[2], Hiroshi Kawabe (1.National Research Institute for Earth Science and Disaster Prevention, 2.Technicallink Kabushiki kaisya)

[HDS14-P12] Study on topographic features and landslide development process in slope failure by Typhoon Talas

*Teruyuki Kikuchi[1], Teruyoshi Hatano[2], Satoshi Nishiyama[3] (1.JP-Design Co., Ltd., 2.Electric Power Development Co.,Ltd., 3.Okayama University Graduate School of Environmental and Life Science)

[HDS14-P13] Formation mechanism of bulge of slope that is sign of large-scale collapse

*tatsurou yoshimura[1] (1.Daiichi Fukken Co., Ltd.)

[HDS14-P14] Sediments accumulated in the linear depressions in the Mitsumine area, Kanto Mountains

*Masakazu Mashiko[1], Masahiro Chigira[2] (1.Graduate School of Science, kyoto University, 2.Disaster Prevention Research Institute, Kyoto University)

[J] Poster | H (Human Geosciences)：H-DS Disaster geosciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_15

[H-CG27] Turbidity current: from triggers for the generation to the depositional and morphologic al processes

convener:Miwa Yokokawa(Osaka Institute of Technology), Hajime Naruse(Department of Geology and Mineralogy, Graduate School of Science, Kyoto University), Norihiro Izumi(Faculty of Engineering, Hokkaido University), Ken Ikehara(Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology), Chairperson:Miwa Yokokawa(Osaka Institute of Technology), Norihiro Izumi(Hokkaido University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[HCG27-01] Inverse analysis of turbidity currents using two dimensional shallow water model

*Hajime Naruse[1] (1.Department of Geology and Mineralogy, Graduate School of Science, Kyoto University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[HCG27-02] Inverse Analysis of Experimental Scale Turbidity Currents by Deep Learning Neural Network

*Cai Zhirong[1], Hajime Naruse[1], Qifeng Yao[1] (1.Kyoto University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[HCG27-03] Conditions for development of depositional submarine channels: examination by flume experiments

*Justine Poppeschi[1], Kazushi Nakata[1], Hajime Naruse[1] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[HCG27-04] Cyclic steps formed by long-runout turbidity currents

*Zhuyuan Wu[1], Norihiro Izumi [1] (1.Hokkaido University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[HCG27-05] Is surface sediment remobilization more popular mechanism for generating earthquake-induced turbidity current? Evidence of radiocarbon dates from the westernmost Nankai and Japan Trench subduction zones

*Ken Ikehara[1], Toshiya Kanamatsu[3], Tobias Schwestermann[2], Arata Kioka[2], Michael Strasser[2] (1.Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology, 2.Universität Innsbruck, 3.Japan Agency for Marine-Earth Science and Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[HCG27-06] Shallow-subsurface event stratigraphy along the hadal trench axis of the Japan Trench

*A. Kioka[1], T. Schwestermann[1], J. Moernaut[1], K. Ikehara[2], T. Kanamatsu[3], M. Strasser[1,4] (1.Universität Innsbruck, Austria, 2.GSJ-AIST, Japan, 3.JAMSTEC, Japan, 4.MARUM-U. Bremen, Germany)

[E] Oral | H (Human Geosciences)：H-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 301B 3F

[H-CG27] Turbidity current: from triggers for the generation to the depositional and morphologic al processes

convener:Miwa Yokokawa(Osaka Institute of Technology), Hajime Naruse(Department of Geology and Mineralogy, Graduate School of Science, Kyoto University), Norihiro Izumi(Faculty of Engineering, Hokkaido University), Ken Ikehara(Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology), Chairperson:Hajime Naruse(Kyoto University), Ken Ikehara(AIST)

10:45 AM - 11:07 AM JST | 1:45 AM - 2:07 AM UTC

[HCG27-07] Canyon changes caused by an earthquake-triggered turbidity current in the 2016 M7.8 Kaikōura Earthquake, New Zealand

★Invited Papers

*Joshu J Mountjoy[1], Jamie D Howarth[2], Alan R Orpin[1], Philip M Barnes[1], David A Bowden[1], Ashley A Rowden[1], Alexander C. G. Schimel[1], Caroline Holden[3], Huw J Horgan[2], Scott D Nodder[1], Jayson R Patton[4], Geoffroy Lamarche[1,5], Matt Gerstenberger[3], Aaron Micallef[6], Arne Pallentin[1], Tim Kane[1] (1.NIWA, Wellington. New Zealand, 2.VUW, Wellington. New Zealand, 3.GNS Science, Lower Hutt. New Zealand, 4.HSU, Arcata CA. USA, 5.UoA, Auckland. New Zealand, 6.UoM, Msida. Malta)

11:07 AM - 11:29 AM JST | 2:07 AM - 2:29 AM UTC

[HCG27-08] Far More Prolonged Deep-sea Turbidity Currents triggered by typhoon and earthquake in the Gaoping Submarine Canyon

★Invited Papers

*Yanwei Zhang[1], Zhifei Liu[1], Yulong Zhao[1], Xiaodong Zhang[1] (1.Tongji University)

11:29 AM - 11:51 AM JST | 2:29 AM - 2:51 AM UTC

[HCG27-09] **Filling the gap between turbidity current processes and products in British Columbia fjords**

★Invited Papers

*Sophie Hage[1,2,3] (1.School of Ocean and Earth Sciences, University of Southampton, United Kingdom, 2.National Oceanography Centre Southampton, United Kingdom, 3.Department of Geography, Durham University, United Kingdom)

11:51 AM - 12:13 PM JST | 2:51 AM - 3:13 AM UTC

[HCG27-10] **Sediment transfer from shelf to abyss through giant ganyons and valleys system in deep-sea carbonate slopes (Bahamas)**

★Invited Papers

*Thierry Mulder[1], Hervé Gillet[1], Vincent Hanquiez[1], Audrey Recouvreur[1], Kelly Fauquembergue[1], Johan Le Goff[2], John J.G. Reijmer[2], Emmanuelle Ducassou[1], Margot Joumes, Thibault Cavailhes[1], Elsa Tournadour[5], Jean Borgomano[3], Emmanuelle Poli[4] (1.University of Bordeaux, UMR CNRS 5805 EPOC, Allée Geoffroy Saint Hilaire, Pessac, France, 2.King Fahd Univ. of Petroleum. and Minerals, Dhahran, Saudi Arabia., 3.Aix Marseille University, CNRS, IRD, Collège de France, CEREGE, Aix-en-Provence, France., 4.Total, CSTJF, avenue Larribau, Pau, France, 5.Ifremer, Centre de Brest, Plouzané)

[E] Poster | H (Human Geosciences)：H-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_17

[H-CG27] Turbidity current: from triggers for the generation to the depositional and morphologic al processes

convener:Miwa Yokokawa(Osaka Institute of Technology), Hajime Naruse(Department of Geology and Mineralogy, Graduate School of Science, Kyoto University), Norihiro Izumi(Faculty of Engineering, Hokkaido University), Ken Ikehara(Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology)

[HCG27-P01] The Huapinghsu Canyon (SW East China Sea): morphology and sedimentary processes

*Cheng-Shing Chiang[1], Ho-Shing Yu[2] (1.National Museum of Natural Science, Taiwan, 2.Institute of Oceanography, National Taiwan University, Taipei, Taiwan)

[HCG27-P02] Towards understanding the seismic history of the Nankai Trough using fine-grained turbidites

*Natsumi Okutsu[1], Juichiro Ashi[1], Asuka Yamaguchi[1] (1.The University of Tokyo)

[HCG27-P03] Flood-induced sediment gravity-flow deposits in varved diatomites

*Hana Sasaki[1], Yoshiro Ishihara[2] (1.Graduate School of Science, Fukuoka University, 2.Department of Science, Fukuoka University)

[HCG27-P04] Features of parallel lamination in turbidite sandstones in the Upper Cretaceous Izumi Group in the southern part of the Awaji Island, southwest Japan

*Akane Okuda[1], Hajime Naruse[1] (1.Division of Earth and Planetary Sciences, Graduate school of Science, Kyoto University)

[HCG27-P05] Sediment wave formation on slope base environments: an example of the Neogene Aoshima Formation, Miyazaki Prefecture, Southwest Japan

Shiori Iwao[1], Yuri Onishi[2], *Yoshiro Ishihara[1], Miwa Yokokawa[3] (1.Department of Earth System Science Faculty of Science, Fukuoka University, 2.OYO Corporation, 3.Lab. of Geoenvironment, Osaka Institute of Technology)

[HCG27-P06] A flume experiment on sedimentary structures and grain size distribution of cyclic steps formed by surge-type turbidity currents

*Miwa Yokokawa[1], Kazunori Fujita[1], Isamu Mori[1], Robert Fernandez[2], Matt Czapiga[3], John Berrens[4], Jeffrey Kwang[4], Kensuke Naito[4], Gary Parker[4], Norihiro Izumi[5], Hajime Naruse[6] (1.Osaka Institute of Technology, 2.University of Hull, 3.Technical University of Delft, 4.University of Illinois, 5.Hokkaido University, 6.Kyoto University)

[J] Poster | S (Solid Earth Sciences)：S-GD Geodesy

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[S-GD03] Geodesy General Contributions/Global Geodetic Observing System

convener:Koji Matsuo(Geospatial Information Authority of Japan), Yusuke Yokota(Institute of Industrial Science, The University of Tokyo), Takahiro Wakasugi(Geospatial Information Authority of Japan)

[SGD03-P01] The Study of Sky Condition Prediction and Combination Efficiency Estimation about Multi-GNSS

*Chieh-Ting Chou[1], Yi-Shan - Li[2], Yen-Te - Li[1], Wan-Yu - Yu[1] (1.Department of Environmental Information and Engineering, CCIT, National Defense University, Graduate Student, 2.Department of Environmental Information and Engineering, CCIT, National Defense University, Assistant Professor)

[SGD03-P02] Research on the development of rapid and accurate GNSS routine analysis system (2)

*Hiroyuki Nakagawa[1] (1.The Geospatial Information Authority of Japan)

[SGD03-P03] Characteristics of the Tenryu-Funagira laser extensometer and its detection ability of slow slips

*Akio Katsumata[1], Akiteru Takamori[2], Akito Araya[2] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Earthquake Research Institute, University of Tokyo)

[SGD03-P04] Performance evaluation of laser strainmeters

*Akiteru Takamori[1], Akito Araya[1], Akio Katsumata[2], Wataru Morii[3], Kouseki Miyo[4], Masatake Ohashi[4] (1.Earthquake Research Institute, University of Tokyo, 2.Meteorological Research Institute, 3.Disaster Prevention Research Institute, Kyoto University, 4.Institute for Cosmic Ray Research, University of Tokyo)

[SGD03-P05] Calculation Method of the Tidal Love Numbers with the Fluid Core Resonance of the Solid Earth

*Yuji Harada[1,2], Shuhei Okubo[3] (1.State Key Laboratory of Lunar and Planetary Science, Space Science Institute, Macau University of Science and Technology, 2.Ocean Hemisphere Research Center, Earthquake Research Institute, University of Tokyo, 3.Center for High Energy Geophysics Research, Earthquake Research Institute, University of Tokyo)

[SGD03-P06] Integrating PSInSAR and Hydrogeophysical Methods for the Characterization of a Earth fissure in the eastern Beijing plain

*Menglin Zhao[1], juan wang[1], wang xu[1], bing hu[1], yisheng chen[1] (1.Capitai Normal University)

[J] Poster | S (Solid Earth Sciences)：S-GD Geodesy

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_18

[S-GD03] Geodesy General Contributions/Global Geodetic Observing System

convener:Koji Matsuo(Geospatial Information Authority of Japan), Yusuke Yokota(Institute of Industrial Science, The University of Tokyo), Takahiro Wakasugi(Geospatial Information Authority of Japan)

[SGD03-P01] The Study of Sky Condition Prediction and Combination Efficiency Estimation about Multi-GNSS

*Chieh-Ting Chou[1], Yi-Shan - Li[2], Yen-Te - Li[1], Wan-Yu - Yu[1] (1.Department of Environmental Information and Engineering, CCIT, National Defense University, Graduate Student, 2.Department of Environmental Information and Engineering, CCIT, National Defense University, Assistant Professor)

[SGD03-P02] Research on the development of rapid and accurate GNSS routine analysis system (2)

*Hiroyuki Nakagawa[1] (1.The Geospatial Information Authority of Japan)

[SGD03-P03] Characteristics of the Tenryu-Funagira laser extensometer and its detection ability of slow slips

*Akio Katsumata[1], Akiteru Takamori[2], Akito Araya[2] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Earthquake Research Institute, University of Tokyo)

[SGD03-P04] Performance evaluation of laser strainmeters

*Akiteru Takamori[1], Akito Araya[1], Akio Katsumata[2], Wataru Morii[3], Kouseki Miyo[4], Masatake Ohashi[4] (1.Earthquake Research Institute, University of Tokyo, 2.Meteorological Research Institute, 3.Disaster Prevention Research Institute, Kyoto University, 4.Institute for Cosmic Ray Research, University of Tokyo)

[SGD03-P05] Calculation Method of the Tidal Love Numbers with the Fluid Core Resonance of the Solid Earth

*Yuji Harada[1,2], Shuhei Okubo[3] (1.State Key Laboratory of Lunar and Planetary Science, Space Science Institute, Macau University of Science and Technology, 2.Ocean Hemisphere Research Center, Earthquake Research Institute, University of Tokyo, 3.Center for High Energy Geophysics Research, Earthquake Research Institute, University of Tokyo)

[SGD03-P06] Integrating PSInSAR and Hydrogeophysical Methods for the Characterization of a Earth fissure in the eastern Beijing plain

*Menglin Zhao[1], juan wang[1], wang xu[1], bing hu[1], yisheng chen[1] (1.Capitai Normal University)

[J] Oral | S (Solid Earth Sciences)：S-GD Geodesy

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 304 3F

[S-GD03] Geodesy General Contributions/Global Geodetic Observing System

convener:Koji Matsuo(Geospatial Information Authority of Japan), Yusuke Yokota(Institute of Industrial Science, The University of Tokyo), Takahiro Wakasugi(Geospatial Information Authority of Japan), Chairperson:Kensuke Kokado(GSI of Japan), Yusuke Yokota

1:50 PM - 2:05 PM JST | 4:50 AM - 5:05 AM UTC

[SGD03-01] Activities and future perspective of GGOS Working Group Japan

*Basara Miyahara[1] (1.GSI of Japan)

2:05 PM - 2:20 PM JST | 5:05 AM - 5:20 AM UTC

[SGD03-02] Discussion

*Koji Matsuo[1] (1.Geospatial Information Authority of Japan)

2:20 PM - 2:35 PM JST | 5:20 AM - 5:35 AM UTC

[SGD03-03] VLBI-GNSS Co-location Survey at the Ishioka Geodetic Observing Station

*Saho Matsumoto[1], Michiko Umei[1], Haruka Ueshiba[1], Shinobu Kurihara[1], Tadao Kikkawa[1], Takahiro Wakasugi[1] (1.GSI of Japan)

2:35 PM - 2:50 PM JST | 5:35 AM - 5:50 AM UTC

[SGD03-04] Research of Crustal Deformation Model for Next Version of Japanese Geodetic Datum

*Kensuke Kokado[1] (1.GSI of Japan)

2:50 PM - 3:05 PM JST | 5:50 AM - 6:05 AM UTC

[SGD03-05] Construction of a laser-strainmeter network for accurate seismic and geodetic observations

*Akito Araya[1], Akiteru Takamori[1], Wataru Morii[2], Akio Katsumata[3], Akio Kobayashi[3], Takeo Ito[4], Takashi Okuda[4], Makoto Okubo[5] (1.Earthquake Research Institute, University of Tokyo, 2.Disaster Prevention Research Institute, Kyoto University, 3.Meteorological Research Institute, Japan Meteorological Agency, 4.Graduate School of Environmental Studies, Nagoya University, 5.Natural Science Cluster, Kochi University)

[J] Oral | S (Solid Earth Sciences)：S-GD Geodesy

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 304 3F

[S-GD03] Geodesy General Contributions/Global Geodetic Observing System

convener:Koji Matsuo(Geospatial Information Authority of Japan), Yusuke Yokota(Institute of Industrial Science, The University of Tokyo), Takahiro Wakasugi(Geospatial Information Authority of Japan), Chairperson:Yuji Harada(Macau University of Science and Technology), Koji Matsuo

3:35 PM - 3:50 PM JST | 6:35 AM - 6:50 AM UTC

[SGD03-06] UNAVCO GNSS Data: Real-time High-rate Streams, Geodetic Earthquake Magnitudes, Cloud Computing and Future Machine Learning Frameworks

*David A Phillips[1], Kathleen Hodgkinson[1], David Mencin[1], Charles Meertens[1], Thomas Herring[2], Walter Szeliga[3], Timothy Melbourne[3], Mark Murray[4], Glen Mattioli[1], Christine Puskas[1] (1.UNAVCO, Inc. Boulder, 2.Massachusetts Institute of Technology, 3.Central Washington University, 4.USGS)

3:50 PM - 4:05 PM JST | 6:50 AM - 7:05 AM UTC

[SGD03-07] **On application of GNSS-techniques for early tsunami warning in the Sea of Japan**

*Grigorii Viktorovich Nechaev[1,2,3], Nikolai Shestakov[2,3], Hiroaki Takahashi[1], Mako Ohzono[1] (1.Institute of Seismology and Volcanology, Graduate Schooll of Science, Hokkaido University, 2.Far Eastern Federal University, 3.Institute for Applied Mathematics FEB RAS)

4:05 PM - 4:20 PM JST | 7:05 AM - 7:20 AM UTC

[SGD03-08] Measurements of occurrence of solar conjunction with the orbits of Asian QZSS/IGSO satellites

Cancelled

*Fujinobu Takahashi[1] (1.Yokohama National University)

4:20 PM - 4:35 PM JST | 7:20 AM - 7:35 AM UTC

[SGD03-09] Sea level evaluation in northern Australian coast

*Yuta Tokui[1], Kosuke Heki[1] (1.Hokkaido University)

4:35 PM - 4:50 PM JST | 7:35 AM - 7:50 AM UTC

[SGD03-10] Implications from geomagnetic observation for the interannual fluctuations of Earth rotation

*Seiki Asari[1], Masanori Kurihara[1], Kenji Morinaga[1], Shingo Nagamachi[1] (1.Kakioka Magnetic Observatory, Japan Meteorological Agency)

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[S-SS07] Rigorous Seismicity Modelling and Hypothesis Testing

convener:Jiancang Zhuang(Institute of Statistical Mathematics), Danijel Schorlemmer(GFZ German Research Centre for Geosciences), Matt Gerstenberger(GNS Science), Hiroshi Tsuruoka(Earthquake Research Institute, Tokyo Univ.)

[SSS07-P01] Development of Physics-based Ground Motion Simulation in A Hybrid Approach and Applications to Seismic Hazard Assessment in Taiwan

*Ming-Che Hsieh[1], Yin-Tung Yen[1], Kuo-Fong Ma[2,3] (1.Disaster Prevention Technology Research Center, Sinotech Engineering Consultants (Inc.), Taiwan, 2.Department of Earth Sciences, National Central University, Taiwan, 3.Earthquake-Disaster & Risk Evaluation and Management Center, National Central University, Taiwan)

[SSS07-P02] Increasing Earthquake Forecast Testability - CSEP Future Developments

*Danijel Schorlemmer[1], Naoshi Hirata[2], Fabrice Cotton[1], Matt Gerstenberger[3], Thomas Jordan[7], Warner Marzocchi[4], William Savran[7], Maximilian Werner[5], Stefan Wiemer[6], Thomas Beutin[1], David D Jackson[8], Philip Maechling[7], Sum Mak[1], Kazuyoshi Nanjo[9], Yosihiko Ogata[10], David Rhoades[3], Hiroshi Tsuruoka[2], Graeme Weatherill[1], Jiancang Zhuang[10] (1.GFZ German Research Centre for Geosciences, 2.Earthquake Research Institute, University of Tokyo, Japan, 3.GNS Science, Lower Hutt, New Zealand, 4.University of Naples, Naples, Italy, 5.University of Bristol, Bristol, United Kingdom, 6.ETH Zurich, Zurich, Switzerland, 7.University of Southern California, Los Angeles, USA, 8.University of California Los Angeles, Los Angeles, USA, 9.University of Shizuoka, Shizuoka, Japan, 10.Institute of Statistical Mathematics, Tachikawa, Japan)

[SSS07-P03] Precision versus uncertainty in regional seismic hazard mapping

*Matt Gerstenberger[1], Danijel Schorlemmer[2] (1.GNS Science, 2.GFZ-Potsdam)

[SSS07-P04] An extreme value analysis of seismograms designed for early forecast of aftershocks

*Kaoru Sawazaki[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SSS07-P05] Spatio-temporal clustering of successive earthquakes: data analyses of global data.

*THYSTERE MATONDO BANTIDI[1], Takeshi Nishimura[1] (1.Tohoku University)

[SSS07-P06] Kanto 3 month testing class results of CSEP Japan

*Hiroshi Tsuruoka[1], Naoshi Hirata[1] (1.Earthquake Research Institute, Tokyo Univ.)

[SSS07-P07] Long-term earthquake risk in North China estimated from a modern catalogue

Ziyao Xiong[2], *Jiancang Zhuang[1], Shiyong Zhou[2] (1.Institute of Statistical Mathematics, 2.Peking University)

[SSS07-P08] Distributions of focal mechanisms in background seismicity and earthquake clusters in Japan

*Jiancang Zhuang[1,2], Eri Maita[2] (1.Institute of Statistical Mathematics, 2.Graduate University for Advanced Studies)

[SSS07-P09] New Ground Motion Prediction Equations for Western Saudi Arabia

*Ryota Kiuchi[1,2], Walter Mooney[1], Hani Zahran[3] (1.U.S. Geological Survey, 2.Disaster Prevenetion Research Institute, Kyoto University, 3.Saudi Geological Survey)

[SSS07-P10] Study on the spatial and temporal change of velocity structure before and after 2003 Chengkung earthquake, Taiwan

*TING YA LIANG[1], Wen-Yen Chang[1,2,3], Strong Wen[4] (1.National DONG HWA University, 2.Eastern Taiwan Earthquake Research Center, 3.National Center for Research on Earthquake Engineering, 4.National Chung Cheng University)

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A10 TOKYO BAY MAKUHARI HALL

[S-SS07] Rigorous Seismicity Modelling and Hypothesis Testing

convener:Jiancang Zhuang(Institute of Statistical Mathematics), Danijel Schorlemmer(GFZ German Research Centre for Geosciences), Matt Gerstenberger(GNS Science), Hiroshi Tsuruoka(Earthquake Research Institute, Tokyo Univ.), Chairperson:Matthew Gerstenberger(GNS Science, New Zealand), Danijel Schorlemmer(GFZ-Potsdam, Germany)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SSS07-01] Improving medium-term earthquake forecasts by compensating the EEPAS model for the time-lag

★Invited Papers

David Rhoades[1], Christophersen Annemarie[1], *Matt Gerstenberger[1] (1.GNS Science)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SSS07-02] Earthquake probability forecast incorporating non-seismic data

*Peng Han[1], Jiancang Zhuang[2], Yosihiko Ogata[2], Katsumi Hattori[3] (1.Southern University of Science and Technology, Shenzhen, China, 2.The Institute of Statistical Mathematics, Tokyo, Japan , 3.Chiba University, Chiba, Japan)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SSS07-03] **Extended versions of the space-time ETAS model and application to the 2016 Kumamoto earthquake sequence**

★Invited Papers

*YICUN GUO[1], Jiancang Zhuang[1], Yosihiko Ogata[1] (1.The Institute of Statistical Mathematics, Tokyo, Japan)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SSS07-04] CSEP Japan results and future developments

*Naoshi Hirata[1], Hiroshi Tsuruoka[1], Danijel Schorlemmer[3], Jiancang Zhuang[2] (1.Earthquake Research Institute, the University of Tokyo, 2.Institute of Statistical Mathematics, 3.GFZ German Research Centre for Geosciences)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SSS07-05] From the studies of historical earthquakes to the implication of single fault to multiple fault segments ruptures in seismic hazard analysis

★Invited Papers

*Kuo-Fong Ma[1,2,3], Mingshen Yen[1], Yiwun Liao[1], Henyi Su[2] (1.Earthquake - Disaster & Risk Evaluation and Managment (E-DREaM) Center, National Central University, Taiwan, ROC, 2.Department of Earth Sciences, National Central University, Taiwan, ROC, 3.Institute of Earth Sciences, Academia Sinica, Taiwan, ROC)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SSS07-06] **High resolution space-time models forecasting 3D seismicity beneath the Greater Tokyo Area**

★Invited Papers

*Yosihiko Ogata[1,2], Koichi Katsura, Hiroshi Tsuruoka[2], Naoshi Hirata[2] (1.Research Organization of Information and Systems, The Institute of Statistical Mathematics, 2.Earthquake Research Institute, The University of Tokyo)

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A09 TOKYO BAY MAKUHARI HALL

[S-SS11] Seismic wave propagation: Theory and Application

convener:Kiwamu Nishida(Earthquake Research Institute, University of Tokyo), Kazuya Shiraishi(Japan Agency for Marine-Earth Science and Technology), Takao Nibe(JAPEX), Kaoru Sawazaki(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Tsutomu Takahashi(JAMSTEC)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SSS11-01] Power Spectrum of Random Heterogeneity of the Solid Earth

*Haruo Sato[1] (1.Tohoku Unvieristy)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SSS11-02] Estimation of spatio-temporal changes of seismic scattering property associated with the 2008 Iwate-Miyagi Nairiku earthquake from sparse modeling of seismic ambient noise CCFs

*Takashi Hirose[1], Hisashi Nakahara[1], Takeshi Nishimura[1], Michel Campillo[2] (1.Graduate School of Science, Tohoku University, 2.University Grenoble Alpes, CNRS, ISTerre)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SSS11-03] Surface roughness of the Philippine Sea plate at Nankai subduction zone

*Tsutomu Takahashi[1], Ayako Nakanishi[1], Shuichi Kodaira[1], Yoshiyuki Kaneda[2] (1.JAMSTEC, 2.Kagawa University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SSS11-04] Source location of volcanic earthquakes and tremors at Sakurajima volcano based on seismic correlation

*Theodorus Permana[1], Takeshi Nishimura[1], Hisashi Nakahara[1] (1.Solid Earth Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SSS11-05] **Crustal Structure Investigation in Northern Taiwan - Localized Wavefield Inversion of TAIGER T6 Wide Angle Refraction/Reflection Data**

*Fandy Adji Fachtony[1], How-wei Chen[1] (1.Institute of Geophysics, National Central University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SSS11-06] Self-organized criticality induced by randomness in block-spring models and the Gutenberg=Richter law

*Hidetsugu Sakaguchi [1] (1.Kyushi University)

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A09 TOKYO BAY MAKUHARI HALL

[S-SS11] Seismic wave propagation: Theory and Application

convener:Kiwamu Nishida(Earthquake Research Institute, University of Tokyo), Kazuya Shiraishi(Japan Agency for Marine-Earth Science and Technology), Takao Nibe(JAPEX), Kaoru Sawazaki(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Kiwamu Nishida(東京大学地震研究所)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SSS11-07] Land-Atmosphere Interaction in the low-frequency seismic band and inversion for shallow elasticity structure

*Toshiro Tanimoto[1], Jiong Wang[1] (1.Department of Earth Science, University of California, Santa Barbara, CA93106, USA)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SSS11-08] Noise correlation analysis of S-net records

*Ryota Takagi[1], Genti Toyokuni[1], Mare Yamamoto[1] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SSS11-09] Atmospheric waves from the gas explosion in Sapporo on December 16, 2018, recorded by seismometers

*Kazunori Yoshizawa[1] (1.Faculty of Science, Hokkaido University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SSS11-10] Time-lapse monitoring of seismic velocity associated with the 2011 Shinmoedake eruption using seismic interferometry

*Kiwamu Nishida[1], Yuta Mizutani[1] (1.Earthquake Research Institute, University of Tokyo)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SSS11-11] Temporal variations of seismic velocity and azimuthal anisotropy in near-surface rock and soil at KiK-net downhole array sites

*Taka'aki Taira[1], Li-Wei Chen[1], Hiroe Miyake[2] (1.Berkeley Seismological Laboratory, University of California, Berkeley, 2.The University of Tokyo)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SSS11-12] **Denoising Ambient Seismic Field Correlation Functions with Deep Autoencoders**

*Loic Viens[1], Chris Van Houtte[2] (1.Disaster Prevention Research Institute, Kyoto University, 2.GNS Science)

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | Convention Hall A 2F

[S-SS13] Strong Ground Motion and Earthquake Disaster

convener:Masayuki Kuriyama(Central Research Institute of Electric Power Industry), Kazuhiro Somei(Geo-Research Institute), Chairperson:Nobuyuki Morikawa(National Research Institute for Earth Science and Disaster Resilience), Ryoichi Nakamura(Earthquake Research Institute, The University of Tokyo)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SSS13-25] **Determination of dynamic characteristics of existing buildings at various site conditions in Eskisehir, Turkey**

*Onur Kaplan[1], Seiji Tsuno[2], Hiroaki Yamanaka[3], Mehmet Safa Arslan[4], Oguz Ozel[4] (1.Eskisehir Technical University, 2.Railway Technical Research Institute , 3.Tokyo Institute of Technology , 4.Istanbul University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SSS13-26] **ICDP DSeis 10: Near-field Observations for the M5.5 Orkney, South Africa Earthquake**

Tatsunari Yasutomi[1], *James Mori[1], Hiroshi Ogasawara[2] (1.Earthquake Hazards Division, Disaster Prevention Research Institute, Kyoto University, 2.Ritsumeikan University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SSS13-27] Number of earthquakes from seismic activity model of the national seismic hazard maps for Japan

*Nobuyuki Morikawa[1], Junichi Miyakoshi[2], Hiroyuki Fujiwara[1] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Ohsaki Research Institute, Inc.)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SSS13-28] Comparative examination of the Probabilistic Seismic Hazard Maps in Japan with observed maximum seismic intensities for various periods

*Takamoto Muneta[1], Kazuki Koketsu[1] (1.Earthquake Research Institute, The University of Tokyo)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SSS13-29] A Study on the Ground Motion Characteristics close to the Basin Edge

Ryota Hamabe[2], *Shinichi Matsushima[1], Takashi Azuma[3], Florent De Martin[4] (1.Disaster Prevention Research Institute, Kyoto University, 2.Graduate School of Engineering, Kyoto University, 3.National Institute of Advanced Industrial Science and Technology, 4.French Geological Survey)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SSS13-30] Spectrum Characteristics of MeSO-net seismograms – Effect of Underground Installation -

*Ryoichi Nakamura[1], Hiroshi Tsuruoka[1], Aitaro Kato[1], Shin'ichi Sakai[1], Naoshi Hirata[1], Takahiro Shiina[1] (1.Earthquake Research Institute, The University of Tokyo)

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Convention Hall A 2F

[S-SS13] Strong Ground Motion and Earthquake Disaster

convener:Masayuki Kuriyama(Central Research Institute of Electric Power Industry), Kazuhiro Somei(Geo-Research Institute), Chairperson:Yasumaro Kakehi(Department of Planetology, Graduate School of Science, Kobe University), Hisashi Nakahara(Solid Earth Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SSS13-31] Interpretation of attenuation of high-frequency waves from the intraslab, interplate, and outer-rise earthqukakes of Northeastern Japan

*Yasumaro Kakehi[1], Yu Ogasawara[1] (1.Graduate School of Science, Kobe University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SSS13-32] **Effect analysis of soil interlayer on seismic dynamic response and failure mode of metro station structure**

*Shuai Huang[1], Yuejun Lyu[1], Yanju Peng[1] (1.Institute of Crustal Dynamics,China Earthquake Administration)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SSS13-33] **Investigation on the Applicability of V_{S30} Estimation Models for the Beijing Plain Area**

*Yi Fang, Yanju Peng, Zhijie Jiang

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SSS13-34] Early prediction of PGA and Sa using ANN

*Ting Yu Hsu[1] (1.Taiwan Tech)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SSS13-35] Analysis of strong-motion acceleration records based on the Generalized Pareto distribution

*Hisashi Nakahara[1] (1.Solid Earth Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University)

[J] Poster | S (Solid Earth Sciences)：S-SS Seismology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[S-SS13] Strong Ground Motion and Earthquake Disaster

convener:Masayuki Kuriyama(Central Research Institute of Electric Power Industry), Kazuhiro Somei(Geo-Research Institute)

[SSS13-P01] Observation of Aftershock due to the 2018 Hokkaido Eastern Iburi Earthquake and Microtremor observation in the Damaged Area

*Isamu Nishimura[1], Tatsuya Noguchi[2], Yusuke Ono[2], Masanori Kohno[2], Keishin Hibi[1] (1.Graduate School of Sustainability Science,Tottori Univercity,Department of Engineering,Social Systems and Civil Engineering Program, 2.Department of Engineering Tottori Univercity)

[SSS13-P02] **Nonlinear site amplification for high intensity ground motions during the 2018 Mw 6.6 Hokkaido eastern Iburi earthquake**

*Yadab Prasad Dhakal[1], Takashi Kunugi[1], Takeshi Kimura[1], Wataru Suzuki[1], Shin Aoi[1] (1.National Research Institute for Earth Science and Disaster Resilience (NIED))

[SSS13-P03] Microtremor array measurements at strong motion recording stations, HKD127 and IBUH01, in 2018 Hokkaido Iburi earthquake.

*Takuto Kogawa[1], Koji Tokimatsu[1], Izuru Okawa[1], Hitoshi Tanaka[1], Kentaro Motoki[2] (1.TOKYO SOIL RESEARCH CO.,LTD., 2.KOBORI RESEARCH COMPLEX INC.)

[SSS13-P04] Subsurface structure model based at diffuse-field theory in Oiwake region: Simultaneous inversion analysis on adjacent two sites

*Moeko Koie[1], Kentaro Motoki[1], Kenichi Kato[1], Takuto Kogawa[2] (1.KOBORI RESEARCH COMPLEX INC., 2.TOKYO SOIL RESEARCH CO., LTD.)

[SSS13-P05] Exploration of the velocity structure model in the Mukawa town, damaged area during the 2018 Hokkaido eastern Iburi earthquake

*Michiko Shigefuji[1], Nobuo TAKAI[2], Jun Horita[3], Shingo Nomoto[3], Takahiro Maeda[4], Hiroaki Takahashi[2], Masayoshi Ichiyanagi[2], Hiroaki Yamanaka[5], Kosuke Chimoto[5], Seiji Tsuno[6], Masahiro Korenaga[6], Nobuyuki Yamada[7] (1.Kyushu University, 2.Hokkaido University, 3.Geo-Technical Research Co.,Ltd, 4.National Research Institute for Earth Science and Disaster Resilience, 5.Tokyo Institute of Technology, 6.Railway Technical Research Institute, 7.Kochi University)

[SSS13-P06] Source Process of the 2018 Hokkaido Eastern Iburi Earthquake Inferred from Strong Motion Data and Green's Functions Based on Three-Dimensional Velocity Structure Model

*Kimiyuki Asano[1], Tomotaka Iwata[1] (1.Disaster Prevention Research Institute, Kyoto University)

[SSS13-P07] Source process of the 2018 Hokkaido Eastern Iburi earthquake derived from strong motion data

*Hisahiko Kubo[1], Wataru Suzuki[1], Asako Iwaki[1], Shin Aoi[1], Haruko Sekiguchi[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.DPRI, Kyoto University)

[SSS13-P08] Broadband ground-motion simulation of the 2018 Hokkaido Eastern Iburi earthquake

*Asako Iwaki[1], Nobuyuki Morikawa[1], Takahiro Maeda[1], Hisahiko Kubo[1], Hiroyuki Fujiwara[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SSS13-P09] **Estimation of 1D S-wave velocity structures in Kumamoto plain and Mashiki town using a waveform inversion of S-wave**

*Kengo Muroi[1], Hiroaki Yamanaka[1], Kosuke Chimoto[1], Seiji Tsuno[2], Masahiro Korenaga[2], Hiroe Miyake[3], Nobuyuki Yamada[4] (1.Tokyo Institute of Technology, 2.Railway Technical Research Institute, 3.The University of Tokyo, 4.Kochi University)

[SSS13-P10] Investigation to estimate high-frequency Empirical Green’s tensor derivatives (EGTD) using aftershocks for the 2016 Kumamoto earthquake

*Sayumi Yoshida[1], Horike Masanori [1], Ken Miyakoshi[2] (1.HANSHIN CONSULTANTS Co., Ltd., 2.Geo-Research Institute)

[SSS13-P11] Estimation of Site Amplification Characteristics in Kumamoto plain by Spectral Separation Analysis Using Aftershock Records of the 2016 Kumamoto Earthquake

*Tomomi Iida[1], Hiroaki Yamanaka[1], Kosuke Chimoto[1], Daiki Shinoyama[8], Seiji Tsuno[5], Masahiro Korenaga[5], Nobuyuki Yamada[7], Hiroe Miyake[6], Tatsuo Kanno[3], Michiko Shigefuji[3], Masayuki Yoshimi[2], Shinichi Matsushima[4], Hiroshi Kawase[4], Kimiyuki Asano[4], Tomotaka Iwata[4] (1.Tokyo institute of Technology, 2.National Institute of Advanced Industrial Science and Technology, 3.Kyushu University, 4.Kyoto University, 5.Railway Technical Research Institute, 6.The University of Tokyo, 7.Kochi Unicersity, 8.Central Research Institute of Electric Power Industry)

[SSS13-P12] Kinematic and dynamic source models of the 2016 Mj6.4 Kumamoto third large earthquake

*Kunikazu Yoshida[1], Ken Miyakoshi[1] (1.Geo-Research Institute)

[SSS13-P13] Source rupture process and strong motion generation area assuming the curved fault model for the 2003 northern Miyagi prefecture earthquake

*Kazuhiro Somei[1], Ken Miyakoshi[1], Yujia Guo[1] (1.Geo-Research Institute)

[SSS13-P14] Estimation of source rupture process during the 2018 Shimane-ken seibu earthquake using strong motion data

*Susumu Kurahashi[1], Ken Miyakoshi[2] (1.Aichi Institute of Technology, 2.Geo-Research Institute)

[SSS13-P15] An estimation of SMGA of M6 class earthquakes based on strong motion records near the source regions

*Kentaro Motoki[1], Kenichi Kato[1], Tetsuo Shiota[2] (1.Kobori Research Complex, 2.Shikoku Electric Power Company)

[SSS13-P16] Difference in short-period level between the surface and buried fault rupture crustal earthquake in Japan

*Shohei Yoshida[1], Takao Kagawa[1], Tatsuya Noguchi[1] (1.Graduate School of Engineering, Tottori University)

[SSS13-P17] Probabilistic seismic hazard assessment of response spectra for whole Japan (part 1: Selection of ground motion prediction equations)

*Nobuyuki Morikawa[1], Junichi Miyakoshi[2], Hiroyuki Fujiwara[1] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Ohsaki Research Institute, Inc.)

[SSS13-P18] Probabilistic seismic hazard assessment of response spectra for whole Japan (part 2: Probabilistic seismic hazard assessment)

*Junichi Miyakoshi[1], Takeshi Morii[1], Nobuyuki Morikawa[2], Hiroyuki Fujiwara[2] (1.Ohsaki Research Institute, Inc., 2.National Research Institute for Earth Science and Disaster Resilience)

[SSS13-P19] **Simulation of Long-period Ground Motion around The Fujikawa-kako Fault Zone during the 2018 Northern Osaka Earthquake**

*Seina Hashimoto[1], Hiroaki Yamanaka[1], Kosuke Chimoto[1], Masahiro Korenaga[2], Seiji Tsuno[2], Hiroe Miyake[3], Shigeki Senna[4] (1.Tokyo Institute of Technology School of Enviroment and Society, 2.Railway Technical Research Institute, 3.The University of Tokyo, 4.National Research Institute for Earth Science and Disaster Prevention)

[SSS13-P20] Site amplification factors for KiK-net stations in and around Ibaraki Prefecture estimated by the coda normalization method

*Jun Kawahara[1], Takahiro Nakamura[1], Takuji Yamada[1] (1.Graduate School of Science and Engineering, Ibaraki University)

[SSS13-P21] Estimation of earthquake ground level in Horinouchi area in the 2014 Northern Nagano earthquake

*RYOTA KAWAI[1], Hiroaki Yamanaka[1], Kosuke Chimoto[1], Seiji Tsuno[2], Masahiro Korenaga[2] (1.Interdisciplinary Graduate School of Science and Engineering,Tokyo institute of Technology, 2.Railway Technical Research Institute)

[SSS13-P22] Ground type classification for strong ground motion prediction based on characteristics of phase-velocity curves from microtremor explorations

*Atsushi Wakai[1], Shigeki Senna[1], Hisanori Matsuyama[2], Yatagai Atsushi[2], Yoshiaki Inagaki[2], Hiroyuki Fujiwara[2] (1.National Research Institute for Earth Science and Disaster Prevention, 2.OYO Corporation)

[SSS13-P23] **Establishment of the Underground Structure Model for Seismic Damage Estimation**

*Shigeki Senna[1], Atsushi Wakai[1], Hiroyuki Fujiwara[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SSS13-P24] Consideration of liquefaction damage rate based on liquefaction damage in recent years

*Shigeki Senna[1], Ozawa Kyoko[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SSS13-P25] Estimation of surface earthquake record at MeSO-NET observation points

*Shigeki Senna[1], Atsushi Wakai[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SSS13-P26] Possibility of estimating phase velocity of Love wave using Horizontal components in microtremor array surveys in the case of Nishio

*Kotoyo Tsuchida[1], Masanori Horike[1], Koji Yamada[1], Masaki Suehiro[1], Sayumi Yoshida[1] (1.HANSHIN CONSULTANTS COMPANY LIMITED)

[SSS13-P27] Enhancement of shallow velocity structure models based on array microtremor explorations for Tokai region, Central Japan

*Atsushi Wakai[1], Shigeki Senna[1], Yatagai Atsushi[2], Yoshiaki Inagaki[2], Hisanori Matsuyama[2], Hiroyuki Fujiwara[1] (1.National Research Institute for Earth Science and Disaster Prevention, 2.OYO Corporation)

[SSS13-P28] Validation of seismic bedrock structure model in the Shimousa region, Chibe prefecture, Japanusing seismic interferometry to strong motion

*Kosuke Chimoto[1], Hiroaki Yamanaka[1] (1.Tokyo Institute of Technology)

[SSS13-P29] Microtremor survey for subsurface velocity structure of Saga plain

*Masayuki Yoshimi[1], Michiko Shigefuji[2], Tadashi Maruyama[1] (1.Geological Survey of Japan, AIST, 2.Kyushu University)

[SSS13-P30] Densely microtremor observation to estimation of subsurface structure in Hane and Kute area, Ohda City, Shimane Prefecture, Japan

*Tatsuya Noguchi[1], Yoshito Yamaguchi, Yuhei Morita, Isamu Nishimura[1], Shohei Yoshida[1], Takao Kagawa[1] (1.Department of Management of Social Systems and Civil Engineering, Civil Engineering Course Graduate School of Engineering, Tottori University)

[SSS13-P31] Densely microtremor observation to estimation of subsurface structure in Nishizono and Yura area, Hokuei Town, Tottori Prefecture, Japan

*Tatsuya Noguchi[1], Katsuya Tomeoku, Isamu Nishimura[1], Shohei Yoshida[1], Takao Kagawa[1] (1.Department of Management of Social Systems and Civil Engineering, Civil Engineering Course Graduate School of Engineering, Tottori University)

[SSS13-P32] Seismic reflection survey in the Kathmandu Valley, Nepal.

*Kota Koshika[1], Yusuke Kawasaki[1], Om Pradhan[1], Masato Yamamoto[1], Dai Nobuoka[1], Yoshikazu Matsubara[1], Hisanori Matsuyama[1], Monika Jha[2], Chintan Timisina[2], Suresh Shrestha[2], Mukunda Bhattarai[2], Dinesh Nepali[2], Soma Nath Sapkota[2], Hiroe Miyake[3], Kazuki Koketsu[3] (1.OYO Corporation, 2.Department of Mines and Geology, 3.Earthquake Research Institute, University of Tokyo)

[SSS13-P33] Broadband Microtremor Array Exploration at and around Tribhuvan International Airport, Kathmandu, Nepal

*Toshiaki Yokoi[1], Takumi Hayashida[1], Mukunda Bhattarai[2], Tara Pokharel[2], Suresh Shrestha[2], Chintan Timsina[2], Sunita Bhatarrai[2], Dinesh Nepali[2] (1.International Institute of Seismology and Earthquake Engineering, Building Research Institute, Japan, 2.Department of Mines and Geology, Ministry of Industry, Commerce and Supplies, Nepal)

[SSS13-P34] Distribution of average S-wave velocities by small-scale (5 to 15 meters) microtremor arrays in and around Hue City, Thua Thien-Hue province, Vietnam

*Ikuo Cho[1], Makoto OKUBO[2] (1.National Institute of Advanced Industrial Science and Technology, 2.Kochi University)

[SSS13-P35] Microtremor Array Exploration in the Syiah Kuala University, Banda Aceh, Indonesia

*Makoto OKUBO[1] (1.Natural Science Cluster, Kochi University)

[SSS13-P36] **Turkey-Japan Joint Project on Modeling of Geological Structures for Strong Ground Motion Simulations due to Crustal Earthquakes in Eskisehir Basin, Turkey, by Using Seismic Interferometry Method**

*Mehmet Safa Arslan[1], Kosuke Chimoto[2], Asim Oguz Ozel[1], Hiroaki Yamanaka[2] (1.ISTANBUL UNIVERSITY-CERRAHPASA, 2.TOKYO INSTITUTE OF TECHNOLOGY)

[SSS13-P37] **Nonlinear Ground Motion Response During the 2016 Meinong Taiwan Earthquake**

*Kuo-Liang Wen[1], Chun-Te Chen[2] (1.National Central University, Department of Earth Sciences, 2.Academia Sinica, Institute of Earth Sciences)

[SSS13-P38] Earthquake damage of the 2017 Pohang earthquake in South Korea

*Mikyung Choi[1], Sun-Cheon Park[1], Dong-Hyo Sohn[1], Seolhan You[1], Jongsun Sun[1], Seongheum Cho[1], Duk-Kee Lee[1] (1. Korea Meteorological Administration)

[J] Poster | S (Solid Earth Sciences)：S-SS Seismology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_20

[S-SS13] Strong Ground Motion and Earthquake Disaster

convener:Masayuki Kuriyama(Central Research Institute of Electric Power Industry), Kazuhiro Somei(Geo-Research Institute)

[SSS13-P01] Observation of Aftershock due to the 2018 Hokkaido Eastern Iburi Earthquake and Microtremor observation in the Damaged Area

*Isamu Nishimura[1], Tatsuya Noguchi[2], Yusuke Ono[2], Masanori Kohno[2], Keishin Hibi[1] (1.Graduate School of Sustainability Science,Tottori Univercity,Department of Engineering,Social Systems and Civil Engineering Program, 2.Department of Engineering Tottori Univercity)

[SIT21-13] Evolution of the Earth mantle and its possible interaction with core: view from olivine and its inclusions study

★Invited Papers

*Alexander V Sobolev[1], Valentina G. Batanova[2] (1.ISTerre Institute of Earth Sciences, 2.Vernadsky Institute of Geochemistry and Analytical Chemistry, Russian Academy of Sciences, Kosygina str. 19, Moscow 119991, Russia.)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SIT21-14] Discussion

*Tsuyoshi Iizuka[1] (1.University of Tokyo)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SIT21-15] Ultralow-velocity zones possibly explained by light element-enriched iron compounds

*Liang Yuan[1], Eiji Ohtani[1], Xiang Wu[2], Shengxuan Huang[3], Daijo Ikuta[1], Tatsuya Sakamaki[1], Seiji Kamada[1], Hiroshi Fukui[4,5], Satoshi Tsutsui[6], Hiroshi Uchiyama[6], Daisuke Ishikawa[5,6], Naohisa Hirao[6], Alfred Q. R. Baron[5] (1.Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University, Sendai 980-8578, Japan, 2.State Key Laboratory of Geological Processes and Mineral Resources, China University of Geosciences, Wuhan 430074, China, 3.Key Laboratory of Orogenic Belts and Crustal Evolution, MOE, Peking University and School of Earth and Space Sciences, Peking University, Beijing 100871, China, 4.Center for Novel Material Science under Multi-Extreme Conditions, Graduate School of Material Science, University of Hyogo, Hyogo 678-1297, Japan, 5.Materials Dynamics Laboratory, RIKEN SPring-8 Center, Hyogo 679-5148, Japan, 6.Japan Synchrotron Radiation Research Institute (JASRI), SPring-8, Hyogo, 679-5198, Japan)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SIT21-16] High-precision $^{142}W/^{144}W$ ratios of oceanic island basalts and Large Igneous Province basalts.

Asako Takamasa[1], *Katsuhiko Suzuki[1], Yusuke Fukami[2], Tsuyoshi Iizuka[3] (1.Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology, 2.Department of Subsurface Geobiological Analysis and Research, Japan Agency for Marine-Earth Science and Technology, 3.Graduate School of Science, The University of Tokyo)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SIT21-17] **Some technological developments in high temperature generation using KMA and precise melting/phase relations of minerals and rocks under deep mantle conditions**

*Tetsuo Irifune[1,2], Youmo Zhou[1], Takeshi Arimoto[1], Hideharu Kuwahara[1], Ryuichi Nomura[3], Masayuki Nishi[1], Momoko Yamaguchi[1], Yoshinori Tange[4], Takahiro Kuribayashi[5], Zhaodong Liu[6] (1.Geodynamics Research Center, Ehime University, 2.Eearth Life Science Institute, Tokyo Institute of Technology, 3.Hakubi Center/ Graduate School of Human and Environmental Studies, Kyoto University, 4.Research & Utilization Division, Japan Synchrotron Research Institute, 5.Graduate School of Science, Tohoku University, 6.Institute of Super Hard Materials, Jilin University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SIT21-18] Zr isotope constraints on early Earth differentiation

*Tsuyoshi Iizuka[1], Keita Itano[1], Shinji Yamamoto[2] (1.University of Tokyo, 2.Yokohama National University)

[E] Poster | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_12

[S-IT21] Interaction and Coevolution of the Core and Mantle in the Earth and Planets

convener:Kenji Kawai(Department of Earth and Planetary Science, School of Science, University of Tokyo), Tsuyoshi Iizuka(University of Tokyo), Kenji Ohta(Department of Earth and Planetary Sciences, Tokyo Institute of Technology), Taku Tsuchiya(Geodynamics Research Center, Ehime University)

[SIT21-P01] Sample-scale compositional variation of the Inada granite, Ibaraki, Japan -toward the reduction of geoneutrino flux estimation errors from the Japanese crust-

★Invited Papers

*Kenta Ueki[1], Minami Kazuki[2], Tsuyoshi Iizuka[3], Sanshiro Enomoto[4], Hiroyuki Tanaka[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, University of Tokyo, 3.Department of Earth and Planetary Science, University of Tokyo, 4.Center for Experimental Nuclear Physics and Astrophysics, University of Washington)

[SIT21-P02] Towards a better estimation of the temperature distribution beneath the Japanese Islands

*Akiko Tanaka[1], Makoto Yamano[2], Hideki Hamamoto[3], Shusaku Goto[4], Takumi Matsumoto[5] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 2.Earthquake Research Institute, The University of Tokyo, 3.Center for Environmental Science in Saitama, 4.Institute for Geo-Resources and Environment National Institute of Advanced Industrial Science and Technology, 5.National Research Institute for Earth Science and Disaster Resilience)

[SIT21-P03] The estimation of the neutrino flux from the crust of the Japanese islands using the geochemical database

*Satoru Haraguchi[1], Kenta Ueki[1], Hikaru Iwamori[1,2,3] (1.Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, the University of Tokyo, 3.Tokyo Institute of Technology)

[SIT21-P04] **Viscosity of potassium titanosilicate melt at high pressure**

*Akio Suzuki[1] (1.Department of Earth Science, Graduate School of Science, Tohoku University)

[SIT21-P05] **Lattice thermal conductivity of wadsleyite and ringwoodite at the mantle transition zone pressures**

*seiji kimura[1], Kenji Ohta[6], Takaaki Kawazoe[2], Kei Hirose[3], Hiroyuki Kagi[4], Takashi Yagi[5] (1.Department of Earth and Planetary Sciences Tokyo Institute of Technology, 2.Department of Earth and Planetary Systems Science, Hiroshima University, 3.Earth-Life Science Institute, Tokyo Institute of Technology, 4.Geochemical Research Center, Graduate School of Science, University of Tokyo, 5.National Institute of Advanced Industrial Science and Technology, 6.Department of Earth and Planetary Sciences, Tokyo Institute of Technology)

[SIT21-P06] In-situ X-ray observations of the olivine-spinel transformation under shear deformation: preliminary results on the reaction-induced weakening

*Tomoaki Kubo[1], Moriyama Kazuya[1], Yuichiro Mori[1], Masahiro Imamura[1], Sanae Koizumi[2], Yu Nishihara[3], Akio Suzuki[4], Yuji Higo[5] (1.Kyushu Univ., 2.ERI, 3.GRC Ehime Univ., 4.Tohoku Univ., 5.JASRI)

[SIT21-P07] Internally resistive heated diamond anvil cell experiments with metal encapsulated minerals

*YAMAMOTO TOMONARI[1], Kenji Ohta[1], Sho Suehiro[1], Hayato Inoue[1] (1.Tokyo Institute of Technology)

[SIT21-P08] Shear deformation on post-spinel

*Daisuke Yamazaki[1], Noriyoshi Tsujino[1], Yu Nishihara[2] (1.Institute for Planetary Materials, Okayama University, 2.GRC, Ehime University)

[SIT21-P09] **Lattice thermal conductivity of $CaSiO_3$ perovskite at high pressures and high temperatures**

*Kotaro Onga[1], Kenji Ohta[1], Akira Hasegawa[1,2], Takashi Yagi[2], Kei Hirose[3,4], Yasuo Ohishi[5] (1.Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology, 3.Earth-Life Science Institute, Tokyo Institute of Technology, 4.Department of Earth and Planetary Science, The University of Tokyo, 5.Japan Synchrotron Radiation Research Institute)

[SIT21-P10] **Polycrystalline diamond sintered from ultradispersed nanodiamonds**

*Masayuki Nishi[1,2], Koichiro Yamamoto[1], Youmo Zhou[1], Tetsuo Irifune[2,1] (1.Geodynamics Research Center, Ehime University, 2.Earth-Life Science Institute, Tokyo Institute of Technology)

[SIT21-P11] Thermal conductivity measurements on iron and MgO periclase at high pressure and high temperature similar to the Earth's mid-lower mantle conditions

*Akira Hasegawa[1,2], Kenji Ohta[2], Takashi Yagi[1], Kei Hirose[3,4] (1.National Institute of Advanced Industrial Science and Technology, 2.Tokyo Institude of Technology, 3.Earth-Life Science Institute, Tokyo Institude of Technology, 4.The University of Tokyo)

[SIT21-P12] Azimuthal anisotropy in the lowermost mantle beneath Philippine from ScS-S times

*Satoru Tanaka[1] (1.Department of Deep Earth Structure and Dynamics Research Japan Agency for Marine-Earth Science and Technology)

[SIT21-P13] Detailed 3-D S-velocity structure within D" at the western Pacific LLSVP margin: smaller scale plumes and paleoslabs

*Yuki Suzuki[1], Kenji Kawai[1], Robert J. Geller[1], Satoru Tanaka[2], Weerachai Siripuvaraporn[3], Songkhun Boonchaisuku[3], Noisagool Sutthipong[3], Yasushi Ishihara[2], Taweoon Kim, Koji MIYAKAWA[4], Nozomu Takeuchi[4] (1.The University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology, 3.Mahidol University, 4.Earthquake Research Institute, The University of Tokyo)

[SIT21-P14] Possible interaction between the core and mantle inferred from a core surface flow model

*Masaki Matsushima[1] (1.Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology)

[SIT21-P15] Determination of the noble gas partition coefficients between metal-silicate melts under high-pressure and high-temperature conditions

*Tomotaka Tanaka[1], Hideharu Kuwahara[2], Satoshi Kishi[1], Ryuichi Nomura[3], Kenji Mibe[5], Hiroyuki Kagi[4], Shigehiko Tateno[6], Hirochika Sumino[1] (1.Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo , 2.Geodynamics Research Center, Ehime University, 3.Kyoto University, 4.Geochemical Research Center, Graduate School of Science, University of Tokyo, 5.Earthquake Research Institute, University of Tokyo, 6.Earth-Life Science Institute, Tokyo Institute of Technology)

[SIT21-P16] **Measurement of T-dependent electrical resistivity of solid and liquid Fe and Pt at fixed P**

*Innocent Ezenwa[1], Takashi Yoshino[1] (1.Institute for Planetary Materials, Okayama University)

[SIT21-P17] Ancient, highly depleted mantle constrained by Re-Os isotope and highly-siderophile element compositions of French Polynesian xenoliths

*Norikatsu Akizawa[1], Akira Ishikawa[2], Katsuhiko Suzuki[3], Tetsu Kogiso[4] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 3.Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 4.Graduate School of Human and Environmental Studies, Kyoto University)

[SIT21-P18] First-principles prediction of hydrogen partitioning between the core and mantle

*Atsuroh Ohba[1], Taku Tsuchiya[1] (1.Ehime University Geodynamics Research Center)

[SIT21-P19] Microvolume stable isotope measuremetns and its applicaiton for high-pressure high-temperature experimental run products

*Madhusoodhan Satish-Kumar[1], Shinnosuke Aoyama[1] (1.Department of Geology, Faculty of Science, Niigata University)

[SIT21-P20] Electrical resistivity of hcp Fe-Si alloys at high pressure and temperature

*Hayato Inoue[1], Sho Suehiro[1], Kenji Ohta[1], Kei Hirose[2,3], Yasuo Ohishi[4] (1.Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Department of Earth and Planetary Science, The University of Tokyo, 4.Japan Synchrotron Radiation Research Institute)

[SIT21-P21] Electrical resistivity and thermal conductivity of fcc Fe: Implications for the Mercury's core

★Invited Papers

*Hitoshi Gomi[1], Takashi Yoshino[1] (1.Okayama University)

[SIT21-P22] Lateral heterogeneity in the lowermost outer core (F layer) of the Earth revealed by seismic analyses

*Toshiki Ohtaki[1], Satoshi Kaneshima[2], Taku Tsuchiya[3] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST), 2.Department of Earth and Planetary Sciences, Kyushu University,

3.Geodynamics Research Center, Ehime University)

[SIT21-P23] Flows and light element distribution in the outer core associated with heterogeneous growth of the inner core of the Earth

*Shin-ichi Takehiro[1], Youhei SASAKI[2] (1.Research Institute for Mathematical Sciences, Kyoto University, 2.Department of Mathematics, Kyoto University)

[SIT21-P24] Sharpness of the hemispherical boundary in the inner core beneath the northern Pacific

*Ryohei Iritani[1], Hitoshi Kawakatsu[1], Nozomu Takeuchi[1] (1.Earthquake Research Institute, Univ. of Tokyo)

[SIT21-P25] Stable carbon isotope fractionation in Fe-C system from first principles

*Haruhiko Dekura[1], Taku Tsuchiya[1] (1.Geodynamics Research Center, Ehime University)

[E] Poster | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_22

[S-IT21] Interaction and Coevolution of the Core and Mantle in the Earth and Planets

convener:Kenji Kawai(Department of Earth and Planetary Science, School of Science, University of Tokyo), Tsuyoshi Iizuka(University of Tokyo), Kenji Ohta(Department of Earth and Planetary Sciences, Tokyo Institute of Technology), Taku Tsuchiya(Geodynamics Research Center, Ehime University)

[SIT21-P01] Sample-scale compositional variation of the Inada granite, Ibaraki, Japan -toward the reduction of geoneutrino flux estimation errors from the Japanese crust-

★Invited Papers

*Kenta Ueki[1], Minami Kazuki[2], Tsuyoshi Iizuka[3], Sanshiro Enomoto[4], Hiroyuki Tanaka[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, University of Tokyo, 3.Department of Earth and Planetary Science, University of Tokyo, 4.Center for Experimental Nuclear Physics and Astrophysics, University of Washington)

[SIT21-P02] Towards a better estimation of the temperature distribution beneath the Japanese Islands

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 105 1F

[S-VC35] Mitigation of volcanic disasters - basic and applied researches

convener:Shinji Takarada(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Mitsuhiro Yoshimoto(Mount Fuji Research Institute, Yamanashi Prefectural Government), Yasuhiro Ishimine(Research and Education Center for Natural Hazards, Kagoshima University), Tomohiro Kubo(National Research Institute for Earth Science and Disaster Prevention), Chairperson:Mitsuhiro Yoshimoto(山梨県富士山科学研究所), Yasuhiro Ishimine(鹿児島大学地域防災教育研究センター)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SVC35-07] Developing Ash-fall impact forecasting content.

*Tomohiro Kubo[1], Yosuke Miyagi[1], Setsuya Nakada[1], Eisuke Fujita[1], Masamitsu Miyamura[1] (1.National Research Institute for Earth Science and Disaster Prevention)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SVC35-08] New Websites and a Pamphlet of IVHHN

*Yasuhiro Ishimine[1] (1.Research and Education Center for Natural Hazards, Kagoshima University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SVC35-09] State of river water pollution derived from the recent volcanic activity of Mt Iwo-Yama, Kirishima volcanoes

*Yoshikazu Kikawada[1], Haruka Yamamoto[2], Wei Deng, Megumi Fukai (1.Faculty of Science and Technology, Sophia University, 2.Graduate School of Science and Technology, Sophia University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SVC35-10] Development of information tools for evacuation and rescue in the event of volcanic disaster

*Yosuke Miyagi[1], Setsuya Nakada[1], Tomohiro Kubo[1], Mitsuhiro Yoshimoto[2], Ryo Honda[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Mount Fuji Research Institute, Yamanashi Prefectural Government)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SVC35-11] **Ignimbrite, tephra-fall, caldera and fatalities of major volcanoes in the East and Southeast Asia**

*Shinji Takarada[1], Joel Calupas Bandibas[1] (1.Geological Survey of Japan, AIST)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SVC35-12] On the climber’s attitudes to the Volcanic mitigation for active volcanoes.

*Hideyuki Itoh[1], Chizuru Totani[2], Mizuho Arai[2] (1.Faculty of policy studies, Iwate prefectural University, 2.Asia air Survey, Co.Ltd.)

[J] Poster | S (Solid Earth Sciences)：S-VC Volcanology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University)

[SVC38-P01] The structure of Showa-Shinzan Yaneyama Usu by seismic reflection surveys

*Ryuichi Takei[1], Tomoki Tsutsui[1,2], Yuya Tada[2], Tomoya Moriwaki[2], Yosuke Aoki[3], Hiroshi Aoyama[4], Go Maruyama[5] (1.Graduate School of International Resource Sciences, The University of Akita, 2.Faculty of International Resource Sciences, The University of Akita, 3.Earthquake Research Institute, The University of Tokyo, 4.Graduate school of Science, The University of Hokkaido, 5.Marutec Co., Ltd.)

[SVC38-P02] Ground deformation associated with the 2014-2015 and the 2018-2019 volcanic activities at Azumayama

*Jun Okada[1], Shigeo Matsuura[2], Katsuya Ohmi[2], Takuya Yamamura[2], Yu Nihara[3], Susumu Seki[3] (1.Volcanology Research Department (Sendai Office), Meteorological Research Institute, JMA, 2.Seismology and Volcanology Division, Sendai Regional Headquarters, JMA, 3.Regional Volcanic Observation and Warning Center, Sendai Regional Headquarters, JMA)

[SVC38-P03] BP-type and BT-type volcanic earthquakes in Azumayama

*Yusuke Yoshigai[1], Yuichi Morita[2], Katsuya Ohmi[3], Yu Nihara[4], Tsukasa Kobayashi[1] (1.Volcanological Division, Japan Meteorological Agency, 2.Earthquake Research Institute, University of Tokyo, 3.Seismology and Volcanology Division, Sendai Regional Headquarters, Japan Meteorological Agency, 4.Regional Volcanic Observation and Warning Center, Sendai Regional Headquarters, Japan Meteorological Agency)

[SVC38-P04] The occurrence and petrology of the fine-grained pyroclastic materials of the Futatsudake-Shibukawa eruption in Haruna volcano.

*Teruyoshi Maruyama[1], Yuki Suzuki[2] (1.Department of Earth Sciences, School of Education , Waseda University, 2.Department of Earth Sciences, Faculty of Education and Integrated Arts of Sciences, Waseda University)

[SVC38-P05] The occurrence and petrology of the block and ash flow deposit from the Futatsudake-Shibukawa eruption, Haruna volcano

*Yuki Suzuki[1], Ryouto Fukushima[2] (1.Department of Earth Sciences, Faculty of Education and Integrated Arts of Sciences, Waseda University, 2.Department of Earth Sciences, School of Education, Waseda University)

[SVC38-P06] Report of Volcanic Activity at Kusatsu-Shiranesan in 2018

*Tsukasa Kobayashi[1], Koji Kato[1], Koichi Suemine[1], Kazuhiro Kimura[1], Yusuke Yoshigai[1], Yasuo Ogawa[2], Kenji Nogami[2], Wataru Kanda[2], Akihiko Terada[2] (1.Volcanological Division, Japan Meteorological Agency, 2.Volcanic Fluid Research Center, Tokyo Institute of Technology)

[SVC38-P07] Noble gas isotope composition of fumaroles and hydrothermal gases around Kusatsu-Shirane volcano

*Kotaro Toyama[1], Hirochika Sumino[1], Kaori Kawana[1], Yoshihide Akiyama[1], Takeshi Ohba[2], Muga Yaguchi[3], Akihiko Terada[4] (1.Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo, 2.Department of chemistry, School of Science, Tokia University, 3.Meteorological Research Institute, 4.Volcanic Fluid Research Center, Tokyo Institute of Technology)

[SVC38-P08] Self-potential and geomagnetic total intensity observations at Motoshirane volcano after the 2018 eruption

*Akira Yamazaki[1], Hideki Iino[1], Tatsurou Tanaka[1] (1.Kakioka Magnetic Observatory)

[SVC38-P09] Eruption processes of the 3rd and 4th stage of Niigata-Yakeyama Volcano, Japan, inferred from microlite texture and chemical composition

*Takumi Yoshida[1], Takeshi Saito[1] (1.Shinshu University)

[SVC38-P10] Estimation of subsurface structure of Shinyu crater lake, Tateyama Caldera, based on the water level and seismic observation data

*Ryohei Kawaguchi[1], Naoko Saito[2], Shin'ya Onizawa[1] (1.Meteorological Research Institute, 2.Toyama local Meteorological office, Japan Meteorological Agency)

[SVC38-P11] Real time monitoring of underground temperature in Jigokudani, Midagahara volcano using LPWA devices

*Tohru Watanabe[1], Toyama branch NTT West[2] (1.Gradudate School of Science and Engineering, University of Toyama, 2.Nippon Telegraph and Telephone West Corporation)

[SVC38-P12] Varying chemical and isotopic compositions of fumarolic gases from the summit and from the 1962-63 eruptive vents at Yakedake Volcano, Japan

*Takeshi Saito[1], Shun Sawamura[2], Kazuhiro Amita[3], Taketoshi Mishima[4], Shinji Ohsawa[4] (1.Institute of Science, Academic Assembly School of Science and Technology, Shinshu University, 2.Graduate School of Science and Technology, Shinshu University, 3.Graduate School of Engineering Science, Akita University, 4.Beppu Geothermal Research Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

[SVC38-P13] Eruption age determination of the latest two lava flows and characteristics of volcaniclastic materials from the recent activity of Yokodake Volcano, Japan

*Hiroya Nitta[1], Takeshi Saito[1], Yorinao Shitaoka[2] (1.Shinshu University of Science and Technology, 2.Department of Environment System, Faculty of Geo-environmental Science, Rissho University)

[SVC38-P14] Estimating the date of the 2007 eruption of Mount Ontake Volcano using waveform correlation

*Shuhei Nishijima[1], Toshiko Terakawa[1], Shinichiro Horikawa[1] (1.Graduate School of Environmental Studies, Nagoya University)

[SVC38-P15] Seismic activity beneath Mt. Ontake volcano before and after the 2007 and 2014 eruptions

*Yoshiko Yamanaka[1], Shinichiro Horikawa[1], Yuta Maeda[1] (1.Graduate School of Encironmental Studies, University of NAGOYA)

[SVC38-P16] Effect of rain and snowmelt correction of tiltmeter data
- Application example for Ontakesan Volcano -

*Kazuhiro Kimura[1,5], Katsuhisa Kawashima[2], Takane Matsumoto[2], Akihiko SASAKI[4], Tsutomu Iyobe[3], Junichi Miyamura[1], Masaki Nakahashi[1] (1.Japan Meteorological Agency, 2.Research Institute for Natural Hazards and Disaster Recovery, Niigata University, 3.Faculty of Engineering, Kyoto University, 4.Department of Geography and Environmental Studies, Kokushikan University, 5.Graduate School Science and Technology, Niigata University)

[SVC38-P17] **Spatial Variation of b-value around Mt. Fuji influenced by the Eastern Shizuoka Earthquake of 15 March 2011**

*Takumi Murakoshi[1], Tomonari Miyashita[2] (1.National Defense Academy, 2.JASDF)

[SVC38-P18] Present condition of submarged volcano, Teishi Knoll, off Ito, Eastern Izu Peninsula

*Toshiro Yamanaka[1], Yoshifumi Kawada[2], Takuro Noguchi[3], Mayumi Hatta[3], Kei Okamura[3] (1.Tokyo Univ. Marine Science and Technology, 2.Tohoku University, 3.Kochi University)

[SVC38-P19] Descriptions and age of volcanic products before the caldera formation in the northern part of Izu-Oshima, off Tokyo, Pacific Ocean

*Satoshi Terayama[1], Takehiko Suzuki[1], Makoto Kobayashi[2] (1.Tokyo Metropolitan University, 2.Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University)

[SVC38-P20] Time change of p-value by Schuster method using earthquakes around Izu-Ohsima summit

*Hiroyuki Takayama[1] (1.Volcanological Division 1st labolatory, Meteorological Research Institute)

[SVC38-P21] Standard stratigraphy and characteristic properties of late Quaternary tephras on the Niijima-island: Report of geochemistry and refractive indices of volcanic glass shards, orthopyroxene, hornblende, and cummingtonite

*Kaori Aoki[1], Makoto Kobayashi[1], Fumikatsu NISHIZAWA[1,2], Masanori Murata[1], Daisuke Ishimura[1], Takehiko Suzuki[1] (1.Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University, 2.Mount Fuji Research Institute, Yamanashi Prefectural Government)

[SVC38-P22] **Tephrostratigraphy and its eruption history of the Latest Activity in the Kozushima Volcano, the Izu Islands**

*Makoto Kobayashi[1], Masanori Murata[1], Fumikatsu NISHIZAWA[2], Takehiko Suzuki[1,3] (1.Research Center for Volcanic Hazards and their mitigations, Tokyo Metropolitan Univ., 2.Fuji Research Institute, Yamanashi Prefectural

Government, 3.Department of Geography, Tokyo Metropolitan Univ.)

[SVC38-P23] Characteristics of hypocenter distribution connected with velocity structures in and around Miyakejima, Kozushima and Hachijojima volcanoes

*Hiroko Hagiwara[1], Hidefumi Watanabe[1] (1.Tokyo Metroplitan Government)

[SVC38-P24] Deformation of Miyakejima volcano measured by GNSS campaign observation (2013-2015)

*Haruna Watanabe[1], Takeshi Matsushima[2], Miyo Fukui, Atsushi Watanabe[3], Jun Oikawa[3], Takashi OKUDA[4], Taku Ozawa[5], Yosuke Miyagi[5] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University, 3.Earthquake Research Institute, University of Tokyo, 4.Earthquake and Volcanology Research Center, 5.National Research Institute for Earth Science and Disaster Resilience)

[SVC38-P25] Characteristic properties of distal and proximal tephras in the Mikurajima Island, Izu Islands.

*Tomohiro Tano[1], Takehiko Suzuki[1,2], Makoto Kobayashi[2], Masanori Murata[2] (1.Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, 2.Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University)

[SVC38-P26] Pseudo thermal anomalies in the shortwave infrared bands of the Himawari-8 AHI and their correction for volcano thermal observation

*Takayuki Kaneko[1], ATSUSHI YASUDA[1], Yoshizaki Yoshito[2], Takasaki Kenji[3], Yoshiaki HONDA[4] (1.Earthquake Research Institute, University of Tokyo, 2.Meteorological Satellite Center, Japan Meteorological Agency, 3.Japan Fisheries Research and Education Agency, 4.Center for Environmental Remote Sensing, Chiba University)

[SVC38-P27] Shallow earthquakes in Unzen Volcano inferred from dense seismic observation and resistivity structure

*Hashimoto Tasuku[1], Koki Aizawa[2], Takeshi Matsushima[2], Hiroshi Shimizu[2], Yuto Hayashida[1], Yuhei Yuasa[1], Kaori Tsukamoto[1], Yuto Yamamoto[3], Kanta Miyano[3], Megumi Kamizono[1], Satoshi Matsumoto[2] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University, 3.Department of Earth and Planetary Sciences, School of Science, Kyushu University)

[SVC38-P28] Characteristics of shallow volcanic earthquakes beneath the summit of Unzen Volcano

*Kanta Miyano[1], Hiroshi Shimizu[2], Takeshi Matsushima[2], Satoshi Matsumoto[2], Koki Aizawa[2], Hashimoto Tasuku[3], Yuto Hayashida[3], Yuhei Yuasa[3] (1.Department of Earth and Planetary Sciences, School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University, 3.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University)

[SVC38-P29] Pyroclastic deposits and the stratigraphy on the outcrop to north east from Mt.Unzen

*Daisuke Nagai[1] (1.Mt.Unzen disaster memorial hall)

[SVC38-P30] Relative gravity changes in Aso Volcano (Kumamoto Prefecture) observed from 2015 to 2018

*Yusuke Miyauchi[1], Takahito Kazama[1], Yoichi Fukuda[1], Shin Yoshikawa[2], Takahiro Ohkura[2], Jun Nishijima[3], Yasuhiro Fujimitsu[3] (1.Graduate School of Science, Kyoto University, 2.Aso Volcanological Laboratory, Kyoto University, 3.Graduate School of Engineering, Kyushu University)

[SVC38-P31] Precise leveling survey in Aso volcano, 2018

*Takahiro Ohkura[1], Shin Yoshikawa[1], Hiroyuki Inoue[1], Akihiko Yokoo[1], Mitsuru Utsugi[1], Keigo Yamamoto[2], Kazunari Uchida[4], Yuta Maeda[5], Shinichiro Horikawa[5], Kenjiro Matsuhiro[5], Takashi OKUDA[5], Kazushi Tanoue[5], Fumiaki Kimata[7], Masayuki Murase[6], Hitoshi Mori[6], Taketoshi Mishima[3], Shintaro Komatsu[2], Masaki Takaya[3], Jun Oikawa[8], Kyoka Ishii[3], Yusuke Miyauchi[3], Ikuma Kimura[3], Masaki Uchida[3], Kazuho Nakai[3], Kosei Takishita[3], Keita Chiba[4], Hashimoto Tasuku[4], Yoshinosuke Kamiya[4], Yuto Yamamoto[4] (1.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University, 2.DPRI, Kyoto University, 3.Graduate School of Science, Kyoto University, 4.Graduate School of Science, Kyushu University, 5.Graduate School, Nagoya University, 6.College of Human and Society, Nihon University, 7.TRIES, 8.ERI,Univ.of Tokyo)

[SVC38-P32] Magma evolution during the Aso-3 caldera-forming eruption cycle deduced from the chemistry of plagioclase phenocrysts

*yuki matsukida[1], Tsuyoshi Iizuka[1], Takayuki Ushikubo[2], Kenji Shimizu[2], Nobuo Geshi[3], Isoji MIYAGI[3], Morihisa Hamada[2] (1.the University of Tokyo, 2.Japan Agency for Marine-Earth and Science Technology, 3.The National Institute of Advanced Industrial Science and Technology)

[SVC38-P33] Relationship between duration of eruption tremor and eruption volume

*Azusa Mori[1], Hiroyuki Kumagai[1] (1.Nagoya University Environmental Studies)

[SVC38-P34] Crustal deformation accompanied with the eruption of Shinmoe-dake in early March 2018

*Tsuyoshi Watanabe[1], Takashi Yokota[1], Susumu Kurahashi[1], Kenta Enomoto[1] (1.Aichi Institute of Technology)

[SVC38-P35] Sources under Iwo-yama, Kirishima Volcanoes derived from GNSS observation and Precise leveling survey.

*Yuki Koga[1], Takeshi Matsushima[2], Kazunari Uchida[2], Dan Muramatsu[1], Yuichi Iwasa[1] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu university , 2.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University)

[SVC38-P36] Regional vertical deformation around Aira caldera from GNSS data

*Kazuho Nakai[1], Masato Iguchi[2], Takahiro Ohkura[3] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2.Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University, 3.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

[SVC38-P37] Vertical ground deformation in Sakurajima volcano measured by precise leveling survey (during Nov. 2017 - Nov. 2018)

*Keigo Yamamoto[1], Takeshi Matsushima[2], Shin Yoshikawa[3], Hiroyuki Inoue[3], Tadaomi Sonoda[1], Kosei Takishita[1], Kazuho Nakai[1], Masaki Uchida[3], Ryo Oyanagi[3], Yoshinosuke Kamiya[2], Takahiro Ohkura[3] (1.Disaster Prevention Research Institute, Kyoto University, 2.Fuculty of Sciences, Kyushu University, 3.Gruduate School of Science, Kyoto University)

[SVC38-P38] Spatiotemporal gravity variations from the 1990s in Sakurajima Volcano, revealed by repeated relative gravity measurements

*Ryo Oyanagi[1], Takahito Kazama[1], Keigo Yamamoto[2], Hiromitsu Oshima[3], Kazumi Okada[3], Tadaomi Sonoda[2], Masato Iguchi[2] (1.Graduate School of Science, Kyoto University, 2.DPRI, Kyoto University, 3.ISV, Hokkaido University)

[SVC38-P39] Investigation into the crater of Sakurajima volcano during eruption using UAV

*Shunsuke Miura[1], Takumi Mochiduki[1], Kouji Fujita[1], Toshihiro Urayama[1], Hisashi Sasaki[1], Tatsuro Chiba[1] (1.Asia Air Survey Co.,Ltd)

[SVC38-P40] **Seismic refraction and wide-angle reflection experiment in southern Kyushu, Japan: (3) the 2018 exploration report**

*Hiroki Miyamachi[1], Hiroaki Takahashi[2], Hiroshi Aoyama[2], Mako Ohzono[2], Takahiro Shiina[6], Masamitsu Takada[2], Masayoshi Ichiyanagi[2], Teruhiro Yamaguchi[2], Yuki Susukida[2], Saito Kazuma[2], Chihiro Ito[2], Yoshio Murai[2], Tatsuya Nakagaki[2], Tomoki Tsutsui[3], Ryuichi Takei[3], Yuuya Tada[3], Mare Yamamoto[4], Satoshi Hirahara[4], Takashi NAKAYAMA[4], Ryosuke Azuma[4], Syuichi Suzuki[4], Toshinori Sato[5], Eiji Kurashimo[6], Miwako Ando[6], Shinichi Tanaka[6], Satoshi Ikezawa[6], Tomoaki Yamada[6], Kazuo Nakahigashi[7], Yuta Maeda[8], Shinichiro Horikawa[8], Kenjirou Matsuhiro[8], Takashi OKUDA[8], Shuhei Tsuji[8], Naoki Sogawa[8], Hiroshi Katao[9], Takuo Shibutani[9], Tsutomu Miura[9], Nakagawa Jun[9], Itaru Yoneda[9], Takeshi Tameguri[9], Kosei Takishita[9], Kazuho Nakai[9], Yusuke Yamashita[9], Takeshi Matsushima[10], Kazunari Uchida[10], Rintaro Miyamachi[10], Hiroshi Yakiwara[1], Shuichiro Hirano[1], Takeshi Kubo[1], Kenyu Sakao[1] (1.Kagoshima University, 2.Hokkaido University, 3.Akita University, 4.Tohoku University, 5.Chiba University, 6.University of Tokyo, 7.Tokyo University of Marine Science and Technology, 8.Nagoya University, 9.Kyoto University, 10.Kyushu University)

[SVC38-P41] Flow and emplacement mechanism of Koya Ignimbrite

*Keiko Suzuki-Kamata[1], Reina NAKAOKA[1], Tomomi Yamane[2] (1.Kobe Ocean-Bottom Exploration Center , 2.Department of Planetology, Graduate School of Science, Kobe University)

[SVC38-P42] Investigating Origin of landslide-like bathymetric feature at southern Mt.Kaimon using bathymetric and multichannel seismic reflection surveys

*hiroto yamaguchi[1], Satoshi Shimizu[2], Hikaru Iwamaru[2], Mamoru Sano[2], Nobukazu Seama[3,2], Misaki Horiuchi[3], Tetsuo Matsuno[2,3], Yoshiyuki Tatsumi[2,3] (1.Department of Planetology, Faculty of Science, Kobe university, 2.Kobe ocean-bottom exploration center, 3.Department of Planetology, Graduate School of Science, Kobe university)

[SVC38-P43] Occurrence and distribution of pyroclastic fall deposits of Kuchinoerabujima volcano 2018-2019 eruption

*Masashi NAGAI[1], Shojiro Nakagawa[2], Yu Iriyama[1], Takahiro Miwa[1], Toshikazu Tanada[1], Hideki Ueda[1], Setsuya Nakada[1] (1.Volcano Research Department, National Research Institute for Earth Science and Disaster Resilience, 2.Yakushima Chigaku Club)

[SVC38-P44] Ground Deformation around Domestic Active Volcanoes detected by InSAR of ALOS-2/PALSAR-2

*Takafumi Taniguchi[1], Isao Kageyama[1], Okuyama Satoshi[2], Shinobu Ando[2] (1.Japan Meteorological Agency, 2.Meteorological Research Institute)

[SVC38-P45] **Volcano-hydrothermal inflation revealed by the spatial variation of stress field at the Tatun Volcano Group, northern Taiwan**

*Hsin-Chieh Pu[1], Cheng-Horng Lin[2,3,4,5], Ya-Ju Hsu[2], Li-Chin Chang[3] (1.Central Weather Bureau, Taiwan, ROC., 2.Institute of Earth Sciences, Academia Sinica, Taipei, Taiwan, ROC., 3.Taiwan Volcano Observatory at Tatun, Taipei, Taiwan, ROC., 4. Department of Geosciences, National Taiwan University, Taipei 10617, Taiwan, ROC., 5.National Center for Research on Earthquake Engineering, National Applied Research Laboratories, Taipei, Taiwan, ROC.)

[SVC38-P46] Topographic change and crustal deformation associated with December 2018 eruption of Krakatau volcano in Indonesia

*Hiroshi Yarai[1], Tomokazu Kobayashi[1], Shinya Yamada[1] (1.GSI of Japan)

[J] Poster | S (Solid Earth Sciences)：S-VC Volcanology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_25

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University)

[SVC38-P01] The structure of Showa-Shinzan Yaneyama Usu by seismic reflection surveys

*Ryuichi Takei[1], Tomoki Tsutsui[1,2], Yuya Tada[2], Tomoya Moriwaki[2], Yosuke Aoki[3], Hiroshi Aoyama[4], Go Maruyama[5] (1.Graduate School of International Resource Sciences, The University of Akita, 2.Faculty of International Resource Sciences, The University of Akita, 3.Earthquake Research Institute, The University of Tokyo, 4.Graduate school of Science, The University of Hokkaido, 5.Marutec Co., Ltd.)

[SVC38-P02] Ground deformation associated with the 2014-2015 and the 2018-2019 volcanic activities at Azumayama

*Jun Okada[1], Shigeo Matsuura[2], Katsuya Ohmi[2], Takuya Yamamura[2], Yu Nihara[3], Susumu Seki[3] (1.Volcanology Research Department (Sendai Office), Meteorological Research Institute, JMA, 2.Seismology and Volcanology Division, Sendai Regional Headquarters, JMA, 3.Regional Volcanic Observation and Warning Center, Sendai Regional Headquarters, JMA)

[SVC38-P03] BP-type and BT-type volcanic earthquakes in Azumayama

*Yusuke Yoshigai[1], Yuichi Morita[2], Katsuya Ohmi[3], Yu Nihara[4], Tsukasa Kobayashi[1] (1.Volcanological Division, Japan Meteorological Agency, 2.Earthquake Research Institute, University of Tokyo, 3.Seismology and Volcanology Division, Sendai Regional Headquarters, Japan Meteorological Agency, 4.Regional Volcanic Observation and Warning Center, Sendai Regional Headquarters, Japan Meteorological Agency)

[SVC38-P04] The occurrence and petrology of the fine-grained pyroclastic materials of the Futatsudake-Shibukawa eruption in Haruna volcano.

*Teruyoshi Maruyama[1], Yuki Suzuki[2] (1.Department of Earth Sciences, School of Education , Waseda University, 2.Department of Earth Sciences, Faculty of Education and Integrated Arts of Sciences, Waseda University)

[SVC38-P05] The occurrence and petrology of the block and ash flow deposit from the Futatsudake-Shibukawa eruption, Haruna volcano

*Yuki Suzuki[1], Ryouto Fukushima[2] (1.Department of Earth Sciences, Faculty of Education and Integrated Arts of Sciences, Waseda University, 2.Department of Earth Sciences, School of Education, Waseda University)

[SVC38-P06] Report of Volcanic Activity at Kusatsu-Shiranesan in 2018

*Tsukasa Kobayashi[1], Koji Kato[1], Koichi Suemine[1], Kazuhiro Kimura[1], Yusuke Yoshigai[1], Yasuo Ogawa[2], Kenji Nogami[2], Wataru Kanda[2], Akihiko Terada[2] (1.Volcanological Division, Japan Meteorological Agency, 2.Volcanic Fluid Research Center, Tokyo Institute of Technology)

[SVC38-P07] Noble gas isotope composition of fumaroles and hydrothermal gases around Kusatsu-Shirane volcano

*Kotaro Toyama[1], Hirochika Sumino[1], Kaori Kawana[1], Yoshihide Akiyama[1], Takeshi Ohba[2], Muga Yaguchi[3], Akihiko Terada[4] (1.Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo, 2.Department of chemistry, School of Science, Tokia University, 3.Meteorological Research Institute, 4.Volcanic Fluid Research Center, Tokyo Institute of Technology)

[SVC38-P08] Self-potential and geomagnetic total intensity observations at Motoshirane volcano after the 2018 eruption

*Akira Yamazaki[1], Hideki Iino[1], Tatsurou Tanaka[1] (1.Kakioka Magnetic Observatory)

[SVC38-P09] Eruption processes of the 3rd and 4th stage of Niigata-Yakeyama Volcano, Japan, inferred from microlite texture and chemical composition

*Takumi Yoshida[1], Takeshi Saito[1] (1.Shinshu University)

[SVC38-P10] Estimation of subsurface structure of Shinyu crater lake, Tateyama Caldera, based on the water level and seismic observation data

*Ryohei Kawaguchi[1], Naoko Saito[2], Shin'ya Onizawa[1] (1.Meteorological Research Institute, 2.Toyama local Meteorological office, Japan Meteorological Agency)

[SVC38-P11] Real time monitoring of underground temperature in Jigokudani, Midagahara volcano using LPWA devices

*Tohru Watanabe[1], Toyama branch NTT West[2] (1.Gradudate School of Science and Engineering, University of Toyama, 2.Nippon Telegraph and Telephone West Corporation)

[SVC38-P12] Varying chemical and isotopic compositions of fumarolic gases from the summit and from the 1962-63 eruptive vents at Yakedake Volcano, Japan

*Takeshi Saito[1], Shun Sawamura[2], Kazuhiro Amita[3], Taketoshi Mishima[4], Shinji Ohsawa[4] (1.Institute of Science, Academic Assembly School of Science and Technology, Shinshu University, 2.Graduate School of Science and Technology, Shinshu University, 3.Graduate School of Engineering Science, Akita University, 4.Beppu Geothermal Research Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

[SVC38-P13] Eruption age determination of the latest two lava flows and characteristics of volcaniclastic materials from the recent activity of Yokodake Volcano, Japan

*Hiroya Nitta[1], Takeshi Saito[1], Yorinao Shitaoka[2] (1.Shinshu University of Science and Technology, 2.Department of Environment System, Faculty of Geo-environmental Science, Rissho University)

[SVC38-P14] Estimating the date of the 2007 eruption of Mount Ontake Volcano using waveform correlation

*Shuhei Nishijima[1], Toshiko Terakawa[1], Shinichiro Horikawa[1] (1.Graduate School of Environmental Studies, Nagoya University)

[SVC38-P15] Seismic activity beneath Mt. Ontake volcano before and after the 2007 and 2014 eruptions

*Yoshiko Yamanaka[1], Shinichiro Horikawa[1], Yuta Maeda[1] (1.Graduate School of Encironmental Studies, University of NAGOYA)

[SVC38-P16] Effect of rain and snowmelt correction of tiltmeter data
- Application example for Ontakesan Volcano -

*Kazuhiro Kimura[1,5], Katsuhisa Kawashima[2], Takane Matsumoto[2], Akihiko SASAKI[4], Tsutomu Iyobe[3], Junichi Miyamura[1], Masaki Nakahashi[1] (1.Japan Meteorological Agency, 2.Research Institute for Natural Hazards and Disaster Recovery, Niigata University, 3.Faculty of Engineering, Kyoto University, 4.Department of Geography and Environmental Studies, Kokushikan University, 5.Graduate School Science and Technology, Niigata University)

[SVC38-P17] **Spatial Variation of b-value around Mt. Fuji influenced by the Eastern Shizuoka Earthquake of 15 March 2011**

*Takumi Murakoshi[1], Tomonari Miyashita[2] (1.National Defense Academy, 2.JASDF)

[SVC38-P18] Present condition of submarged volcano, Teishi Knoll, off Ito, Eastern Izu Peninsula

*Toshiro Yamanaka[1], Yoshifumi Kawada[2], Takuro Noguchi[3], Mayumi Hatta[3], Kei Okamura[3] (1.Tokyo Univ. Marine Science and Technology, 2.Tohoku University, 3.Kochi University)

[SVC38-P19] Descriptions and age of volcanic products before the caldera formation in the northern part of Izu-Oshima, off Tokyo, Pacific Ocean

*Satoshi Terayama[1], Takehiko Suzuki[1], Makoto Kobayashi[2] (1.Tokyo Metropolitan University, 2.Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University)

[SVC38-P20] Time change of p-value by Schuster method using earthquakes around Izu-Ohsima summit

*Hiroyuki Takayama[1] (1.Volcanological Division 1st labolatory, Meteorological Research Institute)

[SVC38-P21] Standard stratigraphy and characteristic properties of late Quaternary tephras on the Niijima-island: Report of geochemistry and refractive indices of volcanic glass shards, orthopyroxene, hornblende, and cummingtonite

*Kaori Aoki[1], Makoto Kobayashi[1], Fumikatsu NISHIZAWA[1,2], Masanori Murata[1], Daisuke Ishimura[1], Takehiko Suzuki[1] (1.Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University, 2.Mount Fuji Research Institute, Yamanashi Prefectural Government)

[SVC38-P22] **Tephrostratigraphy and its eruption history of the Latest Activity in the Kozushima Volcano, the Izu Islands**

*Makoto Kobayashi[1], Masanori Murata[1], Fumikatsu NISHIZAWA[2], Takehiko Suzuki[1,3] (1.Research Center for Volcanic Hazards and their mitigations, Tokyo Metropolitan Univ., 2.Fuji Research Institute, Yamanashi Prefectural

Government, 3.Department of Geography, Tokyo Metropolitan Univ.)

[SVC38-P23] Characteristics of hypocenter distribution connected with velocity structures in and around Miyakejima, Kozushima and Hachijojima volcanoes

*Hiroko Hagiwara[1], Hidefumi Watanabe[1] (1.Tokyo Metroplitan Government)

[SVC38-P24] Deformation of Miyakejima volcano measured by GNSS campaign observation (2013-2015)

*Haruna Watanabe[1], Takeshi Matsushima[2], Miyo Fukui, Atsushi Watanabe[3], Jun Oikawa[3], Takashi OKUDA[4], Taku Ozawa[5], Yosuke Miyagi[5] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University, 3.Earthquake Research Institute, University of Tokyo, 4.Earthquake and Volcanology Research Center, 5.National Research Institute for Earth Science and Disaster Resilience)

[SVC38-P25] Characteristic properties of distal and proximal tephras in the Mikurajima Island, Izu Islands.

*Tomohiro Tano[1], Takehiko Suzuki[1,2], Makoto Kobayashi[2], Masanori Murata[2] (1.Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, 2.Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University)

[SVC38-P26] Pseudo thermal anomalies in the shortwave infrared bands of the Himawari-8 AHI and their correction for volcano thermal observation

*Takayuki Kaneko[1], ATSUSHI YASUDA[1], Yoshizaki Yoshito[2], Takasaki Kenji[3], Yoshiaki HONDA[4] (1.Earthquake Research Institute, University of Tokyo, 2.Meteorological Satellite Center, Japan Meteorological Agency, 3.Japan Fisheries Research and Education Agency, 4.Center for Environmental Remote Sensing, Chiba University)

[SVC38-P27] Shallow earthquakes in Unzen Volcano inferred from dense seismic observation and resistivity structure

*Hashimoto Tasuku[1], Koki Aizawa[2], Takeshi Matsushima[2], Hiroshi Shimizu[2], Yuto Hayashida[1], Yuhei Yuasa[1], Kaori Tsukamoto[1], Yuto Yamamoto[3], Kanta Miyano[3], Megumi Kamizono[1], Satoshi Matsumoto[2] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University, 3.Department of Earth and Planetary Sciences, School of Science, Kyushu University)

[SVC38-P28] Characteristics of shallow volcanic earthquakes beneath the summit of Unzen Volcano

*Kanta Miyano[1], Hiroshi Shimizu[2], Takeshi Matsushima[2], Satoshi Matsumoto[2], Koki Aizawa[2], Hashimoto Tasuku[3], Yuto Hayashida[3], Yuhei Yuasa[3] (1.Department of Earth and Planetary Sciences, School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University, 3.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University)

[SVC38-P29] Pyroclastic deposits and the stratigraphy on the outcrop to north east from Mt.Unzen

*Daisuke Nagai[1] (1.Mt.Unzen disaster memorial hall)

[SVC38-P30] Relative gravity changes in Aso Volcano (Kumamoto Prefecture) observed from 2015 to 2018

*Yusuke Miyauchi[1], Takahito Kazama[1], Yoichi Fukuda[1], Shin Yoshikawa[2], Takahiro Ohkura[2], Jun Nishijima[3], Yasuhiro Fujimitsu[3] (1.Graduate School of Science, Kyoto University, 2.Aso Volcanological Laboratory, Kyoto University, 3.Graduate School of Engineering, Kyushu University)

[SVC38-P31] Precise leveling survey in Aso volcano, 2018

*Takahiro Ohkura[1], Shin Yoshikawa[1], Hiroyuki Inoue[1], Akihiko Yokoo[1], Mitsuru Utsugi[1], Keigo Yamamoto[2], Kazunari Uchida[4], Yuta Maeda[5], Shinichiro Horikawa[5], Kenjiro Matsuhiro[5], Takashi OKUDA[5], Kazushi Tanoue[5], Fumiaki Kimata[7], Masayuki Murase[6], Hitoshi Mori[6], Taketoshi Mishima[3], Shintaro Komatsu[2], Masaki Takaya[3], Jun Oikawa[8], Kyoka Ishii[3], Yusuke Miyauchi[3], Ikuma Kimura[3], Masaki Uchida[3], Kazuho Nakai[3], Kosei Takishita[3], Keita Chiba[4], Hashimoto Tasuku[4], Yoshinosuke Kamiya[4], Yuto Yamamoto[4] (1.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University, 2.DPRI, Kyoto University, 3.Graduate School of Science, Kyoto University, 4.Graduate School of Science, Kyushu University, 5.Graduate School, Nagoya University, 6.College of Human and Society, Nihon University, 7.TRIES, 8.ERI,Univ.of Tokyo)

[SVC38-P32] Magma evolution during the Aso-3 caldera-forming eruption cycle deduced from the chemistry of plagioclase phenocrysts

*yuki matsukida[1], Tsuyoshi Iizuka[1], Takayuki Ushikubo[2], Kenji Shimizu[2], Nobuo Geshi[3], Isoji MIYAGI[3], Morihisa Hamada[2] (1.the University of Tokyo, 2.Japan Agency for Marine-Earth and Science Technology, 3.The National Institute of Advanced Industrial Science and Technology)

[SVC38-P33] Relationship between duration of eruption tremor and eruption volume

*Azusa Mori[1], Hiroyuki Kumagai[1] (1.Nagoya University Environmental Studies)

[SVC38-P34] Crustal deformation accompanied with the eruption of Shinmoe-dake in early March 2018

*Tsuyoshi Watanabe[1], Takashi Yokota[1], Susumu Kurahashi[1], Kenta Enomoto[1] (1.Aichi Institute of Technology)

[SVC38-P35] Sources under Iwo-yama, Kirishima Volcanoes derived from GNSS observation and Precise leveling survey.

*Yuki Koga[1], Takeshi Matsushima[2], Kazunari Uchida[2], Dan Muramatsu[1], Yuichi Iwasa[1] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu university , 2.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University)

[SVC38-P36] Regional vertical deformation around Aira caldera from GNSS data

*Kazuho Nakai[1], Masato Iguchi[2], Takahiro Ohkura[3] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2.Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University, 3.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

[SVC38-P37] Vertical ground deformation in Sakurajima volcano measured by precise leveling survey (during Nov. 2017 - Nov. 2018)

*Keigo Yamamoto[1], Takeshi Matsushima[2], Shin Yoshikawa[3], Hiroyuki Inoue[3], Tadaomi Sonoda[1], Kosei Takishita[1], Kazuho Nakai[1], Masaki Uchida[3], Ryo Oyanagi[3], Yoshinosuke Kamiya[2], Takahiro Ohkura[3] (1.Disaster Prevention Research Institute, Kyoto University, 2.Fuculty of Sciences, Kyushu University, 3.Gruduate School of Science, Kyoto University)

[SVC38-P38] Spatiotemporal gravity variations from the 1990s in Sakurajima Volcano, revealed by repeated relative gravity measurements

*Ryo Oyanagi[1], Takahito Kazama[1], Keigo Yamamoto[2], Hiromitsu Oshima[3], Kazumi Okada[3], Tadaomi Sonoda[2], Masato Iguchi[2] (1.Graduate School of Science, Kyoto University, 2.DPRI, Kyoto University, 3.ISV, Hokkaido University)

[SVC38-P39] Investigation into the crater of Sakurajima volcano during eruption using UAV

*Shunsuke Miura[1], Takumi Mochiduki[1], Kouji Fujita[1], Toshihiro Urayama[1], Hisashi Sasaki[1], Tatsuro Chiba[1] (1.Asia Air Survey Co.,Ltd)

[SVC38-P40] **Seismic refraction and wide-angle reflection experiment in southern Kyushu, Japan: (3) the 2018 exploration report**

*Hiroki Miyamachi[1], Hiroaki Takahashi[2], Hiroshi Aoyama[2], Mako Ohzono[2], Takahiro Shiina[6], Masamitsu Takada[2], Masayoshi Ichiyanagi[2], Teruhiro Yamaguchi[2], Yuki Susukida[2], Saito Kazuma[2], Chihiro Ito[2], Yoshio Murai[2], Tatsuya Nakagaki[2], Tomoki Tsutsui[3], Ryuichi Takei[3], Yuuya Tada[3], Mare Yamamoto[4], Satoshi Hirahara[4], Takashi NAKAYAMA[4], Ryosuke Azuma[4], Syuichi Suzuki[4], Toshinori Sato[5], Eiji Kurashimo[6], Miwako Ando[6], Shinichi Tanaka[6], Satoshi Ikezawa[6], Tomoaki Yamada[6], Kazuo Nakahigashi[7], Yuta Maeda[8], Shinichiro Horikawa[8], Kenjirou Matsuhiro[8], Takashi OKUDA[8], Shuhei Tsuji[8], Naoki Sogawa[8], Hiroshi Katao[9], Takuo Shibutani[9], Tsutomu Miura[9], Nakagawa Jun[9], Itaru Yoneda[9], Takeshi Tameguri[9], Kosei Takishita[9], Kazuho Nakai[9], Yusuke Yamashita[9], Takeshi Matsushima[10], Kazunari Uchida[10], Rintaro Miyamachi[10], Hiroshi Yakiwara[1], Shuichiro Hirano[1], Takeshi Kubo[1], Kenyu Sakao[1] (1.Kagoshima University, 2.Hokkaido University, 3.Akita University, 4.Tohoku University, 5.Chiba University, 6.University of Tokyo, 7.Tokyo University of Marine Science and Technology, 8.Nagoya University, 9.Kyoto University, 10.Kyushu University)

[SVC38-P41] Flow and emplacement mechanism of Koya Ignimbrite

*Keiko Suzuki-Kamata[1], Reina NAKAOKA[1], Tomomi Yamane[2] (1.Kobe Ocean-Bottom Exploration Center , 2.Department of Planetology, Graduate School of Science, Kobe University)

[SVC38-P42] Investigating Origin of landslide-like bathymetric feature at southern Mt.Kaimon using bathymetric and multichannel seismic reflection surveys

*hiroto yamaguchi[1], Satoshi Shimizu[2], Hikaru Iwamaru[2], Mamoru Sano[2], Nobukazu Seama[3,2], Misaki Horiuchi[3], Tetsuo Matsuno[2,3], Yoshiyuki Tatsumi[2,3] (1.Department of Planetology, Faculty of Science, Kobe university, 2.Kobe ocean-bottom exploration center, 3.Department of Planetology, Graduate School of Science, Kobe university)

[SVC38-P43] Occurrence and distribution of pyroclastic fall deposits of Kuchinoerabujima volcano 2018-2019 eruption

*Masashi NAGAI[1], Shojiro Nakagawa[2], Yu Iriyama[1], Takahiro Miwa[1], Toshikazu Tanada[1], Hideki Ueda[1], Setsuya Nakada[1] (1.Volcano Research Department, National Research Institute for Earth Science and Disaster Resilience, 2.Yakushima Chigaku Club)

[SVC38-P44] Ground Deformation around Domestic Active Volcanoes detected by InSAR of ALOS-2/PALSAR-2

*Takafumi Taniguchi[1], Isao Kageyama[1], Okuyama Satoshi[2], Shinobu Ando[2] (1.Japan Meteorological Agency, 2.Meteorological Research Institute)

[SVC38-P45] **Volcano-hydrothermal inflation revealed by the spatial variation of stress field at the Tatun Volcano Group, northern Taiwan**

*Hsin-Chieh Pu[1], Cheng-Horng Lin[2,3,4,5], Ya-Ju Hsu[2], Li-Chin Chang[3] (1.Central Weather Bureau, Taiwan, ROC., 2.Institute of Earth Sciences, Academia Sinica, Taipei, Taiwan, ROC., 3.Taiwan Volcano Observatory at Tatun, Taipei, Taiwan, ROC., 4. Department of Geosciences, National Taiwan University, Taipei 10617, Taiwan, ROC., 5.National Center for Research on Earthquake Engineering, National Applied Research Laboratories, Taipei, Taiwan, ROC.)

[SVC38-P46] Topographic change and crustal deformation associated with December 2018 eruption of Krakatau volcano in Indonesia

*Hiroshi Yarai[1], Tomokazu Kobayashi[1], Shinya Yamada[1] (1.GSI of Japan)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | IC 2F

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Takehiko Suzuki, Maya Yasui

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SVC38-01] Tephrochoronology in the southwest part of basaltic Izu-oshima volcanic island during last 20,000 years, off Tokyo, Pacific Ocean

*Takehiko Suzuki[1], Satoshi Terayama[1], Jun Matsukaze[1], Yuichi Kato[1] (1.Faculty of Urban Environmental Sciences, Tokyo Metropolitan University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SVC38-02] **Tephrostratigraphy at Daisan-yama and Jinai-jima, and correlation with eruption deposits from Mamashitaura Volcanoes in Niijima Volcano, Izu-islands**

*Makoto Kobayashi[1], Masanori Murata[1], Kaori Aoki[1], Daisuke Ishimura[1,2], Takehiko Suzuki[1,2] (1.Research Center for Volcanic Hazards and Their Mitigations, Tokyo Metropolitan Univ., 2.Department of Geography, Tokyo Metropolitan Univ.)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SVC38-03] Constration of pre-eruptive process using crystal clot: A case study of Unzen 1991-95 eruption

*Kurumi Iwahashi[1], ATSUSHI YASUDA[1] (1.Earthquake Research Institute,The University of Tokyo)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SVC38-04] Petrological study of Pinatubo 1991 eruption ~ Discussions of magma plumbing model~

*Tomohisa Tamura[1,2], Mitsuhiro Nakagawa[2] (1.West Japan Engineering Consultants, Inc., 2.Earth and Planetary System Science, Hokkaido University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SVC38-05] Rediscovery of the Higuruma Debris Avalanche Deposit in Asama-Kurofu Volcano

*Maya Yasui[1], Masaki Takahashi[1], Tatsuo Kanamaru[1] (1.College of Humanities and Sciences, Nihon University)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | IC 2F

[S-VC39] Hydrothermal systems of volcanoes

convener:Yasuhiro Fujimitsu(Department of Earth Resources Engineering, Faculty of Engineering, Kyushu University), Wataru Kanda(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Takeshi Ohba(Department of chemistry, School of Science, Tokia University), Chairperson:Yasuhiro Fujimitsu(Faculty of Engineering, Kyushu University), Takeshi Ohba, Wataru Kanda

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SVC39-01] Hydrothermal system of Tokachidake volcano, Japan: Examination from multi-disciplinary surveys

*Ryo Takahashi[1], Noritoshi Okazaki[1], Makoto Tamura[1] (1.Geological Survey of Hokkaido, Hokkaido Research Organization)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SVC39-02] Fumarole and hot spring activities after the 2015 eruption of Hakone Volcano and their relationships with the seismicity and crustal deformation

*Kazutaka Mannen[1], Masatake Harada[1], Yohei Yukutake[1], George Kikugawa[1] (1.Hot Springs Research Institute of Kanagawa Prefecture)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SVC39-03] A possible geothermal source at around 4 km depth estimated by the seismic observation in Ibusuki geothermal area

*Junzo Kasahara[1,3], Yoko Hasada[2,1], Hiroyasu Kuzume[1] (1.ENAA, 2.Daiwa Exploration and Consulting Co., 3.Shizuoka Univ.)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SVC39-04] Time variation in the chemical and isotopic composition of fumarolic gases at Kusatsu-Shirane volcano Japan

*Takeshi Ohba[1], Muga Yaguchi[2], Nozomi Numanami[1], Kotaro Toyama[3], Hirochika Sumino[3], Urumu Tsunogai[4], Masanori Ito[4], Ryo Shingubara[4] (1.Department of chemistry, School of Science, Tokia University, 2.Meteorological Research Institute, JMA, 3.The University of Tokyo Graduate School of Arts and Sciences Department of Basic Science, 4.Nagoya University Graduate School of Environmental Studies)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SVC39-05] Behavior of Arsenic and Mercury related to hydrothermal activities in Kirishima, Satsuma Iwojima, and Yamagawa, Kyushu Japan

*Motoya Habuchi[1], Harue Masuda[1], Tsuyoshi Shintani[1], Shuzo Furuya[1], Keigo Mori[1], Jun-ichiro Ishibashi[2], Takeshi Matsushima[2], Akinori Takeuchi[3], Syogo Oshima[4], Reo Ikawa[5] (1.Osaka City University, 2.Kyushu University, 3.National Institute for Environmental Studies, 4.West Japan Engineering Consultants, Inc., 5.National Institute of Advanced Industrial Science and Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SVC39-06] The chemical composition of thermal waters from spring and hot pool at Mt. Iwoyama of Kirishima volcano

*Muga Yaguchi[1], Takeshi Ohba[2], Kotaro Toyama[3], Fukuoka Regional Headquarters JMA[4], Kagoshima Meteorological Office JMA[4] (1.Meteorological Research Institute, 2.Tokai University, 3.Graduate School of the University of Tokyo, 4.Japan Meteorological Agency)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | IC 2F

[S-VC39] Hydrothermal systems of volcanoes

convener:Yasuhiro Fujimitsu(Department of Earth Resources Engineering, Faculty of Engineering, Kyushu University), Wataru Kanda(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Takeshi Ohba(Department of chemistry, School of Science, Tokia University), Chairperson:Yasuhiro Fujimitsu(Faculty of Engineering, Kyushu University), Takeshi Ohba, Wataru Kanda

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SVC39-07] Re-examination of origin of the variety in magmatic-hydrothermal fluids

*Hiroshi Shinohara[1] (1.Geological Survey of Japan, AIST)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SVC39-08] **Constraining electrical resistivity structure of volcanoes using multiphase flow modelling: an example of Miyake-jima**

*Marceau Gresse[1], Makoto Uyeshima[1], Takao Koyama[1], Maki Hata[1], Hideaki Hase[2], Koki Aizawa[3], Yusuke Yamaya[4], Yoichi Sasai[5], Jacques Zlotnicki[6], Tawat Rung-Arunwan[1], Hideki Ueda[7] (1.Earthquake Research Institute, The University of Tokyo, Tokyo, Japan, 2.Geothermal Energy Research & Development Co., Ltd., Tokyo, Japan, 3.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University, Fukuoka, Japan., 4.Planning Division, National Institute of Advanced Industrial Science and Technology, Tokyo, Japan, 5.Earthquake Prediction Research Centre, Tokai University, Shizuoka, Japan, 6.CNRS, OPGC-UMR6524, Aubière, France, 7.National Research Institute for Earth Science and Disaster Resilience, Tsukuba, Japan)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SVC39-09] MT survey and 3-D resistivity structure in the Niseko area, southwestern Hokkaido

*Makoto Tamura[1], Toru Mogi[2], Junna Kanahiro[2], Daisuke Oka[1], Junya Maruyama[1], Takahiro Suzuki[1], Noritoshi Okazaki[1] (1.Geological Survey of Hokkaido, Hokkaido Research Organization, 2.Division of Sustainable Resource Engineering, Fucluty of Engineering, Hokkaido University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SVC39-10] **Hydrothermal fluid activity of the Tatun Volcano Group, Taiwan, revealed by self-potentials and seismicity**

*Hong-Jia Chen[1], Zhi-Xian Yang[1], Chien-Chih Chen[1,2], Cheng-Horng Lin[3,4] (1.Department of Earth Sciences, National Central University, Taiwan., 2.Earthquake-Disaster & Risk Evaluation and Management, National Central University, Taoyuan, Taiwan., 3.Institute of Earth Sciences, Academia Sinica, Taipei, Taiwan., 4.Taiwan Volcano Observatory at Tatun, Taipei, Taiwan.)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SVC39-11] Utilizing the electrical conductivity distribution to unravel the hydrothermal system beneath Mt.Hasan composite volcano and its vicinity, southwest Cappodocia, Turkey

*Sabri Bulent Tank[1], Mustafa Karas[1] (1.Bogazici University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SVC39-12] Three-dimensional Magnetotelluric Inversion to map geothermal structures in Eburru Geothermal field, Kenya.

*JUSTUS MAITHYA[1], Yasuhiro FUJIMITSU[2] (1.Graduate School of Engineering, Department of Earth Resources Engineering, Kyushu University, 2.Faculty of Engineering, Department of Earth Resources Engineering, Kyushu University)

[J] Poster | S (Solid Earth Sciences)：S-VC Volcanology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_14

[S-VC39] Hydrothermal systems of volcanoes

convener:Yasuhiro Fujimitsu(Department of Earth Resources Engineering, Faculty of Engineering, Kyushu University), Wataru Kanda(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Takeshi Ohba(Department of chemistry, School of Science, Tokia University)

[SVC39-P01] Changes in the chemistry of spring water related to the recent volcanic activity of Mt Iwo-Yama, Kirishima volcanic area

*Haruka Yamamoto[1], Yoshikazu Kikawada[2], Megumi Fukai, Wei Deng (1.Graduated school of Fuculty of Sience and Technology Sophia University, 2.Fuculty of Sience and Technology Sophia University)

[SVC39-P02] Hydrothermal circulation process related to phreatic eruption of Iwo-Yama at Kirishima volcanoes

*Keigo Mori[1], Harue Masuda[1], Tsuyoshi Shintani[1], Motoya Habuchi[1], Syuzou Furuya[1], Jun-ichiro Ishibashi[2], Takeshi Matsushima[2], Syogo Oshima[3], Reo Ikawa[4] (1.Osaka City University, 2.Kyushu University, 3.West Japan Engineering Consultants, Inc., 4.AIST)

[SVC39-P03] Determination on the stable isotopic compositions of H_2O in a volcanic plume

*Masanori Ito[1], Urumu Tsunogai[1], Koji U Takahashi[2], Fumiko Nakagawa[1] (1.Nagoya University, Graduate School of Environmental Studies, 2.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SVC39-P04] **Radon measurements at Aso volcano: an experimental automatic radon station operative within the proximal zone of Nakadake**

*Corrado CIGOLINI[1], Shin Yoshikawa[2], Tomo Shibata[3], Marco Laiolo[1], Diego Coppola[1] (1.Department of Earth Sciences, University of Torino, Italy, 2.Aso Volcanological Laboratory, Kyoto University, Japan, 3.Institute for Geothermal Sciences, Graduate school of Science, Kyoto University, Japan)

[SVC39-P05] Evolution of the hydrothermal system of Aso volcano during the 2014-2016 eruption period, as inferred by the ACTIVE observations

*Takuto Minami[1], Mitsuru Utsugi[2], Hisashi Utada[1], Tsuneomi Kagiyama[3] (1.Ocean Hemisphere Research Institute, Earthquake Research Institute,The University of Tokyo, 2.Aso Volcanological Laboratory, Institute for Geothremal Sciences, Graduate School of Science, Kyoto University, 3.Aso Geopark Promotion Council)

[SVC39-P06] 3-D Inversion of Magnetotelluric data from the Aluto-Langano Geothermal Field, Ethiopia

*Dejene Bekele[1], Yasuhiro FUJIMITSU[2] (1.Graduate School of Engineering, Department of Cooperative Resources Engineering, Kyushu University, 2.Faculty of Engineering, Department of Earth Resources Engineering, Kyushu University)

[SVC39-P07] Interpretation of Gravity Data to Delineate the Geothermal Reservoir Extent and Assess the Geothermal Resource in the Municipality of Isa, Southern Kyushu, Japan

*CARLOS OSMIN POCASANGRE[1], Yasuhiro Fujimitsu[1], Jun Nishijima[1] (1.Department of Earth Resources Engineering, Kyushu University)

[SVC39-P08] Conductive and convective heat fluxes inferred from temperature profile of a borehole in Izu-Oshima volcano

*Shin'ya Onizawa[1] (1.Volcanology Research Department, Meteorological Research Institute, JMA)

[SVC39-P09] Numerical model of the hydrothermal system at the Akakura Caldera in Kurikoma Area

*Yasuhiro Fujimitsu[1], Daichi Yoshioka[2] (1.Department of Earth Resources Engineering, Faculty of Engineering, Kyushu University, 2.Department of Earth Resources Engineering, Graduate School of Engineering, Kyushu University)

[J] Poster | S (Solid Earth Sciences)：S-VC Volcanology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_26

[S-VC39] Hydrothermal systems of volcanoes

convener:Yasuhiro Fujimitsu(Department of Earth Resources Engineering, Faculty of Engineering, Kyushu University), Wataru Kanda(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Takeshi Ohba(Department of chemistry, School of Science, Tokia University)

[SVC39-P01] Changes in the chemistry of spring water related to the recent volcanic activity of Mt Iwo-Yama, Kirishima volcanic area

*Haruka Yamamoto[1], Yoshikazu Kikawada[2], Megumi Fukai, Wei Deng (1.Graduated school of Fuculty of Sience and Technology Sophia University, 2.Fuculty of Sience and Technology Sophia University)

[SVC39-P02] Hydrothermal circulation process related to phreatic eruption of Iwo-Yama at Kirishima volcanoes

[J] Oral | S (Solid Earth Sciences)：S-TT Technology & Techniques

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 303 3F

[S-TT45] Synthetic Aperture Radar

convener:Youhei Kinoshita(University of Tsukuba), Yu Morishita(Geospatial Information Authority of Japan), Shoko Kobayashi(Tamagawa University), Takahiro Abe(Earth Observation Research Center, Japan Aerospace Exploration Agency), Chairperson:Shoko Kobayashi(Tamagawa University), Kazuya Ishitsuka(Kyoto University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[STT45-01] Extraction of ground changes near the crater by the eruption of Kilauea volcano.

*Fujiyama Kaho[1], Masanobu Shimada[1], Yuki Kimoto[1], Kenta Yoshioka[1] (1.TokyoDenki University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[STT45-02] ALOS-2 observation of the 2017 Sefidsang earthquake, northeastern Iran: a blind shallow-dipping thrust event near the Eastern Kopeh Dagh

*Nematollah Ghayournajarkar[1], Yo Fukushima[2] (1.Graduate School of Science, Tohoku University, 2.International Research Institute of Disaster Science, Tohoku University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[STT45-03] **InSAR ground displacements and slip distribution associated with secondary fault slips of the 2016 Kumamoto earthquake**

*Yo Fukushima[1], Daisuke Ishimura[2] (1.International Research Institute of Disaster Science, Tohoku University, 2.Department of Geology, Tokyo Metropolitan University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[STT45-04] Surface displacements at the Kumamoto plain using persistent scatterer interferometry and comparison with groundwater levels

*Kazuya Ishitsuka[1], Takeshi Tsuji[2] (1.Kyoto Univ., 2.Kyushu Univ.)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[STT45-05] Forest fire detection in the low biomass dry forest with JICA-JAXA Forest Early Warning System in the Tropics (JJ-FAST).

*Manabu Watanabe[1], Christian Naohide koyama[1], Masato Hayashi[2], Izumi Nagatani[2], Takeo Tadono[2], Masanobu Shimada[1,2] (1.School of Science and Engineering, Tokyo denki university, 2.JAXA/EORC)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[STT45-06] Nominal operation results of Japanese ALOS-2

★Invited Papers

*Shinichi Sobue[1] (1.Japan Aerospace Exploration Agency)

[J] Oral | S (Solid Earth Sciences)：S-TT Technology & Techniques

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 303 3F

[S-TT45] Synthetic Aperture Radar

convener:Youhei Kinoshita(University of Tsukuba), Yu Morishita(Geospatial Information Authority of Japan), Shoko Kobayashi(Tamagawa University), Takahiro Abe(Earth Observation Research Center, Japan Aerospace Exploration Agency), Chairperson:Yohei Kinoshita(RESTEC), Takahiro Abe(JAXA)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[STT45-07] Estimation of velocity distribution of Shirase Glacier derived from SAR data obtained by ERS-1/2 tandem mission

*Koichiro Doi[1,2], Yuichi Aoyama[1,2], Kazuki Nakamura[3], Tsutomu Yamanokuchi[4], Kazuo Shibuya[1] (1.National Institute of Polar Research, 2.SOKENDAI, 3.College of Engineering, Nihon University, 4.RESTEC)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[STT45-08] Heavy rainfall-induced displacement of more than 2.5m in the Kushiro Marsh in 2016, detected by ALOS-2 SAR

*Satoshi Fujiwara[1], Yu Morishita[1], Takayuki Nakano[1], Yuji Miura[1], Yasuaki Kakiage[1], MURAMATSU Hiroki[1], Hiroshi Une[1] (1.GSI of Japan)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[STT45-09] Surface deformation of Asama Volcano, Japan, detected by time-series InSAR combining persistent and distributed scatterers, 2014-2018

*Yosuke Aoki[1], Xiaowen Wang[1] (1.Earthquake Research Institute, University of Tokyo)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[STT45-10] Improvement of Airborne L-band-SAR (Pi-SAR-L2) Coherence by Pixel by Pixel Resampling

*Makoto Murakami[1], Masato Furuya[1], Taku Ozawa[4], Youichiro Takada[1], Yosuke Aoki[3], Masanobu Shimada[2], Shohei Narita[1] (1.Hokkaido University, 2.Tokyo Denki University, School of Science and engineerring, 3.Earthquake Research Institute, The University of Tokyo, 4. National Research Institute for Earth Science and Disaster Resilience)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[STT45-11] Ionospheric delay estimation in SAR interferometry: Significance of the method using the split-spectrum double-difference interferogram

*Taku Ozawa[1] (1.National Research Institute for Earth Science and Disaster Resilience)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[STT45-12] Detecting surface displacement accosiated with the 2018 slow slip event around Boso peninsla by use of Sentinel-1 InSAR with atmospheric correction

*Youhei Kinoshita[1], Tadahiro Nimura[1], Ryoichi Furuta[1] (1.RESTEC, Remote Sensing Technology Center of Japan)

[J] Poster | S (Solid Earth Sciences)：S-TT Technology & Techniques

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_15

[S-TT45] Synthetic Aperture Radar

convener:Youhei Kinoshita(University of Tsukuba), Yu Morishita(Geospatial Information Authority of Japan), Shoko Kobayashi(Tamagawa University), Takahiro Abe(Earth Observation Research Center, Japan Aerospace Exploration Agency)

[STT45-P01] Development of InSAR tropospheric phase delay correction system at MRI (2nd report)

*Okuyama Satoshi[1], Shinobu Ando[1], Toshiki Shimbori[1] (1.Meteorological Research Institute)

[STT45-P02] Mitigation of atmospheric delay in InSAR for fair estimate of crustal deformation at Azumayama volcano

*Kana Abe[1], Yoshiko Ogawa[1], Yasuhiro Hisada[1], Hirohide Demura[1], Taku Ozawa[2], Satoshi Miura[3], Akira Kusakabe[1], Takehiro Arai[1] (1.The University of Aizu, 2.National Research Institute for Earth Science and Disaster Resilience, 3.Graduate School of Science, Tohoku University)

[STT45-P03] Unusual displacement observed in InSAR analysis results of fumarolic area of active volcanos: An example of the Kamiyu district in Hakone Volcano

*Ryosuke Doke[1], Kazuhiro Itadera[1] (1.Hot Springs Research Institute of Kanagawa Prefecture)

[STT45-P04] Detection of Deformation Signals at Mud Volcanoes in Semau Island, Indonesia

*Naufal Setiawan[1], Masato Furuya[1] (1.Hokkaido University)

[STT45-P05] Extraction of supraglacial lakes on debris-covered glacier using ALOS-2/PALSAR-2

Chikako Kinefuchi[2], *Chiyuki Narama[1], Tsutomu Yamanokuchi[3], Takeo Tadono[4] (1.Niigata University, Program of Field Research in the Environmental Sciences, 2.Graduate School of Science and Technology, Niigata University, 3.RESTEC, 4.JAXA)

*Shin-ichi Ito[1], Masayuki Kano[2], Hiromichi Nagao[1] (1.The University of Tokyo, 2.Tohoku University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[STT46-04] Bayesian approach for statistical modeling and forecasting of aftershock activities

★Invited Papers

*Takahiro Omi[1] (1.Institue of Industrial Science, the University of Tokyo)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[STT46-05] **Bias Correction for the Distribution of Aftershocks Within Short-Term Period Immediately After Large Main Shock**

*Kosuke Morikawa[1], Hiromichi Nagao[2], Shin-ichi Ito[2], Shin'ichi Sakai[2], Naoshi Hirata[2] (1.Osaka University, 2.Earthquake Research Institute, The University of Tokyo)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[STT46-06] Deep-learning-based Earthquake Detection for Continuous Seismic Network Records

*Keisuke Yano[1], Takahiro Shiina[2], Sumito Kurata[1], Aitaro Kato[2], Fumiyasu Komaki[1], Shin'ichi Sakai[2], Naoshi Hirata[2] (1.Graduate School of Information Science and Technology, The University of Tokyo, , 2.Earthquake Research Institute, The University of Tokyo)

[J] Poster | S (Solid Earth Sciences)：S-TT Technology & Techniques

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_16

[S-TT46] Seismic Big Data Analysis Based on the State-of-the-Art of Bayesian Statistics

convener:Hiromichi Nagao(Earthquake Research Institute, The University of Tokyo), Aitaro Kato(Earthquake Research Institute, the University of Tokyo), Takuto Maeda(Graduate School of Science and Technology, Hirosaki University), Keisuke Yano(The university of Tokyo)

[STT46-P01] P-wave Polarity Determination of Waveform Data Observed in Western Japan, Using Deep Learning

*Shota Hara[1], Yukitoshi Fukahata[2], Yoshihisa Iio[2] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University)

[STT46-P02] Trans-dimensional Bayesian inversion for a radially anisotropic S-wave velocity model in the crust and upper mantle: Application to the Australian continent

*Toru Taira[1], Kazunori Yoshizawa[2] (1.Graduate School of Science, Hokkaido University, 2.Faculty of Science, Hokkaido University)

[STT46-P03] Seismic wavefield imaging based on dense seismic networks using replica exchange Monte Carlo method

*Masayuki Kano[1], Hiromichi Nagao[2,3], Kenji Nagata[4,5], Shin-ichi Ito[2,3], Kei Hasegawa[2], Shin'ichi Sakai[2], Shigeki Nakagawa[2], Muneo Hori[2], Naoshi Hirata[2] (1.Graduate school of science, Tohoku University, 2.Earthquake Research Institute, The University of Tokyo, 3.Graduate School of Information Science and Technology, The University of Tokyo, 4.AIST, 5.Japan Science and Technology Agency)

[STT46-P04] Bayesian oscillator decomposition for seismic data

*Takeru Matsuda[1] (1.The University of Tokyo)

[STT46-P05] Uncertainty evaluation of source parameter estimates by MCMC in Oklahoma

*Nana Yoshimitsu[1], Takuto Maeda[2], William Ellsworth[3] (1.The University of Tokyo, Earthquake Research Institute, 2.Hirosaki University, 3.Stanford Univerisy)

[J] Poster | S (Solid Earth Sciences)：S-TT Technology & Techniques

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_28

[S-TT46] Seismic Big Data Analysis Based on the State-of-the-Art of Bayesian Statistics

convener:Hiromichi Nagao(Earthquake Research Institute, The University of Tokyo), Aitaro Kato(Earthquake Research Institute, the University of Tokyo), Takuto Maeda(Graduate School of Science and Technology, Hirosaki University), Keisuke Yano(The university of Tokyo)

[E] Oral | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-CG49] Hard-Rock Drilling Science: From Continental to Deep Sea Drilling, and Oman Project

convener:Katsuyoshi Michibayashi(Department of Earth and Planetary Sciences, Nagoya University), Eiichi TAKAZAWA(Department of Geology, Faculty of Science, Niigata University), Norikatsu Akizawa(Department of Ocean Floor Geoscience, Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Katsuyoshi Michibayashi

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SCG49-01] **Geochemical and Geochronological Constraints on the Origin and Emplacement of the East Taiwan Ophiolite: Implication for Subduction Initiation of the South China Sea.**

*Chiou-ting Lin[1], Ron A. Harris[2], Wei-dong Sun[1], Guo-liang Zhang[1] (1.Center of Deep Sea Research, Institute of Oceanology, Chinese Academy of Sciences, 2.Department of Geology, Brigham Young University)

3:45 PM - 4:05 PM JST | 6:45 AM - 7:05 AM UTC

[SCG49-02] Towards a complete profile of hydrothermal alteration in the lower oceanic crust and uppermost mantle; Insights from the Oman Drilling Project and ChikyuOman2017 and 2018

★Invited Papers

*Damon A H Teagle[1], Michelle Harris[2], Gretchen Früh-Green[3], Eiichi TAKAZAWA[4], Katsuyoshi Michibayashi[5], Peter B Kelemen[6], Oman Drilling Project Science Team[1] (1.Ocean & Earth Science, National Oceanography Centre Southampton, University of Southampton, SO14-3ZH, Southampton, UK, 2.School of Geography, Earth and Environmental Sciences, Plymouth University, UK, 3.Earth Sciences, ETH Zürich, Switzerland, 4.Geology, Niigata University, Japan, 5.Earth and Planetary Sciences, Nagoya University, Japan, 6.LDEO, Columbia University, New York, USA)

4:05 PM - 4:25 PM JST | 7:05 AM - 7:25 AM UTC

[SCG49-03] Peridotite alteration in OmanDP cores

★Invited Papers

*Peter B Kelemen[1], Juan Carlos de Obeso[1], Craig Manning[2], Marguerite Godard[3], Wolfgang Bach[4], Merry Yue Cai[1], Saebyul Choe[5], Judith Coggon[6], Eric Ellison[7], Alireza Eslami[8], Katy Evans[9], Michelle Harris[10], Wolf-Achim Kahl[4], Jürg Matter[6], Katsu Michibayashi[11], Keichi Okazaki[12], Philippe Pézard[3], Damon A.H. Teagle[6], Alexis Templeton[7], OmanDP Oman Drilling Project Science Team (1.LDEO, 2.UCLA, 3.U. Montpellier, 4.U. Bremen, 5.AMNH, 6.U. Southampton, 7.U. Colorado, 8.U. Tehran, 9.Curtin U., 10.U. Plymouth, 11.Nagoya U., 12.JAMSTEC)

4:25 PM - 4:40 PM JST | 7:25 AM - 7:40 AM UTC

[SCG49-04] Low-salinity aqueous fluid inclusions in dolomite veins of a listvenite of Oman Drilling Project Phase 1

*Tatsuhiko Kawamoto[1], Hiroki Sato[2], Toma Takahashi[3], Juan Miguel Guotana[4], Tomoaki Morishita[4], Peter B Kelemen[5], Jude Ann Coggon[6], Michelle Harris[7], Juerg Michael Matter[6], Katsuyoshi Michibayashi[8], Eiichi TAKAZAWA[9], Damon A H Teagle[6], The Oman Drilling Project Phase 1 Science Party (1.Department of Geoscience, Faculty of Science, Shizuoka University, 2.Faculty of Science, Kyoto University, 3.Faculty of Geosciences and Civil Engineering, Kanazawa University, 4.Division of Natural Sciences, Graduate School of Natural Science and Technology, Kanazawa University, 5.Lamont-Doherty Earth Observatory, Columbia University, 6.School of Ocean and Earth Science, National Oceanography Centre Southampton, University of Southampton, 7.School of Geography, Earth and Environmental Sciences, Plymouth University, 8.Department of Earth Planetary Sciences, Graduate School of Environmental Studies, Nagoya University, 9.Institute of Science and Technology, Niigata University)

4:40 PM - 5:00 PM JST | 7:40 AM - 8:00 AM UTC

[SCG49-05] Hydration and development of fracture network within oceanic lower crust: an evidence from CM1A of Oman Drilling

★Invited Papers

*Atsushi Okamoto[1], Kazuki Yosida[1], Ryosuke Oyanagi[2], Oman Drilling Project Phase 2 Science Party[3] (1.Graduate School of Environmental Studies, 2.JAMSTEC, 3.Oman Drillng Project Phase 2 Science Party)

[J] Oral | S (Solid Earth Sciences)：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[S-CG56] Ocean Floor Geosciences

convener:Kyoko Okino(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Arata Kioka, Atsushi Noda

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SCG56-25] Observational plans of the South Sandwich Arc by R/V Hakuho Maru: Toward understanding formation and evolution of the world southernmost arc-trench system

*Asuka Yamaguchi[1], Kenichiro Tani[2], Minoru Ikehara[3] (1.Atomosphere and Ocean Research Institute, The University of Tokyo, 2.National Museum of Nature and Science, 3.Center for Advanced Marine Core Research, Kochi University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SCG56-26] Seismic imaging of the source zone of the 2011 Tohoku-oki earthquake

*Dapeng Zhao[1], Xin Liu[1] (1.Department of Geophysics, Tohoku University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SCG56-27] Drastic export of organic carbon to hadal trench driven by megathrust earthquake

*A. Kioka[1], T. Schwestermann[1], J. Moernaut[1], K. Ikehara[2], T. Kanamatsu[3], C. M. McHugh[4], C. dos Santos Ferreira[5], G. Wiemer[5], N. Haghipour[6], A. J. Kopf[5], T. I. Eglinton[6], M. Strasser[1,5] (1.Universität Innsbruck, Austria, 2.GSJ-AIST, Japan, 3.JAMSTEC, Japan, 4.Queens-CUNY, USA, 5.MARUM-U. Bremen, Germany, 6.ETH Zürich, Switzerland)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SCG56-28] How do trench-fill sediments subduct under the accretionary wedge?

*Atsushi Noda[1], Hiroaki Koge[2], Yasuhiro Yamada[3], Ayumu Miyakawa[1], Juichiro Ashi[2] (1.National Institute of Advanced Industrial Science and Technology, 2.Atomosphere and Ocean Research Institute, The University of Tokyo, 3.Japan Agency for Marine-Earth Science and Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SCG56-29] Formation process of a slope basin in the Nankai Accretionary prism reconstructed from high-resolution SBP integrated with core data of ODP Site 1175 and Site 1176

*Yuichi Okuma[1], Asuka Yamaguchi[1], Hiroaki Koge[1], Rina Fukuchi[1], Juichiro Ashi[1] (1.Atmosphere and Ocean Research Institute, the University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SCG56-30] About the turbidity current considered that it occurred in the northern Suruga Bay, Central Japan by the typhoon No.24. -The traces of the accidents and the phenomenon at the sea floor detected the OBSs Array-

*Nakao Nagisa[1], Hisatoshi Baba[2], Hiroshi Sato[3], Kayoko Tsuruga[4], Izumi Sakamoto[2], Takahito Nishimiya[5], Masanao Shinohara[3], Shintaro Abe[6] (1.Tokai University, 2.Department of Marine and Earth Science, Tokai University, 3.Earthquake Research Institute, University of Tokyo, 4.Tokyo University of Marine Science and Technology, 5.Meteorological Research Institute, Japan Meteorological Agency, 6.Association for the Development of Earthquake Prediction)

[J] Poster | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_17

[S-CG56] Ocean Floor Geosciences

convener:Kyoko Okino(Atmosphere and Ocean Research Institute, The University of Tokyo)

[SCG56-P01] Signature of plume-ridge interaction on bathymetry and geochemistry along mid-ocean ridges: Insights from the Réunion Plume and Central Indian Ridge

*Clement Vincent[1], Jung-Woo Park[1], Sang-Mook Lee[1], Jonguk Kim[2], Sang-Joon Pak[2] (1.Seoul National University, 2.Korea Institute of Ocean Science and Technology)

[SCG56-P02] Spreading rate and its stability of Chile Ridge near the Chile Triple Junction

*Takanori Ishihara[1], Takeshi Matsumoto[1] (1.Ryukyu university)

[SCG56-P03] Newly Mapped Seamounts on the Antarctic Plate off Southern Chile

*Toshiya Fujiwara[1], Natsue Abe[2], Naomi Harada[3], Mirai MR16-09 Leg 2 Shipboard Science Party (1.Research and Development Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology, 2.Research and Development Center for Ocean Drilling Science, 3.Research and Development Center for Global Change)

[SCG56-P04] Surface-ship gravimetry on board MR16-09 Cruise by R/V MIRAI - Characteristrics of gravity anomaly around the Chile Triple Junction

*Takeshi Matsumoto[1], Takanori Ishihara[1] (1.Faculty of Science, University of the Ryukyus)

[SCG56-P05] Magnetic and Magnetotelluric surveys across the Afar depression, transition between continental rifting and sea-floor spreading

*Ryokei Yoshimura[1], Naoto Ishikawa[2], Tesfaye Kidane[3], Shin-ichi Kagashima[4], Nobutatsu Mochizuki[5], Ameha Atnafu Muluneh[3], Kirika Kitagawa[4], Taito Ikema[6] (1.Disaster Prevention Research Institute, Kyoto University, 2.Graduate School of Human and Environmental Studies, Kyoto University, 3.Addis Ababa University, 4.Faculty of Science, Yamagata University, 5.Priority Organization for Innovation and Excellence, Kumamoto University, 6.Faculty of Science, Kyoto University)

[SCG56-P06] **Evolution of oceanic core complexes in the Shikoku Basin: when backarc basins cease to open**

*Kyoko Okino[1], Yasuhiko Ohara[2,3], Masakazu Fujii[4], Tomoko Hanyu[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Japan Coast Guard, 3.Japan Agency for Marine-Earth Science and Technology, 4.National Institute of Polar Research)

[SCG56-P07] Thermal evolution of the Lanzo orogenic peridotite massif in western Alps: implications on thermal structure near subcontinental lithosphere-asthenosphere boundary

*Tomo Aoki[1], Kazuhito Ozawa[1], Jean-Louis Bodinier[3], Françoise Boudier[2] (1.The University of Tokyo, 2.Montpellier 2 University, 3.Geosciences Montpellier)

[SCG56-P08] Comparison of the back-arc basins of the South and the Central Ryukyus in the northwest Pacific

*Kohsaku Arai[1], Ayanori Misawa[1], Takahiko Inoue[1] (1.Institute of Geology and Geoinformation, National Institute of Advanced Industrial and Technology)

[SCG56-P09] Geochemistry and zircon U-Pb ages of mafic rocks in the Mikabu and Sorachi-Yezo belts: Comparison with the Shatsky Rise

*Naoto Kimura[1], Yuji Ichiyama[1], Shohei Takahashi[1], Hisatoshi Ito[2], Akihiro Tamura[3], Tomoaki Morishita[3] (1.Chiba University, 2.Central Research Institute of Electric Power Industry, 3.Kanazawa University)

[SCG56-P10] Submersible magnetics reveals relationship between off-axis volcanism and hydrothermal systems of the Kairei and Yokoniwa fields at the Central Indian Ridge

*Masakazu Fujii[1], Kyoko Okino[2] (1.National Institute of Polar Research and SOKENDAI, 2.Atmosphere and Ocean Research Institute, The University of Tokyo)

[SCG56-P11] Shipboard magnetic and gravity surveys around the Iheya North Knoll and the Iheya Minor Ridge in the Mid-Okinawa Trough: Preliminary results of KR18-14 Leg1/Leg2 cruises

*Kazuya Kitada[1], Takafumi Kasaya[1], Hisanori Iwamoto[1], Yoshifumi Nogi[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute of Polar Research)

[SCG56-P12] A shallow scientific drilling at Higashi Ensei Hydrothermal Field, Okinawa Trough

*Hidenori Kumagai[1], Takafumi Kasaya[1], Shuhei Totsuka[2], Shinsuke Kawagucci[1], Hideaki Machiyama[1], Koichi Iijima[1], Hirofumi Yamamoto[1], junji kaneko[1], Yusuke Ohta[3], Shohei Albert Tomita[3], Shogo Komori[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kyushu Univ., 3.Kyoto Univ., 4.AIST)

[SCG56-P13] Mineralogical and geochemical study of sediment cores collected from the Gondou hydrothermal field in the Okinawa Trough

*Jun-ichiro Ishibashi[1,2], Shuhei Totsuka[2], Akihi Tsutsumi[2], Naru Tsukamoto[2], Yusuke Kira[2], Kazuhiko Shimada[1], Toru Yamasaki[3], Ken Ikehara[3], Toshiro Nagase[4], Yutaro Takaya[5,9], Kei Ikehata[6], Takashi Goto[7], Chitaro Gouzu[7], Ryuichi Shinjo[8], Hideaki Machiyama[9], Koichi Iijima[9], Hirofumi Yamamoto[9], Hidenori Kumagai[9] (1.Department of Earth and Planetary Sciences, Kyushu University, 2.Graduate School of Science, Kyushu University, 3.National Institute of Advanced Industrial Science and Technology, 4.Tohoku University Museum, 5.School of Creative Science and Enginerring, Waseda University, 6.Faculty of Life and Environmental Sciences, University of Tsukuba, 7.Hiruzen Institute for Geology and Chronology, 8.Faculty of Science, University of the Ryukyus, 9.Japan Agency for Marine-Earth Science and Technology)

[SCG56-P14] New type of self-potential anomaly observed near a hydrothermal site of Oomuro-dashi volcano, Izu-Ogasawara arc

*Yoshifumi Kawada[1,2], Takafumi Kasaya[2] (1.International Research Institute of Disaster Science, Tohoku University, 2.Japan Agency for Marine-Earth Science and Technology)

[SCG56-P15] Numerical simulation of submarine hydrothermal ore-deposits due to a coupled process of fluid migration and reactive geochemical transport

*Claudia Fujita[1], Hajime Yamamoto[1], Jun-ichiro Ishibashi[2], Takeshi Tsuji[3] (1.Taisei Corporation, 2. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 3.Department of Earth Resources Engineering, Faculty of Science, Kyushu University)

[SCG56-P16] Mineral composition and grain size distribution of REY-rich mud in the Minamitorishima EEZ: Implication for formation process of extremely REY-rich mud

*Sakai Takumi[1], Erika Tanaka[1], Kazutaka Yasukawa[1,2], Junichiro Ohta[2,1], Koichiro Fujinaga[2,1], Kentaro Nakamura[1], Yasuhiro Kato[3,1,2] (1.Department of Systems Innovation, School of Engineering, University of Tokyo, 2.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 3.Frontier Research Center for Energy and Resources, School of Engineering, The University of Tokyo)

[SCG56-P17] **Geochemical and morphological features of manganese micronodules in REY-rich mud within the Minamitorishima EEZ, western North Pacific Ocean**

*Satoshi Kino[1], Kazutaka Yasukawa[1,2], Keishiro Azami[1], Erika Tanaka[1], Koichiro Fujinaga[2,1], Kentaro Nakamura[1], Yasuhiro Kato[1,2] (1.Department of Systems Innovation, School of Engineering, University of Tokyo, 2.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology)

[SCG56-P18] Seafloor sediment thickness around the Japan and Kurile trenches obtained by traveltime analysis for PS converted wave recoded by ocean bottom seismograms

*Ryosuke Azuma[1], Genti Toyokuni[1], Ryota Takagi[1], Syuichi Suzuki[1], Makiko Sato[1], Takashi NAKAYAMA[1], Naoki Uchida[1], Ryota Hino[1] (1.Recearch Center for Prediction of Earthquake and Volcanic Eruption, Graduate School of Science, Tohoku University)

[SCG56-P19] Examination of critical taper theory based on bathymetry data in subduction zones

*Hiroaki Koge[1], Juichiro Ashi[1], Jin-Oh Park[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[SCG56-P20] Active structures of the Sagami Bay Fault by high-resolution sub-bottom profiling and pin-point core sampling

*Juichiro Ashi[1], Asuka Yamaguchi[2], Natsumi Okutsu[1], Ayanori Misawa[3] (1.Graduate School of Frontier Sciences, The University of Tokyo, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.National Institute of Advanced Industrial Science and Technology)

[SCG56-P21] Fault Distribution and Structural Characteristic in the Nankai Trough Area, Japan

*Rei Arai[1], Narumi Takahashi[1], Minako Katsuyama[1], Shigeyoshi Tanaka[1], Hiromi Kamata[1], Tomoyuki Sato[2], Takahiko Inoue[2], Yoshiyuki Kaneda[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute of Advanced Industrial Science and Technology, 3.Kagawa University)

[SCG56-P22] Seismicity in the central Ryukyu Trench by the Ocean Bottom Seismometers

*Ren Yakabu[1], Mamoru Nakamura[1], Yusuke Yamashita[2], Masanao Shinohara[3], Tomoaki Yamada[3], Hajime Shiobara[3], Kimihiro Mochizuki[3] (1.University of the Ryukyus, 2.DPRI, Kyoto University, 3.ERI, Tokyo University)

[SCG56-P23] Seismic structure of subducted Philippine Sea plate beneath Kyushu inferred from Po/So waves

*Azusa Shito[1] (1.Institute of Seismology and Volcanology, Kyushu University)

[SCG56-P24] Slope failure features and their distribution in the forearc off northwestern Sumatra

*Kenji Hirata[1], Toshiya Fujiwara[2], Ayanori Misawa[3], Kohsaku Arai[3] (1.National Research Institue for Earth Science and Diaster resilience, 2.Japan Agency for Marine-Earth Science and Technology, 3.National Institute of Advanced Industrial Science and Technology)

[SCG56-P25] Origin and migration of fluid in the Sumatra subduction input: application of a geochronological method using a long-lived radioisotope of dissolved iodine

*Satoko Owari[1], Hitoshi Tomaru[1] (1.Chiba university)

[SCG56-P26] Challenge to Future Deep-Water Mapping: Unmanned Bathymetric Survey Competition "Shell Ocean Discovery XPRIZE"

*MASANAO SUMIYOSHI[1] (1.Hydrographic and Oceanographic Department, Japan Coast Guard)

[SCG56-P27] Prototype of deep-sea ocean bottom pressure recorder with self-calibration capability using “A-0-A” approach for detection of long-term crustal deformation

*Yusaku Ohta[1], Ryota Hino[1], Syuichi Suzuki[1], Makiko Sato[1], Yui Nishimagi[1], Hiroaki Kajikawa[2], Tokihiko Kobata[2] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 2.National Metrology Institute of Japan, National Institute of Advanced Industrial Science and Technology)

[SCG56-P28] Noise reduction and surface wave array dispersion measurements applied to NOMan's broadband OBS data

*Yuki Kawano[1], Takehi Isse[1], Hitoshi Kawakatsu[1], Akiko Takeo[1], Hajime Shiobara[1] (1.Earthquake Research Institute, The University of Tokyo)

[SCG56-P29] High-tech dredge system for abyssal bedrock research; dredge system with acoustic real time monitoring on deep sea floor.

*Teruaki Ishii[1], Yukihiro - Kida[2], Izumi - Sakamoto[3], Shiki - - Machida[4] (1.Center for Integrated Research and Education of Natural Hazards, Sizuoka University, 2.JAMSTEC, 3.Toukai University, 4.Chiba Institute of Technology)

[SCG56-P30] Construction of Database System on Offshore Faults around Japan

*Hiromi Kamata[1], Narumi Takahashi[1,2], Shigeyoshi Tanaka[1], Rei Arai[1], Minako Katsuyama[1], Ayako Nakanishi[1], Hiroyuki Fujiwara[2], Tsuneo Ohsumi[2], Takahiko Inoue[3], Tomoyuki Sato[3], Yoshiyuki Kaneda[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Research Institute for Earth Science and Disaster Resilience, 3.National Institute of Advanced Industrial Science and Technology, 4.Kagawa University)

[SCG56-P31] **An integration method for multiple sets of seafloor backscatter intensity data**

*Shiki Machida[1,2], Taichi Sato[3], Kazutaka Yasukawa[2] (1.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 2.University of Tokyo, 3.AIST)

[SCG56-P32] A precise calculation of average depth for ETOPO1

*Yasushi Harada[1], Sae Horiuchi[1] (1.School of Marine Science and Technology, Tokai University)

[J] Poster | S (Solid Earth Sciences)：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_29

[S-CG56] Ocean Floor Geosciences

convener:Kyoko Okino(Atmosphere and Ocean Research Institute, The University of Tokyo)

[SCG56-P01] Signature of plume-ridge interaction on bathymetry and geochemistry along mid-ocean ridges: Insights from the Réunion Plume and Central Indian Ridge

*Clement Vincent[1], Jung-Woo Park[1], Sang-Mook Lee[1], Jonguk Kim[2], Sang-Joon Pak[2] (1.Seoul National University, 2.Korea Institute of Ocean Science and Technology)

[SCG56-P02] Spreading rate and its stability of Chile Ridge near the Chile Triple Junction

*Takanori Ishihara[1], Takeshi Matsumoto[1] (1.Ryukyu university)

[SCG56-P03] Newly Mapped Seamounts on the Antarctic Plate off Southern Chile

*Toshiya Fujiwara[1], Natsue Abe[2], Naomi Harada[3], Mirai MR16-09 Leg 2 Shipboard Science Party (1.Research and Development Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology, 2.Research and Development Center for Ocean Drilling Science, 3.Research and Development Center for Global Change)

[SCG56-P04] Surface-ship gravimetry on board MR16-09 Cruise by R/V MIRAI - Characteristrics of gravity anomaly around the Chile Triple Junction

*Takeshi Matsumoto[1], Takanori Ishihara[1] (1.Faculty of Science, University of the Ryukyus)

[SCG56-P05] Magnetic and Magnetotelluric surveys across the Afar depression, transition between continental rifting and sea-floor spreading

*Ryokei Yoshimura[1], Naoto Ishikawa[2], Tesfaye Kidane[3], Shin-ichi Kagashima[4], Nobutatsu Mochizuki[5], Ameha Atnafu Muluneh[3], Kirika Kitagawa[4], Taito Ikema[6] (1.Disaster Prevention Research Institute, Kyoto University, 2.Graduate School of Human and Environmental Studies, Kyoto University, 3.Addis Ababa University, 4.Faculty of Science, Yamagata University, 5.Priority Organization for Innovation and Excellence, Kumamoto University, 6.Faculty of Science, Kyoto University)

[SCG56-P06] **Evolution of oceanic core complexes in the Shikoku Basin: when backarc basins cease to open**

*Kyoko Okino[1], Yasuhiko Ohara[2,3], Masakazu Fujii[4], Tomoko Hanyu[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Japan Coast Guard, 3.Japan Agency for Marine-Earth Science and Technology, 4.National Institute of Polar Research)

[SCG56-P07] Thermal evolution of the Lanzo orogenic peridotite massif in western Alps: implications on thermal structure near subcontinental lithosphere-asthenosphere boundary

*Tomo Aoki[1], Kazuhito Ozawa[1], Jean-Louis Bodinier[3], Françoise Boudier[2] (1.The University of Tokyo, 2.Montpellier 2 University, 3.Geosciences Montpellier)

[SCG56-P08] Comparison of the back-arc basins of the South and the Central Ryukyus in the northwest Pacific

[SCG61-11] Ductile deformation explains the physics of friction and genesis of earthquakes

*James Daniel Paul Moore[1], Stefan Nielsen[2], Lars N Hansen[3] (1.Earth Observatory of Singapore, 2.University of Durham, 3.University of Oxford)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SCG61-12] The seismic moment, stress drop, and strain energy release for the rupture of asperities

*Mitsuhiro Matsu'ura[1] (1.Institute of Statistical Mathematics)

[E] Poster | B (Biogeosciences)：B-BG Biogeosciences & Geosphere-Biosphere Interactions

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

[B-BG01] Elemental cycling in terrestrial and coastal ecosystems- Carbon and Nitrogen perspectives

convener:Punyasloke Bhadury(Indian Institute of Science Education and Research Kolkata)

[BBG01-P01] Forest-CEW: A Forest Ecosystems Model for Carbon-Energy-Water Processes.

*Zhenghong Tan[1] (1.Hainan University China)

[BBG01-P02] **Interdependent Dynamics of LAI-ET across Roofing Landscapes: the Mongolian and Tibetan Plateaus**

*Li Tian[1] (1.Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences)

[BBG01-P03] **Particle Phase Organic compounds (PAHs and VOCs) at Two Big Cities (Dhaka and Rajshahi) in Bangladesh**

*Islam Nazrul nazrulislam6727@gmail.com[1], Tanzina Tul Karim[1], Rasheda Nahida[1], Nusrat Mousume[1], Farha Jeba[1], Abdus Salam[1] (1.Department of Chemistry, University of Dhaka, Dhaka-1000, Bangladesh)

[BBG01-P04] **Diversity and activity of diazotrophs in the coastal waters of Southeastern Arabian Sea (SEAS)**

*JABIR THAJUDEEN[1], Mohamed Hatha Abdullah (1.Cochin University of Science and Technology India)

[BBG01-P05] **Bloom of *Palmerina hardmaniana*, a marine centric planktonic diatom in a coastal mangrove ecosystem- implication for coastal carbon cycling**

*Punyasloke Bhadury[1] (1.Centre for Climate and Environmental Studies and Department of Biological Sciences, Indian Institute of Science Education and Research Kolkata)

[BBG01-P06] Dynamics of Carbon and Nitrogen influx in large river system: Isotopic study from river Ganga, India

*Anurag Kumar[1], Prasanta Sanyal[1,2], Punyasloke Bhadury[3,2] (1.Department of Earth Sciences, Indian Institute of Science Education and Research Kolkata, Mohanpur 741246, India, 2.Centre for Climate and Environmental studies, Indian Institute of Science Education and Research Kolkata, Mohanpur 741246, India, 3.Department of Biological Sciences, Indian Institute of Science Education and Research Kolkata, Mohanpur 741246, India)

[E] Poster | B (Biogeosciences)：B-BG Biogeosciences & Geosphere-Biosphere Interactions

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_31

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 201A 2F

[B-BG01] Elemental cycling in terrestrial and coastal ecosystems- Carbon and Nitrogen perspectives

convener:Punyasloke Bhadury(Indian Institute of Science Education and Research Kolkata),
Chairperson:Punyasloke Bhadury(Indian Institute of Science Education and Research Kolkata)

3:35 PM - 4:00 PM JST | 6:35 AM - 7:00 AM UTC

[BBG01-01] **Modelling nitrogen and carbon cycles in Hooghly estuary along with adjacent mangrove ecosystem**

★Invited Papers

*Santanu Ray[1] (1.Systems ecology and ecological modelling laboratory, Dept. of Zoology, Visva-Bharati University, Santiniketan 731235, India)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[BBG01-02] ^{17}O-rich nitrate as a tracer for constraining nitrogen transformations in coastal sediments

*Chawalit Charoenpong[1,2], Scott D Wankel[2], Carolyn Buchwald[3,2], Wiebke Ziebis[4] (1.Chulalongkorn University, 2.Woods Hole Oceanographic Institution, 3.Dalhousie University, 4.University of Southern California)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[BBG01-03] **Exploring changes in bacterioplankton community structure in response to tannic acid, a major component of litterfall, in a mangrove ecosystem: a laboratory mesocosm approach**

*Anwesha Ghosh[1] (1.Integrative Tax Microb Ecol Res Group, Dept. of Biol Sci, IISERK)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[BBG01-04] **Diel variations of dissolved inorganic carbon in the Pearl River plume and the northern South China Sea shelf upwelling during summer**

*Wei-Jen Huang[1], Kai-Jung Kao[1], Yu-Shih Lin[1], James T. Liu[1], Chen-Tung Arthur Chen[1] (1.National Sun Yat-sen University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[BBG01-05] **Spatial and vertical variations of carbon and nitrogen isotopes of larch forest and NDVI in Eastern Siberia**

*Aleksandr Nogovitcyn[1], Atsuko Sugimoto[2], Ruslan Shakhmatov[1], Tomoki Morozumi[1], Shunsuke Tei[2], Yumiko Miyamoto[2], Trofim Maximov[3,4] (1.Graduate School of Environmental Science, Hokkaido University, Sapporo, Hokkaido, Japan, 2.Arctic Research Center, Hokkaido University, Sapporo, Hokkaido, Japan, 3.Institute for Biological Problems of Cryolithozone, Siberian Blanch of Russian Academy of Sciences, Yakutsk, Yakutia, Russia, 4.International Center for Biogeoscience Educational and Scientific Trainings (BEST), North-Eastern Federal University, Yakutsk, Yakutia, Russia)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[M-IS02] Drilling Earth Science

convener:Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS)), Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Azumi Kuroyanagi(Tohoku University Museum, The Center for Academic Resources and Archives, Tohoku University), Kosei E. Yamaguchi(Toho University and NASA Astrobiology Institute), Chairperson:Azumi Kuroyanagi(Tohoku University), Kan Hsiung(JAMSTEC)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[MIS02-01] Planktonic foraminiferal biostratigraphy in the South China Sea IODP Exp. 367 U 1499

*Akira Furusawa[1], Hiroki Hayashi[1] (1.Interdisciplinary Graduate School of Science and Engineering, Shimane University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[MIS02-02] High heat with slow cooling of rift margin in the South China Sea, IODP Exp.368

*Arito Sakaguchi[1,2], Nobuaki Osono[1], Keita Nakano[1] (1.Yamaguchi Univ., 2.JAMSTEC)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[MIS02-03] Abundant ferromanganese microparticles in oxic pelagic sediments (IODP Exp. 329)

*Go-Ichiro Uramoto[1,2], Yuki Morono[2], Naotaka Tomioka[2], Shigeyuki Wakaki[2], Ryoichi Nakada[2], Rota Wagai[3], Kentaro Uesugi[4], Akihisa Takeuchi[4], Masato Hoshino[4], Yoshio Suzuki[4,5], Satoshi Mitsunobu[6], Fumito Shiraishi[7], Hiroki Suga[5], Yasuo Takeichi[8], Yoshio Takahashi[5], Fumio Inagaki[2] (1.Kochi University, 2.Japan Agency for Marine-Earth Science and Technology, 3.National Agriculture and Food Research Organization, 4.Japan Synchrotron Radiation Research Institute, 5.University of Tokyo, 6.Ehime University, 7.Hiroshima University, 8.High Energy Accelerator Research Organization)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[MIS02-04] **Regional stratigraphic framework, Gas Hydrate occurrence and distribution of National Gas Hydrate Program Expedition 02 (NGHP-02) Area-B, offshore eastern India**

*KanHsi Hsiung[1], Saneatsu Saito[1], Toshiya Kanamatsu[1], Yoshinori Sanada[1], Yasuhiro Yamada[1], KYAW MOE[1], Yohei Hamada[1], Yasuyuki Nakamura[1], HungYu Wu[1] (1.Japan Agency for Marine-Earth Science and Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[MIS02-05] Fluid flow and diagenetic process in frontal thrust zone off Cape Muroto in the Nankai Trough

*Akira Ijiri[1], Shigeyuki Wakaki[1], Yoshiro Nishio[2], Yohei Hamada[1], Tsuyoshi Ishikawa[1], Fumio Inagaki[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kochi University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[MIS02-06] Recent progress and perspective on paleomagnetism by means of deep-sea drilling

*Toshitsugu Yamazaki[1], Yuhji Yamamoto[2], Toshiya Kanamatsu[3], Yuho Kumagai[4], Norihiro Nakamura[4] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Center for Advanced Marine Core Research, Kochi University, 3.Japan Agency for Marine-Earth Science and Technology, 4.Tohoku University)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[M-IS02] Drilling Earth Science

convener:Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS)), Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Azumi Kuroyanagi(Tohoku University Museum, The Center for Academic Resources and Archives, Tohoku University), Kosei E. Yamaguchi(Toho University and NASA Astrobiology Institute), Chairperson:Kosei Yamaguchi(Toho University), Yasuhiro Yamada(JAMSTEC)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS02-07] Patterns in natural fractures during transitions between stress regimes

*Nikita Dubinya[1] (1.The Schmidt Institute of Physics of the Earth of the Russian Academy of Sciences)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS02-08] ICDP DSeis 1: Introduction into JpGU 2019 papers on Drilling into Seismogenic zones of M2.0-5.5 earthquakes in South African gold mines

*Hiroshi Ogasawara[1], Bennie Liebenberg[2], Martin Ziegler[3], Yasuo Yabe[4], Ray Durrheim[5], Musa Manzi[5], Tullis C Onstott[6], Thomas Weirsberg[7] (1.Faculty of Science and Engineering, Ritsumeikan University, 2.Moab Khotsong mine, South Africa, 3.ETH, Zurich Dep. Earth Sciences, 4.Graduate School of Science, Tohoku Univ., 5.Univ. Witwatersrand, School of Geoscience, South Africa, 6.Princeton Univ., Dept. Geoscience, USA, 7.GFZ, Potzdam, Germany)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS02-09] ICDP DSeis 2: Preliminary results of physical property measurement and XRD analysis of the M5.5 fault material recovered from DSeis Project

*Tetsuro Hirono[1], Yuki Yukoyama[1], Shunya Kaneki[2], Hiroshi Ogasawara[3], Yasuo Yabe[4], Takuya Matsuzaki[5], Yuhji Yamamoto[5], Hidekazu Tokuyama[5], Tullis C. Onstott[6], Martin Ziegler[7], Durrheim Ray[8], Esterhuizen van Heerden[9], Bennie Liebenberg[9], The ICDP DSeis team (1.Department of Earth and Space Science, Graduate School of Science, Osaka University, 2.Disaster Prevention Research Institute, Kyoto University, 3.Ritsumeikan University, 4.Tohoku University, 5.Center for Advanced Marine Core Research, Kochi University, 6.Princeton University, 7.ETH Zurich, 8.Witwatersrand University, 9.Moab Khotsong mine)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS02-10] ICDP DSeis 3: Spatial variation in stress state in the source region of Orkeny earthqauke (M5.5) based on analyses of the ICDP-DSeis borehole cores

*Yasuo Yabe[1], Akimasa Ishida[2], Kosuke Sugimura[2], Kanematsu Makoto[2], Mitsuya Higashi[2], Shunsuke YOSHIDA[2], Bennie Liebenberg[7], Takatoshi Ito[3], Akio Funato[5], Bryan Watson[6], Raymond Durrheim[4], Hiroshi Ogasawara[2] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 2.Faculty of Science and Engeneer, Ritsumeikan University, 3.Institute of Fluid Science, Tohoku University, 4.School of Geoscience, University of the Witwatersrand, 5.Fukada Geological Institute, 6.School of Mining Engeneering, University of the Witwatersrand, 7.Moab Khotsong mine)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS02-11] Applications of DCDA method for in-situ crustal stress measurement - Rock core samples from NIED seismic observation wells -

*Kentaro Omura[1], Weiren Lin[2], Takatoshi Ito[3], Akio Funato[4] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Graduate School of Engineering, Kyoto University, 3.Institute of Fluid Science, Tohoku University, 4.Fukada Geological Institute)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[MIS02-12] Temperature depth profile in a 700 m deep vertical borehole in Aso volcanic zone

*Weiren Lin[1], Susumu Shibutani[1,2], Koichiro Sado[2], Nana Kamiya[1], Tatsuhiro Sugimoto[1], Terasu Sano[1], Kazuya Ishitsuka[1], Xiaoqiu Yang[4], Aiming Lin[3] (1.Graduate School of Engineering, Kyoto University, 2.Chi-ken Sogo Consultants Co., Ltd., 3.Graduate School of Science, Kyoto University, 4.South China Sea Institute of Oceanology, Chinese Academy of Sciences)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[M-IS02] Drilling Earth Science

convener:Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS)), Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Azumi Kuroyanagi(Tohoku University Museum, The Center for Academic Resources and Archives, Tohoku University), Kosei E. Yamaguchi(Toho University and NASA Astrobiology Institute), Chairperson:Yumiko Harigane(産総研), Natsue Abe(R&D Center for Ocean Drilling Science, JAMSTEC)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS02-13] Estimation of Shear Stress and Lithology Prediction Using Machine Learning and Surface Drilling Data

Tomoya Inoue[1], *Ryuta Tanaka[1], Junya Ishiwata[1] (1.Japan Agency for Marine-Earth Science and Technology)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS02-14] Overview of drilling of crust-mantle boundary of Oman ophiolite: the ICDP Oman Drilling Project

*Eiichi TAKAZAWA[1,4], Damon A H Teagle[2], Katsuyoshi Michibayashi[3], Yoshihiko Tamura[4], Jude Ann Coggon[2], Juerg Matter[2], Peter B Kelemen[5], Oman Drilling Project Phase 2 Science Party (1.Department of Geology, Faculty of Science, Niigata University, 2.University of Sauthampton, 3.Nagoya University, 4.JAMSTEC, 5.Columbia University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS02-15] Geophysical Logging of Crust-Mantle boundary at Oman Ophiolite

*Yasuhiro Yamada[1], Kyaw Moe[1], Philippe Pezard[2], Juerg Matter[3], OmanDP Science Party (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.Géosciences Montpellier, Université de Montpellier, 3.Southampton University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS02-16] Overview of the physical property measurements, ChikyuOman 2017 and 2018: Crust and Mantle sections from ICDP Oman Drilling Project Phase I and II

*Natsue Abe[1], Keishi Okazaki[1,11], Ikuo Katayama[2], Kohei Hatakeyama[2], Yuya Akamatsu[2], Benoit Ildefonse[3], Ole Ivar ulven[4], Gilbert Hong[5], Wenlu Zhu[6], Benoit Cordonnier[4], Katsuyoshi Michibayashi[7], Eiichi TAKAZAWA[8], Michell Harris[12], Damon Teagle[10], Peter Kelemen[9], Marguerite Goddard[3], Jurg Matter[10], Jude Coggon[10], The Oman Drilling Project Science Party (1.Japan Agency for Marine-Earth Science and Technology, 2.Hiroshima University, 3.Universitè de Montpellier, 4.University of Oslo, 5.Seoul National University, 6.University of Maryland, 7.Nagoya University, 8.Niigata University, 9.Columbia University, 10.University of Southampton, 11.Kanazawa University, 12.Polymouth University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS02-17] Exploring the deep subseafloor biosphere and biogeochemical carbon cycling beneath the Arctic ocean

*Fumio Inagaki[1], Steffen Leth Jørgensen[2], Rolf Birger Pedersen[2] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.Department of Earth Science, University of Bergen, Norway)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_19

[M-IS02] Drilling Earth Science

convener:Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS)), Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Azumi Kuroyanagi(Tohoku University Museum, The Center for Academic Resources and Archives, Tohoku University), Kosei E. Yamaguchi(Toho University and NASA Astrobiology Institute)

[MIS02-P01] Utilization and curation of frozen core samples in IODP and implementation of the Nagoya Protocol in ocean drilling science

*Nan XIAO[1] (1.Japan Agency for Marine Earthe Science and Technology)

[MIS02-P02] In-situ rock strength calculated from drilling parameters. Comparison of results from various sites.

*Adam Wspanialy[1], Yasuhiro Yamada[1], Saneatsu Saito[1], KYAW MOE[1] (1.Japan Agency for Marine-Earth Science and Technology)

[MIS02-P03] Interaction between submarine landslides and subseafloor sedimentary microbiome: Chikyu SCORE Expedition 910 off Cape Erimo

*Tatsuhiko Hoshino[1], Go-Ichiro Uramoto[2], Satoshi Tonai[2], Yuki Morono[1], Akira Ijiri[1], Shino Suzuki[1], Yusuke Kubo[1], Fumio Inagaki[1], Chikyu SCORE Exp. 910 Scientists . (1.Japan Agency for Marine-Earth Science and Technology, 2.Kochi University)

[MIS02-P04] High-resolution continuous records of the chemical composition of the marine sediment off Cape Erimo, Hokkaido, Japan

*Masafumi MURAYAMA[1], Shinsuke Yagyu[3], Satoshi Tonai[2], Go-Ichiro Uramoto[3], Yasuhiro Yamada[4], Fumio Inagaki[4], Yusuke Kubo[5] (1.Faculty of Agriculture and Marine Science, Kochi University, 2.Faculty of Science and Technology, Kochi University, 3.Center for Advanced Marine Core Research, Kochi University, 4.Research and Development Center for Ocean Drilling Science, JAMSTEC, 5.Center for Deep Earth Exploration, JAMSTEC)

[MIS02-P05] Thermal property measurements of core samples retrieved from Futagawa fault drilling

*Terasu Sano[1], Weiren Lin[1], Susumu Shibutani[1,2], Nana Kamiya[1], Tatsuhiro Sugimoto[1], Kazuya Ishitsuka[1], Aiming Lin[3] (1.Graduate School of Engineering, Kyoto University, 2.Chi-ken Sogo Consultants Co., Ltd.,, 3.Graduate School of Science, Kyoto University)

[MIS02-P06] Results of geotechnical tests on shallow sediment cores recovered from Lord Howe Rise, off eastern Australia: Implications for future Lord Howe Rise riser drilling

*Takamitsu Sugihara[1], Kan Aoike[1], Saneatsu Saito[2], Tatsuya Murayama[1], Kentaro Takeda[1], Takuya Onodera[3], Ayumi Sumikawa[3], Yukari Kido[1], Yoshinori Sanada[1] (1.Center for deep earth exploration, Japan Agency for Marine-Science and Technology, 2.Research and development center for ocean drilling science, Japan Agency for Marine-Science and Technology, 3.Nippon Marine Enterprises, Ltd.)

[MIS02-P07] ICDP DSeis 4: Drilling, core logging, and in-hole geophysical logging of ICDP DSeis drilling into the M5.5 aftershock zones in a South African gold mines.

*Shunsuke YOSHIDA[1], Tadokoro Ryogo[1], Kosuke Sugimura[1], Kanematsu Makoto[1], Mitsuya Higashi[1], Benni Liebenberg[2], Esterhuizen van Heerden[2], Stephen Tau[3], Siyanda Mngadi[3], Ray Durrheim[3], Martin Ziegler[4], Yusuke Mukuhira[5], Ronald Conze[6], Yasuo Yabe[7], Shunya Kaneki[8], Yuki Yokoyama[9], Nomqhele Nkosi[10], Dave Roberts[10], Sifiso Buccio[11], Hiroshi Ogasawara[1] (1.Graduate school of science and engineering, Ritsumeikan , 2.Moab Khotsong mine, Vijoenskroon, 3.Univ. Witwatersrand, School of Geoscience, 4.ETH, Zurich Dep. Earth Sciences, 5.Inst. Fluid Science, Tohoku Univ., 6.GFZ, Potzdam, 7.Graduate School of Science, Tohoku Univ., 8.Disaster Prevention Research Inst., Kyoto Univ., 9.Graduate School of Science,Osaka Univ., 10.Mandela Mining Precinct, CSIR, 11.Council for Geoscience)

[MIS02-P08] ICDP DSeis 5: Diametrical Core Deformation Analysis of the M5.5 aftershock zone core - stress concentration at reflective intrusives and transition in stress regimes.

*Kosuke Sugimura[1], Shunsuke YOSHIDA[1], Ryogo Tadokoro[1], Hiroshi Ogasawara[2], Akimasa Ishida, Yasuo Yabe[3], Takatoshi Ito[4], Akio Funato[5], Siyanda Mngadi[6], Ray Durrheim[6] (1.Graduate school of science and engineering, Ritsumeikan, 2.College of Science and Engineering, Ritsumeikan Univ., 3.Graduate School of Science, Tohoku Univ., 4.Inst. Fluid Science, Tohoku Univ., 5.Fukada Geological Institute, 6.Univ. Witwatersrand, School of Geoscience)

[MIS02-P09] ICDP DSeis 6: Deformation Rate Analysis of the M5.5 aftershock zone core - stress concentration at reflective intrusives

*Kanematsu Makoto[1], Mitsuya Higashi[1], Yasuo Yabe[2], Shuhei Abe[2], Bryan Watson[3], Ray Durrheim[3], Hiroshi Ogasawara[1] (1.Ritsumeikan Univ., 2.Tohoku Univ., 3.Univ. Witwatersrand)

[MIS02-P10] ICDP DSeis 7: compilation of stress information and comparison with calculated stresses in the M5.5 aftershock zones

*Mitsuya Higashi[1], Yasuo Yabe[2], Kosuke Sugimura[1], Akimasa Ishida, Makoto Kanematsu[1], Shunsuke YOSHIDA[1], Ryogo Tadokoro[1], Takatoshi Ito[4], Akio Funato[5], Hiroshi Ogasawara[3] (1.Graduate School of Science and Engineering, Ritsumeikan Univ., 2.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 3.College of Science and Engineering, Ritsumeikan Univ., 4.Inst. Fluid Science, Tohoku Univ., 5.Fukada Geological Institute)

[MIS02-P11] ICDP DSeis 8: the M5.5 fault structure and reflective intrusives in legacy 3D seismic reflection data

*Noda Taku[1], Musa Manzi[2], Hiroyuki Ogasawara[1], Lindsay Linzer[2], Stephanie Enslin[2], Ray Durrheim[2], Hiroshi Ogasawara[1] (1.Ritsumeikan Univ., 2.Univ. Witwatersrand)

[MIS02-P12] ICDP DSeis 9: are streaks in the M5.5 aftershocks potentially located on highly stressed intrusive?

*Ryogo Tadokoro[1], Katsuya Ishibashi[2], Horiuchi Shigeki[3], Hiroshi Ogasawara[4] (1.Graduate School of Science and Engineering, Ritsumeikan Univ., 2.School of Science and Engineering, Ritsumeikan Univ., 3.Homeseismo ltd., 4.College of Science and Engineering, Ritsumeikan Univ.)

convener:Yasuhito Sekine(Earth-Life Science Insitute, Tokyo Institute of Technology), Tomohiro Usui(Earth-Life Science Institute, Tokyo Institute of Technology), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Takazo Shibuya(Japan Agency for Marine-Earth Science and Technology), Chairperson:Yasuhito Sekine(Dept. Earth & Planetary Sci., University of Tokyo), Keisuke Fukushi, Tomohiro Usui

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MIS11-07] Finding of oxidized sulfur species in carbonates from a Martian meteorite Allan Hills 84001 using μ-XANES

*Kajitani Iori[1], Gaku Tanabe[1], Ryoichi Nakada[2], Tomohiro Usui[3], Mizuho Koike[3], Fumihiro Matsuura[4], Tetsuya Yokoyama[1] (1.Tokyo Institute of Technology, 2.Japan Agency for Marine-Earth Science and Technology, 3.Institute of Space and Astronautical Science, 4.Earth-Life Science Institute)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MIS11-08] A study on Martian water environment based on the μ-XRF-XANES analysis for the secondary minerals formed in a nakhlite meteorite (Y 000593) vein

*Keika Suzuki[1], Hiroki Suga[1], Akira Yamaguchi[2], Tomohiro Usui[3], Oki Sekizawa[4], Kiyofumi Nitta[4], Yoshio Takahashi[1] (1.University of Tokyo, 2.National Institute of Polar Research, 3.JAXA, ISAS, 4.JASRI/SPring-8)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MIS11-09] Influence of water and clay minerals for slope angles on Mars

*Yuhki Matsuoka[1], Ikuo Katayama[1], Rina Noguchi[2], Tomohiro Usui[2] (1.Department of Earth and Planetary Systems Science, Hiroshima University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MIS11-10] **Dark Streak Features in Mongolia: Implications for Formation Mechanisms of Recurring Slope Lineae on Mars**

*Maya Nakamura[1,2], Yasuhito Sekine[1], Keisuke Fukushi[3], Noriko Hasebe[3], Davaadorj Davaasuren[4], Yoshio Takahashi[2], Hitoshi Hasegawa[5], Takuro Ogura[6], Koki Morida[3], Tuvshin Gerelmaa[4] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.Department of Earth and Planetary Science, The University of Tokyo, 3.Institute of Nature & Environmental Technology, Kanazawa University, 4.Department of Geography, National University of Mongolia, 5.Department of Global Environment and Disaster Prevention, Kochi University, 6.Department of Socio-Cultural Environmental Science, The University of Tokyo)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MIS11-11] The occurrence of perchlorate salt in and around the Taklimakan Desert, China

*Haibo Qin[1,2], Shitong Yang[1], Qing Chang[3], Chihiro Miyamoto[1], Yoshio Takahashi[1] (1.Department of Earth and Planetary Science, Graduate School of Science, 2.State Key Laboratory of Environmental Geochemistry, Institute of Geochemistry, Chinese Academy of Sciences, 3.Japan Agency for Marine-Earth Science and Technology)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MIS11-12] Measurement technique to quantify OH radicals photochemically generated on the ice surface

*Akihiro Yabushita[1], Hiroaki Nishimoto[1], Akira Harata[1] (1.Interdisciplinary Graduate School of Engineering Sciences, Kyushu University)

[J] Oral | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 201A 2F

[M-IS13] Biogeochemistry

convener:Keisuke Koba(Center for Ecological Research, Kyoto University), Hideaki Shibata(Field Science Center fot Northern Biosphere, Hokkaido University), Naohiko Ohkouchi(Japan Agency for Marine-Earth Science and Technology), Youhei Yamashita(Faculty of Environmental Earth Science, Hokkaido University), Chairperson:Keisuke Koba(Kyoto University), Yoshiyuki Inagaki, Kazumichi Fujii

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS13-01] **Root meets clays: Tree root plasticity in podzolized soil**

*Kazumichi Fujii[1], Naoki Makita[2], Martin Küttim[3], Shinya sugita[3] (1.Forestry and Forest Products Research Institute, 2.Shinshu University, 3.Tallinn University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS13-02] Nitrogen transformation process in newly created salt marsh in the aftermath of the 2011 Great East Japan Earthquake

*Keitaro Fukushima[1], Kazuma Hashimoto[2], Megumi Kuroiwa[3], Katsuhide Yokoyama[2], Yuichi Suwa[3] (1.Center for Ecological Research, Kyoto University, 2.Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University, 3.Faculty of Science and Engineering, Chuo University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS13-03] Succession of soil nitrification potential at a glacier foreland in Svalbard

*Kentaro Hayashi[1], Yukiko Tanabe[2,3], Keisuke Ono[1], Maki Asano[4], Shohei Hattori[5], Masaki Uchida[2,3], Masahito Hayatsu[1] (1.Institute for Agro-Environmental Sciences, NARO, 2.National Institute of Polar Research, 3.SOKENDAI, 4.University of Tsukuba, 5.Tokyo Institute of Technology)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS13-04] **Transition of soil organic carbon in a volcanic ash soil derived from Towada volcano, Japan**

*JITHYA NAWODI WIJESINGHE[1], Jun Koarashi[2], Mariko Atarashi Andoh[2], Yoko Saito Kokubu[3], Noriko Yamaguchi[4], Takashi Sase[5], Mamoru Hosono[6], Yudzuru Inoue[7], Yuki Mori[1], Syuntaro Hiradate[1] (1.Soil Science Laboratory, Faculty of Agriculture, Kyushu University, Fukuoka 819-0395, Japan, 2.Nuclear Science and Engineering Center, Japan Atomic Energy Agency, Ibaraki 319-1195, Japan, 3.Tono Geoscience Center, Japan Atomic Energy Agency,Gifu 509-5102, Japan, 4.National Agriculture and Food Research Organization, Institute for Agro-environmental Sciences, 3-1-3 Kan-nondai, Tsukuba, Ibaraki 305-8604, Japan, 5.Boreal Laboratory for Phytolith Research, Iwate 028-7302,Japan, 6.Tokyo Natural History Research Structure,Tokyo 162-0052, Japan, 7.Faculty of Applied Information Technology, Nagasaki Institute of Applied Science,Nagasaki 851-0193, Japan)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS13-05] General pattern of carbon and nitrogen isotopic variation across a wide range of soils and its controlling factors

*Rota Wagai[1], Masako Kajiura[1], Yudzuru Inoue[2], Maki Asano[3], Chie Hayakawa[4] (1.NARO, Institute for Agro-Environmental Sciences, 2.Nagasaki Institute of Applied Science, 3.University of Tsukuba, 4.University of Tokyo)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[MIS13-06] Nutrient sources in some Japanese forest ecosystems: the contribution of precipitation, weathering and litter fall

*Yoshiyuki Inagaki[1], Kazumichi Fujii[1] (1.Forestry and Forest Products Research Institute)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 201A 2F

[M-IS13] Biogeochemistry

convener:Keisuke Koba(Center for Ecological Research, Kyoto University), Hideaki Shibata(Field Science Center fot Northern Biosphere, Hokkaido University), Naohiko Ohkouchi(Japan Agency for Marine-Earth Science and Technology), Youhei Yamashita(Faculty of Environmental Earth Science, Hokkaido University), Chairperson:Keisuke Koba(Kyoto University), Yohei Yamashita, Kazuya Nishina, Kazumichi Fujii

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS13-07] Ultrahigh-resolution mass spectral analysis of dissolved organic matter in rainfall, throughfall and soil water in temperate forest stands, western Japan

*Junichiro Ide[1], Keitaro Yamase[2], Seonghun Jeong[3], Noki Makita[4], Hiroshi Nishimura[5], Keitaro Fukushima[6], Kyoichi Otsuki[7], Mizue Ohashi[8] (1.Institute of Decision Science for a Sustainable Society, Kyushu University, 2.Forestry and Forest Products Research Institute, Hyogo Prefectural Technology Center for Agriculture, Forestry and Fisheries, 3.Graduate School of Bioresources and Bioenvironmental Sciences, Kyushu University, 4.Faculty of Science, Shinshu University, 5.Research Institute for Sustainable Humanosphere, Kyoto University, 6.The Center for Ecological Research, Kyoto University, 7.Faculty of Agriculture, Kyushu University, 8.School of Human Science and Environment, University of Hyogo)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS13-08] Basin-scale transport of allochthonous humic-like fluorescent dissolved organic matter by the North Pacific Intermediate water

*Youhei Yamashita[1], Jun Nishioka[2], Hajime Obata[3], Hiroshi Ogawa[3] (1.Faculty of Environmental and Earth Science, 2.Institute of Low Temperature Science, Hokkaido University, 3.Atmosphere and Ocean Research Institute, The University of Tokyo)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS13-09] Bacterial contribution to dissolved organic matter in a large monomictic lake (Lake Biwa) indicated by amino acids enantiomers

*Yasuhiko T. Yamaguchi[1], Chikage Yoshimizu[2], Ichiro Tayasu[2], Keisuke Koba[3], Kazuhide Hayakawa[1] (1.Lake Biwa Environmental Research Institute, 2.Research Institute for Humanity and Nature, 3.Center for Ecological Research, Kyoto University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS13-10] High-sensitivity tracer assay for oxygen consumption rate in ocean and lakes using ^{17}O as a tracer

*Urumu Tsunogai[1], Shogo Kashiwagi[1], Masanori Ito[1], Fumiko Nakagawa[1], Chiho Sukigara[1] (1.Graduate School of Environmental Studies, Nagoya University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS13-11] Ecology of bacterioplankton inhabiting oxygenated hypolimnia of deep freshwater lakes

*Yusuke Okazaki[1] (1.National Institute of Advanced Industrial Science and Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS13-12] Nitrous oxide emission from the drainage and the production processes in oil palm plantation on peatland

*Kazuya Nishina[1], Lulie Melling[2], Ryuichi Hirata[1], Yoshiyuki Takahashi[1], Sakae Toyoda[3], Kotaro Terajima[3], Masayuki Itoh[4] (1.NIES National Institute of Environmental Studies, 2.SARAWAK Tropical Peat Research Institute, 3.Tokyo Institute of Technology, 4.University of Hyogo)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS14] Global climate change driven by the Southern Ocean and the Antarctic Ice Sheet

convener:Osamu Seki(Institute of Low Temperature Science, Hokkaido University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Ryu Uemura(University of the Ryukyus), Ryosuke Makabe(National Institute of Polar Research), Chairperson:Sam Sherriff-Tadano(University of Tokyo)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS14-06] **High resolution ocean temperatures reconstructions over the last glacial-interglacial in the Kerguelen region, Southern Ocean.**

*Matthieu Civel[1,2], Xavier Crosta[3], Giuseppe Cortese[4], Elisabeth Michel[5], Alain Mazaud[5], Samuel Jaccard[6], Lena Thöle[6], Minoru Ikehara[1], Takuya Itaki[2] (1.Center for Advanced Marine Core Research, Kochi University, Japan, 2.Geological Survey of Japan, AIST, Tsukuba, Japan, 3.UMR 5805 CNRS EPOC, Université de Bordeaux, France, 4.GNS Science, Lower Hutt, New Zealand, 5.LSCE-IPSL, CEA-CNRS-UVSQ, 91198 Gif-sur-Yvette, France, 6.Institute of Geological Sciences & Oeschger Centre for Climate Change Research, University of Bern, Switzerland)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS14-07] Present-day crustal motion and gravity change in East Antarctica: implications for the mantle viscosity and Holocene Antarctic Ice Sheet change inferred from GIA modeling

*Jun'ichi Okuno[1,2], Koichiro Doi[1,2], Yuichi Aoyama[1,2], Takeshige Ishiwa[1], Akihisa Hattori[2], Yoichi Fukuda[3] (1.National Institute of Polar Research, 2.SOKENDAI, 3.Kyoto University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS14-08] **Reconstruction of the East Antarctic ice sheet variability during the last 3 myrs in the central & eastern Droning Maud Land, East Antarctica**

*Yusuke Suganuma[1,2], Moto Kawamata[2], Kota Katsuki[3], Tatsuo Kanamaru[4], Heitaro Kaneda[5], Takushi Koyama[6], Tanabe Yukiko[1,2], Daisuke Shibata[7], Takeshige Ishiwa[1], Takuya Itaki[8], Jun'ichi Okuno[1,2], Osamu Seki[9], Itsuki Suto[10], Masakazu Fujii[1,2], Hideki Miura[1,2] (1.National institute of Polar Research, 2.SOKENDAI, 3.Shimane University, 4.Nihon University, 5.Chiba University, 6.Oita University, 7.Tsukuba University, 8.GSJ, AIST, 9.Hokkaido University, 10.Nagoya University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS14-09] Vertical ice flow motions obtained from year-round GNSS observations on Shirase Glacier, Antarctica

*Yuichi Aoyama[1,2], Koichiro Doi[1,2], Daisuke Hirano[3], Takeshi Tamura[1,2], Shigeru Aoki[3], Kazuo Shibuya[1] (1.National Institute of Polar Research, 2.SOKENDAI, 3.Institute of Low Temperature Science, Hokkaido University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS14-10] **Operation plan and design of the Antarctic exploration AUV "MONACA"**

*Hirokazu Yamagata[1], Toshihiro Maki[1], Hiroshi Yoshida[2], Yoshifumi Nogi[3] (1.Institute of Industrial Science, The University of Tokyo, 2.Japan Marine Science and Technology Center, 3.National Institute of Polar Research)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[MIS14-11] Geophysical insights into tectonic, volcanic, sedimentation, and glacial processes in Indian and Southern Oceans: Preliminary geophysical results of R/V *Hakuho-maru* KH-19-1 cruise

*Masakazu Fujii[1], Hiroshi Sato[2], Minoru Ikehara[3], Yoshifumi Nogi[1], Taichi Sato[4], Yasuyuki Nakamura[5], Eri Helen Amsler[6], Sam Sherriff-Tadano[7] (1.National Institute of Polar Research and SOKENDAI, 2.Senshu University, 3.Kochi University, 4.AIST, 5.JAMSTEC, 6.University of Bern, 7.AORI, UTokyo)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Convention Hall B 2F

[M-IS14] Global climate change driven by the Southern Ocean and the Antarctic Ice Sheet

convener:Osamu Seki(Institute of Low Temperature Science, Hokkaido University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Ryu Uemura(University of the Ryukyus), Ryosuke Makabe(National Institute of Polar Research), Chairperson:Takeshige Ishiwa(National institute of Polar Research)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS14-12] Simulations of glacial ocean carbon cycle with a parameterization of stratification dependence of vertical diffusivity

*Hidetaka Kobayashi[1], Akira Oka[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS14-13] Impacts of precession on the periodicity of climate and AMOC variabilities

*Sam Sherriff-Tadano[1] (1.Atmosphere and Ocean Research Institute, the University of Tokyo)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS14-14] Warming and climate feedbacks in the southern high latitude driven by obliquity, precession-eccentricity, and atmospheric CO2

*Kanon Kino[1], Ayako Abe-Ouchi[1,2], Ryouta O'ishi[1], Fuyuki SAITO[2], Masakazu Yoshimori[1] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS14-15] Origin of Circumpolar Deep Water intruding onto the Amundsen and Bellingshausen Sea continental shelves

*Yoshihiro Nakayama[1,2], Menemenlis Dimitris[2], Hong Zhang[2], Michael Schodlok[2], Eric Rignot[2,3] (1.Institute of Low Temperature Science, Hokkaido University, 2.NASA's Jet Propulsion Laboratory, 3.Uniersity of California, Irvine)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS14-16] Ocean and material circulation in the southern part of the Australian Antarctic Basin in 2018/2019 summer - preliminary results from Kaiyomaru KY18-04 cruise

*Katsuro Katsumata[1], Daisuke Hirano[2], Daiki Nomura[2], Kaihe Yamazaki[2], Yoichiro Koh[2], Masaaki Kiuchi[2], Shigeru Aoki[2], Hiroto Murase[3] (1.JAMSTEC, 2.Hokkaido Univ., 3.NRI-FSF)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS14-17] Mooring observation aiming direct current measurement and quantitative evaluation of Meridional Circulation of Southern Ocean

*Kitade Yujiro[1], Kohei Mizobata[1], Kazuho Watanabe[1], Linquiao Chen[3], Gaopin Guo[3], Shigeru Aoki[2], Shyuki Ushio[4], Keishi Shimada[1], Kay I. Ohshima[2] (1.Tokyo University of Marine Science and Technology, 2.Hokkaido University, 3.Shanghi Ocean University, 4.National Institute of Polar Research)

[J] Poster | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_21

[M-IS14] Global climate change driven by the Southern Ocean and the Antarctic Ice Sheet

convener:Osamu Seki(Institute of Low Temperature Science, Hokkaido University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Ryu Uemura(University of the Ryukyus), Ryosuke Makabe(National Institute of Polar Research)

[MIS14-P01] Preliminary study on the effect of low-salinity ice melting water on biomass and composition of ice algae

*Keigo Takahashi[1], Ryosuke Makabe[2,3], Shintaro Takao[2,3], Tsuneo Odate[2,3], Masato Moteki[1,2] (1.Tokyo University of Marine Science and Technology, 2.National Institute of Polar Research, 3.The Graduate University for Advanced Studies (SOKENDAI))

[MIS14-P02] Effects of lugol's fixtation on preservation of samples for carbon and nitrogen stable isotope and molecular analyses

*Masayoshi Sano[1], Ryosuke Makabe[1,2], Ayu Yamamoto[3], Norio Kurosawa[4], Masato Moteki[2,3], Tsuneo Odate[1,2] (1.National Institute of Polar Research, 2.The Graduate University for Advanced Studies, 3.Tokyo University of Marine Science and Technology, 4.Soka University)

[MIS14-P03] The application of environmental DNA for the monitoring of Antarctic marine ecosystem

*Aiko Tachibana[1], Ryosuke Makabe[2], Masato Moteki[1] (1.Tokyo University of Marine Science and Technology, 2.National Institute of Polar Research)

[MIS14-P04] Coincidental occurrence process of frazil ice and high biomass off Amery Ice Shelf

*Yoshihiko Machimura[1], Kay I. Ohshima[2], Kazuki Nakata[3], Masato Ito[2], Yasushi Fukamachi[2,4], Ryosuke Makabe[5], Shintaro Takao[5], Sohey Nihashi[6] (1.Graduate School of Environmental Sciences, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Remote Sensing Technology Center of Japan, 4.Arctic Research Center, Hokkaido University, 5.National Institute of Polar Research, 6.National Institute of Technology, Tomakomai College)

[MIS14-P05] Feeding habit of the Antarctic amphipod *Themisto gaudichaudii* of Vincennes Bay (East Antarctica) during austral summer

*Junji Matsushita[1], Ryosuke Makabe[2], Masato Moteki[1] (1.Tokyo University of Marine Science and Technology, 2.National Institute of Polar Research)

[MIS14-P06] Time-series observation of subsurface chlorophyll *a* maximum in the seasonal ice zone of the Southern Ocean

*Ayuko Kagesawa[1], Masayoshi Sano[2], Shintaro Takao[1,2], Ryosuke Makabe[1,2], Kohei Mizobata[3], Norio Kurosawa[4], Masato Moteki[2,3], tuneo Odate[2] (1.The Graduate University for Advanced Studies, 2.National Institute of Polar Research, 3.Tokyo University of Marine Science and Technology, 4.Soka University)

[MIS14-P07] Seasonality in sulfur isotopic compositions of atmospheric sulfate and its implications for atmospheric sulfur cycles in East Antarctica

*Sakiko Ishino[1], Shohei Hattori[1], Joel Savarino[2], Michel Legrand[2], Susanne Preunkert[2], Bruno Jourdain[2], Francis Albarede[3], Emmanuelle Albalat[3], Naohiro Yoshida[1,4] (1.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 2.Institut des Geoscience de l'Environnement, Université Grenoble Alpes/CNRS, 3.Ecole Normale Supérieure (LGL-TPE), 4.Earth-Life Science Institute, Tokyo Institute of Technology)

[MIS14-P08] Penultimate glacial-interglacial transition viewed from the Dome Fuji ice core, Antarctica

*Ikumi Oyabu[1,2], Kenji Kawamura[1,3,4], Kyotaro Kitamura[1] (1.National Institute of Polar Research, Research Organization of Information and Systems, 2.Japan Society for the Promotion of Science, 3.SOKENDAI (The Graduate University of Advanced Studies), 4.Japan Agency for Marine Science and Technology (JAMSTEC))

[MIS14-P09] Reconstruction of Antarctic ice sheet dynamics in the Last Interglacial

*Mutsumi Iizuka[1], Osamu Seki[1], Takuya Itaki[2], Tomohisa Irino[1], Minoru Ikehara[4], Saiko Sugisaki[2], Masanobu Yamamoto[1], Keiji Horikawa[5], Yuusuke Suganuma[3] (1.Hokkaido university, 2.Geological Survey of Japan, 3.National Institute of Polar Research , 4.Center for Advanced Marine Core Research, Kochi University, 5.University of Toyama)

[MIS14-P10] Pliocene CO2 concentration estimated from Southern Ocean SST

*Osamu Seki[1], Tomohiro Shimono[2] (1.Institute of Low Temperature Science, Hokkaido University, 2.Guraduate School of Environmental Science)

[MIS14-P11] **Lithogenic fluxes across a transect in the SW Indian Ocean since the last glacial inception**

*Eri Helen Amsler[1], Walter Geibert[2], Gerhard Kuhn[2], Minoru Ikehara[3], Samuel Jaccard[1] (1.Institute of Geological Sciences and Oeschger Centre for Climate Change Research, University of Bern, Switzerland, 2.Alfred-Wegener-Institut Helmholtz-Zentrum für Polar- und Meeresforschung, Bremerhaven, Germany, 3.Center for Advanced Marine Core Research, Kochi University, Kochi, Japan)

[MIS14-P12] Changes in composition of fossil diatoms from Ross Sea under gradual warming climate from MIS M2

*Saki Ishino[1], Itsuki Suto[2], Rob M. McKay[3], Laura De Santis[4], Denise K. Kluhanek[5], Expedition 374 Scientists (1.National Institute of Advanced Industrial Science and Technology, 2.Department of Earth and Planetary Sciences Graduate School of Environmental Studies, Nagoya University, 3.Victoria University, 4.Instituto Nazionale di Oceanografia e di Geofisica Sperimentale, 5.Texas A&M University)

[MIS14-P13] Geological insights into formation of Conrad Rise, Southern Ocean: Preliminary geological results of R/V *Hakuho-maru* KH-19-1 cruise

*Hiroshi Sato[1], Masakazu Fujii[2,3], Hiroki Matsui[4], Minoru Ikehara[4] (1.School of Business Administration, Senshu University, 2.NIPR, 3.SOKENDAI, 4.Center for Advanced Marine Core Research, Kochi University)

[MIS14-P14] Fossil chrysophyte cysts as a new paleoenvironmental proxy

*Yuji Kato[1,2], Itsuki Suto[1] (1.Graduate School of Environmental Studies, Nagoya University, 2.Center for Advanced Marine Core Research, Kochi University (JSPS Research Fellowship for Young Scientists))

[MIS14-P15] Spatiotemporal variability of surface mass balance along the JARE traverse route for 1991–2019

*Shun Tsutaki[1], Hideaki Motoyama[2,3], Ayako Abe-Ouchi[1,4], Shuji Fujita[2,3], Kenji Kawamura[2,3,4] (1.The University of Tokyo, 2.National Institute of Polar Research, 3.The Graduate University for Advanced Studies, 4.Japan Agency for Marine-Earth Science and Technology)

[MIS14-P16] The weathering of granitic rocks in the Sør-Rondane Mountains, East Antarctica

*Tatsuo Kanamaru[1], Yusuke Suganuma[2], hisashi Oiwane[3], Hideki Miura[2], Makoto Miura[4], Jun'ichi Okuno[2], Hideaki Hayakawa[5] (1.Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University, 2.National Institute of Polar Research, 3.Musuhi LLC, 4.Department of Earth and Planetary Sciences, Kanazawa University, 5.Institute for Cosmic Ray Research, University of Tokyo)

[MIS14-P17] Summary of the 2nd Year Activities of the Project on the Interaction of the solid Earth and the
Antarctic Ice Sheet:

*Yoichi Fukuda[1], Jun Nishijima[2], Takahito Kazama[1], Kazuki Nakamura[3], Koichiro Doi[4], Yusuke Suganuma[4], Jun'ichi Okuno[4], Akito Araya[5], Heitaro Kaneda[6], Yuichi Aoyama[4], Hideki Miura[4] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Graduate School of Engineering, Kyushu University, 3.Faculty of Engineering, Nihon University, 4.National Institute of Polar Research, 5.ERI, University of Tokyo, 6.Graduate School of Science, Chiba University)

[MIS14-P18] Late Pleistocene to Holocene sea-level change in East Antarctica revealed by glacial isostatic adjustment modeling

*Takeshige Ishiwa[1], Jun'ichi Okuno[1,2], Yusuke Suganuma[1,2], Hideki Miura[1,2] (1.National Institute of Polar Research, 2.SOKENDAI)

[MIS14-P19] An modeling study of Antarctic ice sheet of the Last Glacial Maximum and the last deglaciation

*Takashi Obase[1], Ayako Abe-Ouchi[1,2], Ralf Greve[3], Fuyuki SAITO[2] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology, 3.Institute of Low Temperature Science, Hokkaido University)

[MIS14-P20] Development of a coupled ice-sheet/earth rebound model for Antarctic ice-sheet simulation

*Fuyuki SAITO[1], Ayako Abe-Ouchi[2,1], Jun'ichi Okuno[3], Takashi Obase[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere and Ocean Research Institute, University of Tokyo, 3.National Institute of Polar Research)

[MIS14-P21] Polar amplifications in the past warm periods obtained from MIROC 4m AOGCM

*Taro Higuchi[1], Ayako Abe-Ouchi[1], Wing-Le Chan[1], Sam Sherriff-Tadano[1] (1.Atmospheric and Ocean Research Institute, the University of Tokyo)

[MIS14-P22] Using a coupled AOGCM to study the Antarctic climate of the mid-Pliocene warm period

*Wing-Le Chan[1], Ayako Abe-Ouchi[1,2] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.National Institute of Polar Research)

[MIS14-P23] CMIP5 model analysis of future changes in ocean net primary production by focusing on different response among the individual oceans and models

*Akira Oka[1], Yuki Nakamura[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[MIS14-P24] Factor analysis of the millennial time-scale climate variability in glacial periods

*Miki Akari[1], Ayako Abe-Ouchi[2], Sam Sherriff-Tadano[2] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

[MIS14-P25] First continuous profiler observation of wintertime Antarctic coastal polynya

*Shigeru Aoki[1], Kazuya Ono[1], Daisuke Hirano[1], Masato Itoh[1], Tomohide Noguchi[2], Satoshi Ozawa[2] (1.Hokkaido University, 2.Marine Works Japan)

[MIS14-P26] Surface topography survey for bared rock and accumulated snow in Antarctica by Unmanned Aero Vehicle

*Yuichi Aoyama[1,2,3], Akihisa Hattori[2,3], Hajime Oishi[3,4], Koichiro Doi[1,2,3], Yoshifumi Nogi[1,2] (1.National Institute of Polar Research, 2.SOKENDAI, 3.The 59th Japanese Antarctic Research Expedition, 4.NEC Networks & System Integration Corporation)

[MIS14-P27] The analysis of long-term Mooring observation records in the northernmost area of seasonal sea ice zone in the Southern Ocean

*Kazuho Watanabe[1], Kohei Mizobata[1], Yujiro Kitade[1] (1.Tokyo University of Marine Science and Technology)

[MIS14-P28] Preliminary observation report on chlorofluorocarbons (CFCs) and sulfur hexafluoride (SF_6) off the Cape Darnley in the summer of 2019

*Yoshihiko Ohashi[1], Michiyo Yamamoto-Kawai[1], Kenichi Sasaki[2], Sayaka Kumakawa[1], Naoyuki Tamura[1], Kay I. Ohshima[3] (1.Tokyo University of Marine Science and Technology, 2.Japan Agency for Marine-Earth Science and Technology, 3.Institute of Low Temperature Science, Hokkaido University)

[MIS14-P29] Mechanism of sea-ice production variation in Amundsen Sea Polynya

*Sohey Nihashi[1], Kouta Mine[1], Kazuki Nakata[2] (1.National Institute of Technology, Tomakomai College, 2.RESTEC)

[MIS14-P30] Estimation of thin ice thickness and discrimination of ice type from AMSR2 passive microwave data

*Kazuki Nakata[1], Tamaru Naoya[1], Sohey Nihashi[2], Kay I. Ohshima[3] (1.Remote Sensing Technology Center of Japan, 2.National Institute of Technology, Tomakomai College, 3.Institute of Low Temperature Science, Hokkaido University)

[M-IS14] Global climate change driven by the Southern Ocean and the Antarctic Ice Sheet

convener:Osamu Seki(Institute of Low Temperature Science, Hokkaido University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Ryu Uemura(University of the Ryukyus), Ryosuke Makabe(National Institute of Polar Research)

[MIS14-P01] Preliminary study on the effect of low-salinity ice melting water on biomass and composition of ice algae

*Keigo Takahashi[1], Ryosuke Makabe[2,3], Shintaro Takao[2,3], Tsuneo Odate[2,3], Masato Moteki[1,2] (1.Tokyo University of Marine Science and Technology, 2.National Institute of Polar Research, 3.The Graduate University for Advanced Studies (SOKENDAI))

[MIS14-P02] Effects of lugol's fixtation on preservation of samples for carbon and nitrogen stable isotope and molecular analyses

*Masayoshi Sano[1], Ryosuke Makabe[1,2], Ayu Yamamoto[3], Norio Kurosawa[4], Masato Moteki[2,3], Tsuneo Odate[1,2] (1.National Institute of Polar Research, 2.The Graduate University for Advanced Studies, 3.Tokyo University of Marine Science and Technology, 4.Soka University)

[MIS14-P03] The application of environmental DNA for the monitoring of Antarctic marine ecosystem

*Aiko Tachibana[1], Ryosuke Makabe[2], Masato Moteki[1] (1.Tokyo University of Marine Science and Technology, 2.National Institute of Polar Research)

[MIS14-P04] Coincidental occurrence process of frazil ice and high biomass off Amery Ice Shelf

*Yoshihiko Machimura[1], Kay I. Ohshima[2], Kazuki Nakata[3], Masato Ito[2], Yasushi Fukamachi[2,4], Ryosuke Makabe[5], Shintaro Takao[5], Sohey Nihashi[6] (1.Graduate School of Environmental Sciences, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Remote Sensing Technology Center of Japan, 4.Arctic Research Center, Hokkaido University, 5.National Institute of Polar Research, 6.National Institute of Technology, Tomakomai College)

[MIS14-P05] Feeding habit of the Antarctic amphipod *Themisto gaudichaudii* of Vincennes Bay (East Antarctica) during austral summer

*Junji Matsushita[1], Ryosuke Makabe[2], Masato Moteki[1] (1.Tokyo University of Marine Science and Technology, 2.National Institute of Polar Research)

[MIS14-P06] Time-series observation of subsurface chlorophyll *a* maximum in the seasonal ice zone of the Southern Ocean

*Ayuko Kagesawa[1], Masayoshi Sano[2], Shintaro Takao[1,2], Ryosuke Makabe[1,2], Kohei Mizobata[3], Norio Kurosawa[4], Masato Moteki[2,3], tuneo Odate[2] (1.The Graduate University for Advanced Studies, 2.National Institute of Polar Research, 3.Tokyo University of Marine Science and Technology, 4.Soka University)

[MIS14-P07] Seasonality in sulfur isotopic compositions of atmospheric sulfate and its implications for atmospheric sulfur cycles in East Antarctica

*Sakiko Ishino[1], Shohei Hattori[1], Joel Savarino[2], Michel Legrand[2], Susanne Preunkert[2], Bruno Jourdain[2], Francis Albarede[3], Emmanuelle Albalat[3], Naohiro Yoshida[1,4] (1.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 2.Institut des Geoscience de l'Environnement, Université Grenoble Alpes/CNRS, 3.Ecole Normale Supérieure (LGL-TPE), 4.Earth-Life Science Institute, Tokyo Institute of Technology)

[MIS14-P08] Penultimate glacial-interglacial transition viewed from the Dome Fuji ice core, Antarctica

*Ikumi Oyabu[1,2], Kenji Kawamura[1,3,4], Kyotaro Kitamura[1] (1.National Institute of Polar Research, Research Organization of Information and Systems, 2.Japan Society for the Promotion of Science, 3.SOKENDAI (The Graduate University of Advanced Studies), 4.Japan Agency for Marine Science and Technology (JAMSTEC))

[MIS14-P09] Reconstruction of Antarctic ice sheet dynamics in the Last Interglacial

*Mutsumi Iizuka[1], Osamu Seki[1], Takuya Itaki[2], Tomohisa Irino[1], Minoru Ikehara[4], Saiko Sugisaki[2], Masanobu Yamamoto[1], Keiji Horikawa[5], Yuusuke Suganuma[3] (1.Hokkaido university, 2.Geological Survey of Japan, 3.National Institute of Polar Research , 4.Center for Advanced Marine Core Research, Kochi University, 5.University of Toyama)

[MIS14-P10] Pliocene CO2 concentration estimated from Southern Ocean SST

*Osamu Seki[1], Tomohiro Shimono[2] (1.Institute of Low Temperature Science, Hokkaido University, 2.Guraduate School of Environmental Science)

[MIS14-P11] **Lithogenic fluxes across a transect in the SW Indian Ocean since the last glacial inception**

*Eri Helen Amsler[1], Walter Geibert[2], Gerhard Kuhn[2], Minoru Ikehara[3], Samuel Jaccard[1] (1.Institute of Geological Sciences and Oeschger Centre for Climate Change Research, University of Bern, Switzerland, 2.Alfred-Wegener-Institut Helmholtz-Zentrum für Polar- und Meeresforschung, Bremerhaven, Germany, 3.Center for Advanced Marine Core Research, Kochi University, Kochi, Japan)

[MIS14-P12] Changes in composition of fossil diatoms from Ross Sea under gradual warming climate from MIS M2

*Saki Ishino[1], Itsuki Suto[2], Rob M. McKay[3], Laura De Santis[4], Denise K. Kluhanek[5], Expedition 374 Scientists (1.National Institute of Advanced Industrial Science and Technology, 2.Department of Earth and Planetary Sciences Graduate School of Environmental Studies, Nagoya University, 3.Victoria University, 4.Instituto Nazionale di Oceanografia e di Geofisica Sperimentale, 5.Texas A&M University)

[MIS14-P13] Geological insights into formation of Conrad Rise, Southern Ocean: Preliminary geological results of R/V *Hakuho-maru* KH-19-1 cruise

*Hiroshi Sato[1], Masakazu Fujii[2,3], Hiroki Matsui[4], Minoru Ikehara[4] (1.School of Business Administration, Senshu University, 2.NIPR, 3.SOKENDAI, 4.Center for Advanced Marine Core Research, Kochi University)

[MIS14-P14] Fossil chrysophyte cysts as a new paleoenvironmental proxy

*Yuji Kato[1,2], Itsuki Suto[1] (1.Graduate School of Environmental Studies, Nagoya University, 2.Center for Advanced Marine Core Research, Kochi University (JSPS Research Fellowship for Young Scientists))

[MIS14-P15] Spatiotemporal variability of surface mass balance along the JARE traverse route for 1991–2019

*Shun Tsutaki[1], Hideaki Motoyama[2,3], Ayako Abe-Ouchi[1,4], Shuji Fujita[2,3], Kenji Kawamura[2,3,4] (1.The University of Tokyo, 2.National Institute of Polar Research, 3.The Graduate University for Advanced Studies, 4.Japan Agency for Marine-Earth Science and Technology)

[MIS14-P16] The weathering of granitic rocks in the Sør-Rondane Mountains, East Antarctica

*Tatsuo Kanamaru[1], Yusuke Suganuma[2], hisashi Oiwane[3], Hideki Miura[2], Makoto Miura[4], Jun'ichi Okuno[2], Hideaki Hayakawa[5] (1.Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University, 2.National Institute of Polar Research, 3.Musuhi LLC, 4.Department of Earth and Planetary Sciences, Kanazawa University, 5.Institute for Cosmic Ray Research, University of Tokyo)

[MIS14-P17] Summary of the 2nd Year Activities of the Project on the Interaction of the solid Earth and the
Antarctic Ice Sheet:

*Yoichi Fukuda[1], Jun Nishijima[2], Takahito Kazama[1], Kazuki Nakamura[3], Koichiro Doi[4], Yusuke Suganuma[4], Jun'ichi Okuno[4], Akito Araya[5], Heitaro Kaneda[6], Yuichi Aoyama[4], Hideki Miura[4] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Graduate School of Engineering, Kyushu University, 3.Faculty of Engineering, Nihon University, 4.National Institute of Polar Research, 5.ERI, University of Tokyo, 6.Graduate School of Science, Chiba University)

[MIS14-P18] Late Pleistocene to Holocene sea-level change in East Antarctica revealed by glacial isostatic adjustment modeling

*Takeshige Ishiwa[1], Jun'ichi Okuno[1,2], Yusuke Suganuma[1,2], Hideki Miura[1,2] (1.National Institute of Polar Research, 2.SOKENDAI)

[MIS14-P19] An modeling study of Antarctic ice sheet of the Last Glacial Maximum and the last deglaciation

*Takashi Obase[1], Ayako Abe-Ouchi[1,2], Ralf Greve[3], Fuyuki SAITO[2] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology, 3.Institute of Low Temperature Science, Hokkaido University)

[MIS14-P20] Development of a coupled ice-sheet/earth rebound model for Antarctic ice-sheet simulation

*Fuyuki SAITO[1], Ayako Abe-Ouchi[2,1], Jun'ichi Okuno[3], Takashi Obase[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere and Ocean Research Institute, University of Tokyo, 3.National Institute of Polar Research)

[MIS14-P21] Polar amplifications in the past warm periods obtained from MIROC 4m AOGCM

*Taro Higuchi[1], Ayako Abe-Ouchi[1], Wing-Le Chan[1], Sam Sherriff-Tadano[1] (1.Atmospheric and Ocean Research Institute, the University of Tokyo)

[MIS14-P22] Using a coupled AOGCM to study the Antarctic climate of the mid-Pliocene warm period

*Wing-Le Chan[1], Ayako Abe-Ouchi[1,2] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.National Institute of Polar Research)

[MIS14-P23] CMIP5 model analysis of future changes in ocean net primary production by focusing on different response among the individual oceans and models

*Akira Oka[1], Yuki Nakamura[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[MIS14-P24] Factor analysis of the millennial time-scale climate variability in glacial periods

*Miki Akari[1], Ayako Abe-Ouchi[2], Sam Sherriff-Tadano[2] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

[MIS14-P25] First continuous profiler observation of wintertime Antarctic coastal polynya

*Shigeru Aoki[1], Kazuya Ono[1], Daisuke Hirano[1], Masato Itoh[1], Tomohide Noguchi[2], Satoshi Ozawa[2] (1.Hokkaido University, 2.Marine Works Japan)

[MIS14-P26] Surface topography survey for bared rock and accumulated snow in Antarctica by Unmanned Aero Vehicle

*Yuichi Aoyama[1,2,3], Akihisa Hattori[2,3], Hajime Oishi[3,4], Koichiro Doi[1,2,3], Yoshifumi Nogi[1,2] (1.National Institute of Polar Research, 2.SOKENDAI, 3.The 59th Japanese Antarctic Research Expedition, 4.NEC Networks & System Integration Corporation)

[MIS14-P27] The analysis of long-term Mooring observation records in the northernmost area of seasonal sea ice zone in the Southern Ocean

*Kazuho Watanabe[1], Kohei Mizobata[1], Yujiro Kitade[1] (1.Tokyo University of Marine Science and Technology)

[MIS14-P28] Preliminary observation report on chlorofluorocarbons (CFCs) and sulfur hexafluoride (SF_6) off the Cape Darnley in the summer of 2019

*Yoshihiko Ohashi[1], Michiyo Yamamoto-Kawai[1], Kenichi Sasaki[2], Sayaka Kumakawa[1], Naoyuki Tamura[1], Kay I. Ohshima[3] (1.Tokyo University of Marine Science and Technology, 2.Japan Agency for Marine-Earth Science and Technology, 3.Institute of Low Temperature Science, Hokkaido University)

[MIS14-P29] Mechanism of sea-ice production variation in Amundsen Sea Polynya

*Sohey Nihashi[1], Kouta Mine[1], Kazuki Nakata[2] (1.National Institute of Technology, Tomakomai College, 2.RESTEC)

[MIS14-P30] Estimation of thin ice thickness and discrimination of ice type from AMSR2 passive microwave data

*Kazuki Nakata[1], Tamaru Naoya[1], Sohey Nihashi[2], Kay I. Ohshima[3] (1.Remote Sensing Technology Center of Japan, 2.National Institute of Technology, Tomakomai College, 3.Institute of Low Temperature Science, Hokkaido University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[M-IS15] Evolution of Pelagic Realm

convener:Atsushi Matsuoka(Department of Geology, Faculty of Science, Niigata University), Katsunori Kimoto(Japan Agency for Marine-Earth Science and Technology), Toshiyuki Kurihara(Graduate School of Science and Technology, Niigata University), Tetsuji Onoue(Earth and Environmental Sciences, Graduate School of Science and Technology, Kumamoto University)

[MIS15-P01] Ichthyolith stratigraphy constraints on ages and areas of REY-rich mud deposition in the South Pacific Ocean

*Shugo Minabe[1], Kazuhide Mimura[1], Kentaro Nakamura[1], Junichiro Ohta[2,1], Kazutaka Yasukawa[1,2], Koichiro Fujinaga[2,1], Shiki Machida[2], Yasuhiro Kato[3,1,2] (1.Department of Systems Innovation, School of Engineering, The University of Tokyo, 2.Ocean Resource Research Center for Next Generation, Chiba Institute of Technology, 3.Frontier Research Center for Energy and Resources, School of Engineering, The University of Tokyo)

[MIS15-P02] Radiolarian phylogeny around the Jurassic–Cretaceous boundary

*Atsushi Matsuoka[1] (1.Department of Geology, Faculty of Science, Niigata University)

[MIS15-P03] Late Silurian and Early Devonian radiolarian assemblages from the Yokokurayama and Konomori areas in the Kurosegawa belt, Southwest Japan

*Toshiyuki Kurihara[1], Kaori Tsuchiya[2] (1.Graduate School of Science and Technology, Niigata University, 2.Faculty of Science, Niigata University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_36

[M-IS15] Evolution of Pelagic Realm

convener:Atsushi Matsuoka(Department of Geology, Faculty of Science, Niigata University), Katsunori Kimoto(Japan Agency for Marine-Earth Science and Technology), Toshiyuki Kurihara(Graduate School of Science and Technology, Niigata University), Tetsuji Onoue(Earth and Environmental Sciences, Graduate School of Science and Technology, Kumamoto University)

[MIS15-P01] Ichthyolith stratigraphy constraints on ages and areas of REY-rich mud deposition in the South Pacific Ocean

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 302 3F

[M-IS15] Evolution of Pelagic Realm

convener:Atsushi Matsuoka(Department of Geology, Faculty of Science, Niigata University), Katsunori Kimoto(Japan Agency for Marine-Earth Science and Technology), Toshiyuki Kurihara(Graduate School of Science and Technology, Niigata University), Tetsuji Onoue(Earth and Environmental Sciences, Graduate School of Science and Technology, Kumamoto University), Chairperson:Atsushi Matsuoka, Toshiyuki Kurihara

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MIS15-01] **Environmental changes of the North Pacific Ocean through the Cenozoic era recorded in DSDP/ODP pelagic clay cores**

*Kazuhide Mimura[1], Katsushi Yamamoto[1], Kentaro Nakamura[1], Kazutaka Yasukawa[1,2], Junichiro Ohta[2], Koichiro Fujinaga[2,1], Shiki Machida[2], Yoichi Usui[3], Yasuhiro Kato[1,2] (1.Department of Systems Innovation, School of Engineering, the University of Tokyo, 2.ORCeNG, Chiba Institute of Technology, 3.JAMSTEC)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MIS15-02] Reconstruction of oceanic redox conditions in the Lower Jurassic (Pliensbachian–Toarcian) pelagic deep-sea bedded chert sequence of the Mino Belt, central Japan

*Katsuhito Soda[1] (1.Department of Earth and Environmental Sciences, Faculty of Science, Kumamoto University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MIS15-03] Conodont biostratigraphy of Anisian pelagic deep-sea sedimentary rocks deposited in the pelagic Panthalassa—Integration with radiolarian biozones—

*Shun Muto[1], Satoshi Takahashi[1], Satoshi Yamakita[2], Katsuhito Soda[3], Tetsuji Onoue[3] (1.Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo, 2.Faculty of Education, University of Miyazaki, 3.Faculty of Advanced Science and Technology)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MIS15-04] Triassic marine Os isotope record reconstructed from a pelagic chert succession, Sakahogi section, Mino Belt, southwest Japan

★Invited Papers

*Tatsuo Nozaki[1,2,3,4], Takashi Nikaido[5], Tetsuji Onoue[6], Yutaro Takaya[7,1,2,4], Keiko Sato[1], Jun-Ichi Kimura[8], Qing Chang[8], Daisuke Yamashita[6], Honami Sato[4,1], Katsuhiko Suzuki[1], Yasuhiro Kato[2,4], Atsushi Matsuoka[5] (1.JAMSTEC/R&D CSR, 2.Univ. of Tokyo, 3.Kobe Univ., 4.ChibaTech, 5.Niigata Univ., 6.Kumamoto Univ., 7.Waseda Univ., 8.JAMSTEC/D-SEG)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MIS15-05] **The preservation of radiolarians across the Jurassic-Cretaceous (J/K) boundary in the Bosso Valley section, Central Italy**

*XIN LI[1], Atsushi Matsuoka[2], Angela Bertinelli[3], Marco Chiari[4] (1.State Key Laboratory of Palaeobiology and Stratigraphy, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences, 2.Niigata University, 3.Università degli Studi di Perugia, 4. Istituto di Geoscienze e Georisorse)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MIS15-06] Radiolarian faunas around the Jurassic-Cretaceous boundary in the Bosso Valley section, central Italy

*Atsushi Matsuoka[1], XIN LI[2], Marco Chiari[3], Angela Bertinelli[4] (1.Department of Geology, Faculty of Science, Niigata University, 2.Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciense, 3.C.N.R., Istituto di Geoscienze e Georisorse, sede secondaria di Firenze, 4. Dipartimento di Fisica e Geologia, Università degli Studi di Perugia)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 201B 2F

[M-IS17] History X Earth and Planetary Science

convener:Yasuyuki Kano(Earthquake Research Institute, The University of Tokyo), Kei Yoshimura(Institute of Industrial Science, The University of Tokyo), Hiroaki Isobe(Faculty of Fine Arts, Kyoto City University of Arts), kiyomi iwahashi(National Institute of Japanese Literature), Chairperson:Yasuyuki Kano(東京大学 地震研究所), Kiyomi Iwahashi, Hiroaki Isobe, Kei Yoshimura, Harufumi Tamazawa

9:05 AM - 9:30 AM JST | 12:05 AM - 12:30 AM UTC

[MIS17-01] Document based reconstruction of environment of forests in the Edo period

★Invited Papers

*SATOSHI SHIROUZU[1] (1.Chuogakuin University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[MIS17-02] Studies of Babylonian Astronomical Diaries: Today and the Future

*Yasuyuki Mitsuma[1] (1.The University of Tokyo)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[MIS17-03] Characteristics of the Sunspots that Produce Large Solar Flares and the Possibility to Investigate these Events Utilizing Historical Observational Records

*Shin Toriumi[1] (1.National Astronomical Observatory of Japan)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[MIS17-04] An Approach of Environmental History to the "14th Century Crisis"

*Isahaya Yoichi[1] (1.Slavic-Eurasian Research Center, Hokkaido University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[MIS17-05] Recovery of the Asian monsoon variations since the late 19th century by the data rescue activities in ACRE-Japan

*Jun Matsumoto[1,2], Tomoshige Inoue[1], Fumiaki Fujibe[1], Jun-Ichi Hamada[1], Taiichi Hayashi[3], Toru Terao[4], Fumie Murata[5], Hisayuki Kubota[6], Ikumi Akasaka[7], Hirotaka Kamahori[8], Nobuhiko Endo[9], Haruhiko Yamamoto[10], Shigeru Kobayashi[11], Yoshitaka Muraji[12] (1.Deaprtment of Geography, Tokyo Metropolitan University, 2.Department of Coupled Ocean-Atmosphere-Land Processes Research, 3.Kyoto University, 4.Kagawa University, 5.Kochi University, 6.Hokkaido University, 7.Senshu University, 8.Meteorological Research Institute, 9.NARO/NIAES, 10.Yamaguchi University, 11.Osaka University, 12.EScoT)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS17] History X Earth and Planetary Science

convener:Yasuyuki Kano(Earthquake Research Institute, The University of Tokyo), Kei Yoshimura(Institute of Industrial Science, The University of Tokyo), Hiroaki Isobe(Faculty of Fine Arts, Kyoto City University of Arts), kiyomi iwahashi(National Institute of Japanese Literature), Chairperson:Hiroaki Isobe, Kei Yoshimura, Kiyomi Iwahashi, Yasuyuki Kano(東京大学 地震研究所), Harufumi Tamazawa

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS17-06] Historical big data: integrated analysis of the past world by the workflow that bridges data structuring gaps

*Asanobu Kitamoto[1,2,3], Mika Ichino[1,2] (1.National Institute of Informatics, 2.ROIS-DS Center for Open Data in the Humanities, 3.SOKENDAI)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS17-07] Felt earthquakes in Tokyo (Edo) based on historical daily records and seismic intensity data

*Kenji Satake[1] (1.Earthquake Research Institute, University of Tokyo)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS17-08] Climate and social changes in ancient Japan construed by use of high resolution reconstruction of the Climate in Historical Time

*Katsunori IMAZU[1], Takeshi Nakatsuka[2] (1.OKAYAMA University Graduate School of Humanities and Social Sciences, 2.Research Institute for Humanity and Nature)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS17-09] Absolute ages for huge eruptions of Towada Caldera and Baitoushan volcano in the 10th century as seen from dendrochronological studies and historical documents

*Masataka Hakozaki[1], Fusa Miyake[2], Masaki Sano[3], Katsuhiko Kimura[4], Toshio Nakamura[2], Mitsuru Okuno[5], Minoru Sakamoto[1], Takeshi Nakatsuka[6,2] (1.National Museum of Japanese History, 2.Nagoya University, 3.Waseda University, 4.Fukushima University, 5.Fukuoka University, 6.Research Institute for Humanity and Nature)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS17-10] How can we activate collaborations with history and archaeology? – Lesson from Historical Climate Adaptation project

★Invited Papers

*Takeshi Nakatsuka[1,2] (1.Research Institute for Humanity and Nature, 2.Graduate School of Environmental Studies, Nagoya University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_22

[M-IS17] History X Earth and Planetary Science

convener:Yasuyuki Kano(Earthquake Research Institute, The University of Tokyo), Kei Yoshimura(Institute of Industrial Science, The University of Tokyo), Hiroaki Isobe(Faculty of Fine Arts, Kyoto City University of Arts), kiyomi iwahashi(National Institute of Japanese Literature)

[MIS17-P01] Perspective of 'History X Earth and Planetary Science'

*Yasuyuki Kano[1], Hiroaki Isobe[2], Kei Yoshimura[3], Kiyomi Iwahashi[4], Harufumi Tamazawa[5,2] (1.Earthquake Research Institute, The University of Tokyo, 2.Faculty of Fine Arts, Kyoto City University of Arts, 3.Institute of Industrial Science, The University of Tokyo, 4.National Institute of Japanese Literature, 5.Disaster Prevention Research Institute, Kyoto University)

[MIS17-P02] Reexamination of intensity distribution of Japanese historical earthquakes using attenuation relation

*Yasuyuki Kano[1], Junzo Ohmura[2] (1.Earthquake Research Institute, The University of Tokyo, 2.Diasaster prevention Research institute, Kyoto University)

[MIS17-P03] Rekisuke: a system for sharing bibliographic information of historical documents through Interdisciplinary collaboration

★Invited Papers

*Mika Ichino[1,2], Yukie Hashimoto, Kooiti Masuda[3], Asanobu Kitamoto[2,1], Junpei Hirano[4] (1.Center for Open Data in the Humanities, Joint Support-Center for Data Science Research, Research Organization of Information and Systems , 2.National Institute of Informatics, 3.Tokyo Metropolitan University, 4.Faculty of Liberal Arts, Teikyo University)

[MIS17-P04] Analysis of reconstruction processes after the 1707 Hoei eruption of Fuji Volcano based on old maps

*Junzo Ohmura[1] (1.Research Institute for Earthquake Prediction, Disaster Prevention Research Institute, Kyoto University)

[MIS17-P05] Workshop of Word Survey about Earth and Planetary Phenomena by Citizen

*Harufumi Tamazawa[1,2], kiyomi iwahashi[3] (1. Disaster Prevention Research Institute Kyoto University, 2.Faculty of Fine Arts, Kyoto City University of Arts, 3.National Institute of Japanese Literature)

[MIS17-P06] Observational Data in the first half of 20th century to join modern scientific Observation and historical documents: A Usage example ob Photographic Plate of Kwasan Observatory

*Harufumi Tamazawa[1], Reizaburo Kitai[4], Hiroaki Isobe[2], Satoru UeNo[3], Takahito Sakaue[3] (1. Disaster Prevention Research Institute Kyoto University, 2.Faculty of Fine Arts, Kyoto City University of Arts, 3.Astronomical Observatory, Graduate School of Science, Kyoto University, 4.Bukkyo University)

[MIS17-P07] Climate changes and lords' control in the early modern period in Japan

*Kaoru kamatani[1], Masaki Sano[2], Takeshi Nakatsuka[3] (1.Ritsumeikan University, 2.Waseda University, 3.Research Institute for Humanity and Nature)

[MIS17-P08] Intense geomagnetic storm during Maunder minimum possibly by quiescent filament eruption

*Hiroaki Isobe[1], Yusuke Ebihara[2], Harufumi Tamazawa[1], Akito Davis Kawamura[3], Hisashi Hayakawa[4] (1.Faculty of Fine Arts, Kyoto City University of Arts, 2.Research Institute for Sustainable Humanosphere, Kyoto University, 3.Graduate School of Science, Kyoto University, 4.Graduate School of Letters, Osaka University)

[MIS17-P09] Reconstructing 1931 flood in Yangtze River basin and its application to Chinese economic history

*CHANG LIU[1], Akiyuki Kawasaki[1], Tomoko Shiroyama[2] (1.Department of Civil Engineering, Graduate School of Engineering, the University of Tokyo, 2.Department of Economics, Graduate School of Economics, the University of Tokyo)

[MIS17-P10] Seismicity Analysis Using Felt Reports and Attenuation Relation of Seismic Intensity

*Takeo Ishibe[1], Koji Iwasa[1], Mitsuko Furumura[1], Ritsuko S. Matsu'ura[1] (1.Association for the Development of Earthquake Prediction)

[MIS17-P11] Radiocarbon dating of Japanese tree rings – chronological research and Japanese calibration curve

*Minoru Sakamoto[1,2], Masataka Hakozaki[1], Takumi Mitsutani[3], Takeshi Nakatsuka[4,5] (1.National Museum of Japanese History, 2.The Graduate University for Advanced Studies, 3.Nara National Research Institute for Cultural Properties, 4.Research Institute for Humanity and Nature, 5.Nagoya University)

[MIS17-P12] Usage of Historical Documents with Scientific Understandings in the field of Solar Physics

*Akito Davis Kawamura[1], Hisashi Hayakawa[2], Harufumi Tamazawa[3], Hiroaki Isobe[3], Kazunari Shibata[1] (1.Astronomical Observatory, Kyoto University, 2.Graduate School of Letters, Osaka University, 3.Faculty of Fine Arts, Kyoto City University of Arts)

[MIS17-P13] The study of the relationship between the flood of Kitakami River and sociaty in the end of Edo period

*Daisuke Sato[1], Yoshitaka Takahashi[2] (1.International Reserch Institute of Disaster Science Tohoku University , 2.Tokyo University of Agriculture and Technology)

[MIS17-P14] Reconstruction of Historical Weather with Data Assimilation Using Old Diaries

*Kei Yoshimura[1], Panduka Neluwala[2], Mika Ichino[3], Kooiti Masuda[4], Junpei Hirano[5] (1.Institute of Industrial Science, The University of Tokyo, 2.University of Peradeniya , 3.National Institute of Informatics, 4.Tokyo Metropolitan University, 5.Teikyo University)

[MIS17-P15] Examination of data range for fitting Omori-Utsu law to temporal decay of aftershocks presented in historical materials on the 1830 Kyoto earthquake: Reason for the difference of numbers of aftershocks in the same place

*Kentaro Hattori[1], Junzo Ohmura[2], Ichiro Nakanishi[1] (1.Kyoto Univ., 2.Bukkyo Univ.)

[MIS17-P16] Tsunami trace height of the AD 1854 Ansei Tokai tsunami around the lake Hamanako inferred from historical maps

*ebina yuichi[1], Kentaro Imai[2], Yoshinobu Tsuji[3], hiroyuki iwase[4] (1.International Research Institute of Disaster Science, 2.JAMSTEC, 3.Fukuda Geological Instite, 4. (C)ECOH CORPORATION)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_37

[M-IS17] History X Earth and Planetary Science

convener:Yasuyuki Kano(Earthquake Research Institute, The University of Tokyo), Kei Yoshimura(Institute of Industrial Science, The University of Tokyo), Hiroaki Isobe(Faculty of Fine Arts, Kyoto City University of Arts), kiyomi iwahashi(National Institute of Japanese Literature)

[MIS17-P01] Perspective of 'History X Earth and Planetary Science'

*Yasuyuki Kano[1], Hiroaki Isobe[2], Kei Yoshimura[3], Kiyomi Iwahashi[4], Harufumi Tamazawa[5,2] (1.Earthquake Research Institute, The University of Tokyo, 2.Faculty of Fine Arts, Kyoto City University of Arts, 3.Institute of Industrial Science, The University of Tokyo, 4.National Institute of Japanese Literature, 5.Disaster Prevention Research Institute, Kyoto University)

[MIS17-P02] Reexamination of intensity distribution of Japanese historical earthquakes using attenuation relation

*Yasuyuki Kano[1], Junzo Ohmura[2] (1.Earthquake Research Institute, The University of Tokyo, 2.Diasaster prevention Research institute, Kyoto University)

[MIS17-P03] Rekisuke: a system for sharing bibliographic information of historical documents through Interdisciplinary collaboration

★Invited Papers

*Mika Ichino[1,2], Yukie Hashimoto, Kooiti Masuda[3], Asanobu Kitamoto[2,1], Junpei Hirano[4] (1.Center for Open Data in the Humanities, Joint Support-Center for Data Science Research, Research Organization of Information and Systems , 2.National Institute of Informatics, 3.Tokyo Metropolitan University, 4.Faculty of Liberal Arts, Teikyo University)

[MIS17-P04] Analysis of reconstruction processes after the 1707 Hoei eruption of Fuji Volcano based on old maps

*Junzo Ohmura[1] (1.Research Institute for Earthquake Prediction, Disaster Prevention Research Institute, Kyoto University)

[MIS17-P05] Workshop of Word Survey about Earth and Planetary Phenomena by Citizen

*Harufumi Tamazawa[1,2], kiyomi iwahashi[3] (1. Disaster Prevention Research Institute Kyoto University, 2.Faculty of Fine Arts, Kyoto City University of Arts, 3.National Institute of Japanese Literature)

[MIS17-P06] Observational Data in the first half of 20th century to join modern scientific Observation and historical documents: A Usage example ob Photographic Plate of Kwasan Observatory

*Harufumi Tamazawa[1], Reizaburo Kitai[4], Hiroaki Isobe[2], Satoru UeNo[3], Takahito Sakaue[3] (1. Disaster Prevention Research Institute Kyoto University, 2.Faculty of Fine Arts, Kyoto City University of Arts, 3.Astronomical Observatory, Graduate School of Science, Kyoto University, 4.Bukkyo University)

[MIS17-P07] Climate changes and lords' control in the early modern period in Japan

*Kaoru kamatani[1], Masaki Sano[2], Takeshi Nakatsuka[3] (1.Ritsumeikan University, 2.Waseda University, 3.Research Institute for Humanity and Nature)

[MIS17-P08] Intense geomagnetic storm during Maunder minimum possibly by quiescent filament eruption

*Hiroaki Isobe[1], Yusuke Ebihara[2], Harufumi Tamazawa[1], Akito Davis Kawamura[3], Hisashi Hayakawa[4] (1.Faculty of Fine Arts, Kyoto City University of Arts, 2.Research Institute for Sustainable Humanosphere, Kyoto University, 3.Graduate School of Science, Kyoto University, 4.Graduate School of Letters, Osaka University)

[MIS17-P09] Reconstructing 1931 flood in Yangtze River basin and its application to Chinese economic history

*CHANG LIU[1], Akiyuki Kawasaki[1], Tomoko Shiroyama[2] (1.Department of Civil Engineering, Graduate School of Engineering, the University of Tokyo, 2.Department of Economics, Graduate School of Economics, the University of Tokyo)

[MIS17-P10] Seismicity Analysis Using Felt Reports and Attenuation Relation of Seismic Intensity

*Takeo Ishibe[1], Koji Iwasa[1], Mitsuko Furumura[1], Ritsuko S. Matsu'ura[1] (1.Association for the Development of Earthquake Prediction)

[MIS17-P11] Radiocarbon dating of Japanese tree rings – chronological research and Japanese calibration curve

*Minoru Sakamoto[1,2], Masataka Hakozaki[1], Takumi Mitsutani[3], Takeshi Nakatsuka[4,5] (1.National Museum of Japanese History, 2.The Graduate University for Advanced Studies, 3.Nara National Research Institute for Cultural Properties, 4.Research Institute for Humanity and Nature, 5.Nagoya University)

[MIS17-P12] Usage of Historical Documents with Scientific Understandings in the field of Solar Physics

*Akito Davis Kawamura[1], Hisashi Hayakawa[2], Harufumi Tamazawa[3], Hiroaki Isobe[3], Kazunari Shibata[1] (1.Astronomical Observatory, Kyoto University, 2.Graduate School of Letters, Osaka University, 3.Faculty of Fine Arts, Kyoto City University of Arts)

[MIS17-P13] The study of the relationship between the flood of Kitakami River and sociaty in the end of Edo period

*Daisuke Sato[1], Yoshitaka Takahashi[2] (1.International Reserch Institute of Disaster Science Tohoku University , 2.Tokyo University of Agriculture and Technology)

[MIS17-P14] Reconstruction of Historical Weather with Data Assimilation Using Old Diaries

*Kei Yoshimura[1], Panduka Neluwala[2], Mika Ichino[3], Kooiti Masuda[4], Junpei Hirano[5] (1.Institute of Industrial Science, The University of Tokyo, 2.University of Peradeniya , 3.National Institute of Informatics, 4.Tokyo Metropolitan University, 5.Teikyo University)

[MIS17-P15] Examination of data range for fitting Omori-Utsu law to temporal decay of aftershocks presented in historical materials on the 1830 Kyoto earthquake: Reason for the difference of numbers of aftershocks in the same place

*Kentaro Hattori[1], Junzo Ohmura[2], Ichiro Nakanishi[1] (1.Kyoto Univ., 2.Bukkyo Univ.)

[MIS17-P16] Tsunami trace height of the AD 1854 Ansei Tokai tsunami around the lake Hamanako inferred from historical maps

*ebina yuichi[1], Kentaro Imai[2], Yoshinobu Tsuji[3], hiroyuki iwase[4] (1.International Research Institute of Disaster Science, 2.JAMSTEC, 3.Fukuda Geological Instite, 4. (C)ECOH CORPORATION)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 301A 3F

[M-IS18] Geophysical fluid dynamics-Transfield approach to geoscience

convener:Keita Iga(Atmosphere and Ocean Research Institute, The University of Tokyo), Shigeo Yoshida(Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University), Takatoshi Yanagisawa(Department of Deep Earth Structure and Dynamics Research, Japan Agency for Marine-Earth Science and Technology), Hidenori AIKI(Nagoya University), Chairperson:Kensuke Nakajima

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS18-01] Axisymmetric disturbance on an axisymmetric shallow water vortex

*Toshihisa Itano[1] (1.National Defense Academy)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS18-02] Numerical studies on the classification of flow regimes of the 3-D thermal convection of rotating fluids

*Masanori Kameyama[1,2] (1.Geodynamics Research Center, Ehime University, 2.Japan Agency for Marine-Earth Science and Technology)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS18-03] Diffusive behavior of columnar vortices in rotating thermal convection

*Daisuke Noto[1], Yuji Tasaka[2], Takatoshi Yanagisawa[3], Yuichi Murai[2] (1.Graduate School of Engineering, Hokkaido University, 2.Faculty of Engineering, Hokkaido University, 3.Japan Agency for Marine-Earth Science and Technology)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS18-04] Liquid metal flows driven by a rotating magnetic field

*Koki Sawada[1], Vladimir Galindo[2], Tobias Vogt[2], Sven Eckert[2], Yuji Tasaka[3], Yuichi Murai[3] (1.Graduate School of Engineering, Hokkaido University , 2.Helmholtz-Zentrum Dresden-Rossendorf, 3.Faculty of Engineering, Hokkaido University,)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS18-05] A symmetry-breaking self-regulating dynamo generating Mercury’s anomalous magnetic field

*Futoshi Takahashi[1], Hisayoshi Shimizu[2], Hideo Tsunakawa[3] (1.Faculty of Sciences, Kyushu University, 2.Earthquake Research Institute, University of Tokyo , 3.Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology)

convener:Keisuke Suzuki(Department of Environmental Sciences, Faculty of Science, Shinshu University), Yoshihiko Kariya(Department of Environmental Geography, Senshu University), Akihiko SASAKI(Department of Geography and Environmental Studies, Kokushikan University), Chiyuki Narama(Niigata University, Department of Science)

[MIS20-P01] Development of fluvial terraces and landslides since the late Pleistocene in the Shirata River basin, southeastern side of Amagi Volcano, Izu Peninsula, Japan

*Nao Tokumoto[1], Yoshihiko Kariya[2], Kuniyasu Mokudai[3] (1.Undegraduate, Senshu Univ., 2.Senshu Univ., 3.Japan Geoservice Inc.)

[MIS20-P02] Variation trends of air temperature and snow depth in the Japanese Alps

*Keisuke Suzuki[1], Akihiko SASAKI[2] (1.Faculty of Science, Shinshu University, 2.Faculty of Literature, Kokushikan University)

[MIS20-P03] Abundant tardigrades found in snow pack in Mt.Gassan in Yamagata Prefecture, Japan

*MASATO ONO[1] (1.Chiba University)

[MIS20-P04] Variation of stable isotope ratios of precipitation in the Japanese Alps Region

*Tsukasa Katsuragawa[1], Tsutomu Yamanaka[2], Akihiko SASAKI[3], Yuki Kurokumo[1], Motoshi NISHIMURA[1], Shimizu Hironori[1], Keisuke Suzuki[4] (1.Graduate School of Science and Technology,Shinshu University, 2.Faculty of Life and Environmental Sciences, University of Tsukuba, 3.Department of Geography and Environmental Studies, Kokushikan University, 4.Department of Environmental Sciences, Faculty of Science, Shinshu University)

[MIS20-P05] Probable glacier detritus found at downstream site of the Yokoo moraines in the northern Japanese Alps: its geological characteristics and implications

*Manami Ishibashi[1], Yoshihiko Kariya[2], Kuniyasu Mokudai[3] (1.Undergraduate Senshu Univ., 2.Senshu Univ., 3.Japan Geo serivice Inc.)

[MIS20-P06] Recent Geomorphological changes of rock slopes in Hakuba-Daisekkei

*Hirotaka Sugiyama[1], Chiyuki Narama[2], Hiroshi Inoue[3] (1.Graduate School of Science and Technology, Niigata University, 2.Faculty of Science, Niigata University, 3.National Reserch Institute for Earth Science and Disaster Resilience)

[MIS20-P07] Behavior of inorganic ions in air deposition and surface runoff water in an alpine headwater catchment of Mt. Norikura

*Hironori Shimizu[1], Akihiko Sasaki[2], Keisuke Suzuki[3] (1.Graduate School of Science and Technology, Shinshu University , 2.Department of Geography and Environmental Studies, Kokushikan University, 3.Faculty of Science, Shinshu University)

[MIS20-P08] Activity of gravity faults in the Tateyama caldera, Hida Mountains, during the past 55 years

*Kotaro FUKUI[1], Hajime IIDA[1] (1.Tateyama Caldera Sabo Museum)

[MIS20-P09] Community, population and genetic structures of benthic invertebrates in alpine and sub-alpine ponds of the Kamikochi area and the Yari-Hotaka Mountain Ranges

*Keisuke Inoue[1], Koji Tojo[1] (1.Biology Department, Faculty of Science, Shinshu University)

[MIS20-P10] Water and carbon use of fine root in four tree species at the forest limit

*Hikari Yahara[1], Wakana Azuma[2], Mai Kamakura[2], Naoki Makita[1] (1.Graduate School of Science and Technology Shinshu University, 2.Graduate School of Agriculture Kyoto University)

[MIS20-P11] Visible-near infrared spectral reflectance explains variations in fine root traits of woody species

*Natsuko Tanikawa[1], Tatsuro Nakaji[3], Miwa Kobatake[2], Naoki Makita[2] (1.Graduate School of Science and technology, Shinshu University, 2.Faculty of Science, Shinshu University, 3.Field Science Center for Northern Biosphere)

[MIS20-P12] Heat Balance Analysis of Cold Air Pool Formation in Kamikochi

*Sayuri Koyama[1], Motoshi NISHIMURA[2], Keisuke Suzuki[3] (1.Graduate school of science and technorogy, Shinshu University, 2.Interdisciplinary Graduate school of Science and Technology, Shinshu university, 3.Department of

Environmental Sciences, Faculty of Science, Shinshu University)

[MIS20-P13] A finding of fossil trees buried in dammed-lake deposits formed by the Dondokosawa rock avalanche of the late 9th century in the Akaishi Mountains, and its significance

*Takashi Kimura[1], Ryuji Yamada[1], Yoshihiko Kariya[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Senshu University)

[MIS20-P14] What alpine plants attract visitors in the Daisetsuzan national park, northern, Japan?

*Yukihiro Amagai[1], Kota Mameno[1,2], Hiroyuki Oguma[1], Takahiro Kubo[1] (1.National Institute for Environmental Studies, 2.Hokkaido University)

[MIS20-P15] Spatio-temporal variations of algal snow in Mt. Gassan, Yamagata prefecture, Japan

*Suzuki Takumi[1], Nozomu Takeuchi[1], Tsubasa Takahashi[1] (1.Chiba University)

[MIS20-P16] Feeding of a wingless stonefly living on snow surface in Mt. Gassan, Yamagata prefecture, Japan

*Risako Yonechi[1], Nozomu Takeuchi[1] (1.Chiba University)

[MIS20-P17] Drainage from glacial lake in Achinathang village, Ladakh Range on 4 August 2017

Maho Saotome[2], *Chiyuki Narama[1], Naoki Sakurai[2] (1.Niigata University, Program of Field Research in the Environmental Sciences, 2.Graduate School of Science and Technology, Niigata University)

[MIS20-P18] Recent glacier variations at Mt. Kenya using aerial digital image

*Chiyuki Narama[1], kenshiro Arie[2], MIZUNO KAZUHARU[3] (1.Program of Field Research in the Environmental Sciences, Niigata University , 2.Graduate School of Science and Technology, Niigata University, 3.Graduate School of Letters, Kyoto University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_39

[M-IS20] Mountain Science

convener:Keisuke Suzuki(Department of Environmental Sciences, Faculty of Science, Shinshu University), Yoshihiko Kariya(Department of Environmental Geography, Senshu University), Akihiko SASAKI(Department of Geography and Environmental Studies, Kokushikan University), Chiyuki Narama(Niigata University, Department of Science)

[MIS20-P01] Development of fluvial terraces and landslides since the late Pleistocene in the Shirata River basin, southeastern side of Amagi Volcano, Izu Peninsula, Japan

*Nao Tokumoto[1], Yoshihiko Kariya[2], Kuniyasu Mokudai[3] (1.Undegraduate, Senshu Univ., 2.Senshu Univ., 3.Japan Geoservice Inc.)

[MIS20-P02] Variation trends of air temperature and snow depth in the Japanese Alps

*Keisuke Suzuki[1], Akihiko SASAKI[2] (1.Faculty of Science, Shinshu University, 2.Faculty of Literature, Kokushikan University)

[MIS20-P03] Abundant tardigrades found in snow pack in Mt.Gassan in Yamagata Prefecture, Japan

*MASATO ONO[1] (1.Chiba University)

[MIS20-P04] Variation of stable isotope ratios of precipitation in the Japanese Alps Region

*Tsukasa Katsuragawa[1], Tsutomu Yamanaka[2], Akihiko SASAKI[3], Yuki Kurokumo[1], Motoshi NISHIMURA[1], Shimizu Hironori[1], Keisuke Suzuki[4] (1.Graduate School of Science and Technology,Shinshu University, 2.Faculty of Life and Environmental Sciences, University of Tsukuba, 3.Department of Geography and Environmental Studies, Kokushikan University, 4.Department of Environmental Sciences, Faculty of Science, Shinshu University)

[MIS20-P05] Probable glacier detritus found at downstream site of the Yokoo moraines in the northern Japanese Alps: its geological characteristics and implications

*Manami Ishibashi[1], Yoshihiko Kariya[2], Kuniyasu Mokudai[3] (1.Undergraduate Senshu Univ., 2.Senshu Univ., 3.Japan Geo serivice Inc.)

[MIS20-P06] Recent Geomorphological changes of rock slopes in Hakuba-Daisekkei

*Hirotaka Sugiyama[1], Chiyuki Narama[2], Hiroshi Inoue[3] (1.Graduate School of Science and Technology, Niigata University, 2.Faculty of Science, Niigata University, 3.National Reserch Institute for Earth Science and Disaster Resilience)

[MIS20-P07] Behavior of inorganic ions in air deposition and surface runoff water in an alpine headwater catchment of Mt. Norikura

*Hironori Shimizu[1], Akihiko Sasaki[2], Keisuke Suzuki[3] (1.Graduate School of Science and Technology, Shinshu University , 2.Department of Geography and Environmental Studies, Kokushikan University, 3.Faculty of Science, Shinshu University)

[MIS20-P08] Activity of gravity faults in the Tateyama caldera, Hida Mountains, during the past 55 years

*Kotaro FUKUI[1], Hajime IIDA[1] (1.Tateyama Caldera Sabo Museum)

[MIS20-P09] Community, population and genetic structures of benthic invertebrates in alpine and sub-alpine ponds of the Kamikochi area and the Yari-Hotaka Mountain Ranges

*Keisuke Inoue[1], Koji Tojo[1] (1.Biology Department, Faculty of Science, Shinshu University)

[MIS20-P10] Water and carbon use of fine root in four tree species at the forest limit

*Hikari Yahara[1], Wakana Azuma[2], Mai Kamakura[2], Naoki Makita[1] (1.Graduate School of Science and Technology Shinshu University, 2.Graduate School of Agriculture Kyoto University)

[MIS20-P11] Visible-near infrared spectral reflectance explains variations in fine root traits of woody species

*Natsuko Tanikawa[1], Tatsuro Nakaji[3], Miwa Kobatake[2], Naoki Makita[2] (1.Graduate School of Science and technology, Shinshu University, 2.Faculty of Science, Shinshu University, 3.Field Science Center for Northern Biosphere)

[MIS20-P12] Heat Balance Analysis of Cold Air Pool Formation in Kamikochi

*Sayuri Koyama[1], Motoshi NISHIMURA[2], Keisuke Suzuki[3] (1.Graduate school of science and technorogy, Shinshu University, 2.Interdisciplinary Graduate school of Science and Technology, Shinshu university, 3.Department of

Environmental Sciences, Faculty of Science, Shinshu University)

[MIS20-P13] A finding of fossil trees buried in dammed-lake deposits formed by the Dondokosawa rock avalanche of the late 9th century in the Akaishi Mountains, and its significance

*Takashi Kimura[1], Ryuji Yamada[1], Yoshihiko Kariya[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Senshu University)

[MIS20-P14] What alpine plants attract visitors in the Daisetsuzan national park, northern, Japan?

*Yukihiro Amagai[1], Kota Mameno[1,2], Hiroyuki Oguma[1], Takahiro Kubo[1] (1.National Institute for Environmental Studies, 2.Hokkaido University)

[MIS20-P15] Spatio-temporal variations of algal snow in Mt. Gassan, Yamagata prefecture, Japan

*Suzuki Takumi[1], Nozomu Takeuchi[1], Tsubasa Takahashi[1] (1.Chiba University)

[MIS20-P16] Feeding of a wingless stonefly living on snow surface in Mt. Gassan, Yamagata prefecture, Japan

*Risako Yonechi[1], Nozomu Takeuchi[1] (1.Chiba University)

[MIS20-P17] Drainage from glacial lake in Achinathang village, Ladakh Range on 4 August 2017

Maho Saotome[2], *Chiyuki Narama[1], Naoki Sakurai[2] (1.Niigata University, Program of Field Research in the Environmental Sciences, 2.Graduate School of Science and Technology, Niigata University)

[MIS20-P18] Recent glacier variations at Mt. Kenya using aerial digital image

*Chiyuki Narama[1], kenshiro Arie[2], MIZUNO KAZUHARU[3] (1.Program of Field Research in the Environmental Sciences, Niigata University , 2.Graduate School of Science and Technology, Niigata University, 3.Graduate School of Letters, Kyoto University)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 106 1F

[M-IS23] Planetary Volcanology

convener:Rina Noguchi(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University), Kyoko S. Kataoka(Research Institute for Natural Hazards and Disaster Recovery, Niigata University), Shizuka Otsuki(Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan, Advanced Industrial Science and Technology), Chairperson:Rina Noguchi(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Nobuo Geshi(GSJ/AIST)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[MIS23-01] Growth and evolution of isolated volcanic island, Nishinoshima, Ogasawara

★Invited Papers

*Fukashi Maeno[1] (1.Earthquake Research Institute, University of Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[MIS23-02] The style of magmatism on terrestrial planets of various sizes predicted from numerical models of mantle dynamics

*Masaki Ogawa[1] (1.Division of General Systems Studies, Graduate School of Arts and Sciences, University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[MIS23-03] Lunar and Matian lava tubes and explorations to them through their skylight holes

*Junichi Haruyama[1], Takahiro Iwata[1], Yukio Yamamoto[1], Tetsuya Kaku[2,1], Wataru Miyake[2], Atsushi Kumamoto[3], Ken Ishiyama[1], yokota yasuhiro[4], Takumi Ono[2,1] (1.Japan Aerospace Exploration Agency, 2.Tokai University, 3.Tohoku University, 4.Kochi University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[MIS23-04] Volcanic activity on Io, formation of the atmosphere, and escape of atmosphere to the magnetosphere

*Fuminori Tsuchiya[1], Ryoichi Koga[1], Mizuki Yoneda[2], Masato Kagitani[1], Kazuo Yoshioka[4], Reina Hikida[4], Go Murakami[3], Tomoki Kimura[1], Atsushi Yamazaki[3], Hajime Kita[3], Ichiro Yoshikawa[4] (1.Tohoku University, 2.Tadano, 3.ISAS/JAXA, 4.The University of Tokyo)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[MIS23-05] Cryovolcanism, a critical review

*Kei Kurita[1] (1.Earthquake Research Inst.,The University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[MIS23-06] Cryovolcanisms on Solar System bodies: Observations, importance, and future perspectives

★Invited Papers

*Yasuhito Sekine[1] (1.Earth-Life Science Insitute, Tokyo Institute of Technology)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_25

[M-IS23] Planetary Volcanology

convener:Rina Noguchi(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University), Kyoko S. Kataoka(Research Institute for Natural Hazards and Disaster Recovery, Niigata University), Shizuka Otsuki(Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan, Advanced Industrial Science and Technology)

[MIS23-P01] **A possible method of lava flow temperature estimation by lava tube cave of Earth,Moon and Mars**

*Tsutomu Honda[1] (1.Vulcano-speleological Society)

[MIS23-P02] Process of magma eruption on the Moon

*Tomokatsu Morota[1] (1.Graduate School of Environmental Studies, Nagoya University)

[MIS23-P03] Statistical analysis of grain morphology generated under hypervelocity impact experiment as an analog of volcanic explosion

*Rina Noguchi[1], Shizuka Otsuki[2], Ayako I Suzuki, Sunao Hasegawa[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Geological Survey of Japan, AIST)

[MIS23-P04] Disequilibrium precipitation of salts during rapid freezing of brine: Implications for cryovolcanisms and formation of sodium carbonate of bright spots on Ceres.

*Masahiro Yoda[1,2], Yasuhito Sekine[2], Shuya Tan[1,2] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Earth-Life Science Institute, Tokyo Institute of Technology)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 201B 2F

[M-IS28] Fluid-sediment migration and geo-bio interaction

convener:Robert Jenkins(School of Geosciences and Civil Engineering, College of Science and Engineering, Kanazawa University), Tomohiro Toki(Faculty of Science, University of the Ryukyus), Akira Ijiri(Japan Agency for Marine-Earth Science and Technology), Takami Nobuhara(Science Education (Geology), Faculty of Education, Shizuoka University), Hiromi Kayama WATANABE(Japan Agency for Marine-Earth Science and Technology), Miho Asada(Japan Agency for Marine-Earth Science and Technology), Chairperson:Tomohiro Toki, Robert Jenkins(Kanazawa University)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS28-01] Upper Pliocene large lucinid communities with cold-seep carbonates from the Shimajiri Group in the Miyagi-jima Island off the central part of Okinawa-jima Island, Japan

*Takami Nobuhara[1], Robert Jenkins[2], Shin-ichi Nomura[3] (1.Science Education (Geology), Faculty of Education, Shizuoka University, 2.School of Natural System, College of Science and Engineering, Kanazawa University, 3.Chiba Prefectural Kisarazu High School)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS28-02] Chemosynthetic fossil community in Early Cretaceous methane seep from Yubari City, Hokkaido

*Nanami Shimazu[1], Robert Jenkins[1] (1.Kanazawa University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS28-03] Marine Snow Hypothesis: What is controling faunal composition of the methane-seep since Mesozoic?

*Robert Jenkins[1] (1.School of Geosciences and Civil Engineering, College of Science and Engineering, Kanazawa University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS28-04] *In situ* Sr isotope analysis of methane-seep carbonates: insight into ancient subseafloor fluid circulation

★Invited Papers

*Yusuke Miyajima[1], Michał Jakubowicz[2,3], Takafumi Hirata[1] (1.Geochemical Research Center, Graduate School of Science, The University of Tokyo, 2.Institute of Geoecology and Geoinformation, Adam Mickiewicz University, Poland, 3.Isotope Laboratory, Adam Mickiewicz University, Poland)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS28-05] Monitoring CH_4 amounts deep inside deep-water mud volcanoes

★Invited Papers

*A. Kioka[1], T. Tsuji[2], H. Otsuka[3], J. Ashi[3] (1.Universität Innsbruck, Austria, 2.Kyushu University, Japan, 3.The University of Tokyo, Japan)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS28-06] Discussion

*Robert Jenkins[1] (1.School of Natural System, College of Science and Engineering, Kanazawa University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_26

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MGI33-09] 3-dimensional Fracture Network Analysis by Persistent Homology

*Miyuki Miyazawa[1], Anna Suzuki[2], Atsushi Okamoto[1], Hiroyuki Shimizu[3], Ippei Obayashi[4], Yasuaki Hiraoka[4,5], Takatoshi Ito[2] (1.Graduate School of Environmental Studies, Tohoku University, 2.Institute of Fluid Science, Tohoku University, 3.Kajima Corporation, 4.The Advanced Institute for Materials Research, Tohoku University, 5.Kyoto University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MGI33-10] Characteristic patterns and minimal dynamics of correlated seismicity in Japanese island region

*mitsuhiro toriumi[1] (1.Japan agency of marine science and technology)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-TT Technology & Techniques

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 104 1F

[M-TT46] New phase of GPS/GNSS application as an integrated earth observation system

convener:Yoshinori Shoji(The Second Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute), Kaoru Ichikawa(Research Institute for Applied Mechanics, Kyushu University), Yusaku Ohta(Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University), Takuya Tsugawa(National Institute of Information and Communications Technology), Chairperson:Yusaku Ohta

9:00 AM - 9:30 AM JST | 12:00 AM - 12:30 AM UTC

[MTT46-01] The latest status of Quasi-Zenith Satellite System (QZSS) and its future expansion

★Invited Papers

*Satoshi Kogure[1] (1.QZSS Straetegy Office, National Space Policy Secretariate, Cabinet Office)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[MTT46-02] Application of the GNSS-A for other academic fields and fundamental marine information network

*Yusuke Yokota[1], Tadashi Ishikawa[2], Shun-ichi Watanabe[2] (1.Institute of Industrial Science, The University of Tokyo, 2.Hydrographic and Oceanographic department, Japan Coast Guard)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[MTT46-03] Feasibility of the GNSS carrier phase to fault slip approach for the estimation of slip phenomena in subduction zone

*Yusuke Tanaka[1], Yusaku Ohta[1], SHINICHI MIYAZAKI[2] (1.Tohoku University, 2.Kyoto University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[MTT46-04] Assimilation experiments of GNSS-derived ZTD and Sentinel-derived products into WRF to improve forecasts of severe rain events in Italy

*Eugenio Realini[1], Martina Lagasio[2], Luca Pulvirenti[2], Antonio Parodi[2], Andrea Gatti[1], Giulio Tagliaferro[1], Giovanna Venuti[3], Stefano Barindelli[3], Emanuele Passera[4], Alessio Rucci[4], Nazzareno Pierdicca[5], Bjorn Rommen[6] (1.Geomatics Research & Development srl, 2.CIMA Research Foundation, 3.Dept. of Civil and Environmental Engineering, Politecnico di Milano, 4.TRE Altamira srl, 5.Dept. of Information Engineering, Electronics and Telecommunications, Sapienza Univ. of Rome, 6.European Space Agency (ESA-ESTEC))

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[MTT46-05] **An analysis of tropospheric delays using goGPS software on all GEONET stations during the passage of Typhoon Jebi in September 2018**

*Andrea Gatti[1], Eugenio Realini[1], Giulio Tagliaferro[1] (1.Geomatics Research & Development srl)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-TT Technology & Techniques

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 104 1F

[M-TT46] New phase of GPS/GNSS application as an integrated earth observation system

convener:Yoshinori Shoji(The Second Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute), Kaoru Ichikawa(Research Institute for Applied Mechanics, Kyushu University), Yusaku Ohta(Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University), Takuya Tsugawa(National Institute of Information and Communications Technology), Chairperson:Takuya Tsugawa

10:45 AM - 11:05 AM JST | 1:45 AM - 2:05 AM UTC

[MTT46-06] **A new perspective of the storm-time dynamics of the ionosphere using global GNSS-TEC observation data**

★Invited Papers

*Atsuki Shinbori[1], Yuichi Otsuka[1], Takuya Sori[1], Takuya Tsugawa[2], Michi Nishioka[2] (1.Institute for Space-Earth Environment Research (ISEE), Nagoya University, 2.National Institute of Information and Communications Technology (NICT))

11:05 AM - 11:20 AM JST | 2:05 AM - 2:20 AM UTC

[MTT46-07] Ionospheric space weather studies for GNSS users

*Takuya Tsugawa[1], Kornyanat Hozumi[1], Punyawi Jamjareegulgarn[2], Supnithi Pornchai [2], Susumu Saito[3], Yuichi Otsuka[3,4], Shinichi Hama[1], Takahiro Naoi[1], Mamoru Ishii[1] (1.NICT, 2.KMITL, 3.ENRI, 4.Nagoya Univ.)

11:20 AM - 11:35 AM JST | 2:20 AM - 2:35 AM UTC

[MTT46-08] QZSS geostationary satellite for ionospheric TEC observations

*Kosuke Heki[1] (1.Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University)

11:35 AM - 11:50 AM JST | 2:35 AM - 2:50 AM UTC

[MTT46-09] Precise estimation of total electron content by double-shell model using local receiver network

*Takashi Maruyama[1,2], Kornyanat Hozumi[1], Guanyi Ma[2], Qingtao Wan[2] (1.National Institute of Information and Communications Technology, 2.National Astronomical Observatories, Chinese Academy of Sciences)

11:50 AM - 12:05 PM JST | 2:50 AM - 3:05 AM UTC

[MTT46-10] Investigation of sea surface height detection by Global Navigation Satellite System Reflectometry (GNSS-R)

*Osamu Isoguchi[1], Kaoru Ichikawa[2], Yukihito Kitazawa[3] (1.RESTEC, 2.Kyushu Univ., 3.ISAS/JAXA)

12:05 PM - 12:15 PM JST | 3:05 AM - 3:15 AM UTC

[MTT46-11] Discussion

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-TT Technology & Techniques

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[M-TT46] New phase of GPS/GNSS application as an integrated earth observation system

convener:Yoshinori Shoji(The Second Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute), Kaoru Ichikawa(Research Institute for Applied Mechanics, Kyushu University), Yusaku Ohta(Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University), Takuya Tsugawa(National Institute of Information and Communications Technology)

[MTT46-P01] Continuous acoustic ranging from a GNSS buoy for the new method of seafloor crustal deformation measurements

*Keiichi Tadokoro[1], Natsuki Kinugasa[1], Teruyuki Kato[2], Yukihiro Terada[3], Akira Futamura[4], Kenjiro Matsuhiro[1] (1.Research Center for Seismology, Volcanology and Earthquake and Volcano Research Center, Nagoya University, 2.Hot Springs Research Institute of Kanagawa Prefecture, 3.Kochi National College of Technology, 4.National Institute of Technology, Yuge College)

[MTT46-P02] Accuracy and precision assessment of the real-time kinematic GNSS time series for moored buoy using three-axis programable moving table

*Yusaku Ohta[1], Misae Imano[1], Motoyuki Kido[2] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 2.IRIDeS, Tohoku University)

[MTT46-P03] GNSS-R altimetry using a Geostationary Satellite

*Kaoru Ichikawa[1], Tatsuki Okumura[2], Masanori Konda[3], Yasuyuki Baba[4] (1.Res. Inst. Appl. Mech., Kyushu Univ., 2.Dept. ESST, Interdicipl. Grad. School Eng. Sc., Kyushu Univ., 3.Graduate School of Science, Kyoto Univ., 4.Disaster Prevention Res. Inst., Kyoto Univ.)

[MTT46-P04] Estimation of typhoon wind speed using CYGNSS observations: A case study of Typhoon Lan in 2017

*Kako Shinichiro[1], Hiroyuki Tomita[2], Kaoru Ichikawa[3] (1.Graduate School of Science and Engineering, Kagoshima University, 2.Institute for Space-Earth Environment, Nagoya University, 3.Research institute for Applied Mechanics, Kyushu University)

[MTT46-P05] Ionospheric and seismic effects caused by the North Korea nuclear tests realized on 2006-2017

Nataliia Perevalova[2], *Nikolai Shestakov[1], Anna Dobrynina[3,4], Dmitry Kostylev[7], Meng Guojie[5], Wei-Wei Wu[5,6] (1.Institute for Applied Mathematics FEB RAS, Vladivostok, Russia; Far Eastern Federal University, Vladivostok, Russia, 2.Institute of Solar-Terrestrial Physics SB RAS, Irkutsk, Russia, 3.Institute of the Earth's Crust SB RAS, Irkutsk, Russia , 4.Geological institute SB RAS, Ulan-Ude, Russia , 5.Institute of Earthquake Forecasting, China Earthquake Administration, Beijing, China, 6.College of Surveying and Geo-informatics, Tongji University, Shanghai, China, 7.Sakhalin Branch of Federal Research Center Geophysical Survey RAS, Yuzhno_Sakhalinsk, Russia)

[MTT46-P06] Relationships between Water Vapor Concentration Index derived from GNSS and Surface Wind Convergence during Localized Heavy Rainfall in Tokyo in Summer

*Yoshihito Seto[1], Yoshinori Shoji[2], Nobumitsu Tsunematsu[3], Hideo Takahashi[1] (1.Department of Geography, Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University, 2.Meteorological Research Institute, 3.Tokyo Metropolitan Research Institute for Environmental Protection)

[MTT46-P07] Development of novel ground-based microwave radiometer for earth science -preliminary report-

*Ryuichi Ichikawa[1], Hideki Ujihara[1], Shinsuke Satoh[1], Jun Amagai[1], Yusaku Ohta[2], Basara Miyahara[3], Hiroshi Munekane[3], Taketo Nagasaki[4], Osamu Tajima[5], Kentaro Araki[6], Takuya Tajiri[6], Hiroshi Takiguchi[7], Takeshi Matsushima[8], Nobuo Matsushima[9], Tatsuya Momotani[10], Kenji Utsunomiya[10] (1.National Institute of Information and Communications Technology, 2.Tohoku University, 3.Geospatial Information Authority of Japan, 4.High Energy Accelerator Research Organization, 5.Kyoto University, 6.Meteorological Research Institute, JMA, 7.Japan Aerospace eXploration Agency, 8.Kyushu University, 9.National Institute of Advanced Industrial Science and Technology, 10.Japan Weather Association)

[MTT46-P08] Refractivity Distributions over the Kanto Plain Obtained by Dual-polarization Radar

*Hiromu Seko[1], Eiichi Sato[1], Hiroshi Yamauchi[2] (1.Meteorological Research Institute, 2.Japan Meteorological Agency)

[MTT46-P09] Spatial and temporal distribution of tropospheric water vapor observed by a Raman lidar and a GNSS receiver network over Shigaraki, Japan

*Masanori Yabuki[1], Toshitaka Tsuda[1], Yuya Kawano[2], Yusaku Tottori[2], Makoto Tsukamoto[2], Eiji Takeuchi[2] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.EKO Instruments Co., Ltd.)

[MTT46-P10] **Study of the Mechanisms of Severe Thunderstorm in Tokyo Metropolitan Area using High Frequent Assimilation of GNSS and Other Ground-based Observations**

*Yoshinori Shoji[1], Tetsu Sakai[2], Ahoro Adachi[1], Satoru Yoshida[2], Tomohiro Nagai[2] (1.The Second Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute, 2.The Third Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-TT Technology & Techniques

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_43

[M-TT46] New phase of GPS/GNSS application as an integrated earth observation system

convener:Yoshinori Shoji(The Second Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute), Kaoru Ichikawa(Research Institute for Applied Mechanics, Kyushu University), Yusaku Ohta(Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University), Takuya Tsugawa(National Institute of Information and Communications Technology)

[MTT46-P01] Continuous acoustic ranging from a GNSS buoy for the new method of seafloor crustal deformation measurements

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-TT Technology & Techniques

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 106 1F

[M-TT46] New phase of GPS/GNSS application as an integrated earth observation system

convener:Yoshinori Shoji(The Second Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute), Kaoru Ichikawa(Research Institute for Applied Mechanics, Kyushu University), Yusaku Ohta(Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University), Takuya Tsugawa(National Institute of Information and Communications Technology), Chairperson:Yoshinori Shoji(Meteorological Research Institute)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MTT46-12] Study on tropospheric delay variations extracted from a short baseline analysis and their application to meteorological observation

*Takayuki Yoshihara[1], Susumu Saito[1], Atsushi Kezuka[1], Shinji Saitoh[1] (1.Electronic Navigation Research Institute, National Institute of Maritime, Port and Aviation Technology)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MTT46-13] Water vapor estimation using digital terrestrial broadcasting waves
- Field test in Tokyo metropolitan area and trial production of small devices -

*Seiji Kawamura[1], Hiroshi HANADO[1], Hiroki Ohta[1], Yoshinobu Matsumura[2], Ryosuke Mori[2], Kazuyoshi Noda[2], Teruaki Hasegawa[2] (1.National Institute of Information and Communications Technology, 2.Socionext Inc.)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MTT46-14] Water vapor estimation via propagation delay of 920MHz wireless communication signal

*Nobuyasu Shiga[1], Satoshi Yasuda[1], Seiji Kawamura[1], Hiroshi HANADO[1], Ryuichi Ichikawa[1], Hironori Iwai[1], Shinsuke Satoh[1] (1.National Institute of Information and communications technology)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MTT46-15] Comparison of a water vapor observation with GPS and high sensitivity microwave radiometer, KUMODeS

*Taketo Nagasaki[1], Osamu Tajima[2], Ryuichi Ichikawa[3], Hiroshi Takiguchi[4], Kentaro Araki[5], Hiroshi Ishimoto[5] (1.High Energy Accelerator Research Organization, IPNS, 2.Kyoto University, 3.National Institute of Information and Communications Technology, 4.Japan Aerospace Exploration Agency, 5.Meteorological Research Institute)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MTT46-16] Development and Observation of Water Vapor Raman Lidars for Localized Torrential Rainfall Prediction

*Tomohiro Nagai[1], Tetsu Sakai[1], Satoru Yoshida[1], Toshiharu Izumi[2], Sho Yokota[1], Hiromu Seko[1], Yoshinori Shoji[1], Koichi Shiraishi[3] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Japan Meteorological Agency, 3.Fukuoka University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MTT46-17] Study of Water Vapor Monitoring in the Open Ocean using Kinematic Precise Point Positioning

*Yoshinori Shoji[1], Teruyuki Kato[2], Yukihiro Terada[3], Toshitaka Tsuda[4], Masanori Yabuki[4] (1.The Second Laboratory of Meteorological Satellite and Observation System Research Department, Meteorological Research Institute, 2.Hot Springs Research Institute/Kanagawa Prefectural Government, 3.Natinal Institute of Technology, Kochi College, 4.Research Institute for Sustainable Humanosphere/Kyoto Unversity)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-TT Technology & Techniques

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_11

[M-TT47] GEOSCIENTIFIC APPLICATIONS OF HIGH-DEFINITION TOPOGRAPHY AND GEOPHYSICAL DATA IN THE ANTHROPOCENE

convener:Yuichi S. Hayakawa(Faculty of Environmental Earth Science, Hokkaido University), Shigekazu Kusumoto(Graduate School of Science and Engineering for Research, University of Toyama), Christopher A Gomez(Kobe University Faculty of Maritime Sciences Volcanic Risk at Sea Research Group)

[MTT47-P01] High-definition topography monitoring after riverbed cultivation in the Echi River, central Japan

*Takuro Ogura[1,2], Satoshi Asano[3], Toshiaki Mizuno[3], Yoshihiro Azuma[3], Takeshi Kitai[4], Yuichi S Hayakawa[5,6], Kotaro Iizuka[6] (1.Graduate School of Frontier Sciences, The University of Tokyo, 2.Graduate School of Environmental Science, Hokkaido University, 3.Lake Biwa Environmental Research Institute , 4.Lake Biwa Museum, 5.Faculty of Environmental Earth Science, Hokkaido University, 6.Center for Spatial information Science, The University of Tokyo)

[MTT47-P02] **Spatial distribution of land surface displacements in the crater of Tateyama Midagahara Volcano using high-definition topographic data**

*Yuichi S. Hayakawa[1], Shigekazu Kusumoto[2], Takuro Ogura[3,4] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Graduate School of Science and Engineering for Research, University of Toyama, 3.Graduate School of Frontier Science, The University of Tokyo, 4.Graduate School of Environmental Science, Hokkaido University)

[MTT47-P03] Study on a simplified measurement of water depth and reconstruction of the riverbed form by using SfM and MVS.

*OSAWA KOTA[1], Tadafumi Niizato [2], Katsuaki Mitachi[3], Makoto Kawamura[1], Masahiro Ohkawa[1] (1.Mitsubishi Materials Techno corporation , 2.Japan Atomic Energy Agency, 3.ATOM TRANSPORT SERVICE CO., LTD)

[MTT47-P04] Ground Penetrating Radar Imaging of Moisture and Water movement in volcanic soil

*Christopher A Gomez[1] (1.Kobe University Faculty of Maritime Sciences Volcanic Risk at Sea Research Group)

[MTT47-P05] **Estimating Eruptive Volumes of Mud Volcano Southwestern Taiwan by Using UAV and SfM-MVS Photogrammetry**

*CHIA-YING LIU[1], Ray Y Chuang[1], Horng-Yue Chen[2] (1.Department of Geography, National Taiwan University, 2.Academia Sinica, Institute of Earth Sciences)

[MTT47-P06] Increasing temporal depth of urban Land-Use Regression Models by wind-data driven dynamic buffer generation

*Tilman Leo Hohenberger[1], King Wai Leung[1] (1.Division of Environment and Sustainability, Hong Kong University of Science and Technology)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-TT Technology & Techniques

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_44

[U-05] Large-scale Research Projects: Master Plan 2020 and its beyond

convener:Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Shigeko Haruyama(Department of Environmental Science, Graduate School of Bioresouces,Mie University), Ryoichi Fujii(Research Organization of Information and Systems), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Chairperson:Eiichi Tajika, Shigeko Haruyama

Many of top sciences in Earth and Planetary Science (EPS) are progressed by big projects that require 10 billion JPY or more in 10 years or so. In order to realize such projects, we need an arena where they are brushed up through critical reviews among various fields in EPS. Deeper mutual understandings through serious discussions there will enable us to reach a final consensus on the priorities of the projects. The Master Plan (MP) of Large-scale Research issued by the Science Council of Japan strongly motivates us to follow the process described above. Indeed some of the selected projects have been funded by the Ministry of Education, Culture, Sports, Science & Technology since 2010.
Since the current Master Plan 2017 is going to be thoroughly revised in 2020, we propose to hold a session in which large-scale research projects are concisely introduced and critically reviewed. This session is to be convened by JpGU and EPS Committee of Science Council of Japan.

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

International Astro-Bioscience Research Center

*Yukio Isozaki[1]

1. Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo

“Large Scientific Research Projects” under national strategic perspectives naturally comprise multidisciplinary efforts of Japanese scientists, by aggregating cutting-edge technology and knowledge to tackle research issues that had yet to be explored by anyone and bringing about dramatic development of those fields. Such projects will continue to necessiate strategic, systematic promotion through a long-term outlook, while garnering the support and understanding of the general public and society overall. As to the earth and planetary sciences in Japan during the late 20th and early 21st centuries, most researches focused on individual fields, such as studies on atmosphere, ocean, surface environment, solid earth (plate, plume, geomagnetism etc.). Nonetheless, in the views from abroad, most of efforts appear to have been concentrated in transplanting ideas and technology from western communities without nurturing domestic original ones. Under the limited financial budget of Japan, there is one hopeful possibility in earth science, which enables multispheric system studies involving core, mantle, surface crust, biosphere, and outer space. The most advantageous estate in Japan is the “earth history samples” collected from various countries during the last 30 years bu Japanese earth scientists. As there is non-such analogue in the rest of the world, we should build a new project centered by a research center “Astro-Bioscience”, which promote intimate network with many countries centered in Japan in order to reveal the entire history of the Earth and life. This project is directly linked to the sustainability of our planet, to which all humans on the Earth are facing today.

International Center for Space Weather Science and Education, Kyushu University, 5. Research Organization of Information and Systems

Energy from the sun is divided into radiation and solar wind (high-speed particles), which are maximum at the equatorial and polar regions, respectively. We study the flow of the energy and materials in the whole atmosphere by establishing following two large atmospheric radars at these singular points, and global observation network.
(1) Equatorial fountain
The energy and material flows that occur in all height regions of the equatorial atmosphere are named as "Equatorial Fountain." These processes from the bottom also cause various effects in the upper atmosphere. We establish Equatorial MU Rdar (EMU radar) in Indonesia as main instrument for the studies.
(2) Energy inputs into polar upper atmosphere and its response
The energy/particle inflow results in auroral Joule heating and ion drag of the atmosphere. The ion outflow from the polar ionosphere controls ambient plasma constituents in the magnetosphere. We will contribute the international EISCAT_3D radar project that has started in northern Scandinavia since 2017.
(3) Global network of observation and data
We develop a global observation network of compact radio and optical remote sensing equipment from the equator to polar region. Data from the observations will be archived and utilized by the data exchange framework of IUGONET.

This project was selected as one of important projects in both Masterplan 2014 and 2017. It was also selected as a new project in the roadmap 2014 by the Japanese Ministry of Education, Culture, Sports, Science and Technology. We continue proposing the project to Masterplan 2020.

Development of the global earth observation system using satellites

*Shinichi Sobue[1], Yoshiaki HONDA[3], Shuichi Rokugawa[2], Akira Iwasaki[2], Nobuhiro Takahashi[4], Yukari Takayabu[2], Riko Oki[1], Toshiyoshi Kimura[1], Teruyuki Nakajima[1], Takeo Tadono[1], Kosuke Yamamoto[1]

1. Japan Aerospace Exploration Agency, 2. University of Tokyo, 3. Chiba University, 4. Nagoya University

Global efforts to solve social and scientific issues related to the earth environment are ongoing globally and it is critical to develop and operate a global earth observation system. Especially, as also shown in “Yume road map”, the satellite-based observation system is indispensable tool from present to future. However, the Earth Observation Satellite, which simultaneously realizes the two functions of both scientific and practical observation, such as the GCOM series and the TRMM / GPM series, is marked as the "advancement of other remote sensing and sensor technologies" and there is no long-term plan beyond 2020 in the chart of the space basic program.

"Advanced Earth Science Research Working Group (WG)", one of the working groups of Task Force Remote Sensing Subcommittee (TF; 23 academic societies + 2 organizations), we created the "Earth Observation Grand Design" which shows the strategies for realizing the proposals of the Science Council of the scientific community and various institutions concerning Earth Observation after the successful endorsement at the TF general assembly. The purpose of this “Earth Observation Grand Design” is aimed at proposing Earth observation mission towards the space related ministries and agencies’ with brining consensus of new earth observation satellites missions from the academic societies and organizations in TF.

In the Earth Observation Grand Design published in 2018, the following five missions are proposing through a simple selection / review process as a mission to be realized in the short term, in addition to the mission described in the chart of space basic plan.

A) Mission on elucidating global climate change / water circulation mechanism

B) Mission for forest biomass estimation

C) Mission to reduce short life air pollution

D) Mission concerning elucidation of cloud and rainfall process

E) Mission concerning monitoring and elucidation of global environmental change (global radiation enforcement force and ecosystem change affecting global warming)

Based on the consent of the TF Executive Committee in late 2018, as a first step to evolve the above selection process with revision of Earth Observation Grand Design, we called for new satellite earth observation missions from a wider field and selected those missions, including ongoing satellites series missions such as high resolution optical and SAR mission, GHGs missions and geostationary observation missions, while ensuring fairness and transparency. We will make a primary selection of the proposal and

©2019. Japan Geoscience Union. All Right Reserved.

will discuss further by JpGU 's special session coming. As a result, we will select additional missions as well as deepen consideration of promising proposals and establish a feedback process from experts toward realizing the mission.

By using those proposed missions, global climate change and water circulation mechanism will be studied to solve various social problems such as improvement of accuracy of global warming prediction, high accuracy of weather forecast, disaster, etc. These missions will also be expected to contribute to the achievement of Society 5.0 and UN / SDGs that compatibility of social tasks.

Promotion of Scientific Research on Climate and Earth System Sciences Using Aircrafts

*Makoto Koike[1,2]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2. The Meteorological Society of Japan

The aim of this proposal is to promote climate and earth system research in the area of atmospheric science, oceanography, glaciology, volcanology, and ecology by introducing a dedicated aircraft for Earth observations.

The Earth’s environment has been changing rapidly, particularly as manifested by global warming, and the changes are imposing large impacts on the fundamental structures of our lives, including socio-economic activities and supplies of water and food. It is critically important to fully understand the current status of the changes and to investigate the controlling processes, in order to predict future changes and protect human society and ecosystems from serious damage. At present, direct atmospheric observations by aircraft are lacking in important geographical regions; they are needed for understanding greenhouse gases, aerosol-cloud interactions, and the hydrologic cycle, including predictions of typhoons and torrential downpours. Japan lacks an aircraft dedicated to scientific measurements, so Japanese scientists have been obliged to charter commercial aircraft for their experiments. Therefore it has been difficult to plan and conduct systematic aircraft experiments, which are indispensable for studies of climate and Earth system science.

In this study, we plan to acquire a dedicated aircraft and outfit it with an observation system that will be designed and utilized by scientists from a variety of fields and institutions on a long-term basis. Our aim is to enable the systematic planning of next-generation Earth observations and research activities by operating instrumented aircraft platforms on a long-term basis and attaining the highest levels of scientific outcome and impacts. We plan to provide today’s scientists and the next generation of scientists with exciting opportunities to use aircraft platforms to pursue new scientific ideas and to develop and use new technologies and methodologies. It is also planned to extend these new research opportunities to foreign scientists so that this Japanese system serves as a center of research and promotes Earth observations throughout Asia. The basic scientific knowledge obtained by this program will be made public in order to contribute to the welfare of world societies. All the processes involved in this research plan, including organizing scientists and activities, selection and scheduling of instruments, soliciting proposals, making field measurements, data archiving, and using the data, will be transparent to all scientific communities.

We plan to use the Gulfstream IV type aircraft as rental from a private company such as Diamond Air Service. The total cost is 15.5 billion Japanese yen for ten year project. The Institute for Space-Earth Environmental Research of Nagoya University has established the “Center for Orbital and Suborbital Observations” in order to play a central role in aircraft observations. This center will organize and manage activities related to aircraft observations in close cooperation with scientists from several institutions in Japan, such as the University of Tokyo, Chiba University, the Meteorological Research Institute, the National Institute for Environmental Studies, the National Institute of Polar Research, and the National Institute of Information and Communications Technology. We can receive advice and support aeronautical section of JAXA on determination of test plan and flight conditions in the flight test to realize more efficient and safety flight experiment. Through this study, we will contribute to SDSs and Future

Global deployment of Deep Argo floats toward accurate prediction of future climate and ecosystem changes

*Toshiyuki Hibiya[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Long-term assessment and conservation of marine bio-resources are crucial in securing the global food supply. Given the very rapid warming of global climate at present, however, marine environmental changes could be a very serious threat to human beings. Actually, acidification of surface seawater and decrease of dissolved oxygen in subsurface layers have been detected recently; if these trends are significant, an irreversible global/oceanic change in a longer time scale would be realistic. The deep oceanic circulation plays a key role in the marine environmental change. A recent numerical model suggests a global temperature change of more than 4°C and a decrease of marine biological production by 20% under a condition of weakened deep oceanic circulation. The actual feature and mechanism of the deep oceanic circulation are still largely unknown, and the comprehensive observation of deep sea would be also important in the assessment of oceanic ecosystem.

The Oceanographic Society of Japan submitted a research proposal in association with the 16 academic societies in theFisheries/Oceanography Research Liaison Counciland the Paleontological Society of Japan.The proposal aims to unveil the deep oceanic circulation, which is currently acting as the bottleneck in reproducingpast and future climate variability and global environmental changes in numerical models.More specifically, the proposal focuses on observation of turbulence in the deep sea with a turbulence sensor attached to the deep-sea Argo float (target depth more than 4000 meters) or "Deep NINJA". More than 10 floats of this type with conventional temperature and salinity sensors are in actual operation in the Southern Ocean. By deploying approximately 1000 floats, observation of temperature, salinity and turbulence will be conducted globally from the ocean surface to seafloor. The obtained data will be incorporated into a coupled atmosphere-ocean global climate model, and the simulation conducted using the leading Japanese supercomputer facility would yield an accurate reproduction and prediction of the past and future climate. Responses of biological community to the reproduced paleo-environmental changes can be validated by paleontological data such as microfossil record in sediment core, and the validation further refine the model prediction. A far more accurate prediction of future climate, marine biological production and marine bio-resources will be achieved through the proposed research project.

A new aspect of the polar science: integrated observations of the ice sheet mass loss for better prediction of the sea level rise

*Takuji Nakamura[1], Shin Sugiyama[2], Ayako Abe-Ouchi[3], Teruo Aoki[4], Yoshifumi Nogi[1], Takeshi Tamura[1]

1. National Institute of Polar Research, 2. Institute of Low Temperature Science, Hokkaido Univ., 3. Atmosphere and Ocean Research Institute, the University of Tokyo, 4. The Graduate School of Natural Science and Technology, Okayama University

Recently the global environmental change is of great interest for the governments and general public, as well as scientists on the earth and planets. The Arctic and the Antarctic regions significantly affect global environment and also provide invaluable information on its variation. In the Arctic region, for example, temperature increase due to the global warming is the largest on the globe. The climate change is most significantly emerging which causes change of ecology, human economic activity and life. On the other hand, very little is known on the response of the huge Antarctic ice sheet to the global warming, and hence a possible change in Antarctic region on a global scale and its prediction are of greatest interest. Variations in both polar regions are not independent but connected through the ocean and atmosphere circulations, and therefore it is necessary to consider them to be one unified system. Moreover, the Arctic and Antarctic regions are the best observation and/or investigation field for space/planetary sciences, atmospheric/hydrospheric sciences, and solid earth sciences, indicating that the polar regions are important windows for earth and planetary sciences.

Greenland Ice Sheet amounts about 9 % of total ice mass on the glove, and its mass loss is becoming faster due to the rapid warming in the Arctic region. This causes acceleration of the global sea level rise. On the other hand, the Antarctic Ice Sheet, which as about an order larger mass, also indicating a significant mass loss in the western part. Once the East Antarctic Ice Sheet also started to melt quickly, which has much larger mass than the West Antarctic Ice Sheet, the sea level rise would become fatal. Thus, it is very important to understand the current variation of the ice sheets, which could cause more than 60 m of sea level rise as a total amount, and monitor its trend.

This proposal focuses on the sea level rise due to the ice sheet mass loss. We propose to carry out integrated observations at remote sites in the Antarctica and Greenland, by deploying new technical challenge with un-manned and remote controlled system. Then, by unifying in-situ observations, detailed analyses, satellite observations and numerical modelings, we plan to clarity variations of the ice sheet and ocean in the past and at present, then improve the forecast of future sea level rise, which might rapidly proceed even within this century.

New frontier of Earth, Space and Life Sciences pioneered by the innovative developments of new-generation mass spectrometry

*Kentaro Terada[1]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University

So far, various mass spectrometers, which can determine elemental abundance, isotopic composition and molecular weight of macromolecule have greatly contributed to understanding of the Earth, Space and Life sciences. Above all, high-precision isotopic measurements of natural samples using sensitive mass spectrometers provide us an important clue to decipher the origin and evolution of the Earth and/or Solar system. Whereas, it is also known that many unresolved scientific issues are still remained because of technical restrains of “general-purpose” commercially-available mass spectrometers. Therefore, the “science-oriented” development of mass spectrometer has been highly desired.

Here, Osaka University, Geochemical Society Japan, and Mass Spectrometry Society of Japan collectively propose the ideas of an innovative development of mass spectrometers that are specialized for the “Scientific issues”, which consists of two directions; (1) high-sensitive and high-spacial resolution and/or (2) reduction in size and weight with high-mass resolution. These innovative development conducted by Osaka University would pioneer a new horizon of the Earth and Planetary Science such a decipher of the pre-solar history, on-site real–time geo-cosmo-chemistry so on. These technical innovation of mass spectrometers designed for the cruel Earth and space Science would also promote the other science such as agriculture, material science and life science, so on.

Building of archive and curating system for astrogeoscience materials

*Tsuyoshi Komiya[1]

1. Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo

We, Geological Society of Japan, propose “Building of archive and curating system for astrogeoscience materials” for Master Plan 2020.

Approximately 150 years passed after foundation of modern science in Japan. The Japanese researchers collected great amounts of terrestrial samples and meteorites, from over the world as well as Japan, using national and private funds during this period. Natural history is traditionally regarded as important in European countries and USA, but it is neglected more or less in Japan. As a result, Japan is far behind the European countries and USA as regards the preservation of the samples for future work, and curating system of the samples.

However, many paradigms were born from the well-organized sample archive such as Burgess Shale collection for the Cambrian Explosion and recent discovery of deep-sea economic deposit, and so on.

In addition, social responsibility of science is often emphasized in many European courtiers and USA: Open access of scientific journals, data and original samples, and guarantee of reliability of original data. However, Japan is also far behind other countries including China regards the open access.

We would like to propose building of archive and curating system for astrogeoscience materials for the future works and social responsibility.

This program is proposed by Geological society of Japan, and supported by AIST (Geological survey of Japan), National Institute of Polar Research, National Museum of Nature and Science, JAMSTEC, Kanagawa Prefectural museum of Natural History, and departments of Earth and Planetary sciences of 28 universities.

In 2017, we submitted a proposal for the Masterplan for Advancing Major Academic Research, entitled “Earthquake and volcanic eruption prediction science through integrated onland, seafloor and ocean drilling observations -Challenge of the spatio-temporal informatics in subduction zones- “, to the Science Council of Japan. Here, we integrate this plan with the ocean-buoy GNSS observatory project and high-pressure (down to the mantle) experiments project to create a high-precision, time-lapse imaging around the subduction zones, in order to delineate the earthquake and volcanic eruption scenarios and eventually to predict the far fate of the Earth and ocean. For this purpose, we propose to construct a real-time observatory network for earthquake and crustal deformation monitoring through seafloor cables and GNSS buoys. We also propose to obtain (and try to reproduce) the state and property around the subduction zones and in the mantle, by means of ultra-deep drilling and ultra-high pressure experiments. We are extremely interested in the mantle rheology, which is primarily controlled by the thermal structure and the abundance in volatiles (e.g. water), which we believe is only possible by integration of geophysical observation and by ground-truthing, insitu experiments.

Construction of the Cooperative Research Infrastructure for Intelligent Muography in Earth and Planetary Sciences, Other Sciences, and Society

*Hiroyuki Tanaka[1]

1. Earthquake Research Institute, the University of Tokyo

Since 10 years ago when Japan first used muography to visualise the internal structure of volcanoes for the first time (with elementary particle originated in the universe), this technique has been evolving. In 2019, at least 7 ventures were generated in Canada, Finland, France, Israel, Spain, UK, and USA. Japan still holds the technological initiative in this field, and based on this advantageous position, we will construct the cooperative research infrastructure for intelligent muography in earth and planetary sciences, other sciences, and society by adding the artificial intelligent function.

[U-05] Large-scale Research Projects: Master Plan 2020 and its beyond

convener:Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Shigeko Haruyama(Department of Environmental Science, Graduate School of Bioresouces,Mie University), Ryoichi Fujii(Research Organization of Information and Systems), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Chairperson:Eiichi Tajika, Shigeko Haruyama

Many of top sciences in Earth and Planetary Science (EPS) are progressed by big projects that require 10 billion JPY or more in 10 years or so. In order to realize such projects, we need an arena where they are brushed up through critical reviews among various fields in EPS. Deeper mutual understandings through serious discussions there will enable us to reach a final consensus on the priorities of the projects. The Master Plan (MP) of Large-scale Research issued by the Science Council of Japan strongly motivates us to follow the process described above. Indeed some of the selected projects have been funded by the Ministry of Education, Culture, Sports, Science & Technology since 2010.
Since the current Master Plan 2017 is going to be thoroughly revised in 2020, we propose to hold a session in which large-scale research projects are concisely introduced and critically reviewed. This session is to be convened by JpGU and EPS Committee of Science Council of Japan.

3:30 PM - 3:53 PM JST | 6:30 AM - 6:53 AM UTC

Discussion

Consortium for Planetary Exploration

*Yoshi-Yuki Hayashi[1], Shigeto Watanabe[2,5], Taishi Nakamoto[3,4]

1. Department of Planetology/CPS, Graduate School of Science, Kobe University, 2. SGEPSS, 3. The Japanese Society for Planetary Sciences, 4. Dept. of Earth and Planetary Sciences, Tokyo Institute of Technology, 5. Hokkaido Information University

Consortium for Planetary Exploration is planed to establish a set of distributed infrastructures in the fields of solar system sciences in Japan to plan, promote, and realize Japanese solar system exploration missions by supporting, cooperating and/or leading the mission implementing agency, JAXA, from the viewpoint of sciences, and also promoting international corporations among other organizations in the world, and help the science community maximize scientific outcomes from those missions. The consortium is to fulfill the lack of scientific leaders of such fields as data reduction, simulation modeling, instrument development, material analyses who have good experience and expertise both of the solar system sciences and the mission planning and driving, and also fundamental environments for research and development. More importantly, the focus of the consortium plan is not only to improve the number of researchers and the fundamental environments, but to cultivate graduate students and young scientist to be working on those places. The requirement for the consortium will be briefly summarized in the presentation.

Japanese contribution to CAESAR: comet astrobiology exploration sample return

*Tomoki Nakamura[1], Kazuhiko Yamada[2], Yoshihiro Furukawa[1], Yuki Kimura[3], Aki Takigawa[4], Tomohiro Usui[2], Hitoshi Kuninaka[2], Team CAESAR SRC team

1. Tohoku University, 2. ISAS/JAXA, 3. Hokkaido University, 4. Kyoto University

Comet is the most ideal target for Japanese planetary scientists who investigate the origin of the solar systems, particularly the origin of habitable planets. However, the mission scale of the comet sample return exceeds the Japanese space mission capability. Thus, the involvements to an international mission is more realistic strategy to share the science values of cometary sample return. A NASA NEW Frontier 4 cometary sample return proposal team requested JAXA to participate in the proposal, providing key devices and knowledge which have acquired in previous successful missions. This Master Plan proposal explains the science and engineering contributions to the NEW Frontier 4 proposal from Japan so far and in the future and how this mission provides valuable opportunities to the Japanese planetary science community.

Comets contain minerals, volatiles, and organic compounds that formed before the formation of the solar system. Thus, the cometary sample is a key material to access the origin of our solar system and the origin of life’s building blocks in space. Comet astrobiology exploration sample return (CAESAR) is the first mission to bring the macro cometary materials to the Earth without significant alteration. Japanese planetary science community have a strategy to promote the missions which investigate the formation of habitable planetary environments and its continuation. The target of CAESAR fits the strategy and particularly, investigates the materials which formed our planetary system and the origin of prebiotic organic compounds. This mission is one of the two finalist of NASA New Frontier 4 mission that has been selected from 12 proposals. JAXA is a major partner in the CAESAR mission, developing a sample return capsule based on the heritage of Hayabusa mission. Japanese sciences have also involved in the proposal planning and will be responsible for several sample analysis. The sample return of CAESAR is the most challenging among of the history of human’s sample return mission, trying to get the most abundant sample form the most far objects with the lowest temperature. This provides significant science values and also provides significant engineering heritage for Japanese communities

The early evolution of solar system stars from the conversion of interplanetary dusts into planetary materials. Hayabusa and Hayabusa 2 have strategy to investigate materials formed in the inner region of the solar system. CAESAR have complementary strategy to investigate the samples form outer region of the solar system in which material before the formation of the solar system present abundantly than inner solar system. In the astrobiological motivation, CAESAR has complementary strategy to Hayabusa 2 mission. CAESAR investigates cometary organics which have been provided mostly with micrometeorites to the Earth whereas Hayabusa 2 investigates organic compounds which have been provided mostly with meteorites. These achievements will contribute significantly to understand the origin of solar system and the origin of prebiotic organic compounds on the Earth.

CAESAR-JAPAN is working as a preproject (Phase A), developing components of sample return capsule and revising the proposal. The final selection for NASA New Frontier 4 will be open this summer. After the first step analysis, the CAESAR sample will be distributed to international science community including Japan. This will contribute significantly in planetary science, astrobiology, astronomy, and related

Strategic Mars exploration: Orbiter and EDL demonstration mission for space weather, climate, and aquatic environment

*Kanako Seki[1], Shigeto Watanabe[2], Taishi Nakamoto[3], Naoki Terada[4], Atsushi Yamazaki[5], Ayako Matsuoka[5], Tomohiro Usui[5], Yasuhito Sekine[3], Kazuhisa Fujita[5], Shoichiro Yokota[6], Satoshi Kasahara[1], Yoshifumi Saito[5], Hiromu Nakagawa[4], Atsushi Kumamoto[4], Hiroyuki Maezawa[7], Mars Orbiter and EDL Technology Demonstration Mission Planning Team

1. Graduate School of Science, University of Tokyo, 2. Department of Cosmosciences, Hokkaido University, 3. Tokyo Institute of Technology, 4. Graduate School of Science, Tohoku University, 5. ISAS, JAXA, 6. Graduate School of Science, Osaka University, 7. Department of Physical Science, Osaka Prefecture University

This presentation will report on outline of the strategic Mars exploration with an orbiter and EDL technology demonstration to investigate the space weather, climate, and aqua-environment at Mars, which is to be submitted to the Master Plan 2020 of the Science Council of Japan. The research project was previously proposed from Society of Geomagnetism and Earth, Planetary and Space Sciences (SGEPSS) as “Exploration of the space weather and climate at Mars,” which is listed in the Master Plan 2017 of the Science Council of Japan as the large scientific research project number 79, category number 24-2. The project has been developed since then through discussions over larger related academic communities including the planetary science. Here we propose the renewed project as a joint proposal between SGEPSS and the Japanese Society for Planetary Sciences.
In the roadmap of the solar system exploration in coming 20 years, understanding of the formation and evolution of the habitable environment is regarded as an essential goal of the planetary science. Among various targets, Mars is an idealtarget for comparative planetology and astrobiological researches, since it once had a habitable environment with an abundant water on its surface. Mars sample return mission with international collaborations is under planning for the 2030’s. In order for Japan to play a leading role there,implementation of our original strategic Mars exploration missions in 2020’s is under vital demands from both the scientific and technological points of view.
As an important step in the Japanese strategic Mars exploration to strengthen our ability to contribute the future Martian exploration scenario by ISECG (international space exploration coordination group), this project combines the orbiter and EDL (entry, descending, and landing) technology demonstration, focusing on the responses of Martian environment to extreme solar variations and its co-evolution with subsurface aquatic environment.The mission will elucidate influence of the active sun on the habitable environment and provide the basis for our future landing exploration in 2030’s. In particular, by investigating the instantaneous response to extreme solar variations, which can be usual conditions in ancient sun, we will obtain the key knowledge to understand how atmospheric escape to space contributes to the loss of habitable environment from ancient Mars. The project will also provide knowledge about Martian radiation environment and will achieve demonstration of key technologies for the future landing exploration as well as important information of possible landing sites.In order to achieve the goal, we identified three observational requirements and 11 model payloads for the mission. In the presentation, details of these items will be also introduced.

The previous version of reply document for the Request For Information (RFI) on "the purpose, strategy, and roadmap of each committee" released by ISAS was submitted on Feb. 2015, and then revised on Jan. 2018. The document has been revised again following the change in circumstances surrounding our community regarding solar and extra-solar system exploration. The revision has been conducted by recommended or self appointed members of the Japanese Society for Planetary Sciences. The new version of the reply document of the RFI will be published on the web site of the Japanese Society for Planetary Sciences after the request for public comments from the members of Japanese Society for Planetary Sciences.
The reply document contains the status of domestic and international planetary exploration programs, brief explanation on on-going and near-future missions, a list of instruments under development in Japan, and the roadmap of planetary explorations proposed by the Japanese Society for Planetary Sciences.
In this presentation we will present our roadmap of planetary explorations in coming 20 years.

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University), Chairperson:笠羽 康正, Kazuo Yoshioka(The University of Tokyo)

The giant planets provide many keys to understanding planetary processes. They play an important role in shaping our solar system, and the physical and chemical processes they harbor also provide a unique opportunity to study the phenomena relevant for studying Earth and other planets, including exoplanetary systems. In this session, we discuss a wide range of topics encompassing the giant planets and their moons, including their origins, interiors, atmospheres, compositions, surface features, and electromagnetic fields. To advocate for current and future outer planets exploration (Cassini, Juno, New Horizons, JUICE, and beyond), we also call for discussions on future missions to explore giant planet systems, including how to develop better international cooperation. Discussion in this latter category will include progress in developing a solar sail mission concept for observing the Jupiter system and its trojan asteroids.

Frontier Research Institute for Interdisciplinary Sciences, Tohoku University

The satellite Io, which has many volcanoes and is located at 5.9 R_J from the center of Jupiter, is a powerful plasma source in the magnetosphere. The resulting specificity of the Jupiter's magnetosphere is the magnitude of energy that circulates internally. Previous researches, using data obtained by Voyager and Cassini spacecraft and chemical models complementarily, showed that the pickup energy of heavy ions originating from volcanoes on Io and the energy of hot electrons are converted into radiation reaching ~3 TW. However, the origins of hot electrons, that is, heating and/or transport mechanisms are still unrevealed. Therefore, in this research, we focus on the response to the change in the amount of plasma supplied to the magnetosphere and explore the above problem. In this study, the radial distributions of plasma density and temperature were derived from the intensities of emission lines in the extreme ultraviolet range obtained by Hisaki satellite. In this presentation, we will show the results using data obtained from December 2014 to May 2015. The activation of volcanoes on Io in early January 2015 was confirmed by ground-based infrared observations.

Volcanic change of the distribution of Io's neutral oxygen cloud observed by Hisaki

*Ryoichi Koga[1], Fuminori Tsuchiya[1], Masato Kagitani[1], Takeshi Sakanoi[1], Tomoki Kimura[1], Ichiro Yoshikawa[2], Kazuo Yoshioka[2], Go Murakami[3], Atsushi Yamazaki[3], Howard Todd Smith[4], Fran Bagenal[5]

1. Tohoku University, 2. The University of Tokyo, 3. ISAS/JAXA, 4. Johns Hopkins University, 5. University of Colorado

Io has a thin atmosphere created by volcanism and sublimation from the surface frost. Io's atmospheric oxygen atoms are heated by atmospheric sputtering, and escape from Io's gravity, forming a neutral oxygen cloud around Io's orbit. The neutral cloud is important as a source of the Io plasma torus. Previous studies derived the distribution and density of the equilibrium neutral oxygen cloud, and showed changes in Io's volcanism can lead to increase densities of both neutral clouds and Io plasma torus. Koga et al (2018) showed the distribution of Io's neutral oxygen cloud from Hisaki observation data during a volcanically quiet period (November and December in 2014). The equilibrium neutral oxygen cloud consists of a dense region distributed around Io (the "banana cloud") and a longitudinally uniform, diffuse region distributed along Io's orbit. However, the evolution of the distribution of neutral clouds was not understood. In this study, we analyzed the Hisaki satellite observations of the spatial distribution of OI 130.4 nm emissions around Io's orbit during a volcanic event in 2015.
The radial distribution shows the oxygen cloud spread outward during the volcanically active period. The outer edge of the OI emission was 7 R_J (Jupiter radii) before the volcanic activity, but it spread to around 8-8.6 R_J during the volcanically active period. We also estimated the oxygen number density outward Io's orbit represented as $n(r)=n_0(r/r_0)^{\gamma}$, where r is radial distnace from Jupiter, r_0 is 5.9 R_J (orbit of Io), n_0 is a number density at 5.9 R_J, γ is a power law slope of the profile. The number density at Io's orbit (where north-south thickness is 1.2 R_J) increased to 88±9 cm^{-3} during the active period that is more than twice as large as the number density during the quiet period (40 cm^{-3}). The power law slope outward Io's orbit during the active period (γ=-5.5±1.3) is similar to that during the quiet period (γ=-5.3). The azimuthal distribution shows the neutral oxygen cloud during the active period also consists of the banana cloud and diffuse region distributed along Io's orbit, but both of the regions enlarge. The observation results show the main escape process of neutrals from Io's graivity remains atmospheric sputtering, but the escape rate of them significantly increased during a volcanically active period. One of the possible mechanisms to increase the escape rate is that the sublimation frost area increases and the density of sublimation driven atmosphere also increases. Another mechanism is that plumes increase the height of the exobase, and the area of atmospheric sputtering increases.

In 2013, we got an opportunity to have an extreme ultra-violet (EUV) space telescope orbiting around the Earth, the Hisaki satellite. The strong EUV emissions come from both magnetospheric plasma and aurora through electron impact excitation of ions and molecular hydrogen, respectively. From the spectral observation, we can obtain not only total amount of energy deposited in each region but characteristic energy of electrons. Hisaki is dedicated for observing solar system planets. The monitoring capability of HISAKI provided us discoveries of dynamical behavior of the giant magnetosphere. Here, we show new pictures of Jovian magnetosphere obtained from the Hisaki satellite observation. This paper includes following topics: (1) Origin of hot electron in the inner magnetosphere, (2) Transient brightening of Jovian aurora and subsequent global expansion of the disturbance in the whole magnetosphere, (3) Global response of the magnetosphere to volcanic activity of the satellite Io, (4) Solar wind effects on the inner and middle magnetospheres, (5) Driver of radial diffusion in the Jovian radiation belt, (6) Electromagnetic magnetosphere-satellite interaction, and (7) Identification of new emission lines and new energy states of ion.

The University of Tokyo

Ionospheric Hall and Pedersen conductivities are important parameters in determining the electric potential distribution and plasma convection in a magnetosphere-ionosphere system. At Jupiter, meteoric ions deposited by meteoroid ablation are expected to play a major role in the ionospheric conductivities [e.g., Cloutier et al., 1978]. Hall and Pedersen conductivities are expected to be axisymmetric at Jupiter due to the long lifetime of meteoric ions. This study evaluates the modification of the potential distribution and plasma convection in the inner magnetosphere caused by the axisymmetric ionospheric conductivities at Jupiter.

We have developed a photochemical model and an ionospheric potential solver to evaluate the contributions of meteoric ions to the Jovian ionospheric conductivities and dawn-to-dusk electric field in the inner magnetosphere. Our photochemical model includes chemical reactions taken from Kim et al. [1994, 2001], mass deposition of meteoric atoms and ions by meteoroid ablation, ionizations by precipitating electrons, and ambipolar diffusion of ions. The input parameters of field-aligned currents are taken from the Region 2-like current in Khurana [2001] and axisymmetric Hill current. Our ionospheric potential solver has been developed using the methods in Nakamizo et al. [2012]. We calculate the global distribution of ionospheric conductivities using ion and electron density profiles acquired from the photochemical model. The ionospheric potential distribution and the resulting dawn-to-dusk electric field in the inner magnetosphere are obtained by the ionospheric potential solver.

Our simulation results reveal that the largest contributions to the Hall and Pedersen conductivities occur in the meteoric ion layer, and the resulting height-integrated conductivities are axisymmetric in the middle- and low- latitudes. Meteoric ions dominate the ion densities in the altitude region of 350 - 450 km with a peak electron number density of ~10^{11} [m^{-3}]. The obtained electron density profile is almost constant at any local time in the middle- and low-latitudes because the lifetimes of H^+ in the high altitude and meteoric ions in the lower altitude ionosphere are sufficiently longer than the half Jovian day (~ 5h). The ionospheric conductivities reach their maxima at the meteoric ion layer, and the height-integrated Hall and Pedersen conductivities become axisymmetric in the middle- and low- latitudes. At high latitudes, the conductance are enhanced at dawn side associated with the Region 2-like upward field-aligned current. The dawn-to-dusk electric field generated in the inner magnetosphere is 4 - 27 [mV/m] around Io’ s orbit. For comparison, we model another case of ionosphere without H^+ and meteoric ions. In this case, the ionospheric conductance are entirely smaller than the former case, and diminished at night side. The resulting dawn-to-dusk electric field is 45 - 270 [mV/m] around Io’ s orbit in this case.

©2019. Japan Geoscience Union. All Right Reserved.

In order to evaluate the validity of our results, we compare our results to observations. Observations by the Hisaki satellite revealed that the variation of dawn-to-dusk brightness intensity ratio of Io plasma torus coincided with a rapid increase in the solar wind dynamic pressure. The correlation between them can be explained by the existence of a dawn-to-dusk electric field of ~4 - 9 [mV/m] around Io's orbit [Murakami et al., 2016]. Our model results are almost consistent with the Hisaki observations in the case of the existence of meteoric ions in the lower ionosphere. It is concluded that the existence of meteoric ions in the lower ionosphere causes the axisymmetric enhanced ionospheric conductance at Jupiter. The large axisymmetric conductance results in the small dawn-to-dusk electric field in the inner magnetosphere, and our model results can be supported by the Hisaki observations.

The magnetospheres of Saturn and Jupiter as viewed by Cassini and Juno

*G Provan[1], Stanley W. H. Cowley[1], Emma Jane Bunce[1]

1. University of Leicester

The magnetospheres of the gas giants Saturn and Jupiter are believed to be driven to varying degrees by external drivers, planetary rotation and internal plasma sources. Both planets are rapid rotators with active volcanic moons and complicated ring systems. Their auroras are key indicators to the magnetosphere-ionosphere coupling at the giant planets. At Saturn Planetary Period Oscillations (PPOs) are observed throughout the magnetosphere, including during Cassini’ s Grand Finale on field lines mapping to Saturn’ s rings. In this paper we will report on the latest results from the Cassini and Juno missions, including both the latest observations and theoretical modelling. We will elucidate on a series of studies determining properties of Saturn’ s PPOs throughout the Cassini mission, and compare our results with those derived from analysis of Saturn kilometric radiation emissions from the Voyager, Ulysses, and Cassini mission. We will further model the magnetosphere-ionosphere coupling current at Jupiter and compare these results with observations from the Juno spacecraft and HST observations. We will finish by detailing some of the outstanding questions in the field.

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder), Chairperson:Takeshi Horinouchi

Akatsuki, being in Venus orbit since December 2015, has acquired a volume of high-quality data, unveiled many new phenomena and is allowing researchers to investigate the underlying mechanisms. As the data accumulate, numerical models and theories are being advanced as well. We are no doubt living in the new golden era of Venus studies. This session invites papers of the new scientific results with Akatsuki data and the latest results of theoretical and numerical works. We expect participants of this session share the latest research results through presentations and discussion.

Super-rotation of Venusian atmosphere in the equatorial region may be caused by the density driven separation

*Adhithiyan Neduncheran[1], Ugur Guven[1,2], Ananyo Bhattacharya[3]

1. University of Petroleum and Energy Studies, India, 2. United Nations Centre for Space Science and Technology Education in Asia and the Pacific, 3. Sardar Vallabhbhai National Institute of Technology,India

On Venus, the clouds move nearly 60 times faster than the rotation of the planet. Super-rotation of the Venusian atmosphere is an intriguing phenomena and the reasons are still unclear. The super-rotation is possibly due to Venus being tidally locked to Sun as a consequence of which the planet experiences maximum heating in the equatorial zones causing meridional flows in the lower latitudes. The latent heat trapped by the Carbon dioxide gradually rises above due to its increased kinetic energy, which increases the motion of the cloud layers over time. Previous works done shows that the clouds are highly unstable in the altitude ranging from 49-55Km and below 30Km as per *Zasova et al* 2006 (doi:10.1016/j.pss.2007.01.011). This work shall put forth a possibility of density driven separation of cloud layers and its viscosity which helps in the super-rotation of the clouds. Similar hypothesis were presented by *Lebonnois et al* 2017 (DOI: 10.1038/NGEO2971). Using the known densities of atmospheric constituents, and applying the principles of viscosity and fluid dynamics, a simulation in COMSOL Multiphysics is done and analyzed for the flow behavior in the atmospheric layers ranging between 20Km and 80Km with respect to it’ s horizontal distance. The possible reasons regarding the flow will be discussed considering the solar convection in the equatorial region.

Venus is the nearest neighbor planet, which has a size similar to that of the earth. However, unlike the earth, Venus is covered with thick - clouds floating at 45-70 km altitudes (Nakamura et al. 2011). It is considered that the clouds are photochemically generated by oxidation of and . In the visible region, light reflected by the clouds are poorly absorbed and few structures are noticeable. On the other hand, in the ultraviolet (UV) region, inhomogeneity of albedo has been identified to be inhomogeneous distribution of UV absorbers above the layer of UV scattering. It has been identified that in the Venusian atmosphere absorbs light in the wavelength region between 200 nm and 320 nm, but chemical species responsible for the absorption in the wavelength region longer than 320 nm is still unidentified. and are candidates (Perez et al. 2018). The UV absorbers play an important role in the atmospheric dynamics, controlling vertical thermal stability by heating at the top of convection layer. The dynamics may feedback the distribution of the UV absorbers by transport of them from the lower atmosphere. Details of the chemical and dynamical coupling are still unknown.

We analyzed images obtained by the Longwave Infrared Camera (LIR) and Ultraviolet Imager (UVI) onboard the Venus orbiter Akatsuki. LIR takes images of thermal radiation in the wavelength range of 8-12 μm emitted from the cloud-tops (Fukuhara et al., 2011). Temperature distributions are derived from the images. Disturbances seen in the temperature distributions are thought to be caused by atmospheric waves and tides, changes in the cloud-top altitude and adiabatic heating and cooling due to convection, direct heating by the UV absorbers, and so on. UVI takes images of the solar radiation reflected by the clouds with narrow bandpass filters centered at the 283 and 365 nm wavelengths, which correspond to the absorption bands of and unknown absorbers (Yamazaki et al., 2018).

Observations at 365 nm often find clouds with a little radiation in the middle latitudes. Such clouds with low radiation (bright) are covering on the clouds with high radiation (dark). The bright clouds are hard to receive the supply of UV absorbers from the lower layer (Titov et al., 2008). We found such bright distributions in the middle latitudes of images taken by LIR and UVI. Examples (on January 26, 2017) are shown in figures. The fact that we can see the similar distributions at different wavelengths means that two cameras observe clouds almost the same altitude. Therefore, we are studying of the dynamics of cloud top distributions at middle latitudes to use data taken by LIR and UVI.

We converted the UV radiation obtained into the absorption rate. Furthermore, we compared by combining the absorption rate and the temperature. The combined image is displayed more reddish when the temperature is higher and it is displayed more blueish when UV absorption rate is higher. Example are shown in figures. The figure is displayed blackish in the equatorial region and whitish in the polar region. In the middle latitudes where we pay attention, the temperature is high and the amount of absorption is small, so it is displayed reddish. In this presentation, we will introduce some examples like this, and will present relationships between temperature and , temperature and unknown absorbers.

As a next step, we will further study the relationship between temperature and UV absorbers for each

latitude and local time, and will clarify what atmospheric dynamics is occurring at the cloud top.

Orographic Gravity Waves in the Venus Atmospheric

Fast zonal winds called “super-rotation” are predominant globally in the Venus atmosphere, whose wind speed reaches ~100 m/s at ~70 km level (Schubert et al., 1980). Based on the zonal winds inferred from UV cloud images taken by the Venus Monitoring Camera onboard the Venus Express orbiter, Bertaux et al. (2016) pointed out that the zonal wind at ~70 km might be decreased by about 20 m/s over the Aphrodite terra, and suggested that the gravity waves generated by the Venus topography propagate upward, breaking at the cloud levels, giving their momentum to the atmosphere and decreasing of zonal wind. Young et al. (1987, 1994) numerically investigated the excitation and propagation processes of the gravity waves. Their results show that the gravity waves with horizontal wavelengths of 50 –800 km can propagate to the cloud levels if the zonal wind near the surface is of 2.2–3.0 m/s. However, the momentum transfer by the gravity waves is not examined. In the present study, we investigate the gravity waves in the Venus atmosphere with a focus on their momentum transfer using a cloud resolving numerical model named Cloud Resolving Storm Simulator (CReSS). Our preliminary results suggest that the orographic gravity waves can propagate upward and reach the cloud levels, as shown by Young et al. (1987, 1994). We will examine the momentum transfer by the gravity waves and discuss its effect on the super-rotation.

Atmospheric structures simulated by T21 and T63 Venus GCMs with radiative transfer

*Masaru Yamamoto[1], Kohei Ikeda[2], Masaaki Takahashi[2]

1. Research Institute for Applied Mechanics, Kyushu University, 2. National Institute for Environmental Studies

Radiative forcing and topography are important in the formations of the thermal and wind structures on Venus. The surface topography forces stationary waves, which induce large-scale stationary bow-shaped wave pattern (Fukuhara et al. 2017) and conspicuous variation of cloud-top zonal flow (Bertaux et al. 2016) over the Aphrodite Terra. The topographical and radiative effects on Venus' atmosphere general circulation have been investigated using a T21L52 Venus AGCM at Atmosphere and Ocean Research Institute, Univ. Tokyo (Ikeda 2011). Our Venus GCM with the topographical data and radiative code simulated solar-locked and geographical atmospheric structures on Venus (Yamamoto et al. 2019). The model reproduced the wind structure near the subsolar point and the slowness of zonal wind over the Aphrodite Terra. Furthermore it showed that (1) the sub-rotation is formed near the surface in and around high land and mountains, (2) weakly stable layer is formed at 10-20 km at low latitudes, and (3) the zonal wind is weakened at the cloud top over the Aphrodite Terra. The third result implies that the negative wind deviation of the topographically forced stationary wave produces the slowness of the cloud-top zonal wind around the Aphrodite Terra. The GCM with the radiative code estimated the heat budget in the lower and middle atmospheres and reproduced the static stability similar to the observation. For the simulated zonal-mean structure, an equatorial fast flow of ~90 m/s and mid-latitude jets of ~120 m/s are formed around the cloud top. A poleward flow of >8 m/s is formed above the cloud layer, where the imbalance between solar and infrared radiative heating is large. Around the cloud top where the solar radiative heating balances the infrared one, a poleward flow is small (~1 m/s) and confined within the equatorward flank of the jet core. In and around the jet core, indirect circulations are formed by the eddy heat fluxes owing to the thermal tide and baroclinic waves. In solar-fixed coordinates, differences are significant between the zonal and dayside averages of the meridional wind and its related fluxes within the cloud layer. This suggests that we must carefully estimate the zonal-mean Hadley circulation, eddy momentum flux, and eddy heat flux from the one-side hemisphere. Most of the abovementioned features obtained from the T21 GCM are also seen in the T63 GCM. In this presentation, under the realistic thermal and topographical condition, the effects of the high resolution are also discussed. If we have room or time in this presentation, we briefly show the momentum budget, together with the heat budget shown in Yamamoto et al. (2019).

Thermal-tides structure at the cloud level of Venus derived from Akatsuki/LIR observations

*Toru Kouyama[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Takeshi Imamura[3], Masahiko Futaguchi[4], Takeru Yamada[2], Masahiro Akiba[2], Yeon Joo lee, Takao M. Sato[7], Shin-ya Murakami[5], George HASHIMOTO[6], Takehiko Satoh[5], Masato Nakamura[5]

1. AIST, 2. Rikkyo Univ., 3. Tokyo Univ., 4. Toho Univ., 5. JAXA, 6. Okayama Univ., 7. Hokkaido Information Univ.

Atmospheric acceleration due to thermal-tides excited in the cloud layer has been considered as one of main contributors for maintaining the atmospheric super-rotation in Venus, where zonal wind speed of the atmosphere at the cloud top (~70 km) rotates more than 60 times faster than the rotation speed of the solid body of Venus. The structures of the thermal-tides have been confirmed firstly in a temperature field and in zonal and meridional wind fields at the cloud top level by tracking cloud motions in several Venus exploration missions. In numerical studies, it has been confirmed that the thermal-tides structure is composed of diurnal, semi-diurnal, and higher frequent components which enhance at different altitudes and latitudes. Since they may contribute atmospheric acceleration according to their enhancement, observational monitoring should be important to understand what components of thermal-tides are dominant in different latitudes. On the other hand, there have been less observational studies about the latitudinal structures of thermal-tides in temperature fields due to time limitation for ground-based observations and limitation of spatial coverage for previous satellite observations.

In this study, we investigated latitudinal profiles of diurnal, semi-diurnal, and higher frequent components of thermal-tides in the temperature field obtained from long-term observation data by Longwave Infrared Camera (LIR) onboard Akatsuki that catches thermal emission from Venusian cloud layer (60-70km). We used the LIR data from October 2016 to December 2018 in which LIR had been remained to be turned on to prevent unexpected temperature increasing in LIR images, and we selected a specified emission angle (60˚) in the analysis to minimize emission angle dependence of a limb darkening effect.

Thanks to the global coverage of LIR observation in both dayside and night side, a global thermal-tides structure (local time-latitude coordinate) was firstly obtained by averaging the long-term LIR observation. By applying Fourier analysis to the thermal-tides structure, we found that the semi-diurnal component was clearly dominant in lower latitudes (< 30˚) whereas the diurnal component became significant in higher latitudes (> 45˚), and both diurnal and semi-diurnal tides showed almost equatorial symmetric profiles. These characteristics were consistent with a numerical expectation in a global circulation model by Takagi et al. (2018). In addition, the diurnal component showed clear phase tilting in mid-latitudes, which may indicate latitudinal energy transportation due to the diurnal component, while the semi-diurnal and other components with higher wavenumbers did not show such clear phase tilting in low-mid latitudes.

In this presentation, we will provide the structures of each thermal tide components, and latitudinal profiles of their amplitudes and phases, and we will also discuss thermal-tides structures at different

periods for more detail discussion about variability of the tides.

From Venus to Mars: viewpoint of comparative meteorology

*Takeshi Imamura[1], Kazunori Ogohara[2], Hiromu Nakagawa[3], Shohei Aoki[3]

1. The University of Tokyo, 2. University of Shiga Prefecture, 3. Tohoku University

The next Japanese planetary mission focusing on atmospheric science will be the Mars observation in the MMX (Martian Moons eXploration) mission. The spacecraft will enter a near-equatorial, high-altitude, circular orbit around Mars in 2025 and stay in orbit for 3 years. During this Mars-orbiting phase, the spacecraft will collect samples from Phobos and remotely observe Phobos, Deimos and Mars. Continuous, high-resolution, multi-wavelength, global observations of the Mars atmosphere enable monitoring of meteorological processes driving dust/water cycle in the atmosphere-surface system. The instruments used will be a near-infrared imaging spectrometer and multi-band cameras.

The Mars observation in MMX is considered a natural extension of the Venus orbiter Akatsuki. The observation sequence of MMX is similar to that of Akatsuki in that global images are acquired at short time intervals from an equatorial orbit similarly to Earth's meteorological satellites. From the viewpoint of comparative meteorology, Martian meteorology is contrasted with Venusian meteorology in many aspects. Examples include: superrotation on Venus vs. strong high-latitude jets on Mars; weak thermal forcing on Venus vs. strong thermal forcing on Mars; internal oscillation on Venus vs. seasonal cycle on Mars; wave-driven circulation on Venus vs. heat-driven circulation on Mars; slow convection on Venus vs. fast convection on Mars; uniform aerosols on Venus vs. variable aerosols on Mars; weak vertical coupling on Venus vs. strong vertical coupling on Mars. In order to maximize scientific achievements, feedbacks from Akatsuki to MMX are required.

Discussion

A two-stage evolution model of Venus’ s mantle and its implication for the Earth

*Masaki Ogawa[1]

1. Division of General Systems Studies, Graduate School of Arts and Sciences, University of Tokyo

There are two elementary processes that exert control over the evolution of the mantle in Venus and the Earth. The first is the magmatism-mantle upwelling (MMU) feedback: Suppose an upwelling flow in the solid mantle generates magma by decompression melting. The buoyancy of the magma boosts the upwelling flow itself. This positive feedback makes the magmatism and the upwelling flow vigorous. The second is mantle burst. The solid-solid phase transitions at the top of the lower mantle makes the convective flow across the phase boundaries pulsating, provided that the mantle is hot enough to cause an active magmatism. When coupled with the MMU feedback, this pulse of mantle upwelling flow causes an extensive magmatism in the upper mantle. Because of these two elementary processes, the mantle of Venus evolves in two stages. On the earlier stage when the mantle is strongly heated by radioactive elements, mantle bursts repeatedly occurs to episodically resurface Venus. As the radioactive elements decay, however, the mantle evolves into the later stage. Mantle bursts subside, and only a mild magmatism occurs at the top of the mantle to continuously resurface the planet. When a model of tectonic plates is added to this model of Venus, I obtained a two-stage evolution model of the Earth. On the earlier stage, mantle bursts repeatedly occur to make plate motion chaotic and the mantle compositionally rather homogeneous. On the later stage, in contrast, mantle bursts subside, and plate motion becomes more steady; ridge magmatism differentiates the mantle, and basaltic materials accumulate on the core-mantle boundary to form thermo-chemical piles similar to the Large Low Shear wave Velocity Provinces.

Interaction between the thermosphere and the cloud-level atmosphere of Venus studied with simultaneous observations by Hisaki and Akatsuki

*Yusuke Nara[1], Takeshi Imamura[1], Ichiro Yoshikawa[1], Kazuo Yoshioka[1], Kei Masunaga[2], Atsushi Yamazaki[3], Shigeto Watanabe[4], Manabu Yamada[5], Yeon Joo Lee[1], Naoki Terada[6], Kanako Seki[1]

1. The University of Tokyo, 2. Swedish Institute of Space Physics, 3. ISAS/JAXA, 4. Hokkaido Information University, 5. Chiba Institute of Technology, 6. Tohoku University

In the thermosphere of Venus, the flow directing from sub-solar to anti-solar (SS-AS) is dominant driven by large temperature gradient associated with a long Venusian solar day which is ~117 Earth days. According to a numerical study by Mayr et al. (1985), the SS-AS flow without drag would exceed 300 m s^{-1} at the maximum.
It is believed that the drag force generated by gravity waves breaking effectively decelerates the thermospheric wind speed. Zalcucha et al. (2013) developed a Venus Thermosphere General Circulation Model in the presence of the gravity wave-drag, which accelerates the atmosphere when the gravity waves are broken. The model showed the SS-AS flow speed of 100-200 m s^{-1}.
The periodical variation that indicates the atmospheric waves in the thermosphere was observed by Masunaga et al. (2017). They analyzed OI dayglow variation using data obtained by the Extreme Ultraviolet Spectroscope for Exospheric Dynamics (EXCEED) on-board the Hisaki spacecraft and detected the periodicity of ~4 days only on the dawn side. They pointed out planetary-scale waves in the middle atmosphere which are expected to be exist in Venus might responsible for the variations in the thermosphere, while the existence of the planetary-scale waves at that time was not confirmed.
In this study, we investigated the vertical coupling between cloud-level atmosphere and the thermosphere of Venus, focusing on the role of atmospheric waves. To find the evidence for the wave propagation, we used data that are obtained simultaneously by Hisaki and Akatsuki spacecraft on the dawn side of Venus in June 2017.
Analyzing the time series of the atomic O dayglow emissions measured by the EXCEED and the UV images which reflect the spatial distribution of unidentified absorbers at the cloud top (~70 km) obtained by the Ultraviolet Imager (UVI), we identified characteristic periodicities of 3.5 days in both data. The wind velocity deduced with cloud tracking from UV images suggests that the 3.5-day periodicity can be associated with Kelvin waves at the cloud top; however, Kelvin waves should decay with height through radiative damping and will not reach the thermosphere. We propose an indirect process in which the Kelvin waves change the wind field periodically and examine how the vertically propagating small-scale gravity waves influence the thermospheric dayglow with a simplified numerical model.

Mesoscale Dyanmics in the Venus Atmosphere

*Kevin McGouldrick[1], Javier Peralta[2], Takehiko Satoh[2]

1. University of Colorado Boulder, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The Akatsuki Spacecraft is capable of observing the full disk of Venus at a number of filter-specified wavelengths, with time cadence on the order of an hour, and for up to nine days at a time (until the orbit brings the spacecraft so close that Venus exceeds the instrumental fields of view). Because of this, it is capable of supporting the elucidiation of both global atmospheric dynamics (i.e., the super-rotation) and mesoscale atmospheric dynamics. Here, we describe the analysis of the driving dynamics associated with mesoscale features observed in the Akatsuki IR2 camera data. This work focuses on just a single orbit of Akatsuki, but the features and behaviors we describe appear to be common in the Venus atmosphere. We make comparisons with similar terrestrial phenomena; and assess the implications for energy and momentum transport that may affect the overall global atmospheric dynamics. Three of the four filters in Akatsuki's IR2 camera image the night side of the planet in emitted radiation. These filters have central wavelegnths of 1.74 micron, 2.26 micron, and 2.32 micron, which are most sensitive to the conditions between about 50 km and 60 km altitude, in the midst of the lower and middle, condensational, cloud deck of Venus.

1. Graduate School of Frontier Sciences, The University of Tokyo, 2. College of Science, Rikkyo University, 3. National Institute of Advanced Industrial Science and Technology

Planetary-scale waves are thought to play crucial roles in the maintenance of the general circulation of the Venusian atmosphere. However, observational clues are limited, and the nature of such waves is poorly constrained. Here we analyze for the first time the cloud-top temperature field to deduce the periods (frequency) and the spatial structures of planetary-scale waves using LIR image data acquired continuously. Since the systematic (absolute) error in LIR data of around 3 K is larger than the expected amplitudes of the temperature oscillations of around 1 K, the waves are hard to detect by deducing temperature variations with time. In this study, we analyze oscillations of the zonal gradient of the temperature in each image associated with planetary-scale waves. The small random (relative) error in LIR data of 0.3 K enables detection of such small-amplitude waves with this method. Through spectral analyses of the time series of the temperature gradient spanning 142 Earth days from 18 May 2017, distinct oscillations with periods of 3.5 days, 4.9 days and 5.2 days were discovered. All of these modes show almost constant phases along the latitude, indicating that they are planetary-scale waves. Based on the wave period and the latitude dependence of the amplitude, the 3.5-day wave is identified as a Kelvin wave and the 4.9-day and 5.2-day waves seem to be hemispherically-symmetric Rossby waves. The amplitudes of these waves changed with time during the observation period.

Using a modern three-dimensional general circulation coupled atmosphere/ocean model [1] we recently demonstrated [2] that climatic conditions may have permitted liquid water on Venus' surface for ~2 billion years in its early history. Similar such conditions on Earth are believed amenable to the rise of life. Several assumptions were made based on what little data we have for early Venus such as; the type of solar spectrum extant at that time, orbital parameters, estimates of a shallow ocean from Pioneer Venus D/H ratios, and topography from the Magellan Mission. We also assumed that it would have had an atmosphere similar to modern day Earth: 1 bar N2, 400ppmv CO2, 1ppmv CH4. I will discuss the motivations behind these assumptions and additional parameter space studies with direct relevance to hypothetical exoplanetary Venus-like worlds found at the inner edge of the liquid water habitable zone. Finally, I will show how our studies demonstrate that the reason for Venus' present climatic state is unlikely to be related to the gradual warming of our sun over the past 4Gyr as is commonly believed

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder), Chairperson:Kevin McGouldrick

Akatsuki, being in Venus orbit since December 2015, has acquired a volume of high-quality data, unveiled many new phenomena and is allowing researchers to investigate the underlying mechanisms. As the data accumulate, numerical models and theories are being advanced as well. We are no doubt living in the new golden era of Venus studies. This session invites papers of the new scientific results with Akatsuki data and the latest results of theoretical and numerical works. We expect participants of this session share the latest research results through presentations and discussion.

We present the cloud top structure of Venus retrieved from a total of 93 dayside images acquired at a wide variety of solar phase angles (0-120 deg) by the 2.02-μm channel of the 2-μm Camera (IR2) onboard Japanese Venus orbiter, Akatsuki, during the period from April 4 to May 25, 2016. Since the 2.02-μm channel locates in a CO_2 absorption band, the sunlight reflected from Venus allows us to determine the cloud top altitude corresponding to unit aerosol optical depth at 2.02 μm with radiative transfer calculation. Firstly, the observed solar phase angle dependence and zonal variation of the reflected sunlight in the equatorial region were used to construct a baseline model characterized by cloud top altitude , Mode 2 radius , and cloud scale height which are 70.287 km, 1.26 μm and 5.1 km, respectively. Secondly, individual cloud top altitudes were retrieved with the assumption that the last two values are valid for the entire planet. The latitudinal structure of cloud top altitude is symmetrical with respect to the equator: the averaged cloud top locates at a constant altitude of 68-70 km equatorward of ±45 deg but rapidly drops in latitudes of 50-60 deg and reaches 61 km poleward of ±70 deg. The averaged cloud top in the equatorial region indicates the tendency to increase from early morning (~7 h) and reach a maximum near early afternoon (~14 h) and decrease toward late afternoon (~17 h). The magnitude of the change is in the order of 1 km. After high-pass filtering of the cloud top altitude maps, small-amplitude features including stationary structures occur within several hundred meters and typically show less contrast than those at two channels (283 and 365 nm) of the Ultraviolet Imager (UVI). Although the long, zonal or tilted streaky features poleward of ~45 deg are clearly identifiable, the features in low and middle latitudes are usually faint and do not necessarily appear as the local variation in cloud top altitude where mottled and patchy patterns are seen in the UV channels, suggesting the existence of convection and turbulence at the cloud top level.

Formation of superrotation studied by a TEM model

*Takeshi Horinouchi[1]

1. Faculty of Environmental Earth Science, Hokkaido University

Recently, a number of studies have reported the formation of atmospheric superrotation in three-dimensional Venus GCMs. However, its mechanism has not been fully understood, which is partly due to the difficulty of model data analysis and possible numerical problems (Lebonnois et al 2012). Earlier studies with two-dimensional models by Matsuda (1980, 1982) and Yamamoto and Yoden (2013) provided useful insights, but to assess their applicability is not straightforward, since these studies are based on the Boussinesq approximation and use fixed uniform eddy diffusivity and Newtonian cooling rate. Here, I present the results of numerical simulations with a two-dimensional axi-symmetric model to overcome these difficulties. The model is based on the transformed Eulerian mean (TEM) equations supporting deep atmosphere over multiple scale heights, and it conserves total zonal angular momentum very well when surface friction is tuned off. The model does not use prescribed eddy diffusivity. Instead, effects of dynamical instabilities (convective, symmetric, barotropic-baroclinic instabilities) are parameterized. The model was initialized with the uniform solid-body rotation at the rate of the planetary rotation and run under radiative forcing similar to that in the recent Venus AFES simulations. A realistic superrotation emerged, and it reached a statistical steady state. It is revealed that the dynamical disturbances associated with dynamical instabilities can work like eddy diffusivity in the Gierasch mechanism to create a local maximum of the angular momentum within the atmosphere. The steady-state meridional circulation is multi-layered. The surface friction works to keep the angular momentum at low levels. Effects of thermal tides will be investigated elsewhere.

Morphological Feature Extraction from Venus' Cloud Images Using Principal Component Analysis

*Minori Narita[1], Takeshi Imamura[1], Yusuke Nara[1], Yeon Joo Lee, Shigeto Watanabe[2], Atsushi Yamazaki[3], Takehiko Satoh[3], Makoto Taguchi[4], Tetsuya Fukuhara[4], Manabu Yamada[5]

We applied principal component analysis (PCA) to Venus' multi-wavelength image data obtained by Venus orbiter Akatsuki, to extract latent morphological patterns for each wavelength and compare them to reveal similarities and dissimilarities between the wavelengths. Statistical approaches that extract latent features using massive amounts of data have hardly been done in Venus researches. The new analysis showed that tilted streaky features are dominant at all wavelengths, especially in mid-latitudes; this feature can be explained by the combination of the latitudinal gradient of the mean zonal velocity and the meridional circulation. Moreover, the result shows a strong morphological similarity between cloud height and ultraviolet absorbers.

We preprocessed images as follows. We used data in which images have been projected onto the latitude-longitude coordinate (Level-3 data). We used the following four wavelengths; near-infrared 2.02 μm (cloud height), thermal infrared 10 μm (cloud top temperature), ultraviolet 283 nm (SO_2 distribution at the cloud top), and ultraviolet 365 nm (an unknown UV absorber). First, we performed photometric correction using Minnaert Law (except for 10 μm images). Then these images are high-pass filtered by subtracting a Gaussian-smoothed image from each original image to extract scales smaller than 6 degrees both in latitude and longitude. Lastly, we extracted image patches from these images to increase the number of samples and extract specific spatial scale. The size of the image patches is 12 degrees in latitude/longitude. The total number of image patches is around 60,000 for each wavelength. Also, we analyzed images in low-latitudes and mid-latitudes separately.

We performed PCA for the image patches. PCA converts a set of observational data into a set of linearly uncorrelated variables called principal components and enables to extract spatial features that appear in data frequently. We focus on 20 most major principal components for each wavelength, and we also calculated the contribution ratios. As a result, it turned out that tilted streaky features are dominant both in low and middle latitudes. Considering that zonal winds have a latitudinal gradient and that a slow, poleward meridional circulation exists, cloud parcels are stretched obliquely while drifting from low latitudes to middle latitudes. Moreover, we found that SO_2 (283 nm) and the unknown UV absorber (365 nm) have spatial patterns similar to that of the cloud height (2.02 μm). It indicates that mechanisms that make the distribution of clouds and these chemical compounds in low latitudes are common. As unique patterns for a specific wavelength, it is worth noting that streaks in the north-south direction prevail in patterns of the cloud top temperature (10 μm). Considering that meridional bow-shaped structures are observed at this wavelength, it seems that these structures are appearing as the main principal component. Besides, the statistical approach could successfully extract streaky features from 10 μm as well, while we cannot recognize such features at this wavelength by our eyes because of apparent dominance of random, patchy features. In conclusion, we successfully extracted statistical spatial patterns in Venus' clouds and enabled further discussions about physical properties corresponding to each wavelength more in detail.

Principal Components of UV Albedo Variability in Venus' Atmosphere as seen at 283 nm

*Pushkar Kopparla[1], Yeon Joo Lee[1], Takeshi Imamura[1], Atsushi Yamazaki[2]

1. GSFS, University of Tokyo, 2. ISAS, JAXA

We explore the dominant modes of variability in the observed albedo at the cloud tops of Venus using the Akatsuki UVI 283 nm observations over the period Dec 2016 to May 2018. The observations consist of images of the dayside of Venus, most often observed at intervals of 2 hours, but interspersed with longer gaps. The orbit of the spacecraft does not allow for continuous observation of the full dayside, and the unobserved regions cause significant gaps in the dataset. The missing data are interpolated and the dataset is then subjected to a principal component analysis (PCA) to find six oscillating patterns in the albedo. Some of the spatial patterns and the time scales of these modes correspond to well known physical processes in the atmosphere of Venus such as short period atmospheric waves and the overturning circulation, while others defy a simple explanation. We also a find a hemispheric mode that has not been identified before and discuss its implications.

Planetary-scale waves on Venus cloud top cause periodical fluctuations in winds and also UV brightness. The candidates of these waves are 4-day Kelvin wave and 5-day Rossby wave of zonal wavenumber 1, however, their temporal evolutions are poorly understood. In this work, we conducted time-resolved periodical analysis in 365 nm brightness and cloud tracking wind fluctuations obtained by UVI onboard AKATUSKI Japanese Venus Climate Orbiter from January to September 2017, and we have revealed the dramatical evolution of planetary-scale waves and the dynamical connection between wave and planetary-scale UV features.

During the observation season, we could find prominent ~5-day periodicity in both wind and brightness fluctuations, whose phase velocity was slower than dayside mean zonal winds (or the super-rotation) by > 35 ms^{-1}. We succeeded to reconstruct the horizontal wind field related to the observed 5-day mode, and since planetary-scale vortices, whose the center existed ~35° latitudes, having large equatorial symmetric structures in the latitudinal direction were found, it can be a strong manifestation of the retrograde propagating Rossby wave. The observed Rossby wave subjected to temporal changes of enhancing and attenuating in the amplitude of wind fluctuations with ~100-day time scale. According to the temporal evolution of the Rossby wave, white cloud belts in 45° --60° latitudinal regions began rippling synchronously in both hemispheres. Moreover, the Rossby wave deformed the planetary-scale dark UV feature in the equatorial region, and that should be the reason for significant 5.1-day periodicity in brightness variation. Before the Rossby wave enhancement, weak 3.8-day periodical signals can be observed in zonal wind and brightness variations in the equatorial region. This is a suggestive prograde propagating Kelvin wave, and this might be the reason for the origin of dark clusters in the equatorial region.

While wave activities during the observation season from January to September 2017 were clear, significant periodical wind or brightness fluctuations were not always confirmed in the other observation seasons. In orther to investigate the reason for active and inactive behaviors in planetary-scale waves, we will compare seasons when significant planetary-scale waves were observed and they were not focusing on the connection with mean zonal wind speed, global UV albedo, and cloud top temperature.

The Venusian atmosphere is covered by clouds with super-rotating winds whose accelerating mechanism is still not well understood. Fastest wind speeds occur at the top of the clouds (about 70 km height), and they have been studied for decades thanks to their visual contrast in dayside ultraviolet images caused by the presence of a yet unknown absorber. The middle clouds (at about 50-55 km) can be observed using near-infrared wavelengths (800-950 nm) and they exhibit much weaker contrasts. Here we present the first long-term study of the dayside middle clouds of Venus at middle to low latitudes thanks to the combination of the full dataset of Akatsuki/IR1 images acquired at 900 nm during the year 2016 (A-I), complemented with observations of Venus with small telescopes and band-pass filters 1.0-1.1 μm and 884-900 nm (J-L). Thanks to the analysis of more than 1,000 images, we report the discovery of new cloud morphologies, like fast sharp discontinuities (C), elongated "hook-like" stripes (B,J) and a single case of mesoscale wave packet (I). Surprisingly, the albedo of Venus at 900 nm exhibit periodical hemispherical asymmetry (E-F), and clouds' contrasts varying from 3% to 21%. These contrasts are larger than reported in previous missions, and they are suggestive of important changes in the optical thickness of the clouds or they might imply the presence of a new atmospheric absorber at near-infrared wavelengths. Finally, we also present more than 500 wind measurements from IR1 images and —for the first time— with ground-based observations. The mean zonal winds are observed to peak at the equator, while the combination with data from Venus Express reveals long-term variations in the zonal winds of ˜20 m/s along 10 years.

New thermal infrared camera for fine horizontal brightness temperature structures at the cloud-top level of Venus

*Tetsuya Fukuhara[1], Makoto Taguchi[1], Takeshi Imamura[2], Sanjay S Limaye[3]

1. Rikkyo University, 2. The University of Tokyo, 3. University of Wisconsin

The Longwave Infrared Camera (LIR), which is an uncooled microbolometer camera, is currently acquiring thermal infrared images (8-12 μm) of Venus and depicting the cloud-top brightness temperatures from Akatsuki orbiter around Venus since December 2015. The outstanding result of LIR has been the discovery of an interhemispheric bow-shaped structure meridionally stretching 10,000 km across the equator at the Venus cloud-top. Over several days of observations, the bow-shaped structure remains relatively fixed in position above the highland on the slowly rotating surface, despite the background atmospheric super rotation at ~100 m/s. We infer that the bow-shaped structure is the result of an atmospheric gravity wave generated in the lower atmosphere by mountain topography that then propagated upwards [1]. This indicates that the horizontal temperature distribution seen at the cloud-top level represents not only direct physical property at the cloud-top but also influence of dynamics in the lower atmosphere. In fact, preliminary observation of LIR has detected fine structure (~100 km) in temperature distribution from close-up observations near the periapsis. We suggest that this may be caused by the upward propagation of a gravity wave, which is generated by the convection layer at ~40 km altitude. However, the spatial resolution of LIR seems insufficient to understand the origins of such a fine structure. We need better observations at higher spatial resolution than possible from LIR in Akatsuki's orbit.

We propose that a future Venus orbiter carries an updated version of the uncooled microbolometer camera (BOL) with 1024x768 pixels and angular resolution of ~0.01 deg/pixel to detect fine temperature structure on the cloud-tops. When the orbiter is typically injected to a high-inclined elliptical orbit with altitude of 500-50,000 km, BOL provides a spatial resolution of 8.5 km at apoapsis and 0.08 km at periapsis, respectively. It will be enough to observe the fine temperature structure at the cloud-top. Further, BOL will capture the fine temperature structure at polar region near the "eye" of the hemispheric vortex situated over the poles, where the horizontal temperature varies drastically near the Venus cloud-tops. VIRTIS instrument on Venus Express orbiter showed complex structures at near infrared wavelengths [2]. Akatsuki from its near equatorial elliptical orbit cannot observe the fine structure in polar regions.

During 2012-2014, we developed an uncooled micro-bolometer array (UMBA) camera for the 50 kg class Earth observing satellite based on the experience of LIR development [3]. The camera with the pixel size of 640 ×480 was launched in 2014 and successfully detect a small wildfire which was main observation target for the mission. The results showed that its performance was better than expected. Furthermore, the newest UMBA camera with the pixel size increased to 1024 ×768 has been developed for the next wildfire mission to take finer spatial resolution image with ~0.01 deg/pixel. Unfortunately, this camera has lost the launch opportunity. However, the flight-model has been assembled and has passed function tests. Since BOL does not need heavy cryogenic systems, its mass and size are less than ~1 kg and 100 mm x 100 mm x 120 mm, respectively; it would be a relatively small mass increment for the future Venus mission.

The most extensive observations of Venusian mesosphere have been performed by Venus Express (VEX) up to 2014 (e.g., Patzold et al., 2007; Mahieux et al., 2015). These observations have found the highly spatial and temporal variations in the thermal structure. The temperature discrepancies between observations by VEX/SOIR and general circulation models in the altitude of 80 - 100 km have not been properly interpreted (Bougher et al., 2015; Gilli et al., 2017). In addition, the mesospheric dynamics located between retrograde superrotational zonal wind (cloud deck) and subsolar-to-antisolar flow (above 120 km altitude) have not been well understood due to lack of observations. On the other hand, the lower thermosphere has been observed by mid-infrared heterodyne spectrometer (MIR-HS). Temperature in this region varied extensively between 140 K and 240 K, and wind velocity changed intensely from 130 m/s to 190 m/s for a terrestrial day (Sornig et al., 2013; Krause et al., 2018). Temperature and wind variations such as periodicity and locality in Venusian mesosphere and lower thermosphere have not been comprehended. The purpose of our observations is to solve it with continuous observations by MIR-HS.
Our Mid-Infrared Laser Heterodyne Instrument (MILAHI) have been inserted to Tohoku 60 cm telescope located the summit of Mt. Haleakala in Maui, Hawaii (Nakagawa et al., 2016). MILAHI has 10 um CO_2 laser as local oscillator. The field of view is 4 arcsec with 60 cm telescope and in the wavelength of 10 um. MIR-HS can retrieve temperature and wind in different altitude between dayside observations and nightside observations. CO_2 emerge non-local thermodynamic equilibrium emission from 100 –120 km altitude in dayside (Lopez-Valverde et al., 2011). Temperature and wind are derived from Doppler width and Doppler shift of the emission spectra, respectively. In nightside, CO_2 in the mesosphere absorbs background radiation from the cloud deck. Temperature profile and wind are retrieved from this absorption spectra with radiative transfer equation and inverse method of AMATERASU developed in National Institute of Information and Communications Technology.
Dayside observations were conducted between 24th and 27th in June, 2018. Apparent diameter was 15 arcsec and apparent dayside was half of the disk in this term. Observed points were North, South, disk center, and equator with integration times of 30 - 55 minutes. Each observed point gave different temperature variation feature. Temperature variation range was 170 - 220 K in agreement with Sonnabend et al. (2010). Temperature distribution showed both latitudinal dependence in 25th and convergence at 200 K in 26th.
Nightside observations were conducted from 11th to 13th, 19th, and 20th in November, 2018. Apparent diameter of Venus changed between 55.4 and 49.4 arcsec after inferior conjunction. We observed equator with three days, north 33 degree and south 33 degree for diurnal and latitudinal variations with integration times of 80 - 130 minutes. The observed spectra in the unit of relative intensity are under conversion because the retrieval with AMATERASU is necessary to use absolute radiation. We will show retrieved temperature profile and wind velocity at this presentation.

Local time dependence of limb darkening seen in the thermal infrared Venus disk

*Masahiro Akiba[1]

1. Rikkyo University

Brightness temperature of the Venus disk obtained by Longwave Infrared Camera (LIR) onboard Akatuski shows clear limb darkening in the low and middle latitudes. Limb darkening is an apparent temperature decrease from the center to the limb of the Venus disk. It is caused by thermal and radiative characteristics that the sensing altitude of LIR increases as an emission angle, which is a zenith angle of direction of emission from the Venus atmosphere to the sensor, increases and that the atmospheric temperature monotonically decreases with altitude. In higher latitudes limb brightening is observed, because an inversion layer exists at the cloud-top altitudes in higher latitudes. In other word a profile of the limb darkening reflects vertical distributions of atmospheric temperature and optical thickness of cloud particles. Taylor et al. [1980] presented local time dependence of limb darkening using brightness temperature data obtained by the Pioneer Venus orbiter, but did not mention its physical mechanism. In this study brightness temperature distributions obtained by LIR when Akatsuki was in the altitude range from 60,000 to 100,000 km during the period from October 19, 2016 to July 17, 2018 were analyzed to investigate temperature and cloud particle property at the cloud-tops. Each brightness temperature image with 328 x 248 pixels was divided into 3280 x 2480 sub-pixels, and 32 successive images were accumulated after precise adjustment of the Venus disk position to improve S/N. Brightness temperature profiles as a function of the emission angle were derived for 24 local time zones and 9 zonal belts with a latitudinal width of 10˚ within ±45˚. A degree of limb darkening and a brightness temperature at the disk center were determined by least-square function fitting. As a result, the degree of limb darkening shows a clear semi-diurnal variation, and is the strongest at 11h and 22h and the weakest at 7h and 18h in local time. The amplitude of semi-diurnal variation peaks at the equator, whereas its phase seems constant in all latitudes. The temperature at the disk center also shows a semi-diurnal variation with a phase shift of approximately two hours earlier than the phase of the degree of limb darkening and a slight diurnal variation in higher latitudes. These semi-diurnal and diurnal components observed by LIR are consistent with the past observation of thermal tides in the Venus atmosphere by VENERA 15 [Zasova et al., 2007]. The physical mechanism of the semi-diurnal and diurnal thermal tide components seen in the degree of limb darkening and cloud-top temperature will be discussed.

Stationary wavy features and Banded structures at Venusian cloud top extracted by averaging multiple LIR images

*Kiichi Fukuya[1], Takeshi Imamura[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Toru Kouyama[3]

1. Univ. of Tokyo, 2. Rikkyo Univ., 3. AIST

Venus' cloud-top temperature distribution is now continuously mapped by LIR (Long-wave Infrared camera) mounted on the Venus orbiter Akatsuki. Fukuhara et al. (2017) analyzed LIR data and reported the existence of bow-shaped structures extending over 10,000 km in the north-south direction. The features are fixed in position without flowing with the super-rotation and appear above highlands with altitudes higher than 3 km. It was suggested based on a comparison with numerical simulations that the features are gravity waves generated by near-surface flows impinging on mountains. Kouyama et al. (2017) observed stationary features over 4 Venus days and revealed that the features tend to occur in the local afternoon. Gravity waves, whose restoring force is buoyancy, transport horizontal momentum in the vertical direction and accelerate or decelerate the background wind when they dissipate. Therefore, stationary gravity waves influence the general circulation of the atmosphere. In order to estimate the influence, it is essential to reveal the spatial and temporal distributions of gravity waves.
In the previous studies using LIR data, only planetary-scale stationary features have been investigated. On the other hand, Peralta et al. (2017) analyzed the data taken by VIRTIS onboard Venus Express, and reported the existence of many small-scale stationary features; however, VIRTIS can observe the night side only, and the observations were confined to the high latitude of the southern hemisphere because of the geometry of the orbit. Therefore, we intend to investigate with a new analysis method the topographical and local time dependency of small-scale, weak stationary features by using LIR data, which can observe all latitude regions at any local time. Though the S/N ratio of LIR is lower than VIRTIS, averaging of multiple images can suppress noises and at the same time emphasize stationary patterns. By using this method, small-scale, stationary wave trains were newly found above relatively-low topographic rises with altitudes of 1-3 km. In addition to stationary features, zonally-elongated banded structures were also found in averaged LIR images. Such structures have once been detected in LIR images taken during Akatsuki's Venus flyby in 2010 (Taguchi et al., 2012); the new analysis confirmed that banded structures are ubiquitous at the cloud top. The orientations of the banded structures are different from those of dark streaks found in ultraviolet images.

Akatsuki's IR2 Nightside Photometry Restoration by Deconvolution

*Choon Wei Vun[1], Takehiko Satoh[2,1], Kevin McGouldrick[3], Takeshi Horinouchi[4], Takao M. Sato[5]

1. SOKENDAI, 2. ISAS/JAXA, 3. University of Colorado Boulder, 4. Hokkaido University, 5. Hokkaido Information University

Akatsuki’ s IR2 camera captures images of Venus at different filters: 1.735um, 2.26um, and 2.32um. At near-dawn/dusk views (phase angles ~90 to 115 degree) of these images, the nightside photometry is contaminated by the intense dayside reflectance. As the potential well of a pixel is overfilled with incoming generated photoelectrons, the pixel is saturated and hence no longer contain information. This saturation can occur in the dayside and nightside near the terminator.
Owing to the saturation problem, main task of the restoration process is thus to simulate both day and night sides to replace the information loss in saturation. Point spread function (PSF) of the IR2 camera was modeled using Moffat function with observation of experimental image taken of point source street light before launch. Then, deconvolution by model-PSF can restore the nightside photometry of unsaturated pixels. Dayside reflectance was modeled with Lambert’ s law, where its distribution is multiplied by an F factor (W m^{-2} sr^{-1} um^{-1}). Methods of finding the F factor will be shown.
We present our Restoration by Deconvolution (RD) results of the selected dates. The restored images were limb darkening corrected. Efficiency of RD can be restored to ~0.005 sigma in standard deviation accuracy when performed on synthetic image with known answer image.
Correlation plot of unsaturated nightside radiances between two filters (2.26mm and 1.735mm) were produced to extract possible ‘branch’ phenomena. The branching in the correlation plot indicates the differences in optical depths of different particle size modes [1].
Restoration of nightside pixels also opens up the opportunity to study the cloud dynamics transiting from the dayside into the nightside. Moreover, interesting cloud features such as vortices, instabilities, and streaks are more distinct in recovered images. This in overall opens up new window to understanding the evolution of cloud motion in the middle layer.

Enormous cloud cover as seen by Akatsuki/IR2 on the night-side disk of Venus

*Takehiko Satoh[1,2], Choon Wei Vun[2], Takao M. Sato[3], Takeshi Horinouchi[4], George HASHIMOTO[5], Kevin McGouldrick[6]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. Department of Space Science, SOKENDAI, 3. Department of Business and Information Systems, Hokkaido Information University, 4. Faculty of Environmental Earth Science, Hokkaido University, 5. Department of Earth Science, Okayama University, 6. LASP, University of Colorado Boulder

Night-side observations in transparency windows of CO_2 atmosphere of Venus allow visualizing inhomogeneous clouds in ~50 to ~60 km altitudes. The IR2 camera on board Akatsuki captured such images at 1.735, 2.26, and 2.32 um wavelengths. In the IR2 night-side data, an enormous cloud of greater opacity and very sharp edge in the front (western end) is seen repeatedly. This feature seems to encircle the planet with a period of ~4.5 days (Peralta).
Although interesting, property of particles in this feature was not studied before due to difficulty of photometric measurements in IR2 night-side data. This difficulty comes from a combination of the intense day crescent and extended tail of IR2 point-spread function (multiple reflection in the detector is the cause). We have developed a technique to restore the contrast of the night-side data by deconvolution so that the photometric studies can be done with IR2 night-side data.
The data acquired on 18th and 27th August 2016 are analyzed. We have performed a series of radiative transfer computations to reproduce both 1.735- and 2.26-um opacities in this enormous cloud. Properties of the cloud partices will be presented and possible mechanism of this remarkable phenomenon will be discussed.

The global variation of Venus cloud obtained from IR1 camera onboard AKATSUKI

*Seiko Takagi[1], Naomoto Iwagami, Yukihiro Takahashi[1], Mitsuteru Sato[1]

1. Hokkaido University, Graduate School of Science

Venus is our nearest neighbor, and has a size very similar to the Earth's. However, previous observations discovered an extremely dense (92 bar at the surface) and CO_2-rich atmosphere, with H_2SO_4 thick clouds. The Venus cloud consists of H_2SO_4 main cloud deck at 47 −70 km, with thinner hazes above and below. The upper haze on Venus lies above the main cloud surrounding the planet, ranging from the top of the cloud (70 km) up to as high as 90 km. Near infrared (0.986 um) dayside image of Venus has taken by solid state imaging (SSI) of the Galileo spacecraft (NASA). It appears almost flat, there are some small scale features with a contrast of 3 %[Belton et al., 1991]. In Takagi and Iwagami. (2011), it may be calculated that the source of the contrast of the order of 3 % in near infrared Venus dayside image is due to variation in the cloud optical thickness. On December 7, 2015, AKATSUKI (JAXA) approached Venus and the Venus orbit insertion was successful. After the Venus orbit insertion, many 0.90 um Venus dayside images were taken by the 1 um near infrared camera (IR1) onboard AKATSUKI. In this study, Venus cloud variations are investigated from 0.90 um Venus dayside images taken by IR1 camera globally. Further, meteorological some changes that contribute to cloud variation are examined in using radiative transfer calculation with high altitude cloud model obtained from Venus Express/SOIR observation. Furthermore, I will introduce observation plan with PIRKA telescope of Hokkaido University.

Development of a Venus' cloud formation scheme for a convection resolving model

*Ko-ichiro SUGIYAMA[1], Nozomu Fukuhara[1], Masatsugu Odaka[2], Kensuke Nakajima[3], Masaki Ishiwatari[2], Takeshi Imamura[4], Yoshi-Yuki Hayashi[5]

1. National Institute of Technology, Matsue College, 2. Department of Cosmoscience, Graduate School of Science, Hokkaido University, 3. Department of Earth and Planetary Sciences,Flculty of Sciences,Kyushu University, 4. Graduate School of Frontier Sciences, The University of Tokyo, 5. Department of Planetology, Graduate School of Science, Kobe University / Center for Planetary Science (CPS)

Although convection has been suggested to occur in the lower part of Venus' cloud layer by some observational evidences, its structure remains to be clarified. In the previous studies, Baker et al. (1998, 2000), Imamura et al. (2014), and Lefevre et al. (2017) try to simulate Venus' cloud-level convection, but their models they utilized do not consider cloud formation process. Our purpose is to develop new cloud formation scheme and to perform numerical simulation using the scheme in order to investigate a possible structure of Venus' cloud-level convection and clouds distribution.

Our cloud formation scheme is based on Imamura and Hashimoto (1998). The number densities of sulfuric acid (H2SO4) and water (H2O) in the gas and liquid phases are calculated. Sedimentation of H2SO4-H2O solution droplets and chemical reactions of sulfuric acid are also considered. The scheme is implemented into our convection resolving model developed by Sugiyama et al. (2009). The model is based on the quasi-compressible system (Klemp and Wilhelmson, 1978), and is used in the simulations of the atmospheric convections of Jupiter (Sugiyama et al., 2011, 2014) and Mars (Yamashita et al. 2017).

In our poster, we will show the details of our cloud formation scheme and demonstrate some results of our calculation using similar settings of Imamura et al. (2014).

Zonal mean structure of Venus atmosphere observed in a Venus general circulation model with explicit radiative transfer

*Yoshi-Yuki Hayashi[1], Chisato Shiojiri[1], Hiroki Kashimura[1], Yoshiyuki O. Takahashi[1]

1. Department of Planetology/CPS, Graduate School of Science, Kobe University

Zonal mean zonal wind in Venus atmosphere is different from those in other planetary atmospheres. It is a strong prograde wind in all latitudinal ranges and is referred to as super-rotation. This unique zonal wind has been investigated by a lot of previous researchers with numerical simulations as well as ground-based and spacecraft observations. Among the studies with numerical simulations, in 2010s, Lebonnois et al. (2010) and Ikeda (2010) performed general circulation model simulations with an explicit radiative transfer model and successfully represented strong prograde zonal wind. These studies overcome a shortcoming of previous studies, in which models use Newtonian cooling as a radiative forcing.

In our group, we have been developing a general circulation model for planetary atmospheres. In addition, we have just developed a Venus radiation model, which can be used in a general circulation model. In this study, by implementing the radiation model into our general circulation model, we try to perform general circulation model simulations of Venus atmosphere and investigate the zonal mean structure of Venus atmosphere and evaluate differences between previous studies.

The general circulation model used in this study is DCPAM (http://www.gfd-dennou.org/library/dcpam/). The model is based on primitive equation system and the equation system is solved by a spectral transform method. The DCPAM includes physical processes of radiation and turbulent mixing processes. In addition, heat diffusion in soil is considered to evaluate surface temperature. The radiation model implemented into the DCPAM has also been developed in our group, and is based on a correlated k-distribution method. Radiative fluxes calculated by this radiation model are compared well with observed ones. By the use of the model, we performed two experiments with and without surface orographic variation. Resolution of experiments is T15L52, in which the model has 48 (longitude) times 24 (latitude) grids in horizontal direction and 52 layers in vertical direction. Initial conditions for those experiments are the same, and are
motionless atmospheres with horizontally uniform temperature distribution based on VIRA. With this initial condition, the model is integrated for 150000 Earth days with diurnal variation and with no seasonal variation, i.e. zero
obliquity.

Statistically steady states are achieved after about 100000 Earth days from the start of integrations. In steady state, prograde zonal winds with velocity of about 50 m/s in low and middle latitude are maintained at cloud layer in both experiments with and without orographic variation, although the velocity is about a half of that observed in Venus
atmosphere.

Meridional circulation observed in the model has large direct cells in both hemispheres. The direct cells in the experiment without surface orography have vertical extent from the ground up to top of the model, except for low latitude region just above the ground where indirect cells form. However, in the experiment with surface orography, the cells are split in the vertical direction at bottom of cloud layer. In addition to direct cells, several indirect cells are also observed in the experiments. One of those is indirect cell at

©2019. Japan Geoscience Union. All Right Reserved.

cloud layer in high latitude. Other ones are several indirect cells which extends from the ground up to bottom of cloud layer in the experiment with surface orography. These indicate that the effects of surface orography can be observed below the cloud layer, clearly.

In the presentation, results of analysis on zonal mean structure observed in the model, such as angular momentum, will also be presented.

Gravity wave packets detected in radio occultation temperature profiles of the Venus atmosphere

*Ryota Mori[1], Takeshi Imamura[1], Javier Peralta[2]

1. The University of Tokyo, 2. Japan Aerospace Exploration Agency

Temperature profiles has been obtained from 2016 by the radio occultation experiment in the Venus orbiter mission Akatsuki. The radio occultation experiment is a method that measures the change of the atmospheric refractive index as a change of the frequency of the signal received on the ground. At the opportunity when the radio wave transmitted from Akatsuki toward the Earth pass through the planetary atmosphere, the wave is refracted and then reaches the receiving station. We can retrieve the vertical profiles of the pressure and the temperature from each refractive index profiles. In the temperature profile obtained in this way, variations due to various atmospheric disturbances are observed. We focus on gravity waves which are thought to play an import role in driving the general atmosphere circulation.

Gravity waves are small-scale waves with the restoring force being the buoyancy in the atmosphere. Gravity waves play a role in carrying the momentum in the vertical direction. So, it results in acceleration or deceleration of the mean wind by passing momentum on the background atmosphere while dissipating. This process should affect the global structure of the high-speed zonal wind. However, since gravity waves have properties that the spatial scale is small and the wave period is relatively short, it is difficult to capture the spatial structure by observation. The latitudinal profile of the amplitude of short vertical-scale temperature disturbances, which are thought to be associated with gravity waves, has been investigated; however, the dominant wavelength and the typical vertical extent have not been studied.

In this study, we applied wavelet analysis to the temperature profiles and extracted spatially localized temperature disturbances. Though there have been studies that apply Fourier transform to the temperature data, Fourier transform assumes infinitely lasting waves and it is not suitable for extracting spatially localized wave packets. Wavelet analysis is an effective way of obtaining the periods and the amplitudes of waves in such finite intervals. In this presentation, we report the result of wavelet analysis applied to the temperature data obtained with high vertical resolution by radio holographic method. From the obtained results, we also report the relationship between the length and the packet length of gravity wave in the atmosphere.

Status of lightning hunt in Venus with Akatsuki/LAC and Pirka telescope

*Yukihiro Takahashi[1,2], Mitsuteru Sato[1,2], Masataka Imai[3], Ralph Lorenz[4], Seiko Takagi[1,2], Ono Tatsuharu[1]

1. Graduate School of Science, Hokkaido University, 2. Faculty of Science, Hokkaido University, 3. National Institute of Advanced Industrial Science and Technology,, 4. Applied Physics Laboratory, Johns Hopkins University

The existence of lightning discharge in Venus has been controversial for three decades, which might be attributed to the luck of conclusive observational evidence. There had been no satellite payload intentionally designed for the detection of lightning phenomena using radio wave or optical sensor. LAC, lightning and airglow camera, on board Akatsuki spacecraft, is the first sensor optimized for the lightning optical flash measurement in planets other than the Earth. It is expected that LAC could conclude this 30-year discussion on the existence of lightning in Venus. Unique performance of LAC compared to other equipment used in the previous exploration of Venus is the high-speed sampling rate at 20 kHz with 32 pixels of Avalanche Photo Diode (APD) matrix, enabling us to distinguish the natural optical lightning flash from other pulsing noises, including artificial electrical noise and cosmic rays. We selected OI 777 nm line for lightning detection, which is expected to be the most prominent emission in CO2-dominant atmosphere based on the laboratory experiments.

The triggering parameter was set so as to optimize for the light curve similar to the normal lightning in the Earth and data obtained totally for about 4 hours were examined. However, we couldn’ t find any lightning signals. Adding to this triggering parameter set, we added one more parameter set, optimized for sprite type emission with duration of up to 10s of ms. Furthermore, in order to investigate fainter emissions, we are now conducting successive force triggering recordings without any threshold, achieving 5 times better sensitivity than the intensity of 1 digital unit at best.

The total coverage of the LAC lightning hunt became 81.6 [million km2-hr], meaning 81 percent detectability of previous results with ground-based telescope by Hansell et al. (1995). Here we report the detailed strategy and the latest status of the LAC observation in 2018, and discuss the future observation plan.

Also we will make ground observation with a high-speed photometer installed at Pirka telescope, a 1.6-m reflector deployed by Hokkaido University. Here we report the initial results of lightning flash observation with it.

Possibility of electric discharge in the Venusian atmosphere due to the super-rotation of clouds

*Adhithiyan Neduncheran[1], Ugur Guven[1,2], Ananyo Bhattacharya[3]

1. University of Petroleum and Energy Studies, India, 2. United Nations Centre for Space Science and Technology Education in Asia and the Pacific, 3. Sardar Vallabhbhai National Institute of Technology,India

Several evidences of electromagnetic bursts were measured by various landers and orbiters studying Venus atmosphere (Venera landers, Venus Express and the Pioneer Venus Orbiter). The electromagnetic bursts that are taking place in the cloud region in the form of lightning or fluorescence might be a result of momentum transfer, solar convection and charge dispersion in the clouds of Venus. While the lightning in Earth takes place mostly in the equatorial region, in case of Venus it is possible for lightning to occur in the polar regions, considering the kinetic energy transfer and the formation of dipoles in both hemispheres of Venus. The meridional and zonal flows can interact and cause the charge separation which possibly lead to electromagnetic bursts in different spectrum and in different regions in Venus. In labs, it is observed that SO2 emissions in UV region cause fluorescence which is one of the major phenomena taking place in the cloud tops. Based on the photochemical model published by *Krasnopolsky 2011(*doi:10.1016/j.icarus.2011.11.012) and the principle of refraction, we present the possibility of lightning/fluorescence phenomena being caused by the super-rotation of the clouds in the Venusian atmosphere.

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

Mon. May 27, 2019 5:15 PM - 6:30 PM JST | Mon. May 27, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-PS05] Recent advances of Venus science

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Takeshi Horinouchi(Faculty of Environmental Earth Science, Hokkaido University), Masaru Yamamoto(Research Institute for Applied Mechanics, Kyushu University), Kevin McGouldrick(University of Colorado Boulder)

Akatsuki, being in Venus orbit since December 2015, has acquired a volume of high-quality data, unveiled many new phenomena and is allowing researchers to investigate the underlying mechanisms. As the data accumulate, numerical models and theories are being advanced as well. We are no doubt living in the new golden era of Venus studies. This session invites papers of the new scientific results with Akatsuki data and the latest results of theoretical and numerical works. We expect participants of this session share the latest research results through presentations and discussion.

New thermal infrared camera for fine horizontal brightness temperature structures at the cloud-top level of Venus

*Tetsuya Fukuhara[1], Makoto Taguchi[1], Takeshi Imamura[2], Sanjay S Limaye[3]

1. Rikkyo University, 2. The University of Tokyo, 3. University of Wisconsin

The Longwave Infrared Camera (LIR), which is an uncooled microbolometer camera, is currently acquiring thermal infrared images (8-12 μm) of Venus and depicting the cloud-top brightness temperatures from Akatsuki orbiter around Venus since December 2015. The outstanding result of LIR has been the discovery of an interhemispheric bow-shaped structure meridionally stretching 10,000 km across the equator at the Venus cloud-top. Over several days of observations, the bow-shaped structure remains relatively fixed in position above the highland on the slowly rotating surface, despite the background atmospheric super rotation at ~100 m/s. We infer that the bow-shaped structure is the result of an atmospheric gravity wave generated in the lower atmosphere by mountain topography that then propagated upwards [1]. This indicates that the horizontal temperature distribution seen at the cloud-top level represents not only direct physical property at the cloud-top but also influence of dynamics in the lower atmosphere. In fact, preliminary observation of LIR has detected fine structure (~100 km) in temperature distribution from close-up observations near the periapsis. We suggest that this may be caused by the upward propagation of a gravity wave, which is generated by the convection layer at ~40 km altitude. However, the spatial resolution of LIR seems insufficient to understand the origins of such a fine structure. We need better observations at higher spatial resolution than possible from LIR in Akatsuki's orbit.

We propose that a future Venus orbiter carries an updated version of the uncooled microbolometer camera (BOL) with 1024x768 pixels and angular resolution of ~0.01 deg/pixel to detect fine temperature structure on the cloud-tops. When the orbiter is typically injected to a high-inclined elliptical orbit with altitude of 500-50,000 km, BOL provides a spatial resolution of 8.5 km at apoapsis and 0.08 km at periapsis, respectively. It will be enough to observe the fine temperature structure at the cloud-top. Further, BOL will capture the fine temperature structure at polar region near the "eye" of the hemispheric vortex situated over the poles, where the horizontal temperature varies drastically near the Venus cloud-tops. VIRTIS instrument on Venus Express orbiter showed complex structures at near infrared wavelengths [2]. Akatsuki from its near equatorial elliptical orbit cannot observe the fine structure in polar regions.

During 2012-2014, we developed an uncooled micro-bolometer array (UMBA) camera for the 50 kg class Earth observing satellite based on the experience of LIR development [3]. The camera with the pixel size of 640 ×480 was launched in 2014 and successfully detect a small wildfire which was main observation target for the mission. The results showed that its performance was better than expected. Furthermore, the newest UMBA camera with the pixel size increased to 1024 ×768 has been developed for the next wildfire mission to take finer spatial resolution image with ~0.01 deg/pixel. Unfortunately, this camera has lost the launch opportunity. However, the flight-model has been assembled and has passed function tests. Since BOL does not need heavy cryogenic systems, its mass and size are less than ~1 kg and 100 mm x 100 mm x 120 mm, respectively; it would be a relatively small mass increment for the future Venus mission.

Temperature and wind variations in Venusian mesosphere and lower thermosphere by mid-infrared heterodyne spectrometer in 2018

*Kosuke Takami[1], Hiromu Nakagawa[1], Hideo Sagawa[2], Isao Murata[1], Yasumasa Kasaba[1]

1. Graduate School of Science, Tohoku University, 2. Division of Science, Kyoto Sangyo University

The most extensive observations of Venusian mesosphere have been performed by Venus Express (VEX) up to 2014 (e.g., Patzold et al., 2007; Mahieux et al., 2015). These observations have found the highly spatial and temporal variations in the thermal structure. The temperature discrepancies between observations by VEX/SOIR and general circulation models in the altitude of 80 - 100 km have not been properly interpreted (Bougher et al., 2015; Gilli et al., 2017). In addition, the mesospheric dynamics located between retrograde superrotational zonal wind (cloud deck) and subsolar-to-antisolar flow (above 120 km altitude) have not been well understood due to lack of observations. On the other hand, the lower thermosphere has been observed by mid-infrared heterodyne spectrometer (MIR-HS). Temperature in this region varied extensively between 140 K and 240 K, and wind velocity changed intensely from 130 m/s to 190 m/s for a terrestrial day (Sornig et al., 2013; Krause et al., 2018). Temperature and wind variations such as periodicity and locality in Venusian mesosphere and lower thermosphere have not been comprehended. The purpose of our observations is to solve it with continuous observations by MIR-HS.
Our Mid-Infrared Laser Heterodyne Instrument (MILAHI) have been inserted to Tohoku 60 cm telescope located the summit of Mt. Haleakala in Maui, Hawaii (Nakagawa et al., 2016). MILAHI has 10 um CO_2 laser as local oscillator. The field of view is 4 arcsec with 60 cm telescope and in the wavelength of 10 um. MIR-HS can retrieve temperature and wind in different altitude between dayside observations and nightside observations. CO_2 emerge non-local thermodynamic equilibrium emission from 100 –120 km altitude in dayside (Lopez-Valverde et al., 2011). Temperature and wind are derived from Doppler width and Doppler shift of the emission spectra, respectively. In nightside, CO_2 in the mesosphere absorbs background radiation from the cloud deck. Temperature profile and wind are retrieved from this absorption spectra with radiative transfer equation and inverse method of AMATERASU developed in National Institute of Information and Communications Technology.
Dayside observations were conducted between 24th and 27th in June, 2018. Apparent diameter was 15 arcsec and apparent dayside was half of the disk in this term. Observed points were North, South, disk center, and equator with integration times of 30 - 55 minutes. Each observed point gave different temperature variation feature. Temperature variation range was 170 - 220 K in agreement with Sonnabend et al. (2010). Temperature distribution showed both latitudinal dependence in 25th and convergence at 200 K in 26th.
Nightside observations were conducted from 11th to 13th, 19th, and 20th in November, 2018. Apparent diameter of Venus changed between 55.4 and 49.4 arcsec after inferior conjunction. We observed equator with three days, north 33 degree and south 33 degree for diurnal and latitudinal variations with integration times of 80 - 130 minutes. The observed spectra in the unit of relative intensity are under conversion because the retrieval with AMATERASU is necessary to use absolute radiation. We will show retrieved temperature profile and wind velocity at this presentation.

Local time dependence of limb darkening seen in the thermal infrared Venus disk

*Masahiro Akiba[1]

1. Rikkyo University

Brightness temperature of the Venus disk obtained by Longwave Infrared Camera (LIR) onboard Akatuski shows clear limb darkening in the low and middle latitudes. Limb darkening is an apparent temperature decrease from the center to the limb of the Venus disk. It is caused by thermal and radiative characteristics that the sensing altitude of LIR increases as an emission angle, which is a zenith angle of direction of emission from the Venus atmosphere to the sensor, increases and that the atmospheric temperature monotonically decreases with altitude. In higher latitudes limb brightening is observed, because an inversion layer exists at the cloud-top altitudes in higher latitudes. In other word a profile of the limb darkening reflects vertical distributions of atmospheric temperature and optical thickness of cloud particles. Taylor et al. [1980] presented local time dependence of limb darkening using brightness temperature data obtained by the Pioneer Venus orbiter, but did not mention its physical mechanism. In this study brightness temperature distributions obtained by LIR when Akatsuki was in the altitude range from 60,000 to 100,000 km during the period from October 19, 2016 to July 17, 2018 were analyzed to investigate temperature and cloud particle property at the cloud-tops. Each brightness temperature image with 328 x 248 pixels was divided into 3280 x 2480 sub-pixels, and 32 successive images were accumulated after precise adjustment of the Venus disk position to improve S/N. Brightness temperature profiles as a function of the emission angle were derived for 24 local time zones and 9 zonal belts with a latitudinal width of 10˚ within ±45˚. A degree of limb darkening and a brightness temperature at the disk center were determined by least-square function fitting. As a result, the degree of limb darkening shows a clear semi-diurnal variation, and is the strongest at 11h and 22h and the weakest at 7h and 18h in local time. The amplitude of semi-diurnal variation peaks at the equator, whereas its phase seems constant in all latitudes. The temperature at the disk center also shows a semi-diurnal variation with a phase shift of approximately two hours earlier than the phase of the degree of limb darkening and a slight diurnal variation in higher latitudes. These semi-diurnal and diurnal components observed by LIR are consistent with the past observation of thermal tides in the Venus atmosphere by VENERA 15 [Zasova et al., 2007]. The physical mechanism of the semi-diurnal and diurnal thermal tide components seen in the degree of limb darkening and cloud-top temperature will be discussed.

Stationary wavy features and Banded structures at Venusian cloud top extracted by averaging multiple LIR images

*Kiichi Fukuya[1], Takeshi Imamura[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Toru Kouyama[3]

1. Univ. of Tokyo, 2. Rikkyo Univ., 3. AIST

Venus' cloud-top temperature distribution is now continuously mapped by LIR (Long-wave Infrared camera) mounted on the Venus orbiter Akatsuki. Fukuhara et al. (2017) analyzed LIR data and reported the existence of bow-shaped structures extending over 10,000 km in the north-south direction. The features are fixed in position without flowing with the super-rotation and appear above highlands with altitudes higher than 3 km. It was suggested based on a comparison with numerical simulations that the features are gravity waves generated by near-surface flows impinging on mountains. Kouyama et al. (2017) observed stationary features over 4 Venus days and revealed that the features tend to occur in the local afternoon. Gravity waves, whose restoring force is buoyancy, transport horizontal momentum in the vertical direction and accelerate or decelerate the background wind when they dissipate. Therefore, stationary gravity waves influence the general circulation of the atmosphere. In order to estimate the influence, it is essential to reveal the spatial and temporal distributions of gravity waves.
In the previous studies using LIR data, only planetary-scale stationary features have been investigated. On the other hand, Peralta et al. (2017) analyzed the data taken by VIRTIS onboard Venus Express, and reported the existence of many small-scale stationary features; however, VIRTIS can observe the night side only, and the observations were confined to the high latitude of the southern hemisphere because of the geometry of the orbit. Therefore, we intend to investigate with a new analysis method the topographical and local time dependency of small-scale, weak stationary features by using LIR data, which can observe all latitude regions at any local time. Though the S/N ratio of LIR is lower than VIRTIS, averaging of multiple images can suppress noises and at the same time emphasize stationary patterns. By using this method, small-scale, stationary wave trains were newly found above relatively-low topographic rises with altitudes of 1-3 km. In addition to stationary features, zonally-elongated banded structures were also found in averaged LIR images. Such structures have once been detected in LIR images taken during Akatsuki's Venus flyby in 2010 (Taguchi et al., 2012); the new analysis confirmed that banded structures are ubiquitous at the cloud top. The orientations of the banded structures are different from those of dark streaks found in ultraviolet images.

Akatsuki's IR2 Nightside Photometry Restoration by Deconvolution

*Choon Wei Vun[1], Takehiko Satoh[2,1], Kevin McGouldrick[3], Takeshi Horinouchi[4], Takao M. Sato[5]

1. SOKENDAI, 2. ISAS/JAXA, 3. University of Colorado Boulder, 4. Hokkaido University, 5. Hokkaido Information University

Akatsuki’ s IR2 camera captures images of Venus at different filters: 1.735um, 2.26um, and 2.32um. At near-dawn/dusk views (phase angles ~90 to 115 degree) of these images, the nightside photometry is contaminated by the intense dayside reflectance. As the potential well of a pixel is overfilled with incoming generated photoelectrons, the pixel is saturated and hence no longer contain information. This saturation can occur in the dayside and nightside near the terminator.
Owing to the saturation problem, main task of the restoration process is thus to simulate both day and night sides to replace the information loss in saturation. Point spread function (PSF) of the IR2 camera was modeled using Moffat function with observation of experimental image taken of point source street light before launch. Then, deconvolution by model-PSF can restore the nightside photometry of unsaturated pixels. Dayside reflectance was modeled with Lambert’ s law, where its distribution is multiplied by an F factor (W m^{-2} sr^{-1} um^{-1}). Methods of finding the F factor will be shown.
We present our Restoration by Deconvolution (RD) results of the selected dates. The restored images were limb darkening corrected. Efficiency of RD can be restored to ~0.005 sigma in standard deviation accuracy when performed on synthetic image with known answer image.
Correlation plot of unsaturated nightside radiances between two filters (2.26mm and 1.735mm) were produced to extract possible ‘branch’ phenomena. The branching in the correlation plot indicates the differences in optical depths of different particle size modes [1].
Restoration of nightside pixels also opens up the opportunity to study the cloud dynamics transiting from the dayside into the nightside. Moreover, interesting cloud features such as vortices, instabilities, and streaks are more distinct in recovered images. This in overall opens up new window to understanding the evolution of cloud motion in the middle layer.

Enormous cloud cover as seen by Akatsuki/IR2 on the night-side disk of Venus

*Takehiko Satoh[1,2], Choon Wei Vun[2], Takao M. Sato[3], Takeshi Horinouchi[4], George HASHIMOTO[5], Kevin McGouldrick[6]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. Department of Space Science, SOKENDAI, 3. Department of Business and Information Systems, Hokkaido Information University, 4. Faculty of Environmental Earth Science, Hokkaido University, 5. Department of Earth Science, Okayama University, 6. LASP, University of Colorado Boulder

Night-side observations in transparency windows of CO_2 atmosphere of Venus allow visualizing inhomogeneous clouds in ~50 to ~60 km altitudes. The IR2 camera on board Akatsuki captured such images at 1.735, 2.26, and 2.32 um wavelengths. In the IR2 night-side data, an enormous cloud of greater opacity and very sharp edge in the front (western end) is seen repeatedly. This feature seems to encircle the planet with a period of ~4.5 days (Peralta).
Although interesting, property of particles in this feature was not studied before due to difficulty of photometric measurements in IR2 night-side data. This difficulty comes from a combination of the intense day crescent and extended tail of IR2 point-spread function (multiple reflection in the detector is the cause). We have developed a technique to restore the contrast of the night-side data by deconvolution so that the photometric studies can be done with IR2 night-side data.
The data acquired on 18th and 27th August 2016 are analyzed. We have performed a series of radiative transfer computations to reproduce both 1.735- and 2.26-um opacities in this enormous cloud. Properties of the cloud partices will be presented and possible mechanism of this remarkable phenomenon will be discussed.

The global variation of Venus cloud obtained from IR1 camera onboard AKATSUKI

*Seiko Takagi[1], Naomoto Iwagami, Yukihiro Takahashi[1], Mitsuteru Sato[1]

1. Hokkaido University, Graduate School of Science

Venus is our nearest neighbor, and has a size very similar to the Earth's. However, previous observations discovered an extremely dense (92 bar at the surface) and CO_2-rich atmosphere, with H_2SO_4 thick clouds. The Venus cloud consists of H_2SO_4 main cloud deck at 47 −70 km, with thinner hazes above and below. The upper haze on Venus lies above the main cloud surrounding the planet, ranging from the top of the cloud (70 km) up to as high as 90 km. Near infrared (0.986 um) dayside image of Venus has taken by solid state imaging (SSI) of the Galileo spacecraft (NASA). It appears almost flat, there are some small scale features with a contrast of 3 %[Belton et al., 1991]. In Takagi and Iwagami. (2011), it may be calculated that the source of the contrast of the order of 3 % in near infrared Venus dayside image is due to variation in the cloud optical thickness. On December 7, 2015, AKATSUKI (JAXA) approached Venus and the Venus orbit insertion was successful. After the Venus orbit insertion, many 0.90 um Venus dayside images were taken by the 1 um near infrared camera (IR1) onboard AKATSUKI. In this study, Venus cloud variations are investigated from 0.90 um Venus dayside images taken by IR1 camera globally. Further, meteorological some changes that contribute to cloud variation are examined in using radiative transfer calculation with high altitude cloud model obtained from Venus Express/SOIR observation. Furthermore, I will introduce observation plan with PIRKA telescope of Hokkaido University.

Development of a Venus' cloud formation scheme for a convection resolving model

*Ko-ichiro SUGIYAMA[1], Nozomu Fukuhara[1], Masatsugu Odaka[2], Kensuke Nakajima[3], Masaki Ishiwatari[2], Takeshi Imamura[4], Yoshi-Yuki Hayashi[5]

1. National Institute of Technology, Matsue College, 2. Department of Cosmoscience, Graduate School of Science, Hokkaido University, 3. Department of Earth and Planetary Sciences,Flculty of Sciences,Kyushu University, 4. Graduate School of Frontier Sciences, The University of Tokyo, 5. Department of Planetology, Graduate School of Science, Kobe University / Center for Planetary Science (CPS)

Although convection has been suggested to occur in the lower part of Venus' cloud layer by some observational evidences, its structure remains to be clarified. In the previous studies, Baker et al. (1998, 2000), Imamura et al. (2014), and Lefevre et al. (2017) try to simulate Venus' cloud-level convection, but their models they utilized do not consider cloud formation process. Our purpose is to develop new cloud formation scheme and to perform numerical simulation using the scheme in order to investigate a possible structure of Venus' cloud-level convection and clouds distribution.

Our cloud formation scheme is based on Imamura and Hashimoto (1998). The number densities of sulfuric acid (H2SO4) and water (H2O) in the gas and liquid phases are calculated. Sedimentation of H2SO4-H2O solution droplets and chemical reactions of sulfuric acid are also considered. The scheme is implemented into our convection resolving model developed by Sugiyama et al. (2009). The model is based on the quasi-compressible system (Klemp and Wilhelmson, 1978), and is used in the simulations of the atmospheric convections of Jupiter (Sugiyama et al., 2011, 2014) and Mars (Yamashita et al. 2017).

In our poster, we will show the details of our cloud formation scheme and demonstrate some results of our calculation using similar settings of Imamura et al. (2014).

Zonal mean structure of Venus atmosphere observed in a Venus general circulation model with explicit radiative transfer

*Yoshi-Yuki Hayashi[1], Chisato Shiojiri[1], Hiroki Kashimura[1], Yoshiyuki O. Takahashi[1]

1. Department of Planetology/CPS, Graduate School of Science, Kobe University

Zonal mean zonal wind in Venus atmosphere is different from those in other planetary atmospheres. It is a strong prograde wind in all latitudinal ranges and is referred to as super-rotation. This unique zonal wind has been investigated by a lot of previous researchers with numerical simulations as well as ground-based and spacecraft observations. Among the studies with numerical simulations, in 2010s, Lebonnois et al. (2010) and Ikeda (2010) performed general circulation model simulations with an explicit radiative transfer model and successfully represented strong prograde zonal wind. These studies overcome a shortcoming of previous studies, in which models use Newtonian cooling as a radiative forcing.

In our group, we have been developing a general circulation model for planetary atmospheres. In addition, we have just developed a Venus radiation model, which can be used in a general circulation model. In this study, by implementing the radiation model into our general circulation model, we try to perform general circulation model simulations of Venus atmosphere and investigate the zonal mean structure of Venus atmosphere and evaluate differences between previous studies.

The general circulation model used in this study is DCPAM (http://www.gfd-dennou.org/library/dcpam/). The model is based on primitive equation system and the equation system is solved by a spectral transform method. The DCPAM includes physical processes of radiation and turbulent mixing processes. In addition, heat diffusion in soil is considered to evaluate surface temperature. The radiation model implemented into the DCPAM has also been developed in our group, and is based on a correlated k-distribution method. Radiative fluxes calculated by this radiation model are compared well with observed ones. By the use of the model, we performed two experiments with and without surface orographic variation. Resolution of experiments is T15L52, in which the model has 48 (longitude) times 24 (latitude) grids in horizontal direction and 52 layers in vertical direction. Initial conditions for those experiments are the same, and are
motionless atmospheres with horizontally uniform temperature distribution based on VIRA. With this initial condition, the model is integrated for 150000 Earth days with diurnal variation and with no seasonal variation, i.e. zero
obliquity.

Statistically steady states are achieved after about 100000 Earth days from the start of integrations. In steady state, prograde zonal winds with velocity of about 50 m/s in low and middle latitude are maintained at cloud layer in both experiments with and without orographic variation, although the velocity is about a half of that observed in Venus
atmosphere.

Meridional circulation observed in the model has large direct cells in both hemispheres. The direct cells in the experiment without surface orography have vertical extent from the ground up to top of the model, except for low latitude region just above the ground where indirect cells form. However, in the experiment with surface orography, the cells are split in the vertical direction at bottom of cloud layer. In addition to direct cells, several indirect cells are also observed in the experiments. One of those is indirect cell at

©2019. Japan Geoscience Union. All Right Reserved.

cloud layer in high latitude. Other ones are several indirect cells which extends from the ground up to bottom of cloud layer in the experiment with surface orography. These indicate that the effects of surface orography can be observed below the cloud layer, clearly.

In the presentation, results of analysis on zonal mean structure observed in the model, such as angular momentum, will also be presented.

Gravity wave packets detected in radio occultation temperature profiles of the Venus atmosphere

*Ryota Mori[1], Takeshi Imamura[1], Javier Peralta[2]

1. The University of Tokyo, 2. Japan Aerospace Exploration Agency

Temperature profiles has been obtained from 2016 by the radio occultation experiment in the Venus orbiter mission Akatsuki. The radio occultation experiment is a method that measures the change of the atmospheric refractive index as a change of the frequency of the signal received on the ground. At the opportunity when the radio wave transmitted from Akatsuki toward the Earth pass through the planetary atmosphere, the wave is refracted and then reaches the receiving station. We can retrieve the vertical profiles of the pressure and the temperature from each refractive index profiles. In the temperature profile obtained in this way, variations due to various atmospheric disturbances are observed. We focus on gravity waves which are thought to play an import role in driving the general atmosphere circulation.

Gravity waves are small-scale waves with the restoring force being the buoyancy in the atmosphere. Gravity waves play a role in carrying the momentum in the vertical direction. So, it results in acceleration or deceleration of the mean wind by passing momentum on the background atmosphere while dissipating. This process should affect the global structure of the high-speed zonal wind. However, since gravity waves have properties that the spatial scale is small and the wave period is relatively short, it is difficult to capture the spatial structure by observation. The latitudinal profile of the amplitude of short vertical-scale temperature disturbances, which are thought to be associated with gravity waves, has been investigated; however, the dominant wavelength and the typical vertical extent have not been studied.

In this study, we applied wavelet analysis to the temperature profiles and extracted spatially localized temperature disturbances. Though there have been studies that apply Fourier transform to the temperature data, Fourier transform assumes infinitely lasting waves and it is not suitable for extracting spatially localized wave packets. Wavelet analysis is an effective way of obtaining the periods and the amplitudes of waves in such finite intervals. In this presentation, we report the result of wavelet analysis applied to the temperature data obtained with high vertical resolution by radio holographic method. From the obtained results, we also report the relationship between the length and the packet length of gravity wave in the atmosphere.

Status of lightning hunt in Venus with Akatsuki/LAC and Pirka telescope

*Yukihiro Takahashi[1,2], Mitsuteru Sato[1,2], Masataka Imai[3], Ralph Lorenz[4], Seiko Takagi[1,2], Ono Tatsuharu[1]

1. Graduate School of Science, Hokkaido University, 2. Faculty of Science, Hokkaido University, 3. National Institute of Advanced Industrial Science and Technology,, 4. Applied Physics Laboratory, Johns Hopkins University

The existence of lightning discharge in Venus has been controversial for three decades, which might be attributed to the luck of conclusive observational evidence. There had been no satellite payload intentionally designed for the detection of lightning phenomena using radio wave or optical sensor. LAC, lightning and airglow camera, on board Akatsuki spacecraft, is the first sensor optimized for the lightning optical flash measurement in planets other than the Earth. It is expected that LAC could conclude this 30-year discussion on the existence of lightning in Venus. Unique performance of LAC compared to other equipment used in the previous exploration of Venus is the high-speed sampling rate at 20 kHz with 32 pixels of Avalanche Photo Diode (APD) matrix, enabling us to distinguish the natural optical lightning flash from other pulsing noises, including artificial electrical noise and cosmic rays. We selected OI 777 nm line for lightning detection, which is expected to be the most prominent emission in CO2-dominant atmosphere based on the laboratory experiments.

The triggering parameter was set so as to optimize for the light curve similar to the normal lightning in the Earth and data obtained totally for about 4 hours were examined. However, we couldn’ t find any lightning signals. Adding to this triggering parameter set, we added one more parameter set, optimized for sprite type emission with duration of up to 10s of ms. Furthermore, in order to investigate fainter emissions, we are now conducting successive force triggering recordings without any threshold, achieving 5 times better sensitivity than the intensity of 1 digital unit at best.

The total coverage of the LAC lightning hunt became 81.6 [million km2-hr], meaning 81 percent detectability of previous results with ground-based telescope by Hansell et al. (1995). Here we report the detailed strategy and the latest status of the LAC observation in 2018, and discuss the future observation plan.

Also we will make ground observation with a high-speed photometer installed at Pirka telescope, a 1.6-m reflector deployed by Hokkaido University. Here we report the initial results of lightning flash observation with it.

Possibility of electric discharge in the Venusian atmosphere due to the super-rotation of clouds

*Adhithiyan Neduncheran[1], Ugur Guven[1,2], Ananyo Bhattacharya[3]

1. University of Petroleum and Energy Studies, India, 2. United Nations Centre for Space Science and Technology Education in Asia and the Pacific, 3. Sardar Vallabhbhai National Institute of Technology,India

Several evidences of electromagnetic bursts were measured by various landers and orbiters studying Venus atmosphere (Venera landers, Venus Express and the Pioneer Venus Orbiter). The electromagnetic bursts that are taking place in the cloud region in the form of lightning or fluorescence might be a result of momentum transfer, solar convection and charge dispersion in the clouds of Venus. While the lightning in Earth takes place mostly in the equatorial region, in case of Venus it is possible for lightning to occur in the polar regions, considering the kinetic energy transfer and the formation of dipoles in both hemispheres of Venus. The meridional and zonal flows can interact and cause the charge separation which possibly lead to electromagnetic bursts in different spectrum and in different regions in Venus. In labs, it is observed that SO2 emissions in UV region cause fluorescence which is one of the major phenomena taking place in the cloud tops. Based on the photochemical model published by *Krasnopolsky 2011(*doi:10.1016/j.icarus.2011.11.012) and the principle of refraction, we present the possibility of lightning/fluorescence phenomena being caused by the super-rotation of the clouds in the Venusian atmosphere.

Graduate School of Science, Kyoto University

We are conducting a 1.8-m aperture off-axis telescope project PLANETS under international collaborations. In this presentation, we report the current status of PLANETS project and our scientific targets, and also promote use cases in other research fields in astronomy and planetary/exoplanetary sciences. PLANETS is characterized by low-scattering and high-contrast capability thanks to off-axis mirror system, and also by monitoring observation. We mainly concern variations in planetary atmospheres, faint gases produced from satellites, exoplanetary atmosphere, and also welcome other targets that match to the advantages of PLANETS. Continuous monitoring is essential to understanding the planetary atmospheric phenomena, and therefore, own facilities with even small- and medium sized telescopes and instruments are important. We have demonstrated that continuous monitoring is effective for understanding planetary and satellite phenomena using small telescopes at the summit of Mt. Haleakala, Hawaii (3050 m altitudes). We are now operating 40 cm (T40) and 60 cm (T60) telescopes at Haleakala combined with high-resolution spectrometers in visible and infrared ranges to observe faint atmospheric emissions/absorptions, such as plasma and neutral torus produced by Jupiter’s satellite Io, neutral torus produced by Saturn’s satellite Enceladus, gases in Venus and Mars, sodium gasses of Mercury, and so on. The polarization imager DIPOL-2 is also installed to measure the weak polarization of exoplanetary light. Our and guest investigators’ observations are also linked to Mercury, Venus (Akatsuki), Mars (Mars Express, MAVEN) and Jupiter (Juno) missions.
To achieve precise spectroscopy and polarimetry for faint emissions/absorption in planetary/exoplanetary atmospheres and satellites, PLANET’s a 1.8-m aperture with low-scattered light optics is necessary. PLANETS project is managed by the PLANETS Foundation (www.planets.life), which is an internationally organized entity whose board members are from several institutes in Japan, USA, Germany, Brazil, and France. This off-axis optical system brings us unrivaled high-dynamic range scientific capabilities on coronagraphy and polarimetry. It will have a Gregoian focus with a FOV of 6' (Fno=13) and a Coude focus with a FOV of 20" (Fno=49). The main mirror is Clearceram Z-HS with a diameter of 1850 mm, which is now on the final polishing process. We are designing mechanical structure of telescope for both cases of equatorial mount and azimuthal-elevation mount. We are also designing a mirror support structure in two ways, active support and passive support. We are aiming to get first light with PLANETS telescope within next several years.

Martian Moon eXploration MMX: science objectives and their promotion

*Kiyoshi Kuramoto[1,2], Yasuhiro Kawakatsu[2], Masaki Fujimoto[2], Jean Pierre Bibring[3], David Lawrence[4], Hidenori Genda[5], Naru Hirata[6], Takeshi Imamura[7], Shingo Kameda[8], Koji Matsumoto[9], Hideaki Miyamoto[7], Tomokatsu Morota[10], Hiroshi Nagaoka[2], Hiromu Nakagawa[11], Tomoki Nakamura[11], Kazunori Ogawa[12], Hisashi Otake[2], Masanobu Ozaki[2], Sho Sasaki[13], Hiroki Senshu[14], Shogo Tachibana[7,2], Naoki Terada[11], Tomohiro Usui[2], Koji Wada[14], Sei-ichiro WATANABE[10], MMX study team

1. Hokkaido Univ., 2. JAXA, 3. IAS, 4. APL, 5. ELSI, 6. Aizu Univ., 7. Univ. of Tokyo, 8. Rikkyo Univ., 9. NAOJ, 10. Nagoya Univ., 11. Tohoku Univ., 12. Kobe Univ., 13. Osaka Univ., 14. Chiba Inst. Tech.

Martian Moons eXploration, the next Japanese sample return mission following Hayabusa 2, is under extensive study for the upshift to phase B with a schedule to be launched in 2024 and return to Earth in 2029. MMX will make close-up observations of Phobos and Deimos over ~3 years and sample return from a moon, from which the origin of the Martian moons will be conclusively revealed. Simultaneously, the formation and evolution of a habitable planet having liquid water and atmosphere will be elucidated from the deep search for both moons and parallel Mars atmosphere observations, by making the best use of the inherent nature of the moons that have long history since the formation stage of Mars and orbits near the parent planet. Particularly, MMX will shed light on the formation and early evolution of Mars and the volatile transport from the outer planet region to inner one in early solar system, which are hardly assessed from the survey of Martian surface geology alone. Mission instruments to be on board are telescope camera (TENGOO), multiband visible camera (OROCHI), infrared spectroscopic imager (MacrOmega), gamma-ray and neutron spectrometer (MEGANE), light detection and ranging (LIDAR), dust monitor (CMDM), ion mass spectrum analyzer (MSA) and sampler. A rover is also under study as an additional science instrument to probe the moon’s surface microscopic structure and composition. To achieve the mission science objectives, it is essentially important to conduct close interplay among analyses of data from multi-instruments, sample analyses, and theoretical studies. To traverse the instrument development teams and data analysis, sample analysis and theoretical scientists, the MMX science board is going to be organized the sub-science teams, which will produce the best initial scientific results fully answering the mission objectives and conduct preparations for observations, data analyses, sample analyses in parallel with theoretical studies.

Implantation of Martian Materials in the Inner Solar System by a Mega Impact on Mars

*Ryuki Hyodo[1], Hidenori Genda[1]

1. Tokyo Institute of Technology, Earth Life Science Institute

The rare asteroids, called A-type asteroids, orbit within the Hungarian region and within the main asteroid belt region. They have olivine-rich spectral features [DeMeo&Carry 2013]. Their origin is still under debate even though some could be mantle materials fragmented and ejected by a catastrophic impact of differentiated primordial asteroid [Sanchez et al. 2014]. On the other hand, olivine is a major mineral of the Martian upper mantle with ~60 wt% [e.g. Bertka&Fei 1997, Zuber 2001]. Also, at the surface of Martian grabens, such as Nili Fossae, an olivine-rich signature is detected [Hoefen et al. 2003, Mustard et al. 2009].

Recent studies showed that a giant impact may occur on Mars and it produced Mars-orbiting debris from which Martian moons, Phobos and Deimos, acreete [Rosenblatt et al. 2016, Hesselbrock&Minton 2017, Hyodo et al. 2017, Canup&Salmon 2018]. Recently, Polishook et al. (2017) suggested that such Martian-moon forming impact may also produce debris that escapes from Mars' gravitational field, and some of them may have delivered to the asteroid region. However, quantitative arguments such as mass, composition and orbits of the impact ejecta have been not studied yet.

In this talk, we will present our recent work [Hyodo&Genda 2018, ApJL] that investigated the compositional and thermodynamic properties of the impact ejecta produced by a giant impact that forms Martian moons [Hyodo et al. 2017]. We also present their mass and heliocentric orbits and discuss the possibility of forming rare A-type asteroids.

We perform high-resolution SPH simulations of Mars' giant impact (impactor mass of ~0.03 mass of Mars, impact velocity of ~6 km/s and impact angle of 45 degrees without pre-impact Martian spin). We found that the giant impact produced the following escaping debris [Hyodo&Genda 2018, ApJL]:

1. Mass of ~$10^{-2}M_{Mars}$
2. ~20wt% originates from Mars and the rest originates from the impactor
3. ~50% of the Martian material originates from Martian mantle (between 50 and 200 km in depth)
4. Temperature ranges between 1000 and 4000K with a peak around 2000 K

Assuming the Mg# (=Mg/(Mg+Fe) in mol) of bulk silicate Mars of ~75% [Elkins-Tanton et al. 2003] and thus ($Mg_{0.75}$, $Fe_{0.25}$) SiO_4olivine solid solution as a major mineral of the Martian upper mantle, solidus and liquidus temperatures are about 1850 K and 2000 K [Bowen&Schairer 1935]. Then, using our SPH simulations, we found that ~10% of escaping Martian mantle debris does not melt but ~70% of the debris completely melts. In the case of partial melting (2000 K), ~20% of the Martian mantle debris avoids melting and thus they would preserve their primitive minerarogy. Hence, the unmelted Martian mantle material (olivine-rich material) is estimated to be about ~2% of the total ejected mass (~1.7×10^{20}kg). This mass is much larger than those of current A-type asteroids found in the Hungarian region (~2.8×10^{15}kg) and the current main asteroid belt (~8.9×10^{18}kg).

The orbits of the ejected particles are distributed between ~0.5-3.0 AU with eccentricity upto ~0.6 and

©2019. Japan Geoscience Union. All Right Reserved.

inclination up to ~0.3 radian. Detailed stidues on the long-term evolution of the debris is required but the initial orbits of the debris shows that they can easily reach the asteroid belt region and thus unmelted Martian mantle material (a maximum of ~2% of the total debris mass) is potentially expected to settle into stable orbits as rare A-type asteroids found in the Hungarian and main asteroid belt regions.

We also expect that the debris hit the pre-existing asteroids with impact velocity larger than 5 km/s. The nominal collision velocity between existing asteroid is ~5km/s [Bottke et al. 1994]. Such high-velocity collision between the debris and pre-existing asteroid may record a reset of ^{40}Ar–^{39}Ar age and/or impact melts [Kurosawa&Genda 2018] and thus the timing of the giant impact on Mars may be recorded in some chondrite.

Hydrodynamic escape of a reduced proto-atmosphere on early Mars

*Tatsuya Yoshida[1], Kiyoshi Kuramoto[1]

1. Hokkaido University

The short growth time of proto-Mars inferred from analyses of Martian meteorites implies that the proto-Mars likely gravitationally maintained both the solar nebula component and the impact degassed component as a proto-atmosphere. Planetary building blocks containing metallic iron should induce production of reduced volatiles such as H_2, CH_4 and CO because metallic iron acts as a reductant for the degassed component (Kuramoto and Matsui, 1996). Atmospheres with reduced compositions are promising sites for photochemical production of organic matters precursory for life (Schlesinger and Miller, 1983). If a reduced proto-atmosphere was formed and maintained on early Mars, it may be important as a field for synthesis of organic matters linked to the emergence of life organisms.

However, the reduced proto-atmosphere once possibly formed on a rocky planet has been considered to be rapidly lost by hydrodynamic escape. Hydrodynamic escape occurs when radiative heating of an atmosphere accelerates a radial outflow of an atmosphere against the planetary gravity and it is possibly induced by the extreme ultraviolet (EUV) flux of the young Sun. Previous numerical studies (Lammer et al., 2013; Erkaev et al., 2014) estimate the atmospheric escape rate of an oxidized Martian proto-atmosphere, suggesting that the proto-atmosphere with the amount equivalent to ~100 bar could have been lost per 10 Myr under the EUV flux 100 times the present. But their result likely depends on the assumption that molecules are fully dissociated into atoms. Since the gravity on Mars is small, it is likely that a considerable fraction of molecules stays undissociated in the escape outflow. If infrared active molecules are included in the atmosphere, they may reduce the atmospheric escape rate by radiative cooling. If the atmospheric escape rate decreases, the reduced environment that is suitable for producing organic matters likely continues for a long time. So far, the effect of radiative cooling on hydrodynamic escape remains poorly understood. Here, we develop a one-dimensional hydrodynamic escape model which include radiative cooling processes and photochemical processes for a multi-component atmosphere. We calculate the escape rate of a reduced Martian proto-atmosphere and estimate the duration of the reduced environment on early Mars.

We solved the fluid equations for a multi-component gas assuming spherical symmetry considering radiative processes and photochemical processes. These equations are solved by numerical integration about time until the physical quantities settle into steady profiles. We use the UV spectrum 100 Myr after the birth of the Sun estimated by the observations of solar-type G stars. We consider CO and CH_4 as radiative coolant, and consider their energy transitions with high emissivity. We calculate the radiative cooling rate by using the photon escape probability. In this modeling, a hybrid-type atmosphere in which the degassed component and solar nebula component are mixed is supposed with 18 chemical components including photolysis products.

The mass escape rate decreases more than one order as the mixing fraction of CO and CH_4 increases > 10% because of the energy loss by radiative cooling of CO and CH_4. Concurrently, the mass fractionation between H_2 and other heavier species occurs more remarkably. Time scale for H_2 loss may be longer than 100 Myr when the the degassed component is larger than ~1.0×10^{21} kg equivalent to ~100 bar atmosphere. In many simulation cases, CO and CH_4 are left behind implying that the reduced environment further continues until these reduced species are oxidized by photolysis. Our result suggests

©2019. Japan Geoscience Union. All Right Reserved.

a reduced environment on early Mars may have continued more than 100 Myr and played an important role producing organic matters.

Orbital evolution of Martian moons by rotating Martian proto-atmosphere with low angular momentum

*Ryo Matsuoka[1], Kiyoshi Kuramoto[1]

1. Department of Cosmosciences, Graduateschool of Science, Hokkaido University

Martian moons, Phobos and Deimos has radii about several km to 10 km, and irregular shapes. Their low albedos and reflectance spectra are similar to those of primitive carbonaceous asteroid which supports “capture scenario” for their origin.

In previous studies considering the capture due to energy dissipation by gas drag from the Martian proto-atmosphere caused by the gravitational bound of the nebula gas, it is possible to circularize the moons’ orbit (Hunten 1979, Sasaki 1990). While this spherically symmetric atmospheric structure can make moon’s orbit circular, it is impossible to attenuate the orbital inclination of the moon. Also, the satellite constantly receives atmospheric drag and cause moons to fall into Mars eventually. Although the giant impact theory (e.g. Rosenblatt+ 2016) explains such moons’ orbital feature, it is difficult to form moons with carbonaceous composition because of high temperature environment during moon formation. On the other hand, in context of capture scenario, Matsuoka & Kuramoto (2018, JpGU) considered the atmospheric rotation and showed that the attenuation of inclination occurred and the orbital shrinking was inhibited. However, since this atmosphere has extremely large angular momentum (1.3 times the Martian spin anugular momentum) due to Keplerian rotation beyond the co-rotational radii, thus it seems difficult to realize to form. Also, there is a problem that moons are formed and stay beyond Deimos’ orbit. In this study, we construct models of rotating atmosphere with much small anugular momentm and show that it is more advantageous in explaining the orbital features of the current Martian moons.

This study assumed that atmospheric rotation is limited within the Bondi radii and the velocity field is modeled as follows so that the rotational velocity becomes continuous by changes with distance. (1) Mars surface to co-rotational radii R_C: co-rotational atmosphere with Mars’ spin. (2) co-rotational radii to Bondi radii R_B: attenuated atmospheric rotation with distance given by $v(r)=((R_B-r)/(R_B-R_C))^{\Gamma} v_K(r)$ (v_K is a Keplerian velocity, Γ is a constant which we set unity in this study). (3) Bondi radii to Hill radii: stationary atmosphere connecting nebula at Hill radii. Such atmosphere can be regarded as a case that has not enough angular momentum to make Keplerian rotation outside the co-rotational radii. The density field of the atmosphere was determined by the balance of centrifugal force by this velocity field, Mars gravity and pressure gradient, and the drag force by these velocity field and density field were given to the equation of motion of moons. This atmosphere has low angular momentum of only 0.14 % of the Martian spin angular momentum.

In numerical experiments, moons have the inward radial velocity component in all regions, but the orbital shrinkage is suppressed near the co-rotational radii due to small speed difference between moons and atmosphere. The typical timescale of attenuation of semi-major axes of Phobos size moons is the order of 10^4 yr or more. This timescale sharply increased as approaching the co-rotational radii, indicating that the moons stay well in this region. This result naturally explains the initial position near the co-rotational radii of moons before tidal orbital evolution. Since there is a speed difference between moons and the atmosphere even if the inclination takes small value, the attenuation of inclination occurs efficiently. In contrast to timescale of inclination decay derived in our previous study that is rapidly increasing with the

©2019. Japan Geoscience Union. All Right Reserved.

decay of inclination, timescale derived in this study has an upper limit of several thousand years for a Phobos size moon. This result explains small orbital inclination of the current Martian moons. Such tendencies are recognized in the same way when Γ has different positive values, and in the cases of the Deimos size moons, such orbital evolution occur more rapidly than those of Phobos size moons.

N-body simulations of Moon formation with cooling evolution of the protolunar disk

*Takanori Sasaki[1], Natsuki Hosono[2]

1. Department of Astronomy, Kyoto University, 2. Japan Agency for Marine-Earth Science and Technology

The previous studies about Moon formation focused on the first and last stages: the giant impact process (~1 day) has been investigated by SPH simulations, and the lunar accretion process (~1 month) from the circumterrestrial particulate disk has been investigated by N-body simulations. Although the Moon formation process should proceed on the cooling timescale of the protolunar disk (~100 years), there has been no study to simulate the long-term evolution of the disk. In this study, we developed an N-body code to simulate the cooling evolution of a protolunar disk in vapor/melt equilibrium, and executed long-term N-body simulations for the disk evolution and lunar accretion processes simultaneously with PEZY-SC processors. Our result showed that "mini-Moons" system would form instead of forming a single Moon.

Possibility of giant planet formation by pebble accretion in Class 0/I YSOs

*Yuki Tanaka[1], Yusuke Tsukamoto[2]

1. Tokyo Institute of Technology, 2. Kagoshima University

Recently, pebble accretion in protoplanetary disks attracts attention in theoretical works of planet formation. In this process, it is thought that cm-sized particles, so-called pebbles, drift inward in the disk, and growth of planets will be accelerated due to accretion of pebbles onto proto-planets. Various theoretical works which assume pebble accretion, such as giant planet formation and formation of super-Earths systems, have been done so far.

Meanwhile, recent radio observations by ALMA have revealed that existence of clear gaps and rings in many very young protoplanetary disks. Mechanisms to generate these structures of gaps and rings are yet to be investigated, and many theoretical models have been proposed. One of these hypotheses is that gas giants in the disks carve gaps in the dust disks and create such structures. Numerical simulations which assumed the existence of the planet have been shown that gaps and rings similar to the observations can be represented. However, a time-scale for planet formation will be long because the observed radii of gaps and rings are relatively large, so it is unclear whether the planet with enough mass to create a gap can form in very young disks.

Here we focus on planet formation in much earlier stages, Class 0/I phases. Combining an analytical model of a gravitationally unstable disk around Class 0/I YSOs with a model of pebble accretion, we investigate possibility of giant planet formation in the early stages of disk evolution. We find that in many cases a time-scale of pebble accretion in the condition of Class 0/I YSOs is much shorter compared to that in a typical protoplanetary disk, because of larger mass accretion rates. We also find, however, the accretion time-scale is not always a decreasing function of the gas accretion rate, and the time-scale can be longer as the increase of the gas accretion rate depending on parameters. Using derived time-scales, we investigate growth of proto-planets with different parameters such as the gas accretion rate and dust-to-gas mass ratio. Based on our results, we discuss a required initial mass of the proto-planets to form cores of the giant planets within Class 0/I phases.

The effect of the three-dimensional gas flow around an embedded planet on pebble accretion

*Ayumu Kuwahara[1], Hiroyuki Kurokawa[2]

1. Tokyo Institute of Technology, 2. Earth-Life Science Institute

Pebble accretion is a new model of planet formation, which may overcome several problems remaining in conventional planetesimal accretion theory. Accreting mm—cm-sized particles, called pebbles, onto the proto-cores can form the massive cores faster than accreting the planetesimals. In addition to the formation of the Jovian cores in a realistic timescale, pebble accretion scenario can explain the formation of various types of planets—for instance, close-in super Earths, water-rich planets, and the size distribution of terrestrial planets in the solar system. The key point of this scenario is that the pebbles experience not only the gravitational interaction with the proto-cores but also gas drag. The hydrodynamic effect is important when we consider the planet formation via pebble accretion.

Previous works have found the three-dimensional flow field around an embedded planet. Gas from the protoplanetary disk enters the Bondi or Hill sphere of the planet at high latitude and exits through the mid-plane region in the isothermal condition (Kuwahara et al. 2019). This recycling mechanism may have both positive and negative effect on the accretion of solid materials. When the particles are moving in the region at high latitude of the planet, the accretion may be promoted by the inflow of gas. On the other hand, if the particles are in the mid-plane region, the accretion of the particles can be suppressed by the outflow barrier. Though some studies considered the accretion of dust particles in the realistic flow field (Ormel 2013; Popovas et al. 2018ab), the effect on the accretion efficiency is not fully understood. This study aims to understand the hydrodynamic effect and to obtain the accretion efficiency of particles for the range of planetary masses and particle sizes.

In this study, using the numerical data obtained from three-dimensional hydrodynamical simulations, we numerically integrated the equation of motion of pebbles including the gravitational interactions and gas drag under the influence of the flow field in three dimensions. We also performed the similar calculations on the Keplerian shear flow field without the effect of planet gravity on the flow, then investigated how the description of the pebble accretion changed on the flow pattern, pebble size, and dimensionless planetary mass, $m=R_{\mathrm{Bondi}}/H$, where R_{Bondi} and H are the Bondi radius of the planet and disk scale height, respectively.

In the flow field, we found that the description of pebble accretion differs from that of in the Keplerian shear flow. Pebbles at high altitude tend to descend toward the planet because of the downward stream of gas. The accretion rate of pebbles became smaller than in the Keplerian shear flow. In spite of the pebbles descend toward the planet, the accretion of pebbles can be suppressed because of the effect of the flow field. Since the gas flows rapidly in the vicinity of the planet, the gas flow field deflects the trajectories of the pebble in the vicinity of the planet and reduces its accretion rate. The flow field has the stronger effect on the smaller pebbles. Based on these results, we will discuss the implications for planet formation via pebble accretion.

Icy pebble accretion onto terrestrial planets: the effect of gas flow

*Hiroyuki Kurokawa[1], Ayumu Kuwahara[2], Satoshi Okuzumi[2]

1. Earth-Life Science Institute, Tokyo Institute of Technology, 2. Tokyo Institute of Technology

Earth, the only life-hosting planet we know, is characterized by the small water fraction in the bulk composition: the ocean mass being 0.023% of the Earth mass. Because the abundance of water control the physical and chemical evolution of planets by atmosphere-hydrosphere-lithosphere interactions and by changing the mantle properties, unveiling how water-depleted planets form is crucial for understanding the emergence of habitability on them. Pevious studies have pointed out that icy pebble accretion following the snow line migration in protoplanetary disks typically deliver an excess amount of water to terrestrial planets unless the initial size of the disk is small (30--50 au) or a giant planet in the outer orbit (e.g., Jupiter in our solar system) formed early (Morbidelli et al. 2016; Sato et all. 2016; Ida et al. 2019). In contrast to the previous studies where the accretion rate derived for pebbles moving in (sub-) Keplerian flow, we used the accretion rate derived for pebbles moving in the gas flow perturbed by the gravity of the planet (Kuwahara et al. 2019; Kuwahara et al. in prep.). The presence of horseshoe region and outflow shuts off the accretion of small pebbles. We show that, because migrating icy pebbles at ~1 au are small, the gas flow significantly suppress the accretion onto Earth-sized planets, whereas Mars-sized planets accretes a significant amount of icy pebbles. Our results suggest that Earth-like, water-depleted rocky planets may form in a disk-size range wider than previously considered and in the systems where no giant planet exists.

Delivery of ammonia ice to Ceres by pebble accretion

*Yuto Nara[1], Satoshi Okuzumi[1], Hiroyuki Kurokawa[2]

1. Tokyo Institute of Technology, 2. Earth-Life Science Institute, Tokyo Institute of Technology

Recent studies with the spectrometer onboard the Dawn spacecraft detected the presence of ammoniated phyllosilicates on the surface of Ceres. It is presumed that ammonia may have reacted with the phyllosilicates on Ceres during differentiation. Ammonia can not exist alone as a solid in the current temperature at the location of Ceres. It has yet to be shown how ammonia is delivered to Ceres.

In this study, by adopting a theory "Ceres formed a protoplanetary core around the current main asteroid belt and accreted ammonia-bearing ice pebbles there", we aim to give constraints on the free parameters of the protosolar nebula. We numerically calculate the growth and radial inward drift of icy dust particles, and the evolution of the surface density of the gas flow and the disk temperature in a viscous disk. We employ a formula of pebble accretion presented by a previous study to quantify the amount of ammonia-bearing ice pebbles delivered to asteroids at 2.8 au.

We find that when the free parameters of the protosolar nebula satisfy certain conditions, Ceres accretes ammonia-bearing ice pebbles with ~ 10 –100 km thickness on its surface by pebble accretion. This result can explain the observations that there is ~ 15km of relief with craters on the surface of Ceres, and the ammoniated phyllosilicates on its surface were formed globally. In our result, we support the disk model with strong turbulence. Moreover, we suggest if ammoniated phyllosilicates come from pebble accretion, the amount of ammoniated phyllosilicates on planets' surface strongly depends on accreting planet masses.

Volatile-driven cryovolcanic eruption on asteroid Ceres as a probe to its interior

*Koki Yumoto[1], Yuichiro Cho[1], Seiji Sugita[1]

1. Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo

Introduction: Imageries from NASA's DAWN mission revealed the presence of localized bright spots (or faculae) exhibiting brighter materials with likely composition of anhydrous sodium carbonate (De Sanctis et al., 2016) within the dark Ceres surface. These materials are assumed to be remnants of cryovolcanic ejecta which ascended from brine reservoirs thorough impact induced fractures. Quick et al., (2018) showed that excess pressure caused by the gradual freezing chamber could be a driving source for its ascent. However, DAWN image revealed the presence of both explosive (e.g. Vinalia faculae) and effusive (i.e. Cerealia facula and Ahuna Mons) eruptions, implying the possibility that fragmentations of cryomagma are induced by exsolved volatiles and this could be a primal driving source.
Objectives: Volatile exsolution are known to play an important role in ascent dynamics of silicate volcanism, and it enables ascent of relatively high density cryomagmas, but their contributions to cryovolcanism are not well understood. This study attempts to obtain new constraints on the properties of a subsurface brine reservoir and conduit geometry based on phase equilibria and model calculations.
Model: The equilibrium composition of CO_2-H_2O-NaCl system by Akinfiev & Diamond (2010) was used as the cryomagma composition. The cryomagma is assumed to have a viscosity of 10^5-10^8 Pa s (Quick et al., 2018), and this slurry-like rheology constrains the temperature within the solidus and liquidus curves along decompression. If we assume ascents to be isothermal at velocity $>10^{-3}$ m/s (Quick et al., 2018) and salinity lower than the stability region of hydrohalites, then the temperature of cryomagma should be within ~260 - 270 K, consistent with impact simulation (Bowling et al., 2018), and salinity <~20 wt%. One-dimensional 2-phase (i.e. cryomagma and exsolved gaseous volatile) steady flow in a cryovolcanic conduit was modelled with the theory developed by Kozono & Koyaguchi (2009) for terrestrial volcanoes. Major modifications in our model were, adjustment of the henry's law, application of choking condition at the surface, and the liquid stability of CO_2. The depth, volatile content, viscosity of brine reservoir, and conduit radius were constrained from the estimated explosive eruption velocity of Vinalia faculae 26 - 54 m/s (Quick et al., 2018) derived from its emplaced radius.
Result and Discussion: Calculation results indicated that for a given viscosity (e.g, 10^5 Pa s), a series of combinations of conduit radius and volatile content, ranging from 10 m and 4 - 7 wt% to 50 m and 0.8 - 3 wt%, 200 m and 0.7 - 3 wt%, can achieve the above eruption velocity. Note that plausible conduit radii should lie within 1 - 100 m (Fagents 2003) and robust upper limit is given by observed radii of vent-like feature ~200 m. We found that reservoir depths have little influence on eruption velocities. For a given viscosity (10^6 Pa s), similar combinations of conduit radius and volatile content ranging from 50 m and 2 - 3 wt% to 200 m and 0.7 - 3 wt% can achieve the eruption velocity. Although higher viscosity $>10^7$ Pa s can achieve similar eruption velocity when a larger conduit radius >100 m is assumed, such large conduits are not consistent with estimations (Quick & Marsh, 2016). Results for explosive eruptions experienced fragmentation at >100 m depth and showed that volatiles could drive the ascent and cause fragmentation of cryomagmas. If effusive eruptions occurred from the same reservoir, conduit radii should be <1 m. However, the probable abundance of such conduits is inconsistent with the lack of effusive eruptions on Ceres and thus could have formed differently, such as diapiric ascents (Buczkowski et al., 2018). Our model calculations showed that cryomagmas could be volatile-driven and may cause fragmentations to erupt explosively. Also, constraints from our calculation showed that Ceres subsurface could be volatile-rich than previously assumed.

Ice sheet formation on synchrnously rotating earth-like planets in M-dwarf abitable zones

Soma Arai[1], Kiyoshi Kuramoto[1], *Masaki Ishiwatari[1], Shunichi Kamata[1]

1. Department of Cosmosciences, Graduate school of Science, Hokkaido University

It is considered that terrestrial planets near M-dwarf are synchronously rotating (Von Bloh et al, 2007). Some of such planets exist in the habitable zone defined by vertical one-dimensional atmospheric models and are expected to have liquid water on their surface. However, in synchronously rotating planets, there is a possibility that all of liquid water are lost since water vapor transported form warm day-side to cold night-side is condensed on night-side surface as ice. In order to examine this problem, Menou (2013) conducted atmospheric general circulation model (AGCM) experiments using a synchronously rotating planet configuration with surface water of 50m depth. He estimated ice sheet thickness formed on the planet surface based on the calculated amounts of precipitation and surface evaporation. The result is that the amount of ice sheet on night-side can reach the all amount of surface water given to the planet. In his estimation, GCM results obtained without topography were utilized. Since surface height will change according to the growth of ice sheet, atmospheric circulation are influenced by topography of ice sheet and distributions of precipitation and surface evaporation are also changed. Therefore, the ice sheet thickness can be different from the values estimated by Menou (2013). In this study, in order to consider the effect of the topography produced by ice sheet formation in the night-side, we perform GCM experiment with changing surface height distribution.

The model utilized is DCPAM5(https://www.gfd-dennou.org/library/dcpam/). Atmospheric constituents and parameters such as planet radius are same as those of Earth. We perform two kinds of experiments: one is aqua-planet experiment in which all surface are covered with water or ice, the another is land-planet experiment in which initial water of 20cm depth is given to day-side surface and water transport on the surface is neglected. In land-planet experiment, surface liquid water distribution is determined by atmospheric transport. The value of surface albedo is fixed to 0.15. First, integration for 1500 days with no topography is performed, then thickness of ice sheet is prognosed with considering melting of ice at the bottom of ice sheet and condensation of ice on the surface calculated from distributions of precipitation and surface evaporation. Then, using the horizontal distribution of surface height estimated by the above method, integration for 1500 days is performed and ice sheet height is prognosed again. With repeating these procedures, we search for equilibrium states in which ice sheet thickness becomes constant in time. The results of land planet experiment show that an equilibrium state with ice sheet over 4000m height can be obtained. Contrary to this, in aqua-planet experiment, equilibrium state are not been obtained in our experiment. Ice sheets with height over 10000m are formed in the night-side, although the value of ice sheet height is transient. The result of the experiment with topography determined by the above estimated ice sheet height show that day-side surface temperature become lower than 273K, and therefore, globally ice-covered state can emerge. As for the reason, we consider that day-side surface is cooled by cold air blowing from night-side with high elevation to day-side with low elevation. Since albedo change due to the ice sheet formation is neglected in our experiments, our result suggests that the atmospheric circulation influenced by ice sheet topography can produce globally ice-covered state.

Three-dimensional linear calculation for non-isothermal type 1 planetary migration

*Kohei Okada[1], Hidekazu Tanaka[1]

1. Tohoku University

Planet migration is one of the serious problems in the standard theory of planet formation. A planet excites density waves, that causes a rapid inward migration in a protoplanetary disk. In this study, we formulate the linear wave excitation by a planet in three-dimensional non-isothermal gaseous disks and calculate the torque on the planet more correctly than previous studies.
The torque on a planet has been studied by linear and non-linear calculations. In previous three-dimensional linear calculations the torque was calculated only for isothermal disks. This is because the three-dimensional linear equation has the term that is strongly divergent at corotation in non-isothermal disks. This problem has not been resolved yet and we cannot test non-linear three-dimensional calculations with linear calculations.
In linear studies of gravitational interaction between a planet and a three-dimensional gaseous disk, there are two-dimensional waves that do not have the z-component of velocity and three-dimensional waves that have non-zero v_z. Only three-dimensional waves have a divergent term but it is known that the absolute values of the torque in three-dimensional waves are much small than those of two-dimensional waves in the isothermal disk. In this study, therefore, we ignored three-dimensional waves and examined the torque on a planet in three-dimensional non-isothermal disk approximately. Actually since there is no sign of divergent in previous non-linear hydro-dynamical simulations, this approximation seems good.
With this approximation, we carry out the three-dimensional non-isothermal linear calculation. The obtained torque coincides with non-linear three-dimensional hydro-dynamical simulations. Because of this, we confirmed that our three-dimensional linear calculation is accurate.

Dependence of Central star mass on Protoplanetary disk evolution

*Ryuunosuke Nakano[1], Takeru Suzuki[1], Masahiro Ogihara[2], Eiichiro Kokubo[2]

1. University of Tokyo, 2. National Astronomical Observatory of Japan

More than 4000 outer planets have been discovered in recent years. The discovery of rocky planets such as the Earth is increasing with this. On the other hand, how such a planetary system was born and evolved has a big uncertainty factor. Understanding the evolution of protoplanetary disks are fundamentally important in considering the formation and evolution of planets. The disk is made of dust and gas and plays a central role in the formation and evolution of rocks and planets, but in order to clarify the dynamics and growth of dust, it is necessary to understand the physical state of the background gas component. It is still unknown how the dissipation of the disk is done by photoevaporation from the central star and by the wind of the magnetically driven disk wind but how they contribute over time and also depend on the difference in mass of the central star.

In this study, a one-dimensional radial simulation of gas components of protoplanetary disks was done in consideration of photoevaporation by X-ray (Owen et al. 2010) and magnetically driven disk wind (Suzuki & Inutsuka et al., 2009). We investigated how the evolution of the disk changes by the difference of the central star mass.

We performed the evolution of protoplanetary disks with different masses of the central stars. If we define the evaporation time at 1au as the time when the surface density there falls below the observable level, it is shorter for a more massive central star, because the photoevaporation is more efficient.

In contrast, the evaporation time at the snowline shows the opposite trend; the evaporation is more rapid for disks with less massive central stars. This is because the location of the snowline has a very sensitive dependence on the mass of a central star.

Radiation Hydrodynamic Simulations of the Formation of Circumplanetary Disks

*Yuri Fujii[1], Oliver Gressel[2], Kengo Tomida[3], Udo Zieglar[2]

1. Institute for Advanced Research, Nagoya University, 2. Leibniz Institute for Astrophysics Potsdam, 3. Osaka University

Formation of regular moons and/or planetary atmospheres are governed by the gas flow into the vicinity of forming giant planets. Gas around a sufficiently massive planet is thought to form a circumplanetary disk instead of falling directly onto the planet. Recent studies, however, have shown that the circumplanetary gas forms an expanded envelope rather than a thin, rotationally supported Keplerian disk in cases where the gas temperature is very high. Thus, calculating the temperature of the accretion flow properly is important to determine the disk structure. We performed three-dimensional radiation hydrodynamic simulations of the formation of circumplanetary disks with an equation of states that considers effects such as hydrogen dissociation and helium and hydrogen ionization. The region within the deep potential of the planet reached very high temperature regime, however, we observe a disk to form in our simulations.

Inefficient Magnetic Accretion Heating in Protoplanetary Disks: Evolution of The Snow Line

*Shoji Mori[1], Xuening Bai[2], Satoshi Okuzumi[3]

1. Department of Astronomy, The University of Tokyo, 2. Tsinghua Center for Astrophysics, Tsinghua University, 3. Department of Earth and Planetary Sciences, Tokyo Institute of Technology

The structures of the inner region of protoplanetary disks are essential for understanding the formation process of terrestrial planets. The gas temperature in the region is thought to be determined by accretion heating, which is conventionally attributed to turbulent dissipation. Because the turbulent dissipation occurs in the disk, the released heat accumulates in the disk and thereby effectively increases the disk temperature. However, recent studies have suggested that the inner disk (a few AU) is largely laminar, with accretion primarily driven by magnetized disk winds, as a result of nonideal magnetohydrodynamic (MHD) effects from weakly ionized gas, suggesting an alternative heating mechanism by Joule dissipation.

Purpose of this study is to investigate the accretion heating with the nonideal MHD effects and to understand thermal structure in the inner disk region. We perform local stratified MHD simulations including nonideal MHD effects and investigate the role of Joule heating and the resulting disk vertical temperature profiles. We find that Joule heating occurs at several scale heights above the midplane, making the midplane temperature much lower than that with the conventional viscous heating model. Also, 80 % of the accretion energy is flown out by the disk wind. Our results further suggest that the midplane temperature in the inner region is almost entirely determined by irradiation heating. We also discuss the evolution of the water snow line based on our results and the formation process of the earth.

Formation of super-Earths and their atmospheres with *N*-body simulations

*Masahiro Ogihara[1], Yasunori Hori[2,1]

1. National Astronomical Observatory of Japan, 2. Astrobiology Center

A large number of super-Earths have been discovered by various exoplanet search programs that include the Kepler mission, which provide the perfect opportunity for a development of planet formation theory. In fact, recent *N*-body simulations have made major progress in understanding the origin of close-in super-Earths (e.g., Izidoro et al. 2017; Ogihara et al. 2018). In these previous studies, they focus on orbital properties (e.g., period-ratio distribution) and aim to reproduce them.

In this study, we also pay attention to the amount of atmospheres and make further progress in formation models of super-Earths. According to the mass-radius relation of transiting super-Earths, it is unlikely that they generally possess massive atmospheres. This is consistent with the fact that the occurrence rate of hot Jupiters is considerably smaller than that of close-in super-Earths. The amount of atmospheres would provide useful constraints on the development of formation models of super-Earths. The gas accretion onto super-Earth cores depends on several factors (e.g., formation history, disk evolution); therefore it is crucial to follow the planetary growth, the orbital evolution, and the atmospheric accretion self-consistently.

We perform *N*-body simulations of super-Earth formation in an evolving disk considering the accretion of atmospheres. In our simulations, we also consider the pebble accretion, which is a physical process in which protoplanets grow rapidly through accumulation of small particles under gas drag. The pebble accretion would help to accelerate the core formation of gas giants in the outer region. Moreover, the pebble accretion may play an important role in the accretion of close-in super-Earths.

In this presentation, we are going to discuss several important questions about the origin of super-Earths. For example, we aim to reveal realistic formation processes by results of *N*-body simulations that include the atmospheric accretion, the pebble accretion, and the disk evolution. Then we discuss properties of formed super-Earths and compare with observed super-Earth systems. We also determine whether the pebble accretion can prevent the accumulation of massive atmospheres.

The orbital stability of planets in resonances: the evolution of mass ratio

*Yuji Matsumoto[1], Masahiro Ogihara[2]

1. Academia Sinica Institute of Astronomy and Astrophysics, 2. National Astronomical Observatory of Japan

Many systems composed of Earth or super-Earth sized planets are observed to date (e.g., Gillon et al., 2017). In some systems, three or four adjacent planets are in a series of mean motion resonances, called resonant chains (Mills et al., 2016; Luger et al., 2017). The resonant chain can be reproduced when the planets migrate inward (e.g., Ogihara & Ida 2009; Izidoro et al., 2017; Bitsch et al., 2019). After gas depletion, planets in resonant chain become orbitally unstable when their number exceeds the critical number that the planets are stable in resonance (Matsumoto et al., 2012). Izidoro et al. (2017) showed over half systems hold more than five planets in their simulations that planets are stable in resonant chain after gas depletion. The disagreement of the number of planets in resonant chain between observations and simulations can be explained by some mechanism reduces the orbital stability of planets in resonances.

The mass ratios between planets in close-in orbits and their central stars would not keep the same value after their formation. There are some mechanisms that super-Earths lose their envelopes, e.g., energy limited escape (Owen 2018). Also, young stars lose their mass by the stellar wind and coronal mass ejection (Cranmer 2017).

We perform simulations that the planets trapped in the first order resonant chain considering their mass ratio change. At first, planets migrate in the disk gas and are trapped in the resonant chain composed of the same resonant commensurability. Then, the disk gas is removed and the mass ratio between planets and the central star is changed, exponentially. When the number of planets in resonant chain exceeds the critical number corresponding resonant chain, their crossing time increases as the mass ratio decreases since the separation normalized by Hill radii becomes larger. In the cases that the resonant systems hold less planets than the critical number, planets sometimes cause orbital instability when their mass ratios change. In some conditions, the orbits of planets in resonant chain become unstable, when their mass ratios decrease only a few percent. Such instabilities tend to occur in systems that hold more planets.

Experimental study on the structure of shock remnant magnetization

*Shota Kato[1], Masahiko Sato[1], Kosuke Kurosawa[2], Masashi Ushioda[3], Sunao Hasegawa[4]

1. The University of Tokyo, 2. Planetary Exploration Research Center, Chiba Institute of Technology, 3. Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology, 4. Japan Aerospace Exploration Agency

The history of planetary magnetism is a key to understanding the evolution of planets. We focus on shock remnant magnetization (SRM) as a record of the magnetic field of planets: the magnetic anomaly field from SRM of a planetary crust can be measured by spacecraft magnetometers. It is essential to understand the structure of SRM for estimating planetary paleofield from magnetic field data because the observed magnetic anomaly field above craters is determined by the sum of the contribution of the materials beneath the crater with the SRM. In this study, the structure of SRM is experimentally investigated by using a two-stage light gas gun placed at the Institute of Space and Astronautical Science(ISAS) of Japan Aerospace and Exploration Agency(JAXA). We measured the SRM of 3 mm cube samples cut from basalt cylinders shocked in the weak magnetic field. The characteristic features of SRM structure are as follows: (1) The intensity of SRM tends to increase with increasing the distance in less than ~10 mm from the collision point. (2) The intensity of SRM tends to decrease with increasing the distance in more than ~10 mm from the collision point. Then the intensity of SRM of blocks are compared with the pressure and temperature from iSALE (Impact-SALE) calculation. In this talk, we will discuss the structure of SRM and the relationship between the SRM structure and the calculated change in pressure and temperature.

Acknowledgement: We appreciate the developers of iSALE, including G. Collins, K. Wünnemann, B. Ivanov, J. Melosh, and D. Elbeshausen.

Low-dispersion spectra of lunar impact flashes in 2018 Geminids

*Masahisa Yanagisawa[1], Yuki Uchida[1], Seiya Kurihara[1], Shinsuke Abe[2], Ryota Fuse[2], Keisuke Onodera[3,4], Ryuhei Yamada[5]

1. The University of Electro-Communications, 2. Nihon University, 3. SOKENDAI (The Graduate University for Advanced Studies), 4. Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 5. The University of Aizu

In the collisions in the solar system, there are many cases where the collisions occur at speeds exceeding 10 km/s, which are difficult to reproduce in laboratory experiments. In such a collision, melting, evaporation, and ionization of silicate, iron, etc. which do not occur at a speed lower than this occur. Understanding of high-speed collisions accompanying such processes is an important issue for planetary sciences. However, it is not clear yet what kind of phenomenon actually occurs. We can approach this problem from the observation of lunar impact flashes.

Several research results have been reported on the occurrence frequency and brightness of lunar impact flashes and their time variations. However, there are few reports on their spectra. As part of the SAKURA Japan-France joint observation project, that is, the joint observation of meteoroids' impacts as lunar seismic sources, we observed the flashes due to the collisions of December Geminids' meteoroids by simple spectral cameras for visible wavelength (Fig. 1) [1]. At the University of Electro-Communications (Chofu-shi, Tokyo), observations were made with two spectral cameras attached to a Newtonian telescope with an aperture of 450 mm and a focal length of 2015 mm and a Schmidt–Cassegrain telescope with an aperture of 280 mm and an effective focal length of 920 mm. At Nihon University (Funabashi-shi, Chiba Prefecture), observations were carried out mainly with an ordinary movie camera attached to a telescope with a 400 mm aperture.

Thirteen flashes were detected by the observations at the University of Electro-Communications on 15th December, 2018 (JST) and nine of them were detected simultaneously at Nihon University. For those that were not detected at the same time, it is conceivable that there are differences in the sensitivity of the observation devices and temporary interruptions of observation, but the examination in detail is a future task. We named these 13 events from A to M. Their locations on the lunar surface are shown in Fig. 2 [2]. Their spectra were obtained by comparing their spectral images with those of comparison stars which were observed every 30 minutes [2, 3]. An example is shown in Fig. 3. Most of the flash spectra can be approximated well by the blackbody radiation spectrum of about 3000 K, but some are not. For the former, they would be due to the blackbody radiations from micro-droplets of melted rocks generated at the impacts. On the other hand, there is a possibility that the latter may be reflection of sunlight by space debris.

High velocity cratering experiments on sand-gypsum targets simulating asteroids

*Ryo Sugimura[1], Masahiko Arakawa[1], Minami Yasui[1], Takuya Ishiguro[1]

1. Kobe University

A lot of impact craters are found on asteroids. To clarify the impact cratering processes on asteroids, many researchers conducted impact cratering experiments using various materials such as sand, ice, and basalt. Housen and Holsapple (2011) proposed crater scaling laws and it enable us to extrapolate experimental results to asteroid impact results on the surface. They referred rocky materials having the compressive strength larger than several MPa to constructed the crater scaling laws, but it is unclear whether these scaling laws can be applied to porous materials having low strength or not. Therefore, we conducted impact cratering experiments in order to study the cratering processes on porous rocky asteroids with low strength and the effects of the strength on the crater size and the ejecta velocity. Then, we propose the crater scaling laws applicable to low strength porous materials.

A low strength target was made by mixing quart sands with the diameter of 100 μm with porous gypsum. The mixing ratio of sand to gypsum was changed from 2:1 to 30:1 in the wt.%, and the measured tensile strength was found to change with this mixing ratio. Impact experiments were conducted by using a two-stage light gas gun, and an Al spherical projectile with the size of 2mm was launched at the velocity of 2, 4 and 6km/s. The impact-cratering process was observed by using a high-speed video camera at the framing speed of 10^5fps. Furthermore, we set a 1cm-slit on the target surface to observe 2-dimensional ejecta flow: the slit can exclude most of the ejecta covering through the line of sight of the high-speed camera. This 2-dimensional ejecta observation gave us an accurate relationship between the initial position and the velocity of ejecta fragments.

The tensile strength of the porous mixed sample was measured by a Brazilian test and we found that the tensile strength was changed in the three orders of magnitude from 1MPa to 1kPa with the increase of the sand volume content from 30 to 50%.

The morphology of the recovered crater was characterized by two regions: they are a spall region and a pit region. The spall region looks rough circle but actually it has a polygonal shape with a shallow depth, and it is formed by tensile wave reflected from the surface. The pit region exists at the center of the crater and it has a semi-spherical shape with the diameter rather smaller than the spall region. This spherical region could be formed by the compressive wave and the shear failure was expected in this region. The spall diameter was found to increase with the decrease of the target tensile strength, however the crater depth, which is defined as the depth from the initial surface to the pit floor, showed constant, irrespective of the tensile strength. Moreover, it is very difficult to recognize features characterizing a pit and a spall region in the crater interior for the low strength target as low as 1kPa.

We constructed a crater size scaling law on the strength regime by using our results and compared it to the previous studies obtained for a high strength material. Then, the obtained scaling law for a weak target was written by , where $\pi_R$is the scaled crater radius and $\pi_Y$is the scaled strength in the conventional scaling laws. We found that our $\pi_R$was smaller than the $\pi_R$of frozen sand but larger than the $\pi_R$of porous gypsum. We also constructed the crater scaling law for the crater depth, and it was written by , where π_d is the scaled crater depth, and then it is obvious that $\pi_d$was almost constant, irrespective of

©2019. Japan Geoscience Union. All Right Reserved.

the tensile strength. The reason why our π_R is smaller than the result of frozen sand is considered to be due to the impact energy being consumed by collapsing tiny porous in the gypsum in the target.

Experimental study on collisional processes of highly porous ice balls simulating Saturn's ring particles

*Yukari Toyoda[1], Minami Yasui[1], Masahiko Arakawa[1]

1. Graduate School of Science, Kobe University

Introduction: Saturn's rings consist of mm- to meter-sized particles of water ice, and they collide with each other at the relative speed slower than a few cm/s. After the collisions, the ring particles coagulate or rebound or fracture, and it could affect the evolution and the structure of Saturn's rings. Saturn's rings were a very thin disk (the thickness thinner than 100-200 m) and this is because the particles collide with each other inelastically so the kinetic energy might dissipate effectively. Therefore, in order to clarify the formation processes and the evolution of Saturn's rings, it is necessary to investigate the collisional properties of the ring particles. In particular, it is very important to examine the effects of material properties of the ring particles and the impact velocity on the coefficient of restitution (*e*).

It is estimated from ground observations and planetary explorations that the ring particles are speculated to be a non-porous ice, porous ice (snow), non-porous ice covered with frost etc. Previous studies have investigated the e of non-porous ice and that covered by the frost, but the e of porous ice (snow) has not been investigated yet in detail. In this study, we focused on the porosity of Saturn's ring particles and examined the dependence of the porosity on the relationship between the *e* and the impact velocity.

Experimental methods: We used ice balls with a smooth surface and snowballs with the porosity of 45, 50, 60% having the diameter of 3 cm to simulate the Saturn's ring particles. We conducted free fall experiments of the balls on an ice plate with a smooth surface and a granite plate. The impact velocity changed from 0.8 to 280 cm/s. We measured the e by two methods. One is an acoustic emission (AE) method. The AE sensor was attached on the plate and it could detect the elastic wave by each collision of the ball. So the impact and the rebound velocities of the ball could be calculated by measuring the time interval between the collisions. Another is a laser displacement meter method. A laser displacement meter was used to measure the position of the free falling ball with time. The e was calculated from the time interval between the collisions of the ball, as same as AE method.

Experimental Results: In the case of ice ball- ice plate collision, the e was almost constant (~0.9) at low impact velocity (quasi-elastic region), while as the impact velocity exceeded a critical velocity, the e decreased drastically (inelastic region). This critical velocity, v_c, was obtained to be 24.5 cm/s. In the inelastic region, the relationship between the e and the impact velocity could be fitted by using the empirical equation, $e=e_{qe}(v_i/v_c)^{-\log(v_i/v_c)}$, where v_i is the impact velocity and e_{qe} is the average value of the e in the quasi-elastic region. In the case of ice ball-granite plate collision, the relationship between the e and the impact velocity was similar to that of ice ball-ice plate collision, but the v_c was obtained to be 11.2 cm/s, which is almost a half of the ice ball-ice plate collision result.

The e of the snowball continued to decrease as the impact velocity increased and the critical velocity, v_c, could not be appeared for both collisions on the granite plate and the ice plate. Furthermore, the e of the

©2019. Japan Geoscience Union. All Right Reserved.

snowball decreased as the porosity increased monotonically, but they merged with each other at the impact velocity lower than 10 cm/s. This is because the kinetic energy of the snowball was consumed by crushing the pores near the impact point on the snowball surface at higher impact velocities. We found that the relationship between the impact velocity and the e could be shown by $e=a\cdot v_i^{-b}$ where a and b are constant. The a was obtained as 0.9 - 0.97, irrespective of the porosity, while the b increased with the increase of the porosity.

IN-SITU FORMATION OF THE URANIAN SATELLITES FROM WIDE DEBRIS DISK FORMED BY GIANT IMPACT

*Ishizawa Yuya[1], Takanori Sasaki[1], Natsuki Hosono[2]

1. Department of Astronomy, Kyoto University, 2. JAMSTEC

We adopted the so-called giant impact scenario to explain both the large axial tilt of Uranus and the formation of the Uranian regular satellites simultaneously. Hydrodynamic simulations for a giant impact onto proto-Uranus have been carried out, which showed that the giant impact can explain the large axial tilt of Uranus and also suggested that ejected materials produced by the giant impact could be distributed throughout the current orbits of the Uranian regular satellites.
In this study, we modeled wide debris disks of solids with several conditions, and performed N-body simulations to investigate the in-situ satellite formation from the wide debris disks to constrain the parameters of debris disks for the in-situ satellite formation. We found that the five major satellites formed around the current orbits from wide debris disks with several times the total satellite mass. Although one or two large satellites usually form inside the current orbits of the major satellites, such satellites would migrate inward due to the tidal torque from the planet and finally be disrupted by the planetary tides or fall onto the planet over several hundred million years. We also propose that the Uranian rings could form from the disrupted satellites and the inner regular satellites could form by use of the ring materials.

Effect on the obliquity due to a giant impact on a rotating ice giant

*Kenji Kurosaki[1], Shu-ichiro Inutsuka[1]

1. Department of Physics, Nagoya University

Solar system planets have intrinsic rotation period and obliquity. Especially, Uranus's obliquity is 98 degrees, which is larger than Jupiter, Saturn, and Neptune. Obliquity of Uranus is to the giant impact event. However, previous studies ignored the pre-impact rotation of Uranus. To understand the tilted rotation axis via a giant impact, we calculate the giant impact on a rotating target. We use Godunov Smoothed Particle Hydrodynamics simulation. We include that a giant impact can reproduce the present obliquity of Uranus if the impactor collides on anti-rotating direction.

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University), Chairperson:Wataru Fujiya, Shin Ozawa

This session will focus on the evolution in the Solar System with interaction and co-evolution in minerals, water, organic matter, and noble gas in meteorites and interplanetary dust particles. New innovative analytical and theoretical techniques in various fields will be discussed. The developing methods are welcome to submit for the future mainstream of meteorite study. In order to explore the planetary materials and their evolution, both meteorite studies and experimental approaches are necessary. In this session, we will discuss these topics from extraterrestrial sample analyses and experimental works. Research works on undifferentiated and differentiated meteorites and parent body processes such as aqueous alteration, thermal metamorphism, shock metamorphism, volcanic activity, and core-mantle-crust differentiation are especially included in this session.

Evaluation of shock metamorphism of eucrites by X-ray diffraction analysis

*Rei Kanemaru[1], Naoya Imae[2,1], Akira Yamaguchi[2,1], Hirotugu Nishido[3]

1. The Graduate University for Advanced Studyies, 2. National Institute of Polar Research, 3. Okayama University of scienece

Introduction

Eucrites have been considered to come from the surface crust of asteroid 4 Vesta. Eucrites experienced varying degrees of shock and thermal metamorphism. The scaling of the degree of shock metamorphism necessary for the understanding of the formation history of Vesta. However, the degree of shock metamorphism has not been established. Recent studies of X-ray diffraction (XRD) analyses using the in-plane rotation of polished thin sections (PTSs) for ordinary chondrites [2] showed that the XRD technique has a potential for the classification and identification of shock and metamorphic stages. In this study, we applied this technique for the thin or thick sections of 13 basaltic and 3 cumulate eucrites. We show that the bulk XRD data may be a useful indicator for characterizing the shock degree for eucrites.

Measurement and analytical methods

We performed X-ray measurement by SmartLab (RIGAKU) at National Institute of Polar Research, Tokyo, on the condition of Cu Kα with 40 kV and 40 mA through the slit of 10 x 5 mm in size.

We defined the shock degrees of studied eucrites from A to D by the petrographic and mineralogical features of thin and thick sections: shock degree A (unshocked) = sharp optical extinction of plagioclase and pyroxenes, shock degree B (low) = weak undulatory extinction or mosaicism of plagioclase and pyroxene, shock degree C (moderate) = the presence of maskelynite, and shock degree D (high) = most (>70-80 vol%) of the plagioclase converted to maskelynite. The degrees of A, B, and C, D for eucrites roughly correspond to 0, 1 and 2 of shock stage for basaltic meteorites defined by Bischoff and Stöffler. (1992) [3], and S1, S2-4, and S5 for enstatite chondrites by defined Rubin et al. (1997) [4], respectively.

Results

We obtained the XRD patterns of 12 eucrites exhibiting the high degree of randomness (e.g., Agoult), whereas four eucrites show the feature of the crystal orientation (e.g., Moama). We identified the peaks of plagioclase, pigeonite, and augite from the XRD patterns of eucrites. The bulk XRD data of each eucrite shows the positive correlation between the full width at half maximum (FWHM) values (for both mean and total) and the shock degree estimated from the textures. On the other hand, the number of the peak in the XRD pattern shows a negative correlation for the increasing of shock degree.

The specific peaks of plagioclase (especially -202) show the decreasing peak intensity and the increasing FWHM values for the increasing shock degree. The peak of pyroxene (pigeonite 310 and augite -311) (2theta = ~30.7º) also shows the increasing FWHM value of pyroxenes for the increasing shock degree.

Discussion

The increase of the averaged FWHM values for each eucrite are related to the shock metamorphism of pyroxene and plagioclase. The negative correlation between the peak intensities of plagioclase and shock degree implies the maskelynitization of plagioclase by shock metamorphism. In particular, most of the plagioclase peaks in A-87272, the strongest shocked sample (D) studied here, have disappeared. The pyroxene peaks show a positive correlation between the FWHM value and shock degree, whereas there is no correlation between the peak intensity and shock degree. This indicates that the shock metamorphism produces the strain in pyroxenes.

In-plane rotation of PTSs method of XRD analysis for eucrites is affected by the crystal orientation in the meteorites, especially coarse-grained unbrecciated rocks and crystalline portions in brecciated rocks.

©2019. Japan Geoscience Union. All Right Reserved.

Nevertheless, we suggest that the FWHM is a useful indicator for measurements of the shock degree of eucrites, since this factor is not affected by the randomness of the crystal orientation of the meteorites.

Hf-W dating of main-group pallasites

*Yoshitaka Homma[1], Tsuyoshi Iizuka[1], Akira Ishikawa[2]

1. Department of Earth and Planetary Science, The University of Tokyo, 2. Department of Earth and Planetary Sciences, Tokyo Institute of Technology

Pallasites are stony-iron meteorites consisting mainly of olivine and FeNi metal, providing us a unique opportunity to study an interior of their parent body. Classically, pallasites have been thought to represent the core-mantle boundary of their parent body, since there are some links with IIIAB irons, which are the representative of the core (e.g. Clayton & Mayeda, 1996). Yet, some recent studies suggest pallasite formed at a shallower region than the core-mantle boundary likely by impact mixing (e.g. Yang et al., 2010; Tarduno et al., 2012). Chronological investigations of pallasites are important since they enable to determine the ages and the timescales of crystallization of pallasite minerals. Although the Al-Mg dating of pallasite olivine yielded a model age of 1.27 Myrs after the CAI formation (Baker et al., 2012), other chronological constraints are still required for resolving the two contrasting models of pallasite formation. Here we apply the Hf-W chronology to four pallasites to constrain when the metal segregated on their parent body. Previously reported W isotopic data of pallasites show a large variation in $\varepsilon^{182/184}$W (Quitté et al., 2005), some of which correspond to the model ages older than CAIs. These isotopic data may reflect multiple causes and effects, such as a nucleosynthetic anomaly, radiogenic and neutron capture effects. We combined the W and the Pt isotopic measurements to evaluate the neutron capture effect which may lead to misinterpretation in age. Also, we measured unradiogenic W isotopes to estimate if the nucleosynthetic anomaly existed in the pallasite parent body. The obtained $\varepsilon^{182/184}$W values corrected for the neutron capture effect by using Pt isotope data range from -3.53 ±0.14 to -3.45 ±0.18, which correspond to the model Hf-W ages of -0.30 ±1.43 to 0.31 ±1.74 Myrs after the CAI formation. Moreover, the $\varepsilon^{183/184}$W values are indistinguishable from the terrestrial value, suggesting that the pallasite parent body accreted in the inner solar system. The model Hf-W ages obtained in this study are coincident with the model Hf-W ages of magmatic irons (Kruijer et al., 2013) and the model Al-Mg age of pallasite olivine, suggesting its magmatic origin rather than impact origin. The implication is that the pallasite metal was originated from the planetary core and was segregated within first 2 Myrs of the solar system evolution.

Mineralogical study of TCIs in CM carbonaceous chondrites

*Akane Iemoto[1], Yusuke Seto[1], Akira Miyake[2]

1. Graduate School of Science, Kobe University, 2. Graduate School of Science, Kyoto University

Introduction

TCIs, intergrowths of tochilinite ($6(Fe_{0.9}S)\cdot 5[(Mg,Fe)(OH)_2]$) and cronstedtite (Fe-bearing serpentine) occur in most of CM chondrites, which are considered to be aqueous alteration products on the chondrite parent bodies. Based on the textures and chemistries, they can be divided into two types. Type I appears as massive and are generally found in chondrules, while type II exhibits fibrous textures and are generally found within the matrix. Many researchers support that kamacite in chondrules had been altered into type-I TCIs. However, precursors or alteration processes of type-II TCIs are still remains unknown. TCIs potentially provide important information regarding aqueous environments on chondrite parent bodies. Here, we report microtextures of type-II TCIs in 4 CM chondrites and review the formation process.

Materials and methods

We observed the following CM chondrites; QUE97990 (2.6), Murchison (2.5), Nogoya (2.2), Cold Bokkeveld (2.2). The number in parenthesis are the alteration index for CM chondrites proposed by Rubin et al. (2007), in which they defined the index ranging from 2.6 (moderately altered) to 2.0 (highly altered). Textural observation and chemical analyses were performed using an SEM-EDS (JEOL, JSM6480LAII), and nanometer-scale observations using an STEM-EDS (JEOL, JEM2100F) after processing into thin films using an FIB (FEI, Quanta 3Di).

Results and discussion

In QUE97990 and Murchison, less altered meteorites in this study, the type-II TCIs are distributed in the matrices. They are aggregates of a few μm-sized tochilinite and cronstedtite, where thin tochilinite veins occurred inside cronstedtite, suggesting that tochilinite had formed after the formation of cronstedtite. This gives us a constraint on the aqueous condition of CM chondrites. In Nogoya, the TCIs texture showed that very fine serpentine-rich region is located at core, and toward rim, gradually changed to fibrous cronstedtite and mixed-layer phase (alternate layer phase of tochilinite and cronstedtite structure in nanometer scale). The TCIs of Cold Bokkeveld also showed the core-rim structure, where core is often rich in mixed layer phase, and rim is consists of relatively coarse-grained tochilinite and cronstedtite. In the latter two highly altered CM chondrites, the both core showed very fine, fibrous, and fluffy texture, and no evidence of precursor material, suggesting that type-II TCIs were directly formed from water solution.

Importance of 10Be as a key indicator of (solar) cosmic ray irradiation in the early solar system

*Hajime Hiyagon[1], Yuuki Tanimura[1], Tomoya Nakamura[1], Kohei Fukuda[3], Wataru Fujiya[4], Naoji Sugiura[1], Takanori Kagoshima[2], Naoto Takahata[2], Yuji Sano[2]

Beryllium-10, which decays to ^{10}B with a half-life of 1.4 Myr, is produced mainly by spallation reactions of solar system materials induced by solar or galactic cosmic rays, but not by thermonuclear reactions in stars. Possible existence of ^{10}Be in the early solar system materials, therefore, has significant importance in considering irradiation processes near the early Sun or in the molecular cloud [1].

Excesses in ^{10}B correlated with Be/B ratios in a number of CAIs from CV chondrites [2-9] suggest the presence of live ^{10}Be at the time of CAI formation. The inferred initial ^{10}Be/^{9}Be ratios are mostly within the range of (0.5-1) x 10^{-3}, though the data are restricted to coarse-grained CAIs from CV chondrites. Recent studies including small CAIs from CH/CB chondrites [10-12] show that the initial ^{10}Be/^{9}Be ratios may be much higher and more variable (from ~10^{-4} to ~10^{-2}), suggesting that the origin of ^{10}Be in CAIs is spallation reactions induced by solar cosmic rays.

Data for chondrules are scarce. Sugiura (2001) [13] analyzed anorthite in chondrules from the Y82094 (ungrouped C3.2) chondrite and found a possible correlation between ^{10}B excesses and Be/B ratios, but the results are not conclusive due to relatively large errors. We further conducted Be-B isotope analyses for chondrules in Y82094 chondrite using NanoSIMS at the Atmosphere and Ocean Research Institute, The University of Tokyo [14]. Resolvable excesses in ^{10}B are found in some of the Y82094 chondrules, but ^{10}Be was probably not alive at the time of the chondrule formation. Some carriers of excess ^{10}B are required in the precursor materials of these chondrules.

Here we review recent progress in Be-B isotopic studies and discuss their importance in understanding the irradiation processes in the early solar system. We will also show our some new results on Be-B systematics for chondrules from Y82094 (C 3.2) and NWA7936 (LL 3.15) chondrite.

Introduction

Oxygen isotopic compositions can be used to identify the origins of planetary materials. Components of carbonaceous chondrites show wide range of oxygen isotopic compositions ($\delta^{17,18}$O: ~-50–0 ‰) that keep nearly constant δ^{17}O/ δ^{18}O ratio of ~1 [e.g.,[1]]. The isotopic variation is thought to be resulted from both mass-dependent isotope fractionation and mixing of two distinct reservoirs of ^{16}O-rich and ^{17,18}O-rich in the solar nebula. The composition of the ^{16}O-rich reservoir has been estimated from the isotopic compositions of CAIs and AOAs which were originated from the reservoir [e.g.,[2]]. Recently, Fe-rich material originated from the ^{17,18}O-rich reservoir, called cosmic symplectite (COS), has been reported from the primitive carbonaceous chondrite Acfer 094 [3]. COS have the heaviest oxygen isotopic composition ($\delta^{17,18}$O: ~180 ‰) among solar materials and consist of nanometer-scaled symplectitically intergrowth of magnetite and Fe-Ni sulfides [3,4]. They are thought to have formed by oxidation of Fe-Ni metal and sulfides by ^{17,18}O-rich water or water vapor in the early Solar System. However, petrological and mineralogical information of COS still remain limited. In this study, we performed synchrotron radiation-based X-ray computed tomography (SR-XCT) and NanoSIMS analysis to investigate the origin of COS.

Results and discussion

First, we observed a polished Acfer 094 section (~2.2 mm^2) by FE-SEM and found five COS grains. The COS grains (~10 μm) show rope-like structure like as COS reported by Abe et al. (2017) [5]. One of the five COS grains was extracted as a block (~25×25×30 μm) using FIB and analyzed by high spatial resolution (~100 nm) SR-XCT at SPring-8 BL47XU. The 3D image shows that the COS grain has irregular shape with many topographic depressions on the surface and contains small (<1 μm) inclusions. The inclusions are not connected to the outside of the COS by clack, ensuring that they were trapped when the host COS formed. We made a cross section surface of the inclusions using FIB and analyzed it by FE-SEM. The inclusions have Na, S, O rich compositions, and such material was not observed in the surrounding matrix. We confirmed that the COS, host of the inclusions, consist of symplectitically intergrowth of magnetite and Fe-Ni sulfides.

We obtained oxygen isotopic composition of the COS gain using NanoSIMS. The COS grain has ^{17,18}O-rich composition (δ^{17}O = 159.06 ±5.79 (1 σ) ‰, δ^{18}O = 166.31 ±3.18 (1 σ) ‰) which is similar to the COS grains reported by previous study [3]. We could not check the difference in oxygen isotopic compositions between the inclusions and the host COS because the inclusions were too small to obtain their compositions.

The inclusions found in this study have not been reported from other COS grains. It is possible that

©2019. Japan Geoscience Union. All Right Reserved.

previous studies could not find the inclusions because most of the inclusions were plucked from the host COS during sample polishing. In fact, many COS grains reported in previous studies contain abundant pores which probably formed by plucking of inclusions. If inclusion is common in COS, it is important to constrain the origin of COS. We will present the results of further TEM analysis of the COS and their inclusions, and discuss the origin of them.

Chondrule-like objects and refractory inclusions in GEMS-bearing Antarctic micrometeorites and an interplanetary dust particle.

*Takaaki Noguchi[1], Noriaki Ohashi[2], John P. Bradley[3], Daisuke Nakashima[4], Tomoki Nakamura[4], Makoto Kimura[5], Takayuki Ushikubo[6], Noriko T. Kita[7], Naoya Imae[5]

Glass with embedded metal and sulfide (GEMS) is regarded as a characteristic component of cometary dust. GEMS-bearing Antarctic micrometeorites (AMMs) and interplanetary dust particles (IDPs) containing chondrules and refractory inclusions are important to understand comets as well as P- and D-type asteroids.

We found three chondrules and a refractory inclusion (RI) in GEMS-bearing AMMs and IDP. We investigated them by TEM, FE-SEM, FE-EPMA, and SIMS. All the chondrules belong to type II (Mg# <90). An AMM contains a spinel-hibonite-perovskite (sp-hb-pv) inclusion, in which spinel contains tiny (<100 nm) Ti-bearing Zr oxides and Mo- and Ru-bearing Ir-Os alloy and that perovskite contains Y and Zr, suggestive of ultra-refractory nature. All the fine-grained matrices are highly porous and contain GEMS, olivine, low-Ca pyroxene including enstatite whisker, high-Ca pyroxene, pyrrhotite. In addition, the matrix and the embedded RI contains minor phyllosilicate. Oxygen isotopic ratios of olivine and pyroxene in two chondrules are plotted 0.7‰ below and 2.7‰ above the terrestrial fractionation line on the three-oxygen isotope diagram, respectively. Oxygen isotope ratios of spinel in the RI are $\delta^{18}O$ of -43.8‰ to -45.1‰ and $\delta^{17}O$ of -44.8‰ to -46.8‰, respectively. Resolvable ^{26}Mg excesses ($\delta^{26}Mg^*$ ~ 13±2‰ and 14±3‰) are observed in hibonite with $^{27}Al/^{24}Mg$ ratios of 35-43, while spinel show marginal excess (~1‰).

The olivine/(olivine + low-Ca pyroxene) ratios were deduced from the mid-infrared spectra of asteroids and comets; those of B-, G-, and C-type asteroids, P- and D-type asteroids, and comets are <12%, 36-52%, and >50%, respectively. The ratios of the matrices in the samples range from 0.4 to 0.61, which are well above the values of B-, G-, and C-type asteroids and comparable with those of P- and D-type asteroids and comets. Therefore, P- and D-type asteroids and comets seem to be more plausible as parent bodies of these AMMs and an IDP than B-, G-, and C-type asteroids. If that is the case, P- and D-type asteroids and comets contain abundant GEMS. Ferromagnesian silicates with Mg#<90 in the chondrules distribute around $\Delta^{17}O$ ~0‰ in the Mg# vs $\Delta^{17}O$ diagram like those in the Stardust samples. This seems to be consistent with the hypothesis that P- and D-type asteroids were migrated from the Kuiper belt. The chondrules were formed in more oxidizing conditions than chondrules in CR chondrites because type II chondrules in them occupy only ~1%.

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University), Chairperson:Yoko Kebukawa, Shin Ozawa

This session will focus on the evolution in the Solar System with interaction and co-evolution in minerals, water, organic matter, and noble gas in meteorites and interplanetary dust particles. New innovative analytical and theoretical techniques in various fields will be discussed. The developing methods are welcome to submit for the future mainstream of meteorite study. In order to explore the planetary materials and their evolution, both meteorite studies and experimental approaches are necessary. In this session, we will discuss these topics from extraterrestrial sample analyses and experimental works. Research works on undifferentiated and differentiated meteorites and parent body processes such as aqueous alteration, thermal metamorphism, shock metamorphism, volcanic activity, and core-mantle-crust differentiation are especially included in this session.

The parent bodies of carbonaceous chondrites are thought to be C-type asteroids based on the similarity of visible (Vis) -infrared (IR) spectra between carbonaceous chondrites and C-type asteroids [e.g., 1-5]. Several C-type asteroids are thought to have been heated and dehydrated judging from their spectra which are similar to the spectra of experimentally-heated chondrites [1,6]. The Hayabusa2 spacecraft of the Japan Aerospace Exploration Agency (JAXA) was arrived at the target C-type asteroid 162173 Ryugu in June 2018. Ryugu spectra exhibit a weak 2.72-μm OH absorption band that is present across the surface of the asteroid, and nearly always darker than values typical for carbonaceous chondrites [7,8]. The meteorites whose spectral features are most similar to Ryugu are shocked or moderately-heated carbonaceous chondrites. In this study, we performed spectral analysis in Vis-NIR range and mineralogical analysis in micro scale using carbonaceous chondrites that heated dehydrated on their parent bodies.

Spectral and mineralogical analyses were performed using nine naturally-heated and dehydrated carbonaceous chondrite samples (seven CM, one CI, and one CV chondrites), which classified into heating stages (HS) from I to IV based on X-ray diffraction results [9]. In-situ heating of samples at 120–400 ˚C was performed during spectral measurements and successfully removed absorption water and part of rehydrated water from chondrite samples. Lewis Cliff (LEW) 87022 (unheated CM), Jbilet Winselwan, and Dhofar 735 (heated at 600–900 ˚C [10]) were used for transmission electron microscope (TEM) analysis.

Reflectance spectra of HS-I samples show the positive slope in Vis- IR range and the significant 0.7- and 3-μm absorption bands. The 0.7-μm band appears in only HS-I sample spectra. With increasing heating degree, (1) Vis-IR slope decreases, (2) the 0.7- and 3-μm bands decrease, and (3) Mid-IR spectral feature (i.e. Christiansen feature (CF) and Reststrahlen bands (RB)) shifts toward longer wavelength. TEM/EDX analyses showed that the matrix of severely-heated chondrites consists of tiny olivine, low-Ca pyroxene, and fine Fe- and Ni-rich metal grains (<1 μm). It is indicated that in proportion to the heating degree, amorphization and dehydration of serpentine and tochilinite from HS-I to HS-II might cause the 0.7- and 3-μm band weakening, and spectral slope and albedo decreasing of spectra. Then, formation of secondary olivine and pyroxene, and FeNi-rich metal grains at HS-IV would be responsible for the 3-μm band depth decreasing, spectral slope and albedo increasing, CF peak shift, and RB changes of chondrite spectra.

We plan to compare other IR reflectance spectra of asteroids, such as those acquired by AKARI [11], to better interpret remotely sensed data of Bennu (NASA’s OSIRIS-REx mission target) and Ryugu. Future NIRS3 observations before/after the Small Carry-on Impactor (SCI) crater experiment and lab analyses of returned samples will reveal additional compositional properties of Ryugu.

Heterogeneity of oxygen and carbon isotopic compositions within carbonate grains in the Yamato 791198 CM chondrite and evolution of isotope ratios during aqueous alteration

*Wataru Fujiya[1], YUTO AOKI[1], Takayuki Ushikubo[2], Ko Hashizume[1]

1. Ibaraki University, College of Science, 2. Kochi Institute for Core Sample research, Japan Agency for Marine-Earth Science and Technology

Carbonate minerals are ubiquitous in CM chondrites and formed by aqueous alteration in their parent body [1]. Previous studies have revealed a large variation in C isotope ratios of CM carbonates with $\delta^{13}C$ values ranging from ~20 to ~90 ‰[e.g., 2,3]. However, the reason for this variability has remained poorly understood. Here, we conducted in-situ C- and O-isotope measurements by SIMS along crystal growth within single carbonate grains in Yamato 791198 (CM 2.4) to trace the change in $\delta^{13}C$ values during aqueous alteration.

First, we obtained color CL images of seven calcite ($CaCO_3$) grains with an FE-EPMA. Then, we measured O and C isotope ratios of the calcite grains with the CAMECA ims-1280HR. Typically, the isotope measurements were carried out on three different points for each calcite grain. Finally, we obtained quantitative chemical compositions and elemental maps of Mg, Si, Ca, Mn, and Fe of the calcite grains using the same FE-EPMA as that for the CL images.

All grain analysed exhibit a clear zoning of Mn, Mg, and Fe. The zoning is well correlated with CL images. The heterogeneous distribution of minor elements and CL intensity likely reflects the crystal growth of these grains.

The O isotope ratios of the calcite grains significantly vary with the $\delta^{18}O$ values ranging from ~22 to ~38 ‰. The O isotope ratios plot on a single trend line in an O three-isotope plot with a slope of ~0.61, slightly steeper than the terrestrial fractionation line, reflecting a progressive O-isotope exchange between initially ^{16}O-poor water and ^{16}O-rich rock [4,5]. The $\delta^{18}O$ values also vary within single calcite grains, demonstrating crystal growth from a relatively dark CL core to a red CL periphery.

The $\delta^{13}C$ values of the calcite grains range from 17 to 32 ‰. This range is much smaller than that observed for different carbonate grains or bulk meteorite samples by previous studies. Especially, the $\delta^{13}C$ variations within individual grains are only 4 ‰at most except for one grain. Previous studies have suggested that the observed $\delta^{13}C$ variation was produced by the Rayleigh-type isotopic fractionation by the escape of ^{13}C-poor methane [2], or equilibrium isotopic fractionation reflecting variable formation temperatures of carbonates [3]. However, the small intra-grain $\delta^{13}C$ variations associated with the large $\delta^{18}O$ change observed in this study cannot be explained by such processes. Instead, here we propose that the $\delta^{13}C$ values of dissolved carbon species in aqueous solutions were locally heterogeneous, and did not significantly change during carbonate formation.

Characteristics of Oxygen isotope ratios of chondrules and isolated olivine grains from Tagish Lake C2 chondrite

*Takayuki Ushikubo[1], Makoto Kimura[2]

1. Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2. National Institute for Polar Research

Recent studies on oxygen isotope systematics of chondrules show that chondrules in individual chondrite groups have characteristic distributions in their oxygen isotope ratios and Mg# (molar % of MgO/(MgO+FeO)) [1, 2]. The correlations between Mg# and $D^{17}O$ values (= $d^{17}O_{VSMOW}$ - 0.52 ×$d^{18}O_{VSMOW}$) of chondrules can be explained by mixing of ^{16}O-rich anhydrous dusts and an ^{16}O-poor oxidizing agent (most likely H_2O ice) in chondrule forming regions [3]. Based on similar Mg# - $D^{17}O$ correlations between CR chondrite chondrules and cometary silicate particles from comet Wild 2, it has been proposed that many of cometary silicate particles formed in the outer regions of the asteroid belt [e.g. 4, 5]. The Tagish Lake meteorite (ungrouped C2) is an appropriate sample to investigate the Mg# - $D^{17}O$ systematics of silicate particles formed in the outer regions of the asteroid belt because the Tagish Lake meteorite probably derived from a D-type asteroid [6]. Previous oxygen isotope studies on olivine grains from Tagish Lake and Tagish Lake-like meteorites [e.g. 7] show that their Mg# - $D^{17}O$ systematics are similar to that of CR chondrite chondrules. Here, we report new oxygen isotope data of olivine grains from the Tagish Lake meteorite for better understandings of the Mg# - $D^{17}O$ systematics of silicate particles in the outer regions of the asteroid belt.

Two polished epoxy mounts of the Tagish Lake meteorite, TL-KC-1 (8mm ×5mm) and TL-KC-2 (4mm × 3mm), were prepared for this study. Due to extensive aqueous alteration in the Tagish Lake parent body, phyllosilicates and other secondary phases such as magnetite and carbonates replace primary anhydrous phases. However, remaining olivine grains in chondrules and matrix tend to have sharp grain boundaries and no apparent evidence for the Mg-Fe exchange between olivine grains and matrix was observed. No alteration features were observed in these grains. Forty chondrules and isolated olivine grains (hereafter “ferromagnesian inclusions”) were selected for oxygen isotope measurements (34 type I [Mg#>= 90] and 6 type II [Mg#<90]). Oxygen isotope ratios of olivine grains were measured with an ion microprobe, CAMECA IMS 1280-HR at Kochi Institute. A 20 kV accelerated Cs^+ primary beam (~30 pA, ~3 um in diameter) was used. The analytical conditions were similar to those in [1].

Oxygen three-isotope ratios of ferromagnesian inclusions from Tagish Lake are distributed along the PCM (primitive chondrule minerals) line [1]. Most type I ferromagnesian inclusions are relatively ^{16}O-rich ($D^{17}O$ = -7.4 to -3.9‰) and type II ferromagnesian inclusions are relatively ^{16}O-poor ($D^{17}O$ >= -3‰). Of six type II ferromagnesian inclusions, two inclusions have $D^{17}O$ ~ 0‰, which are recognized in in Tagish Lake-like meteorites, CR chondrites, and cometary silicate particles, but are almost absent in other carbonaceous chondrites [e.g., 2-5, 7]. The present results are further evidence for the link between ferromagnesian inclusions accumulated into asteroids in the outer regions of the asteroid belt (possibly D-type asteroids) and silicate particles accumulated into cometary nuclei in the Kuiper belt. As discussed in [4, 5, 8], type II silicates are common in cometary silicate particles, which is distinct from ferromagnesian inclusions in Tagish Lake(-like) meteorites and CR chondrites. Most cometary silicate particles formed in H_2O ice enriched oxidizing regions. Such regions were probably farther than where typical ^{16}O-rich type I chondrules of carbonaceous chondrites formed.

Extreme ^{16}O-rich CAIs in Isheyevo chondrite

*Naoya Sakamoto[1], Noriyuki Kawasaki[2]

1. Creative Research Institution, Hokkaido University, 2. Natural History Sciences, Hokkaido University

Oxygen in the solar system is believed to be formed by mixing of ^{16}O-rich and ^{16}O-poor reservoirs [e.g. 1 and references therein]. The ^{16}O-poor end member ($\Delta^{17}O$ = +85‰) was found from magnetite in cosmic symplectite and infers that the ^{16}O-poor reservor is H_2O [2]. Nevertheless candidates of ^{16}O-rich end member were reported from one chondrule named a006 ($\Delta^{17}O$ = -37‰) [3], 4 Ca-Al-rich inclusions (CAIs) ($\Delta^{17}O$ = -37 to -32‰) [4,5] and the Sun ($\Delta^{17}O$ = -28‰) [6] relative to other CAIs ($\Delta^{17}O$ = -23‰) [e.g. 7], characteristics of the reservoir are unclear because of the diversity of few samples. In this study, we surveyed extreme ^{16}O-rich CAIs in Isheyevo chondrites to investigate the ^{16}O-rich end menber.

Thirteenthick sections of Isheyevo chondrite were newly prepared. X-ray elemental maps were obtaind for whole sections by FE-SEM-EDS. Al-rich inclusions on the sections were picked up as many as possible for isotope analysis in order to prevent biased sample selection. Oxygen isotope analysis for the inclusions were performed by SIMS.

Oxygen isotopic compositions of 263 CAIs were measured and 4 extreme ^{16}O-rich CAIs were found. Two CAIs are composed of grossite core rimmed by spinel, melilite and Ti-rich diopside layer and others lack diopside and/or melilite. While the heterogeneous composition of grossite ($\Delta^{17}O$ = -36 to -32‰) would be affected by altered feature of grossite, the spinel grains have uniform ^{16}O-rich compsition ($\Delta^{17}O$ = -37‰). If we draw a line in 3 oxygen isotope diagram with the extreme ^{16}O-rich spinel and spinel in chondules near the CAI, the slope is in good agreement with a slope of olivine in a006 chondrule and porphiritic olivine chondrule infer that the oxygen isotopic composition of the spinel grains maintain the signature of an^{16}O-rich end member of the Solar System.

Variations in initial $^{26}Al/^{27}Al$ ratios among fine-grained CAIs in the reduced CV chondrites

*Noriyuki Kawasaki[1], Changkun Park[2], Naoya Sakamoto[1], Hisayoshi Yurimoto[1,3]

1. Hokkaido University, 2. KOPRI, 3. ISAS/JAXA

Ca-Al-rich inclusions (CAIs) are oldest solids formed in the Solar System [1] and composed of high-temperature condensates from a solar-composition gas [2]. Most of CAIs are thought to have contained detectable amounts of live ^{26}Al, a short-lived radionuclide with a half-life of ~0.7 Myr, at their formation [3]. Recent high-precision $^{26}Al–^{26}Mg$ mineral isochron studies using secondary ion mass spectrometry (SIMS) revealed detailed distributions of initial $^{26}Al/^{27}Al$ values, $(^{26}Al/^{27}Al)_0$, for individual CAIs in the reduced CV chondrites [e.g., 4–9]; coarse-grained, igneous CAIs and fluffy Type A CAIs show similar variations in $(^{26}Al/^{27}Al)_0$ respectively, which range from ~5.2 to ~4.2 $\times10^{-5}$. In this study, we obtained new $^{26}Al–^{26}Mg$ mineral isochrons of five fine-grained, spinel-rich CAIs (FGIs) from the reduced CV chondrites Efremovka, Vigarano and TIL 07007 by *in situ* measurements using a SIMS instrument (CAMECA ims-1280HR installed at Hokkaido University). Since FGIs are likely to be condensates from a solar nebular gas, $^{26}Al–^{26}Mg$ mineral isochrons of them enable a more systematic comparison of $(^{26}Al/^{27}Al)_0$ between CAIs formed by condensation and by melt crystallization than has previously been achieved. The obtained $^{26}Al–^{26}Mg$ mineral isochrons for five FGIs give $(^{26}Al/^{27}Al)_0$ of (5.19 ±0.17) $\times10^{-5}$, (5.00 ± 0.17) $\times10^{-5}$, (4.53 ±0.18) $\times10^{-5}$, (4.43 ±0.31) $\times10^{-5}$, and (3.35 ±0.21) $\times10^{-5}$. The $(^{26}Al/^{27}Al)_0$ for two FGIs are essentially identical to the whole-rock CAI value of $(^{26}Al/^{27}Al)_0$ ~ 5.2 $\times10^{-5}$ [10, 11], while those for other three FGIs are clearly lower than the whole-rock CAI value. The range of $(^{26}Al/^{27}Al)_0$ values for the FGIs, from (5.19 ±0.17) to (3.35 ±0.21) $\times10^{-5}$, corresponds to a formation age spread of 0.44 ±0.07 Myr. These variations are slightly larger than those for igneous CAIs ranging from ~5.2 to ~4.2 $\times10^{-5}$ [5, 6]. Our data imply that CAI condensation events continued for, at least, ~0.4 Myr at the very beginning of our Solar System, if ^{26}Al was distributed homogeneously in the forming region. Alternatively, the observed variations would also raise a possibility of heterogeneous distributions of ^{26}Al in the forming region, corresponding to a range over, at least, $3.4 \times10^{-5} < (^{26}Al/^{27}Al)_0 < 5.2 \times10^{-5}$.

Petrographic study of compact type A CAIs with partial melting process

*Akimasa Suzumura[1], Yusuke Seto[2], Shoichi Itoh[1]

1. Graduate school of Science, Kyoto University, 2. Graduate school of Science, Kobe University

Refractory inclusions (Ca-Al-rich inclusions (CAIs)) in chondritic meteorites are the oldest substances formed in the Solar System (Connelly et al., 2012). Coarse-grained CAIs are classified into three subtypes, type A, B and C, according to their petrologic features (e.g., Grossman 1975). Compact type A CAIs (CTAs) are expected to be formed in the earliest stage of solar nebula and experienced a partial melting at least once (e.g., Simon et al., 1999). Yurimoto et al. (1998) have explained the heterogeneous oxygen isotope distributions among constituent minerals in Compact Type A CAIs have formed by the partial melting model. The indicator of partial melting is necessary to discuss the formation of the entire CAIs. However, there are only a few studies that referring to the formation processes of CTAs from the perspective of crystal growth in partial melting states (Ito et al., 2004, Park et al., 2012, Kawasaki et al., 2017). Generally, spinel in CTAs are poikilitically enclosed by melilite or fassaite, and estimated to be first crystallized mineral from CAI melt (Stolper, 1982). Namely, spinel in CTAs is expected to preserve valuable information of the thermal histories such as partial melting processes. Therefore, we focus on the petrological and mineralogical feature of spinel grains in CTAs. The studied CTA (KU-N) is included in a polished thin section of North West Africa 7865 reduced CV3 carbonaceous chondrite. Yoneyama et al. (2016) had studied the same CTA, and concluded that they experienced multiple partial melting. We have undertaken petrographic and mineralogical investigations of the CTA (KU-N-02) focusing on micro-textures resulting from partial melting (local compositional zoning, grain morphology and relationships of crystallographic orientation), using a polarizing microscope, scanning electron microscope (SEM) and electron back scatter diffraction (EBSD).

In the KU-N-02 CTA, spinel crystals are enclosed by melilite or fassaite. The former (up to 50 μm in size) is substantially euhedral but the edges are rounded, while the latter (about 10 - 100 μm in size) are almost euhedral with sharp edges. On the surfaces of both type of spinel grains, small perovskite particles with sizes of several μm are ubiquitously present.

In interior KU-N-02 CAI, single crystal melilite with spinel inclusions showed a remarkable compositional zoning Single crystal melilite show core-to-rim normal zoning, with decreasing Al and increasing Mg from core to rim. In the melilite single crystal, the area of about 10 μm wide around the spinel surfaces has Åk-rich compositions in comparison. By EBSD analyses, Åk-rich melilite crystal orientation and Åk-poor melilite crystal orientation is same. Therefore, Åk-rich melilite part (~10μm) surrounding spinel are crystallized after Åk-poor melilite. Because of these results, it is difficult to explain how Åk-rich part surrounding spinel in a melilite crystal crystallized by a single stage cooling. This texture indicates that the boundary area between spinel and melilite had eutectically melted at high temperature by some heating process, and then Mg/Al contents had been redistributed to melilite and spinel during rapid cooling. Accordingly, this partial melting probably resulted in the unique morphology and the crystallographic orientation relationship of the spinel enclosed by melilite and Local composition zoning of the melilite.

[J] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

Mon. May 27, 2019 3:30 PM - 5:00 PM JST | Mon. May 27, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University)

This session will focus on the evolution in the Solar System with interaction and co-evolution in minerals, water, organic matter, and noble gas in meteorites and interplanetary dust particles. New innovative analytical and theoretical techniques in various fields will be discussed. The developing methods are welcome to submit for the future mainstream of meteorite study. In order to explore the planetary materials and their evolution, both meteorite studies and experimental approaches are necessary. In this session, we will discuss these topics from extraterrestrial sample analyses and experimental works. Research works on undifferentiated and differentiated meteorites and parent body processes such as aqueous alteration, thermal metamorphism, shock metamorphism, volcanic activity, and core-mantle-crust differentiation are especially included in this session.

Since a wide variety of organic compounds have been detected in extraterrestrial bodies like carbonaceous chondrites [1] and comets [2], extraterrestrial organics could be essential sources for the first life on the Earth. Amino acids in carbonaceous chondrites increased after acid-hydrolysis, which suggested that not only free amino acids but also amino acid precursors were present in them. Laboratory experiments simulating extraterrestrial environments showed that not free amino acids but amino acid precursors were mainly formed [3, 4]. Though amino acid precursors in meteorites and products of laboratory simulations have not been well identified, aminonitriles and hydantoins could be candidates. On the other hands, proton irradiation of a mixture of CO, NH_3 and H_2O, which simulated possible reactions among interstellar media, gave complex amino acid precursors with large molecular weights [5]. Such amino acids and amino acid precursors that were formed abiotically in space environments would be exposed to various energy sources in prior to delivery to the primitive Earth. For example, organics in molecular clouds were exposed to galactic cosmic rays (protons and heavy ions). Interstellar organic compounds were irradiated with strong VUV/X-rays from the young Sun. Organic compounds in small bodies were irradiated with gamma rays from such nuclides as ^{26}Al in the earlier stage of the solar system. Organic compounds in interplanetary dust particles were exposed to solar UV/VUV before delivery to Earth atmosphere. Thus it is important to examine stability of amino acids and their precursors against energetic particles and photons. We experimentally investigated the stability of amino acids and their precursors against heavy ions, gamma-rays, UV and soft X-rays.

Target molecules used in the present study were (i) glycine (Gly), (ii) hydantoin (Hyd; a precursor of Gly), and (iii) aminoacetonitrile (AAN; the Strecker-type precursor of Gly). They are used as 5 mM solutions in ammonia water (pH 9). In addition to them, we chose (iv) organic material synthesized from a mixture of CO, NH_3 and H_2O by 2.5 MeV protons from a Tandem accelerator (Tokyo Tech). We will call them CAW. CAW contained complex amino acid precursors with large molecular weights [3].

Experimental: *Heavy ions irradiation*: Aqueous solution of each target molecule was frozen in liquid nitrogen, and was irradiated with 290 MeV/u carbon ions from HIMAC (NIRS, Japan) at 7.5-15 kGy. *Gamma-rays irradiation*: Aqueous solution of each target molecule was irradiated with gamma rays (5-10 kGy) from a ^{60}Co source (Tokyo Tech, Japan). *UV irradiation*: Each target molecule was irradiated with UV from a xenon lamp after dried in pits of an aluminum plate. *Soft X-rays irradiation*: Each target molecule was irradiated with soft X-rays from a synchrotron (NewSUBARU BL-6) for 10 min after dried on aluminum plates. Amino acid analysis: all the target materials were recovered as aqueous solutions, were acid-hydrolyzed (6 M HCl, 110℃, 24 h), and amino acids in them were determined by reversed-phase HPLC after pre-column derivatization with *o*-phthalaldehyde and mercaptoethanol.

Results and Discussion: Since glycine was always major amino acids after acid hydrolysis of all the target materials after irradiation yielded glycine, we will discuss stability of target molecules by using the glycine

©2019. Japan Geoscience Union. All Right Reserved.

yields.

Heavy ions irradiation: Recoveries at 15 kGy were as follows. CAW (95.1%), Hyd (93.6%), Gly (91.8%) and AAN (77.5%). AAN was least stable among all. *Gamma-rays irradiation*: Decomposition of AAN, CAW and Hyd at 10 kGy was not detected, while recovery of Gly was 79.5%. *Soft X-rays irradiation*: recovery ratios were less than 10 % in the case of Gly, Hyd and AAN, while that of CAW was 51.1%. UV-irradiated samples were now under analysis.

Free amino acid (glycine) was generally less stable than amino acid precursors (CAW and Hyd), and CAW was most stable among 4 compounds tested against all the energies. Thus it was suggested that complex amino acid precursors were robust molecules in space, while free amino acids were easy to decompose even if they were formed from their precursors in space.

Production of amino acids by gamma rays during aqueous alteration process in meteorite parent body

*Shinya Asano[1], Isao Yoda[2], Yasuji Muramatsu[3], Yoko Kebukawa[1], Kensei Kobayashi[1]

1. Yokohama national university, 2. Tokyo Institute of Technology, 3. University of Hyogo

[Introduction]Organic compounds such as amino acids are necessary for the birth of life on the earth. Extraterrestrial materials such as meteorites are considered as one of the sources of these amino acids. Since most of these meteorites originated from asteroids, we need to consider the origins of organic matter in asteroids. In the early stage of solar system formation, asteroids beyond the snow line contained ice and low molecular weight organic matter derived from dust. The ice melted due to the heat generated by the radioactive decay of ^{26}Al and aqueous alteration occurred. It is pointed out the complex macromolecular organic materials (insoluble organic matter, IOM) in meteorites may have formed during aqueous alteration (approximately 0 to 150 ˚C.) [1]. Based on this hypothesis, experiments simulating aqueous alteration on asteroids showed that amino acids and high molecular weight organic compounds similar to IOM in meteorites was formed after heating of formaldehyde, ammonia, water [2]. In this study, we aimed to investigate effect of gamma rays generated by radioactive decay of ^{26}Al during aqueous alteration for organic synthesis.
[Experimental]^{60}Co gamma ray source (Tokyo Institute of Technology) was irradiated to glass tubes containing 200 μl of water: formaldehyde: ammonia = 100: 5: 5 (molar ratio). Six different irradiation conditions were applied: 3 kGy/h ×2.5 h, 3 kGy/h ×4 h, 3 kGy/h ×5 h, 1.5 kGy/h ×5 h, 1.5 kGy/h ×8 h, and 1.5 kGy/h ×10 h. For comparison, the same solutions were heated in an oven at 150 ˚C for 24 h. The samples after irradiation were placed on CaF_2 plate and dried, then analyzed by FT-IR. The samples after irradiation were placed on gold plate and dried, then analyzed by X-ray absorption edge near structure analysis (XANES) of Hyogo prefectural university. Also, the samples were subjected to acid hydrolysis (6 M hydrochloric acid, 24 h, 110℃) and analyzed amino acid concentrations by cation exchange HPLC.
[Results and Discussion]<Cation exchange HPLC>Various amino acids such as glycine, alanine, β-alanine were detected from the gamma-ray irradiated samples after acid hydrolysis. Relatively large amount of alanine was produced from the irradiated samples compared to the heated samples. It suggests that the formation path ways of amino acids differ between the irradiated samples and the heated samples.
[Future plan]We are planning to extrapolate the gamma-ray induced amino acid yields to the meteorite parent body environments by extending the irradiation conditions (total dose and irradiation rate) using the calculated value of total dose of gamma ray from ^{26}Al during aqueous alteration. In addition, macromolecular organic compounds will be analyzed using LC-MS.

Kinetic approaches for the thermal history of organic matter in meteorites based on Raman spectra

*Kento Kiryu[1], Yoko Kebukawa[1], Motoko Igisu[2], Takazo Shibuya[2], Kensei Kobayashi[1]

1. Yokohama National Univ., 2. Japan Agency for Marine-Earth Science and Technology

CI, CM, and CR chondrites experienced aqueous alteration in their parent bodies, and contain organic carbon up to a few wt%. More than 70 wt% of it exists in the form of insoluble organic matter (IOM) (e.g., Pizzarello et al., 2006). Organic matter (OM) is susceptible to heating, and changes their structures, reflecting aqueous alteration and/or thermal metamorphisms. Thus, it attracts attention as the index of the parent body processes.

Kebukawa et al. (2010) estimated kinetic parameters for thermal degradation of aliphatic C-H through in-situ heating experiments of IOM and bulk of the Murchison meteorite (CM2) using the Fourier transform infrared micro-spectroscopy (microFTIR) combined with heating stage. They revealed that the peak intensity of aliphatic C-H is a good index of low-temperature and/or short-duration heating in the parent bodies. However, microFTIR is not enough for estimating thermal process of OM under high-temperature and long-duration heating which IR signals of aliphatic C-H are unlikely to be detected. Raman spectroscopy is a complementary tool to IR spectroscopy, since their spectral features of OM in the chondrites reflect thermal changes in aromatic structure in the complex OM (Quirico et al. 2003; Bonal et al., 2006, 2007; Busemann et al., 2007). When chondritic OM is heated, its aromatic structure will be more ordered to graphitic structure. This process is an irreversible, and results in changes of disordered (D_1-: ~1350 cm^{-1}) and graphite bands (G: ~1590 cm^{-1}) in Ramn spectra. Therefore, D_1- and G-bands were often used as indicators of degree of thermal metamorphism, but understanding of kinetic behaviors of the Raman spectral parameters is still limited. Thus, in order to evaluate thermal history of OM in chondrites under high-temperature and/or long-duration heating, we performed a series of heating experiments of the Murchison meteorite powders and kinetic analyses of their Raman spectral parameters.

The Murchison meteorite powders were heated under low oxygen condition in a vacuum furnace for 3-48 h at 600-900˚C. The low-oxygen condition was maintained by a gas mixture of N_2 and H_2 (99:1, v/v). The samples after heating were analyzed using Raman spectrometer with a 532 nm laser (RAMANtouch; Nanophoton). The Raman spectra of all the samples show D_1- and G-bands. We determined 5 Raman spectral parameters: the full width at half maximum (FWHM) and the peak positions of D_1- and G-bands, and the ratio of the peak intensity of D_1- to G-band. The changes in these Raman parameters with time at each temperature will be fitted with algebraic kinetic equations deduced by possible physical mechanisms, and estimate reaction rate constant. Then the apparent activation energies and frequency factors will be calculated by the reaction rates using the Arrhenius equation. Finally, we will establish the Raman parameters as functions of heating temperature and time. Combining previously reported kinetics of aliphatic C-H (Kebukawa et al. 2010), it may allow us to calculate precise time and temperature of thermal processes for chondrites.

Relationship between spatial distribution of organic compounds and minerals in the Murchison meteorite

*Taiyo Sengoku[1], Minako Hashiguchi[1], Hiroshi Naraoka[1]

1. Kyushu University

[Introduction]

Primitive meteorites contain a wide variety of organic compounds. More than 600 species of CHN compounds were identified in the methanol extract of the Murchison meteorite (CM2), in which saturated- and unsaturated-alkylated pyridines ($C_nH_{2n-4}N^+$ and $C_nH_{2n-6}N^+$) as well as alkylimidazoles ($C_nH_{2n-1}N_2^+$) are predominant (Naraoka et al., 2017). Interaction between organic matter and minerals during aqueous alteration is very important in the chemical evolution (e.g. Kebukawa et al., 2010), therefore, it is necessary to investigate the spatial distribution of the organic matter and minerals in the meteorites. In the previous studies, chemical imaging of soluble organic matter (SOM) was performed on the Murray and Murchison meteorites (CM2) by desorption electrospray ionization/high-resolution mass spectrometry (DESI/HRMS), and the different spatial distribution was observed among the different CHN species and/or their alkylated homologues (Naraoka & Hashiguchi, 2018, Hashiguchi & Naraoka, 2018). However, the relationship between the organic compounds and minerals is still unresolved. In this study, the DESI-HRMS imaging and detailed mineralogical observation were performed on fragments of the Murchison meteorite.

[Sample & Method]

Two fragments designated as “np15" (2x3 mm^2) and “np16” (2x2 mm^2) were obtained by chipping from different large fragments of the Murchison meteorite. These fragments were embedded in indium or metal with low-melting point for DESI-HRMS imaging. The DESI-HRMS imaging was performed on each sample for three times. Methanol was used as a spray solvent with the flow rate of 2 μL/min. The electrospray voltage was set to 3 kV. The nebulizer N_2 gas pressure was ~100 psi. The positive ions were collected in a full scan mode (m/z 50-500) with mass resolution of about 140,000 ($m/\Delta m$ at m/z 200) on the sample surface of np15 (4x4 mm^2) and np16 (3.8x3.8 mm^2). For the fragment np16, dry polishing was performed on the sample to remove ~250 μm from the surface and the imaging was performed again, because no signals of CHN compounds were obtained by the 1st set of DESI-HRMS imaging. After the DESI-HRMS imaging, the same sample surface was used to obtain backscattered electron images (BSE) and X-ray elemental maps using SEM/EDS.

[Results & Discussion]

Some alkylated homologues of CHN compounds were detected from np15 by DESI-HRMS imaging. Their exact masses correspond to alkylimidazole ($C_nH_{2n-1}N_2^+$) and saturated- or unsaturated-alkylated pyridine ($C_nH_{2n-4}N^+$ or $C_nH_{2n-6}N^+$) within 3 ppm of mass precision. The spatial distribution was different between $C_nH_{2n-1}N_2^+$ and $C_nH_{2n-4}N^+$, which is consistent with the previous study (Naraoka & Hashiguchi, 2018). On the other hand, no CHN compounds were detected from np16. After removing ~250 μm of the surface of np16 by polishing, some CHN compounds corresponding to $C_nH_{2n-1}N_2^+$ and $C_nH_{2n-6}N^+$ were detected in 3rd DESI-HRMS imaging finally, however, these compounds were not detected by 1st and 2nd analyses. These results indicated that the CHN compounds might have been volatilized from the sample surface

©2019. Japan Geoscience Union. All Right Reserved.

during its storage, and that repeated DESI-HRMS imaging is important to obtain clear signals of SOM from inside of meteorite. The detected CHN compounds showed heterogeneous spatial distribution in the sample surface, which indicate that dry polishing does not affect the spatial distribution of SOM significantly.

In both np15 and polished np16 samples, the CHN compounds distribute mainly in the matrix region (~ few hundreds of square meters) of the meteorite. Although the X-ray elemental mapping showed that CHN compounds-rich region seemed to contain abundant Ca-containing minerals in both fragments, no clear relationship was observed between the averaged chemical compositions of matrix region and the spatial distribution of the CHN compounds. Further detailed analysis will be performed on tiny minerals in the matrix.

O and Al-Mg isotope systematics of a hibonite-melilite-rich fine-grained CAI in the reduced CV chondrite NWA8613

*Sohei Wada[1], Noriyuki Kawasaki[1], Hisayoshi Yurimoto[1,2]

1. Hokkaido University, 2. ISAS/JAXA

Ca–Al-rich inclusions (CAIs) in meteorites are composed of high-temperature condensate minerals from the solar nebular gas [1]. CAIs in CV chondrites are petrographically divided into the coarse-grained CAIs and fine-grained CAIs (FG-CAIs). Complex layer structures of constituent minerals and REE patterns of FG-CAIs suggest they are condensates from the nebular gas [2, 3]. Igneous CAIs that experienced melting and crystallization, such as coarse-grained Type B CAIs, have been extensively studied their formation processes, O-isotope compositions of minerals, and formation ages [4, 5]. On the other hand, such systematic investigations for the formation of FG-CAIs have been poorly conducted. Here, we investigated O- and Al–Mg isotope systematics of a hibonite-melilite-rich FG-CAI from the reduced CV chondrite NWA8613 as well as detailed petrographic observations. The O- and Al–Mg isotope measurements were conducted using SIMS instruments of Hokkaido University (Cameca ims-1270 and ims-1280HR).

The FG-CAI has an irregular shape with a size of approximately 10 ×12 mm and composed mainly of melilite, hibonite, and spinel. O-isotope compositions of the constituent minerals plot along the CCAM line, ranging between $\Delta^{17}O \sim -23‰$ and 0‰. The FG-CAI is petrographically divided into hibonite-rich core, spinel-rich core, melilite-rich inner-mantle, and hibonite-spinel-rich outer mantle. The CAI is rimmed by thin spinel and diopside layers. Melilite crystals are contained in core and mantle. Melilite crystals in the core exhibit normal chemical zoning and O-isotope compositions from $\Delta^{17}O \sim -23‰$ to −10‰ with increasing Åk composition. The melilite crystals in the inner-mantle show chemically complex, oscillatory zoning patterns, but are uniformly ^{16}O-poor ($\Delta^{17}O \sim 0‰$) despite their chemical variations (Åk2–14). Melilite crystals in the outer-mantle exhibit normal chemical zoning and variable O-isotope compositions from $\Delta^{17}O \sim -17‰$ to 0‰ with increasing Åk composition. The spinel and hibonite grains in the FG-CAI are uniformly ^{16}O-rich ($\Delta^{17}O = -23‰$). Al–Mg isotopic compositions of hibonite in the outer-mantle and in the core and melilite in the inner-mantle plot on a single straight line within error; an Al–Mg mineral isochron can be defined to give an initial $^{26}Al/^{27}Al$ value of $(4.50 \pm 0.09) \times 10^{-5}$. Given that the constituent minerals formed by condensation and were accumulated to form the FG-CAI, the nebular gas, from which they condensed, had variable O-isotope compositions between $\Delta^{17}O \sim -23‰$ and 0‰. The Al–Mg systematics of the FG-CAI indicate that these formation events occurred at 0.16 ±0.02 Myr after the formation of canonical CAIs [7], if ^{26}Al was homogeneously distributed. Our data support the presence of the nebular gas with variable O-isotope compositions during the first ~0.2 Myr of the Solar System formation [8].

Observation of Enstatite Whiskers in Fine-grained Rims in the Carbonaceous Chondrite ALH A77307

*Yasuhisa Shirota[1], Masahiro YASUTAKE[1], Satomi Enju[1], Akira Tsuchiyama[1]

1. Division of Earth and Planet, Science, Kyoto University

Introduction Chondritic porous -interplanetary dust particles (CP-IDPs) are material that are suggested to be originated from comets and to be one of the most primitive materials in the solar system (Bradley et al., 1983). CP-IDPs include enstatite ($MgSiO_3$) whiskers. They are thought to be formed by condensation in the solar nebula (Bradley et al., 1983).

Primitive carbonaceous chondrites are affected by little aqueous alteration. Recent studies have discovered enstatite whiskers in matrices in primitive carbonaceous chondrites (Vaccaro et al., 2017; Matsumoto et al., 2018). If such crystals have similar formation processes to those of enstatite whiskers in CP-IDPs, it will constrain the formation processes of not only asteroids but also CP-IDPs. However, only a few enstatite whiskers are observed in carbonaceous chondrites. Therefore, it is not certain whether or not enstatite whiskers are common in carbonaceous chondrites and have same formation processes in CP-IDP.

We conducted a detail petrological observation of matrix in ALH A77307 (CO3.0) to understand distribution of whisker-like enstatite crystals using a scanning electron microscopy (SEM) and to constrain the formation process using a transmission electron microscopy (TEM).

Sample and Methods We observed one of the most primitive CO chondrites ALH A77307. Vaccaro et al. (2017) reported whisker-like enstatite crystals in ALH A77307. SEM/EDS analysis was carried out with an FE-SEM (JEOL JSM-7001F, Kyoto University, Hitachi HT SU6600, ISAS, JAXA) operating at 100 pA probe current and 8 kV accelerating voltage. A TEM thin section including one whisker was extracted using focus ion beam (FIB) (FEI, Helios NanoLab 3G, Kyoto University). TEM analysis was carried out with a (S)TEM/EDS (JEOL JEM-2100T, Kyoto University) operating at 200 kV accelerating voltage.

Result and Discussion We observed fine-grained rims around three chondrules. These rims consist mainly of amorphous silicate, olivine, pyroxene, and Fe,Ni metal, and similar to primitive matrix. The whisker-like enstatite crystals occur in all regions observed and the total number of whiskers found are 12. The maximum size of the whisker is 11.91 μm in length and 0.27 μm in width. We classified whiskers based on criterion the aspect ratio, p, by Bradley et al. (1983). The whiskers are classified as 4 Rods (p>20) and 8 Ribbons (p<20). The abundance of whiskers is >40 mm^{-2}, suggesting that whisker-like enstatite is common in chondrule rims in primitive carbonaceous chondrites although the abundance in CP-IDPs is higher. The aspect ratios are similar to those of enstatite whisker in CP-IDPs. In contrast to enstatite whiskers in CP-IDPs, some whiskers are curved and/or broken. It may be the result of deformation during accumulation on the parent body.

We have observed one ribbon crystal (length 1.21 μm, width 0.16 μm) using TEM. The ribbon crystal was orthoenstatite elongated along [001] axis based on electron diffraction patterns. Three dimensionally, this crystal is thought to be a columnar crystal elongated along [001] or a plate crystal with flattened (010) plane. From this results, this crystal is thought to be a platelet crystal formed by condensation in the solar nebula like enstatite whiskers in CP-IDPs (Bradley et al., 1983) or crystal formed by annealing of

amorphous silicate (Brearley, 1993). To constrain more detail formation process of the whisker-like material in carbonaceous chondrites, mineralogical investigation of whisker-like material, especially rod crystals is needed.

3D observation of whisker-like material in the porous matrix of the Paris CM chondrite by SR-XCT

*Masahiro YASUTAKE[1], Epifanio Vacarro[2], Kentaro Uesugi[3], Akihisa Takeuchi[3], Tsukasa Nakano[4], Akira Tsuchiyama[1]

1. Division of Earth and Planetary Science, Graduate School of Science, Kyoto University, 2. National History Museum, London, 3. JASRI/SPring8, 4. GSJ/AIST

Introduction The chondritic-porous interplanetary dust particles (CP-IDPs) are well-known material, that preserves primitive and pristine features of the early solar system. Enstatite whisker is one of the materials that characterizes CP-IDPs. It is thought that enstatite whiskers are condensates formed in the inner solar system and transferred to the outer regions, where comets formed [e.g. 1, 2]. Recently, whisker-like enstatite crystals were found in the primitive carbonaceous chondrites [3, 4]. However, the whisker-like materials they found could be a cut-plane of thin enstatite plate. By the 2D observation, it is hard to solve this matter. 3D observation based on synchrotron radiation X-ray nano-CT is a strong tool to understand the crystal shape, mineral phase, and rough composition. We conducted a 3D observation to better understand the characteristics of whisker-like materials in primitive carbonaceous chondrites.

Methods We investigated the Paris primitive CM chondrite. Paris was reported to have a very primitive matrix that includes GEMS-like materials [5]. A section of this meteorite was observed and elemental maps of the primitive matrix were obtained by FE-SEM/EDS. A house-shaped CT sample (~25 x 25 x 30 μm) was extracted from the primitive matrix by using a FIB-SEM. CT data of the micro-samples were conducted at beamline BL47XU, SPring-8. CT images were acquired at energies of 7 keV and 7.35 keV with voxel sizes of ~32.2 nm and ~ 33.9 nm, respectively. Mineral phases were estimated using dual-energy tomography (DET) method using the X-ray linear attenuation coefficient (LAC) [6].

Result and Discussion The observed matrix is a part of the fine-grained rim of Type I porphyritic olivine pyroxene chondrule. The matrix is porous and consists mainly of amorphous silicates that include sub-micron sized Fe-rich phases. Whisker-shaped materials are abundant in the CT sample observed. However, fibrous alteration materials were also reported in the matrix of Paris [5]. The whisker-like materials observed might include such products in addition to enstatite. The size of the largest whisker is ~6 μm x ~700 nm x ~350 nm (Fig. 1) and similar to ribbon-type enstatite whisker in the CP-IDPs [1]. This whisker has a curved shape unlike those in CP-IDPs. Probably it reflects deformation during accretion to the parent body and/or planetary processes such as planetary collision.

The LAC values of most whisker materials are hard to obtain quantitatively because refraction of X-ray at the edges of the narrow whiskers enhanced their LAC values. The LAC values of the largest whisker are less affected by refraction and have the range of ~170-180 cm^{-1} and ~250-270 cm^{-1} at 7.00 and 7.35 keV, respectively. These values are consistent with those of pyroxene ($En_{80}Fs_{20}$) and clearly distinguishable from the values of fibrous alteration products (cronstedtite, tochilinite, and ferrihydrite) [5]. The above results suggest that this whisker material is an enstatite whisker. The possibility of olivine whisker (~Fo_{85}) cannot be excluded but forsterite whiskers have not been reported so far. Thus, it is reasonable to consider that the enstatite whiskers accreted to the carbonaceous chondrite parent body.

Crystallographic features such as defects and direction of elongation are still not examined. Investigation of crystallography is required to constrain the formation processes of whiskers, and it will enable us to

©2019. Japan Geoscience Union. All Right Reserved.

compare the enstatite whiskers in carbonaceous chondrites with those in CP-IDPs.

Development of cryogenic SIMS technique for isotope analysis of fluid inclusions

*Isono Yuki[1], Naoya Sakamoto[2], Hisayoshi Yurimoto[3]

1. Department of Natural History Sciences, Hokkaido University, 2. Creative Research Institusion, Hokkaido University, 3. Department of Natural History Sciences, Hokkaido University

Introduction: Fluid inclusions in halite crystals from meteorites provide direct information of extraterrestrial liquid water [1]. In-situ isotope analysis of the fluid inclusions was realized by SIMS equipped with a cold-stage [2]. However, the analytical precision is limited to ±14 ‰(1 σ) for $\delta^{18}O$ due to deep sputter crater to excavate fluid inclusions. One of the methods to improve the analytical precision would be expose fluid inclusions on the sample surface. We froze the fluid inclusions and polish under cryogenic condition in nitrogen atmosphere [3, 4]. In order to measure frozen polished fluid inclusions by SIMS, the surface should be coated by conductive thin layer such as Au. However, the Au thin layer was not enough conducted because condensation of frost particles occurred before introduce the polished sample into Au coater. The sample temperature was −100 ˚C while the dew point in the glove box (−60˚C) was higher than the sample temperature [4]. Therefore we changed the sample temperature.

Changes of sample preparation procedures: The sample preparation system for cryogenic SIMS is composed of a cryo-polisher and Au ion-coater in a glove box [3]. The temperature of polishing set to −35 ˚C. Thus frost condensation on the polished surface was prevented. After polishing, the sample was settled on the bottom of deep well of new designed cryo-coating stage. The cryo-coating stage was precooled to −196 ˚C by liquid nitrogen and the deep well was filled with cool nitrogen gas evaporated from liquid nitrogen in order to prevent frost formation on sample surface. This cooling process is necessary because sublimation temperature of ice is −50 ˚C during Au coating. The sample temperature was estimated to −196 ˚C before taking into the Au coater and warmed up −130 ˚C at taking from the Au coater after Au coating for 4 minutes.
The polished ice embedded in an epoxy disk was set to the cryo-holder and transferred to cryo-stage (−190 ˚C) of Cameca ims-1270 instrument using cryo-transfer system [3]. The liquid nitrogen was supplied by a roots pump to reduce the sample stage vibration. The measurement methods for oxygen isotopes were similar to those of [2].
We obtained mass spectra of oxygen isotopes from H_2O-ice. Intensity of ^{16}O peak was about 2.8 $\times 10^5$ cps and a tale was observed symmetrically at both side of the peak below 3 cps. The interference of tail from $^{16}OH^-$ to $^{17}O^-$ was estimated to be about 10 ‰because the intensity of $^{16}OH^-$ is comparable to ^{16}O peak. Oxygen isotope analysis using $^{16}OH^-$ and $^{17,18}OH^-$ signal would be effective for further high precision oxygen isotope analysis for H_2O ice as well as the tail correction method used in [2].

X-ray diffraction study using Gandolfi attachment: Implications for small extraterrestrial materials

*Naoya Imae[1,2], Makoto Kimura[1]

1. Antarctic Meteorite Research Center, National Institute of Polar Research, 2. SOKENDAI

Introduction

Recent studies have established the bulk features of various chondrite species based on the X-ray diffraction patterns (Howard et al. 2009; Imae and Nakamuta 2018; Imae et al. 2019). In the present study, X-ray diffraction experiments were carried out using Gandolfi attachment in order to apply for small extraterrestrial materials of various kinds of stony meteorites. The present technique is convenient in the laboratory and also useful for rapidly identifying the mineral species without any significant sample loss.

Experiments

We used the X-ray diffractometer in air with the goniometer radius of 30 cm (RIGAKU, SmartLab) at NIPR on the following conditions: (1) CuKa1 with 40 kV, and 30 mA for glass X-ray tube and 40 mA for ceramic X-ray tube, (2) the X-ray beam of 0.4 mm in diameter obtained from the polycapillary focusing optics (CBO-f unit), (3) the strip detector (D/teX Ultra 250) for counting diffracted X-rays, (4) the revolution rate of the goniometer head on the Gandolfi attachment at 30 rpm, and (5) the scan speed of normally 0.2 º/min or 0.5 º/min with the step of 0.01º and the average of the repeated analyses.

Glass fiber (13 μm in diameter) attached with glass rod (1 mm in diameter) was mainly used for holding samples. Both powder and grain samples with the diameter of ~0.2-0.8 mm were used for the measurements.

Powders and single grains for San Carlos olivine and NWA 4719 L6 chondrite were used for the calibration focused on olivine 130 index. So far, 36 stony meteorites have been measured and they are 27 ordinary chondrites (mostly Antarctic meteorites), 5 carbonaceous chondrites, an E chondrite (NWA 7401), a eucrite (Cachari), a diogenite (Bilanga), and an aubrite (Pena Blanca Spring).

Results and discussion

Calibration: The two-theta position of the olivine 130 peak for the powder samples of San Carlos olivine shows nearly consistent value by Yoder and Sahama (1957), on the contrary, the intensity of the San Carlos olivine grains is lower than that of powder on the similar measurement condition, and in addition the position of the two-theta is slightly higher than that of powder. In case of chondrite (NWA 4719 L6), the intensity is significantly lower than San Carlos olivine. Although the two-theta values for powder samples and grain samples are within the mean Fa# range of L group, the intensity of grain is significantly lower than that of powder.

©2019. Japan Geoscience Union. All Right Reserved.

Samples: The systematic differences of olivine 130 two-theta values were observed among ordinary chondrites: 32.18º-32.29º for H, 32.15º-32.21º for L, and 32.13º-32.16º for LL. These ranges include that the two-theta values are obviously higher than the ranges expected from the mean Fa# for three chemical groups (32.18º-32.21º for H, 32.12º-32.16º for L, and 32.08-32.12 for LL, Yoder and Sahama 1957). The existence of orthoenstatite 511 peak is an indicator for equilibrated ordinary chondrites but not definite, since the peak intensity is normally low. More ferroan olivine peak than ordinary chondrites appears from carbonaceous chondrites. EL6 consists of orthoenstatite. Diffraction patterns of achondrites are different from those of chondrites: pigeonite and anorthite peaks for eucrite and dominant orthopyroxene for diogenite, and dominant clinoenstatite for an aubrite. Fine-grained powder samples may represent the bulk chondrite compositions, but not for grains. This may lead to the different diffraction pattern.

Summary

The present technique is useful conveniently for examining limited or small extraterrestrial materials, when we take into consideration the variations for chondrite species depending on the different sample conditions of powder or grain and the relative modal abundance of olivines and pyroxenes for grains with the limited range of variation of the chemical groups.

Trace elements analysis and Ar-Ar dating for microgram-scaled extraterrestrial samples

*Ryuji Okazaki[1], Sekimoto Shun[2]

1. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 2. Institute for Integrated Radiation and Nuclear Science, Kyoto University

In order to elucidate the origin and evolution of planetary materials, it is important to determine the chemical composition and timing of geological events for specific minerals and microscopic portions, such as impact melt pockets, CAIs (Ca- and Al-rich Inclusion), and chondrules. Combination of EMPA, INAA, and noble gas analysis are one of the best way to determine chemical and isotopic compositions of extraterrestrial dust particles (micrometeorites) and spacecraft-returned samples.
As a first step, we have analyzed rock fragments (<several hundreds of micrometer in diameter) recovered from Holbrook L6 chondrite. Neutron irradiation and NAA experiments were conducted at Institute of Integrated Radiation and Nuclear Science, Kyoto Univ. Allende CV3 and Madagascar feldspar were used for standardization of INAA and Ar-Ar analyses, respectively. Each of the sample particles was individually placed in a conical dimple (ϕ1, depth ~ 0.5 mm) of a sapphire disk (ϕ5.5, 1.5 mm thick), and covered with a sapphire disk (ϕ5.5, 0.3 mm thick). Each of the sapphire container was wrapped with pure aluminum foil. These Al-wrapped containers were stacked and sealed in aluminum capsules to perform neutron irradiation at the hydro-irradiation port. After irradiation, the samples were recovered from irradiated glass containers, and moved to non-irradiated containers in order to reduce the radioactivity from the sapphire containers and Al foil. Gamma-ray measurements for short half-life nuclides were performed promptly after collection of the samples. Several months after the irradiation, some of the Holbrook samples were transported to Kyushu Univ. to measure noble gas isotopes.
Concentrations of Co and Ni in two Holbrook samples were determined to be 57 and 157, and 1260 and 13400 ppm, respectively. The Ni/Co ratios of the Holbrook samples are 22 and 85, which are similar to those observed in iron meteorites and chondrites (e.g., Ebihara et al., 2011). The result guarantees our NAA measurement.
Noble gas isotopes (^{36}Ar, ^{38}Ar, ^{39}Ar, and ^{40}Ar) were determined for different two Holbrook samples using stepwise heating method. The bulk ^{39}Ar concentration in the irradiated standard feldspar (K: 12.6 wt%) is 7E-6 cm^{3}STP/g, and the bulk ^{39}Ar/^{40}Ar ratio is 0.026. The result indicates that the neutron flux of KURRI is enough to determine ^{39}Ar for microgram samples with K>0.1 wt%. Using the neutron flux determined by the standard feldspar, with 450 Ma of K-Ar age (ranging 435-461 Ma; Flude et al, 2014), we calculated the Ar-Ar ages for two Holbrook samples (9.4 and 16.8 μg) to be 3795±368Ma (based on 3 plateau ages of 4 stepwise extractions) and 3714±128Ma (based on 4 plateau ages of 7 stepwise extractions). Noble gases extracted at the lowest and highest temperature steps are influenced by atmospheric Ar, resulting unreasonable old Ar-Ar age. Based on these results, we found appropriate extraction temperature for plagioclase-rich microgram samples to be 600, 800, 900, 1000, 1100, 1200, 1400, and 1600 ˚C.
Through this study we have established an analytical method that consists of a combination of EPMA, INAA, and noble gas analyses. The new method will be applied for Antarctic micrometeorites and the Hayabusa2 samples.

Magnetic separation and identification of low-temperature solid particles using their translation caused by a pair of small permanent magnets

*Chiaki Uyeda[1], Wakana Yamaguchi[1], Keiji Hisayoshi[1], Kentaro Terada[1]

1. Institute of earth and Space Science Graduate School of Science Osaka University

Most solid particles in nature are categorized as diamagnetic or weak paramagnetic materials; they are commonly believed to be magnetically inert, and cannot attain strong magnetization to cause specific magnetic motions at practical field intensity. Indeed, strong magnetic field above the level of 10 T were applied in previous studies to induce magnetic levitations. A method to separate solid particles by a field gradient produced by small NdFeB magnets was recently proposed and experimentally approved using a setup operated in microgravity condition [1]. By improving this system, magnetic separation was realized on volatile solid particles, namely H2O and CO2, for the first time [2]. In addition, it was possible to estimate the material of the particle in a non-destructing manner by comparing the experimental value of magnetic susceptibility with a list of published values [1][2]: here the susceptibility was obtained from the velocity of the translating particle without the knowledge of particle mass.

In the present experimental present setup, a pair of small NdFeB plates was attached in a double glass container. A microgravity condition is produced inside the box by free fall from a height of 180 cm. An ensemble of heterogeneous particles translates and separates by magnetic field gradient in free fall. The Hi-vision camera observed the translation and susceptibility is calculated by obtained terminal velocity [1]. The obtained susceptibility of the particle is compared with literature data and materials of particles are estimated.

The field-induced translational motions realized in μg condition can be utilized in various space missions in future; this is because the small but rigid apparatus can separate and identify the heterogeneous particles that is expected to be collected in an on-site mission. One of the major purposes to perform space explorations to the outer solar system was to identify the solid materials that are observed on satellite surfaces or ring. It is concluded by recent observation that the solid particles were mainly composed of ice (Ih) with high purity; previously it was considered that the icy particles of the rings contain significant amount of rock-forming silicates. Hence, for a future task, quantitative information of the minor silicate composition included in the icy particle is required in studying the origin of the Saturn rings.

An efficient method that can non-destructively identify the components of a heterogeneous aggregate sample is desired in various research fields of material science. Using an infrared optical analysis, for example, the material composition of the particle interior is difficult to determine when the sample is larger than 100 μm in diameter. In the case of a conventional mass spectrometer, it is difficult to identify the composition of solid particles without destructing the sample. Although various microprobe devices are effective in performing refined survey on aggregate samples, it is difficult to conclude by these methods whether small particles included in the aggregate are completely discovered and identified without omission. In such cases, the particles should be definitely separated into groups of different materials before performing refined analysis [1-3]. Note that the present proposal of magnetic separation can overcome the abovementioned limitations of the conventional methods, and in future, it may serve as

a standard pretreatment tool of material analysis.

The metallographic cooling rate of the Tafassasset primitive achondrite

*naoji sugiura[1], Tomoko Arai, takafumi matsui

1. Chiba Institute of Technology

Tafassasset (Tafa) is a primitive achondrite with carbonaceous chondrite-like (CC) isotopic (Cr etc.) signatures. Cooling rates and chronological information give valuable insight on the evolution of achondrite parent bodies. Brent et al. [1] constructed an evolutionary model (the parent body with a radius ~17 km, accreted at ~1 Ma after CAI; Tafa is located in the middle of the mantle). It is mainly based on the chronology, but is considered to be supported by the metallographic cooling rate (100~200 C/Ma). But it is said to require refinement. Here we report observations of the metal texture and compositions, based on which a cooling history is derived.

Observation

Fe-Ni grains (average composition ~10 mol.% Ni) in Tafa show various textures. Many grains show kamacite that nucleated on the metal-silicate boundary and expanded inward during cooling. The central part is zoneless plessite which must be martensite at higher temperatures but now is made of kamacite and taenite. An interesting feature is that the boundary of kamacite and interior plessite is made of thin (~a few mm wide) taenite wall, suggesting rapid coolig. The compositions range from 17 to 31 % Ni and the average is ~26% Ni. Considering the difficulties in measuring compositions of thin taenite rim, the real value could be ~31% Ni. The zoneless plessite interior (average composition ~10 mol% Ni) is made of taenite islands in kamacite matrix. The taenite island sizes are usually only a few mm or less and the compositions range, if measurable, from 28 to 39% Ni, and the average is ~34% Ni. Again, the real value is considered to be close to ~39% Ni. A typical distance between taenite islands is ~10 mm. There are isolated zoned taenite grains, the central compositions of which are correlated with the size. There are zoned taenite grains which are surrounded by kamacite. Their compositions at the center mostly do not depend on the size, and is ~10 mol.% Ni. We note that cloudy taenite is not observed in any taenite grains. It is also to be noted that the phosphorous content in metal is nearly zero because phosphide is not observed.

Cooling rates

Estimates of the cooling rates can be made based on the above observations. Plotting on Fig.1 of [2], the isolated taenite data suggest a cooling rate slightly faster than 10^4 C/Ma. The data from zoned taenite surrounded by kamacite, when plotted on the same diagram, suggests a much faster cooling rate, but this may be artifact due to late nucleation of kamacite. Using the concept of closure, the thin taenite wall with ~31% Ni suggests a cooling rate ~10^4 C/Ma. Similarly, taenite islands with ~39% Ni in zoneless plessite suggest a cooling rate ~10^3 C/Ma. Distance between taenite islands could also be used for the cooling rate estimate. Assuming that diffusion in kamacite controls the island separation, a cooling rate of ~10^4 C/Ma is obtained. Absence of cloudy taenite is also consistent with rapid cooling.

Discussion

Although there are variations in the cooling rates depending on the features used for the calculation, it is

©2019. Japan Geoscience Union. All Right Reserved.

clear that the cooling rate of Tafa (~10^4 C/Ma) is much faster than previously considered [2]. In order to cool at this rate, Tafa has to be located at a shallow depth (~1km from the surface). Because of this, the parent body size cannot be constrained well, except that it is much larger than 10 km in order to be kept warm at ~3.5 Ma (Mn-Cr age [3]). The rapid cooling is consistent with the chronological data. All (Hf-W, Pb-Pb, Mn-Cr and Al-Mg) ages may be identical. Or, the Hf-W age may be older than the rest because of the higher closure temperature.

The systematic investigations of high-pressure minerals in lunar basaltic meteorites

*Masaaki Miyahara[1], Kazunari Kozuma[1], Eiji Ohtani[2], Akira Yamaguchi[3], Takeshi Sakai[4], Hiroaki Ohfuji[4], Naotaka Tomioka[5], Yu Kodama[6]

1. Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2. Department of Earth Sciences, Graduate School of Science, Tohoku University, 3. National Institute of Polar Research, 4. Geodynamics Research Center, Ehime University, 5. 5Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 6. Marine Works Japan

The Moon has recorded the impact history for ca. 4.5 Ga, which is closely related with the orbit evolution of asteroids and planets in the solar system. The impact events occurred on the moon can be clarified using lunar meteorites. The lunar meteorites have several kinds of evidence for the impact events: e.g., brecciation, shock-induced melting, and high-pressure polymorphs. The high-pressure polymorph is one of the important clues for clarifying the impact events because we can constrain several physical parameters (e.g., shock pressure) for the impact events. However, only a few lunar meteorites were investigated about the high-pressure polymorphs. Several radio-isotope ages in the lunar meteorites were measured to deduce when the impact events occurred. However, the relevance between the radio-isotope ages and the shock features has not been clear. Accordingly, we initiated to investigate the shock features, especially the shock-induced melting and high-pressure polymorphs in the lunar mare basalt, NWA 032, NWA 479, NWA 2727, NWA 2977, and NWA 4898 using FE-SEM, Raman, EMPA, and FIB-TEM techniques to obtain the clues for clarifying the impact events occurred on the moon.

NWA 032 consisted of a basaltic portion and a small amount of breccia. Olivine, Ca-pyroxene, and low-Ca pyroxene occurred as phenocrysts in the basaltic portion. The matrix was filled with spherulitic textures consisting of plagioclase and Ca-pyroxene. Several shock-melt veins and melt-pockets occurred in the basaltic portion. Several olivine grains next to the shock-met veins have transformed into ringwoodite. The estimated shock pressure is ~13 GPa at least. The petrological and mineralogical features of NWA 479 were similar to those of NWA 032. Olivine grains entrained in the shock-melt veins dissociated into bridgmanite + (Mg, Fe)O. The estimated shock pressure is ~23 GPa at least. NWA 4898 showed the basaltic texture. Olivine occurred as phenocrysts. The matrix portion consisted mainly of Ca-pyroxene and plagioclase. A trace amount of silica minerals was entrained in the shock-melt veins. Some silica minerals in the shock-melt veins were stishovite. Ca-pyroxene next to the shock-melt veins dissociated into ahrensite, pyroxene-glass, and (probably) silicate titanite. The estimated shock pressure is ~9 GPa at least. NWA 2977 showed a gabbroitic texture and consisted mainly of olivine, low-Ca pyroxene, Ca-pyroxene, and plagioclase. Olivine grains next to or entrained in the shock-melt veins have transformed into ringwoodite. The estimated shock pressure is ~16 GPa at least. Two third of NWA 2727 was breccia and the other was gabbroitic. The gabbroitic portion consisted of olivine, low-Ca pyroxene, Ca-pyroxene, and plagioclase. The breccia portion included silica besides the fragments of the gabbroitic portions. Silica minerals entrained in the shock-melt veins or melt-pockets have transformed into coesite. The estimated shock pressure is ~3 GPa at least.

The shock-induced melting textures were observed in all investigated lunar mare basalt samples. Although the high-pressure polymorphs of olivine, Ca-pyroxene, and silica minerals were identified, the high-pressure polymorphs of plagioclase, which are abundant in other shocked meteorites, were not identified. In addition to previous studies [1–3], the present study reveals that many kinds of

©2019. Japan Geoscience Union. All Right Reserved.

high-pressure polymorphs occur in the lunar mare basalt, implying that most lunar mare basalts have experienced the heavy impact events.

Bulk chemical analysis of iron meteorites by LA-ICP-MS

*Akira Yamaguchi[1], Naoki Shirai[2], Makiko K. Haba[3]

1. National Institute of Polar Research, 2. Tokyo Metropolitan University, 3. Tokyo Institute of Technology

Iron meteorites are Fe-Ni alloys with minor elements such as Co, P, S, and C. They are classified on the basis of textures (e.g., Widmanstatten pattern) and bulk chemical compositions (e.g., Ni, Ge, Ir). We performed bulk chemical analysis of iron meteorites by using an LA-ICP-MS and compared with the data obtained by INAA.

We measured five iron meteorites, Canyon Diablo (IAB, coarse octahedrite), Toluca (IAB, coarse octahedrite), Cape York (IIIAB, medium octahedrite), Muonionalusta (IV, fine octahedrite) and Dronino (ungrouped, ataxite) by using an LA-ICP-MS and INAA. Polished thick sections are prepared for LA-ICP-MS analysis. Polished thick sections of the meteorites were examined using an optical microscope, a scanning electron microscope, and an electron microprobe analyzer to observe the textures. A Thermo Element XR ICP-MS coupled to a CETAC LSX-213 laser was operated in low resolution mode (R = 300). The peaks monitored are ^{31}P, ^{34}S, ^{57}Fe, ^{59}Co, ^{60}Ni, ^{65}Cu, ^{69}Ga, ^{74}Ge, ^{95}Mo, ^{99}Ru, ^{103}Rh, ^{105}Pd, ^{182}W, ^{185}Re, ^{189}Os, ^{193}Ir, ^{194}Pt and ^{197}Au. Analyses in line and/or scanning modes were performed on a representative area of polished sections, using a 100 μm beam spot at 20 μm/sec., 20 Hz repetition rate. Typical analytical time was several minutes. Elemental abundances were obtained using Hoba (IVB, ataxite) and North Chile (IIAB, hexahedrite) iron meteorites as standard reference samples.

In INAA, samples weighing about 150 mg were firstly irradiated for 10 sec. at a neutron flux of 4.6 x 1012 $cm^{-2}s^{-1}$ at Institute for Integrated Radiation and Nuclear Science, Kyoto University for the determination of Co, Ni, Cu, Ge, and Rh. The same samples were reirradiated for 4 hrs at a neutron flux of 5.6 x 1012 $cm^{-2}s^{-1}$ at Institute for Integrated Radiation and Nuclear Science, Kyoto University for the determination of Cr, Fe, Co, Ni, Ga, As, Mo, Ru, Sb, W, Re, Os, Ir, Pt and Au.

We determined twenty elements (P, S, Fe, Co, Ni, Cu, Ga, Ge, As, Mo, Ru, Rh, Pd, Sb, W, Re, Os, Ir, Pt, and Au) for the five iron meteorites. Our results obtained by using two analytical methods were generally consistent with each other. However, our data of Muonionalusta are slightly different from literature values due to the large-scale heterogeneity of the meteorite (e.g., due to magmatic process). The abundance of some elements (e.g., Ru, Rh, Re, Ir) obtained from LA-ICP-MS data are higher than those from INAA due to the sample heterogeneity. It is possible to avoid this problem by choosing representative areas of the surface. Our study demonstrates that LA-ICP-MS has the potential to analyze a large number of iron meteorites.

[J] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

Mon. May 27, 2019 5:15 PM - 6:30 PM JST | Mon. May 27, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-PS07] Formation and evolution of planetary materials in the Solar System

convener:Yoko Kebukawa(Faculty of Engineering, Yokohama National University), Wataru Fujiya(Ibaraki University, College of Science), Shin Ozawa(Department of Earth Science, Graduate School of Science, Tohoku University), Megumi Matsumoto(Graduate School of Science, Tohoku University)

This session will focus on the evolution in the Solar System with interaction and co-evolution in minerals, water, organic matter, and noble gas in meteorites and interplanetary dust particles. New innovative analytical and theoretical techniques in various fields will be discussed. The developing methods are welcome to submit for the future mainstream of meteorite study. In order to explore the planetary materials and their evolution, both meteorite studies and experimental approaches are necessary. In this session, we will discuss these topics from extraterrestrial sample analyses and experimental works. Research works on undifferentiated and differentiated meteorites and parent body processes such as aqueous alteration, thermal metamorphism, shock metamorphism, volcanic activity, and core-mantle-crust differentiation are especially included in this session.

Since a wide variety of organic compounds have been detected in extraterrestrial bodies like carbonaceous chondrites [1] and comets [2], extraterrestrial organics could be essential sources for the first life on the Earth. Amino acids in carbonaceous chondrites increased after acid-hydrolysis, which suggested that not only free amino acids but also amino acid precursors were present in them. Laboratory experiments simulating extraterrestrial environments showed that not free amino acids but amino acid precursors were mainly formed [3, 4]. Though amino acid precursors in meteorites and products of laboratory simulations have not been well identified, aminonitriles and hydantoins could be candidates. On the other hands, proton irradiation of a mixture of CO, NH_3 and H_2O, which simulated possible reactions among interstellar media, gave complex amino acid precursors with large molecular weights [5]. Such amino acids and amino acid precursors that were formed abiotically in space environments would be exposed to various energy sources in prior to delivery to the primitive Earth. For example, organics in molecular clouds were exposed to galactic cosmic rays (protons and heavy ions). Interstellar organic compounds were irradiated with strong VUV/X-rays from the young Sun. Organic compounds in small bodies were irradiated with gamma rays from such nuclides as ^{26}Al in the earlier stage of the solar system. Organic compounds in interplanetary dust particles were exposed to solar UV/VUV before delivery to Earth atmosphere. Thus it is important to examine stability of amino acids and their precursors against energetic particles and photons. We experimentally investigated the stability of amino acids and their precursors against heavy ions, gamma-rays, UV and soft X-rays.

Target molecules used in the present study were (i) glycine (Gly), (ii) hydantoin (Hyd; a precursor of Gly), and (iii) aminoacetonitrile (AAN; the Strecker-type precursor of Gly). They are used as 5 mM solutions in ammonia water (pH 9). In addition to them, we chose (iv) organic material synthesized from a mixture of CO, NH_3 and H_2O by 2.5 MeV protons from a Tandem accelerator (Tokyo Tech). We will call them CAW. CAW contained complex amino acid precursors with large molecular weights [3].

Experimental: *Heavy ions irradiation*: Aqueous solution of each target molecule was frozen in liquid nitrogen, and was irradiated with 290 MeV/u carbon ions from HIMAC (NIRS, Japan) at 7.5-15 kGy. *Gamma-rays irradiation*: Aqueous solution of each target molecule was irradiated with gamma rays (5-10 kGy) from a ^{60}Co source (Tokyo Tech, Japan). *UV irradiation*: Each target molecule was irradiated with UV from a xenon lamp after dried in pits of an aluminum plate. *Soft X-rays irradiation*: Each target molecule was irradiated with soft X-rays from a synchrotron (NewSUBARU BL-6) for 10 min after dried on aluminum plates. Amino acid analysis: all the target materials were recovered as aqueous solutions, were acid-hydrolyzed (6 M HCl, 110℃, 24 h), and amino acids in them were determined by reversed-phase HPLC after pre-column derivatization with *o*-phthalaldehyde and mercaptoethanol.

Results and Discussion: Since glycine was always major amino acids after acid hydrolysis of all the target materials after irradiation yielded glycine, we will discuss stability of target molecules by using the glycine

©2019. Japan Geoscience Union. All Right Reserved.

yields.

Heavy ions irradiation: Recoveries at 15 kGy were as follows. CAW (95.1%), Hyd (93.6%), Gly (91.8%) and AAN (77.5%). AAN was least stable among all. *Gamma-rays irradiation*: Decomposition of AAN, CAW and Hyd at 10 kGy was not detected, while recovery of Gly was 79.5%. *Soft X-rays irradiation*: recovery ratios were less than 10 % in the case of Gly, Hyd and AAN, while that of CAW was 51.1%. UV-irradiated samples were now under analysis.

Free amino acid (glycine) was generally less stable than amino acid precursors (CAW and Hyd), and CAW was most stable among 4 compounds tested against all the energies. Thus it was suggested that complex amino acid precursors were robust molecules in space, while free amino acids were easy to decompose even if they were formed from their precursors in space.

[Introduction]Organic compounds such as amino acids are necessary for the birth of life on the earth. Extraterrestrial materials such as meteorites are considered as one of the sources of these amino acids. Since most of these meteorites originated from asteroids, we need to consider the origins of organic matter in asteroids. In the early stage of solar system formation, asteroids beyond the snow line contained ice and low molecular weight organic matter derived from dust. The ice melted due to the heat generated by the radioactive decay of ^{26}Al and aqueous alteration occurred. It is pointed out the complex macromolecular organic materials (insoluble organic matter, IOM) in meteorites may have formed during aqueous alteration (approximately 0 to 150 ˚C.) [1]. Based on this hypothesis, experiments simulating aqueous alteration on asteroids showed that amino acids and high molecular weight organic compounds similar to IOM in meteorites was formed after heating of formaldehyde, ammonia, water [2]. In this study, we aimed to investigate effect of gamma rays generated by radioactive decay of ^{26}Al during aqueous alteration for organic synthesis.
[Experimental]^{60}Co gamma ray source (Tokyo Institute of Technology) was irradiated to glass tubes containing 200 μl of water: formaldehyde: ammonia = 100: 5: 5 (molar ratio). Six different irradiation conditions were applied: 3 kGy/h ×2.5 h, 3 kGy/h ×4 h, 3 kGy/h ×5 h, 1.5 kGy/h ×5 h, 1.5 kGy/h ×8 h, and 1.5 kGy/h ×10 h. For comparison, the same solutions were heated in an oven at 150 ˚C for 24 h. The samples after irradiation were placed on CaF_2 plate and dried, then analyzed by FT-IR. The samples after irradiation were placed on gold plate and dried, then analyzed by X-ray absorption edge near structure analysis (XANES) of Hyogo prefectural university. Also, the samples were subjected to acid hydrolysis (6 M hydrochloric acid, 24 h, 110℃) and analyzed amino acid concentrations by cation exchange HPLC.
[Results and Discussion]<Cation exchange HPLC>Various amino acids such as glycine, alanine, β-alanine were detected from the gamma-ray irradiated samples after acid hydrolysis. Relatively large amount of alanine was produced from the irradiated samples compared to the heated samples. It suggests that the formation path ways of amino acids differ between the irradiated samples and the heated samples.
[Future plan]We are planning to extrapolate the gamma-ray induced amino acid yields to the meteorite parent body environments by extending the irradiation conditions (total dose and irradiation rate) using the calculated value of total dose of gamma ray from ^{26}Al during aqueous alteration. In addition, macromolecular organic compounds will be analyzed using LC-MS.

Kinetic approaches for the thermal history of organic matter in meteorites based on Raman spectra

*Kento Kiryu[1], Yoko Kebukawa[1], Motoko Igisu[2], Takazo Shibuya[2], Kensei Kobayashi[1]

1. Yokohama National Univ., 2. Japan Agency for Marine-Earth Science and Technology

CI, CM, and CR chondrites experienced aqueous alteration in their parent bodies, and contain organic carbon up to a few wt%. More than 70 wt% of it exists in the form of insoluble organic matter (IOM) (e.g., Pizzarello et al., 2006). Organic matter (OM) is susceptible to heating, and changes their structures, reflecting aqueous alteration and/or thermal metamorphisms. Thus, it attracts attention as the index of the parent body processes.

Kebukawa et al. (2010) estimated kinetic parameters for thermal degradation of aliphatic C-H through in-situ heating experiments of IOM and bulk of the Murchison meteorite (CM2) using the Fourier transform infrared micro-spectroscopy (microFTIR) combined with heating stage. They revealed that the peak intensity of aliphatic C-H is a good index of low-temperature and/or short-duration heating in the parent bodies. However, microFTIR is not enough for estimating thermal process of OM under high-temperature and long-duration heating which IR signals of aliphatic C-H are unlikely to be detected. Raman spectroscopy is a complementary tool to IR spectroscopy, since their spectral features of OM in the chondrites reflect thermal changes in aromatic structure in the complex OM (Quirico et al. 2003; Bonal et al., 2006, 2007; Busemann et al., 2007). When chondritic OM is heated, its aromatic structure will be more ordered to graphitic structure. This process is an irreversible, and results in changes of disordered (D_1-: ~1350 cm^{-1}) and graphite bands (G: ~1590 cm^{-1}) in Ramn spectra. Therefore, D_1- and G-bands were often used as indicators of degree of thermal metamorphism, but understanding of kinetic behaviors of the Raman spectral parameters is still limited. Thus, in order to evaluate thermal history of OM in chondrites under high-temperature and/or long-duration heating, we performed a series of heating experiments of the Murchison meteorite powders and kinetic analyses of their Raman spectral parameters.

The Murchison meteorite powders were heated under low oxygen condition in a vacuum furnace for 3-48 h at 600-900˚C. The low-oxygen condition was maintained by a gas mixture of N_2 and H_2 (99:1, v/v). The samples after heating were analyzed using Raman spectrometer with a 532 nm laser (RAMANtouch; Nanophoton). The Raman spectra of all the samples show D_1- and G-bands. We determined 5 Raman spectral parameters: the full width at half maximum (FWHM) and the peak positions of D_1- and G-bands, and the ratio of the peak intensity of D_1- to G-band. The changes in these Raman parameters with time at each temperature will be fitted with algebraic kinetic equations deduced by possible physical mechanisms, and estimate reaction rate constant. Then the apparent activation energies and frequency factors will be calculated by the reaction rates using the Arrhenius equation. Finally, we will establish the Raman parameters as functions of heating temperature and time. Combining previously reported kinetics of aliphatic C-H (Kebukawa et al. 2010), it may allow us to calculate precise time and temperature of thermal processes for chondrites.

Relationship between spatial distribution of organic compounds and minerals in the Murchison meteorite

*Taiyo Sengoku[1], Minako Hashiguchi[1], Hiroshi Naraoka[1]

1. Kyushu University

[Introduction]

Primitive meteorites contain a wide variety of organic compounds. More than 600 species of CHN compounds were identified in the methanol extract of the Murchison meteorite (CM2), in which saturated- and unsaturated-alkylated pyridines ($C_nH_{2n-4}N^+$ and $C_nH_{2n-6}N^+$) as well as alkylimidazoles ($C_nH_{2n-1}N_2^+$) are predominant (Naraoka et al., 2017). Interaction between organic matter and minerals during aqueous alteration is very important in the chemical evolution (e.g. Kebukawa et al., 2010), therefore, it is necessary to investigate the spatial distribution of the organic matter and minerals in the meteorites. In the previous studies, chemical imaging of soluble organic matter (SOM) was performed on the Murray and Murchison meteorites (CM2) by desorption electrospray ionization/high-resolution mass spectrometry (DESI/HRMS), and the different spatial distribution was observed among the different CHN species and/or their alkylated homologues (Naraoka & Hashiguchi, 2018, Hashiguchi & Naraoka, 2018). However, the relationship between the organic compounds and minerals is still unresolved. In this study, the DESI-HRMS imaging and detailed mineralogical observation were performed on fragments of the Murchison meteorite.

[Sample & Method]

Two fragments designated as “np15" (2x3 mm^2) and “np16” (2x2 mm^2) were obtained by chipping from different large fragments of the Murchison meteorite. These fragments were embedded in indium or metal with low-melting point for DESI-HRMS imaging. The DESI-HRMS imaging was performed on each sample for three times. Methanol was used as a spray solvent with the flow rate of 2 μL/min. The electrospray voltage was set to 3 kV. The nebulizer N_2 gas pressure was ~100 psi. The positive ions were collected in a full scan mode (m/z 50-500) with mass resolution of about 140,000 ($m/\Delta m$ at m/z 200) on the sample surface of np15 (4x4 mm^2) and np16 (3.8x3.8 mm^2). For the fragment np16, dry polishing was performed on the sample to remove ~250 μm from the surface and the imaging was performed again, because no signals of CHN compounds were obtained by the 1st set of DESI-HRMS imaging. After the DESI-HRMS imaging, the same sample surface was used to obtain backscattered electron images (BSE) and X-ray elemental maps using SEM/EDS.

[Results & Discussion]

Some alkylated homologues of CHN compounds were detected from np15 by DESI-HRMS imaging. Their exact masses correspond to alkylimidazole ($C_nH_{2n-1}N_2^+$) and saturated- or unsaturated-alkylated pyridine ($C_nH_{2n-4}N^+$ or $C_nH_{2n-6}N^+$) within 3 ppm of mass precision. The spatial distribution was different between $C_nH_{2n-1}N_2^+$ and $C_nH_{2n-4}N^+$, which is consistent with the previous study (Naraoka & Hashiguchi, 2018). On the other hand, no CHN compounds were detected from np16. After removing ~250 μm of the surface of np16 by polishing, some CHN compounds corresponding to $C_nH_{2n-1}N_2^+$ and $C_nH_{2n-6}N^+$ were detected in 3rd DESI-HRMS imaging finally, however, these compounds were not detected by 1st and 2nd analyses. These results indicated that the CHN compounds might have been volatilized from the sample surface

©2019. Japan Geoscience Union. All Right Reserved.

during its storage, and that repeated DESI-HRMS imaging is important to obtain clear signals of SOM from inside of meteorite. The detected CHN compounds showed heterogeneous spatial distribution in the sample surface, which indicate that dry polishing does not affect the spatial distribution of SOM significantly.

In both np15 and polished np16 samples, the CHN compounds distribute mainly in the matrix region (~ few hundreds of square meters) of the meteorite. Although the X-ray elemental mapping showed that CHN compounds-rich region seemed to contain abundant Ca-containing minerals in both fragments, no clear relationship was observed between the averaged chemical compositions of matrix region and the spatial distribution of the CHN compounds. Further detailed analysis will be performed on tiny minerals in the matrix.

O and Al-Mg isotope systematics of a hibonite-melilite-rich fine-grained CAI in the reduced CV chondrite NWA8613

*Sohei Wada[1], Noriyuki Kawasaki[1], Hisayoshi Yurimoto[1,2]

1. Hokkaido University, 2. ISAS/JAXA

Ca–Al-rich inclusions (CAIs) in meteorites are composed of high-temperature condensate minerals from the solar nebular gas [1]. CAIs in CV chondrites are petrographically divided into the coarse-grained CAIs and fine-grained CAIs (FG-CAIs). Complex layer structures of constituent minerals and REE patterns of FG-CAIs suggest they are condensates from the nebular gas [2, 3]. Igneous CAIs that experienced melting and crystallization, such as coarse-grained Type B CAIs, have been extensively studied their formation processes, O-isotope compositions of minerals, and formation ages [4, 5]. On the other hand, such systematic investigations for the formation of FG-CAIs have been poorly conducted. Here, we investigated O- and Al–Mg isotope systematics of a hibonite-melilite-rich FG-CAI from the reduced CV chondrite NWA8613 as well as detailed petrographic observations. The O- and Al–Mg isotope measurements were conducted using SIMS instruments of Hokkaido University (Cameca ims-1270 and ims-1280HR).

The FG-CAI has an irregular shape with a size of approximately 10 ×12 mm and composed mainly of melilite, hibonite, and spinel. O-isotope compositions of the constituent minerals plot along the CCAM line, ranging between $\Delta^{17}O \sim -23‰$ and 0‰. The FG-CAI is petrographically divided into hibonite-rich core, spinel-rich core, melilite-rich inner-mantle, and hibonite-spinel-rich outer mantle. The CAI is rimmed by thin spinel and diopside layers. Melilite crystals are contained in core and mantle. Melilite crystals in the core exhibit normal chemical zoning and O-isotope compositions from $\Delta^{17}O \sim -23‰$ to −10‰ with increasing Åk composition. The melilite crystals in the inner-mantle show chemically complex, oscillatory zoning patterns, but are uniformly ^{16}O-poor ($\Delta^{17}O \sim 0‰$) despite their chemical variations (Åk2–14). Melilite crystals in the outer-mantle exhibit normal chemical zoning and variable O-isotope compositions from $\Delta^{17}O \sim -17‰$ to 0‰ with increasing Åk composition. The spinel and hibonite grains in the FG-CAI are uniformly ^{16}O-rich ($\Delta^{17}O = -23‰$). Al–Mg isotopic compositions of hibonite in the outer-mantle and in the core and melilite in the inner-mantle plot on a single straight line within error; an Al–Mg mineral isochron can be defined to give an initial $^{26}Al/^{27}Al$ value of $(4.50 \pm 0.09) \times 10^{-5}$. Given that the constituent minerals formed by condensation and were accumulated to form the FG-CAI, the nebular gas, from which they condensed, had variable O-isotope compositions between $\Delta^{17}O \sim -23‰$ and 0‰. The Al–Mg systematics of the FG-CAI indicate that these formation events occurred at 0.16 ±0.02 Myr after the formation of canonical CAIs [7], if ^{26}Al was homogeneously distributed. Our data support the presence of the nebular gas with variable O-isotope compositions during the first ~0.2 Myr of the Solar System formation [8].

Observation of Enstatite Whiskers in Fine-grained Rims in the Carbonaceous Chondrite ALH A77307

*Yasuhisa Shirota[1], Masahiro YASUTAKE[1], Satomi Enju[1], Akira Tsuchiyama[1]

1. Division of Earth and Planet, Science, Kyoto University

Introduction Chondritic porous -interplanetary dust particles (CP-IDPs) are material that are suggested to be originated from comets and to be one of the most primitive materials in the solar system (Bradley et al., 1983). CP-IDPs include enstatite ($MgSiO_3$) whiskers. They are thought to be formed by condensation in the solar nebula (Bradley et al., 1983).

Primitive carbonaceous chondrites are affected by little aqueous alteration. Recent studies have discovered enstatite whiskers in matrices in primitive carbonaceous chondrites (Vaccaro et al., 2017; Matsumoto et al., 2018). If such crystals have similar formation processes to those of enstatite whiskers in CP-IDPs, it will constrain the formation processes of not only asteroids but also CP-IDPs. However, only a few enstatite whiskers are observed in carbonaceous chondrites. Therefore, it is not certain whether or not enstatite whiskers are common in carbonaceous chondrites and have same formation processes in CP-IDP.

We conducted a detail petrological observation of matrix in ALH A77307 (CO3.0) to understand distribution of whisker-like enstatite crystals using a scanning electron microscopy (SEM) and to constrain the formation process using a transmission electron microscopy (TEM).

Sample and Methods We observed one of the most primitive CO chondrites ALH A77307. Vaccaro et al. (2017) reported whisker-like enstatite crystals in ALH A77307. SEM/EDS analysis was carried out with an FE-SEM (JEOL JSM-7001F, Kyoto University, Hitachi HT SU6600, ISAS, JAXA) operating at 100 pA probe current and 8 kV accelerating voltage. A TEM thin section including one whisker was extracted using focus ion beam (FIB) (FEI, Helios NanoLab 3G, Kyoto University). TEM analysis was carried out with a (S)TEM/EDS (JEOL JEM-2100T, Kyoto University) operating at 200 kV accelerating voltage.

Result and Discussion We observed fine-grained rims around three chondrules. These rims consist mainly of amorphous silicate, olivine, pyroxene, and Fe,Ni metal, and similar to primitive matrix. The whisker-like enstatite crystals occur in all regions observed and the total number of whiskers found are 12. The maximum size of the whisker is 11.91 μm in length and 0.27 μm in width. We classified whiskers based on criterion the aspect ratio, p, by Bradley et al. (1983). The whiskers are classified as 4 Rods (p>20) and 8 Ribbons (p<20). The abundance of whiskers is >40 mm^{-2}, suggesting that whisker-like enstatite is common in chondrule rims in primitive carbonaceous chondrites although the abundance in CP-IDPs is higher. The aspect ratios are similar to those of enstatite whisker in CP-IDPs. In contrast to enstatite whiskers in CP-IDPs, some whiskers are curved and/or broken. It may be the result of deformation during accumulation on the parent body.

We have observed one ribbon crystal (length 1.21 μm, width 0.16 μm) using TEM. The ribbon crystal was orthoenstatite elongated along [001] axis based on electron diffraction patterns. Three dimensionally, this crystal is thought to be a columnar crystal elongated along [001] or a plate crystal with flattened (010) plane. From this results, this crystal is thought to be a platelet crystal formed by condensation in the solar nebula like enstatite whiskers in CP-IDPs (Bradley et al., 1983) or crystal formed by annealing of

©2019. Japan Geoscience Union. All Right Reserved.

amorphous silicate (Brearley, 1993). To constrain more detail formation process of the whisker-like material in carbonaceous chondrites, mineralogical investigation of whisker-like material, especially rod crystals is needed.

3D observation of whisker-like material in the porous matrix of the Paris CM chondrite by SR-XCT

*Masahiro YASUTAKE[1], Epifanio Vacarro[2], Kentaro Uesugi[3], Akihisa Takeuchi[3], Tsukasa Nakano[4], Akira Tsuchiyama[1]

1. Division of Earth and Planetary Science, Graduate School of Science, Kyoto University, 2. National History Museum, London, 3. JASRI/SPring8, 4. GSJ/AIST

Introduction The chondritic-porous interplanetary dust particles (CP-IDPs) are well-known material, that preserves primitive and pristine features of the early solar system. Enstatite whisker is one of the materials that characterizes CP-IDPs. It is thought that enstatite whiskers are condensates formed in the inner solar system and transferred to the outer regions, where comets formed [e.g. 1, 2]. Recently, whisker-like enstatite crystals were found in the primitive carbonaceous chondrites [3, 4]. However, the whisker-like materials they found could be a cut-plane of thin enstatite plate. By the 2D observation, it is hard to solve this matter. 3D observation based on synchrotron radiation X-ray nano-CT is a strong tool to understand the crystal shape, mineral phase, and rough composition. We conducted a 3D observation to better understand the characteristics of whisker-like materials in primitive carbonaceous chondrites.

Methods We investigated the Paris primitive CM chondrite. Paris was reported to have a very primitive matrix that includes GEMS-like materials [5]. A section of this meteorite was observed and elemental maps of the primitive matrix were obtained by FE-SEM/EDS. A house-shaped CT sample (~25 x 25 x 30 μm) was extracted from the primitive matrix by using a FIB-SEM. CT data of the micro-samples were conducted at beamline BL47XU, SPring-8. CT images were acquired at energies of 7 keV and 7.35 keV with voxel sizes of ~32.2 nm and ~ 33.9 nm, respectively. Mineral phases were estimated using dual-energy tomography (DET) method using the X-ray linear attenuation coefficient (LAC) [6].

Result and Discussion The observed matrix is a part of the fine-grained rim of Type I porphyritic olivine pyroxene chondrule. The matrix is porous and consists mainly of amorphous silicates that include sub-micron sized Fe-rich phases. Whisker-shaped materials are abundant in the CT sample observed. However, fibrous alteration materials were also reported in the matrix of Paris [5]. The whisker-like materials observed might include such products in addition to enstatite. The size of the largest whisker is ~6 μm x ~700 nm x ~350 nm (Fig. 1) and similar to ribbon-type enstatite whisker in the CP-IDPs [1]. This whisker has a curved shape unlike those in CP-IDPs. Probably it reflects deformation during accretion to the parent body and/or planetary processes such as planetary collision.

The LAC values of most whisker materials are hard to obtain quantitatively because refraction of X-ray at the edges of the narrow whiskers enhanced their LAC values. The LAC values of the largest whisker are less affected by refraction and have the range of ~170-180 cm^{-1} and ~250-270 cm^{-1} at 7.00 and 7.35 keV, respectively. These values are consistent with those of pyroxene ($En_{80}Fs_{20}$) and clearly distinguishable from the values of fibrous alteration products (cronstedtite, tochilinite, and ferrihydrite) [5]. The above results suggest that this whisker material is an enstatite whisker. The possibility of olivine whisker (~Fo_{85}) cannot be excluded but forsterite whiskers have not been reported so far. Thus, it is reasonable to consider that the enstatite whiskers accreted to the carbonaceous chondrite parent body.

Crystallographic features such as defects and direction of elongation are still not examined. Investigation of crystallography is required to constrain the formation processes of whiskers, and it will enable us to

©2019. Japan Geoscience Union. All Right Reserved.

compare the enstatite whiskers in carbonaceous chondrites with those in CP-IDPs.

Development of cryogenic SIMS technique for isotope analysis of fluid inclusions

*Isono Yuki[1], Naoya Sakamoto[2], Hisayoshi Yurimoto[3]

1. Department of Natural History Sciences, Hokkaido University, 2. Creative Research Institusion, Hokkaido University, 3. Department of Natural History Sciences, Hokkaido University

Introduction: Fluid inclusions in halite crystals from meteorites provide direct information of extraterrestrial liquid water [1]. In-situ isotope analysis of the fluid inclusions was realized by SIMS equipped with a cold-stage [2]. However, the analytical precision is limited to ±14 ‰(1 σ) for $\delta^{18}O$ due to deep sputter crater to excavate fluid inclusions. One of the methods to improve the analytical precision would be expose fluid inclusions on the sample surface. We froze the fluid inclusions and polish under cryogenic condition in nitrogen atmosphere [3, 4]. In order to measure frozen polished fluid inclusions by SIMS, the surface should be coated by conductive thin layer such as Au. However, the Au thin layer was not enough conducted because condensation of frost particles occurred before introduce the polished sample into Au coater. The sample temperature was −100 ˚C while the dew point in the glove box (−60˚C) was higher than the sample temperature [4]. Therefore we changed the sample temperature.

Changes of sample preparation procedures: The sample preparation system for cryogenic SIMS is composed of a cryo-polisher and Au ion-coater in a glove box [3]. The temperature of polishing set to −35 ˚C. Thus frost condensation on the polished surface was prevented. After polishing, the sample was settled on the bottom of deep well of new designed cryo-coating stage. The cryo-coating stage was precooled to −196 ˚C by liquid nitrogen and the deep well was filled with cool nitrogen gas evaporated from liquid nitrogen in order to prevent frost formation on sample surface. This cooling process is necessary because sublimation temperature of ice is −50 ˚C during Au coating. The sample temperature was estimated to −196 ˚C before taking into the Au coater and warmed up −130 ˚C at taking from the Au coater after Au coating for 4 minutes.
The polished ice embedded in an epoxy disk was set to the cryo-holder and transferred to cryo-stage (−190 ˚C) of Cameca ims-1270 instrument using cryo-transfer system [3]. The liquid nitrogen was supplied by a roots pump to reduce the sample stage vibration. The measurement methods for oxygen isotopes were similar to those of [2].
We obtained mass spectra of oxygen isotopes from H_2O-ice. Intensity of ^{16}O peak was about 2.8 $\times 10^5$ cps and a tale was observed symmetrically at both side of the peak below 3 cps. The interference of tail from $^{16}OH^-$ to $^{17}O^-$ was estimated to be about 10 ‰because the intensity of $^{16}OH^-$ is comparable to ^{16}O peak. Oxygen isotope analysis using $^{16}OH^-$ and $^{17,18}OH^-$ signal would be effective for further high precision oxygen isotope analysis for H_2O ice as well as the tail correction method used in [2].

X-ray diffraction study using Gandolfi attachment: Implications for small extraterrestrial materials

*Naoya Imae[1,2], Makoto Kimura[1]

1. Antarctic Meteorite Research Center, National Institute of Polar Research, 2. SOKENDAI

Introduction

Recent studies have established the bulk features of various chondrite species based on the X-ray diffraction patterns (Howard et al. 2009; Imae and Nakamuta 2018; Imae et al. 2019). In the present study, X-ray diffraction experiments were carried out using Gandolfi attachment in order to apply for small extraterrestrial materials of various kinds of stony meteorites. The present technique is convenient in the laboratory and also useful for rapidly identifying the mineral species without any significant sample loss.

Experiments

We used the X-ray diffractometer in air with the goniometer radius of 30 cm (RIGAKU, SmartLab) at NIPR on the following conditions: (1) CuKa1 with 40 kV, and 30 mA for glass X-ray tube and 40 mA for ceramic X-ray tube, (2) the X-ray beam of 0.4 mm in diameter obtained from the polycapillary focusing optics (CBO-f unit), (3) the strip detector (D/teX Ultra 250) for counting diffracted X-rays, (4) the revolution rate of the goniometer head on the Gandolfi attachment at 30 rpm, and (5) the scan speed of normally 0.2 º/min or 0.5 º/min with the step of 0.01º and the average of the repeated analyses.

Glass fiber (13 μm in diameter) attached with glass rod (1 mm in diameter) was mainly used for holding samples. Both powder and grain samples with the diameter of ~0.2-0.8 mm were used for the measurements.

Powders and single grains for San Carlos olivine and NWA 4719 L6 chondrite were used for the calibration focused on olivine 130 index. So far, 36 stony meteorites have been measured and they are 27 ordinary chondrites (mostly Antarctic meteorites), 5 carbonaceous chondrites, an E chondrite (NWA 7401), a eucrite (Cachari), a diogenite (Bilanga), and an aubrite (Pena Blanca Spring).

Results and discussion

Calibration: The two-theta position of the olivine 130 peak for the powder samples of San Carlos olivine shows nearly consistent value by Yoder and Sahama (1957), on the contrary, the intensity of the San Carlos olivine grains is lower than that of powder on the similar measurement condition, and in addition the position of the two-theta is slightly higher than that of powder. In case of chondrite (NWA 4719 L6), the intensity is significantly lower than San Carlos olivine. Although the two-theta values for powder samples and grain samples are within the mean Fa# range of L group, the intensity of grain is significantly lower than that of powder.

©2019. Japan Geoscience Union. All Right Reserved.

Samples: The systematic differences of olivine 130 two-theta values were observed among ordinary chondrites: 32.18º-32.29º for H, 32.15º-32.21º for L, and 32.13º-32.16º for LL. These ranges include that the two-theta values are obviously higher than the ranges expected from the mean Fa# for three chemical groups (32.18º-32.21º for H, 32.12º-32.16º for L, and 32.08-32.12 for LL, Yoder and Sahama 1957). The existence of orthoenstatite 511 peak is an indicator for equilibrated ordinary chondrites but not definite, since the peak intensity is normally low. More ferroan olivine peak than ordinary chondrites appears from carbonaceous chondrites. EL6 consists of orthoenstatite. Diffraction patterns of achondrites are different from those of chondrites: pigeonite and anorthite peaks for eucrite and dominant orthopyroxene for diogenite, and dominant clinoenstatite for an aubrite. Fine-grained powder samples may represent the bulk chondrite compositions, but not for grains. This may lead to the different diffraction pattern.

Summary

The present technique is useful conveniently for examining limited or small extraterrestrial materials, when we take into consideration the variations for chondrite species depending on the different sample conditions of powder or grain and the relative modal abundance of olivines and pyroxenes for grains with the limited range of variation of the chemical groups.

Trace elements analysis and Ar-Ar dating for microgram-scaled extraterrestrial samples

*Ryuji Okazaki[1], Sekimoto Shun[2]

1. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 2. Institute for Integrated Radiation and Nuclear Science, Kyoto University

In order to elucidate the origin and evolution of planetary materials, it is important to determine the chemical composition and timing of geological events for specific minerals and microscopic portions, such as impact melt pockets, CAIs (Ca- and Al-rich Inclusion), and chondrules. Combination of EMPA, INAA, and noble gas analysis are one of the best way to determine chemical and isotopic compositions of extraterrestrial dust particles (micrometeorites) and spacecraft-returned samples.
As a first step, we have analyzed rock fragments (<several hundreds of micrometer in diameter) recovered from Holbrook L6 chondrite. Neutron irradiation and NAA experiments were conducted at Institute of Integrated Radiation and Nuclear Science, Kyoto Univ. Allende CV3 and Madagascar feldspar were used for standardization of INAA and Ar-Ar analyses, respectively. Each of the sample particles was individually placed in a conical dimple (ϕ1, depth ~ 0.5 mm) of a sapphire disk (ϕ5.5, 1.5 mm thick), and covered with a sapphire disk (ϕ5.5, 0.3 mm thick). Each of the sapphire container was wrapped with pure aluminum foil. These Al-wrapped containers were stacked and sealed in aluminum capsules to perform neutron irradiation at the hydro-irradiation port. After irradiation, the samples were recovered from irradiated glass containers, and moved to non-irradiated containers in order to reduce the radioactivity from the sapphire containers and Al foil. Gamma-ray measurements for short half-life nuclides were performed promptly after collection of the samples. Several months after the irradiation, some of the Holbrook samples were transported to Kyushu Univ. to measure noble gas isotopes.
Concentrations of Co and Ni in two Holbrook samples were determined to be 57 and 157, and 1260 and 13400 ppm, respectively. The Ni/Co ratios of the Holbrook samples are 22 and 85, which are similar to those observed in iron meteorites and chondrites (e.g., Ebihara et al., 2011). The result guarantees our NAA measurement.
Noble gas isotopes (^{36}Ar, ^{38}Ar, ^{39}Ar, and ^{40}Ar) were determined for different two Holbrook samples using stepwise heating method. The bulk ^{39}Ar concentration in the irradiated standard feldspar (K: 12.6 wt%) is 7E-6 cm^{3}STP/g, and the bulk ^{39}Ar/^{40}Ar ratio is 0.026. The result indicates that the neutron flux of KURRI is enough to determine ^{39}Ar for microgram samples with K>0.1 wt%. Using the neutron flux determined by the standard feldspar, with 450 Ma of K-Ar age (ranging 435-461 Ma; Flude et al, 2014), we calculated the Ar-Ar ages for two Holbrook samples (9.4 and 16.8 μg) to be 3795±368Ma (based on 3 plateau ages of 4 stepwise extractions) and 3714±128Ma (based on 4 plateau ages of 7 stepwise extractions). Noble gases extracted at the lowest and highest temperature steps are influenced by atmospheric Ar, resulting unreasonable old Ar-Ar age. Based on these results, we found appropriate extraction temperature for plagioclase-rich microgram samples to be 600, 800, 900, 1000, 1100, 1200, 1400, and 1600 ˚C.
Through this study we have established an analytical method that consists of a combination of EPMA, INAA, and noble gas analyses. The new method will be applied for Antarctic micrometeorites and the Hayabusa2 samples.

Magnetic separation and identification of low-temperature solid particles using their translation caused by a pair of small permanent magnets

*Chiaki Uyeda[1], Wakana Yamaguchi[1], Keiji Hisayoshi[1], Kentaro Terada[1]

1. Institute of earth and Space Science Graduate School of Science Osaka University

Most solid particles in nature are categorized as diamagnetic or weak paramagnetic materials; they are commonly believed to be magnetically inert, and cannot attain strong magnetization to cause specific magnetic motions at practical field intensity. Indeed, strong magnetic field above the level of 10 T were applied in previous studies to induce magnetic levitations. A method to separate solid particles by a field gradient produced by small NdFeB magnets was recently proposed and experimentally approved using a setup operated in microgravity condition [1]. By improving this system, magnetic separation was realized on volatile solid particles, namely H2O and CO2, for the first time [2]. In addition, it was possible to estimate the material of the particle in a non-destructing manner by comparing the experimental value of magnetic susceptibility with a list of published values [1][2]: here the susceptibility was obtained from the velocity of the translating particle without the knowledge of particle mass.

In the present experimental present setup, a pair of small NdFeB plates was attached in a double glass container. A microgravity condition is produced inside the box by free fall from a height of 180 cm. An ensemble of heterogeneous particles translates and separates by magnetic field gradient in free fall. The Hi-vision camera observed the translation and susceptibility is calculated by obtained terminal velocity [1]. The obtained susceptibility of the particle is compared with literature data and materials of particles are estimated.

The field-induced translational motions realized in μg condition can be utilized in various space missions in future; this is because the small but rigid apparatus can separate and identify the heterogeneous particles that is expected to be collected in an on-site mission. One of the major purposes to perform space explorations to the outer solar system was to identify the solid materials that are observed on satellite surfaces or ring. It is concluded by recent observation that the solid particles were mainly composed of ice (Ih) with high purity; previously it was considered that the icy particles of the rings contain significant amount of rock-forming silicates. Hence, for a future task, quantitative information of the minor silicate composition included in the icy particle is required in studying the origin of the Saturn rings.

An efficient method that can non-destructively identify the components of a heterogeneous aggregate sample is desired in various research fields of material science. Using an infrared optical analysis, for example, the material composition of the particle interior is difficult to determine when the sample is larger than 100 μm in diameter. In the case of a conventional mass spectrometer, it is difficult to identify the composition of solid particles without destructing the sample. Although various microprobe devices are effective in performing refined survey on aggregate samples, it is difficult to conclude by these methods whether small particles included in the aggregate are completely discovered and identified without omission. In such cases, the particles should be definitely separated into groups of different materials before performing refined analysis [1-3]. Note that the present proposal of magnetic separation can overcome the abovementioned limitations of the conventional methods, and in future, it may serve as

a standard pretreatment tool of material analysis.

The metallographic cooling rate of the Tafassasset primitive achondrite

*naoji sugiura[1], Tomoko Arai, takafumi matsui

1. Chiba Institute of Technology

Tafassasset (Tafa) is a primitive achondrite with carbonaceous chondrite-like (CC) isotopic (Cr etc.) signatures. Cooling rates and chronological information give valuable insight on the evolution of achondrite parent bodies. Brent et al. [1] constructed an evolutionary model (the parent body with a radius ~17 km, accreted at ~1 Ma after CAI; Tafa is located in the middle of the mantle). It is mainly based on the chronology, but is considered to be supported by the metallographic cooling rate (100~200 C/Ma). But it is said to require refinement. Here we report observations of the metal texture and compositions, based on which a cooling history is derived.

Observation

Fe-Ni grains (average composition ~10 mol.% Ni) in Tafa show various textures. Many grains show kamacite that nucleated on the metal-silicate boundary and expanded inward during cooling. The central part is zoneless plessite which must be martensite at higher temperatures but now is made of kamacite and taenite. An interesting feature is that the boundary of kamacite and interior plessite is made of thin (~a few mm wide) taenite wall, suggesting rapid coolig. The compositions range from 17 to 31 % Ni and the average is ~26% Ni. Considering the difficulties in measuring compositions of thin taenite rim, the real value could be ~31% Ni. The zoneless plessite interior (average composition ~10 mol% Ni) is made of taenite islands in kamacite matrix. The taenite island sizes are usually only a few mm or less and the compositions range, if measurable, from 28 to 39% Ni, and the average is ~34% Ni. Again, the real value is considered to be close to ~39% Ni. A typical distance between taenite islands is ~10 mm. There are isolated zoned taenite grains, the central compositions of which are correlated with the size. There are zoned taenite grains which are surrounded by kamacite. Their compositions at the center mostly do not depend on the size, and is ~10 mol.% Ni. We note that cloudy taenite is not observed in any taenite grains. It is also to be noted that the phosphorous content in metal is nearly zero because phosphide is not observed.

Cooling rates

Estimates of the cooling rates can be made based on the above observations. Plotting on Fig.1 of [2], the isolated taenite data suggest a cooling rate slightly faster than 10^4 C/Ma. The data from zoned taenite surrounded by kamacite, when plotted on the same diagram, suggests a much faster cooling rate, but this may be artifact due to late nucleation of kamacite. Using the concept of closure, the thin taenite wall with ~31% Ni suggests a cooling rate ~10^4 C/Ma. Similarly, taenite islands with ~39% Ni in zoneless plessite suggest a cooling rate ~10^3 C/Ma. Distance between taenite islands could also be used for the cooling rate estimate. Assuming that diffusion in kamacite controls the island separation, a cooling rate of ~10^4 C/Ma is obtained. Absence of cloudy taenite is also consistent with rapid cooling.

Discussion

Although there are variations in the cooling rates depending on the features used for the calculation, it is

©2019. Japan Geoscience Union. All Right Reserved.

clear that the cooling rate of Tafa (~10^4 C/Ma) is much faster than previously considered [2]. In order to cool at this rate, Tafa has to be located at a shallow depth (~1km from the surface). Because of this, the parent body size cannot be constrained well, except that it is much larger than 10 km in order to be kept warm at ~3.5 Ma (Mn-Cr age [3]). The rapid cooling is consistent with the chronological data. All (Hf-W, Pb-Pb, Mn-Cr and Al-Mg) ages may be identical. Or, the Hf-W age may be older than the rest because of the higher closure temperature.

The systematic investigations of high-pressure minerals in lunar basaltic meteorites

*Masaaki Miyahara[1], Kazunari Kozuma[1], Eiji Ohtani[2], Akira Yamaguchi[3], Takeshi Sakai[4], Hiroaki Ohfuji[4], Naotaka Tomioka[5], Yu Kodama[6]

1. Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2. Department of Earth Sciences, Graduate School of Science, Tohoku University, 3. National Institute of Polar Research, 4. Geodynamics Research Center, Ehime University, 5. 5Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 6. Marine Works Japan

The Moon has recorded the impact history for ca. 4.5 Ga, which is closely related with the orbit evolution of asteroids and planets in the solar system. The impact events occurred on the moon can be clarified using lunar meteorites. The lunar meteorites have several kinds of evidence for the impact events: e.g., brecciation, shock-induced melting, and high-pressure polymorphs. The high-pressure polymorph is one of the important clues for clarifying the impact events because we can constrain several physical parameters (e.g., shock pressure) for the impact events. However, only a few lunar meteorites were investigated about the high-pressure polymorphs. Several radio-isotope ages in the lunar meteorites were measured to deduce when the impact events occurred. However, the relevance between the radio-isotope ages and the shock features has not been clear. Accordingly, we initiated to investigate the shock features, especially the shock-induced melting and high-pressure polymorphs in the lunar mare basalt, NWA 032, NWA 479, NWA 2727, NWA 2977, and NWA 4898 using FE-SEM, Raman, EMPA, and FIB-TEM techniques to obtain the clues for clarifying the impact events occurred on the moon.

NWA 032 consisted of a basaltic portion and a small amount of breccia. Olivine, Ca-pyroxene, and low-Ca pyroxene occurred as phenocrysts in the basaltic portion. The matrix was filled with spherulitic textures consisting of plagioclase and Ca-pyroxene. Several shock-melt veins and melt-pockets occurred in the basaltic portion. Several olivine grains next to the shock-met veins have transformed into ringwoodite. The estimated shock pressure is ~13 GPa at least. The petrological and mineralogical features of NWA 479 were similar to those of NWA 032. Olivine grains entrained in the shock-melt veins dissociated into bridgmanite + (Mg, Fe)O. The estimated shock pressure is ~23 GPa at least. NWA 4898 showed the basaltic texture. Olivine occurred as phenocrysts. The matrix portion consisted mainly of Ca-pyroxene and plagioclase. A trace amount of silica minerals was entrained in the shock-melt veins. Some silica minerals in the shock-melt veins were stishovite. Ca-pyroxene next to the shock-melt veins dissociated into ahrensite, pyroxene-glass, and (probably) silicate titanite. The estimated shock pressure is ~9 GPa at least. NWA 2977 showed a gabbroitic texture and consisted mainly of olivine, low-Ca pyroxene, Ca-pyroxene, and plagioclase. Olivine grains next to or entrained in the shock-melt veins have transformed into ringwoodite. The estimated shock pressure is ~16 GPa at least. Two third of NWA 2727 was breccia and the other was gabbroitic. The gabbroitic portion consisted of olivine, low-Ca pyroxene, Ca-pyroxene, and plagioclase. The breccia portion included silica besides the fragments of the gabbroitic portions. Silica minerals entrained in the shock-melt veins or melt-pockets have transformed into coesite. The estimated shock pressure is ~3 GPa at least.

The shock-induced melting textures were observed in all investigated lunar mare basalt samples. Although the high-pressure polymorphs of olivine, Ca-pyroxene, and silica minerals were identified, the high-pressure polymorphs of plagioclase, which are abundant in other shocked meteorites, were not identified. In addition to previous studies [1–3], the present study reveals that many kinds of

©2019. Japan Geoscience Union. All Right Reserved.

high-pressure polymorphs occur in the lunar mare basalt, implying that most lunar mare basalts have experienced the heavy impact events.

Bulk chemical analysis of iron meteorites by LA-ICP-MS

*Akira Yamaguchi[1], Naoki Shirai[2], Makiko K. Haba[3]

1. National Institute of Polar Research, 2. Tokyo Metropolitan University, 3. Tokyo Institute of Technology

Iron meteorites are Fe-Ni alloys with minor elements such as Co, P, S, and C. They are classified on the basis of textures (e.g., Widmanstatten pattern) and bulk chemical compositions (e.g., Ni, Ge, Ir). We performed bulk chemical analysis of iron meteorites by using an LA-ICP-MS and compared with the data obtained by INAA.

We measured five iron meteorites, Canyon Diablo (IAB, coarse octahedrite), Toluca (IAB, coarse octahedrite), Cape York (IIIAB, medium octahedrite), Muonionalusta (IV, fine octahedrite) and Dronino (ungrouped, ataxite) by using an LA-ICP-MS and INAA. Polished thick sections are prepared for LA-ICP-MS analysis. Polished thick sections of the meteorites were examined using an optical microscope, a scanning electron microscope, and an electron microprobe analyzer to observe the textures. A Thermo Element XR ICP-MS coupled to a CETAC LSX-213 laser was operated in low resolution mode (R = 300). The peaks monitored are ^{31}P, ^{34}S, ^{57}Fe, ^{59}Co, ^{60}Ni, ^{65}Cu, ^{69}Ga, ^{74}Ge, ^{95}Mo, ^{99}Ru, ^{103}Rh, ^{105}Pd, ^{182}W, ^{185}Re, ^{189}Os, ^{193}Ir, ^{194}Pt and ^{197}Au. Analyses in line and/or scanning modes were performed on a representative area of polished sections, using a 100 μm beam spot at 20 μm/sec., 20 Hz repetition rate. Typical analytical time was several minutes. Elemental abundances were obtained using Hoba (IVB, ataxite) and North Chile (IIAB, hexahedrite) iron meteorites as standard reference samples.

In INAA, samples weighing about 150 mg were firstly irradiated for 10 sec. at a neutron flux of 4.6 x 1012 $cm^{-2}s^{-1}$ at Institute for Integrated Radiation and Nuclear Science, Kyoto University for the determination of Co, Ni, Cu, Ge, and Rh. The same samples were reirradiated for 4 hrs at a neutron flux of 5.6 x 1012 $cm^{-2}s^{-1}$ at Institute for Integrated Radiation and Nuclear Science, Kyoto University for the determination of Cr, Fe, Co, Ni, Ga, As, Mo, Ru, Sb, W, Re, Os, Ir, Pt and Au.

We determined twenty elements (P, S, Fe, Co, Ni, Cu, Ga, Ge, As, Mo, Ru, Rh, Pd, Sb, W, Re, Os, Ir, Pt, and Au) for the five iron meteorites. Our results obtained by using two analytical methods were generally consistent with each other. However, our data of Muonionalusta are slightly different from literature values due to the large-scale heterogeneity of the meteorite (e.g., due to magmatic process). The abundance of some elements (e.g., Ru, Rh, Re, Ir) obtained from LA-ICP-MS data are higher than those from INAA due to the sample heterogeneity. It is possible to avoid this problem by choosing representative areas of the surface. Our study demonstrates that LA-ICP-MS has the potential to analyze a large number of iron meteorites.

[P-EM10] Multi-scale Coupling in the Magnetosphere-Ionosphere-Thermosphere System

convener:Yue Deng(University of Texas at Arlington), Toshi Nishimura(Boston University), Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Yanshi Huang(Harbin Institute of Technology, Shenzhen)

Determining the effects of energy deposition and transport, and momentum exchange across different spatial and temporal scales is an important objective in the M-I-T system, due to the clear evidence of multi-scale forcing. Coupling over multiple scales is also a critical challenge since observational and modeling methodologies for bridging different scales do not presently exist. This session solicits presentations on a wide range of coupling processes in the high-latitude M-I-T system from global to small-scale processes and related solar wind forcing. Relevant topics include (but are not limited to) (1) density structures and temperature gradients (polar cap, cusp, plume, trough, irregularities); (2) convection (flow channels, SAPS) and FAC; (3) energy transfer and deposition by precipitation and ULF waves, conductivity, aurora, and heating; and (4) coupling and feedback into the magnetosphere. Discussions of relevant multi-scale observations by means of multiple instruments, including space and ground-based, modeling and data science are encouraged.

Relativistic electron precipitation (REP) in the polar atmosphere has been paid attention to because it changes atmospheric composition, causing ozone depletion after migrating to the lower altitude during polar winter. A plausible mechanism for REP is the interaction with magnetospheric plasma waves, such as electromagnetic ion cyclotron (EMIC) waves and whistler-mode chorus waves. Previous studies have already shown that EMIC waves can effectively drive REP, however, observational evidence that chorus waves can drive REP was lacking. In this study we present direct comparison between magnetospheric plasma waves and polar mesosphere winter echoes (PMWE) simultaneously observed with the Arase satellite and high-power Mesosphere, Stratosphere and Troposphere (MST) radars in both hemispheres, PANSY and MAARSY. PMWE can be related to the ionization in the mesosphere due to REP. The PMWE were observed at 03-07 UT on March 21, 2017 during the passage of corotating interaction region (CIR), during which the Arase footprints were close to Syowa Station (SYO; −69.00S, 39.58E), Antarctica, and Husafell (HUS; 65.67N, −21.03E), Iceland.
The observational results are summarized as follows. (1) EMIC waves and whistler-mode chorus waves were observed by Arase near the equatorial magnetosphere during 02:30-04:45 UT and 04:45-07:00 UT, respectively. (2) PMWE were detected with both the MAARSY radar at Andøya (AND; 69.30N, 16.04E), Norway, and the PANSY radar at SYO, Antarctica, during 04:45-07:00 UT, which was the recovery phase of an isolated substorm. We believe this is the first time PMWE have been observed in both hemispheres at exactly the same time. (3) During 04:45-07:00 UT, the temporal variation of the chorus wave power was similar to those of the PMWE power in the both hemispheres. (4) The PMWE observed at SYO during 03:00-04:00 UT before the substorm onset was consistent with the occurrence of the EMIC waves. The item (2) shows direct evidence that chorus waves during the substorm recovery phase cause REP. We estimated the resonance energy of electrons interacting with the observed LBC waves, however, the estimated energy was too low to cause PMWE at an altitude lower than 70 km. However, we found that the resonance energy becomes greater than 1 MeV, if LBC waves propagate to the magnetic latitude greater than 30 degrees and resonate with energetic electrons there. As for item (4), the PMWE observed at SYO during 03:00-04:00 can be related to wave-particle interaction with EMIC waves, which may be generated inside the plasmapause by ring-current hot ions with temperature anisotropy. This anisotropy

©2019. Japan Geoscience Union. All Right Reserved.

was caused by magnetospheric compression due to increasing solar wind dynamic pressure during 01:00–06:00 UT just after the arrival of the CIR. Since CIRs are main sources of geomagnetic disturbances during the declining phase of the solar cycle and solar minimum, this event is not rare but rather a common atmospheric response caused by interaction between recurrent large-scale solar wind structures and geospace.

It is expected that mirror images of aurora are observed at geomagnetic conjugate points in the northern and southern auroral zones connected by a geomagnetic field line. However, geomagnetic conjugate auroras often show non-conjugacy, which reflects north-south asymmetry of the solar wind, the magnetosphere and the ionospheres. In other words acceleration mechanism of auroral particles may be studied by comparing aurora simultaneously occurring at geomagnetic conjugate points. A hydrogen Balmer beta emission at the wavelength of 486.1 nm which is the brightest among the proton auroral lines was observed at a pair of geomagnetic conjugate points to compare precipitating particle energy. Two identical Proton Auroral Specrographs (PASs) which obtain auroral spectra along a geomagnetic meridian at a rate of 1 image/min were installed at Tjornes in Iceland and Syowa Station in Antarctica. Data obtained during a period from September 4, 2018 to October 9, 2018 were analyzed to derive an average kinetic energy of precipitating protons along a local geomagnetic field line from a Doppler shift of the H beta line. As a result we are succeeded in simultaneous observations of proton auroras at both conjugate points in 5 nights on September 4, 5, 6, 7 , and 10. The average energies of precipitating protons range from 0 keV to 7 keV, and sometimes show a periodical variation with a period of 4 - 5 min. Conjugacy of precipitating particle energy will be discussed in the presentation.

A regularized deep convolutional general adversarial network (R-DCGAN) for total electron content map completion

*Mingwu Jin[1], Zhou Chen[2,3], Yue Deng[1], Yang Pan[1], Jin-Song Wang[2]

1. University of Texas at Arlington, 2. Institute of Space Science and Technology, Nanchang University, Nanchang, China, 3. Key Laboratory of Space Weather, National Center for Space Weather, China Meteorological Administration, Beijing, China

Observations with a complete global coverage are important for space physics research and applications. However, due to the technical limitations and costs, such a complete global coverage is often unavailable. Thus, data filling algorithms are often pursued to fill missing data gaps to create a global map from the incomplete data. In this work, a novel deep learning algorithm, regularized deep convolutional generative adversarial network (R-DCGAN), is developed by adding an extra discriminator to the conventional DCGAN to fill the missing data of total electron content (TEC) map images. R-DCGAN incorporates the knowledge from reference TEC maps of the International Global Navigation Satellite Systems Service Ionosphere Working Group to achieve much better TEC map completion performance than the conventional DCGAN as demonstrated by both synthetic and real data. The R-DCGAN framework can be extended to other fields of space sciences to address the missing observation data issues.

An intense and large auroral bright spot appears around the magnetic north pole observed by the Special Sensor Ultraviolet Spectrographic Imager (SSUSI) on board four different Defense Meteorological Satellite Program (DMSP) satellites during long time northward IMF conditions. The bright spot is even brighter than aurora in the auroral oval which is about 5-10˚ magnetic latitude equatorward of the bright spot. The bright spot is lasting about 8 hours, and sometimes appears as a cyclone-shape with a clockwise rotation. The DMSP in situ plasma observations suggest that the bright spot is clear associated with electron invert-V acceleration with 10s keV energy electron precipitations around the center regions and 1s keV energy electron precipitations around the egde regions. There are also strong flow shears between the two sides of the bright spot: strong sunward flows on the duskside and antisunward flows on the dawnside. These types of plasma should come from the high-latitude lobe region of the magnetotail due to the high-latitude lobe magnetic reconnections. Is it the evidence of stable lobe reconnection during long time northward IMF conditions? The detail and further analysis should be pursued in the following studies.

Hanson Center for Space Sciences, University of Texas at Dallas, Richardson, Texas, USA

A statistical study of ion upflow and field-aligned currents (FACs) has been performed in the topside ionosphere of both hemispheres for magnetic quiet and disturbed times by using DMSP satellite observations from 2010-2013. Distributions in MLT/MLAT reveal that ion upflow shows a dawn-dusk asymmetry distribution that corresponds well with the region 1 field-aligned currents. In addition, there are highest occurrence regions near noon and within the near midnight auroral disturbance area. These correspond to cusp and nightside dynamical processes, respectively. Both the ion upflow occurrence and FAC regions expand equatorward to a wider area during disturbed times.

SAPS in the 2013 March 17 Storm Event: Initial Results from the Coupled Magnetosphere-Ionosphere-Thermosphere Model

*Dong Lin[1,2], Wenbin Wang[2], Wayne Scales[1], Kevin Pham[2], Jing Liu[2], Binzheng Zhang[2], Viacheslav Merkin[3], Xueling Shi[1]

Subauroral polarization stream (SAPS) are latitudinally narrow flow channels of large westward plasma drifts in the subauroral ionosphere. In this study, the global structure and dynamic evolution of SAPS are investigated by using the National Center for Atmospheric Research (NCAR) Coupled Magnetosphere-Ionosphere-Thermosphere (CMIT) model with Ring Current extension, namely the LFM-TIEGCM-RCM (LTR) model, to simulate the 2013 St. Patrick's Day storm event. This is the first time that the global distribution and temporal evolution of SAPS are investigated using first-principle models. The model shows a strong westward ion drift channel formed equatorward of the auroral electron precipitation boundary on the duskside, which is identified as the SAPS structure. The simulated ion drift velocity and auroral electron precipitation sampled along the trajectory of the DMSP F18 satellite are in good agreement with the satellite measurements. SAPS initiate in the pre-dusk sector when the interplanetary magnetic field (IMF) turns southward. SAPS latitude generally decreases with magnetic local time (MLT) from dusk to midnight. The SAPS channel shows wedge, inverse wedge, and crescent morphologies during the storm, and becomes discontinuous when the IMF is weakly southward. The SAPS mean latitude has a correlation coefficient of 0.77 with the Dst index. The mean latitude moves equatorward and the flow channel broadens in the storm main phase. The simulation results are consistent with observational studies. They also illustrate the global distributions and highly dynamic behaviors of SAPS that are not readily apparent from observation data.

Westward turning motions of nighttime medium-scale traveling ionospheric disturbances (MSTIDs) at the equatorward side of the dusk side auroral oval associated with auroral brightening

*Sneha Yadav[1,2], Kazuo Shiokawa[1], Shin-ichiro Oyama[1,3,4], Yuichi Otsuka[1]

1. ISEE, Nagoya University, Nagoya, Japan, 2. SPL, VSSC, India, 3. Ionosphere Research Unit, University of Oulu, Oulu, Finland, 4. NIPR, Tachikawa, Japan

The characteristics of high-latitude nighttime medium-scale traveling ionospheric disturbances (MSTIDs) have not been well investigated using all-sky imagers because of the hindrance caused by the bright aurora. The limited results on the propagation characteristics of MSTIDs over high-latitudes hindered the progress in our understanding on these dynamical structure. In a case study carried out by Shiokawa et al. (JGR, 2012), an event of oscillating MSTIDs was reported over Tromsø (69.6˚N, 19.2˚E; corrected geomagnetic latitude: 66.6˚N), which was observed to be associated with auroral brightening. However, after this case study, which comprised of only one event, no observations showing oscillating motion of MSTIDs have been reported till date. In this study, for the first time, the comprehensive investigation on the westward turning of the MSTIDs in the equatorward side of the dusk side auroral oval has been performed. The all-sky imaging data of 630.0 nm airglow emissions during 2010-2018 are used to study the motions of MSTIDs over Tromsø. The results indicate that the nighttime MSTIDs primarily exhibit eastward motion under quiet magnetic conditions but turned in the westward direction during the active geomagnetic conditions. The turning of MSTIDs in the westward direction were invariably associated with the auroral brightening observed at the poleward edge of the all-sky image and localized magnetic field perturbations observed by ground-based magnetometers at Tromsø. The interesting aspect of the observations is the fact that these westward moving MSTIDs again turned in the eastward direction when the geomagnetic disturbance ceases. The SuperDARN (Super Dual Auroral Radar Network) convection maps revealed that the location of Tromsø was inside/outside the convection cell region during the time of appearance of westward/eastward moving MSTIDs. The Doppler shift measurement of the 630-nm airglow by a Fabry-Perot interferometer at Tromsø showed that northeastward winds were predominant during the appearance of eastward moving MSTIDs. The cause of the observed MSTIDs remains in question as they might either be triggered by atmospheric gravity waves or by Perkins instability. These experimental evidences suggest that the MSTIDs tend to move eastward in accordance with the background F-region dynamo electric field, but show westward motion under the influence of electric field associated with auroral activities in the dusk side of two-cell convection pattern.

[P-EM10] Multi-scale Coupling in the Magnetosphere-Ionosphere-Thermosphere System

convener:Yue Deng(University of Texas at Arlington), Toshi Nishimura(Boston University), Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Yanshi Huang(Harbin Institute of Technology, Shenzhen)

Determining the effects of energy deposition and transport, and momentum exchange across different spatial and temporal scales is an important objective in the M-I-T system, due to the clear evidence of multi-scale forcing. Coupling over multiple scales is also a critical challenge since observational and modeling methodologies for bridging different scales do not presently exist. This session solicits presentations on a wide range of coupling processes in the high-latitude M-I-T system from global to small-scale processes and related solar wind forcing. Relevant topics include (but are not limited to) (1) density structures and temperature gradients (polar cap, cusp, plume, trough, irregularities); (2) convection (flow channels, SAPS) and FAC; (3) energy transfer and deposition by precipitation and ULF waves, conductivity, aurora, and heating; and (4) coupling and feedback into the magnetosphere. Discussions of relevant multi-scale observations by means of multiple instruments, including space and ground-based, modeling and data science are encouraged.

Relativistic electron precipitation (REP) in the polar atmosphere has been paid attention to because it changes atmospheric composition, causing ozone depletion after migrating to the lower altitude during polar winter. A plausible mechanism for REP is the interaction with magnetospheric plasma waves, such as electromagnetic ion cyclotron (EMIC) waves and whistler-mode chorus waves. Previous studies have already shown that EMIC waves can effectively drive REP, however, observational evidence that chorus waves can drive REP was lacking. In this study we present direct comparison between magnetospheric plasma waves and polar mesosphere winter echoes (PMWE) simultaneously observed with the Arase satellite and high-power Mesosphere, Stratosphere and Troposphere (MST) radars in both hemispheres, PANSY and MAARSY. PMWE can be related to the ionization in the mesosphere due to REP. The PMWE were observed at 03-07 UT on March 21, 2017 during the passage of corotating interaction region (CIR), during which the Arase footprints were close to Syowa Station (SYO; −69.00S, 39.58E), Antarctica, and Husafell (HUS; 65.67N, −21.03E), Iceland.
The observational results are summarized as follows. (1) EMIC waves and whistler-mode chorus waves were observed by Arase near the equatorial magnetosphere during 02:30-04:45 UT and 04:45-07:00 UT, respectively. (2) PMWE were detected with both the MAARSY radar at Andøya (AND; 69.30N, 16.04E), Norway, and the PANSY radar at SYO, Antarctica, during 04:45-07:00 UT, which was the recovery phase of an isolated substorm. We believe this is the first time PMWE have been observed in both hemispheres at exactly the same time. (3) During 04:45-07:00 UT, the temporal variation of the chorus wave power was similar to those of the PMWE power in the both hemispheres. (4) The PMWE observed at SYO during 03:00-04:00 UT before the substorm onset was consistent with the occurrence of the EMIC waves. The item (2) shows direct evidence that chorus waves during the substorm recovery phase cause REP. We estimated the resonance energy of electrons interacting with the observed LBC waves, however, the estimated energy was too low to cause PMWE at an altitude lower than 70 km. However, we found that the resonance energy becomes greater than 1 MeV, if LBC waves propagate to the magnetic latitude greater than 30 degrees and resonate with energetic electrons there. As for item (4), the PMWE observed at SYO during 03:00-04:00 can be related to wave-particle interaction with EMIC waves, which may be generated inside the plasmapause by ring-current hot ions with temperature anisotropy. This anisotropy

©2019. Japan Geoscience Union. All Right Reserved.

was caused by magnetospheric compression due to increasing solar wind dynamic pressure during 01:00–06:00 UT just after the arrival of the CIR. Since CIRs are main sources of geomagnetic disturbances during the declining phase of the solar cycle and solar minimum, this event is not rare but rather a common atmospheric response caused by interaction between recurrent large-scale solar wind structures and geospace.

Westward turning motions of nighttime medium-scale traveling ionospheric disturbances (MSTIDs) at the equatorward side of the dusk side auroral oval associated with auroral brightening

*Sneha Yadav[1,2], Kazuo Shiokawa[1], Shin-ichiro Oyama[1,3,4], Yuichi Otsuka[1]

1. ISEE, Nagoya University, Nagoya, Japan, 2. SPL, VSSC, India, 3. Ionosphere Research Unit, University of Oulu, Oulu, Finland, 4. NIPR, Tachikawa, Japan

The characteristics of high-latitude nighttime medium-scale traveling ionospheric disturbances (MSTIDs) have not been well investigated using all-sky imagers because of the hindrance caused by the bright aurora. The limited results on the propagation characteristics of MSTIDs over high-latitudes hindered the progress in our understanding on these dynamical structure. In a case study carried out by Shiokawa et al. (JGR, 2012), an event of oscillating MSTIDs was reported over Tromsø (69.6˚N, 19.2˚E; corrected geomagnetic latitude: 66.6˚N), which was observed to be associated with auroral brightening. However, after this case study, which comprised of only one event, no observations showing oscillating motion of MSTIDs have been reported till date. In this study, for the first time, the comprehensive investigation on the westward turning of the MSTIDs in the equatorward side of the dusk side auroral oval has been performed. The all-sky imaging data of 630.0 nm airglow emissions during 2010-2018 are used to study the motions of MSTIDs over Tromsø. The results indicate that the nighttime MSTIDs primarily exhibit eastward motion under quiet magnetic conditions but turned in the westward direction during the active geomagnetic conditions. The turning of MSTIDs in the westward direction were invariably associated with the auroral brightening observed at the poleward edge of the all-sky image and localized magnetic field perturbations observed by ground-based magnetometers at Tromsø. The interesting aspect of the observations is the fact that these westward moving MSTIDs again turned in the eastward direction when the geomagnetic disturbance ceases. The SuperDARN (Super Dual Auroral Radar Network) convection maps revealed that the location of Tromsø was inside/outside the convection cell region during the time of appearance of westward/eastward moving MSTIDs. The Doppler shift measurement of the 630-nm airglow by a Fabry-Perot interferometer at Tromsø showed that northeastward winds were predominant during the appearance of eastward moving MSTIDs. The cause of the observed MSTIDs remains in question as they might either be triggered by atmospheric gravity waves or by Perkins instability. These experimental evidences suggest that the MSTIDs tend to move eastward in accordance with the background F-region dynamo electric field, but show westward motion under the influence of electric field associated with auroral activities in the dusk side of two-cell convection pattern.

[P-EM10] Multi-scale Coupling in the Magnetosphere-Ionosphere-Thermosphere System

convener:Yue Deng(University of Texas at Arlington), Toshi Nishimura(Boston University), Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Yanshi Huang(Harbin Institute of Technology, Shenzhen), Chairperson:Yue Deng(University of Texas at Arlington), Huixin Liu(Kyushu University, Japan), Yanshi Huang(Harbin Institute of Technology, Shenzhen, China), Yukitoshi Nishimura(Boston University)

Determining the effects of energy deposition and transport, and momentum exchange across different spatial and temporal scales is an important objective in the M-I-T system, due to the clear evidence of multi-scale forcing. Coupling over multiple scales is also a critical challenge since observational and modeling methodologies for bridging different scales do not presently exist. This session solicits presentations on a wide range of coupling processes in the high-latitude M-I-T system from global to small-scale processes and related solar wind forcing. Relevant topics include (but are not limited to) (1) density structures and temperature gradients (polar cap, cusp, plume, trough, irregularities); (2) convection (flow channels, SAPS) and FAC; (3) energy transfer and deposition by precipitation and ULF waves, conductivity, aurora, and heating; and (4) coupling and feedback into the magnetosphere. Discussions of relevant multi-scale observations by means of multiple instruments, including space and ground-based, modeling and data science are encouraged.

Auroral fragmentation into patches and pressure balance condition in the source magnetosphere

*Kazuo Shiokawa[1], Katsuki Nishi[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

The auroral fragmentation into patches has been reported by Shiokawa et al. (JGR, 2010; 2014) as finger-like structures developed in the diffuse aurora with horizontal scale sizes of 5-25 km (small scale) and 40-100 km (large scale). The development of these finger-like structures divides the diffuse aurora into patches. Thus we call it as the auroral fragmentation which is a cause of the patchy auroral structures in the diffuse aurora. Hashimoto et al. (JGR, 2015) made a statistical analysis of these auroral finger-like structures and found their occurrence rates of 13% and 4 % for large- and small-scale events, respectively. They also indicated that the finger-like structures tend to occur at the beginning of the substorm recovery phase in the post-midnight and dawn sectors. The auroral finger-like structure suggests the development of pressure-driven instability in the magnetosphere. Recently Nishi et al. (JGR, 2017) made the first conjugate measurement of the auroral finger-like structures with the THEMIS-E satellite at ~8 Re in the magnetosphere. They found clear anti-phase oscillations between the magnetic and plasma pressures in the post-midnight plasma sheet. This anti-phase variation is consistent with the idea of the pressure-driven instability. On the other hand, Nishi et al. (JGR, 2018a) reported that a conjugate event with the RBSP-A satellite at ~5.5 Re does not show systematic phase relationship between the magnetic and plasma pressures. Then Nishi et al. (JGR, 2018b) investigate statistical features of the phase relationship between magnetic and plasma pressures using two-year THEMIS-E observations in the nightside plasma sheet and obtained a high occurrence of the anti-phase oscillations between the magnetic and plasma pressures. In the presentation, we will review these recent results on the auroral fragmentation and pressure balance condition in the source magnetosphere, and discuss possible physical mechanism that contributes these phenomena.

Formation and Evolution of Polar Cap Ionospheric Patches and Their Associated Upflows and Scintillations: A Review

*Qing-He Zhang[1], Zan-Yang Xing[1], Yong Wang[1], Yu-Zhang Ma[1]

1. Institute of Space Sciences, Shandong University, Weihai, China

Polar cap patches are common phenomena, especially during southward interplanetary magnetic field (IMF) conditions, in the polar ionosphere. We summarized the recent new progress about the formation and evolution of patches as well as their impact on the magnetosphere-ionosphere-thermosphere (M-I-T) coupling processes and space weather. The dayside reconnection and bursty sunward return flows produced by the modulation of nightside reconnection, are confirmed as the dominated mechanisms to separate the entering ionization into islands (patches). The patches evolve along streamlines of the Dungey convection cycle from the dayside to the nightside and exit the polar cap modulated by pulsed nightside reconnection. However, they slowly move and rapidly fade away behind a lobe “reverse” convection cell when the IMF suddenly changed to northward. Rapidly moving patches are associated with clear ion upflows due to frictional heating and offer more upwelling ion fluxes. Patches often produce significant scintillations due to strong density gradients at their edges, especially during their merging into the auroral oval, which will result in variable disturbances to High Frequency (HF) radio communications, over-the-horizon radar location errors, disruption and errors to satellite navigation and communication.

Global ionospheric disturbances during the 6-10 September 2017 solar storms

*Shunrong Zhang[1]

1. MIT Haystack Observatory

Solar activity during the period of 6-10 September 2017 is characterized with a series of very strong flares and powerful coronal mass ejections (CMEs). Observations indicate more than two dozens of M-class and 4 X-class flares being emmitted from the solar Active Region 12673. In particular, one of these flares led to a halo-type CME which traveled earth-bound at ~1570 km/s apparent speed. With the arrival of this CME, IMF Bz turned to southward and reached a minimum of -30 nT at 23:25 UT on 7 September, triggering a Kp 8 geomagnetic storm with a sudden commencerment at ~2300 UT and a minimum Dst ~ -150 nT near 0100 UT on 8 September. These conditions caused very significant geospace disturbances, in particular, ionospheric disturbances with various spatial and temporal scales. In this presentation, we report flare induced ionospheric perturbations and post-flare traveling ionospheric disturbances (TIDs), storm-enhanced density (SED) plumes at subauroral and high latitudes of the dayside ionosphere, subauroral polarization streams (SAPs), and large scale TIDs over the globe. Our discussion will focus on some unique post-flare ionospheric oscillation and TID features, TIDs at high latitudes, and gigantic cross-hemispheric ionospheric electron density depletion channels. This study is based primarily on ground-based GNSS and Millstone Hill incoherent scatter radar observations.

Multiscape Coupling of Sub-auroral Polarization Streams

*Nozomu Nishitani[1], Tomoaki Hori[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

Sub-Auroral Polarization Streams (SAPS) are fast westward flows slightly equatorward of the auroral precipitation boundary, and manifestations of magnetosphere-coupling processes. Recenty it was shown that SAPS sometimes contain perturbation in westward speed, typically with temporal scale of a few minutes (e.g., Hori et al., GRL, 2018). However, it has not yet been clear how small the temporal scales of these perturbations can be and how perturbations with different temporal scales are related to each other. In this paper, multiscape coupling of the sub-auroral polarization streams will be studied, using multiple events observed mainly by the SuperDARN Hokkaido East / West radars.

Scale sizes of mass density enhancements inferred from accelerometer measurements

*Yanshi Huang[1], Cheryl Huang[2]

1. Harbin Institute of Technology, Shenzhen, China, 2. Space Physics Directoriate, Air Force Research Laboratory, Kirtland AFB, USA

The spatial scale sizes of neutral mass density enhancements inferred from the accelerometer measurements on CHAMP and GRACE satellites are analyzed. Density enhancements are found as the peaks with more than 30% above the average density baseline fitted over a 90 degree magnetic latitude window. The widths of mass density peaks are defined in two different methods, one using the maximum above the average density baseline, the other method using the two minima surrounding each one density peak above a threshold value. We study various cases including one-peak and multi-peak cases using high-resolution density data from year 2002 to 2010. The results give a statistical understanding of the scale sizes of the density enhancements observed at high and polar latitudes. The scale sizes using the baseline are rather independent of solar activity, and the average is over 2500 km, whereas the scale sizes using adjacent density minima vary with solar activity, and the mean value is more than 1000 km. No significant different results are found between northern and southern hemisphere. We also investigate the impact of these mass density peaks on the orbit-averaged densities.

Meso-scale forcing in the upper atmosphere: sources and impacts

*Yue Deng[1], Qingyu Zhu[1], Cissi Lin[1]

1. University of Texas at Arlington

We present a systematical study crossing both data analysis and model simulation to improve the specification of the energy and momentum inputs into the ionosphere-thermosphere (IT) system, especially at the meso-scale, and the system response. Our results are organized in two parts. First, two-years of Swarm satellite field-aligned current (FAC) data have been analyzed in order to study the distributions of mean pattern and variability of FACs on different scales (small scale: <150 km; mesoscale: 100~500 km; large scale: >500 km). The FAC distributions are then implemented in the Global Ionosphere-Thermosphere Model (GITM) to assess relative contributions of FACs at different scales to Joule heating. To enhance our capability to directly simulate the meso- and small-scale structures, GITM has been improved with a local patch grid refinement capability. Utilizing GITM with the new grid structure, the meso- and small-scale gravity wave perturbations have been included at the lower boundary of GITM to simulate the influence of meso- and small-scale gravity waves on the upper atmosphere.

NASA Heliophysics Division Space Weather Update

*Nicola Justine Fox[1]

1. NASA Headquarters

NASA is a mission driven agency whose science mission is focused on discovering the secrets of the universe, looking for life elsewhere, and safeguarding and improving life on Earth. Heliophysics plays a key role in every aspect of the NASA science mission, including understanding the drivers of and enabling the prediction of space weather. Heliophysics has an established research program that motivates and funds solar and space physics, which is the essence and foundation of space weather research. Recently, the Heliophysics Division established a Space Weather Science Applications Program, SnAP. The objective of this competed program is to enable the transition of the knowledge and understanding of space weather to operation environments, by partnering with sister agencies, the commercial sector, and academia. SnAP leverages relevant NASA capabilities to reach this objective. This talk provides an overview of space weather research and SnAP in the NASA Heliophysics Division

NOAA's Current and Future Space Weather Architecture

*Elsayed R Talaat[1]

1. NOAA National Environmental Satellite, Data, and Information Service

NOAA observational responsibilities in support of space weather forecasting are in the context of significant, numerous, complementary international and domestic efforts. Each measurement plays a unique role at different phases of the forecasting or event characterization process. This paper overviews the current suite of observation that NOAA maintains and utilizes on various platforms, NOAA's forecasting capability, contributions to research efforts, and the status of the NOAA/NESDIS plan forward efforts for the Space Weather Follow-On (SWFO) program to provide needed continuity. This paper will also brief the NOAA space weather goals within the NOAA Satellite Observing System Architecture.

Community Coordinating Modeling Center (CCMC): A hub for collaborative assessment and improvement of space weather capabilities.

*Maria M Kuznetsova[1], M. Leila Mays[1], Edward J Semones[2], Peter J Macneice[1], Lutz Rastaetter[1], Ja Soon Shim[1], Yihua Zheng[1], Katherine Garcia-Sage[1], Joycelyn Jones[1], Yaireshka m Collado-Vega[1], Richard E Mullinix[1], Chiu Wiegand[1]

1. NASA Goddard Space Flight Center, 2. NASA Johnson Space Center

The Community Coordinated Modeling Center (CCMC, http://ccmc.gsfc.nasa.gov) was established at the end of past millennium as a multi-agency strategic investment in the US space weather program. The CCMC has two main goals: 1) to support space weather research and model development aiming to advance understanding of space weather phenomena and to improve forecasting; 2) to facilitate development of space weather applications and deployment of operational capabilities. The CCMC hosts a rapidly growing collection of space weather models and applications, provides simulations services to the international research community through a one-of-a-kind runs-on-request system, and maintains real-time simulations and perpetual archives of space weather information streams. In support of NASA missions, the CCMC provides support for mission planning, develops applications for space weather monitoring and forecasting, and provides space environment analysis services. In partnership with NASA Space Radiation Analysis Group (SRAG) and international modeling community the CCMC is building a flexible system for Solar Proton Event (SPE) risk assessment and forecasting in support of human exploration. Unbiased testing, evaluating and prototyping of new models and forecasting techniques for potential transition to operational organizations (R2O) is one of the primary CCMC functions. To establish internationally recognized metrics and benchmarks the CCMC initiated an international community-wide Forum for Space Weather Capabilities Assessment. Guided by the unfolding activities of Forum working teams as well as by the needs of operational agencies and end users to quantify and track improvements over time, the CCMC has begun to develop an extensive information technology infrastructure to support validation activities through a centralized database and an interactive web-based framework. The presentation will highlight the recent progress and discuss opportunities for international research initiatives aiming to improve space weather forecasting capabilities.

Different flux evolutions of relativistic electrons of the outer belt associated with high-speed coronal hole streams; Arase and Van Allen Probes observations

*Yoshizumi Miyoshi[1], Satoshi Kurita[1], Ryuho Kataoka[2], Shinji Saito[1], Vania Jordanova[3], Iku Shinohara[4], Takefumi Mitani[4], Takeshi Takashima[4], Nana Higashio[4], Satoshi Kasahara[5], Shoichiro Yokota[6], Tomoaki Hori[1], Kunihiro Keika[5], Yoshiya Kasahara[7], Shoya Matsuda[4], Atsushi Kumamoto[8], Fuminori Tsuchiya[8], Masafumi Shoji[1], Ayako Matsuoka[1], Mariko Teramoto[1], Harlan Spence[9], Geoff Reeves[3], Daniel Baker[10]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. NIPR, 3. Los Alamos National Laboratory, 4. JAXA, 5. University of Tokyo, 6. Osaka University, 7. Kanazawa University, 8. Tohoku University, 9. University of New Hampshire, 10. University of Colorado

Relativistic and ultra-relativistic electrons increase largely during the high-speed coronal hole streams, and the enhanced flux levels are controlled by the solar wind speed and the prolonged southward IMF. Such flux enhancements associated with high-speed streams have been observed by Arase/HEP and XEP instruments as well as Van Allen Probes/MagEIS and REPT. Some coronal hole streams produce large flux enhancement of both relativistic and ultra-relativistic electrons, while other coronal holes produce large flux enhancement of relativistic electrons (~2 MeV) but do not produce enhancement of ultra-relativistic electrons. In this presentation, we will show evolutions of the energy spectrum of relativistic electrons during the coronal hole streams and discuss how evolutions of the energy spectrum are related to chorus wave activities that are derived from Arase/PWE measurements and the proxy data from the low-altitude satellite data.

Study on the predictability of imminent giant solar flares based on the theory of double-arc instability

*Kanya Kusano[1], Tomoya Iju[2], Yumi Bamba[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. NAOJ

Solar flares are catastrophic explosions in the solar corona and sometimes may cause a severe space weather disaster in geo-space and the infrastructure. Although many efforts have been taken for understanding and predicting the onset of solar flares, it is still difficult to accurately predict when, where and how large giant solar flares will occur. Here, we propose a new type of solar flare prediction scheme called the κ-scheme. The κ-scheme is the totally physics-based prediction, and it is capable of providing the information of the location as well as the energy of imminent giant solar flares. The prediction is performed by evaluating how small reconnection can trigger the onset of the double-arc instability, which was recently proposed as the initial driver of solar flares by Ishiguro and Kusano (2017), using the nonlinear force-free field extrapolation. We carried out the analysis of more than 200 active regions in the solar cycle 24 by applying the κ-scheme to the SDO/HMI data. The result shows that most of the imminent giant solar flares larger than the GOES X2 class are predictable with the κ-scheme.

Update of space weather research and operation activities in NICT

*Mamoru Ishii[1]

1. National Institute of Information and Communications Technology

Since September 6 2017, when X9.3 solar flare occured most of Japanese people were scared of it, the situation of Japanese spacw weather operation has been changed so much. The ionosphere observing network has been set more robustly with dual systems. A back up center of space weather information service has been installed at NICT Kobe branch. In addition, we will begin 24/7 operation of space weather forecast services in FY2019.We have been collaborating with academic researchers under the framework of PSTEP which will finish the end of FY2019. Through the activities, we have provided some applications for better service than before. A radio propagatoin simulator, HF-START, and the estimation system of human radiation on flight, WASAVIES will be up on our web soon. In addition, we continue to discuss hazardous map against severe space weather disasters, which will be published within a year.I would like to share our information and have close cooperation with Asia Oceania space weather researchers and operators.

Commercial Space Weather Activities From a USA small Business Perspertive

*Chigomezyo Mudala Ngwira[1], Geoff Crowley[1], Chad Fish[1]

1. Atmospheric and Space Technology Research Associates, LLC

This talk offers a brief overview of ASTRA (Atmospheric and Space Technology Research Associates), a small business company based in Louisville, Colorado USA. ASTRA was born out of the vision for applying fundamental space physics knowledge to real-world problems. Its motto is Science + Technology + Applications –Bringing it all together. Founded in 2005, ASTRA has become a system design and technology development company. ASTRA is a leader in the “New Space” small satellite revolution specializing in miniaturized sensors, and data modeling and analytics for the government and commercial customers. ASTRA leverages its scientific and engineering expertise to develop unique solutions in HF radar and radio, GPS systems, satellite remote sensing, CubeSats/Smallsats, and LiDAR. ASTRA's technical background spans fundamental space physics disciplines of the upper atmosphere, data analysis and modeling of the complex coupling of the meso-iono- thermosphere, as well as LEO constellation design, spacecraft design, instrument sensor design and manufacture, and space to earth communications.

Development of coronal mass ejection arrival time forecasting system using interplanetary scintillation observations

*Kazumasa Iwai[1], Daikou Shiota[2], Munetoshi Tokumaru[1], Ken'ichi Fujiki[1], Mitsue Den[2], Yûki Kubo[2]

Coronal mass ejections (CMEs) sometimes cause disturbances in the environment of the Earth. However, prediction of the arrival of CMEs still remains a challenge. We have developed a data assimilation forecasting system of the CME arrival time by combining radio interplanetary scintillation (IPS) observations and a global magnetohydrodynamic (MHD) simulation of the inner heliosphere. In this system, the initial speed of a CME is roughly derived from the white light coronagraph observations. Then, the propagation of the CME is calculated by global MHD simulation (Shiota et al. submitted in this session). The IPS is estimated by the three-dimensional density distribution of the inner heliosphere derived from the MHD simulation. The estimated IPS is compared with the actual IPS observation made by the Institute for Space-Earth Environmental Research, Nagoya University. The estimated IPS shows good agreement with the observed IPS. We demonstrated the working of the simulation system using a typical halo CME event generated by a X9.3 flare observed on September 5, 2017. We found that the CME simulation that estimates IPS most similar to the observation can most accurately predict the time of arrival of the CME to the Earth. These results suggest that the accuracy of the CME arrival time will be improved if the current MHD simulations include IPS data.

Development of real-time prediction system of CME arrival and magnetic field with SUSANOO-CME MHD simulation

*Daikou Shiota[1,2], Seiji Yashiro[3], Kazumasa Iwai[2]

1. National Institute of Information and Communications Technology (NICT), 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Catholic University

The predictions of CME arrival to the Earth and the southward magnetic field brought by the CMEs are one of crucial tasks for space weather forecast.
We have developed an MHD simulation capable of reproducing the interplanetary propagation of multiple CMEs with internal magnetic flux rope (Shiota & Kataoka 2016) called as SUSANOO-CME. The simulation solves propagation of solar wind and CMEs in the inner heliosphere from 25 solar radii where all the balk flow exceeds fast mode speed. The information of solar wind and CME is specified at the inner boundary with empirical and analytical models using real-time observations of the Sun and the corona.
Recently, we have been constructing a new prediction system of CME impacts (CME arrival and magnetic field) utilizing SUSANOO-CME with the real-time solar observations for the purpose of use in space weather forecast in NICT. The system is capable of preforming ensemble simulation with different sets of multiple CME input parameters, which is controlled from web-browser based interfaces. The results of ensemble simulation can be evaluated with real-time IPS observation in Nagoya University (the detail is reported by Iwai et al. submitted in this session). We will report the current status of the development and discuss the future directions.

The Role of a Tiny Brightening in a Huge Geo-effective Solar Eruption Leading to the St Patrick's Day Storm

*Yumi Bamba[1,2], Satoshi Inoue[1], Keiji Hayashi[1,3,4]

1. Institute for Space-Earth Environmental Research/Nagoya University, 2. Institute if Space and Astronautical Science/Japan Aerospace Exploration Agency, 3. Key Laboratory of Solar Activity, National Astronomical Observatories, Chinese Academy of Sciences, 4. State Key Laboratory for Space Weather, National Space Science Center, Chinese Academy of Sciences

The largest magnetic storm in solar cycle 24 was caused by a fast coronal mass ejection (CME) that was related to a small C9.1 flare that occurred on 15 March 2015 in solar active region (AR) NOAA 12297. The purpose of this study is to understand the onset mechanism of the geo-effective huge solar eruption. We focused on the C2.4 flare that occurred prior to the C9.1 flare of the filament eruption. The magnetic field structure in the AR was complicated: there were several filaments including the one that erupted and caused the CME. We hence carefully investigated the photospheric magnetic field, brightenings observed in the solar atmosphere, and the three-dimensional coronal magnetic field extrapolated from nonlinear force-free field modeling, using data from *Hinode* and *Solar Dynamics Observatory*. We found three intriguing points : (1) There was a compact but noticeably highly twisted magnetic field structure that is represented by a small filament in the C2.4 flaring region, where a tiny precursor brightening was observed before the C2.4 flare. (2) The C2.4 flaring region is located in the vicinity of a foot point of the closed field that prohibits the filament from erupting. (3) The filament shows a sudden eruption after the C2.4 flare and accompanying small filament eruption. From our analysis, we suggest that a small magnetic disturbance that was represented by the tiny precursor brightening at the time of the C2.4 flare is related to the trigger of the huge filament eruption.

Critical Parameters of Photospheric Magnetic Field to Produce Eruptive Solar Flares and CMEs in Active Regions

*Pei Hsuan Lin[1], Kanya Kusano[1], Daikou Shiota[2], Satoshi Inoue[1], KD Leka[1,3], Yuta Mizuno[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. National Institute of Information and Communications Technology, 3. NorthWest Research Associates

Solar flares and coronal mass ejections (CMEs) are eruptive phenomena caused by magnetic field in the solar corona. In particular, large eruptive events originate in active regions (AR) on the solar surface. However, it is still unclear what determines the capability of an AR to produce eruptive flares and CMEs, and it hinders our ability to predict CMEs. In this study, we propose a new parameter r_m to measure the possibility that a flare on an AR can be eruptive and produce a CME. The parameter r_m is defined by the ratio of the magnetic flux of twist higher than a threshold T_c to the overlying magnetic flux. The value of rm for each AR can be estimated using the nonlinear force-free field (NLFFF) extrapolation. Based on the data obtained by the Solar Dynamics Observatory (SDO)/Helioseismic and Magnetic Imager (HMI), we calculated the values of r_m for 29 ARs at 51 times before to flares larger than M5.0 class. We find that the foot-point of field lines with twist larger than 0.2 can well represent the flare ribbons, and we thus evaluated r_m for T_c=0.2 as a critical parameter for producing eruptive flares and CMEs using discriminant analysis. The result shows that r_m is moderately able to discriminate ARs which have capability to produce CME-accompanied flares.

Simulation study on internal velocity field variation of eruptive prominence

*Takafumi Kaneko[1], Kanya Kusano[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

Solar prominences, cool dense plasma clouds in the hot tenuous corona, sometimes erupt and evolve into coronal mass ejections. Prominence eruptions have attracted interest in the researches of space weather as well as solar physics. It is known that the interior of prominences is turbulent. Recent observational statistical studies reported that standard deviation of the Doppler velocity in the eruptive prominences started to increase several hours before eruptions even when the mean velocity was nearly zero. This finding is useful to predict prominence eruptions; however, the physical relationship between the magnetically-driven eruptive mechanisms (i.e., magnetohydrodynamic instabilities) and the internal velocity field variation of prominence has not been revealed.
In this study, we performed three-dimensional magnetohydrodynamic simulation including gravity, radiative cooling, and thermal conduction to reproduce eruption of turbulent prominence. In our simulation, a bipolar magnetic field is randomly introduced along the polarity inversion line of the sheared coronal arcade field. A magnetic flux rope is created by reconnection between the bipole and the coronal arcade field. Cool dense prominence is formed in the flux rope by radiative condensation. The prominence erupts after the flux rope exceeds the critical height of torus instability. Before the eruption, the height of flux rope axis monotonically increases; however, the velocity field inside the prominence has complicated distribution containing both upflows and downflows. We confirmed that the increase in standard deviation of the vertical velocity is quantitatively consistent with the observational results. To investigate the relationship with the magnetic field, we compared the histogram of the velocity components perpendicular and parallel to the magnetic field. As a result, we found that the upflows and downflows stem from perpendicular and parallel velocity, respectively. This result indicates that upflows and downflows are driven by Lorentz force and gravity along magnetic field, respectively. We also found that the increase in standard deviation of perpendicular velocity is larger than that of parallel velocity, suggesting that the increase in standard deviation of vertical velocity is caused mainly by increase in Lorentz force.

Is intensity of auroral electrojet predictable?

*Yusuke Ebihara[1], Takashi Tanaka[2], Naoki Kamiyoshikawa[3]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Kyushu University, 3. Mitsubishi Electric Corporation

A large amount of energy (of the order of 10^{11} W) is consumed in the auroral ionosphere as Joule dissipation during the substorm expansion phase. The origin of the energy consumed in the auroral ionosphere is in the solar wind, but the energy flow and conversion in between are problematic. Previously, the energy consumed in the ionosphere is thought to consist of the directly driven (DD) component and the loading and unloading (UL) component. The DD component is thought to respond to the magnetic energy entering the magnetosphere, and hence, the DD component is probably predictable. The UL component, on the other hand, is thought to be unpredictable because it might depend on the amount of released energy in the lobe. On the basis of the global magnetohydrodynamics (MHD) simulation, we show that the maximum intensity of the auroral electrojet (and the Joule dissipation rate) during the substorm expansion is well correlated with the magnetic energy entering the magnetosphere. The correlation coefficient between them is 0.90 (and 0.97). There are a few key reasons. First, the amount of the released energy from the lobe increases with the southward component of interplanetary magnetic field (SBZ) and the solar wind velocity, meaning that the amount of the released energy is regulated by the solar wind parameters. Secondly, the magnetic energy released from the lobe goes into the near-Earth reconnection region, and seems not to contribute significantly to the generation of the field-aligned current associated with the substorm expansion. Thirdly, the release of the energy lasts for ~10 minutes, whereas the auroral electrojet keeps developing for 15 minutes and more. Fourthly, 40-90% of the magnetic energy entering the magnetosphere comes from the solar wind kinetic energy for the southward IMF. About 2% of the entering energy goes into the ionosphere during the expansion phase. The ratio is almost independent of the solar wind condition. These simulation results may suggest that the maximum intensity of the auroral electrojet (and the Joule dissipation rate) is predictable when the magnetic energy entering the magnetosphere is adequately predicted.

Geoelectromagnetics with the Geophysical Instrument Combination of Hydro-Québec, AUTUMNX, and USArray Magnetotellurics

*Martin G Connors[1], Sébastien Guillon[2], Adam Schultz[3], Naoto Imamura[3]

1. Athabasca University, 2. Hydro-Québec TransÉnergie, 3. Oregon State University

Geoelectromagnetics is a term used by Bolduc et al. (2000) regarding a pioneering study in which electric fields near a part of the Hydro-Québec transmission network were measured during an intense auroral event. To fully characterize space weather effects on an electric power transmission network, we must proceed from the source currents and their variations, through the changing magnetic fields near Earth's surface, to the electric fields induced in the Earth and to some extent in the conducting structures directly, to electric currents flowing in the grid, and finally to the effects of such currents, ranging from voltage distortion to possible equipment damage. The more data can be measured at each link in this complex chain, the better will be our ability to monitor current events in a precautionary manner and assess the robustness of the grid to varying levels of stress.

The Hydro-Québec network has had enhanced monitoring capabilities (as well as improved ability to deal with geomagnetic stresses) since 1989 (Guillon et al., 2016). The last link of the chain, effects, is able to be well quantified, especially through measures of voltage distortion. Direct measurements of transformer grounding currents, essentially the geomagnetically induced currents (GIC) themselves, are available at a few points. The AUTUMNX magnetic network (Connors et al., 2015) complemented grid instrumentation in Québec starting in 2014, and has produced a new view of the association of magnetic variations with signals in the grid. Magnetotellurics (MT) tends to operate in campaign mode, but also measures the electric field, including at relevant low frequencies, giving a more complete indication of the geoelectromagnetic environment while also providing measurements of the frequency dependent electromagnetic impedance of the ground, which can be used to reconstruct the electrical conductivity structure of the Earth's crust and mantle.

We illustrate these comprehensive geoelectromagnetic measurements with the case of the magnetic storm of September 7-9 2017, during which the NSF EarthScope MT array installed by Oregon State University was operating in the northeastern US, near the Hydro-Québec grid, at a time when the electrojet had expanded southward. We find a close correlation of times of large magnetic field variation, measured electric fields, and harmonic distortion in the grid.

While we note the complications stressed by Love et al. (2018), we feel that the enhanced MT monitoring advocated by Love et al. (2016), would give more knowledge of geological structure and geoelectric response in northeastern North America. In this way, our understanding of GIC would be greatly improved, in the areas of understanding basic processes and hazard assessment.

Quantifying the Latitudinal Extent of the Aurorae During Large Geomagnetic Storms

*Sean Blake[1,2], Antti Pulkkinen[1], Pete Schuck[1]

1. NASA Goddard Space Flight Center, Space Weather Laboratory, Greenbelt, Maryland, USA, 2. Catholic University of America, Department of Physics, Washington DC, USA

As geomagnetic storms grow larger, the extent of the auroral ovals can be seen to travel further towards the equator. During the famous Carrington event for example, the aurora was reportedly seen as far South as Cuba. Accompanying the auroras are large electric currents in the ionosphere. The magnetic signature of these ionospheric currents can be detected on the ground in magnetic observatories around the world in the form of increased magnetic variations. These variations can lead to large local geoelectric fields, posing a risk to the operation of power networks around the world.

It is therefore necessary to estimate the extent of the aurora and accompanying geoelectric fields during infrequent and large-scale (1-in-100 year) events. Using three decades of historical geomagnetic data from around the world, we have developed a method to detect and quantify the extent of the auroral oval (or latitude threshold) using ground-based data. We use this to statistically estimate the southernmost extent for storms with Dst values < -600 nT, as well as the geoelectric field strengths at these latitude thresholds.

In addition, building on the work by Ngwira et al. (2014) by using magnetospheric and ionospheric magnetohydrodynamic simulations, we simulate 'worst-case' scenario superstorms of different magnitudes. Applying our threshold detecion to the magnetic field outputs of these simulations enable us to estimate the latitude thresholds for storms of magnitudes not seen in the modern era.

Simulation of Geomagnetically Induced Current (GIC) Flowing in 500 kV Power Grid in Japan Including a Three-Dimensional Ground Inhomogeneity

*Satoko Nakamura[1], Yusuke Ebihara[1], Shigeru Fujita[2], Tada-nori Goto[3], Shinichi Watari[4]

1. Research Institute for Sustainable Humanosphere, Kyoto University., 2. Meteorological College, Japan Meteorological Agency, 3. Graduate School of Engineering, Kyoto University, 4. National Institute of Information and Communications Technology

We evaluate geomagnetically induced currents (GICs) flowing in the Japanese power grid during severe space weather by using several methods. First, the three-dimensional distribution of the geomagnetically induced electric field (GIE) was calculated by using the 3D finite-difference time-domain (FDTD) method with a three-dimensional electrical conductivity model constructed from a global relief model and a global map of sediment thickness. To simulate a time evolution of magnetic storms, the sheet current with its intensity inferred from the ground magnetic disturbance for famous magnetic storms is imposed. We compared the calculated GICs with the observed ones at substations around Tokyo, and found a certain agreement when the uneven distribution of GIE is incorporated with the simulation. The simulation result shows that GIE exhibits localized, uneven distribution that can be attributed to charge accumulation due to the inhomogeneous conductivity below the Earth's surface. The charge accumulation becomes large when the conductivity gradient vector is parallel, or anti-parallel to the incident electric field. For given GIE, we calculated the GICs flowing in a simplified 500 kV power grid network in Japan. The influence of the inhomogeneous ground conductivity on GIC appears to depend on a combination of the location of substations and the direction of the source current. Second, we assume conductivity anomaly simulating a plate boundary to test the effect of large-scale underground structure on GICs. We find that these structures may strongly enhance GIC just above them. Finally, we derive transfer functions between the GIC observation at 4 substations in Japan and geomagnetic field recorded at the Kakioka station. The transfer functions are not always applicable for Japanese GIC. We will discuss the validity of the assumption of uniform ground and influence of the time variation of earthing resistance of substations.

Reproducibility of the geomagnetically induced currents in Hokkaido with a two-layer conductivity model

*Takashi Kikuchi[1,2], Yusuke Ebihara[2], Kumiko K. Hashimoto[3], Shinichi Watari[4]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Institute for Sustainable Humanosphere, Kyoto University, 3. Kibi International University, 4. National Institute of Information and Communications Technology

Watari et al. [SW 2009], based on the GIC measurements in Hokkaido, Japan (35.7 GM Lat), found that the GIC is well correlated with the y-component magnetic field (By) (correlation coefficients > 0.8) and poor correlations with Bx,z and dBx,y,z/dt. The good correlation between the GIC and By would help predict the GIC if we have capabilities of reproducing the magnetosphere-ionosphere currents responsible for ground magnetic disturbances. To use the GIC- By relationship for the GIC prediction, we need to clarify if the good correlation is valid for any period/time scale (T) of disturbances. To address this issue, we made correlation analyses for the geomagnetic sudden commencements and pulsations (T=1-10m), substorm positive bays (30m), quasi-periodic DP2 fluctuations (20-60m), and geomagnetic storms (1-20h) as well as quiet-time diurnal variations (3-12h). We found that the correlation is good for short period (cc > 0.8 for T < 1 h), but poor for long periods (cc < 0.3 for T > 6 hours). Using the conventional induction theory based on the Faraday’s, Ampere’s and Ohm’s laws, we calculated the electric field (GIE) induced by By as a convolution of dBy/dt and step response of a uniform conductor. The GIE is found to be better correlated with the GIC for the long-period disturbances (cc > 0.9), whereas the correlation with By remains better for short period disturbances. This result requires us to use two models depending on the period of disturbances. To obtain a model applicable to any period, we made constructed a two-layer model with higher conductivity on the top. We show that the two-layer model is capable of reproducing the GIC with high correlations (cc > 0.9) for any period of disturbances ranging from 1 min to 10 hours. It should be noted; however, the capability of the model may depend on the direction of the power transmission line relative to the coast line and also depend on the structure of the Earth’s conductivity.

Fan-shaped aurora as seen from Japan during a great magnetic storm on 11 February 1958

*Ryuho Kataoka[1], Shiori Uchino[1], yasunori Fujiwara[1], Shigeru Fujita[1], Kazuaki Yamamoto[2]

1. National Institute of Polar Research, 2. National Institute of Japanese Literature

A fan-shaped aurora was photographed at Memambetsu, Hokkaido Japan during a great magnetic storm on Feb 11, 1958. This is the first and oldest photograph record of auroras as observed in Japan, and many hand-written drawings were also recorded at the same time during the February 1958 event, giving a rare opportunity of the coexistence of photograph images and hand-written drawings. In fact, the combination of photographs and drawings of the 1958 event reminds us of the great red aurora with fan-shaped white pillars as illustrated during other great magnetic storms in 1872 and in 1770. From the analysis of newly digitized microfilm data, it is also found that the fan-shaped aurora appeared during the peak activity of magnetic storm, and moved westward at 0.4 km/s at 400 km altitude at 38-40 deg magnetic latitudes, which is consistent with the enhanced convection pattern in middle latitude during storm time. Such a fan-shaped aurora can be a fundamental characteristic of middle-latitude evening-to-midnight auroras during great magnetic storms, which show the most destabilized transient appearance of the inner magnetosphere.

As space physics becomes both more interdisciplinary and more intertwined with commercial and government operations, there is a need for a framework to easily identify what projects can be used for specific applications and how close each project is to routine autonomous or on-demand implementation and operation. We have developed the Application Usability Level (AUL) framework and encourage publication of instrument-like papers for delivering and publicizing AULs to help the community quantify the progress of successful applications, metrics, and validation efforts.

In a given project within the AUL framework, there is typically a diverse eco-system of individuals necessary to ultimately produce a useful space weather product or productive research collaboration. For example, in the case of non-academic fields, users and researchers alike may benefit from a translator, i.e. a *broker*, who may help with the effective transition from research to operations. *Independent validators* are another essential player for validation efforts and comparing like products for a specified application. In many cases, the different players throughout the process will act in multiple roles as well as act in different roles for different projects and AUL pathways.

This paper we discuss the collaborative roles that lead from basic research to successful application within or outside the scientific community and provide examples of how this collaborative application ecosystem is maintained. We will also provide examples of space weather projects using the AUL framework, and show how it can contribute to the project's success. As always, a healthy eco-system can result in benefits for the end user and new exciting research opportunities.

This work has been completed as part of the activities of the Assessment of Understanding and Quantifying Progress working group which is part of the International Forum for Space Weather Capabilities Assessment.

The Operational Space Weather Forecast at NICT, Japan

*Kosuke Sakai[1], Kentaro Ukawa[1], Kentaro Kawahara[1], Mamoru Ishii[2], Yuki Kubo[2]

1. Systems Engineering Consultants Co., LTD., 2. National Institute of Information and Communications Technology

At the Space Weather Forecast Center of the National Institute of Information and Communications Technology, the latest 24-hour outlines and forecasts of space weather are provided to space weather users every day.
Delivers of space weather information have been continuously performed for over 50 years as ISES Regional Warning Center, Japan, and operators in the space weather forecast center are in charge of this task.
The operational work is conducted 7 days a week. Operators collect and analyze various observation data and simulation results provided from domestic and overseas collaborators, and summarize current space weather conditions before daily briefing at 14:30 JST.
In order to determine the next 24-hour forecast, operators organize a discussion meeting with specialists, and deliver forecasts before the due at 16 JST.
In addition, operators hold regular monthly meetings, consider the results of the forecasts, and feed back to improve next forecast accuracy.
When a remarkable space weather phenomenon occurs, operators has a responsibility to deliver alerts information immediately.
In this presentation, we introduce the daily work content of the space weather forecaster and the procedure up to deciding the content of the forecast with actual case examples.
In addition, we will also introduce contrivances and other measures to operate 365 days a year without breaks.

The Probability of Satellite Anomalies by a Disastrous Solar Flare

*Daikichi SEKI[1,2,3]

1. Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University, 2. Centre for the Study of Existential Risk, University of Cambridge, 3. Astronomical Observatory, Kyoto University

The Sun has a potential risk of various socioeconomic impacts on our human society. It often produces various eruptive phenomena such as a solar flare and a coronal mass ejection, which sometimes bring adverse effect to us like satellite anomalies, radiation exposure, and huge blackouts. Recently, it was revealed that a “super-flare”, a flare whose energy is 100 times larger than X10-class flare, can occur once in 1000 years from statistical and theoretical points of view [Maehara et al. 2012, Shibayama et al. 2013, Shibata et al. 2013].

However, though there are many assessment studies of “moderate” solar eruptive phenomena, the assessment of “disastrous” solar eruptive phenomena like a super-flare has been little conducted. For this reason, this research aims to evaluate the frequency (or probability) and the possible socioeconomic damage of a super-flare, especially focusing on satellite anomalies.

Using various data sets about satellites, their anomalies, flares, and plasma environment around the Earth*, 154 X-class flare events with 9 relating parameters (peak flux of X-ray (0.1–0.8 nm), integral fluxes of electron (> 2 MeV) and of proton (> 1, 5, 10, 30, 50, 60, 100 MeV)) were selected. To avoid multi-collinearity, Ridge regression model was used to compute the regression to the satellite anomaly rate (1/satellite/event). Also 10-fold cross validation was performed. After obtaining the model, the possible plasma parameters in case of X1000-class flare assumed by Takahashi et al. 2016 were input into the model.

As a result, we obtained the model with its coefficient of determination of 0.607 and its Pearson correlation coefficients of 0.691 ±0.212 (for 100 times randomly chosen dataset). Assuming that electron and proton with any energy follow the same scaling law, with applying scaling law by Takahashi et al. 2016, 0.573 satellite anomaly rate (57.3% per satellite per event) was obtained. It should be noted that the scaling law provided by Takahashi et al. 2016 is upper limit, so in the actual case, rate should be lower. The validity of assumption, the comparison between this research and others (Pilipenko et al. 2006; Iucci et al. 2005; Odenwald et al, 2006, 2007), and the possible socioeconomic loss will be also discussed.

Operational Forecasting of Solar Flares using Deep Neural Network

*Naoto Nishizuka[1], Yuki Kubo[1], Komei Sugiura[1], Mitsue Den[1], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology

Solar flares are the largest explosive phenomena in the Heliosphere. They affect the earth by X-ray and UV emissions, high energy particles, and magnetic storms, causing troubles of satellites and blackout in a large area. To reduce the risk of social impact caused by solar flares and space weather, it is very important to predict solar flares with high accuracy. In our institute NICT, we have predicted solar flares in the daily forecasting meeting by an empirical method. However, the amount of solar observation data is so huge that we cannot deal with all the data by hands.

Here we developed an operational system of solar flare prediction using a deep neural network (DNN), named Deep Flare Net (DeFN; Nishizuka et al. 2018 ApJ), and we started to run it in the operation. The model can predict probabilities of the maximum class of flares occurring in the following 24 hr. The training dataset is maded by 3x10^5 images during 2010-2015 taken by SDO, from which we detected active regions and calculated 79 features for each region attached with the flare occurrence labels (X, M, C). We used features in our previous work (Nishizuka et al. 2017) and added novel features for operational prediction: coronal hot brightening at 131 A (T=10^7 K) and the histories of X-ray and 131 A emissions 1 and 2 hr before an image. The prediction data in the near real-time is downloaded from JSOC server operated by Stanford University and NASA, and all the active regions and features are automatically detected and calculated. The prediction results will be shown in the web site of NICT. In this talk, we will introduce our DeFN model and operational forecasting system and would like to discuss how it works in the daily operations.

Spring-Autumnal asymmetry in geomagnetic activity and its origin over last 140 years

*Hao Luo[1], Xiaoming Sha[1]

1. IGGCAS

Spring-Autumnal asymmetry (SA asymmetry) from years 1873-2010 in the geomagnetic activity is investigated based on the geomagnetic indices (aa, Ap and Kp). Results have shown that in general the SA asymmetry of the geomagnetic activity appears to be alternation, except for the interval during which the change of dominant solar dipole magnetic field polarity occurs. Our study implies that both the polarity of the main solar dipole field and the north-south asymmetry of the sunspot area in the two solar hemispheres control the strength of the south component (*Bs*) of the interplanetary magnetic field (IMF) near the Earth and the resulting SA asymmetry of the geomagnetic activity in the corresponding seasons. A simple sector structure model is devised to establish the relationship between the polarity of solar main dipole magnetic field, the IMF *Bs* component and the corresponding SA asymmetry in the geomagnetic activity. This is confirmed by examining the solar wind parameters from the spacecraft observations during the recent decades.

Searching 18.6 year tidal modulation impact in a global gridded ocean oxygen dataset with its improvements

*Shoshiro Minobe[1]

1. Earth and Planetary Sciences, Faculty of Science, Hokkaido University

The 18.6 year modulation of tidal mixing plays important roles in the ocean as reported by regional analyses by Osafune and Yasuda (2006, 2010) and others. In those studies, they found that ocean water properties including dissolved oxygen concentration vary at the 18.6 year period in a manner consistent with the vertical mixing changes due to the tidal mixing modulation. Dissolved oxygen concentration is interesting not only as a tracer but also because it is important in marine ecosystems. In particular, superposition of 18.6 year variability in addition to the oxygen decline trend known as the ocean deoxygenation due to the global warming can cause more serious damages for marine animals in the specific phase of tidal modulation.

The present study aims to understand the impacts of 18.6 year tidal mixing modulation in the ocean oxygen field more systematically than the previous studies did by analyzing a global gridded dataset of dissolved oxygen concentration. A preliminary analysis using the dataset used by Ito et al. (2017 GRL) for upper 1,000 m indicates that the 18.6 year variation of oxygen concentration also occurs in regions where previous studies did not reported tidal modulation influence, including a region near the Izu-Ogasawa Ridge. In order to obtain the better spatial and temporal coverage, the dataset is and will be improved with two steps. One is to expand its vertical coverage to the top 1,000 m to 6,000 m, and the other is to use the latest version of the World Ocean Database released in September 2018. The first step has been completed, and the second step is planned to be completed in this summer. At the presentation, the analysis results based on the latest gridded dataset will be shown.

Contribution of tidal energy dissipation to variations of transient climate response and steric sea level rise through ocean heat uptake

*Michio Watanabe[1], Hiroaki Tatebe[1], Tatsuo Suzuki[1], Kaoru Tachiiri[1]

1. Japan Agency for Marine-Earth Science and Technology

Micro-scale turbulent mixing due to tide-induced internal wave breaking is a key process to determine the strength and pattern of the global ocean overturning circulation, that redistributes the heat all over the world ocean. Heat redistribution in the ocean have a strong impact on ocean heat uptake (OHU), thus transient climate response (TCR) and steric sea level rise (SLR) under the global warming. To study the impact of the vertical diffusivity distribution on the TCR and steric SLR, we ran a climate model of which value of CO_2 concentration is increased by 1% yr^{-1} for 150 years, employing each of two vertical diffusivity distributions in the ocean, an empirical one-dimensional one (CTRL) and a three-dimensional one considering tidal energy dissipation (TED). In TED under the pre-industrial forcing, the larger sea ice in the Southern Ocean prevents the air-sea heat flux, leading to weaker bottom water formation and lower air temperature than in CTRL. The less effective heat transport to the deep layers in TED causes less OHU and larger TCR than in CTRL by about 0.16˚C. In addition, smaller ocean heat content change in TED than in CTRL leads to significant future sea-level depression of ~0.4 m in the Southern Ocean. Since OHU under the global warming is controlled by the distribution of vertical diffusivity, it is necessary to clarify its global distribution in the real ocean for reliable TCR estimation and future SLR projection.

A Wave Resolving Simulation for Upper Ocean Turbulence Driven by Wave-Current Interaction

*Yutaka Yoshikawa[1], Yasushi Fujiwara[1], Yoshimasa Matsumura[2]

1. Graduate School of Science, Kyoto University, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Turbulence in the upper ocean sets bulk properties of the upper ocean. For example, turbulence deepens the surface mixed layer (ML) and entrains low-temperature water below the layer to determine the ML depth and sea surface temperature (SST), which are key parameters for large-scale ocean and climate processes. Quantitative evaluation and parameterization of the upper ocean turbulence thus have crucial importance on the large-scale studies.

Recent studies revealed that turbulence induced by the surface wave has larger impact on the ML deepening than ever considered. Good example is drastic deepening of the ML and significant decrease in SST simulated in the summer Southern Ocean if parameterized wave-induced mixing is included in the simulation (e.g., Li et al. 2016). Among three types of wave-induced turbulence, surface wave breaking, Langmuir turbulence (LT) and nonbreaking-wave induced turbulence (NBWT), the latter two are considered to have significant impacts on the ML deepening. LT is associated with Langmuir circulations (LCs), the secondary circulations driven by the surface waves interacted with the wind-driven currents (e.g., Leibovich 1980). Previous theoretical studies (Craik and Leibovich 1976) showed that the interaction can be represented solely by the vortex force, vortex tilting by the Stokes drift (the Lagrangian velocity due to the surface wave) in the wave-filtered momentum equation. Many simulations with this vortex force representation have been performed so far (e.g., Skyllingstad and Denbo 1995). However, this theoretically-derived representation has not been validated by field or numerical experiments. As a consequence, there are controversial discussions about the validity of the representation and hence the simulation results with the representaion (e.g., Mellor 2016 and Ardhuin et al. 2017). NBWT on the other hand is suggested to be caused without winds (e.g., Qiao et al. 2004; Babanin 2006), but no detailed mechanism was proposed for the turbulence generation. As a result, some people consider that NBWT is the same as LT, even though LT is dependent on winds while NBWT is not. Thus, mechanism of the wave-induced turbulence is not clearly understood.

The present study is intended to clarify dynamics involved in the wave-induced turbulence. To this aim, we developed a new numerical model in which surface waves are explicity and accurately simulated. This wave-resolving simulation provides an unique opportunity to investigate how the surface waves drive / induce turbulence. We used this model to simulate LC at first (Fujiwara et al. 2018). A wave-tank simulation was performed in which a monochromatic surface wave propagated in the surface wind direction. We found that LCs were successfully reproduced through the wave-current interaction (see attached figure). Vorticity analysis showed that the interaction is well represented by the vortex force. We also performed the simulation without the surface wind, and found that NBWT was certainly generated. The virtual wave stress was found to be a key for NBWT generation in our simulation, which induced velocity shear near the surface that interacted with the surface wave as was found in the LC simulation. The wave-resolving simulation also provided an alternative Eulerian view of the vortex force that was originally viewed from the Lagrangian frame (Stokes drift), that is, rectified vortex tilting/shrinking/streatching by orbital motions of the surface waves.

Revisiting the Characteristics of Mixing Efficiency in the Brazil Basin

*Takashi Ijichi[1], Louis St. Laurent[1], Kurt Polzin[1]

1. Woods Hole Oceanographic Institution

It is still controversial whether or not the dissipation flux coefficient Γ, often referred to as the “mixing efficiency”, is a global constant of 0.2. A primary justification for continuing to use this conventional value comes from a number of dedicated tracer-release/microstructure surveys done over the past three decades. Most notably, studies in the Brazil Basin have been the basis for examining the characteristics of mixing in the abyssal interior of the global ocean. Here, using recent microstructure data also collected in the Brazil Basin, we revisit the characteristics of Γ in the abyssal interior. It is shown that Γ, estimated from averaged profiles of the TKE dissipation rate and the thermal variance dissipation rate, actually lies around 0.2 in the pycnocline, but on the other hand, it tends to increase up to 0.4-0.8 toward the bottom. Such near-bottom high efficiency appears to be associated with weak stratification in the bottom water. Furthermore, one microstructure profile appears to reach down to within the thin bottom boundary layer: Γ abruptly decreases to $O(10^{-2})$ within 50 m above the bottom, which is reasonable given the no buoyancy flux condition at the bottom. We will also examine these results using the earlier generation microstructure datasets collected in the Brazil Basin.

Instabilities of finite-amplitude internal wave beams

*Yohei Onuki[1], Yuki Tanaka[2]

1. Research Institute for Applied Mechanics, Kyushu University, 2. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Previous studies have shown that instability of small-amplitude internal wave beams, generated by a surface tide flowing over topography, is most significant at a particular latitude where parametric subharmonic instability (PSI) excites inertial oscillations. Here we extend the discussion to the case of finite-amplitude beams using a new kind of Floquet approach. The disturbance growth rate obtained is quantified in terms of two non-dimensional parameters A and F: velocity shear divided by the buoyancy frequency and the Coriolis parameter divided by the beam frequency. If A is small, PSI is indeed the principle mode under the condition $F < 0.5$ with the maximum growth rate achieved when the equality holds. As A is increased, however, instability comes to occur even for $F > 0.5$ but the location of the maximum instability shifts towards lower F, thus totally changing its latitudinal dependence. The resulting energy spectrum is significantly Doppler shifted, and therefore distinguished from that made by PSI. These findings are useful to quantify the energy loss of internal wave beams that causes water mixing prevailing in the major generation sites of internal tides.

Evaluation of nutrient flux enhanced by double diffusion in the Kuroshio using glider measurements

*Keunjong Lee[1], Ryo Yamamoto[1], Ichiro Yasuda[1], Takahiro Tanaka[2]

1. Atmosphere and Ocean Research Institute, 2. Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency

Kuroshio is a very strong current, western boundary current of North Pacific subtropical current system. Strong vertical mixing intensifies through various physical processes were reported in the vicinity of the Kuroshio system. Consequently, this enhanced mixing is considered to supply the nutrients from the lower layer to the euphotic layer and improve the biological productivity.

Extensive measurements were carried out to investigate the detailed structures of turbulence, hydrography, chlorophyll-a using a glider, SeaExplorer manufactured by Alseamar whose 1st science mission, equipped with two shear probes, fast response thermistor, CTD, dissolved oxygen sensor, fluorometer. The fine measurement of 66 casts lasted for 7 days during 20-27, June 2017. Although only 30 % of data acquired by shear probe were survived under the criterion following Peterson et al., (2014), a newly developed method estimating turbulent intensity using a FP07 sensor was introduced.

While, calculated vertical nutrient flux is not quite high supporting biological productivity as we expected. Contribution of double diffusion which intensify the vertical diffusivity could be considered as development of chlorophyll-a patch at subsurface. Previous research already introduced the possibility of enhanced mixing from double diffusion (Nagai et al., 2015, Inoue et al., 2007) and Hamilton et al., (1989) showed underestimation of vertical nutrient flux without using vertical eddy diffusivity for salt in case of salt finger. Interacted with low salinity water which was occurred during our mission show another evidence for supporting this hypothesis.

Following the parameterization of McDougall and Ruddick (1992), mixing efficiency for salt finger and enhancement of salt(nutrient) flux were estimated to be somewhat effective. Parameterized nutrient flux in salt finger favorable layer is 37% larger than the turbulent nutrient flux accepting mixing efficiency 0.2 proposed by Osborn et al., (1980). This value needs to be examined through statistical approach or more careful insight and will be discussed later.
The full path of glider shows Kuroshio interact with various waters with different salinity and temperature. For example, low salinity and low temperature water intruded at subsurface during 23-24, June. Around 600 m during 26-27, June we also found salinity minimum which was assumed with North Pacific Intermediate Water. This feature reminds us considerable nutrient flux with vertical mixing by double diffusive processes in addition to mechanical turbulence. Double diffusive process might be attributed to the intrusion, development, modification of relatively low salinity waters. We found double diffusive regime occurs especially at upper boundary of relatively low salinity layer.

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University), Chairperson:Shin-Ichi Ito(The University of Tokyo)

The ocean accounts for about 50% of global net primary production. This production is significant for carbon cycling and ecosystem functioning, and is related directly or indirectly to a variety of climatic and ecological phenomena. The responses to natural and anthropogenic environmental stressors that influence marine production and diversity can cause perturbations to marine ecosystems that alter trophic dependencies and interactions among organisms at a range of space and time scales. Quantification of the principal mechanisms driving spatio-temporal variability of marine ecosystem remains to be done, especially in terms of evaluation of uncertainty in responses. As a result, evaluating vulnerability of marine ecosystems to environmental change requires systematic and holistic approaches that integrate physics to ecology and are based in observations and modelling. In addition, expectations to deliver these science to public society is raising. This session aims to provide a venue for not only discussing recent advances in understanding marine biogeochemical cycles, ecosystems and their interactions, but also networking with a variety of people to seed new ideas in marine ecological research. Observational, modeling and conceptual studies, including technological development and operational applications, that consider linkages among biogeochemical and ecosystem processes, biodiversity, and the effects of multiple stressors from molecular to planetary scales are encouraged.

Projected coastal hypoxia in a coupled bio-physical model of the California Current System.

*Enrique N Curchitser[1], Raphael Dussin[1,2], Charles Stock[3], Nicoals van Oostende[4]

1. Rutgers University New Brunswick, 2. Lamont-Doherty Earth Observatory of Columbia University, 3. NOAA Geophysical Fluid Dynamics Laboratory, 4. Princeton University

Recent observations have shown an increase of the hypoxic area on the shelf in the California upwelling system. Climate projections suggest this increase would continue over the 21st century. However, the low-resolution ocean component of today’ s climate models in this region are hampered by the flawed representation of upwelling and coastal processes.To achieve a more realistic solution, we ported the NOAA-GFDL biogeochemical model COBALT into the regional ocean model ROMS permitting a seamless representation of the biogeochemistry across scales. With the 7km California Current implementation, we carry out sensitivity experiments for the projected changes in biogeochemical and physical drivers of coastal hypoxia : oxygen and nutrients in source waters, solubility and upwelling-favorable wind. We describe here the results obtained and assess the relative impact of drivers of coastal hypoxia in this system.

Decadal salinity variation in the western North Pacific correlated with the strength of the Oyashio and the Kuroshio Extension

*Hitoshi Kaneko[1], Takeshi Okunishi[2], Shinya Kouketsu[3], Sachihiko Itoh[1], Takashi Seto[4], Hiroshi Kuroda[5], Yugo Shimizu[4]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 3. Japan Agency for Marine-Earth Science and Technology, 4. National Research Institute of Fisheries Science, Japan Fisheries Research and Education Agency, 5. Hokkaido National Fisheries Research Institute, Japan Fisheries Research and Education Agency

Decadal changes in salinity around the density (~1026.8 kg m^{-3}) of North Pacific Intermediate Water (NPIW) were investigated in the regions from the Oyashio to the Kuroshio Extension (KE), called as the Mixed Water Region (MWR), based on the long-term-data-sets provided from numerical reanalysis. Based on the reanalysis data provided by an ocean forecast system of the Japan Fisheries Research and Education Agency (FRA-ROMS; 1992–2012, horizontal resolutions of 0.1˚), we found that during increase of the Oyashio velocity in the upstream region, negative salinity anomaly accompanied with the southward velocity at the density was enhanced between 144–145˚E just south of 40˚N. In addition, to examine influences from the downstream region of the Oyashio, we made a lag-correlation analysis focusing on the decadal variation of KE stability calculated from the zonal average (142–165˚E) of the meridional gradient of the sea surface height (34.5–37.0˚E) as the KE strength (KES). The result showed that signals of significant negative correlation appeared around the density from Hokkaido to the north region of KE. Through the composite analysis based on the KE stability, we found that the stable KE could also lead similar anomaly distribution around the north region of KE. We examined relationships between decadal tendency and each component of salinity fluxes at the density along the north-south boundary of the region of 38–40˚N, and 142–145˚E. Concerning estimation of the salinity fluxes, we employed time-mean components (S, V) and eddy components (s', v'), and then, we calculated products of them (Sv', $s'V$, $s'v'$). Decadal tendency of salinity (ds'/dt) was negatively correlated with the meridional difference of Sv' ($-0.5 < r < -0.47$, 95% confidence interval). Whereas Sv' at northern boundary was also negatively correlated with ds'/dt ($-0.45 < r < -0.42$), the correlation between ds'/dt and Sv' at southern boundary was small ($0.03 < r < 0.07$). The result suggested that the southward Oyashio would play an important role for decadal salinity variation in the MWR.

Multiscale routes to supply nutrients through the Kuroshio nutrient stream

*Takeyoshi Nagai[1], Sophie Clayton[2], Yusuke Uchiyama[3]

1. Department of Ocean Sciences, Tokyo University of Marine Science and Technology, 2. Ocean, Earth & Atmospheric Sciences, Old Dominion University, 3. Kobe University

In this study, the role of the Kuroshio as a nutrient conduit is discussed using results from eddy-resolving, and nested high-resolution numerical simulations using Regional Oceanic Modeling System (ROMS) coupled with a N^2PZD^2 ecosystem model, and results from recent in-situ observations. The eddy-resolving simulation can reproduce the elevated nutrient concentrations along the Kuroshio compared to those in ambient waters of the same density, similar to the Gulf Stream. The nested simulations show that nutrients in the upstream Kuroshio can be supplied to euphotic zone by strong diapycnal mixing associated with the Kuroshio over topography. This large nutrient input is consistent with the very strong turbulent mixing observed directory in the upstream Kuroshio regions, where the Kuroshio flows over the seamounts and on the continental slope. The autonomous microstructure float observations also suggest that the large turbulent nitrate diffusive flux occurs in the Izu Ridge, along the Kuroshio. These diapycnal processes may explain why the basin scale nutrient elevation on the density surface along the Kuroshio path is maintained. During winter-spring, in the model downstream Kuroshio Extension, a large nitrate induction of O(10 mmol N m^2day^{-1}), comparable to or greater than wintertime diffusive nitrate flux, occurs through the inclined mixed layer base, which is strongly influenced by the mesoscale structures.

Seasonal variability of upper-ocean primary production around the Kuroshio analyzed using a ROMS-NPZD model

*Xu Zhang[1], Yusuke Uchiyama[1,2], Yota Suzue[3], Hidekatsu Yamazaki[4]

1. Kobe University, 2. Port and Airport Research Institute, 3. Construction Technique Institute Engineering Co., Ltd., 4. Tokyo University of Marine Science and Technology

Biological processes have significant influences on the global carbon cycle on all time scales. In the coastal regions, nutrient supply to the surface by river discharge and coastal upwelling leads to active primary production. The Kuroshio, one of the strongest western boundary currents, flows off the Japan, accompanied by intense eddy activities influencing on biogeochemical processes around its path. In general, localized upwelling due to mesoscale cyclonic eddies brings nutrient-rich subsurface water to the nutrient-depleted upper ocean to enhance near-surface primary productivity. In the present study, a climatological ocean modeling is developed for the marginal seas along the Kuroshio off Japan based on ROMS (Shchepetkin and McWilliams, 2005; 2008) coupled with an NPZD biogeochemical model (Fasham *et al.*, 1990; Gruber *et al.*, 2006). The model domain encompasses both the Kuroshio and its Extension regions in a submesoscale eddy-permitting configuration with a horizontal grid spacing of 3 km. The simulation is conducted for 10 years and the results for the 10th year are used for our analysis. A nitrogen budget analysis indicates that nitrogen exists mostly in the phyto- and zooplankton compartments in both the Kuroshio and Kuroshio Extension regions during the spring bloom. The increased zooplankton further enriches detritus that settles down by about 100 m, leading to an increase of ammonium below the mixed layer. In winter, eddy-induced nitrate transport is enhanced in the region about 1˚ away from the Kuroshio axis. The baroclinic instability due to the surface cooling in winter generates meso- and submesoscale eddies and substantially promotes eddy-induced vertical nitrate transport.

Nutrient and light conditions at subsurface chlorophyll maximum: physical-biogeochemical observations along a mid-Pacific meridional transect

*Sachihiko Itoh[1], Hitoshi Kaneko[1], Shinya Kouketsu[2], Takeshi Okunishi[3], Hiroshi Ogawa[1], Mitsuhide Sato[4], Hiroaki Saito[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Japan Agency for Marin-Earth Science and Technology, 3. Tohoku National Fisheries Research Institute, Fisheries Research Agency, 4. The Hong Kong University of Science and Technology

Subsurface chlorophyll maximum (SCM) occurs in a stratified water column that nutrient is depleted in the surface layer. When fully developed, such as those in calm subtropical regions, SCMs were often observed at depth where both nutrient and light availabilities are at a marginal level. Following resource competition theory, the low resource condition is likely generated by a group of phytoplankton with a low resource requirement, which expels other groups through decreasing nutrients and/or deepening the nutricline. Numerical models formulating the phytoplankton dependency on nutrients and light can reproduce some of characteristics of SCM including seasonal and geographical variability. However, comprehensive observations of the SCM and environmental conditions are still limited especially in the open ocean. In the present study, shipboard physical and biogeochemical observations were conducted along 170˚W from the South Pacific Subtropical Front up to Bering Sea during Boreal and Austral summers.

Characteristics of SCMs were estimated from multiple vertical profiles of chlorophyll fluorescence attached to a Conductivity Temperature Depth profiler (CTD), and nutrient concentrations were determined from water samples. Depths of profiles by sensors and water sample data were determined through projections onto potential density coordinate to eliminate effects of internal wave heaving, which are critical in analyzing processes around SCMs. To evaluate diffusive nutrient flux, vertical diffusivity was calculated using a microstructure profiler and multiplied by vertical gradient of nutrient concentrations. Vertical profiles of photosynthetically available radiation (PAR) were estimated using surface PAR from Moderate Resolution Imaging Spectroradiometer (MODIS), averaged over two weeks until shipboard observation, and diffuse attenuation coefficients of downwelling irradiance calculated from *in situ* PAR measurements.

In subtropical regions from 40˚S to 30˚N, except for that at the equator, SCMs were found in 80–150 m, around or slightly deeper than 1% light level relative to the surface. Depth of SCM was deepest in the middle of subtropical gyres, no shallower than 100 m in 15–25˚. Although considerably shallower than subtropical regions, SCMs were also observed at the equator and temperate and subpolar regions in the range of 15–40 m. There are significant positive correlations between the depths of SCM and 1% light level, where SCM depth was generally deeper than the 1% light level in the subtropical regions. However, PAR at SCMs was not uniform but ranged from 0.1–0.7 mol photon m^{-2} day^{-1} within the subtropical regions, and shows a negative correlation with the SCM depth. The SCM depth also shows a strong positive correlation with the depth of maximum subsurface nitrate flux. Considering effects of pure external factors that are not affected by phytoplankton to the SCM depth, we found a positive relationship with absolute dynamic topography indicating the depth of pycnocline.

©2019. Japan Geoscience Union. All Right Reserved.

Although 1% light levels can indicate the SCM depth through the linear correlation for the wide geographical range in the mid-Pacific, it is not concluded that SCM was formed under the limitation of light alone. This is followed by a fact that PAR at the 1% levels is not uniform but depends on the surface PAR, by which the relationship between PAR values at SCMs and depths of SCMs become insignificant. As deep penetration of light is caused by the low productivity in the surface water, we cannot simply consider cause and effect for the above relationship. On the other hand, as the dynamic topography is not affected by phytoplankton, its relationship between the SCM depth suggests that the large-scale hydrographic structure has some influences on the formation of SCMs. In the presentation, we will further discuss the details of the physical processes and their possible impacts on subsurface phytoplankton production.

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University), Chairperson:Yoshimasa Matsumura(Atmosphere and Ocean Research Institute, The University of Tokyo)

The ocean accounts for about 50% of global net primary production. This production is significant for carbon cycling and ecosystem functioning, and is related directly or indirectly to a variety of climatic and ecological phenomena. The responses to natural and anthropogenic environmental stressors that influence marine production and diversity can cause perturbations to marine ecosystems that alter trophic dependencies and interactions among organisms at a range of space and time scales. Quantification of the principal mechanisms driving spatio-temporal variability of marine ecosystem remains to be done, especially in terms of evaluation of uncertainty in responses. As a result, evaluating vulnerability of marine ecosystems to environmental change requires systematic and holistic approaches that integrate physics to ecology and are based in observations and modelling. In addition, expectations to deliver these science to public society is raising. This session aims to provide a venue for not only discussing recent advances in understanding marine biogeochemical cycles, ecosystems and their interactions, but also networking with a variety of people to seed new ideas in marine ecological research. Observational, modeling and conceptual studies, including technological development and operational applications, that consider linkages among biogeochemical and ecosystem processes, biodiversity, and the effects of multiple stressors from molecular to planetary scales are encouraged.

Discussion

A Lagrangian view of spring phytoplankton blooms

*Shinichiro Kida[1], Taka Ito[2]

1. Research Institute for Applied Mechanics, Kyushu University, 2. Georgia Institute of Technology

The basic mechanism behind spring phytoplankton blooms is investigated using a 1-dimensional Lagrangian NPZD model, where the movement and transfers of nutrient parcels are solved by tracking a nitrogen parcel. The Lagrangian framework is useful for understanding how the nitrogen cycle works in the ocean since it naturally follows the movement of materials through the turbulent ocean environment. The model reveals that the onset of spring blooms depends on the cumulative euphotic age, which is the total time that inorganic nutrient is exposed to light before the photosynthetic conversion to phytoplankton biomass. This is regardless of the underlying mechanism, such as critical depth hypothesis or critical turbulence hypothesis. The difference between the two modes lies in how cumulative euphotic age is accumulated and this can be distinguished by examining the cumulative euphotic age spectrum. We further examined the impact of mortality by comparing the model experiments with and without mortality. The cumulative euphotic age necessary for a spring bloom is found to increase, as expected, but the spectral shapes remained similar.

Significance of acclimation process in simulating chlorophyll distribution in the Arctic Ocean

*Yoshio Masuda[1], Yasuhiro Yamanaka[1], Takafumi Hirata[1], Hideyuki Nakano[2]

1. Graduate School of Environmental Earth Science, Hokkaido University, 2. Meteorological Research Institute

Recently, our team has developed a new oceanic ecosystem model (FlexPFT-3D) based on a novel theory for phytoplankton physiology (Smith et al. 2015). Different from our previous models (NEMURO, MEM), the model represents phytoplankton acclimation processes in which phytoplankton change their stoichiometry (nitrogen:carbon:chlorophyll:iron) according to the change of a surrounding environment. A clear improvement was found in chlorophyll distributions in oceanic interior and the Arctic Ocean. Arctic chlorophyll concentration in the new model is comparable to the observation, while it is underestimated in the previous models. In the Arctic Ocean, significant seasonal environmental change exists especially in a light condition. The new model can represent increase in the rate of chlorophyll to carbon biomass in the summer and resulting increase in the phytoplankton specific growth rate; those contribute to the improvement in simulating Arctic chlorophyll concentration.

Responses of lower-trophic level ecosystem to nutrient variation in the central part of the Seto Inland Sea

*Naoki Yoshie[1], Hayato Mizuguchi[1], Xinyu Guo[1], Michio Yoneda[2], Katsuyuki Abo[2], Tomoaki Kono[2], Tatsunori Fujita[3]

1. Center for Marine Environmental Studies, Ehime University, 2. Japan Fisheries Research and Education Agency, 3. Kagawa Prefectural Fisheries Research Center

The Seto Inland Sea is a representative coastal sea in Japan, and various environmental problems such as harmful algae bloom and hypoxia associated with the eutrophication have occurred during 50 years. The nutrient supplies from the terrestrial region related to the human activity have been reduced through the efforts for environmental cleanup over the last several decades. As a result of such excessive environmental cleanup, oligotrophic condition frequently occurred in this region in recent years. The relationships among oligotrophication, primary productivity, and fishery resources such as anchovy in this region are not clear. In this study, we investigated the responses of the lower-trophic level ecosystem in the central Seto Inland Sea to the nutrient variations using a plankton functional types model eNEMURO (4N-4P-4Z-3D). We used two different nutrient conditions for the model based on the time series observations, one was in 2005 with the good catch of anchovy larvae, and another was in 2011 with the poor catch of them. The model results showed that the spring diatom bloom in 2011 was much lower than those in 2005 due to the low nutrient concentrations in the spring of 2011. The meso-zooplankton biomass in the spring of 2011 was also lower than those in 2005 associated with the reduced spring diatom bloom in 2011. We summarized that the interannual variation of nutrient concentrations in the spring may control the interannual variation of anchovy stocks by regulating the scale of the spring diatom bloom in this region.

Effects of the temperature and fish size on metabolism and swimming performance of Pacific chub mackerel *Scomber japonicus* in the Northwest Pacific

*Chenying Guo[1], Shin-ichi Ito[1], Michio Yoneda[2], Hajime Kitano[2]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Fisheries Research and Education Agency Japan

Pacific chub mackerel (*Scomber japonicus*) is a small pelagic and important commercial fish species widely distributed throughout the coastal areas of the Northwestern, Northeastern, and Southeastern Pacific. Swimming energetic and metabolic data of Northwestern stock at two growth stage (young juvenile of 6.1±0.3 cm and immature of 16.5±1.4 cm fork length) were measured under various temperature (18˚C and 24˚C for young juvenile, 14˚C and 18˚C for immature) using a variable-speed swim-tunnel respirometer, and the new data were compared with the previous data from Northeastern Pacific stocks. For young juveniles, the maximum sustainable swimming speeds (U_{max}) was 50.0±6.5 cm s^{-1} at 24˚C, significantly higher than at 18˚C of 30.7±2.5 cm s^{-1}. For the immature individuals, U_{max} showed no significant increase while temperature changed from 14 to 18˚C, and did not vary significantly from Northeastern Pacific individuals within the same size range. At a given temperature of 18˚C, U_{max} of immatures was significantly higher than those of young juveniles. For all individuals, the mass-specific oxygen consumption rate (V_{O2}) increased exponentially with swimming speed (U, in cm s^{-1}). At a given speed, V_{O2} increased with temperature; at a given temperature of 18˚C, V_{O2} of immature individuals were lower than those of young juveniles. These effects of the temperature and fish size on V_{O2} were consistent with previous studies of chub mackerel of Northeastern stocks, however, compared with Northeastern stocks within the same size range, V_{O2} of Northwestern individuals acclimated to 14˚C did not vary at a given speed, while those acclimated to 18˚C showed higher V_{O2} , indicating the Northwestern stock was more sensitive for temperature on metabolism.

Sensitivity analyses of growth and migration of Japanese anchovy (*Engraulis japonicus*) in the East China Sea using a fish growth-migration model.

*Shin-ichi Ito[1], Takashi Setou[2], Michio Yoneda[2], Motomitsu Takahashi[2], Michiya Matsuyama[3], Chenying Guo[1], Takashi Kitagawa[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Fisheries Research and Education Agency Japan, 3. Kyushu University

Japanese anchovy (Engraulis japonicus) is an important species not only as an exploited species but also as prey for variety of predators including marine mammals, tunas, mackerels, flounders, etc. However, the biomass of Japanese anchovy have shown large fluctuation and is one of the main actors of the fish species alternation responding to basin scale climate variabilities. From the stock management views, three sub-populations are defined in Japan: Pacific stock, Tsushima stock (also called the East China Sea stock), and Seto-inland Sea stock. There is evidence (different weights-at-age and longevity) of three sub-populations of anchovy within the Japan system. While he three sub-populations of anchovy share their spawning grounds, the migration route and nursery grounds are divided. In addition, while Seto-inland Sea sub-populations do not show a large migration, Pacific and Tsushima sub-populations make long distance ontogenetic migrations, On the contrary, there is no evidence of a similar migration of juvenile anchovies in the California Current system. Therefore, we are focusing on the movement (advection and migration) routes of eggs, larvae, and juveniles from the spawning grounds to the adult grounds. We developed a fish-migration and growth model using environmental conditions derived from simulations of a coupled ocean circulation and ecosystem model. For the ocean circulation model, a high resolution (1/10 deg.) FRA-ROMS (Fisheries Research Agency - Regional Ocean Modeling System) was used. For the marine ecosystem model, eNEMURO, an extended version of NEMURO (North Pacific Ecosystem Model for Understanding Regional Oceanography) was used. The larvae transported to southern part of Kyushu Island in Japan (current main fisheries ground for anchovy larvae) were reasonably reproduced in the model. The sensitivity analyses of swimming efficiency will be conducted respect to the migration route of anchovy.

Discussion

Micro-scale patchiness enhances trophic transfer efficiency and potential plankton biodiversity

Recent observations have revealed ubiquitous intermittency in phytoplankton distributions at the micro (mm) scale, and a few recent modelling studies have suggested that this micro-scale variability impacts plankton ecosystem dynamics and biodiversity. Modelling is an essential tool for studying complex food webs, by linking the observed ecological patterns with experimental findings to understand mechanisms and make future predictions. However, so far almost all ecosystem models have been developed based on the mean-field approach, i.e. assuming well mixed environmental conditions within each discretely resolved grid cell. Although this is reasonable for examining patterns at the meso- (km) to global scales, it is not realistic for plankton, which experience micro-scale variability in aquatic environments where predator-prey overlap can substantially enhance trophic transfer. Similar to a recent study that addressed variability at the scale of ocean fronts, we have recently used Reynolds decomposition and truncated Taylor series to develop ‘moment closure’ models accounting for micro-scale variability in the distributions of Nutrients and Phytoplankton (NP closure model), and also Zooplankton (NPZ closure model). Compared to conventional ecosystem models based on the mean-field approach, these closure models yield qualitatively different dynamics.

Using a generalized plankton ecosystem modelling framework, including models of differing trophic complexity and with different grazing functional responses, we investigate how micro-scale variability affects plankton biodiversity and ecosystem function. Specifically, we apply the closure modelling approach to test the functional forms often assumed in ecosystem models against observed micro-scale intermittency as quantified by the coefficient of variation (CV) (ratio of standard deviation to mean) of micro-scale fluorescence field, which is a proxy for phytoplankton biomass. With both saturating and non-saturating grazing functions and in all model configurations considered, we find that micro-scale variability consistently supports the highest trophic level present, i.e. enhances Tansfer Efficiency, and expands the model stability domain, potentially sustaining biodiversity by allowing species with a wider range of trait values to coexist. Based on our observations and model results we hypothesise a novel answer to the “paradox of the plankton” (Hutchinson, 1961) for such calm, low-nutrient oceanic environments: Heretofore under-appreciated high levels of micro-scale variability may explain the great diversity of plankton present in these vast low-nutrient regions of the ocean.

Long term observations of marine snow, using cabled observatory system

*Marika Takeuchi[1,2], Mark Doubell[3], Jim Mitchell[2], Hidekatsu Yamazaki[1]

1. Tokyo University of Marine Science and Technology, 2. Flinders University, 3. South Australia Research and Development Institute

Marine aggregates are formed through coagulation of small biogenic and non-biogenic components. Visible ones, known as marine snow, are typically larger than 0.5mm. Aggregates are well recognised as hotspots of microbial and planktonic activities. Aggregates formation is an important pathway for transferring organic matter from surface to deep ocean, hence the impatcs of aggregates in carbon flux is significant. However, field observations of aggregates have been challenging and not many long-term observational results have been reported.
In this study, we analysed in-situ observations of aggregates using a high-resolution plankton camera mounted on cabled observatory OCEANS. OCEANS has been continuously collecting hydrographic data and images of aggregates simultaneously since 2014. Here we will present a few months of in-situ observations results to show aggregates size and population change over time. Turbulence and other plankton distributions are compared to aggregates.

An insight into the area characteristic of seasonal change in nitrogen isotope ratio based on a marine nitrogen isotope model

*Chisato Yoshikawa[1], Masahito Shigemitsu[1], Akitomo Yamamoto[1], Akira Oka[2], Naohiko Ohkouchi[1]

1. JAMSTEC, 2. AORI

The condition of nitrogenous nutrient in the surface water is an important factor that determines the primary production and the carbon cycle in the ocean. Nitrogen isotope ratios ($\delta^{15}N$) of nitrate, sinking particles, sediments have been widely used as a proxy for the condition of nitrogenous nutrient in the surface water. However, the interpretation of $\delta^{15}N$ values are not simple. The $\delta^{15}N$ value of surface primary producer records $\delta^{15}N$ value of nitrate supplied to the euphotic layer, nitrate utilization efficiency and rate of N_2 fixation. As there are multiple possibilities for the interpretation, $\delta^{15}N$ values should be interpreted with ample consideration of the characteristics of surface nitrogen cycle by region. In this study we show the area characteristic of seasonal change in $\delta^{15}N$ value by using a global ocean nitrogen isotope model in order to improve the interpretation of observed $\delta^{15}N$ values. We installed a marine nitrogen isotope model (Yoshikawa et al., 2005) with denitrification (Shigemitsu et al., 2016) and N_2 fixation (Coles et al., 2007) schemes into an off-line biogeochemical model that is driven by climatological monthly mean physical fields obtained from the outputs of a preindustrial control simulation performed with MIROC 3.2 (K-1 Model Developers, 2004). The simulated $\delta^{15}N$ of sinking particles had a global distribution similar to the observed $\delta^{15}N$ of surface sediments (Tesdal et al., 2013). The simulated sinking particles were enriched in ^{15}N in the eastern and western tropical North Pacific and the Indian Ocean where water column denitrification occurs and were depleted in ^{15}N in the Sargasso Sea, the Kuroshio extension region, and the Indian Ocean where N_2 fixation occurs. The seasonal variations in $\delta^{15}N$ of sinking particles vary considerably from one region to another. In this talk, we will report the seasonal $\delta^{15}N$ patterns categorized by region and the factors in the determination of those seasonal patterns.

Modeling variability of ^{15}N stable isotope enrichment within the planktonic food chain

*S. Lan Smith[1], Yoshikazu Sasai[1], Chisato Yoshikawa[2]

1. Marine Ecosystem Dynamics Research Group, RCGC, Japan Agency for Marine-Earth Science and Technology, Yokohama, Japan, 2. Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology, Yokosuka, Japan

The stable isotope ^{15}N is widely used an indicator of trophic level, and has been incorporated into ecosystem models in order to understand nitrogen cycling and trophic transfer. However, such studies typically consider only the average enrichment per trophic level. We present a recently developed model of the dynamic fractionation of the stable isotope ^{15}N in lower-trophic ecosystems of the North Pacific. The model accounts for the dynamics of trophic transfer from nutrients (nitrate and ammonium) to phytoplankton, and to two idealized zooplankton compartments representing herbivores and carnivores, respectively. The $d^{15}N$ signal of herbivores tracks that of phytoplankton, with a nearly constant offset, i.e., enrichment by a nearly constant factor. However, the modeled $d^{15}N$ difference between carnivores and herbivores varies seasonally, and depends on the mortality rate (turnover time or effective lifespan) of the carnivores. Seasonal variations of modeled $d^{15}N$ signals differ with trophic level because carnivores integrate the signal from their ^{15}N uptake over longer timescales compared to herbivores. Thus, the model reproduces the lower observed variability of $d^{15}N$ for carnivorous zooplankton (chaetognaths) and the more variable $d^{15}N$ for largely herbivorous zooplankton (copepods). Our results imply that for interpreting observed $d^{15}N$ values, it is important to consider not only the average enrichment per trophic level, but also the dynamics of ^{15}N fractionation and the timing of observations, e.g. to avoid unrealistic estimates of trophic linkages based on seasonally biased observations.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

Mon. May 27, 2019 3:30 PM - 5:00 PM JST | Mon. May 27, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University)

The ocean accounts for about 50% of global net primary production. This production is significant for carbon cycling and ecosystem functioning, and is related directly or indirectly to a variety of climatic and ecological phenomena. The responses to natural and anthropogenic environmental stressors that influence marine production and diversity can cause perturbations to marine ecosystems that alter trophic dependencies and interactions among organisms at a range of space and time scales. Quantification of the principal mechanisms driving spatio-temporal variability of marine ecosystem remains to be done, especially in terms of evaluation of uncertainty in responses. As a result, evaluating vulnerability of marine ecosystems to environmental change requires systematic and holistic approaches that integrate physics to ecology and are based in observations and modelling. In addition, expectations to deliver these science to public society is raising. This session aims to provide a venue for not only discussing recent advances in understanding marine biogeochemical cycles, ecosystems and their interactions, but also networking with a variety of people to seed new ideas in marine ecological research. Observational, modeling and conceptual studies, including technological development and operational applications, that consider linkages among biogeochemical and ecosystem processes, biodiversity, and the effects of multiple stressors from molecular to planetary scales are encouraged.

Impact of the nutrient transport through the Tsushima Strait on the ecosystem in the Japan Sea

*Ryota Shibano[1], Akihiko Morimoto[1], Katsumi Takayama[2], Tetsutaro Takikawa[3], Masashi Ito[4]

1. Center for Marine Environmental Studies, Ehime University, 2. Research Institute for Applied Mechanics, Kyushu University, 3. Graduate School of Fisheries and Environmental Sciences, Nagasaki University, 4. Fisheries Oceanography Department, Japan Sea National Fisheries Research Institute

The Japan Sea is a semi-closed sea with narrow and shallow straits such as the Tsushima/Korea Strait. The nutrient transports through the Tsushima Strait have an impact the ecosystem around the coast of Japan. The nutrient transports are originated in the sources from the sea, Kuroshio (Pacific), Taiwan Strait, and Yellow Sea, and the sources from the land, Changjiang river, Yellow river, and dusts. We investigated the ship cruise data in the strait from 2005 to 2017 to reveal the interannual variations in the volume transport, nutrient concentration, and nutrient transport. The nutrient transport in the strait has large interannual variations of ±50% compared to the average transport.

The recently studies indicated the contribution ratio in the nutrient transports on the sources from the Kuroshio and the rivers also change, when the yearly nutrient transport changes (e.g. Morimoto et al., 2012).

We developed a coupled ocean circulation and ecosystem model, in which the lateral boundary condition is applied based on observation data, and investigated the biogeochemical responses in the Japan Sea and the East China Sea to the interannual variations in the nutrient flux through the Tsushima Strait. We discussed about the contribution ratio in the nutrient flux on the 6 sources from Kuroshio, Taiwan Strait, Changjiang river, Yellow river, the dust, and the bottom (Yellow Sea).

Revisiting vertical variations in stoichiometry during oceanic organic matter decomposition

*Masahito Shigemitsu[1], Michio Aoyama[1], Toshimasa Doi[1], Taichi Yokokawa[1], Akihiko Murata[1]

1. Japan Agency for Marine-Earth Science and Technology

Using the new global nutrient data set, we re-evaluate basin-wide stoichiometric ratios of remineralization estimated by Anderson and Sarmiento (1994) (hereinafter, AS94). For the same latitudinal ranges of the Atlantic, Indian and Pacific Oceans as in AS94, we construct one or two end-member mixing models on 14 neutral surfaces and estimate the stoichiometric ratios with a probabilistic approach. Unlike the results of AS94, significant vertical variations in the stoichiometry are found in the Atlantic and Pacific, while relatively constant stoichiometry with depth is found in the Indian Ocean, similar to AS94. The decreases in the C/P and $-O_2$/P ratios with depth in the Atlantic could be caused via dark DIC fixation by chemoautotrophs in the deep waters. In the Pacific, changes in organic matter composition with depth would be the most important factor in the increases in stoichiometry with depth. In all the basins, the N/P ratios are probably affected by benthic denitrification, as in AS94. The P/C/-O_2ratios (mean and $5^{th}$to 95^{th} percentile) are estimated to be 1/111(97 to 129)/155(149 to 163) in the depths below 2000 m of the Indian and Pacific Oceans, where DIC fixation and vertical change in organic matter composition have little influence on the stoichiometry estimates. We suggest that chemoautotrophic DIC fixation and the effect of change in organic matter composition with depth on the stoichiometry in waters above 2000 m should be considered for large-scale biogeochemical modeling and estimation of oceanic uptake of anthropogenic carbon from observational data.

Reproduction of iron-rich intermediate water in the Sea of Okhotsk by high resolution biogeochemical model.

*Hatsumi Nishikawa[1], Humio Mitsudera[1], Hiroshi Yoshinari[2], Takuya Nakanowatari[3], Tomohiro Nakamura[1], Keisuke Uchimoto[4], Hiroyasu Hasumi[5]

1. Institute of Low Temperature Science, Hokkaido University, 2. National Institute for Environmental Studies, 3. Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 4. Research Institute of Innovative Technology for the Earth, 5. Atmosphere and Ocean Research Institute, University of Tokyo

Recent observation studies suggest that iron supply from sediment on the northwest continental shelf the Okhotsk Sea plays an important role for the subarctic primary production (e.g. Nishioka et al., 2013). Dense shelf water (DSW) takes up iron from sediment, thereby transporting iron into the Okhotsk Sea intermediate water. However, observational data is still limited.

To clarify detailed structure of iron circulation in the North Pacific, we develop the high-resolution biogeochemical model. However, our model did not reproduce high iron concentration in the intermediate water the Sea of Okhotsk. We use biogeochemical model developed by Parekh et al. (2005). They set the value of total ligand concentration to constant value in all place. Recent observations, however, suggest that ligand concentration varies with sea area and depth. Then, we conducted a new experiment with the ligand concentration changed in the vertical direction. The iron concentration intermediate water of the new experiment becaame higher than before.

The global oceanic iron distribution estimated by data assimilation approach

*Doi Toshimasa[1], Satoshi Osafune[1], Shuhei Masuda[1], Hajime Obata[2], Kazuhiro Misumi[3], Jun Nishioka[4]

1. Japan Agency for Marine-Earth Science and Technology, 2. The University of Tokyo, 3. Central Research Institute of Electric Power Industry, 4. Hokkaido University

Since distribution of oceanic iron is considered as one of the restriction factors of phytoplankton activity, it is necessary for a pelagic lower trophic level ecosystem model to take into account the effect of iron. In this study, we constructed a three dimensional gridded data of oceanic iron concentration by using both available in situ observation and simple iron cycle model. For the physical process of iron transport, the advection/diffusion model was used along with the flow field of ESTOC (Estimated State of Global Ocean for Climate Research). The falling atmospheric dust in the sea-surface and flux from the sediment at sea floor of the coast were set as the input of the iron. The scavenging or desorption by particulate matter in the water column were employed as the control variables and we constructed the simple iron cycle model. The optimized set of control parameters was obtained based on a Green's function approach by using available in situ iron concentration observations. The results showed that the iron concentration in the southern hemisphere is lower than northern hemisphere, and the low iron regions were well reproduced around the regions of high nutrient / low chlorophyll. Moreover, it is suggested that the Atlantic Ocean is more affected by the atmospheric dust compared with the Pacific Ocean.

A high-resolution multi-purpose particle tracking framework for coastal areas near Japan

*Yoshimasa Matsumura[1], Shota Katsura[1], Masao Kurogi[2], Hideyuki Nakano[3], Takateru Yamagishi[4]

1. Atmosphere and Ocean Research Institute, University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology, 3. Meteorological Research Institute, Japan Meteorological Agency , 4. Research organization for Information Science and Technology

A comprehensive and multi-purpose particle tracking framework using latest high resolution velocity field in the coastal regions near Japan is developed.
The particle tracking system uses accurate fourth order Runge-Kutta method and implements random-walk based diffusivity, and is built-in the recent versions of MRI.com (an OGCM developed in Meteorological Research Institute, Japan Meteorological Agency) and kinaco (a non-hydrostatic ocean model developed in Atmosphere and Ocean Research Institute, University of Tokyo) for *on-line* use. Each particle is able to store up to seven arbitrary properties (such as size, age, exposed temperature, orientation, mass and buoyancy, etc.) and record the history of them.

The code is effectively parallelized (using MPI and OpenMP hybrid technique) and allows ~O(10^{10}) particles on modern massive-parallel supercomputers, and is also ported to GPU architecture using CUDA language.

This particle tracking framework has no particular target in a priori, and can be applied to various purposes for both physical oceanography (from large scale tracking of water masses to small scale modeling of suspended sediment matter or frazil ice crystals) and ocean biogeochemistry (tracking of trace elements, Laglangian modeling of plankton and detritus, individual based modeling of fishes and marine resources), only by defining appropriate properties and inserting a few lines of code that manipulats them corresponding to the particular target use.

In the presentation, we will introduce an application of this framework to the tracking of passive particles scattered in the coastal areas near Japan using velocity field provided by the latest very high resolution ocean modeling (~300 m mesh). Each model particle records its trajectory and the history of exposed environment, and can be interpreted as eggs or larvae (before acquiring swimming ability) of species of corresponding spawning areas and seasons as well as the tracers for small scale water mass exchanges.

Numerical study on seasonality of ocean litters collected at the Dongsha Island in the northern South China Sea

*Yi-Chia Hsin[1], Chia-Ying Ko[2], Ming-Shiou Jeng[3]

1. Research Center for Environmental Changes, Academia Sinica, 2. Institute of Fisheries Science, National Taiwan University, 3. Biodiversity Research Center, Academia Sinica

Distribution of ocean litters collected at the Dongsha Island, an isolated island in the northern South China Sea, shows a significant seasonal change. More litters were accumulated in the northern (southern) part of the island in winter (summer). By means of backward-tracking simulation by considering the effect of both ocean currents and winds (i.e., windage), a series of numerical experiments are carried out to clarify the possible source and mechanisms for the observational seasonal change of litters. Results exhibit that, in winter, low-windage litters are mainly from the western Philippine Sea via the Luzon Strait while the high-windage ones are contributed from the Taiwan Strait. In summer, litters from the southwestern South China Sea, i.e. east of Vietnam, could be a major origin.

A key spot and timing to monitor chlorophyll-a in the Kuroshio western boundary current

*Takafumi Hirata[1]

1. Faculty of Environmental Earth Science, Hokkaido University

The Kuroshio western boundary current originates from the subtropics in the Western Pacific and carries a thermal energy and oceanic water mass towards the north, including the south coasts and offshore islands of Japan. In spite of the oligotrophy of the origin water that the Kuroshio carries, the Kuroshio water is known for spawning and feeding grounds of commercial/non-commercial fish larvae, explaining a higher fisheries production in the region. Thus, it puzzles an oceanographic and ecological relationships among nutrient fields, standing stock and productivity of organisms. In order to understand the complex Kuroshio ecosystems, phytoplankton dynamics is investigated using remote sensing data, namely phytoplankton pigment or chlorophyll-a observed by Advanced Himawari Imager (AHI) onboard Himawari-8. The area-integrated, and the area average of, Kuroshio chlorophyll-a was found predictable from a chlorophyll-a measurement in the 134-136 ˚E, where the Kuroshio current direction is most stable between 130-150 ˚E . An analysis of short term variability (< 1 year) of the Kuroshio chlorophyll-a concentration revealed that a cumulative, and monthly average of, chlorophyll-a over a month in the Kuroshio surface water could be estimated from a chlorophyll-a measurement at a single day in the month. These results suggest that there is a key spot and timing to monitor the phytoplankton activities in the Kuroshio current.

Impacts of cyclonic eddies on phytoplankton biomass and phenology in the Kuroshio Extension region

*Eko Siswanto[1], Yoshikazu Sasai[1]

1. Japan Agency for Marine-Earth Science and Technology

Two-decade ocean color chlorophyll-a concentration (CHL, a metric of phytoplankton biomass) data from 1997 to 2017 were used to comprehend the impact of cyclonic eddies on phytoplankton biomass and phenology in the Kuroshio Extension region (KE) of the western North Pacific Ocean. The CHL data have 4-km and 8-day spatiotemporal resolution and were acquired from the ESA Ocean Colour-Climate Change Initiative (http://www.esa-oceancolour-cci.org/). Prior to defining spring bloom onset, spatiotemporal gaps in CHL data were filled by applying empirical orthogonal function-based interpolation. The analysis was mainly focused on the winter season (January-March) as oceanographic conditions during the winter largely control phytoplankton spring bloom in terms of both magnitude and onset. Based on winter sea surface height anomaly (SSHa), cyclonic eddies (negative SSHa) were dominant mainly within the periods from 1998 to 2001 and from 2005 to 2009, whereas anti-cyclonic eddies (positive SSHa) were dominant mainly within the periods from 2002 to 2004 and from 2011 to 2015. Based on datasets from all seasons, the concurrences of negative SSHa and positive phytoplankton chlorophyll anomaly (CHLa) were observed, albeit not always. This indicates an eddy-induced upwelling supplies nutrients to the near-surface layer. Upwelled nutrients eventually promote phytoplankton growth. Such a concurrence of low SSHa and high CHLa was less obvious during the winter indicating that another factor (such as intense winter vertical mixing) also non-trivially controlled nutrient input to the surface layer, and hence CHLa variability. Overall temporal mean indeed showed that the active cyclonic eddy area (approximately south of the Kuroshio Current main axis) was characterized by high CHLa, low SSHa, and shoaled mixed layer. In this study, a Cumulative Sum method was applied to find phytoplankton spring bloom onset. Correlation between SSHa and spring bloom onset time was investigated, and it was found that approximately over the active cyclonic eddy area, positive correlation between winter/late winter SSHa and time of spring bloom onset was observed. Such a positive correlation indicates that cyclonic eddies during the winter likely tended to advance phytoplankton spring bloom onset.

Diagnostic estimation and uncertainties of nutrient limitation of phytoplankton growth in Michaelis-Menten functional form

*Taketo Hashioka[1], Maki Noguchi Aita[1]

1. Japan Agency for Marine-Science and Technology

Michaelis-Menten functional form (MM) is most widely used relationship of nutrient limitation of phytoplankton growth in large-scale ecosystem models. In MM functional form, the choice of parameter value of a half-saturation constant is a key point for controlling the strength of nutrient limitation. In general, the half-saturation constant increase with the size of the phytoplankton cell depending on the surface-to-volume ratio by diffusive hypothesis, and wide ranges of values are reported from observational studies. On the other hand, the most of Plankton Functional Types (PFT) models represent a phytoplankton type as one representative PFT with one global parameter. The parameter value is chosen in the observed range as a most reasonable value that could reproduce observed chl-a or nutrient concentration in each model. As a result, there are uncertainties of the global pattern of nutrient limitation among models. In this study, we diagnostically estimated the nutrient limitation using various parameter set of different global PFT models form CMIP5 together with the observation based nutrient concentrations (World Ocean Atlas for macro nutrient and multi-model median for dissolved iron and ammonium concentration). Then we show uncertainties and robustness of estimation of nutrient limitation in the current PFT models with MM functional form.

Modeling productivity in lower trophic levels in Otsuchi Bay, northeast of Japan, using a nested OGCM with a biogeochemical component

*Takashi T Sakamoto[1], L. Shogo Urakawa[2], Sachihiko Itoh[1], Hiroyasu Hasumi[1], Kiyoshi Tanaka[1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Meteorological Research Institute, Japan Meteorologica Agancy

Otsuchi Bay is located on the northeast coast of Honshu Island, Japan, where was extensively damaged by the huge tsunamis caused by the 2011 off the Pacific coast of Tohoku Earthquake. Motivated by how the biogeochemical circumstance and fishery resource recover, some observations have been conducted in the bay, but those have not been enough because of several restrictions and human resources. Aimed at filling the observational shortage and the acquirement of some information about physical and low trophic fields, a modeling approach has been discussed. Using a triply-nested OGCM and a downscaling method, the authors succeeded to reproduce seasonal variability of the circulation in the bay, and also showed a seasonality of the water exchange mechanism between the bay and the open ocean (Sakamoto et al. 2017). In order to know the low trophic processes in the bay, a numerical simulation using a nested OGCM with a NPZD model is conducted. The OGCM is an improved version of Sakamoto et al’ s (2017) model, and the NPZD one is based on Nagata and Hasumi (2014). In this poster, our modeling strategy and some results will be presented. The final goal of this study is to perform hindcasting simulations of the bay with realistic boundary conditions, that are the river runoff, the atmospheric forcings, and the open ocean states.

Keywords: downscaling, nest-modeling, NPZD model

Change in lower trophic level ecosystems to decadal scale variation of climate system in the North Pacific Ocean

*Maki Noguchi Aita[1], Kazuaki Tadokoro[2], Yoshiki Komuro[3], Taketo Hashioka[1], Naomi Harada[1]

1. Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology, 2. Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 3. Institute of Arctic Climate and Environment Research, Japan Agency for Marine-Earth Science and Technology

The changes related to interdecadal climate variations, such as the Pacific Decadal Oscillation and the 18.6-y tidal cycle, have been discussed in many marine ecosystem studies. By analyzing data from observation of nutrient concentrations, decreasing and increasing trends of nutrients in the surface and subsurface layers, have been reported in many studies. Changes have also been observed in the biomass of phytoplankton and zooplankton. To clarify variability of lower trophic level productivity and its controlling factor, we simulated changes in the marine ecosystem caused by interdecadal climate variability, using the JRA55-do (Japanese 55-year atmospheric reanalysis) dataset from 1958 to 2017 to drive an ecosystem model, NEMURO, embedded in a global three-dimensional physical-biological coupled model, ‘COCO-NEMURO’. We compared and verified ecosystem model results with observations of phytoplankton and zooplankton species composition data collected by the Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency (FRA). Our model results showed that changes in biomass and nutrient concentration greatly differ depending on the region. According to our model results, sea surface temperature (SST) was very low during mid 1960s to mid 1970s, then SST increased after the mid 1970s to the end of 1990s in the western subarctic North Pacific. Changes in phytoplankton biomass was follow to this. However, the change in SST and phytoplankton and zooplankton biomass were contrary to this in the western subtropical North Pacific. We also checked decadal time series of annual mean sea ice concentration, SST, and phytoplankton biomass in the eastern Bering Sea and the western Arctic. The simulated sea ice concentration in the eastern Bering Sea decreased from the late 1970s to the early 1980s, while it was higher in the early 1990s and the late 2000s. The SST had its peaks in the late 1970s and the early 2000s. The phytoplankton biomass was inversely correlated with the sea ice concentration. In the western Arctic, the simulated sea ice concentration (SST) showed negative (positive) trends on the decadal timescale. The phytoplankton biomass has also been increasing, but its trend was not so simple. To elucidate the mechanism that sustains marine ecosystems, we will also analyze focusing on primary producers and zooplankton to key link to higher trophic levels.

Estimation of experienced environment of jack mackerel in the East China Sea

*Tomihiko Higuchi[1], Motomitsu Takahashi[2], Kotaro Shirai[1], Shin-ichi Ito[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Seikai National Fisheries Research Institute,FRA

Jack mackerel *Trachurus japonicus* is distributed on the continental shelf waters along the subtropical Kuroshio Current and the Tsushima Warm Current in the western North Pacific. The East China Sea (ECS) is one of major region for jack mackerel and understanding the recruitment processes of jack mackerel into the fishing grounds in the ECS is important. However, marine environment such as water temperature that jack mackerel actually experiences is not directly observed yet. In this study, oxygen ($\delta^{18}O$) and carbon ($\delta^{13}C$) stable isotope of jack mackerel otolith were analyzed and the experienced environment was estimated. When we compared $\delta^{18}O$ of otolith caught in between three different station with different temperature, average of $\delta^{18}O$ varied and was negatively correlated with water temperature of sampling station. Most of individual indicated that $\delta^{13}C$ relatively increased from core part to edge in otolith. Thus, these results suggest that otolith of jack mackerel recorded experienced environment. However, because jack mackerel migrate vertically, it needs to consider vertical profile of seawater temperature and other parameters such as salinity and prey availability. A combination with fish distribution information and ecological modeling may help the improvement of estimation for detail experienced environment.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

Mon. May 27, 2019 5:15 PM - 6:30 PM JST | Mon. May 27, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[A-OS12] Marine ecosystems and biogeochemical cycles: theory, observation and modeling

convener:Shin-ichi Ito(Atmosphere and Ocean Research Institute, The University of Tokyo), Takafumi Hirata(Faculty of Environmental Earth Science, Hokkaido University), Enrique N Curchitser(Rutgers University New Brunswick), Eileen E Hofmann(Old Dominion University)

The ocean accounts for about 50% of global net primary production. This production is significant for carbon cycling and ecosystem functioning, and is related directly or indirectly to a variety of climatic and ecological phenomena. The responses to natural and anthropogenic environmental stressors that influence marine production and diversity can cause perturbations to marine ecosystems that alter trophic dependencies and interactions among organisms at a range of space and time scales. Quantification of the principal mechanisms driving spatio-temporal variability of marine ecosystem remains to be done, especially in terms of evaluation of uncertainty in responses. As a result, evaluating vulnerability of marine ecosystems to environmental change requires systematic and holistic approaches that integrate physics to ecology and are based in observations and modelling. In addition, expectations to deliver these science to public society is raising. This session aims to provide a venue for not only discussing recent advances in understanding marine biogeochemical cycles, ecosystems and their interactions, but also networking with a variety of people to seed new ideas in marine ecological research. Observational, modeling and conceptual studies, including technological development and operational applications, that consider linkages among biogeochemical and ecosystem processes, biodiversity, and the effects of multiple stressors from molecular to planetary scales are encouraged.

Impact of the nutrient transport through the Tsushima Strait on the ecosystem in the Japan Sea

*Ryota Shibano[1], Akihiko Morimoto[1], Katsumi Takayama[2], Tetsutaro Takikawa[3], Masashi Ito[4]

1. Center for Marine Environmental Studies, Ehime University, 2. Research Institute for Applied Mechanics, Kyushu University, 3. Graduate School of Fisheries and Environmental Sciences, Nagasaki University, 4. Fisheries Oceanography Department, Japan Sea National Fisheries Research Institute

The Japan Sea is a semi-closed sea with narrow and shallow straits such as the Tsushima/Korea Strait. The nutrient transports through the Tsushima Strait have an impact the ecosystem around the coast of Japan. The nutrient transports are originated in the sources from the sea, Kuroshio (Pacific), Taiwan Strait, and Yellow Sea, and the sources from the land, Changjiang river, Yellow river, and dusts. We investigated the ship cruise data in the strait from 2005 to 2017 to reveal the interannual variations in the volume transport, nutrient concentration, and nutrient transport. The nutrient transport in the strait has large interannual variations of ±50% compared to the average transport.

The recently studies indicated the contribution ratio in the nutrient transports on the sources from the Kuroshio and the rivers also change, when the yearly nutrient transport changes (e.g. Morimoto et al., 2012).

We developed a coupled ocean circulation and ecosystem model, in which the lateral boundary condition is applied based on observation data, and investigated the biogeochemical responses in the Japan Sea and the East China Sea to the interannual variations in the nutrient flux through the Tsushima Strait. We discussed about the contribution ratio in the nutrient flux on the 6 sources from Kuroshio, Taiwan Strait, Changjiang river, Yellow river, the dust, and the bottom (Yellow Sea).

Keywords: Tsushima Warm Current, nutrient transport, the Sea of Japan

Revisiting vertical variations in stoichiometry during oceanic organic matter decomposition

*Masahito Shigemitsu[1], Michio Aoyama[1], Toshimasa Doi[1], Taichi Yokokawa[1], Akihiko Murata[1]

1. Japan Agency for Marine-Earth Science and Technology

Using the new global nutrient data set, we re-evaluate basin-wide stoichiometric ratios of remineralization estimated by Anderson and Sarmiento (1994) (hereinafter, AS94). For the same latitudinal ranges of the Atlantic, Indian and Pacific Oceans as in AS94, we construct one or two end-member mixing models on 14 neutral surfaces and estimate the stoichiometric ratios with a probabilistic approach. Unlike the results of AS94, significant vertical variations in the stoichiometry are found in the Atlantic and Pacific, while relatively constant stoichiometry with depth is found in the Indian Ocean, similar to AS94. The decreases in the C/P and $-O_2$/P ratios with depth in the Atlantic could be caused via dark DIC fixation by chemoautotrophs in the deep waters. In the Pacific, changes in organic matter composition with depth would be the most important factor in the increases in stoichiometry with depth. In all the basins, the N/P ratios are probably affected by benthic denitrification, as in AS94. The P/C/-O_2ratios (mean and $5^{th}$to 95^{th} percentile) are estimated to be 1/111(97 to 129)/155(149 to 163) in the depths below 2000 m of the Indian and Pacific Oceans, where DIC fixation and vertical change in organic matter composition have little influence on the stoichiometry estimates. We suggest that chemoautotrophic DIC fixation and the effect of change in organic matter composition with depth on the stoichiometry in waters above 2000 m should be considered for large-scale biogeochemical modeling and estimation of oceanic uptake of anthropogenic carbon from observational data.

Reproduction of iron-rich intermediate water in the Sea of Okhotsk by high resolution biogeochemical model.

*Hatsumi Nishikawa[1], Humio Mitsudera[1], Hiroshi Yoshinari[2], Takuya Nakanowatari[3], Tomohiro Nakamura[1], Keisuke Uchimoto[4], Hiroyasu Hasumi[5]

1. Institute of Low Temperature Science, Hokkaido University, 2. National Institute for Environmental Studies, 3. Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 4. Research Institute of Innovative Technology for the Earth, 5. Atmosphere and Ocean Research Institute, University of Tokyo

Recent observation studies suggest that iron supply from sediment on the northwest continental shelf the Okhotsk Sea plays an important role for the subarctic primary production (e.g. Nishioka et al., 2013). Dense shelf water (DSW) takes up iron from sediment, thereby transporting iron into the Okhotsk Sea intermediate water. However, observational data is still limited.

To clarify detailed structure of iron circulation in the North Pacific, we develop the high-resolution biogeochemical model. However, our model did not reproduce high iron concentration in the intermediate water the Sea of Okhotsk. We use biogeochemical model developed by Parekh et al. (2005). They set the value of total ligand concentration to constant value in all place. Recent observations, however, suggest that ligand concentration varies with sea area and depth. Then, we conducted a new experiment with the ligand concentration changed in the vertical direction. The iron concentration intermediate water of the new experiment becaame higher than before.

The global oceanic iron distribution estimated by data assimilation approach

*Doi Toshimasa[1], Satoshi Osafune[1], Shuhei Masuda[1], Hajime Obata[2], Kazuhiro Misumi[3], Jun Nishioka[4]

1. Japan Agency for Marine-Earth Science and Technology, 2. The University of Tokyo, 3. Central Research Institute of Electric Power Industry, 4. Hokkaido University

Since distribution of oceanic iron is considered as one of the restriction factors of phytoplankton activity, it is necessary for a pelagic lower trophic level ecosystem model to take into account the effect of iron. In this study, we constructed a three dimensional gridded data of oceanic iron concentration by using both available in situ observation and simple iron cycle model. For the physical process of iron transport, the advection/diffusion model was used along with the flow field of ESTOC (Estimated State of Global Ocean for Climate Research). The falling atmospheric dust in the sea-surface and flux from the sediment at sea floor of the coast were set as the input of the iron. The scavenging or desorption by particulate matter in the water column were employed as the control variables and we constructed the simple iron cycle model. The optimized set of control parameters was obtained based on a Green's function approach by using available in situ iron concentration observations. The results showed that the iron concentration in the southern hemisphere is lower than northern hemisphere, and the low iron regions were well reproduced around the regions of high nutrient / low chlorophyll. Moreover, it is suggested that the Atlantic Ocean is more affected by the atmospheric dust compared with the Pacific Ocean.

A high-resolution multi-purpose particle tracking framework for coastal areas near Japan

*Yoshimasa Matsumura[1], Shota Katsura[1], Masao Kurogi[2], Hideyuki Nakano[3], Takateru Yamagishi[4]

1. Atmosphere and Ocean Research Institute, University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology, 3. Meteorological Research Institute, Japan Meteorological Agency , 4. Research organization for Information Science and Technology

A comprehensive and multi-purpose particle tracking framework using latest high resolution velocity field in the coastal regions near Japan is developed.
The particle tracking system uses accurate fourth order Runge-Kutta method and implements random-walk based diffusivity, and is built-in the recent versions of MRI.com (an OGCM developed in Meteorological Research Institute, Japan Meteorological Agency) and kinaco (a non-hydrostatic ocean model developed in Atmosphere and Ocean Research Institute, University of Tokyo) for *on-line* use. Each particle is able to store up to seven arbitrary properties (such as size, age, exposed temperature, orientation, mass and buoyancy, etc.) and record the history of them.

The code is effectively parallelized (using MPI and OpenMP hybrid technique) and allows ~O(10^{10}) particles on modern massive-parallel supercomputers, and is also ported to GPU architecture using CUDA language.

This particle tracking framework has no particular target in a priori, and can be applied to various purposes for both physical oceanography (from large scale tracking of water masses to small scale modeling of suspended sediment matter or frazil ice crystals) and ocean biogeochemistry (tracking of trace elements, Laglangian modeling of plankton and detritus, individual based modeling of fishes and marine resources), only by defining appropriate properties and inserting a few lines of code that manipulats them corresponding to the particular target use.

In the presentation, we will introduce an application of this framework to the tracking of passive particles scattered in the coastal areas near Japan using velocity field provided by the latest very high resolution ocean modeling (~300 m mesh). Each model particle records its trajectory and the history of exposed environment, and can be interpreted as eggs or larvae (before acquiring swimming ability) of species of corresponding spawning areas and seasons as well as the tracers for small scale water mass exchanges.

Numerical study on seasonality of ocean litters collected at the Dongsha Island in the northern South China Sea

*Yi-Chia Hsin[1], Chia-Ying Ko[2], Ming-Shiou Jeng[3]

1. Research Center for Environmental Changes, Academia Sinica, 2. Institute of Fisheries Science, National Taiwan University, 3. Biodiversity Research Center, Academia Sinica

Distribution of ocean litters collected at the Dongsha Island, an isolated island in the northern South China Sea, shows a significant seasonal change. More litters were accumulated in the northern (southern) part of the island in winter (summer). By means of backward-tracking simulation by considering the effect of both ocean currents and winds (i.e., windage), a series of numerical experiments are carried out to clarify the possible source and mechanisms for the observational seasonal change of litters. Results exhibit that, in winter, low-windage litters are mainly from the western Philippine Sea via the Luzon Strait while the high-windage ones are contributed from the Taiwan Strait. In summer, litters from the southwestern South China Sea, i.e. east of Vietnam, could be a major origin.

A key spot and timing to monitor chlorophyll-a in the Kuroshio western boundary current

*Takafumi Hirata[1]

1. Faculty of Environmental Earth Science, Hokkaido University

The Kuroshio western boundary current originates from the subtropics in the Western Pacific and carries a thermal energy and oceanic water mass towards the north, including the south coasts and offshore islands of Japan. In spite of the oligotrophy of the origin water that the Kuroshio carries, the Kuroshio water is known for spawning and feeding grounds of commercial/non-commercial fish larvae, explaining a higher fisheries production in the region. Thus, it puzzles an oceanographic and ecological relationships among nutrient fields, standing stock and productivity of organisms. In order to understand the complex Kuroshio ecosystems, phytoplankton dynamics is investigated using remote sensing data, namely phytoplankton pigment or chlorophyll-a observed by Advanced Himawari Imager (AHI) onboard Himawari-8. The area-integrated, and the area average of, Kuroshio chlorophyll-a was found predictable from a chlorophyll-a measurement in the 134-136 ˚E, where the Kuroshio current direction is most stable between 130-150 ˚E . An analysis of short term variability (< 1 year) of the Kuroshio chlorophyll-a concentration revealed that a cumulative, and monthly average of, chlorophyll-a over a month in the Kuroshio surface water could be estimated from a chlorophyll-a measurement at a single day in the month. These results suggest that there is a key spot and timing to monitor the phytoplankton activities in the Kuroshio current.

Impacts of cyclonic eddies on phytoplankton biomass and phenology in the Kuroshio Extension region

*Eko Siswanto[1], Yoshikazu Sasai[1]

1. Japan Agency for Marine-Earth Science and Technology

Two-decade ocean color chlorophyll-a concentration (CHL, a metric of phytoplankton biomass) data from 1997 to 2017 were used to comprehend the impact of cyclonic eddies on phytoplankton biomass and phenology in the Kuroshio Extension region (KE) of the western North Pacific Ocean. The CHL data have 4-km and 8-day spatiotemporal resolution and were acquired from the ESA Ocean Colour-Climate Change Initiative (http://www.esa-oceancolour-cci.org/). Prior to defining spring bloom onset, spatiotemporal gaps in CHL data were filled by applying empirical orthogonal function-based interpolation. The analysis was mainly focused on the winter season (January-March) as oceanographic conditions during the winter largely control phytoplankton spring bloom in terms of both magnitude and onset. Based on winter sea surface height anomaly (SSHa), cyclonic eddies (negative SSHa) were dominant mainly within the periods from 1998 to 2001 and from 2005 to 2009, whereas anti-cyclonic eddies (positive SSHa) were dominant mainly within the periods from 2002 to 2004 and from 2011 to 2015. Based on datasets from all seasons, the concurrences of negative SSHa and positive phytoplankton chlorophyll anomaly (CHLa) were observed, albeit not always. This indicates an eddy-induced upwelling supplies nutrients to the near-surface layer. Upwelled nutrients eventually promote phytoplankton growth. Such a concurrence of low SSHa and high CHLa was less obvious during the winter indicating that another factor (such as intense winter vertical mixing) also non-trivially controlled nutrient input to the surface layer, and hence CHLa variability. Overall temporal mean indeed showed that the active cyclonic eddy area (approximately south of the Kuroshio Current main axis) was characterized by high CHLa, low SSHa, and shoaled mixed layer. In this study, a Cumulative Sum method was applied to find phytoplankton spring bloom onset. Correlation between SSHa and spring bloom onset time was investigated, and it was found that approximately over the active cyclonic eddy area, positive correlation between winter/late winter SSHa and time of spring bloom onset was observed. Such a positive correlation indicates that cyclonic eddies during the winter likely tended to advance phytoplankton spring bloom onset.

Diagnostic estimation and uncertainties of nutrient limitation of phytoplankton growth in Michaelis-Menten functional form

*Taketo Hashioka[1], Maki Noguchi Aita[1]

1. Japan Agency for Marine-Science and Technology

Michaelis-Menten functional form (MM) is most widely used relationship of nutrient limitation of phytoplankton growth in large-scale ecosystem models. In MM functional form, the choice of parameter value of a half-saturation constant is a key point for controlling the strength of nutrient limitation. In general, the half-saturation constant increase with the size of the phytoplankton cell depending on the surface-to-volume ratio by diffusive hypothesis, and wide ranges of values are reported from observational studies. On the other hand, the most of Plankton Functional Types (PFT) models represent a phytoplankton type as one representative PFT with one global parameter. The parameter value is chosen in the observed range as a most reasonable value that could reproduce observed chl-a or nutrient concentration in each model. As a result, there are uncertainties of the global pattern of nutrient limitation among models. In this study, we diagnostically estimated the nutrient limitation using various parameter set of different global PFT models form CMIP5 together with the observation based nutrient concentrations (World Ocean Atlas for macro nutrient and multi-model median for dissolved iron and ammonium concentration). Then we show uncertainties and robustness of estimation of nutrient limitation in the current PFT models with MM functional form.

Modeling productivity in lower trophic levels in Otsuchi Bay, northeast of Japan, using a nested OGCM with a biogeochemical component

*Takashi T Sakamoto[1], L. Shogo Urakawa[2], Sachihiko Itoh[1], Hiroyasu Hasumi[1], Kiyoshi Tanaka[1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Meteorological Research Institute, Japan Meteorologica Agancy

Otsuchi Bay is located on the northeast coast of Honshu Island, Japan, where was extensively damaged by the huge tsunamis caused by the 2011 off the Pacific coast of Tohoku Earthquake. Motivated by how the biogeochemical circumstance and fishery resource recover, some observations have been conducted in the bay, but those have not been enough because of several restrictions and human resources. Aimed at filling the observational shortage and the acquirement of some information about physical and low trophic fields, a modeling approach has been discussed. Using a triply-nested OGCM and a downscaling method, the authors succeeded to reproduce seasonal variability of the circulation in the bay, and also showed a seasonality of the water exchange mechanism between the bay and the open ocean (Sakamoto et al. 2017). In order to know the low trophic processes in the bay, a numerical simulation using a nested OGCM with a NPZD model is conducted. The OGCM is an improved version of Sakamoto et al’ s (2017) model, and the NPZD one is based on Nagata and Hasumi (2014). In this poster, our modeling strategy and some results will be presented. The final goal of this study is to perform hindcasting simulations of the bay with realistic boundary conditions, that are the river runoff, the atmospheric forcings, and the open ocean states.

Keywords: downscaling, nest-modeling, NPZD model

Change in lower trophic level ecosystems to decadal scale variation of climate system in the North Pacific Ocean

*Maki Noguchi Aita[1], Kazuaki Tadokoro[2], Yoshiki Komuro[3], Taketo Hashioka[1], Naomi Harada[1]

1. Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology, 2. Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 3. Institute of Arctic Climate and Environment Research, Japan Agency for Marine-Earth Science and Technology

The changes related to interdecadal climate variations, such as the Pacific Decadal Oscillation and the 18.6-y tidal cycle, have been discussed in many marine ecosystem studies. By analyzing data from observation of nutrient concentrations, decreasing and increasing trends of nutrients in the surface and subsurface layers, have been reported in many studies. Changes have also been observed in the biomass of phytoplankton and zooplankton. To clarify variability of lower trophic level productivity and its controlling factor, we simulated changes in the marine ecosystem caused by interdecadal climate variability, using the JRA55-do (Japanese 55-year atmospheric reanalysis) dataset from 1958 to 2017 to drive an ecosystem model, NEMURO, embedded in a global three-dimensional physical-biological coupled model, ‘COCO-NEMURO’. We compared and verified ecosystem model results with observations of phytoplankton and zooplankton species composition data collected by the Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency (FRA). Our model results showed that changes in biomass and nutrient concentration greatly differ depending on the region. According to our model results, sea surface temperature (SST) was very low during mid 1960s to mid 1970s, then SST increased after the mid 1970s to the end of 1990s in the western subarctic North Pacific. Changes in phytoplankton biomass was follow to this. However, the change in SST and phytoplankton and zooplankton biomass were contrary to this in the western subtropical North Pacific. We also checked decadal time series of annual mean sea ice concentration, SST, and phytoplankton biomass in the eastern Bering Sea and the western Arctic. The simulated sea ice concentration in the eastern Bering Sea decreased from the late 1970s to the early 1980s, while it was higher in the early 1990s and the late 2000s. The SST had its peaks in the late 1970s and the early 2000s. The phytoplankton biomass was inversely correlated with the sea ice concentration. In the western Arctic, the simulated sea ice concentration (SST) showed negative (positive) trends on the decadal timescale. The phytoplankton biomass has also been increasing, but its trend was not so simple. To elucidate the mechanism that sustains marine ecosystems, we will also analyze focusing on primary producers and zooplankton to key link to higher trophic levels.

Estimation of experienced environment of jack mackerel in the East China Sea

*Tomihiko Higuchi[1], Motomitsu Takahashi[2], Kotaro Shirai[1], Shin-ichi Ito[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Seikai National Fisheries Research Institute,FRA

Jack mackerel *Trachurus japonicus* is distributed on the continental shelf waters along the subtropical Kuroshio Current and the Tsushima Warm Current in the western North Pacific. The East China Sea (ECS) is one of major region for jack mackerel and understanding the recruitment processes of jack mackerel into the fishing grounds in the ECS is important. However, marine environment such as water temperature that jack mackerel actually experiences is not directly observed yet. In this study, oxygen ($\delta^{18}O$) and carbon ($\delta^{13}C$) stable isotope of jack mackerel otolith were analyzed and the experienced environment was estimated. When we compared $\delta^{18}O$ of otolith caught in between three different station with different temperature, average of $\delta^{18}O$ varied and was negatively correlated with water temperature of sampling station. Most of individual indicated that $\delta^{13}C$ relatively increased from core part to edge in otolith. Thus, these results suggest that otolith of jack mackerel recorded experienced environment. However, because jack mackerel migrate vertically, it needs to consider vertical profile of seawater temperature and other parameters such as salinity and prey availability. A combination with fish distribution information and ecological modeling may help the improvement of estimation for detail experienced environment.

[A-OS13] Ocean circulation and material cycle in coastal seas

convener:Kiyoshi Tanaka(University of Tokyo), Akihiko Morimoto(Ehime University), Yuichi Hayami(Saga University), Kazuhiko Ichimi(Seto Inland Sea Regional Research Center, Kagawa University), Chairperson:Kiyoshi Tanaka, Akihiko Morimoto

Coastal seas have high biodiversity and high productivity, while various environmental problems such as eutrophication, red tide, and hypoxia are caused by human activity. In order to understand material cycle and various phenomena and to maintain sustainable environment in coastal seas, interdisciplinary research is needed. In the present session, we invite researchers who are interested in physical phenomena, material cycle, biological responsive dynamics, and their interactions in coastal seas. Neither study area nor study method is confined. We welcome presentations of wide-range topics to communize our knowledge in coastal seas.

On-demand development of bay-scale models using the Japanese Coastal Ocean Monitoring and Forecasting System

*Kei Sakamoto[1], Hideyuki Nakano[1], Shogo Urakawa[1], Takahiro Toyoda[1], Hiroyuki Tsujino[1], Goro Yamanaka[1]

1. Meteorological Research Institute

We have developed the "Japanese Coastal Ocean Monitoring and Forecasting System" (MOVE/MRI.COM-JPN) to reproduce oceanic conditions across the coastal seas around Japan, based on an ocean model with horizontal resolution of approximately 2 km and a 4-dimensional variational data assimilation system. The Japan Meteorological Agency plans to use this system as a platform for various coastal marine operations, and details of the system are explained in Sakamoto et al. (2019) and Hirose et al. (2019) (submitted to Ocean Dynamics). However, the model resolution of 2 km is a minimum necessary requirement for continental shelf regions in contact with open oceans and relatively large inland seas such as the Seto Inland Sea, and it is a future task to provide information targeting bay-scale regions which are more closely related to society, including small bays, inland seas and straits. As a solution, a model covering the entire coastal seas around Japan with a resolution of several hundred meters is planned, but a current ordinary computer cannot perform its enormous calculations. In this respect, it seems feasible to deploy an array of bay-scale models of high resolution and small domain, which are nested from MOVE/MRI.COM-JPN, but management costs of a lot of models are concerned in that case. Therefore, we are considering an approach to develop bay-scale models on demand for a future expansion of MOVE/MRI.COM-JPN. As a first step towards this, we began developing a package that can quickly build a bay-scale model. Currently, the package consists mainly of three elements. The first is our numerical model MRI.COM. In addition to an offline-nesting function, it is possible to introduce dynamics important in coastal seas of Japan, such as river runoff, sea ice, tides and the inverse barometer effect. The second is a package of pre-processing and analysis tools named "MRI.COM eXperimental Environment". This helps a model developer to easily create model configurations such as topography data. The third is analysis data of the coastal seas around Japan produced by MOVE/MRI.COM-JPN. By using this data for the initial value and lateral boundary condition of a bay model, we can start a model experiment anytime after 2008. Using this package, we have created a Nagasaki Bay model with resolution of 100 m and an Osaka Bay model with resolution of 200 m. We reproduced seiches called "Abiki" by the Nagasaki Bay model, and the storm surge caused by Typhoon Jebi in September 2018 by the Osaka Bay model. The poster presentation will also show these results.

Long term measurement of the current at the bay head in the Suruga Bay, Japan. part 2

*Takaaki Katsumata[1,4], Masato Niki[2], Akihiko Tanaka[1], Hiroyuki Tan[1,3], Kyoko Takashima[2], Takashige Sugimoto

1. Liberal Arts Education Center, Shimizu Campus, Tokai University., 2. School of Marine Science and Technology, Tokai University, 3. Japan Unmanned Vehicle exploration Agency, 4. NPO, the association for the environmental conservation of the ocean

The Suruga Bay is located on a southern coast in the main island of Japan, and the bay facing to the Kuroshio front. Fishery in the bay are strongly influenced by a variables of rivers inflows and intruding of Kuroshio water (Sugimoto et al., 2009; Tanaka et al.,2009; Katsumata, 2016). But we have a little knowledge for these variations. Therefore, we measured the profile of the current by ferry mounted ADCP, at the line of the “Suruga Bay Ferry” cruise cross the bay head from a western coast to eastern coast, i.e., Shimizu Port to Toi Port, since 2008. We currently continuing measuring the current in the bay about near 10 years. The anticlockwise circulation at the bay head of the Suruga Bay has at least 100 m thick from surface layer. The circulation in bay head has clearly seasonal variation, it is relate difference of stratified period and non-stratified one. This current data include the period of typical large meander of Kuroshio.

Bottom-water intrusion and subsequent water exchange induced by Yamase around Mutsu Bay

*Satomi Fujisaki[1], Atsuhiko Isobe[1], Izumi Ogida[2], Yuki Kosaka[2]

1. Kyushu university, 2. Aomori Prefectural Fisheries Research Institute

Bottom-water intrusion in the Bungo channel, which is the cold-water intrusion onto the continental shelf from the Kuroshio intermediate layer, was studied by Takeoka et al. (2000). The bottom-water intrusion in the Bungo channel occurs when the Kuroshio Current passes along the Kyushu of the Bungo channel (Kaneda et al., 2002). In the case of Mutsu Bay, bottom-water temperature fluctuated by more than 3 degree Celsius during summer (June –September). However, Tsugaru Warm Current is not so strong compared with Kuroshio and, thus, we had to find other mechanisms for the bottom-water intrusion to occur. We here focused on Yamase which is a cold, moist and westward wind blowing from the Okhotsk Sea during summer and analyzed water temperature, current velocity and wind velocity.

Ocean buoy automatic monitoring system (hereinafter, buoy system) at three points of Mutsu Bay (Tairadate, Aomori, Higashiwan) have observed water temperature, current velocity, salinity, and so forth at a depth of 1m, 15m, 30m every single hour. An observation ship “Natsudomari” records water temperature, salinity, and so forth at eleven points of Mutsu Bay once a month. Water temperature and current velocity from 2008 to 2017 (buoy system), water temperature from 1981 to 2016 (Natsudomari), water temperature from 1981 to 2010 (Japan Oceanographic Data Center (J-DOSS)) and water temperature deviation in August from 2008 to 2017 in Tsugaru Strait (Hokkaido Research Organization) were obtained. Wind data at Oma observatory free of terrain-derived disturbances was obtained from the Japan Meteorological Agency.
A correlation analysis of time series between water temperature (5 –15 days) at Tairadate, Aomori, Higashiwan and zonal wind at Oma was performed. The days when daily average easterly (westerly) wind velocity was greater than 2 m/s was referred to as “eastern (western) wind day”. Composite maps of cross sections of water temperature in Tsugaru Strait and Mutsu Bay was created on the eastern and western wind day, respectively. The relationship between annually average bottom-water temperature at Aomori and Higashiwan and eastern winds at Oma was investigated during summer (June –September) from 2008 to 2017. Water temperature in 2011 was excluded because water temperature in Tsugaru Strait was extraordinarily low.

Long-period bottom-water temperature (about 10 days) at Tairadate and Aomori, both of which are located in western Mutsu Bay, remarkably fluctuated, that is, bottom-water intrusion occurred in the western part of Mutsu Bay. The correlation coefficients between the bottom temperature and Oma winds were 0.68 at Tairadate (a significance level of 0.05) and 0.75 at Aomori (a significance level of 0.05). Consequently, it was suggested that zonal wind induced bottom-water intrusion in western Mutsu Bay. Moreover, the composite maps stated that cold-water < 10 degree Celsius intruded onto the bottom of Mutsu Bay from Tsugaru Strait during eastern wind days. These findings suggest that westward Yamase triggers bottom-water intrusion in Mutsu Bay. However, as bottom-water temperature become lower, bottom-water intrusion was prevented even when Yamase blows continuously.

The Generation Process of the Bottom Intrusion in the Bungo Channel

*Kana Maetani[1], Akihiko Morimoto[2], Xinyu Guo[2], Toru Miyama[3]

1. Graduate School of Science and Engineering, Ehime University, 2. Center for Marine Environmental Studies, Ehime University, 3. Japan Agency for Marine-Earth Science and Technology

Introduction

The Bungo Channel is one of the two channels that connect to the Pacific Ocean and the Seto Inland Sea, and located between Kyushu and Shikoku Islands. Marine environment in the Bungo Channel is strongly influenced by the disturbances from open ocean. It is known that a cold-water intrusion from open sea, called a “Bottom Intrusion”, occurs in the lower layer from summer to autumn (Kaneda *et al.,* 2002). Since the Bottom Intrusion is difficult to observe because of its occurrence position, generation mechanism and intrusion process of the Bottom Intrusion have not been revealed yet. However, recently the Bottom Intrusion has been reproduced in numerical models with high resolution and high accuracy. Therefore, there is a possibility that we can figure out its three-dimensional structure and generation processes by analyzing model outputs. However, there is a possibility that the Bottom Intrusion and the intrusion of the cold-water in the numerical model do not have the same mechanism in real ocean. At first, we compare model output and observed data that derived from a mooring system at the central part of the Bungo Channel. After conforming reproduction of the model in terms of the Bottom Intrusion, we analyze the model output to understand the intrusion process of cold-water into the Bungo Channel.

Data

The observation data used in this study were measured by ADCP (Acoustic Doppler Current Profiler), thermometer and salinometer that were moored at the central part of the Bungo Channel, from 6 July to 17 October, 2016. We also used a model output of JCOPE-T-NEDO that is developed by JAMSTEC.

Results and Discussion

We analyzed two cases of the Bottom Intrusion that occurred 14 August and 10 September in 2016 because variations in current velocity and water temperature in the model consist well with those in observation. In these two cases, the cold-water mass was supplied to the shelf slope nearby N32.72˚, E132.45˚, and was crossed the 200m isobath by the anticlockwise flow in the shelf slope. As a result, a density gradient between the cold-water mass and relatively light water in the Bungo Channel was generated. The density gradient makes a northeastward density driven current in the lower layer in the Bungo Channel, and the current advects the cold-water mass into the Bungo Channel.

Furthermore, it is found from observation data that there is a case that northward flow became stronger in not lower layer but middle layer. When the northward flows became stronger in middle layer, a northeast flow also developed in northwestern part of the Bungo Channel. When strong northward flow occurred in the middle layer, water temperature in the central part of the Bungo Channel was not always dropped. This might be because the water mass transported by the strong northward flow in the middle layer came from shallower depth in the shelf edge compared with the case of Bottom Intrusion. However, the reason why velocity increased at middle layer is not clear at the moment, so that proceeding analysis is needed in addition to the Bottom Intrusion.

Characteristics of bottom intrusion in the Bungo Channel

*Akihiko Morimoto[1], Shuya Fujita[1], Hidetaka Takeoka[1], Xinyu Guo[1]

1. Ehime University

Bungo Channel is located between Kyushu and Shikoku and faces to the Pacific Ocean. A cold water mass with high nutrients intermittently intrudes into the Bungo Channel from summer to autumn. The phenomenon is called “Bottom Intrusion (BI)”. According to Kaneda et al., (2002), the BI occurs in neap tide of summer with the current of 15 cm/s. However, when we analyzed moored current and water temperature data at the central part of the Bungo Channel, we could not see the relation between the BI and moon age. There is a possibility that the discrepancy between our analysis and Kaneda et al. (2002) is caused by the different year data. In the present study, we reexamine the characteristics of the BI, especially relationship between the BI and moon age, using long-term water temperature data.

At the Uchiumi in the central part of the Bungo Channel, multilayer water temperature has observed since 1995. At other five stations (Hoketsu, Yusu, Shitaba, Fukuura, Okinoshima), Ehime University has also observed multilayer water temperature since 2008. In the present study, we analyze the deepest data at each station to understand the characteristics of the BI. We defined the BI as follows. Water temperature continually drops for 30 hours and its drop range is more than 0.5 ℃. At first, we analyzed water temperature data at 60 m depth in Uchiumi from 1997 to 2011. The BI occurred evenly in every moon age, we could not recognize the relation between BI and neap tide as Kaneda et al, (2002) pointed out. In addition, such kind of relation was not seen in other stations except in Yusu. Water temperature drops in Uchiumi were from 0.5 –7.0 ℃. We thought range of water temperature drop might affect to the relation. Therefore, we divided two cases, drop range is more or less than 2 ℃. We could not see the relation of neap tide in both cases. Furthermore, we investigated the relation between the BI and neap tide in each year, but we could not recognize the relation.

From the above analysis, it was found that the BI occurs without relation of moon age. However there is the relation only in Yusu. A vertical mixing area is located west of Yusu. Therefore, the BI might be blocked by the strong mixing associated with spring tide. This is why the BI occurs in neap tide in Yusu. Kaneda et al., (2002) clearly showed the relation between BI and moon age. The relation at Uchiumi was for only two years of 17 years. We will discuss why there was the relation in 1995-1996.

Role of Kuroshio Current in fish resource variability off southwest Japan

*Yushi Morioka[1], Sergey Varlamov[1], Yasumasa Miyazawa[1]

1. Japan Agency for Marine-Earth Science and Technology

Western boundary currents in the subtropics play a pivotal role in transporting warm water from the tropics that contribute to development of highly diverse marine ecosystem in the coastal regions. As one of the western boundary currents in the North Pacific, the Kuroshio Current (hereafter the Kuroshio) exerts great influences on biological resource variability off southwest Japan, but few studies have examined physical processes that attribute the coastal fish resource variability to the basin-scale Kuroshio variability. Using the high-quality fish catch data and high-resolution ocean reanalysis results, this study identifies statistical links of interannual fish resource variability off Sukumo Bay, Shikoku island of Japan, to subsurface ocean temperature variability in the Kuroshio. The subsurface ocean temperature variability off the south of Sukumo Bay exhibits vertically coherent structure with sea-surface height variability, which originates from the westward-propagating oceanic Rossby waves generated through surface wind anomalies in the Northwest Pacific. Although potential sources of the atmospheric variability remain unclarified, the remotely-induced oceanic Rossby waves contribute to fish resource variability off Sukumo Bay. These findings have potential applications to other coastal regions along the western boundary currents in the subtropics where the westward-propagating oceanic Rossby waves contribute to the coastal ocean temperature variability.

[A-OS13] Ocean circulation and material cycle in coastal seas

convener:Kiyoshi Tanaka(University of Tokyo), Akihiko Morimoto(Ehime University), Yuichi Hayami(Saga University), Kazuhiko Ichimi(Seto Inland Sea Regional Research Center, Kagawa University), Chairperson:Akihiko Morimoto, Yuichi Hayami

Coastal seas have high biodiversity and high productivity, while various environmental problems such as eutrophication, red tide, and hypoxia are caused by human activity. In order to understand material cycle and various phenomena and to maintain sustainable environment in coastal seas, interdisciplinary research is needed. In the present session, we invite researchers who are interested in physical phenomena, material cycle, biological responsive dynamics, and their interactions in coastal seas. Neither study area nor study method is confined. We welcome presentations of wide-range topics to communize our knowledge in coastal seas.

Variation in hypoxic water mass in Ariake Sea -what consumed the dissolved oxygen?-

*Yuichi Hayami[1], Naoki Fujii[1], Hiroyuki Takasu[2], Yu Umezawa[3], Minoru Wada[2]

1. Saga University, 2. Nagasaki University, 3. Tokyo University of Agriculture and Technology

In the inner most area of Ariake Sea, the estuarine circulation is dominated in summer. Therefore, the suspended material is transported toward offshore in the surface layer and toward inward and accumulated in the bottom layer. Simultaneously, there is a conspicuous spring-neap variation where stratification is enhanced and bottom water hypoxia develops in neap tide and stratification is reduced and hypoxia is moderated in spring tide. However, it was not clarified that such variation in hypoxia was driven only by the physical process or affected by some biological process such as biological oxygen demand. In order to clarify the variation in mass transport and ecosystem, we made surveys in the inner most area of Ariake Sea in the summer of 2018. We made 6 transect surveys with a boat during a spring-neap cycle during continuous measurements of temperature, salinity, currents, DO and turbidity with moorings.

During the mooring observation period, as a typhoon attacked Ariake Sea on 27 July, most of the mooring instruments were once recovered. The surface mooring instruments was set again on 30 July, and other ones were set again on 1 August. Another typhoon attacked on 14 August but the mooring observation was continued. Between these 2 typhoons, transect surveys were conducted on 1, 5, 8 and 12 August during low tide. It was in neap tide on 5 August and in spring tide on 12 August. The water column was well mixed in the morning of 1 August at the mooring station (Stn. 3) due to strong tidal mixing in spring tide and wind induced mixing by the typhoon. The temperature decreased and salinity increased in the bottom layer toward neap tide. Stratification was strongest on 8 August. Then the stratification became weaker and the water column was entirely mixed again on 11 August. The bottom water DO decreased from 1 August and became lower than 3 mg/L on 4 August. The bottom DO was kept lower than 3 mg/L until 10 August. In the surface layer, the bloom of *Chattonella* sp. occurred from late July. It continued at least until 13 August. The results of the transect survey indicated that the cold and saline water intruded from offshore to enhance the stratification and formed hypoxic water mass. On 12 August, stratification weakened and the hypoxic water mass was disappeared in the coastal area. But, in the offshore area, weak hypoxic water mass was formed. High turbidity layer was formed over the bottom in the coastal area on 1 August. But the turbidity decreased on 5 and 8 August. The turbidity increased again and became highest on 12 August. The experiment to estimate the oxygen demand of the bottom water was conducted on the each survey day. The oxygen demand decreased from 1 to 5 August then increased and became maximum on 12 August. In order to estimate the contribution of bacterial respiration and chemical oxygen consumption to the total oxygen demand in water, we made incubation experiment with Chloramphenicol and formalin. Chloramphenicol was added to stop the bacterial respiration. Formalin was added to measure the chemical oxygen consumption. The bacterial respiration occupied about 80 % of the total oxygen demand on 6 August. However, almost all the oxygen demand was occupied by the respiration except for the bacterial respiration on 13 August. There was almost no chemical oxygen demand on each date. There was a high correlation between chlorophyll a concentration and oxygen demand (R=0.90). There was a correlation between turbidity and oxygen demand. But it was weaker than chlorophyll a (R=0.61).

The hypoxic water mass was generated by the cold and saline water intrusion occurred between spring

©2019. Japan Geoscience Union. All Right Reserved.

tide and neap tide. However, the oxygen demand in the bottom water decreased in this period. It indicated that the formation of hypoxia was generated by the physical process and the change in oxygen demand did not affected. The oxygen demand in spring tide was larger than in neap tide. It would be due to the active resuspension of organic matter by the strong tidal mixing. There was a high correlation between chlorophyll a and oxygen demand of water. But most of the oxygen demand when the hypoxic water mass was formed was bacterial respiration. The contribution of the phytoplankton respiration was small. They suggested the oxygen demand was mainly generated by the decomposition of organic matter derived from phytoplankton by bacteria. The red tide of *Chattonella* sp occurred continuously during the observation period. The maximum chlorophyll a concentration reached 72.3 ug/L. The organic matter supply from the red tide would fuel the oxygen consumption in the bottom layer.

Influence of Nori aquaculture-induced change in light environment on phytoplankton dynamics

*Naoya Minamiura[1], Soichi Yamaguchi[1]

1. Kyushu University

In the Ariake Sea in winter, Nori aquaculture is conducted actively, and its production is the largest in Japan. On the other hand, color bleaching of Nori due to red tide occurrence has become a big problem. From previous research, it is known that the red tide occurrence involves the improvement of the light environment. At the time of Nori aquaculture season, Nori aquaculture net is set densely in the coastal area, and leaf blade is attached to the net and it grows. It can be easily imagined that such net and leaf blade have great influence on the light environment in water, but there are no examples studied so far. In this study, by continuous on-site observation of the photon quantum amount in the Nori aquaculture area and the non-Nori aquaculture area, the influence of Nori aquaculture on the light environment is evaluated, and the influence is evaluated by dynamic growth of leaf blade as a function. We investigated how phytoplankton dynamics by incorporating these results into numerical simulation changes.
We installed a photon meter (DEFI2-L by JFE Advantech Co., Ltd.) and pressure gauge (DEFI2-D10 by JFE Advantech Co., Ltd.) respectively in the sea area just under the Nori aquaculture and in the non-Nori aquaculture area possessed by the Saga Prefecture Fisheries Experiment from January 15 to 25 in 2019. This continuous observation was carried out at 5 second intervals. As a result of the observation, it was revealed that the photon quantum amount decreased by about 75% on average just under Nori aquaculture area. The reduction of this photon (light shielding factor y) was expressed as a function of the leaf length (x unit: cm), and the following equation was obtained.

$y=0.86e^{-0.1\times x}$

Next, we developed a numerical ecosystem model that takes this light shielding factor into consideration and examined how it affects phytoplankton dynamics. Calculation was carried out separately into two patterns with and without light shielding factor in Nori aquaculture area. In consideration of the light shielding factor, the phytoplankton biomass was reduced in the vicinity of the Nori aquaculture area in the inner part of Ariake sea, compared to the case without consideration. This indicates that Nori aquaculture suppresses the growth of phytoplankton by deteriorating the light environment in water.

Enhanced West Philippine Sea intrusion diminishes hypoxia conditions in the Pearl River estuary

*Hon-Kit Lui[1,2], Chen-Tung Arthur Chen[1], Wei-Ping Hou[2], Jian-Ming Liau[2]

1. Department of Oceanography, National Sun Yat-sen University, 2. Taiwan Ocean Research Institute, National Applied Research Laboratories

The hypoxia condition (dissolved oxygen <2 mg/L) in the Pearl River estuary is worsening in the past decade, partly due to the rising anthropogenic activities. For instance, excess nutrients cause enhanced biological productivity in the surface ocean. Yet, dead phytoplankton sink to the bottom of the coastal zone, where they decompose and consume oxygen. If the oxygen consumption rate exceeds the supply rate, then hypoxia or even anoxia may develop, leading to so-called dead zones. Here we show that a strong invasion of high dissolved oxygen but low nutrients West Philippine Sea seawater into the South China Sea in the form of Kuroshio occurred around 2003-2004. Apparently due to the oxygen supply carried by the remnants of the intruded Kuroshio, little hypoxia developed off the Pearl River estuary, where the anoxic condition develops in some years with weak Kuroshio intrusion.

North Pacific seawater radiocarbon recorded in abalone shells obtained from Otsuchi Bay, Japan

*Ota Kosuke[1], Yusuke Yokoyama[1,2], Yosuke Miyairi[2], Jun Hayakawa[2], Naomi Sato[2], Hideki Fukuda[2], Kiyoshi Tanaka[2]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Reconstructing past ocean currents in the coastal regions is needed to better understand the relationship between oceanographic changes and coastal ecosystems. Seawater radiocarbon is a unique proxy to understand the properties of water masses. However, the knowledge of the water mass distribution is limited to the low latitude regions as the only well-established proxy for it is reef-building corals. Alternative archives are required for high latitude regions. Here we measured $\Delta^{14}C$ values of three abalone shells using accelerator mass spectrometry (AMS) and counted the shell growth checks which were made in the winter season. Abalone shells were obtained from Otsuchi Bay, where the cold Oyashio Current and the warm Kuroshio Current converge. The Oyashio Current has more depleted radiocarbon than the Kuroshio Current. We compared $\Delta^{14}C$ values of abalone shells with the sea surface temperature anomaly in Sanriku region. $\Delta^{14}C$ values of abalone shells range from 5.4 ‰to 31‰ and indicated seasonal variations. $\Delta^{14}C$ values decreased by about 5 ‰in shell growth checks that indicates winter season.We found this decrease of $\Delta^{14}C$ values of abalone shells are consistent with the significantly mixing of water brought by the Oyashio Current. $\Delta^{14}C$ value of abalone shells clearly shows the Oyashio Current inflow in 2013, 2015 and 2017 and it can be used to reconstruct fluctuations between past water masses. In addition, the $\Delta^{14}C$ values of abalone shells are possibly affected by their habitat. Abalone at 2 m to 6 m depth exhibited higher $\Delta^{14}C$ values than those in abalone at 6 m to 10 m depth. This trend resulted from cold water from the Oyashio Current having a greater influence on deeper water. These radiocarbon records indicate past seawater conditions in northern Japan, where the Oyashio and Kuroshio currents converge, can be reconstructed using abalone shells.

Spreading of Radioactive Cesium off Joban coast through Large River Discharge

*Kiyoshi Tanaka[1], Seiya Nagao[2], Yujiro Kitade[3], Masato Niki[4], Takaaki Katsumata[4], Toru Miyama[5]

1. University of Tokyo, 2. Kanazawa University, 3. Tokyo University of Marine Science and Technology, 4. Tokai University, 5. Japan Agency for Marine-Earth Science and Technology

A hydrographic observation was conducted off the Joban coast during September 7 to 12, 2011 (six months after the 2011 Great East Japan Earthquake), using a CTD profiler and a ship-mounted ADCP (R/V Tansei-Maru cruise KT-11-22). At the same time, water-samplings for radioactive cesium measurements were conducted at a depth of 10 m. The radioactivity of cesium (134Cs and 137Cs) was measured for the AMP/Cs compound using gamma-ray spectrometry at the Low Level Radioactivity Laboratory of Kanazawa University. There was a negative correlation between the radioactive cesium and salinity in the sea surface (at the depth of 10 m), indicating more radioactive cesium was included in less saline water. Abundant freshwater is discharged from three large rivers (Tone, Naka, and Kuji Rivers) into the observational area. What is important is that several days before the observation, there was extremely heavy rainfall in the upper reaches of the rivers, which resulted in that discharge of the Tone River exceeded 2000 m^3/s on September 4. Therefore, it was suggested that the highly concentrated radioactive cesium in the sea surface originated from the land through the rivers. Moreover, it was shown that spreading of the river water and radioactive cesium is strongly influenced by the Kuroshio Current.

Development of a river-ocean seamless model for simulating river discharges around Kyushu

*Takahiro Tsutsumi[1], Shinichiro Kida[2], Ryusuke Kuroki[3], Yosuke Alexandre Yamashiki[3]

1. Interdisciplinary Graduate School of Engineering Science, Kyushu University, 2. Research Institute for Applied Mechanics, Kyushu University, 3. Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University

Regional-scale torrential rainfalls cause river discharges that are capable of abruptly changing the oceanic condition over a wide area. It is necessary to simultaneously solve multiple rivers for capturing such events that are also often associated with flooding over land. Many coastal areas are also affected by multiple rivers but many of the conventional river-models to simulate the influence of rivers on a regional scale. The object of this research is to develop a river-ocean seamless model for simulating river discharges around Kyushu during and after weather events. By using an Isopycnal-Layered model following Kida and Yamashiki (2015), we developed a model that focuses on the island of Kyushu and the heavy rain event in September 2015. The model reproduces the increase in river flow due to the heavy rain and when compared to observations, we found some rivers to show slow water propagation speed from upstream to downstream, while some rivers reproduce the actual observation well. We plan to conduct a sensitively experiment to verify the cause behind this difference in the reproducibility of the model.

[A-OS13] Ocean circulation and material cycle in coastal seas

convener:Kiyoshi Tanaka(University of Tokyo), Akihiko Morimoto(Ehime University), Yuichi Hayami(Saga University), Kazuhiko Ichimi(Seto Inland Sea Regional Research Center, Kagawa University)

Coastal seas have high biodiversity and high productivity, while various environmental problems such as eutrophication, red tide, and hypoxia are caused by human activity. In order to understand material cycle and various phenomena and to maintain sustainable environment in coastal seas, interdisciplinary research is needed. In the present session, we invite researchers who are interested in physical phenomena, material cycle, biological responsive dynamics, and their interactions in coastal seas. Neither study area nor study method is confined. We welcome presentations of wide-range topics to communize our knowledge in coastal seas.

An experimental study on degradation and fragmentation of marine plastic debris

*YUSEI YAMAGUCHI[1]

1. KYUSHU UNIVERSITY

Marine contamination due to plastic debris,especially microplastics, is attracting worldwide attention at the present time. It has already been reported that microplastics are present over the world's ocean, but the process of their formation has not been clarified in detail.In this study, we aim to elucidate the process in which plastics drifting on the surface of the sea are degraded by ultraviolet rays and fragmentized by physical processes such as waves. We attempt to reproduce the regradation and fragmentationan processes in a laboratory experiment. First, an ultraviolet irradiation experiment was conducted. The ratio of the ultraviolet intensity between a high-pressure UV lamp irradiated and sunlight was measured under the sunny, cloudy, and rainy conditions.Thereafter, plastic (polyethylene without additives) pieces of the same size were irradiated with ultraviolet rays under a high-pressure UV lamp. The degraded plastic pieces were entered into a plastic tube wite seawater and sand, which was rotated to represented motion by waves in shorelines to fragmentize. The change of fragmentation rate of the plastic pieces will be examined by varying the irradiation time and the rotating times, respectively.

Seafloor environment based on grain and concentrations of carbon, nitrogen and sulfur of surface sediment in Ise and Mikawa bays

*Atsuko Amano[1], Koji Seike[1]

1. National institute of Advanced Industrial Science and Technology

This study reconstructed seafloor environment based on the spatial distribution of grain size and concentrations of total organic carbon (TOC), total nitrogen (TN) and total sulfur (TS) in the surface sediments collected at 44 sites of Ise and Mikawa bays. Silt sediments with 6-8ϕ deposit in the interior and central parts of these bays and values of grain size decrease to sand sediment with 1-4ϕi toward the bay mouth from the central part. Concentrations of TOC, TN and TS show relatively higher values at the interior and central parts and decrease at the bay mouth. Ratios of TOC and TN (C/N) are 8-9 at the most parts of the bays and increase to over 10 in the offshore part of Kiso river mouth at Ise Bay. The distribution pattern of grain size indicates that tidal current velocity decrease from the bay mouth to the central part of the bay and hydrodynamic condition is a stagnant in the interior and central parts. The patterns of TOC, TN and TS concentrations means that organic matter likely deposit and become a reductive condition in the interior and central part of the bays. Values of C/N indicate organic matter originated from marine plankton mainly deposit, however the amount of terrestrial organic matter in sediments increases the offshore of Kiso river mouth.

Hydrographic observations of estuarine circulation in Suruga Bay, Japan

*Kiyoshi Tanaka[1], Masato Niki[2], Kunio Kutsuwada[2], Akio Ishida[3], daisuke Takahashi[2], Takaaki Katsumata[2], Kazuyuki Uehara[2]

1. University of Tokyo, 2. Tokai University, 3. Tokoha University

Sergestid shrimp (‘Sakura-ebi’ in Japanese), *Sergia lucens*, is an important marine product in Suruga Bay, south coast of Japan. Large-scale commercial catch of *Sergia lucens* is conducted only in Suruga Bay and around Taiwan. Although the reason abundant catch of *Sergia lucens* is limited to these areas has not yet been clarified thoroughly, two factors likely play important roles: One is a steep continental slope adjacent to a deep basin, and the other is large volume of river discharge. Therefore, we made a high-resolution hydrographic observation (shipboard ADCP and CTD) in the innermost region of Suruga Bay, where the mouth of the Fuji River is connected directly to the steep continental slope and an anticyclonic (clockwise) eddy tends to form. The observation suggested that an estuarine baroclinic circulation formed there. It is likely that a counter flow of subsurface water located around a depth of 20 m is entrained into the surface river plume at the river mouth.

Residence time of river water in the Jakarta Bay

*Akihiko Morimoto[1], Endro Soeyanto[2], Yuichi Hayami[3], Agus Sudaryanto[2], Suhendar Sachoemar[2]

1. Ehime University, 2. BPPT, Indonesia, 3. Saga University

Jakarta bay faces to capital city of Indonesia, and its width and length are about 30km and 10km, respectively. The Jakarta Bay is shallow with maximum depth of 20m and opens to Java Sea. Massive materials supply through rivers into the bay. Since maintenance rate of sewage system is a few percentages, enormous nutrients, organic matters, and garbage. It is expected that marine environment in the Jakarta Bay has become worse. However, we do not know the environment at the moment because of lack of observed data. We have conducted hydrographic survey since December 2015 to capture current status of marine environment in the Jakarta Bay. It was found from our observation that hypoxia occurred throughout the year. Magnitude of hypoxia was small in rainy season but large in dry and transition seasons. Since tropical region like Jakarta Bay is heated at the sea surface during all seasons, water temperature becomes homogenous in vertical. Therefore, density stratification is controlled by fresh water supply from rivers. Considering this fact, it is expected that stratification develops in rainy season, and hypoxia occurs due to decreasing of vertical flux of oxygen. However, our observation did not show the situation.

In the present study, we develop a three dimensional model to understand seasonal variation in density stratification in the Jakarta Bay and to know residence time of river water in the bay. We developed a model based on POM. The model is driven by tidal forcing, surface wind, and river discharge from 10 rivers, and we reproduced physical field in 2016. Calculated sea surface salinity distributions coincided well with observations except in dry season. Sea surface current shows eastward or northeastward currents in February and May, and westward and northwestward in September and December. From the sea surface current pattern, it is implied that fresh water supplied from Citarum river might flow out to Java Sea immediately. In order to know residence time of river waters, we calculated age of river water using CART theory (Deleersnijder et al., 2001). Age of river water in May was about 15 days and that in September was about 50 days. This result suggests that density stratification in the Jakarta Bay might be controlled by not only total river discharge but also residence time of river water. At the presentation, we will introduce a result of contribution ratio of each river to salinity in the Jakarta Bay

[A-OS15] Freshwater discharge through rivers and estuaries to the ocean

convener:Shinichiro Kida(Research Institute for Applied Mechanics, Kyushu University), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Humio Mitsudera(Institute of Low Temperature Science, Hokkaido University), Chairperson:Shinichiro Kida(RIAM, Kyushu University), Humio Mitsudera(Hokkaido University, Institute of Low Temperature Science), Yosuke Yamashiki(GSAIS Kyoto University)

The water cycle from land to the ocean involves complex dynamics of rivers and buoyancy driven flows in estuaries and the ocean. Recent progress in satellite observations and numerical models are beginning to illuminate how this water cycle occurs on various time scales globally and regionally. This session welcomes various process studies that investigate the dynamics and material circulation related to the freshwater cycle from land to the ocean such as surface runoff, river transport, estuarine circulation, and coastal river plumes based on numerical, observational, or theoretical studies.

The forefront research for flow and water quality estimations in coastal area using geo-stationary and polar orbital satellites data

*Yuji Sakuno[1]

1. Graduate School of Engineering, Hiroshima University

Continuous estimation of the flow velocity and water quality distribution in a wide area at high resolution is extremely important in order to understand the natural phenomena occurring at the interface between the river and the ocean. In recent years,satellite remote sensing is expected as a powerful tool to grasp such phenomena. In this presentation, a case study of flow velocity estimation using the stationary meteorological satellite "Himawari-8" data, which observes sea surface temperature (SST) at 10 minute intervals at first. A strong flow velocity distribution of about 0.5 m/s was detected by applying the image correlation method to continuous SST images in the southern part of the Lombok Straits of Indonesia in the study area. Such a method can measure the flow velocity distribution of wide channel at low cost, so it is particularly effective in waters where there is a remarkable water temperature difference. Meanwhile, the heavy rain in western Japan occurred in July 2018, and a large amount of sediment from the land flowed out to the Seto Inland Sea. As a result, oyster beds for aquaculture were broken or red tide damage caused by a large amount of nutrient salt was occurred. The state of such huge flood were monitored by the polar orbital earth observation satellite such as Landsat-8, Sentinel-2 (10 m to 30 m spatial resolution) and GCOM-C (250 m spatial resolution). The polar orbital satellite has lower observation frequency than geostationary satellite, but there is an advantage that detailed distribution of sediment discharge from river and red tide distribution can be visualized. Combining such stationary / polar orbital satellite data, measured data, numerical model and other technologies will make it possible to monitor coastal environments connecting the open ocean and rivers more quickly and in detail in the future.

Rainfall-Runoff-Inundation Processes and Modeling in a Humid Tropical River Basin

*Takahiro Sayama[1], Kodai Yamamoto[2], Ryoko Araki[2], Apip Apip[3], Eva Mia Siska[1], Kaoru Takara[4]

1. Disaster Prevention Research Institute, Kyoto University, 2. Graduate School of Engineering, Kyoto University, 3. LIPI, Indonesia, 4. Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University

Large-scale plantations of palm and acacia trees have caused 50 % reduction of natural forests in the 25 years between 1985 to 2009 in Sumatra, Indonesia. Deforestation of natural forest might have changed water cycle in the area including runoff and evapotranspiration, which may lead to possible changes in flood and drought conditions. Downstream parts of river basins in Sumatra spreads wetlands with rich ecosystems, though such environment have degraded due to land cover changes over the last few decades to agricultural areas. Drying the wetlands by drainage for rice cropping and other agricultures caused various issues including peatland fire and haze in surrounding regions. In addition to the land cover change, climate change may give significant impact on the hydrologic cycle in this region. Climate change in humid tropical region in South East Asia has been difficult to be predicted due to local atmospheric cycle. Furthermore, hydrologic process understandings and their representations by simulation models are the important scientific step toward adequate assessment of land cover and climate changes. Among various hydrologic processes, rainfall-runoff processes in tropical climate conditions characterized also by deep weathered soil layers have been poorly understood. Our study is conducted based on field investigation with respect to rainfall-runoff processes in the mountainous hillslope in Sumatra to understand the fundamental characteristics of rainfall-runoff in this region, and to represent the feature particularly with a thick soil layer, in our distributed hydrologic model. After the calibration and validation of the model at the river basin scale in the Batanghari River basin, we assess the impact of the climate change by inputting the rainfall.

Some findings from the field monitoring are summarized below. According to a simple cone penetration experiment, the soil depths in the hillslope were estimated to be about 1.5 ~ 4.5 meters. Furthermore, the soil sample experiment at surface, 30 cm and 60 cm depths showed that saturated hydraulic conductivities were as high as 7,200 mm/h while the volumetric water content maintain also high (0.45~0.50) with negative suction between 1~10 m. Such characteristics should be explained due to the aggregated soil in humid tropics. In our site, the foot of the slope (SK1) has thicker soil layer (4.5 m), while it is reduced to 1.5 m about 20 m upstream along the hillslope (SK3). Groundwater table exists at the depths of about 3 ~ 4 m depth consistently at SK1 (bottom) and SK2 (middle) and the groundwater table responses rapidly to rainfall. With the high saturated hydraulic conductivity and high infiltration rate, especially in the natural forest area, we conceptualize the rainfall-runoff in this region is dominated by fairly quick vertical infiltration into the thick soil layer and the recharge to the groundwater table. Based on the above process understandings, we represent the process in the Rainfall-Runoff-Inundation (RRI) model to the entire Batanghari River basin to simulate streamflow at the river basin scale.

Role of river inflows from Kamchatka Peninsula in the Okhotsk Sea

*Toru Miyama[1], Humio Mitsudera[2]

1. Application Laboratory, Japan Agency for Marine-Earth Science and Technology, , 2. Institute of Low Temperature Science, Hokkaido University

The Okhotsk Sea is a unique ocean in that sea ice forms at the lowest latitude in the world. The sea ice formation plays important roles in water mass formations not only in the Okhotsk Sea but also in the North Pacific Ocean. The river inflows from the surrounding coasts affect the sea ice formation by changing stratification. Especially, the contribution from the river inflow from the Amur River on the western side of the Okhotsk Sea has been widely discussed. The roles of the Amur River in chemical and biological cycles have been also investigated. On the hand, the role of the river inflows from the Kamchatka Peninsula on the eastern side of the Okhotsk Sea is not well known.
In this study, we simulated the northern part of the Okhotsk Sea to investigate the roles of river inflows from the Kamchatka Peninsula. FVCOM (Finite-Volume, Primitive equation Community Ocean Model; Chen et al. 2003) was used. JRA55-do (Tsujino et al., 2018) was used for the atmospheric forcing. The river inflow dataset also came from JRA55-do based on Suzuki et al. (2017). The unstructured horizontal grid spacing was decreased from about 9.0 km at the southern boundary to about 1.4 km along the northern boundary.
The model runs with and without the river inflows from the Kamchatka Peninsula were compared. The salinity significantly increased without the river inflow along the coast of Kamchatka (by more than 1 unit at maximum). The salinity increase also spread toward the western Okhotsk Sea. With these changes in salinity, ice formation in the Okhotsk Sea was also affected.

Keywords: Okhotsk Sea, sea ice, river inflow

CHLOROPHYLL ESTIMATION OF LAKE AND COASTAL WATER USING REMOTE SENSING APPROACH

*Shweta Yadav[1], Yamashiki Yosuke[1], Junichi Susaki[1], Kanako Ishikawa[2], Yoh Yamashita[1]

1. Kyoto University, 2. LBERI

Chlorophyll-a is an optically active compound (OAC) commonly used as a proxy for phytoplankton biomass in an aquatic environment. Retrieving the concentration of chlorophyll-a remains a challenge due to the presence of several OAC particularly in water bodies which are in proximity to the land-based activities. In this study, an effort has been made to estimate the chlorophyll-a concentration of both the freshwater Lake Biwa and the coastal water of Wakasa Bay in Japan. A spectral decomposition algorithm was used to determine the chlorophyll-a using the satellite images. The algorithm was applied to the satellite images from two different sensors namely Landsat-8 /OLI and Sentinel-2A/MSI. The satellite-derived chlorophyll-a concentration for the lake and coastal water from two different sensors were compared to assess the performance of both the sensors. The accuracy of the chlorophyll-a results derived from the images was evaluated with the in-situ measurement data of the chlorophyll-a for the Lake Biwa and the coastal water of Wakasa Bay. Both satellite sensors appear to give the best results for the coastal water ($R^2 > 0.80$) with an RMSE < 0.3 μg/L. However, slight underestimation of chlorophyll-a noted for the Landsat-8 image with an increase in chlorophyll-a concentration. For the lake water, Sentinel-2A results were relatively better ($R^2 > 0.70$) than Landsat-8, with an RMSE of < 1.0 μg/L. The obtained results will be useful to evaluate the primary productivity of both freshwater and coastal water body.

Maritime-continent coastal region as land-sea-air triple boundary layer and bio-anthroposphere

*Manabu D. Yamanaka[1]

1. Research Institute for Humanity and Nature / Professor Emeritus of Kobe University

Imbalance of radiative processes determining climate is compensated by atmospheric-oceanic circulations and latent heating. The latent heat generated mainly by equatorial cumulonimbus clouds concerns both overheating and circulation pumping. Since the equatorial atmosphere is almost free from Coriolis force making cyclones, the diurnal-cycle sea-land heat contrast is the most principal mechanism to generate cumulonimbus and thus rainfall. The earth’ s longest coastline of Indonesian maritime continent (IMC) generates the largest regional rainfall and latent heat controlling the global climate (Yamanaka et al., 2018, *Prog. Earth Planet. Sci.*, **5**(21), 1-28). Massive fresh water sustains the biosphere with biodiversity over the peatland of major islands of the IMC, which also concern the carbon cycle through making peats and coals as geologically long-term reservoirs. We homo sapiens originated from the tropical Africa and evacuated to the temperate zone, where coexistence with other species was easier and thus proliferation and civilization were achieved with making the tropics a field for grabbing both alive and fossilized bio-resources. On one hand, the human population is governed by the rain water for survival, agricultural and industrial use. On the other hand, the human activity after the industrial revolution has been consuming the fossil fuels, and has been modifying the peatland for plantations, which release massive greenhouse gases. Such interactions are being studied mainly in the eastern coast of Sumatera and the southern coast of Kalimantan, under an interdisciplinary project (RIHN Tropical Peatland Society Project, 2017-21). Based on rainfall variabilities of mesoscale (with radars, and as functions of coastal distance), intraseasonal to interannual scales (based on operational data) and interdecadal to centennial scales (by historical data rescue), we may discuss a “saturation” of anthroposphere in the tropical coastal region such as the IMC peatland.

River-ocean interaction at the Ganges-Brahmaputra river mouth

*Shinichiro Kida[1], Dai Yamazaki[2]

1. Research Institute for Applied Mechanics, Kyushu University, 2. Institute of Industrial Sciences, The University of Tokyo

The Ganges-Brahmaputra river is a major source of freshwater for the Bay of Bengal. River discharge occurs through the Ganges-Brahmaputra Delta, which consists of multiple river mouths. The seasonal cycle of this river discharge is observed with a minimum from late winter to early spring and a maximum from late summer to early fall. The seasonal cycle of the sea surface height for the Bay of Bengal, on the other hand, shows the presence of the Kelvin waves propagating from the equatorial Indian Ocean. We investigated how these two processes may interact at the river mouths based on a high-resolution numerical model that resolves the various channels of the Ganges-Brahmaputra Delta. The model simulates the basic seasonal cycle of the river discharge that is comparable to observations, with a river plume forming from the major river mouth and along the coast. Preliminary results suggest significant river-ocean interaction in narrow channels and, at times, reverse the direction of the river flow.

[A-OS15] Freshwater discharge through rivers and estuaries to the ocean

convener:Shinichiro Kida(Research Institute for Applied Mechanics, Kyushu University), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Humio Mitsudera(Institute of Low Temperature Science, Hokkaido University)

The water cycle from land to the ocean involves complex dynamics of rivers and buoyancy driven flows in estuaries and the ocean. Recent progress in satellite observations and numerical models are beginning to illuminate how this water cycle occurs on various time scales globally and regionally. This session welcomes various process studies that investigate the dynamics and material circulation related to the freshwater cycle from land to the ocean such as surface runoff, river transport, estuarine circulation, and coastal river plumes based on numerical, observational, or theoretical studies.

MERIT Hydro: Global 90m-resolution hydrography map based on latest topography datasets.

*Dai Yamazaki[1]

1. Institute of Industrial Sciences, The University of Tokyo

High-resolution raster hydrography maps are a fundamental data source for many geoscience applications. Here we introduce MERIT Hydro, a new global flow direction map at 3 arc-second resolution (~90 m at the equator) derived from the latest elevation data (MERIT DEM) and water body datasets (G1WBM, GSWO, and OpenStreetMap). We developed a new algorithm to extract river networks near-automatically by separating actual inland basins from dummy depressions caused by the errors in input elevation data. After a minimum amount of hand-editing, the constructed hydrography map shows good agreement with existing quality-controlled river network datasets in terms of flow accumulation area and inland basin distribution. The location of river streamlines was realistically aligned with existing satellite-based global river channel data. Comparison to GRDC gauges confirmed the accuracy of drainage basin delineation for global river networks in most cases. Discrepancies in flow accumulation area were found mostly in arid river basins containing depressions that are occasionally connected at high water levels and thus resulting in uncertain watershed boundaries. MERIT Hydro improves on existing global hydrography datasets in terms of spatial coverage (between N90 and S60) and representation of small streams, mainly due to increased availability of high-quality baseline geospatial datasets. The new flow direction and flow accumulation maps, along with accompanying supplementary layers on hydrologically adjusted elevation and channel width, will advance geoscience studies related to river hydrology at both global and local scales.

Comparison of model performance between global- and regional-scale river models in simulating compound flooding in coastal deltas in the world’s continental rivers

*Hiroaki Ikeuchi[1,2], Dai Yamazaki[2], Yukiko Hirabayashi[3]

1. Graduate School of Engineering, The University of Tokyo, 2. Institute of Industrial Science, The University of Tokyo, 3. Graduate School of Engineering and Science, Shibaura Instittute of Technology

Compound flooding, the co-occurrence of river and coastal flooding, is a major threat for delta regions and is rapidly gaining both social and academic attention. Global river models are widely used these days for various purposes such as flood forecast, flood risk assessment, and earth system sciences, and they can be used for flood risk assessment in delta regions as well. CaMa-Flood is a state-of-the-art global hydrodynamic model replicating river routing and floodplain inundation dynamics, and recently it has been applied to conduct compound flooding simulation by coupling a global tide and surge reanalysis data for the first time. However, because the model solves 1 dimensional momentum equations, complex water flow processes in river-coast interface may not be fully expressed.

The objective of this study is to enhance our understanding on issues in modelling compound flooding in the framework of global river models. To achieve this, we compare the difference in model performance between a global- and a regional-scale river model for the simulation of flood inundation in delta regions. We selected CaMa-Flood as a global model and LISFLOOD-FP as a regional model respectively. The reason for the choice of these models is that both the momentum equation and the sub-grid approximation of floodplain inundation dynamics are the same in the models, which enables us to compare the model performance in terms of dimensions, i.e., 1 dimensional flow equation for CaMa-Flood, and 2 dimension for LISFLOOD-FP. We proposed a method to construct LISFLOOD-FP model based on the topography and river channel bathymetry taken in CaMa-Flood to make the input topographical data as similar as possible. Simulation results suggest that while the overall flood extent was similar for both models, the spatial pattern of floodplain inundation depth differed because of the unit-catchment shape, i.e., the spatial unit of calculation taken in the CaMa-Flood model.

Observation of a river plume by drone-mounted visible/infrared cameras

*Kenta Araki[1], Shinichiro Kida[2], Atsuhiko Isobe[2]

1. Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2. Research Institute for Applied Mechanics, Kyushu University

Introduction

Thermal infrared observations of the sea surface temperature (SST) from satellites are important for understanding the ocean. However, the use of satellites is still difficult for observing coastal oceanic process with small spatio-temporal scales. The purpose of this study is to use drones and observe ocean color and SST distributions of the coastal area with a spatial resolution of about a few centimeters. Drones can be used for remote sensing of the sea surface from an altitude less than 150m.

Observation

On September 11, 2018, we conducted observations of the coastal ocean at the Iyonada of the western Seto inland sea and the Hiji river using the Ehime University research ship “Isana”. We used drone-mounted visible and infrared cameras and took images of the sea surface from 100m above the sea level. A total of 18 images were acquired over the observation time of about 7 minutes. The area covered by each image of the visible image and the infrared image are 100 m ×70 m and 80 m ×60 m, respectively. We also pursued CTD observations at the same time to examine the oceanic structure across the front.

Result and Discussion

In the observed infrared image, we found vignetting, which is a difference in brightness from the center to the periphery of the image. Therefore, we will need to remove this impact of vignetting to understand the actual SST distribution. Observed visible image showed the river plume clearly so we are currently working to detect the location of the front that matches with the infrared image. We plan to present the microstructure of the front found in the visible and infrared images. We also plan to compare the vertical cross section of the front obtained from CTD data with the sea surface temperature observed in the infrared image.

Numerical simulation of typhoon storm surge in the LUOYUAN Bay

*Nan Yuan[1], Humio Mitsudera [1]

1. Hokkaido University, the Institute of Low Temperature Science

According to the statistics of China Marine Disaster Bulletin published in May 2018, from 2008 to 2017, around 100 billion financial loss happened in each year due to marine disasters. Over 80% loss was caused by storm surges. Further, unfortunately, the FUJIAN Province is a place they prefer to visit. The research area, the LUOYUAN bay, is located on the northeastern area of the FUJIAN Province, which was so inconspicuous that not so many researchers concerned the storm surges happened there. However, it brings demands of study with the increase of financial developments and people’s settling down in this area. Therefore, this research started.

For studying the response of the sea level in this area to a storm, a high-resolution model with the ADvanced CIRCulation model (ADCIRC) was established first. It used unstructured fine grids, and the topography from electronical chart partially and coastline data with resolution 1:10000. By comparing the simulated water level with the observation, we can see that both match with each other quite well. Furthermore, via harmonic analysis and contrasting with previous studies, the accuracy of this model was verified.

Based on the model, some experiments were conducted to assess the response inside of the bay to different kinds of typhoon, primarily with different intensities on the north-south (N-S) moving path, and the northwest-southeast (NW-SE) moving path. Results are as follows. On the one hand, there are common features we can understand easily: the surge increases gradually with the strength of typhoons, and the peak-value surge can reach approximately 3 meters if a typhoon landed as a SUPER TYPHOON; the low pressure of a typhoon and strong wind will lead to a surge, and this surge would be more obvious when the typhoon passes near coastal areas; because of the cyclonic structure of a typhoon, it is easier for a typhoon that moves on an offshore path to induce the rising of water level on the southern part of bay than the northern part. On the other hand, there are also other findings that might be difficult to understand just by imagination: for the N-S path, there is a steep reduction of the sea level inside of the bay after the peak-value time. Such a rapid reduction of sea levels does not happen for the NW-SE path but for those in the southern area along the FUJIAN Province. By analyzing the data, we consider that wind direction and the shape of the bay would be the main reasons causing this phenomenon. Further, there is an oscillation in the sea level after peak-value time for the typhoon on the N-S path, and a larger reduction exists inside of the bay than the outside. Resonance between the different frequency of sea level changes, caused by various moving speeds of typhoons, and the local natural frequency of the bay might have some effects. We attempt to investigate resonance for the future study. The experiments with various parallel paths to the N-S path, as well as those parallel to the NW-SE path, also give similar results.

Laboratory and numerical experiments on the ballooning of river-plume bulge

*fujita yusuke[1], Atsuhiko Isobe[2]

1. interdiscipinary graduate school of engineering science, Kyushu Univercity, 2. Research Institude for Applied Mechanics Kyushu Univ

Ballooning (infinitely growing) of river-plume bulges are observed only in laboratory and numerical experiments, but in the actual ocean we have no infinitely growing bulges. Thus, the mechanism of river-plume bulges remains obscure in detail. In this study, we focus on the dependence of growing rate of a bulge on the curvature of the line connecting estuary axis and coastline (i.e., the curvature of river-plume release) to elucidate the mechanism to cause the ballooning. First, we conducted a rotating water tank experiments under an extreme condition. Namely, we adopted two curvature: The one is that a coastline lies in parallel with the estuary axis (infinite curvature radius), and the other is that the coastline takes a right angle to the estuarine axis (null curvature radius). In the experiment with the right angle, the ballooning of river-plume bulge was observed as observed in conventional experiments. Meanwhile, when the angle between the coastline and estuarine axis was parallel, the bulge formation was not observed. We next conducted experiments using a numerical model that we could control the parameters governing fluid motion to clarify the mechanism of the ballooning. We adopted unstructured Finite Volume Coastal Ocean Model in which we can freely change the curvature using triangle cell grids.

Seasonal productions of dinoflagellate cysts in relation to environmental characteristics in Jinhae-Masan Bay, Korea: One year sediment trap observation

*Hyeon Ho Shin[1]

1. Korea Institute of Ocean Science and Technology

To investigate dinoflagellate cyst production and seasonality in relation to major environmental factors, such as water temperature, salinity, chlorophyll-*a* (chl-*a*) and dissolved nutrients, and to propose dinoflagellate cysts as possible biological indicators for the reconstruction of past environmental conditions, a sediment trap study was conducted for one year, from March 2011 to February 2012, in Jinhae-Masan Bay, Korea. Marked increases in dinoflagellate cyst production were documented in Jinhae-Masna Bay during two distinct seasons (summer and late autumn) characterized by different environmental conditions. Summer (July and August) was characterized by relatively high water temperature, dissolved inorganic nitrogen (DIN), and chl-*a* concentrations and low salinity, whereas late autumn (November and December) exhibited high dissolved inorganic phosphorus, low water temperature and high salinity, compared to those of the summer. Fourteen dinoflagellate cyst taxa were identified. These assemblages were dominated by *Brigantedinium* species (round brown cyst), cysts of *Scrippsiella* species, *Spiniferites* species and cysts of *Alexandrium* species (ellipsoidal cyst). The total flux of dinoflagellate cysts ranged from 781 cysts m^{-2} day^{-1} to 5,602 cysts m^{-2} day^{-1}, and the production of autotrophic dinoflagellate cysts was mainly restricted to the warmest months (July-September) and autumn. Multivariable analysis revealed that the production of major dinoflagellate cysts, excluding those of *Brigantedinium* species, can be enhanced by environmental conditions during summer in Jinhae-Masan Bay. In particular, the increased production of cysts of *Scrippsiella* species was related to increased water temperature, and the increased production production of *Spiniferites* species was associated with lower salinity. Two peaks in cyst production of *Alexandrium* species in August and November corresponded with significant increases in DIN and DIP; however, no significant relationship was found between the production of *Brigantedinium* species and environmental factors in Jinhae-Masan Bay. These results suggest that the cysts of *Scrippsiella* species, *Spiniferites* species and cysts of *Alexandrium* species present in sediment samples from Jinhae-Masan Bay can be used as biological indicators to reconstruct past environmental conditions involving relatively high water temperature, low salinity and enhanced nutrient level.

The ocean is storing between a fourth and a third of anthropogenic CO_2 (C_{anth}) emissions. Monitoring the oceanic CO_2 sink is critical to assessing the global carbon budget. We estimate total C_{anth} storage and accumulation rates from 14 Pacific hydrographic sections that have been occupied two to four times over the past decades, with most sections having been recently measured as part of the Global Ocean Hydrographic Investigations Program (GO-SHIP). The C_{anth} sink over the top 1500 m of the Pacific increased from 8.6 (±1.1, 1 σ) Pg of carbon decade^{-1} from 1995 to 2005 to 10.8 (±1.1) PgC decade^{-1} from 2005 to 2015. We estimate 1.2 of this observed 2.2 PgC decade^{-1} increase in the rate of accumulation between decades is attributable to atmospheric anthropogenic CO_2 increases alone, while the remaining increase is consistent with recent literature suggesting there was an increase in the ocean carbon sink during the mid-2000s. Methods that allow for analysis of multiple occupations of sections and comparisons between different sections spaced irregularly in time are introduced. The accuracy of the resulting C_{anth} accumulation reconstructions is limited by the accuracy of the data, suggesting that a continuation of repeat hydrographic surveys with a high emphasis on obtaining multiple independent realizations of the most accurate possible measurements is a critical piece of future carbon cycle monitoring.

Spatio-temporal variability of surface water pCO2 and nutrients in the tropical Pacific from 1981 to 2015

*Sayaka Yasunaka[1], Shinya Kouketsu[1], P.G. Strutton[2], A.J. Sutton[3], Akihiko Murata[1], Shin-ichiro Nakaoka[4], Yukihiro Nojiri[4]

1. Japan Agency for Marine-Earth Science and Technology, 2. University of Tasmania, 3. NOAA, 4. NIES

We present a synthesis of surface water partial pressure of CO_2 (pCO_2) and nutrient observations in the tropical Pacific from 1981 to 2015. The e-folding scale for interannual variability of pCO_2 is estimated to be 6˚ in latitude, 13˚ in longitude, and 2 months with a signal-to-noise ratio of 4. When El Niño occurs, pCO_2 along the equator is reduced due to weakening of the easterly wind and reduced upwelling of CO_2 rich subsurface water. The surface seawater pCO_2 trend is positive in all regions with an area average of 1.8 ±0.1 μatm/yr. However, along the equator the trend is > 2 μatm/yr linked to the Pacific Decadal Oscillation forcing. Surface nutrient concentrations in the central to eastern tropics along the equator decreased during El Niño periods, but there are not enough data to characterize the trends of nutrients in the tropical Pacific.

We present a synthesis of surface water partial pressure of CO_2 (pCO_2) and nutrient observations in the tropical Pacific from 1981 to 2015. The e-folding scale for interannual variability of pCO_2 is estimated to be 6˚ in latitude, 13˚ in longitude, and 2 months with a signal-to-noise ratio of 4. When El Niño occurs, pCO_2 along the equator is reduced due to weakening of the easterly wind and reduced upwelling of CO_2 rich subsurface water. The surface seawater pCO_2 trend is positive in all regions with an area average of 1.8 ±0.1 μatm/yr. However, along the equator the trend is > 2 μatm/yr linked to the Pacific Decadal Oscillation forcing. Surface nutrient concentrations in the central to eastern tropics along the equator decreased during El Niño periods, but there are not enough data to characterize the trends of nutrients in the tropical Pacific.

1. Japan Meteorological Agency, 2. Meteorological Research Institute, Japan Meteorological Agency

The atmospheric concentration of carbon dioxide (CO_2) has reached 146% of the pre-industrial level resulting from the increase of CO_2 emissions by human activities. On the other hand, the ocean has absorbed about 30% of the anthropogenic CO_2, which leads to the regulation of the atmospheric CO_2 increase (IPCC, 2013). Midorikawa et al. (2012) found that the increase of the partial pressure of oceanic CO_2 (pCO_2^{sea}) along 137˚E recently decelerates though that of atmospheric CO_2 accelerates. The variability of pCO_2^{sea} is affected by the changes in sea surface temperature and salinity, dissolved inorganic carbon (DIC), and total alkalinity, and the investigation of the DIC changes in the surface seawater helps us to understand the oceanic absorption of atmospheric CO_2. In this study, the variability of DIC in surface seawater is examined from subarctic to equatorial region along 165˚E, one of the repeat hydrographic sections of Japan Meteorological Agency (JMA).

Using the observation data collected by JMA’ s Research Vessels in the 165˚E section and surface ocean CO_2 atlas (SOCAT) version 6, we calculated the mean trend of DIC in surface seawater during the period of 1996-2017. We found that DIC increases slower around 10˚N, and faster around 30˚N than atmospheric CO_2. Also, DIC growth rate is similar to the rate of atmospheric CO_2 increase in the equatorial region.

The variability of the DIC trend averaged for 10 years indicates that the DIC growth rate has increased in the equatorial region and decreased around 30˚N.

Assuming that the CO_2 above the surface mixed layer depth (MLD) mixes very well with air, we used a simple and new method to estimate air-sea CO_2 disequilibrium value at the MLD (C_{diseq}) as follow [*Li et al.*, 2019];

$$C_{diseq} = C_{MLD} - C_{sat,\,MLD} - C_{soft,\,MLD} - C_{carb,\,MLD}$$

where C_{MLD} is the observed dissolved inorganic carbon (DIC); $C_{sat,\,MLD}$ is saturated DIC; $C_{soft,\,MLD}$ is derived from the remineralization of organic matter; $C_{carb,\,MLD}$ is derived from the dissolution of $CaCO_3$ in the MLD. We collected the DIC and total alkalinity (TA) samples in the subarctic North Pacific in four seasons, and measured all the DIC and TA by using semi-closed cell simultaneous method [*Li et al.*, 2016].

C_{diseq} in this region changed from −38.29 to −56.93 μmol kg^{-1} in wintertime and from −9.65 to 1.02 μmol kg^{-1} summertime, indicating a strong seasonal change in C_{diseq}. Appling these values of C_{diseq} to the approach for estimating C_{ant} in this region, we also found a strong seasonal variation in C_{ant}.

An evaluation of current and future ocean acidification based on pCO_2 database around Okinawa Island

*Naohiro Kosugi[1], Hiroyuki Tsujino[1], Masao Ishii[1]

1. Meteorological Research Institute

1. Introduction

Ocean acidification is caused by the dissolution of anthropogenic CO_2 into seawater. When CO_2 is dissolved in seawater, pH and the carbonate ion concentration decrease. A variety of marine organisms may be adversely affected since they use calcium carbonate as the main component of hard tissues such as shells and skeletons.

Coral reefs in the tropical zone are thought to be vulnerable to ocean acidification as they have a skeleton of aragonite which is a form of calcium carbonate. Ocean acidification will have adverse impacts on not only coral reefs but also whole tropical ecosystem since coral reefs are important for spawning, hatching, and habitat for many organisms.

Many coral reefs exist around Okinawa and bring a lot of benefits there by fishery and tourism. Geographically, coral reefs around Okinawa are located at the higher latitudinal area where the water temperature drops largely in winter.

In this study, we use the Surface Ocean CO_2 Atlas (SOCAT) database to evaluate the progress of ocean acidification around Okinawa from the 1980s to the present. Based on the results, we project the progress of acidification under future CO_2 concentration scenarios. This projection will reproduce seasonal variation in pCO_2 and aragonite saturation (Ω_A) there more realistically than existing predictions on a global scale.

2. Methods

The data of surface water temperature (SST), salinity (SSS) and pCO_2 around Okinawa (24-30˚N, 123-130˚E) were extracted from SOCAT database. We used the results of hydrographic observations conducted by the Japan Meteorological Agency in the same area between 2010 and 2017 in order to derive an empirical equation between salinity and total alkalinity (TA). Ω_A were calculated from pCO_2 and estimated TA using the CO2SYS program.

3. Results

In 1982-2016, pCO_2 showed a long-term trend of increase (Fig. a). At the same time, pCO_2 was high in summer and low in winter. Long-term and seasonal variation in pCO_2 was separated by using the method by Ishii et al., [2011]. As a result, the component of the long-term trend was +1.49±0.26 μatm/year (95% CI). This was as high as the rate of increase in atmospheric pCO_2 at Mauna Loa in Hawaii in the same period (+1.73±0.04 μatm/year).

TA was basically proportional to salinity (TA = 2297.1 / SSS * 35). In some areas near the shelf in the East China Sea, however, there was a positive anomaly from this relation. This may be due to the influence of river water originated from the Changjiang River. Another equation was applied (TA = 1347 + 897.6 / 34.2 * SSS) to the data to the north of 26˚N with SSS < 34.2 from July to September.

As for Ω_A, a long-term trend -0.0102±0.0018/year was calculated in the same manner as pCO_2. Previous studies showed that the coral reef habitat coincided with the area where Ω_A does not fall seasonally below 3.0 [Kleypas et al., 1999]. In the present situation, Ω_A around Okinawa island (SST > 21˚C in winter) was kept at 3.0 or more throughout the year.

©2019. Japan Geoscience Union. All Right Reserved.

4. Future projections
We can project the fluctuation in the ocean pCO_2 and Ω_A under future CO_2 concentration scenarios assuming that the current difference between in pCO_2 in the atmosphere and the ocean (ΔpCO_2) will not change in the future. Monthly ΔpCO_2 was averaged from the SOCAT database. CO_2 concentrations for the Representative Concentration Pathways (RCPs) were used to calculate atmospheric pCO_2 up to 2100 [Meinshausen et al., 2011]. Climatology of SST and SSS from 1982 to 2014 was calculated from Northwest Pacific Ocean Long-term Reanalysis Data Set (FORA-WNP30) and applied to the prediction. In the RCP 2.6 scenario, Ω_A will be at 3.0 or larger during this century. However, in the RCP 8.5 scenario, Ω_A will drop seasonally below 3.0 in the north of Okinawa island around 2030. In that scenario, Ω_A will be lower than 3.0 throughout the year in the 2060s (Fig. C). If the current increase in atmospheric CO_2 continues, coral reefs around Okinawa will be seriously affected by ocean acidification in the near future. On the other hand, there is a possibility that a suitable environment for coral reefs around Okinawa can be maintained under a strict emission reduction.

Reconstruction of spatiotemporal change of anthropogenic fixed nitrogen in the western North Pacific

*Yutaka Watanabe[1], Kouichi Fujita[1], BOFENG LI[1]

1. Hokkaido University

We constructed parameterizations for the estimation of ocean fixed nitrogen (N) in the western North Pacific. Parameterizations (N_p), determined as a function of temperature (T), potential density (sigma-theta) and dissolved oxygen (DO), provided strong correlations with direct measurements for ocean nitrogen (N_p = −2.24T −4.70sigma-theta −0.0970DO + 182.2; the coefficient of determination (r^2) = 0.988; the root mean square error (RMSE) = 1.25 umol kg^{-1}). Predicted N values were consistent with previous independent hydrographic observations, generally within the above error. By applying T, sigma-theta and DO time-series data from ship observations to our parameterization, large seasonal variations in N were demonstrated in detail. Using the parameterization technique along with the time series of observed N (N_{obs}) found the significant increasing rate of oceanic anthropogenic fixed nitrogen (N_{anth}) in the past four decades in the western North Pacific subtropical region.

On the mechanism of significant increasing trend of silicate in intermediate layer of Oyashio region

*Tsuneo Ono[1]

1. Fisheries Research and Education Agency

A large multi-decadal increasing trend of Silicate was found in the intermediate later of Oyashio region [Whitney et al., 2013]. The rate of silicate increase was significantly rather than those observed in other nutrients under the asamption of normal Redfield ratio, but mechanism of such large Si increase has long remaind unknown.
Here, I demonstrate that the observed silicate increase can be exprained by the facts that 1)Rapid warming of intermediate waters of Okhotsk Sea had deepen isopycnal surfaces and 2)this causes steep increase of silicate concentration in the water that mixes with Oyashio waters on a same density surface.

Systematics of aluminum, manganese, iron, cobalt, and lead in the North Pacific Ocean observed during ocean-section study of GEOTRACES Japan

*Yoshiki Sohrin[1], Linjie Zheng[1]

1. Institute for Chemical Research, Kyoto University

Trace metals in seawater are critical parameters in oceanography as trace nutrients for organisms, tracers in the modern ocean, and proxies in paleoceanography [1]. The international study programme GEOTRACES based on intercalibrated methods is revealing global distributions and temporal variations of trace metals in the ocean (http://www.geotraces.org). We have developed a method for multielemental determination of Al, Mn, Fe, Co, Ni, Cu, Zn, Cd, and Pb in seawater using NOBIS Chelate-PA1 resin [2, 3], and revealed basin-scale and full-depth sectional distributions of the trace metals in the North Pacific during three GEOTRACES Japan cruises of R/V Hakuho Maru: a 160°W section during KH-05-2, a 165°E section (GP18) during KH-11-7, and a 47°N section (GP02) during KH-12-4. The elements showed different speciations and distributions. The fraction of labile particulate (lp) species was calculated as the difference between the total dissolvable (td) species and dissolved (d) species. The lpM/tdM ratio, where M refers to an element, is highest for Al, at 0.66 ±0.31 (average ±sd, *n*= 489), and lowest for Pb, at 0.02 ± 0.08 (*n*= 575). The distribution of each element is uniquely related to ocean circulation. We propose that the enrichment factor of dM, defined as *EF*(dM) = $(dM/dAl)_{seawater}/(M/Al)_{upper\ crust}$, where $(M/Al)_{upper\ crust}$ is the molar ratio in upper crustal abundance, can be a good parameter for the sources. As an example, the *EF*(dPb) found in this study is on the same order of magnitude as the *EF* values for aerosols found in the literature, suggesting that the deposition of aerosols is a major source for dPb. The lpFe dominates tdFe and is strongly correlated with lpAl: lpFe = 0.543 lpAl −0.12, r^2= 0.968, *n*= 510. The results also indicate that the dFe concentration corrected for lithogenic contribution improves the linear relationship with phosphate. Thus, we suggest that the mechanism controlling a scavenged element of Al significantly affects the biogeochemistry of Fe. Based on the concurrent observation of these metals, we confirm that the width of the boundary scavenging zone is approximately 500 km off the Aleutian shelf. We estimate an inventory of tdFe in the North Pacific as 1.1 ×10^{12}mol, and this is approximately four times that of dFe. The results emphasise the potential importance of lpFe in the ocean iron cycle.

Mon. May 27, 2019 9:00 AM - 10:30 AM JST | Mon. May 27, 2019 12:00 AM - 1:30 AM UTC | 301A 3F

[A-OS19] Dynamics of oceanic and atmospheric waves, vortices, and circulations

convener:Yuki Tanaka(Graduate School of Science, The University of Tokyo), Ryo Furue(APL/JAMSTEC), Yukiharu Hisaki(University of the Ryukyus), Norihiko Sugimoto(Keio University, Department of Physics), Chairperson:Norihiko Sugimoto, Ryo Furue

Oceanic and atmospheric dynamics aims at abstracting general principles from observed phenomena and constructing a system of mathematical models, thereby leading to the understanding, prediction, and parameterization of those phenomena. It provides perspectives for the advancement of sciences in various areas such as wind waves, swells, internal waves, Rossby waves, equatorial waves, tides, eddies, meandering of jets and fronts, general circulation, boundary layers, and ocean-atmosphere coupled modes. It has also been and will continue to be benefited by new uses of ideas and methods from such theories as resonance, nonlinear interaction, spectral analysis, probability, statistics, and dynamical systems. In this session, we solicit presentations on observational, experimental, numerical, and theoretical studies of oceanic and atmospheric dynamics and on exploratory use of new ideas and methods. We also welcome presentations on interdisciplinary studies in fields such as ecosystems, climate, and environment.

This study derived Ekman pumping velocity without assuming that the velocity in the free atmosphere is not slow to be neglected and not homogeneous. Unlike the classic solution that is widely recognized, the solution can be unstable when the flow in the free atmosphere satisfies some conditions. The solution shows that the flow is more likely unstable when the velocity is fast and spatial variation of relative vorticity is large. One example that would be applied to Earth’ s atmosphere is secondary eyewall formation in tropical cyclone, which has been one of the hottest topics in typhoon research field in the last decades. The authors successfully showed the secondary eyewall formation in simulated cyclones is attributed to the Ekman pumping instability.

Extratropical Cyclone Structures around Japan -Comparison between Extratropical Cyclones Developing around Japan and those in Northwestern Atlantic Ocean-

*Eigo Tochimoto[1], Hiroshi Niino[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

Extratropical cyclones (ECs), which have horizontal scale of several thousands and time scale of a week, develop mainly in mid-latitude. They affect daily weather and sometimes cause extreme rainfall and severe winds, which result in meteorological disasters. ECs also affect climate variability: They interact with low-frequency variability such as North Atlantic oscillation. It is also pointed out that diabatic effects associated with ECs contribute to the initiation of atmospheric blocking.

Generally, there are two major conceptual model of ECs. The first model is Norwegian model, which was proposed in the beginning of 20 century. In this model, cold fronts catch up with warm fronts, and then occluded fronts form in the mature stage of ECs. The second model is Shapiro-Keyser model, which was proposed in 1990’s. In this model, an occluded front does not form, and bentback fronts extending rearward from the EC center develop. These two conceptual models are proposed mainly with the results of studies in the Northwestern Atlantic Ocean and Europe. Although the Northwestern Pacific is one of the major storm tracks, difference in EC structures between Northwestern Atlantic and Northwestern Pacific Oceans have not been well understood. In addition, a considerable number of ECs also passes over the Sea of Japan and Okhotsk Sea. Thus, the objective of our study is to clarify the differences in structures between ECs that develop around Japan and those develop in Atlantic Ocean

Firstly, ECs are automatically detected with the tracking method developed by Hodges (1994, 1995, 1999). Secondly, ECs that develop in Okhotsk Sea or the Sea of Japan (OJC), Northwestern Pacific (POC) and Northwestern Atlantic (AOC) were selected based on the locations where the ECs underwent the maximum deepening rate (in Bergeron; Sanders and Gyakum 1980). In the present study, only ECs with Bergeron larger than 0.5 are used to examine the structures of fully-developing ECs. In the composite analysis, physical variables are superposed with respect to the cyclone center. Furthermore, to examine differences in frontal characteristics between POCs and AOCs, atmospheric fronts are objectively detected with a method using thermal front parameter (e.g., Schemm et al. 2015).

The composite analysis shows clear differences in structures between OJCs, POCs and AOCs: OJCs have relatively strong cold fronts compared to warm fronts at KT, especially in Spring. On the other hand, both warm and cold fronts develop well for POCs and AOCs. Differences in frontal characteristics between POCs and AOCs are most notable in warm fronts. Warm fronts for AOCs tend to extend eastward or east-northeastward from the EC center, while those for POCs southeastward. It is also noted that bentback fronts for AOCs are stronger than those for POCs.

An analysis using a frontogenesis function shows that this difference in warm front is mainly due to the effect of shear deformation: the shear deformation in the southeast quadrant of POCs is larger than that of AOCs, resulting in development of the warm fronts in the southeast quadrant of the EC center for POCs, which are most notable in warm fronts.

Application of a new wave energy flux formulation to assessment of tropical wave propagation dynamics: Diagnostics for the tropical synoptic-scale wave disturbances in the Maritime Continent-northern Australian region

*Fukutomi Yoshiki[1], Hidenori Aiki[1]

1. Institute for Space-Earth Environmental Reasearch, Nagoya University

A two-dimensional (horizontal) wave energy flux (WEF) formulation derived by Aiki et al. (2017, PEPS) is used to diagnose the dynamics of the tropical synoptic-scale waves (TSWs) propagating across the Maritime Continent and northern Australian (MCNA) region. The new WEF vectors are considered to be useful to assess energy dispersion characteristics of various types of waves in both the tropics and extratropics. The WEF is defined by adding a rotational flux term that includes Ertel potential vorticity (EPV)-based flow to the eddy geopotential flux. We computed eddy components of EPV-based stream function and corresponding wind fields from the atmospheric reanalysis (JRA-55) data using a numerical inversion technique to estimate the additional rotational flux term. The TSWs analyzed in this study have periods of about 2-8 days and zonal wavelengths of about 3000-4000 km (Fukutomi 2018, submitted to JGR). These waves propagate westward at approximately 8 m/s along the mean monsoon westerly flow extending from the Indian Ocean to the western Pacific. Wave troughs and ridges form a well-organized wave train in the MCNA region. Eastward amplification of wave troughs and ridges due to group propagation occurs along the monsoon westerly flow. WEF diagnostics confirm that wave energy propagation facilitates the downstream development of the synoptic-scale wave train and the mean monsoon westerly flow acts as a tropical waveguide. Distribution and behavior of the WEF vectors are compared with those of traditional wave activity and energy flux vectors. Applicability of this new tool to other types of the tropical waves and extratropical waves is also discussed.

Direct measurement of turbulent fluxes at sea-air interface by micrometeorological technique

*Fumiyoshi Kondo[1], Shujiro Komiya[2], Kosuke Noborio[3], Hidenori Aiki[4], Kunio Kutsuwada[5], Mitsuo Uematsu[6], Osamu Tsukamoto[7]

1. Japan Coast Guard Academy, 2. Max Planck Institute for Biogeochemistry, 3. Meiji University, 4. Nagoya University , 5. Tokai University, 6. The University of Tokyo, 7. Okayama University

Accurate parameterizations of sea–air momentum, sensible and latent heats, trace gases (e.g. greenhouse gases including CO_2 and CH_4), and aerosol fluxes are important in sea–air interaction. Coupled ocean–atmosphere global climate models require high accuracy of the net surface heat flux for the prediction of climate change, and process–based understanding of particle formation from bubble bursting to realistically predict the climate effect of marine aerosols. Precise measurements of the CO_2 gas transfer across the air–sea interface provide a better understanding of the global carbon cycle. The eddy covariance technique is the definitive method to directly determine these sea–air fluxes, but it requires measurements of the vertical and downwind components of air velocity, air temperature, humidity, trace gases, and aerosol over a sufficiently long averaging period (> 30 min) and with sufficient frequency response (< 10 Hz). One of the greatest difficulties in measuring sea–air flux by the eddy covariance technique over the open ocean is the apparent wind velocity caused by the wave–induced platform motion. As a result, the uncorrected eddy covariance results are all strongly biased, and especially represent unrealistic momentum fluxes. Improved ship motion correction scheme with Kalman filter results in a significant reduction in both the bias and the scatter of momentum fluxes. Previous studies over the oceans have shown that the eddy covariance CO_2 flux was larger than the bulk CO_2 flux estimated by the mass balance technique. Our results suggest that the density correction due to the air pressure fluctuation, which is assumed to be negligible in the WPL correction, is required to evaluate the accurate eddy covariance CO_2 flux over the ocean.

Swell-Dominant Surface Waves Inherent in the Shape of the Rias Coast facing the western North Pacific

*Kosei Komatsu[1,2], Takaki Fujii[1,2], Kiyoshi Tanaka[2]

1. Graduate School of Frontier Sciences, The University of Tokyo, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Real-time monitoring of wind and surface waves in Otsuchi Bay, a ria located in the northeastern portion of Japan, had been continued over four years since October 2012, using a mooring buoy with an ultrasonic anemometer and a single-mode GPS wave sensor. The monitoring revealed that waves in the bay were dominated by swells propagated from the northeastern offshore region in all seasons. Time-lag correlation coefficient between the significant wave height in the bay and the offshore wind velocity component blowing in the direction to the bay was maximized in the region approximately 300 km northeast of the bay, from which waves developed by the local wind are accessible within the corresponding time-lag to the bay at a speed of the group velocity of the swell observed in the bay. As an interesting feature common to swell-dominant waves observed in the rias bays adjacent to Otsuchi Bay, the region of the significant correlation between the wave height and the offshore wind velocity extends to the direction that faces the bay mouth. It implies that the source region of the swell depends heavily on the coastal shape of the bay. Consequently, the relation between the offshore wind field and the decay-rate of the swells propagating to Otsuchi Bay indicates that the source region of the swell influential in the bay is located in the offshore region several hundreds of kilometers northeast of the bay, which is on the typical migration route of high and low pressures in the Northern temperate zone.

Variabilities of the Sea Surface Height in the Kuril Basin of the Okhotsk Sea: Coherent shelf-trapped mode and Rossby wave-like mode

*Vigan Mensah[1], Kay I. Ohshima[1]

1. Institute of Low Temperature Science

Time series analysis of Sea Surface Height anomaly (SSHa) is conducted in the Kuril Basin of the Sea of Okhotsk. The mapping methodology of the satellite-derived SSHa data is optimized to mitigate the effects of sea ice on the SSHa field during winter and the early spring. In particular, we found that conducting an objective mapping of along-track SSHa data with correlation length and time scales adapted to the Kuril Basin considerably reduces the number of missing data days in this region. A Complex Empirical Orthogonal Functions (CEOF) is then used to analyze the SSHa field, and the first 3 modes, representing 54 % of the total variability are delineated here. The focus is brought on the first and third modes. The first mode mainly represents the coherent variability trapped over the shelves all along the coast and Kuril Islands. Both seasonal (high over the shelves in winter) and interannual variations are strongly correlated with the alongshore wind stress. These variations can be well explained by the arrested topographic waves. The third mode is a propagating mode, with trains of southwestward propagating anomalies. Their characteristics are consistent with those of westward propagating Rossby waves, whose energy propagates from the Kuril Straits towards the Kuril Basin.

[A-OS19] Dynamics of oceanic and atmospheric waves, vortices, and circulations

convener:Yuki Tanaka(Graduate School of Science, The University of Tokyo), Ryo Furue(APL/JAMSTEC), Yukiharu Hisaki(University of the Ryukyus), Norihiko Sugimoto(Keio University, Department of Physics), Chairperson:Yukiharu Hisaki(琉球大学理学部), Hidenori AIKI

Oceanic and atmospheric dynamics aims at abstracting general principles from observed phenomena and constructing a system of mathematical models, thereby leading to the understanding, prediction, and parameterization of those phenomena. It provides perspectives for the advancement of sciences in various areas such as wind waves, swells, internal waves, Rossby waves, equatorial waves, tides, eddies, meandering of jets and fronts, general circulation, boundary layers, and ocean-atmosphere coupled modes. It has also been and will continue to be benefited by new uses of ideas and methods from such theories as resonance, nonlinear interaction, spectral analysis, probability, statistics, and dynamical systems. In this session, we solicit presentations on observational, experimental, numerical, and theoretical studies of oceanic and atmospheric dynamics and on exploratory use of new ideas and methods. We also welcome presentations on interdisciplinary studies in fields such as ecosystems, climate, and environment.

Dynamics of water exchange processes at a deep submarine canyon off the western coast of the Sakhaline which causes the origin of the cold water belt along the Soya Warm Current

*Humio Mitsudera[1], Hiroyuki Iida[2]

1. Institute of Low Temperature Science, Hokkaido University, 2. Graduate School of Environmental Science

A cold water belt (CWB) is observed off the Soya Warm Current, the former of which appears from the west coast of the Sakhaline Island. Observations of the CWB (Kuma et al., 2016; Iida et al., 2018) indicates that the CWB, characterized by a cold and saline water (temperature 7℃, and salinity 34.0), is derived from the lower part of the thermocline in the Japan Sea basin. This implies that the cold and saline water in the Japan Sea basin should overcome the shelf break, which is not easy in general, and be transported to the vicinity of the coast of Sakhaline. The aim of this study is to elucidate mechanisms of water exchange between the Japan Sea basin (continental slope) and the continental shelf.

We first analyzed the output of a general circulation model OFES with the 1/30° resolution. It was found that the water over the continental slope enters the continental slope at a deep submarine canyon off the Kholmsk city on the west coast of the Sakhaline. Further, a barotropic model using Princeton Ocean Model (POM) with a realistic topography shows the exchange at the canyon in a similar manner to OFES, even though water exchange would not readily occur at the shelf break because of a potential vorticity (PV) barrier. We thus conducted numerical experiments using idealized topographic features mimicing the canyon off the Kholmsk in order to understand the barotropic exchange processes. The throughflow across the Soya Strait occurs owing to the adjustment of sea level difference between the Japan Sea and the Sea of Okhotsk by long shelf waves. It was found that the shelf waves are scattered into the second and third mode waves at the canyon, which have large transport over the continental slope; the scattered flow over the continental slope directed southward, and enters the continental shelf at the canyon. Further, nonlinearity is important in the vicinity of the canyon during the scattering process. Specifically: 1) nonlinearity produces a wave guide across the shelf break overcoming the PV barrier, by bringing low PV water from the continental slope to the continental shelf; 2) High-order mode waves (higher than 4^{th} mode) are retarded from propagation because of the background flow caused by 1^{st} -3^{rd} modes, making the flow over the continental slope steady. The nonlinear steady flow over the slope upwells at the canyon and connects to the flow over the shelf, and consequently flows through the strait.

Finally. hydrographic data during 1960-1985, archived at the Japan Hydrographic Data Center, was analyzed. Potential temperature and salinity from July to October was used. It was confirmed that the upwelling occurs at the canyon off the Kholmsk.

Generation Mechanism of Tropical Instability Waves in the Equatorial Pacific Ocean

*Yuki Tanaka[1], Toshiyuki Hibiya[1]

1. Graduate School of Science, The University of Tokyo

Tropical instability waves (TIWs) are prominent features observed in the eastern to central equatorial Pacific, which typically have a wavelength of ~1000 km and a period of ~25 days, propagating westward at a speed of ~0.5 m/s. Although TIWs are thought to be generated by meridional shear between the westward-flowing South Equatorial Current (SEC) and the eastward-flowing North Equatorial Countercurrent (NECC), the decisive parameter responsible for the occurrence of the instability has not yet been fully understood. Because the meridional and vertical momentum and heat transfer by TIWs are essential to drive the equatorial ocean circulation and affect the air-sea interactions related to the global climate, a better understanding of the generation mechanism of the TIWs is prerequisite for improving models' capability to predict climate variations.

In this study, we show that a linear stability analysis using a 1.5-layer shallow water model with a zonal mean flow on the equatorial beta plane can successfully predict an unstable mode whose phase speed and meridional structure are both very similar to those of the TIWs simulated in an eddy-resolving ocean general circulation model (OGCM), although the wavelength and the growth rate are somewhat larger and smaller, respectively. This unstable mode can be interpreted as resulting from a coupling between a Rossby wave propagating eastward in the negative potential vorticity (PV) gradient just north of the equator (~1°–3.5°N) while advected westward by the SEC, and a Rossby wave propagating westward in the positive PV gradient further north (~3.5°–8°N) while weakly advected eastward by the NECC. The unstable mode tends to have smaller growth rate as the negative PV gradient becomes weaker, and even disappears when it is completely absent.

The negative PV gradient just north of the equator thus plays an essential role in forming the unstable mode. Actually, the seasonal and interannual variability of the TIWs simulated in the OGCM is shown to be significantly controlled by the strength of the negative PV gradient, suggesting the possibility that it can serve as a key parameter for a dynamically based parameterization of the heat and momentum transfer associated with TIWs in coarse-resolution OGCMs.

Annual Rossby waves below the pycnocline in the Indian Ocean

*Motoki Nagura[1]

1. Japan Agency for Marine-Earth Science and Technology

In-situ observations in the Indian Ocean had long been limited to sporadic ship observations, which hampered the progress of observational research of basin-wide circulation and variability. The implementation of Argo profiling float program since 2004 dramatically improved this situation, and now abundant in-situ observations obtained from Argo floats are available. This study uses the resulting temperature and salinity observations between the sea surface and 2000 m depth and float trajectories at 1000 m depth to examine annual variability in pressure and horizontal velocity. Annual variability below the pycnocline is large in amplitude in the Arabian Sea and between 10˚S and 20˚S in the South Indian Ocean. Wavenumbers were estimated by fitting a straight line to annual harmonic phase. Results showed that vertical wavenumber tends to decrease poleward in both hemispheres, and vertical wavelength is more than tripled from about 5,000 m at 5˚N/S to 16,000 m at 20˚N/S. The inverse radius of deformation squared (defined as f^2m^2/N^2) does not show clear dependence on latitude, because poleward increase in the magnitude of the Coriolis parameter (f) compensates for poleward decrease in vertical wavenumber (m), and Brunt-Väisälä frequency (N) varies little meridionally in the analysis domain. According to the dispersion relation of linear, quasi-geostrophic Rossby waves at a rest state, these meridional structures in m and deformation radius result in steeper angle of ray trajectory at a higher latitude in the longitude-depth plane. Energy estimated from in situ observations shows a consistent pattern with this expectation. The line of constant phase of annual pressure harmonic is steeper in angle at higher latitudes, which is also expected from the uniform deformation radius and constant N. This result indicates that energy penetrates deeper at higher latitudes.

Eddies observed by Argo floats

*Katsuro Katsumata[1]

1. JAMSTEC

Eddies play an important role in the oceanic general circulation theory, specifically its meridional overturning component. Due to the limited spatial extent, however, synoptic observation of the eddy field has been difficult and its quantitative arguments have depended mostly on numerical simulation outputs. Argo floats, which revolutionalised phycical oceanographic observations, demonstrate their capability in the eddy observation (albeit at limited depths).
Under the Temporal Residual Mean framework, the most natural coordinate system for ocean circulation theories, we estimated the eddy transport above the mean 1000 dbar surface by using the hydrographic and drift velocity data from Argo floats. Eddy transport is strong in the western boundaries and in the Southern Ocean. In the midlatitude oceans, it is weaker and equatorwords. In the southern part of the Antarctic Circumpolar Current (ACC), it is larger than 10 Sv poleward.
In the Southern Ocean, we can discuss the vertical transport of zonal momentum input by the westerly wind and responses of the ACC to variable wind localised to topographic features.

Rhythmic Phenomena in Nonlinear Systems and Oceanic General Circulation

*Shinya Shimokawa[1], Tomonori Matsuura[2]

1. National Research Institute for Earth Science and Disaster Prevention, 2. University of Toyama

Various oscillation phenomena such as transition between meander and non- meander paths of western boundary current such as the Kuroshio exist in the oceanic general circulation. These phenomena can be related to nonlinear rhythmic phenomena such as synchronization, stochastic resonance and stochastic synchronization. Synchronization 1) is a phenomenon for an adjustment of rhythms of two or more self-sustained oscillating systems, which have different periods. Stochastic resonance 2) is a phenomenon in which a kind of noise amplifies and elicits weak signals under detection thresholds. Both phenomena are observed in various nonlinear systems such as climate system, living system, and electric circuits. Also, the coupling of both phenomena was found and is called stochastic synchronization 3).

Thus, we investigate the responses of oceanic double-gyre to external wind forcing with and without noise using a 1.5 layer quasi-geostrophic model, and considered the possible role of nonlinear rhythmic phenomena in oceanic general circulation 4)-7). The variable parameter is the amplitude of external seasonal forcing, α, the amplitude of red noise, ε, and the Reynolds number, Re.

Synchronization at two times the period of the forcing occurs at a parameter range of α and Re without noise (ε =0). For cases with adequate (not too weak and not too strong) noise, potential signals in the system appear at the front as actual signals (i.e., stochastic resonance) such as intermittent large variations in energy. Also, by adding red noise to external forcing, synchronization (i.e., stochastic synchronization) occurs when the amplitude of external forcing is smaller than that in the case without noise. These results suggest that potential signals in the system are amplified and appear as stochastic resonance or synchronization in relation to the added noise.

Control of the ocean circulation by bottom topography and generation of mesoscale disturbances

*Yuri Kase[1], Tomonori Matsuura[1]

1. National university corporation University of Toyama

One of the representative ocean current in the North Pacific is the Kuroshio. The Kuroshio which is the western boundary current of the North Pacific subtropical gyre leaves off the coast of Choshi, Chiba Prefecture, and it will be the eastward Kuroshio extension. At about 160° E, the Kuroshio-extension current encounters the Shatsky rise extending north and south, and fluctuation of flow path and generation of mesoscale disturbances due to flow-topography interaction is seen around this topography. We study the mechanism of phenomena as geophysical fluid dynamics in the North Pacific, mainly generation of mesoscale disturbances due to flow-topography interaction in rotating stratified fluid, by modeling which is target of the North Pacific.

We simulated four cases with different ocean bottom topography using the eddy resolving 3-layer QG model (Hogg et al., 2010) based on the quasi-geostrophic vorticity equation for the generation of the mesoscale disturbances accompanied the main flow path variation.

In Figure 1, the strong flow in each case is seen near the west-coast and mid-latitudes, and in case 1 where no topography is given, the most noticeable double gyre and the zonal strong flow as the gyre's front are seen. It can be inferred that this double gyre corresponds to the North Pacific subtropical gyre / subpolar gyre, and the flow on the front corresponds to the Kuroshio extension because we give the wind stress corresponding to the North Pacific about this time. On the other hand, in case 2, 3, and 4, which topography is given in each case, the strong flow near the mid-latitude is obstructed or meandered depending on the topography, and there is the long-lived eddy as an anticyclonic eddy over the topography. Especially, paying attention to the meandering flow behind the topography, and comparing case 3 and case 4, we can see that the addition of "corn" to "kamaboko" strengthens the flow of two wavelengths behind "kamaboko" (in case 4 of Figure 1).

Figure 2 shows the spatial patterns of the 10 years mean values of the squared disturbances of the potential vorticity in layer 1. The higher value area has the stronger and finer mesoscale disturbances. The development of the mesoscale disturbances in each case is seen at the west-coast, the mid-latitude area and the area surrounding the topography, corresponding to the strong flow as seen in Figure 1. In addition, when comparing case 3 and case 4, the addition of "corn" to "kamaboko" strengthens the meandering flow which has two wavelengths behind "kamaboko" (in case 4 of Figure 1), and the mesoscale disturbances are developed along the flow (in case 4 of Figure 2). From these results, it is suggested that the baroclinic instability is strengthened around the topography. We think the mechanism as described later; flow is disturbed by the influence of the topography, and the interface (of two layers) height anomaly increases, so the potential energy becomes large (strengthened baroclinic instability), and then the enlarged potential energy is released as kinetic energy (resolution of the baroclinic instability), and the mesoscale disturbances develop. It was suggested that how to change the flow and the degree of strengthened its baroclinic instability depend on the shape, arrangement and combination of the topography. And it was found that the bottom topography plays an important role in the generation of mesoscale disturbances.

©2019. Japan Geoscience Union. All Right Reserved.

Hereafter, by modeling which is given “kamaboko”, “corn” as a bottom topography imitating the Izu Ridge and the Shatsky rise (Tam massif) in the North Pacific, respectively, and simulating in some cases which have defferent positions (latitude / longitude) and heights of the topography, we presume that it is possible to realize the application of the mechanism of phenomena from the simulation results to the real phenomena.

The generation mechanism of the atmospheric super rotation on Venus is one of the most important topics in the Earth and planetary sciences. Here we reproduced the fully developed super-rotation for the first time in a Venus general circulation model (GCM) driven by a zonally-averaged component of the *realistic* solar heating only. Our GCM enables us to perform long term simulations with medium resolution higher than those used in previous studies. It is newly found that mean meridional circulation driven by the *realistic* solar heating can generate the fully developed super-rotation of ~100 m s^{-1} with the vertical eddy viscosity smaller than 0.02 m^2 s^{-1} (see below Figure). Existence of the range of the vertical eddy viscosity in which the fast super-rotation can be generated by the reasonable solar heating has broad implications for the atmospheric sciences in light of optimal parameters for the GCMs.

Fully developed super-rotation driven by the mean meridional circulation in a Venus GCM, Norihiko Sugimoto, Masahiro Takagi, and Yoshihisa Matsuda, *Geophysical Research Letters*, (2019), doi.org/10.1029/2018GL080917.

At the altitude of approximately 60-70 km in the Venus atmosphere, there is an interesting phenomenon called “cold collar” where the temperature of the polar region is higher than that of the surroundings (latitude of about 60-80 degrees). The Japanese Venus Atmospheric GCM For the Earth Simulator (AFES-Venus) succeeded for the first time in the reproduction of cold collar[1]. However, the temperature difference between the pole and the surroundings is small compared with that observed. Recently, using the Local Ensemble Transform Kalman Filter (LETKF), we have succeeded in developing the Venus AFES LETKF Data Assimilation System (VALEDAS)[2]. In this study, we investigated the reproducibility of cold collar by the data assimilation of French Venus Atmospheric GCM(LMD/VGCM) in which cold collar is realistically reproduced[3]. We prepared idealized observation data assuming radio occultation measurement by small satellites. We will report the reproducibility of cold collar by changing the conditions such as observation point, observation number, and time interval. Figure shows three vertical profiles of temperature observations at 85 degrees North every Earth hour (obtained by temperature field from 30-90 degrees North at the altitude of about 66 km). Therefore, such kind of future mission would be promising.

Relationship between solar wind and atmospheric circulation

*Paul Prikryl[1]

1. Physics Department University of New Brunswick and Geomagnetic Laboratory Natural Resources Canada

More than four decades have passed since the discovery of a relationship between solar wind magnetic sector boundary structure and the winter mid-latitude upper-tropospheric vorticity/circulation [1,2]. These results have been later confirmed and various physical mechanisms proposed [3,4]. Solar wind to magnetosphere - ionosphere - atmosphere (MIA) coupling process generates internal atmospheric gravity waves propagating upward and downward from the lower thermosphere sources at high latitudes [5]. If ducted over long distances in the lower atmosphere they can reach troposphere [6,7]. Despite significantly reduced wave amplitude, but subject to amplification upon over-reflection in the upper troposphere, the gravity waves can trigger moist instabilities to initiate convective bursts [4]. The latent heat release is the source of energy leading to intensification of extratropical storms and convective bursts have been linked to rapid intensification of tropical cyclones. Recent studies [8,9,10] showed that explosive extratropical cyclones and rapid intensification of tropical cyclones tend to follow arrivals of solar wind high-speed streams and interplanetary coronal mass ejections. The solar wind MIA coupling is most intense during the arrivals of co-rotating interaction regions and interplanetary shocks at the leading edge of high-speed solar wind when the amplitudes of aurorally-generated gravity waves are largest. If these gravity waves trigger moist instabilities in extratropical and tropical cyclones to initiate convective bursts the intensification of cyclones leads to enhanced atmospheric circulation.

Contribution of the Atlantic storm track to the Euro-Russian blocking maintenance in summer 2010

*Akira Yamazaki[1]

1. Application Laboratory, Japan Agency for Marine-Earth Science and Technology

A long-lived blocking anticyclone occurred over western Russia during summer of 2010. This blocking persisted especially during the whole July over the western Russia and caused various weather extremes in the Eurasian continent. In this study, we investigate the mechanism and predictability of Euro-Russian blocking in terms of the interaction between blocking and synoptic eddies or storm tracks, that is, the eddy feedback mechanism. The author adopts the selective absorption mechanism (SAM, Yamazaki and Itoh 2013) to explain the maintenance mechanism and predictability of Euro-Russian blocking during July. Using an ensemble data assimilation system and an AGCM with the same forecast model, we conducted ensemble medium-range (7 days) forecast experiments. Isentropic trajectory analyses suggested that the SAM can work even in the summertime blocking event and the mechanism is more effective for forecast members in which the blocking is successfully forecast. We also conducted a sensitivity experiments in which the Atlantic storm track was suppressed by a piecewise potential vorticity inversion method to evaluate the impact of the storm track on the maintenance of the blocking. The result indicates that the blocking can be substantially maintained by the feedback from the storm track. The results suggested that the Atlantic storm track can substantially contribute to the maintenance of Euro-Russian blocking and its predictability.

Instabilities in Ekman layer and roll structures in a tropical cyclone boundary layer

*Junshi Ito[1], Hiroshi Niino[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

Taking advantage of the huge computational power of a massive parallel supercomputer (K-supercomputer), a large eddy simulation of entire tropical cyclones by use of a numerical weather prediction model was conducted. In the numerical results, three kinds of roll structures are found in the boundary layer (See figure; Ito et al., 2017). An analysis of linear instabilities in Ekman layer suggests that the mechanisms to form the rolls are associated with two kinds of growth modes (inflection point and parallel instabilities) of the Ekman layer.

Mathematical description of the internal waves in a proximity of the bottom of the Ocean.

*andrei giniatoulline[1], german tobar[1]

1. Department of Mathematics, Los Andes University, Bogota, Colombia, South America

We construct an explicit solution for a boundary value problem in a layer at the bottom of the Ocean for a system of partial differential equations which describes the motion of a viscous rotating stratified fluid. As an effect of Coriolis and gravitational forces, there arise internal waves in the fluid. We prove the existence and uniqueness of the solution.
For a model in the half-space, for the constructed solutions we find the asymptotical behavior for large values of t. We prove the existence of the following boundary layer phenomena: the asymptotical decay of the solution is slower as we approach the boundary plane of the bottom.
The obtained results can be used not only for modeling the flows at the bottom of the Ocean, but also for the flows in the lower Atmosphere.

How deterministic are the deep zonal jets?

*Ryo Furue[1], Masami Nonaka[1], Hideharu Sasaki[1]

1. APL/JAMSTEC

Eddy-resolving oceanic general circulation models (OGCMs) often show eastward and westward alternating flows below the main thermocline in the velocity field averaged over one year or longer. They are commonly termed the “deep jets”. They are fairly coherent zonally, extending tens of degrees, and vertically, extending down to 1000–2000 m. Their meridional wavelength (distance between eastward flows) is typically 3º–5º. Although they tend to be masked by the general circulation near the surface, their pressure anomalies exist there and has been detected in satellite-observed sea-surface height fields. Recently, a compilation of high-resolution ADCP sections and an analysis on geostrophic velocity based on Argo showed the horizontal and vertical structure of the jets (Cravatte et al. 2017).

In an analysis of OFES , an eddy resolving model, deep jets tend to systematically migrate toward the equator between 20º–30ºN and S (Richards et al. 2006) with a period of approximately 4 years. On the other hand, Qiu et al. (2013) proposed a mechanism that generates a series of stationary deep jets at fixed distances from the equator.

A number of mechanisms have been proposed to explain the existence and the properties of these deep jets, some of them suggesting that the positions and strengths of the jets are determined by external forcing (“deterministic”) and others, that they are (or should be) only statistically determined (“stochastic”).

To determine how deterministic the deep jets are, we use a 10-member ensemble of runs of OFES 2, an OGCM for the Earth Simulator version 2, which is a semi-global model with a 0.1º horizontal resolution. Its surface forcing is based on JRA55-do, a timeseries of atmospheric conditions derived from a reanalysis product. The ensemble runs are started from the beginning of 1965 and extended to the end of 2016; their difference comes solely from slight differences in their initial conditions.

As the left panel of the figure below shows, equatorward phase propagation of deep jets is clear between 20º–30ºN, whereas poleward propagation is discernible between 5º–15ºN. Along 33º and 40ºN are rather persistent eastward jets flanked by westward jets on their equatorward sides. North of 40ºN, the jets tend to be somewhat stronger and less stable and to have shorter meridional wavelengths.

The variance among the ensemble members initially grows rapidly but stabilizes in 5–10 years (not shown). The right panel of the figure below indicates how well the positions of eastward jets agree among the ensemble members. Except for the equatorial currents (like the primary and secondary Tsuchiya Jets) and those stable jets near 33º and 40ºN, the axes of the jets more or less vary among ensemble members. Nevertheless, some coherence is also evident; in particular, the poleward-propagating jets in the 5º–15ºN band tend to agree among themselves. In the equatorward-propagating regime 20º–30ºN, coherent propagation sometimes emerges. If the tropical (equatorward of 15ºN) jets are deterministic, their migration may be due to some slow change in external forcing.

The impact of tidal mixing on the Indonesian Throughflow

*Kohki Shiroyama[1], Shinichiro Kida[2], Hideharu Sasaki[3], Ryo Furue[3]

1. Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2. Research Institute for Applied Mechanics Kyushu University, 3. JAMSTEC. APL

The Indonesian Seas are where the Indonesian Throughflow (ITF) flows from the Pacific to the Indian Ocean. The sea surface temperature of the ITF plays an important role in the development of the atmospheric deep convection above these seas. In the Indonesian Seas, the bottom topography is rough and likely induces strong tidal mixing. To examine the impact of tidal mixing on the water mass properties of the ITF, we examined the temperature, salinity, and velocity of the ITF by using OFES2, a quasi-global ocean circulation model that includes global tidal mixing parameterization. We find the impact of tidal mixing to change the water mass properties of the ITF and its flow structure, especially above seamounts and at the straits. The vertical distribution of water mass properties at these location shows more uniform profile. This is considered that tidal mixing has a strong effect on the ITF at narrow location like Straits. We plan to analysis more to investigate the cause of these changes.

Verification for subsurface oceanic structure in OFES outputs driven by different wind data sets (NCEP/NCAR and QSCAT)in the tropical Pacific Ocean

*Hiroshige Fukunaga[1], Kunio Kutsuwada[1], Akira Kakiuchi[1], Yuma Yanagida[1], Hideharu Sasaki[2], Yoshikazu Sasai[2]

1. Tokai University, 2. JAMSTEC

1 Introduction
OFES is a numerical model that reproduces oceanic circulation and structure with high resolution by inputting sea surface flux (momentum heat and freshwater). Intercomparison between two types of OFESruns (NCEPrun and QSCATrun) driven by different wind datasets with no different surface heat flux revealed that the thermocline depth near 10˚N is about 50m shallower in the NCEPrun than that in the QSCATrun. The integrated meridional geostrophic transports from the east boundary in the NCEPrun are about 10Sv larger than in the QSCATrun (Kutsuwada et al 2018).
In this study we examine oceanic structures and zonally-integrated meridional geostrophic transports in the southern hemisphere by making intercomparison between the two OFES runs together with comparison with the MOAA-GPV data set constructed by Argo float observations.
2 Data
OFES is high resolution semi-global ocean circulation model developed by JAMSTEC based on Modular Ocean Model ver.3 developed by NOAA. It can reproduce ocean circulation and structure with high resolution. As the external force driving the model we use two different types of wind data sets by numerical re-analysis (NCEP NCAR) and satellite measurement (QuikSCAT).
We averaged spatially for horizontal resolution from 0.1˚x0.1˚to 1˚x1˚. In the vertical direction we converted all simulated data such as temperature salinity and current with depth interval of 10m using Akima-method from sea surface(2.5m) to 6065m.
3 Method
Using dynamic height anomaly we calculate geostrophic current that is integrated vertically from sea surface to depth h (m). We use the depth of no motion of 2000m.The meridional Sverdrup transport corresponds vertically integrated flow from sea surface to depth of no motion (the maximum depth of wind driven circulation) and is given by the sum of the Ekman transport (calculated from Coriolis parameter and zonal wind-stress) and geostrophic transport.
In this study we verify the correspondence between geostrophic transports which are obtained from oceanic data and wind-driven transports calculated from sea surface wind data.
4 Result
The thermocline depth near 10S in the NCEPrun is about 50m shallower than that in the QSCATrun. The zonally-integrated meridional geostrophic transports from the east boundary in the NCEPrun is 10 Sv smaller than in the QSCATrun. Comparison of the two runs with the MOAA-GPV showed that the temperatures in the NCEPrun are lower than those in the MOAA-GPV at 50-400m depth while the QSCATruns is almost similar to the MOAA-GPV above 200m. In comparison for the integrated meridional geostrophic transports the values in the QSCATrun are smaller than those in the NCEPrun and similar to those in the MOAA-GPV. These results mean that in the southern hemisphere the QSCATrun reproduces real oceanic structures with higher reliability than the NCEPs one the same as that in the northern hemisphere.
Comparison in the meridional profile of zonally-averaged wind stress curl (WSC) showed that the NCEPs

©2019. Japan Geoscience Union. All Right Reserved.

WSC has larger values in a zone of 10˚S corresponding to negative maximum than the QSCAT and also the same differences as that in a zone of 10˚N corresponding to positive maximum. The geostrophic transports from the QSCATrun correspond the wind-driven flow calculated from QSCATs wind data closely at low latitude which suggests that the Sverdrup balance holds in these regions.

Inter-comparison of ocean wave data from drifting buoys, moored GPS buoys
and reanalysis data

*Yukiharu Hisaki[1]

1. University of the Ryukyus

Observation of surface wave data such as wave height and period are important for practical and scientific purposes. However, wave observations by moored buoys around Japan are only by GPS buoys, which are located about 10 km from the coast. The observations of wave heights and periods by Japan Meteorological Agency (JMA) drifting buoys were conducted from 2000. Wave data from drifting buoys are inter-compared with GPS buoys and ERA-Interim reanalysis data. The GPS wave data are compared with those from drifting buoys and ERA-Interim data, when a drifting buoy is close to a GPS buoy position, and the number of comparison is limited. The data period of wave data of drifting buoys and ERA-Interim data is from 2000 to 2018. The agreement of wave heights between from GPS and drifting buoys is better than that between from GPS and ERA-Interim data. The agreement of wave periods between from GPS and drifting buoys is not much better than that between from GPS and ERA-Interim data. There are cases that wave periods by drifting buoys are much longer than those from GPS buoys. The dependency of wave parameter differences between from drifting buoys and ERA-Interim data on drifting buoy speeds is investigated.
The drifting current components to the mean wave directions are evaluated from the drifting currents estimated from the drifting buoy positions and the ERA interim mean wave directions.
The differences of wave heights between from drifting buoys and ERA-Interim data are larger as faster current speeds.
The ERA-Interim wave heights are underestimated when current directions are opposite to mean wave directions. The ERA-Interim wave heights are overestimated current directions are following to wave directions. The ratio as drifting wave period/ERA-Interim wave period is smaller as increasing opposing current component, which is consistent with the Doppler shift.

Merge and Separation of ocean eddies around the Kuroshio Extension

*koutarou matsuhashi[1], Kazuyuki Uehara[1]

1. The Graduate School of Marine Science Technology

Oceanic mesoscale eddies make ow complicate and produce non-steady states in the ocean general circulation. These eddies are in addition considered to play a important role of heat and material transports. Therefore understanding of dynamics of mesoscale eddies and its roles are one of main tasks in Physical Oceanography. In particular the area around the Kuroshio Extension has very high activity of mesoscale eddies due to the Kuroshio Extension meanderings. Therefore, phenonmena of merging and seperating eddies frequently are observed in this area. Matsuoka et al.(2016) classified events of eddy merges and separations using a high resolution ocean general circulation model. In this study, at first we define mesoscale eddies using the second invariant of the velocity gradient tensor(this is equivalent with the Okubo-Weiss parameter) computed from sea surface height anomalies (AVISO), secondly we track the eddies, and finally, we discuss changes in physical parameters on events of eddy merging and seperating.

Influence of eddy-trapped water mass reaching 137E survey line using OGCM and a particle-tracking method

*Hideyuki Nakano[1], Hiroyuki Tsujino[1], Kei Sakamoto[1], Shogo Urakawa[1], Takahiro Toyoda[1], Goro Yamanaka[1], Yoshimasa Matsumura[2]

1. Meteorological Research Institute, 2. Atmosphere and ocean research Institute, the University of Tokyo

Mesoscale eddies are known to play a major role in water mass formation and transport. In recent years, several studies have estimated eddy-trapped transport (e.g., Zhang et al 2014), arguing that this can be comparable to the mean-flow transport. However, these estimates are based on satellite observation and ideal vortex vertical structure of eddies, not based on direct ones. In this study, we directly diagnose the eddy-trapped transport by using eddy-resolving Ocean General Circulation Model (OGCM) and off-line particle tracking method. We focus on the eddy-trapped watermass reaching the 137E survey line, which is maintained for more than 50 years by the Japan Meteorological Agency and the importance of eddy activity is pointed out. Along 137E meridional section, a total of about 1 million particles are released every August during 1993 to 2017. Using daily output and offline-particle tracking method, reverse tracking is performed until each particle reaches the mixed-layer, where each particle is ventilated and its properties significantly change due to air-sea interaction. Each particle is divided into typical water mass categories, judging from its temperature, salinity, potential vorticity and location during the ventilation. Whether or not each particle is trapped in the mesoscale eddies is judged by Okubo-Weiss parameter. Distribution of ventilated areas of typical water masses such as Tropical Water (TW), Subtropical Mode Water (STMW), Eastern Subtropical Mode Water (ESTMW), Lighter variety of Central Mode Water (L-CMW) is realistically reproduced. About 20% of TW are present in mesoscale eddies during ventilation, and 60% of the them are present in anticyclonic ones. About half of them (~10% of the total TW) reach137E in a state trapped in the eddies. Their trajectories are almost westward, whereas the trajectories not trapped in eddies are the west-southwest direction reflecting the subtropical circulation. Arrival times from the ventilated area nearly the same for the both, except for the subtropical countercurrent where the average flow is eastward and the arrival time is shorter for those trapped in the eddies. About 30% of STMW are present in eddies during ventilation, and about 80% of them are present in anticyclonic ones. About 1/3 of them (~10% of total STMW) reach 137E in a state trapped in eddies. For the STMW, the arrival time is longer for those trapped in the eddies, and their trajectories are not simple westward. Less than 20% of ESTMW and L-CMW are present in eddies during ventilation, and the ratio between the anticyclonic and cyclonic eddies is almost the same. Only 1/4 of them (5% of the total water masses) reach 137E in a state trapped in eddies. Even though the trajectory of the water mass trapped in the eddies show a clear east-west direction like TW, the arrival time is longer for the water mass trapped in the eddies. This estimate that 5-10% of these water masses reaching 137E trapped in a state eddies may be smaller than the recent estimate in past studies. These differences are also discussed.

A study on the variability of the deep ocean circulation during glacial climate with a climate model of intermediate complexity

*Taigo Ando[1], Akira Oka[1]

1. Atmosphere and Ocean Research Institute, University of Tokyo

Ice core reconstructions show that there were abrupt climate changes termed Dansgaard-Oscillation (D-O) oscillations during glacial period, which are most characterized by about 10 ℃ of temperature changes in Greenland within a few decades. Many studies have pointed out the connection between D-O oscillations and changes in the Atlantic Meridional Overturning Circulation (AMOC), while details of its variability is still missing. Previous modeling studies have suggested that the variability of the AMOC including D-O oscillations are invoked by freshwater input from melted ice-sheets into the deep-water formation region in the North Atlantic (e.g. Rahmstrf, 2002). However, some recent model simulations exhibit abrupt and spontaneous oscillations without freshwater forcing in glacial climate (Peltier and Vettoretti, 2014; Brown and Galbraith, 2016), and more researchers are considering that the mechanism of D-O oscillations is involved within the ocean dynamics and its interactions with the atmosphere and sea ice. Since global coupled models usually used in previous simulations contain many processes of the atmosphere and the ocean, they require high computational costs and it is difficult to identify the processes contributing to D-O oscillations from the model simulations. On the other hand, earth system models of intermediate complexity with lighter computational costs have difficulties in reproducing climate features.
In this study, we modified the model in which the atmosphere component is simplified to the energy-balanced model (MIROC-lite, Oka et al., 2011, 2017) by using results of a full-coupled model (MIROC, Hasumi and Emori, 2001) as parameters so as to have equivalent performance to the full-coupled model, then conducted simulations of glacial climate with the model. This model is expected to be effective for investigating the cause of the spontaneous oscillations of full-coupled models since it can better represent thermal feedback between the atmosphere and the ocean by predicting atmosphere temperature from energy balance compared to ocean-only models. In our presentation, we discuss the performance of the model and its implications for the mechanism of D-O oscillations.

Mon. May 27, 2019 5:15 PM - 6:30 PM JST | Mon. May 27, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

[A-OS19] Dynamics of oceanic and atmospheric waves, vortices, and circulations

convener:Yuki Tanaka(Graduate School of Science, The University of Tokyo), Ryo Furue(APL/JAMSTEC), Yukiharu Hisaki(University of the Ryukyus), Norihiko Sugimoto(Keio University, Department of Physics)

Oceanic and atmospheric dynamics aims at abstracting general principles from observed phenomena and constructing a system of mathematical models, thereby leading to the understanding, prediction, and parameterization of those phenomena. It provides perspectives for the advancement of sciences in various areas such as wind waves, swells, internal waves, Rossby waves, equatorial waves, tides, eddies, meandering of jets and fronts, general circulation, boundary layers, and ocean-atmosphere coupled modes. It has also been and will continue to be benefited by new uses of ideas and methods from such theories as resonance, nonlinear interaction, spectral analysis, probability, statistics, and dynamical systems. In this session, we solicit presentations on observational, experimental, numerical, and theoretical studies of oceanic and atmospheric dynamics and on exploratory use of new ideas and methods. We also welcome presentations on interdisciplinary studies in fields such as ecosystems, climate, and environment.

The generation mechanism of the atmospheric super rotation on Venus is one of the most important topics in the Earth and planetary sciences. Here we reproduced the fully developed super-rotation for the first time in a Venus general circulation model (GCM) driven by a zonally-averaged component of the *realistic* solar heating only. Our GCM enables us to perform long term simulations with medium resolution higher than those used in previous studies. It is newly found that mean meridional circulation driven by the *realistic* solar heating can generate the fully developed super-rotation of ~100 m s^{-1} with the vertical eddy viscosity smaller than 0.02 m^2 s^{-1} (see below Figure). Existence of the range of the vertical eddy viscosity in which the fast super-rotation can be generated by the reasonable solar heating has broad implications for the atmospheric sciences in light of optimal parameters for the GCMs.

Fully developed super-rotation driven by the mean meridional circulation in a Venus GCM, Norihiko Sugimoto, Masahiro Takagi, and Yoshihisa Matsuda, *Geophysical Research Letters*, (2019), doi.org/10.1029/2018GL080917.

Data assimilation of the Venus atmosphere assuming radio occultation measurement by small satellites

*Mirai Abe[1], Norihiko Sugimoto[1], Yukako Kikuchi[2], Asako Hosono[3], Hiroki Ando[4], Masahiro Takagi[4], Itziar Garate Lopez[5], Sebastien Lebonnois[6], Chi Ao[7]

At the altitude of approximately 60-70 km in the Venus atmosphere, there is an interesting phenomenon called “cold collar” where the temperature of the polar region is higher than that of the surroundings (latitude of about 60-80 degrees). The Japanese Venus Atmospheric GCM For the Earth Simulator (AFES-Venus) succeeded for the first time in the reproduction of cold collar[1]. However, the temperature difference between the pole and the surroundings is small compared with that observed. Recently, using the Local Ensemble Transform Kalman Filter (LETKF), we have succeeded in developing the Venus AFES LETKF Data Assimilation System (VALEDAS)[2]. In this study, we investigated the reproducibility of cold collar by the data assimilation of French Venus Atmospheric GCM(LMD/VGCM) in which cold collar is realistically reproduced[3]. We prepared idealized observation data assuming radio occultation measurement by small satellites. We will report the reproducibility of cold collar by changing the conditions such as observation point, observation number, and time interval. Figure shows three vertical profiles of temperature observations at 85 degrees North every Earth hour (obtained by temperature field from 30-90 degrees North at the altitude of about 66 km). Therefore, such kind of future mission would be promising.

Relationship between solar wind and atmospheric circulation

*Paul Prikryl[1]

1. Physics Department University of New Brunswick and Geomagnetic Laboratory Natural Resources Canada

More than four decades have passed since the discovery of a relationship between solar wind magnetic sector boundary structure and the winter mid-latitude upper-tropospheric vorticity/circulation [1,2]. These results have been later confirmed and various physical mechanisms proposed [3,4]. Solar wind to magnetosphere - ionosphere - atmosphere (MIA) coupling process generates internal atmospheric gravity waves propagating upward and downward from the lower thermosphere sources at high latitudes [5]. If ducted over long distances in the lower atmosphere they can reach troposphere [6,7]. Despite significantly reduced wave amplitude, but subject to amplification upon over-reflection in the upper troposphere, the gravity waves can trigger moist instabilities to initiate convective bursts [4]. The latent heat release is the source of energy leading to intensification of extratropical storms and convective bursts have been linked to rapid intensification of tropical cyclones. Recent studies [8,9,10] showed that explosive extratropical cyclones and rapid intensification of tropical cyclones tend to follow arrivals of solar wind high-speed streams and interplanetary coronal mass ejections. The solar wind MIA coupling is most intense during the arrivals of co-rotating interaction regions and interplanetary shocks at the leading edge of high-speed solar wind when the amplitudes of aurorally-generated gravity waves are largest. If these gravity waves trigger moist instabilities in extratropical and tropical cyclones to initiate convective bursts the intensification of cyclones leads to enhanced atmospheric circulation.

Contribution of the Atlantic storm track to the Euro-Russian blocking maintenance in summer 2010

*Akira Yamazaki[1]

1. Application Laboratory, Japan Agency for Marine-Earth Science and Technology

A long-lived blocking anticyclone occurred over western Russia during summer of 2010. This blocking persisted especially during the whole July over the western Russia and caused various weather extremes in the Eurasian continent. In this study, we investigate the mechanism and predictability of Euro-Russian blocking in terms of the interaction between blocking and synoptic eddies or storm tracks, that is, the eddy feedback mechanism. The author adopts the selective absorption mechanism (SAM, Yamazaki and Itoh 2013) to explain the maintenance mechanism and predictability of Euro-Russian blocking during July. Using an ensemble data assimilation system and an AGCM with the same forecast model, we conducted ensemble medium-range (7 days) forecast experiments. Isentropic trajectory analyses suggested that the SAM can work even in the summertime blocking event and the mechanism is more effective for forecast members in which the blocking is successfully forecast. We also conducted a sensitivity experiments in which the Atlantic storm track was suppressed by a piecewise potential vorticity inversion method to evaluate the impact of the storm track on the maintenance of the blocking. The result indicates that the blocking can be substantially maintained by the feedback from the storm track. The results suggested that the Atlantic storm track can substantially contribute to the maintenance of Euro-Russian blocking and its predictability.

Instabilities in Ekman layer and roll structures in a tropical cyclone boundary layer

*Junshi Ito[1], Hiroshi Niino[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

Taking advantage of the huge computational power of a massive parallel supercomputer (K-supercomputer), a large eddy simulation of entire tropical cyclones by use of a numerical weather prediction model was conducted. In the numerical results, three kinds of roll structures are found in the boundary layer (See figure; Ito et al., 2017). An analysis of linear instabilities in Ekman layer suggests that the mechanisms to form the rolls are associated with two kinds of growth modes (inflection point and parallel instabilities) of the Ekman layer.

Mathematical description of the internal waves in a proximity of the bottom of the Ocean.

*andrei giniatoulline[1], german tobar[1]

1. Department of Mathematics, Los Andes University, Bogota, Colombia, South America

We construct an explicit solution for a boundary value problem in a layer at the bottom of the Ocean for a system of partial differential equations which describes the motion of a viscous rotating stratified fluid. As an effect of Coriolis and gravitational forces, there arise internal waves in the fluid. We prove the existence and uniqueness of the solution.
For a model in the half-space, for the constructed solutions we find the asymptotical behavior for large values of t. We prove the existence of the following boundary layer phenomena: the asymptotical decay of the solution is slower as we approach the boundary plane of the bottom.
The obtained results can be used not only for modeling the flows at the bottom of the Ocean, but also for the flows in the lower Atmosphere.

Keywords: Internal waves, Stratified fluid, Rotating fluid, Boundary layer

How deterministic are the deep zonal jets?

*Ryo Furue[1], Masami Nonaka[1], Hideharu Sasaki[1]

1. APL/JAMSTEC

Eddy-resolving oceanic general circulation models (OGCMs) often show eastward and westward alternating flows below the main thermocline in the velocity field averaged over one year or longer. They are commonly termed the “deep jets”. They are fairly coherent zonally, extending tens of degrees, and vertically, extending down to 1000–2000 m. Their meridional wavelength (distance between eastward flows) is typically 3º–5º. Although they tend to be masked by the general circulation near the surface, their pressure anomalies exist there and has been detected in satellite-observed sea-surface height fields. Recently, a compilation of high-resolution ADCP sections and an analysis on geostrophic velocity based on Argo showed the horizontal and vertical structure of the jets (Cravatte et al. 2017).

In an analysis of OFES , an eddy resolving model, deep jets tend to systematically migrate toward the equator between 20º–30ºN and S (Richards et al. 2006) with a period of approximately 4 years. On the other hand, Qiu et al. (2013) proposed a mechanism that generates a series of stationary deep jets at fixed distances from the equator.

A number of mechanisms have been proposed to explain the existence and the properties of these deep jets, some of them suggesting that the positions and strengths of the jets are determined by external forcing (“deterministic”) and others, that they are (or should be) only statistically determined (“stochastic”).

To determine how deterministic the deep jets are, we use a 10-member ensemble of runs of OFES 2, an OGCM for the Earth Simulator version 2, which is a semi-global model with a 0.1º horizontal resolution. Its surface forcing is based on JRA55-do, a timeseries of atmospheric conditions derived from a reanalysis product. The ensemble runs are started from the beginning of 1965 and extended to the end of 2016; their difference comes solely from slight differences in their initial conditions.

As the left panel of the figure below shows, equatorward phase propagation of deep jets is clear between 20º–30ºN, whereas poleward propagation is discernible between 5º–15ºN. Along 33º and 40ºN are rather persistent eastward jets flanked by westward jets on their equatorward sides. North of 40ºN, the jets tend to be somewhat stronger and less stable and to have shorter meridional wavelengths.

The variance among the ensemble members initially grows rapidly but stabilizes in 5–10 years (not shown). The right panel of the figure below indicates how well the positions of eastward jets agree among the ensemble members. Except for the equatorial currents (like the primary and secondary Tsuchiya Jets) and those stable jets near 33º and 40ºN, the axes of the jets more or less vary among ensemble members. Nevertheless, some coherence is also evident; in particular, the poleward-propagating jets in the 5º–15ºN band tend to agree among themselves. In the equatorward-propagating regime 20º–30ºN, coherent propagation sometimes emerges. If the tropical (equatorward of 15ºN) jets are deterministic, their migration may be due to some slow change in external forcing.

The impact of tidal mixing on the Indonesian Throughflow

*Kohki Shiroyama[1], Shinichiro Kida[2], Hideharu Sasaki[3], Ryo Furue[3]

1. Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2. Research Institute for Applied Mechanics Kyushu University, 3. JAMSTEC. APL

The Indonesian Seas are where the Indonesian Throughflow (ITF) flows from the Pacific to the Indian Ocean. The sea surface temperature of the ITF plays an important role in the development of the atmospheric deep convection above these seas. In the Indonesian Seas, the bottom topography is rough and likely induces strong tidal mixing. To examine the impact of tidal mixing on the water mass properties of the ITF, we examined the temperature, salinity, and velocity of the ITF by using OFES2, a quasi-global ocean circulation model that includes global tidal mixing parameterization. We find the impact of tidal mixing to change the water mass properties of the ITF and its flow structure, especially above seamounts and at the straits. The vertical distribution of water mass properties at these location shows more uniform profile. This is considered that tidal mixing has a strong effect on the ITF at narrow location like Straits. We plan to analysis more to investigate the cause of these changes.

Verification for subsurface oceanic structure in OFES outputs driven by different wind data sets (NCEP/NCAR and QSCAT)in the tropical Pacific Ocean

*Hiroshige Fukunaga[1], Kunio Kutsuwada[1], Akira Kakiuchi[1], Yuma Yanagida[1], Hideharu Sasaki[2], Yoshikazu Sasai[2]

1. Tokai University, 2. JAMSTEC

1 Introduction
OFES is a numerical model that reproduces oceanic circulation and structure with high resolution by inputting sea surface flux (momentum heat and freshwater). Intercomparison between two types of OFESruns (NCEPrun and QSCATrun) driven by different wind datasets with no different surface heat flux revealed that the thermocline depth near 10˚N is about 50m shallower in the NCEPrun than that in the QSCATrun. The integrated meridional geostrophic transports from the east boundary in the NCEPrun are about 10Sv larger than in the QSCATrun (Kutsuwada et al 2018).
In this study we examine oceanic structures and zonally-integrated meridional geostrophic transports in the southern hemisphere by making intercomparison between the two OFES runs together with comparison with the MOAA-GPV data set constructed by Argo float observations.
2 Data
OFES is high resolution semi-global ocean circulation model developed by JAMSTEC based on Modular Ocean Model ver.3 developed by NOAA. It can reproduce ocean circulation and structure with high resolution. As the external force driving the model we use two different types of wind data sets by numerical re-analysis (NCEP NCAR) and satellite measurement (QuikSCAT).
We averaged spatially for horizontal resolution from 0.1˚x0.1˚to 1˚x1˚. In the vertical direction we converted all simulated data such as temperature salinity and current with depth interval of 10m using Akima-method from sea surface(2.5m) to 6065m.
3 Method
Using dynamic height anomaly we calculate geostrophic current that is integrated vertically from sea surface to depth h (m). We use the depth of no motion of 2000m.The meridional Sverdrup transport corresponds vertically integrated flow from sea surface to depth of no motion (the maximum depth of wind driven circulation) and is given by the sum of the Ekman transport (calculated from Coriolis parameter and zonal wind-stress) and geostrophic transport.
In this study we verify the correspondence between geostrophic transports which are obtained from oceanic data and wind-driven transports calculated from sea surface wind data.
4 Result
The thermocline depth near 10S in the NCEPrun is about 50m shallower than that in the QSCATrun. The zonally-integrated meridional geostrophic transports from the east boundary in the NCEPrun is 10 Sv smaller than in the QSCATrun. Comparison of the two runs with the MOAA-GPV showed that the temperatures in the NCEPrun are lower than those in the MOAA-GPV at 50-400m depth while the QSCATruns is almost similar to the MOAA-GPV above 200m. In comparison for the integrated meridional geostrophic transports the values in the QSCATrun are smaller than those in the NCEPrun and similar to those in the MOAA-GPV. These results mean that in the southern hemisphere the QSCATrun reproduces real oceanic structures with higher reliability than the NCEPs one the same as that in the northern hemisphere.
Comparison in the meridional profile of zonally-averaged wind stress curl (WSC) showed that the NCEPs

©2019. Japan Geoscience Union. All Right Reserved.

WSC has larger values in a zone of 10˚S corresponding to negative maximum than the QSCAT and also the same differences as that in a zone of 10˚N corresponding to positive maximum. The geostrophic transports from the QSCATrun correspond the wind-driven flow calculated from QSCATs wind data closely at low latitude which suggests that the Sverdrup balance holds in these regions.

Inter-comparison of ocean wave data from drifting buoys, moored GPS buoys
and reanalysis data

*Yukiharu Hisaki[1]

1. University of the Ryukyus

Observation of surface wave data such as wave height and period are important for practical and scientific purposes. However, wave observations by moored buoys around Japan are only by GPS buoys, which are located about 10 km from the coast. The observations of wave heights and periods by Japan Meteorological Agency (JMA) drifting buoys were conducted from 2000. Wave data from drifting buoys are inter-compared with GPS buoys and ERA-Interim reanalysis data. The GPS wave data are compared with those from drifting buoys and ERA-Interim data, when a drifting buoy is close to a GPS buoy position, and the number of comparison is limited. The data period of wave data of drifting buoys and ERA-Interim data is from 2000 to 2018. The agreement of wave heights between from GPS and drifting buoys is better than that between from GPS and ERA-Interim data. The agreement of wave periods between from GPS and drifting buoys is not much better than that between from GPS and ERA-Interim data. There are cases that wave periods by drifting buoys are much longer than those from GPS buoys. The dependency of wave parameter differences between from drifting buoys and ERA-Interim data on drifting buoy speeds is investigated.
The drifting current components to the mean wave directions are evaluated from the drifting currents estimated from the drifting buoy positions and the ERA interim mean wave directions.
The differences of wave heights between from drifting buoys and ERA-Interim data are larger as faster current speeds.
The ERA-Interim wave heights are underestimated when current directions are opposite to mean wave directions. The ERA-Interim wave heights are overestimated current directions are following to wave directions. The ratio as drifting wave period/ERA-Interim wave period is smaller as increasing opposing current component, which is consistent with the Doppler shift.

Merge and Separation of ocean eddies around the Kuroshio Extension

*koutarou matsuhashi[1], Kazuyuki Uehara[1]

1. The Graduate School of Marine Science Technology

Oceanic mesoscale eddies make ow complicate and produce non-steady states in the ocean general circulation. These eddies are in addition considered to play a important role of heat and material transports. Therefore understanding of dynamics of mesoscale eddies and its roles are one of main tasks in Physical Oceanography. In particular the area around the Kuroshio Extension has very high activity of mesoscale eddies due to the Kuroshio Extension meanderings. Therefore, phenonmena of merging and seperating eddies frequently are observed in this area. Matsuoka et al.(2016) classified events of eddy merges and separations using a high resolution ocean general circulation model. In this study, at first we define mesoscale eddies using the second invariant of the velocity gradient tensor(this is equivalent with the Okubo-Weiss parameter) computed from sea surface height anomalies (AVISO), secondly we track the eddies, and finally, we discuss changes in physical parameters on events of eddy merging and seperating.

Influence of eddy-trapped water mass reaching 137E survey line using OGCM and a particle-tracking method

*Hideyuki Nakano[1], Hiroyuki Tsujino[1], Kei Sakamoto[1], Shogo Urakawa[1], Takahiro Toyoda[1], Goro Yamanaka[1], Yoshimasa Matsumura[2]

1. Meteorological Research Institute, 2. Atmosphere and ocean research Institute, the University of Tokyo

Mesoscale eddies are known to play a major role in water mass formation and transport. In recent years, several studies have estimated eddy-trapped transport (e.g., Zhang et al 2014), arguing that this can be comparable to the mean-flow transport. However, these estimates are based on satellite observation and ideal vortex vertical structure of eddies, not based on direct ones. In this study, we directly diagnose the eddy-trapped transport by using eddy-resolving Ocean General Circulation Model (OGCM) and off-line particle tracking method. We focus on the eddy-trapped watermass reaching the 137E survey line, which is maintained for more than 50 years by the Japan Meteorological Agency and the importance of eddy activity is pointed out. Along 137E meridional section, a total of about 1 million particles are released every August during 1993 to 2017. Using daily output and offline-particle tracking method, reverse tracking is performed until each particle reaches the mixed-layer, where each particle is ventilated and its properties significantly change due to air-sea interaction. Each particle is divided into typical water mass categories, judging from its temperature, salinity, potential vorticity and location during the ventilation. Whether or not each particle is trapped in the mesoscale eddies is judged by Okubo-Weiss parameter. Distribution of ventilated areas of typical water masses such as Tropical Water (TW), Subtropical Mode Water (STMW), Eastern Subtropical Mode Water (ESTMW), Lighter variety of Central Mode Water (L-CMW) is realistically reproduced. About 20% of TW are present in mesoscale eddies during ventilation, and 60% of the them are present in anticyclonic ones. About half of them (~10% of the total TW) reach137E in a state trapped in the eddies. Their trajectories are almost westward, whereas the trajectories not trapped in eddies are the west-southwest direction reflecting the subtropical circulation. Arrival times from the ventilated area nearly the same for the both, except for the subtropical countercurrent where the average flow is eastward and the arrival time is shorter for those trapped in the eddies. About 30% of STMW are present in eddies during ventilation, and about 80% of them are present in anticyclonic ones. About 1/3 of them (~10% of total STMW) reach 137E in a state trapped in eddies. For the STMW, the arrival time is longer for those trapped in the eddies, and their trajectories are not simple westward. Less than 20% of ESTMW and L-CMW are present in eddies during ventilation, and the ratio between the anticyclonic and cyclonic eddies is almost the same. Only 1/4 of them (5% of the total water masses) reach 137E in a state trapped in eddies. Even though the trajectory of the water mass trapped in the eddies show a clear east-west direction like TW, the arrival time is longer for the water mass trapped in the eddies. This estimate that 5-10% of these water masses reaching 137E trapped in a state eddies may be smaller than the recent estimate in past studies. These differences are also discussed.

A study on the variability of the deep ocean circulation during glacial climate with a climate model of intermediate complexity

*Taigo Ando[1], Akira Oka[1]

1. Atmosphere and Ocean Research Institute, University of Tokyo

Ice core reconstructions show that there were abrupt climate changes termed Dansgaard-Oscillation (D-O) oscillations during glacial period, which are most characterized by about 10 ℃ of temperature changes in Greenland within a few decades. Many studies have pointed out the connection between D-O oscillations and changes in the Atlantic Meridional Overturning Circulation (AMOC), while details of its variability is still missing. Previous modeling studies have suggested that the variability of the AMOC including D-O oscillations are invoked by freshwater input from melted ice-sheets into the deep-water formation region in the North Atlantic (e.g. Rahmstrf, 2002). However, some recent model simulations exhibit abrupt and spontaneous oscillations without freshwater forcing in glacial climate (Peltier and Vettoretti, 2014; Brown and Galbraith, 2016), and more researchers are considering that the mechanism of D-O oscillations is involved within the ocean dynamics and its interactions with the atmosphere and sea ice. Since global coupled models usually used in previous simulations contain many processes of the atmosphere and the ocean, they require high computational costs and it is difficult to identify the processes contributing to D-O oscillations from the model simulations. On the other hand, earth system models of intermediate complexity with lighter computational costs have difficulties in reproducing climate features.
In this study, we modified the model in which the atmosphere component is simplified to the energy-balanced model (MIROC-lite, Oka et al., 2011, 2017) by using results of a full-coupled model (MIROC, Hasumi and Emori, 2001) as parameters so as to have equivalent performance to the full-coupled model, then conducted simulations of glacial climate with the model. This model is expected to be effective for investigating the cause of the spontaneous oscillations of full-coupled models since it can better represent thermal feedback between the atmosphere and the ocean by predicting atmosphere temperature from energy balance compared to ocean-only models. In our presentation, we discuss the performance of the model and its implications for the mechanism of D-O oscillations.

Discussion

The use of natural abundances of stable isotopes to elucidate the nitrogen dynamics in plant-soil systems

*Keisuke Koba[1]

1. Center for Ecological Research, Kyoto University

Nitrogen (N) dynamics in terrestrial ecosystems are quite complex because of its high turnover due to the high biological N demand by plants and microbes. The uses of the natural abundance of stable N and oxygen (O) isotopes have been carried out in many ways to elucidate the N dynamics in intact terrestrial ecosystems. The methodological progress ("denitrifier method") can allow us to measure not only N but also O isotope ratios with samples with low N amounts. We applied this analytical method to elucidate the fate of nitrate. Among many fates of nitrate in terrestrial ecosystems, plant nitrate uptake is quite difficult to evaluate. In this talk, I will introduce our results on the uptake of the soil nitrate by tundra plants where soil net nitrification rates are quite low.

Reconstruction of local temporal variation on atmospheric sulfur hexafluoride concentration in the Kyoto Basin by multiple environmental tracer and mass transport analyses

*Koki Kashiwaya[1], Taishi Hori[1], Ryuta Hazama[2], Yoichi Sakuma[3], Katsuaki Koike[1]

1. Kyoto University, 2. Osaka Sangyo University, 3. Tokyo Institute of Technology

Groundwater is a valuable water resource and understanding groundwater flow regime is indispensable to maintain its quantity and quality at favorable conditions and to achieve its sustainable use. Residence time is an indicator reflecting flow regime of groundwater and various environmental tracers can be used to estimate residence time. Sulfur hexafluoride (SF_6) is one of such dating tracer and is frequently used to estimate residence time of relatively young groundwater. SF_6 residence time is estimated by comparing temporal variation curve of atmospheric SF_6 concentration with concentration obtained from measurement of groundwater sample. Groundwater dating with SF_6 is sometimes difficult in urban areas because of locally elevated atmospheric SF_6 concentration and/or contamination. If local temporal change of atmospheric SF_6 concentration can be reconstructed, and if contaminated samples can be detected, they help to increase accuracy of groundwater dating with SF_6. Therefore, we tried to estimate local temporal change of atmospheric SF_6 concentration in the Kyoto Basin. Groundwater samples were collected from 47 wells in the basin and concentrations of tritium and SF_6 were determined. Air samples were also collected at three points to reconstruct the variation curve. Additionally, groundwater flow and mass transport analyses were conducted using MODFLOW and MT3DMS. The groundwater flow and mass transport models were calibrated by comparisons with actually measured water levels and tritium concentrations. Several temporal variation curves of local temporal variation on atmospheric SF_6 concentration were considered, and using these curves, mass transport analysis of SF_6 was conducted. Finally, the calculated and actually measured SF_6 concentrations in groundwater were compared and the temporal variation curve with which error between the calculated and measured values was minimum was selected. In the presentation, residence time of groundwater in the Kyoto Basin is presented and plausibility of the selected temporal curve is discussed.

Quantitative reconstruction of the humidity in the moisture source region based on the ^{17}O-excess in precipitation on a subtropical island

Yuina Uechi[1], *Ryu Uemura[1]

1. University of the Ryukyus

A high-precision analysis of the triple oxygen isotope composition of water provides a new tracer denoted as ^{17}O-excess. In theory, the ^{17}O-excess can be interpreted as variations in the relative humidity in moisture source regions for precipitation. However, recent studies on ^{17}O-excess in the precipitation in polar and dry regions suggest the importance of snow formation and raindrop re-evaporation processes. To date, whether humidity in the moisture source region can be quantified based on observations of ^{17}O-excess in precipitation has not been proven. Here, we show a 2 year record of the ^{17}O-excess in precipitation on a maritime island in the East Asian monsoon region, Okinawa, Japan. We demonstrate that the reconstructed relative humidity is quantitatively consistent with observations in the oceanic moisture source region. This result suggests that the ^{17}O-excess in precipitation on the subtropical island is determined largely by diffusional fractionation during evaporation in the ocean. These results suggest that the ^{17}O-excess in precipitation in tropical and subtropical regions is a unique quantitative tracer for the relative humidity in oceanic moisture source regions and thus will be a useful tracer and proxy for hydrological and paleoclimate studies.

This study focuses on identifying the deep groundwater recharge system in Kathmandu Valley, Nepal using various environmental tracers. The Kathmandu Valley is one of the largest intermontane basin that covers an area of 625 km^2. The average altitude of the valley floor is 1350 m above sea level and is surrounded by the hills rising more than 2800 m. Rainfall in the basin is mostly seasonal with roughly 80% of the 1755 mm average annual total arriving between June and September during monsoon season. Groundwater samples were collected from 10 deep tube wells covering almost all parts of the valley and 2 shallow dug wells located at the central part of the valley. All the collected samples were then subjected to the analysis of major dissolved ions, hydrogen and oxygen stable isotopes and radiocarbon.

Groundwater ion composition using Hexa-diagram showed that the deep groundwater of the Kathmandu Valley tends to be relatively young in the outer peripheral area. Meanwhile for the groundwater located in the central area tends to be older. However, for the shallow wells located at the central area, the higher values of ion composition were derived from the effect of human activities. Relatively high pMC values obtained from radiocarbon were detected from the shallow groundwater at central part of the valley and from the deep groundwater samples those were collected from the peripheral area. On the other hand, the deep groundwater at the central part of valley was observed with low pMC values.

Relatively heavier stable isotopes of hydrogen were observed from both the deep groundwater and the shallow groundwater in the central part of the valley. Along with the pMC values, these results also suggests the possibility of vertical groundwater recharge from the shallow groundwater to the deep groundwater in central part of the valley. However, isotopically depleted groundwater recorded from the peripheral areas also concludes the recharge in this basin occurs from the mountain areas.

AKNOWLEDGMENTS: This study was supported by the JSPS KAKENHI Grant Number is 18K11617. It was also partly supported by the Science and Technology Research Partnership for Sustainable Development Program (SATREPS, Project Manager: Professor Narendra Man Shakya and Professor Futaba Kazama) of the Japan International Cooperation Agency (JICA)/Japan Science and Technology Agency (JST).

Discussion

The discharge rate of the Arima-type deep brine discharge in Ooshika-mura, Nagano Prefecture

*Fumitake Kusuhara[1]

1. Central Research Institute of Electric Power Industry

Arima-type hot spring water is thought to originate from the dehydration from the hydrous minerals in a subducting slab. In the present research, this dehydrated saline water is called “ADB (Arima-type Deep Brine)”. It is important to estimate the amount of the discharge of ADB in order to understand the water circulation in subduction zones. Few studies, however, have been conducted on such estimation because the chemical and isotopic compositions of the ADB is unknown.Ooshika-Mura is located at the southern part of Nagano prefecture, central Japan. It is thought that the ADB is diluted by local meteoric water, gushes out at several points (e.g. the Kashio hot spring, famous as the Arima-type hot spring), and flows into the 4 rivers in the region. In the present research, the flow rate and Cl- concentration of river water is measured at several points along each river. The flow rate of the ADB is estimated at each observation point, based on the results of above measurements and the previous study on the chemical and isotopic composition of the ADB in the researched region. These estimated flow rate values are regarded as the discharge rate of the ADB discharge inside the upstream watershed areas. The ADB discharge rate over the whole area of Ooshika-Mura is estimated approximately 0.8 L/s, by summing up each flow rate at the most downstream point of each river. The estimation is consistent with previous calculation of the dehydration rate from subducting slabs. More than 50% of the discharged ADB in the whole area concentrates within a few kilometers of the confluence of Kashio River and Shiokawa River. The fault plane of the MTL intersects with the Shiokawa River at the area, which is consistent with the ADB discharging model in Kii peninsula, shown by the previous study.

Sublacustrine hydrothermal system of the active crater lake, Yudamari of Aso Volcano inferred from Mg budget of the lake

*Shinji Ohsawa[1], Takeshi Saito[2], Kazuhiro Amita[3]

1. Institute for Geothermal Sciences, Graduate School of Science, Kyoto University, 2. Academic Assembly School of Science and Technology, Shinshu University, 3. Graduate School of Engineering Science, Akita University

The crater lake, Yudamari, formed in the first crater of Mt. Nakadake, Aso Volcano, contains a large amount of dissolved components such as chloride ion (Cl) and magnesium ion (Mg), without the surface outflow of the lake. This kind of water quality is formed under the influence of subaqueous volcanic gas flowing into the lake. From analysis of the isotope composition of the Yudamari water samples (δ D and δ^{18}O), it was found that a large change occurred in the water isotope composition when the lake which became extremely acidic caused the dissolution of chemical components from rocks (oral presentation in the same session last year). In the period when the lake became extremely acidic, the volume of the lake and the water budget were demanded in detail (Saito et al., 2008). We calculated the Mg balance of the lake including the hydrological parameters reported there, and found that a large amount of Mg from 5 to 10 tons per day was eluted from the rock to the lake. Assuming chemical composition and density of the original rock subjected to the acid leaching and converting the Mg leaching amount to the volume of the rock, it is 50 to 200 cubic meters. This is an amazing phenomenon in which a cubic rock from 3 to 6 m is completely altered in one day. The elution of such a large amount of rock components is not caught up in the dissolution reaction only on the bottom surface of the lake. It strongly supports the existence of the subaqueous hydrothermal system that the lake water circulates continuously and reacts with the rock, for example, it is often assumed under the lake of a high temperature and strongly acidic crater lake called active crater lake similar to Yudamari.

Spatial distribution of chemical compositions, hydrogen and oxygen isotopic ratios of stream water of the Shimanto River area, southwestern Japan

*Masaaki Takahashi[1], Hinako Shimizu[1], Kohei Kazahaya[1], Masaya Yasuhara[2,1]

1. The National Institute of Advanced Industrial Science and Technology, 2. Rissho University

109 river water samples were collected from 101 locations in the Shimanto River system and adjacent streams in the western part of Kochi Prefecture and southern part of Ehime Prefecture in December 2007, November 2008, and December 2009, for the purpose of understanding how the distribution of δD and δ^{18}O can be explained by geographical parameters (latitude (LAT), altitude (ELV) and inland degree (Distance from the nearest seashore; DS)) and meteorological parameters (mean annual temperature (MAT) and mean annual precipitation (MAP)), and what is the difference in those explanatory variables of the distribution of δD and δ^{18}O compared to the national level. As a result, it was found that the spatial distribution of δD, δ18O of stream water in the Shimanto area can be shown in detail by using ELV and DS as geographical parameters and MAP as meteorological parameters as explanatory variables.

An isotopic study on shallow groundwater origins in a densely-populated area in Shinagawa, central Tokyo, Japan

*Masaya Yasuhara[1], Akihiko Inamura[2], Takashi Nakamura[3], Kazuyoshi Asai[4]

1. Rissho Univ., 2. Geological Survey of Japan, AIST, 3. Yamanashi Univ., 4. Geo Science Laboratory

Stable isotopes (δ D and δ^{18}O) and hydrochemical tracers (electric conductivity, NH_4^+, NO_3^-, Cl^-) of water were applied to quantify 1) rainfall infiltration (natural recharge), 2) water supply leakage, and 3) sewage leakage in a shallow aquifer in a densely-populated area in Shinagawa, central Tokyo, Japan. Despite of a quite small area about 0.5 km (E-W) by 1 km (N-S), shallow groundwater took on a wide range of values: 28 ~70 mS/m electric conductivity, 0.0 ~9.1 mg/L NH_4^+, 0.1 ~ 36.2 mg/L NO_3^-, 4.8 ~46.6 mg/L Cl^-, and -8.7 ~-7.4‰ δ^{18}O. A ternary mixing model was used based on the Cl^-concentration and d^{18}O of three plausible origins of groundwater to estimate fractions of each component in shallow groundwater in the study area. As a result, a fraction of sewage leakage in groundwater proved large for one well as much as 70%, while for some wells rainfall infiltration contributed more than 80% of water to the formation of groundwater. These remarkable differences in contribution of urban leakage to the shallow aquifer may result from the different state of the water infrastructure in the vicinity of the respective wells.

Geochemical features for spring at Izu Peninsula

*Kazuyoshi Asai[1], Kazumi Asai[1]

1. Geo Science Laboratory

IZU Peninsula is mainly composed of volcanic rocks and hot springs are located all over the area. This study focused on shallow groundwater with high circulation rate. Spring water was collected from 18 site and its dissolved ion, stable isotopes, CFCs and SF6 were determined. Based on the analysis results, we discuss charactaristics of water chemistry, origin and residence time.

Acidification process of shallow groundwater in an alluvial fan in Ueda City, Nagano, Japan

Ran Takahashi[1], *Masaya Yasuhara[2], Seongwon Lee[2], Takashi Nakamura[3], Kazuyoshi Asai[4]

1. Undergraduate student, Rissho Univ., 2. Rissho Univ., 3. Yamanashi Univ., 4. Geo Science Laboratory

The Koganezawa River water in Ueda City, Nagano Prefecture, has strong acidic nature under the influence of pyrite ore deposits once mined in its upstream reach. Sulfate-rich acidified shallow groundwater with pH range of 5 to 6 in the Koganezawagawa River alluvial fan has long been attributed to the infiltration of river water into shallow aquifers beneath the fan (Akutsu, 1958). This study, with the help of a multi-tracer method, aims to improve the information on the present hydrological environment of the Koganezawa River alluvial fan and to clarify its groundwater quality formation process with emphasis on the acidification process of shallow groundwater.
Survey on the Koganezawa River water and shallow groundwater (well water and spring water) of the alluvial fan was conducted from August to November 2018. As a result, 1) groundwater acidity is associated with nitrate and sulfate ions for the left and right banks of the river, respectively, 2) groundwater in the right bank shows lower pH than that in the left bank, and 3) oxygen ($\delta^{18}O$) and hydrogen (δD) isotopic ratios are low for the groundwater in the right bank, compared with that in the left bank. These results strongly suggest the sulfate-rich acidified and isotopically depleted river water infiltrates mainly into the right bank, affecting its shallow groundwater quality. The two end-member mixing analysis, based on the concentration of sulfate (SO_4^{2-}) and nitrate (NO_3^-) ions, indicates a contribution of the infiltrated river water to the formation of the groundwater in the right bank is in the range 8 to 31 %. Furthermore, from the nitrogen ($\delta^{15}N$) and sulfur ($\delta^{34}S$) stable isotopic ratios, it is estimated that nitrogen and sulfur in groundwater in the left bank is likely to be of manure origin. It can be concluded that acidification of shallow groundwater in the Koganezawa River alluvial fan is due to river water infiltration for the right bank, while manuring for the left bank.

Keywords: acidified river water, alluvial fan, river water infiltration, shallow groundwater, groundwater acidification, multi-tracer method

Hydroecological study on fresh water copepod in Chino-ike ('Bloody lake'), an ephemeral lake on the top of Mt. Akagi, central Japan

Hirano Yuri[1], *Masaya Yasuhara[2], Seongwon Lee[2], Yasuhiro Funyu[3], Nozomu Iwasaki[2], Natsumi Shimoda[2]

1. Undergraduate student, Rissho Univ., 2. Rissho Univ., 3. Graduate student, Rissho Univ.

Chino-ike, located on the top of Mt. Akagi at an elevation of ca. 1400 m, is known as an ephemeral lake in which water only appears from early summer to late autumn. Because of being an ephemeral lake, no fish exists there and its ecosystem is mainly composed of plankton. The representative species of plankton in Chino-ike is Acanthodiaptomus pacificus (A. pacificus). Chino-ike is also called “Blood lake” because its water surface used to turn red due to an outbreak of A. pacificus in autumn. This study aims to clarify the ecosystem in Chino-ike with special emphasis on the life cycle of A. pacificus.
The survey was conducted in June, October and December of 2018. In 2018, lake water appeared at 0:00 on October 1 and lasted until 10:00 on October 19. The maximum water depth of 98 cm was recorded at 5:00 on October 3 (Y. Funyu, unpublished data). At the time of the survey on October 16, the maximum water depth was 37 cm, when plankton samples was collected at 17 points of 13 locations including those from different depths at specific locations. The number of plankton in a given volume of lake water was counted on the samples in the laboratory. For the surveys in June and December when the lake dried up, surface soil samples were collected at the same locations for counting the number of dormant eggs and individuals of plankton.
On October 16, most of the collected A. pacificus was copepodite larva. Higher population density was foundat deeper water depths with a maximum density of 477 individuals per litre at 32 cm depth in the center of the lake. From Kadota (1971), it takes at least four months for A. pacificus to develop from an egg to a copepodite larva. But the growth of A. pacificus in Chino-ike was found to be much faster. Because of short-term persistence of water in 2018, it is estimated that A. pacificus in Chino-ike shortened its life cycle and is likely to spend a dry winter in the form of a diapausing larva. From now on, we are elucidating to clarify food habits of A. pacificus on the basis of carbon and nitrogen isotopes as well as to find dormant eggs and individuals in the Chino-ike surface soils .

Keywords: Mt. Akagi, ephemeral lake, Acanthodiaptomus pacificus, aquatic ecology, diapause, carbon and nitrogen isotopes

Cross-sectional distribution in water chemistry and oxygen and hydrogen isotopic ratios in Fuku River, Saitama, Japan

*Manatsu Kimura[1], Yasuhara Masaya[2], Seongwon Lee[2]

1. Graduate School of Geo-Environmental Science, Rissho University, 2. Faculty of Geo-Environmental Science, Rissho University

When discussing water environment of a river, it is essential to know not only the concentration of substances contained in river water but also the dissolved load which is a product of concentration of a given substance and river flow rate. It is therefore important to measure river flow rate and concentration of a given substance with accuracy. In the case of estimating the dissolved load, however, concentration of the substance is often represented by that at a single point in a river cross section, generally by the surface water sample at the center of flow, and less attention has not been paid to its representativeness in a river cross section. It also has been the case with hydrogen and oxygen isotopes, which are often used as tracers in the study on water environment of a river.
In this context, we carried out a field survey in December 2018 to elucidate a detailed concentration distribution of water chemistry (dissolved major ions and heavy metals) and isotopes (dD and $d^{18}O$) for the river cross section 7.7 m wide and ca. 0.5 m deep in Fuku River, Saitama, Japan. As a result, the difference in concentration over the whole cross section of the river was found to be 7.2 % or less for each of the dissolved major ions, whereas as much as 95 % for the dissolved heavy metals. For dD and $d^{18}O$ isotopes, there were differences in those ratios of some ‰and ca. 0.3‰, respectively. It should therefore be noted that considerable over- or underestimation in the dissolved load of substances is likely to happen when estimation is made by a conventional way in which the concentration of substances over the whole cross section is represented by a single surface water sample at the center of flow. This is particularly pronounced for the dissolved heavy metals. When evaluating the dissolved loads in rivers, it is therefore necessary to pay much more attention on where to sample water in a river cross section as well as how to measure the river flow rate accurately.

On concentration and origin of chloride ion in small rivers in Jyoboji area, Fujioka, Gunma, Japan

*Taketoshi Hasegawa[1], Masaya Yasuhara[2], Seongwon Lee[2]

1. Rissho University Graduate School of Geo-environmental Science Environmental Systems Science, 2. Rissho Univ.

Ten short streams including Minamizawa-gawa, each of them is about 1 km long, in Joboji area on the left bank of Kanna River, Fujioka City, were investigated in July and December 2018 for the chloride ion concentration, load of chloride ion, and origin of chloride ion in stream waters. Saline low-temperature small springs (“Yashio mineral springs”) are seeping naturally on some spots in the area.

The concentration of chloride ion of Yashio mineral springs were between 4,798 mg/L and 11,892 mg/L in August, and between 5,162 mg/L and 11,032 mg/L in December. The concentration of chloride ion was very high in the streams; for example, in Minamizawa-gawa, the maximum concentration of chloride ion ranged up to 632.5 mg/L in July, while up to 213.7 mg/L in December. The load of chloride ion in Minamizawa-gawa was calculated to be as much as 45 kg/day in December, accounting for 90 % of the total load of chloride ion transported by these ten streams. In spite of being a short stream 1 km long, the hydrogen (δ D) and oxygen (δ 18O) isotopic ratios of Minamizawa-gawa in December showed a sharp increase from -54.5 ‰and -8.0 ‰in headwaters to -46.7 ‰and -7.3 ‰at a downstream end portion, respectively. In addition, the Li/Cl ratio of Minamisawa-gawa was found to be more than 0.001 for most of its watercourse with a maximum ratio of 0.0018 at a downstream end portion. These characteristics of the chloride ion, δ D and δ 18O isotopes, and Li/Cl ratio are attributed to the deep-seated fluid which flows upward through the Sambagawa crystalline schists and mixes with shallow water bodies.

Keywords: stream water, chloride ion, dissolved load, stable isotopes of water, Yasio mineral springs, deep-seated fluid

Geochemical characteristics and origin of groundwater in central to eastern Hokkaido

*Yusei Nakagaki[1]

1. Chiba University

Japanese island arc is located in the subduction system where the groundwater migration/circulation is significant. Groundwater has chemical history of dissolved components that come from deep part. There are many reports about chemical composition of groundwater in Hokkaido. However, there is little geochemical research about chemical constituents derived from deep in the groundwater in Hokkaido. The relationship between geological features and chemical characteristics of groundwater remains unknown. This study focused on the geochemistry of deep fluid collected from hot springs in central to eastern Hokkaido area to understand the origin and underground geochemical processes by analyzing main and trace elements, hydrocarbon gas, and oxygen-hydrogen isotopes.

The concentrations of dissolved major elements such as Cl, suggested that groundwater in Hokkaido is mainly of seawater origin. The δ18O and δD values, however, indicate that the fluid also contains meteoric water. The redox condition of deep environment had changed the concentrations of Mn and SO4, and the weathering of sedimentary rocks had increased the amount of Si, respectively. Iodine was significantly enriched compared to seawater, resulting from the deposition of I-rich marine algae in the internal shallow water zone. Concentrations of trace elements such as Pb, Zn, and Li vary among sampling locations, which indicates elution of Pb and Zn by the weathering of minerals, and release of Li from clay minerals in high temperature environment.

Identification of hydrological characteristics on the groundwater recharge in volcanic and non-volcanic mountains

*sano anna[1], Takashi Nakamura[1], Kei Nishida[1]

1. International Research Center for River Basin Environment, University of YAMANASHI

Kofu basin is located at the central part of Japan, Yamanashi and lies 300 km away from Japan Sea. 80% of this basin area is covered by the mountains that are originated from the volcanism and diastrophism with various geological settings. This study focuses on identifying the groundwater recharge processes in Kai city derived from volcanic mountain and Minami Alps city formed from the fault block mountains, located at the western Kofu basin of Yamanashi prefecture. Water samples were collected from major river, deep tube wells and mountain springs at 2011 to 2013 and 2018.
Spring water collected from the mountains and river water were observed with almost similar depleted value ranges. However, in both cities, the high d-excess values are detected. Higher d-excess value in the mountain might occur from the higher rainfall and snow during winter season, whereas the low d-excess values detected on the alluvial fan might be due to the less winter rainfall and snow in comparison with mountain area. The spatial distributions of the d-excess values and the Cl^- concentrations suggested the Minami Alps city is recharged from the water infiltrated at the mountain to the alluvial fan. Meanwhile, water originated from mountain is recharged to the hill, but it is not recharged to the alluvial fan in Kai city. Thus, the combination of d-excess value and Cl- tracer is useful in identifying the groundwater recharge process of areas with different geological origin.

Analysis of spring water formation mechanism used by ^{222}Rn concentration at Masutomi-Onsen located in Yamanashi, Japan

*Eiki Mochizuki[1], Takuya Hayakawa[1], Hiroshi Kobayashi[1]

1. Yamanashi Institute of Public Health and Environment

The ^{222}Rn content of Masutomi-Onsen in the northern part of Yamanashi Prefecture is one of the best in the country and many users are visiting as spa resort areas. In order to use this hot spring for a long term, planned use, it is important to clarify the current formation mechanism of spring water.
In Masutomi-Onsen, it is reported that the sedimentary rock near the surface of the earth is a source of ^{222}Rn. Therefore, the behaviors of the ^{222}Rn concentration and other component concentrations except ^{222}Rn are considered to be different. Therefore, we attempted to estimate the formation mechanism of spring water based on ^{222}Rn concentration and other component concentration.
In this study, we regularly monitored Nyuzawa spring in the Masutomi-Onsen area for 2 years from April, 2016 to March, 2018, about discharge amount , ^{222}Rn concentration , other component concentrations, and water temperature.
As a result, periodic fluctuations were observed in ^{222}Rn concentration range from 3,700 to 7,800 Bq / kg. However, except for Unusual decrease in concentration at October 2017 and March 2018, other component concentrations, discharge amount, and water temperature were constant.
In October 2017 and March 2018 in which Unusual decrease in other component concentration was observed, both were consistent with the time when the periodic fluctuation of ^{222}Rn concentration showed minimum. lot of rain was observed immediately before monitoring, and it seemed that this was related to ^{222}Rn and other component concentration reduction. From this, we analyzed the variation of ^{222}Rn concentration , Unusual decrease of other component concentrations and the relevance of precipitation.
When water was supplied to the surface by rainfall, ^{222}Rn concentration decreased, and Then it took 4 months to recover. other component concentrations were constant regardless of the amount of precipitation except Unusual decrease.
I set the following hypothesis to explain this. ^{222}Rn arising from sedimentary rocks becomes ^{222}Rn gas in the soil, and this ^{222}Rn gas is one of ^{222}Rn sources in spring water. Normally, shallow groundwater does not intersect with spring water, but shallow groundwater deprives ^{222}Rn gas according to its amount, so ^{222}Rn concentration in spring water fluctuates.
In order to verify this hypothesis, we confirmed the relationship between shallow groundwater level estimated from precipitation and ^{222}Rn concentration, and as a result, a significant negative correlation was observed, and a result supporting the hypothesis was obtained.
From these facts, it was possible to explain formation mechanism of spring water based on ^{222}Rn concentration, other component concentrations and precipitation in Nyuzawa spring.

Keywords: hot spring, Masutomi-Onsen, Yamanashi prefecture, Radon-222, formation mechanism

Migration Behavior of Radiocesium Derived from the Fukushima Dai-Ichi Nuclear Power Plant Accident in Natsui River and Tone River

*Deddy Irawan Permana Putra[1], Shinya Ochiai[2], Seiichi Tomihara[3], Shun Watanabe[4], Kyuma Suzuki[4], Seiya Nagao[2]

1. Kanazawa University, Graduate School of Natural Science and Technology, 2. Low Level Radioactivity Laboratory, Kanazawa University, 3. Aquamarine Fukushima, 4. Gunma Prefectural Fisheries Experiment Station

The accident of Fukushima Dai-ichi Nuclear Power Plant due to the Tohoku earthquake, which occurred on 11 March 2011, has released a large amount of radioactive materials to the atmosphere. This accident resulted contamination of radioactive cesium (^{134}Cs and ^{137}Cs) on land, rivers and sea around Fukushima Prefecture. Radioactive cesium widely deposited on land and transported from watershed through river system to the ocean. In this study concentration of ^{134}Cs and ^{137}Cs in river water has been investigated for dissolved and particulate phase. River water sample was collected at a fixed station from the Tone River and the Natsui River at normal and high flow condition during 2018-2019. Suspended solids were separated using continuous flow centrifugation and dissolved cesium were co-precipitated using ammonium molybdophosphate (AMP) method.
The AMP precipitated and suspended solids were dried to determined radioactive cesium concentration using HPGe gamma spectrometry. Investigations of cesium concentration in the rivers have been performed to understand factors controlling transport of radiocesium during different condition. The maximum concentration of ^{134}Cs and ^{137}Cs at normal condition was 0.7 mBq $L^{-1}$and 7.9 mBq L^{-1}in the Tone River, and 1.1 mBq $L^{-1}$and 11 mBq L^{-1}in the Natsui River, respectively. After the rainy events and typhoon, the concentration of ^{134}Cs and ^{137}Cs in river water was increased. Total concentration of ^{134}Cs after the rainy events in the Tone River and the Natsui River was 18 –37 mBq $L^{-1}$and 40 mBq L^{-1} respectively, and concentration for ^{137}Cs was 211 –411 mBq $L^{-1}$and 447 mBq L^{-1}respectively. During the study period, 97-100 % of ^{134}Cs and ^{137}Cs was distributed by suspended solid in the Tone River and 95-100 % of ^{134}Cs and ^{137}Cs in the Natsui River after the rainy events. These results indicate that behavior of suspended solids is a main factor controlling variation of concentration of ^{134}Cs and ^{137}Cs in both rivers.

Geochemical features for spring at Izu Peninsula

*Kazuyoshi Asai[1], Kazumi Asai[1]

1. Geo Science Laboratory

IZU Peninsula is mainly composed of volcanic rocks and hot springs are located all over the area. This study focused on shallow groundwater with high circulation rate. Spring water was collected from 18 site and its dissolved ion, stable isotopes, CFCs and SF6 were determined. Based on the analysis results, we discuss charactaristics of water chemistry, origin and residence time.

Keywords: IZU Peninsula , spring, water chemistry, origin, residence time

Acidification process of shallow groundwater in an alluvial fan in Ueda City, Nagano, Japan

Ran Takahashi[1], *Masaya Yasuhara[2], Seongwon Lee[2], Takashi Nakamura[3], Kazuyoshi Asai[4]

1. Undergraduate student, Rissho Univ., 2. Rissho Univ., 3. Yamanashi Univ., 4. Geo Science Laboratory

The Koganezawa River water in Ueda City, Nagano Prefecture, has strong acidic nature under the influence of pyrite ore deposits once mined in its upstream reach. Sulfate-rich acidified shallow groundwater with pH range of 5 to 6 in the Koganezawagawa River alluvial fan has long been attributed to the infiltration of river water into shallow aquifers beneath the fan (Akutsu, 1958). This study, with the help of a multi-tracer method, aims to improve the information on the present hydrological environment of the Koganezawa River alluvial fan and to clarify its groundwater quality formation process with emphasis on the acidification process of shallow groundwater.
Survey on the Koganezawa River water and shallow groundwater (well water and spring water) of the alluvial fan was conducted from August to November 2018. As a result, 1) groundwater acidity is associated with nitrate and sulfate ions for the left and right banks of the river, respectively, 2) groundwater in the right bank shows lower pH than that in the left bank, and 3) oxygen ($\delta^{18}O$) and hydrogen (δD) isotopic ratios are low for the groundwater in the right bank, compared with that in the left bank. These results strongly suggest the sulfate-rich acidified and isotopically depleted river water infiltrates mainly into the right bank, affecting its shallow groundwater quality. The two end-member mixing analysis, based on the concentration of sulfate (SO_4^{2-}) and nitrate (NO_3^-) ions, indicates a contribution of the infiltrated river water to the formation of the groundwater in the right bank is in the range 8 to 31 %. Furthermore, from the nitrogen ($\delta^{15}N$) and sulfur ($\delta^{34}S$) stable isotopic ratios, it is estimated that nitrogen and sulfur in groundwater in the left bank is likely to be of manure origin. It can be concluded that acidification of shallow groundwater in the Koganezawa River alluvial fan is due to river water infiltration for the right bank, while manuring for the left bank.

Keywords: acidified river water, alluvial fan, river water infiltration, shallow groundwater, groundwater acidification, multi-tracer method

Hydroecological study on fresh water copepod in Chino-ike ('Bloody lake'), an ephemeral lake on the top of Mt. Akagi, central Japan

Hirano Yuri[1], *Masaya Yasuhara[2], Seongwon Lee[2], Yasuhiro Funyu[3], Nozomu Iwasaki[2], Natsumi Shimoda[2]

1. Undergraduate student, Rissho Univ., 2. Rissho Univ., 3. Graduate student, Rissho Univ.

Chino-ike, located on the top of Mt. Akagi at an elevation of ca. 1400 m, is known as an ephemeral lake in which water only appears from early summer to late autumn. Because of being an ephemeral lake, no fish exists there and its ecosystem is mainly composed of plankton. The representative species of plankton in Chino-ike is Acanthodiaptomus pacificus (A. pacificus). Chino-ike is also called “Blood lake” because its water surface used to turn red due to an outbreak of A. pacificus in autumn. This study aims to clarify the ecosystem in Chino-ike with special emphasis on the life cycle of A. pacificus.
The survey was conducted in June, October and December of 2018. In 2018, lake water appeared at 0:00 on October 1 and lasted until 10:00 on October 19. The maximum water depth of 98 cm was recorded at 5:00 on October 3 (Y. Funyu, unpublished data). At the time of the survey on October 16, the maximum water depth was 37 cm, when plankton samples was collected at 17 points of 13 locations including those from different depths at specific locations. The number of plankton in a given volume of lake water was counted on the samples in the laboratory. For the surveys in June and December when the lake dried up, surface soil samples were collected at the same locations for counting the number of dormant eggs and individuals of plankton.
On October 16, most of the collected A. pacificus was copepodite larva. Higher population density was foundat deeper water depths with a maximum density of 477 individuals per litre at 32 cm depth in the center of the lake. From Kadota (1971), it takes at least four months for A. pacificus to develop from an egg to a copepodite larva. But the growth of A. pacificus in Chino-ike was found to be much faster. Because of short-term persistence of water in 2018, it is estimated that A. pacificus in Chino-ike shortened its life cycle and is likely to spend a dry winter in the form of a diapausing larva. From now on, we are elucidating to clarify food habits of A. pacificus on the basis of carbon and nitrogen isotopes as well as to find dormant eggs and individuals in the Chino-ike surface soils .

Cross-sectional distribution in water chemistry and oxygen and hydrogen isotopic ratios in Fuku River, Saitama, Japan

*Manatsu Kimura[1], Yasuhara Masaya[2], Seongwon Lee[2]

1. Graduate School of Geo-Environmental Science, Rissho University, 2. Faculty of Geo-Environmental Science, Rissho University

When discussing water environment of a river, it is essential to know not only the concentration of substances contained in river water but also the dissolved load which is a product of concentration of a given substance and river flow rate. It is therefore important to measure river flow rate and concentration of a given substance with accuracy. In the case of estimating the dissolved load, however, concentration of the substance is often represented by that at a single point in a river cross section, generally by the surface water sample at the center of flow, and less attention has not been paid to its representativeness in a river cross section. It also has been the case with hydrogen and oxygen isotopes, which are often used as tracers in the study on water environment of a river.
In this context, we carried out a field survey in December 2018 to elucidate a detailed concentration distribution of water chemistry (dissolved major ions and heavy metals) and isotopes (dD and $d^{18}O$) for the river cross section 7.7 m wide and ca. 0.5 m deep in Fuku River, Saitama, Japan. As a result, the difference in concentration over the whole cross section of the river was found to be 7.2 % or less for each of the dissolved major ions, whereas as much as 95 % for the dissolved heavy metals. For dD and $d^{18}O$ isotopes, there were differences in those ratios of some ‰and ca. 0.3‰, respectively. It should therefore be noted that considerable over- or underestimation in the dissolved load of substances is likely to happen when estimation is made by a conventional way in which the concentration of substances over the whole cross section is represented by a single surface water sample at the center of flow. This is particularly pronounced for the dissolved heavy metals. When evaluating the dissolved loads in rivers, it is therefore necessary to pay much more attention on where to sample water in a river cross section as well as how to measure the river flow rate accurately.

On concentration and origin of chloride ion in small rivers in Jyoboji area, Fujioka, Gunma, Japan

*Taketoshi Hasegawa[1], Masaya Yasuhara[2], Seongwon Lee[2]

1. Rissho University Graduate School of Geo-environmental Science Environmental Systems Science, 2. Rissho Univ.

Ten short streams including Minamizawa-gawa, each of them is about 1 km long, in Joboji area on the left bank of Kanna River, Fujioka City, were investigated in July and December 2018 for the chloride ion concentration, load of chloride ion, and origin of chloride ion in stream waters. Saline low-temperature small springs (“Yashio mineral springs”) are seeping naturally on some spots in the area.

The concentration of chloride ion of Yashio mineral springs were between 4,798 mg/L and 11,892 mg/L in August, and between 5,162 mg/L and 11,032 mg/L in December. The concentration of chloride ion was very high in the streams; for example, in Minamizawa-gawa, the maximum concentration of chloride ion ranged up to 632.5 mg/L in July, while up to 213.7 mg/L in December. The load of chloride ion in Minamizawa-gawa was calculated to be as much as 45 kg/day in December, accounting for 90 % of the total load of chloride ion transported by these ten streams. In spite of being a short stream 1 km long, the hydrogen (δ D) and oxygen (δ 18O) isotopic ratios of Minamizawa-gawa in December showed a sharp increase from -54.5 ‰and -8.0 ‰in headwaters to -46.7 ‰and -7.3 ‰at a downstream end portion, respectively. In addition, the Li/Cl ratio of Minamisawa-gawa was found to be more than 0.001 for most of its watercourse with a maximum ratio of 0.0018 at a downstream end portion. These characteristics of the chloride ion, δ D and δ 18O isotopes, and Li/Cl ratio are attributed to the deep-seated fluid which flows upward through the Sambagawa crystalline schists and mixes with shallow water bodies.

Keywords: stream water, chloride ion, dissolved load, stable isotopes of water, Yasio mineral springs, deep-seated fluid

Geochemical characteristics and origin of groundwater in central to eastern Hokkaido

*Yusei Nakagaki[1]

1. Chiba University

Japanese island arc is located in the subduction system where the groundwater migration/circulation is significant. Groundwater has chemical history of dissolved components that come from deep part. There are many reports about chemical composition of groundwater in Hokkaido. However, there is little geochemical research about chemical constituents derived from deep in the groundwater in Hokkaido. The relationship between geological features and chemical characteristics of groundwater remains unknown. This study focused on the geochemistry of deep fluid collected from hot springs in central to eastern Hokkaido area to understand the origin and underground geochemical processes by analyzing main and trace elements, hydrocarbon gas, and oxygen-hydrogen isotopes.

The concentrations of dissolved major elements such as Cl, suggested that groundwater in Hokkaido is mainly of seawater origin. The δ18O and δD values, however, indicate that the fluid also contains meteoric water. The redox condition of deep environment had changed the concentrations of Mn and SO4, and the weathering of sedimentary rocks had increased the amount of Si, respectively. Iodine was significantly enriched compared to seawater, resulting from the deposition of I-rich marine algae in the internal shallow water zone. Concentrations of trace elements such as Pb, Zn, and Li vary among sampling locations, which indicates elution of Pb and Zn by the weathering of minerals, and release of Li from clay minerals in high temperature environment.

Identification of hydrological characteristics on the groundwater recharge in volcanic and non-volcanic mountains

*sano anna[1], Takashi Nakamura[1], Kei Nishida[1]

1. International Research Center for River Basin Environment, University of YAMANASHI

Kofu basin is located at the central part of Japan, Yamanashi and lies 300 km away from Japan Sea. 80% of this basin area is covered by the mountains that are originated from the volcanism and diastrophism with various geological settings. This study focuses on identifying the groundwater recharge processes in Kai city derived from volcanic mountain and Minami Alps city formed from the fault block mountains, located at the western Kofu basin of Yamanashi prefecture. Water samples were collected from major river, deep tube wells and mountain springs at 2011 to 2013 and 2018.
Spring water collected from the mountains and river water were observed with almost similar depleted value ranges. However, in both cities, the high d-excess values are detected. Higher d-excess value in the mountain might occur from the higher rainfall and snow during winter season, whereas the low d-excess values detected on the alluvial fan might be due to the less winter rainfall and snow in comparison with mountain area. The spatial distributions of the d-excess values and the Cl^- concentrations suggested the Minami Alps city is recharged from the water infiltrated at the mountain to the alluvial fan. Meanwhile, water originated from mountain is recharged to the hill, but it is not recharged to the alluvial fan in Kai city. Thus, the combination of d-excess value and Cl- tracer is useful in identifying the groundwater recharge process of areas with different geological origin.

Analysis of spring water formation mechanism used by ^{222}Rn concentration at Masutomi-Onsen located in Yamanashi, Japan

*Eiki Mochizuki[1], Takuya Hayakawa[1], Hiroshi Kobayashi[1]

1. Yamanashi Institute of Public Health and Environment

The ^{222}Rn content of Masutomi-Onsen in the northern part of Yamanashi Prefecture is one of the best in the country and many users are visiting as spa resort areas. In order to use this hot spring for a long term, planned use, it is important to clarify the current formation mechanism of spring water.
In Masutomi-Onsen, it is reported that the sedimentary rock near the surface of the earth is a source of ^{222}Rn. Therefore, the behaviors of the ^{222}Rn concentration and other component concentrations except ^{222}Rn are considered to be different. Therefore, we attempted to estimate the formation mechanism of spring water based on ^{222}Rn concentration and other component concentration.
In this study, we regularly monitored Nyuzawa spring in the Masutomi-Onsen area for 2 years from April, 2016 to March, 2018, about discharge amount , ^{222}Rn concentration , other component concentrations, and water temperature.
As a result, periodic fluctuations were observed in ^{222}Rn concentration range from 3,700 to 7,800 Bq / kg. However, except for Unusual decrease in concentration at October 2017 and March 2018, other component concentrations, discharge amount, and water temperature were constant.
In October 2017 and March 2018 in which Unusual decrease in other component concentration was observed, both were consistent with the time when the periodic fluctuation of ^{222}Rn concentration showed minimum. lot of rain was observed immediately before monitoring, and it seemed that this was related to ^{222}Rn and other component concentration reduction. From this, we analyzed the variation of ^{222}Rn concentration , Unusual decrease of other component concentrations and the relevance of precipitation.
When water was supplied to the surface by rainfall, ^{222}Rn concentration decreased, and Then it took 4 months to recover. other component concentrations were constant regardless of the amount of precipitation except Unusual decrease.
I set the following hypothesis to explain this. ^{222}Rn arising from sedimentary rocks becomes ^{222}Rn gas in the soil, and this ^{222}Rn gas is one of ^{222}Rn sources in spring water. Normally, shallow groundwater does not intersect with spring water, but shallow groundwater deprives ^{222}Rn gas according to its amount, so ^{222}Rn concentration in spring water fluctuates.
In order to verify this hypothesis, we confirmed the relationship between shallow groundwater level estimated from precipitation and ^{222}Rn concentration, and as a result, a significant negative correlation was observed, and a result supporting the hypothesis was obtained.
From these facts, it was possible to explain formation mechanism of spring water based on ^{222}Rn concentration, other component concentrations and precipitation in Nyuzawa spring.

In the Kanto plain, which has the Tokyo metropolitan area, one of the world's largest urban areas, groundwater has been developed extensively in various places as an important water resource. While groundwater development has supported the development and expansion of urban areas, it has led to decreases in groundwater resource and land subsidence. As the measures, the national government and municipalities have regulated groundwater pumping by laws and ordinances. However, in recent years, groundwater demands have been increasing again as private water sources at facilities such as hospitals, as responding to the increase in the burden of maintenance cost of water supply and sewage infrastructure due to the declining population, and as water resource against for emergent water source for natural disasters. Responding to these groundwater demands, basin-scale water resources management is required in order to properly use of groundwater without reoccurring land subsidence. In addition, in order to properly manage water resources, it is essential to grasp the influence of the use of groundwater in each region and to grasp changes in regional groundwater flow.

The authors have carried out the studies on groundwater flow system in the plain part of Saitama prefecture, located in the central Kanto plain, to clarify the process and the mechanism of the transition of groundwater flow accompanying groundwater development. Groundwater flow in this area has been changing due to the groundwater development and the pumping restrictions. In order to respond to the future groundwater demand, that is, to predict how the groundwater flow will change with future groundwater re-development in various places, it is necessary not only to grasp the current state of groundwater flow but also to understand the mechanism of the historical change of groundwater flow due to groundwater development. In addition, in this area, the groundwater flow has been also affected by the groundwater use in the surrounding prefectures. Thus, it is also required to grasp the regional groundwater flow in regional scale.

In this area, hydraulic heads in the developed aquifers have recovered due to groundwater pumping regulation. In this process, although the overall hydraulic head distribution of the area has not changed, the difference of water heads in the area has decreased. These results show that although the mechanism of groundwater flow has not changed significantly, the groundwater flux may have decreased. However, the current hydraulic head distribution and the groundwater flow mechanism are quite different from the original ones (state before large-scale development). This suggests that groundwater flow in the area is just a state in which land subsidence is kept and it is becoming a new steady state. In this presentation, based on the results of our studies, we will discuss the groundwater flow in the current condition and in the historical changes with human activities in the area, and issues to grasp regional groundwater flow appropriately.

Integrated groundwater monitoring required for sustainable basin water resources management: Evaluation of effects of groundwater development utilized existing observation well network in the Tokyo metropolitan area

*Akinobu Miyakoshi[1], Takeshi Hayashi[2], Shoichi Hachinohe[3], Hideki Hamamoto[3]

1. Geological Survey of Japan, AIST, 2. Faculty of Education and Human Studies, Akita University, 3. Center for Environmental Science in Saitama

Three-dimensional subsurface temperature distribution and its long-term change were examined by repeated observations of temperature-depth profiles at monitoring wells since 2000 in order to evaluate effects of regional-local groundwater flow change due to groundwater development and pumping regulation, urbanization and climate change on groundwater and subsurface thermal environment in the Tokyo metropolitan area, Japan. Results of these studies have suggested that groundwater and subsurface thermal environment shows complex changes over a long term, wide area and deep part in the metropolis. Miyakoshi et al. (2017) have reported the subsurface warming at the shallow part in the southern part of the Kanto Plain from the comparison of temperature-depth profiles measured at the land subsidence and groundwater level observation well distributed in Tokyo and Saitama prefecture in the past 10 years. It was considered that effect of the subsurface warming reaches deeper at the upland corresponding to groundwater recharge area in comparison with the lowland. Miyakoshi et al. (2016) have reported the temperature changes was found at 100 to 300m deep in the southern part of Gunma and Tochigi prefecture by the comparison between present data and past data measured in 1960s and 1970s in the northern part of the plain. This temperature change at the deep part was induced by the effects of groundwater flow changes due to groundwater development and pumping regulation in this area. These results show that the changes in groundwater flow is detected as an anomaly of subsurface temperature distribution and its change.

These previous studies are based on the intermittent repeated measurement in several years. On the other hand, groundwater development shows changes according to social groundwater demand by different periods, and recent demand shows increasing tendency. Groundwater monitoring which respond quickly to its environmental change is required at the regional scale in addition to water resource management at the basin scale, in order to sustainable management of groundwater resource. The groundwater environmental change includes subsurface thermal environmental changes caused by waste heat from surface/underground buildings and climate change. Subsurface temperature monitoring has been conducted since 2012 at 6 wells in Tokyo (Miyakoshi et al., 2017) and since 2007 at 4 wells in Saitama prefecture. These monitoring results showed the continues warming tendency at the shallow part, however differences in the rates of warming and seasonal fluctuation trend were found and it was shown the effects of reginal groundwater flow changes due to artificial effects.

Additionally, it is assumed that not only pumping volume and time but also depth of groundwater development will change with diversified groundwater demand. In order to accord such diversification of groundwater development, it is required to integrate usage of current observation wells and to accumulate efficiently groundwater data. Monitoring of temperature-depth profile by using distributed temperature sensing technology (Yamano and Goto, 2001; Bense et al., 2016) is cited as an example of integrated subsurface temperature observation at the observation wells in addition to temperature monitoring at the several depths by using temperature data loggers, and these monitoring results are expected to detect changes of groundwater flux at the several aquifers. It is possible to detect and

STORMWATER DRAINAGE SYSTEM OF AN INDIAN TOWN: WHETHER SUSTAINABLE?

*Rajesh Kumar Vishwakarma[1], Dr. Himanshu Joshi[1]

1. Indian Institute of Technology, Roorkee

In the last few decades, the world has witnessed rapid urbanization. One of the many complex problems which have come up with increased urbanization is that of rapid drainage of storm water from the inhabited areas. This paper presents sustainability evaluation of storm water drainage system of an Indian urban town and interpretation of the findings in order to explore solution. To determine and monitor the implementation of sustainable storm water paradigm, the sub-committee for development of “National (Indian) sustainable habitat parameters on urban storm water management” has developed the key parameters and indicators which are: Natural drainage system index, Drainage coverage (constructed) index, Permeability index, Water bodies rejuvenation index, water body vulnerability index, Water logging index, Area vulnerability index, Storm water discharge quality index and Rainfall intensity index etc. The sustainability indices for the storm water have been computed within the limit on 0 to 1 scale. Interpretation of the computed indices has thrown light on the current status of the system and the desired developments.

Using a genetic algorithm to investigate the spatial arrangement of low impact development facilities: a case study of National Taiwan University campus.

*Chung-Yuan Liang[1], Gene Jiing-yun You[1]

1. National Taiwan University

With urban development, surface runoff and peak flow in cites continuously increase and the insufficient capacity of the sewer system induces more and more urban flooding problems. Low Impact Development (LID), one of the source control strategies, uses functionally equivalent hydrologic landscape to improve the ability of infiltration and retention so that the hydrologic condition of the urban surface can be more returned to the pre-development state. Although LID is a kind of the source control strategies, previous studies seldom focus on the spatial arrangement of LID in an urban watershed but only focus on the mechanism units of LID facilities or simple case studies of its implications. This study took the main campus of National Taiwan University (NTU) as a case study. We combined SWMM and a genetic algorithm (GA) to simulate under 36 different rainfall scenarios. The program optimizes installed area size of LID in each sewershed with two different budgetary constraints. By this way, we can know what kind of watershed allocation of LID is more effective for reducing peak flow. In addition, statistical and hydrologic methods are used to analyze the results of optimization. Through analyzing the mechanism of a single unit of LID and optimizing the installed area size of LID in each subcatchment, we can find out how LID reduce peak flow from the microscale and the macroscale. This mechanism of LID also corresponds to the analysis results from optimization, which elaborated that the first priority of setting LID is located at the midstream of the main line where the peak flow concentrates on the peak outflow of the basin rather than before it or after it. In the end, we suggest a LID spatial arrangement strategy for the reference to further city planning.

[A-HW25] Water Environment and Geology in Urban Areas

convener:Takeshi Hayashi(Faculty of Education and Human Studies, Akita University)

The scope of this session is to create an interdisciplinary forum on the most recent advances in water environment and environmental geology research in urban areas. Various kinds of studies concerning environmental issues on water and geology in urban areas (e.g. water balance, water cycle, water resource development and management, inundations, hydrogeology, pollution and remediation, geohazard, basic law on the water cycle) are welcome from academia, industry, and government as well as wider geographic diversity.

In the Kanto plain, which has the Tokyo metropolitan area, one of the world's largest urban areas, groundwater has been developed extensively in various places as an important water resource. While groundwater development has supported the development and expansion of urban areas, it has led to decreases in groundwater resource and land subsidence. As the measures, the national government and municipalities have regulated groundwater pumping by laws and ordinances. However, in recent years, groundwater demands have been increasing again as private water sources at facilities such as hospitals, as responding to the increase in the burden of maintenance cost of water supply and sewage infrastructure due to the declining population, and as water resource against for emergent water source for natural disasters. Responding to these groundwater demands, basin-scale water resources management is required in order to properly use of groundwater without reoccurring land subsidence. In addition, in order to properly manage water resources, it is essential to grasp the influence of the use of groundwater in each region and to grasp changes in regional groundwater flow.

The authors have carried out the studies on groundwater flow system in the plain part of Saitama prefecture, located in the central Kanto plain, to clarify the process and the mechanism of the transition of groundwater flow accompanying groundwater development. Groundwater flow in this area has been changing due to the groundwater development and the pumping restrictions. In order to respond to the future groundwater demand, that is, to predict how the groundwater flow will change with future groundwater re-development in various places, it is necessary not only to grasp the current state of groundwater flow but also to understand the mechanism of the historical change of groundwater flow due to groundwater development. In addition, in this area, the groundwater flow has been also affected by the groundwater use in the surrounding prefectures. Thus, it is also required to grasp the regional groundwater flow in regional scale.

In this area, hydraulic heads in the developed aquifers have recovered due to groundwater pumping regulation. In this process, although the overall hydraulic head distribution of the area has not changed, the difference of water heads in the area has decreased. These results show that although the mechanism of groundwater flow has not changed significantly, the groundwater flux may have decreased. However, the current hydraulic head distribution and the groundwater flow mechanism are quite different from the original ones (state before large-scale development). This suggests that groundwater flow in the area is just a state in which land subsidence is kept and it is becoming a new steady state. In this presentation, based on the results of our studies, we will discuss the groundwater flow in the current condition and in the historical changes with human activities in the area, and issues to grasp regional groundwater flow appropriately.

Gulf Stream and Kuroshio are synchronized

*Tsubasa Kohyama[1], Hiroaki Miura[1], Shoichiro Kido[1]

1. Department of Earth and Planetary Science, The University of Tokyo

The Gulf Stream and the Kuroshio transport heat from the tropics to the extratropics, and their temperature variations affect densely-populated areas in the northern hemisphere through extreme weather and fisheries production. The two warm ocean currents are separated by the North American continent, and thus, they cannot exchange heat by the oceanic circulation within a few years.

In this presentation, however, we show that sea surface temperatures (SST) of the two warm currents are synchronized for interannual to decadal time scales. This synchronization, which we refer to as the Boundary Current Synchronization (BCS), is associated with the meridional migrations of the atmospheric jet stream. The singular value decomposition (SVD) analysis between SST and zonal wind shows that, from the conventional viewpoint, BCS is explained as the covariability shared by the Pacific Decadal Oscillation and the Northern Annular Mode. Nevertheless, the SVD time series exhibit high correlations with the zonal-mean meridional SST difference between subtropics and midlatitudes, which supports the notion that BCS may be understood better as the annular mode of the upper ocean.

We also discuss some implications for extreme weather and climate change. The regression map of 2-meter temperature on the BCS index exhibits a similar pattern to the temperature pattern in July 2018, which implies an essential relationship between BCS and the abnormally hot summer. BCS also connects two apparently unrelated global warming responses: the western boundary currents warm faster than the global mean, and that the atmospheric jet stream shifts poleward.

A study on mixed layer depth variability in the Kuroshio Extension region based on a frontal Ekman model

*Tomoki Tozuka[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

In oceanic frontal regions, surface geostrophic currents have a vertical shear aligned with the density front that can balance a portion of the surface wind stress, and only the portion of the wind stress that is not in balance with the surface geostrophic shear (i.e. "effective wind stress") forces an ageostrophic Ekman spiral. Thus, if the front were uniform with depth, it is expected that the vertical velocity at tthe mixed layer base is better represented by the curl of the effective wind stress, rather than the full wind stress. In this study, we have examined the above in the Kuroshio Extension region, where a prominent sea surface temperature front exists, and some preliminary results based on an analysis of a high-resolution ocean assimilation product are presented.

Mechanisms of Reemergence in the North Pacific revealed by Mixed Layer Heat Budget Analysis

*Kazumichi Murata[1], Shoichiro Kido[1], Tomoki Tozuka[1]

1. Department of Earth and Planetary Science, School of Science, The University of Tokyo

Wintertime sea surface temperature (SST) anomalies that disappear in summer and recur in the following winter is called “reemergence”. Previous studies suggested that temperature anomalies that subduct into the subsurface during the shoaling phase of the mixed layer are preserved under the mixed layer due to isolation from atmospheric forcing and reentrained into the surface mixed layer. Since reemergence is considered to play an important role in the Pacific Decadal Oscillation, it is important to understand its mechanisms, but past studies are mostly based on statistical analyses. Therefore, in this thesis, the mechanisms of reemergence in the North Pacific is clarified quantitatively by an online mixed layer heat budget analysis with an ocean model simulation.

Following a method proposed by a previous study, areas with reemergence are detected and the focus of this study is the Reemergence Area (RA, 35˚-40˚N, 155˚-145˚W) in the central North Pacific. In the RA, the Reemergence Years (RYs) are determined and the mixed layer heat budget analysis is conducted with the integration of the Regional Ocean Model System (ROMS) covering the RA. In contrast to past studies that suggested importance of anomalous entrainment term, it is shown that several mechanisms are operating in reemergence. In particular, the anomalous Ekman meridional advection of the mean meridional temperature gradient induced by zonal wind stress anomalies plays an important role in many RYs. Also, coincidence in the sign of SST anomalies in winter and surface heat flux anomalies in the following autumn leads to recurrence of SST anomalies in some RYs. On the other hand, the conventional

©2019. Japan Geoscience Union. All Right Reserved.

mechanism related to the mean entrainment of anomalous temperature contributes to reemergence in two RYs.

Formation mechanism for the North Pacific Transition domain SST and SSS fronts

Japan Agency for Marine-Earth Science and Technology

The North Pacific Transition Domain is the area where water exchange between subtropical and subarctic is carried out and there are SST and SSS fronts. The Transition domain is very important area for air-sea interaction, ocean mixed layer formation, biological production, and so on. In this study, to clarify SST and SSS fronts structure and its formation mechanism in the transition domain, we analyzed the data of drifting buoys observation in 2015 and 2017 and modelled particles trajectory.

The buoy trajectories and the modelled trajectories captured the flow structure (i.e. front structure) in detail. They suggest that the flow structure in the transition domain is dominated by low rise bottom topography. We also showed mixing ratio of the subarctic and the subtropical seawater in the Transition domain using the particle tracking. In addition, it was also found that the place where the sea water tends to stagnate well corresponds to the place where the SST deviation appears due to the variation of the Isojet jet J1 indicated by Mitsudera et al. (2018).

Impact of the Kuroshio front on frontal structure of an extratropical cyclone associated with heavy precipitation

*Hidetaka Hirata[1], Ryuichi Kawamura[2], Mayumi K Yoshioka[1], Masami Nonaka[3], Kazuhisa Tsuboki[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Department of Earth and Planetary Sciences, Kyushu University, 3. Application Laboratory, Japan Agency for Marine-Earth Science and Technology

It is well known that sea surface temperature (SST) fronts associated with warm ocean currents create horizontal thermal gradients in the near-surface atmosphere in the mid-latitudes. These thermal gradients may affect frontal structure of extratropical cyclones passing near warm currents. Moreover, fronts influenced by the mid-latitude ocean may be related to the occurrence of heavy precipitation. To answer these questions, we examined the impact of the SST front along the Kuroshio Current (Kuroshio front) on the frontal structure of an extratropical cyclone associated with heavy precipitation by utilizing observational data, objective analysis data, and regional cloud-resolving numerical experiments. This study paid special attention to an extratropical cyclone and related heavy precipitation on Miyake Island in early January 2017. When the cyclone intensified around the Kuroshio front, two surface fronts developed around the cyclone center. One was a warm front. The other was a non-classic front, which was called the outer front in this study, forming on the northern side of the warm front. A line-shaped precipitation band and a comma head-shaped precipitation band appeared along the outer front and along the bent-back warm front, respectively. During the passage of these bands, heavy precipitation was observed on Miyake Island. Looking at the evolution of the outer front, we found that it was located just along the Kuroshio front in its early life. During the formation stage of the incipient outer front, sensible heat supply was evident from the Kuroshio Current, whereas it was small on the northern side of the oceanic front. This meridional difference in sensible heating caused frontogenesis along the Kuroshio front, which led to the initial formation of the front. Thus, the Kuroshio front played an important role in the formation of the incipient outer front, contributing to the occurrence of the heavy precipitation.

Intra-seasonal variability of oceanic low-level cloud in summertime North Pacific and its interaction with sea surface temperature

*Naoya Takahashi[1], Tadahiro Hayasaka[1]

1. Center for Atmospheric and Oceanic Studies, Graduate School of Science, Tohoku University,

Oceanic low-level cloud (i.e. fog, stratus, and stratocumulus) properties are important to determine radiative cooling at the sea surface via reflecting incident solar radiation, and they strongly interact with sea surface temperature (SST) with positive feedback process (Norris et al. 1998). Despite the importance of the role of low-level cloud in climate change or air-sea interaction, the mechanism of cloud evolution on short time-scale is not well investigated. Thus, the objective of this study is to reveal the evolution of low-level cloud cover (LCC) associated with cloud controlling parameters (e.g. SST, horizontal temperature advection, relative humidity in atmospheric boundary layer, and so on) on short time scale which cannot be revealed by monthly-mean dataset.

For cloud data, we used the level-3 daily gridded data product from MODIS imager (MYD08_D3) with 1 degree of horizontal resolution. OISST and ERA-Interim are used for SST and meteorological parameters, respectively. Spatial and temporal resolutions of these dataset are interpolated into that of MODIS. Target region is western North Pacific (150E-180E, 30N-40N) where standard deviation of LCC in summertime (JJASO) is large. Target period is each summertime from 2003 to 2016. To extract the shorter time-scale variability, we applied Lanczos band-pass filter for each variable. The extracted time scale by the band-pass filter is discussed in the next paragraph.

To investigate dominant time scales of LCC and SST, Fast Fourie Transform (FFT) analysis is applied. The results of FFT analysis for each variable show that 3-7-day and 20-100-day are dominant time-scale for LCC. The dominant time scale of temperature advection (Tadv) is similar to shorter one of LCC, which implies that Tadv is a key factor to control LCC on synoptic time scale rather than SST. On the other hand, for more longer time scale (20-100-day; intra-seasonal time scale), the correlation between SST and LCC is consistent with the previous studies (Norris 2000). To investigate the evolution process of LCC and SST on both time-scale, we applied the band-pass filter to them with two time-scale; (1) 3-7 day and (2) 20-100 day.

We further conducted phase composite analysis for each time scale. The result shows that (1) variation of SST (Tadv) lags (leads) to that of LCC on both time scales but (2) propagating direction of LCC anomaly and associated specific and relative humidity is eastward (westward) on synoptic (intra-seasonal) time scale. The difference in amplitude and propagation direction of LCC on each time-scale depend on different atmospheric dynamics and variation of associated moisture field. The above results also suggest that anomalous dry-cold Tadv is a trigger to increasing in LCC and SST decreasing is followed by them. This lead-lag relationship among each variable is clear on the intra-seasonal time scale. Temperature budget analysis for ocean mixed-layer shows that the SST decreasing is caused by shortwave cooling due to low-level cloud radiative effect and enhanced latent heat release. It emphasizes an importance of anomalous Tadv for the intra-seasonal variations of not only LCC but also SST.

Sea surface temperature trend in the East China Sea during the 20th century simulated by a regional ocean model

*Yoshi N Sasaki[1], Chisato Umeda[1]

1. Hokkaido University

It has been reported that the East China Sea is one of the region where the sea surface temperature (SST) trend during the 20th century is a couple of times larger than the global mean SST trend. However, the detailed spatial structure of the SST trend in the East China Sea, especially in the early 20th century, and its quantitative mechanism have not been understood. The present study examines the SST trend in the East China Sea from 1901 to 2010 by using a regional ocean modeling system (ROMS) with an eddy-resolving horizontal resolution (0.1˚) from 1871 to 2010. The spatial pattern of our simulation resembles that of the observations. That is, our simulation can reproduce the SST rise along the Kuroshio axis and over the continental shelf along the coast of China. The amplitude of the SST trend in the simulation is within the range between the two observations. The heat budget analysis revealed that the oceanic advection induced the SST rise in both regions. More specifically, the acceleration of the ocean currents plays an important role in the warming of the SST in both regions. In contrast, surface net heat flux acted as the damping of the SST rise.

Kuroshio Extension and Gulf Stream's influences on the variability of near-surface baroclinicity and the associated atmospheric fields

*Bunmei Taguchi[1], Kazuaki Nishii[2], Hisashi Nakamura[1,3]

1. Research Center for Advanced Science and Technology, The University of Tokyo, 2. Graduate School of Bioresources, Mie University, 3. Application Laboratory, Japan Agency of Marine-Earth Science and Technology

Evidence is mounting that mid-latitude western boundary currents (WBCs) can influence large-scale atmospheric circulation variability on interannual-to-decadal time scales. It is, however, still unclear how significantly such extra-tropical oceanic influences stand out of the intense variability intrinsic to the mid-latitude atmosphere. Here we examine the influences of extra-tropical oceanic frontal zone and its variability in the Gulf Stream (GS) and Kuroshio Extension (KE) regions on winter-season atmospheric variability in 20-member ensemble historical AGCM simulations with a horizontal resolution about 100km prescribed with satellite-observed, high-resolution sea surface temperature (SST) and sea-ice variability for the period 1982-2013. We focus on the near-surface baroclinicity $\boldsymbol{B}$ at 925 hPa as the quantity that is crucial for baroclinic eddy growth in the troposphere and is likely to be highly constrained by underlying oceanic frontal zones via air-sea heat exchange. We characterize the $\boldsymbol{B}$ variability separately in the GS and KE regions by applying EOF analysis to DJF-mean $\boldsymbol{B}$ across all the ensemble members and to that based on JRA55 reanalysis and then examine atmospheric and sea surface fields associated with their leading modes.

The simulations capture well the spatial structure of the observed $\boldsymbol{B}$ variability in both the WBC regions. Their leading modes (EOF1), explaining 42% (35%) of the total variance, represents intensifications of $\boldsymbol{B}$ over the GS (KE). While the EOF1 in the GS region is associated with enhanced storm track activity and westerly jet aloft, and geopotential height anomalies that resemble the negative phase of North Atlantic Oscillation (NAO), the EOF1 in the KE region is associated with a meridional dipole in height anomalies that resembles Western Pacific pattern. Further analysis of surface heat flux and SST anomalies contrasts the role of the two WBCs in the variability of $\boldsymbol{B}$ and the associated atmospheric features. Specifically, the enhanced $\boldsymbol{B}$ in the GS region is associated with enhanced heat release from the ocean, but with no SST anomalies, when cold air outbreaks spread across the sharp SST front over the GS. Over the KE, on the other hand, ocean-induced warm SST anomalies enhance heat release from the ocean, strengthening the overlying $\boldsymbol{B}$. Consistently, the evolution of observed PC1 time series is captured by the ensemble mean of the simulated PC1 in the KE region (r=0.46) but not in GS region (r=0.05). The former indicates the KE-induced SST anomalies adds a predictable component to $\boldsymbol{B}$ and the associated atmospheric variability in the North Pacific, while the latter reflects the variability mainly initiated by intrinsic NAO.

Baroclinic Annular Mode in the Southern Hemisphere: Its Reproducibility and Sensitivity to Ocean Fronts assessed in Aqua-Planet Experiments

*Morio Nakayama[1], Masatoshi Mizukoshi[1], Hisashi Nakamura[1], Yu Kosaka[1], Bunmei Taguchi[1], Masato Mori[1], Fumiaki Ogawa[2]

1. RCAST, the University of Tokyo , 2. The University of Bergen

Large-scale tropospheric variability in the extratropical Southern Hemisphere is characterized by two major and independent modes. One is the barotropic annular mode or the Southern Annular Mode (SAM), which represents meridional shifts of the eddy-driven polar front jet (PFJ; Thompson and Wallace, 2000). The other is the Baroclinic Annular Mode (BAM), which represents pulsing of stormtrack activity (Thompson and Woodworth, 2014).

In this study, the sensitivity of BAM to the midlatitude oceanic frontal zone is assessed through aqua-planet experiments in which, after the removal of landmasses, zonally symmetric distributions of sea-surface temperature (SST) are prescribed as the lower boundary condition of an atmospheric general circulation model AFES. In our control experiment, climatological SST profiles observed over the South Indian Ocean in austral summer and winter are prescribed in the model northern and southern hemispheres, respectively. The profiles are characterized by frontal SST gradient at 45˚ latitude. In our NF experiment, the frontal SST gradients are removed by raising SST artificially poleward of the front. The two experiments are both conducted over 3600 days under a perpetual condition with insolation fixed to the boreal summer solstice.
As in the observations, BAM signatures in the control experiment represent pulsing of the climatological stormtrack anchored in the vicinity of the oceanic front. By contrast, in the NF experiment without the oceanic frontal zone, BAM cannot be reproduced: BAM-associated anomalies of eddy kinetic energy and poleward eddy heat flux are reduced by ~30% and ~50%, respectively, and their peaks are displaced equatorward by ~5˚ from the oceanic frontal zone. Our experiments therefore suggest that the oceanic frontal zone enhances and anchors the BAM variability by strengthening stormtrack activity through maintaining near-surface baroclinicity. Specifically, anomalous sensible heat flux from the ocean acts to restore the meridional gradients in surface air temperature modified by anomalous meridional eddy heat flux associated with BAM, and this effect is greatly enhanced under the frontal SST gradient.

Hydro-climatic variation in northwestern China and its multi-decadal to multi-centennial teleconnection with the Pacific Ocean

*Harry F Lee[1]

1. The Chinese University of Hong Kong

Northwestern (NW) China region locates in the boundary region between the Westerlies and the Asian Monsoon. Due to its unique geographical setting, scientific studies that examine the long-term dynamics of the hydro-climate there have received particular attention in recent years. However, these studies are often constrained by the availability of instrumental precipitation records. The present study seeks to address this issue. I based on historical drought/flood records to trace the geographic extent of drought anomalies as well as the intra-regional precipitation variability in NW China in AD580–2008, covering the periods with and without instrumental precipitation records. Moving correlation and wavelet analyses were applied to find their significant determinants. Results show that El Niño Southern Oscillation (Indo-Pacific warm pool sea surface temperature) is the major multi-decadal to centennial (centennial to multi-centennial) determinant of the hydro-climatic variability in NW China. The associated mechanism is anchored with the change of Asian Summer Monsoonal precipitation, while it is driven by different factors at different time-scales. The above findings may help predict the occurrence of drought in the boundary region between the Westerlies and the Asian Monsoon in the extratropics.

Atmospheric zonal-mean meridional circulation and midlatitude oceanic fronts

*Kazuaki Nishii[1], Bunmei Taguchi[2], Hisashi Nakamura[2]

1. Graduate School of Bioresources, Mie University, 2. Research Center for Advanced Science and Technology, The University of Tokyo

It is known that, in the zonal-mean tropospheric circulation, diabatic heating drives a thermally direct meridional overturning circulation (MOC) called the Hadley cell. While in the midlatitudes, zonal-mean vertical motion is driven mainly by atmospheric eddies, forming a thermally indirect MOC called the Ferrel cell where warmer (cooler) air apparently sinks (rises) in lower (higher) latitudes. Here we found a thermally-direct, shallow MOC embedded in the downward branch of the zonal mean Ferrel cell in the wintertime northern hemisphere in most of the latest generation reanalysis datasets. AGCM simulations reveal that this local MOC, made of upward (downward) motion around latitudes to the equatorward (poleward) side of midlatitude oceanic fronts, is driven by differential diabatic heating across the ocean fronts due to surface turbulent heat flux from the ocean and precipitation brought by synoptic-scale eddies. The compensating meridional flow in the lowermost atmosphere is northerlies, which decelerates surface westerlies just over the oceanic fronts through the Coriolis force. The decelerated surface westerlies by oceanic fronts in turn exert wind-stress curl forcing that tends to weaken oceanic subpolar and subtropical gyres, indicative of an air-sea coupled feedback that would destruct, rather than maintain, the oceanic fronts.

[A-CG33] Extratropical oceans and atmosphere

convener:Kazuaki Nishii(Graduate School of Bioresources, Mie University), Yoshi N Sasaki(Hokkaido University), Hatsumi Nishikawa(Institute of Low Temperature Science, Hokkaido University), Shun Ohishi(Division for Land-Ocean Ecosystem Research, Institute for Space-Earth Environmental Research, Nagoya University)

The extratopical ocean had been considered passive to atmospheric variability. Recent studies, however, revealed some active role of the extratopical ocean in modulating the atmosphere. The goal of this session is to deepen our understanding of the air-sea interaction in the extratropics. A wide variety of researches whose topics range from mesoscale to basin-scale, and from daily to global warming are welcomed. Researches on cloud, aerosol, and ecosystem related to the extratopical air-sea interaction are also welcomed.

Analysis of water exchange processes at the Subarctic Boundary of the North Pacific using particle tracking method

*Ashida Hayato[1], Humio Mitsudera[2], Hatsumi Nishikawa[2]

1. Department of Earth and Planetary Sciences, School of Science, Hokkaido University, 2. Institute of Low Temperature Science, Hokkaido University

The Mixed Waters Region (MWR) of the North Pacific are thought to be an important region for climate change and ecological fluctuations. In the MWR, two quasi stationary jets are formed away from the Western Boundary [Isoguchi et al., 2006]. Mitsudera et al. [2018] showed the relationship between the jets and the topography of only 500 m near the jets.

Contours of the average sea surface height indicates bifurcation between the subarctic and the subtropical circulation on the west coast of the North American continent. The boundary passes through J2 that is the eastern quasi stationary jet [Isoguchi et al., 2006] and coincide with the latitude line of 40˚N near 160˚E which is known as the Subarctic Boundary. Focusing on the area of 38 - 42˚N, 155 - 165˚E (referred to as Box), we set particles in Box and tracked them.

J2 is a noticeable flow in the vicinity of the Box, which is formed due to the presence of a low topography at 43˚N 167˚E north east of Box. Particle pathways are greatly affected by J2. Nevertheless, a majority of the water that passes south of 40˚N in the Box goes to the subtropical region and is not affected by J2.

The water of Kuroshio origin (Kuro) is accounted for the majority of the water entering the Box, and the water of Oyashio origin (Oya) is a little. Kuro that enters the Box exceeds 60% in south of 40˚N in the Box. Most of Kuro flowed out from the southern side of the Box goes to the subtropical circulation, but Kuro flowed out from north of 40˚N in the Box enters the subarctic circulation. Since particles emanated from the northern side of the Box is thought to be susceptible to J2, J2 would play a great role in transporting Kuro to the subarctic region. The proportion of Oya coming into the Box is about 10% to the south of 40˚N, while 30 to 40% to the north of 40˚N. Therefore, Oya also changes its proportion at 40˚N as a boundary. Oya is likely to return to the subarctic circulation, but Oya entering subtropical circulation is also seen.
J2 therefore plays a role of carrying water out from the Box, which has high temperature and high salinity derived from subtropical circulation, to the subarctic circulation where temperature and salinity is low. It is thought that the topography of only 500m in the North Pacific, where the depth is about 6000m, affects the ocean circulation.

Method to evaluate the effect of obduction on properties in the ocean mixed layer

*Yoshimi Kawai[1]

1. Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology

Repeat hydrographic surveys revealed that the warming already extended to the global abyssal waters. The circulation of heat, freshwater and materials absorbed into the ocean, however, has not been investigated enough. The ocean mixed layer in the extratropics usually becomes deepest in winter or early spring due to strong surface cooling and wind stress. In the following warm season, the seasonal pycnocline is formed in the upper layer, and the remnant of the winter mixed layer below the seasonal pycnocline is isolated from the atmosphere. While some part of the isolated layer is entrained into the mixed layer again in the following winter, the other part is transported along an isopycnal surface into the permanent pycnocline irreversibly. The latter process is referred to as “subduction”, and one of the major processes by which properties of the upper layer facing the atmosphere are transferred into the ocean interior. The opposite process of subduction is “obduction”: water of the permanent pycnocline is entrained into the mixed layer when it deepens in autumn and winter. This process is also expected to be important for the atmosphere, especially its long-term variations, since it brings anomalies of temperature, carbon dioxide, and other properties in the ocean interior to the surface layer. Subduction and obduction rates are great in regions where the winter mixed layer becomes deeper.
The budget of the ocean mixed layer consists of five components: surface forcing, Ekman advection, geostrophic advection, entrainment, and residual. The sum of these five terms is equal to the temporal change rate of a quantity such as temperature and salinity. The entrainment in mixed-layer deepening is further separated into two components: the erosion of the permanent pycnocline, and the erosion of water mass that was within the mixed layer in the previous winter. The former is just obduction, and the latter means that the water mass that was in contact with the atmosphere in the previous winter is again entrained into the mixed layer within one year, which is referred to as “re-entrainment” in this paper expediently. The contribution of the obduction on the ocean mixed layer budget has not been examined. The authors proposes a method to evaluate it, and examines the budget by using the Argo MOAA GPV dataset. The effect of the obduction on temperature and salinity in the ocean mixed layer is notably large in the Bering Sea and around 40ºN west of the Date Line.

Keywords: Obduction, Ocean mixed layer, Entrainment

Influence of the interannual-scale Bering Sea ice variation on cold air outbreaks

*Mizuki Iida[1], Shusaku Sugimoto[1], Toshio Suga[1]

1. Physical Oceanography Laboratory Department of Geophysics, Graduate School of Science, Tohoku University

In the Northern Hemisphere winter, cold air outbreaks occur over East Asia and the eastern North America. Quantitative estimation of a cold air mass was developed recently and this allowed us to detect two climatological cold air streams (Iwasaki et al., 2014): the East Asian stream and the North American stream. Cold air incursions are strongly affected by the terrain and land–sea distributions, and the cold air mass is lost due to diabatic heating over the northwestern parts of the North Pacific and the North Atlantic, which are downstream regions of the two streams (Kanno et al., 2015). The East Asian stream passes over the Bering Sea covered by ice. It is expected that the Bering Sea ice would affect the path and formation/loss of cold air mass. However, the influence of sea ice, including the Bering Sea, on the cold air mass has been unclear. We investigate a temporal relationship between the Bering Sea ice and the cold air mass and discuss its cause from the view point of large-scale atmosphere patterns, by applying statistical methods. In addition, we try to describe an influence of cold air mass on ocean mixed layer temperature and depth. Following a pioneering work by Iwasaki et al. (2014), we calculate negative heat content (NHC), which is regarded as a cold air mass amount below potential temperature of 280K, by using ERA-Interim data. We use the Bering Sea ice concentration from NOAA OISST v2 dataset. Analysis period is 37 years of 1982-2018, and we focus on February because the Bering Sea ice concentration has the largest value and the largest variance. In order to extract the NHC and atmosphere patterns related to the Bering Sea ice variation, we perform a composite analysis. Here, we define two categories (high and low ice concentration years) based on the regional time series of Bering Sea ice concentration (160˚ E-150˚W, 55˚N-65˚N); high (low) ice concentration years are defined as years in which sea ice concentration is above (below) plus (minus) one standard deviation from the long-term mean. In high ice concentration years, NHC is found in the Bering Sea and the Bering Strait, showing southward NHC flux. NHC loss is dominated over a region south of the Bering Sea. Composite maps of sea level pressure and geopotential height show remarkably large amplitude in the central North Pacific, indicating a change of the Aleutian Low intensity. We checked a relationship between the Bering Sea ice concentration and large-scale atmospheric patterns such as Pacific/North Atlantic pattern, West Pacific pattern, and El Nino. Interestingly, the Bering Sea ice concentration is not significantly correlated with climate indices representing the atmosphere patterns mentioned above. Our result implies that the Bering Sea ice concentration has a potential to affect the cold air mass outbreak and the NHC. In the presentation, we introduce an impact of the NHC loss on the underlying ocean.

Mon. May 27, 2019 1:45 PM - 3:15 PM JST | Mon. May 27, 2019 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[H-DS11] Subaqueous Landslides and Their Anthropogenic Impact for Coastal Regions

convener:Yujin Kitamura(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS))

A large number of people inhabit coastal areas around the world that are susceptible to natural catastrophes and subaqueous landslides are one of such hazards as demostrated recently. The risk associated with the occurrence of subaqueous landslides is not only constrained to passive margins or subduction zones but any of water areas is also susceptible to their occurrence since subaqueous failures can be triggered at very low slope angles. This realization poses a significant challenge that requires the collection of vast amounts of information and data to unravel the true nature of these events and their potential risk to coastal communities. Despite these challenges, recent technical and engineering advances in the acquisition and processing of sea floor and shallow subsurface data are encouraging. There has also been a concerted effort by scientists from different earth-science disciplines to increase interdisciplinary cooperation at an international level to advance our collective understanding of subaqueous landslides and their consequences.
This session calls for technical contributions covering all aspects of subaqueous landslide research including but not limited to: physical properties of deformed sediments (pre- and post- deformation), role of interstitial fluids in subaqueous landslide development, slope stability and risk assessments, geomorphological and sedimentological/stratigraphic descriptions, tsunamigenic risk and modeling, description of ancient subaqueous landslides, sand-box models and numerical simulations of subaqueous landslides. Case studies from lacustrine landslides and subaerial coastal landslides transitioning into the marine realm are also welcome. Case studies associated with the broader topic of subaqueous gravity-driven flows (e.g.: turbidites and transitional flows) and their relationship with seafloor faulting are also of interest to this session. Participants of IUGS project S4SLIDE IGCP-640 sponsor this session.

Deformed sediment gravity flow deposits associated with bypassing slides: an example from the Miocene Ushikiri Formation, Southwest Japan

*Miki Kobayashi[1], Tetsuya Sakai[2]

1. Nippon Koei, 2. Shimane University

The Middle Miocene Ushikiri Formation in Shimane Peninsula, southwest Japan, is interpreted to have been deposited on the shelf margin to the middle continental shelf, and is known to contain unique sediment gravity flow deposits, similar to hybrid sediment gravity flow deposits (turbidite + debrite). Intensely deformed mud clasts have been described from this formation. However, their formation has not been focused on previous studies. The present study aims to characterize the deformation of sandstone beds and mud clasts contained within the sediment gravity flow deposits and to discuss of the deformation process of the sediments.

Many of the sandstone beds in the upper Ushikiri Formation (averaging 0.6 m thick) are bipartite, with lower parts showing characteristics similar to Ta or Ta-b turbidites with rich mud clasts. The upper parts of the sandstone beds are represented by poorly-sorted muddy sand with scattered mud clasts having debrite-like features. The small mud clasts in the lower part show features different from those in ordinary turbidites: some are subject to injection of surrounding sand and some scattered in sands show jigsaw-puzzle patterns, suggesting in situ mud clast fragmentation. Some mud clasts are intensely stretched. The beds also host large mud clasts (maximum length: ca 3 m), in which deformation structures, such as slump folds, are well developed. Mud clast shapes are not consistent with internal deformation structures and the most of them have sharp margins. The sand around some large mud clasts shows local liquefaction. Local grading is also found above the large mud clasts and does not continue beyond the edge of the mud clasts.

The injection of sand into mud clasts and their in situ fragmentation into jigsaw-puzzle patterns can be explained by liquefaction of beds with overburden pressure. A possible pressure source is slides that passed over a freshly deposited turbidite bed. When a slide bypassed the sand bed, the bed once deposited as turbidite easily liquefied under the moving slide mass, having led overburden pressure in the bed that caused injection and in situ fragmentation. On the contrary, the large mud clasts may have been fragments ripped from a major sliding body that bypassed the studied locality. Local liquefaction around large mud clasts indicates they sank or were forced into the bed from above. The presence of local grading above the mud clasts can be explained by local resuspension of sand around the mud clasts when they sank into the sand. The above mentioned sediment deformation process is supported by beds with a slide deposit above a sandy part having similar mud clast deformation.
The bypassing of the slide may have been due to hydroplaning of the slide mass. The slide deposits are represented by up to 2 m thick of large mud block rich sediments with variety of deformation structures, which grades from an underlying debrite-like bed that consists of poorly-sorted muddy sand with rich mud clasts with injection of surrounding muddy sand. Some mud clasts in the muddy sandstone beds are intensely stretched, implying that shear stress exerted within the beds. The poorly-sorted muddy sand is thus interpreted as a fluid layer, which has been existed below the moving landslide mass, having triggered the hydroplaning.

Submarine Landslide and Resulting Tsunami on the Continental Shelf Slope off Shikoku

*Youdai Gon[1], Toshitaka Baba[1], Tetsuo Matsuno, Mitsuru Hayashi, Hiroshi Ichihara

1. Tokushima University graduate school

Submarine landslide occurs mainly due to earthquake shaking damaging marine infrastructure such as submarine communication and causing tsunami. The bathymetry in the Nankai Trough has traces of numerous submarine landslides. One of them is located on the continental shelf 24 km off the Shikoku coast. The submarine landslide off Shikoku would have a potential causing tsunami. Therefore, in this study, with the purpose revealing the topographical features of the submarine landslide off Shikoku in detail, multi-narrow beam surveys were conducted. We also discuss the tsunami potential of the submarine landslide from numerical simulations.

The multi-narrow beam surveys were conducted once in 2017 and twice in 2018 covering an area 30 km x 20 km by a training ship, Kobe University Graduate School of Maritime Sciences Attachment Practice Ship Fukae Maru. The acquired bathymetric map indicated four head scarps neighboring to each other (hereafter scarp A, B, C, D from the west). Sediment deposition was confirmed below scarp A. The scarp A seems to be younger than the other scarps. The slopes collapsed multiple times implying occurrence of a new collapse in the future.

Tsunami calculations were carried out for slump A, B and C. But, from the topographic features, slump B and C were assumed to be a simultaneous collapse. We also assumed new two submarine landslides (slump E and F) to the east of slump D with the same size of sump A. In the calculation results, the tsunamis arrive at about 15 min. after the initiation of slump A and the simultaneous slump B and C. For slump E and F, tsunami arrives at about 20 min. The maximum tsunami heights were estimated to be about 2 m, 2 m, 4.5 m and 5 m for slump A, B-C, E and F, respectively. We are going to conduct more simulations to evaluate risk of tsunami caused by the submarine landslide tsunamis in the study area.

Sedimentary environment estimated from physical properties of sediment core collected during the cruise of Hakuho-maru KH-18-3 in the South Yatsushiro sea, western Kyushu.

*Koki Hori[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Scientists

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University , 2. Department of Earth and Environmental Sciences, Graduate School of Science and Engineering , Kagoshima University

The research cruise KH-18-3 was carried out in the South Yatsushiro sea from 27th to 30th July 2018. The purpose of this cruise is to clarify the occurrence history of the submarine landslides in the Yatsushiro sea. In this survey, bottom surface sediment samples were collected by using Piston corer which is 6 meters long.
The study on physical properties of event sediment using core samples are conducted in ocean areas around the world. For example, Prior et al. (1984) reported that Mass transport deposits (MTD) commonly have a higher density than surrounding, sediments that are not submarine landslide origin. Therefore, in this study, the physical properties that serve as the basic information of the core samples were measured. In addition, we estimated the sedimentary environment in the survey area by applying tidal current, sedimentation rate, and bottom surface muddy rate in the south Yatsushiro sea (Rifardi et al.,1998) and conventional radiocarbon ages of piston core samples recovered in the same area reported by Inoue et al. (2011).

Core samples were collected from 11 sites (core name:PC01 to PC11) in the south Yatsushiro sea where the Taura-Tsunagi Oki fault group and Minamata Oki fault group are distributed.
All analyses other than the grain size distribution analysis were conducted at the Center for Advanced Marine Core Research, Kochi University. Initially, GRA density, Magnetic susceptibility and fractional porosity were measured using Whole round multi sensor core logger (MSCL-W). After the analysis, core samples were divided vertically and visual observation and color measurement of them were performed. Subsequently, a vane shear test and sub-samples which were used for MAD measurements and grain size distribution analysis collecting were performed at approximately 50 cm intervals, respectively, and the test and two sampling location were the same points.

Area 1 is under condition of rather stagnant water masses or rather weak tidal current system and is characterized fine-grained sediments. We estimated age of core samples by comparing physical properties reported by Inoue et al. (2011) because sampling point in this area matched with piston coring points of Inoue et al. (2011) and the behaviors of both physical properties were similar. As a result, a gap of more than 7000 years of sediment age is estimated at depth of 2 to 3 meters in area 1a (PC01 to PC03) and it is presumed that sediments indicating the age of about 10,000 years BP exist at depth of several tens of centimeters from the seabed surface in area 1b (PC06, PC07). In addition, K-Ah volcanic ash layer (7.3ka) could not be confirmed from sediments in both sea areas. From this, it is assumed that there was an event such as a submarine landslide or erosion with the lower part of the tephra as a sliding or eroding surface.
Since we could not obtain an index to estimate the age of the PC 08 to PC 11, we estimated the sedimentary environment using only the physical properties of sediments. PC08 and PC10 (Area 2) is located near the strait of Goshoura-jima and sisi-jima island, under influence of strong tidal and bottom currents, and is characterized by coarse sediments. Especially, upward grain refinement was observed and

©2019. Japan Geoscience Union. All Right Reserved.

the tendency that the porosity decreases within each monolayer is repeated in PC10. From this, it is assumed that the upper sediment functions as an impermeable layer against the lower sediment, and the drainage is difficult to proceed. PC 09 and PC 11 (Area 3) are relatively close to supply sources such as Minamata River and Komenotsu River, and are characterized as relatively coarse sediments. From the depth of 60 cm of PC09, and from the outermost surface layer in PC 11, the porosity does not decrease almost from around 60%. From this, it is estimated that the new sediment has been recently cleared recently.

Introduction

The 2016 Kumamoto Earthquake was sourced from a part of active faults of the Futagawa-Hinagu fault zones. The southwestern part of Hinagu fault zone forms the Yatsushiro section as a group of submarine active faults. Earthquake shaking occasionally triggers submarine landslide, however, any record of submarine landslide in this area has not been reported. We therefore conducted research cruise with R/V Hakuho-maru and recovered sediment cores in Yatsushiro sea. As it is known that the shear strength decreases at the bottom of mass transport deposits, we conducted vane shear test with the cores. We also referred the variation of magnetic susceptibility to establish core correlation with previous works.

Method

Here we conducted four-days research cruise with R/V Hakuho-maru (KH-18-3) in July, 2018 to reveal submarine landslide records and benthic environment in Yatsushiro sea. We used six-meters-long piston corers and cored at 11 sites and recovered cores were cut into 6 sections onboard. Cores were analyzed at Kochi Kore Center using X-ray CT scanner, multi-sensor core logger (gamma ray density: GRD; and magnetic susceptibility: MS), core imaging apparatus, visual core description, color spectroscope, X-ray fluorescence core scanner (Itrax). Vane shear apparatus is used with split core section and tested every about 50 cm.

Results and Discussion

Sediments are dominated by matrices of olive gray to black sand or mud. CT value, MS and GRD generally increase with depth. As MS shows cyclic fluctuation, we classified into several MS units by defining units with each broad peak. Our MS units was correlated with previous studies of high resolution seismic profile by Yagi et al. (2016) and piston cores by Inoue et al. (2011). MS units was in good agreement with Yagi's seismic profile. It is inferred that our samples include the sediments during Late Glacial Maximum to Jomon Transgression below hiatus. MS data by Inoue et al. (2011) and this study are in accordance with each other. The event layers Inoue suggested are discriminable in our cores which are characterized as local maximum of MS. Iron shows high concentration around the event layers so that the iron is a candidate for indicator for searching the events. We assume that this iron anomaly is caused by the rapid deposition during eventic turbidites.

The results of vane shear test showed that the strength increases with depth with a change in its rate at assumed hiatus. This shows that the sediments below hiatus was further deeply buried and compacted. At sites PC04 to PC06, the strength is low at their surface, indicating that the hiatus at these sites are very shallow and thus the recent surface erosion is assumed.

Identification of turbidites in the Yatsushiro Sea surface sediment core samples from non-destructive measurements: Hakuho-maru KH-18-3 Cruise, Yatsushiro Sea, Western Kyushu, Japan

*Ryoya Goto[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Cruise Scientist

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Department of Earth and Environmental Sciences, Graduate School of Science, Kagoshima University

Submarine active faults in Yatsusiro Sea, western Kyushu, Japan, constitute the Yatsushiro section of Hinagu fault zone in its southwest end (AIST et al., 2011). The 2016 Kumamoto Earthquake was sourced from a part of active faults of the Futagawa-Hinagu fault zones (JMA, 2018), and survey has hardly conducted in the sea area after the earthquake occurrence. Earthquake shaking occasionally triggers turbidity currents by submarine landslides and resuspension of unconsolidated sediments on the seafloor (Ikehara et al., 2018). In recent years, the study of earthquake occurrence history using earthquake turbidites formed by turbidity currents is being conducted throughout the world. As earthquake-origin turbidity currents can take place in very gentle slope (e.g. the Mississippi-Delta 0.01°: D. B. Prior et al., 1978), its occurrence is sufficiently thought even in Yatsushiro Sea. However, any record of earthquake turbidites in this area has not been reported. In this study, identification of turbidites in the Yatsushiro Sea surface sediment core samples from non-destructive measurements.

Here we conducted four-days research cruise Hakuho-maru KH-18-3 in July, 2018. We conducted sub-bottom profiling on eight lines, piston coring at 11 sites in Yatsushiro Sea, western Kyushu, Japan. Recovered cores are analyzed by X-ray CT scanner, multi-sensor core logger, core imaging apparatus, visual core description, color spectroscope and X-ray fluorescence core scanner (Itrax) in the Center for Advanced Marine Core Research, Kochi University. With reference to the previous studies (Iwai et al., 2014, JGS abstract; Isabel Rodríguez-Germade et al, 2015; Okutsu et al., 2017, JGS abstract), the behavior of Ca/Ti and Fe/Ti where the peak was observed at the base of turbidites, and the behavior of Fe/Ti and Zr/Ti where the peak was observed at the base of volcaniclastics turbidites.

Our results revealed turbidites and volcaniclastics turbidites in six piston coring sites (PC01 to PC06). As all of sites are located in the Taura-Tsunagioki fault group or Minamataoki fault group, turbidites were considered to be present in all of sites. However, turbidites were identified from PC01 to PC06, but not identified from PC07 to PC11. According to Rifardi et al. (1998), PC01 to PC06 are located in the sea area where the deposition rate is high, and PC07 to PC11 are located in the sea area where the deposition rate is slow.

As turbidite is formed by various factors besides earthquakes, it is necessary to consider whether the turbidites identified in this study are earthquake turbidites. In addition, to investigate the history of earthquakes, it is also a future task to conduct individual sample measurements (such as grain size distribution analysis) and dating.

Revised columnar section based on grain size distribution analysis of samples from Hakuho-maru KH-18-3 in Yatsushiro sea

*Yuta Ikebata[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Scientists Family

1. Kyusyu University Graduate School Of Science Earth and Planetary Science, 2. Graduate school of science, Kagoshima University

Hakuho-maru KH-18-3 was held in the Yatsushiro Sea from 27th to 30th July 2018 for clarifying history of occurrence of submarine landslides. Earthquake is a one of big trigger of submarine landslides, and submarine landslides occurs in an very easy slope. Kumamoto earthquake occurred at April, 2016 and a lot of surveys in the land area were conducted but survey in the sea area weren't conducted much. In the Yatsushiro sea, the occurrence of submarine landslides caused by earthquake of the Futagawa-Hinagu fault zones can be considered sufficiently. Therefore, in this study, the creation of the columnar section which is the basic information of the submarine landslide accreditation was made based on the grain size distribution analysis.

In the Expedition, eleven piston cores(6m) from PC01 to PC11 were collected in the southern part of Yatsushiro sea, and the obtained core was subjected to non-destructive measurement and individual sample measurement at the Kochi Core Center. For non-destructive measurement, CT images and core continuous images were taken, and for individual sample measurement, Density, Magnetic susceptibility, porosity, vane shear strength, color, concentration change of major elements were examined. Grain size distribution analysis was conducted at Kagoshima University. Samples used for grain size distribution analysis were collected every 50 cm and analyzed with a laser diffraction type grain size distribution analyzer. Since it is difficult to judge the stratum boundary only with the result of grain size distribution measurement at intervals of 50 cm, it was judged by using γ ray density, magnetic susceptibility and color measurement result which are continuous data.

Grain size distribution analysis revealed PC01 to PC07 are muddy cores and PC08 to PC11 contains much sand. Grain size of PC01, PC04, PC06, PC07, PC09, PC11 are very different in Grain size distribution analysis and visual core description. Based on the results of the grain size distribution analysis, the stratum boundary was determined from the change commonly seen in the γ ray density, magnetic susceptibility and color, and a columnar section was prepared. In Rifardi et al.(1998), the distribution of mud content in the Yatsushiro Sea has been surveyed. As a result of comparing the columnar map of this study with its distribution for each sampling point, cores excluding PC08 corresponded well. It is thought that it is influenced by the supply of sediment by river and stagnant water mass, tide current as in previous research. Also, in Inoue et al.(2011), which was a reference for determining the core harvest point, dating is done in the same area. At Hori(2019MS), we compare the data with Inoue et al.(2011) and estimate the core age of this research. We also compare the columnar section made in this study with the columnar section of Inoue et al.(2011), using the comparative categories determined at the time of estimating the age. As a result, PC01 and PC02 were in good agreement, PC06 and PC07 had different stratum in the surface layer. This is probably because the sampling site of PC06 is actually about 150 m far from Inoue et al.(2011) and the sampling site of PC07 is actually about 111 m far from Inoue et al.(2011), and the sedimentary environment is slightly different. Also, in the grain size distribution analysis of this study, there is a possibility that coarse grains may be selectively left out when putting the sample into the machine, and it may be doubtful in accuracy.

[H-DS11] Subaqueous Landslides and Their Anthropogenic Impact for Coastal Regions

convener:Yujin Kitamura(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS))

A large number of people inhabit coastal areas around the world that are susceptible to natural catastrophes and subaqueous landslides are one of such hazards as demostrated recently. The risk associated with the occurrence of subaqueous landslides is not only constrained to passive margins or subduction zones but any of water areas is also susceptible to their occurrence since subaqueous failures can be triggered at very low slope angles. This realization poses a significant challenge that requires the collection of vast amounts of information and data to unravel the true nature of these events and their potential risk to coastal communities. Despite these challenges, recent technical and engineering advances in the acquisition and processing of sea floor and shallow subsurface data are encouraging. There has also been a concerted effort by scientists from different earth-science disciplines to increase interdisciplinary cooperation at an international level to advance our collective understanding of subaqueous landslides and their consequences.
This session calls for technical contributions covering all aspects of subaqueous landslide research including but not limited to: physical properties of deformed sediments (pre- and post- deformation), role of interstitial fluids in subaqueous landslide development, slope stability and risk assessments, geomorphological and sedimentological/stratigraphic descriptions, tsunamigenic risk and modeling, description of ancient subaqueous landslides, sand-box models and numerical simulations of subaqueous landslides. Case studies from lacustrine landslides and subaerial coastal landslides transitioning into the marine realm are also welcome. Case studies associated with the broader topic of subaqueous gravity-driven flows (e.g.: turbidites and transitional flows) and their relationship with seafloor faulting are also of interest to this session. Participants of IUGS project S4SLIDE IGCP-640 sponsor this session.

Deformed sediment gravity flow deposits associated with bypassing slides: an example from the Miocene Ushikiri Formation, Southwest Japan

*Miki Kobayashi[1], Tetsuya Sakai[2]

1. Nippon Koei, 2. Shimane University

The Middle Miocene Ushikiri Formation in Shimane Peninsula, southwest Japan, is interpreted to have been deposited on the shelf margin to the middle continental shelf, and is known to contain unique sediment gravity flow deposits, similar to hybrid sediment gravity flow deposits (turbidite + debrite). Intensely deformed mud clasts have been described from this formation. However, their formation has not been focused on previous studies. The present study aims to characterize the deformation of sandstone beds and mud clasts contained within the sediment gravity flow deposits and to discuss of the deformation process of the sediments.

Many of the sandstone beds in the upper Ushikiri Formation (averaging 0.6 m thick) are bipartite, with lower parts showing characteristics similar to Ta or Ta-b turbidites with rich mud clasts. The upper parts of the sandstone beds are represented by poorly-sorted muddy sand with scattered mud clasts having debrite-like features. The small mud clasts in the lower part show features different from those in ordinary turbidites: some are subject to injection of surrounding sand and some scattered in sands show jigsaw-puzzle patterns, suggesting in situ mud clast fragmentation. Some mud clasts are intensely stretched. The beds also host large mud clasts (maximum length: ca 3 m), in which deformation structures, such as slump folds, are well developed. Mud clast shapes are not consistent with internal deformation structures and the most of them have sharp margins. The sand around some large mud clasts shows local liquefaction. Local grading is also found above the large mud clasts and does not continue beyond the edge of the mud clasts.

The injection of sand into mud clasts and their in situ fragmentation into jigsaw-puzzle patterns can be explained by liquefaction of beds with overburden pressure. A possible pressure source is slides that passed over a freshly deposited turbidite bed. When a slide bypassed the sand bed, the bed once deposited as turbidite easily liquefied under the moving slide mass, having led overburden pressure in the bed that caused injection and in situ fragmentation. On the contrary, the large mud clasts may have been fragments ripped from a major sliding body that bypassed the studied locality. Local liquefaction around large mud clasts indicates they sank or were forced into the bed from above. The presence of local grading above the mud clasts can be explained by local resuspension of sand around the mud clasts when they sank into the sand. The above mentioned sediment deformation process is supported by beds with a slide deposit above a sandy part having similar mud clast deformation.
The bypassing of the slide may have been due to hydroplaning of the slide mass. The slide deposits are represented by up to 2 m thick of large mud block rich sediments with variety of deformation structures, which grades from an underlying debrite-like bed that consists of poorly-sorted muddy sand with rich mud clasts with injection of surrounding muddy sand. Some mud clasts in the muddy sandstone beds are intensely stretched, implying that shear stress exerted within the beds. The poorly-sorted muddy sand is thus interpreted as a fluid layer, which has been existed below the moving landslide mass, having triggered the hydroplaning.

Introduction

The 2016 Kumamoto Earthquake was sourced from a part of active faults of the Futagawa-Hinagu fault zones. The southwestern part of Hinagu fault zone forms the Yatsushiro section as a group of submarine active faults. Earthquake shaking occasionally triggers submarine landslide, however, any record of submarine landslide in this area has not been reported. We therefore conducted research cruise with R/V Hakuho-maru and recovered sediment cores in Yatsushiro sea. As it is known that the shear strength decreases at the bottom of mass transport deposits, we conducted vane shear test with the cores. We also referred the variation of magnetic susceptibility to establish core correlation with previous works.

Method

Here we conducted four-days research cruise with R/V Hakuho-maru (KH-18-3) in July, 2018 to reveal submarine landslide records and benthic environment in Yatsushiro sea. We used six-meters-long piston corers and cored at 11 sites and recovered cores were cut into 6 sections onboard. Cores were analyzed at Kochi Kore Center using X-ray CT scanner, multi-sensor core logger (gamma ray density: GRD; and magnetic susceptibility: MS), core imaging apparatus, visual core description, color spectroscope, X-ray fluorescence core scanner (Itrax). Vane shear apparatus is used with split core section and tested every about 50 cm.

Results and Discussion

Sediments are dominated by matrices of olive gray to black sand or mud. CT value, MS and GRD generally increase with depth. As MS shows cyclic fluctuation, we classified into several MS units by defining units with each broad peak. Our MS units was correlated with previous studies of high resolution seismic profile by Yagi et al. (2016) and piston cores by Inoue et al. (2011). MS units was in good agreement with Yagi's seismic profile. It is inferred that our samples include the sediments during Late Glacial Maximum to Jomon Transgression below hiatus. MS data by Inoue et al. (2011) and this study are in accordance with each other. The event layers Inoue suggested are discriminable in our cores which are characterized as local maximum of MS. Iron shows high concentration around the event layers so that the iron is a candidate for indicator for searching the events. We assume that this iron anomaly is caused by the rapid deposition during eventic turbidites.

The results of vane shear test showed that the strength increases with depth with a change in its rate at assumed hiatus. This shows that the sediments below hiatus was further deeply buried and compacted. At sites PC04 to PC06, the strength is low at their surface, indicating that the hiatus at these sites are very shallow and thus the recent surface erosion is assumed.

Identification of turbidites in the Yatsushiro Sea surface sediment core samples from non-destructive measurements: Hakuho-maru KH-18-3 Cruise, Yatsushiro Sea, Western Kyushu, Japan

*Ryoya Goto[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Cruise Scientist

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Department of Earth and Environmental Sciences, Graduate School of Science, Kagoshima University

Submarine active faults in Yatsusiro Sea, western Kyushu, Japan, constitute the Yatsushiro section of Hinagu fault zone in its southwest end (AIST et al., 2011). The 2016 Kumamoto Earthquake was sourced from a part of active faults of the Futagawa-Hinagu fault zones (JMA, 2018), and survey has hardly conducted in the sea area after the earthquake occurrence. Earthquake shaking occasionally triggers turbidity currents by submarine landslides and resuspension of unconsolidated sediments on the seafloor (Ikehara et al., 2018). In recent years, the study of earthquake occurrence history using earthquake turbidites formed by turbidity currents is being conducted throughout the world. As earthquake-origin turbidity currents can take place in very gentle slope (e.g. the Mississippi-Delta 0.01°: D. B. Prior et al., 1978), its occurrence is sufficiently thought even in Yatsushiro Sea. However, any record of earthquake turbidites in this area has not been reported. In this study, identification of turbidites in the Yatsushiro Sea surface sediment core samples from non-destructive measurements.

Here we conducted four-days research cruise Hakuho-maru KH-18-3 in July, 2018. We conducted sub-bottom profiling on eight lines, piston coring at 11 sites in Yatsushiro Sea, western Kyushu, Japan. Recovered cores are analyzed by X-ray CT scanner, multi-sensor core logger, core imaging apparatus, visual core description, color spectroscope and X-ray fluorescence core scanner (Itrax) in the Center for Advanced Marine Core Research, Kochi University. With reference to the previous studies (Iwai et al., 2014, JGS abstract; Isabel Rodríguez-Germade et al, 2015; Okutsu et al., 2017, JGS abstract), the behavior of Ca/Ti and Fe/Ti where the peak was observed at the base of turbidites, and the behavior of Fe/Ti and Zr/Ti where the peak was observed at the base of volcaniclastics turbidites.

Our results revealed turbidites and volcaniclastics turbidites in six piston coring sites (PC01 to PC06). As all of sites are located in the Taura-Tsunagioki fault group or Minamataoki fault group, turbidites were considered to be present in all of sites. However, turbidites were identified from PC01 to PC06, but not identified from PC07 to PC11. According to Rifardi et al. (1998), PC01 to PC06 are located in the sea area where the deposition rate is high, and PC07 to PC11 are located in the sea area where the deposition rate is slow.

As turbidite is formed by various factors besides earthquakes, it is necessary to consider whether the turbidites identified in this study are earthquake turbidites. In addition, to investigate the history of earthquakes, it is also a future task to conduct individual sample measurements (such as grain size distribution analysis) and dating.

Revised columnar section based on grain size distribution analysis of samples from Hakuho-maru KH-18-3 in Yatsushiro sea

*Yuta Ikebata[1], Yujin Kitamura[2], Hakuho-maru KH-18-3 Scientists Family

1. Kyusyu University Graduate School Of Science Earth and Planetary Science, 2. Graduate school of science, Kagoshima University

Hakuho-maru KH-18-3 was held in the Yatsushiro Sea from 27th to 30th July 2018 for clarifying history of occurrence of submarine landslides. Earthquake is a one of big trigger of submarine landslides, and submarine landslides occurs in an very easy slope. Kumamoto earthquake occurred at April, 2016 and a lot of surveys in the land area were conducted but survey in the sea area weren't conducted much. In the Yatsushiro sea, the occurrence of submarine landslides caused by earthquake of the Futagawa-Hinagu fault zones can be considered sufficiently. Therefore, in this study, the creation of the columnar section which is the basic information of the submarine landslide accreditation was made based on the grain size distribution analysis.

In the Expedition, eleven piston cores(6m) from PC01 to PC11 were collected in the southern part of Yatsushiro sea, and the obtained core was subjected to non-destructive measurement and individual sample measurement at the Kochi Core Center. For non-destructive measurement, CT images and core continuous images were taken, and for individual sample measurement, Density, Magnetic susceptibility, porosity, vane shear strength, color, concentration change of major elements were examined. Grain size distribution analysis was conducted at Kagoshima University. Samples used for grain size distribution analysis were collected every 50 cm and analyzed with a laser diffraction type grain size distribution analyzer. Since it is difficult to judge the stratum boundary only with the result of grain size distribution measurement at intervals of 50 cm, it was judged by using γ ray density, magnetic susceptibility and color measurement result which are continuous data.

Grain size distribution analysis revealed PC01 to PC07 are muddy cores and PC08 to PC11 contains much sand. Grain size of PC01, PC04, PC06, PC07, PC09, PC11 are very different in Grain size distribution analysis and visual core description. Based on the results of the grain size distribution analysis, the stratum boundary was determined from the change commonly seen in the γ ray density, magnetic susceptibility and color, and a columnar section was prepared. In Rifardi et al.(1998), the distribution of mud content in the Yatsushiro Sea has been surveyed. As a result of comparing the columnar map of this study with its distribution for each sampling point, cores excluding PC08 corresponded well. It is thought that it is influenced by the supply of sediment by river and stagnant water mass, tide current as in previous research. Also, in Inoue et al.(2011), which was a reference for determining the core harvest point, dating is done in the same area. At Hori(2019MS), we compare the data with Inoue et al.(2011) and estimate the core age of this research. We also compare the columnar section made in this study with the columnar section of Inoue et al.(2011), using the comparative categories determined at the time of estimating the age. As a result, PC01 and PC02 were in good agreement, PC06 and PC07 had different stratum in the surface layer. This is probably because the sampling site of PC06 is actually about 150 m far from Inoue et al.(2011) and the sampling site of PC07 is actually about 111 m far from Inoue et al.(2011), and the sedimentary environment is slightly different. Also, in the grain size distribution analysis of this study, there is a possibility that coarse grains may be selectively left out when putting the sample into the machine, and it may be doubtful in accuracy.

[H-DS11] Subaqueous Landslides and Their Anthropogenic Impact for Coastal Regions

convener:Yujin Kitamura(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Yasuhiro Yamada(Japan Agency for Marine-Earth Science and Technology (JAMSTEC), R&D Center for Ocean Drilling Science (ODS)), Chairperson:Yujin Kitamura(Kagoshima University), Masayuki Utsunomiya(Research Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Yasuhiro Yamada(JAMSTEC)

A large number of people inhabit coastal areas around the world that are susceptible to natural catastrophes and subaqueous landslides are one of such hazards as demostrated recently. The risk associated with the occurrence of subaqueous landslides is not only constrained to passive margins or subduction zones but any of water areas is also susceptible to their occurrence since subaqueous failures can be triggered at very low slope angles. This realization poses a significant challenge that requires the collection of vast amounts of information and data to unravel the true nature of these events and their potential risk to coastal communities. Despite these challenges, recent technical and engineering advances in the acquisition and processing of sea floor and shallow subsurface data are encouraging. There has also been a concerted effort by scientists from different earth-science disciplines to increase interdisciplinary cooperation at an international level to advance our collective understanding of subaqueous landslides and their consequences.
This session calls for technical contributions covering all aspects of subaqueous landslide research including but not limited to: physical properties of deformed sediments (pre- and post- deformation), role of interstitial fluids in subaqueous landslide development, slope stability and risk assessments, geomorphological and sedimentological/stratigraphic descriptions, tsunamigenic risk and modeling, description of ancient subaqueous landslides, sand-box models and numerical simulations of subaqueous landslides. Case studies from lacustrine landslides and subaerial coastal landslides transitioning into the marine realm are also welcome. Case studies associated with the broader topic of subaqueous gravity-driven flows (e.g.: turbidites and transitional flows) and their relationship with seafloor faulting are also of interest to this session. Participants of IUGS project S4SLIDE IGCP-640 sponsor this session.

Discussion

Distribution and sedimentological characteristics of the submarine landslides filling Hidaka Trough, offshore southern Hokkaido, northern Japan with special attention to the uppermost Quaternary submarine landslide bodies

*Hiroyuki Arato[1]

1. Graduate School of International Resource Sciences, Akita University

In the last few years, many examples of submarine landslides have been reported worldwide, and their systematic and genetic researches have been initiated. The studies in distribution, sedimentary pattern and mechanism of submarine landslides are remarkably important mainly from the following two reasons: (1) Submarine landslides affect significantly the state of surrounding water mass due to long distance migration of huge volume sediment mass within relatively short time period. One of the critical phenomena is megatsunami induced by submarine landslides, (2) Secondly nature of submarine landslides is deeply related to transportation mechanisms of siliciclastic sediments into tectonically formed sedimentary basins and their burial processes. In this study, two dataset of 3D seismic survey are utilized to describe some submarine landslide examples, under the owner’ s permission. They are Geophysical Survey and Basin Evaluation Projects “2013FY Hidaka Shujo Kaibon 3D”(hereinafter, called HSK-3D) and “2014FY Hidaka Shujo Kaibon Seibu 3D” (HSKW-3D), acquired at the offshore southern Hokkaido by Ministry of Economy, Trade and Industry (METI).
The surveys cover the northeastern marginal slope and a part of central basin floor of Hidaka Trough elongated NW-SE direction. Water depth of covering area ranges from 577 to 1,156 mBMSL. The seismic reflector indicating seabed have been traced by using “seeded autotracking” function of PETREL, then a time structural contour map for the surface, which is equivalent to bathymetric map, have been drawn. Based on the topographic features, the survey area can be subdivided broadly into two types; one is characterized generally by smooth sea bottom surface, and another by irregular or rough surface in seismic scale. The area of smooth sea bottom cover approximately southwestern two thirds portion of HSKW-3D and a part of the western HSK-3D areas. On the other hand, northeastern one thirds of HSKW-3D, northwestern corner of HSK-3D, and northeastern portion and some extending areas are characterized by irregularly swollen, or roughly heaped unsmooth sea bottom surface. Such irregular topographic features of the seabed can be interpreted formed by Holocene or the youngest Quaternary submarine landslides from the point of view of their distribution within the basin. Within cross sectional views of the seismic data, those landslide bodies are observed as externally discontinuous and internally chaotic layers within orderly stacking parallel layered succession in seismic facies. These youngest submarine landslides seen in recent topography can largely be classified into 4 groups; called i) Shizunai, ii) Urakawa, iii) Samani and iv) Erimo Submarine Landslide, and they are laterally arrayed from northwest to southeast and running down generally from northeast to southwest on the continental slope of Hidaka Trough (Figure).
In addition, many buried submarine landslide bodies in the sediments filling the Hidaka Trough (e.g., Monbetsu SLS) can be recognized by seismic facies interpretation in the cross sections and time slice images. In the Hidaka Trough, Cretaceous to Quaternary sediments ranging up to 10km in thickness are present. Four horizons, A, B, C and D had been selected and traced within the sedimentary succession in this study. On the basis of chronostratigraphic correlation to the preceding studies, B, C, and D are correlative to intra-middle Pleistocene equivalent to the base of NPD12, base of middle Pleistocene Calabrian, and base of Pliocene, respectively. Horizon A is inferred as a horizon in the upper Pleistocene

©2019. Japan Geoscience Union. All Right Reserved.

or Holocene. At least more than 3 landslide events can be detected in the stratigraphic unit between seabed and horizon A. In the unit between horizons A and B, 3 to 5 events are recognized, and there are equivalent numbers of landslide events in the unit between horizons B and C. Almost sediments are interpreted as chaotic seismic facies below horizon D.

Origin and distribution of mass-transport deposits in the Pleistocene forearc basin, central Japan, deduced from tephro- and biostratigraphy

*Masayuki Utsunomiya[1], Yuzuru Yamamoto[2], Kiyohide Mizuno[1]

1. Geological Survey of Japan, AIST, 2. JAMSTEC

We introduce a field-based study on the basin-wide mass-transport deposits (MTDs) by means of biostratigraphy and the marker tephra beds. The Kazusa Group, the Pleistocene forearc-basin fill exposed in central Japan, is characterized by high sedimentation rate and its stratigraphy is well-established. We focused on three MTDs referred to as MTDs-8–10. They consist of folded blocks that range from tens of centimeters to more than tens of meters in width and thickness, in a sandy mud matrix commonly containing volcaniclastics (e.g., pumice grains and euhedral crystals). The overall thickness of these MTDs ranges from ~20 to 100 m. Based on the lateral correlation of the tephra marker beds, these MTDs can be traced laterally for more than several tens of kilometers. MTD-8 (1.3 Ma) and MTD-9 (1.2 Ma) contain blocks characterized by folding, internal minor faulting, different attitude of bedding planes from the general trend, and occasionally overturned. The blocks in MTD-8 contain tephra beds and calcareous nannofossils that are typically found in the older strata down to 250 m below it, which suggest that the blocks are considered to have originated from the upstream excavated area and spread out laterally to cover the open seabed. On the other hand, MTD-10 (1.2 Ma) is characterized by a laterally-stacking pattern showing lamp-flat geometry, and the original stratigraphic positions of the blocks are consistent with the host strata, indicative of translational movement. The sedimentary dykes were observed in the basal slide plane, suggesting excess pore pressure within the slip zone. The different modes of occurrence are likely to be a result of local variation in slope gradient and distance of downslope migration. That is, initial phase of mass transportation on low-gradient slope represented a slide (MTD-10), whereas moving over a sufficiency long distance exhibited more mixtured and deformed slump (MTDs-8 and 9). Combination of studies on MTD textures, tephro- and biostratigraphy has great advantage to know their spatial distribution, original stratigraphic position where the MTDs were initiated, and mechanism to generate variable occurrence of MTDs.

Physico-chemical properties of sediment cores from Yatsushiro Sea, western Kyushu

*Yujin Kitamura[1], Ryoya Goto[2], Koki Hori[2], Yuta Ikebata[2], Haruka Kageyama[2], Kuniyo Kawabata[1], Daiki Oyama[1], Kaede Yamasaki[2], Hakuho-maru KH-18-3 Scientists

1. Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Submarine active faults in Yatsushiro sea, western Kyushu, constitute the Yatsushiro section of Hinagu fault zone in its southwest end. The 2016 Kumamoto Earthquake was sourced from a part of active faults of the Futagawa-Hinagu fault zones. Earthquake shaking occasionally triggers submarine landslide. As submarine landslide can take place in very gentle slope (< 1˚), Yatsushiro sea is yet to be a scene for it although the area is a shallow and relatively small sedimentary basin. However, any record of submarine landslide in this area has not been reported.

Minamata bay, southern Yatsushiro sea, is known to be mercury pollution from a chemical plant drainage. A complex space-time distribution of mercury content in the sediments has been revealed (Tomuyasu et al., 2014). As the transportation of the mercury-containing clastics depends on sedimentation rate and/or water current, submarine landslide is a candidate for the factor of drastic change in benthic environment.

Here we conducted four-days research cruise Hakuho-maru KH-18-3 in July, 2018 to reveal submarine landslide records and benthic environment in Yatsushiro sea. We conducted subbottom profiling, piston coring at 11 sites, and multiple coring at 13 sites). Recovered cores are analyzed by X-ray CT scanner, multi-sensor core logger, core imaging apparatus, visual core description, color spectroscope, X-ray fluorescence core scanner (Itrax), and so do discrete samples by vane shear tester, picnometer with sediments and by Radon monitor with sea water and pore water.

Our results revealed clear difference in the lower part of each core compared to the upper part. By referring piston cores and their age data by Inoue et al. (2011), these distinctive units is caused by hiatus between about 3 to 8 ka. The lower sediments below the hiatus are characterized by rather high vane shear strength, low porosity and abundant terrigenous sediments. The depth of hiatus varies in site by site, which suggests difference in local depositional environment. Sedimentation rate of recent 50 years which Rifardi et al. (1998) inferred from superficial sediments cannot be applied for whole core, but the rate in longer time scale must be further smaller.

[H-DS12] Advanced Remote Sensing toward Mega-Disaster Response

convener:Young-Joo Kwak(ICHARM-UNESCO: International Centre for Water Hazard And Risk Management), Wataru Takeuchi(Institute of Industrial Science, The University of Tokyo)

Natural disaster under climate change is a serious threat to sustainable development, and in recent years natural disasters, i.e., hydro-geo-meteorological hazards and risks, have been frequently experienced in many countries by both developing and developed countries.
To achieve Sustainable Development Goals (SDGs), this session introduces papers focused on both principles and applications of remote sensing to promote investment in disaster risk reduction using integrated GIS and space infra data. Advanced remote sensing with Earth observation (EO) data appears to be the way forward in reducing damages and the death toll or affected people at local, national, regional and global levels.
We encourage the presentation of new research findings and novel approaches on land surface dynamics due to mega disasters between near-real time observation and long-term trends with water/hydrological cycle, such as floods, tropical cyclones (typhoons), storm surges, earthquakes, tsunamis, landslides, and wildfires.

Understanding the distribution and duration of power outages after a disaster is a precursor to minimizing their harmful consequences, especially to vulnerable communities. Here, we use satellite-derived daily estimates of lights to monitor electricity restoration efforts in Puerto Rico following Hurricane Maria, which caused the longest blackout in US history. Within all settlements, we track how long it took to restore electricity, and assess the characteristics of communities that shouldered the most extended outages. Our results show an 80% decrease in lights, in total, immediately after Hurricane Maria. During the recovery, a disproportionate share of long-duration power failures (> 120 days) occurred in rural municipalities (41% of rural municipalities vs. 29% of urban municipalities), and in the northern and eastern districts. Unexpectedly, we also identify significant disparities in electricity recovery within municipalities. Land use, proximity to highways, and the structure and density of the built environment were all factors that influenced restoration times. For many urban municipalities, poor residents lived in less dense, detached housing—where power restoration lagged. The results demonstrate the capability of nighttime satellite imagery to monitor power availability at a high spatial resolution, linking monitoring efforts to neighborhood-scale demographic data. They also identify the unintended consequences of current density-based power restoration protocols. Through the integration of in-situ, satellite, and socioeconomic data products, disaster responses to long-term events can become more strategic to minimize harm, incorporating adaptive community capacity as an additional variable to determine where power should be restored.

Flood inundation forecasting coupled with in-situ water level and satellite data

*Young-Joo Kwak[1], Jonggeol Park[2], Wataru Takeuchi[3]

1. ICHARM-UNESCO: International Centre for Water Hazard And Risk Management, 2. Tokyo University of Information and Sciences, 3. University of Tokyo

With extreme weather events, catastrophic floods occur as one of the major disasters in the world. With the development of spaceborne optical and SAR (synthetic aperture radar) sensors, flood detection algorithms should be progressively developed to produce more accurate flood maps

Despite very limited satellite-based data, this study introduces good examples of snapshot flood detection and flood inundation forecasting focusing on short-term flood extent change using a new index-based flood algorithm with a synchronized floodwater index ($SfWI^2$). MODIS (MODerate resolution Imaging Spectroradiometer, NASA-USGS) time series data were mainly employed to detect the annual and potential flood extent of 2017. The pilot study was selected in the mega deltas over vast low-lying areas of Bangladesh and India (i.e., the 2017 flood in the basins of the Ganges, Brahmaputra and Magna rivers) As preliminary results, the resultant maps represented the dynamics of flood extent and flood propagation process. This approach shows a methodological possibility for instant and comprehensive flood mapping at the international river-basin level. For application to a global flood mapping, reliable satellite-derived flood maps will contribute flood risk management. In order to improve the accuracy of rapid flood mapping, we should solve many ambiguities in particular, surface complexity, i.e., urbanized mega-delta floodplains.

Long term monitoring of flood damage in the coastal area of Bangladesh

*Park Jonggeol[1], Young-Joo Kwak[2]

1. Tokyo University of Information Sciences, 2. ICHARM-UNESCO

The major natural hazards which Bangladesh has to confront regularly include floods, cyclones and accompanying storm surge. Flooding from river waters overflowing the banks, particularly during monsoon, is an annual phenomenon. On average, one-third of the country goes under water every year. In this study, we investigated the flooding area of Bangladesh using time series MOD13A2 data of 15 years. Discriminant analysis using both NDVI and MDWI is more effective than extracting water bodies using existing NDWI only. The flash flood was from the Indian plateau bordering the northern part of Bangladesh to flow from April to May and a wide wetland was formed and the longest flooding period in Bangladesh was revealed as it is as it is the rainy season.

Automatic shoreline detection and coastal change detection using multiple satellite data in Bangladesh

*Young-Joo Kwak[1]

1. ICHARM-UNESCO: International Centre for Water Hazard And Risk Management

The Bangladesh government has been faced with the risk of coastal erosion as one of the urgent issues in land use planning and coastal management. As a preliminary investigation, an automated algorithm was proposed focusing on shoreline detection using multiple satellite data. The selected study site is located in the estuary of the Meghna River around the Gulf of Bengal in Bangladesh.

We employed Landsat-7, -8 data (90m and 30m spatial resolution, respectively) and ALOS, ALOS-2 (12.5m and 25m spatial resolution, respectively) to detect accurate coastal lines during the similar snapshot period.

As a result of automatic shoreline detection and coastal change detection by the interpretation and classification, the average rate of coastal line change was 0.5km (eroded) per year for the period between 2010 and 2019 in case of Meghna River along Noahkali (Noler Char). In addition, the resultant coastal change line was also verified by ground truth and field survey data using a small unmanned aerial vehicle (sUAV: Quadcopter with a flight control system, ©DJI Technology Co. Ltd., China) for comprehensive validation.

This feasibility study will continually investigate the characteristics of short-term and long-term changes with the relationship between hydrological parameters such as precipitation, river discharge, wave, and tidal effect.

[H-DS12] Advanced Remote Sensing toward Mega-Disaster Response

convener:Young-Joo Kwak(ICHARM-UNESCO: International Centre for Water Hazard And Risk Management), Wataru Takeuchi(Institute of Industrial Science, The University of Tokyo)

Natural disaster under climate change is a serious threat to sustainable development, and in recent years natural disasters, i.e., hydro-geo-meteorological hazards and risks, have been frequently experienced in many countries by both developing and developed countries.
To achieve Sustainable Development Goals (SDGs), this session introduces papers focused on both principles and applications of remote sensing to promote investment in disaster risk reduction using integrated GIS and space infra data. Advanced remote sensing with Earth observation (EO) data appears to be the way forward in reducing damages and the death toll or affected people at local, national, regional and global levels.
We encourage the presentation of new research findings and novel approaches on land surface dynamics due to mega disasters between near-real time observation and long-term trends with water/hydrological cycle, such as floods, tropical cyclones (typhoons), storm surges, earthquakes, tsunamis, landslides, and wildfires.

Understanding the distribution and duration of power outages after a disaster is a precursor to minimizing their harmful consequences, especially to vulnerable communities. Here, we use satellite-derived daily estimates of lights to monitor electricity restoration efforts in Puerto Rico following Hurricane Maria, which caused the longest blackout in US history. Within all settlements, we track how long it took to restore electricity, and assess the characteristics of communities that shouldered the most extended outages. Our results show an 80% decrease in lights, in total, immediately after Hurricane Maria. During the recovery, a disproportionate share of long-duration power failures (> 120 days) occurred in rural municipalities (41% of rural municipalities vs. 29% of urban municipalities), and in the northern and eastern districts. Unexpectedly, we also identify significant disparities in electricity recovery within municipalities. Land use, proximity to highways, and the structure and density of the built environment were all factors that influenced restoration times. For many urban municipalities, poor residents lived in less dense, detached housing—where power restoration lagged. The results demonstrate the capability of nighttime satellite imagery to monitor power availability at a high spatial resolution, linking monitoring efforts to neighborhood-scale demographic data. They also identify the unintended consequences of current density-based power restoration protocols. Through the integration of in-situ, satellite, and socioeconomic data products, disaster responses to long-term events can become more strategic to minimize harm, incorporating adaptive community capacity as an additional variable to determine where power should be restored.

With extreme weather events, catastrophic floods occur as one of the major disasters in the world. With the development of spaceborne optical and SAR (synthetic aperture radar) sensors, flood detection algorithms should be progressively developed to produce more accurate flood maps

Despite very limited satellite-based data, this study introduces good examples of snapshot flood detection and flood inundation forecasting focusing on short-term flood extent change using a new index-based flood algorithm with a synchronized floodwater index ($SfWI^2$). MODIS (MODerate resolution Imaging Spectroradiometer, NASA-USGS) time series data were mainly employed to detect the annual and potential flood extent of 2017. The pilot study was selected in the mega deltas over vast low-lying areas of Bangladesh and India (i.e., the 2017 flood in the basins of the Ganges, Brahmaputra and Magna rivers) As preliminary results, the resultant maps represented the dynamics of flood extent and flood propagation process. This approach shows a methodological possibility for instant and comprehensive flood mapping at the international river-basin level. For application to a global flood mapping, reliable satellite-derived flood maps will contribute flood risk management. In order to improve the accuracy of rapid flood mapping, we should solve many ambiguities in particular, surface complexity, i.e., urbanized mega-delta floodplains.

Long term monitoring of flood damage in the coastal area of Bangladesh

*Park Jonggeol[1], Young-Joo Kwak[2]

1. Tokyo University of Information Sciences, 2. ICHARM-UNESCO

The major natural hazards which Bangladesh has to confront regularly include floods, cyclones and accompanying storm surge. Flooding from river waters overflowing the banks, particularly during monsoon, is an annual phenomenon. On average, one-third of the country goes under water every year. In this study, we investigated the flooding area of Bangladesh using time series MOD13A2 data of 15 years. Discriminant analysis using both NDVI and MDWI is more effective than extracting water bodies using existing NDWI only. The flash flood was from the Indian plateau bordering the northern part of Bangladesh to flow from April to May and a wide wetland was formed and the longest flooding period in Bangladesh was revealed as it is as it is the rainy season.

Automatic shoreline detection and coastal change detection using multiple satellite data in Bangladesh

*Young-Joo Kwak[1]

1. ICHARM-UNESCO: International Centre for Water Hazard And Risk Management

The Bangladesh government has been faced with the risk of coastal erosion as one of the urgent issues in land use planning and coastal management. As a preliminary investigation, an automated algorithm was proposed focusing on shoreline detection using multiple satellite data. The selected study site is located in the estuary of the Meghna River around the Gulf of Bengal in Bangladesh.

We employed Landsat-7, -8 data (90m and 30m spatial resolution, respectively) and ALOS, ALOS-2 (12.5m and 25m spatial resolution, respectively) to detect accurate coastal lines during the similar snapshot period.

As a result of automatic shoreline detection and coastal change detection by the interpretation and classification, the average rate of coastal line change was 0.5km (eroded) per year for the period between 2010 and 2019 in case of Meghna River along Noahkali (Noler Char). In addition, the resultant coastal change line was also verified by ground truth and field survey data using a small unmanned aerial vehicle (sUAV: Quadcopter with a flight control system, ©DJI Technology Co. Ltd., China) for comprehensive validation.

This feasibility study will continually investigate the characteristics of short-term and long-term changes with the relationship between hydrological parameters such as precipitation, river discharge, wave, and tidal effect.

The sources of landslides occurred by the 2018 Hokkaido Eastern Iburi Earthquake

*Satoshi Ishimaru[1], Wataru Hirose[1], Gentaro Kawakami[1], Ryo Takahashi[1], Yoshihiro Kase[1], Ken'ichi Koshimizu[1], Hiromichi Koyasu[1], Masahiro Chigira[2], Jun Tajika[3]

1. Geological Survey of Hokkaido, 2. Kyoto University, 3. Docon Co., Ltd.

An earthquake of M6.7 was occurred at 37km depth in East Iburi, Hokkaido, on September 6, 2018. This earthquake caused numerous landslides in Azuma town with seismic intensities of 7 or 6+. The number of landslides reached 8000 in area of 20km by 20km. The type of these landslides is almost debris slide on the base of tephra layers, excluding rock slide and rock fall near the epicenter.

1 Distribution of tephra layers

Thick tephra layers interleaved with kuroboku, cover on hill slopes in the area of numerous landslides. The tephras derived from Shikotsu caldera and surrounding volcanoes, about 50 km west of Atsuma town. Main tephra layers in the hillslope are Spfa1 pumice of 48ka from Shikotsu caldera, En-a pumice of 20ka from Eniwa volcano, and Ta-d pumice of 9ka, Ta-c pumice of 3ka, Ta-b pumice of AD1667, and Ta-a pumice of 1739 from Tarumai volcano. En-a layer is thick, 1m more, in the northern area with numerous landslides, and Ta-d layer is thick, 1m more, in the southern area. These tephra layers are the main parts of landslides by this earthquake.

2 Tephras on hillslope with geomorphological evolution

Slope surficial deposit moved active affected by solifluction due to freeze-thaw cycles in the last glacial period, more than 10ka. For the reason, Spfa1 and En-a could not remain on hillslopes, except for valley head slopes and the foot of the slope accumulated surficial deposits, or crest slopes. On the other hand, the lower part of slopes was eroded by increased fluvial activity related to warmer and wetter during the late glacial period. Therefore, Spfa1 and En-a from the last glacial period do not cover on the lower valley-side slopes, but Ta-d covers on slope deposits on weathered rock there.

En-a covering the slope, for example valley head slope, is underlain by the reworked Spfa1. The volcanic soil with Spfa1 contains easily water and has slippery. On the other hand, Ta-d often is underlain by reworked En-a on the lower valley-side slope. These reworked tephras and the unit of the base of Ta-d layer with high absorbability, described below, would be slide layers in this earthquake.

3 Cases of landslides

Cases of landslides of thick Ta-d in the southern area of the disaster area and of thick En-a in the northern area are shown below.

3.1 The southern part covered thick Ta-d

A landslide at Asahi, located at the west side of Yoshino at the most severe disaster, was occurred on a flat slope at the lower valley-side slope. The collapse was occurred from the lower convex break of slope. It is 35m high, 35m wide, and 90m long. The vertical surface of the 3m thick soil layers with tephras, is exposed at the both sides of the landslide. Pale yellowish water-rich volcanic ash with striations adhere to the slip surface on thin slope deposit on weathered rock. The sliding surface was in a fine-pumice layer containing much moisture at the lowest part of Ta-d layer, according to outcrop observation of both sides of this failure. The upper part of Ta-d layer of 130cm thick, is redish brown pumice with weathered clay, and the lower part of it is dull gray coarse pumice with high permeability. The moving body slid and deposited as almost kept stratigraphic structure.

3.2 The northern area covered thick En-a

A landslide at the right bank of the upper Abira river is at 80m high, 45m wide, and 230m long. The collapsed debris buried the Abira river. The landform of the slope was divided into upper and lower parts

©2019. Japan Geoscience Union. All Right Reserved.

by a break line of inclination. The source of collapse was mainly the upper, a valley head slope, shaped shallow flat slope which is covered by En-a. The lower part was a V-shaped valley before the earthquake. The moving body run on the upper of V-shaped slope along the valley and deposited over the Abira river. Acording to observation of the exposed outcrops by the failure, thin Ta-d and the above layers cover on En-a of 130cm thick. En-a is pumice of 1-2mm diameter with rich-pyroxene. The sliding surface was on the lower volcanic ash, mixed glassy Spfa1, beneath En-a.

4 Shapes of slope failures in each southern and northern area of the disaster area

In the southern part of the disaster area, almost slopes except of steep are covered thick Ta-d. The main source of collapses is thick Ta-d by the earthquake. Therefore, the collapses were occurred numerous on the slope covered by thick Ta-d, especially the lower valley-side slope, which is steep. On the other hand, in the northern area of disaster area, because Ta-d layer is thin, even though it is on the lower valley-side slope, the collapse of Ta-d is rare. The collapses of thick En-a on the valley head slopes are unevenly distributed. Because each geomorphological unit at the source of collapses in the northern and the southern is different, their shapes are different in each region.

Feature of landslide of pyroclastic fall deposits induced by 2018 Hokkaido Eastern Iburi Earthquake, and its relation with damage

*Jun Tajika[1], Kazuo Amemiya[2], Masahiro Chigira[3], Satoshi Ishimaru[4], Akio Koike[1], Hidetoshi Kon[1], Kenji Kizaki[5], Nobuo Yamane[6]

1. Docon Co.,Ltd., 2. Bousai Chishitsu Kogyo Co.,Ltd., 3. Kyoto University, 4. Geological Survey of Hokkaido, HRO, 5. Kizaki PE Office, 6. Terre Research Co.

Many landslides occurred by the 2018 Hokkaido Eastern Iburi Earthquake around Atsuma-cho . Rapid landslide consisting of Holocene pyroclastic fall deposit (Debris slide by the classification of Varnes, 1978) gave the human damage of 36 above all. We show the topographical and geological cause and morphological characteristic of the landslides and discuss about relations with the human damage.

Tephra mainly derived from Shikotsu, Eniwa and Tarumai volcanos cover on sedimentary rocks for Neogene of the base in Atsuma area. Among these tephra, the Tarumai d pyroclastic fall deposit (Ta-d: 9ka) thickly distributes in this area as a central axis of distribution. Ta-d (thickness 1-2m), the tephra (Ta-c,-b,-a) and black soil (total thickness approximately 1.5-3m) which did mantle bedding was translationally sliding as landslide body. The sliding layer was formed in several centimeters above from the base of the Ta-d pumice at the slope where Ta-d directly covered the mudstone and mudstone rubble. The thickness of the layer was 1-3cm and is made of creamy clay including the halloysite. In addition, the sliding layer was formed in the weathered volcanic soil including pumice derived from Eniwa a and Shikotsu 1 Tephra in the area where the Ta-d covers up the volcanic soil.

The landslides in Atsuma area into following 7 types based from form and another feature of the slide, i.e. 1) Type Gv: Extremely gentle, shallow valley from, 2) Type Sv: Gently shallow valley form. 3) Type Dv: Deep valley form with alluvial cone or landslip lobe 4) Type Hv: Hanging valley form, 5) Type Ps: Planer slope, 6) Type Cf: Complex of Some valley form collapses along the small stream, and 7) type Ol: Gently landslide caused by overlapping of other slides.

Although there is difference in some clarity, the cutting of the layered bedding of Ta-d is often seen at the slope end in these slopes. The valley wall slope that Ta-d covers is eroded by small stream in the Type Cf. Because the thinning and omission of Ta-d occur at an exit of the hanging valley in the Type Hv , it is in a near condition for "lower part cutting". In addition, the convex break of slope angle and a man-made small cut is often observed in the foot of the collapse scarp with the Types Sv, Dv and Ps.

The landslide body of each type was moved with mostly maintaining of bedding form from the source area to the depositional area. The terminal form of slides has many variations, i.e. from stacking of plural sliding bodies which make thrust on the front, to separating and crushed into many blocks. Fluidized slide material such as the Type Cf made depositional lobes like a debris-avalanche or a debris-flow deposit in the terminal area. The distance from the base of slope to the tip of the sliding body of Types Cf, Hv and Dv were generally longer than the type Ps. The thickness of landslide body was about 1.5-3m which was reflected from the total thickness of stratified Ta-d and other tephra and black soil, and reaches 3-5m in the part which some bodies stacked at the terminal. The damaged buildings were located at the mouth of small stream and were located in the accumulation area of the landslides. Height of the first floor of the house is almost about 3m.

©2019. Japan Geoscience Union. All Right Reserved.

The geological cause of landslide is that The Ta-d tephra distributes widely with the mantle bedding. The pumice of Ta-d is weathered and halloysite formed in it. Furthermore, the tephra was cutting in the foot of slope in many places by natural and artificial process. On the other hand, the Eastern Eburi Earthquake showed that a landslide will occur by all means in the sloping ground including extremely gentle area that pyroclastic fall deposit cover with mantle bedding when the large-scale inland earthquake occurs. Because it is impossible to predict earthquake, inhabitants of the slope area cannot evacuate beforehand. The preventive measures construction is not necessarily realistic. It is necessary to avoid building house at the mouth of small valley and to make a bedroom in the places more than second floor for reducing human damage.

Influence of slope cutting on failures induced by the July heavy rain, and the Iburi-tobu earthquake, 2018.

*Hidehisa Nagata[1]

1. Fu-Sui-Do Company Limited

Many cases of failure induced by slope cutting have been also reported in the past. Some examples are added here by the July heavy rain from June 28 to July 8 and the Hokkaido Iburi-tobu earthquake on September 6, 2018. In the July heavy rain, many slope failures occurred widely main in western part of Japan including Hiroshima, Ehime and Gifu Prefectures. The Iburi-tobu earthquake caused collapses in high density in the hilly area around at Atsuma Town, Hokkaido.

Case A (Hokkaido): a failure that 20 m in width and 50 m in length caused by the Iburi-tobu earthquake. It is smaller scale one in the many failures by the earthquake. Similar to many other cases, sliding surface is the base of Tarumai-d tephra (9ka) lying under 2.5 m from the earth surface. The slope toe has been cut about 3 m in height for a hut. As a result, inclined weak layer became to daylight in the cutting slope.

Case B (Ehime Prefecture): a 30 m wide failure occurred on an orange grove slope by the July heavy rain. It is initially surface failure 0.5 m in depth, although the secondary 2 m deep failure continued on the left side. A trail for working passes at the top of the failure, and a pipe for sprinkling was buried along the trail. Leaked water from the pipe might cause the initial failure, so many small gullies run from the top. Otherwise, groove into strongly weathered Cretaceous sandstone is possible factor of the failure.

Case C (Gifu Prefecture): a forest road shoulder composed of highly weathered Jurassic Hida Granite was collapsed 25 m in width. The failure occurred on a shallow valley slope and the road passes through the upper part of the slope in up-hill grade. Although this valley has only small catchment area originally, rain water was drained from upper neighboring valley through the road and flowed out to the road shoulder along small undulations on the road. This large quantity of water caused the failure. Involving catchment area was enlarged at least 8.5 times than before the road opened.
There are many sites needed slope cutting for architecture and civil structure and dense network of forest road is required for proper management of forestry and agriculture. However, any slope cutting causes hydrological and geomorphological changes despite of its scale. When large impacts like heavy rain or earthquake occur, modified landforms can be a factor of landslide. Slope failures are induced by daylighting of weak layer in the case A, and by flowing water in the upper part of slope in the cases B and C. Moreover, construction of the forest road made drainage area increase by capture of the upper neighboring valley in the case C. On the planning of slope cutting, appropriate design, construction and maintenance should be taken considering microlandforms, subsurface geological properties and structures.

Slope failures occurred in the southwest part of the Izu-oshima Island in geological time, NE Japan

*Takehiko Suzuki[1], Masahiro Chigira[2]

1. Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, 2. Disaster Prevention Research Institute, Kyoto University

So-called “loam” composed of primary fall-out tephras and tephric soil deposits (tephric loess) is one of the factors cause earthquake-induced landslide. To evaluate potential of slope failure by this combination in the Japanese Island, earthquake-induced landslides potential assessment should be examined in relevant areas, considering frequency of landslides in geological time. To estimate this, we examined unconformities within “loam” on the Izu-oshima Island, Tokyo, where thick loam has been formed during last 19 ka. We identified at a maximum six unconformities suggesting possibility of occurrences of landslides during the period between 19-1.8 ka.

The strain rate observation by the borehole inclinometer on the bedrock creep slopes in Akadani-west area

*Atsuhiko Kinoshita[1,2], Yasutaka Tanaka[2], Wataru Sakurai[1], Taro Uchida[1], Koichiro Hayashi[3], Yasuuchi Kubota[3], Katsushi Kawato[4]

1. National Institute for Land and Infrastructure Management, 2. Sediment Disaster Prevention Technology Center, Kinki Developing Regional Bureau, Ministry of Land, Infrastructure, Transport and Tourism , 3. OYO Corporation, 4. NIPPON ENGINEERING CONSULTANTS CO., LTD.

In the disaster around Kii Peninsula in 2011, many deep-seated landslides were occurred. In order to reduce the damage, it is necessary to establish the method of the extracting dangerous slopes and to consider the countermeasures in advance. So far, the method of reading the micro topography from the topographic map such as the laser profiler, the method of judging the degree of danger from geological / topographical overview have been proposed. On the other hand, there are few cases where the strain rate was observed at the landslide dangerous slope such as the bedrock creep slope. For this reason, the validity of the past method has not been fully verified. In this study, we conducted the boring survey and observed the strain rate by borehole inclinometer on two slopes of Akadani-west area. Also, based on this observation value, the validity of the risk method by the past study was examined.

First, we calculated the strain rate (the value obtained by dividing the length of the landslide scarp by the slope length) from the topographical data obtained by the laser profiler at the two slopes in Akadani-west area. We also evaluated the risk of the two slopes using the method to evaluate the risk from geology and topography by Chigira et al. In addition, we conducted the airborne electromagnetic survey, and the degree of strain was also investigated from the resistivity distribution of the ground. By these methods, after evaluating the degree of risk, two boring investigations were conducted on each of the two slopes. At the borehole location, the strain rate was observed by the borehole inclinometer. Through these, the consistency of the observed data and the risk assessment results was verified.

The strain rate of Akadani-west I district was 4.1%, and the risk by the method by geology / topography was IV. The strain rate of Akadani-west II district was 2.7%, and the risk by the method by geology / topography was II. From this, we have found that the degree of the risk in the Akadani-west I district is higher than that of II by the risk assessment by the past research. In addition, the strain rate by the borehole inclinometer was 0.6mm/year, 1.0mm/year in Akadani I and II districts, respectively. For this reason, we have found that the danger level in the Akadani-west II district is higher by the observed data. On the other hand, in the resistivity distribution by the airborne electromagnetic survey, a large change in resistivity was seen in Akadani-west II area, and it was found that the consistency with the actual observed data was obtained. From this, we have found that there is a possibility that the degree of the risk can be accurately evaluated by combining the plural methods.

Assessing Potential Landslide Areas Due to Earthquake Using Three-Dimensional Resistivity Datasets from Across a Wide Area

*Yusuke Sakai[1], Taro Uchida[1], YASUMASA FUJIWARA[2]

1. National Institute for Land and Infrastructure Management , 2. Eight-Japan Engineering Consultants

In recent years, sediment disasters due to earthquake have often occurred, including in the 2011 Great East Japan Earthquake, the 2016 Kumamoto Earthquake, the 2018 Hokkaido Eastern Iburi Earthquake. Measures for preventing and reducing the damage of sediment disaster due to earthquake are an urgent issue, because Nankai Trough Earthquakes are expected in the future. A variety of methods for assessing seismic landslide susceptibility have been proposed and their accuracy verified. In those methods, topographic parameters such as inclination of slope, curvature of slope, and relief are commonly used as controlling factors.

It has also been reported that underground structure has a large impact on seismic landslide occurrence, as in the case of the landslide that occurred around the Aso Volcanological Laboratory of Kyoto University in the 2016 Kumamoto Earthquake. Therefore, underground structure can be considered critical information for improving the predictability of potential landslide areas. However, geological maps only plot spatial patterns of the underground condition, and boring is required to obtain point information of underground structure in the depth direction. This lack of three-dimensional information of underground structures is one of key obstacles to evaluating potential landslide areas due to earthquake across a wide area.

Therefore, we used resistivity spatial patterns measured by airborne electromagnetic survey (AES). Airborne electromagnetic survey Based on electromagnetic induction, AES is an exploration technique for obtaining three-dimensional resistivity across a wide area by measuring the response to an induced electromagnetic field with an electromagnetic sensor from a helicopter.

The purpose of this study was to test the applicability of three-dimensional resistivity data to assessing seismic landslide susceptibility. We used three-dimensional resistivity data from the central cone of Aso Volcano measured before the 2016 Kumamoto Earthquake and landslide distribution maps made from airborne laser scanner datasets and orthoimages from before and after the earthquake. We identified the three-dimensional resistivity patterns in seismic landslide areas before landslide occurrence. Based on our findings, we argue the applicability of three-dimensional data for assessing seismic landslide susceptibility.

Discussion

Prediction of shallow landslides and debris flow by rainstorm: dynamic hazard mapping toward disaster mitigation

*Yuki Matsushi[1]

1. Disaster Prevention Research Institute, Kyoto University

This study demonstrates a strategy for predicting location, timing, and magnitude of rainfall-induced shallow landslides and areas affected by subsequent debris flows. Spatial distribution of soil layers was modeled for evaluating thickness of sliding material on hillslopes, which provides a basis for predicting source area and volume of shallow landslides and simulating subsurface hydrological processes. Soil accumulation in hollows was calculated on a geographic information system using a 1 m-meshed digital terrain model with soil production by bedrock weathering and transport by soil creep. The output was validated by a ground-based survey in the actual terrain in a selected watershed. The shear strength of the bulk soil was evaluated by direct shear tests using undisturbed specimens, and quantification of soil reinforcement by tree roots through an in-situ survey at soil pits. Hydrological monitoring was carried out at representative hillslopes for modeling fluctuation in subsurface pore-water pressure by rainwater infiltration. By coupling all of those data and modeling, we analyzed the hillslope instability, and then compared the output with a landslide inventory map to confirm the accuracy and precision of the prediction. Time-series change in areas of debris flow runout was estimated based on assumed equivalent coefficient of friction as a function of hillslope wetness in the watershed. Such dynamic mapping of geohazard fills a demand in disaster mitigation in local communities for increasing events of heavy rainfall.

Land slide warning judgment mesh information of the Meteorological Agency using the Soil Water Index

*KENJI OKADA[1]

1. Japan Meteorological Agency

Soil Water Index shows the risk of land slide disasters caused by rain in real time and the land slide warning judgment mesh information released by the Japan Meteorological Agency using it.
Most of the dead due to land slide disasters in the last two decades occurred with the Soil Water Index value updating the maximum value in the last 10 years.

A future direction of remedial measures for sediment disaster reduction from the viewpoint of enhancing a workable early warning system

*Masaru Kunitomo[1,2,3,4], Shigetaka Takiguchi[1,2,3,4], Fumiaki Akazawa[1,2,3,4], Kazuyuki Imai[1,2,3,4]

1. Ministry of Land, Infrastructure, Transport and Tourism, 2. Water and Disaster Management Bureau, 3. Sediment and Erosion Control Department, 4. Sediment and Erosion Control Planning Division

Due to “Heavy rain of July 2018”, more than 2500 sediment disasters occurred mainly in the western part of Japan. The number is equivalent to approximately 2.3 times of the annual average. Why were such a lot of people killed in this disaster, despite various measures for precaution?

The Ministry of Land, Infrastructure, Transport and Tourism (MLIT) established a committee in order to take remedial measures for sediment disaster reduction from the view point of enhancing a workable early warning system, after not only revealing the facts on cause of the disaster but reviewing our measure have been taken.

With understanding that the lack of residents’ awareness of sediment disaster risk may be a major cause of this disaster, on the other hand, mutual assistance plan among local community may work well for evacuation at the sites with no victim, the committee proposed the MLIT to;
Build the early warning system nationwide based on a community mutual assistance plan for evacuation, Get residents to aware of their risk on sediment disasters, Enhance the national and prefectural support system to build the capacity of municipalities and residents, Improve the accuracy of sediment disaster alert to encourage residents at risk to evacuate precautionary, Build disaster-prevention facilities such as debris basins to reduce evacuation risk and to prevent crucial infrastructures from debris flows as well as sediment-rich flood, with the object of climate change adaptation. As a remedial measures for sediment disaster reduction from the viewpoint of enhancing a workable early warning system.

The estimation of frequency for deep-seated landslide with carbon dating in Kii mountain area

*Yasutaka Tanaka[1], Toshiaki Kotake[1], Hiroaki Sugawara[1], Atsuhiko Kinoshita[1], Yoshito Ogawauchi[2], Minami Fujiwara[2]

1. Sediment Disaster Prevention Technology Center, Kinki Regional Developing Bureau, Ministry of Land, Infrastructure, Transport and Tourism, 2. Japan Conservation Engineers & CO., LTD.

Typhoon 12 in 2011 induced deep-seated landslides in Kii mountain area. In Kii mountain area, heavy rainfall also induced great damage by large scale landslide in 1889. From above we need the frequency of deep-seated landslide to construct countermeasure for sediment disaster in Kii mountain area.

Although previous report shows the method to use tephra for estimation of frequency of deep-seated landslide, in Kii mountain area we can find few point of tephra sedimentation. In recent years some study shows the methods to estimate frequency of sediment disaster with chips of wood and carbides. In this study we applied the method with chips of wood and carbides to estimation of frequency of deep-seated landslide in Kii mountain area.

In this study we proposed the research flow to pick sample shown as below;

a) Extracting landslide deposit by LiDAR

b) Preliminary research in field

c) Main research in field and picking sample up

d) Analysis sample with carbon dating

In a) we extracted the site where landslide dams may have been as landslide deposit to observe along river side closely with topographic map by LiDAR. In b) we investigate access route to the research site and whether chip of wood and carbide are or are not roughly. In c) we investigated closely and picked sample up with special sampler we developed for this research. This sampler can collect sample including soil. In d) we analyzed samples and organized carbon dating data.
We collected 28 samples in 11 landslide deposits. Especially it was easier to collect samples in upper and bottom of landslide deposits and underwater deposits than other sites. The research flow and special sampler we developed can help to collect sample effectively. In addition we found deep-seated landslide occurred once in 100 ~ 150 years in Kii mountain area from analysis of carbon date. This result isn't inconsistent with the past disaster reports. However, carbon dating has some error. To estimate accurately we need more investigation.

Tephra stratigraphy and a slope failure of about 4,000 years ago on the slope of the Late Pleistocene Janoo Volcano in the northwestern of Aso Caldera

*Yasuto Hirata[1], Keiichi Ueta[1], Riichiro Miyawaki[2], Katsutoshi Iemura[2], Toshitaka Yokoyama[2], Akiko Miyawaki[2]

1. Central Research Institute of Electric Power Industry, 2. Hanshin Consultants

In the west part of Aso Caldera, the 2016 Kumamoto Earthquake caused surface earthquake faults along the Futagawa and Hinagu fault zone, triggering numerous landslides and some lateral spreads on tephra. Janoo Volcano is located on the line that extrapolates from the end of the earthquake fault zone to the northeast in the disaster area. We carried out an excavation and boring exploration at the south slope of Janoo Volcano and measured chemical compositions of lava and radiocarbon ages of volcanic soil. The results elucidated the succession of volcanic products after the formation of Janoo Scoria Cone and showed a slope failure about 4,000 years ago. The eruption ages of key beds were estimated with calibrated method as follows: Janoo Scoria (>15.5 ka), ACP1: Aso Central Pumice 1 (~4.0 ka), Kishimadake Lava and Kishimadake Scoria (~3.7 ka), Ojodake Scoria (3.5±0.1 ka), and Kometsuka Lava (3.0±0.1 ka). Fine sandy ashes deeper than 8 m and the surface part of Janoo Scoria weathered to become yellowish and included small dislocations that are the normal sense and parallel to the surface of Janoo Scoria. The volcanic soil layer on the sandy ash was separated as 1-meter-tall blocks, and they were arranged into an imbricated form of overturned strata. This deposit was covered with a 2 m thick of soft volcanic soil moved from the upper slope. All the above tephra layers were consistently covered with ACP1. Consequently, these deformation and sedimentary structures suggest that the tephra on Janoo Scoria sild down successively from the slope toe toward the top just before the eruption of ACP1. This ancient slope failure seems to be triggered by earthquake because its depth and material are similar to those of landslides by the 2016 Kumamoto Earthquake.

Analysis of causal factors of landslides during 2017 northern Kyusyu torrential rainfall disaster by using decision tree

*Hiromu Daimaru[1], Wataru Murakami[1], Yuki Tsurusaki[2]

1. Forestry and Forest Products Research Institute, 2. Fukuoka Agriculture and Forestry Research Center

Causal factors of landslides induced by torrential rainfall in July 2017 in Kyushu Island were analyzed by decision tree. The landslides were mapped from orthophotos produced by GSI and overlay analysis with radar-AMeDAS rainfall data, slope, geology tree age and vegetation were conducted by using the decision tree classifier of the Scikit-learn Python module. Landslide map was defined by existence or non-existence of landslide in each 200m size grid and overlain by geological map by AIST, slope map from 10m DEM by GSI and digital forest map by Fukuoka Prefecture. The distribution of landslides was principally controlled by rainfall distribution. Slope was the secondary factor on landslide susceptibility and threshold slope decreased with rainfall intensity. Geology was the third factor. granite area was rather vulnerable comparing with metamorphic rocks and Tertiary volcanic rocks. Effect of tree age was evident in where 12hr rainfall was less than 500mm. On the other hand, effect of tree species seemed to be minor factor comparing with other factors.

Geologic characteristics of rock mass failures caused by the heavy rain event of July 2018 in Uwajima, Ehime

*Shintaro Yamasaki[1]

1. Disaster Prevention Research Institute, Kyoto University

The heavy rain event of July 2018 caused many rock mass failures around Hokezu bay area in Uwajima city and Seiyo city, Ehime. This paper reports geologic characteristics of those failures. The rock mass failures are relatively small, because they occur on relatively low relief topography. The scarps of failures are weathered, and have dense cracks and separating planes cutting slope or mountain flanks. Webby weak mineral veins and fault fractures are found at some failure sites. These characteristics have lowered strength of the rock mass microscopically and macroscopically in the area. Because of the low strength, gravitational deformation probably proceeds in small slope, and it forms flow path to penetrate with abundant rain water in the slope before collapse. The Hokezu bay area is a characteristic low relief area in Shimanto belt in Sikoku. Similar low relief topographic areas are distributed along Butsuzo tectonic line traversing Shikoku island.

On the failure mechanism of embankments in Mabi Town during the Heavy rain of July, 2018, Japan

*Gonghui Wang[1]

1. Disaster Prevention Research Institute, Kyoto University

From late June to mid-July, 2018, successive heavy rainfall hit a wide area of southwestern Japan, resulting in widespread sediment-related disasters and devastating floods. Among these disasters, the flooding resulting from the failures of embankments along Oda River and some other tributary rivers in Mabi Town, Okayama Prefecture, was the deadliest. To understand the possible failure mechanisms of these embankment, field geotechnical investigation and geophysical surveys were conducted. Centrifuge tests were also performed to examine the instability processes of embankment with increase of water level on the river. The results indicate that the leakage in the embankments along the tributary rivers may have resulted in retrogressive failures on the embankments, while overtopping may have played a key role in the final rapid breaching of the embankment.

Keywords: failure of embankment, failure mechanism, Internal structure of embankement, foundation of embankment, Centrifuge test

Interpretation of landslide surface deformation around the branch basins of Sun Kosi river in Nepal using InSAR images

*Otake Shunpei[1], Hiroshi, P. Sato[1]

1. College of Humanities and Sciences, Nihon University

On 25 Apr 2015, Gorkha earthquake (Mw 7.8) occurred at 80 km NW from Kathmandu, Nepal. After that, the largest aftershock (Mw 7.3) occurred on 12 May 2015 at 75 km ENE from Kathmandu. These earthquakes caused landslide disasters and big damages. Nepal has wide mountain area, and landslides disasters tend to be induced by both conditions as follows. On the one hand many earthquakes occur in Nepal, where is on the collision and subduction area related Indo-Australian and Eurasian plate. On the other hand they have much rain in monsoon season there. Therefore, landslide caused by these earthquakes may be reactivated. It is important to monitor landslide surface deformation because it contributes to prevent landslide disasters after these earthquakes. In this study we focused on the area where the largest aftershock occurred, and tried to detect landslide surface deformations after the largest aftershock.

Recently InSAR (Synthetic Aperture Rader interferometry) has been used to detect landslide surface deformation. Then, we used and adopt it for the study area, where is the watershed of Sun Koshi river branches which includes epicenter of the largest aftershock. In this study two InSAR images were produced, which was taken on 12 Sep 2016/30 Jan 2017 and on 30 Jan 2017 /11 Sep 2017. Then, landslide surface deformations were interpreted on the two InSAR images, and the interpreted areas were delineated and the center of the area were mapped. And location of such the detected sites were analyzed related with distance from the epicenter, elevation, slope aspect, deformation amount along LoS (line of sight) known from InSAR image, interpreted deformation area, lithological units of geology, and the watersheds of the branches.

As a result of the interpretation, 29 and 25 deformation sites were detected on InSAR image taken on 12 Sep 2016/30 Jan 2017 and on 30 Jan 2017 /11 Sep 2017, respectively. As a result of the analysis, it was found that ca. 70 % of the detected sites locate in the elevation of 1,500-2,999 m, and that the averaged area of deformation per one site was larger on 30 Jan 2017 /11 Sep 2017 image than on 12 Sep 2016/30 Jan 2017 image. For the former result, it is thought that low Himalayan meta-sedimentary rocks gave more detected sites than other lithological units and the rocks tend to be widely distributed in this elevation belt. For the latter result, it is thought that effect of precipitation in rainy season are related more closely with landslide surface deformation interpreted on 30 Jan 2017 /11 Sep 2017 image than on 12 Sep 2016/30 Jan 2017 image.

The large scale landslides triggered by The 2018 Sulawesi Earthquake, Indonesia

*Masashi Omata[1], Toshiyuki Adachi[2], Takao Yamakoshi[3], Kenichi Matsui[4], Tosho Iwamatsu[1], Susumu Takagishi[1], Chiho Motojima[1], Yuu Okuizumi[1], Umito Wada[1]

1. PASCO CORPORATION, 2. LDP Upper House member, 3. SABO & LANDSLIDE TECNICAL CENTER, 4. Nobuyuki Adzchi Office

On 28 September 2018, a large earthquake occurred near Palu City, Sulawesi, Indonesia. The magnitude of the earthquake was 7.5. According to the information broadcast after the earthquake, the nearly flat terrain greatly moved laterally. The authors carried out a satellite imagery interpretation survey with using the post-earthquake imageries of Pleiades and SPOT-7. The survey revealed that there are at least three areas which seem to have moved laterally with long distance. It seems to be lateral spread in view of situations reported in the press information. Two large lateral spreads stand in the eastern side of the city and one in the western side. The two lateral spreads in the east side are 1.5 km wide and 2.5 km long and 1 km wide and 3.5 km long, respectively while the one in the western side is 0.4 km wide and 1 km long. In the upper part of the spreads, there is area of brown bare soil while there seems ropy in the lower part of the spreads. One of them seemed to be greatly fluidized and reached further in the down streams. These spreads seem to initiate from the knick point near lower edge of fluvial fans where a lot of subsurface flow is likely to return onto ground surface. A press says that local people call these phenomena as "nalodo", which means "get absorbed into mud". This implies that similar disasters repeated in the past.

Keywords: lateral spread, satellite imagery, earthquake, SPOT-7, Pleiades, Indonesia

Relationship of the grand deformation and topography in Sapporo City at the 2018 Hokkaido Eastern Iburi Earthquake confirmed by InSAR analysis

*Akihiro Yokota[1], Tomohiro Nishimura[2], Kiyoyuki Shigeno[1], Kenichi Honda[2], Sakae Mukoyama[2]

1. Meiji Consultant Co., Ltd, 2. Kokusai Kogyo Co., Ltd

In the 2018 Hokkaido Eastern Iburi Earthquake, ground displacement and building damage occurred extensively. It is thought that it is important to promptly grasp the damage caused by a natural disaster in order to advance disaster reduction. In this study, the results of SAR analysis using Sentinel - 1 satellite were investigated for validity and cause using interpretation of aerial photograph and field survey.

As a result of SAR analysis, displacement was observed in Satozuka・Utsukushigaoka・Kiyota, Kiyota Ward, Hiragishi, Toyohira Ward, and Fushiko・Naebo, Higashi Ward in Sapporo City. For these districts, I performed an investigation by the local survey and aerial photo reading.

As a result of investigation, the spot that ground movement produced confirmed that I agreed with the spot where big displacement was estimated on InSAR analysis. The correlation with the old topography and the Embankment place is high in the ground change confirmed this time

It was revealed that I could grasp the damage situation of the wide area in a short time by using the inSAR data with the, Sentinel-1 satellite about the ground damage after the 2018 Hokkaido Eastern Iburi Earthquake.

Keywords: Interferometric SAR, Ground displacement, 2018 Hokkaido Eastern Iburi Earthquake

Estimation of co-seismic surface displacement and ground deformation associated with the 2018 Hokkaido Eastern Iburi Earthquake, based on differential InSAR and differential LiDAR DEM analysis.

*Kenichi Honda[1], Norichika Asada[1], Naruo Mushiake[1], Tomohiro Nishimura[1], Sakae Mukoyama[1]

1. Kokusai Kogyo Co.,LTD.

It is important to detect the damage situation of the building quickly when an earthquake occurs for the initial response. Satellite remote sensing can measure a wide area, and is expected to obtain the damage at the time of a disaster. However, the observation frequency of the satellite, the analysis processing time, selection of information required at the beginning are suggested as problems for practical use.
This paper introduces information which can be provided by Coherence Change Detection and differential LiDAR DEM analysis when an earthquake occurs. Especially, it will introduce the earthquakes which occurred in 2018, the 2018 Hokkaido Eastern Iburi Earthquake.
On 6 September 2018, an earthquake of magnitude 6.7 hit southern Hokkaido, which is the largest and northernmost prefecture of Japan. Interferometric analysis was carried out using images of Sentinel-1 before (August 25) and after (September 6) the earthquake to estimate the damage of the building due to the ground deformation and the deterioration of the coherence. In addition, the same analysis was carried out using the image of ALOS-2.
Figure shows an example of Kiyota Ward in Sapporo City where liquefaction occurred. In the interferometry image using Sentinel-1, deviation was discontinuous or shown as noise, so extraction of the deviation was difficult. However, the area which buildings were damaged could be extracted from the coherence change detection.
On the other hand, the degradation of coherence when using ALOS-2 is Low, so the damage area can be extracted from the deviation of the interferometry image as a ground deformation. This difference is thought to be due to the difference in the sensitivity of the observation wavelength band.
For comparison, the particle image velocimetry method was applied to calculate 3-D vectors of co-seismic deformation. The result shows deformation of the housing area, which was developed over the valley that was filled up with soil, agrees with SAR analysis result.
In this case, since Sentinel-1 observed the disaster area about 3 hours after the earthquake, the image was analyzed on the day and the results were provided to local staff. Field confirmation was carried out the day after the earthquake, and the results were provided to the affected local governments. Except for the day of the earthquake, the weather was bad for the disaster area for several days, so it was not possible to take aerial photos using the aircraft. 2018 Hokkaido Eastern Iburi Earthquake is a case where utilization of the satellite SAR, which can quickly extracts damaged area, became advantageous.
Obtaining disaster damage by satellite remote sensing is effective. However, field survey and aircraft surveillance are carried out as soon as the disaster occurred in Japan, and satellite remote sensing has not be practically used in many situations. However, similar to the 2018 Hokkaido Eastern Iburi Earthquake, if acquiring the satellite data and providing analysis results could be carried out quickly, satellite remote sensing can be an option for understanding the damage at early disaster response stage. Furthermore, estimation the light damaged area is difficult by aerial photographs, therefore estimation by SAR coherence change detection are considered importance.
Finally, I wish to express my deepest condolences to those who lost loved ones in these disasters, and also to express my sympathy to all who were affected.

Geological features of landslides of pyroclastic fall deposits induced by the 2018 Eastern Iburi Earthquake and other previous earthquakes

*Masahiro Chigira[1], Jun Tajika[3], Satoshi Ishimaru[2], Takehiko Suzuki[4]

1. Disaster Prevention Research Institute, Kyoto University, 2. Hokkaido Geological Survey, Hokkaido Research Organization, 3. Docon Co. Ltd, 4. Tokyo Metropolitan University

2018 Eastern Iburi Earthquake induced numerous numbers of landslides in Atsuma town and its neighborhood with the seismic intensities of 7 and 6+. This was one of the most devastating earthquake-induced landslide hazards in Japan. Geographical Information Authority of Japan published a map showing the distribution of landslides, which counted 8000 in an area of 400 km^2. Most of the landslides were of pyroclastic fall deposits and highly mobile. Those deposits were of Ta-d pumice of 9 ka and En-a pumice of 20 ka, and their sliding surfaces were made within specific beds, which were the bottom of Ta-d, reworked Ta-d in its base or reworked En-a beneath Ta-d, or volcanic soil with pumice grains beneath the Ta-d or volcanic soil beneath En-a. The materials that accommodated the sliding surfaces were heavily weathered to be rich in halloysite, which mineral has been found from the sliding surface materials of previous earthquake-induced landslides of pyroclastic fall deposits and is supposed to be very weak to earthquake shaking. The depths of the landslides varied from 2 to 3 m. Most of the beds that slid were undercut at the lower portion of the slopes, because of man-made cutting or convex slope breaks of which origin is in dispute.

Landslides similar to the landslides stated above have previously occurred in Japan, Indonesia, and El Salvador. They were 1923 Kanto, 1949 Imaichi, 1968 Tokachi-Oki, 1978 Izu-Oshima-Kinkai, 1984 Naganoken-Seibu, and 2011 Tohoku earthquakes in Japan, 2001 El Salvador earthquake, and 2009 Padang earthquake in Indonesia (Chigira and Suzuki 2016). The oldest beds that accommodated a sliding surface and was dated was 330 ka and the youngest was 9 ka of Ta-d. The beds of the sliding surfaces were rich in halloysite and most of the landslides were undercut like those by Eastern Iburi earthquake.

Earthquake ground motion properties of mountainous district in Totsukawa village, Nara pref. based on the seismic observation –A fundamental study of landslides caused by earthquake –

*Tomoyuki Iida[1], Ryuji Yamada[1], Shigeki Senna[1], Hidemitsu Tokui[2], Tetsuya Onodera[2], Hiroshi Kawabe

1. National Research Institute for Earth Science and Disaster Prevention, 2. Technicallink Kabushiki kaisya

The quantity of seismic information has been accumulated enormously in Japan since seismometer networks, such as K-NET or KiK-net, were completed nationwide. However, most of seismometers are installed in the plain area or hill area, and there are extremely few seismometers installed in the mountainous area where landslides may occur. Therefore, the information about earthquake ground motion properties in the mountainous area, such as the amplification characteristic which may greatly influence landslides, is not enough. It is expected that factors such as the relative position of topography will affect earthquake ground motion properties in the mountainous area together with the ground structure such as AVS30 (the average shear-wave velocity in the upper 30 m). Therefore, we pay particular attention to the influence of topography on earthquake ground motion properties and continuously observe earthquake ground motions at the ridge.

NARH01, one of the KiK-net observation spots, is situated on the ridge which extends to the east and west direction. Two seismometers are installed on NARH01, one is on the surface and another one is underground of approximately 100-m depth. The geology of this area is accretionary wedge called the Shimanto layer. We installed accelerometers (Hakusan industry JU210) in four places of around NARH01 and started the earthquake observation continuously from November, 2017, in order to supplement the observation data of NARH01 and grasp earthquake ground motion properties at each part of the slope. Setting points of the accelerometers are located at the direct perigee of the NARH01 (823 m above sea level), the east-west point on the eastern ridge along the extension of the ridge line (733 m), the north-south point on the northern slope perpendicular to the ridge line (670 m), and the valley bottom (565 m).

During the observation period over one year, we could observe four small earthquakes that were also observed by NARH01 (one of them is the North Osaka earthquake on June 18th, 2018). The result of Fourier spectrum analysis shows that amplification properties of the earthquake ground motion will be affected by the topography, ground structure, and relative position of epicenter.

Study on topographic features and landslide development process in slope failure by Typhoon Talas

*Teruyuki Kikuchi[1], Teruyoshi Hatano[2], Satoshi Nishiyama[3]

1. JP-Design Co., Ltd., 2. Electric Power Development Co.,Ltd., 3. Okayama University Graduate School of Environmental and Life Science

1. Introduction

We have not established a prediction of landslide. The cause of this landslide is complicatedly related to the predisposition.In order to clarify the process leading to the slope failure, accumulation and analysis of cases and long-term observation and evaluation are necessary.The microtopography before disaster occurrence can clarify the process of collapse occurrence.Therefore, we tried to examine the topographic features and the landslide development process of the place where the collapse occurred, by micro-topography interpretation on the location of the slope failure occurrence site.

2. Location

Typhoon Talus crossing western Japan from 2 September to 5 September 2011 brought rain close to 2000 mm to the Kii mountain range, causing more than 50 deep-seated landslides. The scope covered by this research is the upper Totsu-gawa. In this basin, the LiDAR-data before and after the disaster is being carried out by the Kinki Regional Development Bureau, Ministry of Land, Infrastructure and Transport. Particularly in areas where many collapses occurred, the accumulated rainfall exceeded 600 mm. In addition, it corresponds to the distribution area of the Shimanto belt in the upper reaches of the Totsu-gawa, and the north to northwest slope is the dip slope.

3. Method

The verification, 38 places with a collapse area of 1,000 m^2 or more that collapsed due to the Talus. We tried micro topography interpretation of the aerial laser topographic map before the collapse. The authors chose main scarp, flank, and knickpoint, which are topographies showing the gravitational deformation of the mountain body as the topography of micro topography interpretation. In addition, as the characteristic topography recognized in the deep layer collapse in the Kii mountain range, the terminal cliff and the gravitationaldeformation appeared surface in which the back slope and the moving rock body are not completely separated are targeted. In addition, the gully was the topography showing the influence of surface water and groundwater. These micro topographies were classified into three types of "nothing", "unclear" and "clear". Next, as an index showing the developmental state of the collapsed terrain, we consider it in relation with the landslide topography development process.

4. Result

As a result of micro-topography interpretation in Table 1, seven places with the topographical features total as 1 to 3 were observed as the first group. For these, the clear of main scarp, flank is not recognized, and the gravitationaldeformation at the top of the slope is the subject. Comparing the collapsed range, the moving body is unclear. This can be classified as the earliest gravity deformation in the landslide topography development process shown in Table 2, which is very close to the initial stage. I concluded

©2019. Japan Geoscience Union. All Right Reserved.

that this is also the stage of the earlier stage in the transitional stage. The topographical features of the second group are total number 3 to 7, including main scarp,flank or include clear topographical features. Since the gravitationaldeformation, knickpoint,terminal cliff is remarkable, it can be considered that gravity deformation is being clarified. The whole contour is partially clear. Although they are transitional stage, they are thought to be close to the main moving stage. It was separated from the late stage of the transitional stage. The third group has a total number of topographical features of 4 to 12, and it is a group including main scarp. Terminal cliff and accompanying knickpoint are also often clear. Gravitationaldeformation and knickpoint are clear in the slope. This is thought to be due to weight deformation progressing, juvenile landslide sliding surface connected and "main moving stage" equivalent.

5. Discussion

According to this study, the appearance of main scarp, gully, flank is uncertain though topographic features in the early and late stages of the transitional stage, but the appearance of gravitationaldeformation and terminal cliff was high probability. In addition, if it is a landslide slide in a narrow sense, it is thought that it undergoes a stepwise development process from the early stage to the late stage of the transitional stage, but in Talus in 2011 it has collapsed even at the earlier stage. The gravitational deformation which is frequently observed at this stage is thought to have appeared on the surface because it corresponds to gravitational rock creep and the structure of the basement rock is sound. Focusing on such gravitationaldeformation, we think that there is a possibility of predicting collapse by understanding the features.

Formation mechanism of bulge of slope that is sign of large-scale collapse

*tatsurou yoshimura[1]

1. Daiichi Fukken Co., Ltd.

The fracture is distributed around main scarp and side cliff in slope failure. The formation of landslide mass results from dividing into parts by fracture. "Landslide mass formation model by dividing into fracture" was verified in large-scale landslide. The thick debris is distributed in the center part of the landslide mass. Bulge of slope is admitted before collapses. Bulge of slope is caused by seismic motion and the thick debris.

Sediments accumulated in the linear depressions in the Mitsumine area, Kanto Mountains

*Masakazu Mashiko[1], Masahiro Chigira[2]

1. Graduate School of Science, kyoto University, 2. Disaster Prevention Research Institute, Kyoto University

Many problems about the mechanisms of an occurrence or a development of deep-seated gravitational slope deformations (DGSDs) are left behind. We are now researching in the Mitsumine area, Kanto Mountains, where is occupied by the Shimanto accretionary complex, in other to resolve the problems about the mechanisms of DGSDs. As a part of the research, simplified boring are executed in linear depressions near a ridge and boring cores composed by accumulated sediments are acquired.

Boring are operated in two different linear depressions and cores have reached the bedrock at the depth of 6.75 m to 6.95 m. Both cores have almost same characteristics; from the surface to the depth of 1.0 m, these are blackish brown humified soil or clay, and other parts deeper than 1.0 m are occupied by brown clay.
The date when the linear depressions or DGSDs on the hillslope emergenced will be estimated by specifying the tephras included in the boring cores. We have observed the ratio of volcanic glasses in the cores every 20 cm and have recognized three peaks; the depth of 2.20 m in P1 (upstream side), 2.40 m in P2 (downstream side), and 6.00 m in P2. Other researches performed in the Mitsumine area have revealed that the depositions include several tephras, such as Aira-Tn (AT) tephra (26~29 ka), Ontake-Pumice 1 (On-Pm1) (100 ka), and Yatsugatake-Kawakami (Yt-Kw) tephra (170 ka). It is likely that each volcanic glasses in the boring cores originated in one of these tephras. We are now trying to observate the refractive index of volcanic glasses to identify the tephras in the core completely.

For the explication of the mechanism of DGSDs in this area, it is indispensable to reveal the geomophological and geological characteristics in the area. We carry on not only analysis of the sediments accumulated in the linear depositions but also geological site investigations.

[J] Poster | H (Human Geosciences)：H-DS Disaster geosciences

Mon. May 27, 2019 5:15 PM - 6:30 PM JST | Mon. May 27, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_15

[H-DS14] Geohazards in humid, tectonically active countries and their precursors

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Hiroshi YAGI(Faculty of Art, Science and Education, Yamagata University), Satoru Kojima(Department of Civil Engineering, Gifu University), Taro Uchida(National Institute for Land and Infrastructure Management)

This session covers mass movements of landslide, slope failure, debris flow, and gravitational slope deformation in tectonically active, humid countries, and aims to discuss on their mechanisms, characteristics of occurrence sites, the significance in geological time scale, and the methodology to mitigate their affects by researchers with various related research fields. In particular, papers about 2017 northern Kyushu rainstorm, 2018 Osaka earthquake, 2018 Western Japan rainstorm, and 2018 Hokkaido earthquake are welcome

The estimation of frequency for deep-seated landslide with carbon dating in Kii mountain area

*Yasutaka Tanaka[1], Toshiaki Kotake[1], Hiroaki Sugawara[1], Atsuhiko Kinoshita[1], Yoshito Ogawauchi[2], Minami Fujiwara[2]

1. Sediment Disaster Prevention Technology Center, Kinki Regional Developing Bureau, Ministry of Land, Infrastructure, Transport and Tourism, 2. Japan Conservation Engineers & CO., LTD.

Typhoon 12 in 2011 induced deep-seated landslides in Kii mountain area. In Kii mountain area, heavy rainfall also induced great damage by large scale landslide in 1889. From above we need the frequency of deep-seated landslide to construct countermeasure for sediment disaster in Kii mountain area.

Although previous report shows the method to use tephra for estimation of frequency of deep-seated landslide, in Kii mountain area we can find few point of tephra sedimentation. In recent years some study shows the methods to estimate frequency of sediment disaster with chips of wood and carbides. In this study we applied the method with chips of wood and carbides to estimation of frequency of deep-seated landslide in Kii mountain area.

In this study we proposed the research flow to pick sample shown as below;

a) Extracting landslide deposit by LiDAR

b) Preliminary research in field

c) Main research in field and picking sample up

d) Analysis sample with carbon dating

In a) we extracted the site where landslide dams may have been as landslide deposit to observe along river side closely with topographic map by LiDAR. In b) we investigate access route to the research site and whether chip of wood and carbide are or are not roughly. In c) we investigated closely and picked sample up with special sampler we developed for this research. This sampler can collect sample including soil. In d) we analyzed samples and organized carbon dating data.
We collected 28 samples in 11 landslide deposits. Especially it was easier to collect samples in upper and bottom of landslide deposits and underwater deposits than other sites. The research flow and special sampler we developed can help to collect sample effectively. In addition we found deep-seated landslide occurred once in 100 ~ 150 years in Kii mountain area from analysis of carbon date. This result isn't inconsistent with the past disaster reports. However, carbon dating has some error. To estimate accurately we need more investigation.

Tephra stratigraphy and a slope failure of about 4,000 years ago on the slope of the Late Pleistocene Janoo Volcano in the northwestern of Aso Caldera

*Yasuto Hirata[1], Keiichi Ueta[1], Riichiro Miyawaki[2], Katsutoshi Iemura[2], Toshitaka Yokoyama[2], Akiko Miyawaki[2]

1. Central Research Institute of Electric Power Industry, 2. Hanshin Consultants

In the west part of Aso Caldera, the 2016 Kumamoto Earthquake caused surface earthquake faults along the Futagawa and Hinagu fault zone, triggering numerous landslides and some lateral spreads on tephra. Janoo Volcano is located on the line that extrapolates from the end of the earthquake fault zone to the northeast in the disaster area. We carried out an excavation and boring exploration at the south slope of Janoo Volcano and measured chemical compositions of lava and radiocarbon ages of volcanic soil. The results elucidated the succession of volcanic products after the formation of Janoo Scoria Cone and showed a slope failure about 4,000 years ago. The eruption ages of key beds were estimated with calibrated method as follows: Janoo Scoria (>15.5 ka), ACP1: Aso Central Pumice 1 (~4.0 ka), Kishimadake Lava and Kishimadake Scoria (~3.7 ka), Ojodake Scoria (3.5±0.1 ka), and Kometsuka Lava (3.0±0.1 ka). Fine sandy ashes deeper than 8 m and the surface part of Janoo Scoria weathered to become yellowish and included small dislocations that are the normal sense and parallel to the surface of Janoo Scoria. The volcanic soil layer on the sandy ash was separated as 1-meter-tall blocks, and they were arranged into an imbricated form of overturned strata. This deposit was covered with a 2 m thick of soft volcanic soil moved from the upper slope. All the above tephra layers were consistently covered with ACP1. Consequently, these deformation and sedimentary structures suggest that the tephra on Janoo Scoria sild down successively from the slope toe toward the top just before the eruption of ACP1. This ancient slope failure seems to be triggered by earthquake because its depth and material are similar to those of landslides by the 2016 Kumamoto Earthquake.

Analysis of causal factors of landslides during 2017 northern Kyusyu torrential rainfall disaster by using decision tree

*Hiromu Daimaru[1], Wataru Murakami[1], Yuki Tsurusaki[2]

1. Forestry and Forest Products Research Institute, 2. Fukuoka Agriculture and Forestry Research Center

Causal factors of landslides induced by torrential rainfall in July 2017 in Kyushu Island were analyzed by decision tree. The landslides were mapped from orthophotos produced by GSI and overlay analysis with radar-AMeDAS rainfall data, slope, geology tree age and vegetation were conducted by using the decision tree classifier of the Scikit-learn Python module. Landslide map was defined by existence or non-existence of landslide in each 200m size grid and overlain by geological map by AIST, slope map from 10m DEM by GSI and digital forest map by Fukuoka Prefecture. The distribution of landslides was principally controlled by rainfall distribution. Slope was the secondary factor on landslide susceptibility and threshold slope decreased with rainfall intensity. Geology was the third factor. granite area was rather vulnerable comparing with metamorphic rocks and Tertiary volcanic rocks. Effect of tree age was evident in where 12hr rainfall was less than 500mm. On the other hand, effect of tree species seemed to be minor factor comparing with other factors.

Geologic characteristics of rock mass failures caused by the heavy rain event of July 2018 in Uwajima, Ehime

*Shintaro Yamasaki[1]

1. Disaster Prevention Research Institute, Kyoto University

The heavy rain event of July 2018 caused many rock mass failures around Hokezu bay area in Uwajima city and Seiyo city, Ehime. This paper reports geologic characteristics of those failures. The rock mass failures are relatively small, because they occur on relatively low relief topography. The scarps of failures are weathered, and have dense cracks and separating planes cutting slope or mountain flanks. Webby weak mineral veins and fault fractures are found at some failure sites. These characteristics have lowered strength of the rock mass microscopically and macroscopically in the area. Because of the low strength, gravitational deformation probably proceeds in small slope, and it forms flow path to penetrate with abundant rain water in the slope before collapse. The Hokezu bay area is a characteristic low relief area in Shimanto belt in Sikoku. Similar low relief topographic areas are distributed along Butsuzo tectonic line traversing Shikoku island.

On the failure mechanism of embankments in Mabi Town during the Heavy rain of July, 2018, Japan

*Gonghui Wang[1]

1. Disaster Prevention Research Institute, Kyoto University

From late June to mid-July, 2018, successive heavy rainfall hit a wide area of southwestern Japan, resulting in widespread sediment-related disasters and devastating floods. Among these disasters, the flooding resulting from the failures of embankments along Oda River and some other tributary rivers in Mabi Town, Okayama Prefecture, was the deadliest. To understand the possible failure mechanisms of these embankment, field geotechnical investigation and geophysical surveys were conducted. Centrifuge tests were also performed to examine the instability processes of embankment with increase of water level on the river. The results indicate that the leakage in the embankments along the tributary rivers may have resulted in retrogressive failures on the embankments, while overtopping may have played a key role in the final rapid breaching of the embankment.

Keywords: failure of embankment, failure mechanism, Internal structure of embankement, foundation of embankment, Centrifuge test

Interpretation of landslide surface deformation around the branch basins of Sun Kosi river in Nepal using InSAR images

*Otake Shunpei[1], Hiroshi, P. Sato[1]

1. College of Humanities and Sciences, Nihon University

On 25 Apr 2015, Gorkha earthquake (Mw 7.8) occurred at 80 km NW from Kathmandu, Nepal. After that, the largest aftershock (Mw 7.3) occurred on 12 May 2015 at 75 km ENE from Kathmandu. These earthquakes caused landslide disasters and big damages. Nepal has wide mountain area, and landslides disasters tend to be induced by both conditions as follows. On the one hand many earthquakes occur in Nepal, where is on the collision and subduction area related Indo-Australian and Eurasian plate. On the other hand they have much rain in monsoon season there. Therefore, landslide caused by these earthquakes may be reactivated. It is important to monitor landslide surface deformation because it contributes to prevent landslide disasters after these earthquakes. In this study we focused on the area where the largest aftershock occurred, and tried to detect landslide surface deformations after the largest aftershock.

Recently InSAR (Synthetic Aperture Rader interferometry) has been used to detect landslide surface deformation. Then, we used and adopt it for the study area, where is the watershed of Sun Koshi river branches which includes epicenter of the largest aftershock. In this study two InSAR images were produced, which was taken on 12 Sep 2016/30 Jan 2017 and on 30 Jan 2017 /11 Sep 2017. Then, landslide surface deformations were interpreted on the two InSAR images, and the interpreted areas were delineated and the center of the area were mapped. And location of such the detected sites were analyzed related with distance from the epicenter, elevation, slope aspect, deformation amount along LoS (line of sight) known from InSAR image, interpreted deformation area, lithological units of geology, and the watersheds of the branches.

As a result of the interpretation, 29 and 25 deformation sites were detected on InSAR image taken on 12 Sep 2016/30 Jan 2017 and on 30 Jan 2017 /11 Sep 2017, respectively. As a result of the analysis, it was found that ca. 70 % of the detected sites locate in the elevation of 1,500-2,999 m, and that the averaged area of deformation per one site was larger on 30 Jan 2017 /11 Sep 2017 image than on 12 Sep 2016/30 Jan 2017 image. For the former result, it is thought that low Himalayan meta-sedimentary rocks gave more detected sites than other lithological units and the rocks tend to be widely distributed in this elevation belt. For the latter result, it is thought that effect of precipitation in rainy season are related more closely with landslide surface deformation interpreted on 30 Jan 2017 /11 Sep 2017 image than on 12 Sep 2016/30 Jan 2017 image.

The large scale landslides triggered by The 2018 Sulawesi Earthquake, Indonesia

*Masashi Omata[1], Toshiyuki Adachi[2], Takao Yamakoshi[3], Kenichi Matsui[4], Tosho Iwamatsu[1], Susumu Takagishi[1], Chiho Motojima[1], Yuu Okuizumi[1], Umito Wada[1]

1. PASCO CORPORATION, 2. LDP Upper House member, 3. SABO & LANDSLIDE TECNICAL CENTER, 4. Nobuyuki Adzchi Office

On 28 September 2018, a large earthquake occurred near Palu City, Sulawesi, Indonesia. The magnitude of the earthquake was 7.5. According to the information broadcast after the earthquake, the nearly flat terrain greatly moved laterally. The authors carried out a satellite imagery interpretation survey with using the post-earthquake imageries of Pleiades and SPOT-7. The survey revealed that there are at least three areas which seem to have moved laterally with long distance. It seems to be lateral spread in view of situations reported in the press information. Two large lateral spreads stand in the eastern side of the city and one in the western side. The two lateral spreads in the east side are 1.5 km wide and 2.5 km long and 1 km wide and 3.5 km long, respectively while the one in the western side is 0.4 km wide and 1 km long. In the upper part of the spreads, there is area of brown bare soil while there seems ropy in the lower part of the spreads. One of them seemed to be greatly fluidized and reached further in the down streams. These spreads seem to initiate from the knick point near lower edge of fluvial fans where a lot of subsurface flow is likely to return onto ground surface. A press says that local people call these phenomena as "nalodo", which means "get absorbed into mud". This implies that similar disasters repeated in the past.

Relationship of the grand deformation and topography in Sapporo City at the 2018 Hokkaido Eastern Iburi Earthquake confirmed by InSAR analysis

*Akihiro Yokota[1], Tomohiro Nishimura[2], Kiyoyuki Shigeno[1], Kenichi Honda[2], Sakae Mukoyama[2]

1. Meiji Consultant Co., Ltd, 2. Kokusai Kogyo Co., Ltd

In the 2018 Hokkaido Eastern Iburi Earthquake, ground displacement and building damage occurred extensively. It is thought that it is important to promptly grasp the damage caused by a natural disaster in order to advance disaster reduction. In this study, the results of SAR analysis using Sentinel - 1 satellite were investigated for validity and cause using interpretation of aerial photograph and field survey.

As a result of SAR analysis, displacement was observed in Satozuka・Utsukushigaoka・Kiyota, Kiyota Ward, Hiragishi, Toyohira Ward, and Fushiko・Naebo, Higashi Ward in Sapporo City. For these districts, I performed an investigation by the local survey and aerial photo reading.

As a result of investigation, the spot that ground movement produced confirmed that I agreed with the spot where big displacement was estimated on InSAR analysis. The correlation with the old topography and the Embankment place is high in the ground change confirmed this time

It was revealed that I could grasp the damage situation of the wide area in a short time by using the inSAR data with the, Sentinel-1 satellite about the ground damage after the 2018 Hokkaido Eastern Iburi Earthquake.

Estimation of co-seismic surface displacement and ground deformation associated with the 2018 Hokkaido Eastern Iburi Earthquake, based on differential InSAR and differential LiDAR DEM analysis.

*Kenichi Honda[1], Norichika Asada[1], Naruo Mushiake[1], Tomohiro Nishimura[1], Sakae Mukoyama[1]

1. Kokusai Kogyo Co.,LTD.

It is important to detect the damage situation of the building quickly when an earthquake occurs for the initial response. Satellite remote sensing can measure a wide area, and is expected to obtain the damage at the time of a disaster. However, the observation frequency of the satellite, the analysis processing time, selection of information required at the beginning are suggested as problems for practical use.
This paper introduces information which can be provided by Coherence Change Detection and differential LiDAR DEM analysis when an earthquake occurs. Especially, it will introduce the earthquakes which occurred in 2018, the 2018 Hokkaido Eastern Iburi Earthquake.
On 6 September 2018, an earthquake of magnitude 6.7 hit southern Hokkaido, which is the largest and northernmost prefecture of Japan. Interferometric analysis was carried out using images of Sentinel-1 before (August 25) and after (September 6) the earthquake to estimate the damage of the building due to the ground deformation and the deterioration of the coherence. In addition, the same analysis was carried out using the image of ALOS-2.
Figure shows an example of Kiyota Ward in Sapporo City where liquefaction occurred. In the interferometry image using Sentinel-1, deviation was discontinuous or shown as noise, so extraction of the deviation was difficult. However, the area which buildings were damaged could be extracted from the coherence change detection.
On the other hand, the degradation of coherence when using ALOS-2 is Low, so the damage area can be extracted from the deviation of the interferometry image as a ground deformation. This difference is thought to be due to the difference in the sensitivity of the observation wavelength band.
For comparison, the particle image velocimetry method was applied to calculate 3-D vectors of co-seismic deformation. The result shows deformation of the housing area, which was developed over the valley that was filled up with soil, agrees with SAR analysis result.
In this case, since Sentinel-1 observed the disaster area about 3 hours after the earthquake, the image was analyzed on the day and the results were provided to local staff. Field confirmation was carried out the day after the earthquake, and the results were provided to the affected local governments. Except for the day of the earthquake, the weather was bad for the disaster area for several days, so it was not possible to take aerial photos using the aircraft. 2018 Hokkaido Eastern Iburi Earthquake is a case where utilization of the satellite SAR, which can quickly extracts damaged area, became advantageous.
Obtaining disaster damage by satellite remote sensing is effective. However, field survey and aircraft surveillance are carried out as soon as the disaster occurred in Japan, and satellite remote sensing has not be practically used in many situations. However, similar to the 2018 Hokkaido Eastern Iburi Earthquake, if acquiring the satellite data and providing analysis results could be carried out quickly, satellite remote sensing can be an option for understanding the damage at early disaster response stage. Furthermore, estimation the light damaged area is difficult by aerial photographs, therefore estimation by SAR coherence change detection are considered importance.
Finally, I wish to express my deepest condolences to those who lost loved ones in these disasters, and also to express my sympathy to all who were affected.

Geological features of landslides of pyroclastic fall deposits induced by the 2018 Eastern Iburi Earthquake and other previous earthquakes

*Masahiro Chigira[1], Jun Tajika[3], Satoshi Ishimaru[2], Takehiko Suzuki[4]

1. Disaster Prevention Research Institute, Kyoto University, 2. Hokkaido Geological Survey, Hokkaido Research Organization, 3. Docon Co. Ltd, 4. Tokyo Metropolitan University

2018 Eastern Iburi Earthquake induced numerous numbers of landslides in Atsuma town and its neighborhood with the seismic intensities of 7 and 6+. This was one of the most devastating earthquake-induced landslide hazards in Japan. Geographical Information Authority of Japan published a map showing the distribution of landslides, which counted 8000 in an area of 400 km^2. Most of the landslides were of pyroclastic fall deposits and highly mobile. Those deposits were of Ta-d pumice of 9 ka and En-a pumice of 20 ka, and their sliding surfaces were made within specific beds, which were the bottom of Ta-d, reworked Ta-d in its base or reworked En-a beneath Ta-d, or volcanic soil with pumice grains beneath the Ta-d or volcanic soil beneath En-a. The materials that accommodated the sliding surfaces were heavily weathered to be rich in halloysite, which mineral has been found from the sliding surface materials of previous earthquake-induced landslides of pyroclastic fall deposits and is supposed to be very weak to earthquake shaking. The depths of the landslides varied from 2 to 3 m. Most of the beds that slid were undercut at the lower portion of the slopes, because of man-made cutting or convex slope breaks of which origin is in dispute.

Landslides similar to the landslides stated above have previously occurred in Japan, Indonesia, and El Salvador. They were 1923 Kanto, 1949 Imaichi, 1968 Tokachi-Oki, 1978 Izu-Oshima-Kinkai, 1984 Naganoken-Seibu, and 2011 Tohoku earthquakes in Japan, 2001 El Salvador earthquake, and 2009 Padang earthquake in Indonesia (Chigira and Suzuki 2016). The oldest beds that accommodated a sliding surface and was dated was 330 ka and the youngest was 9 ka of Ta-d. The beds of the sliding surfaces were rich in halloysite and most of the landslides were undercut like those by Eastern Iburi earthquake.

Chigira, M. & Suzuki, T. 2016. Prediction of earthquake-induced landslides of pyroclastic fall deposits. In: Aversa, S., Cascini, L., Picarelli, L. & Scavia, C. (eds.) Landslides and Engineered Slopes. Experience, Theory and Practice. Associone Geotecnica Italiana, Rome, 93-100

Earthquake ground motion properties of mountainous district in Totsukawa village, Nara pref. based on the seismic observation –A fundamental study of landslides caused by earthquake –

*Tomoyuki Iida[1], Ryuji Yamada[1], Shigeki Senna[1], Hidemitsu Tokui[2], Tetsuya Onodera[2], Hiroshi Kawabe

1. National Research Institute for Earth Science and Disaster Prevention, 2. Technicallink Kabushiki kaisya

The quantity of seismic information has been accumulated enormously in Japan since seismometer networks, such as K-NET or KiK-net, were completed nationwide. However, most of seismometers are installed in the plain area or hill area, and there are extremely few seismometers installed in the mountainous area where landslides may occur. Therefore, the information about earthquake ground motion properties in the mountainous area, such as the amplification characteristic which may greatly influence landslides, is not enough. It is expected that factors such as the relative position of topography will affect earthquake ground motion properties in the mountainous area together with the ground structure such as AVS30 (the average shear-wave velocity in the upper 30 m). Therefore, we pay particular attention to the influence of topography on earthquake ground motion properties and continuously observe earthquake ground motions at the ridge.

NARH01, one of the KiK-net observation spots, is situated on the ridge which extends to the east and west direction. Two seismometers are installed on NARH01, one is on the surface and another one is underground of approximately 100-m depth. The geology of this area is accretionary wedge called the Shimanto layer. We installed accelerometers (Hakusan industry JU210) in four places of around NARH01 and started the earthquake observation continuously from November, 2017, in order to supplement the observation data of NARH01 and grasp earthquake ground motion properties at each part of the slope. Setting points of the accelerometers are located at the direct perigee of the NARH01 (823 m above sea level), the east-west point on the eastern ridge along the extension of the ridge line (733 m), the north-south point on the northern slope perpendicular to the ridge line (670 m), and the valley bottom (565 m).

During the observation period over one year, we could observe four small earthquakes that were also observed by NARH01 (one of them is the North Osaka earthquake on June 18th, 2018). The result of Fourier spectrum analysis shows that amplification properties of the earthquake ground motion will be affected by the topography, ground structure, and relative position of epicenter.

Study on topographic features and landslide development process in slope failure by Typhoon Talas

*Teruyuki Kikuchi[1], Teruyoshi Hatano[2], Satoshi Nishiyama[3]

1. JP-Design Co., Ltd., 2. Electric Power Development Co.,Ltd., 3. Okayama University Graduate School of Environmental and Life Science

1. Introduction

We have not established a prediction of landslide. The cause of this landslide is complicatedly related to the predisposition.In order to clarify the process leading to the slope failure, accumulation and analysis of cases and long-term observation and evaluation are necessary.The microtopography before disaster occurrence can clarify the process of collapse occurrence.Therefore, we tried to examine the topographic features and the landslide development process of the place where the collapse occurred, by micro-topography interpretation on the location of the slope failure occurrence site.

2. Location

Typhoon Talus crossing western Japan from 2 September to 5 September 2011 brought rain close to 2000 mm to the Kii mountain range, causing more than 50 deep-seated landslides. The scope covered by this research is the upper Totsu-gawa. In this basin, the LiDAR-data before and after the disaster is being carried out by the Kinki Regional Development Bureau, Ministry of Land, Infrastructure and Transport. Particularly in areas where many collapses occurred, the accumulated rainfall exceeded 600 mm. In addition, it corresponds to the distribution area of the Shimanto belt in the upper reaches of the Totsu-gawa, and the north to northwest slope is the dip slope.

3. Method

The verification, 38 places with a collapse area of 1,000 m^2 or more that collapsed due to the Talus. We tried micro topography interpretation of the aerial laser topographic map before the collapse. The authors chose main scarp, flank, and knickpoint, which are topographies showing the gravitational deformation of the mountain body as the topography of micro topography interpretation. In addition, as the characteristic topography recognized in the deep layer collapse in the Kii mountain range, the terminal cliff and the gravitationaldeformation appeared surface in which the back slope and the moving rock body are not completely separated are targeted. In addition, the gully was the topography showing the influence of surface water and groundwater. These micro topographies were classified into three types of "nothing", "unclear" and "clear". Next, as an index showing the developmental state of the collapsed terrain, we consider it in relation with the landslide topography development process.

4. Result

As a result of micro-topography interpretation in Table 1, seven places with the topographical features total as 1 to 3 were observed as the first group. For these, the clear of main scarp, flank is not recognized, and the gravitationaldeformation at the top of the slope is the subject. Comparing the collapsed range, the moving body is unclear. This can be classified as the earliest gravity deformation in the landslide topography development process shown in Table 2, which is very close to the initial stage. I concluded

©2019. Japan Geoscience Union. All Right Reserved.

that this is also the stage of the earlier stage in the transitional stage. The topographical features of the second group are total number 3 to 7, including main scarp,flank or include clear topographical features. Since the gravitationaldeformation, knickpoint,terminal cliff is remarkable, it can be considered that gravity deformation is being clarified. The whole contour is partially clear. Although they are transitional stage, they are thought to be close to the main moving stage. It was separated from the late stage of the transitional stage. The third group has a total number of topographical features of 4 to 12, and it is a group including main scarp. Terminal cliff and accompanying knickpoint are also often clear. Gravitationaldeformation and knickpoint are clear in the slope. This is thought to be due to weight deformation progressing, juvenile landslide sliding surface connected and "main moving stage" equivalent.

5. Discussion

According to this study, the appearance of main scarp, gully, flank is uncertain though topographic features in the early and late stages of the transitional stage, but the appearance of gravitationaldeformation and terminal cliff was high probability. In addition, if it is a landslide slide in a narrow sense, it is thought that it undergoes a stepwise development process from the early stage to the late stage of the transitional stage, but in Talus in 2011 it has collapsed even at the earlier stage. The gravitational deformation which is frequently observed at this stage is thought to have appeared on the surface because it corresponds to gravitational rock creep and the structure of the basement rock is sound. Focusing on such gravitationaldeformation, we think that there is a possibility of predicting collapse by understanding the features.

Formation mechanism of bulge of slope that is sign of large-scale collapse

*tatsurou yoshimura[1]

1. Daiichi Fukken Co., Ltd.

The fracture is distributed around main scarp and side cliff in slope failure. The formation of landslide mass results from dividing into parts by fracture. "Landslide mass formation model by dividing into fracture" was verified in large-scale landslide. The thick debris is distributed in the center part of the landslide mass. Bulge of slope is admitted before collapses. Bulge of slope is caused by seismic motion and the thick debris.

Keywords: large-scale collapse, bulge of slope, seismic motion, relief inversion, gamma-ray survey

Sediments accumulated in the linear depressions in the Mitsumine area, Kanto Mountains

*Masakazu Mashiko[1], Masahiro Chigira[2]

1. Graduate School of Science, kyoto University, 2. Disaster Prevention Research Institute, Kyoto University

Many problems about the mechanisms of an occurrence or a development of deep-seated gravitational slope deformations (DGSDs) are left behind. We are now researching in the Mitsumine area, Kanto Mountains, where is occupied by the Shimanto accretionary complex, in other to resolve the problems about the mechanisms of DGSDs. As a part of the research, simplified boring are executed in linear depressions near a ridge and boring cores composed by accumulated sediments are acquired.

Boring are operated in two different linear depressions and cores have reached the bedrock at the depth of 6.75 m to 6.95 m. Both cores have almost same characteristics; from the surface to the depth of 1.0 m, these are blackish brown humified soil or clay, and other parts deeper than 1.0 m are occupied by brown clay.
The date when the linear depressions or DGSDs on the hillslope emergenced will be estimated by specifying the tephras included in the boring cores. We have observed the ratio of volcanic glasses in the cores every 20 cm and have recognized three peaks; the depth of 2.20 m in P1 (upstream side), 2.40 m in P2 (downstream side), and 6.00 m in P2. Other researches performed in the Mitsumine area have revealed that the depositions include several tephras, such as Aira-Tn (AT) tephra (26~29 ka), Ontake-Pumice 1 (On-Pm1) (100 ka), and Yatsugatake-Kawakami (Yt-Kw) tephra (170 ka). It is likely that each volcanic glasses in the boring cores originated in one of these tephras. We are now trying to observate the refractive index of volcanic glasses to identify the tephras in the core completely.

For the explication of the mechanism of DGSDs in this area, it is indispensable to reveal the geomophological and geological characteristics in the area. We carry on not only analysis of the sediments accumulated in the linear depositions but also geological site investigations.

[H-CG26] Deltas and estuaries: multidisciplinary analyses of complex river-mouth systems

convener:Yoshiki Saito(Estuary Research Center, Shimane University), Guan-Hong Lee(Inha University), David L Dettman(University of Arizona), Kazuaki Hori(Department of Geography, Graduate School of Environmental Studies, Nagoya University), Chairperson:Yoshiki Saito(Shimane Univ/ GSJ, AIST), David Dettman(University of Arizona)

This session has foci on morphodynamics, material cycling, and sustainability in deltas and estuaries. We invite contributions that advance research on deltas and estuaries as complex river-mouth systems from modern and ancient examples, and that develop integrated frameworks for delta & estuary dynamics modeling on a broad range of temporal and spatial scales: from studies of coastal evolution over the Quaternary to small-scale sediment/material transport processes. We also invite physical processes studies based on field observations, numerical simulation and flume experiments. Finally, the conveners encourage contributions that promote data collection and sharing for both advancing science and local problem solving, that consider policy and governance issues linked to the sustainable development of deltas and estuaries, and that use in-situ and satellite data for modeling and risk assessment.

Recent Changes of the Asian Major Deltas

*Paul Liu[1]

1. North Carolina State University Raleigh

In the past 50 years, sediments from major Asian rivers have sharply decreased 80-90% due to the increased human activities (like building dams, overusing water, or sand mining) and climatic changes. Many of those river deltas have been experiencing severe coastal erosions, like the Yellow, Red, Mekong, Chao Phraya, and Indus, etc. Most of these deltas have turned from constructive growing mode to destructive declining mode, for example, the Mekong Delta has shown overall negative net land gain starting ~ 2005. Our studies also show not only the deltaic shorelines are retreating, but also some delta’s subaqueous portions are under strong erosion, such as the Yangtze, Mekong, Chao Phraya and Indus, etc.

Matching trends in channel width, sinuosity, and depth along the fluvial to marine transition zone of tide-dominated river deltas: the need for a revision of depositional and hydraulic models

*Marcello Gugliotta[1], Yoshiki Saito[1]

1. Shimane University

Along their fluvial to marine transition zone, tide-dominated river deltas show upstream to downstream trends in channel width, sinuosity, and depth, which at present have been only partially reported. This review article aims to describe these morphological trends from five modern tide-dominated river deltas using original data collected from satellite images and bathymetric maps and published data from field surveys. All the studied channels show similar trends with two distinct tracts separated by areas of morphological changes. The upstream tracts are characterized by constant width, relatively high sinuosity, and seaward-increasing depth, and are mainly controlled by the fluvial dynamics. The downstream tracts are characterized by seaward-increasing width, relatively low sinuosity, and seaward-decreasing depth, and are mainly controlled by the tidal dynamics. The delineation of this morphological configuration of the channels is crucial to understand the responses of deltas to the interacting riverine and marine processes. Additionally, this has important implications for depositional and hydraulic models, and for the long-term evolution and the assessment of human-induced versus natural modifications of these systems.

Effects of an Estuarine Dam on Sediment Flux Mechanisms in a Macrotidal Estuary

Steven Miguel Figueroa[1], *Guan-Hong Lee[1]

1. Inha University

Sediment flux convergence traps sediment in many estuaries of the world coast. This sediment flux can be decomposed into a mean-flow flux and correlation flux to better understand the mechanisms driving the sediment trapping in estuaries. Humans have modified and are modifying many natural estuarine systems, however it isn’ t well understood what affects humans can have on sediment flux mechanisms and flux convergence in altered estuaries. Geum Estuary is a shallow, macrotidal estuary on the eastern Yellow Sea which has experienced tidal amplification and enhanced depositional rates following the operation of an estuarine dam since 1994. Geum Estuary thus serves as a good case for studying decomposed sediment fluxes for a shallow, macrotidal estuary affected by an estuarine dam. To quantify the sediment fluxes, we measured current and acoustic backscatter profiles at 1.5 km and 6.5 km seaward of the estuarine dam in Geum Estuary, over a period of two neap-spring cycles during which six episodic dam discharges occurred. Suspended sediment concentration (SSC) was estimated from acoustic backscatter and sediment flux was computed as the product of current velocity and SSC. The flux was decomposed into a mean-flow flux and correlation flux using 36-hr Lanczos filters. Additionally, ship-borne surveys were conducted at the two stations seaward of the estuarine dam to investigate more closely the role of dam-induced horizontal salinity gradient and vertical stratification on sediment resuspension and flocculation tidal asymmetries. Results indicated landward flux at both moorings with a negative flux gradient indicating deposition. Landward directed correlation flux was the dominant term. Its magnitude was proportional to the tidal range and tidal asymmetry and was found to occur in the bottom boundary layer. Seaward directed mean-flow fluxes were caused by the episodic dam discharges. Their magnitude was proportional to the discharge volume and was greatest in the surface layer of the water column. At the seaward station, periodic stratification occurred following the dam discharge and resulted in tidal asymmetries in resuspension and flocculation providing evidence for landward flux due to tidal straining. Overall the data confirms that the estuarine dam controls the seaward mean-flow fluxes, and these fluxes are smaller when the dam is closed. Furthermore, the proportionality of the correlation flux with tidal range provides supports that the dam enhanced the landward correlation fluxes because of the tidal amplification effect. Finally, the tidal straining effect was confirmed to occur in a macrotidal estuary with an estuarine dam.

Late Pleistocene sedimentary evolution of the north Jiangsu coastal plain revealed by OSL dating based chronostratigraphy

*Lei Gao[1], Hao Long[1], Ping Zhang[2], Toru Tamura[3,4], Ji Shen[1]

1. Nanjing Institute of Geography and Limnology, CAS,China, 2. Geological Survey of Jiangsu Province (GSJP), Key Lab of EFGD, Ministry of LR, China, 3. Geological Survey of Japan (GSJ), AIST, 4. Graduate School of Frontier Sciences, The University of Tokyo

In the past decades, many Chinese geoscientists carried out numerous research works to investigate the sedimentary history of the Jiangsu coastal plain. However, we still have limited understanding of history prior to the Holocene because of the lack of reliable chronology. In this study, we applied quartz optically stimulated luminescence dating (OSL) techniques to determine the ages of 11 sediment samples from a 30-m-long core (EGWY02) drilled from the north Jiangsu coastal plain. The sedimentary facies of the core were identified based on observation, grain-size analysis, colors and textures of sediments. The stratigraphy of the core was then correlated to three cores collected in the adjacent area (Zhang et al., 2010; Xia and Zhang, 2018). In our core, we identified two marine transgressive events T1 and T2 at intervals of 3-5 and 21-27 m deep, respectively. The timing of T1 and T2 were dated as 7.1±0.9 ka and > 77±6 ka, respectively. The interval of T1 is overlain by a littoral sedimentary facies deposited over the last 2 ka. Three layers of “stiff clay” (SC) were identified at depths of 1-2, 8-12 and 27-30 m and are interpreted terrestrial deposits. The first SC layer was dated about 1.8±0.1 ka while the second layer was between 44±3 ka and 72±6 ka. In addition, we recognized fluvial deposits at interval of 12-21 m deep, which was dated from 72 to 77 ka. A lacustrine layer was also identified at 5-8 m deep and dated as 41-44 ka. Our OSL dating application to the core EGWY02 thus clarified that the sedimentary succession represents two transgressive episodes in relation to the last interglacial (MIS 5) and post glacial periods (MIS 1), intervened by the terrestrial environments related to the MIS 4-2. Further application of the OSL dating to the subsurface sediment cores will unveil the pre-Holocene environmental changes in the Jiangsu coastal plain, which was possibly affected by the paleo-Yangtze River.

The sedimentary environments and provenance of the late Quaternary sediments, in South Yellow Sea shelf, eastern China

*Yong Yin[1]

1. School of Geography and Ocean Science, Nanjing University

The late Quaternary sedimentary systems are mainly controlled by sea-level changes, sediment supply and regional subsidence. The late Quaternary source materials of South Yellow Sea shelf were controlled by Yellow and Yangtze rivers. So sediment provenance is very important not only for “source to sink (S2S)” processes but also for land-sea interaction.

The South Yellow Sea is a semi-enclosed epicontinental sea between China to the west and Korea Peninsula to the east. Since the late Quaternary, the South Yellow Sea has experienced several eustatic sea-level changes and sediment supplies alternatively from old Yellow and Yangtze Rivers. Previous work did not documented the late Quaternary environments and sediment provenance in this region. Several boreholes are used: 1) to synthesize the long term sedimentary environments since the late Quaternary; 2) to discriminate the source materials and appraise the contribution of Yellow and Yangtze rivers; 3) to evaluate the driving forces controlling the formation of South Yellow Sea shelf.

The sedimentary facies analysis indicates the South Yellow Sea shelf experienced fluvial and tidal influenced fluvial environments during MIS6. Then the fluvial environment was replaced by tidal flat, estuary and delta front environments during the transgression taking place in MIS5. Delta front environments dominated the South Yellow Sea shelf during the transgression occurred in MIS3. During MIS2, the shelf was cut by network of valleys and filled with coarse materials within the fluvial channels and fine materials beyond the channels. During the Holocene, transgression environment developed in early period followed by tidal dominated coast to shelf environments in late period in South Yellow Sea shelf and estuary to delta environments in Yangtze River mouth area.

Detrital zircon U-Pb ages were employed to analyze the provenance of source materials. By comparison of Yangtze and Yellow rivers U-Pb age spectrum, the Yangtze River is characterized by 100~300Ma and 700~900Ma zircons and Yellow River is dominated by 300~500Ma and 1800~2000Ma zircons. The zircons younger than 150Ma merely found in Yangtze affiliated sediments and the zircons between 1300 and 1600 Ma only found in Yellow River affiliated sediments. For zircons between 1800 and 2000Ma and between 2200 and 2500Ma, the particles from Yellow River are more than those from Yangtze River. The results indicate the late Quaternary sediments are mostly from the old Yangtze River and occasionally influenced by Yellow River, e.g. during some periods in MIS6 and MIS2 and Holocene.

The core-recorded strata have revealed the study area experienced the similar estuary to delta processes in MIS 5 as the Yangtze delta in the Holocene. The deltaic successions dominate the South Yellow Sea shelf during the MIS 5 and MIS 3. The source province indicates the old Yangtze attributed a lot to delta sediments. Sea-level cycles and source material supplies play an important role in the late Quaternary coast and shelf successions.

Deltafront Clinoform of Abandoned Yellow River Delta in Jiangsu Province, China

*LIANGYONG ZHOU[1]

1. Qingdao Institute of Marine Geology China Geological Survey

The abandoned Yellow River delta in Jiangsu province is a major sediment supplier to the South Yellow Sea and East China Sea. In this study, comparison of historical maps, two cores and three seismic profiles were used to examine its deltafront clinoform (nearshore clinoform). The original historical maps and nautical charts since AD 1750s were collected and compared after calibration, showing the accretion of the shoreline before 1855, when the Yellow River shifted to the Bohai Sea. Near Sheyang River mouth, two 20m-long cores onshore (1 m above present sea level) and offshore (6 m bellow present sea level) were on a line normal to the shoreline. Samples og both cores were dated using AMS ^{14}C and OSL(Optical Stimulated Luminescence) dating technologies. Ages in bottoms of the cores are 43000 to 44000 cal yr BP. At approximate 17.5m bellow present sea level in both cores, yellow and younger (younger than 5000 yr BP) silt sediment occurs. Several young ages in upper part of two cores were obtained, and these show a clear clinoform pattern. Furthermore, seismic profiles across the offshore core show the deltafront clinoform. The upper part weak reflector or transparent part in seismic profiles become thinner seaward and the lower part is strong reflectors. Sea bottom nearshore show a convex shape, but the seaward low gradient part show erosional gullies. The evolution of the deltafront clinoform was revealed in profiles and in plan view.

Holocene evolution and Anthropocene destruction of the Krishna delta, east coast of India: delta lobe shifts, human impact, and sea-level history

Kakani Nageswara Rao[2], *Yoshiki Saito[1], K.Ch.V. Nagakumar[4], Sumiko Kubo[3], Shilpa Pandey[5], Zhen Li[6], G. Demudu[2], A.S. Rajawat[7]

1. Estuary Research Center, Shimane University, 2. Andhra University, 3. Waseda University, 4. Centre for Water Resources and Management, 5. Birbal Sahni Institute of Palaeosciences, 6. University of Victoria, 7. Space Applications Centre

Holocene evolution of the Krishna delta was inferred using landform characteristics and 11 sediment cores with 59 Accelerator Mass Spectrometry ^{14}C dates. Landform assemblage in 5880 km^2area of the Krishna delta indicated the upper river-built fluvial plain and the lower marine-built beach-ridge delta plain with the maximum landwardbeach ridge located at˜30 km from the shoreline separating the two plains. Sedimentary facies and their ages showed the Holocene marine sediment overlying the Pleistocene basement and progressively thickened seaward from <10 m to 25 m below the present sea level. The basal mangrove peat layers indicated that the sea level rose from −9 m to −3 m during 8.3–6.3 cal ky BP before stabilizing at the present level around 5 cal ky BP.
Considering the spatiotemporal variations of sediment facies and sediment accumulation rates and the configuration of the palaeo beach ridges (former shorelines), we surmised five major stages in the growth of 3539 km^2area of the Krishna delta beach-ridge plain during the last 6 cal ky BP with distinct lateral and seaward migration of delta lobes (depocentre shifts). Delta progradation was accelerated in the last 500 years, forming an out-building lobate delta. However, predominant erosion along the sediment-starved Krishna delta front coast during the past 50 years, due to impoundment of the riverine inputs at the burgeoning upstream dams pushed the Krishna delta into a persistent a destruction phase after ˜6,000 years of delta progradation.

Offset in radiocarbon ages between marine bioclast and terrestrial plant pairs in the Holocene sediments around Japan

*Nakanishi Toshimichi[1,2], Futoshi Nanayama[3,4], Atsushi Urabe[5], Kazuaki Hori[6], Wan Hong[7]

1. Kyoto Univ., 2. JAEA, 3. AIST, 4. Kumamoto Univ., 5. Niigata Univ., 6. Nagoya Univ., 7. KIGAM

To identify chronological and spatial changes in the radiocarbon (^{14}C) marine reservoir effects, the ^{14}C ages of eight pairs of marine bioclasts and terrestrial plants were measured from the same horizons of one core of Holocene sediments around Japan (Nakanishi et al. 2013, 2015, 2017abc). The reservoir ages ranged from 60 to 1100 years, scattered over the period 100-10,200 cal BP, which were significantly larger than the values from “prebomb” samples of known age, before AD 1955 in this area. These results indicate that the information on reservoir effects is indispensable for chronological control not only from prebomb samples but also from geological and archaeological samples. Moreover, the effects also reflects the influence of complex river-mouth systems such as deltas and estuaries. To determine the direct chronological changes of the marine reservoir effect between the Kuroshio and Tsushima Currents, radiocarbon ages from pairs of marine bioclasts and terrestrial plants were measured from the same stratigraphic horizons within three cores of Holocene sediments beneath the Sukumo Plain, Miyazaki Plain, and Oki Islands, in west Japan. Subsequently, the results were compared with values from the Oita Plain and Hakata Bay on the northern coast of Kyushu (Nakanishi et al. 2017ac), as well as the Korean Peninsula (Nakanishi et al. 2013, 2015, 2017b). The study was partially funded by the Japan Society for the Promotion of Science Kakenhi grant number 18H01310.

Assessment of MEIS for Marine Spatial Planning in the Nakdong River Estuary, Busan Metropolitan City, South Korea

*Jun-Ho Lee[1], Han Jun Woo[1], Hoi-Soo Jung[1], Chan Mi Park[1]

1. Korea Institute of Ocean Science and Technology

The Nakdong River has a length of nearly 510 km, with a drainage basin of around 23,400 km^2 in South Korea. The Nakdong River Estuary (NRE) in Busan city is a typical example of an estuary in which the throughput is manipulated artificially. The Noksan barrage, built in 1934, blocks the flow of the West Nakdong River, and the NRE barrage was completed between 1983 and 1987 to regulate the flow of the East Nakdong River. With the construction of several huge industrial complexes on reclaimed land near the NRE barrage in the last 65 years, the hydraulic circulation in the NRE has undergone dramatic changes in river discharge and geomorphic configuration, such as the formation of a series of barrier islands. In this study, marine environmental information system (MEIS) data collected after May 2015 were applied to support marine spatial planning (MSP) in the brackish water zone of NRE. The MEIS data in NRE consists of landscape classification of sub-environments, surface sediment distributions, characteristics of suspended sediment, short-term sedimentation, stratification index analysis in channels, closed circuit television (CCTV) using 4G long term evolution (LTE), automatic weather stations (AWS) in real time, calculated residual flow (R_f), net suspended sediment loads (Q_S), and net suspended sediment flux (F_S) in main stream inlet using mooring station, *etc*. The NRE could be divided into areas continuously managed by government, marine protected areas, areas for the development of marine attractions, areas conserved for research education, and coastal areas subject to safety management, e*tc*. For MSP, it was possible to use comparative data of the characteristics of environmental changes in the estuarine watershed to prepare the NRE for the partial opening or drainage extension in 2019 to 2021. This study aims to discuss how to predict environmental change after partial or full opening in NRE barrage and use ecological-based environmental maps in the process of MSP. The development of marine spatial planning mapping in NRE is much necessary for the nation at a time when the diversity of marine use and the demand for policies regarding marine space rapidly increase.

[1]Korean Seas Geosystem Research Unit, Korea Institute of Ocean Science & Technology, 385 Yeongdo, Busan 49111, Republic of Korea

The Nakdong River has a length of nearly 510 km, with a drainage basin of around 23,400 km^2 in South Korea. The Nakdong River Estuary (NRE) in Busan city is a typical example of an estuary in which the throughput is manipulated artificially. The Noksan barrage, built in 1934, blocks the flow of the West Nakdong River, and the NRE barrage was completed between 1983 and 1987 to regulate the flow of the East Nakdong River. With the construction of several huge industrial complexes on reclaimed land near the NRE barrage in the last 65 years, the hydraulic circulation in the NRE has undergone dramatic changes in river discharge and geomorphic configuration, such as the formation of a series of barrier islands. In this study, marine environmental information system (MEIS) data collected after May 2015 were applied to support marine spatial planning (MSP) in the brackish water zone of NRE. The MEIS data in NRE consists of landscape classification of sub-environments, surface sediment distributions, characteristics of suspended sediment, short-term sedimentation, stratification index analysis in channels, closed circuit television (CCTV) using 4G long term evolution (LTE), automatic weather stations (AWS) in real time, calculated residual flow (R_f), net suspended sediment loads (Q_S), and net suspended sediment flux (F_S) in main stream inlet using mooring station, *etc*. The NRE could be divided into areas continuously managed by government, marine protected areas, areas for the development of marine attractions, areas conserved for research education, and coastal areas subject to safety management, *etc*. For MSP, it was possible to use comparative data of the characteristics of environmental changes in the estuarine watershed to prepare the NRE for the partial opening or drainage extension in 2019 to 2021. This study aims to discuss how to predict environmental change after partial or full opening in NRE barrage and use ecological-based environmental maps in the process of MSP. The development of marine spatial planning mapping in NRE is much necessary for the nation at a time when the diversity of marine use and the demand for policies regarding marine space rapidly increase.

Tidal changes at Asian deltas in response to future sea-level rise

*Katsuto Uehara[1]

1. Kyushu University

A numerical model has been employed to assess the impact of sea level rise on tidal regimes in the East China Sea and the South China Sea with a special interest on tidal changes at around the deltaic region where the elevation is low and coasts are vulnerable to changes in water levels. The model covers the East and South China seas as a whole with a spatial resolution of 2 minutes (approx. 3 km). A preliminary result for the East China Sea suggests recognizable changes in the amplitude of M2 tides and M2 tidal currents at region such as Hangzhou Bay, the Changjiang Estuary and Haizhou Bay when the sea-level was raised by 1 m. Off the Changjiang Estuary, for example, tidal velocity increased for more than 10 cm/s at deep channels while decreased by about 5 cm/s on shoals. These results indicate that the sea-level rise may alter equilibrium among water currents and seafloor and modify the bottom topography of large estuaries and subaquatic deltas through the induced changes in tides and tidal currents.

A governing equation of non-deltaic transgressive profile: 2D numerical simulation and flume experiments

*Junhui Wang[1,2,3], Tetsuji Muto[3]

1. China University of Petroleum (Beijing), 2. State Key Laboratory of Petroleum Resources and Prospecting, China, 3. Nagasaki University

An alluvial river subject to relative sea level rise has a critical length (L_{crt}), beyond which the river can no longer sustain deltaic sedimentation but behaves to develop an estuarine environment. In such cases, there occurs non-deltaic rapid transgression. It is not difficult to imagine that non-deltaic transgression is pervasive in geological records, since most of the world large rivers would have “over-extended” to as far as the shelf edges during glacial or lowstand sea level periods. The configuration of non-deltaic transgressive profiles deserves a study because (1) it would provide a criterion for identifying non-deltaic transgression in the past and thus the fact of over-extension of the feeder alluvial river, and (2) it would constrain arguments on sediment transportation to the deep-water depositional systems.

Suppose that a river has an over-extended alluvial length of L ($>>L_{crt}$). During non-deltaic transgression, all the sediment fed by the river is consumed for alluvial aggradation and thus allocated in the subaerial realm. On the assumption that the supplied sediment is evenly distributed along the river profile which is approximately regarded as linear and has an averaged slope of α, the local transgressive slope Ψcan be expressed as:

$$\Psi = \alpha L / [L - \Lambda_{2D}(1+\alpha^2)^{0.5}] \quad (1)$$

We set an x–z coordinate system (x: basinward horizontal, z: vertical) that originates from the intersection of the initial horizontal line and the hinterland profile. Let x to be positive downstream and z to be positive upward. Equation 1 can be rewritten as:

$$\Psi_{x,z} = \alpha(\gamma x+z) / [(\gamma x+z) - \Lambda_{2D}(\gamma - \alpha)] \quad (2)$$

where $\gamma$is the averaged hinterland slope.

Equation 2 can be regarded as the derivative function of the governing equation of the non-deltaic transgressive profile, which can be expressed as:

$$\partial \eta_{x,z} / \partial x = \alpha(\gamma x+z) / [(\gamma x+z) - \Lambda_{2D}(\gamma - \alpha)] \quad (3)$$

where $\eta_{x,z}$ denotes the non-deltaic transgressive profile expressed as the pathway of shoreline. Note that sediment compaction is not considered.

Equation 3 can hardly be solved analytically but by numerical simulation. The solutions that we have obtained indicate that $\eta_{x,z}$ takes a concave-upward geometry with upstream-increasing gradient.

To test our numerical model, a series of 2D physical experiments was performed at Nagasaki University. The experiments were conducted using a 4 m-long and 2.0 cm-wide, open flume, from the upstream end of which sediment and water were fed at constant rates. Before each experimental run, we built a sufficiently long river profile inside the flume, to model the initial over-extended alluvial river ($L >> L_{crt}$). The initial river lengths were different by runs (L_0, ranging from 120–350 cm) and were set to be within a range of 0.139–0.158 (α). The hinterland slope was set as a constant value of 0.612 (γ). In each run, there occurred non-deltaic transgression as soon as base level started to rise.

©2019. Japan Geoscience Union. All Right Reserved.

Any of the resulting profiles of non-deltaic transgression shows a concave-upward geometry. The downstream end of the profile was tangent to the initial river profile (thus $\alpha \sim \Psi$). To the upstream, Ψ gradually increased, and approached a value as large as γ when the alluvial river was sufficiently shortened. The non-deltaic transgressive profiles generated in the experiments match well with the numerical model, implying that equation 3 can account for the non-deltaic transgressive profile in nature.

[H-CG26] Deltas and estuaries: multidisciplinary analyses of complex river-mouth systems

convener:Yoshiki Saito(Estuary Research Center, Shimane University), Guan-Hong Lee(Inha University), David L Dettman(University of Arizona), Kazuaki Hori(Department of Geography, Graduate School of Environmental Studies, Nagoya University)

This session has foci on morphodynamics, material cycling, and sustainability in deltas and estuaries. We invite contributions that advance research on deltas and estuaries as complex river-mouth systems from modern and ancient examples, and that develop integrated frameworks for delta & estuary dynamics modeling on a broad range of temporal and spatial scales: from studies of coastal evolution over the Quaternary to small-scale sediment/material transport processes. We also invite physical processes studies based on field observations, numerical simulation and flume experiments. Finally, the conveners encourage contributions that promote data collection and sharing for both advancing science and local problem solving, that consider policy and governance issues linked to the sustainable development of deltas and estuaries, and that use in-situ and satellite data for modeling and risk assessment.

Deltafront Clinoform of Abandoned Yellow River Delta in Jiangsu Province, China

*LIANGYONG ZHOU[1]

1. Qingdao Institute of Marine Geology China Geological Survey

The abandoned Yellow River delta in Jiangsu province is a major sediment supplier to the South Yellow Sea and East China Sea. In this study, comparison of historical maps, two cores and three seismic profiles were used to examine its deltafront clinoform (nearshore clinoform). The original historical maps and nautical charts since AD 1750s were collected and compared after calibration, showing the accretion of the shoreline before 1855, when the Yellow River shifted to the Bohai Sea. Near Sheyang River mouth, two 20m-long cores onshore (1 m above present sea level) and offshore (6 m bellow present sea level) were on a line normal to the shoreline. Samples og both cores were dated using AMS ^{14}C and OSL(Optical Stimulated Luminescence) dating technologies. Ages in bottoms of the cores are 43000 to 44000 cal yr BP. At approximate 17.5m bellow present sea level in both cores, yellow and younger (younger than 5000 yr BP) silt sediment occurs. Several young ages in upper part of two cores were obtained, and these show a clear clinoform pattern. Furthermore, seismic profiles across the offshore core show the deltafront clinoform. The upper part weak reflector or transparent part in seismic profiles become thinner seaward and the lower part is strong reflectors. Sea bottom nearshore show a convex shape, but the seaward low gradient part show erosional gullies. The evolution of the deltafront clinoform was revealed in profiles and in plan view.

Holocene evolution and Anthropocene destruction of the Krishna delta, east coast of India: delta lobe shifts, human impact, and sea-level history

Kakani Nageswara Rao[2], *Yoshiki Saito[1], K.Ch.V. Nagakumar[4], Sumiko Kubo[3], Shilpa Pandey[5], Zhen Li[6], G. Demudu[2], A.S. Rajawat[7]

1. Estuary Research Center, Shimane University, 2. Andhra University, 3. Waseda University, 4. Centre for Water Resources and Management, 5. Birbal Sahni Institute of Palaeosciences, 6. University of Victoria, 7. Space Applications Centre

Holocene evolution of the Krishna delta was inferred using landform characteristics and 11 sediment cores with 59 Accelerator Mass Spectrometry ^{14}C dates. Landform assemblage in 5880 km^2area of the Krishna delta indicated the upper river-built fluvial plain and the lower marine-built beach-ridge delta plain with the maximum landwardbeach ridge located at˜30 km from the shoreline separating the two plains. Sedimentary facies and their ages showed the Holocene marine sediment overlying the Pleistocene basement and progressively thickened seaward from <10 m to 25 m below the present sea level. The basal mangrove peat layers indicated that the sea level rose from −9 m to −3 m during 8.3–6.3 cal ky BP before stabilizing at the present level around 5 cal ky BP.
Considering the spatiotemporal variations of sediment facies and sediment accumulation rates and the configuration of the palaeo beach ridges (former shorelines), we surmised five major stages in the growth of 3539 km^2area of the Krishna delta beach-ridge plain during the last 6 cal ky BP with distinct lateral and seaward migration of delta lobes (depocentre shifts). Delta progradation was accelerated in the last 500 years, forming an out-building lobate delta. However, predominant erosion along the sediment-starved Krishna delta front coast during the past 50 years, due to impoundment of the riverine inputs at the burgeoning upstream dams pushed the Krishna delta into a persistent a destruction phase after ˜6,000 years of delta progradation.

Offset in radiocarbon ages between marine bioclast and terrestrial plant pairs in the Holocene sediments around Japan

*Nakanishi Toshimichi[1,2], Futoshi Nanayama[3,4], Atsushi Urabe[5], Kazuaki Hori[6], Wan Hong[7]

1. Kyoto Univ., 2. JAEA, 3. AIST, 4. Kumamoto Univ., 5. Niigata Univ., 6. Nagoya Univ., 7. KIGAM

To identify chronological and spatial changes in the radiocarbon (^{14}C) marine reservoir effects, the ^{14}C ages of eight pairs of marine bioclasts and terrestrial plants were measured from the same horizons of one core of Holocene sediments around Japan (Nakanishi et al. 2013, 2015, 2017abc). The reservoir ages ranged from 60 to 1100 years, scattered over the period 100-10,200 cal BP, which were significantly larger than the values from “prebomb” samples of known age, before AD 1955 in this area. These results indicate that the information on reservoir effects is indispensable for chronological control not only from prebomb samples but also from geological and archaeological samples. Moreover, the effects also reflects the influence of complex river-mouth systems such as deltas and estuaries. To determine the direct chronological changes of the marine reservoir effect between the Kuroshio and Tsushima Currents, radiocarbon ages from pairs of marine bioclasts and terrestrial plants were measured from the same stratigraphic horizons within three cores of Holocene sediments beneath the Sukumo Plain, Miyazaki Plain, and Oki Islands, in west Japan. Subsequently, the results were compared with values from the Oita Plain and Hakata Bay on the northern coast of Kyushu (Nakanishi et al. 2017ac), as well as the Korean Peninsula (Nakanishi et al. 2013, 2015, 2017b). The study was partially funded by the Japan Society for the Promotion of Science Kakenhi grant number 18H01310.

Assessment of MEIS for Marine Spatial Planning in the Nakdong River Estuary, Busan Metropolitan City, South Korea

*Jun-Ho Lee[1], Han Jun Woo[1], Hoi-Soo Jung[1], Chan Mi Park[1]

1. Korea Institute of Ocean Science and Technology

The Nakdong River has a length of nearly 510 km, with a drainage basin of around 23,400 km^2 in South Korea. The Nakdong River Estuary (NRE) in Busan city is a typical example of an estuary in which the throughput is manipulated artificially. The Noksan barrage, built in 1934, blocks the flow of the West Nakdong River, and the NRE barrage was completed between 1983 and 1987 to regulate the flow of the East Nakdong River. With the construction of several huge industrial complexes on reclaimed land near the NRE barrage in the last 65 years, the hydraulic circulation in the NRE has undergone dramatic changes in river discharge and geomorphic configuration, such as the formation of a series of barrier islands. In this study, marine environmental information system (MEIS) data collected after May 2015 were applied to support marine spatial planning (MSP) in the brackish water zone of NRE. The MEIS data in NRE consists of landscape classification of sub-environments, surface sediment distributions, characteristics of suspended sediment, short-term sedimentation, stratification index analysis in channels, closed circuit television (CCTV) using 4G long term evolution (LTE), automatic weather stations (AWS) in real time, calculated residual flow (R_f), net suspended sediment loads (Q_S), and net suspended sediment flux (F_S) in main stream inlet using mooring station, *etc*. The NRE could be divided into areas continuously managed by government, marine protected areas, areas for the development of marine attractions, areas conserved for research education, and coastal areas subject to safety management, e*tc*. For MSP, it was possible to use comparative data of the characteristics of environmental changes in the estuarine watershed to prepare the NRE for the partial opening or drainage extension in 2019 to 2021. This study aims to discuss how to predict environmental change after partial or full opening in NRE barrage and use ecological-based environmental maps in the process of MSP. The development of marine spatial planning mapping in NRE is much necessary for the nation at a time when the diversity of marine use and the demand for policies regarding marine space rapidly increase.

A governing equation of non-deltaic transgressive profile: 2D numerical simulation and flume experiments

*Junhui Wang[1,2,3], Tetsuji Muto[3]

1. China University of Petroleum (Beijing), 2. State Key Laboratory of Petroleum Resources and Prospecting, China, 3. Nagasaki University

An alluvial river subject to relative sea level rise has a critical length (L_{crt}), beyond which the river can no longer sustain deltaic sedimentation but behaves to develop an estuarine environment. In such cases, there occurs non-deltaic rapid transgression. It is not difficult to imagine that non-deltaic transgression is pervasive in geological records, since most of the world large rivers would have “over-extended” to as far as the shelf edges during glacial or lowstand sea level periods. The configuration of non-deltaic transgressive profiles deserves a study because (1) it would provide a criterion for identifying non-deltaic transgression in the past and thus the fact of over-extension of the feeder alluvial river, and (2) it would constrain arguments on sediment transportation to the deep-water depositional systems.

Suppose that a river has an over-extended alluvial length of L ($>>L_{crt}$). During non-deltaic transgression, all the sediment fed by the river is consumed for alluvial aggradation and thus allocated in the subaerial realm. On the assumption that the supplied sediment is evenly distributed along the river profile which is approximately regarded as linear and has an averaged slope of α, the local transgressive slope Ψcan be expressed as:

$$\Psi = \alpha L / [L - \Lambda_{2D}(1+\alpha^2)^{0.5}] \quad (1)$$

We set an x–z coordinate system (x: basinward horizontal, z: vertical) that originates from the intersection of the initial horizontal line and the hinterland profile. Let x to be positive downstream and z to be positive upward. Equation 1 can be rewritten as:

$$\Psi_{x,z} = \alpha(\gamma x+z) / [(\gamma x+z) - \Lambda_{2D}(\gamma - \alpha)] \quad (2)$$

where $\gamma$is the averaged hinterland slope.

Equation 2 can be regarded as the derivative function of the governing equation of the non-deltaic transgressive profile, which can be expressed as:

$$\partial \eta_{x,z} / \partial x = \alpha(\gamma x+z) / [(\gamma x+z) - \Lambda_{2D}(\gamma - \alpha)] \quad (3)$$

where $\eta_{x,z}$ denotes the non-deltaic transgressive profile expressed as the pathway of shoreline. Note that sediment compaction is not considered.

Equation 3 can hardly be solved analytically but by numerical simulation. The solutions that we have obtained indicate that $\eta_{x,z}$ takes a concave-upward geometry with upstream-increasing gradient.

To test our numerical model, a series of 2D physical experiments was performed at Nagasaki University. The experiments were conducted using a 4 m-long and 2.0 cm-wide, open flume, from the upstream end of which sediment and water were fed at constant rates. Before each experimental run, we built a sufficiently long river profile inside the flume, to model the initial over-extended alluvial river ($L >> L_{crt}$). The initial river lengths were different by runs (L_0, ranging from 120–350 cm) and were set to be within a range of 0.139–0.158 (α). The hinterland slope was set as a constant value of 0.612 (γ). In each run, there occurred non-deltaic transgression as soon as base level started to rise.

©2019. Japan Geoscience Union. All Right Reserved.

Any of the resulting profiles of non-deltaic transgression shows a concave-upward geometry. The downstream end of the profile was tangent to the initial river profile (thus $\alpha \sim \Psi$). To the upstream, Ψ gradually increased, and approached a value as large as γ when the alluvial river was sufficiently shortened. The non-deltaic transgressive profiles generated in the experiments match well with the numerical model, implying that equation 3 can account for the non-deltaic transgressive profile in nature.

[H-CG27] Turbidity current: from triggers for the generation to the depositional and morphologic al processes

convener:Miwa Yokokawa(Osaka Institute of Technology), Hajime Naruse(Department of Geology and Mineralogy, Graduate School of Science, Kyoto University), Norihiro Izumi(Faculty of Engineering, Hokkaido University), Ken Ikehara(Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology), Chairperson:Miwa Yokokawa(Osaka Institute of Technology), Norihiro Izumi(Hokkaido University)

Recent developments of field observation, physical and numerical experiments, and mathematical analysis have brought us a better understanding of the dynamics of turbidity currents and relevant morphology and bedforms. Applying new findings to rock records, more profound understanding of turbidites have been achieved. It has been found that different triggers and/or sources generate distinctive features of turbidity currents, resulting in various appearances of rock records and morphology. The integration of such new knowledge on turbidity currents is important not only from scientific but also practical points of view, such as assessments of natural hazards, and exploration of resources. This international session welcomes all kinds of approaches for the turbidity currents such as field observation, physical and numerical experiments, mathematical analysis, and studies from rock records.

Inverse analysis of turbidity currents using two dimensional shallow water model

*Hajime Naruse[1]

1. Department of Geology and Mineralogy, Graduate School of Science, Kyoto University

Quantitative reconstruction of flow properties from turbidites is a long-standing problem in deep-sea sedimentology. If this is realized, magnitudes of past hazardous events may be estimated from geologic records containing seismo-(tsunami-)generated turbidites. Also, entire geometry of turbidite reservoir can be inferred by flow reconstruction. Thus, inverse analysis of turbidity currents contributes to disaster-risk assessment, and is of economic importance. Here we propose a new methodology to reconstruct flow properties of turbidity currents from three-dimensional geometry of deposits. In this method, a two-dimensional shallow-water model of turbidity currents was employed as the forward model. Numerical simulation was repeated to obtain horizontal distribution of thickness of turbidites under various initial conditions, and then this synthetic data set was used for supervised training of a deep-learning neural network (DNN). After the training phase finished, DNN properly estimated initial conditions of turbidity currents (e.g. initial flow height, velocity, etc.) from artificial test data set that was also produced from the forward model. To summarize, the machine learning produced the inverse model of turbidity currents that can estimate paleo-hydraulic conditions from synthetic or ancient turbidites. In previous methods, the computational cost of two dimensional model was too high to be employed as the forward model for turbidite inversion. On the other hand, our methodology can reconstruct initial conditions of turbidity currents instantaneously. Although production of the training data set requires 1000s times repetition of calculation, the problem of calculation efficiency can be easily solved by using PC cluster. In future study, it is expected to apply the new methodology to actual turbidites measured in 3D seismic profiles or by high-resolution sampling on modern sea floor.

Inverse Analysis of Experimental Scale Turbidity Currents by Deep Learning Neural Network

*Cai Zhirong[1], Hajime Naruse[1], Qifeng Yao[1]

1. Kyoto University

In this study, inverse analysis of turbidite deposited in flume experiments will be performed using a new machine learning method. The results of inverse analysis will serve to verify the accuracy of the machine learning method.

Understanding of the hydraulic conditions of turbidity current remains limited due to its destructive nature and its unpredictable occurrences. Thus, the inverse analysis of turbidity currents from ancient deposits of submarine fans is required for estimating the conditions of flows in the natural environments.

In the past, inverse modeling of turbidity currents was done in a trial and error fashion by adjusting initial conditions of numerical models, which is high in calculation load, making such technique very expensive and highly impractical. Naruse (2017 AGU Fall Meeting) developed a completely new method for inverse analysis of turbidity currents using a deep learning neural network. In this method, training data is generated by a numerical model, and a neural network for reconstructing hydraulic conditions of turbidity currents from turbidite is produced by machine learning of the training dataset. However, the validity of this new inverse model has not yet been tested in actual deposits. Therefore, this study aims to verify the method by flume experiments.

Currently, the initial conditions of a dataset produced by a flume experiment sized forward model program is used to test the applicability of the neural network method when applied to flume experiment size data. Three thousand sets of training data were fed into the neural network as training data. Another two hundred separate cases were used as test data to verify the accuracy of prediction by the neural network. The result shows initial flow velocity can be predicted relatively accurately. The initial concentrations of the finer grain size class and the initial flow height was partially reconstructed. The flow duration, the coarser grain size classes and the slopes within the flume could not be predicted. After tuning of the neural network and the forward model, the neural network trained for flume sized data will be applied to flume experiment results.

Conditions for development of depositional submarine channels: examination by flume experiments

*Justine Poppeschi[1], Kazushi Nakata[1], Hajime Naruse[1]

1. Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University

Although submarine channels are ubiquitously observed in various submarine fans, it is also known that submarine fans lacking continuous leveed channels are common depending on regions. However, the governing parameters to determine this diversity in developments of leveed channels has not been clarified yet. This is because there has been no previous researches that successfully reproduced depositional leveed channel topography in experimental flumes. Therefore, the formative conditions of depositional submarine channels have not been clarified yet. Here, we conducted flume experiments, aiming to reproduce depositional submarine channels for understanding their formative conditions. As a result, we succeeded to form experimental topography that resemble natural depositional submarine channels showing a ceiling river structure with levees in all five experiments. Comparing the experimental topography with the actual submarine fans, the relative depth of the experimental channel was slightly shallow, but features such as the spatial variation of the channel width showed similar trends to those of the actual submarine channels. Thus, we imply that purely depositional submarine channels can be formed without presence of precursor of erosive features. Furthermore, experimental conditions of this study were in the region where the previous study predicted that submarine channels cannot be formed, suggesting that further investigation is needed to discover the governing parameters for developments of submarine leveed channels.

Cyclic steps formed by long-runout turbidity currents

*Zhuyuan Wu[1], Norihiro Izumi [1]

1. Hokkaido University

It has been found that a variety of submarine morphology such as submarine fans, submarine rivers, and submarine canyons, has been formed by turbidity currents which travel relatively long distance (long-run out turbidity currents). The long-run out turbidity currents have a number of features similar to open channel flow. They have an equilibrium (or quasi-equilibrium at least) state, and are accompanied by hydraulic jumps when they transition from supercritical to subcritical flow regimes. In this research, with the use of the assumption that an equilibrium state can be achieved in the high-concentrated lower layer near the bottom of long-run out turbidity currents, we propose an analytical model with the use of the layer-averaged governing equations, which reproduces cyclic steps with relatively long wavelengths accompanied by periodic internal hydraulic jumps.

Integrating the Reynolds-averaged Navier-Stokes equations and continuity equation over the high concentrated lower layer, we obtain the boundary layer approximated (layer-averaged) momentum and continuity equations. In the integration, it is possible to simplify the governing equations by ignoring the entertainment from the top of the high concentrated lower layer with the assumption that the Reynolds stress becomes almost zero and the shear stress almost vanishes there. In addition to the momentum equations and continuity equation, we employ the diffusion/dispersion equation of suspended sediment, and the continuity equation of sediment (Exner equation).

The unknown variables in the problem are four: the velocity, the layer thickness, the layer-averaged suspended sediment concentration, and the bed elevation. The governing equations are the layer-averaged momentum and continuity equations, the layer-averaged diffusion/dispersion equation of suspended sediment, and the continuity equation of sediment (Exner equation). The boundary conditions for this problem are that the momentum has to be continuous before and after each hydraulic jump. More specifically, the velocity and the layer thickness have to satisfy the jump condition before and after each jump. In addition, the suspended sediment concentration has to be continuous at the jump.

We solve the problem numerically, and obtain the wavelengths of steps. The wavelength of a long-run out turbidity current is determined by the thickness of the high-concentration layer near the bottom. It is shown that the wavelengths obtained in the analysis agree relatively well with the observation.

Is surface sediment remobilization more popular mechanism for generating earthquake-induced turbidity current? Evidence of radiocarbon dates from the westernmost Nankai and Japan Trench subduction zones

*Ken Ikehara[1], Toshiya Kanamatsu[3], Tobias Schwestermann[2], Arata Kioka[2], Michael Strasser[2]

1. Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology, 2. Universität Innsbruck, 3. Japan Agency for Marine-Earth Science and Technology

Deep-sea turbidite has been used for reconstructing past large earthquake history. Surface sediment remobilization is a relatively new idea for generating earthquake-induced turbidite, although submarine landslide has been considered as major mechanism for earthquake-induced turbidite deposition. Surface sediment remobilization has been reported from the Chilean lakes, forearc slopes along the Nankai and Japan Trench subduction zones. However, the detailed mechanism of surface sediment resuspension, remobilization and initiation of turbidity current is still unknown. For better understanding of the mechanism, it is important to understand the spatio-temporal occurrence of surface sediment remobilization. We obtained some cores from a small basin on the forearc slope in Hyuga-nada off Kyushu, and the Japan Trench floor. Fine-grained turbidites were found in the cores. Paired radiocarbon dates of the turbidite muds and hemipelagic muds between the turbidites show only small age differences. This indicates that it is unnecessary to occur bathymetry-scale (with >several meters bathymetric change) submarine landslides by earthquake ground shaking for generation of the turbidites. Large surface sediment resuspension by earthquake ground shaking at the sedimented slope near the depositional area (basin) is thought to be an important process for repeated deposition of earthquake-induced turbidites in the basin.

Shallow-subsurface event stratigraphy along the hadal trench axis of the Japan Trench

*A. Kioka[1], T. Schwestermann[1], J. Moernaut[1], K. Ikehara[2], T. Kanamatsu[3], M. Strasser[1,4]

1. Universität Innsbruck, Austria, 2. GSJ-AIST, Japan, 3. JAMSTEC, Japan, 4. MARUM-U. Bremen, Germany

The giant AD 2011 Tohoku-oki earthquake has been documented to remobilize a wide area of surface sediment, redistributing from the slope into the >7 km deep Japan Trench forming distinct event deposits in hadal terminal basins (Ikehara et al., 2016; Kioka et al., 2019). Other than the 2011 earthquake, similarly large earthquakes are historically known along the Japan Trench, and respective deposits have been described in recent studies from cores retrieved from the Japan Trench (Ikehara et al., 2016). Yet, little is understood about (i) the temporal and spatial distribution of event deposits along the entire trench axis, (ii) how the spatial extent may link to the rupture area of historically-reported earthquakes, and (iii) whether older deposits may indicate prehistoric large earthquakes along the Japan Trench. We herein study dm-scale vertical resolution subbottom profiler data acquired during 2012–2018 using PARASOUND and TOPAS recording systems installed on R/Vs Sonne and Shinsei-Maru over the entire Japan Trench area (36.0˚–40.5˚N), in order to investigate the event-stratigraphic distribution of acoustically-transparent layers that represent sediment remobilization event deposits. The subbottom profiler data generally record well up to ~40 m below the seafloor. Transparent bodies of the upper ~10 m correlate well to event layers reported from sediment cores linked to major historic earthquake such as the AD 2011 Tohoku-oki, AD 1454 Kyotoku, and AD 869 Jogan events. Mapping of these event deposits in the spatially-extensive subbottom profiler data allows to study the spatial distribution of these events and its comparison to their reconstructed rupture areas. Furthermore, the lower part of the hitherto only acoustically-imaged stratigraphic succession of isolated trench-floor basins along the Japan Trench also documents several thick acoustically-transparent bodies. Preliminary interpretation suggests several of the bodies could be event deposits triggered by old large earthquakes. While ground-truth of this interpretation and absolute dating requires long coring efforts in the ultra-deep Japan Trench, our study yields relative stratigraphic information and quantitative constraints of along strike variation of sediment volumes redistributed by episodic events along the Tohoku seismogenic margin.

Based on repeat seafloor measurements and samples we show that the M_w 7.8 November 2016 Kaikōura earthquake (New Zealand) triggered widespread landslides in a large-scale bedrock submarine canyon. These landslides initiated a powerful “canyon-flushing” event and turbidity current that travelled > 680 km along one of the world’s longest deep-sea channels, the Hikurangi Channel. To our knowledge these observations provide the first direct quantification of seafloor landscape change and large-scale sediment transport associated with an earthquake-triggered full canyon flushing event. Our results augment observations from smaller scale turbidites confined to large submarine canyons (e.g. repeat surveying in Monterey Canyon) that move stored material within canyons but do not export sediment to the deep ocean or erode into underlying substrate. The inter-event period for the Kaikōura Canyon flushing event, calculated from back analysis of triggering strong ground motion, is ~140 years. Combined with observed erosion into bedrock this indicates a canyon incision rate of 40 mm y^{-1}, substantially higher than most terrestrial rivers. Significant geomorphic change occurred within the canyon including erosion up to 60m depth in the upper canyon, scour hole formation, and down canyon movement of mega-scale bedforms constructed of gravel-boulder sized sediments. The event synchronously transferred 850 Mt of sediment and 7 Mt organic carbon to the deep ocean. Our observations demonstrate that earthquake-triggered canyon flushing is a primary driver of submarine canyon development and material transfer from active continental margins to the deep ocean.

Far More Prolonged Deep-sea Turbidity Currents triggered by typhoon and earthquake in the Gaoping Submarine Canyon

*Yanwei Zhang[1], Zhifei Liu[1], Yulong Zhao[1], Xiaodong Zhang[1]

1. Tongji University

Submarine turbidity currents are argued to deliver more sediment along their long-runout propagation than other dynamic processes from shelf to deep sea. The *in situ* temporal and spatial features of turbidity currents are urgently required for a better quantitative constraints on sediment transport and deposition in the deep sea. Here, we document yearlong direct monitoring of turbidity currents in the middle reach at a water depth of 1265 m and the lower reach at 2425 m on the margin of the Gaoping Submarine Canyon off Taiwan, which has the wettest typhoons and active earthquakes. Both the two moorings (~35 km apart) were equipped with sediment traps and various sensors to collect particles consecutively with 18 days interval and to record velocity, sediment concentration, temperature and salinity with 20 min interval. Seven turbidity currents are identified consistently at these two reaches with enhanced sediment flux, which was recorded by a time-series sediment trap at 30 m above the seafloor. By combining the atmospheric measurements and earthquake data, four turbidity currents are triggered by the four powerful typhoons crossed Taiwan during typhoon season in boreal summer 2015, and one event is attributed to the M_L 6.5 Kaohsiung earthquake in southern Taiwan in February 2016. The two types of turbidity currents associated with individual typhoon and earthquake show a sustained duration ranging from 9 to 41 days, far more prolonged than the longest documented deep-sea turbidity currents (~10 days) in other locations. The flow velocity observed on the margin (~0.2 m/s) is much weaker than that in the thalweg of the canyon (> 5.8 m/s) inferred from the break of cables. For the first time, our observation provides the variability of the timing and hydrographic properties of the turbidity currents triggered by individual mechanisms for better constraints on flow capacity and sediment redistribution.

Filling the gap between turbidity current processes and products in British Columbia fjords

*Sophie Hage[1,2,3]

1. School of Ocean and Earth Sciences, University of Southampton, United Kingdom, 2. National Oceanography Centre Southampton, United Kingdom, 3. Department of Geography, Durham University, United Kingdom

Turbidity currents are one of the volumetrically most important processes to transfer sediments from land to sea. Fast-moving, powerful turbidity currents can damage seafloor infrastructure and carve submarine channels. These submarine channels feed deep sea fans, which are the largest sediment accumulations on Earth. Such huge sediment accumulations sequester organic carbon over geologic timescales and are thus thought to play a role in the global carbon cycle. Despite the global significance of turbidity currents, the link between flow processes (e.g. triggering mechanisms, seafloor erosion) and depositional products is still poorly constrained. This lack of knowledge is mainly due to the difficulty to monitor flows and to directly sample the associated deposits to these flows. Here we present direct observations of turbidity currents and their deposits in two Canadian fjords: Howe Sound and Bute Inlet in British Columbia. As these two fjords are connected at their head to glacier-fed rivers, they are excellent sites to study the transport and fate of particles from land to submarine sites. Using these new observations, this talk will cover three research themes: 1) How do dilute river plumes generate turbidity currents? 2) What is the depositional architecture/facies resulting from supercritical turbidity currents and crescentic bedforms? 3) How are organic carbon mixtures distributed in turbidites and what are the implications for the carbon cycle?

Sediment transfer from shelf to abyss through giant ganyons and valleys system in deep-sea carbonate slopes (Bahamas)

*Thierry Mulder[1], Hervé Gillet[1], Vincent Hanquiez[1], Audrey Recouvreur[1], Kelly Fauquembergue[1], Johan Le Goff[2], John J.G. Reijmer[2], Emmanuelle Ducassou[1], Margot Joumes, Thibault Cavailhes[1], Elsa Tournadour[5], Jean Borgomano[3], Emmanuelle Poli[4]

Bahamas are one of the rare present-day study areas in the world that allows to understand carbonate particle transfer from platform to deep-sea. A lot of ancient (DSDP/ODP, Bacar cruises) and recent (Carambar Cruises) dataset have been collected from 30 m to 5,000 m water depth. It includes high-resolution multibeam mapping, backscatter imaging, very-high resolution seismics and gravity cores. These new high-resolution data expose in great details the deep-water sedimentary system in the southern part of Exuma Sound (ES) and the northern part of Little Bahama Bank (LBB, Bahamas). The data reveal the detailed and complex morphology of giant valleys like the Great and Little Abaco canyons (GAC and LAC) along the LBB slope, the Great Bahama Canyon between LBB and Eleuthera Island, being the deepest canyon in the world, and the Exuma Valley/Canyon in the ES area. In all cases, present-day off-bank transport is initiated by two ways: (1) When a cold atmospheric front occurs, high-density, cold surface water sinks and entrains fine-grained particles through density cascading. This process is at the origin of the deposition of the Holocene Prograding Wedge that began to form 13.6 ka ago with a maximum growing at 4 ka when the platform was flooded. (2) During hurricanes when the fine-grained particles deposited on the shelf are resuspended and pushed off the platform through tidal passes. There, acceleration of tidal currents generates tidal flushing. On the LBB smooth slopes, coarse-grained particles (ooids and bioclasts) are trapped in tidal deltas and only fine-grained carbonate particles reach the upper slope. In Exuma area, steeper slopes allow transfer of coarse-grained particles that reach the ES slope and finally supply coarse-grained (bioclasts-rich) turbidity currents and concentrated/hyperconcentrated flows that are channeled down to the Atlantic Abyssal Plain though giant valleys. Along the valley, they form classical spill-over levee deposits. Four of these large valleys extending parallel to the shelf are presented. They all probably extend along structural directions. In GAC, finely-grained sediments originate essentially from the canyon flanks, driven by sediment slides as well as many secondary slope gullies and smaller tributaries. In LAC, gullies directly drain the upper LBB slope providing coarser particles. In the Exuma Valley/Canyon, a part of the material comes from the slope of adjacent islands and cays through small-scale gravity processes and mass failures. A substantial part of the sediments also originate from along-slope sediment flow erosion. In all areas, the valleys abruptly turn into deep canyons incising the Bahama Escarpment (BE). The canyons link the LBB and ES sedimentary systems to the deep abyssal plain of the Western North Atlantic where water depth exceeds 5,000 m. The transition occurs through major knickpoints with outsized chutes exceeding several hundred of meters in height. The sudden transformation from a wide valley to a deep narrow canyon occurs as a result of flow erosion of the underlying lower Cretaceous carbonate platform stack. Huge hydraulic jumps as well as enormous and permanent plunge pools and related deposits were identified at the transition. Dissolution processes in the carbonate deposits may also play a part in the formation of theses outsized plunge pools. In ES, the high kinetic flow energy constrained by narrow and deeply incised canyon formed a wide fan-shaped channel-levee complex on the abyssal plain. The latter is made up of coarse-grained carbonate turbidites and concentrated density-flow deposits that are mixed with fine-grained siliciclastics transported along

©2019. Japan Geoscience Union. All Right Reserved.

the BE by the energetic Western Boundary Undercurrent. Conversely the canyon mouth of the LBB system only reveals a small channeled lobe. Seismic data on this system at water depth > 4500 show the distalmost deposits are younger than mid-Miocene, suggesting that the activity of the canyon is very recent.

The Haupinghsu Canyon (also known as the Mienhua Canyon) is a multi-head submarine canyon which indents the shelf in the southwestern part of the East China Sea. Using seismic reflection sections and bathymetric mapping, we reveal erosive sedimentary processes responsible for entrenched thalweg and sediment dispersal of the canyon that are closely related to turbidity currents in the canyon during the late Pleistocene. The canyon system consists of three distinct units: (1) tributary canyon heads which cut into the shelf, (2) wide trough cut by entrenched thalweg, and (3) narrow V-shaped canyon with steep walls on the slope.

The Haupinghsu Canyon head incises into the shelf for a relatively long distance of about 100 km. During the last lowstand of the East China Shelf the canyon head was located in an area with sediment supply close to the paleo-river mouths. The second segment of the upper reach is dominated by a deeply incised canyon pathway with trough-like morphology. Canyon morphology is interpreted as a result of erosive sediment flows along the entrenched thalweg that caused downcutting into the canyon floor. We infer that erosive flows in the canyon resulted from hyperpycnal currents at the river mouths during periods of lowstand sea level. Moreover, sediment-gravity flows may be generated from the collapse of V-shaped canyon walls that may be over-steepened by tectonic deformation.
