Tue. May 28, 2019

[J] Oral | U (Union)：Union

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 101 1F

[U-03] Future of Scientific Publishing in Geosciences

convener:Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Hirokuni Oda(Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Chairperson:Hirokuni Oda, Hodaka Kawahata

9:00 AM - 9:30 AM JST | 12:00 AM - 12:30 AM UTC

[U03-01] Game-change of scholarly communication based on papers and the role of learned society and peer-review

★Invited Papers

*Kazuhiro Hayashi[1] (1.National Institute of Science and Technology Policy)

9:30 AM - 10:00 AM JST | 12:30 AM - 1:00 AM UTC

[U03-02] The future of the journal metrics and new trend of the scholarly publishing

★Invited Papers

*Yoshiko Tanahashi[1] (1.Clarivate Analytics)

10:00 AM - 10:30 AM JST | 1:00 AM - 1:30 AM UTC

[U03-03] Underlying Issues and Problems in Publishing International Scientific Journals in Japan. “DNA Research” As A Case Study.

★Invited Papers

*Michio Oishi[1] (1.Kazusa DNA Research Institute)

[J] Oral | U (Union)：Union

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 101 1F

[U-03] Future of Scientific Publishing in Geosciences

convener:Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Hirokuni Oda(Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Chairperson:Hirokuni Oda, Hodaka Kawahata

10:45 AM - 11:05 AM JST | 1:45 AM - 2:05 AM UTC

[U03-04] Review of editorial work for PEPS in 2018-2019 and new strategy for 2019–2020

★Invited Papers

*Yasufumi Iryu[1] (1.Institute of Geology and Paleontology Graduate School of Science Tohoku University)

11:05 AM - 11:25 AM JST | 2:05 AM - 2:25 AM UTC

[U03-05] "Earth, Planets and Space" An Open Access Journal: Past, Present and and Future

★Invited Papers

*Yasuo Ogawa[1], Kiyoshi Baba[2] (1.Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology, 2.Earthquake Research Institute, University of Tokyo)

11:25 AM - 11:55 AM JST | 2:25 AM - 2:55 AM UTC

[U03-06] Scientific Research Output and Publication: research article, data, and digital transformation

★Invited Papers

*Yasuhiro Murayama[1] (1.Strategic Program Produce Office, National Institute of Information and Communications Technology)

11:55 AM - 12:15 PM JST | 2:55 AM - 3:15 AM UTC

[U03-07] **Enhancing dissemination of research activities to international communities by Japanese Geoscience Union**

★Invited Papers

*Hodaka Kawahata[1] (1.Atmosphere Ocean Research Institute, the University of Tokyo)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University), Chairperson:Kunio Sayanagi(Hampton University), Takeshi Kuroda

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PPS01-06] Radiative transfer simulation including a non-LTE model for terahertz observations of Ganymede's atmosphere

*Takayoshi Yamada[1], Ladislav Rezac[2], Richard Larsson[2], Paul Hartogh[2], Naohiro Yoshida[3], Yasuko Kasai[1,3] (1.National Institute of Information and Communications Technology, 2.Max Planck Institute for Solar System Research, 3.Tokyo Institute of Technology)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PPS01-07] Vertical Mass Flux by the 2010-2011 Great Storm of Saturn

*Kunio M. Sayanagi[1], Jacob L. Gunnarson[1], John J. Blalock[1], Richard K. Achterberg[2], F. Michael Flasar[2], Andrew P. Ingersoll.[3], Shawn P. Ewald[3], Ulyana A. Dyudina[3] (1.Hampton University, 2.NASA Goddard Space Flight Center, 3.California Institute of Technology)

9:30 AM - 9:48 AM JST | 12:30 AM - 12:48 AM UTC

[PPS01-08] Microwave observations of the giant planets - Cassini/Radar and Juno/MWR

★Invited Papers

*Cheng Li[1], Virgil Adumitroaie[2], John Arballo[2], Sushil K Atreya[3], Scott J Bolton[4], Andrew Ingersoll[1], Michael Janssen[2], Steven Levin[2], Jonathan Lunine[5], Glenn Orton[2], Paul Steffes[6], Hunter Waite[4] (1.California Institute of Technology, 2.Jet Propulsion Laboratory, 3.University of Michigan Ann Arbor, 4.Southwest Research Institute, 5.Cornell University, 6.Georgia Institute of Technology)

9:48 AM - 10:06 AM JST | 12:48 AM - 1:06 AM UTC

[PPS01-09] Tracing Formation and Evolution of Outer Solar System Bodies through Stable Isotopes and Noble Gas Abundances

★Invited Papers

*Kathleen Mandt[1] (1.Johns Hopkins University Applied Physics Laboratory)

10:06 AM - 10:24 AM JST | 1:06 AM - 1:24 AM UTC

[PPS01-10] Icy Giant Planet Exploration

★Invited Papers

*Sushil K Atreya[1], Mark D. Hofstadter[2], Amy Simon[3], Kim R. Reh[2], Olivier Mousis[4], Krista Soderlund[5] (1.University of Michigan Ann Arbor, 2.Jet Propulsion Laboratory, 3.Goddard Space Flight Center, 4.Laboratoire d'Astrophysique de Marseille, 5.University of Texas at Austin)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University), Chairperson:Jun Kimura(Osaka University), 鎌田 俊一(北海道大学創成研究機構)

10:45 AM - 11:03 AM JST | 1:45 AM - 2:03 AM UTC

[PPS01-11] Saturn's ring rain and Enceladus' subsurface ocean as seen by the Cassini Cosmic Dust Analyser

★Invited Papers

*Sean Hsu[1], Sascha Kempf[1], Mihaly Horanyi[1], Ralf Srama[2], James O'Donoghue[3] (1.LASP, University of Colorado, Boulder, CO, USA, 2.IRS, University of Stuttgart, Stuttgart, Germany, 3.NASA Goddard Space Flight Center, Greenbelt, Maryland, USA)

11:03 AM - 11:18 AM JST | 2:03 AM - 2:18 AM UTC

[PPS01-12] Titan Trek: A New Online NASA Visualization and Analysis Portal for Saturn’s Largest Moon

*Emily Law[1], Brian Hamilton Day[2] (1.NASA Jet Propulsion Laboratory, 2.NASA Ames Research Center)

11:18 AM - 11:36 AM JST | 2:18 AM - 2:36 AM UTC

[PPS01-13] Internal structure of icy moons: ice-ocean systems as commonly seen in the outer solar system

★Invited Papers

*Hauke Hussmann[1] (1.DLR Institute of Planetary Research)

11:36 AM - 11:51 AM JST | 2:36 AM - 2:51 AM UTC

[PPS01-14] Callisto as a keystone to reproduce the formation process of the Jovian system

*Yasuhito Sekine[1], Shunichi Kamata[2], Yuhiko Aoyama[3], Masahiro Ikoma[3], Takayuki Tanigawa[4] (1.Earth-Life Science Insitute, Tokyo Institute of Technology, 2.Creative Res. Institution, Hokkaido Univerisity, 3.Dept of Earth and Planetary Sci., University of Tokyo, 4.Nat'l Inst. Tech., Ichinoseki Col.)

11:51 AM - 12:09 PM JST | 2:51 AM - 3:09 AM UTC

[PPS01-15] Origin of Jupiter Trojan asteroids: To be explored by OKEANOS

★Invited Papers

*Yoko Kebukawa[1], Tatsuaki Okada[2], Motoo Ito[3], Jun Aoki[4], Yosuke Kawai[4], Jun Matsumoto[2], Noel Grand[5], Arnaud Buch[6], Michisato Toyoda[4], Hervé Cottin[5], Hisayoshi Yurimoto[7,2], Hajime Yano[2], Takahiro Iwata[2], Osamu Mori[2] (1.Yokohama National University, 2.Japan Aerospace Exploration Agency, 3.Kochi Institute for Core Sample Research JAMSTEC, 4.Osaka University, 5.LISA, Université Paris-Est Créteil, 6.Ecole Centrale Paris, 7.Hokkaido University)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University)

[PPS01-P01] Critical Role of Entry Probes in Giant Planet Exploration

*Sushil K Atreya[1], Olivier Mousis[2] (1.University of Michigan Ann Arbor, 2.Laboratoire d'Astrophysique de Marseille)

[PPS01-P02] OKEANOS – Jupiter Trojan Asteroid Rendezvous and Landing Experiments Using a Solar Power Sail

*Tatsuaki Okada[1,2], Takahiro Iwata[1], Yoko Kebukawa[3], Motoo Ito[4], Jun Aoki[5], Yosuke Kawai[5], Shoichiro Yokota[5], Yoshifumi Saito[1], Kentaro Terada[5], Michisato Toyoda[5], Hikaru Yabuta[6], Hisayoshi Yurimoto[1,7], Shuji Matsuura[8], Kohji Tsumura[9], Daisuke Yonetoku[10], Tatehiro Mihara[11], Ayako Matsuoka[1], Reiko Nomura[12], Hajime Yano[1], Takayuki Hirai[13], Atsushi Kumamoto[9], Ryosuke Nakamura[14], Stephan Ulamec[15], Ralf Jaumann[15], Jean-Pierre Bibring[16], Noel Grand[17], Cyril Szopa[18], Ernesto Palomba[19], Jorn Helbert[15], Alain Herique[20], Matthias Grott[15], Hans-Ulrich Auster[21], Goester Klingelhoefer[22], Fumi Yoshida[13], Makoto Yoshikawa[1], Jun Matsumoto[1], Toshihiro Chujo[1], Masanori Matsushita[1], Takanao Saiki[1], Hideki Kato[1], Osamu Mori[1], Junichiro Kawaguchi[1] (1.Japan Aerospace Exploration Agency, 2.University of Tokyo, 3.Yokohama National University, 4.Japan Agency for Marine-Earth Science and Technology, 5.Osaka University, 6.Hiroshima University, 7.Hokkaido University, 8.Kwansei Gakuin University, 9.Tohoku University, 10.Kanazawa University, 11.RIKEN, 12.National Astronomical Observatory of Japan, 13.Chiba Institute of Technology, 14.National Institute of Advanced Industrial Science and Technology, 15.German Aerospace Center, 16.Institut d'Astrophysique Spatiale, 17.LISA, 18.LATMOS, 19.INAF-IAPS, 20.IPAG, 21.TU Braunschweig, 22.Leibniz Universität Hannover)

[PPS01-P03] Magnetic field model of Jovian magnetosphere

*Naoya Momoki[1], Hiroaki TOH[1] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University)

[PPS01-P04] Enhancement of the Jovian thermospheric temperature above the Great Red Spot based on the infrared spectroscopic data obtained with IRTF/iSHELL

*Ayumu Kambara[1], Hajime Kita[2], Takeshi Sakanoi[1], Yasumasa Kasaba[1], Masato Kagitani[1], Haruna Watanabe[1] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PPS01-P05] Pulsation-like variation of Jovian infrared polar emission observed by Subaru 8-m: H3+ and methane emissions

*Yasumasa Kasaba[1], Haruna Watanabe[1], Hajime Kita[2], Chihiro Tao[3], Takeshi Sakanoi[1], Masato Kagitani[1], Orton Glenn[1,4], James Sinclair[4] (1.Planetary Plasma and Atmospheric Research Center, 2.ISAS/JAXA, 3.NICT, 4.NASA/JPL)

[PPS01-P06] Structure of Io plasma torus observed with the Tohoku 60-cm telescope

*Masato Kagitani[1], Fuminori Tsuchiya[1], Kazuo Yoshioka[2], Go Murakami[3], Tomoki Kimura[1], Ryoichi Koga[1], Reina Hikida[4], Takeshi Sakanoi[1] (1.Graduate School of Science, Tohoku University, 2.Graduate School of frontier Science, The University of Tokyo, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4.Department of Earth and Planetary Science, Graduate School of Science, Tokyo University)

[PPS01-P07] Ion Scale Height Variability in Hisaki Io Torus Observations

*Nicholas McCord Schneider[1], Carl Schmidt[2], Masato Kagitani[3], Yasumasa Kasaba[3], Tomoki Kimura[3], Go Murakami[4], Fuminori Tsuchiya[3], Hajime Kita[3], Reina Hikida[5], Ichiro Yoshikawa[5], Kazuo Yoshioka[5] (1.LASP, University of Colorado Boulder, 2.Boston University, 3.Tohoku University, 4.ISAS/JAXA, 5.University of Tokyo)

[PPS01-P08] Size of the Smallest Particles in Saturn's Rings

*Keiji Ohtsuki[1], Hiroshi Kawamura[1], Naoyuki Hirata[1], Hiroshi Daisaka[2], Hiroshi Kimura[3] (1.Graduate School of Science, Kobe University, 2.Graduate School of Commerce and Management, Hitotsubashi University, 3.Planetary Exploration Research Center, Chiba Institute of Technology)

[PPS01-P09] The Radio & Plasma Wave Investigation (RPWI) for JUICE for the investigation of Jupiter and Icy Moons System: Contributions from Japan

*Yasumasa Kasaba[1], Hiroaki Misawa[1], Fuminori Tsuchiya[1], Atsushi Kumamoto[2], Yuto Katoh[2], Tomoki Kimura[2], Hajime Kita[3], J.-E. Wahlund[4] (1.Planetary Plasma and Atmospheric Research Center, Tohoku University, 2.Department of Geophysics, Tohoku University, 3.ISAS/JAXA, 4.IRF Uppsala, Sweden)

[PPS01-P10] Magnetic field experiment at Jupiter icy moons (JUICE J-MAG) and in-flight alignment calibration

*Ayako Matsuoka[1], Michele Karen Dougherty[2], Patrick Brown[2], Futoshi Takahashi[3], Hisayoshi Shimizu[4], Masaki Matsushima[5] (1.Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Imperial College London, 3.Kyushu University, 4.University of Tokyo, 5.Tokyo Institute of Technology)

[PPS01-P11] Science targets of the GAnymede Laser Altimeter (GALA) for the JUICE mission

*Jun Kimura[1], Shunichi Kamata[2], Koji Matsumoto[3], Noriyuki Namiki[3], Keigo Enya[4], Masanori Kobayashi[5], Hiroshi Araki[3], Hirotomo Noda[3], Ko Ishibashi[5], Hauke Hussmann[6], Kay Lingenauber[6] (1.Osaka University, 2.Hokkaido University, 3.National Astronomical Observatory Japan, 4.ISAS/JAXA, 5.Chiba Institute of Technology, 6.German Aerospace Center (DLR), Berlin)

[PPS01-P12] Current status of the antenna developments, the data processing, scientific target for JUICE/SWI JAPAN.

*YASUKO KASAI[1], JUICE SWI Japanese Team (1.National Institute of Information and Communications Technology (NICT))

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University)

[PPS01-P01] Critical Role of Entry Probes in Giant Planet Exploration

*Sushil K Atreya[1], Olivier Mousis[2] (1.University of Michigan Ann Arbor, 2.Laboratoire d'Astrophysique de Marseille)

[PPS01-P02] OKEANOS – Jupiter Trojan Asteroid Rendezvous and Landing Experiments Using a Solar Power Sail

*Tatsuaki Okada[1,2], Takahiro Iwata[1], Yoko Kebukawa[3], Motoo Ito[4], Jun Aoki[5], Yosuke Kawai[5], Shoichiro Yokota[5], Yoshifumi Saito[1], Kentaro Terada[5], Michisato Toyoda[5], Hikaru Yabuta[6], Hisayoshi Yurimoto[1,7], Shuji Matsuura[8], Kohji Tsumura[9], Daisuke Yonetoku[10], Tatehiro Mihara[11], Ayako Matsuoka[1], Reiko Nomura[12], Hajime Yano[1], Takayuki Hirai[13], Atsushi Kumamoto[9], Ryosuke Nakamura[14], Stephan Ulamec[15], Ralf Jaumann[15], Jean-Pierre Bibring[16], Noel Grand[17], Cyril Szopa[18], Ernesto Palomba[19], Jorn Helbert[15], Alain Herique[20], Matthias Grott[15], Hans-Ulrich Auster[21], Goester Klingelhoefer[22], Fumi Yoshida[13], Makoto Yoshikawa[1], Jun Matsumoto[1], Toshihiro Chujo[1], Masanori Matsushita[1], Takanao Saiki[1], Hideki Kato[1], Osamu Mori[1], Junichiro Kawaguchi[1] (1.Japan Aerospace Exploration Agency, 2.University of Tokyo, 3.Yokohama National University, 4.Japan Agency for Marine-Earth Science and Technology, 5.Osaka University, 6.Hiroshima University, 7.Hokkaido University, 8.Kwansei Gakuin University, 9.Tohoku University, 10.Kanazawa University, 11.RIKEN, 12.National Astronomical Observatory of Japan, 13.Chiba Institute of Technology, 14.National Institute of Advanced Industrial Science and Technology, 15.German Aerospace Center, 16.Institut d'Astrophysique Spatiale, 17.LISA, 18.LATMOS, 19.INAF-IAPS, 20.IPAG, 21.TU Braunschweig, 22.Leibniz Universität Hannover)

[PPS01-P03] Magnetic field model of Jovian magnetosphere

*Naoya Momoki[1], Hiroaki TOH[1] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University)

[PPS01-P04] Enhancement of the Jovian thermospheric temperature above the Great Red Spot based on the infrared spectroscopic data obtained with IRTF/iSHELL

*Ayumu Kambara[1], Hajime Kita[2], Takeshi Sakanoi[1], Yasumasa Kasaba[1], Masato Kagitani[1], Haruna Watanabe[1] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PPS01-P05] Pulsation-like variation of Jovian infrared polar emission observed by Subaru 8-m: H3+ and methane emissions

*Yasumasa Kasaba[1], Haruna Watanabe[1], Hajime Kita[2], Chihiro Tao[3], Takeshi Sakanoi[1], Masato Kagitani[1], Orton Glenn[1,4], James Sinclair[4] (1.Planetary Plasma and Atmospheric Research Center, 2.ISAS/JAXA, 3.NICT, 4.NASA/JPL)

[PPS01-P06] Structure of Io plasma torus observed with the Tohoku 60-cm telescope

*Masato Kagitani[1], Fuminori Tsuchiya[1], Kazuo Yoshioka[2], Go Murakami[3], Tomoki Kimura[1], Ryoichi Koga[1], Reina Hikida[4], Takeshi Sakanoi[1] (1.Graduate School of Science, Tohoku University, 2.Graduate School of frontier Science, The University of Tokyo, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4.Department of Earth and Planetary Science, Graduate School of Science, Tokyo University)

[PPS01-P07] Ion Scale Height Variability in Hisaki Io Torus Observations

*Nicholas McCord Schneider[1], Carl Schmidt[2], Masato Kagitani[3], Yasumasa Kasaba[3], Tomoki Kimura[3], Go Murakami[4], Fuminori Tsuchiya[3], Hajime Kita[3], Reina Hikida[5], Ichiro Yoshikawa[5], Kazuo Yoshioka[5] (1.LASP, University of Colorado Boulder, 2.Boston University, 3.Tohoku University, 4.ISAS/JAXA, 5.University of Tokyo)

[PPS01-P08] Size of the Smallest Particles in Saturn's Rings

*Keiji Ohtsuki[1], Hiroshi Kawamura[1], Naoyuki Hirata[1], Hiroshi Daisaka[2], Hiroshi Kimura[3] (1.Graduate School of Science, Kobe University, 2.Graduate School of Commerce and Management, Hitotsubashi University, 3.Planetary Exploration Research Center, Chiba Institute of Technology)

[PPS01-P09] The Radio & Plasma Wave Investigation (RPWI) for JUICE for the investigation of Jupiter and Icy Moons System: Contributions from Japan

*Yasumasa Kasaba[1], Hiroaki Misawa[1], Fuminori Tsuchiya[1], Atsushi Kumamoto[2], Yuto Katoh[2], Tomoki Kimura[2], Hajime Kita[3], J.-E. Wahlund[4] (1.Planetary Plasma and Atmospheric Research Center, Tohoku University, 2.Department of Geophysics, Tohoku University, 3.ISAS/JAXA, 4.IRF Uppsala, Sweden)

[PPS01-P10] Magnetic field experiment at Jupiter icy moons (JUICE J-MAG) and in-flight alignment calibration

*Ayako Matsuoka[1], Michele Karen Dougherty[2], Patrick Brown[2], Futoshi Takahashi[3], Hisayoshi Shimizu[4], Masaki Matsushima[5] (1.Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Imperial College London, 3.Kyushu University, 4.University of Tokyo, 5.Tokyo Institute of Technology)

[PPS01-P11] Science targets of the GAnymede Laser Altimeter (GALA) for the JUICE mission

*Jun Kimura[1], Shunichi Kamata[2], Koji Matsumoto[3], Noriyuki Namiki[3], Keigo Enya[4], Masanori Kobayashi[5], Hiroshi Araki[3], Hirotomo Noda[3], Ko Ishibashi[5], Hauke Hussmann[6], Kay Lingenauber[6] (1.Osaka University, 2.Hokkaido University, 3.National Astronomical Observatory Japan, 4.ISAS/JAXA, 5.Chiba Institute of Technology, 6.German Aerospace Center (DLR), Berlin)

[PPS01-P12] Current status of the antenna developments, the data processing, scientific target for JUICE/SWI JAPAN.

*YASUKO KASAI[1], JUICE SWI Japanese Team (1.National Institute of Information and Communications Technology (NICT))

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Masateru Ishiguro(Seoul National University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PPS03-01] The shape and origin of the rubble-pile asteroid Ryugu

★Invited Papers

*Sei-ichiro WATANABE[1,5], Masatoshi Hirabayashi[2], Naru Hirata[3], Naoyuki Hirata[4], Rina Noguchi[5], Yuri Shimaki[5], Hitoshi Ikeda[6], Eri Tatsumi[7], Makoto Yoshikawa[5], Shota Kikuchi[5], Hikaru Yabuta[8], Tomoki Nakamura[9], Shogo Tachibana[7,5], Yoshiaki Ishihara[10], Tomokatsu Morota[1], Kohei Kitazato[3], Naoya Sakatani[5], Koji Matsumoto[11,12], Koji Wada[13], Hiroki Senshu[13], Chikatoshi Honda[3], Tatsuhiro Michikami[14], Hiroshi Takeuchi[5], Toru Kouyama[15], Rie Honda[16], Robert Gaskell[17], Eric Palmer[17], Olivier S. Barnouin[18], Patrick Michel[19], Paul Abell[20], Yukio Yamamoto[5], Satoshi Tanaka[5], Kei Shirai[5], Moe Matsuoka[5], Seiji Sugita[5,7], Tatsuaki Okada[5], Noriyuki Namiki[11], Masahiko Arakawa[4], Masateru Ishiguro[21], Kazunori Ogawa[4], Fuyuto Terui[5], Takanao Saiki[5], Satoru Nakazawa[5], Yuichi Tsuda[5], Hayabusa2 Science Team (1.Division of Earth and Planetary Sciences, Graduate School of Science, Nagoya University, 2.Auburn University, 3.University of Aizu, 4.Kobe University, 5.ISAS, JAXA, 6.Research and Development Directorate, JAXA, 7.University of Tokyo, 8.Hiroshima University, 9.Tohoku University, 10.National Institute for Environmental Studies, 11.National Astronomical Observatory of Japan, 12.SOKENDAI, 13.Chiba Institute of Technology, 14.Kindai University, 15.National Institute of Advanced Industrial Science and Technology, 16.Kochi University, 17.Planetary Science Institute, 18.John Hopkins University, 19.Universite Cote d'Azur, Observatorie de la Cote d'Azur, 20.NASA, Johnson Space Center, 21.Seoul National University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PPS03-02] Results of Hayabusa2 Near Infrared Spectroscopy at Asteroid Ryugu

*Takahiro Iwata[1], Kohei Kitazato[2], Masanao Abe[1], Makiko Ohtake[1], Yusuke Nakauchi[1], Moe Matsuoka[1], KOHJI TSUMURA[3], Shuji Matsuura[4], Lucie Riu[1], NIRS3 Team (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.The University of Aizu, 3.Tohoku University, 4.Kwansei Gakuin University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PPS03-03] Impact experiment on asteroid Ryugu by Small-Carry on impactor of Hayabusa-2 and observation of the impact ejecta by a Deployable CAMera-3

★Invited Papers

*Masahiko Arakawa[1], Takanao Saiki[2], Toshihiko Kadono[3], Yasuhiko Takagi[4], Koji Wada[5], Yu-ichi Iijima[2], Hiroshi Imamura[2], Chisato Okamoto[1], Yuri Shimaki[2], Kei Shirai[2], Satoru Nakazawa[2], Masahiko Hayakawa[2], Naru Hirata[6], Hajime Yano[2], Hirotaka Sawada[2], Kazunori Ogawa[1], Ko Ishibashi[5], Hiroshi Kimura[5], Masanori Kobayashi[5], Naoya Sakatani[2], Hajime Hayakawa[2], Rie Honda[7], Seiji Sugita[8], Tomokatsu Morota[9], Shingo Kameda[10], ERI TATSUMI[8], Chikatoshi Honda[6], yokota yasuhiro[2], Toru Kouyama[11], Manabu Yamada[5], Hidehiko Suzuki[12], Kazuo Yoshioka[13], Yuichiro Cho[8], Moe Matsuoka[2] (1.Graduate School of Science, Kobe University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.University of Occupational and Environmental Health, 4.Aichi Toho University, 5.Planetary Exploration Research Center, Chiba Institute of Technology, 6.Dep. of Computer Science and Engineering, Univ. of Aizu, 7.Department of Science and Technology, System of Natual Science, Kochi University, 8.Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo, 9.Graduate School of Environmental Studies, Nagoya University, 10.School of Science, Rikkyo University, 11.National Institute of Advanced Industrial Science and Technology, 12.Department of physics, Meiji university, 13.Graduate School of frontier Science, The University of Tokyo)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PPS03-04] Impact cratering experiments on glass beads with bead size frequency distribution: Implications for cratering process on asteroid Ryugu

*Minami Yasui[1], Masahiko Arakawa[1], Sunao Hasegawa[2], Yuya Yamamoto[1], Ryo Sugimura[1] (1.Graduate School of Science, Kobe University, 2.ISAS, JAXA)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PPS03-05] Enhancement of impact heating in strength-supported media

*Kosuke Kurosawa[1], Hidenori Genda[2], Shigeru Wakita[2], Thomas M Davison[3], Ryuki Hyodo[2], Tomoki Nakamura[4] (1.Planetary Exploration Research Center, Chiba Institute of Technology, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Department of Earth Science & Engineering, Imperial College London, 4.Department of Earth Science, Tohoku University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PPS03-06] Global Thermal Inertia and Surface Roughness of Asteroid 162173 Ryugu by TIR on Hayabusa2

*Yuri Shimaki[1], Hiroki Senshu[2], Naoya Sakatani[1], Tatsuaki Okada[1,3], Tetsuya Fukuhara[4], Satoshi Tanaka[1], Makoto Taguchi[4], Takehiko Arai[5], Hirohide Demura[6], Yoshiko Ogawa[6], Kentaro Suko[6], Tomohiko Sekiguchi[7], Toru Kouyama[8], Jun Takita[9], Tsuneo Matsunaga[10], Takeshi Imamura[3], Takehiko Wada[1], Sunao Hasegawa[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Chiba Institute of Technology, 3.University of Tokyo, 4.Rikkyo University, 5.Ashikaga University, 6.University of Aizu, 7.Hokkaido University of Education, 8.National Institute of Advanced Industrial Science and Technology, 9.Hokkaido Kitami Hokuto High School, 10.National Institute for Environmental Studies)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Olivier Barnouin(Johns Hopkins University Applied Physics Laboratory)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PPS03-07] Asteroid Ryugu's parent body and its properties inferred from Haybusa2 multi-band imaging observations

★Invited Papers

*Seiji Sugita[1,6], Rie Honda[2], Tomokatsu Morota[3], Shingo Kameda[4], ERI TATSUMI[1], Chikatoshi Honda[7], yokota yasuhiro[2,5], Toru Kouyama[8], Naoya Sakatani[5], Manabu Yamada[6], Hidehiko Suzuki[10], Kazuo Yoshioka[1], Yuichiro Cho[1], Moe Matsuoka[5], Kazunori Ogawa[9], Deborah Domingue[11], Hideaki Miyamoto[1], Olivier Barnouin[12], Patrick Michel[13], Carolyn Ernst[12], Sei-ichiro WATANABE[3], Yuichi Tsuda[5] (1.University of Tokyo, 2.Kochi University, 3.Nagoya University, 4.Rikkyo University, 5.JAXA/ISAS, 6.Chiba Institute of Technology, PERC, 7.University of Aizu, 8.National Institute of Advanced Industrial Science and Technology, 9.Kobe University, 10.Meiji University, 11.Planetary Science Institute, 12.Johns Hopkins University/Applied Physics Laboratory, 13.Observatoire de la Coˆte d'Azur)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PPS03-08] REDDENING PROCESS OF THE RYUGU SURFACE BASED ON THE CRATER SIZE-FREQUENCY DISTRIBUTION

*Tomokatsu Morota[1], Yuichiro Cho[2], Masanori Kanamaru[3], Rie Honda[4], Shingo Kameda[5], ERI TATSUMI[2], yokota yasuhiro[6], Toru Kouyama[7], Hidehiko Suzuki[8], Manabu Yamada[9], Naoya Sakatani[6], Chikatoshi Honda[10], Masahiko Hayakawa[6], Kazuo Yoshioka[2], Moe Matsuoka[6], Tatsuhiro Michikami[11], Hideaki Miyamoto[2], Hiroshi Kikuchi[2], Ryodo Hemmi[2], Masatoshi Hirabayashi[12], Naoyuki Hirata[13], Naru Hirata[10], Carolyn Ernst[14], Olivier Barnouin[14], Hirotake Sawada[6], Seiji Sugita[2] (1.Nagoya University, 2.The University of Tokyo, 3.Osaka University, 4.Kochi University, 5.Rikky University, 6.JAXA, 7.AIST, 8.Meiji University, 9.Chiba Institute of Technology, 10.The University of Aizu, 11.Kindai University, 12.Auburn University, 13.Kobe University, 14.Johns Hopkins University/Applied Physics Laboratory)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PPS03-09] Preliminary report on global distribution visible spectra of asteroid Ryugu based on clustering

*Rie Honda[1], Yasuhiro Yokota[1,2], Eri Tatsumi[3], Antonella Barucci[12], Davide Perna[13], Moe Matsuoka[2], Deborah Domingue[14], Tomokatsu Morota[4], Shingo Kameda[5], Toru Kouyama[15], Hidehiko Suzuki[6], Manabu Yamada[10], Naoya Sakatani[2], Chikatoshi Honda[7], Lucille LeCorre[14], Masahiko Hayakawa[2], Kazuo Yoshioka[3], Yuichiro Cho[3], Yukio Yamamoto[2], Naru Hirata[7], Naoyuki Hirata[8], Tomoki Nakamura[9], Takahiro Hiroi[11], Hirotaka Sawada[2], Yuki Fujii[1], Seiji Sugita[3], Ryo Hayashi[1] (1.Kochi University, 2.ISAS/JAXA, 3.University of Tokyo, 4.Nagoya University, 5.Rikkyo University, 6.Meiji University, 7.Aizu University, 8.Kobe University, 9.Tohoku University, 10.Chiba Institute of Technology, 11.Brown University, 12.Paris Observatory, 13.INAF, 14.Planetary Science Institute, 15.National Institute of Advanced Industrial Science and Technology)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PPS03-10] Visible spectra of small bright spots on asteroid 162173 Ryugu

*Chiho Sugimoto[1], Eri Tatsumi[1], Yuichiro Cho[1], Kazuo Yoshioka[1], Hirotaka Sawada[2], Yasuhiro Yokota[2], Naoya Sakatani[2], Masahiko Hayakawa[2], Moe Matsuoka[2], Rie Honda[3], Tomokatsu Morota[4], Shingo Kameda[5], Manabu Yamada[6], Toru Kouyama[7], Hidehiko Suzuki[8], Chikatoshi Honda[9], Kazunori Ogawa[10], Deborah Domingue[11], Patrick Michel[12], Seiji Sugita[1] (1.University of Tokyo, 2.JAXA/ISAS, 3.Kochi University, 4.Nagoya University, 5.Rikkyo University, 6.Chiba Institute of Technology, 7.AIST, 8.Meiji University, 9.University of Aizu, 10.Kobe University, 11.Planetary Science Institute, 12.Nice Observatory)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PPS03-11] Geomorphological characteristics of asteroid Ryugu: implications to its evolutional history

*Hideaki Miyamoto[1], Ryodo Hemmi[1], Hiroshi Kikuchi[1], Goro Komatsu[2], Chikatoshi Honda[3], Tatsuhiro Michikami[4], Tomokatsu Morota[5], Yuichiro Cho[1], Olivier S Barnouin[6], Sho Sasaki[7], Naru Hirata[3], Naoyuki Hirata[8], Rie Honda[10], Shingo Kameda[11], ERI TATSUMI[1], Yasuhiro Yokota[12], Toru Kouyama[13], Hidehiko Suzuki[14], Manabu Yamada[15], Naoya

Sakatani[12], Masahiko Hayakawa[12], Kazuo Yoshioka[1], Moe Matsuoka[12], Masatoshi Hirabayashi[9], Hirotaka Sawada[12], Seiji Sugita[1] (1.University of Tokyo, 2.D'Annunzio University, 3.Aizu University, 4.Kinki University, 5.Nagoya University, 6.Johns Hopkins University, 7.Osaka University, 8.Kobe University, 9.Auburn University, 10.Kouchi University, 11.Rikkyo University, 12.ISAS/JAXA, 13.AIST, 14.Meiji University, 15.Chiba Inst Tech)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PPS03-12] Global distribution of sub-meter boulders measured with texture analysis of Ryugu images

*Naoya Tanabe[1], Yuichiro Cho[1], ERI TATSUMI[1], Tomokatsu Morota[4], Chikatoshi Honda[9], Tatsuhiro Michikami[11], Patrick Michel[12], Carolyn Ernst[13], Olivier S Barnouin[13], Kazuo Yoshioka[1], Sawada Hirotaka[2], yokota yasuhiro[2,3], Naoya Sakatani[2], Masahiko Hayakawa[2], Moe Matsuoka[2], Rie Honda[3], Shingo Kameda[5], Manabu Yamada[6], Toru Kouyama[7], Hidehiko Suzuki[8], Kazunori Ogawa[10], Seiji Sugita[1] (1.University of Tokyo, 2.JAXA/ISAS, 3.Kochi University, 4.Nagoya University, 5.Rikkyo University, 6.Chiba Inst. Tech., PERC, 7.AIST, 8.Meiji University, 9.University of Aizu, 10.Kobe University, 11.Kindai University, 12.Observatoire de la Côte d'Azur, 13.Johns Hopkins University APL)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Masanao Abe(Institute of Space and Astronautical Science, JAXA)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PPS03-13] Brightness and morphology variations on surface boulders of 162173 Ryugu: Space Weathering, Breccia, and Thermal Cracks

*Sho Sasaki[1], Seiji Sugita[2], Eri Tatsumi[2], Hideaki Miyamoto[3], Chikatoshi Honda[4], Tomokatsu Morota[5], Masatoshi Hirabayashi[6], Shiho Kanda[1], Naru Hirata[4], Takahiro Hiroi[7], Tomoki Nakamura[8], Takaaki Noguchi[9], Rie Honda[10], Tatsuhiro Michikami[11], Sei-ichiro Watanabe[5], Noriyuki Namiki[12], Patrick Michel[13], Shingo Kameda[14], Toru Kouyama[15], Hidehiko Suzuki[16], Manabu Yamada[17], Hiroshi Kikuchi[3], Yuichiro Cho[2], Kazuo Yoshioka[18], Masahiko Hayakawa[19], Moe Matsuoka[19], Rina Noguchi[19], Naoya Sakatani[19], Hirotaka Sawada[19], yokota yasuhiro[19,10], Makoto Yoshikawa[19] (1.Department of Earth and Space Science, School of Science, Osaka University, 2.Department of Earth and Planetary Science, School of Science, University of Tokyo, 3.Department of Systems Innovation, School of Engineering, University of Tokyo, 4.University of Aizu, 5.Graduate School of Environmental Studies, Nagoya University, 6.Auburn University, 7.Brown University, 8.Department of Earth and Planetary Materials Sciences, Faculty of Science, Tohoku University, 9.Department of Arts and Science, Kyushu University, 10.Department of Science and Technology, System of Natural Science, Kochi University, 11.Faculty of Engineering, Kinki University, 12.RISE Project, National Astronomical Observatory of Japan, 13.Observatoire de la Cote d'Azur, 14.School of Science, Rikkyo University, 15.National Institute of Advanced Industrial Science and Technology, 16.Department of physics, Meiji university, 17.Planetary Exploration Research Center, Chiba Institute of Technology, 18.School of frontier Science, University of Tokyo, 19.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PPS03-14] Topography of large craters and equatorial bulge of 162173 Ryugu

*Noriyuki Namiki[1,2], Takahide Mizuno[3], Hiroki Senshu[4], Hirotomo Noda[1,2], Koji Matsumoto[1,2], Naru Hirata[5], Ryuhei Yamada[5], Yoshiaki Ishihara[6], HItoshi Ikeda[3], Hiroshi Araki[1,2], Keiko Yamamoto[1,2], Shinsuke Abe[7], Fumi Yoshida[4], Arika Higuchi[1], Sho Sasaki[10], Shoko Oshigami[1], Seiitsu Tsuruta[1], Kazuyoshi Asari[1], Seiichi Tazawa[1], Makoto Shizugami[1], Hideaki Miyamoto[8], Hirohide Demura[5], Jun Kimura[10], Toshimichi Otsubo[9] (1.National Astronomical Observatory of Japan, 2.SOKENDAI (The Graduate University for Advanced Studies), 3.Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science, 4.Chiba Institute of Technology, 5.The University of Aizu, 6.National Institute of Advanced Industrial Science and Technology, 7.Nihon University,8Osaka University, 8.The University of Tokyo, 9.Hitotsubashi University, 10.Osaka University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PPS03-15] Observation of 1064 nm normal albedo around equator of the Ryugu using the Hayabusa2 LIDAR

*Ryuhei Yamada[1], Keiko Yamamoto[2], Hiroshi Araki[2], Hirotomo Noda[2], Hiroki Senshu[3], Noriyuki Namiki[2], Koji Matsumoto[2], Fumi Yoshida[3], Shinsuke Abe[4], Naru Hirata[1] (1.The University of Aizu, Department of Computer Science and Engineering, 2.National Astronomical Observatory of Japan, 3.Chiba Institute of Technology, 4.Nihon University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PPS03-16] Improved Trajectory of Hayabusa2 by Combining LIDAR Data and a Shape Model

*Koji Matsumoto[1], Hirotomo Noda[1], Yoshiaki Ishihara[2], Hiroki Senshu[3], Keiko Yamamoto[1], Naru Hirata[4], Naoyuki Hirata[5], Noriyuki Namiki[1], Toshimichi Otsubo[6], Sei-ichiro WATANABE[7], Takahide Mizuno[8], Yukio Yamamoto[8], Hitoshi Ikeda[8], Naoko Ogawa[8], Shota Kikuchi[8], Takanao Saiki[8], Yuichi Tsuda[8] (1.RISE Project, National Astronomical Observatory of Japan, 2.National Institute for Environmental Studie, 3.Chiba Institute of Technology, 4.The University of Aizu, 5.Kobe University, 6.Hitotsubashi University, 7.Nagoya University, 8.JAXA)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PPS03-17] Present status of preparation for the Ryugu sample curation returned by the Hayabusa2

*Toru Yada[1], Masanao Abe[1], Aiko Nakato[1], Kasumi Yogata[1], Kanako Sakamoto[1], Masahiro Nishimura[1], Tatsuaki Okada[1], Yuki Nakano[2], Miwa Yoshitake[1], Kazuya Kumagai[3], Ayako Iwamae[3], Shizuho Furuya[1], Shogo Tachibana[4,1],

Hisayoshi Yurimoto[1,2] (1.Japan Aerospace Exploration Agency, 2.Hokkaido University, 3.Marine Works Japan Ltd., 4.University of Tokyo)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PPS03-18] Analysis of the grain from the asteroid Ryugu proposed by the Phase 2 curation “Team KOCHI”

*Motoo Ito[1], Naotaka Tomioka[1], Masayuki Uesugi[2], Kentaro Uesugi[2], Ohigashi Takuji[3], Akira Yamaguchi[4], Naoya Imae[4], Yuzuru Karouji[5], Naoki Shirai[6], Toru Yada[5], Masanao Abe[5] (1.Kochi Institute for Core Sample Research, JAMSTEC, 2.JASRI, 3.UVSOR Synchrotron Facility, Institute for Molecular Science, 4.National Institute Polar Research, 5.JAXA, 6.Tokyo Metropolitan University)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

*Keisuke Hosokawa[1], Hiroyuki Nakata[2], Kumiko K. Hashimoto[3], Ichiro Tomizawa[1], Jun Sakai[1], Takashi Kikuchi[4] (1.University of Electro-Communications, 2.Chiba University, 3.Kibi International University, 4.ISEE, Nagoya University)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Danny Summers, Yoshizumi Miyoshi(ISEE, Nagoya University)

1:45 PM - 2:05 PM JST | 4:45 AM - 5:05 AM UTC

[PEM13-01] Developing an improved understanding of Earth's outer radiation belt electrons with combined observations from Van Allen Probes, MMS, and Arase

★Invited Papers

*Drew L Turner[1], Ian Cohen[2], Alexander Boyd[1,3], Joseph Fennell[1], Geoff Reeves[3], Yoshizumi Miyoshi[4] (1.Aerospace Corporation El Segundo, 2.Johns Hopkins University Applied Physics Lab, 3.Los Alamos National Laboratory, 4.Nagoya University)

2:05 PM - 2:25 PM JST | 5:05 AM - 5:25 AM UTC

[PEM13-02] Recent results from Van Allen Probes and future prospects from the CeREs Cubesat

★Invited Papers

*Shrikanth G Kanekal[1], Daniel N Baker[2], Ashley Greeley[1], Lauren Blum[1], Quintin Schiller[1], David G Sibeck[1], Hong Zhao[2], Xinlin Li[2], Allison Jaynes[3] (1.NASA Goddard Space Flight Center, 2.LASP, University of Colorado, Boulder, 3.Univeristy of Iowa)

2:25 PM - 2:40 PM JST | 5:25 AM - 5:40 AM UTC

[PEM13-03] **Optimal Use of Time Lags Between MMS Spacecraft : Application to the Estimation of Wave-Vectors**

*Gerard Marcel CHANTEUR[1,2,3], Drew L. Turner, Olivier Le Contel[1,2,3], Alessandro Retino[1,2,3], Laurent Mirioni[1,2,3] (1.CNRS, 2.SORBONNE UNIVERSITE, 3.ECOLE POLYTECHNIQUE)

2:40 PM - 2:55 PM JST | 5:40 AM - 5:55 AM UTC

[PEM13-04] Conjugate observation of EMIC waves by Arase and RBSP with associated POES and AARDDVARK detected electron precipitation

*Aaron T. Hendry[1], Ondrej Santolik[1,2], Yoshizumi Miyoshi[3], Yoshiya Kasahara[4], Yasumasa Kasaba[5], Ayako Matsuoka[6], Craig J Rodger[7], Mark Clilverd[8], Masafumi Shoji[3], Shoya Matsuda[6], Craig Kletzing[9], Iku Shinohara[6] (1.Dept. of Space Physics, Inst. of Atmospheric Physics, Czech Acad. of Science, 2.Fac. of Mathematics and Physics, Charles Univ., 3.Inst. for Space Earth Environmental Research, Nagoya Univ., 4.Graduate School of Natural Science and Technology, Kanazawa Univ., 5.Planetary Plasma and Atmospheric Research Center, Tohoku Univ., 6.Inst. of Space and Astronautical Science, Japan Aerospace Exploration Agency, 7.Dept. of Physics, Univ. of Otago, 8.British Antarctic Survey (NERC), 9.Dept. of Physics and Astronomy, Univ. of Iowa)

2:55 PM - 3:10 PM JST | 5:55 AM - 6:10 AM UTC

[PEM13-05] Over-darkening pulsating aurora: simultaneous observations with Arase and an all-sky camera in Scandinavia

*Keisuke Hosokawa[1], Yoshizumi Miyoshi[2], Shin-ichiro Oyama[2], Yasunobu Ogawa[3], Satoshi Kurita[2], Yoshiya Kasahara[4], Mitsunori Ozaki[4], Yasumasa Kasaba[5], Satoshi Yagitani[4], Shoya Matsuda[6], Fuminori Tsuchiya[5], Atsushi Kumamoto[5], Iku Shinohara[6], Ryoichi Fujii[7] (1.Department of Communication Engineering and Informatics, University of Electro-Communications, 2.ISEE, Nagoya University, 3.National Institute of Polar Research, 4.Kanazawa University, 5.Tohoku University, 6.ISAS/JAXA, 7.Research Organization of Information and Systems)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Yoshizumi Miyoshi(ISEE, Nagoya University), Danny Summers

3:30 PM - 3:50 PM JST | 6:30 AM - 6:50 AM UTC

[PEM13-06] Deformation of electron pitch angle distributions caused by chorus waves observed by the Arase satellite

★Invited Papers

*Satoshi Kurita[1], Yoshizumi Miyoshi[1], Satoshi Kasahara[2], Shoichiro Yokota[3], Yoshiya Kasahara[4], Shoya Matsuda[5], Ayako Matsuoka[5], Iku Shinohara[5] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.The University of Tokyo, 3.Graduate School of Science, Osaka University, 4.Information Media Center, Kanazawa University, 5.ISAS/JAXA)

3:50 PM - 4:10 PM JST | 6:50 AM - 7:10 AM UTC

[PEM13-07] Electron scattering by isolated chorus elements observed near the magnetospheric equator

★Invited Papers

*Satoshi Kasahara[1], Yoshizumi Miyoshi[2], Shoichiro Yokota[3], Yoshiya Kasahara[4], Shoya Matsuda[5], Ayako Matsuoka[5], Kunihiro Keika[1], Tomoaki Hori[2], Iku Shinohara[5] (1.The university of Tokyo, 2.Nagoya University, 3.Osaka University, 4.Kanazawa University, 5.Institute of Space and Astronautical Science)

4:10 PM - 4:25 PM JST | 7:10 AM - 7:25 AM UTC

[PEM13-08] Continuous precipitation of low-energy electrons associated with pulsating aurora obtained by the Reimei satellite

*Takeshi Sakanoi[1], Fukizawa Mizuki[1], Yoshizumi Miyoshi[2], Yusuke Ebihara[3], Kazushi Asamura[4], Masafumi Hirahara[2] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.ISEE, Nagoya University, 3.RISH, Kyoto University, 4.ISAS/JAXA)

4:25 PM - 4:40 PM JST | 7:25 AM - 7:40 AM UTC

[PEM13-09] Origin of energetic electron precipitation with fast fluctuation: Data-driven simulations using the ERG plasma wave observations

*Shinji Saito[1], Yoshizumi Miyoshi[2], Shoya Matsuda[3], Satoshi Kurita[2], Yoshiya Kasahara[4], Atsushi Kumamoto[5], Fuminori Tsuchiya[5], Ayako Matsuoka[3] (1.Graduate School of Science, Nagoya University, 2.ISEE, Nagoya University , 3.ISAS/JAXA, 4.Kanazawa University, 5.Tohoku University)

4:40 PM - 4:55 PM JST | 7:40 AM - 7:55 AM UTC

[PEM13-10] Conjugated quasi-periodic ELF/VLF emissions between the Arase satellite and both Van Allen Probes

*Claudia Martinez Calderon[1,2], Frantisek Nemec[3], Kazuo Shiokawa[2], Yuto Katoh[1], Yoshiya Kasahara[4], Shoya Matsuda[2], Fuminori Tsuchiya[1], Atsushi Kumamoto[1], Mariko Teramoto[2], Ayako Matsuoka[5], Yoshizumi Miyoshi[2], Ondrej Santolik[6,3], George Hospodarksy[7] (1.Dept. Geophys., Grad. Sch. Sci., Tohoku University, 2.Instute for Space-Earth Environmental Research, Nagoya University, 3.Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, 4.Kanazawa University, 5.Japan Aerospace Exploration Agency, 6.Institute of Atmospheric Physics, Prague, Czech Republic, 7.Department of Physics and Astronomy, University of Iowa, USA)

[E] Poster | P (Space and Planetary Sciences)：P-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-CG22] Shock responses of planetary materials elucidated from meteorites and dynamic compression experiments

convener:Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Takuo Okuchi(Institute for Planetary Materials, Okayama University)

[PCG22-P01] discussion

*Takuo Okuchi[1], Toshimori Sekine[2] (1.Institute for Planetary Materials, Okayama University, 2.Center for High Pressure Science and Technology Advanced Research)

[PCG22-P02] Shock-compressed behavior of quartz by XFEL

*Tomoko Sato[1], Yoshinori Tange[2], Yusuke Seto[3], Toshimori Sekine[4,5], Norimasa Ozaki[4], Toyohito Nishikawa[4], Kohei Miyanishi[4], Kensuke Matsuoka[4], Ryosuke Kodama[4], Tadashi Togashi[2], Yuichi Inubushi[2], Toshinori Yabuuchi[6], Makina Yabashi[6] (1.Hiroshima University, 2.Japan Synchrotron Radiation Research Institute, 3.Kobe University, 4.Osaka University, 5.Center for High Pressure Science &Technology Advanced Research, 6.RIKEN)

[PCG22-P04] **Laser-shock experiments of dense polymorphs of Mg_2SiO_4: technical developments using synthetic single crystals**

*Narangoo Purevjav[1], Takuo Okuchi[1], Norimasa Ozaki[2], Takayoshi Sano[3], Yuhei Umeda[2], Shintaro Morioka[2], Nobuki Kamimura[2] (1.Institute for Planetary Materials, Okayama University, 2.Graduate School of Engineering, Osaka University, 3.Institute of Laser Engineering, Osaka University)

[PCG22-P05] Richtmyer-Meshkov instability in inhomogeneous density materials and its application to planetary science

*Takayoshi Sano[1] (1.Institute of Laser Engineering, Osaka University)

[PCG22-P06] Impact-induced dehydration reactions of Fe- and Al-hydrates as potential storage, carrier and source of water

*Tsubasa Tobase[1], Toshimori Sekine[1], Ginga Kitahara[2], Makoto Tokuda[2], Akira Yoshiasa[2], Makoto Takafuji[2], Tsutomu Mashimo[2], Nobuaki Kawai[2] (1.HPSTAR, 2.Graduate School of Science and Technology, Kumamoto University)

[PCG22-P07] Crystallization of amorphous $MgSiO_3$ by shock compression

*Akane Arasuna[1], Masayuki Okuno[1], Nobuaki Kawai[2] (1.Kanazawa University, 2.Kumamoto University)

[PCG22-P08] First-principle study of the structural and electronic properties of N-doped $MgAl_2O_4$ spinel

*Chi Pui Tang[1], Pak Kin Leong[1], Toshimori Sekine[2,3] (1.State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology, 2.Center for High Pressure Science and Technology Advanced Research (HPSTAR) Shanghai Laboratory of HPSTAR, Shanghai, P.R. China, 3.Graduate School of Engineering, Osaka University)

[PCG22-P09] Transparency of shock-compressed single crystal diamond

*Kento Katagiri[1], Norimasa Ozaki[1,2], Kohei Miyanishi[2], Yuhei Umeda[1], Shintaro Morioka[1], Takayoshi Sano[2], Ryosuke Kodama[1,2] (1.Osaka University, 2.Institute of Laser Engineering, Osaka Unversity)

[PCG22-P10] Pb-Pb dating of the NWA 7203 angrite and relationship to its shock metamorphism

*Hideyuki Hayashi[1], Takashi Mikouchi[1], Yuji Sano[1], Martin Bizzarro[2] (1.The university of Tokyo, 2.University of Copenhagen)

[PCG22-P11] Shock recovery of high-pressure phase of SiO_2 using high-power laser

*Tadashi Kondo[1], Hiromoto Kengo[1], Tatsuhiro Sakaiya[1], Hidenori Terasaki[1], Keisuke Shigemori[2], Youichiro Hironaka[2] (1.Department of Earth and Space Science, Graduate School of Science Osaka University, 2.Institute of Laser Engineering, Osaka University)

[PCG22-P12] Hugoniot measurement of calcite under meteorite collision condition

*Fukui Keiya[1], Norimasa Ozaki[1,2], Yuhei Umeda[1], Kohei Miyanishi[3], Kento Katagiri[1], Shintaro Morioka[1], Takayoshi Sano[3], Ryosuke Kodama[1,2,3] (1.Graduate School of Engineering,Osaka univ., 2.PPC, Osaka Univ., 3.ILE, Osaka Univ.)

[PCG22-P13] Direct observation of the transformation toughening of tetragonal stabilized zirconia under shock deformation condition by ns time-resolved XRD.

*Sota Takagi[1,2], Kouhei Ichiyanagi[2,3], Nobuaki Kawai[4], Ryo Fukaya[2], Shunsuke Nozawa[2], Atsushi Kyono[1], Nobumasa Funamori[2], Shin-ichi Adachi[2] (1.University of Tsukuba, 2.KEK PF, 3.Jichi Medical University, 4.Kumamoto University)

[E] Oral | P (Space and Planetary Sciences)：P-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-CG22] Shock responses of planetary materials elucidated from meteorites and dynamic compression experiments

convener:Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Takuo Okuchi(Institute for Planetary Materials, Okayama University), Chairperson:Toshimori Sekine(HPSTAR & Osaka University), Ai-Cheng Zhang(Nanjing University)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PCG22-01] Shock-induced phase transformation in howardite-eucrite-diogenite meteorites

★Invited Papers

*Ai-Cheng Zhang[1,2], De-Liang Chen[1], Run-Lian Pang[1] (1.School of Earth Sciences and Engineering, Nanjing University, China, 2.CAS Center for Excellence in Comparative Planetary, China)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PCG22-02] Lattice-shear-induced metastable formation of high-pressure silicates in shocked meteorites

★Invited Papers

*Naotaka Tomioka[1], Takuo Okuchi[2], Masaaki Miyahara[3] (1.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2.Institute for Planetary Materials, Okayama University, 3.Department of Earth and Planetary Systems Science, Hiroshima University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PCG22-03] Can high-pressure polymorphs clarify an ordinary chondrite parent-body breakup?

*Masaaki Miyahara[1], Akira Yamaguchi[2], Masato Saitoh[1], Kanta Fukimoto[1], Takeshi Sakai[3], Hiroaki Ohfuji[3], Naotaka Tomioka[4], Yu Kodama[5], Eiji Ohtani[6] (1.Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2.National Institute of Polar Research, 3.Geodynamics Research Center, Ehime University, 4.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 5.Marine Works Japan, 6.Department of Earth Sciences, Graduate School of Science, Tohoku University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PCG22-04] Linking occurrence and texture of dense silicate minerals in shocked meteorites with laser-shock experimental results of Mg_2SiO_4 analyzed by XFEL probe

*Takuo Okuchi[1], Narangoo Purevjav[1], Norimasa Ozaki[2], Takeshi Matsuoka[2], Yusuke Seto[3], Yoshinori Tange[4], Toshinori Yabuuchi[5], Naotaka Tomioka[6], Toshimori Sekine[7], Ryosuke Kodama[2] (1.Institute for Planetary Materials, Okayama University, 2.Graduate School of Engineering, Osaka University, 3.Graduate School of Science, Kobe University, 4.Japan Synchrotron Radiation Research Institute, 5.RIKEN Harima Branch, 6.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 7.Center for High Pressure Science and Technology Advanced Research)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PCG22-05] **Laser-shock evolution of organic molecules in carbonaceous meteorite**

*Hikaru Yabuta[1], Hikaru Fujioka[2], Tatsuhiro Sakaiya[2], Tadashi Kondo[2], Sohsuke Ohno[3], Kosuke Kurosawa[3], Toshihiko Kadono[4], Keisuke Shigemori[5], Yoichiro Hironaka[5], Takamitsu Yamanaka[6] (1.Hiroshima University, Department of Earth and Planetary Systems Science, 2.Osaka University, Department of Earth and Space Science, 3.Chiba Institute of Technology, Planetary Exploration Research Center (PERC), 4.University of Occupational and Environmental Health, 5.Osaka University, Institute of Laser Engineering, 6.Center for High Pressure Science & Technology Advanced Research, Shanghai, China)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PCG22-06] Shock barometer using cathodoluminescence and synchrotron angle-dispersive x-ray diffraction analyses of minerals

★Invited Papers

*Masahiro KAYAMA[1] (1.Tohoku University)

[E] Oral | P (Space and Planetary Sciences)：P-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-CG22] Shock responses of planetary materials elucidated from meteorites and dynamic compression experiments

convener:Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Takuo Okuchi(Institute for Planetary Materials, Okayama University), Chairperson:Takuo Okuchi(Okayama University), Yongjae Lee(Yonsei University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PCG22-07] Dynamic Compression at Pohang X-ray Free Electron Laser Facility (PAL-XFEL)

★Invited Papers

*Yongjae Lee[1] (1.Yonsei University, Seoul, Korea)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PCG22-08] Exploration of extreme melt states of silicate usign high-power laser and XFEL

★Invited Papers

*Norimasa Ozaki[1] (1.Osaka University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PCG22-09] Hugoniot measurements for silicate: Understanding silicate magma under the planetary impacts

*Yuhei Umeda[1], Norimasa Ozaki[1], Toshimori Sekine[2], Bruno Albertazzi[3], Alessandra Benuzzi-Mounaix[3], Riccardo Bolis[3], Marco Guaruaglini[3], Kento Katagiri[1], Kodama Ryosuke[1], Michel Koeing[3], Kohei Miyanishi[4], Shintaro Morioka[1], Toyohito Nishikawa[1], Syugo Ohi[5], Alessandra Ravasio[3], Yoichi Sakawa[4], Takayoshi Sano[4], Tomoko Sato[6] (1.Graduate School of Engineering, Osaka Univ., 2.Center for High Pressure Science & Technology Advanced Research, 3.Ecole Polytechnique, 4.Institute of Laser Engineering, Osaka University, 5.Shiga Univ., 6.Graduate School of Science, Hiroshima University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PCG22-10] **An experimental design to determine iron melting at the Earth's core conditions via in-situ X-ray diffraction technique at high power laser facility**

★Invited Papers

*Hao Liu[1] (1.Laser fusion research center)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PCG22-11] **Study on transport properties of liquid iron and iron alloy under high temperature and high pressure using the laser shock technique**

*Kohei Miyanishi[1], Norimasa Ozaki[2], Satoshi Ohmura[3], Marion Harmand[4], Andy Krygier[5], Toyohito Nishikawa[2], Yuhei Umeda[2], Shigemori Keisuke[1], Youichi Sakawa[1], Takayoshi Sano[1], Ryosuke Kodama[1,2] (1.Institute for Laser Engineering, Osaka University, 2.Graduate school of engineering, Osaka University, 3.Faculty of Engineering, Hiroshima Institute of Technology, 4.IMPMC, Sorbonne Université, 5.LLNL)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PCG22-12] **Laser shock compression in LFRC**

*Liang Sun[1] (1.Laser Fusion Research Center, CAEP)

[J] Oral | P (Space and Planetary Sciences)：P-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University), Chairperson:Masaki Nishino(名古屋大学宇宙地球環境研究所), Hiroyuki Maezawa(大阪府立大学大学院理学系研究科)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PCG25-01] On the observational constraint on time and spatial variation of Titan's atmospheric trace gases driven with the ALMA solar system big-data

*Takahiro IINO[1,2], Hideo Sagawa[3], Takashi Tsukagoshi[4] (1.The University of Tokyo, 2.Tokyo Univ. of Agr. and Tech., 3.Kyoto Sangyo University, 4.NAOJ)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PCG25-02] Transport and energization of planetary ions in the magnetospheric flanks of Mercury

*Sae Aizawa[1], Dominique Delcourt[2], Naoki Terada[1] (1.Graduate School of Science,Tohoku University, 2.LPC2E, CNRS)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PCG25-03] Exploring the real-time prediction of Mercury's magnetosphere

*Manabu Yagi[1], Kanako Seki[2], Yosuke Matsumoto[3], Dominique C. Delcourt[4], Francois Leblanc[4] (1.RIKEN Center for Computational Science, 2.Graduate School of Science, University of Tokyo, 3.Graduate School of Science, Chiba University, 4.The National Center for Scientific Research)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PCG25-04] Model study on the contribution of various physical processes for generation and dissipation of Mercury's exosphere

*Yudai Suzuki[1], Kazuo Yoshioka[1] (1.University of Tokyo)

[J] Oral | P (Space and Planetary Sciences)：P-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University), Chairperson:Hiromu Nakagawa(Planetary Atmosphere Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University), Kanako Seki(Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo,)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PCG25-05] Updated status and science goals of the BepiColombo mission

*Go Murakami[1], Hajime Hayakawa[1], Masaki Fujimoto[1], BepiColombo Project Team (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PCG25-06] A Novel High-Moment Multifluid Model for Mercury: From the Planetary Conducting Core to the Dynamic Magnetosphere

*Chuanfei Dong[1], Liang Wang[1], Ammar Hakim[1], Amitava Bhattacharjee[1], James A Slavin[2], Gina A DiBraccio[3], Kai Germaschewski[4] (1.Princeton University, 2.University of Michigan, Ann Arbor, 3.NASA Goddard Space Flight Center, 4.University of New Hampshire)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PCG25-07] DSMC simulation of slow hydrodynamic escape from terrestrial planets

Kaori Terada[1], *Naoki Terada[1], Hitoshi Fujiwara[2] (1.Graduate School of Science, Tohoku University, 2.Faculty of Science and Technology, Seikei University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PCG25-08] The influence of Martian crustal magnetic fields on atmospheric escape

*Dave A Brain[1,2], Robin Ramstad[1], Yaxue Dong[1], Tristan Weber[1], Shogo Inui[2], Kanako Seki[2], Andrew Poppe[3], Riku Jarvinen[4], Jim McFadden[3], Jasper Halekas[5], Jared Espley[6], David Mitchell[3], Laila Andersson[1], Bruce Jakosky[1] (1.University of Colorado, 2.University of Tokyo, 3.University of California Berkeley, 4.Finnish Meteorological Institute, 5.University of Iowa, 6.NASA Goddard Space Flight Center)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PCG25-09] Effects of the IMF direction on atmospheric escape under a weak intrinsic magnetic field at Mars

*Shotaro Sakai[1], Kanako Seki[1], Naoki Terada[2], Hiroyuki Shinagawa[3], Ryoya Sakata[1], Takashi Tanaka[3,4], Yusuke Ebihara[5] (1.Graduate School of Science, The University of Tokyo, 2.Graduate School of Science, Tohoku University, 3.National Institute of Information and Communications Technology, 4.International Center for Space Weather Science and Education, Kyushu University, 5.Research Institute for Sustainable Humanosphere, Kyoto University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PCG25-10] Simulating solar energetic electron precipitation and drift at Mars

*Rebecca Jolitz[1], Chuanfei Dong[2], Dave A Brain[1], Steve Bougher[3], Christina Lee[4], Rob Lillis[4], Shannon Curry[4], Bruce Jakosky[1] (1.Univ. of Colorado Boulder, 2.Princeton Univ., 3.Univ. of Michigan, 4.Univ. of California Berkeley)

[J] Oral | P (Space and Planetary Sciences)：P-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University), Chairperson:Takeshi Imamura(Graduate School of Frontier Sciences, University of Tokyo), Naoki Terada(School of Science, Tohoku University)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PCG25-11] Effects of the intrinsic magnetic field on the ion loss from ancient Mars

*Ryoya Sakata[1], Kanako Seki[1], Shotaro Sakai[1], Naoki Terada[2], Hiroyuki Shinagawa[3], Takashi Tanaka[3,4] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Graduate School of Science, Tohoku University, 3.National Institute of Information and Communications Technology, 4.International Center for Space Weather Science and Education, Kyushu University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PCG25-12] Global characterization of wave perturbations in the middle atmosphere on Mars

*Hiromu Nakagawa[1], Naoki Terada[1], Hannes Groller[7], Roger Yelle[7], Montmessin Franck[8], Schneider M Nicholas[4], England Scott[5], Kanako Seki[6], Takeshi Kuroda[3], Hitoshi Fujiwara[2], Takeshi Imamura[6], Kaori Terada[1], Nao Yoshida[1], Justin I Deighan[4], Sonal K Jain[4], Bruce M Jakosky[4] (1.Planetary Atmosphere Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University, 2.Seikei University, 3.National Institute of Information and Communications Technology, 4.Laboratory for Atmospheric and Space Physics, University of Colorado, 5.Aerospace and Ocean Engineering, Virginia Tech, 6.Department of Earth and Planetary Science, University of Tokyo, 7.Lunar and Planetary Laboratory Science, University of Arizona, 8.LATMOS, UVSQ/CNES/IPSL)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PCG25-13] Seasonal variation of the dayside N_2/CO_2 at 140 km altitude derived from MAVEN/IUVS

*Nao Yoshida[1], Hiromu Nakagawa[1], Naoki Terada[1], Nicholas Schnider[2], Scott Evans[3], Sonal Jain[2], Hitoshi Fujiwara[4], Takeshi Imamura[5], Justin Deighan[2], Ian Stewart[2], Michael Stivens[6], Roger Yelle[7] (1.Dep. Geophysics Graduate School of Science Tohoku University, 2.Laboratory for Atmospheric and Space Physics, Boulder, USA, 3.Computational Physics, Inc., Springfield, Virginia, USA, 4.Faculty of Science and Technology, Seikei University, 5.Department of Complexity Science and Engineering, Graduate School of Frontier Sciences, The University of Tokyo, 6.Naval Research Laboratory, Washington, USA, 7.Department of Planetary Sciences, University of Arizona)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PCG25-14] Automated segmentation of Martian dust storms in MGS/MOC images using a deep learning technique

*Kazunori Ogohara[1], Ryusei Gichu[2] (1.School of Engineering, University of Shiga Prefecture, 2.Graduate School of Engineering, University of Shiga Prefecture)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PCG25-15] Investigation of variation mechanisms of the Jovian radiation belt using ALMA

*Hajime Kita[1], Hideo Sagawa[2], Takahiro Iino[3], Chihiro Tao[4], Takeshi Kuroda[4], Fuminori Tsuchiya[5], Hiroaki Misawa[5], Yasumasa Kasaba[5], Masaki Fujimoto[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency , 2.Faculty of Science, Kyoto Sangyo University, 3.Nature and Science Museum, Tokyo University of Agriculture and Technology, 4.National Institute of Information and Communications Technology, 5.Tohoku University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PCG25-16] Jupiter's radio Riddle arcs observed by LWA and Juno

*Kazumasa Imai[1], Charles A. Higgins[2], Masafumi Imai[3], Tracy Clarke[4] (1.Department of Social Design Engineering, National Institute of Technology, Kochi College, 2.Middle Tennessee State University, 3.University of Iowa, 4.Naval Research Laboratory)

[J] Poster | P (Space and Planetary Sciences)：P-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University)

[PCG25-P01] Particle-in-cell simulation on the dayside magnetopause in a small-scale magnetosphere

*Hideyuki Usui[1], Satoki oki[1], Yohei Miyake[1], Naoki Terada[2], Kanako Seki[3], Yuto Katoh[2], Manabu Yagi[4] (1.Graduate school of system informatics Kobe University, 2.Graduate school of science, Tohoku University, 3.Graduate school of science, University of Tokyo, 4.Riken R-CCS)

[PCG25-P02] Developments and performance evaluations of 0.48 THz band heterodyne receivers for the future Mars terahertz sensor missions with micro-satellites

*Ayaka Tomihara[1], Satoshi Matsumoto[1], Hiroyuki Maezawa[1], Yasuko Kasai[2], Shigeru Yamada[2], Takeshi Kuroda[2], Takayoshi Yamada[2], Toshiyuki Nishibori[3], Yutaka Hasegawa[3], Yasumasa Kasaba[4], Richard Larsson[5], Shinichi Nakasuka[6] (1.Osaka Prefecture University, Osaka, Japan, 2.National Institute of Information and Communications Technology (NICT), Tokyo, Japan, 3.Japan Aerospace Exploration Agency, 4.Tohoku University, Tohoku, Japan, 5.Max planck Institute Solar System Research, Göttingen Germany, 6.Tokyo University, Tokyo, Japan)

[PCG25-P03] Time response of the self-regulation of H and O escapes from Mars

*Shungo Koyama[1], Naoki Terada[1], Hiromu Nakagawa[1], Takeshi Kuroda[2] (1.Graduate School of Science, Tohoku University, 2.National Institute of Information and Communications Technology)

[PCG25-P04] Study of ion composition in the polar plume from Mars based on MAVEN observations

*Sakakura Kotaro[1], Kanako Seki[1], Shogo Inui[1], Shotaro Sakai[1], David A Brain[2], James P McFadden[3], Jasper S Halekas[4], Gina A Dibraccio[5], Bruce Jakosky[2] (1.Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo, Tokyo, Japan., 2.Laboratory for Atmospheric and Space Physics, University of Colorado Boulder, Boulder, Colorado, USA., 3.Space Sciences Laboratory, University of California, Berkeley, California, USA., 4.Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa, USA., 5.Solar System Exploration Division, NASA Goddard Space Flight Center, Greenbelt, MD, USA.)

[PCG25-P05] Automated detection of Martian dust devils in multiframe images observed by the MER/Spirit rover.

*Kazuki Yajima[1], Kazunori Ogohara[2] (1.Graduate School of Engineering, The University of Shiga Prefecture, 2.School of Engineering, The University of Shiga Prefecture)

[PCG25-P06] Temperature change during the global dust storm period obtained by ground observation of the Martian mesosphere by infrared heterodyne spectroscopy

*Akiho Miyamoto[1], Hiromu Nakagawa[1], Kosuke Takami[1], Takeshi Kuroda[1,3], Isao Murata[2], Naoki Terada[1], Nao Yoshida[1], Katsushige Toriumi[1], Shohei Aoki[4], Yasumasa Kasaba[1] (1.Graduate School of Sciences in Tohoku University, 2.Graduate School of Environmental Sciences, 3. National Institute of Information and Communications Technology, 4.Royal Belgian Institute for Space Aeronomy(IASB-BIRA))

[PCG25-P07] Observation of Neptune's storms with Pirka telescope

*Yuuki Sato[1], Yukihiro Takahashi[1], Seiko Takagi[1], Mitsuteru Sato[1], Ono Tatsuharu[1] (1.Graduate School of Science, Hokkaido University)

[PCG25-P08] The study of Jupiter's zonal wind formation mechanism based on cumulonimbus observation

*Tatsuharu Ono[1], Yukihiro Takahashi[1], Shigeto Watanabe[1], Seiko Takagi[1] (1.Department of Cosmosciences, Graduate School of Science, Hokkaido University)

[PCG25-P09] Development of a radial diffusion model of Jovian inner magnetospheric plasma aimed at comparison with HISAKI satellite observation

*Kazuki Yamaguchi[1], Takeshi Sakanoi[1], Fuminori Tsuchiya[1], Masato Kagitani[1], Ryoichi Koga[1], Tomoki Kimura[2] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Frontier Research Institute for Interdisciplinary Sciences, Tohoku University)

[PCG25-P10] Pitch angle scattering due to elastic collisions between magnetospheric 500eV-50keV electrons and neutral H_2O originated from Enceladus: Test particle simulation

*Hiroyasu Tadokoro[1], Yuto Katoh[2] (1.Musashino University, 2.Tohoku University)

[PCG25-P11] Study of Jovian atmosphere dynamics by a multi-band imaging observation

Hayate Ito[1], Sumito Hirota[2], Isshi Tabe[3], *Hidehiko Suzuki[1] (1.Meiji university, 2.Kawasaki municipal science museum, 3.Association of Lunar and Planetary Observers in Japan)

[PCG25-P12] Examination of the relation between Jupiter's inner magnetosphere and magnetic reconfiguration events

*Hiroaki Misawa[1] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University)

[PCG25-P13] Effects of the charged particles of solar wind on planetary atmospheres

*Shinji Karasawa[1] (1.Miyagi National College of Technology Professor emeritus)

[J] Poster | P (Space and Planetary Sciences)：P-CG Complex & General

[AAS03-07] A Mechanism for the Maintenance of Sharp Tropical Margins

★Invited Papers

*Hirohiko Masunaga[1], Brian Earle Mapes[2] (1.Nagoya University, 2.University of Miami)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AAS03-08] Observational Evidence of Mixed Rossby-Gravity Waves as a Driving Force for the MJO Convective Initiation and Propagation

*Daisuke Takasuka[1,2], Masaki Satoh[1], Satoru Yokoi[2] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AAS03-09] A characteristic of the MJO as a part of enhanced large-scale zonal circulation

*Tamaki Suematsu[1], Hiroaki Miura[2] (1.Atmosphere and Ocean Reaserch Institute, The University of Tokyo, 2.School of Science, The University of Tokyo)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AAS03-10] **The role of the moisture on the occurrences and distribution of the Amazonian mesoscale convective systems**

*Amanda Rehbein[1,2], Masaki Satoh[2], Tercio Ambrizzi[1] (1.Univ. of Sao Paulo, 2.Univ. of Tokyo)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AAS03-11] Interdecadal Change of the Impact of Eurasian Snow on Spring Precipitation Over Southern China

*Dingrui Cao[1] (1.Zhejiang University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AAS03-12] Atmospheric Rivers and related atmospheric circulations associated with Japanese disastrous precipitation in warm season

Naho Suetou[1], *Akiyo Yatagai[1], Yukari Takayabu[2] (1.Graduate School of Science and Technology/Hirosaki University, 2.Atmosphere and Ocean Research Institute/The University of Tokyo)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 106 1F

[A-OS17] Kuroshio Large Meander

convener:Toru Miyama(Japan Agency for Marine-Earth Science and Technology, Application Laboratory), Norihisa Usui(Meteorological Research Institute), Takashi Setou(National Research Institute of Fisheries Science, Fisheries Research and Education Agency), Chairperson:Toru Miyama, Takashi Setou, Norihisa Usui

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AOS17-01] The progress of the Kuroshio large meander in and after 2017

★Invited Papers

*Toshiyuki Sakurai[1], Mikitoshi Hirabara[1], Yoshikazu Fukuda[1], Mika Kimura[1], Kotaro Mine[1], Masaomi Takahashi[1], Kensaku Kobayashi[1], Yuka Okunaka[1], Hiromu Kobayashi[1] (1.Japan Meteorological Agency)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AOS17-02] Influences of the Kuroshio path variation south of Honshu on summer surface air temperature in Kanto district, Japan

*Shusaku Sugimoto[1] (1.Graduate School of Science, Tohoku University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AOS17-03] Bio-chemilcal difference between the large meander and the non case of the Kuroshio current

*Takashi Setou[1], Tuneo Ono[2], Kiyotaka Hidaka[1], Yugo Shimizu[1], Atsushi Nishimoto[1], Sayaka Sogawa[1], Akira Kusaka[1], Daisuke Ambe[1], Daiki Itoh[1], Takashiko Kameda[1], Yutaka Hiroe[3] (1.National Research Institute of Fisheries Science, Fisheries Research and Education Agency , 2.National Research Institute of Far Seas Fisheires,Fisheries Research and Education Agency , 3.National Research Institute of Far Seas Fisheires,Seikai National Fisheries Research Institute)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AOS17-04] The late arrival of 2017-18 Japanese eel recruitment and its links to ocean circulation

*Yu-Lin Eda Chang[1], Yasumasa Miyazawa[1], Michael Miller[2], Katsumi Tsukamoto[2] (1.Application Laboratory, Japan Agency for Marine-Earth Science and Technology, 2.Department of Aquatic Bioscience, The University of Tokyo)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AOS17-05] A probabilistic forecast of the Kuroshio current path variability using an 80-member ensemble simulation.

*Kunihiro Aoki[1], Yasumasa Miyazawa[1], Tsutomu Hihara[1] (1.JAMSTEC)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AOS17-06] Long-term forecast of the Kuroshio large meander in 2017

*Norihisa Usui[1], Nariaki Hirose[1], Kei Sakamoto[1], Yosuke Fujii[1], Nadao Kohno[1] (1.Meteorological Research Institute)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[A-OS17] Kuroshio Large Meander

convener:Toru Miyama(Japan Agency for Marine-Earth Science and Technology, Application Laboratory), Norihisa Usui(Meteorological Research Institute), Takashi Setou(National Research Institute of Fisheries Science, Fisheries Research and Education Agency)

[AOS17-P01] Temporal and spacial changes in relative vorticity along the Kuroshio axis

*Yuya Hirano[1], Kazuyuki Uehara[1] (1.The Graduate School of Geo-environmental Science, Tokai University)

[AOS17-P02] The Kuroshio large meander in 2017 and its coastal impact reproduced by a 2-km resolution assimilation model

*Nariaki Hirose[1], Norihisa Usui[1], Kei Sakamoto[1], Goro Yamanaka[1], Nadao Kohno[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

[AOS17-P03] Reintesification of the Kuroshio Large Meander in Summer 2018

*Toru Miyama[1], Yasumasa Miyazawa[1] (1.Japan Agency for Marine-Earth Science and Technology, Application Laboratory)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

[A-OS17] Kuroshio Large Meander

convener:Toru Miyama(Japan Agency for Marine-Earth Science and Technology, Application Laboratory), Norihisa Usui(Meteorological Research Institute), Takashi Setou(National Research Institute of Fisheries Science, Fisheries Research and Education Agency)

[AOS17-P01] Temporal and spacial changes in relative vorticity along the Kuroshio axis

*Yuya Hirano[1], Kazuyuki Uehara[1] (1.The Graduate School of Geo-environmental Science, Tokai University)

[AOS17-P02] The Kuroshio large meander in 2017 and its coastal impact reproduced by a 2-km resolution assimilation model

*Nariaki Hirose[1], Norihisa Usui[1], Kei Sakamoto[1], Goro Yamanaka[1], Nadao Kohno[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

[AOS17-P03] Reintesification of the Kuroshio Large Meander in Summer 2018

*Toru Miyama[1], Yasumasa Miyazawa[1] (1.Japan Agency for Marine-Earth Science and Technology, Application Laboratory)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 106 1F

[A-OS18] Physical Oceanography (General)

convener:Yoshimi Kawai(Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology), Tomoki Tozuka(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Kitade Yujiro(Tokyo University of Marine Science and Technology), Chairperson:Yoshimi Kawai(Japan Agency for Marine-Earth Science and Technology), Tomoki Tozuka(The University of Tokyo)

1:50 PM - 2:05 PM JST | 4:50 AM - 5:05 AM UTC

[AOS18-01] **Real-Time Subsurface Moorings as a Promising Component of Global Ocean Monitoring System**

*Jianing Wang[1], Fan Wang[1] (1.Institute of Oceanology, Chinese Academy of Sciences)

2:05 PM - 2:20 PM JST | 5:05 AM - 5:20 AM UTC

[AOS18-02] Seasonal Variation of the Mixed Layer Depth at 60°S and its governing dynamics

*Matheus Ferreira Azevedo[1], Yujiro Kitade[1], Shigeru Aoki[2] (1.Tokyo University of Marine Science and Technology, 2.Institute of Low Temperature Science, Hokkaido University)

2:20 PM - 2:40 PM JST | 5:20 AM - 5:40 AM UTC

[AOS18-03] **21st-Century Flood Hazards along the U.S. Atlantic Coast: Impacts of Sea Level Rise and Tropical Cyclone Climatology Change**

★Invited Papers

*Reza Marsooli[1], Ning Lin[2], Kerry Emanuel[3] (1.Stevens Institute of Technology, 2.Princeton University, 3.Massachusetts Institute of Technology)

2:40 PM - 3:00 PM JST | 5:40 AM - 6:00 AM UTC

[AOS18-04] **The Effect of Ocean Waves on an Explosive Cyclone Development: Investigation with a Coupled Model**

★Invited Papers

*Yuki Kita[1], Takuji Waseda[1] (1.University of Tokyo)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[A-OS18] Physical Oceanography (General)

convener:Yoshimi Kawai(Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology), Tomoki Tozuka(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Kitade Yujiro(Tokyo University of Marine Science and Technology)

[AOS18-P01] Mathematical modeling for initial profile of tsunami by instantaneous- or slow-faulting

*Chi-Min Liu[1] (1.Chienkuo Technology University)

[AOS18-P02] Geoid height and sea surface changes due to the 2004 Sumatra-Andaman earthquake and the 2012 Indian-Ocean earthquake from satellite gravimetry and satellite altimetry

★Invited Papers

*Yusaku Tanaka[1] (1.Earthquake Research Institute)

[AOS18-P03] An irregularly shaped warm eddy observed by Chinese underwater gliders

*Huabin MAO[1] (1.South China Sea Institute of Oceanology)

[AOS18-P04] sea surface cooling in the northern South China Sea observed using Chinese underwater glider

*Chunhua Qiu[1] (1.Sun Yat-sen University)

[AOS18-P05] Airborne SAR observation of dependence of ocean surface backscattering on wind direction

*Akitsugu Nadai[1] (1.NICT National Institute of Information and Communications Technology)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 106 1F

[A-OS20] Global ocean observing systems, obtained results and system optimization: toward OceanObs19

convener:Shigeki Hosoda(Japan Marine-Earth Science and Technology), Shuhei Masuda(Japan Agency for Marine-Earth Science and Technology), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), Fujiki Tetsuichi(Japan Agency for Marine-Earth Science and Technology), Chairperson:Shigeki Hosoda(Japan Agency for Marine-Earth Science and Technology)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AOS20-01] Global Ocean Observing System: The Past, the Present and the Future

★Invited Papers

*Toshio Suga[1,2] (1.Graduate School of Science, Tohoku University, 2.JAMSTEC)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AOS20-02] Observed long-term change and variability in the global upper-ocean stratification

*Ryohei Yamaguchi[1], Toshio Suga[1,2] (1.Graduate School of Science, Tohoku University, 2.Japan Agency for Marine-Earth Science and Technology)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AOS20-03] Estimation of changes in salinity and dissolved oxygen based on observational networks

★Invited Papers

*Shinya Kouketsu[1] (1.JAMSTEC Japan Agency for Marine-Earth Science and Technology)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AOS20-04] Remotely forced decadal physical and biogeochemical variability of North Pacific Subtropical Mode Water over the last 40 years

*Daisuke Sasano[1], Eitarou Oka[2], Yudai Yamada[2], Enyo Kazutaka[1], Toshiya Nakano[1], Masao Ishii[3] (1.Japan Meteorological Agency, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.Meteorological Research Institute)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AOS20-05] Asessing the impact of the global ocean observing system using ocean data assimilation systems

*Yosuke Fujii[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AOS20-06] **Global ocean state estimation with new float observations**

*Shuhei Masuda[1], Satoshi Osafune[1], Tadashi Hemmi[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

[A-OS20] Global ocean observing systems, obtained results and system optimization: toward OceanObs19

convener:Shigeki Hosoda(Japan Marine-Earth Science and Technology), Shuhei Masuda(Japan Agency for Marine-Earth Science and Technology), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), Fujiki Tetsuichi(Japan Agency for Marine-Earth Science and Technology)

[AOS20-P01] Fresh bias with pressure dependency at the measurements of SBE 41CP for deep float

*Taiyo Kobayashi[1] (1.Japan Agency for Marine-Earth Science and Technology)

[AOS20-P02] Long-term thermohaline variations in the North Pacific subtropical gyre observed by repeat hydrography along the 165°E meridian

*Yuma Kawakami[1,2], Yoshiteru Kitamura[1], Toshiya Nakano[1,2] (1.Japan Meteorological Agency, 2.Meteorological Research Institute)

[AOS20-P03] First detection of chlorofluorocarbons into bottom layer in the Melanesian Basin of the North Pacific

*Toshiya NAKANO[1], Kazutaka ENYO[1], Daisuke SASANO[1], Shogo URAKAWA[2], Hiroyuki TSUJINO[2], Hideyuki NAKANO[2], Masao ISHII[2] (1.Japan Meteorological Agency, 2.Meteorological Research Institute)

[AOS20-P04] **Global grid mapping of temperature and salinity based on Argo float data**

*Shigeki Hosoda[1] (1.Japan Marine-Earth Science and Technology)

[AOS20-P05] **Evolutions of water mass anomalies in the upper North Pacific based on Argo data, in STMW, ESTMW, and CMW.**

*Tong Wang[1], Toshio Suga[1,2], Shinya Kouketsu[2] (1.Graduate School of Science, Tohoku University, 2.Research and Development Center for Global Change, JAMSTEC)

[AOS20-P06] Impacts of temperature measurements from sea turtles on seasonal prediction around the Arafura Sea

*Takeshi Doi[1], Andrea Storto[2], Takuya Fukuoka[3], Hiroyuki Suganuma[4], Katsufumi Sato[3] (1.JAMSTEC, 2.CMRE, 3.The University of Tokyo, 4.ELNA)

[AOS20-P07] Physical and biogeochemical processes from winter to spring in the south of the Kuroshio Extension

*Chiho Sukigara[1], Ryuichiro Inoue[2], Takeyoshi Nagai[1], Andrea J Fassbender[3], Yuichiro Takeshita[3], Stuart P Bishop[4], Eitarou Oka[5] (1.Tokyo University of Marine Science and Technology, 2.Japan Agency for Marine-Earth Science and Technology, 3.Monterey Bay Aquarium Research Institute, 4.North Carolina State University, 5.The University of Tokyo)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

[A-OS20] Global ocean observing systems, obtained results and system optimization: toward OceanObs19

convener:Shigeki Hosoda(Japan Marine-Earth Science and Technology), Shuhei Masuda(Japan Agency for Marine-Earth Science and Technology), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), Fujiki Tetsuichi(Japan Agency for Marine-Earth Science and Technology)

[AOS20-P01] Fresh bias with pressure dependency at the measurements of SBE 41CP for deep float

*Taiyo Kobayashi[1] (1.Japan Agency for Marine-Earth Science and Technology)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 103 1F

[A-HW23] Hydrology & Water Environment

convener:Isao Machida(Geological Survey of Japan), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Takeshi Hayashi(Faculty of Education and Human Studies, Akita University), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Chairperson:Isao Machida(Geological Survey of Japan, AIST)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[AHW23-01] Method for measuring the pore air pressure in the mountainous slope for rainfall-runoff processes research

★Invited Papers

*Sho Iwagami[1], Shoji Noguchi[1], Takanori Shimizu[1], Tayoko Kubota[1], Shin'ichi Iida[1], Makoto Araki[1] (1.Forestry and Forest Products Research Institute, Forest Research and Management Organization, National Research and Development Agency)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[AHW23-02] **A method to quantify the influence of total water storage change on climate elasticity of streamflow**

*Yin Tang[1] (1.Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Science)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[AHW23-03] **Trade-off analysis of discharge-desiltation-turbidity and sediment simulation of a combined reservoir–river system under multi-phase and multi-layer conjunctive releasing operation**

*Chien-Lin Huang[1], Nien-Sheng Hsu[1], Gene Jiing-Yun You[1] (1.National Taiwan University, Taiwan)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[AHW23-04] Gradient change of soil moisture effect on next-day precipitation identified via a Random Forest-Granger causality model

*Lu Li[1], Wei ShangGuan[1], Shu Peng Zhang[1], Jin Jing Pan[1], Nan Wei[1], Yong Jiu Dai[1] (1.Guangdong Province Key Laboratory for Climate Change and Natural Disaster Studies, School of Atmospheric Sciences, Sun Yat-sen University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[AHW23-05] **Using data-driven methods to explore the predictability of surface soil moisture with FLUXNET site data**

*jinjing Pan[1] (1.Guangdong Province Key Laboratory for Climate Change and Natural Disaster Studies, School of Atmospheric Sciences, Sun Yat-sen University.)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[AHW23-23] Global Analyis of the Hydrological Sensitivity to Climate Variability

*Marisol Dominguez[1], Hugo Alberto Gutierrez-Jurado[1] (1.University of Texas at El Paso)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 103 1F

[A-HW23] Hydrology & Water Environment

convener:Isao Machida(Geological Survey of Japan), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Takeshi Hayashi(Faculty of Education and Human Studies, Akita University), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Chairperson:Megumi Watanabe

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[AHW23-06] **A review on the global soil property maps for Earth system model**

Yongjiu Dai[1], *Wei Shangguan[1], Dagang Wang[2], Nan Wei[1], Qinchuan Xin[2], Hua Yuan[1], Shupeng Zhang[1], Shaofeng Liu[1], Fapeng Yan[3], Xingji Lu[1] (1. Guangdong Province Key Laboratory for Climate Change and Natural Disaster Studies, School of Atmospheric Sciences, Sun Yat-sen University, 2.School of Geography and Planning, Sun Yat-sen University, 3.College of Global Change and Earth System Science, Beijing Normal University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AHW23-07] **Estimating near surface soil moisture at a high spatial resolution using an in-situ data based model**

*Indishe Prabath Senanayake[1], In-Young Yeo[1,2], Natthachet Tangdamrongsub[3,4], Garry R Willgoose[1], Gregory R Hancock[5], Tony Wells[1], Bin Fang[6], Venkataraman Lakshmi[6], Jeffrey P Walker[7] (1.School of Engineering, Faculty of Engineering and Built Environment, The University of Newcastle, Callaghan, NSW 2308, Australia., 2.Department of Geographical Sciences, University of Maryland, College Park, MD 20742, USA., 3.Earth System Science Interdisciplinary Center, University of Maryland, College Park, Maryland, USA., 4.Hydrological Sciences Laboratory, NASA Goddard Space Flight Center, Greenbelt, Maryland, USA., 5.School of Environmental and Life Sciences, Faculty of Science, The University of Newcastle, Callaghan, NSW 2308, Australia., 6.School of Earth Ocean and Environment, University of South Carolina, Columbia, SC 29223, United States., 7.Department of Civil Engineering, Monash University, Clayton, Victoria 3800, Australia.)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AHW23-08] Representation of dams in global flood inundation simulations by coupling the global hydrological model H08 and the global hydrodynamic model CaMa-Flood

*Julien Eric Boulange[1], Naota Hanasaki[1] (1.National Institute for Environmental Studies)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AHW23-09] An investigation into a potential long subglacial river beneath the Greenland ice sheet using SICOPOLIS simulations.

*Christopher Chambers[1], Ralf Greve[1], Bas Altena[2], Pierre-Marie Lefeuvre[2] (1.Hokkaido University, 2.University of Oslo)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AHW23-10] **Changes in Annual Rainfall patterns in the Democratic Republic of Congo: Congo river basin**

*Chetan Sharma[1], Chandra Shekhar Prasad Ojha[1] (1.Indian Institute of Technology Roorkee)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AHW23-11] Seasonality in the extreme precipitation events linked to temperature over Japan

*Sridhara Nayak[1], Tetsuya Takemi[1] (1.Disaster Prevention Research Institute, Kyoto University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CC Cryospheric Sciences & Cold District Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 201B 2F

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University), Chairperson:Ryu Uemura(University of the Ryukyus), Ikumi Oyabu(National Institute of Polar Research)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[ACC26-01] Aerosols and climate change in the Arctic in the historical experiments using the MRI Earth System Model

★Invited Papers

*Naga Oshima[1], Taichu Y Tanaka[1], Tsuyoshi Koshiro[1], Makoto Deushi[1], Takuro Aizawa[1], Masahiro Hosaka[1], Hideaki Kawai[1], Seiji Yukimoto[1], Iizuka Yoshinori[2], Kumiko Goto-Azuma[3], Teruo Aoki[4] (1.Meteorological Research Institute, 2.Institute of Low Temperature Science, Hokkaido University, 3.National Institute of Polar Research, 4.Okayama University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[ACC26-02] Particles in ice layers of SIGMA-A ice core, northwestern Greenland

*Kaoru Kawakami[1,2], Yoshinori Iizuka[2], Sumito Matoba[2], Teruo Aoki[3], Shin Sugiyama[2], Takuto Ando[4] (1.Graduate School of Environmental Science, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Graduate School of Natural Science and Technology, Okayama University, 4.Arctic Research Center, Hokkaido University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[ACC26-03] Snow modification due to climate change in southeastern high-accumulation area of Greenland over the last 60 years evaluated by physical properties of firn core.

*Takuto Ando[1], Iizuka Yoshinori[2,3], Mai Shibata[2,3], Sumito Matoba[2,3], Shin Sugiyama[2,3], Satoru Adachi[4], Satoru Yamaguchi[4], Koji Fujita[5], Akira Hori[6], Teruo Aoki[7], Shuji Fujita[8] (1.Arctic Research Center, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Graduate School of Environmental Science, Hokkaido University, 4.National Research Institute for Earth Science and Disaster Resilience, 5.Graduate School of Environmental Studies, Nagoya University, 6.Department of Civil and Environmental Engineering, Kitami Institute of Technology, 7.Graduate School of Natural Science and Technology, Okayama University, 8. National Institute of Polar Research)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[ACC26-04] **Temporal variations of concentrations, size distributions, and seasonal variations of anthropogenic and natural black carbon in Greenland**

*Kumiko Goto-Azuma[1,2], Yoshimi Ogawa-Tsukagawa[1], Yutaka Kondo[1], Remi Dallmayr[1,10], Motohiro Hirabayashi[1], Jun Ogata[1], Kyotaro Kitamura[1], Kenji Kawamura[1,2], Hideaki Motoyama[1,2], Sumito Matoba[3], Teruo Aoki[4], Nobuhiro Moteki[5], Sho Ohata[5], Tatsuhiro Mori[6], Makoto Koike[5], Yuki Komuro[7], Akane Tsushima[8,9], Naoko Nagatsuka[1], Wataru Shigeyama[1,2], Koji Fujita[9] (1.National Institute of Polar Research, 2.SOKENDAI, 3.Hokkaido University, 4.Okayama University, 5.University of Tokyo, 6.University of Science, 7.Yamagata University, 8.Research Institute for Humanity and Nature, 9.Nagoya University, 10.AWI)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[ACC26-05] Mineral composition of dust layers in a shallow ice core drilled in Pamir Alay Mountains of Central Asia

*Shunsuke Takeuchi[1], Nozomu Takeuchi[1], Koji Fujita[2], Kenji Kawamura[3], Akane Tsushima[2], Vladimir Aizen[4] (1.Chiba University, 2.Nagoya University, 3.National Institute of Polar Research, 4.Idaho University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[ACC26-06] Estimation of snow surface patterns from the coast to the inland, Dome-Fuji Station, of Antarctica, using camera images

*Konosuke Sugiura[1], Kengo Watanabe[1], Naohiko Hirasawa[2], Kenji Kawamura[2], Fumio Nakazawa[2], Hiroshi Ohno[3], Shuji Fujita[2], Ikumi Oyabu[2], Takashi Yamanouchi[2], Hideaki Motoyama[2] (1.University of Toyama, 2.National Institute of Polar Research, 3.Kitami Institute of Technology)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CC Cryospheric Sciences & Cold District Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 201B 2F

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University), Chairperson:Nozomu Takeuchi(千葉大学), Kenji Kawamura(国立極地研究所)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACC26-07] Isolation of living fungi from Antarctic ice cores

★Invited Papers

*Masaharu Tsuji[1] (1.National Institute of Polar Research)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACC26-08] **Study of ancient fungi resting in the polar ice cores and its future prospects**

*Fumio Nakazawa[1,2], Masaharu Tsuji[1], Satoshi Imura[1,2] (1.National Institute of Polar Research, 2.SOKENDAI (The Graduate University of Advanced Studies))

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACC26-09] **Flux, provenance and modification of terrestrial dust and sea salt in the Dome C and Dome Fuji ice cores from Last Glacial Maximum to early Holocene by ice-sublimation and single-particle measurement of soluble and insoluble particles**

*Ikumi Oyabu[1,2], Iizuka Yoshinori[3], Kenji Kawamura[1,4,5], Eric Wolff[6], Mirko Severi[7], Margareta Hansson[8] (1.National Institute of Polar Research, Research Organization of Information and Systems, 2.Japan Society for the Promotion of Science, 3.Institute of Low Temperature Science, Hokkaido University, 4.SOKENDAI (The Graduate University of Advanced Studies), 5.Japan Agency for Marine Science and Technology (JAMSTEC), 6.Department of Earth Sciences, University of Cambridge, 7.Department of Chemistry “Ugo Schiff”, University of Florence, 8.Department of Physical Geography, Stockholm University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACC26-10] Spatial variation of surface mass balance over the last few millennia in the Dome Fuji area from the analyses of shallow ice cores

*Kenji Kawamura[1], Ikumi Oyabu[1], Fumio Nakazawa[1,2], Shuji Fujita[1,2], Kyohei Yamada[1], Naoyuki Kurita[4], Shun Tsutaki[5], Hiroshi Ohno[6], Konosuke Sugiura[7], Kumiko Goto-Azuma[1,2], Hideaki Motoyama[1,2], Ayako Abe-Ouchi[5,3] (1.National Institute of Polar Research, Research Organization of Information and Systems, 2.SOKENDAI (The Graduate University of Advanced Studies), 3.JAMSTEC, 4.Nagoya University, 5.University of Tokyo, 6.Kitami Institute of Technology, 7.University of Toyama)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[ACC26-11] Sensitivity of global nonhydrostatic atmospheric model to changes in orbital forcing for the early Holocene

*Minoru Chikira[1], Ayako Abe-Ouchi[1], Masaki Satoh[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[ACC26-12] **Roles of sea ice–surface wind feedback in maintaining contrasting modes of glacial Atlantic meridional overturning circulation and climate**

*Sam Sherriff-Tadano[1], Ayako Abe-Ouchi[1] (1.Atmosphere and Ocean Research Institute, the University of Tokyo)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CC Cryospheric Sciences & Cold District Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 201B 2F

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University), Chairperson:Ayako Abe-Ouchi(東京大学大気海洋研究所), Sam Sherriff-Tadano(University of Tokyo)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[ACC26-13] Simulated Dansgaard-Oeschger like oscillations and abrupt climate changes

*Ayako Abe-Ouchi[1,2,3], Wing-Le Chan[1], Sam Sherriff-Tadano[1], Takashi Obase[1], Masakazu Yoshimori[1], Akira Oka[1], Kenji Kawamura[3], Rumi Ohgaito[2] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.JAMSTEC, 3.National Institute of Polar Research)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[ACC26-14] **Reproduction of the increasing amplitude and period in the glacial cycles using a model incorporating diatomaceous activity.**

*Tasuku Akagi[1], Takahiro Hasegawa[2] (1.Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 2.Graduate School of Science, Kyushu University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[ACC26-15] Development of an Ice Sheet Model coupled General Circulation Model and application of Energy Balance Model on the estimation of Ice Sheet mass balance

*Ryouta O'ishi[1], Ayako Abe-Ouchi[2,1], Fuyuki SAITO[2], Takashi Obase[1] (1.Atmosphere and Ocean Research Institute, the Universitoy of Tokyo, 2.JAMSTEC)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[ACC26-16] An ice-flow modeling study for evaluation of sites for and oldest ice core around Dome Fuji, Antarctica

★Invited Papers

*Takashi Obase[1], Ayako Abe-Ouchi[1,2], Fuyuki SAITO[2], Shun Tsutaki[1], Shuji Fujita[3], Kenny Matsuoka[4], Kenji Kawamura[3,5,2], Ralf Greve[6] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology, 3.National Institute of Polar Research, Research Organization of Information and Systems, 4.Norwegian Polar Institute, 5.SOKENDAI (The Graduate University of Advanced Studies), 6.Institute of Low Temperature Science, Hokkaido University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[ACC26-17] International studies of ice sheet and bedrock at Dome Fuji, East Antarctica

*Shuji Fujita[1,2], Kenji Kawamura[1,2,10], Prasad Gogineni[3], Ayako Abe-Ouchi[4], David Braaten[5], Jean-Charles Gallet[6], Elisabeth Isaksson[6], Brice van Liefferinge[6], Kenny Matsuoka[6], Charles O'Neill[3], John Paden[5], Fernando Rodriguez-Morales[5], Ryan A. Taylor[3], Shun Tsutaki[4], Jie-Bang Yan[3], Kumiko Goto-Azuma[1,2], Ralf Greve[7], Stephen Hudson[6], Jack Kohler[6], Shriniwas Kolpuke[3], Linfeng Li[3], Geir Moholdt[6], Hideaki Motoyama[1,2], Fumio Nakazawa[1], Takashi Obase[4], Hiroshi Ohno[8], Ikumi Oyabu[9,1], Fuyuki Saito[10], Konosuke Sugiura[11] (1.National Institute of Polar Research, Research Organization of Information and Systems(ROIS), 2.Department of Polar Science, The Graduate University for Advanced Studies (SOKENDAI), Japan, 3.The University of Alabama, USA, 4.Atmosphere and Ocean Research Institute, The University of Tokyo, Japan, 5.CReSIS, University of Kansas, USA, 6.Norwegian Polar Institute, Norway, 7.Institute of Low Temperature Science, Hokkaido University, Japan, 8.Kitami Institute of Technology, Japan, 9.JSPS, Japan, 10.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Japan, 11.University of Toyama, Japan)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[ACC26-18] Possible cause for rapid deformation of ice from glacial periods, investigated from laboratory-based deformation experiments and microstructural observations

*Tomotaka Saruya[1], Morimasa Takata[1], Tomoyuki Homma[1], Nobuhiko Azuma[1], Kumiko Goto-Azuma[2,3] (1.Nagaoka University of Technology, 2.National Institute of Polar Research, 3.SOKENDAI (The Graduate University for Advaced Research))

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CC Cryospheric Sciences & Cold District Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University)

[ACC26-P01] Pollen analysis of ice cores drilled in the Pamir-Arai Mountains, central Asia

*Haruka Ogaya[1], Nozomu Takeuchi[1], Koji Fujita[2], Kenji Kawamura[3], Akane Tsushima[4], Vladimir Aizen[5], Azamat Osmonov[6] (1.Chiba University, 2.Nagoya University, 3.National Institute of Polar Research, 4.Research Institute for Humanity and Nature, 5.University of Idaho, 6.Central Asian Institute of Applied Geo-Science)

[ACC26-P02] Variations in mineralogy of dust in the Greenland SIGMA-D ice core over the past 100 years using SEM

*Naoko Nagatsuka[1], Kumiko Goto-Azuma[1,2], Akane Tsushima, Hideaki Motoyama[1,2], Sumito Matoba[3], Koji Fujita[4], Tetsuhide Yamasaki[5], Yukihiko Onuma[6], Masahiro Minowa[7], Teruo Aoki[8], Motohiro Hirabayashi[1] (1.National Institute of Polar Research, 2.SOKENDAI, 3.Institute of Low Temperature Science, Hokkaido University, 4.Graduate School of Environmental Studies, Nagoya University, 5.Avangnaq Arctic Project Corp., 6.Institute of Industrial Science, University of Tokyo, 7.Universidad Austral de Chile, 8.Graduate School of Natural Science and Technology, Okayama University)

[ACC26-P03] Size and shape of solid particles in a Greenland ice core

*Wataru Shigeyama[1,2], Kumiko Goto-Azuma[2,1], Kaori Fukuda[2], Fumio Nakazawa[2,1], Morimasa Takata[3], Tomoyuki Homma[3], Nobuhiko Azuma[3], Dorthe Dahl-Jensen[4] (1.The Graduate University for Advanced Studies (SOKENDAI), School of Multidisciplinary Sciences, Department of Polar Science, 2.National Institute of Polar Research, 3.Nagaoka University of Technology, 4.University of Copenhagen)

[ACC26-P04] Methane concentration measurements of the Dome Fuji ice core using Continuous Flow Analysis system

Ikumi Oyabu[1], Miho Arai[1,4,5], *Kenji Kawamura[1,2,3], Kyotaro Kitamura[1], Jun Ogata[1], Kumiko Goto-Azuma[1,2] (1.National Institute of Polar Research, Research Organization of Information and Systems, 2.SOKENDAI (The Graduate University of Advanced Studies), 3.JAMSTEC, 4.Yamagata University, 5.Weathernews Inc.)

[ACC26-P05] A basal topographic map in the Dome Fuji region constructed from the ground-based radar survey in the JARE 59

*Shun Tsutaki[1], Takashi Obase[1], Shuji Fujita[2,3], Ayako Abe-Ouchi[1,4], Kenji Kawamura[2,3,4], Kenichi Matsuoka[5], Hiroshi Ohno[6], Ikumi Oyabu[2,7], Fumio Nakazawa[2], Konosuke Sugiura[8] (1.The University of Tokyo, 2.National Institute of Polar Research, 3.The Graduate University for Advanced Studies, 4.Japan Agency for Marine-Earth Science and Technology, 5.Norwegian Polar Institute, 6.Kitami Institute of Technology, 7.Japan Society for the Promotion of Science, 8.University of Toyama)

[ACC26-P06] Performance of RCIP scheme on 1-d age computation of ice sheet.

*Fuyuki SAITO[1], Takashi Obase[2], Ayako Abe-Ouchi[2,1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere and Ocean Research Institute, University of Tokyo)

[ACC26-P07] Climate changes of the last deglaciation simulated by MIROC AOGCM

*Takashi Obase[1], Ayako Abe-Ouchi[1,2], Sam Sherriff-Tadano[1] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology)

[ACC26-P08] A Last Glacial Maximum experiment using MIROC-ES2L earth system model in comparison with ice core and the other paleo-proxy data

*Rumi Ohgaito[1], Tomohiro Hajima[1], Akitomo Yamamoto[1], Hiroaki Tatebe[1], Michio Kawamiya[1], Ayako Abe-Ouchi[2,1] (1.Japan Agency for Marine-Earth Science and Technology, 2.AORI, Univ. Tokyo)

[ACC26-P09] On the possible bifurcation mechanisms and associated dynamical properties of Dansgaard-Oeschger oscillations

*Takahito Mitsui[1], Ayako Abe-Ouchi[1], Wing-Le Chan[1], Sam Sherriff-Tadano[1] (1.The University of Tokyo)

[ACC26-P10] The role of climate-vegetation feedback in climate changes driven by orbital parameter changes: the Arctic land surfaces and seasonality

*Kanon Kino[1], Ayako Abe-Ouchi[1,2], Ryouta O'ishi[1], Fuyuki SAITO[2], Masakazu Yoshimori[1] (1.Atmosphere and Ocean Research Institute, the University of Tokyo, 2.Japan Agency for Marine-Earth Science and Technology)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CC Cryospheric Sciences & Cold District Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 202 2F

[A-GE30] Conservation and Restoration of Soil Environment at Terrestrial Surface

convener:Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University), Chairperson:Yasushi Mori(Okayama University)

1:50 PM - 2:05 PM JST | 4:50 AM - 5:05 AM UTC

[AGE30-01] Soil Organic Cabon Contents Estimation using Neural Network System

Ikumi Kaida[1], *Yasushi Mori[1], Takayuki Shuku[1] (1.Graduate School of Environmental and Life Science, Okayama University)

2:05 PM - 2:25 PM JST | 5:05 AM - 5:25 AM UTC

[AGE30-02] Methane emission from rice paddies and its response to climate change

★Invited Papers

*Takeshi Tokida[1] (1.Institute for Agro-Environmental Sciences, National Agriculture and Food Research Organization)

2:25 PM - 2:40 PM JST | 5:25 AM - 5:40 AM UTC

[AGE30-03] **Relationship between degradation of rice grain quality due to chalky kernels and available nutrients in soil**

*Shingo Matsumoto[1], Junko Kasuga[1] (1.Shimane University)

2:40 PM - 2:55 PM JST | 5:40 AM - 5:55 AM UTC

[AGE30-04] The effects of trenching and insertion of crop residue on infiltration and soil erosion in a farmland

*Kazutoshi Osawa[1], Yasushi Mori[2], Akira Hoshikawa (1.Utsunomiya University, 2.Graduate school of Environmental and Life Science, Okayama University)

2:55 PM - 3:15 PM JST | 5:55 AM - 6:15 AM UTC

[AGE30-05] Measuring wide-range soil water content using GPS signals

★Invited Papers

*Kosuke Noborio[1], Natsumi Naganuma[1] (1.Meiji University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[A-GE30] Conservation and Restoration of Soil Environment at Terrestrial Surface

convener:Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University)

[AGE30-P01] Analysis of soil erosion on cropland considering future climate change in Okinawa

*Gen Machida[1], Kazutoshi Osawa[1], Hiroyuki Matsui[1] (1.Utsunomiya University)

[AGE30-P02] Linear Macro pore Installation to Reduce Surface Flow

*Masaki Kiyohiro[1], Yasushi Mori[1], Kazutoshi Osawa[2], Akira Hosihkawa[3] (1.Okayama University Graduate school of Environmental and Life Science, 2.Utsunomiya University Faculty of Agriculture, 3.Fund of Coral reef in Sekisei Lagoon)

[AGE30-P03] Conservation of the Rice Terraces of the Philippine Cordilleras Based on the Soil Environmental Factors.

*Tomoyo Kurozumi[1], Yasushi Mori[2], Hiroaki Somura[2], Milagros Ong How[3] (1.Faculty of Environmental Science and Technology, Okayama University, 2.Graduate School of Environmental and Life Science, Okayama University, 3.Universal Harvester Incorporated)

[AGE30-P04] A preliminary study for water and substances simulation modeling in Cordilleras terraced paddy fields, Philippines

*Hiroaki Somura[1], Yasushi Mori[1], Tomoyo Kurozumi[2], Milagros Ong How[3] (1.Graduate School of Environmental and Life Science, Okayama University, 2.Faculty of Environmental Science and Technology, Okayama University, 3.Universal Harvester Incorporated)

*Hiroaki Somura[1], Yasushi Mori[1], Tomoyo Kurozumi[2], Milagros Ong How[3] (1.Graduate School of Environmental and Life Science, Okayama University, 2.Faculty of Environmental Science and Technology, Okayama University, 3.Universal Harvester Incorporated)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 202 2F

[A-GE31] New Roles of Soil Science for Extraterrestrials

convener:Kosuke Noborio(Meiji University), Masaru Mizoguchi(Graduate school of Agricultural and Life Sciences, The University of Tokyo), Chairperson:Naoto Sato

3:30 PM - 4:00 PM JST | 6:30 AM - 7:00 AM UTC

[AGE31-01] Life search on Mars by Life Detection Microscope (LDM)

★Invited Papers

*Yoshitaka Yoshimura[1] (1.College of Agriculture, Tamagawa University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AGE31-02] **Moisture movement in sand during evaporation under reduced pressure**

*Masaru Mizoguchi[1] (1.Graduate school of Agricultural and Life Sciences, The University of Tokyo)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AGE31-03] Gravity effects on liquid behavior in porous media of uniform glass beads.

*Naoto Sato[1], Natsumi Naganuma[2], Kento Nogawa[2], Yuichi Maruo[2], Kosuke Noborio[1] (1.School of Agriculture, Meiji University, 2.Graduate School of Agriculture, Meiji University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AGE31-04] Effects of changes in viscosity under low gravity on infiltration rate

*Kento Nogawa[1], Naoto Sato[2], Yuichi Maruo[1], Natsumi Naganuma[1], Kosuke Noborio[2] (1.Graduate School of Agriculture, Meiji University, 2.School of Agriculture, Meiji University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AGE31-05] Differences in infiltration process on the planets under different gravity.

*Yasushi Mori[1] (1.Graduate School of Environmental and Life Science, Okayama University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[A-GE31] New Roles of Soil Science for Extraterrestrials

convener:Kosuke Noborio(Meiji University), Masaru Mizoguchi(Graduate school of Agricultural and Life Sciences, The University of Tokyo)

[AGE31-P01] Roles of soil science in ectraterestrial space

*Kosuke Noborio[1] (1.Meiji University)

[AGE31-P02] **Characterization of Soil Organic Matter using Fourier Transform Infrared Spectrometer**

*Iwasaki Masayoshi[1], Yasushi Mori[1] (1.okayama university graduate school environmental and life science)

[AGE31-P03] The slowing down of water movement in capillary tubes under microgravity.

*Yuichi Maruo[1], Naoto Sato[1], Natsumi Naganuma[1], Kento Nogawa[1], Kosuke Noborio[2] (1.Graduate school of Agriculture, Meiji University, 2.Meiji University)

[AGE31-P04] Challenges to measuring of the contact angle and the surface tension of water under reduced gravity

*Natsumi Naganuma[1], Naoto Sato[1], Kento Nogawa[1], Yuichi Maruo[1], Kosuke Noborio[2] (1.Graduate School of Agriculture, Meiji University, 2.School of Agriculture, Meiji University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_12

[A-GE31] New Roles of Soil Science for Extraterrestrials

convener:Kosuke Noborio(Meiji University), Masaru Mizoguchi(Graduate school of Agricultural and Life Sciences, The University of Tokyo)

[AGE31-P01] Roles of soil science in ectraterestrial space

*Kosuke Noborio[1] (1.Meiji University)

[AGE31-P02] **Characterization of Soil Organic Matter using Fourier Transform Infrared Spectrometer**

*Iwasaki Masayoshi[1], Yasushi Mori[1] (1.okayama university graduate school environmental and life science)

[AGE31-P03] The slowing down of water movement in capillary tubes under microgravity.

*Yuichi Maruo[1], Naoto Sato[1], Natsumi Naganuma[1], Kento Nogawa[1], Kosuke Noborio[2] (1.Graduate school of Agriculture, Meiji University, 2.Meiji University)

[AGE31-P04] Challenges to measuring of the contact angle and the surface tension of water under reduced gravity

*Natsumi Naganuma[1], Naoto Sato[1], Kento Nogawa[1], Yuichi Maruo[1], Kosuke Noborio[2] (1.Graduate School of Agriculture, Meiji University, 2.School of Agriculture, Meiji University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[A-CG32] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies)

[ACG32-P01] Regional budgets of 3 major greenhouse gases using inverse modelling of atmospheric data

*Prabir Patra[1], Naveen Chandra[1], Jagat Bisht[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

[ACG32-P02] Analysis of hot summer in 2018

*Kazutaka Murakami[1], Kazuhito Ichii[1,2], Yukio Yoshida[1], Haruki Oshio[1], Makoto Saito[1] (1.National Institute for Environmental Studies, 2.Chiba University)

[ACG32-P03] Updated Data-Driven GPP and NEE Estimation Using Machine Learning Algorithms with Remote Sensing and Flux Data

*Zhiyan Liu[1], Kazuhito Ichii[1], Yusuke Hayasi[1], Riku Kawase[1], Masahito Ueyama[2], Yuji Kominami[3] (1.Chiba University, 2.Osaka Prefecture University, 3.Forest Research and Management Organization)

[ACG32-P04] **Response of a Bornean Rainforest to the Climatic Changes imposed by ENSO during 2009-2016**

*Julie Karine Michelon[1], Tomo'omi Kumagai[2,3], Tetsuya Hiyama[3], Hatsuki Fujinami[3], Kazuho Matsumoto[4], Tomonori Kume[5], Takami Saito[6] (1.Graduate School of Environmental Studies, Nagoya University, 2.Graduate School of Agricultural and Life Sciences, The University of Tokyo, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Faculty of Agriculture, University of the Ryukyus, 5.Faculty of Agriculture, Kyushu University, 6.Forest Research and Management Organization)

[ACG32-P05] **Monitoring and Evaluating CO2 Flux in the Grassland Areas of Mongolia**

*Qinxue Wang[1], Tomohiro Okadera[1], Deni Eer[1], Masataka Watanabe[2], Tomohiro Shishime[2], Akihiro Oba[2], Ochirbat Batkhishig[3] (1.National Institute for Environmental Studies, 2.Research and Development Initiative, Chuo University, 3.Institute of Geography and Geoecology, Mongolian Academy of Sciences)

[ACG32-P06] Data-driven monitoring of terrestrial carbon cycle in Mongolia

*ZAYA MART[1], Zhiyan Liu[1], Riku Kawase[1], Kazuhito Ichii[1] (1.Chiba University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_13

[A-CG32] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies)

[ACG32-P01] Regional budgets of 3 major greenhouse gases using inverse modelling of atmospheric data

*Prabir Patra[1], Naveen Chandra[1], Jagat Bisht[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

[ACG32-P02] Analysis of hot summer in 2018

*Kazutaka Murakami[1], Kazuhito Ichii[1,2], Yukio Yoshida[1], Haruki Oshio[1], Makoto Saito[1] (1.National Institute for Environmental Studies, 2.Chiba University)

[ACG32-P03] Updated Data-Driven GPP and NEE Estimation Using Machine Learning Algorithms with Remote Sensing and Flux Data

*Zhiyan Liu[1], Kazuhito Ichii[1], Yusuke Hayasi[1], Riku Kawase[1], Masahito Ueyama[2], Yuji Kominami[3] (1.Chiba University, 2.Osaka Prefecture University, 3.Forest Research and Management Organization)

[ACG32-P04] **Response of a Bornean Rainforest to the Climatic Changes imposed by ENSO during 2009-2016**

*Julie Karine Michelon[1], Tomo'omi Kumagai[2,3], Tetsuya Hiyama[3], Hatsuki Fujinami[3], Kazuho Matsumoto[4], Tomonori Kume[5], Takami Saito[6] (1.Graduate School of Environmental Studies, Nagoya University, 2.Graduate School of Agricultural and Life Sciences, The University of Tokyo, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Faculty of Agriculture, University of the Ryukyus, 5.Faculty of Agriculture, Kyushu University, 6.Forest Research and Management Organization)

[ACG32-P05] **Monitoring and Evaluating CO2 Flux in the Grassland Areas of Mongolia**

*Qinxue Wang[1], Tomohiro Okadera[1], Deni Eer[1], Masataka Watanabe[2], Tomohiro Shishime[2], Akihiro Oba[2], Ochirbat Batkhishig[3] (1.National Institute for Environmental Studies, 2.Research and Development Initiative, Chuo University, 3.Institute of Geography and Geoecology, Mongolian Academy of Sciences)

[ACG32-P06] Data-driven monitoring of terrestrial carbon cycle in Mongolia

*ZAYA MART[1], Zhiyan Liu[1], Riku Kawase[1], Kazuhito Ichii[1] (1.Chiba University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 301A 3F

[A-CG32] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies), Chairperson:Kazuhito Ichii

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[ACG32-01] A high-resolution fossil fuel CO2 emission gridded dataset for tracer transport simulations and flux inversions: An overview, evaluations, applications and future perspectives

★Invited Papers

*Tomohiro Oda[1,2], Shamil Maksyutov [3], Miguel O. Roman [2,4], Zhousen Wang [4], Thomas Lauvaux[6,5], Sha Feng [5], Rostyslav Bun [7,8], James Wang [2,1], Randy Kawa [1], Lesley Ott[1], Steven Pawson[1] (1.NASA Goddard Space Flight Center, Greenbelt, MD, USA , 2.Universities Space Research Association, Columbia, MD, USA , 3.Center for Global Environmental Research, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan , 4.Terrestrial Information Systems Laboratory, NASA Goddard Space Flight Center, Greenbelt, MD, USA , 5.Department of Meteorology and Atmospheric Science, Penn. State University, State College, PA, USA , 6.Laboratoire des sciences du climat et de l'environnement, Gif sur Yvette, France, 7.Lviv Polytechnic National University, Lviv, Ukraine , 8.University of Dąbrowa Górnicza, Górnicza, Poland)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[ACG32-02] **Towards Decreasing the Uncertainty in Global Carbon Dioxide Emission Inventory**

*Richao Cong[1], Makoto Saito[1], Ryuichi Hirata[1], Akihiko Ito[1] (1.Center for Global Environmental Research, National Institute for Environmental Studies)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[ACG32-03] Evaluation of MIROC4-ACTM reanalysis of GHGs concentrations using aircraft

*Jagat Bisht[1], Prabir Patra[1], Naveen Chandra[1], Sergey Gromov[2], Taku Umezawa[3], Andreas Zahn[4], cARL A. M. Brenninkmeijer[5] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Yokohama, Japan, 2.Max Planck Institute for Chemistry, Mainz, Germany, 3.National Institute for Environmental Studies, Tsukuba, Japan, 4.Karlsruhe Institute of Technology (KIT), Institute for Meteorology and Climate Research, Karlsruhe, Germany, 5.Max Planck Institute for Chemistry, Air Chemistry Division, Mainz, Germany)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[ACG32-04] **Carbon flux estimation using NICAM-TM 4D-Var and GOSAT data towards GOSAT-2 Level 4 product**

*Tazu Saeki[1], Yosuke Niwa[1], Makoto Saito[1] (1.National Institute for Environmental Studies)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[ACG32-05] **Attribution of the ambiguity in methane's growth rate shifts during 1988-2016.**

*Naveen Chandra[1], Prabir Patra[1] (1.Japan Agency for Marine Earth Science and Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[ACG32-06] **Ocean uptake and land use change emissions suppressed atmospheric CO_2 growth in the 2015/16 El Niño**

*Masayuki Kondo[1], Peter Landschützer[2], Yousuke Iida[3], Richard Houghton[4], Stephen Sitch[5] (1. Center for Environmental Remote Sensing, Chiba University, 2.Max Planck Institute for Meteorology, 3.Global Environment and Marine Department, Japan Meteorological Agency, 4.Woods Hole Research Center, 5.University of Exeter)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 301A 3F

[A-CG32] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies), Chairperson:Prabir Patra

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[ACG32-07] Observing vegetation seasonal dynamics in Japan with Himawari-8 hypertemporal data

*Tomoaki Miura[1,2], Shin Nagai[2], Kazuhito Ichii[3], Hiroki Yoshioka[4] (1.University of Hawaii at Manoa, 2.Japan Agency for Marine-Earth Science and Technology, 3.Center for Environmental Remote Sensing, Chiba University, 4.Aichi Prefectural University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[ACG32-08] Carbon and Water Fluxes at High spatial Resolutions through Down-Scaling

*Jiquan Chen[1], Pietro Sciusco[1], Ranjeet John[1], Zutao Ouyang[1] (1.Michigan State University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[ACG32-09] **Connecting Satellite Based Spectral Modelling Approach and Forest Inventory to Model Biomass and Carbon Stocks in Natural and Planted Forest over part of Semi-arid zone, India**

*SWATI UNIYAL[1], Siti Raju Rao (1.Andhra University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[ACG32-10] **Allocation of forest net primary production varies by forest age and air temperature**

*Xiang Song[1], Xiaodong Zeng[1], Dongxiao Tian[2] (1.IAP, CAS, 2.Beijing Meteorological Information Center)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[ACG32-11] Analyzing Model Biases in Terrestrial Carbon Cycle Submodels in Earth System Models and Offline Models

*Kazuhito Ichii[1], Kazutaka Murakami[2], Hiroaki Takayama[3], Tomohiro Hajima[3], Kaoru Tachiiri[3] (1.Chiba University, 2.National Institute for Environmental Studies, 3.Japan Agency for Marine-Earth Science and Technology)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[ACG32-12] Assessing terrestrial biogeochemical feedbacks in a strategically geoengineered climate

*Forrest M. Hoffman[1,2], Cheng-En Yang[2,1], Joshua S. Fu[2,1], Simone Tilmes[3], Lili Xia[4], Douglas G. MacMartin[5], Jadwiga H. Richter[3], Michael Mills[3], Ben Kravitz[6] (1.Oak Ridge National Laboratory, 2.University of Tennessee, 3.National Center for Atmospheric Research, 4.Rutgers University, 5.Cornell University, 6.Pacific Northwest National Laboratory)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 104 1F

[A-CG38] Multi-scale ocean-atmosphere interaction in the tropical Indo-Pacific region

convener:Ayako Seiki(Japan Agency for Marine-Earth Science and Technology), Tomoki Tozuka(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Motoki Nagura(Japan Agency for Marine-Earth Science and Technology), Youichi Kamae(Faculty of Life and Environmental Sciences, University of Tsukuba), Chairperson:Ayako Seiki(Japan Agency for Marine-Earth Science and Technology), Motoki Nagura(Japan Agency for Marine-Earth Science and Technology)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[ACG38-01] Various aspects of climate system variability associated with ENSO

★Invited Papers

*Shuhei Maeda[1] (1.Climate Prediction Division, Japan Meteorological Agency)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[ACG38-02] Influence and mechanism of the tropical Pacific variability on the Arctic and its seasonality

*Tsubasa Takigawa[1], Yu Kosaka[1], Bunmei Taguchi[1], Lea Svendsen[2] (1.Research Center for Advanced Science and Technology, University of Tokyo, 2.Bjerknes Centre for Climate Research, University of Bergen)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[ACG38-03] Subsurface nonlinear dynamical heating and ENSO asymmetry in CMIP5: Implications for anthropogenic tropical-warming uncertainties

★Invited Papers

*Michiya Hayashi[1], Fei-Fei Jin[1] (1.Department of Atmospheric Sciences, University of Hawaii at Manoa)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[ACG38-04] **Uncertainty in the projections of ENSO amplitude change under global warming: Role of the response of atmospheric circulation to SST anomalies**

*Jun Ying[1] (1.Second institute of Oceanography, Ministry of Natural Resources)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[ACG38-05] Impact of atmospheric variability on Indian Ocean Dipole mode

*Yuya Baba[1] (1.JAMSTEC Japan Agency for Marine-Earth Science and Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[ACG38-06] Do salinity anomalies matter for the evolution of the IOD? –Experimental assessments using a regional ocean model-

*Shoichiro Kido[1], Tomoki Tozuka[1], Weiqing Han[2] (1.Graduate School of Science, The University of Tokyo, 2.Department of Atmospheric and Oceanic Sciences, University of Colorado Boulder)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 104 1F

[A-CG38] Multi-scale ocean-atmosphere interaction in the tropical Indo-Pacific region

convener:Ayako Seiki(Japan Agency for Marine-Earth Science and Technology), Tomoki Tozuka(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Motoki Nagura(Japan Agency for Marine-Earth Science and Technology), Youichi Kamae(Faculty of Life and Environmental Sciences, University of Tsukuba), Chairperson:Tomoki Tozuka(The University of Tokyo), Youichi Kamae(University of Tsukuba)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACG38-07] Mechanisms of future changes in equatorial upwelling: CMIP5 inter-model analysis

★Invited Papers

*Shoshiro Minobe[1,2], Mio Terada[2], Curtis Deutsch[3] (1.Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 2.Graduate School of Science, Hokkaido University, 3.School of Oceanography, University of Washington)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACG38-08] The Indo-Pacific cross-basin interaction of the decadal climate variability under the progress of the global warming

*Yuma Miyaji[1], Youichi Tanimoto[2] (1.Hokkaido University, Graduate School of Environmental Science, 2.Hokkaido University, Faculty of Environmental Earth Science)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACG38-09] Air-sea flux observation by unmanned autonomous sea surface vehicle in the Tropics - Application of the Wave Glider -

★Invited Papers

*Iwao Ueki[1] (1.JAMSTEC Japan Agency for Marine-Earth Science and Technology)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACG38-10] **Radar-derived Fresh water flux and its possible impact to the oceanic stratification observed during the Years of the Maritime Continent (YMC)**

*Masaki Katsumata[1], Biao Geng[1], Satoru Yokoi[1], Shuichi Mori[1], Iwao Ueki[1] (1.Japan Agency for Marine-Earth Science and Technology)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[ACG38-11] **Driving Mechanism of Inter-Annual Precipitation Variability during Monsoon Season over the Northern Part of Sumatra Island, Indonesia**

*Yahya Darmawan[1,2,3], Huang-Hsiung Hsu[2] (1.Taiwan International Graduation Program, Academia Sinica, 2.Research Center for Environmental Changes, Academia Sinica, 3.Indonesian Agency for Meteorology, Climatology and Geophysics (BMKG))

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[ACG38-12] The impact of diurnal precipitation over the maritime continent on synoptic disturbances and its relation to the MJO

*Ayako Seiki[1], Satoru Yokoi[1], Masaki Katsumata[1], Kunio Yoneyama[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

[A-CG38] Multi-scale ocean-atmosphere interaction in the tropical Indo-Pacific region

convener:Ayako Seiki(Japan Agency for Marine-Earth Science and Technology), Tomoki Tozuka(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Motoki Nagura(Japan Agency for Marine-Earth Science and Technology), Youichi Kamae(Faculty of Life and Environmental Sciences, University of Tsukuba)

[ACG38-P01] Impacts of seasonal transitions of ENSO on frequency of atmospheric rivers over East Asia

*Youichi Kamae[1], Moeka Naoi[2], Hiroaki Ueda[1] (1.Faculty of Life and Environmental Sciences, University of Tsukuba, 2.Graduate School of Life and Environmental Sciences, University of Tsukuba)

[ACG38-P02] Impact of tropical Pacific sea surface temperature on the regional heavy rainfall events in Japan

*Yukiko Imada[1], Hiroaki Kawase[1], Masahiro Watanabe[2], Izuru Takayabu[1] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

[ACG38-P03] The North Pacific pacemaker effect on historical ENSO and its mechanisms

*Yu Kosaka[1], Dillon J. Amaya[2], Wenyu Zhou[2], Yu Zhang[2], Shang-Ping Xie[2], Arthur J. Miller[2] (1.Research Center for Advanced Science and Technology, University of Tokyo, 2.Scripps Institution of Oceanography, University of California San Diego)

[ACG38-P04] **Detection of the dry intrusions from the mid-latitudes to the Equator and their association with MJO**

*Saki Yanagisawa[1], Akiyo Yatagai[1] (1.Hirosaki Univercity)

[ACG38-P05] **Relationship between oceanic and atmospheric variations in the Philippine Sea and modulation of El Nino events**

*Takuya Hasegawa[1], Akira Nagano[2], Iwao Ueki[2], Kentaro Ando[2] (1.Tohoku University, 2.JAMSTEC)

[ACG38-P06] Contribution of oceanic wave propagation from the tropical Pacific to asymmetry of the Ningaloo Nino/Nina

*Hidehiro Kusunoki[1], Shoichiro Kido[1], Tomoki Tozuka[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

[ACG38-P07] The life-cycle of annual waves in the Indian Ocean as identified by a seamless diagnosis for the energy flux

*Zimeng Li[1], Hidenori Aiki[2] (1.Graduate school of environmental studies, Nagoya university, 2.Institute for space-earth environmental research, Nagoya university)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_14

[A-CG38] Multi-scale ocean-atmosphere interaction in the tropical Indo-Pacific region

convener:Ayako Seiki(Japan Agency for Marine-Earth Science and Technology), Tomoki Tozuka(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Motoki Nagura(Japan Agency for Marine-Earth Science and Technology), Youichi Kamae(Faculty of Life and Environmental Sciences, University of Tsukuba)

[ACG38-P01] Impacts of seasonal transitions of ENSO on frequency of atmospheric rivers over East Asia

*Youichi Kamae[1], Moeka Naoi[2], Hiroaki Ueda[1] (1.Faculty of Life and Environmental Sciences, University of Tsukuba, 2.Graduate School of Life and Environmental Sciences, University of Tsukuba)

[ACG38-P02] Impact of tropical Pacific sea surface temperature on the regional heavy rainfall events in Japan

*Yukiko Imada[1], Hiroaki Kawase[1], Masahiro Watanabe[2], Izuru Takayabu[1] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

[ACG38-P03] The North Pacific pacemaker effect on historical ENSO and its mechanisms

*Yu Kosaka[1], Dillon J. Amaya[2], Wenyu Zhou[2], Yu Zhang[2], Shang-Ping Xie[2], Arthur J. Miller[2] (1.Research Center for Advanced Science and Technology, University of Tokyo, 2.Scripps Institution of Oceanography, University of California San Diego)

[ACG38-P04] **Detection of the dry intrusions from the mid-latitudes to the Equator and their association with MJO**

*Saki Yanagisawa[1], Akiyo Yatagai[1] (1.Hirosaki Univercity)

[ACG38-P05] **Relationship between oceanic and atmospheric variations in the Philippine Sea and modulation of El Nino events**

*Takuya Hasegawa[1], Akira Nagano[2], Iwao Ueki[2], Kentaro Ando[2] (1.Tohoku University, 2.JAMSTEC)

*Hidehiro Kusunoki[1], Shoichiro Kido[1], Tomoki Tozuka[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

[ACG38-P07] The life-cycle of annual waves in the Indian Ocean as identified by a seamless diagnosis for the energy flux

*Zimeng Li[1], Hidenori Aiki[2] (1.Graduate school of environmental studies, Nagoya university, 2.Institute for space-earth environmental research, Nagoya university)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 301A 3F

[A-CG39] Biogeochemical cycles in Land Ecosystem

convener:Tomomichi Kato(Research Faculty of Agriculture, Hokkaido University), Kazuhito Ichii(Chiba University), Takeshi Ise(FSERC, Kyoto University), Munemasa Teramoto(National Institute for Environmental Studies), Chairperson:Tomomichi Kato(Hokkaido University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[ACG39-01] Laboratory examination of combined effects of temperature rising and increased water fluctuation on CO_2 release from volcanic ash soils

*Hirohiko Nagano[1], Mariko Atarashi-Andoh[1], Jun Koarashi[1] (1.Japan Atomic Energy Agency)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[ACG39-02] Field observation of GHGs emission from pome palm oil mill effluent (POME) treatment ponds in an oil palm plantation in tropical peatland.

*Yoshiyuki Takahashi[1], Takashi Onodera[2], Ryuichi Hirata[1], Kazuya Nishina[2], Joseph Wenceslaus Waili[3], Kevin Kemudang Musin[3], Edward Baran Aeries[3], Frankie Kiew[3], Guan Xhuan Wong[3], Zufaqar Sa'adi[3], Lulie Melling[3] (1.Center for Global Environmental Research, National Institute for Environmental Studies, 2.Center for Regional Environmental Research, National Institute for Environmental Studies, 3.Sarawak Tropical Peat Research Institute)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[ACG39-03] Soil CO_2 efflux dynamics with land-use changes in Southeast Asia

*HAJIME TOMIMATSU[1], NAISHEN LIANG[1], MUNEMASA TERAMOTO[1], JIYE ZENG[1], ZHAO XIN[1] (1.National Institute for Environmental Studies)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[ACG39-04] Individual-based analyses of the carry-over effects from recent climatic conditions on the interannual variability of LAI of an evergreen conifer stand

*Akihiro Sumida[1], Tsutomu Watanabe[1], Tomiyasu Miyaura[2] (1.Institute of Low Temperature Science, Hokkaido University, 2.Faculty of Science and Technology, Ryukoku University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[ACG39-05] Carbon dioxide balance of an oil palm plantation on tropical peat

*Takashi Hirano[1], Frankie Kiew[2], Ryuichi Hirata[3], Guan Xhuan Wong[2], Edward Baran Aries[2], Kevin Kemudang[2], Joseph Wenceslaus[2], Lo Kim San[2], Lulie Melling[2] (1.Research Faculty of Agriculture, Hokkaido University, 2.Sarawak Tropical Peat Research Institute, 3.CGER, National Institute for Environmental Studies)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[ACG39-06] The effect of heat wave in the summer of 2018 on carbon and water fluxes in an open black spruce forest in an interior Alaska

*Hideki Kobayashi[1], Robert Busey[2], Yongwon Kim[2], Sigrid Dengel[3], Stephen Chan[3] (1.Japan Agency for Marine-Earch Science and Technology, 2.International Arctic Research Center, University of Alaska, Fairbanks, 3.Lawrence Berkeley National Laboratory)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 301A 3F

[A-CG39] Biogeochemical cycles in Land Ecosystem

convener:Tomomichi Kato(Research Faculty of Agriculture, Hokkaido University), Kazuhito Ichii(Chiba University), Takeshi Ise(FSERC, Kyoto University), Munemasa Teramoto(National Institute for Environmental Studies), Chairperson:Tomomichi Kato(Hokkaido University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACG39-07] Evaluation of feasibility of continental vegetation monitoring using Himawari-8.

*Kodai Hayashi[1], Kazuhito Ichii[1], Hiroki Yoshioka[2], Kazutaka Murakami[3], Reiko Ide[3], Kenlo Nasahara[4], Tomoko Akitsu[4], Tomoaki Miura[5] (1.Chiba Univ., 2.Aichi Prefectural Univ., 3.NIES, 4.Tsukuba Univ., 5.Univ. Hawaii)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACG39-08] Estimation of global carbon dioxide emissions by fires

*Tomohiro Shiraishi[1], Ryuichi Hirata[1] (1.National Institute for Environmental Studies)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACG39-09] Interactions between topography, permafrost, and vegetation in Siberian larch forest: a simulation study

*Hisashi Sato[1] (1.Institute of Arctic Climate and Environment Research, Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACG39-10] Data assimilation experiments with MODIS LAI observation and the dynamic global vegetation model SEIB-DGVM in Japan

*Hazuki Arakida[1], Shunji Kotsuki[1], Shigenori Otsuka[1], Takemasa Miyoshi[1] (1.RIKEN Center for Computational Science)

11:45 AM - 12:15 PM JST | 2:45 AM - 3:15 AM UTC

[ACG39-11] Studying ecosystem dynamics with deep neural networks

★Invited Papers

*Takeshi Ise[1], Masanori Onishi[2] (1.FSERC, Kyoto University, 2.Grad. School of Agriculture, Kyoto University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[A-CG39] Biogeochemical cycles in Land Ecosystem

convener:Tomomichi Kato(Research Faculty of Agriculture, Hokkaido University), Kazuhito Ichii(Chiba University), Takeshi Ise(FSERC, Kyoto University), Munemasa Teramoto(National Institute for Environmental Studies)

[ACG39-P01] Long-term warming effect on heterotrophic respiration in a beech forest on Mount Naeba

*Munemasa Teramoto[1], Naishen Liang[1], Masaaki Naramoto[2], Jiye Zeng[1], Zhao Xin[1], Hajime Tomimastu[1] (1.Center for Global Environmental Research, National Institute for Environmental Studies, 2.Faculty of Agriculture, Shizuoka University)

[ACG39-P02] Simple approach to predict flowering and full blooming dates by bi-directional Self Organizing Maps

*Shin Nagai[1], Hiroshi Morimoto[2], Taku M Saitoh[3] (1.Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology, 2.Nagoya University, 3.River Basin Research Center, Gifu University)

[ACG39-P03] Effects of undergrowth mowing on understory carbon balance in a deciduous broadleaf forest of an urban park in central Japan

Guochao Wang[2], *Tomotsugu Yazaki[1], Toshio Kume[1], Takamitsu Kai[3] (1.School of Agriculture, Meiji University, 2.Graduate School of Agriculture, Meiji University, 3.Kurokawa Field Science Center, Meiji University)

[ACG39-P04] Solar-induced chlorophyll fluorescence for detecting ecosystem photosynthetic activity by high-resolution spectrum measurement in a paddy field in Japan

*KANOKRAT BUAREAL[1], Tomomichi Kato[2], Keisuke Ono[3] (1.Graduate School of Global Food Resources, Hokkaido University, Sapporo, Japan, 2.Research Faculty of Agriculture, Hokkaido University, Sapporo, Japan, 3.National Institute for Agro-Environmental Sciences, Tsukuba, Ibaraki, Japan)

[ACG39-P05] Environmental controls on anomalous variation in solar-induced fluorescence during the last 10 years

*Tomomichi Kato[1], Kazuki Mizuno[2] (1.Research Faculty of Agriculture, Hokkaido University, 2.Graduate School of Agriculture, Hokkaido University)

[ACG39-P06] Estimation of terrestrial carbon cycle in Asia using a machine learning and satellite data

*Riku Kawase[1], Kazuhito Ichii[2], Yusuke hayashi[1], Zhiyan Liu[1], Masahito Ueyama[3], Yuji Kominami[4] (1.Chiba University, 2.Center for Environmental Remote Sensing, Chiba University, 3.Osaka Prefecture University, 4.Forest Research and Management Organization)

[ACG39-P07] Estimation of global solar-induced chlorophyll fluorescence (SIF) by terrestrial ecosystem model VISIT and comparison with SIF observed by GOSAT

*Tatsuya Miyauchi[1], Makoto Saito[1], Hibiki M Noda[1], Yukio Yoshida[1], Haruki Oshio[1], Akihiko Ito[1] (1.National Institute for Environmental Studies)

[ACG39-P08] Automatic vegetation identification in the satellite image using a convolutional neural network

*Watanabe Shuntaro[1], Kazuaki Sumi[2], Takeshi Ise[1,3] (1.Field Science Education and Research Center, Kyoto University, 2.Graduate School of Agriculture, Kyoto University, 3.PRESTO, Japan Science and Technology Agency)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_15

[A-CG39] Biogeochemical cycles in Land Ecosystem

convener:Tomomichi Kato(Research Faculty of Agriculture, Hokkaido University), Kazuhito Ichii(Chiba University), Takeshi Ise(FSERC, Kyoto University), Munemasa Teramoto(National Institute for Environmental Studies)

[ACG39-P01] Long-term warming effect on heterotrophic respiration in a beech forest on Mount Naeba

*Watanabe Shuntaro[1], Kazuaki Sumi[2], Takeshi Ise[1,3] (1.Field Science Education and Research Center, Kyoto University, 2.Graduate School of Agriculture, Kyoto University, 3.PRESTO, Japan Science and Technology Agency)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 102 1F

[A-CG40] Coastal Ecosystems - 1. Water Cycle and Land-Ocean Interactions

convener:Masahiko Fujii(Faculty of Environmental Earth Science), Makoto Yamada(Faculty of Economics, Ryukoku University), Jun Shoji(The University of Tokyo), Ryo Sugimoto(Faculty of Marine Biosciences, Fukui Prefectural University), Chairperson:Masahiko Fujii, Makoto Yamada

9:05 AM - 9:20 AM JST | 12:05 AM - 12:20 AM UTC

[ACG40-01] Submarine groundwater discharge from Mt. Fuji in Suruga Bay(VI)

*Yasuhide Muranaka[1], Takafumi Kamitani[1], Noriaki Fushimi[1], Tomoya Oka[1], Masahiko Ono[2], Atsunao Marui[2] (1.Shizuoka Institute of Environment and Hygiene, 2.National Institute of Advanced Industrial Science and Technology)

9:20 AM - 9:35 AM JST | 12:20 AM - 12:35 AM UTC

[ACG40-02] Relationship between the distribution of freshwater groundwater under the seabed at Obama Bay and the surrounding terrain of the land

*Makoto Yamada[1], Ryo Sugimoto[2], Toshimi Nakajima[3] (1.Faculty of Economics, Ryukoku University, 2.Fuculty of Marine Biosciences, Fukui Prefectural University, 3.Fukui Prefectural University)

9:35 AM - 9:50 AM JST | 12:35 AM - 12:50 AM UTC

[ACG40-03] Influence of recirculated submarine groundwater discharge on phytoplankton dynamics in Moune Bay, Kesennuma

*Toshimi Nakajima[1], Takahiro Kusunoki[1], Yoshitake Takao[1], Ryo Sugimoto[1] (1.Fukui Prefectural University)

9:50 AM - 10:05 AM JST | 12:50 AM - 1:05 AM UTC

[ACG40-04] Estimation of contribution rate of Submarine Groundwater Discharge to *Ulva pertusa* using nitrogen stable isotope ratio analysis

*Tatsuhiro Ishida[1], Masaru Takeuchi[1], Toshimi Nakajima[1], Ryo Sugimoto[1], Shiho Kobayashi[2], Keisuke Koba[3], Keitaro Fukushima[3], Osamu Tominaga[1] (1.Fukui Prefectural University, 2.Kyoto University, 3.Center for Ecological Research,Kyoto Univrsity)

10:05 AM - 10:20 AM JST | 1:05 AM - 1:20 AM UTC

[ACG40-05] Evaluation of the environmental condition of Submarine Groundwater Discharge (SGD) using carbon and oxygen stable isotope ratio of the sessile bivalve *Crassostrea nippona* shell

*Osamu Tominaga[1], Takeuchi Masaru[1], Ryo Sugimoto[1], Ishida Tatsuhiro[1], Takeru Hirai[1], Toshimi Nakajima[1], Jun Shoji[2], Hisami Honda[4], Makoto Taniguchi[3] (1.Fukui Prefectural University, 2.Tokyo Univ. AORI, 3.RIHN, 4.Fukui Pref Gov)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 102 1F

[A-CG40] Coastal Ecosystems - 1. Water Cycle and Land-Ocean Interactions

convener:Masahiko Fujii(Faculty of Environmental Earth Science), Makoto Yamada(Faculty of Economics, Ryukoku University), Jun Shoji(The University of Tokyo), Ryo Sugimoto(Faculty of Marine Biosciences, Fukui Prefectural University), Chairperson:Masahiko Fujii, Makoto Yamada

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACG40-06] Influence of climate change on river and submarine groundwater discharge for three decades and the change of nutrient fluxes from the land to the coastal area

*Saki KATAZAKAI[1], Jing ZHANG[2], Kota NOJIMA[3] (1.Graduate School of Science and Engineer, University of Toyama, 2.Graduate School of Science and Engineering for Science, University of Toyama, 3.University of Toyama)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACG40-07] The assessment of human impacts on the distribution patterns of mangroves: a comparative study between the Rewa and Ba delta, Fiji

*Masahiko Fujii[1], Jone Ravuci Sassen[2] (1.Faculty of Environmental Earth Science, 2.Graduate School of Environmental Science)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACG40-08] Landscape factors affect persistence and accumulation of organic carbon in sediment of secondary mangrove forests: A preliminary study

*Toshihiro Miyajima[1], Rempei Suwa[2], Keith Limuel C. Bejasa[3], Rene N. Rollon[3], Maria Lourdes San Diego-McGlone[3], Caroline M.B. Jaraula[3], Fernando P. Siringan[3], Kenji Ono[4], Yasmin H. Primavera Tirol[5], Yosuke Miyairi[1], Yusuke Yokoyama[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Japan International Research Center for Agricultural Sciences, 3.Marine Science Institute, University of the Philippines, 4.Forestry and Forest Products Research Institute, 5.Aklan State University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACG40-09] Multiple benefits of blue carbon ecosystems in promoting blue economy and reinforcing resilience in coastal communities

*Atsushi Watanabe[1] (1.The ocean policy research institute, The Sasakawa peace foundation)

11:45 AM - 12:05 PM JST | 2:45 AM - 3:05 AM UTC

[ACG40-10] Significant storage of organic carbon in mineral matrix in both land and ocean and the role of Fe

★Invited Papers

*Rota Wagai[1] (1.NARO, Institute for Agro-Environmental Sciences)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[A-CG40] Coastal Ecosystems - 1. Water Cycle and Land-Ocean Interactions

convener:Masahiko Fujii(Faculty of Environmental Earth Science), Makoto Yamada(Faculty of Economics, Ryukoku University), Jun Shoji(The University of Tokyo), Ryo Sugimoto(Faculty of Marine Biosciences, Fukui Prefectural University)

[ACG40-P01] Submarine groundwater discharge and dissolved material fluxes quantified by radium isotopes in sandy beach, central Wakasa Bay

*Toshimi Nakajima[1], Ryo Sugimoto[1], Yuta Sumino[1], Makoto Taniguchi[2], Osamu Tominaga[1] (1.Fukui Prefectural University, 2.Research Institute for Humanity and Nature)

[ACG40-P02] Influence of difference in river shape on heat supply to coastal area by hot spring drainage river

*Makoto Yamada[1], Taketoshi Mishima[2], Shinji Ohsawa[2] (1.Faculty of Economics, Ryukoku University, 2.Institute for Geothermal Sciences, Graduate School of Sciences, Kyoto University)

[ACG40-P03] Construction of an artificial outlet channel affects organic carbon accumulation in a coastal lagoon

*Kenta Watanabe[1], Tomohiro Kuwae[1] (1.Port and Airport Research Institute)

[ACG40-P04] Evaluation of the influence of swans, *Cygnus cygnus* on the distribution of seagrass, *Zostera japonica*

*Yoshiyuki TANAKA[1], Fumiyuki SATO[1] (1.Hachinohe Institute of Technology, Department of Life and Environmental Science)

[ACG40-P05] Assessment and future projection of variational characteristics of ocean warming and acidification proxies in Oshoro Bay, Japan

*Masahiko Fujii[1], Takuto Yamaka[2], Shintaro Takao[3] (1.Faculty of Environmental Earth Science, 2.Graduate School of Environmental Science, 3.National Institute of Polar Research)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_16

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[A-CG41] Promotion of Application and Utilization of Aircrafts for Earth sciences

convener:Nobuhiro Takahashi(Institute for Space-Earth Environmental Research, Nagoya University), Makoto Koike(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Toshinobu Machida(National Institute for Environmental Studies), Taro Shinoda(Institute for Space-Earth Environmental Research, Nagoya University)

[ACG41-P01] In situ measurements of aerosol and cloud microphysical properties and cloud seeding experiments over the UAE

*Narihiro Orikasa[1], Masataka Murakami[2,1], Takuya Tajiri[1], Yuji Zaizen[1], Taro Shinoda[2] (1.Meteorological Research Institute, 2.Nagoya Univ., ISEE)

[ACG41-P02] Analysis and Forecast Using Dropsonde Data from the Inner-Core Region of Tropical Cyclone Lan (2017) Obtained during the First Aircraft Missions of T-PARCII

*Kosuke Ito[1], Hiroyuki Yamada[1], Munehiko Yamaguchi[2], Tetsuo Nakazawa[2], Norio Nagahama[3], Kensaku Shimizu[3], Tadayasu Ohigashi[4], Taro Shinoda[5], Kazuhisa Tsuboki[5] (1.University of the Ryukyus, 2.Meteorological Research Institute, 3.Meisei Electric Co. LTD., 4.National Research Institute for Earth Science and Disaster Resilience, 5.Nagoya University)

[ACG41-P03] On the Spatial Distribution of Freezing height of Typhoon Trami

*Nobuhiro Takahashi[1], Yuki Kaneko[2], Kazuhisa Tsuboki[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Japan Aerospace Exploration Agency)

[ACG41-P04] Revision of Research Plan on “Promotion of Climate and Earth System Science Research by Aircraft Observation”

*Nobuhiro Takahashi[1], Makoto Koike[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.School of Science, The University of Tokyo)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_17

[A-CG41] Promotion of Application and Utilization of Aircrafts for Earth sciences

convener:Nobuhiro Takahashi(Institute for Space-Earth Environmental Research, Nagoya University), Makoto Koike(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Toshinobu Machida(National Institute for Environmental Studies), Taro Shinoda(Institute for Space-Earth Environmental Research, Nagoya University)

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 201B 2F

[A-CG41] Promotion of Application and Utilization of Aircrafts for Earth sciences

convener:Nobuhiro Takahashi(Institute for Space-Earth Environmental Research, Nagoya University), Makoto Koike(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Toshinobu Machida(National Institute for Environmental Studies), Taro Shinoda(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Nobuhiro Takahashi(Institute for Space-Earth Environmental Research, Nagoya University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[ACG41-01] In situ observation of typhoon central pressure using dropsondes

*Kazuhisa Tsuboki[1], Hiroyuki Yamada[2], Yukihiro Takahashi[3], Taro Shinoda[1], Tadayasu Ohigashi[4], Munehiko Yamaguchi[5], Hisayuki Kubota[3], Tetsuo Nakazawa[5], Norio Nagahama[6], Kensaku Shimizu[6], Masaya Kato[1], Sachie Kanada[1], Mayumi Yoshioka[1], Nobuhiro Takahashi[1] (1. Institute for Space-Earth Environmental Research, Nagoya University, 2.University of the Ryukyus, 3.Hokkaido University, 4.National Research Institute for Earth Science and Disaster Resilience, 5.Meteorological Research Institute, Japan Meteorological Agency, 6.Meisei Electric Co. Ltd.)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[ACG41-02] New observation strategies for typhoon intensity over the western North Pacific

*Hiroyuki Yamada[1], Kazuhisa Tsuboki[2], Taro Shinoda[2], Hisayuki Kubota[3], Yukihiro Takahashi[3], Norio Nagahama[4], Kensaku Shimizu[4], Tadayasu Ohigashi[5], Kosuke Ito[1], Munehiko Yamaguchi[6], Tetsuo Nakazawa[6] (1.University of the Ryukyus, 2.Nagoya University, 3.Hokkaido University, 4.Meisei Electric, 5.National Research Institute for Earth Science and Disaster Resilience, 6.Meteorological Research Institute, Japan Meteorological Agency)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[ACG41-03] Observing System Experiment for Typhoon Trami (2018) using T-PARCII dropsondes and JMA Global Forecasting System

*Munehiko Yamaguchi[1], Toshiyuki Ishibashi[1], Tetsuo Nakazawa[1], Kosuke Ito[2], Hiroyuki Yamada[2], Tadayasu Ohigashi[3], Norio Nagahama[4], Kensaku Shimizu[4], Hisayuki Kubota[5], Yukihiro Takahashi[5], Masaya Kato[6], Sachie Kanada[6], Mayumi Yoshioka[6], Taro Shinoda[6], Nobuhiro Takahashi[6], Kazuhisa Tsuboki[6] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Faculty of Science, University of the Ryukyus, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Meisei Electric, 5.Graduate School of Science, Hokkaido University, 6.Institute for Space-Earth Environmental Research, Nagoya University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[ACG41-04] Fundamental characteristics of black carbon and iron oxide aerosols in the troposphere revealed from the aircraft measurements

*Nobuhiro Moteki[1], Makoto Koike[1], Sho Ohata[2], Yutaka Kondo[3], Nobuyuki Takegawa[5], Kouji Adachi[4], Naga Oshima[4], Hitoshi Matsui[2], Kazuyuki Kita[6], Tatsuhiro Mori[7], Atsushi Yoshida[1] (1.The Univerisity of Tokyo, 2.Nagoya University, 3.National Institute for Polar Research, 4.Meteorological Research Institute, 5.Tokyo Metropolitan University, 6.Ibaraki University, 7.Tokyo University of Science)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[ACG41-05] Aerosol measurements around the ridge of East Antarctica using a Rogallo wing UAV

*Ryohei Haraguchi[1], Masahiko Hayashi[1], Keiichiro Hara[1], Naohiko Hirasawa[2], Koki Nakata[3], Kei-ichi Ozuka[4,1] (1.Fukuoka University, 2.National Institute of Polar Research, 3.kkt Inovate Co., Ltd, 4.Nippon Tungsten Co., Ltd)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[ACG41-06] Wind Mesurements Based on In-situ Data -Direct Vector Calculation and Hodograph Analyses-

*Masahiko Hayashi[1], Tomoyuki Onohara[1], Ryohei Haraguchi[1,3], Kei-ichi Ozuka[2,4], Kazuo Okabe[3] (1.Faculty of Science, Fukuoka University, 2.Nippon Tungsten Co.,Ltd, 3.SkyRemote Co.,Ltd, 4.FIT-EH, Fukuoka University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[A-CG44] Coastal Ecosystems 2 Coral reefs, seagrass and macroalgal beds, and mangrove

convener:Yu Umezawa(Tokyo University of Agriculture and Technology), Toshihiro Miyajima(Marine Biogeochemistry Group, Division of Ocean-Earth System Science, Atmosphere and Ocean Research Institute, The University of Tokyo), Atsushi Watanabe(The ocean policy research institute, The Sasakawa peace foundation), Tomihiko Higuchi(Atmosphere and Ocean Research Institute, The University of Tokyo)

[ACG44-P01] Characteristics of organic carbon in coastal carbonate sediment accompanied by seagrass meadows

*Toshihiro Miyajima[1] (1.Marine Biogeochemistry Group, Division of Ocean-Earth System Science, Atmosphere and Ocean Research Institute, The University of Tokyo)

[ACG44-P02] **Perceptions of Coastal Communities on Blue Carbon Ecosystems Services at the Municipalities of Eastern Samar and Western Visayas, Philippines**

*Jay Mar Dioquito Quevedo[1], Yuta Uchiyama[1], Kaoru Kakinuma[1], Ryo Kohsaka[1] (1.Tohoku University)

[ACG44-P03] Numerical simulation of typhoon events in Sekisei Lagoon, Okinawa, Japan using a coupled ocean-wave model

*Lawrence Patrick Cases Bernardo[1], Takashi Nakamura[1], Kazuo Nadoka[1] (1.Department of Transdisciplinary Science and Engineering, Tokyo Institute of Technology)

[ACG44-P04] Study of macrobenthic community structure at mesophotic depths in the South Ryukyus based on ROV and AUV seafloor imaging

*Marc Humblet[1], Toshihiro Maki[2], Yasuo Furushima[3], Yukiyasu Noguchi[2], Hiroumi Horimoto[2], Hiroya Yatagai[2], Takashi Sakamaki[2], Shohei Ito[4], Sadao Suzuki[5] (1.Department of Earth and Planetary Sciences, Nagoya University, 2.Institute of Industrial Science, The University of Tokyo, 3.JAMSTEC, 4.FullDepth Co., Ltd., 5.ORE)

[ACG44-P05] Enhancement of antioxidant activity of scleractinian coral *Galaxea Fascicularis* by feeding treatment.

*Hiroyuki Fujimura[1], Sayaka Higa[1], Toshihiro Miyajima[2], Tomihiko Higuchi[2], Sylvain Agostini[3], Ikuko Yuyama[3], Takashi Nakamura[4] (1.University of the Ryukyus, 2.The University of Tokyo, 3.Tsukuba University, 4.Tokyo Institute of Technology)

[ACG44-P06] Effects of environmental stresses on coral bleaching

*Tomihiko Higuchi[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_18

[A-CG44] Coastal Ecosystems 2 Coral reefs, seagrass and macroalgal beds, and mangrove

convener:Yu Umezawa(Tokyo University of Agriculture and Technology), Toshihiro Miyajima(Marine Biogeochemistry Group, Division of Ocean-Earth System Science, Atmosphere and Ocean Research Institute, The University of Tokyo), Atsushi Watanabe(The ocean policy research institute, The Sasakawa peace foundation), Tomihiko Higuchi(Atmosphere and Ocean Research Institute, The University of Tokyo)

[ACG44-P01] Characteristics of organic carbon in coastal carbonate sediment accompanied by seagrass meadows

*Toshihiro Miyajima[1] (1.Marine Biogeochemistry Group, Division of Ocean-Earth System Science, Atmosphere and Ocean Research Institute, The University of Tokyo)

[ACG44-P02] **Perceptions of Coastal Communities on Blue Carbon Ecosystems Services at the Municipalities of Eastern Samar and Western Visayas, Philippines**

*Jay Mar Dioquito Quevedo[1], Yuta Uchiyama[1], Kaoru Kakinuma[1], Ryo Kohsaka[1] (1.Tohoku University)

[ACG44-P03] Numerical simulation of typhoon events in Sekisei Lagoon, Okinawa, Japan using a coupled ocean-wave model

*Lawrence Patrick Cases Bernardo[1], Takashi Nakamura[1], Kazuo Nadoka[1] (1.Department of Transdisciplinary Science and Engineering, Tokyo Institute of Technology)

[ACG44-P04] Study of macrobenthic community structure at mesophotic depths in the South Ryukyus based on ROV and AUV seafloor imaging

*Marc Humblet[1], Toshihiro Maki[2], Yasuo Furushima[3], Yukiyasu Noguchi[2], Hiroumi Horimoto[2], Hiroya Yatagai[2], Takashi Sakamaki[2], Shohei Ito[4], Sadao Suzuki[5] (1.Department of Earth and Planetary Sciences, Nagoya University, 2.Institute of Industrial Science, The University of Tokyo, 3.JAMSTEC, 4.FullDepth Co., Ltd., 5.ORE)

[ACG44-P05] Enhancement of antioxidant activity of scleractinian coral *Galaxea Fascicularis* by feeding treatment.

*Hiroyuki Fujimura[1], Sayaka Higa[1], Toshihiro Miyajima[2], Tomihiko Higuchi[2], Sylvain Agostini[3], Ikuko Yuyama[3], Takashi Nakamura[4] (1.University of the Ryukyus, 2.The University of Tokyo, 3.Tsukuba University, 4.Tokyo Institute of Technology)

[ACG44-P06] Effects of environmental stresses on coral bleaching

*Tomihiko Higuchi[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 102 1F

[A-CG44] Coastal Ecosystems 2 Coral reefs, seagrass and macroalgal beds, and mangrove

convener:Yu Umezawa(Tokyo University of Agriculture and Technology), Toshihiro Miyajima(Marine Biogeochemistry Group, Division of Ocean-Earth System Science, Atmosphere and Ocean Research Institute, The University of Tokyo), Atsushi Watanabe(The ocean policy research institute, The Sasakawa peace foundation), Tomihiko Higuchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Yu Umezawa(Tokyo University of Agriculture and Technology), Toshihiro Miyajima(The University of Tokyo), Tomihiko Higuchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Atsushi Watanabe(Tokyo Institute of Technology)

1:50 PM - 2:10 PM JST | 4:50 AM - 5:10 AM UTC

[ACG44-01] Evaluation of mangrove ecosystems as a dissolved iron supplying system to tropical coastal waters

★Invited Papers

*Yasuhiro Nakanishi[1], Ko Hinokidani[1] (1.Tokyo University of Agriculture)

2:10 PM - 2:25 PM JST | 5:10 AM - 5:25 AM UTC

[ACG44-02] Dissolved organic carbon and optical properties in tropical and subtropical mangrove environments

*Raghab Ray[1], Toshihiro Miyajima[1], Charissa M Ferrera[2], Chia-Jung Lu[1], M.L San Diego-McGlone[2], Hiroshi Ogawa[1], Kazuo Nadaoka[3] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Marine Science Institute, University of the Philippines, Diliman, 3.School of Environment and Society, Tokyo Institute of Technology)

2:25 PM - 2:45 PM JST | 5:25 AM - 5:45 AM UTC

[ACG44-03] Modeling coral polyp-scale bleaching phenomenon and upscaling to reef-scale

★Invited Papers

*Takashi Nakamura[1], Tomihiko Higuchi[2], Toshihiro Miyajima[2], Lawrence Patrick Cases Bernardo[1], Kazuo Nadaoka[1], Atsushi Watanabe[1,3], Hiroyuki Fujimura[4] (1.School of Environment and Society, Tokyo Institute of Technology, 2.AORI, The University of Tokyo, 3.The ocean policy research institute, The Sasakawa peace foundation, 4.University of the Ryukyus)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[ACG44-04] Reversal of surface ocean acidification and recovery potential of calcification: ecology of proton concentration control

*Kazuhiko Ichikawa[1] (1.(post) Graduate School of Environmental Earth Science, Hokkaido University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[ACG44-05] Revisit of massive *Porites* coral growth under the outbreak of crown-of-thorns starfish and thermal stress in Sekisei Lagoon, Japan

*Kohki Sowa[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 102 1F

[A-CG44] Coastal Ecosystems 2 Coral reefs, seagrass and macroalgal beds, and mangrove

convener:Yu Umezawa(Tokyo University of Agriculture and Technology), Toshihiro Miyajima(Marine Biogeochemistry Group, Division of Ocean-Earth System Science, Atmosphere and Ocean Research Institute, The University of Tokyo), Atsushi Watanabe(The ocean policy research institute, The Sasakawa peace foundation), Tomihiko Higuchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Yu Umezawa(Tokyo University of Agriculture and Technology), Toshihiro Miyajima(The University of Tokyo), Atsushi Watanabe(Tokyo Institute of Technology), Tomihiko Higuchi(Atmosphere and Ocean Research Institute, The University of Tokyo)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[ACG44-06] Reconstructing sedimentation process of lagoon sediment in the Eastern Kume Island, Ryukyus

*Wataru Sano[1], Shoko Hirabayashi[2], Yusuke Yokoyama[3], Yosuke Miyairi[3], Kazuhiko Fujita[4], Hironobu Kan[2], Lauren T. Toth[5], Richard B. Aronson[6] (1.Graduate School of Integrated Sciences for Global Society, Kyushu University, 2.Graduate School of Social and Cultural Studies, Kyushu University, 3.Atmosphere and Ocean Research Institute, University of Tokyo, 4.Department of Physics and Earth Sciences, University of the Ryukyus, 5.United States Geological Survey, 6.Florida Institute of Technology)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[ACG44-07] Addressing challenges in long-term coral reef monitoring: Statistical tools to address the effect of new methods

*Iwao Fujii[1,2], Jennifer Selgrath[3,2], Amanda Vincent[2] (1.The Ocean Policy Research Institute of the Sasakawa Peace Foundation, 2.Project Seahorse, Institute of the Oceans and Fisheries, The University of British Columbia, 3.Hopkins Marine Station, Stanford University)

4:00 PM - 4:20 PM JST | 7:00 AM - 7:20 AM UTC

[ACG44-08] Ocean currents and herbivory drive macroalgae-to-coral community shift under climate warming

★Invited Papers

*Naoki H. Kumagai[1], Jorge García Molinos[2], Hiroya Yamano[1], Shintaro Takao[1], Masahiko Fujii[2], Yasuhiro Yamanaka[2] (1.National Institute for Environmental Studies, 2.Hokkaido University)

4:20 PM - 4:35 PM JST | 7:20 AM - 7:35 AM UTC

[ACG44-09] Estimation of temperature of seaweed bed vegetation boundary in the Western Seto Inland Sea using satellite SST

*Naoki Yoshie[1], Anri Kabe[1], Hiromori Shimabukuro[2], Goro Yoshida[2] (1.Center for Marine Environmental Studies, Ehime University, 2.Japan Fisheries Research and Education Agency)

4:35 PM - 4:55 PM JST | 7:35 AM - 7:55 AM UTC

[ACG44-10] Fate of macroalgal organic matter and its effects on in and outside of algal bed

★Invited Papers

*Shigeki Wada[1], Yuko Omori[1], Takeo Hama[1,2] (1.University of Tsukuba, 2.Dokkyo University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 103 1F

[A-CG45] Visible Remote Sensing of Hydrospheric Science and Its Application

convener:Joji Ishizaka(Institute for Space-Earth Environmental Research, Nagoya University), Mitsuhiro Toratani(School of Engineering, Tokai University), Yuji Sakuno(Graduate School of Engineering, Hiroshima University), Toru Hirawake(Faculty of Fisheries Sciences, Hokkaido University), Chairperson:Yuji Sakuno(広島大学大学院工学研究科)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[ACG45-01] Further information in the coastal areas from 250-m resolution multiple bands of GCOM-C “SHIKISAI”

★Invited Papers

*Hiroshi Murakami[1], Manabu Shimizu[2], Goh Onizuka[3] (1.Earth Observation Research Center, Japan Aerospace Exploration Agency, 2.Japan Fisheries Research and Education Agency, 3.National Research Institute of Fisheries and Environment of Inland Sea, Japan Fisheries Research and Education Agency)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[ACG45-02] Features of GCOM-C/SGLI standard atmospheric correction scheme and its processing results

*Mitsuhiro Toratani[1], Kazunori Ogata[2], Hajime Fukushima[3] (1.School of Engineering, Tokai University, 2.Japan Aerospace Exploration Agency/Earth Observation Research Center, 3.Tokai University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[ACG45-03] Verification of GCOM-C/SGLI-derived chlorophyll *a* data in the western North Pacific during May 2018 aboard the R/V *Shinsei Maru*

*Koji Suzuki[1], Stanford B. Hooker[2], Tomonori Isada[1], Kazunori Ogata[3], Mitsuhiro Toratani[4], Hiroshi Murakami[3] (1.Hokkaido University, 2.NASA, 3.JAXA, 4.Tokai University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[ACG45-04] **Toward a global retrieval of in-water optical properties using Deep Neural Network**

*Salem Ibrahim Salem[1], Hiroto Higa[2], Kazuo Oki[1], Taikan Oki[1] (1.The University of Tokyo, 2.Yokohama National University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[ACG45-05] Development of atmosphere and in-water combining algorithm using GCOM-C/SGLI in Tokyo Bay

*Taiga Nakayama[1], HIROTO HIGA[1], Kazuki Ogata[2] (1.Yokohama National University, 2.Japan Aerospace eXploration Agency)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[ACG45-06] Analysis of the uncertainty of backscattering coefficient by radiative transfer simulation in coastal areas and lakes

*Hidehito Taki[1], Hiroto Higa[1], Yoshiyuki Nakamura[1], Takayuki Suzuki[1] (1.Graduate School of Urban Innovation, Yokohama National University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 103 1F

[A-CG45] Visible Remote Sensing of Hydrospheric Science and Its Application

convener:Joji Ishizaka(Institute for Space-Earth Environmental Research, Nagoya University), Mitsuhiro Toratani(School of Engineering, Tokai University), Yuji Sakuno(Graduate School of Engineering, Hiroshima University), Toru Hirawake(Faculty of Fisheries Sciences, Hokkaido University), Chairperson:Joji Ishizaka(名古屋大学宇宙地球環境研究所)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACG45-07] Development of a blue tide estimation method based on the optical properties of sulfur colloid particles by geostationary ocean color satellite

*HIROTO HIGA[1], WATARU NAKAMURA[1] (1.Yokohama National University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACG45-08] Characteristics of water quality and red tide distribution in the Seto Inland Sea immediately after heavy rain in the western Japan by GCOM-C SGLI data

*Yuji Sakuno[1], Hiroto Higa[2], Hiroshi Kobayashi[3], Mitsuhiro Toratani[4] (1.Hiroshima University, 2.Yokohama National University, 3.Yamanashi University, 4.Tokai University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACG45-09] Application of Satellite Remote Sensing to Monitor Eutrophication Status of Inland Lakes

*Wei Yang[1], Bunkei Matsushita[2] (1.Chiba University, 2.University of Tsukuba)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACG45-10] **Exploring the Potentials of Google Earth Engine for Global Assessment of Coastal Eutrophication Based on Chlorophyll-*a* concentration**

*Eligio de Raus Maure[1], Genki Terauchi[1], Joji Ishizaka[2] (1.Northwest Pacific Region Environmental Cooperation Center, 2.Institute for Space-Earth Environmental Research, Nagoya University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[ACG45-11] Seasonal and interannual variability of seagrass distribution detected by Landsat TM, ETM+ and OLI images in western Nanao Bay

*Genki Terauchi[1] (1.Northwest Pacific Region Environmental Cooperation Center)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_11

[A-CG45] Visible Remote Sensing of Hydrospheric Science and Its Application

convener:Joji Ishizaka(Institute for Space-Earth Environmental Research, Nagoya University), Mitsuhiro Toratani(School of Engineering, Tokai University), Yuji Sakuno(Graduate School of Engineering, Hiroshima University), Toru Hirawake(Faculty of Fisheries Sciences, Hokkaido University)

[ACG45-P01] About GCOM-C/SGLI Ocean Standard Products

*Kazunori Ogata[1] (1.Japan Aerospace Exploration Agency)

[ACG45-P02] Verification of GCOM-C/SGLI product in coastal area

*Joji Ishizaka[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

[ACG45-P03] Hyperspectral Radiometry towards Classification of Marine Phytoplankton Groups

*Takafumi Hirata[1], Robert J.W. Brewin[2], Girgio Dall'Olmo[2], Mariana Altenburg Soppa[3], Astrid Bracher[3] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Plymouth Marine Laboratory, 3.Alfred-Wegener Institute for Polar and Marine Research)

[ACG45-P04] Improvement of absorption-based primary production model for SGLI/GCOM-C

*Toru Hirawake[1], Takuhei Shiozaki[2], Hisatomo Waga[1], Koji Suzuki[1] (1.Hokkaido University, 2.JAMSTEC)

[ACG45-P05] Attempt to distinguish river water influencing concentration of chlorophyll *a* off Miho Peninsula

*Akihiko Tanaka[1], Kyoko Takashima[2], Gen Fukuda[2], Takaaki Katsumata[1], Hiroyuki Tan[1], Masato Niki[2], Daisuke Takahashi[2] (1.Liberal Arts Education Center, Shimizu Campus, Tokai University, 2.School of Marine Science and Technology, Tokai University)

[ACG45-P06] **Estimation of chlorophyll-a from RGB digital camera data collected in Ise-Mikawa Bay**

*Akiko N. Mizuno[1], Joji Ishizaka[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

[ACG45-P07] **Seasonal variability of MODIS chlorophyll-a and total suspended matter in the spring-neap tidal cycle in the Ariake Bay, Japan**

*Mengmeng Yang[1], Joji Ishizaka[2], Joaquim I. Goes[3], Hongzhen Tian[4], Elígio R. Maúre[5], Masataka Hayashi[6] (1.Graduate School of Environmental Studies, Nagoya University, Furo-cho, Chikusa-ku, Nagoya, Aichi, Japan., 2.Institute for Space-Earth Environmental Research (ISEE) Nagoya University Furo-cho, Chikusa-ku, Nagoya, Aichi, Japan., 3.Lamont-Doherty Earth Observatory, Marine Biology and Paleo Environment, Columbia University, 61 Route 9W - PO Box 1000, Palisades, NY 10964-8000, US., 4.School of Management and Economy, Tianjin Polytechnic University, Tianjin 300387, China., 5.Dept. of Research and Study, Northwest Pacific Region Environmental Cooperation Center, Toyama, Japan., 6.Science and Technology co., Ltd., 3-9-2, Koubai-cho, Showa, Nagoya, Aichi 466-0031, Japan.)

[ACG45-P08] **Discrimination of green *Noctiluca scintillans* in the upper Gulf of Thailand using remote sensing techniques**

*Jutarak Luang-on[1], Joji Ishizaka[2], Anukul Buranapratheprat[3], Jitraporn Phaksopa[4] (1.Graduate School of Environmental Studies, Nagoya University, 2.Institute for Space-Earth Environmental Research, Nagoya University, Japan, 3.Department of Aquatic Science, Faculty of Science, Burapha University, Thailand, 4.Department of Marine Science, Faculty of Fisheries, Kasetsart University, Thailand)

[ACG45-P09] **Monthly variability of Chlorophyll-a distribution in the Gulf of Thailand**

*Dudsadee Leenawarat[1], Anukul Buranapratheprat[2], Joji Ishizaka[3] (1.Graduate School of Environmental Studies, Nagoya University, Japan, 2.Department of Aquatic Science, Faculty of Science, Burapha University, Thailand, 3.Institute for Space-Earth Environmental Research, Nagoya University, Japan)

[ACG45-P10] AERONET-Ocean Color time series in Ariake Bay.

*yifei wu[1], Joji Ishizaka[2], Mengmeng Yang[1], Naoki Fujii[3], Masahiro Hori[4] (1. Graduate School of Environmental Studies, Nagoya University, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Graduate School of Agriculture, Saga University, 4.EORC, JAXA)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[E] Oral | H (Human Geosciences)：H-DS Disaster geosciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 304 3F

[H-DS09] Landslides and related phenomena

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Gonghui Wang(Disaster Prevention Research Institute, Kyoto University), Fumitoshi Imaizumi(Faculty of Agriculture, Shizuoka University), Chairperson:Fumitoshi Imaizumi

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[HDS09-01] Mechanical behavior modulated by shear surface morphology of simulated shear zone

*Yao Jiang[1], Gonghui Wang[2], Toshitaka Kamai[2] (1.Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, China, 2.Research Center on Landslide, Disaster Prevention Research Institute, Kyoto University, Japan)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[HDS09-02] On the Pre-failure Shear Behavior of Clayey Soil

*Chengrui Chang[1], Gonghui Wang[1] (1.Disaster Prevention Research Institute, Kyoto University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[HDS09-03] **GeoGuard: low-cost GNSS sensors for the continuous monitoring of landslides and structures**

*Andrea Gatti[1], Giulio Tagliaferro[1], Eugenio Realini[1], Stefano Caldera[1] (1.Geomatics Research & Development srl)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[HDS09-04] **Landslide Susceptibility Analysis in the Chenyulan River Watershed, Taiwan**

*Po-Tsun Yeh[1], Kuang-Tsung Chang[1] (1.National Chung Hsing University, Taiwan)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[HDS09-05] Investigating the Relationship Between Tree Height and Landslide Occurrence in the Ikawa Catchment, Central Japan

*Jamie Rhys Evans[1], Fumitoshi Imaizumi [1] (1.Faculty of Agriculture, Shizuoka University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[HDS09-06] Landslides induced by the knickpoint migration in the southern and the eastern margins of the Tibetan Plateau.

*Masahiro Chigira[1], Ching-Ying Tsou[2], Siyuan Zhao[4], Xiong Wu[3] (1.Disaster Prevention Research Institute, Kyoto University, 2.Hirosaki University, 3.Souithwest Jiaotong University, 4.Graduate School of Science, Kyoto University)

[E] Oral | H (Human Geosciences)：H-DS Disaster geosciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 304 3F

[H-DS09] Landslides and related phenomena

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Gonghui Wang(Disaster Prevention Research Institute, Kyoto University), Fumitoshi Imaizumi(Faculty of Agriculture, Shizuoka University), Chairperson:Wang Gonghui, Issei Doi

10:45 AM - 11:15 AM JST | 1:45 AM - 2:15 AM UTC

[HDS09-07] Landslides caused by the 2018 Hokkaido Eastern Iburi Earthquake

★Invited Papers

*Shin-ichiro Hayashi[1], Nobutomo Osanai[1], Takashi Yamada[1], Shin'ya Katsura[1], Takahisa Furuichi[1], Seiji Yanai[2], Yasuharo Murakami[3], Tomoyoshi Miyazaki[4], Yuichiro Tanioka[1], Shigetaka Takiguchi[5], Mayumi Miyazaki[6] (1.Hokkaido University, 2.Ishikawa Prefectural University, 3.Civil Engineering Research Institute for Cold Region, PWRI, 4.Shin Engineering Consultant, Co., Ltd., 5.Ministry of Land, Infrastructure, Transport and Tourism, 6.Pasco Corporation)

11:15 AM - 11:45 AM JST | 2:15 AM - 2:45 AM UTC

[HDS09-08] On the coseismic landslides occurring on tephra slopes during the 2018 Hokkaido Eastern Iburi Earthquake

★Invited Papers

*Gonghui Wang[1], Gen Furuya[2] (1.Disaster Prevention Research Institute, Kyoto University, 2.Toyama Prefectural University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HDS09-09] Seismological and geotechnical surveys on the landslides induced by the 2018 Hokkaido Eastern Iburi earthquake

*Issei Doi[1], Hikaru Osawa[2], Sumio Matsuura[1] (1.Disaster Prevention Research Institute, Kyoto University, 2.Mountain Science Center, University of Tsukuba)

[E] Oral | H (Human Geosciences)：H-DS Disaster geosciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 304 3F

[H-DS09] Landslides and related phenomena

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Gonghui Wang(Disaster Prevention Research Institute, Kyoto University), Fumitoshi Imaizumi(Faculty of Agriculture, Shizuoka University), Chairperson:Fumitoshi Imaizumi, Chigira Masahiro

1:45 PM - 2:15 PM JST | 4:45 AM - 5:15 AM UTC

[HDS09-10] Initiation conditions of debris flows in Ohsawa landslide, Mt. Fuji

★Invited Papers

*Fumitoshi Imaizumi[1], Kazuki Yamamoto[1], Atsushi Ikeda[4], Okihiro Ohsaka[1], Hiroyuki Sugimoto[2], Satoru Suzuki[2], Shinichi Sato[2], Yoshiaki Kashiwabara[3], Naoki Nishimura[3] (1.Faculty of Agriculture, Shizuoka University, 2.Fuji Sabo Office, Ministry of Land, Infrastructure and Transport, 3.Asia Air Survey Co., Ltd., 4.Faculty of Life and Environmental Sciences, Tsukuba University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[HDS09-11] The role of thrust faults with incohesive clayey fault materials to generate deep-seated gravitational slope deformations and catastrophic landslides in the Shimanto accretionary complex

*Noriyuki Arai[1], Masahiro Chigira[1] (1.Disaster Prevention Research Institute,Kyoto University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[HDS09-12] Control effect of huge faults on the structure of surrounding regional rock mass in the whole mountain: implications for the distribution pattern of coseismic landslides

*Chao HUANG[1,2], Yusheng LI[1], Chunhao WU[3], Shujian YI[1,3], Kai LIU[1,4], Gonghui WANG[2] (1.State Key Laboratory of Geohazard Prevention and Geoenvironment Protection, Chengdu University of Technology, China, 2.Disaster Prevention Research Institute, Kyoto University, Japan, 3.Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, China, 4.China Railway Eryuan Engineering Group CO. LTD, China)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_12

[H-DS09] Landslides and related phenomena

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Gonghui Wang(Disaster Prevention Research Institute, Kyoto University), Fumitoshi Imaizumi(Faculty of Agriculture, Shizuoka University)

[HDS09-P01] **Fluidized landslides triggered by the liquefaction of subsurface volcanic deposits during the 2018 Iburi–Tobu earthquake, Hokkaido**

*Jun Kameda[1], Hiro Kamiya[2], Hirokazu Masumoto[1], Tomonori Morisaki[1], Toru Hiratsuka[2], Chisaki Inaoi (1.Department of Natural History Sciences, Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Sciences, School of Science, Hokkaido University)

[HDS09-P02] A comparison between the acoustic signals and seismic signals generated during a dam-break test

★Invited Papers

*Zheng-yi Feng[1], Hao-yang Huang[1], Chia-Ming Chuang[1] (1.Department of Soil and Water Conservation, National Chung Hsing University, Taichung, Taiwan)

[HDS09-P03] Evaluation of factors of safety and landslide risk for a watershed by Scoops3D

*Zheng-yi Feng[1], Chia-Ming Chuang[1], Hao-yang Huang[1] (1.Department of Soil and Water Conservation, National Chung Hsing University, Taichung, Taiwan)

[HDS09-P04] **Fuzzy Clustering Algorithms for Establishing Landslide Susceptibility Map**

*Pei-hsun Tsai[1], Syuan-yi Wang[1], Jie-shin Cheng[1] (1.Chaoyang University of Technology)

[HDS09-P05] **A Study on Landslides and Debris Flows Susceptibility Mapping Using Unmanned Aerial Vehicles**

*Sheng-Jia Liu[1] (1.qwepoi13@gmail.com)

[HDS09-P06] Largescale landslide induced by AD1586 Tensho-Earthquake in Gifu Prefecture, central Japan

*Takahiro Kurimoto[1], Yoshihiko Kariya[2], Kuniyasu Mokudai[3], Ryuji Yamada[4], Takashi Kimura[4] (1.Undergraduate Senshu University, 2.Department of Geography, Senshu University, 3.Japan Geoservice Incorporated, 4.National Research Institute for Earth Science and Disaster Resilience)

[HDS09-P07] Failure Probability of Lushan Landslide, Taiwan

*Wei-Ting Lin[1], Kuang-Tsung Chang[1] (1.National Chung Hsing University)

[HDS09-P08] Interpretation of landslide surface deformation in Kali Gandaki River watershed, Nepal using ALOS-2/PALSAR-2 InSAR image

*Hiroshi, P. Sato[1] (1.College of Humanities and Sciences, Nihon University)

[HDS09-P09] A depth-integrated model for granular flows on the transition of different bed conditions

*Ling-Yi Hsu[1], Chi-Yao Hung[1] (1.National Chung Hsing University)

[HDS09-P10] A viscous granular flow experiment with new refractive index matching material

*Tsai-Jung Lin[1], Chi-Yao Hung[1] (1.National Chung Hsing University)

[HDS09-P11] Sandbox experiments of submarine landslide caused by water film in low permeability layer

*Shogo Kawakita[1], Daisuke Asahina[2], Keiji Kitajima[3], Mitsukazu Nakanishi[3] (1.Graduate School of Science & Technology, Nihon Univ., 2.National Institute of Advanced Industrial Science and Technology, 3.College of Science & Technology, Nihon Univ.)

[HDS09-P12] **Study on Creep Properties of Sand and Cemented Sand**

*JIN-YI YU[1], KUANG-TSUNG CHANG[1] (1.National Chung Hsing University)

[HDS09-P13] The effects of seepage force and the Poisson’s ratio on slope stability

*Hirokazu Fukui[1], Tomomi Terajima[2] (1.Graduate school of Science, Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University)

[HDS09-P14] Study on the factors of seepage erosion

*Szu-Wei Fu[1], Kuang-Tsung Chang[1] (1.National Chung Hsing University)

[HDS09-P15] Deformation of slope models with different orientations of weak planes

*taeyuan tseng[1], Kuang-Tsung Chang[1] (1.National Chung Hsing University)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_20

[H-TT18] Development and application of environmental traceability methods

convener:Ichiro Tayasu(Research Institute for Humanity and Nature), Nobuhito Ohte(Department of Social Informatics, Graduate School of Informatics, Kyoto University), Gabriel J Bowen(University of Utah), Chairperson:Nobuhito Ohte(Kyoto University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[HTT18-01] Environmental traceability methodology by multi-isoscapes

*Ichiro Tayasu[1], Lei Fujiyoshi[1], Shiho Yabusaki[1], Ki-Cheol Shin[1], Takanori Nakano[1], Makoto Taniguchi[1] (1.Research Institute for Humanity and Nature)

9:15 AM - 9:45 AM JST | 12:15 AM - 12:45 AM UTC

[HTT18-02] Exploring physical and biological connections using isoscapes

★Invited Papers

*Gabriel J Bowen[1] (1.University of Utah)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[HTT18-03] Spatial and temporal variations in stable isotopes and soluble ions on high mountain snow surface of Mt. Tateyama, Toyama Prefecture, Japan

*Nozomu Takeuchi[1], Ryo Sugiyama[1] (1.Chiba University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[HTT18-04] Using Sr isotopes to determine the contribution of volcanic ash to Sr and Ca in stream waters in a chert watershed.

*Masami Koshikawa[1], Mirai Watanabe[1], Tomoyoshi Murata[1], Takejiro Takamatsu[1], Shingo Miura[1], Ki-Cheol Shin[2], Takanori Nakano[2] (1.National Institute for Environmental Studies, 2.Research Institute for Humanity and Nature)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[HTT18-05] Influences of soil dust, sea salt and anthropogenic activities on ionic and Sr isotopic compositions of wet deposition in Iran

*Yoriko Yokoo[1], Kosuke Asai[1], Sae Horii[1], Ryo Anma[2], Shiva Mehrabani[3], KiCheol Shin[4] (1.Faculty of Science and Engineering, Doshisha University, 2.Tokushima University, 3.Kurdistan University, 4.RIHN)

[E] Oral | H (Human Geosciences)：H-TT Technology & Techniques

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 302 3F

[H-TT18] Development and application of environmental traceability methods

convener:Ichiro Tayasu(Research Institute for Humanity and Nature), Nobuhito Ohte(Department of Social Informatics, Graduate School of Informatics, Kyoto University), Gabriel J Bowen(University of Utah), Chairperson:Gabriel Bowen(The University of Utah)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[HTT18-06] Long-term increasing trend of line-conditioned excess in groundwater

*Masanori Katsuyama[1] (1.Graduate School of Agriculture, Kyoto University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[HTT18-07] Geochemistry of river water in the Okayama and Tottori Prefectures, Japan

*Katsuyuki Yamashita[1], Takahiro Kamei[1], Yuga Kishimoto[1], Masahiko Mori[1], Aya Ooi[2], Ayaka Onishi[2], Yoko Kurihara[2], Hitoshi CHIBA[1], Takanori Nakano[3], Ki-Cheol Shin[4] (1.Graduate School of Natural Science and Technology, Okayama University, 2.Faculty of Science, Okayama University, 3.Ono City, 4.Research Institute for Humanity and Nature)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HTT18-08] Study on groundwater flow system at Oshino Village in Yamanashi Prefecture – Report 5. Estimation of the residence time in spring water and groundwater at Oshino Village.

*Shiho Yabusaki[1], Makoto Taniguchi[1], Ichiro Tayasu[1], Tomoya Akimichi[1], Noboru Ohomori[2], Ken Gotou[2], Souichirou Watanabe[2], Hitoshi Watanabe[2] (1.Research Institute for Humanity and Nature, 2.Oshino Village)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HTT18-09] The hydrogen and oxygen isotopic compositions of water in the Chikusa River

*Ken'ichi Ohkushi[1], Shiho Yabusaki[2], Ichiro Tayasu[2], Lei Fujiyoshi[2], Takanori Nakano[2], Ki-Cheol Shin[2], Tadashi Yokoyama[3], Hiromune Mitsuhashi[4], Masayuki Itoh[1], Kazuki Yasugi[1] (1.Kobe University, 2.The Research Institute for Humanity and Nature, 3.Ako School for Students with Special Ne, 4.University of Hyogo)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HTT18-10] Dynamics of sulfate and nitrate inferred from stable isotope techniques in Chikusa river watershed, Hyogo Prefecture

*Lei Fujiyoshi[1], Ichiro Tayasu[1], Shiho Yabusaki[1], Takashi F Haraguchi[1], Chikage Yoshimizu[1], Ken'ichi Ohkushi[2], Fumiko Furukawa[2], Masayuki Itoh[2], Yudai Yamamoto[3], Tadashi Yokoyama[4], Hiromune Mitsuhashi[5] (1.The Research Institute for Humanity and Nature, 2.Kobe University, 3.Nagoya University, 4.Hyogo prefectural Ako School for Students with Special Needs, 5.University of Hyogo)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[HTT18-11] Chemistry and sulfur and oxygen isotope ratios of sulfate ion of water soluble component of suspended particulate matter at Okayama city.

*Hitoshi CHIBA[1], Tsubasa Yamamoto[1] (1.Graduate School of Natural Science and Technology, Okayama University)

[E] Oral | H (Human Geosciences)：H-TT Technology & Techniques

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 302 3F

[H-TT18] Development and application of environmental traceability methods

convener:Ichiro Tayasu(Research Institute for Humanity and Nature), Nobuhito Ohte(Department of Social Informatics, Graduate School of Informatics, Kyoto University), Gabriel J Bowen(University of Utah), Chairperson:Ichiro Tayasu(Research Institute for Humanity and Nature)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[HTT18-12] **Do mountain-climbing mammals protect plants from global warming by their vertical seed dispersal?**

*Shoji NAOE[1], Ichiro Tayasu[2] (1.Forestry and Forest Products Research Institute, Forest Research and Management Organization, 2.Research Institute for Humanity and Nature)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[HTT18-13] Spatial distribution of nitrogen stable isotope ratio in deer feces in an agro-environment, Osaka

*Takashi F Haraguchi[1], Ryosuke Koda[2], Ichiro Tayasu[1] (1.Research Institute for Humanity and Nature, 2.RIEAF, Osaka)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[HTT18-14] Nutrient supply from forest to river in eastern Toyama: carbon and nitrogen isotopic composition of Epilithic Organic Matter

*JING ZHANG[1], Ryosuke Masuda[1], SAKI KATAZAKAI[1], Tamihisa Ohta[1], OSAMU INAMURA[2], Fumiko Nakagawa[3] (1.University of Toyama, 2.Uozu Aquarium, 3.Nagoya University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[HTT18-15] Investigation on the possibility of the identification of air pollutant sources using stable isotope ratios of lead and strontium

*Shinji Sakurai[1], Takao Nakagiri[1], Kosuke Tanaka[1], Haruhiko Horino[1], Ki-Cheol Shin[2], Ichiro Tayasu[2], Shiho Yabusaki[2] (1.Osaka Prefecture University, 2.Research Institute for Humanity and Nature)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[HTT18-16] **Magnesium and zinc stable isotopes in stream ecology**

*Kai Nils Nitzsche[1], Yoshikazu Kato[1], Ki-Cheol Shin[1], Hiromitsu Kamauchi[1], Ichiro Tayasu[1] (1.Research Institute for Humanity and Nature)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[HTT18-17] A mechanitic metabolic model of nitrogen stable isotope dynamics in trophic processes

*Reiichiro Ishii[1], Maki Noguchi Aita[2], Eitaro Wada (1.Research Institute for Humanity and Nature, 2.Japan Agency for Marine-Earth Science and Technology)

[E] Poster | H (Human Geosciences)：H-TT Technology & Techniques

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_13

[H-TT18] Development and application of environmental traceability methods

convener:Ichiro Tayasu(Research Institute for Humanity and Nature), Nobuhito Ohte(Department of Social Informatics, Graduate School of Informatics, Kyoto University), Gabriel J Bowen(University of Utah)

[HTT18-P01] Isotopic study on seasonal nitrogen dynamics at Lake Biwa

*Takaaki Ishibashi[1], Ken'ichi Osaka[1], Keisuke Koba[2], Takashi Nakamura[3], Kei Nishida[3] (1.Department of ecosystem study, University of Shiga Prefecture, 2.Center for Ecological Research, Kyoto University, 3.International Research Center for River Basin Environment, University of YAMANASHI)

[HTT18-P02] Relationship between residence time, water quality, and stable isotopes of spring water and groundwater in coastal area of Fukushima prefecture

*Shiho Yabusaki[1], Kazuyoshi Asai[2] (1. Research Institute for Humanity and Nature・Faculty of Symbiotic Systems Science, Fukushima University, 2.Geo Science Laboratory)

[HTT18-P03] Applicability evaluation of CIA due to river and lake

*yusuke hataya[1], SEIKI KAWAGOE[1], Shiho Yabusaki[2], KEN Suzuki[1] (1.fukushima university, 2.Research Institute for Humanity and Nature)

[HTT18-P04] Chemical property analysis of short time scale to determine snowfall source

*Suzuki hiromichi[1], SEIKI KAWAGOE[1], SHO ADACHI[1], Shiho Yabusaki[2] (1.Fukushima University, 2.Research Institute for Humanity and Nature)

[HTT18-P05] Analyzing the origin of surface water in the Saijo Plain, Japan, based on the antimony concentration in the water

*Minoru TOKUMASU[1,2], Ki-Cheol SHIN[3], Yoshihiro YAMADA[4] (1.The United Graduate School of Agricultural Sciences, Ehime University, 2.Saijo City, 3.The Research Institute for Humanity and Nature (RIHN) , 4.Kagawa University, Faculty of Agriculture)

[HTT18-P06] Basic kinetic study on stable isotope ratios of nitrogen compounds: a case study for groundwater in the Kathmandu Valley, Nepal

*Ken Yokozawa[1,2], Kei Nishida[1,3], Takashi Nakamura[1,3], Ken'ichi Osaka[4] (1.University of Yamanashi, 2.Special Graduate Program on River Basin Environmental Science,, 3.ICRE, 4.Department of ecosystem study Univercity of Shiga prefecture)

[HTT18-P07] Usefulness of strontium isotope composition for determining the geographical origin of wasabi and potato

*Takafumi Kamitani[1], Ki-Cheol Shin[2], Sachiko Nakamura[1], Rika Koda[1], Tomoya Oka[1], Noriaki Fushimi[1], Yasuhide Muranaka[1] (1.Shizuoka Institute of Environment and Hygiene, 2.Research Institute for Humanity and Nature)

[HTT18-P08] Reconstruction of sea surface temperature and salinity for the Medieval Climatic Anomaly using a long-lived fossil coral collected at Ishigaki Island, southwestern Japan

*Osamu Abe[1], Maki Morimoto[2], Ryuji Asami[3], Takeshi Nakatsuka[1,4] (1.Graduate School of Environmental Studies, Nagoya University, 2.School of Education, Gifu University, 3.Graduate School of Science, Tohoku University, 4.Research Institute for Humanity and Nature)

[HTT18-P09] Development of the analytical method for sulfur isotope in SO_2 gas

*Masaaki Takahashi[1], Hiroyuki Sase[1], Tsuyoshi Ohizumi[1] (1.Asia Center for Air Pollution Research)

[HTT18-P10] Zinc isotope analysis on human tooth enamel samples to reconstruct diet of the Jomon period.

*Soichiro Kusaka[1], Ki-Cheol Shin[2] (1.Tokai Univ., 2.Research Institute for Humanity and Nature)

*Masato Shinoda[1] (1.Graduate School of Environmental Studies Nagoya University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[HCG28-05] Land use after death and funeral of citizen mainly based on public cemeteries in modern Beijing city

*Haruhiro Doi[1], Yanwei Chai[2], Peiwei Xu[3] (1.Faculty of Education, Oita University, 2.Peking University, 3.Beijing Normal University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[HCG28-06] Restoration and sustainable land management of degraded landscapes in Asia and Africa

★Invited Papers

*OKURO TOSHIYA[1] (1.Graduate School of Agricultural and Life Sciences, The University of Tokyo)

[J] Poster | S (Solid Earth Sciences)：S-GD Geodesy

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[S-GD01] Gravity and Geoid

convener:Tokuro Kodama(Geospatial Information Authority of Japan), Daisuke Oka(Geological Survey of Hokkaido, Environmental and Geological Research Department, Local Independent Administrative Agency, Hokkaido Research Organization)

[SGD01-P01] An Improved GRACE time-varying gravity field model and its application in China and Antarctica

*Yunlong Wu[1], Yi Zhang[1], Zhengbo Zou[1], Minzhang Hu[1] (1.Institute of Seismology, China Earthquake Administration)

[SGD01-P02] Numerical modeling of crustal deformation and gravity change caused by glacier melting in Southeast Alaska

*Kazuhiro Naganawa[1], Takahito Kazama[1] (1.Graduate School of Science, Kyoto University)

[SGD01-P03] Gravity gradient variations considered to have occured 3 months before the Tohoku-Oki earthquake

*Naoki Hasumi[1], Kosuke Heki[1] (1.Hokkaido University Graduate School of Science)

[SGD01-P04] Density structure inferred from gravity and airborne gravity gradiometry data in the northwestern part of Kuju volcano, Oita prefecture

*Jun Nishijima[1], Yasuhiro Fujimitsu[1] (1.Department of Earth Resources Engineering, Graduate School of Engineering, Kyushu University)

[SGD01-P05] On the effect of higher-order terms in the gravity sensor of the superconducting gravimeter

*Yuichi Imanishi[1], Kazunari Nawa[2], Yoshiaki Tamura[3], Hiroshi Ikeda[4] (1.Earthquake Research Institute, The University of Tokyo, 2.AIST, 3.NAOJ, 4.University of Tsukuba)

[SGD01-P06] **Gravity Effect of Local Snow Accumulation obtained from Superconducting Gravimeter and UAV survey at Syowa Station**

*Akihisa Hattori[1], Yuichi Aoyama[1,2], Koichiro Doi[1,2], Hajime Oishi[3], Jun Nishijima[4], Hiroshi Ikeda[5] (1.SOKENDAI (The Graduate University of Advanced Studies), 2.National Institute of Polar Research, 3.NEC Networks & System Integration Corporation, 4.Kyushu University, 5.University of Tsukuba)

[J] Poster | S (Solid Earth Sciences)：S-GD Geodesy

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_26

[S-GD01] Gravity and Geoid

convener:Tokuro Kodama(Geospatial Information Authority of Japan), Daisuke Oka(Geological Survey of Hokkaido, Environmental and Geological Research Department, Local Independent Administrative Agency, Hokkaido Research Organization)

[SGD01-P01] An Improved GRACE time-varying gravity field model and its application in China and Antarctica

[SGD01-P02] Numerical modeling of crustal deformation and gravity change caused by glacier melting in Southeast Alaska

*Kazuhiro Naganawa[1], Takahito Kazama[1] (1.Graduate School of Science, Kyoto University)

[SGD01-P03] Gravity gradient variations considered to have occured 3 months before the Tohoku-Oki earthquake

*Naoki Hasumi[1], Kosuke Heki[1] (1.Hokkaido University Graduate School of Science)

[SGD01-P04] Density structure inferred from gravity and airborne gravity gradiometry data in the northwestern part of Kuju volcano, Oita prefecture

*Jun Nishijima[1], Yasuhiro Fujimitsu[1] (1.Department of Earth Resources Engineering, Graduate School of Engineering, Kyushu University)

[SGD01-P05] On the effect of higher-order terms in the gravity sensor of the superconducting gravimeter

*Yuichi Imanishi[1], Kazunari Nawa[2], Yoshiaki Tamura[3], Hiroshi Ikeda[4] (1.Earthquake Research Institute, The University of Tokyo, 2.AIST, 3.NAOJ, 4.University of Tsukuba)

[SGD01-P06] **Gravity Effect of Local Snow Accumulation obtained from Superconducting Gravimeter and UAV survey at Syowa Station**

*Akihisa Hattori[1], Yuichi Aoyama[1,2], Koichiro Doi[1,2], Hajime Oishi[3], Jun Nishijima[4], Hiroshi Ikeda[5] (1.SOKENDAI (The Graduate University of Advanced Studies), 2.National Institute of Polar Research, 3.NEC Networks & System Integration Corporation, 4.Kyushu University, 5.University of Tsukuba)

[J] Oral | S (Solid Earth Sciences)：S-GD Geodesy

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 303 3F

[S-GD01] Gravity and Geoid

convener:Tokuro Kodama(Geospatial Information Authority of Japan), Daisuke Oka(Geological Survey of Hokkaido, Environmental and Geological Research Department, Local Independent Administrative Agency, Hokkaido Research Organization), Chairperson:Toshiyuki Tanaka, Takahito Kazama

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SGD01-01] Seasonal variation of gravity values at the Ishioka Geodetic Observing Station

*Akira Tomiyama[1], Tokuro Kodama[1], Shuichi Oomori[1], Yoshifumi Hiraoka[1], Toshihiro Yahagi[1] (1.GSI of Japan)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SGD01-02] Installation of the First Gravity Station in the Mount Fuji Research Institute, and the Phase-Free gravity measurement

*Ryo Honda[1], Yuichi Imanishi[2], Kazunari Nawa[3], Toshiyuki Tanaka[4], Tokuro Kodama[5], Akira Tomiyama[5] (1.MFRI, Yamanashi Prefectural Government, 2.ERI, University of Tokyo, 3.GSJ, AIST, 4.TRIES, ADEP, 5.GSI)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SGD01-03] Absolute gravity and GNSS measurements on bedrock outcrops in Dronning Maud Land, East Antarctica

*Takahito Kazama[1], Yuichi Aoyama[2], Yoichi Fukuda[1], Koichiro Doi[2] (1.Graduate School of Science, Kyoto University, 2.National Institute of Polar Research)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SGD01-04] **Capability of ICA Method for separating GIA and Ice Mass Signals in Antarctica**

*SHI TIANYAN[1], Yoichi Fukuda[1] (1.Graduate School of Science, Kyoto University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SGD01-05] Preliminary result of continuous observation with an iGrav superconducting gravimeter at the Teshikaga observatory, eastern Hokkaido, Japan

*Kazunari Nawa[1], Hiroaki Takahashi[2], Mako Ohzono[2], Kazumi Okada[2], Teruhiro Yamaguchi[2], Daisuke Oka[3], Noritoshi Okazaki[3], Ryo Honda[4], Hiroshi Ikeda[5] (1.National Institute of Advanced Industrial Science and Technology, 2.Hokkaido University, 3.Geological Survey of Hokkaido, 4.Mount Fuji Research Institute, 5.University of Tsukuba)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SGD01-06] On the anomalous temporal gravity change between VERA and F-net stations at Ishigakijima, Japan

*Kazunari Nawa[1], Yuichi Imanishi[2], Yoshiaki Tamura[3], Hiroshi Ikeda[4], Takeshi Kimura[5] (1.National Institute of Advanced Industrial Science and Technology, 2.Earthquake Research Institute, The University of Tokyo, 3.National Astronomical Observatory of Japan, 4.University of Tsukuba, 5.National Research Institute for Earth Science and Disaster Resilience)

[J] Oral | S (Solid Earth Sciences)：S-GD Geodesy

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 303 3F

[S-GD01] Gravity and Geoid

convener:Tokuro Kodama(Geospatial Information Authority of Japan), Daisuke Oka(Geological Survey of Hokkaido, Environmental and Geological Research Department, Local Independent Administrative Agency, Hokkaido Research Organization), Chairperson:Kazunari Nawa, Ryo Honda(山梨県富士山科学研究所)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SGD01-07] **Absolute gravity signals at the Sakurajima volcano since 2009 through 2018**

*Shuhei Okubo[1], Keigo Yamamoto[2], Masato Iguchi[2], Yoshiyuki Tanaka[3], Yuichi Imanishi[1], Ryuichi Nishiyama[1], Miwako Ando[1], Atsushi Watanabe[1] (1.Earthquake Research Institute, The University of Tokyo, 2.Disaster Prevention Research Institute, Kyoto University, 3.Graduate School of Science, The University of Tokyo)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SGD01-08] Detection of Earthquake-induced Prompt Gravity Signals in Multi-channel Data

*Masaya Kimura[1], Nobuki Kame[1], Shingo Watada[1], Makiko Ohtani[2], Akito Araya[1], Yuichi Imanishi[1], Masaki Ando[3], Takashi Kunugi[4] (1.Earthquake Research Institute,The University of Tokyo, 2.National Institute of Advanced Industrial Science and Technology, 3.Department of Physics, The University of Tokyo, 4.National Research Institute for Earth Science and Disaster Resilience)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SGD01-09] Evaluation of atmospheric attraction effect using local-scale objective analysis (LANAL)

*Toshiyuki Tanaka[1] (1.Tono Research Institute of Earthquake Science, Association for the Development of Earthquake Prediction)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SGD01-10] Airborne gravity survey for establishment of a new precise gravimetric geoid model

*Tokuro Kodama[1], Akira Tomiyama[1], Shuichi Oomori[1], Erika Wada[1], Toshihiro Yahagi[1], Yoshifumi Hiraoka[1], Hiroshi Kawawa[1] (1.GSI of Japan)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SGD01-11] Gravimetric geoid modeling using airborne gravity data : a case study in Colorado, U.S.A.

*Koji Matsuo[1], Rene Forsberg[2] (1.GSI of Japan, 2.Denmark Technical University)

[J] Oral | S (Solid Earth Sciences)：S-GD Geodesy

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 105 1F

[S-GD02] Engineering Application of Space Geodesy

convener:Seiichi Shimada(Graduate School of Frontier Sciences, University of Tokyo Nippo Co. Ltd.), Shuichi Rokugawa(The University of Tokyo), Basara Miyahara(GSI of Japan), Toshiaki Tsujii(Department of Aerospace Engineering, Osaka Prefecture University), Chairperson:Masaatsu Aichi, Kazuki Sakai

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SGD02-01] Future vision of the society for utilizing highly precise three dimensional positioning data by applying crustal deformation and precise gravimetric geoid model

*Toshihiro Yahagi[1], Kensuke Kokado[1], Kenji Yoshida[1], Takashi Toyofuku[1], Masao Iwata[1], Basara Miyahara[1] (1.GSI of Japan)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SGD02-02] Preliminary study on the application of satelite-based monitoring for land surface displacement to inverse analyses of groundater flow/land subsidence modeling

*Masaatsu Aichi[1] (1.Graduate School of Frontier Sciences, The University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SGD02-03] Monitoring of ground deformation all over Japan by InSAR and utilizing 2.5-D analysis

*Kazuki Sakai[1], Kyonosuke Hayahsi[1], Masaki Kuwahara[1], Tatsuya Yamashita[1], Masaki Honda[1], Hiroshi Munekane[1] (1.GSI of Japan)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SGD02-04] Resource Exploration using Interferometric Synthetic Aperture Radar Measurement Technology

*Shuichi Rokugawa[1], Takako Nakamura[1] (1.The University of Tokyo)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SGD02-05] The application example of GNSS for natural gas development together with PDCA Management Method

★Invited Papers

*Yoshiyuki Muramoto[1], Susumu Hayatsu[1], Michiharu Hiyama[1], Daisuke Murai[1], Shoji Kunisue[1] (1.KANTO NATURAL GAS DEVELOPMENT CO., LTD)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SGD02-06] New threats and countermeasures in the aviation field where the use of GNSS satellite navigation expands

★Invited Papers

*Takeshi Fujiwara[1], Toshiaki Tsujii[2] (1.Japan Aerospace Exploration Agency, 2.Osaka Prefecture University)

[J] Poster | S (Solid Earth Sciences)：S-GD Geodesy

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_15

[S-GD02] Engineering Application of Space Geodesy

convener:Seiichi Shimada(Graduate School of Frontier Sciences, University of Tokyo Nippo Co. Ltd.), Shuichi Rokugawa(The University of Tokyo), Basara Miyahara(GSI of Japan), Toshiaki Tsujii(Department of Aerospace Engineering, Osaka Prefecture University)

[SGD02-P01] Dynamic map for engineering use of GNSS positioning

*Mikio Satomura[1], Seiichi Shimada[1,2], Hirokazu Ito[1], UKEI KAZUYUKI[1], Mikio Sueno[1,3], Shigeru Nakao[4] (1.Nippo Company, Limited, 2.Graduate School of Frontier Sciences, University of Tokyo, 3.Calsystem Company, Limited, 4.Graduate School of Scienece and Engineering, Kagoshima Univeresity)

[SGD02-P02] Utilization of Interferometric Synthetic Aperture Radar Time Series Analysis Technology for Disaster Prevention

*Takako Nakamura[1], Shuichi Rokugawa[1] (1.The University of Tokyo)

[SGD02-P03] The annual and secular movements of vertical component in GEONET sites caused by groundwater usages

*Seiichi Shimada[1], Masaatsu Aichi[1] (1.Graduate School of Frontier Sciences, University of Tokyo)

[J] Poster | S (Solid Earth Sciences)：S-GD Geodesy

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_27

[S-GD02] Engineering Application of Space Geodesy

convener:Seiichi Shimada(Graduate School of Frontier Sciences, University of Tokyo Nippo Co. Ltd.), Shuichi Rokugawa(The University of Tokyo), Basara Miyahara(GSI of Japan), Toshiaki Tsujii(Department of Aerospace Engineering, Osaka Prefecture University)

[SGD02-P01] Dynamic map for engineering use of GNSS positioning

*Mikio Satomura[1], Seiichi Shimada[1,2], Hirokazu Ito[1], UKEI KAZUYUKI[1], Mikio Sueno[1,3], Shigeru Nakao[4] (1.Nippo Company, Limited, 2.Graduate School of Frontier Sciences, University of Tokyo, 3.Calsystem Company, Limited, 4.Graduate School of Scienece and Engineering, Kagoshima Univeresity)

[SGD02-P02] Utilization of Interferometric Synthetic Aperture Radar Time Series Analysis Technology for Disaster Prevention

*Takako Nakamura[1], Shuichi Rokugawa[1] (1.The University of Tokyo)

[SGD02-P03] The annual and secular movements of vertical component in GEONET sites caused by groundwater usages

*Seiichi Shimada[1], Masaatsu Aichi[1] (1.Graduate School of Frontier Sciences, University of Tokyo)

[E] Oral | S (Solid Earth Sciences)：S-SS Seismology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Convention Hall B 2F

[S-SS06] Nankai Trough Seismogenic Zone Experiment: Logging and sampling the seismogenic megathrust

convener:Kyuichi Kanagawa(Graduate School of Science, Chiba University), Demian M Saffer(Pennsylvania State University), Masataka Kinoshita(Earthquake Research Institute, University of Tokyo), Chairperson:Kyuichi Kanagawa(Graduate School of Science, Chiba University), Demian Saffer(Department of Geosciences, Pennsylvania State University), Masataka Kinoshita(Earthquake Research Institute, the University of Tokyo)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SSS06-01] Geoscientific information about plate boundary along the Nankai Trough provided by the GNSS-A

★Invited Papers

*Yusuke Yokota[1], Tadashi Ishikawa[2] (1.Institute of Industrial Science, The University of Tokyo, 2.Hydrographic and Oceanographic department, Japan Coast Guard)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SSS06-02] Deep Drilling at the Nankai Trough: IODP NanTroSEIZE Expedition 358 Summary and First Results

★Invited Papers

*Harold Tobin[1], Takehiro Hirose[7], Matt Ikari[5], Kyuichi Kanagawa[10], Gaku Kimura[3], Masataka Kinoshita[8], Hiroko Kitajima[6], Demian M Saffer[4], Asuka Yamaguchi[9], Lena Maeda[2], Nobu Eguchi[2], Sean Toczko[2] (1.Department of Earth and Space Sciences, University of Washington, 2.JAMSTEC-CDEX, 3.Tokyo Un. of Marine Science-Technology, 4.Penn State University, 5.MARUM Un. of Bremen, 6.Texas A&M University, 7.JAMSTEC-KCC, 8.Un. of Tokyo Earthquake Research Institute, 9.Un. of Tokyo AORI, 10.Chiba University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SSS06-03] Coexistence of soft and hard sediments at deep Nankai accretionary prism, NanTro SEIZE Project, IODP Exp.358

*Arito Sakaguchi[1,2], Michael Strasser[3], Mari Hamahashi[4,5], Takehiro Hirose[2], Hiroko Kitajima[6], Expedition 358 Scientists IODP (1.Yamaguchi Univ., 2.JAMSTEC, 3.University of Innsbruck, 4.University of Tokyo, 5.Nanyang Technological University, 6.Texas A&M University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SSS06-04] Active and passive seismic experiment during the IODP Exp. 358 deep riser drilling in the Nankai Trough, Japan

*Toshinori Kimura[1], Takashi Tonegawa[1], Kazuya Shiraishi[1], Eiichiro Araki[1], Yasuyuki Nakamura[1], Yuka Kaiho[1], Gou Fujie[1], Seiichi Miura[1], Shuichi Kodaira[1], Noriaki Sakurai[1], Yoshinori Sanada[1], Yukari Kido[1], Masataka Kinoshita[2], Narumi Takahashi[3,1], Yuya Machida[1], Shuhei Nishida[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, The University of Tokyo, 3.National Research Institute for Earth Science and Disaster Resilience)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SSS06-05] Microfabric analysis of damaged zone of principal shear zone in the frontal megathrust in the Nankai Trough

*Gaku Kimura[1], Asuka Yamaguchi[2], Yohei Hamada[3], Suguru Yabe[4] (1.Tokyo University of Marine Science and Technology, 2.Atomosphere and Ocean Research Institute, The University of Tokyo, 3.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 4.Japan Agency for Marine-Earth Science and Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SSS06-06] Seismic Imaging of Mud Diapirs in Northern Kumano Basin, Nankai Trough

*Gregory F Moore[1], Miho Asada[2], Shuichi Kodaira[2], Achim Kopf[3] (1.University of Hawaii at Manoa, 2.JAMSTEC, 3.MARUM)

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_16

[S-SS06] Nankai Trough Seismogenic Zone Experiment: Logging and sampling the seismogenic megathrust

convener:Kyuichi Kanagawa(Graduate School of Science, Chiba University), Demian M Saffer(Pennsylvania State University), Masataka Kinoshita(Earthquake Research Institute, University of Tokyo)

[SSS06-P01] Crustal structure in the Nankai Trough seismogenic zone based on renewed depth images and seismic attribute analysis

*Kazuya Shiraishi[1], Yasuhiro Yamada[1], Masataka Kinoshita[2], Gaku Kimura[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, The University of Tokyo, 3.Tokyo University of Marine Science and Technology)

[SSS06-P02] Along-strike variations in protothrust zone characteristics at the Nankai Trough subduction margin

*Hannah Tilley[1], Gregory F Moore[1], Mikiya Yamashita[2], Shuichi Kodaira[2] (1.University of Hawaii at Manoa, 2.JAMSTEC)

[SSS06-P03] Temporal change in seismic velocity in the Nankai subduction zone from cross-correlation analysis of ambient noise

*Tatsunori Ikeda[1], Takeshi Tsuji[1] (1.Kyushu University)

[SSS06-P04] Strength profile of the Nankai accretionary prism evaluated from drilling parameters

★Invited Papers

*Yohei Hamada[1], Manami Kitamura[2], Takehiro Hirose[1], Yasuhiro Yamada[1], Yoshinori Sanada[1], Takamitsu Sugihara[1], Saneatsu Saito[1], KYAW MOE[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute of Advanced Industrial Science andTechnology)

[SSS06-P05] Paleotemperature anomalies deduced from thermal-maturity parameters within the décollement, off Cape of Muroto, Japan

*Nana Kamiya[1,2], Takehiro Hirose[2], Yuzuru Yamamoto[2], Yohei Hamada[2], Stephen A Bowden[3], Man-Yin Tsang[4], Kiho Yang[5], Satoshi Tonai[6], Weiren Lin[1,2] (1.Graduate School of Engineering, Kyoto University, 2.JAMSTEC, 3.University of Aberdeen, 4.University of Toronto, 5.Yonsei University, 6.Kochi University)

[SSS06-P06] Modelling thermal maturity of an accretionary wedge

Utsav Mannu[2], *Masataka Kinoshita[1], Taras Gerya[3] (1.Earthquake Research Institute, University of Tokyo, 2.Department of Earth and Climate Science, IISER Pune, 3.Institute of Geophysics, ETH Zürich)

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_28

*Hidetaka Saomoto[1] (1.National Institute of Advanced Industrial Science and Technology)

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A02 TOKYO BAY MAKUHARI HALL

[S-SS15] Active faults and paleoseismology

convener:Mamoru Koarai(Earth Science course, College of Science, Ibaraki University), Takashi OGAMI(National Institute of Advanced Industrial Science and Technology), Ryosuke Doke(Hot Springs Research Institute of Kanagawa Prefecture), Hisao Kondo(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Mamoru KOARAI(Ibaraki University), Taku Komatsubara(産業技術総合研究所)

3:30 PM - 4:00 PM JST | 6:30 AM - 7:00 AM UTC

[SSS15-01] Historical documents and oral transmissions on historical tsunamis in the Paciffic coast of Tohoku

★Invited Papers

*ebina yuichi[1] (1.International Research Institute of Disaster Science)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SSS15-02] Co-seismic crustal movements along reverse faults which subsidence component is larger than uplifting component

*Taku Komatsubara[1] (1.Institute of Geology and Geoinformation, Advanced Industrial Science and Technology)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SSS15-03] The Iyo-Bungo, southwest Japan, earthquake on September 1st, 1596 as deduced from contemporary historical records

*Katsuhiko Ishibashi[1] (1.Emeritus Professor, Kobe University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SSS15-04] Geologically recorded historical and prehistoric tsunamis in the Tonankai region

*Shigehiro Fujino[1], Haruo Kimura[2], Junko Komatsubara[3], Dan Matsumoto[3], Yuichi Namegaya[3], Yuki Sawai[3], Masanobu Shishikura[3] (1.Faculty of Life and Environmental Sciences, University of Tsukuba, 2.Civil Engineering Research Laboratory, Central Research Institute of Electric Power Industry, 3.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST))

[E] Oral | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A10 TOKYO BAY MAKUHARI HALL

[S-IT21] Interaction and Coevolution of the Core and Mantle in the Earth and Planets

convener:Kenji Kawai(Department of Earth and Planetary Science, School of Science, University of Tokyo), Tsuyoshi Iizuka(University of Tokyo), Kenji Ohta(Department of Earth and Planetary Sciences, Tokyo Institute of Technology), Taku Tsuchiya(Geodynamics Research Center, Ehime University), Chairperson:Kenji Kawai, Sebastian Ritterbex

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SIT21-19] Seismological Explorations of Earth's Outer Core: Normal Mode and Body Wave Analyses

★Invited Papers

*Jessica C E Irving[1], Sanne Cottaar[2], Vedran Lekic[3], Wenbo Wu[4] (1.Princeton University, 2.University of Cambridge, 3.University of Maryland, College Park, 4.California Institute of Technology)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SIT21-20] Discussion

*Kenji Kawai[1] (1.University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SIT21-21] On the 1-D radial convective structure of the Earth’s core inferred from a coupled core-mantle evolution model

*Takashi Nakagawa[1] (1.Department of Earth Sciences, The University of Hong Kong)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SIT21-22] Structural and transport properties of liquid iron-light-element mixtures under outer core conditions

*Satoshi Ohmura[1], Taku Tsuchiya[2] (1.Hiroshima Inst. of Tech., 2.Ehime Univ.)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SIT21-23] Development of New Technology for Geoneutrino Directional Measurement

*Hiroko Watanabe[1] (1.Research Center for Neutrino Science, Tohoku University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SIT21-24] Investigation of multi light elements in iron-silicate-water system using high pressure and temperature neutron experiments: Implications for the Earth's evolution

★Invited Papers

*Riko Iizuka-Oku[1], Hirotada Gotou[2], Ko Fukuyama[1], Hiroyuki Kagi[1] (1.Geochemical Research Center, Graduate School of Science, The University of Tokyo, 2.The Institute for Solid State Physics, The University of Tokyo)

[E] Oral | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A10 TOKYO BAY MAKUHARI HALL

[S-IT21] Interaction and Coevolution of the Core and Mantle in the Earth and Planets

convener:Kenji Kawai(Department of Earth and Planetary Science, School of Science, University of Tokyo), Tsuyoshi Iizuka(University of Tokyo), Kenji Ohta(Department of Earth and Planetary Sciences, Tokyo Institute of Technology), Taku Tsuchiya(Geodynamics Research Center, Ehime University), Chairperson:Noriyoshi Tsujino, Kenta Ueki

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SIT21-25] Low hydrogen contents in the cores of terrestrial planets

★Invited Papers

*Vincent Clesi[1], Mohamed Ali Bouhifd[2], Nathalie Bolfan-Casanova[2], Geeth Manthilake[2], Federica Schiavi[2], Caroline Raepsaet[3], Hélène Bureau[4], Hicham Khodja[3], Denis Andrault[2] (1.Laboratoire de Geologie de Lyon - Terre, Planètes, Environnement, Université Claude Bernard Lyon 1, CNRS, ENS-Lyon, 69622 Villeurbanne, France., 2.Laboratoire Magmas et Volcans, Université Clermont Auvergne, CNRS UMR 6524, OPGC–IRD, Campus Universitaire des Cézeaux, 6 Avenue Blaise Pascal, 63178 Aubière Cedex, France., 3.Laboratoire d'Etude des Eléments Légers, NIMBE, CEA, CNRS, Université Paris-Saclay, CEA Saclay, 91191 Gif sur Yvette Cedex, France., 4.Institut de Minéralogie et de Physique de la Matière et de Cosmochimie, Sorbonne Universités, UMR CNRS-UPMC 7590, 4 place Jussieu, 75252 Paris, France.)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SIT21-26] Discussion

*Taku Tsuchiya[1] (1.Geodynamics Research Center, Ehime University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SIT21-27] Fe_2S: the most iron-rich Fe-S compound at pressures of the inner core

*Shigehiko Tateno[1,2], Haruka Ozawa[2,3], Kei Hirose[1,4], Toshihiro Suzuki[5] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.Institute for Planetary Materials, Okayama University, 3.Nuclear Science and Engineering Center, Japan Atomic Energy Agency, 4.Department of Earth and Planetart Science, The University of Tokyo, 5.Geochemical Research Center, The University of Tokyo)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SIT21-28] First-principles Investigation of Iron Diffusion Properties with Implications to Inner Core Plasticity

★Invited Papers

*Sebastian Ritterbex[1], Taku Tsuchiya[1] (1.GRC Ehime University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SIT21-29] Dependence of the dipole component dominancy on the Rayleigh number and inner core size in geodynamo simulations

*Yuki Nishida[1], Yuto Katoh[1], Hiroaki Matsui[2], Masaki Matsushima[3], Atsushi Kumamoto[1] (1.Department of Geophysics, Graduate School of Science, Tohoku University, 2.Dept. of Earth and Planetary Sciences, University of California, Davis, 3.Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SIT21-30] Elasticity of Fe-Si Alloy

*Taku Tsuchiya[1], Yu Fukunaga[1] (1.Geodynamics Research Center, Ehime University)

[E] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

[S-MP29] Oceanic and Continental Subduction Processes

convener:REHMAN Ur Hafiz(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Tatsuki Tsujimori(Tohoku University), Chin-Ho Tsai(Department of Natural Resources and Environmental Studies, National Dong Hwa University), Kazuaki Okamoto(Faculty of Education, Saitama University)

[SMP29-P01] Zircon U-Pb ages of metasedimentary rocks in the Hakogase (Hida Marginal) area, Fukui Prefecture.

*Atsushi MIYASHITA[1], Tatsuki Tsujimori[2], Daniel Pastor-Galán[3], Yi Keewook[4] (1.Seikei University, 2.Tohoku University, 3.Salamanca University, 4.Korea Basic Science Institue)

[SMP29-P02] Late Permian to Early Triassic back-arc type volcanism in the southern Mongolia volcano-plutonic belt of the Central Asian Orogenic Belt: Implication for timing of the final closure of the Palaeo-Asian Ocean

*Takeshi Imayama[1], Yoichiro Koh[2], Kazumasa Aoki[3], Mototaka Saneyoshi[4], Koshi Yagi[5], Shogo Aoki[4], Yoshihiro Sawada[6], Chiaki Ikawa[5], Tomoya Terada[4], Shinobu Ishigaki[4], Shin Toyoda[3], Khishigjav Tsogtbaatar[7], Buuvei Mainbayar[7] (1.Research Institute of Natural Sciences, Okayama University of Science, 2.Graduate School of Environmental Science, Hokkaido University, 3.Faculty of Science, Okayama University of Science, 4.Faculty of Biosphere - Geosphere Science, Okayama University of Science, 5.Hiruzen Institute for Geology and Chronology, 6.Emeritus Professor of Shimane University, 7.Institute of Paleontology and Geology, Mongolian Academy of Sciences)

[SMP29-P03] Mantle dynamics of slab breakoff constrained from the temporal change of the melting depth estimated from the Cumulate Member of the Ordovician Hayachine-Miyamori Ophiolite

*Takafumi Kimura[1], Kazuhito Ozawa[1] (1.Department of Earth and Planetary Science, The University of Tokyo)

[SMP29-P04] **Evidence of HIMU seamount on the Farallon Plate: Application of *in-situ* Sr-Pb isotope analysis to Franciscan lawsonite-bearing metagreywacke**

*Tomomi Hara[1], Tatsuki Tsujimori[1], Jun-Ichi Kimura[2] (1.Tohoku University, 2.Japan Agency for Marine-Earth Science and Technology)

[SMP29-P05] Boron isotope variations of antigorite serpentinites associated with high-pressure metamorphic rocks: A case study in the Itoigawa–Omi area of the Hida-Gaien Belt, Japan

*Chinatsu Yamada[1], Tatsuki Tsujimori[1], King Chang[2], Jun-Ichi Kimura[2] (1.Tohoku University, 2.Japan Aegency for Marine-Earth Science and Technology)

[SMP29-P06] **Study of zircons structures from the Miocene Shibi-san Granodiorite, Kagoshima Prefecture, Japan**

*Nakabayashi Marimo[1], REHMAN Ur Hafiz[1] (1.Kagoshima University)

[SMP29-P07] **Experimental modeling of eclogite and C-O-H fluid interaction in the subduction zones**

*Nadezda Chertkova[1], Shigeru Yamashita[2], Hiroaki Ohfuji[1], Tetsuo Irifune[1], Hirokazu Kadobayashi[1], Yoshitaka Yamamoto[3] (1.Ehime University, Geodynamics Research Center, 2.Okayama University, Institute for Planetary Materials, 3.National Institute of Advanced Industrial Science and Technology)

[SMP29-P08] Microfabrics of omphacite and garnet in eclogite from the Lanterman Range, northern Victoria Land, Antarctica

*Daeyeong Kim[1], Taehwan Kim[2], Jungmin Kim[3] (1.Division of Polar-Earth Sciences, Korea Polar Research Institute, 2.School of Earth and Environmental Sciences, Seoul National University, 3.Earth and Environmental Sciences, Korea University)

[SMP29-P09] Primordial Apatite from Ophiolite in Taiwan

*Nobuaki Niitsuma[1], Reishi Takashima[2], Yuan Hsi Lee[3] (1.Institute of Geosciences,Shizuoka University, 2.Tohoku University Museum, 3.National Chung-Cheng University, Taiwan)

[SMP29-P10] The evolution of the Cretaceous Jinan Basin in South Korea and the age and tectonic setting for the volcanic rocks in it

*Seung Hwan LEE[1], Chang Whan Oh[1] (1.Department of earth and environmental sciences Chonbuk national university)

[SMP29-P11] GEOCHORONOLOGY AND PETROCHEMISTREY OF LATE PALEOZOIC MAGMATIC ROCKS OF THE MANDAKH AREA, SOUTHEAST MONGOLIA

*Undarmaa Batsaikhan[1], Noriyoshi Tsuchiya[1], Masaoki Uno[1], Yukio Isozaki[2], Uyanga Bold[2], Hikaru Sawada[2] (1.Graduate School of Environmental Studies, Tohoku University, 2.Graduate School of Arts and Sciences The University of Tokyo)

[SMP29-P12] Feedbacks Offshore the Cascadia Margin

*Joan S Gomberg[1] (1.USGS Earthquake Science Center)

[E] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_32

[S-MP29] Oceanic and Continental Subduction Processes

convener:REHMAN Ur Hafiz(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Tatsuki Tsujimori(Tohoku University), Chin-Ho Tsai(Department of Natural Resources and Environmental Studies, National Dong Hwa University), Kazuaki Okamoto(Faculty of Education, Saitama University)

[SMP29-P01] Zircon U-Pb ages of metasedimentary rocks in the Hakogase (Hida Marginal) area, Fukui Prefecture.

*Atsushi MIYASHITA[1], Tatsuki Tsujimori[2], Daniel Pastor-Galán[3], Yi Keewook[4] (1.Seikei University, 2.Tohoku University, 3.Salamanca University, 4.Korea Basic Science Institue)

[SMP29-P02] Late Permian to Early Triassic back-arc type volcanism in the southern Mongolia volcano-plutonic belt of the Central Asian Orogenic Belt: Implication for timing of the final closure of the Palaeo-Asian Ocean

*Takeshi Imayama[1], Yoichiro Koh[2], Kazumasa Aoki[3], Mototaka Saneyoshi[4], Koshi Yagi[5], Shogo Aoki[4], Yoshihiro Sawada[6], Chiaki Ikawa[5], Tomoya Terada[4], Shinobu Ishigaki[4], Shin Toyoda[3], Khishigjav Tsogtbaatar[7], Buuvei Mainbayar[7] (1.Research Institute of Natural Sciences, Okayama University of Science, 2.Graduate School of Environmental Science, Hokkaido University, 3.Faculty of Science, Okayama University of Science, 4.Faculty of Biosphere - Geosphere Science, Okayama University of Science, 5.Hiruzen Institute for Geology and Chronology, 6.Emeritus Professor of Shimane University, 7.Institute of Paleontology and Geology, Mongolian Academy of Sciences)

[SMP29-P03] Mantle dynamics of slab breakoff constrained from the temporal change of the melting depth estimated from the Cumulate Member of the Ordovician Hayachine-Miyamori Ophiolite

[SMP29-P12] Feedbacks Offshore the Cascadia Margin

*Joan S Gomberg[1] (1.USGS Earthquake Science Center)

[E] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A08 TOKYO BAY MAKUHARI HALL

[S-MP29] Oceanic and Continental Subduction Processes

convener:REHMAN Ur Hafiz(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Tatsuki Tsujimori(Tohoku University), Chin-Ho Tsai(Department of Natural Resources and Environmental Studies, National Dong Hwa University), Kazuaki Okamoto(Faculty of Education, Saitama University), Chairperson:Hafiz REHMAN(Kagoshima University), Tatsuki Tsujimori

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SMP29-01] Pb-isotope of Fe-Ni alloy associated with serpentinite: Geochemical constraints on the fluid-mediated hyper-reducing environment in mantle wedge

★Invited Papers

*Mayu Kakefuda[1], Tatsuki Tsujimori[1], Katsuyuki Yamashita[2], Yoshiyuki Iizuka[3] (1.Tohoku University, 2.Graduate School of Natural Science and Technology, Okayama University, 3.Institute of Earth Sciences, Academia Sinica)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SMP29-02] PETROCHEMISTRY AND AGE DETERMINATION OF THE NEWLY DISCOVERED ECLOGITE IN THE WESTERN MONGOLIA

*Kosuke Naemura[1], Erdenjargal Choindonjamts[4], Takenori Kato[5], Otgonkhuu Javkhlan[3], Katsuyoshi Michibayashi[2] (1.Nagoya University Museum, 2.Nagoya University Graduate school of environmental studies, 3.Chinese Academy of Geological Sciences, 4.Mongolian Academy of Sciences, 5.Nagoya University Space-Earth Environmental Research)

2:15 PM - 2:45 PM JST | 5:15 AM - 5:45 AM UTC

[SMP29-03] **Continental subduction, "*Intraslab UHP Metasomatism*", and the formation of metamorphic diamond**

★Invited Papers

*Yoshihide Ogasawara[1] (1.Department of Earth Sciences, Waseda University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SMP29-04] Ultrahigh-pressure pseudotachylyte in a marble

★Invited Papers

*Tadao Nishiyama[1], Tomoya Fujimoto[1] (1.Department of Earth and Environmental Sciences, School of Science, Graduate School of Science and Technology, Kumamoto University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SMP29-05] Dehydration and Deformation process of subducted large Oceanic Pleateau -case study of the Mikabu blueschist-

*Kazuaki Okamoto[1] (1.Faculty of Education, Saitama University)

[E] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A08 TOKYO BAY MAKUHARI HALL

[S-MP29] Oceanic and Continental Subduction Processes

convener:REHMAN Ur Hafiz(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Tatsuki Tsujimori(Tohoku University), Chin-Ho Tsai(Department of Natural Resources and Environmental Studies, National Dong Hwa University), Kazuaki Okamoto(Faculty of Education, Saitama University), Chairperson:Tsai Chin-HO(National Dong Hwa University), Hafiz REHMAN(Kagoshima University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SMP29-06] Unusually high Nb/Ta ratio of fluid-precipitated jadeites from New Idria serpentinite body, California: Implications for extreme fractionation in slab fluids

*Naoko Takahashi[1], Tatsuki Tsujimori[2], Qing Chang[3], Jun-Ichi Kimura[3] (1.Graduate School of Science, Tohoku Univ., 2.CNEAS, Tohoku Univ., 3.Department of Solid Earth Geochemistry, JAMSTEC)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SMP29-07] The collision process interpreted using the systematic change of metamorphic pattern along theQinling–Dabie–Odesan collisional belt between the North and South Korea-China Cratons

★Invited Papers

*Chang Whan Oh[1,2] (1.Department of Earth and Environmental Sciences, Chonbuk National University, Jeonju, Republic of Korea, 2.Environmental Science System Research Center, Chonbuk National University,Jeonju, Republic of Korea)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SMP29-08] Contrasting collision processes between northwest and central Himalaya: examination from the "Lesser Himalayan granites” in Pakistan

*Masatsugu Ogasawara[1], Mayuko Fukuyama[2], Rehanul H Siddiqui[3] (1.Institute of Geology and Geoinformation, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 2.Graduate School of Engineering Science, Akita University, 3.Balochistan University of Information Technology, Engineering and Management Sciences)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SMP29-09] New petrologic indications of subduction metamorphism in the Yuli belt, eastern Taiwan

*Chin-Ho Tsai[1], Chih-Ying Yeh[1], Dominikus Deka Dewangga[1], Yui Kouketsu[2], Masaki Enami[3] (1.Department of Natural Resources & Environmental Studies, National Dong Hwa Univ., 2.Department of Earth & Planetary Sciences, Nagoya Univ., 3.Institute for Space-Earth Environmental Research, Nagoya Univ.)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SMP29-10] **The importance of Mn-nodules on the sea floor during subduction for the formation of ophiolitic diamond**

*Richard Wirth[1] (1.Helmholtz Centre Potsdam GFZ German Research Centre for Geosciences 3.5 Surface Geochemistry)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SMP29-11] **Along-strike variability of primitive magmas inferred from olivine-hosted melt inclusions, southernmost Andean Southern Volcanic Zone, Chile**

*Derek Weller[1,2], Charles R Stern[2] (1.Earthquake Research Institute, 2.University of Colorado)

[E] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[S-MP30] Crust-Mantle Connections

convener:Yoshihiko Tamura(Research Institute for Marine Geodynamics, Japan Agency for Maine-Earth Science and Technology), Osamu Ishizuka(Geological Survey of Japan, AIST), Chris Conway(Geological Survey of Japan)

[SMP30-P01] Secular evolution of proto-Izu-Bonin-Mariana arc volcanism: Constraints from statistical analysis of melt inclusion compositions

*Morihisa Hamada[1], Hikaru Iwamori[1,2], Philipp A. Brandl[3], Takayuki Ushikubo[4], Kenji Shimizu[4], Motoo Ito[4], He Li[5], Ivan P. Savov[6] (1.Department of Solid Earth Geochemistry, Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, University of Tokyo, 3.GEOMAR Helmholtz Centre for Ocean Research Kiel, 4.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 5.Institute of Oceanology, Chinese Academy of Sciences, 6.School of Earth and Environment, University of Leeds)

[SMP30-P02] The Jurassic magmatism of protoliths of Mikabu greenstones in SW Japan: zircon U-Pb dating and trace element analysis

*Hikaru Sawada[1], Yukio Isozaki[1], Shogo Aoki[3], Shuhei Sakata[2], Ryo Hasegawa[1], Yasuo Nakamura[1] (1.Department of General Systems Studies, the University of Tokyo, 2.Department of Chemistry, Gakushuin Universtiy, 3.Department of Applied Science, Okayama University of Science)

[SMP30-P03] **Origin of variable CaO/Al_2O_3 in olivine-hosted melt inclusions from Kibblewhite Volcano, Kermadec Arc**

*Yasuhiro Hirai[1], Yoshihiko Tamura[2], Kaj Hoernle[3], Christian Timm[4], Folkmar Hauff[3], Reinhard Werner[3], Takeshi Hanyu[2], Bogdan Vaglarov[2], Qing Chang[2], Takashi Miyazaki[2], Jun-Ichi Kimura[2] (1.Graduate School of Natural Science and Technology, Kanazawa University, Japan, 2.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Yokosuka, Kanagawa, Japan, 3.GEOMAR Helmholtz Centre for Ocean Research, Kiel, Germany, 4.GNS Science, Lower Hutt, New Zealand)

[SMP30-P04] Ankaramite from Doyo seamount in the Izu-Ogasawara arc: A precursor of continents?

*Yoshihiko Tamura[1], Tomoki Sato[1], Osamu Ishizuka[1,2], Takashi Miyazaki[1], Yasuhiro Hirai[1,3], Mami Takehara[4], Eri Sakamoto[5] (1.JAMSTEC, 2.AIST, 3.Kanazawa Univ., 4.NIPR, 5.NME)

[SMP30-P05] Different Moho reflections adjacent to Minami-Tori Shima and their petrologic origins

*Yoshihiko Tamura[1], Kentaro Kaneda[2], Gou Fujie[1], Akane Ohira[1], Eiichi TAKAZAWA[3], Georges Ceuleneer[4], Katsuyoshi Michibayashi[5], Tomoki Sato[1], Shuichi Kodaira[1], Seiichi Miura[1] (1.Japan Agency for Maine-Earth Science and Technology, 2.Japan Coast Guard, 3.Niigata University, 4.Universite de Toulouse, 5.Nagoya University)

[SMP30-P06] **Melt-rock interaction in plagioclase peridotites from the southern Palawan Ophiolite, Philippines**

*FLORENCE ANNETTE CRUSPERO LABIS[1], BETCHAIDA D PAYOT[1], GABRIEL THEOPHILUS V VALERA[1], JULIUS A PASCO[1], JESLEY MEI A DYCOCO[1] (1.UNIVERSITY OF THE PHILIPPINES)

[SMP30-P07] Intra-oceanic arc magma genesis: a case study from Havre volcano, Kermadec arc

*Chris Conway[1], Kenichiro Tani[2] (1.Geological Survey of Japan, 2.National Museum of Nature and Science)

[E] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_33

[S-MP30] Crust-Mantle Connections

convener:Yoshihiko Tamura(Research Institute for Marine Geodynamics, Japan Agency for Maine-Earth Science and Technology), Osamu Ishizuka(Geological Survey of Japan, AIST), Chris Conway(Geological Survey of Japan)

[SMP30-P01] Secular evolution of proto-Izu-Bonin-Mariana arc volcanism: Constraints from statistical analysis of melt inclusion compositions

*Morihisa Hamada[1], Hikaru Iwamori[1,2], Philipp A. Brandl[3], Takayuki Ushikubo[4], Kenji Shimizu[4], Motoo Ito[4], He Li[5], Ivan P. Savov[6] (1.Department of Solid Earth Geochemistry, Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, University of Tokyo, 3.GEOMAR Helmholtz Centre for Ocean Research Kiel, 4.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 5.Institute of Oceanology, Chinese Academy of Sciences, 6.School of Earth and Environment, University of Leeds)

[SMP30-P02] The Jurassic magmatism of protoliths of Mikabu greenstones in SW Japan: zircon U-Pb dating and trace element analysis

*Hikaru Sawada[1], Yukio Isozaki[1], Shogo Aoki[3], Shuhei Sakata[2], Ryo Hasegawa[1], Yasuo Nakamura[1] (1.Department of General Systems Studies, the University of Tokyo, 2.Department of Chemistry, Gakushuin Universtiy, 3.Department of Applied Science, Okayama University of Science)

[SMP30-P03] Origin of variable CaO/Al_2O_3 in olivine-hosted melt inclusions from Kibblewhite Volcano, Kermadec Arc

*Yasuhiro Hirai[1], Yoshihiko Tamura[2], Kaj Hoernle[3], Christian Timm[4], Folkmar Hauff[3], Reinhard Werner[3], Takeshi Hanyu[2], Bogdan Vaglarov[2], Qing Chang[2], Takashi Miyazaki[2], Jun-Ichi Kimura[2] (1.Graduate School of Natural Science and Technology, Kanazawa University, Japan, 2.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Yokosuka, Kanagawa, Japan, 3.GEOMAR Helmholtz Centre for Ocean Research, Kiel, Germany, 4.GNS Science, Lower Hutt, New Zealand)

[SMP30-P04] Ankaramite from Doyo seamount in the Izu-Ogasawara arc: A precursor of continents?

*Yoshihiko Tamura[1], Tomoki Sato[1], Osamu Ishizuka[1,2], Takashi Miyazaki[1], Yasuhiro Hirai[1,3], Mami Takehara[4], Eri Sakamoto[5] (1.JAMSTEC, 2.AIST, 3.Kanazawa Univ., 4.NIPR, 5.NME)

[SMP30-P05] Different Moho reflections adjacent to Minami-Tori Shima and their petrologic origins

*Yoshihiko Tamura[1], Kentaro Kaneda[2], Gou Fujie[1], Akane Ohira[1], Eiichi TAKAZAWA[3], Georges Ceuleneer[4], Katsuyoshi Michibayashi[5], Tomoki Sato[1], Shuichi Kodaira[1], Seiichi Miura[1] (1.Japan Agency for Maine-Earth Science and Technology, 2.Japan Coast Guard, 3.Niigata University, 4.Universite de Toulouse, 5.Nagoya University)

[SMP30-P06] Melt-rock interaction in plagioclase peridotites from the southern Palawan Ophiolite, Philippines

*FLORENCE ANNETTE CRUSPERO LABIS[1], BETCHAIDA D PAYOT[1], GABRIEL THEOPHILUS V VALERA[1], JULIUS A PASCO[1], JESLEY MEI A DYCOCO[1] (1.UNIVERSITY OF THE PHILIPPINES)

[SMP30-P07] Intra-oceanic arc magma genesis: a case study from Havre volcano, Kermadec arc

*Chris Conway[1], Kenichiro Tani[2] (1.Geological Survey of Japan, 2.National Museum of Nature and Science)

[E] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-MP30] Crust-Mantle Connections

convener:Yoshihiko Tamura(Research Institute for Marine Geodynamics, Japan Agency for Maine-Earth Science and Technology), Osamu Ishizuka(Geological Survey of Japan, AIST), Chris Conway(Geological Survey of Japan), Chairperson:Yoshihiko Tamura(JAMSTEC), Chris Conway, Tomoaki Morishita(Kanazawa University)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SMP30-01] **Noble gas and carbon isotopic compositions of petit-spot lavas from southeast of Marcus Island**

★Invited Papers

*Junji Yamamoto[1], Tetsuma Kawano[2], Naoto Takahata[3], Yuji Sano[3] (1.Hokkaido University Museum, 2.Graduate School of Science, Hokkaido University, 3.Atmosphere and Ocean Research Institute)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SMP30-02] A series of cummingtonite-bearing rhyolites in Niijima, Izu-Bonin arc, Japan: petrological and geochemical constraints

★Invited Papers

*Yoji Arakawa[1], Daisuke Endo[2], Junya Oshika[3], Taro Shinmura[4], Kei Ikehata[1] (1.Earth Evolution Sciences, Faculty of Life and Environmental Sciences, University of Tsukuba, 2.Shimane Prefectural Sanbe Nature Museum Sahimeru (Shimane) , 3.Earth Resoueces Faculty, China University of Geosciences, 4.Faculty of Economics, Kumanoto-Gakuen University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SMP30-03] **Generation of primary andesitic magma in oceanic arcs: Evidence from Kibblewhite Volcano, Kermadec Arc**

★Invited Papers

*Yasuhiro Hirai[1,2], Yoshihiko Tamura[2], Kaj Hoernle[3], Christian Timm[4], Folkmar Hauff[3], Reinhard Werner[3], Bogdan Vaglarov[2], Qing Chang[2], Takashi Miyazaki[2], Jun-Ichi Kimura[2] (1.Graduate School of Natural Science and Technology, Kanazawa University, Japan, 2.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Yokosuka, Kanagawa, Japan, 3.GEOMAR Helmholtz Centre for Ocean Research, Kiel, Germany, 4.GNS Science, Lower Hutt, New Zealand)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SMP30-04] Petrogenesis of high-Mg# andesite lavas from Ruapehu volcano, New Zealand

*Chris Conway[1], Katy Chamberlain[2], Yumiko Harigane[1], Daniel Morgan[3] (1.Geological Survey of Japan, 2.Univ. Derby, 3.Univ. Leeds)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SMP30-05] Hydrous felsic magma generated by unmixing of slab-derived supercritical liquid: evidence from Rishiri Volcano, Kuril Arc

★Invited Papers

*Hajime Taniuchi[1], Takeshi Kuritani[2,3], Tetsuya Yokoyama[4,3], Eizo Nakamura[3], Mitsuhiro Nakagawa[2] (1.Department of Natural History Science, Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Science, Faculty of Science, Hokkaido University, 3.Institute for Planetary Materials, Okayama University, 4.Department of Earth and Planetary Sciences, Tokyo Institute of Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SMP30-06] Genesis of recent mafic volcanism in the Taupo Volcanic Zone, New Zealand: insights into the birth and death of cataclysmic caldera-forming systems?

*Georg F Zellmer[1], Jun-Ichi Kimura[2], Claudine Stirling[3], Gert Lube[1], Phil A Shane[4] (1.Volcanic Risk Solutions, Massey University, Tennent Drive, Palmerston North 4410, New Zealand, 2.Department of Solid Earth Geochemistry, Japan Agency for Marine-Earth Science and Technology [JAMSTEC], Natsushima-cho 2-15, Yokosuka 237-0061, Japan, 3.Department of Chemistry, University of Otago, Dunedin 9054, New Zealand, 4.School of Environment, University of Auckland, Auckland 1142, New Zealand)

[E] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-MP30] Crust-Mantle Connections

convener:Yoshihiko Tamura(Research Institute for Marine Geodynamics, Japan Agency for Maine-Earth Science and Technology), Osamu Ishizuka(Geological Survey of Japan, AIST), Chris Conway(Geological Survey of Japan), Chairperson:Chris Conway, Yoshihiko Tamura(JAMSTEC)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SMP30-07] **Introducing an oceanic core complex in the Shikoku Basin: Mado Megamullion**

★Invited Papers

*Yasuhiko Ohara[1,2], Kyoko Okino[3], Norikatsu Akizawa[3], Masakazu Fujii[4], Yumiko Harigane[5], Naoto Hirano[6], Ken-ichi Hirauchi[7], Osamu Ishizuka[5], Shiki Machida[8], Katsuyoshi Michibayashi[9], Alessio Sanfilippo[10], Jonathan E. Snow[11], Hiroyuki Yamashita[12] (1.Hydrographic and Oceanographic Department of Japan, 2.Japan Agency for Marine-Earth Science and Technology, 3.Atmosphere and Ocean Research Institute, University of Tokyo, 4.National Institute of Polar Research, 5.Geological Survey of Japan/AIST, 6.Tohoku University, 7.Shizuoka University, 8.Chiba Institute of Technology, 9.Nagoya University, 10.University of Pavia, 11.University of Houston, 12.Kanagawa Prefectural Museum of Natural History)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SMP30-08] Spatial variation of petrological and geochemical characteristics of mantle peridotites in Mado Megamullion, Shikoku Basin

*Norikatsu Akizawa[1], Shiki Machida[2], Kyoko Okino[1], Yasuhiko Ohara[3] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 3.Hydrographic and Oceanographic Department of Japan)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SMP30-09] **Magmatism-hydrothermalism interaction along the crust-mantle transition below oceanic spreading centres**

★Invited Papers

*Mathieu Rospabe[1,2], Mathieu Benoit[1], Georges Ceuleneer[1] (1.GET, OMP, Univ. of Toulouse, CNRS, IRD, F-31400 Toulouse, France, 2.JAMSTEC, Yokosuka 237-0061, Japan.)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SMP30-10] **Serpentinization and carbonation of dunites in the western part of the Isua Supracrustal Belt, Southwestern Greenland**

*Juan Miguel Ramirez Guotana[1], Tomoaki Morishita[1], Akihiro Tamura[1], Ikuya Nishio[1], Kenichiro Tani[2], Yumiko Harigane[3], Kristoffer Szilas[4], D. Graham Pearson[5] (1.Kanazawa University, 2.National Museum of Nature and Science, Japan, 3.Institute of Geology and Geoinformation Geological Survey of Japan/AIST, 4.University of Copenhagen, 5.University of Alberta)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SMP30-11] **Petrogenesis of fertile abyssal peridotites of the Pujada Ophiolite, SE Mindanao, Philippines**

*Valerie Shayne Vargas Olfindo[1], Betchaida Duetes Payot[1], Gabriel Theophilus Valera[1], Shoji Arai[2], Tomoyuki Shibata[4], Masako Yoshikawa[3] (1.Rushurgent Working Group, National Institute of Geological Sciences, University of the Philippines, 2.Department of Earth Sciences, Kanazawa University, Kakuma, Kanazawa, Ishikawa 920-1192, Japan, 3.Institute for Geothermal Sciences, Graduate School of Science, Kyoto University, Beppu 874-0903, Japan, 4.Department of Earth and Planetary Systems Science, Hiroshima University, Hiroshima 739-8526, Japan)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SMP30-12] Ultramafic rock in the Hida metamorphic belt: an example of arc plutons

Yohei Ogusu[1], *Tomoaki Morishita[1], Akihiro Tamura[1] (1.Kanazawa University)

[E] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A08 TOKYO BAY MAKUHARI HALL

[S-MP31] Supercontinents and Crustal Evolution

convener:Madhusoodhan Satish-Kumar(Department of Geology, Faculty of Science, Niigata University), Tomokazu Hokada(National Institute of Polar Research), Krishnan Sajeev(Centre for Earth Sciences, Indian Institute of Science), Yasuhito Osanai(Division of Evolution of Earth Environments, Faculty of Social and Cultural Studies, Kyushu University), Chairperson:M. Satish-Kumar(Niigata University), Tomokazu Hokada(National Institute of Polar Research)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SMP31-01] Tectonic development of the East Indian cratonic margin and its status in Columbia Supercontinent

★Invited Papers

*Kaushik Das[1] (1.Hiroshima University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SMP31-02] **Continental crust formation and metamorphism during the Neoarchean–Paleoproterozoic: an example from the Nilgiri Block, southern India**

★Invited Papers

*VINOD O SAMUEL[1] (1.Yonsei University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SMP31-03] Preliminary paleomagnetic studies on the mafic dykes in Western Dharwar craton, South India.

*Silpa Ammini Sasidharan[1], Madhusoodhan Satish-Kumar[2], Naoto Ishikawa[3], Krishnan Sajeev[4] (1.Graduate School of Science and Technology, Niigata University, 2.Department of Geology, Faculty of Science, Niigata University, 3.Graduate School of Human and Environmental Studies, Kyoto University, Kyoto, Japan, 4.Centre for Earth Sciences, Indian Institute of Science, Bangalore, India)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SMP31-04] Syn-metamorphic boron-bearing fluid infiltrations deduced from tourmaline in the Main Central Thrust zone, eastern Nepal Himalayas

★Invited Papers

*Tetsuo Kawakami[1], Harutaka Sakai[1], Katsushi Sato[1] (1.Graduate School of Science, Kyoto University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SMP31-05] **Geochemical characteristics of mafic and felsic igneous rocks (1.9-1.75 Ga) in the Lesser Himalaya: Regional variation and its implications for tectonic setting**

*Ryuichi Shinjo[1], Tomoki Amuro[1], Kohei Oura[1], Kazuya Oshiro[1], Shiro Tahara[1], Harutaka Sakai[2] (1.Department of Physics and Earth Sciences, University of the Ryukyus, 2.Faculty of Science, Kyoto University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SMP31-06] Petrogenesis and tectonic implications of orbicular granodiorite from Yangtze cratonic nucleus

*Yihe Li[1] (1.China University of Geosciences Wuhan)

[E] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_18

[S-MP31] Supercontinents and Crustal Evolution

convener:Madhusoodhan Satish-Kumar(Department of Geology, Faculty of Science, Niigata University), Tomokazu Hokada(National Institute of Polar Research), Krishnan Sajeev(Centre for Earth Sciences, Indian Institute of Science), Yasuhito Osanai(Division of Evolution of Earth Environments, Faculty of Social and Cultural Studies, Kyushu University)

[SMP31-P01] Re-examination of metamorphic and geochronologic events in Rayner Complex and Western Rayner Complex in Antarctica

*Tomokazu Hokada[1,2], Sotaro Baba[3], Atsushi Kamei[4], Ippei Kitano[5], Kenji Horie[1,2], Yoshikuni Hiroi[1,6], Yoichi Motoyoshi[1,2], Mami Takehara[1], Kazuyuki Shiraishi[1] (1.National Institute of Polar Research, 2.The Graduate University for Advanced Studies (SOKENDAI), 3.University of the Ryukyus, 4.Shimane University, 5.Kyushu University, 6.Chiba University)

[SMP31-P02] Composition of constituent minerals in corona-bearing and -free mafic gneisses from the Lützow-Holm Complex at Skallen, East Antarctica

*Yuki Mori[1], Takeshi Ikeda[2] (1.Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University)

[SMP31-P03] “Pseudo-concordance” of U-Pb system in zircon at Harvey Nunatak, Napier Complex, East Antarctica

*Mami Takehara[1] (1.National Institute of Polar Research)

[SMP31-P04] Rapid UHT metamorphism and exhumation of the Lützow-Holm Complex in Antarctica

*Yoshikuni Hiroi[1], Tomokazu Hokada[2], Tatsuro Adachi[3], Yasuhito Osanai[3], Yoichi Motoyoshi[2], Kazuyuki Shiraishi[2] (1.Chiba Univ, 2.National Institute of Polar Research, 3.Kyushu University)

[SMP31-P05] Tectonic History of Hiroo Complex and its implication inpaleo-Kuril Arc evolution

*Sreehari Lakshmanan[1], Tsuyoshi Toyoshima[2], Futoshi Nanayama[3] (1.Graduate School of Science and Technology, Niigata University, Niigata, Japan, 2.Department of Geology, Faculty of Science, Niigata Univ. , 3.Geological Survey of Japan, AIST)

[SMP31-P06] Behaviour of C, O, Sr, Nd and Pb isotopes in high-grade metacarbonate rocks

*Madhusoodhan Satish-Kumar[1], Akari Imura[1], Momoko Shirakawa[2], Gen Shimoda[3], Kosuke T. Goto[3], M A Sanjeewa P K Malaviarachchi[4] (1.Department of Geology, Faculty of Science, Niigata University, 2.Graduate School of Science and Technology, Niigata University, 3.Geological Survey of Japan, 4.University of Peradeniya, Sri Lanka)

[E] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_34

[S-MP31] Supercontinents and Crustal Evolution

convener:Madhusoodhan Satish-Kumar(Department of Geology, Faculty of Science, Niigata University), Tomokazu Hokada(National Institute of Polar Research), Krishnan Sajeev(Centre for Earth Sciences, Indian Institute of Science), Yasuhito Osanai(Division of Evolution of Earth Environments, Faculty of Social and Cultural Studies, Kyushu University)

[SMP31-P01] Re-examination of metamorphic and geochronologic events in Rayner Complex and Western Rayner Complex in Antarctica

*Tomokazu Hokada[1,2], Sotaro Baba[3], Atsushi Kamei[4], Ippei Kitano[5], Kenji Horie[1,2], Yoshikuni Hiroi[1,6], Yoichi Motoyoshi[1,2], Mami Takehara[1], Kazuyuki Shiraishi[1] (1.National Institute of Polar Research, 2.The Graduate University for Advanced Studies (SOKENDAI), 3.University of the Ryukyus, 4.Shimane University, 5.Kyushu University, 6.Chiba University)

[SMP31-P02] Composition of constituent minerals in corona-bearing and -free mafic gneisses from the Lützow-Holm Complex at Skallen, East Antarctica

*Yuki Mori[1], Takeshi Ikeda[2] (1.Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University)

[SMP31-P03] “Pseudo-concordance” of U-Pb system in zircon at Harvey Nunatak, Napier Complex, East Antarctica

*Mami Takehara[1] (1.National Institute of Polar Research)

[SMP31-P04] Rapid UHT metamorphism and exhumation of the Lützow-Holm Complex in Antarctica

*Yoshikuni Hiroi[1], Tomokazu Hokada[2], Tatsuro Adachi[3], Yasuhito Osanai[3], Yoichi Motoyoshi[2], Kazuyuki Shiraishi[2] (1.Chiba Univ, 2.National Institute of Polar Research, 3.Kyushu University)

[SMP31-P05] Tectonic History of Hiroo Complex and its implication inpaleo-Kuril Arc evolution

*Sreehari Lakshmanan[1], Tsuyoshi Toyoshima[2], Futoshi Nanayama[3] (1.Graduate School of Science and Technology, Niigata University, Niigata, Japan, 2.Department of Geology, Faculty of Science, Niigata Univ. , 3.Geological Survey of Japan, AIST)

[SMP31-P06] Behaviour of C, O, Sr, Nd and Pb isotopes in high-grade metacarbonate rocks

*Madhusoodhan Satish-Kumar[1], Akari Imura[1], Momoko Shirakawa[2], Gen Shimoda[3], Kosuke T. Goto[3], M A Sanjeewa P K Malaviarachchi[4] (1.Department of Geology, Faculty of Science, Niigata University, 2.Graduate School of Science and Technology, Niigata University, 3.Geological Survey of Japan, 4.University of Peradeniya, Sri Lanka)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | IC 2F

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Fukashi Maeno, Yosuke Aoki

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SVC38-06] A sequence of volcanic flank collapse and tsunami event on 22 December 2018 at Anak Krakatau volcano, Indonesia

*Fukashi Maeno[1], Takayuki Kaneko[1] (1.Earthquake Research Institute, University of Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SVC38-07] The 2018 eddifice collapse event of Anak Krakatau, Indonesia: Telseismic waveform analysis and tsunami simulation

*Shingo Watada[1], Iyan E. Mulia[1], Masumi Yamada[2], Dimas Sianipar[3] (1.Earthquake Research Institute, University of Tokyo, 2.Disaster Prevention Research Institute, Kyoto University, 3.TIGP-ESS Academia Sinica, National Central University, Taiwan)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SVC38-08] The 2018 edifice collapse event of Anak Krakatau, Indonesia: Landslide movement history estimated from seismic waveforms

*Masumi Yamada[1], Shingo Watada[2], Haruhisa Nakamichi[1], Iyan Mulia[2], Karyono Dr.[3] (1.Disaster Prevention Research Institute, Kyoto University, 2.Earthquake Research Institute, University of Tokyo, 3.Center for Earthquake and Tsunami, BMKG)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SVC38-09] Intense Swarm Activity in the Vicinity of Yake-dake Volcano, Central Japan, Started in November 2018

*Shiro Ohmi[1] (1.Earthquake Hazards Division, Disaster Prevention Research Institute, Kyoto University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SVC38-10] Change of the volcanic activity at Kuju volcano.

*Mori Takehiko[1], Muga Yaguchi[1], Yasushi Kawamura[2], Hideyuki Hiramatsu[3], Keiji Ikeda[2], Sugai Akira[2], Michitomo Sugahara[2], Kenichi Takata[2], Kyo Matsumoto[2], Fukuoka Regional Headquarters Japan Meteorological Agency, Oita Meteorological Office Japan Meteorological Agency (1. Meteorological Research Institute, Japan Meteorological Agency, 2.Fukuoka Regional Headquarters, Japan Meteorological Agency, 3.Oita Meteorological Office, Japan Meteorological Agency)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SVC38-11] Posteruptive Thermoelastic Deflation of Intruded Magma in Usu Volcano, Japan, 1992–2017

*Yosuke Aoki[1], Xiaowen Wang[1] (1.Earthquake Research Institute, University of Tokyo)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | IC 2F

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Jun Oikawa, Takeshi Tameguri

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SVC38-12] Volcanic tremors and ash fall volumes associated with the 2018 vulcanian eruptions of Shinmoe-dake

*Jun Oikawa[1], Yasuhisa Tajima[2] (1.Earthquake Research Institute, University of Tokyo, 2.NIPPON KOEI CO.,LTD.)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SVC38-13] Crustal deformation around the Kirishima Volcano Group detected by GNSS and SAR observation after 2018 eruption.

*Hiroshi Yarai[1], Tomokazu Kobayashi[1], Satoshi Fujiwara[1], Tomokazu Kobayashi[1], Hiroshi Munekane[1], Masaki Honda[1], Kyonosuke Hayahsi[1], Satoshi Kawamoto[1], Atsuko Oowaki[1] (1.GSI of Japan)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SVC38-14] Harmonic tremor during 2011 eruption at Shinmoedake, Japan

*Minoru Takeo[1] (1.Earthquake Research Institute, University of Tokyo)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SVC38-15] Forecasting Volcanic Eruption of Sakurajima Volcano Based on Magma Intrusion Rate

*Masato Iguchi[1], Takeshi Tameguri[1], Jun-ichi Hirabayashi, Haruhisa Nakamichi[1] (1.Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SVC38-16] Tilt and strain change before and after the explosion at Minami-dake, Sakurajima, in 2017

*Kohei Hotta[1], Masato Iguchi[2] (1.University of Toyama, 2.Disaster Prevention Research Institute, Kyoto University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SVC38-17] Pyroclastic Flow Accompanied with an Eruption on June 16, 2018 at Sakurajima Volcano

*Takeshi Tameguri[1], Masato Iguchi[1], Masayuki Maki[2], Haruhisa Nakamichi[1], Daisuke Miki[1] (1.Sakurajima Volcano Research Center,Disaster Prevention Research Institute, Kyoto University, 2.Research Field in Integrated Studies,Kagoshima University)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | IC 2F

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Hiroshi Aoyama, Satoshi Miura

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SVC38-18] Ground deformation observed at the crater area of Tokachidake volcano

*Hiroshi Aoyama[1], Takeshi Hashimoto[1], Ryo Tanaka[1], Hiromitsu Oshima[1], Koichiro Saito[2], Tsuyoshi Michishita[2], Satoshi Okuyama[2], Volcanic Observation and Warning Center Sapporo Regional Headquarters[2] (1.Institute of Seismology and Volcanology, Faculty of Science, Hokkaido University, 2.Japan Meteorological Agency)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SVC38-19] Moment tensor inversion of very-long-period seismicity at Stromboli volcano based on a very-near-field observation

*Shunsuke Sugimura[1,2], Maurizio Ripepe[2], Giorgio Lacanna[2], Denis Legrand[3], Sébastien Valade[4], Takeshi Nishimura[1] (1.Department of Geophysics, Graduate School of Science, Tohoku University, 2.Department of Earth Sciences, University of Florence, Italy, 3.UNAM University, Mexico, 4.GFZ-German Research Centre for Geosciences, Potsdam, Germany)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SVC38-20] Pressure source estimation of tilt changes associated with small explosions at Stromboli volcano

*Ayumu Ishikawa[1], Takeshi Nishimura[1], Hiroshi Aoyama[2], Ryohei Kawaguchi[3], Eisuke Fujita[4], Takahiro Miwa[4], Taishi Yamada[4], Maurizio Ripepe[5], Riccardo Genco[5] (1.Graduate school of science, Tohoku university, 2.Faculty of science, Hokkaido university, 3.Meteorological Research Institute, 4.National Research Institute for Earth Science and Disaster Resilience, 5.University of Florence)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SVC38-21] Seismic and acoustic waves excited by volcanic explosion: analyses of energy ratio and source spectra

*Mohammad Hasib[1], Takeshi Nishimura[1], Hisashi Nakahara[1] (1.Department of Geophysics, Graduate School of Science, Tohoku University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SVC38-22] Field survey report on Zao Volcano (2012–2018)

*Akio Goto[1], Noriyoshi Tsuchiya[2], Nobuo Hirano[2], Miwa Kuri[3], Tetsuya Matsunaka[4], Kengo Sawayama[2] (1.Center for Northeast Asian Studies, Tohoku University, 2.Graduate School of Environmental Studies, Tohoku University, 3.International Research Institute of Disaster Science, Tohoku University, 4.Institute of Nature and Environmental Technology, Kanazawa University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SVC38-23] **Inflation Event of Zao Volcano in 2015**

*Satoshi Miura[1], Mare Yamamoto[1], Masahiro Ichiki[1], Tomotsugu Demachi[1] (1.Graduate School of Science, Tohoku University)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | IC 2F

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Mare Yamamoto, Yuta Maeda(Nagoya University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SVC38-24] A machine-learning-based estimation of large amplitude regions for monitoring volcano seismicity

*Yuta Maeda[1] (1.Nagoya University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SVC38-25] Development of a technique for automatic determination of volcanic earthquakes with unclear onsets - Application to Mt. Asama -

*Takao Ohminato[1], Shigeki Horiuchi[2] (1.Earthquake Research Institute, Tokyo University, 2.Home Seismometer Corporation)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SVC38-26] Amplitude source location method with depth-dependent scattering and attenuation structures for volcano-seismic signals

*Hiroyuki Kumagai[1], John Makario Lonodno[2], Alvaro Esteban Acevedo Rivas[2], Yuta Maeda[1] (1.Graduate School of Environmental Studies, Nagoya University, 2.Colombian Geological Survey)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SVC38-27] Seismic interferometry at active volcanoes in Japan: Analyses of seismic records of JMA for the period from 2012 to 2018

*Takeshi Nishimura[1], Tomoya Takano[1], Takashi Hirose[1], Hisashi Nakahara[1] (1.Department of Geophysics, Graduate School of Science, Tohoku University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SVC38-28] Empirical relation for *Q* factors of crack resonances and its use to estimate source properties of volcanic LP events

*Kimiko Taguchi[1], Hiroyuki Kumagai[1], Yuta Maeda[1], Roberto Torres[2] (1.Nagoya University Environmental Studies, 2.Colombian Geological Survey)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SVC38-29] A study on the radiation pattern for resonating fluid-filled crack

*Mare Yamamoto[1] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University)

[E] Oral | S (Solid Earth Sciences)：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-CG49] Hard-Rock Drilling Science: From Continental to Deep Sea Drilling, and Oman Project

convener:Katsuyoshi Michibayashi(Department of Earth and Planetary Sciences, Nagoya University), Eiichi TAKAZAWA(Department of Geology, Faculty of Science, Niigata University), Norikatsu Akizawa(Department of Ocean Floor Geoscience, Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Eiichi Takazawa(Niigata University), Norikatsu Akizawa(AORI The University of Tokyo)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SCG49-06] Melt transport and compositional heterogeneity of the mantle: a case study of peridotite, dunite, and wehrlite from Atlantis Massif

*Norikatsu Akizawa[1], Gretchen L. Früh-Green[2], Akihiro Tamura[3], Chiori Tamura[1], Tomoaki Morishita[3] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Department of Earth Sciences, Eidgenössische Technische Hochschule-Zürich, 3.Institute of Science and Engineering, Kanazawa University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SCG49-07] Lower crustal accretion processes revealed from the study of gabbroic cores in Holes GT1A and GT2A, the ICDP Oman Drilling Project

*Sayantani Chatterjee[1], Eiichi TAKAZAWA[1], Katsuyoshi Michibayashi[2], Peter B Kelemen[3], Damon A.H. Teagle[4], Oman Drilling Project Phase I Science Party (1.Department of Geology, Faculty of Sciences, Niigata University, Japan, 2.Department of Earth and Environmental Sciences, Nagoya University, Japan, 3.Lamont Doherty Earth Observatory, Columbia University, USA, 4.Southampton Marine and Maritime Institute, University of Southampton, United Kingdom)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SCG49-08] Petrology of Oman listvenite : Implications for carbon cycle in the subduction zone

*Toma Takahashi[1], Tomoaki Morishita[2], Hiroki Sato[3], Juan Miguel Guotana[2], Tatsuhiko Kawamoto[4], Peter B Kelemen[5], Jude Ann Coggon[6], Michelle Harris[7], Juerg Michael Matter[6], Katsuyoshi Michibayashi[8], Eiichi TAKAZAWA[9], Damon A H Teagle[6], The Oman Drilling Project Phase 1 science Party (1.Faculty of Geosciences and Civil Engineering, Kanazawa university, 2.Division of Natural Sciences, Graduate School of Natural Science and Technology, Kanazawa university, 3.Faculty of Science, Kyoto university, 4.Department of Geoscience, Faculty of Science, Shizuoka university, 5.Lamont-Doherty Earth Observatory, Columbia university, 6.School of Ocean and Earth Science, National Oceanography Center Southampton, University of Southampton, 7.School of Geography, Earth and Environmental Sciences, Plymouth University, 8.Department of Earth Planetary Sciences, Graduate School of Environmental Studies, Nagoya university, 9.Institute of Science and Technology, Niigata university)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SCG49-09] PGE and Os isotope variation in the gabbros and peridotites from the Oman DP drilling cores in the Samail ophiolite, Oman

*Ryoko Senda[1,2], Katsuhiko Suzuki[2], Tomoaki Morishita[3], Eiichi TAKAZAWA[4], Katsuyoshi Michibayashi[5], Peter B Kelemen[6], Damon AH Teagle[7], Jude Ann Coggon[7], Marguerite Godard[8], The Oman DP Science Party (1.Faculty of Social and Cultural Studies, Kyushu University, 2.Research and Development Center for Submarine Resources, JAMSTEC, 3.School of Natural System, Colleage of Science and Technology, Kanazawa University, 4.SDepartment of Geology, Faculty of Science, Niigata University, 5.Department of Earth and Planetary Sciences, Nagoya University, 6.Columbia University, 7.University of Southampton, 8.Géosciences Montpellier)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SCG49-10] Overview of drilling of crust-mantle boundary at CM1&2 sites of Wadi Tayin massif of Oman ophiolite: the ICDP Oman Drilling Project

*Eiichi TAKAZAWA[1], Damon A H Teagle[2], Katsuyoshi Michibayashi[3], Yoshihiko Tamura[4], Jude Ann Coggon[2], Juerg Matter[2], Peter B Kelemen[5], Oman Drilling Project Phase 2 Science Party (1.Department of Geology, Faculty of Science, Niigata University, 2.University of Southampton, 3.Nagoya University, 4.JAMSTEC, 5.Columbia University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SCG49-11] Petrological observation of core samples drilled from a mantle section of the Oman ophiolite: A preliminary report of the Oman Drilling Project Phase 2

*Yuji Ichiyama[1], Oman Drilling Project Phase 2 Scientific Party (1.Chiba University)

[E] Oral | S (Solid Earth Sciences)：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-CG49] Hard-Rock Drilling Science: From Continental to Deep Sea Drilling, and Oman Project

convener:Katsuyoshi Michibayashi(Department of Earth and Planetary Sciences, Nagoya University), Eiichi TAKAZAWA(Department of Geology, Faculty of Science, Niigata University), Norikatsu Akizawa(Department of Ocean Floor Geoscience, Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Tomoaki Morishita(Kanazawa University), Katsuyoshi Michibayashi

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SCG49-12] Structural analyses of ultramafic rocks used by X-ray CT core imaging (Oman Drilling Project Phase 2, D/V CHIKYU)

*Katsuyoshi Michibayashi[1], Yuki Kakihata[1], Ikuo Katayama[2], Atsushi Okamoto[3], Keishi Okazaki[4], Peter B Kelemen[5], Eiichi TAKAZAWA[6], Damon A H Teagle[7], Oman Drilling Project Phase 2 Science Party[8] (1.Department of Earth and Planetary Sciences, Graduate School of Environmental Studies, Nagoya University, 2.Hiroshima University, 3.Tohoku University, 4.KCC, JAMSTEC, 5.Columbia University of New York, 6.Niigata University, 7.Southampton University, 8.ICDP)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SCG49-13] Petrophysical characteristics of serpentinized peridotites of Hole BA1B, BA3A and BA4A

*Kakihata Yuki[1], Katsuyoshi Michibayashi[2], Laura Crispini[3], Bjorn Jamtveit[4], Samuel Barbier[5], Joe Aslin[6], Manuel Menzel[7], Marguerite Godard[8] (1.Graduate School of Science, Shizuoka University, 2.Graduate School of Environmental Studies, Nagoya University, 3.University of Genova, 4.University of Oslo, 5.Claude Bernard University Lyon 1, 6.University of Liverpool, 7.Andalusian Earth Science Institute, 8.Géosciences Montpellier, CNRS, Univ. Montpellier)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SCG49-14] Physical properties of the Moho TZ: Implications from ICDP Oman Drilling Project Phase I & II on-board measurements

*Natsue Abe[1,12], Keishi Okazaki[1], Ikuo Katayama[2], Kohei Hatakeyama[2], Yuya Akamatsu[2], Benoit Ildefonse[3], Ulven Ivar Ole[4], Gilvert Hong[5], Wenlu Zhu[6], Benoit Cordonnier[4], Katsuyoshi Michibayashi[7], Eiichi TAKAZAWA[8], Michell Harris[10], Damon Teagle[11], Peter Kelemen[9], Marguerite Godard[3], Jurg Matter[11], Jude Coggon[11], Oman Drilling Project Scientific Party (1.Japan Agency for Marine-Earth Science and Technology, 2.Hiroshima University, 3.Universitè de Montpellier, 4.University of Oslo, 5.Seoul National University, 6.University of Maryland, 7.Nagoya University, 8.Niigata University, 9.Columbia University, 10.Polymouth University, 11.University of Southampton, 12.Kanazawa University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SCG49-15] Seismic anisotropy under high pressure conditions of harzburgite collected from Oman Drilling Project Phase II

*Kohei Hatakeyama[1], Ikuo Katayama[1], Natsue Abe[2], The Oman Drilling Project Phase II Science Party (1.Department of earth and planetary systems science, Hiroshima University , 2.JAMSTEC)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SCG49-16] Understanding of the mode of seafloor spreading and the architecture of upper oceanic crust by oceanfloor drilling at off-Hawaii MoHole candidate site

*Susumu Umino[1], Tomoaki Morishita[1], Mikiya Yamashita[2], Osamu Ishizuka[3] (1.Department of Earth Sciences, Kanazawa University, 2.Japan Agency for Marine-Earth Science and Technology, 3.Geological Survey of Japan, AIST)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_19

[S-CG49] Hard-Rock Drilling Science: From Continental to Deep Sea Drilling, and Oman Project

convener:Katsuyoshi Michibayashi(Department of Earth and Planetary Sciences, Nagoya University), Eiichi TAKAZAWA(Department of Geology, Faculty of Science, Niigata University), Norikatsu Akizawa(Department of Ocean Floor Geoscience, Atmosphere and Ocean Research Institute, The University of Tokyo)

[SCG49-P01] **Permeability profile in the Oman Drilling Project inferred from resistivity measurements**

*Ikuo Katayama[1], Keishi Okazaki[2], Natsue Abe[2], Ole Ivar Ulven[3], Gilbert Hong[4], Wenlu Zhu[5], Benoit Cordonnier[3], Kohei Hatakeyama[1], Yuya Akamatsu[1], Katsuyoshi Michibayashi[6], Marguerite Godard[7], Peter Kelemen[8], Science Party The Oman Drilling Project Phase 2 (1.Hiroshima University, 2.JAMSTEC, 3.University of Oslo, 4.Seoul National University, 5.University of Maryland, 6.Nagoya University, 7.Universitè Montpellier, 8.Columbia University)

[SCG49-P02] Relationship between alteration intensity and elastic wave velocity of gabbroic rocks from ICDP Hole CM1A, Oman Drilling Project Phase II

*Kosuke Kimura[1], Ikuo Katayama[1], Kohei Hatakeyama[1], Yuya Akamatsu[1], Natsue Abe[2], Keishi Okazaki[2], The Oman Drilling Project Phase II Science Party (1.Hiroshima University, 2.JAMSTEC)

[SCG49-P03] Physical property of the fossilized crust-mantle transition zone from ICDP Oman Drilling Project Hole CM1A and CM2B measured onboard D/V Chikyu

*Keishi Okazaki[1], Natsue Abe[1], Kohei Hatakeyama[2], Yuya Akamatsu[2], Ikuo Katayama[2], Eiichi TAKAZAWA[3], Damon A H Teagle[4], Peter B Kelemen[5], Jude Coggon[4], The Oman Drilling Project Phase 2 Science Party (1.Japan Agency for Marine-Earth Science and Technology, 2.Hiroshima University, 3.Niigata University, 4.University of Southampton, 5.Columbia University)

[SCG49-P04] Microstructures of lower crust gabbros from the Oman Ophiolite: Analyses of the drilled cores of the Oman Drilling Project

*Koki Iida[1], Takahiro Fudai[1], Susumu Umino[1], Yuki Kusano[2] (1.Kanazawa University, 2.Geological Survey of Japan)

[SCG49-P05] Olivine fabric and mineral compositions in the Maqsad area of the Samail massif, the southern Oman ophiolite

*Kaho Takahashi[1], Eiichi TAKAZAWA[2,3], Katsuyoshi Michibayashi[4], Kakihata Yuki[4], Ryoko Senda[5] (1.Graduate School of Science and Technology, Niigata University, 2.Department of Geology, Faculty of Science, Niigata University, 3.JAMSTEC, 4.Nagoya University, 5.Kyushu University)

[SCG49-P06] The evolution of melt inclusions in podiform chromitite in Oman

*Yuan YAO[1], Eiichi TAKAZAWA[2,3], Oman Drilling Project Phase 2 Science Party (1.Graduate School of Sciences& Technology, Niigata University, Japan, 2.Department of Geology, Faculty of Science, Niigata University, Japan, 3.Research and Development Center for Ocean Drilling Science, JAMSTEC, Japan)

[SCG49-P07] Melt/fluid - rock reaction inferred from the Wadi Tayin mantle section in the southern Oman ophiolite

*Keisuke ISHII[1], Eiichi TAKAZAWA[2], Akihiro kuriyama[2], Kyouka Someya[2], Yoshihiko Tamura[3] (1.Graduate School of Science and Technology, Niigata University, 2.Department of Geology, Faculty of Science, Niigata University , 3.R&D Center for Ocean Drilling Science, Japan Agency for Marine-Earth Science and Technology)

[SCG49-P08] Numerical simulations for reaction-induced fracture formation of layered gabbro during hydration process

*Kazuki Yoshida[1], Hiroyuki Shimizu[2], Noriyoshi Tsuchiya[1], Atsushi Okamoto[1], Phase 2 Science Party Oman Drilling Project[3] (1.Tohoku university, 2.Geotechnical Analysis Group, Advanced Analysis Department, Civil Engineering Design Division, Kajima Corporation, 3.Oman Drilling Project Phase 2 Science Party)

[SCG49-P09] X-ray CT images of oceanic lithologies obtained on Oman Drilling Project drillcores during ChikyuOman 2017 and 2018

*Katsuyoshi Michibayashi[1], Peter B Kelemen[2], Margurette Godard[3], Eiichi TAKAZAWA[4], Damon A H Teagle[5], The Oman Drilling Project Science Party[6] (1.Department of Earth and Planetary Sciences, Nagoya University, 2.Columbia University, 3.Université Montpellier, 4.Niigata University, 5.Southampton University, 6.ICDP)

[SCG49-P10] Re-examination of the crystallization process of clinopyroxene oikocrysts in layered gabbros at Hess Deep Rift, EPR

*Akane Yasui[1], Takashi Hoshide[1] (1.Graduate School of International Resource Sciences, Akita University)

[SCG49-P11] Structural petrology of peridotites from the Kalaymyo ophiolite

*Kouhei Asano[1,2], Katsuyoshi Michibayashi[1], Jung-Woo Park[3] (1.Graduate School of Environmental Studies, Nagoya University, 2.Shizuoka University, 3.Seoul National University)

[SCG49-P12] Reevaluation of the origin of mafic layers in the Upper Zone of the Horoman Peridotite

*Yumeto KOGURE[1], Eiichi TAKAZAWA[1] (1.Department of Geology, Faculty of Science, Niigata University)

[SCG49-P13] A structural and petrological study of "Shibukawa ultramafic body" in the Sanbagawa belt, western Shizuoka, Japan

*Hikaru Shioya[1,2], Katsuyoshi Michibayashi[1], Ken-ichi Hirauchi[2] (1.Graduate School of Environmental Studies, Nagoya University, 2.Institute of Geosciences, Shizuoka University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SCG54-10] Dislocation textures in shock-compressed MgO and their formation mechanisms

*Kiyoshi Fujino[1], Xun Liu[2], Tsutomu Mashimo[2] (1.Geodynamics Research Center, Ehime University, 2.Institute of Pulsed Power Science, Kumamoto University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SCG54-11] Development of rotational diamond anvil cell and large strain deformation experiments of lower-mantle materials

★Invited Papers

*Shintaro Azuma[1,2], Ryuichi Nomura[3,4], Kentaro Uesugi[5], Yu Nishihara[4], Doi Shunta[4], Takeshi Arimoto[4], Tetsuo Irifune[4] (1.Tokyo Tech., 2.Kyushu Univ., 3.Kyoto Univ., 4.Ehime Univ., 5.Japan Synchrotron Radiation Research Institute (JASRI))

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SCG54-12] Rheology of hcp-iron

*Yu Nishihara[1], Doi Shunta[1], Noriyoshi Tsujino[2], Daisuke Yamazaki[2], Yuji Higo[3] (1.Geodynamics Research Center, Ehime University, 2.Institute of Planetary Materials, Okayama University, 3.Japan Synchrotron Radiation Research Institute)

[J] Poster | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_20

[S-CG54] Rheology, fracture and friction in Earth and planetary sciences

convener:Miki Tasaka(Shimane University), Osamu Kuwano(Japan Agency for Marine-Earth Science and Technology), Ichiko Shimizu(Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University), Hidemi Ishibashi(Faculty of Science, Shizuoka University)

[SCG54-P01] First-principles study on frictional characteristics of gibbsite

*Hanaya Okuda[1], Kenji Kawai[1], Hiroshi Sakuma[2] (1.Department of Earth and Planetary Science, School of Science, University of Tokyo, 2.Research Center for Functional Materials, National Institute for Materials Science)

[SCG54-P02] Feasibility Study of Morphological Characterization to Comminuted Particles by A Particle Characterization Approach (4)

*Daisuke Sasakura[1], Osamu Kuwano[2] (1.MalvernPanalytical Japan ,Div of Spectris Co.Ltd,., 2.JAMSTEC)

[SCG54-P03] Rheological property of basaltic lava at rigid-deformable transition

*Akio Goto[1] (1.Center for Northeast Asian Studies, Tohoku University)

[SCG54-P04] Cataclasitic texture in gabbroic xenoliths of the Fuji 1707 eruption, Japan

*Hidemi Ishibashi[1], Yumiko Harigane[2], ATSUSHI YASUDA[3], Natsumi Hokanishi[3] (1.Faculty of Science, Shizuoka University, 2.Geological Survey of Japan, AIST, 3.Earthquake Research Institute, University of Tokyo)

[SCG54-P05] Heterogeneous deformation and intragranular recrystallization in experimentally deformed fossil-bearing limestone

*Nahyeon Kim[1], Miki Takahashi[2], Jin-Han Ree[1], Haemyeong Jung[3] (1.Korea University, 2.Geological Survey of Japan, AIST, 3.Seoul National University)

[SCG54-P06] Development of the geobarometer using size and mineral species dependence of residual pressure of fluid inclusions

*Yuuki Hagiwara[1], Junji Yamamoto[1] (1.Hokkaido University)

[SCG54-P07] Microstructures and misorientation analysis of quartz in the Sanbagawa metamorphic belt, Shikoku, Japan

*Tadamasa Ueda[1], Ichiko Shimizu[1] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University)

[SCG54-P08] Microstructural & petrological analysis of peridotite xenolith in Noyama-dake, Shimane prefecture ~ implication of plastic deformation during Japan sea opening

*Miki Tasaka[1], Shunsuke Inagawa[1] (1.Shimane University)

[SCG54-P09] Thermodynamic approach to grain boundary premelting in a binary eutectic system

*Akihiro Tsunoda[1], Yasuko Takei[1], Hatsuki Yamauchi[1] (1.Earthquake Research Institute, The University of Tokyo)

[SCG54-P10] Size effects on hardness and fracture toughness of olivine

*Sanae Koizumi[1], Tohru S Suzuki[2], Takehiko Hiraga[1] (1.Earthquake Research Institute,The University of Tokyo, 2.National Institute for Materials Science)

[SCG54-P11] Dislocation creep of dry orthoenstatite aggregates under high *P-T* conditions

*Yumiko Tsubokawa[1], Tomohiro Ohuchi[1], Yuji Higo[2], Yoshinori Tange[2], Tetsuo Irifune[1] (1.Ehime University Geodynamics Research Center, 2.Japan Synchrotron Radiation Research Institute)

[J] Poster | S (Solid Earth Sciences)：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_36

[S-CG54] Rheology, fracture and friction in Earth and planetary sciences

convener:Miki Tasaka(Shimane University), Osamu Kuwano(Japan Agency for Marine-Earth Science and Technology), Ichiko Shimizu(Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University), Hidemi Ishibashi(Faculty of Science, Shizuoka University)

[SCG54-P01] First-principles study on frictional characteristics of gibbsite

[J] Oral | S (Solid Earth Sciences)：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | Convention Hall A 2F

[S-CG61] Dynamics in mobile belts

convener:Yukitoshi Fukahata(Disaster Prevention Research Institute, Kyoto University), Toru Takeshita(Department of Natural History Sciences, Graduate School of Science, Hokkaido University), Hikaru Iwamori(Geochemical Evolution Research Program, Japan Agency for Marine-Earth Science and Technology), Chairperson:Keisuke Yoshida(東北大学大学院理学研究科 地球物理学専攻), Masaoki Uno(東北大学)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SCG61-13] Deciphering dynamics of thermal events at lithosphere-asthenosphere boundary from peridotite xenoliths of Ichinomegata maar, NE Japan

*Yuto Sato[1], Kazuhito Ozawa[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SCG61-14] **Experimental investigation of reaction-induced stress and permeability evolution in MgO–H_2O system**

*Masaoki Uno[1], Hisamu Kasahara[1], Atsushi Okamoto[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SCG61-15] Fluid-Flow, Resistivity and Elastic Wave Velocity Simulation of Digital Rock Fracture and Comparison with Experimental Data

*Kazuki Sawayama[1], Fei Jiang[2], Takuya ISHIBASHI[3], Takeshi Tsuji[4], Yasuhiro Fujimitsu[4] (1.Department of Earth Resources Engineering, Graduate school of engineering, Kyushu University, 2.Department of Mechanical Engineering, Faculty of Engineering, Yamaguchi University, 3.Fukushima Renewable Energy Institute, National Institute of Advanced Industrial Science and Technology, 4.Department of Earth Resources Engineering, Faculty of engineering, Kyushu University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SCG61-16] Fluid distribution in the crust – inference from seismic velocity and electrical conductivity

*Tohru Watanabe[1], Kenta Yoshida[2] (1.Gradudate School of Science and Engineering, University of Toyama, 2.Research and Development Center for Ocean Drilling Science, Japan Agency for Marine-earth Science and Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SCG61-17] The seismological structure about fault zone extending to the lower crust in the northern Kinki district, southwestern Japan

*Shinya Kato[1], Yoshihisa Iio[1], Takuo Shibutani[1], Hiroshi Katao[1], Masayo Sawada[1], Kazuhide Tomisaka[1] (1.Disater Prevention Research Institute, Kyoto University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SCG61-18] Inland repeating earthquakes in the vicinity of low frequency earthquakes around Hakodate, Hokkaido

*Keisuke Yoshida[1], Akira Hasegawa[1], Shinako Noguchi[2], Keiji Kasahara[2] (1.Tohoku University, 2. Association for the Development of Earthquake Prediction)

[J] Oral | S (Solid Earth Sciences)：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Convention Hall A 2F

[S-CG61] Dynamics in mobile belts

convener:Yukitoshi Fukahata(Disaster Prevention Research Institute, Kyoto University), Toru Takeshita(Department of Natural History Sciences, Graduate School of Science, Hokkaido University), Hikaru Iwamori(Geochemical Evolution Research Program, Japan Agency for Marine-Earth Science and Technology), Chairperson:Bunichiro Shibazaki, Daisuke Sato

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SCG61-19] Modeling strain concentration and mountain building processes in central Japan considering heterogeneous rheological structure

*Bunichiro Shibazaki[1] (1.International Institute of Seismology and Earthquake Engineering, Building Research Institute)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SCG61-20] Inelastic strain rate and deviatoric stress field of the seismic gap in west part of Kyushu, Japan, estimated from seismic and geodetic data

*Yuhei Yuasa[1], Satoshi Matsumoto[2], Shigeru Nakao[3], Takeshi Matsushima[2], Takahiro Ohkura[4] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University, 3.Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University, 4.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SCG61-21] Persistent and time-dependent crustal deformation in northern Fossa Magna and its tectonic implications

*Takeshi Sagiya[1], Koki Kumagai[2], Angela Meneses-Gutierrez[3], Nobuhisa Matsuta[4], Daisuke Hirouchi[5], Kenjiro Matsuhiro[2], Takashi OKUDA[2] (1.Disaster Mitigation Research Center, Nagoya University, 2.Graduate School of Environmental Studies, Nagoya University, 3.Disaster Prevention Research Institute, Kyoto University, 4.Graduate School of Education, Okayama University, 5.Faculty of Education, Shinshu University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SCG61-22] Unexpected relationship between ΔCFF and the strain-rate paradox: separation of plastic strain from inelastic strain

*Yukitoshi Fukahata[1], Angela Meneses-Gutierrez[1], Takeshi Sagiya[2] (1.Disaster Prevention Research Institute, Kyoto University, 2.Disaster Mitigation Research Center, Nagoya University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SCG61-23] Active period of inland earthquakes based on numerical simulation of megathrust earthquake cycle incorporating viscoelasticity

*Tsukasa MITOGAWA[1], Takuya NISHIMURA[2] (1.Graduate School of Science, Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SCG61-24] Influence of viscoelastic relaxation on estimated interplate coupling along the Nankai Trough, southwest Japan

*Takuya NISHIMURA[1], Fred F Pollitz[2] (1.Disaster Prevention Research Institute, Kyoto University, 2.U.S. Geological Survey)

[J] Oral | S (Solid Earth Sciences)：S-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Convention Hall A 2F

[S-CG61] Dynamics in mobile belts

convener:Yukitoshi Fukahata(Disaster Prevention Research Institute, Kyoto University), Toru Takeshita(Department of Natural History Sciences, Graduate School of Science, Hokkaido University), Hikaru Iwamori(Geochemical Evolution Research Program, Japan Agency for Marine-Earth Science and Technology), Chairperson:Naoki Uchida, Takeshi Iinuma

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SCG61-25] Revisiting the Forearc Sliver Scenario Along the Southern Kurile Trench to Reconcile Interdisciplinary Observations

*Yuji ITOH[1], Kelin WANG[2], Takuya NISHIMURA[3] (1.Graduate School of Science, Kyoto University, 2.Pacific Geoscience Centre, Geological Survey of Canada, 3.Disaster Prevention Research Institute, Kyoto University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SCG61-26] Segmentation of crustal deformation area within the Sanriku coast, northeast Japan, on the basis of spatial distribution of millennial-scale crustal movements

*Yuichi Niwa[1] (1.Faculty of Science and Engineering, Chuo University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SCG61-27] Shear wave splitting east off NE Japan based on the S-net data

*Naoki Uchida[1], Junichi Nakajima[2], Ryota Takagi[1], Keisuke Yoshida[1], Takashi NAKAYAMA[1], Ryota Hino[1], Tomomi Okada[1], Youichi Asano[3], Sachiko Tanaka[3] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions Graduate School of Science, Tohoku University, 2.Department of Earth and Planetary Sciences, Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, 3.National Research Institute for Earth Science and Disaster Resilience)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SCG61-28] Gravity anomaly due to active faults and crustal rheology in the northeastern Japan arc inferred by fault dislocation model

*Mitsuhiro Hirano[1], Hiroyuki Nagahama[1], Jun Muto[1] (1.tohoku university)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SCG61-29] On the temporal decay of the localized strain rate in the Tohoku region after the Tohoku-Oki earthquake

*Youichiro Takada[1], Tomomi Inamatsu[2] (1.Faculty of Science, Hokkaido University, 2.Dept. Natural History Sciences, Hokkaido University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SCG61-30] Revisiting the Coseismic Slip Distribution of the 2011 Tohoku-oki Earthquake Considering Early Postseismic Deformation, Non-linear Viscoelasticity, and Heterogeneous Structure

*Takeshi Iinuma[1], Ryoichiro Agata[1], Yusaku Ohta[2], Ryota Hino[2], Takane Hori[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.Graduate School of Science, Tohoku University)

[J] Poster | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_21

[S-CG61] Dynamics in mobile belts

convener:Yukitoshi Fukahata(Disaster Prevention Research Institute, Kyoto University), Toru Takeshita(Department of Natural History Sciences, Graduate School of Science, Hokkaido University), Hikaru Iwamori(Geochemical Evolution Research Program, Japan Agency for Marine-Earth Science and Technology)

[SCG61-P01] Three-dimensional imaging of geo-fluid distribution at NE-Japan forearc using wideband magnetotelluric measurements

*Masato Fukai[1], Yasuo Ogawa[1], Kuo Hsuan Tseng[1], Masahiro Ichiki[2], Shinichi Takakura[3] (1.Tokyo Institute of Technology, 2.Tohoku University, 3.National Institute of Advanced Industrial Science and Technology)

[SCG61-P02] **Elastic wave velocity and electrical conductivity in brine-saturated rocks and microstructure of pores**

*Arina Tomioka[1], Tohru Watanabe[1] (1.University of Toyama)

[SCG61-P03] Influence of grain shape and grain size distribution on connectivity of pores in granular materials.

*Katazakai Haruka[1], Tohru Watanabe[1] (1.Toyama University)

[SCG61-P04] Change of pore connectivity in granular materials under axial compression

*MAREMICHI ABE[1], Tohru Watanabe[1] (1.Toyama University)

[SCG61-P05] **Estimation of crustal strength using residual strain of quartz in deformed conglomerate and inhomogenous strain of conglomerate layer -As an example of multiple collision zone of Izu-Bonin arc, Fujikawa valley, Central Japan-**

*Shun Suzuki[1], Kenta Kobayashi[1] (1.Graduate School of Science and Technology, Niigata University)

[SCG61-P06] **An Introduction to Ryoke Cataclastic Rocks in Tsukide, Mie Prefecture, Japan: An Approach Using 3D Reconstructions From Thin Sections**

*Thomas Jing Yi Yeo[1], Toru Takeshita[1] (1.Department of Natural History Sciences, Graduate School of Science, Hokkaido University)

[SCG61-P07] Relationships between spacing and growth or linkage of normal faults in the Miyako Island, South Ryukyu arc, Japan

*Sumire Maeda[1], Makoto Otsubo[1], Daisuke Asahina[1], Yuki Furuno [1] (1.Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan/AIST)

[SCG61-P08] **3D fault architecture along the Median Tectonic Line, eastern Kii Peninsula, SW Japan**

*Norio Shigematsu[1], Takuma Katori[1,2], Jun Kameda[3], Ayumu Miyakawa[4] (1.Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 2.Graduate School of Science and Technology, Niigata University, 3.Department of Natural History and Sciences, Hokkaido University, 4.Research Institute of Geology and Geoinformation, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SCG61-P09] Significant of thrust zone at Fuji river basin in the South Fossa Magna, Southern Yamanashi Prefecture, Central Japan
-Study of Structural geology of Minobu and Neguma fault-

*Minami Madoka[1], Kenta Kobayashi[1] (1. Niigata university department of geology science)

[SCG61-P10] Mineralogical characteristics of fault rocks in the aftershock regions of the 2000 Western Tottori earthquake and its spatial distribution

*Shunya Kaneki[1], Tetsuro Hirono[1], Hideki Mukoyoshi[2], Kenta Kobayashi[3], Toru Takeshita[4] (1.Graduate School of Science, Osaka University, 2.Graduate School of Science and Engineering, Shimane University, 3.Graduate School of Science and Technology, Niigata University, 4.Graduate School of Science, Hokkaido University)

[SCG61-P11] Relationship between seismicity of the 2016 the Central Tottori Earthquake and fault distribution in the aftershock area

*Masayuki Ichimura[1], Hideki Mukoyoshi[2] (1.Graduate School of Natural Science and Technology, Shimane University, 2.Department of Earth Science, Shimane University)

[SCG61-P12] History of fault activity considered from the brittle shear zone and the geological structure near the Cape Otachi, Kumamoto Prefecture

*Keiji Ogashiwa[1], Kenta Kobayashi[1] (1.Niigata University)

[SCG61-P13] Study on fault activity evaluation method (A new attempt to understand fault activities) No.1 - Overall plan and current situation at Shionohira Fault -

*Kazuhiro Aoki[1], Takahiro Watanabe[1], Yukumo Tanaka[1], Kazuyoshi Seshimo[1] (1.Japan Atomic Energy Agency)

[SCG61-P14] Study on fault activity evaluation method (A new attempt to understand fault activities) No.2
- Injection experiment using a SIMFIP probe at Shionohira Fault and southern fault-

*Takahiro Watanabe[1], Yukumo Tanaka[1], Kazuhiro Aoki[1], Yves Guglielmi[2], Paul Cook[2], Florian Soom[2], Wakahama Hiroshi[3], Noujou Haruka[3], Etsuo Iwasaki[3], Masao Kametaka[3], Kazuyoshi Seshimo[1] (1.Japan Atomic Energy Agency, 2.Laurence Berkley National Laboratory, 3.DIA CONSULTANTS)

[SCG61-P15] Dynamic rupture simulation of 2018, Hokkaido Eastern Iburi earthquake: Role of non-planar fault geometry

*Tatsuya Hisakawa[1], Ryosuke Ando[1] (1.The University of Tokyo)

[SCG61-P16] A New Fully-Dynamic Earthquake Cycle Simulator Applicable to Arbitrary Nonplanar Fault Geometries - A Benchmark Test

*Daisuke Sato[1], Nadia Lapusta[2], Hiroyuki Noda[1] (1.Disaster Prevention Research Institute, Kyoto University, 2.California Institute of Technology)

[SCG61-P17] Stress and displacement Green's functions to treat volumetric inelastic strain and elastic inhomogeneity in boundary integral equation method

*Daisuke Sato[1] (1.Disaster Prevention Research Institute, Kyoto University)

[SCG61-P18] Frictional properties of dolerite and granite at intermediate slip rates and controlled ambient temperatures

*Michiyo Sawai[1], Yuuki Yokoyama[1], Kyuichi Kanagawa[1] (1.Chiba University)

[SCG61-P19] Extraction of features of strata using borehole data of geothermal area by multivariate analysis

*Ojima Hiroki[1], Kazuya Ishitsuka[2], Toru Mogi[3], Tatsuya Kajiwara[4], Takeshi Sugimoto[4], Hiroshi Asanuma[5] (1.Department of Socio-Environmental Engineering Hokkaido University, 2.Division of Urban Management, Graduate School of Engineering, Kyoto University, 3.Division of sustainable Resources Engineering, Faculty of Enginieering, Hokkaido University, 4.Geothermal Engineering Co. Ltd, 5.Fukushima Renewable Energy Institute, AIST)

[SCG61-P20] Low-temperature thermochronology of Cretaceous granitoids from the northern Northeast Japan Arc: Towards reconstructing arc-parallel thermal/denudation histories

*Shoma Fukuda[1], Shigeru Sueoka[2], Barry Paul Kohn[3], Noriko Hasebe[4], Akihiro Tamura[5], Tomoaki Morishita[5], Takahiro Tagami[1] (1.Graduate School of Science, Kyoto University , 2.Japan Atomic Energy Agency, 3.School of Earth Sciences, The University of Melbourne, 4.Institute of Nature and Environmental Technology, Kanazawa University, 5.Department of Earth Sciences, Kanazawa University)

[SCG61-P21] Uplift and denudation history of the South Fossa Magna region using low-temperature thermochronometric methods

*Yumi Kobayashi[1], Shigeru Sueoka[2], Shoma Fukuda[1], Barry P. Kohn[3], Tatsunori Yokoyama[2], Noriko Hasebe[4], Akihiro Tamura[5], Tomoaki Morishita[5], Takahiro Tagami[1] (1.Graduate School of Science, Kyoto University, 2.Tono Geoscience Center, Japan Atomic Energy Agency, 3.University of Melbourne, 4.Institute of Nature of Environmental Technology, Kanazawa University, 5.Department of Earth Sciences, Kanazawa University)

[SCG61-P22] Correlation between residual uplift and recurrence interval of the Kanto earthquake based on developmental process of coastal lowland

*Haeng-Yoong Kim[1] (1.Osaka City University, Graduate School of Science, Division of Biology &Geosciences)

[SCG61-P23] Mechanics preserving co-seismic uplift and marine terraces: dissymmetric patterns of co-seismic and inter-seismic deformation

*Kyohei Suzuki[1], Junki Komori[1], Ryosuke Ando[1] (1.Graduate School of Science, University of Tokyo)

[SCG61-P24] Enhanced resolution of stress tensor inversion by using fault instability analysis

★Invited Papers

*Katsushi Sato[1] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University)

[SCG61-P25] Focal mechanisms of the aftershocks of the 2000 Western Tottori Earthquake inferred from P wave first-motion data and spatial stress pattern

*Takaki Iwata[1] (1.Tokiwa University)

[SCG61-P26] Stress tensor inversion in focal area of the 2016 Mw7.8 Kaikoura earthquake, New Zealand

*Miu Matsuno[1], Tomomi Okada[1], Satoshi Matsumoto[2], Yuta Kawamura[2], Yoshihisa Iio[3], Tadashi Sato[1], Stephen C Bannister[4], John Ristau[4], Martha K Savage[5], John Townend[5], Jarg Pettinga[6], Francesca Ghisetti[7], Richard H Sibson[8] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions Graduate School of Science, Tohoku University, 2.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University, 3.Disater Prevention Research Institute, Kyoto University, 4.GNS Science, New Zealand, 5.Victoria University of Wellington, Wellington, New Zealand, 6.University of Canterbury, Christchurch, New Zealand, 7.TerraGeologica, Ruby Bay, New Zealand, 8.University of Otago, Dunedin, New Zealand)

[BCG06-07] Diversity and evolution of biosynthetic enzymes for chlorophyll pigments

★Invited Papers

*Yusuke Tsukatani[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

11:00 AM - 11:20 AM JST | 2:00 AM - 2:20 AM UTC

[BCG06-08] **Microdolomites are not MDACs: microbially-derived carbon source for microcrystalline dolomite found within massive gas hydrates and implications for the shallow marine carbon cycle**

★Invited Papers

*Glen Snyder[1], Ryo Matsumoto[1], Naizhong Zhang[1], Yoshihiro Kakizaki[2], Yohey Suzuki[2], Yuji Sano[3], Naoto Takahata[3], Kentaro Tanaka[3], Takumi Imajo[5], Stephen Bowden[4] (1.Gas Hydrate Research Laboratory, Meiji University, 2.University of Tokyo, 3.AORI, University of Tokyo, 4.University of Aberdeen, Scotland, 5.Tokyo University of Marine Science and Technology)

11:20 AM - 11:35 AM JST | 2:20 AM - 2:35 AM UTC

[BCG06-09] **Discriminative biogeochemical signatures of methanotrophs inhabiting different chemosynthetic fields in an active mud volcano of the Canadian Beaufort Sea**

*Dong-Hun Lee[1], Yung Mi Lee[2], Jung-Hyun Kim[2], Young Keun Jin[2], Charles Paull[3], Helge Niemann[4,5], Ji-Hoon Kim[6], Kyung-Hoon Shin[1] (1.Hanyang Univ., 2.KOPRI, 3.MBARI, 4.NIOZ and Utrecht Univ., 5.CAGE, UiT , 6.KIGAM)

11:35 AM - 11:50 AM JST | 2:35 AM - 2:50 AM UTC

[BCG06-10] Determination of the absolute stereochemistry of the hydroxyl group in 2-hydroxyarchaeol, the main lipid core of methanogenic and methanotrophic archaea

*Noriaki YAMAUCHI[1], Masanori Kaneko[2] (1.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 2.National Institute of Advanced Industrial Science and Technology)

11:50 AM - 12:10 PM JST | 2:50 AM - 3:10 AM UTC

[BCG06-11] Mineral-Microbe interaction – Identification of extracellular electron transfer mechanisms by using MetaOmics approach

★Invited Papers

*Shunichi Ishii[1], Shino Suzuki[1], Kenneth H Nealson[2] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.University of Southern California)

12:10 PM - 12:15 PM JST | 3:10 AM - 3:15 AM UTC

[BCG06-12] Interactive discussion with the invited speakers

*Yoshinori Takano[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

[E] Poster | B (Biogeosciences)：B-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_22

[B-CG06] Earth and Planetary Science Frontiers for Life and Global Environment

convener:Yoshinori Takano(Japan Agency for Marine-Earth Science and Technology (JAMSTEC)), Yohey Suzuki(Graduate School of Science, The University of Tokyo), Shingo Kato(RIKEN), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University)

[BCG06-P01] Dynamisms and characteristics of dissolved organic matter (DOM) in deep aquifer: A scope for deep biosphere

*Atsushi Urai[1,2], Yoshinori Takano[2], Naohiko Ohkouchi[2] (1.Department of Science and Technology, Graduate School of Medicine, Science and Technology, Shinshu University, 2.Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology)

[BCG06-P02] Correlations of magnetosome-related genes in Nitrospirae genomes to magnetosome geometry and redox stratification in deep-sea environments

*Shinsaku Nakano[1], Shingo Kato[2], Mariko Kouduka[1], Toshitsugu Yamazaki[3], Yohey Suzuki[1] (1.Graduate School of Science, The University of Tokyo, 2.RIKEN, 3.Atmosphere and Ocean Research Institute, The University of Tokyo)

[BCG06-P03] Reconstruction of key ecological responses leading to the most recent dead zone formations in Japan Sea through ancient DNA metabarcodring

*Mariko Kouduka[1], Yohey Suzuki[1] (1.Department of Earth and Planetary Science, The University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan.)

[BCG06-P04] Search for microbial CH_4 production processes in lake sediments and surface water associated with cyanobacterial bloom

*Makoto Matsushita[1], Yoshinori Takano[1], Hiroyuki Imachi[1], Atsushi Urai[2], Ho-Dong Park[3], Hiroki Iwata[3], Naohiko Ohkouchi[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Department of Science and Technology, Graduate School of Medicine, Science and Technology, Shinshu University, 3.Department of Environmental Sciences, Faculty of Science, Shinshu University)

[BCG06-P05] Did life emerge in a deep-sea metal sulfide chimney? New insights from an archaeal genome and a nanoscale microbe-silicate assemblage

*Hinako Takamiya[1], Hiroki Mukai[2], Mariko Kouduka[1], Shingo Kato[4], Motoo Ito[3], Yohey Suzuki[1] (1.Earth and Planetary Science Graduate School of Science, The University of Tokyo , 2.National Institute of Advanced Industrial Science and Technology, 3.Kochi Institute for Core Sample Research JAMSTEC, 4.RIKEN)

[BCG06-P06] X-ray computed nano-tomography for visualizing microbial cells and their surrounding environments

*Yuki Morono[1], Go-Ichiro Uramoto[2,1], Kentaro Uesugi[3], Nobuhisa Takeuchi[3], Masayuki Uesugi[3], Kengo Kubota[4], Tatsuhiko Hoshino[1], Fumio Inagaki[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kochi University, 3.Japan Synchrotron Radiation Research Institute, 4.Tohoku University)

[BCG06-P07] Carbon signatures in amino acids during deep-sea anoxic methanotrophy

*Yoshinori Takano[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

[E] Poster | B (Biogeosciences)：B-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_40

[B-CG06] Earth and Planetary Science Frontiers for Life and Global Environment

convener:Yoshinori Takano(Japan Agency for Marine-Earth Science and Technology (JAMSTEC)), Yohey Suzuki(Graduate School of Science, The University of Tokyo), Shingo Kato(RIKEN), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University)

[BCG06-P01] Dynamisms and characteristics of dissolved organic matter (DOM) in deep aquifer: A scope for deep biosphere

*Atsushi Urai[1,2], Yoshinori Takano[2], Naohiko Ohkouchi[2] (1.Department of Science and Technology, Graduate School of Medicine, Science and Technology, Shinshu University, 2.Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology)

[BCG06-P02] Correlations of magnetosome-related genes in Nitrospirae genomes to magnetosome geometry and redox stratification in deep-sea environments

*Shinsaku Nakano[1], Shingo Kato[2], Mariko Kouduka[1], Toshitsugu Yamazaki[3], Yohey Suzuki[1] (1.Graduate School of Science, The University of Tokyo, 2.RIKEN, 3.Atmosphere and Ocean Research Institute, The University of Tokyo)

[BCG06-P03] Reconstruction of key ecological responses leading to the most recent dead zone formations in Japan Sea through ancient DNA metabarcodring

*Mariko Kouduka[1], Yohey Suzuki[1] (1.Department of Earth and Planetary Science, The University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan.)

[BCG06-P04] Search for microbial CH_4 production processes in lake sediments and surface water associated with cyanobacterial bloom

*Makoto Matsushita[1], Yoshinori Takano[1], Hiroyuki Imachi[1], Atsushi Urai[2], Ho-Dong Park[3], Hiroki Iwata[3], Naohiko Ohkouchi[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Department of Science and Technology, Graduate School of Medicine, Science and Technology, Shinshu University, 3.Department of Environmental Sciences, Faculty of Science, Shinshu University)

[BCG06-P05] Did life emerge in a deep-sea metal sulfide chimney? New insights from an archaeal genome and a nanoscale microbe-silicate assemblage

*Hinako Takamiya[1], Hiroki Mukai[2], Mariko Kouduka[1], Shingo Kato[4], Motoo Ito[3], Yohey Suzuki[1] (1.Earth and Planetary Science Graduate School of Science, The University of Tokyo , 2.National Institute of Advanced Industrial Science and Technology, 3.Kochi Institute for Core Sample Research JAMSTEC, 4.RIKEN)

[BCG06-P06] X-ray computed nano-tomography for visualizing microbial cells and their surrounding environments

*Yuki Morono[1], Go-Ichiro Uramoto[2,1], Kentaro Uesugi[3], Nobuhisa Takeuchi[3], Masayuki Uesugi[3], Kengo Kubota[4], Tatsuhiko Hoshino[1], Fumio Inagaki[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kochi University, 3.Japan Synchrotron Radiation Research Institute, 4.Tohoku University)

[BCG06-P07] Carbon signatures in amino acids during deep-sea anoxic methanotrophy

*Yoshinori Takano[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

[J] Oral | B (Biogeosciences)：B-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 105 1F

[B-CG08] Phanerozoic biodiversity change: Extinction and diversification

convener:Yukio Isozaki(Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo), Yusuke Sawaki(The University of Tokyo), Chairperson:Yukio Isozaki(Department of Earth Science and Astronomy, The University of Tokyo), Yusuke Sawaki(The University of Tokyo)

10:50 AM - 11:10 AM JST | 1:50 AM - 2:10 AM UTC

[BCG08-01] **The Ediacaran-Cambrian transition of North China**

★Invited Papers

*Xingliang Zhang[1] (1.State Key Laboratory of Continental Dynamics, Shaanxi Key Laboratory of Early Life and Environments, and Department of Geology, Northwest University)

11:10 AM - 11:30 AM JST | 2:10 AM - 2:30 AM UTC

[BCG08-02] The Qingjiang biota – An extraordinary new Burgess Shale-type fossil Lagerstätte from the early Cambrian of South China

★Invited Papers

*Dongjing Fu[1], Xingliang Zhang[1], Robert R. Gains[2] (1.State Key Laboratory of the Continental Dynamics, Shaanxi Key Laboratory of Early Life and Environment, Department of Geology, Northwest University, Xi'an 710069, PR China, 2.Department of Geology, Pomona College, Claremont, CA 91711, USA)

11:30 AM - 11:50 AM JST | 2:30 AM - 2:50 AM UTC

[BCG08-03] Enhanced flux of extraterrestrial ^{3}He across the Permian–Triassic boundary

★Invited Papers

*Tetsuji Onoue[1], Naoto Takahata[2], Honami Sato[4], Akira Ishikawa[3], Katsuhito Soda[1], Yuji Sano[2], Yukio Isozaki[2] (1.Kumamoto Univ., 2.Univ. Tokyo, 3.Tokyo Inst. Tech., 4.Chiba Inst. Tech.)

11:50 AM - 12:10 PM JST | 2:50 AM - 3:10 AM UTC

[BCG08-04] **End-Triassic Mass Extinction: Causes and Consequences**

★Invited Papers

*Wataru Fujisaki[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Oral | B (Biogeosciences) : B-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 105 1F

[B-CG08] Phanerozoic biodiversity change: Extinction and diversification

convener:Yukio Isozaki(Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo), Yusuke Sawaki(The University of Tokyo), Chairperson:Wataru Fujisaki(Japan Agency for Marine-Earth Science and Technology)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[BCG08-05] Transition of biodiversity in mobile populations and the small world in local subpopulations

*Kota Imaoka[1], Kazuhito Yamasaki[1] (1.Kobe University Graduate school of Science)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[BCG08-06] Rivision of the lowermost Cambrian SSF stratigraphy

*KONO SENA[1], Yukio Isozaki[1], Tomohiko Sato[2], Xingliang Zhang[3], Wei Liu[3] (1.The University of Tokyo School of Arts &Sciences, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Northwest university, China)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[BCG08-07] δ^{88}Sr and^{87}Sr/^{86}Srrecords of the Middle-Late Permian seawater: mass extinction-relevant change in ocean Sr budget

*Tomomi Kani[1], Yukio Isozaki[2], Keiji Misawa[3], Akira Ishikawa[4], Shigekazu Yoneda[5] (1.Kumamoto University, 2.The University of Tokyo, 3.National Institute of Polar Research, 4.Tokyo Tech, School of Science, 5.National Museum of Nature and Science)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[BCG08-08] Formation of stratiform manganese deposits during the Carnian (Late Triassic) “pluvial event” in the pelagic Panthalassa

*Yuki Tomimatsu[1], Tetsuji Onoue[2], Daisuke Yamashita[3], Tatsuo Nozaki[4,5,6,7], Yutaro Takaya[8] (1.Graduate school of Science and Technology, Kumamoto University, 2.Faculty of Advanced Science and Technology, Kumamoto University , 3.Satsumasendai City Office, 4.Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology, 5.Frontier Research Center for Energy and Resources (FRC- ER), Graduate School of Engineering, Tokyo University, 6.Department of Planetology, Graduate School of Science, Kobe University, 7.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 8.Department of Resources and Environmental Engineering School of Creative Science and Enginerring, Waseda University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[BCG08-09] Enrichment of chalcophile elements in Cretaceous–Paleogene boundary clays

*Teruyuki Maruoka[1], Yoshiro Nishio[2] (1.Faculty of Life and Environmental Sciences, University of Tsukuba, 2.Research and Education Faculty, Kochi University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[BCG08-10] Mass extinctions: hierarchy of causes and cosmoclimatological perspective

*Yukio Isozaki[1] (1.Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo)

[J] Poster | B (Biogeosciences)：B-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_23

[B-CG08] Phanerozoic biodiversity change: Extinction and diversification

convener:Yukio Isozaki(Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo), Yusuke Sawaki(The University of Tokyo)

[BCG08-P01] Marine Osmium isotope record across the Aptian/Albian boundary to elucidate the relationship between the Oceanic Anoxic Event 1b and massive volcanic activities at the Southern Kerguelen Plateau

*Hironao Matsumoto[1], Junichiro Kuroda[1], Rodolfo Coccioni[2], Naohiko Ohkouchi[3], Nanako O. Ogawa[3], Saburo Sakai[3], Katsuhiko Suzuki[3], Fabrizio Frontalini[2], Andrea Mazzoli[2] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.DiSPeA, University of Urbino, 3.Japan Agency for Marine-Earth Science and Technology)

[BCG08-P02] Rhaetian (Late Triassic) conodont biostratigraphy of the Panthalassa Ocean and the final extinction of conodonts at the end of the Triassic

*Kanna Yamasaki[1], Daisuke Yamashita[2], Tetsuji Onoue[1] (1.Kumamoto University, 2.Satsumasendai City Office)

[BCG08-P03] Paleoenvironmental changes across the Permian/Triassic boundary sections in the Mino Belt, central Japan

*Shinya Uemura[1], Tetsuji Onoue[1] (1.Kumamoto University)

[BCG08-P04] Geotectonic history of Mona Complex in Anglesey-Lleyn, Wales

*HISASHI ASANUMA[1], Yusuke Sawaki[1], Shigenori Maruyama[2] (1.The University of Tokyo, 2.Earth-Life Science Institute, Tokyo Institute of Technology)

[BCG08-P05] Radiogenic Sr isotope chemostratigraphy of the Ediacaran Doushantuo Formation in the Yangtze Craton, South China

*Yusuke Sawaki[1] (1.The University of Tokyo)

[J] Poster | B (Biogeosciences)：B-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_41

[B-CG08] Phanerozoic biodiversity change: Extinction and diversification

convener:Yukio Isozaki(Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo), Yusuke Sawaki(The University of Tokyo)

[BCG08-P01] Marine Osmium isotope record across the Aptian/Albian boundary to elucidate the relationship between the Oceanic Anoxic Event 1b and massive volcanic activities at the Southern Kerguelen Plateau

*Hironao Matsumoto[1], Junichiro Kuroda[1], Rodolfo Coccioni[2], Naohiko Ohkouchi[3], Nanako O. Ogawa[3], Saburo Sakai[3], Katsuhiko Suzuki[3], Fabrizio Frontalini[2], Andrea Mazzoli[2] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.DiSPeA, University of Urbino, 3.Japan Agency for Marine-Earth Science and Technology)

[BCG08-P02] Rhaetian (Late Triassic) conodont biostratigraphy of the Panthalassa Ocean and the final extinction of conodonts at the end of the Triassic

*Kanna Yamasaki[1], Daisuke Yamashita[2], Tetsuji Onoue[1] (1.Kumamoto University, 2.Satsumasendai City Office)

[BCG08-P03] Paleoenvironmental changes across the Permian/Triassic boundary sections in the Mino Belt, central Japan

*Shinya Uemura[1], Tetsuji Onoue[1] (1.Kumamoto University)

[BCG08-P04] Geotectonic history of Mona Complex in Anglesey-Lleyn, Wales

*HISASHI ASANUMA[1], Yusuke Sawaki[1], Shigenori Maruyama[2] (1.The University of Tokyo, 2.Earth-Life Science Institute, Tokyo Institute of Technology)

[BCG08-P05] Radiogenic Sr isotope chemostratigraphy of the Ediacaran Doushantuo Formation in the Yangtze Craton, South China

*Yusuke Sawaki[1] (1.The University of Tokyo)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[M-IS05] New technologies to monitor thunderstorm and severe weather activities

convener:Mitsuteru Sato(Department of Cosmoscience, Hokkaido University), Yukihiro Takahashi(Department of Cosmosciences, Graduate School of Science, Hokkaido University), Hisayuki Kubota(Hokkaido University), Kozo Yamashita(Ashikaga University, Department of Engineering.)

[MIS05-P01] Study on monitoring of thunderstorm activity based on multiple electrostatic measurement

*Kozo Yamashita[1], Kakeru Kanno[1], Mitsuteru Sato[2], Yukihiro Takahashi[2] (1.Ashikaga Univ., 2.Hokkaido Univ.)

[MIS05-P02] **Contribution of Rainfall and Lightning Activities to the Fair Weather Electric Field Evaluated by 3D GEC Model**

*Kittanapat Bandholnopparat[1], Mitsuteru Sato[2], Yukihiro Takahashi[2], Toru Adachi[3], Masashi Kamogawa[5], Yasuhiro Minamoto[5], Akira Kadokura[6], Tomoo Ushio[4] (1.Department of Cosmosciences, Hokkaido University, Sapporo, Japan, 2.Faculty of Science, Hokkaido University, Sapporo, Japan, 3.Meteorological Research Institute, Tsukuba, Japan, 4.Department of Aerospace Engineering, Tokyo Metropolitan University, Hino, Japan, 5.Tokyo Gakugei University, Tokyo, Japan, 6.National Institute of Polar Research, Tokyo, Japan)

[MIS05-P03] A method for locating lightning discharges using tweek atmospherics

*Masafumi Kanno[1], Hiroyo Ohya[2], Kazuo Shiokawa[3], Hiroyuki Nakata[2], Toshiaki Takano[2] (1.Graduate School of Science and Engineering, Chiba University, 2.Graduate School of Engineering, Chiba University, 3.Institute for Space-Earth Environmental Research, Nagoya University)

[MIS05-P04] Monitoring for lightning activities and thunder cloud development over the Tokyo metropolitan area during the 2018 summer

*Jun-Ichi Hamada[1], Jun Matsumoto[1], Kozo Yamashita[2], Masashi Kamogawa[3], Yukihiro Takahashi[4] (1.Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, 2.Department of Engineering, Ashikaga University, 3.Department of Physics, Tokyo Gakugei University, 4.Department of Cosmosciences, Graduate School of Science, Hokkaido University)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_42

[M-IS05] New technologies to monitor thunderstorm and severe weather activities

convener:Mitsuteru Sato(Department of Cosmoscience, Hokkaido University), Yukihiro Takahashi(Department of Cosmosciences, Graduate School of Science, Hokkaido University), Hisayuki Kubota(Hokkaido University), Kozo Yamashita(Ashikaga University, Department of Engineering.)

[MIS05-P01] Study on monitoring of thunderstorm activity based on multiple electrostatic measurement

*Kozo Yamashita[1], Kakeru Kanno[1], Mitsuteru Sato[2], Yukihiro Takahashi[2] (1.Ashikaga Univ., 2.Hokkaido Univ.)

[MIS05-P02] **Contribution of Rainfall and Lightning Activities to the Fair Weather Electric Field Evaluated by 3D GEC Model**

*Kittanapat Bandholnopparat[1], Mitsuteru Sato[2], Yukihiro Takahashi[2], Toru Adachi[3], Masashi Kamogawa[5], Yasuhiro Minamoto[5], Akira Kadokura[6], Tomoo Ushio[4] (1.Department of Cosmosciences, Hokkaido University, Sapporo, Japan, 2.Faculty of Science, Hokkaido University, Sapporo, Japan, 3.Meteorological Research Institute, Tsukuba, Japan, 4.Department of Aerospace Engineering, Tokyo Metropolitan University, Hino, Japan, 5.Tokyo Gakugei University, Tokyo, Japan, 6.National Institute of Polar Research, Tokyo, Japan)

[MIS05-P03] A method for locating lightning discharges using tweek atmospherics

*Masafumi Kanno[1], Hiroyo Ohya[2], Kazuo Shiokawa[3], Hiroyuki Nakata[2], Toshiaki Takano[2] (1.Graduate School of Science and Engineering, Chiba University, 2.Graduate School of Engineering, Chiba University, 3.Institute for Space-Earth Environmental Research, Nagoya University)

[MIS05-P04] Monitoring for lightning activities and thunder cloud development over the Tokyo metropolitan area during the 2018 summer

*Jun-Ichi Hamada[1], Jun Matsumoto[1], Kozo Yamashita[2], Masashi Kamogawa[3], Yukihiro Takahashi[4] (1.Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, 2.Department of Engineering, Ashikaga University, 3.Department of Physics, Tokyo Gakugei University, 4.Department of Cosmosciences, Graduate School of Science, Hokkaido University)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 101 1F

[M-IS05] New technologies to monitor thunderstorm and severe weather activities

convener:Mitsuteru Sato(Department of Cosmoscience, Hokkaido University), Yukihiro Takahashi(Department of Cosmosciences, Graduate School of Science, Hokkaido University), Hisayuki Kubota(Hokkaido University), Kozo Yamashita(Ashikaga University, Department of Engineering.), Chairperson:Mitsuteru Sato(Faculty of Science, Hokkaido University), Kozo Yamashita(Department of Technology, Ashikaga Institute of Technology)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS05-01] Quasi real-time observation of typhoon and thunderstorms by the system of micro-satellites and ground-based lightning sensors

*Yukihiro Takahashi[4,1], Mitsuteru Sato[1,4], Hisayuki Kubota[4], Kozo Yamashita[2], Tetsuro Ishida[4], Ellison Caparas Castro[3], Purwadi Purwadi[1], Kazuhisa Tsuboki[5], Hiroyuki Yamada[6], Taro Shinoda[5], Loren Joy De Vera Estrebillo[1], Doreena Karmina Abril Pulutan[1] (1.Graduate School of Science, Hokkaido University, 2.Department of Engineering, Ashikaga University, 3.University of the Philippines, Diliman, 4.Faculty of Science, Hokkaido University, 5.Institute for Space-Earth Environmental Research (ISEE), Nagoya University, 6.University of the Ryukyus)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS05-02] **Towards the Implementation of the Understanding Lightning and Thunderstorms for Extreme Weather Monitoring and Information Sharing in the Philippines (ULAT) Project**

★Invited Papers

*Glenn Vincent C. Lopez[1] (1.Advanced Science and Technology Institute)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS05-03] **Airborne observation of Super Typhoon Trami in 2018 for understanding the intensity of tropical cyclone in the Philippine Sea**

★Invited Papers

*Hisayuki Kubota[1], Kazuhisa Tsuboki[2], Hiroyuki Yamada[3], Yukihiro Takahashi[1], Taro Shinoda[2], Tadayasu Ohigashi[4], Munehiko Yamaguchi[5], Kosuke Ito[3], Tetsuo Nakazawa[5], Norio Nagahama[6], Kensaku Shimizu[6], Mitsuteru Sato[1] (1.Hokkaido University, 2.Nagoya University, 3.University of the Ryukyus, 4.National Research Institute for Earth Science and Disaster Resilience, 5.Meteorological Research Institute, 6.Meisei Electronic)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS05-04] Relation between Lightning and Typhoon Activities (Typhoon LAN) in the Western Pacific Region

*Mitsuteru Sato[1], Yukihiro Takahashi[1], Hisayuki Kubota[1], Kozo Yamashita[2], Jun-Ichi Hamada[3], Joel J. Marciano[4] (1.Department of Cosmoscience, Hokkaido University, 2.Department of Engineering, Ashikaga University, 3.Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University, 4.ASTI, DOST)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS05-05] Infrasound multi-site observation of thunders 3: preparation process for SATREPS

★Invited Papers

*Masa-yuki Yamamoto[1] (1.Department of systems engineering, Kochi University of Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS05-06] Data Acquisition System for an Infrasound Network for Thunderstorm Monitoring

*Doreena Karmina Abril Pulutan[1], Yukihiro Takahashi[1], Mitsuteru Sato[1], Hisayuki Kubota[1], Kozo Yamashita[2], Masa-yuki Yamamoto[3] (1.Department of Cosmosciences, Hokkaido University, 2.Department of Engineering, Ashikaga University, 3.Department of Systems Engineering, Kochi University of Technology)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 101 1F

[M-IS05] New technologies to monitor thunderstorm and severe weather activities

convener:Mitsuteru Sato(Department of Cosmoscience, Hokkaido University), Yukihiro Takahashi(Department of Cosmosciences, Graduate School of Science, Hokkaido University), Hisayuki Kubota(Hokkaido University), Kozo Yamashita(Ashikaga University, Department of Engineering.), Chairperson:Yukihiro Takahashi(Hokkaido University), Hisayuki Kubota(Department of Cosmoscience, Hokkaido University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MIS05-07] Estimation of Lightning Location Using V-POTEKA Lightning Observation Network

*Loren Joy De Vera Estrebillo[1], Mitsuteru Sato[2], Yukihiro Takahashi[2], Hisayuki Kubota[2], Kozo Yamashita[3], Junichi Hamada[4], Joel Marciano[5] (1.Department of Cosmosciences, Hokkaido University, 2.Faculty of Science, Hokkaido University, 3.Faculty of Engineering, Ashikaga University, 4.Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University, 5.ASTI/DOST)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MIS05-08] **Observation system for thunderstorm development using ground lightning detection network and thermal infrared camera onboard satellite LAPAN-A4 in Indonesia**

*Purwadi Purwadi[1,2], Yukihiro Takahashi[1], Mitsuteru Sato[1], Kozo Yamashita[3], M. Arif Saifudin[4] (1.Department of Cosmosciences, Hokkaido University, Sapporo 0600810, Japan, 2.Agency for Assessment and Application of Technology (BPPT), Jakarta 10340, Indonesia, 3.Department of Technology, Ashikaga Institute of Technology, Tochigi 3268558, Japan, 4.Indonesian National Institute of Aeronautics and Space (LAPAN), Jawa Barat 16310, Indonesia)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MIS05-09] Remote Sensing Water Quality Determination using Multi-spectral Analysis

*Ahmad Shaqeer Mohamed Thaheer[1], Yukihiro Takahashi[1] (1.Hokkaido University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MIS05-10] Study of cloud effects on atmospheric electric field during lightning activities and snowfall using the 95-GHz cloud radar FALCON-I

★Invited Papers

*Hiroyo Ohya[1], Kota Nakamori[1], Masashi Kamogawa[2], Tomoyuki Suzuki[2], Toshiaki Takano[1], Kazuomi Morotomi[3], Hiroyuki Nakata[1], Kazuo Shiokawa[4] (1.Graduate School of Engineering, Chiba University, 2.Tokyo Gakugei University, 3.Japan Radio Co. Ltd., 4.Nagoya University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MIS05-11] Preferred environmental conditions of precipitation systems in and around Bangladesh observed by ground-based radars

★Invited Papers

*Fumie Murata[1], Shuhei Azuma[2], Toru Terao[3], Quamrul S.M. Hassan[4] (1.Faculty of Science and Technology, Kochi University, 2.Faculty of Science, Kochi University, 3.Faculty of Education, Kagawa University, 4.Bangladesh Meteorological Department)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MIS05-12] Thundercloud gamma-ray observations at Kashiwazaki aiming at source altitude and beaming measurements and a new trial at Tokyo Skytree in FY2018

★Invited Papers

*Kazuhiro Nakazawa[1], Takahiro Matsumoto[2], Yuuki Wada[2], Alexia Fabiani[1], Teruaki Enoto[3], Kazufumi Okuda[2], Yoshihiro Furuta[4], Yuki Aizawa[2], Takayuki Yuasa[5], Harufumi Tsuchiya[4], Mitsuteru Sato[6], Kazuo Makishima[7] (1.Nagoya University, 2.University of Tokyo, 3.Kyoto University, 4.JAEA, 5.RIKEN, 6.Hokkaido University, 7.Kalvi IPMU, University of Tokyo)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 303 3F

[M-IS10] Interface- and nano-phenomena on crystal growth and dissolution

convener:Yuki Kimura(Institute of Low Temperature Science, Hokkaido University), Hitoshi Miura(Graduate School of Natural Sciences, Department of Information and Basic Science, Nagoya City University), Hisao Satoh(Naka Energy Research Laboratory, Mitsubishi Materials Corporation), Katsuo Tsukamoto(Graduate School of Engineering, Osaka University), Chairperson:Yuki Kimura (Institute of Low Temperature Science, Hokkaido University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[MIS10-01] Fabrication of octacalcium phosphate block through a dissolutionprecipitation reaction and its biological evaluation

*Yuki Sugiura[1], Munar L Melvin[2], Kunio Ishikawa[2] (1.National Institute of Advanced Industrial Science and Technology, 2.Kyushu University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[MIS10-02] Development of optimized incineration process of fisheries waste for synthesizing a functional heat storage material

*Hidekazu Kobatake[1], SHinji Kirihara[1] (1.Hirosaki University Institute of Regional Innovation)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[MIS10-03] “Manipulated” Organic Crystallization and Two-step Dissolution Process Attained by Plasmonic Optical Tweezers

*Hiromasa Niinomi[1], Teruki Sugiyama[2,3,4], Miho Tagawa[5], Toru Ujihara[5], Katsuhiko Miyamoto[6,7], Takashige Omatsu[6,7], Jun Nozawa[1], Junpei Okada[1], Satoshi Uda[1] (1.Institute for Materials Research, Tohoku University, 2.Department of Applied Chemistry, National Chiao Tung University, 3.Center for Emergent Functional Matter Science, National Chiao Tung University, 4.Division of Materials Science, Nara Institute of Science and Technology, 5.Institute of Materials and Systems for Sustainability (IMaSS), Nagoya University, 6.Molecular Chirality Research Center (MCRC), Chiba University, 7.Graduate School of Engineering, Chiba University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[MIS10-04] Investigation of liquid cell transmission electron microscopy combined with antisolvent crystallization

*Tomoya Yamazaki[1], Yuki Kimura[1] (1.Institute of Low Temperature Science Hokkkaido University)

10:00 AM - 10:30 AM JST | 1:00 AM - 1:30 AM UTC

[MIS10-05] DNA-guided crystallization of nanoparticles: optimization of crystallization conditions and structure analysis

★Invited Papers

*Miho Tagawa[1], Shoko Kojima[1], Hayato Sumi[1], Arisa Nishibu[1], Takumi Isogai[1], Maasa Yokomori[2], Shunta Harada[1], Toru Ujihara[1], Katsuo Tsukamoto[1] (1.Nagoya University, 2.The University of Tokyo)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 303 3F

[M-IS10] Interface- and nano-phenomena on crystal growth and dissolution

convener:Yuki Kimura(Institute of Low Temperature Science, Hokkaido University), Hitoshi Miura(Graduate School of Natural Sciences, Department of Information and Basic Science, Nagoya City University), Hisao Satoh(Naka Energy Research Laboratory, Mitsubishi Materials Corporation), Katsuo Tsukamoto(Graduate School of Engineering, Osaka University), Chairperson:Hisao Satoh

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS10-06] Growth mechanism of binary colloidal crystals

*Jun Nozawa[1], Suxia Guo[1], Hiromasa Niinomi[1], Junpei Okada[1], Satoshi Uda[1] (1.Tohoku University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS10-07] Solution-Mediated-Transformation Kinetics of Norsethite

*Harutoshi Asakawa[1], Hiroshi Uneda[1], Itaru Echigo[1], Ryuichi Komatsu[1] (1.Graduate School of Sciences and Technology for Innovation Yamaguchi University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS10-08] Formation of low-crystalline magnesium silicate in natural alkaline environment and flow-through experiments

*Yuto Nishiki[1], Misato Shimbashi[1], Tsutomu Sato[2], Tsubasa Otake[2] (1.Graduate School of Engineering, Hokkaido University, 2.Faculty of Engineering, Hokkaido University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS10-09] Homogeneous Nucleation from Vapor in Al-O Binary System

*Shinnosuke Ishizuka[1], Jun Kawano[2], Tomoya Yamazaki[3], Tetsuya Hama[3], Yuki Kimura[3] (1.National Institute for Environmental Studies, 2.Faculty of Science, Hokkaido University, 3.Institute of Low Temperature Science, Hokkaido University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS10-10] Crystal growth hysteresis in birth-and-spread mechanism

*Hitoshi Miura[1] (1.Graduate School of Natural Sciences, Department of Information and Basic Science, Nagoya City University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_24

[M-IS10] Interface- and nano-phenomena on crystal growth and dissolution

convener:Yuki Kimura(Institute of Low Temperature Science, Hokkaido University), Hitoshi Miura(Graduate School of Natural Sciences, Department of Information and Basic Science, Nagoya City University), Hisao Satoh(Naka Energy Research Laboratory, Mitsubishi Materials Corporation), Katsuo Tsukamoto(Graduate School of Engineering, Osaka University)

[MIS10-P01] Theoretical Model of Crystallization through Homogeneous Nucleation in Water Droplets

*Kyoko Kitakami Tanaka[1], Yuki Kimura[2] (1.Tohoku University, 2.Hokkaido University, Institute of Low Temperature Science)

[MIS10-P02] Mean Height of the Self-Assembled Faceted Macrosteps: Steady Crystal Growth/Dissolution in a Reaction- (Interface-) Limited Process

*Noriko Akutsu[1] (1.Faculty of Engineering, Osaka Electro-Communication University)

[MIS10-P03] In-situ observation of natural snow crystals by optical techniques

*Yuki Kimura[1], Tomoya Yamazaki[1], Takao Maki, Yoshinori Furukawa[1] (1.Institute of Low Temperature Science, Hokkaido University)

[MIS10-P04] Visualization of local environment around forming/dissolving carbonate minerals with the fluorescent probe

*Jun Kawano[1], Kotaro Osawa[2], Takashi Toyofuku[3,4], Yukiko Nagai[4,5], Jun-ya Tanaka[6], Takaya Nagai[1] (1.Faculty of Science, Hokkaido University, 2.School of Science, Hokkaido University, 3.JAMSTEC, 4.Tokyo University of Marine Science and Technology, 5.National Museum of Nature and Science of Tokyo, 6.Graduate School of Science, Hokkaido University)

[MIS10-P05] Influence of Ammonium Nitrate on Crystallization of Norsethite from Aqueous Solution

*Itaru Echigo[1], Harutoshi Asakawa[1], Hiroshi Uneda, Ryuichi Komatsu[1] (1.Graduate School of Science and Technology for Innovation Yamaguchi University)

[MIS10-P06] Direct observation of zeolite nucleation from compacted bentonite under hyperalkaline condition

*Hisao Satoh[1], Mayumi Takazawa[2], Daisuke Hayashi[3], Masaya Ida[3] (1.Naka Energy Research Laboratory, Mitsubishi Materials Corporation, 2.Mitsubishi Materials Corporation, 3.Radioactive Waste Management Funding and Research Center)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_43

[M-IS10] Interface- and nano-phenomena on crystal growth and dissolution

convener:Yuki Kimura(Institute of Low Temperature Science, Hokkaido University), Hitoshi Miura(Graduate School of Natural Sciences, Department of Information and Basic Science, Nagoya City University), Hisao Satoh(Naka Energy Research Laboratory, Mitsubishi Materials Corporation), Katsuo Tsukamoto(Graduate School of Engineering, Osaka University)

[MIS10-P01] Theoretical Model of Crystallization through Homogeneous Nucleation in Water Droplets

*Kyoko Kitakami Tanaka[1], Yuki Kimura[2] (1.Tohoku University, 2.Hokkaido University, Institute of Low Temperature Science)

[MIS10-P02] Mean Height of the Self-Assembled Faceted Macrosteps: Steady Crystal Growth/Dissolution in a Reaction- (Interface-) Limited Process

*Noriko Akutsu[1] (1.Faculty of Engineering, Osaka Electro-Communication University)

[MIS10-P03] In-situ observation of natural snow crystals by optical techniques

*Yuki Kimura[1], Tomoya Yamazaki[1], Takao Maki, Yoshinori Furukawa[1] (1.Institute of Low Temperature Science, Hokkaido University)

[MIS10-P04] Visualization of local environment around forming/dissolving carbonate minerals with the fluorescent probe

*Jun Kawano[1], Kotaro Osawa[2], Takashi Toyofuku[3,4], Yukiko Nagai[4,5], Jun-ya Tanaka[6], Takaya Nagai[1] (1.Faculty of Science, Hokkaido University, 2.School of Science, Hokkaido University, 3.JAMSTEC, 4.Tokyo University of Marine Science and Technology, 5.National Museum of Nature and Science of Tokyo, 6.Graduate School of Science, Hokkaido University)

[MIS10-P05] Influence of Ammonium Nitrate on Crystallization of Norsethite from Aqueous Solution

*Itaru Echigo[1], Harutoshi Asakawa[1], Hiroshi Uneda, Ryuichi Komatsu[1] (1.Graduate School of Science and Technology for Innovation Yamaguchi University)

[MIS10-P06] Direct observation of zeolite nucleation from compacted bentonite under hyperalkaline condition

*Hisao Satoh[1], Mayumi Takazawa[2], Daisuke Hayashi[3], Masaya Ida[3] (1.Naka Energy Research Laboratory, Mitsubishi Materials Corporation, 2.Mitsubishi Materials Corporation, 3.Radioactive Waste Management Funding and Research Center)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A02 TOKYO BAY MAKUHARI HALL

[M-IS11] Aqua planetology

convener:Yasuhito Sekine(Earth-Life Science Insitute, Tokyo Institute of Technology), Tomohiro Usui(Earth-Life Science Institute, Tokyo Institute of Technology), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Takazo Shibuya(Japan Agency for Marine-Earth Science and Technology), Chairperson:Yasuhito Sekine(Dept. Earth & Planetary Sci., University of Tokyo), Takazo Shibuya(JAMSTEC), Tomohiro Usui

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[MIS11-13] A forward modeling of infrared reflectance spectra of asteroids

*Hiroyuki Kurokawa[1], Takazo Shibuya[2], Yasuhito Sekine[1], Bethany L Ehlmann[3,4] (1.ELSI, Tokyo Tech, 2.JAMSTEC, 3.Caltech, 4.JPL)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[MIS11-14] Estimation of formation mechanism and morphological condition in calcite concretion

*Takayuki Ihara[1], Sin-iti Sirono[1] (1.Nagoya University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[MIS11-15] Reconstructing groundwater hydrology and water-rock reactions around Gale Crater on early Mars

*Natsumi Noda[1,2], Yasuhito Sekine[1], Shuya Tan[1,2], Takazo Shibuya[3], Hidenori Genda[1] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 3.Department of Subsurface Geobiological Analysis and Research, Japan Agency for Marine-Earth Science and Technology)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[MIS11-16] Habitable zone for a land planet

*Takanori Kodama[1], Hidenori Genda[2], Ryouta O'ishi[3], Ayako Abe-Ouchi[3] (1.University of Bordeaux, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Atmosphere and Ocean Research Institute, University of Tokyo)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[MIS11-17] A study on the dependence of ocean planet climate on solar constant: influence of oceanic heat transport in the case of large absorption coefficients of gray atmosphere

*Yuta Kawai[1,2], Yoshiyuki O. Takahashi[1], Masaki Ishiwatari[5], Kensuke Nakajima[3], Shin-ichi Takehiro[4], Hiroki Kashimura[1,6], Seiya Nishizawa[2], Hirofumi Tomita[2], Yoshi-Yuki Hayashi[1,6] (1.Kobe University, 2.RIKEN Center for Computational Science, 3.Kyusyu University, 4.Kyoto University , 5.Hokkaido University, 6.Center for Planetary Science)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[MIS11-18] Water cycle and its evolution: High-speed H_2O transport to upper atmosphere on Mars

★Invited Papers

*Hiromu Nakagawa[1], Shohei Aoki[1], Nao Yoshida[1], Naoki Terada[1], Takeshi Imamura[2], Kazunori Ogohara[3], Toru Kouyama[4], Hiroki Ando[6], Katsuyuki Noguchi[5], Akiho Miyamoto[1], Kosuke Takami[1], Isao Murata[1], Yasumasa Kasaba[1], IUVS team MAVEN (1.Planetary Atmosphere Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University, 2.Graduate school of Frontier sciences, University of Tokyo, 3.University of Shiga prefecture, 4.The National Institute of Advanced Industrial Science and Technology, 5.Nara Women's university, 6.Kyoto Sangyo university)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_25

[M-IS11] Aqua planetology

convener:Yasuhito Sekine(Earth-Life Science Insitute, Tokyo Institute of Technology), Tomohiro Usui(Earth-Life Science Institute, Tokyo Institute of Technology), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Takazo Shibuya(Japan Agency for Marine-Earth Science and Technology)

[MIS11-P01] Three-dimensional simulations of methane-based hydrological cycles in north-pole regions of Titan

*Takufumi Chida[1,2], Yasuhito Sekine[1], Hidenori Genda[1] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.Department of Earth and Planetary Science, University of Tokyo)

[MIS11-P02] Inclusion of brine into icy shell of Enceladus

*Ryusuke Nishitani[1], Atsushi Tani[2], Sho Sasaki[1], Jun Kimura[1] (1.Department of Earth and Space Sciences, School of Science, Osaka University, 2.Graduate School Human Development and Environment, Kobe University)

[MIS11-P03] Electron irradiations onto ice-salt mixtures at low temperatures: Implications for chemical evolution and oxidant formation on Europa

*Shuya Tan[2,1], Yasuhito Sekine[2], Tetsuya Hama[3] (1.Department of Earth and Planetary Science, Graduate School of Science, the University of Tokyo, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Institute of Low Temperature Science, Hokkaido University)

[MIS11-P04] Water-rock reactions in the parent body of Ryugu

*Takazo Shibuya[1], Yasuhito Sekine[2], Sakiko Kikuchi[1], Keisuke Fukushi[3], Tomoki Nakamura[4], Sei-ichiro WATANABE[5] (1.Japan Agency for Marine-Earth Science and Technology, 2.Tokyo Institute of Technology, 3.Kanazawa University, 4.Tohoku University, 5.Nagoya University)

[MIS11-P05] Investigation of the organic matter in ALH 77307 by STXM

*Hiroki Suga[1], Motoo Ito[2], Yoko Kebukawa[3], Matthew A Marcus[4], Takuji Ohigashi[5], Yoshio Takahashi[1] (1.Graduate School of Science, The University of Tokyo, 2.Kochi Institute for Core Sample Research JAMSTEC, 3.Faculty of Engineering, Yokohama National University, 4.Advanced Light Source, Lawrence Berkeley National Laboratory, 5.UVSOR Synchrotron Facility, Institute for Molecular Science)

[MIS11-P06] The development of UV spectrometer and preliminary measurement of carbonaceous chondrites

*Akira Igarashi[1], Tomoki Nakamura[1], Shingo Kameda[2], Keiichi Moroi[2] (1.Department of Earth and Planetary Materials Sciences, Faculty of Science, Tohoku University, 2.Department of Physics, Faculty of Science, Rikkyo University)

[MIS11-P07] A coupled experimental and thermodynamic study of chondrite-water interaction under anoxic condition

*Sakiko Kikuchi[1], Takazo Shibuya[1] (1.Japan Agency for Marine-Earth Science and Technology)

[MIS11-P08] Two-dimensional numerical experiments on subduction initiation in oceanic lithosphere: Effects of rheological properties of hydrous minerals

*Miki Izumi[1], Masaki Yoshida[2], Ken-ichi Hirauchi[1] (1.Department of Geosciences, Faculty of Science, Shizuoka University, 2.Department of Deep Earth Structure and Dynamics research, Japan Agency for Marine–Earth Science and Technology –JAMSTEC–)

[MIS11-P09] Electrical energy generation at hydrothermal environments in the Solar System estimated by fuel cell model experimentations

*Hiroyuki Kashima[1], Masahiro Yamamoto[1], Ken Takai[1] (1.Japan Agency for Marine-Earth Science and Technology)

[MIS11-P10] Experimental study of abiotic nitrate reduction at a high temperature and high-pressure condition and implication for nitrogen chemistry in Hadean hydrothermal environments

*Manabu Nishizawa[1], Takuya Saito[1], Akiko Makabe[1], Takazo Shibuya[1], Ken Takai[1] (1.Japan Agency for Marine-Earth Science and Technology)

[MIS11-P11] Interaction experiments between eucritic glass and 0.1 M NaCl aqueous solution at 300-500°C and 1.5 kbar: Suggestions on water-rock interactions at the bottom of Europa's subsurface ocean

*Makoto Nagasawa[1,2], Yutaro Takaya[1] (1.Department of Resources and Environmental Engineering, School of Creative Science and Engineering, Waseda University, 2.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

[MIS11-P12] **Relationship between tellurium in the Fe-Mn oxides in the ocean and ambient seawater**

*Yusuke Fukami[1], Teruhiko Kashiwabara[1], Hiroshi Amakawa[1], Takazo Shibuya[1], Akira Usui[2], Katsuhiko Suzuki[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kochi University)

[MIS11-P13] Laboratory reproduction of earthquake faulting beneath the internal ocean of Enceladus

*Takehiro Hirose[1], Takazo Shibuya[2] (1.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2.Japan Agency for Marine-Earth Science and Technology)

[MIS11-P14] Why does Titan have an atmosphere, and why not Ganymede?—The origin of Titan-Ganymede dichotomy

*Yasuhito Sekine[1], Yuhiko Aoyama[2], Masahiro Ikoma[2], Takayuki Tanigawa[3] (1.Earth-Life Science Insitute, Tokyo Institute of Technology, 2.Dept. of Earth and Planetary Sci., University of Tokyo, 3.Section of Liberal Arts and Sciences, National Inst. of Tech., Ichinoseki College)

[MIS11-P15] Development of observation system of gas hydrate forming in the environment simulated near the bottom of icy shell in icy bodies (2)

*Atsushi Tani[1], Kenshiro Moriyama[1] (1.Graduate School of Human Development and Environment, Kobe University)

[MIS11-P16] Rheology of non-water ices inferred from diffusion coefficients: A compilation study

*Naoki Noguchi[1] (1.Graduate School of Technology, Industrial and Social Sciences, Tokushima University)

[MIS11-P17] Swelling behavior of magnesium saturated smectites

Morida Koki, Keisuke Fukushi, Hiroshi Sakuma

*Koki Morida[1] (1.Kanazawa University)

[MIS11-P18] Possibility of hydrogen peroxide as a warming agent on early Mars with oxidized condition

*Yuichi Ito[1], George HASHIMOTO[2], Yoshiyuki O. Takahashi[3], Masaki Ishiwatari[1], Kiyoshi Kuramoto[1] (1.Department of Cosmosciences, Graduate school of Science, Hokkaido University, 2.Department of Earth Sciences, Okayama University, 3.Graduate School of Science, Kobe University)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A02 TOKYO BAY MAKUHARI HALL

[M-IS21] Gas hydrate in environmental-resource sciences

convener:Hitoshi Tomaru(Department of Earth Sciences, Chiba University), Akihiro Hachikubo(Kitami Institute of Technology), Atsushi Tani(Graduate School of Human Development and Environment, Kobe University), Shusaku Goto(Institute for Geo-Resources and Environment National Institute of Advanced Industrial Science and Technology), Chairperson:Naoto Ishida, 戸丸 仁

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS21-01] Equilibrium pressure of clathrate hydrates encaged $^{13}CH_4$

*Yuki Kikuchi[1], Akihiro Hachikubo[1], Takahiro Ozeki[1], Satoshi Takeya[2] (1.Kitami Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology (AIST))

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS21-02] Hydrogen isotopic fractionation of ethane encaged in different crystallographic structure

*Jumpei Matsuda[1], Akihiro Hachikubo[1], Satoshi Takeya[2] (1.Kitami Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology (AIST))

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS21-03] Trend of effect of temperature on C–H symmetric stretching vibrational frequencies of hydrocarbon molecules in 12, 14 and 16-hedra cages of gas hydrates

*Go Fuseya[1], Satoshi Takeya[2], Akihiro Hachikubo[1] (1.Kitami Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology (AIST))

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS21-04] The study on relations of the methane plume and atmospheric methane concentration

*Chiharu Aoyama[1] (1.Tokyo University of Marine Science and Technology)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS21-05] Sampling of Methane Bubble Plumes and Solid Gas Hydrate on the Cascadia Margin, Pacific Northwest

*John E Lupton[1], Tamara Baumberger[1], Robert W. Embley[1], Susan G. Merle[1], Camilla Wilkinson[1], Conrad Young[2] (1.NOAA Pacific Marine Environmental Laboratory, Newport, Oregon, USA, 2.Young Engineering, Ramona, CA. USA)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A02 TOKYO BAY MAKUHARI HALL

[M-IS21] Gas hydrate in environmental-resource sciences

convener:Hitoshi Tomaru(Department of Earth Sciences, Chiba University), Akihiro Hachikubo(Kitami Institute of Technology), Atsushi Tani(Graduate School of Human Development and Environment, Kobe University), Shusaku Goto(Institute for Geo-Resources and Environment National Institute of Advanced Industrial Science and Technology), Chairperson:八久保 晶弘(北見工業大学), 戸丸 仁

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS21-06] The distribution of atmospheric CH_4 concentration and gas plume location in the sea around Japanese islands.

*Shinsuke Aoki[1], Shujiro Komiya[2], Kosuke Noborio[3], Ryo Matsumoto[4] (1.Graduate School of Agriculture, Meiji Universiy, 2.Max Planck Institute, 3.School of Agriculture, Meiji Universiy, 4.Gas Hydrate Laboratory - Meiji University Organization for the Strategic Coordination of Research and Intellectual Property)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS21-07] Reaction/fixation/migration of methane within the gas chimney on the Umitaka Spur, eastern margin of the Japan Sea

*Hitoshi Tomaru[1], Ryo Matsumoto[2] (1.Department of Earth Sciences, Chiba University, 2.Gas Hydrate Research Laboratory, Meiji University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS21-08] Slope failures induced by methane hydrate dissociation: a case of submarine slide in the southwestern Oki Trough, Japan Sea

*Naoto Ishida[1], Shota Morihita[2], Takao Ebinuma[1], Hitoshi Tomaru[3], Ryo Matsumoto[4] (1.Social Systems and Civil Engineering, Graduate School of Engineering, Tottori University, 2.Department of Social Systems and Civil Engineering, Faculty of Engineering, Tottori University, 3.Department of Earth Sciences, Faculty of Science, Chiba University, 4.Gas Hydrate Research Laboratory, Organization for the Strategic Coordination of Research and Intellectual Properties, Meiji University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS21-09] Origin and evolution of H_2S-bearing methane hydrate in the Sea of Japan

*Ryo Matsumoto[1], Tomoko Fukazawa[2], Akihiro Hiruta[1], Glen Snyder[1] (1.Organization for the Strategic Laboratory of Research and Intellectual Properties, Meiji University, 2.Department of Applied Chemistry, School of Science and Technoloty, Meiji University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS21-10] Discovery of gas hydrate at the new point off Abashiri, the Sea of Okhotsk

*Akihiro Hachikubo[1], Jumpei Matsuda[1], Satoshi Yamashita[1], Hirotoshi Sakagami[1], Masaaki Konishi[1], Hirotsugu Minami[1], Kenji Nishina[2], Kenji Sakaguchi[3] (1.Kitami Institute of Technology, 2.Geological Survey of Hokkaido, Hokkaido Research Organization, 3.Kushiro Fisheries Research Institute, Hokkaido Research Organization)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS21-11] All about gas hydrates and heat flow offshore Chile

*LUCIA ALEJANDRA VILLAR MUNOZ[1], IVAN VARGAS-CORDERO[2], JOAQUIM P. BENTO[3], JAN BEHRMANN[1], UMBERTA TINIVELLA[4], MICHELA GIUSTINIANI[4] (1.Helmholtz Centre for Ocean Research, 2.Universidad Andres Bello , 3.Pontificia Universidad Catolica de Valparaiso, 4.Istituto Nazionale di Oceanografia e di Geofisica Sperimentale)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_26

[M-IS21] Gas hydrate in environmental-resource sciences

convener:Hitoshi Tomaru(Department of Earth Sciences, Chiba University), Akihiro Hachikubo(Kitami Institute of Technology), Atsushi Tani(Graduate School of Human Development and Environment, Kobe University), Shusaku Goto(Institute for Geo-Resources and Environment National Institute of Advanced Industrial Science and Technology)

[MIS21-P01] Raman spectroscopic analysis of isotopologue methane hydrates

*Yuki Kikuchi[1], Jumpei Matsuda[1], Akihiro Hachikubo[1], Satoshi Takeya[2] (1.Kitami Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology (AIST))

[MIS21-P02] Gas origin of hydrate-bound gas in Lake Baikal

*Jumpei Matsuda[1], Yuki Kikuchi[1], Akihiro Hachikubo[1], Oleg Khlystov[2], Gennadiy Kalmychkov[3], Marc De Batist[4], Hirotoshi Sakagami[1], Hirotsugu Minami[1], Satoshi Yamashita[1] (1.Kitami Institute of Technology, 2.Limnological Institute, SB RAS, 3.Vinogradov Institute of Geochemistry, SB RAS, 4.Ghent University)

[MIS21-P03] Validation of self-preservation effect of methane and ethane mixed-gas hydrate by Raman spectroscopy

*Yunosuke Hase[1], Jumpei Matsuda[1], Akihiro Hachikubo[1], Satoshi Takeya[2] (1.Kitami Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology (AIST))

[MIS21-P04] Experimental study on the phase equilibrium condition of CO_2 hydrate with marine sediment

*Daisuke Maki[1], Hitoshi Tomaru[1] (1.Graduate School of Science and Engineering, Chiba University)

[MIS21-P05] Raman spectroscopic analysis of structure H gas hydrates encapsulating cyclic hydrocarbons

*Go Fuseya[1], Satoshi Takeya[2], Akihiro Hachikubo[1] (1.Kitami Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology (AIST))

[MIS21-P06] Investigation of self-preservation of argon hydrate by measuring specific surface area

*Yuki Ikeura[1], Daisuke Yahagi[1], Akihiro Hachikubo[1], Satoshi Takeya[2] (1.Kitami institute of technology, 2.National Institute of Advanced Industrial Science and Technology (AIST))

[MIS21-P07] Carbon isotope fractionation of CO_2 during the formation of clathrate hydrate

*Hiromi Kimura[1], Jumpei Matsuda[1], Yuki Kikuchi[1], Akihiro Hachikubo[1], Satoshi Takeya[2] (1.Kitami Institute of Technology, 2.National Institute of Advanced Industrial Science and Technology)

[MIS21-P08] Gas hydrate survey off Tokachi (the Pacific Ocean) in the framework of practical education of Kitami Institute of Technology

*Yunosuke Hase[1], Jumpei Matsuda[1], Yuki Ikeura[1], Akihiro Hachikubo[1], Masaaki Konishi[1], Hirotoshi Sakagami[1], Hirotsugu Minami[1], Satoshi Yamashita[1] (1.Kitami Institute of Technology)

[MIS21-P09] Geochemistry of pore water and gas in shallow sediments from offshore Primorsky Krai, Russia

*Musashi Yokoyama[1], Hitoshi Tomaru[1], Ryo Matsumoto[2], Glen Snyder[2], A.V. Yatsuk[3], D.A Shvalov[3] (1.Department Earth Sciences, Chiba University, 2.Gas Hydrate Research Laboratory, Meiji University, 3.Gas Geochemistry Laboratory, V.I.Ilichev Pacific Oceanological Institute)

[U-03] Future of Scientific Publishing in Geosciences

convener:Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Hirokuni Oda(Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Chairperson:Hirokuni Oda, Hodaka Kawahata

JpGU has launched a new open journal "Progress in Earth and Planetary Science" (PEPS) in 2014 and Impact Factor has been given in 2018. Support from JSPS and MEXT for the promotion of open access journals are fundamental for the development of PEPS. In addition to PEPS, academic societies supporting JPGU also promote academic publishing. This session will discuss future of scientific publishing in Geosciences, specially focused on open access e-journal, data publishing and relationships with author ID etc. Keynote speakers will be invited.

★Invited Papers

*Michio Oishi[1] (1.Kazusa DNA Research Institute)

Game-change of scholarly communication based on papers and the role of learned society and peer-review

*Kazuhiro Hayashi[1]

1. National Institute of Science and Technology Policy

Author reviews current topics of game-changing in scholarly communication base on papers and discuss the significance of learned society and peer review. Both couldn't stay as they are, but still have potential to keep scholarly communication healthier, resulting in transformation of scholarly society to the new research paradigm.

The future of the journal metrics and new trend of the scholarly publishing

*Yoshiko Tanahashi[1]

1. Clarivate Analytics

The future of the journal metrics and new trend of the scholarly publishing will be discussed.Clarivate Analytics has consistent selection criteria from the 1970s to the present as carefully selecting journals to be included in Web of Science. By looking at the selection criteria, I would like to consider a viewpoint for becoming a globally distinctive journal, managing journals from a global perspective, and seeing the journals originating from Japan to face the global research community with strategy. Furthermore, we summarize statistical data of Web of Science into journals related to JpGU, and present the benchmark which is the basis of grasping the current situation of the journal. I summarize the current status of OA journals, Japan's journal, China's journals on Web of Science as statistics and look at recent trends in the field related to JpGU, and a useful point for strategy formulation to raise the presence of the journal.

Underlying Issues and Problems in Publishing International Scientific Journals in Japan. “DNA Research” As A Case Study.

*Michio Oishi[1]

1. Kazusa DNA Research Institute

In this presentation, I would like to discuss certain issues and problems in regards to publishing scientific journals in Japan. My talk is a reflection of my experience as the Editor-in-Chief of the journal “DNA Research” which was launched at the inauguration of the Kazusa DNA Research Institute in 1994.

Firstly, I would like to introduce the current status of DNA Research, an open access journal, regarding the editorial policy and processes, the scope, the publisher, the geographical distribution of the submitted and published papers, the acceptance rate, the impact factor (IF) and some other aspects.

Secondly, I would like to discuss some of the issues and problems in publishing scientific journals in Japan. One important issue is how to ensure objectivity in reviewing manuscripts; a problem often stemming from the unique cultural, social and academic environment of Japan. Another important issue is how to maintain a consistent editorial policy over the long term, ideally by the same Editor-in-Chief, Executive Editor and majority of associated editors. This may be difficult for some journals of academic societies in which editors selected from their members undergo turnover of their duties every few years. Furthermore, since any of these editorial jobs is quite demanding, few scientists active in research are willing to accept or assume these positions. Regarding the financing of scientific journals, we, DNA Research, decided not to seek financial support from outside; the reason will be presented.

Thirdly, I would like to list our efforts to improve the IF of our journal which now stands at between 5 and 6. Most researchers agree that it may not be correct to evaluate scientific journals by IF alone, but it is also true that there is no other reliable way to evaluate scientific journals objectively and quantitatively. In fact, the IF is now also being utilized for the evaluation of researchers themselves for the purposes of their promotion, job accession and others by taking into consideration the IF of the journals where their papers have appeared. These developments have prompted us to take steps to strive for a higher IF for our journal.

Fourthly, I would like to mention the challenge of dealing with online-publication (e-publication) and open access of scientific journals. Online-publication has virtually eliminated costs for the printing and delivery of journals, thus paving a way to publishing papers at lower cost which benefits scientific journals like ours without outside financial support. The open access movement, which was originally conceived as the result of the demand from the general public and research funders in US and EU countries, has become a mainstream trend in the publication of scientific journals. In an open access world, revenues come from the article processing charge (APC) rather than subscription charges, providing a new incentive for higher IF journals, since the level of APC often reflects the IF of the journal. Because of these trends, the number of journals which employ online only publication and/or open access is rapidly increasing, thus creating more competitions among scientific journals which are vying for higher-grade (IF) rankings.
Finally, I would like to discuss the need and possibility of creating a journal such as Nature or Science in Japan which focuses specifically on emerging research in the natural sciences in Asia.

[U-03] Future of Scientific Publishing in Geosciences

convener:Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo), Hirokuni Oda(Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Chairperson:Hirokuni Oda, Hodaka Kawahata

JpGU has launched a new open journal "Progress in Earth and Planetary Science" (PEPS) in 2014 and Impact Factor has been given in 2018. Support from JSPS and MEXT for the promotion of open access journals are fundamental for the development of PEPS. In addition to PEPS, academic societies supporting JPGU also promote academic publishing. This session will discuss future of scientific publishing in Geosciences, specially focused on open access e-journal, data publishing and relationships with author ID etc. Keynote speakers will be invited.

Review of editorial work for PEPS in 2018-2019 and new strategy for 2019–2020

*Yasufumi Iryu[1]

1. Institute of Geology and Paleontology Graduate School of Science Tohoku University

Progress in Earth and Planetary Science (PEPS) is a peer-reviewed, open-access electric journal published by the Japan Geoscience Union in partnership with Springer. PEPS received its first manuscript at the end of 2013 and we published our first papers in April 2014. By the end of the year 2018 we had published 244 scientific articles. In the first half of the year 2018 PEPS received good news. PEPS received its first Impact Factor of 2.481, which was announced in the June 2018 edition of Clarivate Analytics Journal Citation Reports. PEPS currently ranks 66/189 in the category ‘Geosciences, Multidisciplinary’. Whilst this does not yet make us a Q1 journal we are close.

In addition to being funded by the JpGU, PEPS received a grant-in-aid for scientific research from the Japan Society for the Promotion of Science. As the period covered by this five year grant-in-aid drew to an end we applied for funds for the next five fiscal years (2018-2012). Unfortunately our application has been rejected. Due to this, we were forced to raise article processing charges (APC). Since its inception we have always planned for PEPS to become entirely supported by APCs and therefore completely self financing and we have done some analysis and planning towards this goal. Our analysis shows that the most important thing is that we all focus on maintaining and increasing PEPS’ status as one of the leading journals in our field because this is the surest way of increasing our APC income.

New strategy for 2019-2020 is in preparation and will be introduced in the JpGU meeting 2019.

"Earth, Planets and Space" An Open Access Journal: Past, Present and and Future

*Yasuo Ogawa[1], Kiyoshi Baba[2]

1. Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology, 2. Earthquake Research Institute, University of Tokyo

EPS (Earth, Planets and Space) is a peer-reviewed open access journal published on behalf of the following five societies; The Society of Geomagnetism and Earth, Planetary and Space Sciences, The Seismological Society of Japan, The Volcanological Society of Japan, The Geodetic Society of Japan, The Japanese Society for Planetary Sciences. These five societies are all society members of the Japan Geoscience Union.

EPS was established in 1998 as a continuation of the two journals, the Journal of Geomagnetism and Geoelectricity (1949 to 1997) and the Journal of Physics of the Earth (1952 to 1997). In 2014 we started open access publication under the SpringerOpen platform. Open Access publication successfully shortened the publication time, increased visibility of the journal and widened its international readership. We publish average of 190 papers per year and half of the authors are from overseas. One of the qualification indices of the journal, impact factor (IF), is continuously increasing from 1.328 (2014) to 2.773 (2017) and it will also go over 2.6 in 2018. The increasing IF is supported both by increase of highly cited papers and by decrease of uncited papers, suggesting the success of quality control by the editorial board and possibly increasing of the visibility via open access.

The scope of EPS covers Earth and Planetary Sciences, particularly geomagnetism, aeronomy, space science, seismology, volcanology, geodesy, and planetary science. The EPS share common scopes as well as a common journal platform with PEPS (Progress in Earth and Planetary Science). In contrast to PEPS, which emphasizes review papers, EPS is characterized by the following article types: (1) “Express Letter” which aims at fast publications, (2) “Technical reports “, which describe technical developments for scientific researches and (3) “Frontier Letters” for leading edge researches only with the invitation from the editor in chief. EPS promotes topical article collections (what we call special issues) on the first results of geoscientific events (earthquakes and volcanic eruptions) and scientific missions (satellite missions). EPS has been recently successful in attractive special issues.

Aiming at fast and qualified review system, we have expanded editorial board members internationally since 2017. Now we have currently 50 regular editors (including 22 oversea editors). The oversea editors are 10 from Europe, 3 from North America, 5 from Asia, and 3 from Oceania.

As part of the promotion of the journal we have four annual awards to recognize authors and reviewers: (1) EPS Excellent paper awards, (2) EPS Young researcher award, (3) Highlighted Paper Awards and (4) Excellent Paper Awards.

From 2018, EPS has strengthened ties with JpGU. EPS has started collaborative advertisement activities at major domestic and international academic meetings, like JpGU, AGU, EGU and AOGS. EPS has updated the APC (Article Processing Charge) in September 2018 for sustainable operations of the journal.

Enhancing dissemination of research activities to international communities by Japanese Geoscience Union

*Hodaka Kawahata[1]

1. Atmosphere Ocean Research Institute, the University of Tokyo

Progress in Earth and Planetary Science (PEPS) is our official scientific journal established in April 2014 with 51 society members by partnership with Springer. 5 years have passed. This is an English-language peer-reviewed open access e-journal under a collaboration with Springer-Nature. The journal is to be devoted to original articles and reviews (>20%) in the research fields of space and planetary sciences; atmospheric and hydrospheric sciences; human geosciences; solid earth sciences; and bio-geosciences.

In June, 2018, PEPS got the first Impact factor of around 2.48. Now we are taking effective steps (measures) and then hope to get higher IF, around 3, in 2019, hopefully.

JpGU will make an effort to promote the journals which have been published by Japanese Geoscience Societies, taking part in JpGU, including EPS.

Discussion

Radiative transfer simulation including a non-LTE model for terahertz observations of Ganymede's atmosphere

1. National Institute of Information and Communications Technology, 2. Max Planck Institute for Solar System Research, 3. Tokyo Institute of Technology

We are developing a teraherz radiative transfer code, named Atmospheric Teraherz Radiation Simulator (ATRASU), for simulations of sub-millimeter observations of planetary atmospheres.
Because of the tenuous Ganymede atmosphere we need to include non-local thermodynamic equilibrium (non-LTE) conditions of H_2O rotational levels to simulate observations by the Submillimeter Wave Instrument (SWI) on the JUpiter ICy moon Explorer (JUICE). The frequency windows of the JUICE/SWI are 530 to 625 GHz and 1080 to 1275 GHz with 100 kHz spectral resolution.
We developed a deterministic non-LTE solution based on the multilevel Gauss–Seidel method. The simulated energy level populations of H_2O for SWI observations start to deviate from LTE at 100 to 200 km altitude around sub-solar latitudes of 10 degrees. At sub-solar latitudes around 60 degrees the populations are in non-LTE over the entire range, starting from the surface. The difference of the simulated spectra between LTE and non-LTE conditions, and their sensitivity to various parameters, such as collisional rates for H_2O, will be presented.

Vertical Mass Flux by the 2010-2011 Great Storm of Saturn

*Kunio M. Sayanagi[1], Jacob L. Gunnarson[1], John J. Blalock[1], Richard K. Achterberg[2], F. Michael Flasar[2], Andrew P. Ingersoll.[3], Shawn P. Ewald[3], Ulyana A. Dyudina[3]

We present a re-analysis of Cassini Composite Infrared Spectrometer (CIRS) data captured during the 2010-2011 Great Storm of Saturn to calculate the vertical mass flux caused by the storm. The intense cumulus outburst started on December 5, 2010 at 33ºN planetocentric latitude, and the clouds that emanated from the storm engulfed the entire latitude band over the subsequent months. The CIRS observation captured the storm's impact on the tropospheric thermal structure (Achterberg et al. 2014). The change in the thermal structure detected by Achterberg et al. (2014) is caused by the vertical uplifting of mass by the cumulus convection in the storm. We re-analyze the CIRS data processed by Achterberg et al. (2014) to determine the vertical mass flux. Images captured by the Imaging Science Subsystem (ISS) camera showed that active convective phase of the storm lasted until August 2011 (Sayanagi et al. 2013). Our preliminary analysis of CIRS data shows that, by August 2011, between 15ºN and 45ºN latitudes, the storm lifted about 1.65×10^{19} kg of mass to levels above the 700-mbar pressure altitude from levels below.

Analyzing images captured by ISS using the CB2 (750 nm) filter and Cassini Visible and Infrared Mapping Spectrometer (VIMS)'s 5-micron channel reveals that, after August 2011, cumulus activities ceased in the storm's latitudes, and a vast cloudless area grew until it encircled the entire band between 30ºN and 40ºN latitude by January 2012. The cloudless region further grew to the south and reached 20ºN by December 2012. Interestingly, analysis of the CIRS data indicates that the vertical mass flux continued as the clouds cleared after the storm. Our preliminary analysis shows that, between August 2011 and August 2012, 1.9×10^{18} kg more mass was lifted to altitudes above the ~700-mbar level. We hypothesize that the vertical mass flux during the cloud clearing was caused when the tropospheric air parcels became buoyant when they were relieved from the mass loading of the storm clouds.

We note that measuring vertical mass flux caused by a cumulus storm is extremely difficult for storms on Earth because the mass uplifted by the storms is rapidly dispersed and diluted by the storm's environment. In comparison, Saturn's Great Storm of 2010-2011 completely filled the latitude zone between 20˚N and 40˚N; thus, the storm was essentially contained in a closed box, and allowed us to measure the storm's vertical mass flux.

Microwave observations of the giant planets - Cassini/Radar and Juno/MWR

*Cheng Li[1], Virgil Adumitroaie[2], John Arballo[2], Sushil K Atreya[3], Scott J Bolton[4], Andrew Ingersoll[1], Michael Janssen[2], Steven Levin[2], Jonathan Lunine[5], Glenn Orton[2], Paul Steffes[6], Hunter Waite[4]

The thermal emission of a giant planet's atmosphere in the microwave region reveals the thermal structure and composition of the atmosphere below the clouds. During the last decade, the Cassini/Radar instrument mapped Saturn's global thermal radiation at 2.2 cm wavelength. Particularly, in the year 2010, the planet-encircling giant storm on Saturn appeared 16 K brighter than average, revealing desiccation of ammonia gas due to convection and atmospheric dynamics. More recently at Jupiter, the Juno spacecraft has completed a dozen orbits around the planet, making detailed observations of Jupiter's troposphere from north to south and down to pressures of about 200 bars. The results are both astonishing and stimulating. Jupiter's equatorial zone appears cold in all six channels of Juno/MWR, which range from 1.2 –50 cm, whereas the other latitudes are significantly warmer than what was predicted by an adiabatic model. The internal structure of the GRS has also been mapped during orbit 7th close approach. Yet, the interpretation is partly confounded by the inhomogeneous distribution of ammonia gas. We will give an overview of the previous findings, current challenges, and future opportunities of microwave sounding of the giant planets.

Tracing Formation and Evolution of Outer Solar System Bodies through Stable Isotopes and Noble Gas Abundances

*Kathleen Mandt[1]

1. Johns Hopkins University Applied Physics Laboratory

Comparative planetology using isotope geochemistry has played a critical role in understanding processes at work in and the history of outer Solar System bodies [see 1, and references therein]. The $^{12}C/^{13}C$ measured in methane on Titan has enabled us to determine the maximum length of time that methane has been present in the atmosphere [2,3], showing that methane has not been present in Titan's atmosphere throughout the history of the solar system and is limited to no more than 1 billion years (Gyr) [3]. We have also determined how much methane has been converted to organics over that were then deposited on the surface [3] and find agreement with estimates of surface inventories [4]. Observations of $^{14}N/^{15}N$ in HCN and N_2 in the atmosphere of Titan provides direct evidence of how photochemistry influences stable isotopes [5,6]. We have used these observations to determine that Titan's nitrogen originated as NH_3 in the protosolar nebula [7]. All of this work relies on spacecraft-based observations made at Titan. Ground-based observations combined with spacecraft observations are also of high value. The lower limit observed for $^{14}N/^{15}N$ in HCN in Pluto's atmosphere by ALMA [8] combined with New Horizons observations of the atmospheric composition [9] provides a valuable tool for determining the origin of nitrogen for Pluto if the influences of condensation and aerosol trapping on isotopes can be constrained [10] for which work is ongoing. All of this work is relevant to a future Ice Giants mission to Neptune, where the same methods could be applied to Triton and combined with ALMA observations. Furthermore, a mission to Io that makes in situ observations of the isotopic composition of the atmosphere could provide important information about volatile loss and interior processes at Io, assuming production and loss processes can be well constrained. Finally, noble gas abundances have been an important tool for understanding the origin and evolution of volatiles in the terrestrial planet atmospheres [see review in 1]. The recent measurement of cometary noble gas abundances [11] provides important information on the composition of the icy bodies that contributed to the formation of the gas giants, providing constraints for future in situ measurements that should be made with an atmospheric probe [12].

Icy Giant Planet Exploration

*Sushil K Atreya[1], Mark D. Hofstadter[2], Amy Simon[3], Kim R. Reh[2], Olivier Mousis[4], Krista Soderlund[5]

1. University of Michigan Ann Arbor, 2. Jet Propulsion Laboratory, 3. Goddard Space Flight Center, 4. Laboratoire d'Astrophysique de Marseille, 5. University of Texas at Austin

Giant planets hold the secrets of solar system formation, and there is much interest in their exploration. They also serve as analogs for the giant planets in extrasolar systems. While Saturn-Jupiter sized exoplanets number about 500, mini-Neptune and Neptune sized objects (2-5 times Earth) comprise nearly half of approximately 4000 confirmed exoplanets to date. Since the early 1970’s, spacecraft have explored the gas giants, Jupiter and Saturn, extensively using flybys, orbiters and an entry probe (at Jupiter). Voyager 2 is the only spacecraft ever to visit the two icy giants, with a flyby of Uranus in 1986 and Neptune in 1989. Though the Voyager instruments were optimized for observations of Jupiter and Saturn, tantalizing data were collected at Uranus and Neptune as well. Those data have raised such fundamental questions as: did Uranus and Neptune form in the same manner as the gas giants, did they form at their present orbital locations or not, what role did migration play in their formation and evolution, why (and how) does Neptune generate internal heat, whereas Uranus does not, what is responsible for their intrinsic magnetic fields in the absence of a metallic hydrogen phase, why are the rings of Uranus different from Neptune’s rings and what’s maintaining them, why does Neptune’s moon Triton possess an atmosphere of nitrogen and methane, etc. To address these questions and others requires a comprehensive exploration of the icy giant planet systems by an orbiter-probe spacecraft at Uranus or Neptune or both [1], like the Galileo orbiter-probe mission at Jupiter. International partnership is most desirable for maximizing the science return of such a mission. [1] M. Hofstadter, A. Simon, K. Reh, J. Elliott, and the NASA Ice Giants Science Definition Team, Ice Giants Pre-Decadal Survey Report (2017) NASA-JPL-ID-100520, https://www.lpi.usra.edu/icegiants/mission_study/Full-Report.pdf

Discussion

Saturn's ring rain and Enceladus' subsurface ocean as seen by the Cassini Cosmic Dust Analyser

*Sean Hsu[1], Sascha Kempf[1], Mihaly Horanyi[1], Ralf Srama[2], James O'Donoghue[3]

1. LASP, University of Colorado, Boulder, CO, USA, 2. IRS, University of Stuttgart, Stuttgart, Germany, 3. NASA Goddard Space Flight Center, Greenbelt, Maryland, USA

Dust particles serve as microscopic messengers carrying information from sources inaccessible by space probes. The compositional and dynamical information of various dust populations provided by the Cosmic Dust Analyser offer a unique perspective to examine the rings, moons, and their interactions in the Saturnian system. In this talk I will focus on the latest results from the Cassini Grand Finale mission about Saturn's ring rain, i.e., the ring-planet interactions driven by the infall of ring material to Saturn's atmosphere, and its implications about Saturn and its magnificent ring system. I will also provide a brief summary of other major findings by the Cassini Cosmic Dust Analyser, including the discovery of the subsurface ocean and hydrothermal activities within the geologically active moon Enceladus, the composition of interstellar grains, Saturn's diffuse rings, and the electromagnetic interactions of charged nanodust particles with the magnetosphere and the solar wind.

Titan Trek: A New Online NASA Visualization and Analysis Portal for Saturn's Largest Moon

*Emily Law[1], Brian Hamilton Day[2]

1. NASA Jet Propulsion Laboratory, 2. NASA Ames Research Center

In its investigations of Saturn's moons, NASA's Cassini mission and ESA's Huygens lander have returned an immense amount of data detailing the dynamic surface of Saturn's largest moon, Titan. In order to greatly facilitate dissemination, visualization, and analysis of this data, the Cassini mission has partnered with NASA's Solar System Treks Project (SSTP). SSTP has recently released a new online portal (https://trek.nasa.gov/titan/), Titan Trek, that enables mission planners, planetary scientists, engineers, students, and the general public to interactively access, visualize, and analyze Cassini's mapped data products of Saturn's largest moon.

The initial release of Titan Trek provides a suite of interactive tools and incorporates over 130,000 data products from the range of Cassini encounters with Titan, creating a comprehensive Titan research and educational web portal. Titan Trek data products include: Global Radar mosaic, Radar SAR BIDR BIFQI swaths, Global VIMS mosaics, Global ISS mosaic, Vector data (geological units of Afekan region, material flux based on dune orientation, fluvial networks), Nomenclature, ISS footprints, VIMS footprints, and Global radar topography.

We intend to continue to enhance the new Titan Trek portal with new data products as they are released by the Cassini mission including Huygens DISR, Global radiometry, scatterometry, VIMS, ISS, UVIS, CIRS, and other topography products.

Titan Trek is the latest addition to the NASA Solar System Treks Project (SSTP), available at https://trek.nasa.gov. NASA's Solar System Trek online portals provide web-based suites of interactive data visualization and analysis tools providing access to mapped data products from past and current missions for the Moon, Mars, Vesta, etc. As web-based toolsets, the portals do not require users to purchase or install any software beyond current web browsers. These portals are being used for site selection and analysis by NASA and a number of its international partners, supporting upcoming missions.

Internal structure of icy moons: ice-ocean systems as commonly seen in the outer solar system

*Hauke Hussmann[1]

1. DLR Institute of Planetary Research

Among the icy satellites in the outer solar system, several objects have been identified that may contain substantial amounts of liquid water in their interiors. In particular the large satellites, e.g., Europa, Ganymede, Callisto, and Titan may contain subsurface oceans until the present day. However, the example of Enceladus shows that also smaller satellites can have sufficient internal heat sources to maintain liquid water layers. Also Pluto and Triton are potential ocean candidates. The available heat sources differ considerably among the icy moons depending on their initial composition, and thus the amount of radiogenic heating, the tidal interaction with the primary planet, their rheological states and -in some cases- their interaction with other satellites due to orbital resonances. In this talk the current knowledge on the ice-ocean systems in the outer solar system will be summarized. Prospects for their investigation with future planetary missions will be discussed.

Callisto as a keystone to reproduce the formation process of the Jovian system

*Yasuhito Sekine[1], Shunichi Kamata[2], Yuhiko Aoyama[3], Masahiro Ikoma[3], Takayuki Tanigawa[4]

1. Earth-Life Science Insitute, Tokyo Institute of Technology, 2. Creative Res. Institution, Hokkaido Univerisity, 3. Dept of Earth and Planetary Sci., University of Tokyo, 4. Nat'l Inst. Tech., Ichinoseki Col.

Callisto is the outermost Galilean satellite, with 2410 km of radius and 1.83 g/cc of density. The size and mass are comparable to those of another Jovian moon, Ganymede and the largest moon of Saturn, Titan. Unlike Ganymede and Titan, however, heavily-cratered Callisto may have experienced only limited geological activities since its formation. Owing to the low geological activities, Callisto may serve as a “fossil” of the Jovian system formation in the early Solar System. Volatile and isotope compositions of ice materials on Callisto would reflect ice compositions of the building materials of the Jovian satellites, which is critical to constrain the disk temperature of the formation region of proto-Jupiter as well as both shock heating and size of infalling materials onto proto-Jupiter. The interior structure, namely degree of differentiation, of Callisto is essential to constrain the inflow rate of the building materials from the protoplanetary disk. In this talk, we discuss the key observations, e.g., surface materials and interior structure of Callisto, in future missions to constrain the formation process of the Jovian system.

Origin of Jupiter Trojan asteroids: To be explored by OKEANOS

*Yoko Kebukawa[1], Tatsuaki Okada[2], Motoo Ito[3], Jun Aoki[4], Yosuke Kawai[4], Jun Matsumoto[2], Noel Grand[5], Arnaud Buch[6], Michisato Toyoda[4], Hervé Cottin[5], Hisayoshi Yurimoto[7,2], Hajime Yano[2], Takahiro Iwata[2], Osamu Mori[2]

1. Yokohama National University, 2. Japan Aerospace Exploration Agency, 3. Kochi Institute for Core Sample Research JAMSTEC, 4. Osaka University, 5. LISA, Université Paris-Est Créteil, 6. Ecole Centrale Paris, 7. Hokkaido University

The Jupiter Trojan asteroids are expected to be a key to understand planet formation and solar system evolution. The Jupiter Trojan asteroids are an asteroid group at the Lagrangian point (L4 and L5) on the Jupiter's orbit, and their spectral types are mainly D and P type, also called "Red" and "Less red", respectively [1,2]. The origin of these asteroids was considered to be trapped by Jupiter according to the classical planet formation theory [3,4]. On the other hand, according to a relatively new theoretical study such as Nice model, the small bodies formed at the Kuiper belt region are disturbed by giant planet migrations, and some of them trapped at the current Jupiter orbit [5]. Thus, constraining planetary formation theories can be possible by investigating whether the Jupiter Trojan asteroids originated from the outer region of the solar system such as the Kuiper belt area or originated from the current Jupiter orbit region (the extension of the main belt asteroids). The stable isotopic ratios of light elements are expected to be an indicator of the origin of the Jupiter Trojan asteroids. Because heavy isotopes such as ^{2}H (D) and ^{15}N tend to incorporate into water and organic matter in low temperatures (<10-100 K) such as in the outer region of the solar system [6,7]. In fact, heavy isotopes are concentrated in materials from the outer region of the solar system such as comets, and materials from main belt asteroids such as chondrites often show relatively light isotopic ratios [8].

The OKEANOS (Outsized Kite-craft for Exploration and AstroNautics in the Outer Solar system) is a candidate for the upcoming strategic middle-class space exploration to rendezvous with and land on a Jupiter Trojan asteroid using a Solar Power Sail (SPS). The mission concept includes sampling and in-situ analysis of the materials of a Jupiter Trojan asteroid [9]. We plan to analyze isotopic and molecular compositions of volatile materials from organic matter, hydrated minerals, and ice, in order to understand origin and evolution of the Jupiter Trojan asteroids, using a multi-turn time-of-flight type high-resolution mass spectrometry (HRMS) system. Our goal is to improve our understanding of (1) planet formation/migration theories, (2) distribution and evolution of volatile substances in protoplanetary disks, (3) origins and evolution of organic matter, and (4) origin and evolution of the Solar System small bodies beyond the snow line.

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University)

The giant planets provide many keys to understanding planetary processes. They play an important role in shaping our solar system, and the physical and chemical processes they harbor also provide a unique opportunity to study the phenomena relevant for studying Earth and other planets, including exoplanetary systems. In this session, we discuss a wide range of topics encompassing the giant planets and their moons, including their origins, interiors, atmospheres, compositions, surface features, and electromagnetic fields. To advocate for current and future outer planets exploration (Cassini, Juno, New Horizons, JUICE, and beyond), we also call for discussions on future missions to explore giant planet systems, including how to develop better international cooperation. Discussion in this latter category will include progress in developing a solar sail mission concept for observing the Jupiter system and its trojan asteroids.

Critical Role of Entry Probes in Giant Planet Exploration

*Sushil K Atreya[1], Olivier Mousis[2]

1. University of Michigan Ann Arbor, 2. Laboratoire d'Astrophysique de Marseille

Flyby and orbiting spacecraft have explored the giant planets since the early 1970’s. In situ measurements in the troposphere are essential, however, for constraining the models of formation, evolution and interior processes of the giant planets. The models employ abundances and isotopic ratios of key elements, in particular C,N, S, O, He, Ne, Ar, Kr, Xe and D/H, derived from the measurement of their (bulk) reservoir species. That was the scientific rationale for the 1995 Galileo Probe at Jupiter and a Saturn Probe in NASA’s New Frontiers list of candidate missions. Considering that the icy giant planets are distinct from the gas giants, they represent the missing pieces of the puzzle of the formation of the outer solar system, besides being the closest analog for nearly half of the confirmed exoplanets. Thus, their comprehensive exploration with an orbiter-probe spacecraft is essential. The principal focus of this talk is the science, feasibility and implementation strategy of in situ measurements with entry probes at the icy giant planets, Uranus and Neptune, guided by thermochemical models and lessons learned from the Galileo Probe and the ongoing Juno Orbiter. The OKEANOS (Oversize Kite-craft for Exploration and AstroNautics in the Outer Solar system) is a mission under study to rendezvous with and land on a Jupiter Trojan asteroid [1]. The target is a Jupiter Trojan but will be the Saturnian system in the future. It is an engineering mission to demonstrate advanced technologies such as the hybrid thrusting with the enhanced ion engine powered by a 40 x 40 m class large area solar cells to explore the outer solar system cost-effectively. With the new technology, the mission will conduct in-depth scientific measurements for understanding the origin and evolution of the solar system and life. The concept is complementary to NASA Lucy mission [2], multi-flybys to six Jupiter Trojans for understanding the variation of Jupiter Trojans.

Jupiter Trojans are D/P-types enriched in volatiles. They might have experienced almost no or only a low degree of alteration. Their origin and evolution, as well as chemical and physical state still remain unknown. Jupiter Trojans should be a missing link of materials that originate from the inner or the outer solar system by gravity scattering due to migration of giant planets [3]. They are key targets to understand the evolution of astromaterials and the radial distribution of elements and isotopes in the early solar system.

The OKEANOS has been downscaled from the previous proposal [4] due to the severe cost cap. The spacecraft of 1400 kg including a 40 kg lander will be launched in 2027 or later, assisted by gravity of Earth and Jupiter. It will arrive at the target asteroid after a 13-year cruise. 30 kg is allocated for science, 12 kg of which is reserved for international collaboration. Bus instruments such as the optical navigation cameras (ONC-T and -W), LIDAR, and radio science are used for scientific purposes. The lander is like Mascot with uprighting capability on the asteroid surface and 12 kg is allocated for science mission.

During the cruise, science experiments will be carried out from the “deep-space platform”. Measurements of IDPs and magnetic fields will continuously monitor their radial distribution in the solar system and sudden events. The gamma-ray polarimeter will be used for precise positioning of gamma-ray bursts using a very long baseline. Visible to near-infrared telescope will map the zodiacal lights and observe the deep sky under a dust-free condition from outside of the asteroid main belt.

©2019. Japan Geoscience Union. All Right Reserved.

After arrival, global mapping is carried out to characterize the asteroid and select the landing site. The asteroid shape, size, rotation state, and geologic features are imaged by ONC. Gravity is measured by radio tracking and LIDAR. Near-infrared spectroscopy characterizes red or less red patterns, the degree of hydration, mineralogy, and abundance of ices, organics, and brines. Thermal infrared multi-bands inform on thermophysical properties, mineralogy and amorphous phases. A radar probes the surface physical state and also contributes to altimetry. *In situ* experiments with the lander will characterize the footprint and surrounding area by imaging and spectroscopy, followed by measurements of mineralogical, elemental, and organic composition as well as physical, thermal, and magnetic properties at the site. The asteroid surface sample is collected to conduct high-resolution mass spectroscopy (HRMS) based on MULTUM system (infi-TOF type mass spectrometer [5]), especially to determine the isotopic ratios of δD and δ^{15}N and the volatile species contained in the sample. Details will be decided during the critical joint study in 2019. Those experiences will be inherited to future missions.

Magnetic field model of Jovian magnetosphere

*Naoya Momoki[1], Hiroaki TOH[1]

1. Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University

Europa, Ganymede, Callisto are the Jovian icy satellites called Galilean moons, and are possibly with internal oceans each. While ice is almost an insulator electrically, water including ions has high electrical conductivity, and existence of internal oceans can be verified using electromagnetic (EM) induction methods. In this study, we updated the necessary model of the external magnetic field to the icy satellites for the EM induction studies. Namely, parameters of the Euler potential model of the Jovian magnetosphere (Khurana, 1997) were renewed by adding magnetic data from both Galileo and JUNO spacecrafts.

The configuration of the Jovian current sheet was modeled by Khurana [1992] using three parameters, while the Jovian magnetospheric magnetic field modeled by Khurana [1997] was characterized by 14 parameters. We applied a non-linear optimization technique, i.e., the steepest descent method, to the parameters by newly adding magnetic data from Galileo and Juno spacecrafts. We minimized the root mean squared between the model and the data by exploring the parameter space around several initial sets of the parameters.

As a result, time-varying model parameters for each spacecraft orbit were obtained. Their temporal variation may reflect that of both magnetic field and electric current system in the Jovian magnetosphere.The changes of the parameters can be attributed to the interaction between the Jovian magnetosphere and the solar wind. It, therefore, preferable that the temporal variation of the model parameters is incorporated when the updated magnetic field model of the Jovian magnetosphere is applied to the EM induction studies in search for the internal oceans of the icy satellites.

Enhancement of the Jovian thermospheric temperature above the Great Red Spot based on the infrared spectroscopic data obtained with IRTF/iSHELL

*Ayumu Kambara[1], Hajime Kita[2], Takeshi Sakanoi[1], Yasumasa Kasaba[1], Masato Kagitani[1], Haruna Watanabe[1]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

It is known that the thermospheric temperature of all giant planets including Jupiter is several hundred kelvins higher than that expected from solar heating. At mid- to low-latitudes, although the direct atmospheric heating caused by precipitating particles and the energy transportation from high-latitude auroral region have been considered, it is not enough to explain. Another candidate for the heating is energy transportation by atmospheric waves from the lower atmosphere. Recently, O'Donoghue *et al.* [2016] revealed the heating in the thermosphere above the Great red spot from the intensity ratio of two emission lines (3.383um/3.454um) of the vibrational-rotational spectrum of thermospheic H_3^+ taken by IRTF /SpeX (R~2500) in December 2012. They estimated that the temperature above the Great red spot is 1644±161K, and that on surrounding mid- to low-latitude region is 900±42K. They considered that the reason was the energy transport from the lower atmosphere in the Great red spot region, that is, the propagation of atmospheric gravity waves and acousitic waves generated in the Great red spot, the tropospheric anticyclonic storm, to the thermosphere. However, the infrared spectrum observed SpeX might be contaminated by CH_4 line due to its low-resolution capability.
In this study, we carried out the thermosphere temperature observation in the Jovian mid-latitude region near the Great red spot by IRTF/iSHELL on January 11, 2017. This observation was performed with the iSHELL's Lp1-mode (3.265-3.657um), and the data reduction was performed with NASA's data reduction tool Spextool ver. 5.0.1. Similar to the past study by O'Donoghue *et al.* [2016], we adopted the intensity ratio of two emission lines of H_3^+ (3.3839um/3.4548um), and estimated the temperature precisely distinguished from CH_4 line by iSHELL’s higher wavelength resolution (R~75000). As a result, we estimated the thermospheric temperature above the Great red spot to be 910±132K, and that in the surrounding region to be 583±30K, showing about 300K increase on Great red spot. The estimated temperature was lower than that in O’Donoghue *et al.* [2016], there is possibility that the thermosphere temperature varies in time. However, we confirmed the temperature above Great red spot is higher than that in the surrounding region. This suggests the existence of energy transport from the lower to the upper atmosphere in the Great red spot. In the presentation, we report the result of carefully reduction.

Pulsation-like variation of Jovian infrared polar emission observed by Subaru 8-m: H3+ and methane emissions

*Yasumasa Kasaba[1], Haruna Watanabe[1], Hajime Kita[2], Chihiro Tao[3], Takeshi Sakanoi[1], Masato Kagitani[1], Orton Glenn[1,4], James Sinclair[4]

1. Planetary Plasma and Atmospheric Research Center, 2. ISAS/JAXA, 3. NICT, 4. NASA/JPL

In the Jovian high-latitude region, there are emissions with various wavelengths ranges, morphologies, and time variations. They are important tracers of energy injection carried by auroral particles that precipitate from the magnetosphere. The polar IR emissions excited in the Jovian upper atmosphere, which include the H_3^+ aurora and thermal emissions of hydrocarbons, reflect not only the abundance of emission sources but also the thermal structures. Both are affected by auroral precipitation into the source region. It is known that, in the polar region inner than the auroral oval, the flux of auroral precipitation can have time variations over various scales from years to seconds.

The H_3^+ aurora observed in near infrared is emitted in thermosphere / ionosphere from thermally excited H_3^+ ions above the CH_4 homopause. Auroral precipitation ionized H_2 and produce H_3^+ ions through ion chemistries. In previous observational studies, the shortest timescale of H_3^+ auroral intensity change was ~30 min, but detected by ~16-min step imaging. We performed the temporal imaging observation of the Jovian H_3^+ IR aurora with Subaru/IRCS and the H_3^+ narrow-band filter on 31 January 2015 and 25 May 2016. The adaptive optics enabled us to see the target with high spatial resolution (~0.2 arcsec). From the images obtained with time resolution of ~150 s on 25 May 2016, we detected a patch-like auroral feature pulsating with a period of ~10 min in noon sector of northern polar region. On the other hand, we could not find any periodic variations from the data obtained on 31 January 2015, which was obtained as slit-viewer image for the other study, and whose time intervals of ~10–30 min every several images was not optimized to this research. In addition, the location where the patch-like emissions observed with high intensities on 25 May 2016 were not so bright on 31 January 2015. The patch-like auroral feature that was pulsating during our observation period on 25 May 2016 have been sometimes observed in UV, but not always. Previous UV observations reported some pulsating auroral features with the periods of ~2–11 min in the northern polar region. However, the locations of them are not consistent with the patch-like feature in this study. The pulsation period of the X-ray aurora, which has a hot spot coinciding with our patch-like IR aurora, is 40–50 min. This region is estimated to connect magnetically to out of the magnetopause, and auroral precipitation there can be caused by dayside reconnection between the Jovian magnetospheric field and interplanetary field.

On the other hand, the hydrocarbon polar emission observed in mid-infrared is emitted from the whole stratosphere. From their locations and morphologies, it is estimated to be related with auroral particles penetrating under the homopause. However, the mechanisms of this link (composition change and/or heating by particle precipitations) are not well understood. Previous studies found the intensity time variation of polar CH_4 emission over days and months. We tried to detect the time variation of CH_4 emission intensity by continuous imaging observations of the northern polar region over several tens of minutes on 31 March, 24 and 25 May 2018 with Subaru/COMICS. We obtained the images using the 7.8 μm filter, which is sensitive to the CH_4 thermal emissions occurring in the pressure range of 20–0.5 mbar and 1 μbar in the Jovian upper stratosphere, with time resolution of ~1 min. On all observation days, the polar region was not bright in 7.8 μm. In addition, we could not find clear time variations of polar CH_4 emission intensity during our observation periods, 25, 50 and 60 min on 31 March, 24 and 25 May 2018.

This observation result is consistent to the model estimation by *Kuroda et al.* [2014], which suggested the relaxation time of hydrocarbon thermal emissions in the Jovian upper stratosphere, where is a possible source region of polar CH_4 emission, is at least ~10^5 s (~28 h).

Structure of Io plasma torus observed with the Tohoku 60-cm telescope

*Masato Kagitani[1], Fuminori Tsuchiya[1], Kazuo Yoshioka[2], Go Murakami[3], Tomoki Kimura[1], Ryoichi Koga[1], Reina Hikida[4], Takeshi Sakanoi[1]

1. Graduate School of Science, Tohoku University, 2. Graduate School of frontier Science, The University of Tokyo, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Department of Earth and Planetary Science, Graduate School of Science, Tokyo University

Volcanic gases (mainly composed of SO_2, SO and S) originated from jovian satellite Io are ionized by interaction with magnetospheric plasma and then form a donut-shaped region called Io plasma torus. Ion pickup is the most significant energy source on the plasma torus though, distribution of pick-up region and its variability is still unclear. Density profiles of ions along the magnetic field line are determined under condition of diffusive equilibrium. Based on the equilibrium, plasma equator is close to the centrifugal equator though, higher ion anisotropy moves the plasma equator toward the magnetic equator. Measuring ion distribution with enough spatial resolution enables us to derive ion anisotropy which is tightly related to the amount of fresh pickup ion. On this study, we focus on variability of latitudinal structure of Io plasma torus as well as its radial structure using ground-based observation over six month period in 2018. The ground-based observation of sulfur ion emission, [SII] 671.6nm and 673.1nm was made at Haleakala observatory in Hawaii during March through August 2018 using the Tohoku 60-cm telescope (T60). A monochromatic imager with coronagraph attached onto the Cassegrain focus of T60 enables to measure distribution of S^+ with spatial resolution of 0.03 jovian radii (R_J). A digital micro-mirror device DMD was employed to block light from Jupiter disk and Galilean moons. Typical integration time of each frame was 20 minutes and total number of reduced image is 480. We also made observation of neutral sodium cloud extending up to several hundred of R_J as a proxy of supply of neutral particles from Io (Yoneda et al., 2015). Based on observation over the six month, [SII] brightness increases from DOY 80 through 140, then gradually decreases though DOY 230 in 2018. The data reduction of iogenic neutral sodium cloud is still undergoing though, neutral sodium cloud seems to increase from DOY 50 through 135, as [SII] brightness increases. The result suggests that increased volcanic activity from DOY 50-135 caused increase of S+ and brightening of [SII] emission. As for variability of shorter duration, we find [SII] brightening event within a short period (< 2 days) at around 28 through 30 July over a small region (< 30 degrees in longitude). [SII] 671.6 and 673.1 nm emissions are sensitive to cold electron (1-10eV) rather than hot electron (>100eV). Thus, increase of cold electron temperature explains the observed [SII] brightening well as the EUV space telescope Hisaki observed brightening of Io plasma torus associated with injection of hot electron. We also find variation of latitudinal structure of Io plasma torus. Longitudinal peak of S^+ emission at the same system III longitude 279 degree are -0.73, -0.80 and -0.79 R_J on 26, 29 July 7 and August, respectively. The shift of S^+ density peak toward magnetic equator implies higher anisotropy 29 on July and 7 August compared with 26 July. One of the possible explanation of the latitudinal shift of S^+ plasma is an increase of flesh pickup ion which makes higher anisotropy. Further study using Colorado Io Plasma Torus Emission Package (CITEP) will be presented on the presentation to take into account for line-of-sight integration effect of the ground-based observation.

Ion Scale Height Variability in Hisaki Io Torus Observations

*Nicholas McCord Schneider[1], Carl Schmidt[2], Masato Kagitani[3], Yasumasa Kasaba[3], Tomoki Kimura[3], Go Murakami[4], Fuminori Tsuchiya[3], Hajime Kita[3], Reina Hikida[5], Ichiro Yoshikawa[5], Kazuo Yoshioka[5]

1. LASP, University of Colorado Boulder, 2. Boston University, 3. Tohoku University, 4. ISAS/JAXA, 5. University of Tokyo

Ion temperature is a critical variable in Io plasma torus energetics, but is difficult to derive from remote sensing measurements. The relative importance of hot ions vs. hot electrons in powering the torus emissions remains an open question. Torus brightenings, whether caused by episodic changes in the volcanic supply to the torus or periodic System III/IV enhancements, offer the best chance to search for driving variations in hot electrons or ions. Much attention has been paid to hot electron populations, derivable from detailed spectral modeling, but less work has been done on ion temperature. Ground-based studies have successfully derived $T_{\perp}$ from very high resolution spectra, and $T_{||}$ from scale height measurements in images, both over limited datasets. Schneider et al. 1997 found strong longitudinal variations in $T_{||}$ during a week-long dataset, and anti-correlated System III brightness, but more extended followup datasets have not previously been available.

The Hisaki dataset presents the possibility of an unparalleled opportunity to study long-term and short-term variations in ion temperatures. The instrument is not designed to take images of specific emissions, but its large entrance slit accepts the full height and width of the torus. In the ideal case, each spectral emission feature would appear as an image of the torus at its appropriate position in the spectrum, creating an “overlapogram” (as did the Cassini UVIS instrument). In reality, the emissions are blurred due to instrumental resolution and aberrations, and multiple spectral feature overlap. Furthermore, the changing opening angle of the rotating torus adds a spurious apparent scale height variation which must be removed, with special attention to asymmetries introduced by Jupiter's changing tilt. With allowances for all these effects, we will report on our search for ion temperature variations during the first two years of Hisaki observations, and compare our results to a previous independent study by M. Shishido (M.S. thesis, U. Tohoku).

Size of the Smallest Particles in Saturn's Rings

*Keiji Ohtsuki[1], Hiroshi Kawamura[1], Naoyuki Hirata[1], Hiroshi Daisaka[2], Hiroshi Kimura[3]

1. Graduate School of Science, Kobe University, 2. Graduate School of Commerce and Management, Hitotsubashi University, 3. Planetary Exploration Research Center, Chiba Institute of Technology

Spacecraft and ground-based observations have shown that particles in Saturn's main rings have a power-law distribution roughly between centimeter and ten meters, but sub-centimeter particles appear to be lacking. Recent studies based on Cassini observations suggest that the size of the smallest particles is on the order of millimeters. Cohesive force between particles has been proposed to explain the paucity of sub-centimeter particles, but its strength depends on impact velocity. In order to better understand recent Cassini observations about small ring particles, we examine impact velocity between ring particles using N-body simulation including size distribution. We find that most collisions take place at velocities lower than 0.1 cm per second; even in dense rings where particles' velocity dispersion is enhanced by gravitational wakes, they collide at such low velocities because particles tend to move coherently in the wakes. This velocity is too low to detach sub-centimeter particles that are attached to the surface of large ones due to the cohesive force, explaining their paucity in the main rings. On the other hand, more infrequent high-velocity impacts can release millimeter-sized particles strongly attached to the surface of large ones, explaining the observed free millimeter-sized particles with relatively low abundance. We will discuss implications of our results for the observed size of the smallest particles in Saturn's main rings.

The Radio & Plasma Wave Investigation (RPWI) for JUICE for the investigation of Jupiter and Icy Moons System: Contributions from Japan

*Yasumasa Kasaba[1], Hiroaki Misawa[1], Fuminori Tsuchiya[1], Atsushi Kumamoto[2], Yuto Katoh[2], Tomoki Kimura[2], Hajime Kita[3], J.-E. Wahlund[4]

1. Planetary Plasma and Atmospheric Research Center, Tohoku University, 2. Department of Geophysics, Tohoku University, 3. ISAS/JAXA, 4. IRF Uppsala, Sweden

The Radio & Plasma Wave Investigation (RPWI) for the ESA JUICE mission (launch: 2022, Observations: 2030s) provides an elaborate suite of electromagnetic fields and plasma instruments. RPWI focuses on cold plasma studies and will investigate how the transfer of momentum and energy in the Jovian huge magnetosphere and the electrodynamic coupling with the icy Galilean moons. Remote sensing and direction finding of the Jovian radio emissions will be carried out. This capability is also devoted to the ices and the deep interiors of the icy moons. Investigations of the ice shells will be performed by means of a novel passive ground penetrating radar technique, which utilizes Jovian strong radio emissions as the transmitted signal. On the Ganymede orbit, continuous measurements of the electric field with the JUICE Magnetometer (JMAG) measurements will determine the electric coupling between any ocean, the ionosphere, and the magnetosphere, and provide the constraints on the physical characteristics of the subsurface ocean of Ganymede.
For those objectives, RPWI sensors consist of 4 Langmuir probes (LP-PWI) for determination of the vector electric field up to 1.6 MHz and cold plasma properties (including active measurements by LP sweeps and mutual impedance sounding) up to 1.6 MHz, a tri-axial search coil magnetometer (SCM) for determination of the vector magnetic field up to 20 kHz, and a tri-dipole antenna system (RWI) for monitoring of radio emissions (80 kHz - 45 MHz). From Japan, the RWI preamp and its High Frequency receiver with the onboard software will be provided, based on the modifications from the BepiColombo PWI and Arase PWE developments. Since Arase already shows the good performance in the radiation hard environment around Earth, we have enough confidence for the possible functions and performance on the Jovian hard environment. We will also provide Software Wave-Particle Interaction Analyzer (SWPIA) function to RPWI DPU, for the onboard quantitative detection of electromagnetic field - ion interactions, modifying from the Arase SWPIA which is also activating on the space now.
HF reciever will provide the first highly-resolved information of Jovian radio emissions emitted from Jovian multiple regions including lightning activity and icy moons, by the 3-ch receiver system manufactured by Japan and Sweden connected to the 3-elements 1.25-m E-filed dipole antenna system manufactured by Poland and Japan. Highly matured onboard and ground data processing will also be provided by France and Japan. As a byproduct, reflected Jovian emission can also be expected from the boundary of icy crust and conductive liquid subsurface ocean. Such reflection components could be observed as the Lunar surface reflection of terrestrial auroral kilometric radiation (AKR) seen by Kaguya Lunar Radar Sounder. JUICE has the RIME (Radar for Icy Moons Exploration) instrument, an active radar which emits 9 MHz pulse from 16 m tip-to-tip antenna and tries to detect the ocean under ~10 km icy crust. Since the frequency of Jovian radiation is wider (several 100 kHz to several 10s MHz), RPWI will provide complementary information, including the vertical distributions of conductivity and permittivity in the icy crust.
In the srping 2019, we are manufacturing and testing the Flight Models (FM) which will be shipped in June - July 2019 to Europe. The long road are connected to the first Jupiter and outer planet tour of the

Magnetic field experiment at Jupiter icy moons (JUICE J-MAG) and in-flight alignment calibration

*Ayako Matsuoka[1], Michele Karen Dougherty[2], Patrick Brown[2], Futoshi Takahashi[3], Hisayoshi Shimizu[4], Masaki Matsushima[5]

1. Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. Imperial College London, 3. Kyushu University, 4. University of Tokyo, 5. Tokyo Institute of Technology

The magnetometer instrument (J-MAG) is one of the core instruments on the JUICE spacecraft and is critical for resolving prime science objectives of the mission. The importance of a magnetometer instrument on JUICE can be described under following themes. Firstly, the magnetic field drives the plasma processes occurring within the Jupiter system. Understanding such observations allows for a better understanding of dynamical plasma processes, of the generation of aurora and of the various current systems which arise within this rapidly rotating magnetosphere. Secondary, the magnetometer science which is unique to JUICE lies in being able to gain an understanding of the interior structure of the icy moons of Jupiter, specifically those of Ganymede, Callisto and Europa. Of particular interest are knowledge of the depth at which the liquid oceans reside beneath their icy surfaces, the strength of any internal magnetic fields such as at Ganymede and the strength of any induced magnetic fields arising within these oceans.

J-MAG science requirements result in a requirement on the spacecraft to determine accurate knowledge of the orientation of the fluxgate sensors (MAGIBS and MAGOB). Due to the long MAG boom it is not possible to meet J-MAG’ s alignment requirement by mechanical stability alone, therefore the spacecraft includes two orthogonal coils mounted around its body. The coils can be driven with a current which produces a measurable magnetic field vector at the fluxgate sensors. This signal can then be used by the fluxgates to track the variation in the sensor alignment. This technical note describes the results of an analysis using an alignment recovery technique that was developed for the Kaguya mission, applied to the specific case of JUICE, considering the relative positions of the fluxgate sensors with respect to the JACS coils.

We derived equations to calculate the directions of the measurement axes in the frame fixed to the spacecraft, namely alignment angles, from the measurement results of reference magnetic fields generated by JACS. The errors of the alignment angle estimation and their dependence on measurement noise as well as inaccuracy of the coil current intensity are examined. Based on the quantitative results, the requirements to the JACS design and operation to satisfy the requests to the alignment accuracy are determined.

Science targets of the GAnymede Laser Altimeter (GALA) for the JUICE mission

*Jun Kimura[1], Shunichi Kamata[2], Koji Matsumoto[3], Noriyuki Namiki[3], Keigo Enya[4], Masanori Kobayashi[5], Hiroshi Araki[3], Hirotomo Noda[3], Ko Ishibashi[5], Hauke Hussmann[6], Kay Lingenauber[6]

1. Osaka University, 2. Hokkaido University, 3. National Astronomical Observatory Japan, 4. ISAS/JAXA, 5. Chiba Institute of Technology, 6. German Aerospace Center (DLR), Berlin

The JUpiter Icy Moons Explorer (JUICE), led by European Space Agency, has started development toward launch in 2022 (arrival at Jupiter in 2029, and Ganymede orbit insertion in 2032), and we are now developing the GALA instrument onboard JUICE spacecraft collaborating with German Aerospace Center (DLR) and other institutions in Europe. GALA will acquire the key information for understanding the evolution of Jovian icy moons and to play an essential role in the JUICE's purpose: exploration of deep habitat.

Jovian icy moon Ganymede, which is the largest moon in the Solar System and the primary target of the JUICE, can be said to be one of the typical solid bodies along with terrestrial planets in terms of its size and the intrinsic magnetic field originated from the metallic core. However, current knowledge provided by previous explorations is extremely limited since it comes from only several fly-bys. The JUICE will unveil the whole picture of Ganymede by the first orbiting in the history around extra-terrestrial moon. Expected new big picture of the origin and evolution of Ganymede will not only be a key to unveil the origin of diversity among the Solar System bodies, but also contribute to an understanding of exoplanets with a wide diversity.

The GALA will measure a distance between the spacecraft and the surface of icy moons and acquire the topography data (globally for Ganymede, and fly-by region for Europa and Callisto). It will be a first-ever laser altimetry for the icy object. Such information makes surface geologies clear and tremendously improves our understanding of the icy tectonics. By comparing their tectonic styles on the rocky planets/moons, GALA data leads to reconsider the Earth's plate tectonics. In addition, the GALA will confirm a presence/absence of the subsurface ocean by measuring tidal and rotational response, and the gravitational information reflecting the interior structure will be greatly improved. Furthermore, strength and waveform of reflected laser pulse have an information about surface reflectance at the laser wavelength and small-scale roughness. Finally we can see degrees of erosion and space weathering without being affected by illumination condition through GALA measurements.

In order to interpret and understand such measurements, accumulated studies for the Earth over the years will be effectively utilized: e.g., the data for surface topography, roughness and albedo will lead to describe the icy tectonics through the knowledge from terrestrial glaciology and experiments on impact and deformation process. The tidal measurements by GALA will also be a window to see its interior based on our knowledge and experiences cultivated through the past geodetic observations, e.g., the SELENE mission for the terrestrial Moon.

Characterization of the icy moons will be achieved not only from the GALA measurements but also synergy of other scientific instruments onboard JUICE spacecraft, for examples, surface images taken by optical camera (JANUS) will confirm the position of GALA laser footprint to complement the GALA "point" data for precise topographic mapping. A radar sounder (RIME) and a radio science experiment (3GM) probe

©2019. Japan Geoscience Union. All Right Reserved.

the interior structure, especially interior of the icy crust to figure out an occurrence of tectonic features. A visible and infrared imaging spectrometer (MAJIS), an ultraviolet imaging spectrograph (UVS) and a sub-millimeter wave instrument (SWI) will acquire a surface and atmosphere compositional data. A magnetometer (J-MAG) monitors moons' inductive response to the Jovian magnetic field and probes the subsurface ocean with the help of a particle environment package (PEP) and a radio and plasma wave investigation (RPWI). The GALA works closely together with these instruments and plays a leading and a supporting role to clarify the whole picture of Ganymede and other icy moons.

Current status of the antenna developments, the data processing, scientific target for JUICE/SWI JAPAN.

*YASUKO KASAI[1], [Group] JUICE SWI Japanese Team

1. National Institute of Information and Communications Technology (NICT)

The Submillimetre-Wave Instrument (SWI) is one of the 10 scientific payloads on the JUpiter ICy moon Explorer (JUICE). The main scientific objectives of SWI is to investigate the structure, compositions and dynamics of the middle atmosphere of Jupiter and exosphere of its moons, as well as thermophysical properties if the satellite surfaces. SWI observations will provide pioneering direct measurements of atmospheric compositions in Jupiter system. SWI will performed limb and nadir observations in the frequency region 530-600 and 1075-1275 GHz. Japanese contribution is the development of main- and sub- reflectors, actuators for the instruments, feasibility studies, data processing, and scientific contributions. We present Current status of the antenna developments, the data processing, scientific target for JUICE/SWI JAPAN.

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Yasumasa Kasaba(Planetary Plasma and Atmospheric Research Center, Tohoku University), Kunio M. Sayanagi(Hampton University)

The giant planets provide many keys to understanding planetary processes. They play an important role in shaping our solar system, and the physical and chemical processes they harbor also provide a unique opportunity to study the phenomena relevant for studying Earth and other planets, including exoplanetary systems. In this session, we discuss a wide range of topics encompassing the giant planets and their moons, including their origins, interiors, atmospheres, compositions, surface features, and electromagnetic fields. To advocate for current and future outer planets exploration (Cassini, Juno, New Horizons, JUICE, and beyond), we also call for discussions on future missions to explore giant planet systems, including how to develop better international cooperation. Discussion in this latter category will include progress in developing a solar sail mission concept for observing the Jupiter system and its trojan asteroids.

Critical Role of Entry Probes in Giant Planet Exploration

*Sushil K Atreya[1], Olivier Mousis[2]

1. University of Michigan Ann Arbor, 2. Laboratoire d'Astrophysique de Marseille

Flyby and orbiting spacecraft have explored the giant planets since the early 1970’s. In situ measurements in the troposphere are essential, however, for constraining the models of formation, evolution and interior processes of the giant planets. The models employ abundances and isotopic ratios of key elements, in particular C,N, S, O, He, Ne, Ar, Kr, Xe and D/H, derived from the measurement of their (bulk) reservoir species. That was the scientific rationale for the 1995 Galileo Probe at Jupiter and a Saturn Probe in NASA’s New Frontiers list of candidate missions. Considering that the icy giant planets are distinct from the gas giants, they represent the missing pieces of the puzzle of the formation of the outer solar system, besides being the closest analog for nearly half of the confirmed exoplanets. Thus, their comprehensive exploration with an orbiter-probe spacecraft is essential. The principal focus of this talk is the science, feasibility and implementation strategy of in situ measurements with entry probes at the icy giant planets, Uranus and Neptune, guided by thermochemical models and lessons learned from the Galileo Probe and the ongoing Juno Orbiter. The OKEANOS (Oversize Kite-craft for Exploration and AstroNautics in the Outer Solar system) is a mission under study to rendezvous with and land on a Jupiter Trojan asteroid [1]. The target is a Jupiter Trojan but will be the Saturnian system in the future. It is an engineering mission to demonstrate advanced technologies such as the hybrid thrusting with the enhanced ion engine powered by a 40 x 40 m class large area solar cells to explore the outer solar system cost-effectively. With the new technology, the mission will conduct in-depth scientific measurements for understanding the origin and evolution of the solar system and life. The concept is complementary to NASA Lucy mission [2], multi-flybys to six Jupiter Trojans for understanding the variation of Jupiter Trojans.

Jupiter Trojans are D/P-types enriched in volatiles. They might have experienced almost no or only a low degree of alteration. Their origin and evolution, as well as chemical and physical state still remain unknown. Jupiter Trojans should be a missing link of materials that originate from the inner or the outer solar system by gravity scattering due to migration of giant planets [3]. They are key targets to understand the evolution of astromaterials and the radial distribution of elements and isotopes in the early solar system.

The OKEANOS has been downscaled from the previous proposal [4] due to the severe cost cap. The spacecraft of 1400 kg including a 40 kg lander will be launched in 2027 or later, assisted by gravity of Earth and Jupiter. It will arrive at the target asteroid after a 13-year cruise. 30 kg is allocated for science, 12 kg of which is reserved for international collaboration. Bus instruments such as the optical navigation cameras (ONC-T and -W), LIDAR, and radio science are used for scientific purposes. The lander is like Mascot with uprighting capability on the asteroid surface and 12 kg is allocated for science mission.

During the cruise, science experiments will be carried out from the “deep-space platform”. Measurements of IDPs and magnetic fields will continuously monitor their radial distribution in the solar system and sudden events. The gamma-ray polarimeter will be used for precise positioning of gamma-ray bursts using a very long baseline. Visible to near-infrared telescope will map the zodiacal lights and observe the deep sky under a dust-free condition from outside of the asteroid main belt.

©2019. Japan Geoscience Union. All Right Reserved.

After arrival, global mapping is carried out to characterize the asteroid and select the landing site. The asteroid shape, size, rotation state, and geologic features are imaged by ONC. Gravity is measured by radio tracking and LIDAR. Near-infrared spectroscopy characterizes red or less red patterns, the degree of hydration, mineralogy, and abundance of ices, organics, and brines. Thermal infrared multi-bands inform on thermophysical properties, mineralogy and amorphous phases. A radar probes the surface physical state and also contributes to altimetry. *In situ* experiments with the lander will characterize the footprint and surrounding area by imaging and spectroscopy, followed by measurements of mineralogical, elemental, and organic composition as well as physical, thermal, and magnetic properties at the site. The asteroid surface sample is collected to conduct high-resolution mass spectroscopy (HRMS) based on MULTUM system (infi-TOF type mass spectrometer [5]), especially to determine the isotopic ratios of δD and δ^{15}N and the volatile species contained in the sample. Details will be decided during the critical joint study in 2019. Those experiences will be inherited to future missions.

Magnetic field model of Jovian magnetosphere

*Naoya Momoki[1], Hiroaki TOH[1]

1. Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University

Europa, Ganymede, Callisto are the Jovian icy satellites called Galilean moons, and are possibly with internal oceans each. While ice is almost an insulator electrically, water including ions has high electrical conductivity, and existence of internal oceans can be verified using electromagnetic (EM) induction methods. In this study, we updated the necessary model of the external magnetic field to the icy satellites for the EM induction studies. Namely, parameters of the Euler potential model of the Jovian magnetosphere (Khurana, 1997) were renewed by adding magnetic data from both Galileo and JUNO spacecrafts.

The configuration of the Jovian current sheet was modeled by Khurana [1992] using three parameters, while the Jovian magnetospheric magnetic field modeled by Khurana [1997] was characterized by 14 parameters. We applied a non-linear optimization technique, i.e., the steepest descent method, to the parameters by newly adding magnetic data from Galileo and Juno spacecrafts. We minimized the root mean squared between the model and the data by exploring the parameter space around several initial sets of the parameters.

As a result, time-varying model parameters for each spacecraft orbit were obtained. Their temporal variation may reflect that of both magnetic field and electric current system in the Jovian magnetosphere.The changes of the parameters can be attributed to the interaction between the Jovian magnetosphere and the solar wind. It, therefore, preferable that the temporal variation of the model parameters is incorporated when the updated magnetic field model of the Jovian magnetosphere is applied to the EM induction studies in search for the internal oceans of the icy satellites.

Enhancement of the Jovian thermospheric temperature above the Great Red Spot based on the infrared spectroscopic data obtained with IRTF/iSHELL

*Ayumu Kambara[1], Hajime Kita[2], Takeshi Sakanoi[1], Yasumasa Kasaba[1], Masato Kagitani[1], Haruna Watanabe[1]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

It is known that the thermospheric temperature of all giant planets including Jupiter is several hundred kelvins higher than that expected from solar heating. At mid- to low-latitudes, although the direct atmospheric heating caused by precipitating particles and the energy transportation from high-latitude auroral region have been considered, it is not enough to explain. Another candidate for the heating is energy transportation by atmospheric waves from the lower atmosphere. Recently, O'Donoghue *et al.* [2016] revealed the heating in the thermosphere above the Great red spot from the intensity ratio of two emission lines (3.383um/3.454um) of the vibrational-rotational spectrum of thermospheic H_3^+ taken by IRTF /SpeX (R~2500) in December 2012. They estimated that the temperature above the Great red spot is 1644±161K, and that on surrounding mid- to low-latitude region is 900±42K. They considered that the reason was the energy transport from the lower atmosphere in the Great red spot region, that is, the propagation of atmospheric gravity waves and acousitic waves generated in the Great red spot, the tropospheric anticyclonic storm, to the thermosphere. However, the infrared spectrum observed SpeX might be contaminated by CH_4 line due to its low-resolution capability.
In this study, we carried out the thermosphere temperature observation in the Jovian mid-latitude region near the Great red spot by IRTF/iSHELL on January 11, 2017. This observation was performed with the iSHELL's Lp1-mode (3.265-3.657um), and the data reduction was performed with NASA's data reduction tool Spextool ver. 5.0.1. Similar to the past study by O'Donoghue *et al.* [2016], we adopted the intensity ratio of two emission lines of H_3^+ (3.3839um/3.4548um), and estimated the temperature precisely distinguished from CH_4 line by iSHELL’s higher wavelength resolution (R~75000). As a result, we estimated the thermospheric temperature above the Great red spot to be 910±132K, and that in the surrounding region to be 583±30K, showing about 300K increase on Great red spot. The estimated temperature was lower than that in O’Donoghue *et al.* [2016], there is possibility that the thermosphere temperature varies in time. However, we confirmed the temperature above Great red spot is higher than that in the surrounding region. This suggests the existence of energy transport from the lower to the upper atmosphere in the Great red spot. In the presentation, we report the result of carefully reduction.

Pulsation-like variation of Jovian infrared polar emission observed by Subaru 8-m: H3+ and methane emissions

*Yasumasa Kasaba[1], Haruna Watanabe[1], Hajime Kita[2], Chihiro Tao[3], Takeshi Sakanoi[1], Masato Kagitani[1], Orton Glenn[1,4], James Sinclair[4]

1. Planetary Plasma and Atmospheric Research Center, 2. ISAS/JAXA, 3. NICT, 4. NASA/JPL

In the Jovian high-latitude region, there are emissions with various wavelengths ranges, morphologies, and time variations. They are important tracers of energy injection carried by auroral particles that precipitate from the magnetosphere. The polar IR emissions excited in the Jovian upper atmosphere, which include the H_3^+ aurora and thermal emissions of hydrocarbons, reflect not only the abundance of emission sources but also the thermal structures. Both are affected by auroral precipitation into the source region. It is known that, in the polar region inner than the auroral oval, the flux of auroral precipitation can have time variations over various scales from years to seconds.

The H_3^+ aurora observed in near infrared is emitted in thermosphere / ionosphere from thermally excited H_3^+ ions above the CH_4 homopause. Auroral precipitation ionized H_2 and produce H_3^+ ions through ion chemistries. In previous observational studies, the shortest timescale of H_3^+ auroral intensity change was ~30 min, but detected by ~16-min step imaging. We performed the temporal imaging observation of the Jovian H_3^+ IR aurora with Subaru/IRCS and the H_3^+ narrow-band filter on 31 January 2015 and 25 May 2016. The adaptive optics enabled us to see the target with high spatial resolution (~0.2 arcsec). From the images obtained with time resolution of ~150 s on 25 May 2016, we detected a patch-like auroral feature pulsating with a period of ~10 min in noon sector of northern polar region. On the other hand, we could not find any periodic variations from the data obtained on 31 January 2015, which was obtained as slit-viewer image for the other study, and whose time intervals of ~10–30 min every several images was not optimized to this research. In addition, the location where the patch-like emissions observed with high intensities on 25 May 2016 were not so bright on 31 January 2015. The patch-like auroral feature that was pulsating during our observation period on 25 May 2016 have been sometimes observed in UV, but not always. Previous UV observations reported some pulsating auroral features with the periods of ~2–11 min in the northern polar region. However, the locations of them are not consistent with the patch-like feature in this study. The pulsation period of the X-ray aurora, which has a hot spot coinciding with our patch-like IR aurora, is 40–50 min. This region is estimated to connect magnetically to out of the magnetopause, and auroral precipitation there can be caused by dayside reconnection between the Jovian magnetospheric field and interplanetary field.

On the other hand, the hydrocarbon polar emission observed in mid-infrared is emitted from the whole stratosphere. From their locations and morphologies, it is estimated to be related with auroral particles penetrating under the homopause. However, the mechanisms of this link (composition change and/or heating by particle precipitations) are not well understood. Previous studies found the intensity time variation of polar CH_4 emission over days and months. We tried to detect the time variation of CH_4 emission intensity by continuous imaging observations of the northern polar region over several tens of minutes on 31 March, 24 and 25 May 2018 with Subaru/COMICS. We obtained the images using the 7.8 μm filter, which is sensitive to the CH_4 thermal emissions occurring in the pressure range of 20–0.5 mbar and 1 μbar in the Jovian upper stratosphere, with time resolution of ~1 min. On all observation days, the polar region was not bright in 7.8 μm. In addition, we could not find clear time variations of polar CH_4 emission intensity during our observation periods, 25, 50 and 60 min on 31 March, 24 and 25 May 2018.

©2019. Japan Geoscience Union. All Right Reserved.

This observation result is consistent to the model estimation by *Kuroda et al.* [2014], which suggested the relaxation time of hydrocarbon thermal emissions in the Jovian upper stratosphere, where is a possible source region of polar CH_4 emission, is at least ~10^5 s (~28 h).

Structure of Io plasma torus observed with the Tohoku 60-cm telescope

*Masato Kagitani[1], Fuminori Tsuchiya[1], Kazuo Yoshioka[2], Go Murakami[3], Tomoki Kimura[1], Ryoichi Koga[1], Reina Hikida[4], Takeshi Sakanoi[1]

1. Graduate School of Science, Tohoku University, 2. Graduate School of frontier Science, The University of Tokyo, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Department of Earth and Planetary Science, Graduate School of Science, Tokyo University

Volcanic gases (mainly composed of SO_2, SO and S) originated from jovian satellite Io are ionized by interaction with magnetospheric plasma and then form a donut-shaped region called Io plasma torus. Ion pickup is the most significant energy source on the plasma torus though, distribution of pick-up region and its variability is still unclear. Density profiles of ions along the magnetic field line are determined under condition of diffusive equilibrium. Based on the equilibrium, plasma equator is close to the centrifugal equator though, higher ion anisotropy moves the plasma equator toward the magnetic equator. Measuring ion distribution with enough spatial resolution enables us to derive ion anisotropy which is tightly related to the amount of fresh pickup ion. On this study, we focus on variability of latitudinal structure of Io plasma torus as well as its radial structure using ground-based observation over six month period in 2018. The ground-based observation of sulfur ion emission, [SII] 671.6nm and 673.1nm was made at Haleakala observatory in Hawaii during March through August 2018 using the Tohoku 60-cm telescope (T60). A monochromatic imager with coronagraph attached onto the Cassegrain focus of T60 enables to measure distribution of S^+ with spatial resolution of 0.03 jovian radii (R_J). A digital micro-mirror device DMD was employed to block light from Jupiter disk and Galilean moons. Typical integration time of each frame was 20 minutes and total number of reduced image is 480. We also made observation of neutral sodium cloud extending up to several hundred of R_J as a proxy of supply of neutral particles from Io (Yoneda et al., 2015). Based on observation over the six month, [SII] brightness increases from DOY 80 through 140, then gradually decreases though DOY 230 in 2018. The data reduction of iogenic neutral sodium cloud is still undergoing though, neutral sodium cloud seems to increase from DOY 50 through 135, as [SII] brightness increases. The result suggests that increased volcanic activity from DOY 50-135 caused increase of S+ and brightening of [SII] emission. As for variability of shorter duration, we find [SII] brightening event within a short period (< 2 days) at around 28 through 30 July over a small region (< 30 degrees in longitude). [SII] 671.6 and 673.1 nm emissions are sensitive to cold electron (1-10eV) rather than hot electron (>100eV). Thus, increase of cold electron temperature explains the observed [SII] brightening well as the EUV space telescope Hisaki observed brightening of Io plasma torus associated with injection of hot electron. We also find variation of latitudinal structure of Io plasma torus. Longitudinal peak of S^+ emission at the same system III longitude 279 degree are -0.73, -0.80 and -0.79 R_J on 26, 29 July 7 and August, respectively. The shift of S^+ density peak toward magnetic equator implies higher anisotropy 29 on July and 7 August compared with 26 July. One of the possible explanation of the latitudinal shift of S^+ plasma is an increase of flesh pickup ion which makes higher anisotropy. Further study using Colorado Io Plasma Torus Emission Package (CITEP) will be presented on the presentation to take into account for line-of-sight integration effect of the ground-based observation.

Ion Scale Height Variability in Hisaki Io Torus Observations

*Nicholas McCord Schneider[1], Carl Schmidt[2], Masato Kagitani[3], Yasumasa Kasaba[3], Tomoki Kimura[3], Go Murakami[4], Fuminori Tsuchiya[3], Hajime Kita[3], Reina Hikida[5], Ichiro Yoshikawa[5], Kazuo Yoshioka[5]

1. LASP, University of Colorado Boulder, 2. Boston University, 3. Tohoku University, 4. ISAS/JAXA, 5. University of Tokyo

Ion temperature is a critical variable in Io plasma torus energetics, but is difficult to derive from remote sensing measurements. The relative importance of hot ions vs. hot electrons in powering the torus emissions remains an open question. Torus brightenings, whether caused by episodic changes in the volcanic supply to the torus or periodic System III/IV enhancements, offer the best chance to search for driving variations in hot electrons or ions. Much attention has been paid to hot electron populations, derivable from detailed spectral modeling, but less work has been done on ion temperature. Ground-based studies have successfully derived $T_{\perp}$ from very high resolution spectra, and $T_{||}$ from scale height measurements in images, both over limited datasets. Schneider et al. 1997 found strong longitudinal variations in $T_{||}$ during a week-long dataset, and anti-correlated System III brightness, but more extended followup datasets have not previously been available.

The Hisaki dataset presents the possibility of an unparalleled opportunity to study long-term and short-term variations in ion temperatures. The instrument is not designed to take images of specific emissions, but its large entrance slit accepts the full height and width of the torus. In the ideal case, each spectral emission feature would appear as an image of the torus at its appropriate position in the spectrum, creating an “overlapogram” (as did the Cassini UVIS instrument). In reality, the emissions are blurred due to instrumental resolution and aberrations, and multiple spectral feature overlap. Furthermore, the changing opening angle of the rotating torus adds a spurious apparent scale height variation which must be removed, with special attention to asymmetries introduced by Jupiter's changing tilt. With allowances for all these effects, we will report on our search for ion temperature variations during the first two years of Hisaki observations, and compare our results to a previous independent study by M. Shishido (M.S. thesis, U. Tohoku).

Size of the Smallest Particles in Saturn's Rings

*Keiji Ohtsuki[1], Hiroshi Kawamura[1], Naoyuki Hirata[1], Hiroshi Daisaka[2], Hiroshi Kimura[3]

1. Graduate School of Science, Kobe University, 2. Graduate School of Commerce and Management, Hitotsubashi University, 3. Planetary Exploration Research Center, Chiba Institute of Technology

Spacecraft and ground-based observations have shown that particles in Saturn's main rings have a power-law distribution roughly between centimeter and ten meters, but sub-centimeter particles appear to be lacking. Recent studies based on Cassini observations suggest that the size of the smallest particles is on the order of millimeters. Cohesive force between particles has been proposed to explain the paucity of sub-centimeter particles, but its strength depends on impact velocity. In order to better understand recent Cassini observations about small ring particles, we examine impact velocity between ring particles using N-body simulation including size distribution. We find that most collisions take place at velocities lower than 0.1 cm per second; even in dense rings where particles' velocity dispersion is enhanced by gravitational wakes, they collide at such low velocities because particles tend to move coherently in the wakes. This velocity is too low to detach sub-centimeter particles that are attached to the surface of large ones due to the cohesive force, explaining their paucity in the main rings. On the other hand, more infrequent high-velocity impacts can release millimeter-sized particles strongly attached to the surface of large ones, explaining the observed free millimeter-sized particles with relatively low abundance. We will discuss implications of our results for the observed size of the smallest particles in Saturn's main rings.

The Radio & Plasma Wave Investigation (RPWI) for JUICE for the investigation of Jupiter and Icy Moons System: Contributions from Japan

*Yasumasa Kasaba[1], Hiroaki Misawa[1], Fuminori Tsuchiya[1], Atsushi Kumamoto[2], Yuto Katoh[2], Tomoki Kimura[2], Hajime Kita[3], J.-E. Wahlund[4]

1. Planetary Plasma and Atmospheric Research Center, Tohoku University, 2. Department of Geophysics, Tohoku University, 3. ISAS/JAXA, 4. IRF Uppsala, Sweden

The Radio & Plasma Wave Investigation (RPWI) for the ESA JUICE mission (launch: 2022, Observations: 2030s) provides an elaborate suite of electromagnetic fields and plasma instruments. RPWI focuses on cold plasma studies and will investigate how the transfer of momentum and energy in the Jovian huge magnetosphere and the electrodynamic coupling with the icy Galilean moons. Remote sensing and direction finding of the Jovian radio emissions will be carried out. This capability is also devoted to the ices and the deep interiors of the icy moons. Investigations of the ice shells will be performed by means of a novel passive ground penetrating radar technique, which utilizes Jovian strong radio emissions as the transmitted signal. On the Ganymede orbit, continuous measurements of the electric field with the JUICE Magnetometer (JMAG) measurements will determine the electric coupling between any ocean, the ionosphere, and the magnetosphere, and provide the constraints on the physical characteristics of the subsurface ocean of Ganymede.
For those objectives, RPWI sensors consist of 4 Langmuir probes (LP-PWI) for determination of the vector electric field up to 1.6 MHz and cold plasma properties (including active measurements by LP sweeps and mutual impedance sounding) up to 1.6 MHz, a tri-axial search coil magnetometer (SCM) for determination of the vector magnetic field up to 20 kHz, and a tri-dipole antenna system (RWI) for monitoring of radio emissions (80 kHz - 45 MHz). From Japan, the RWI preamp and its High Frequency receiver with the onboard software will be provided, based on the modifications from the BepiColombo PWI and Arase PWE developments. Since Arase already shows the good performance in the radiation hard environment around Earth, we have enough confidence for the possible functions and performance on the Jovian hard environment. We will also provide Software Wave-Particle Interaction Analyzer (SWPIA) function to RPWI DPU, for the onboard quantitative detection of electromagnetic field - ion interactions, modifying from the Arase SWPIA which is also activating on the space now.
HF reciever will provide the first highly-resolved information of Jovian radio emissions emitted from Jovian multiple regions including lightning activity and icy moons, by the 3-ch receiver system manufactured by Japan and Sweden connected to the 3-elements 1.25-m E-filed dipole antenna system manufactured by Poland and Japan. Highly matured onboard and ground data processing will also be provided by France and Japan. As a byproduct, reflected Jovian emission can also be expected from the boundary of icy crust and conductive liquid subsurface ocean. Such reflection components could be observed as the Lunar surface reflection of terrestrial auroral kilometric radiation (AKR) seen by Kaguya Lunar Radar Sounder. JUICE has the RIME (Radar for Icy Moons Exploration) instrument, an active radar which emits 9 MHz pulse from 16 m tip-to-tip antenna and tries to detect the ocean under ~10 km icy crust. Since the frequency of Jovian radiation is wider (several 100 kHz to several 10s MHz), RPWI will provide complementary information, including the vertical distributions of conductivity and permittivity in the icy crust.
In the srping 2019, we are manufacturing and testing the Flight Models (FM) which will be shipped in June - July 2019 to Europe. The long road are connected to the first Jupiter and outer planet tour of the

Magnetic field experiment at Jupiter icy moons (JUICE J-MAG) and in-flight alignment calibration

*Ayako Matsuoka[1], Michele Karen Dougherty[2], Patrick Brown[2], Futoshi Takahashi[3], Hisayoshi Shimizu[4], Masaki Matsushima[5]

1. Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. Imperial College London, 3. Kyushu University, 4. University of Tokyo, 5. Tokyo Institute of Technology

The magnetometer instrument (J-MAG) is one of the core instruments on the JUICE spacecraft and is critical for resolving prime science objectives of the mission. The importance of a magnetometer instrument on JUICE can be described under following themes. Firstly, the magnetic field drives the plasma processes occurring within the Jupiter system. Understanding such observations allows for a better understanding of dynamical plasma processes, of the generation of aurora and of the various current systems which arise within this rapidly rotating magnetosphere. Secondary, the magnetometer science which is unique to JUICE lies in being able to gain an understanding of the interior structure of the icy moons of Jupiter, specifically those of Ganymede, Callisto and Europa. Of particular interest are knowledge of the depth at which the liquid oceans reside beneath their icy surfaces, the strength of any internal magnetic fields such as at Ganymede and the strength of any induced magnetic fields arising within these oceans.

J-MAG science requirements result in a requirement on the spacecraft to determine accurate knowledge of the orientation of the fluxgate sensors (MAGIBS and MAGOB). Due to the long MAG boom it is not possible to meet J-MAG’ s alignment requirement by mechanical stability alone, therefore the spacecraft includes two orthogonal coils mounted around its body. The coils can be driven with a current which produces a measurable magnetic field vector at the fluxgate sensors. This signal can then be used by the fluxgates to track the variation in the sensor alignment. This technical note describes the results of an analysis using an alignment recovery technique that was developed for the Kaguya mission, applied to the specific case of JUICE, considering the relative positions of the fluxgate sensors with respect to the JACS coils.

We derived equations to calculate the directions of the measurement axes in the frame fixed to the spacecraft, namely alignment angles, from the measurement results of reference magnetic fields generated by JACS. The errors of the alignment angle estimation and their dependence on measurement noise as well as inaccuracy of the coil current intensity are examined. Based on the quantitative results, the requirements to the JACS design and operation to satisfy the requests to the alignment accuracy are determined.

Science targets of the GAnymede Laser Altimeter (GALA) for the JUICE mission

*Jun Kimura[1], Shunichi Kamata[2], Koji Matsumoto[3], Noriyuki Namiki[3], Keigo Enya[4], Masanori Kobayashi[5], Hiroshi Araki[3], Hirotomo Noda[3], Ko Ishibashi[5], Hauke Hussmann[6], Kay Lingenauber[6]

1. Osaka University, 2. Hokkaido University, 3. National Astronomical Observatory Japan, 4. ISAS/JAXA, 5. Chiba Institute of Technology, 6. German Aerospace Center (DLR), Berlin

The JUpiter Icy Moons Explorer (JUICE), led by European Space Agency, has started development toward launch in 2022 (arrival at Jupiter in 2029, and Ganymede orbit insertion in 2032), and we are now developing the GALA instrument onboard JUICE spacecraft collaborating with German Aerospace Center (DLR) and other institutions in Europe. GALA will acquire the key information for understanding the evolution of Jovian icy moons and to play an essential role in the JUICE's purpose: exploration of deep habitat.

Jovian icy moon Ganymede, which is the largest moon in the Solar System and the primary target of the JUICE, can be said to be one of the typical solid bodies along with terrestrial planets in terms of its size and the intrinsic magnetic field originated from the metallic core. However, current knowledge provided by previous explorations is extremely limited since it comes from only several fly-bys. The JUICE will unveil the whole picture of Ganymede by the first orbiting in the history around extra-terrestrial moon. Expected new big picture of the origin and evolution of Ganymede will not only be a key to unveil the origin of diversity among the Solar System bodies, but also contribute to an understanding of exoplanets with a wide diversity.

The GALA will measure a distance between the spacecraft and the surface of icy moons and acquire the topography data (globally for Ganymede, and fly-by region for Europa and Callisto). It will be a first-ever laser altimetry for the icy object. Such information makes surface geologies clear and tremendously improves our understanding of the icy tectonics. By comparing their tectonic styles on the rocky planets/moons, GALA data leads to reconsider the Earth's plate tectonics. In addition, the GALA will confirm a presence/absence of the subsurface ocean by measuring tidal and rotational response, and the gravitational information reflecting the interior structure will be greatly improved. Furthermore, strength and waveform of reflected laser pulse have an information about surface reflectance at the laser wavelength and small-scale roughness. Finally we can see degrees of erosion and space weathering without being affected by illumination condition through GALA measurements.

In order to interpret and understand such measurements, accumulated studies for the Earth over the years will be effectively utilized: e.g., the data for surface topography, roughness and albedo will lead to describe the icy tectonics through the knowledge from terrestrial glaciology and experiments on impact and deformation process. The tidal measurements by GALA will also be a window to see its interior based on our knowledge and experiences cultivated through the past geodetic observations, e.g., the SELENE mission for the terrestrial Moon.

Characterization of the icy moons will be achieved not only from the GALA measurements but also synergy of other scientific instruments onboard JUICE spacecraft, for examples, surface images taken by optical camera (JANUS) will confirm the position of GALA laser footprint to complement the GALA "point" data for precise topographic mapping. A radar sounder (RIME) and a radio science experiment (3GM) probe

the interior structure, especially interior of the icy crust to figure out an occurrence of tectonic features. A visible and infrared imaging spectrometer (MAJIS), an ultraviolet imaging spectrograph (UVS) and a sub-millimeter wave instrument (SWI) will acquire a surface and atmosphere compositional data. A magnetometer (J-MAG) monitors moons' inductive response to the Jovian magnetic field and probes the subsurface ocean with the help of a particle environment package (PEP) and a radio and plasma wave investigation (RPWI). The GALA works closely together with these instruments and plays a leading and a supporting role to clarify the whole picture of Ganymede and other icy moons.

Current status of the antenna developments, the data processing, scientific target for JUICE/SWI JAPAN.

*YASUKO KASAI[1], [Group] JUICE SWI Japanese Team

1. National Institute of Information and Communications Technology (NICT)

The Submillimetre-Wave Instrument (SWI) is one of the 10 scientific payloads on the JUpiter ICy moon Explorer (JUICE). The main scientific objectives of SWI is to investigate the structure, compositions and dynamics of the middle atmosphere of Jupiter and exosphere of its moons, as well as thermophysical properties if the satellite surfaces. SWI observations will provide pioneering direct measurements of atmospheric compositions in Jupiter system. SWI will performed limb and nadir observations in the frequency region 530-600 and 1075-1275 GHz. Japanese contribution is the development of main- and sub- reflectors, actuators for the instruments, feasibility studies, data processing, and scientific contributions. We present Current status of the antenna developments, the data processing, scientific target for JUICE/SWI JAPAN.

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Masateru Ishiguro(Seoul National University)

In June 2018, the Hayabusa 2 spacecraft arrived at the target asteroid Ryugu after three and half years journey. In addition, another spacecraft, OSIRIS-REx will soon arrive at its destination Bennu. With these arrivals, the solar system research is about to enter a new era. We have organized this small bodies session since 2012 and had a broad range of discussions from viewpoints of laboratory experiments, observations, space explorations, theoretical modeling, and sample analyses. In particular, this time, we aim to hold this session to bring the latest research on solar system small bodies, focusing on the initial results of Hayabusa 2 and OSIRIS-REx. Presentations in the related fields other than these two asteroidal missions are also welcomed.

In June 2018 Hayabusa2 arrived at near-Earth asteroid (NEA) Ryugu and has been successfully conducting remote-sensing observations from ~20-km or less altitudes and deploying rovers and a lander. Based on images taken by ONC-T, we constructed global shape models of Ryugu [1, 2]. In order to obtain a reliable shape model in a short period, we used two independent methods; the stereophotoclinometry (SPC) technique [3] and the Structure-from-Motion (SfM) technique [4]. Except for boulders and high latitudes, the two models are in good agreement with each other.

The total volume of Ryugu derived from an SPC-based shape model is 0.377±0.005 km^3. Gravity measurement revealed that the asteroid's mass is (4.50±0.06) $\times 10^{11}$ kg. The bulk density is thus obtained as 1.19±0.03 g cm^{-3}. The density is significantly smaller than bulk densities (1.6-2.4 g cm^{-3}) measured for Ch- and Cgh-type having the 0.7-μm absorption [5]. However, it remains within the 0.8–1.5 g cm^{-3} range measured for BCG-types (B-, C-, Cb-, and Cg-type), which might be related to unheated icy asteroids [5]. The low bulk density of Ryugu is consistent with the spectral type (Cb-type) measured by ONC-T and NIRS3 [2, 6].

NIRS3 observations indicate that hydrated minerals are widely spread on the surface of Ryugu [6]. The presence of water ice, however, is unlikely for NEA Ryugu because the radiative equilibrium temperature (~250 K) is higher than the ice sublimation temperature (~230 K) at its central pressure of ~8 Pa and the thermal diffusion time of Ryugu is estimated to be much shorter than the typical dynamical lifetime of NEAs [1]. Note that the parent body of Ryugu located in the Main Belt might have water ice and low density of Ryugu could be ascribed to loss of volatile components without subsequent compaction. If we adopt the grain densities of CM carbonaceous chondrites (CCs), the derived total porosity is 57-63%. Adopting those of Orgueil CI CC, we predict the total porosity to be 50-52%. The estimated total porosity is even higher than that of rubble-pile asteroid Itokawa (44±4%) [8, 9], indicating that Ryugu is also a rubble pile.

Hayabusa2 reveals that Ryugu is a top-shape asteroid; a prominent elevated ridge around the equator. Although dozens of top-shaped asteroid have been found by ground-based radar, Ryugu is the first top-shape asteroid to be directly observed up close by a spacecraft. Bennu is the second one.

Derived surface slopes to the equipotential surface assuming the present shape and uniform interior

demonstrate least variation with latitude if, at some epoch, Ryugu had a spin period of 3.5 hours (about half of the current value) [1]. This suggests that the top shape was formed by centrifugally induced structural failure during a rapid rotation era. The deformation occurred either in the initial re-accumulation stage [10] or in the later quasi-statically spin-up stage (due to the YORP thermal effect) [11]. In the later stage, a deformation process might be induced either on the surface or in the interior, depending on the internal structure. The high porosity nature of Ryugu as well as no significant offset between the centers of figure and gravity suggest that the internal tensile strength of the asteroid is uniform and low.
NIR absorption feature of Ryugu obtained by NIRS3 is similar to those of heated/hocked CI/CM chondrites [6]. However, these meteorites are relatively rare whereas BCG types are abundant, so that another meteoritic counterpart of BCG types are expected. High porosity nature of Ryugu suggests that meteorites originated from BCG-type asteroids would be very fragile and should be destroyed at the atmospheric entry. This is consistent with the scanty of BCG-originated meteorites and a hypothesis that pyroxene-rich interplanetary dust particles (IDPs) are originate from BCG-types based on the mid-IR spectroscopy [5]. Thus, comparative studies of Ryugu and Bennu, not only in material science but also in physical properties and internal structure, are the key to understand the delivery system of water and organic materials from the snow line to Earth.

The Near Infrared Spectrometer (NIRS3) is installed on the Hayabusa2 spacecraft to observe the target C-type asteroid 162173 Ryugu at near infrared wavelengths of 1.8 to 3.2 μm. It aims to obtain reflectance spectra in order to detect absorption bands of hydrated and hydroxide minerals in the 3 μm-band spectral region. Spectra obtained during the cruising and proximity-operation phases have revealed that the performance of NIRS3, using the newly developed linear-image sensor with indium arsenide (InAs) photodiodes, are good enough as expected from the ground performance tests.
Prior to the touch down of Hayabusa2 on the surface of Ryugu, NIRS3 has completed global observations from the Home Position, where the altitude is about 20 km above the surface. NIRS3 also performed low-altitude observations in several opportunities, such as the separation operation of the small rovers and lander, during which the lowest altitude was less than 30 m. Analyzing the spectra, NIRS3 contributed to estimate the temperature of the asteroid surface. After removing the thermal emission, we successfully detected a weak and narrow absorption feature centered at 2.72 μm, which suggests the existence of hydroxyl (OH)-bearing minerals formed by aqueous alteration. This feature is, however, almost uniform over the whole surface in terms of band depth and position. Additionally, it is remarkable that the albedo of Ryugu is extremely low. These results imply the following hypotheses; 1) dehydration caused by heating or space weathering, or 2) masking effects by dark materials on the surface. We will argue about the inspection of the evolution scenario of Ryugu inferred from the above results.

A small carry-on impactor (SCI) equipped on Hayabusa2 is scheduled to be propelled toward to the surface of asteroid Ryugu this spring. Cratering process on Ryugu made by the impactor will simultaneously observed by a deployable camera 3 (DCAM3) detached from Hayabusa2. The mission objective of the impactor is to excavate the asteroid to expose a subsurface material as ejecta deposits around the crater. Thus, not only it enables us to give a good opportunity for obtaining a fresh or subsurface material by a sampler system, remote sensing instruments such as ONC, TIR, NIRS3 onboard Hayabusa2 will also have a good chance to observe the exposed subsurface material. Furthermore, this impact experiment on Ryugu is also a rare opportunity to verify the crater scaling law in the microgravity environment on the real asteroid materials, and is expected to enable us to improve the conventional scaling law, especially for the crater size and the ejecta velocity distribution.

After arrival at Ryugu, the surface morphology observation through remote sensing has turned out that a plenty of boulders cover throughout the surface, and many of the boulders are larger than 10 m. These boulders are distributed almost uniformly and the size frequency distribution of the boulders is a power law distribution with the power law index around -1, indicating relatively large boulders are dominant on the surface. Therefore, taking into account that the precision of an actual impact point toward an aiming point expands several 10 m, the impactor possibly collides with a large boulder, otherwise with small boulders having the power law size distribution, wherever the impactor would aim at on the surface of Ryugu. If the impactor collides with a large boulder, a crater should be formed in the strength regime, and if the impactor collides into a finer-boulder area, a crater will be formed in the gravity regime. The DCAM3 was designed for the observation of not only the impact cratering in the strength regime but also that in the gravity regime.

We believe that we will success to observe impact ejecta induced by the impactor when the SCI and DCAM3 operations are conducted as scheduled. We are planning to present a first report of the DCAM3

©2019. Japan Geoscience Union. All Right Reserved.

observation in this talk, and discuss how to search the impact point on the Ryugu surface using the DCAM3 images, beforehand the onboard imaging instruments. Moreover, the morphology of the ejecta curtain imaged by DCAM3 will bring us a lot of information about the crater formation process. We report the surface condition around the impact point, such as a large block or a small-boulders area, and an excavated area corresponding to the crater size. The DCAM3 will also observe individual dusts in the ejecta curtain to obtain information of the ejecta velocity distribution, so that we may have a chance to introduce these images. However, please note that this presentation strongly depends on the success of the SCI/DCAM3 operation.

Impact cratering experiments on glass beads with bead size frequency distribution: Implications for cratering process on asteroid Ryugu

*Minami Yasui[1], Masahiko Arakawa[1], Sunao Hasegawa[2], Yuya Yamamoto[1], Ryo Sugimura[1]

1. Graduate School of Science, Kobe University, 2. ISAS, JAXA

Some impact craters with a diameter of a few hundred meters are found on asteroid Ryugu while there are few small craters of < several meters on the asteroid. Many boulders are found on Ryugu and they have the size frequency distribution similar to that of impact fragments obtained by the impact experiments of rocky materials [1]. When an impactor collided with a larger boulder compared with the impactor size, the boulder could be disrupted but the crater might not form. Some researchers conducted impact experiments on granular targets with a particle size larger than the projectile size and they found that the crater radius became smaller as the size ratio of the target particle to the projectile was larger [e.g., 2]. In this study, we conducted impact cratering experiments on granular targets having the size frequency distribution similar to that of boulders on Ryugu to examine the relationship between the particle size frequency distribution and the crater size.

We conducted cratering experiments by using a one-stage light gas gun at Kobe University and a two-stage light gas gun at ISAS. We used glass beads having the diameters of 0.1, 1, 3, and 10 mm as a target and prepared four types of target; two targets consist of one size of glass bead (0.1 or 3 mm glass beads) and the others consist of mixing three (1-10 mm) or four (0.1-10 mm) different-sized glass beads with the same mass ratio. We used only four glass bead mixing target at ISAS. At Kobe University, the stainless-steel spheres with a diameter of 2 and 3 mm were used as a projectile and the impact velocity was changed from 53 to 181 m/s. At ISAS, the aluminum projectile with a diameter of 1 mm was used and the impact velocity was changed from 1.2 to 4.4 km/s. The collisional phenomena were recorded by high speed camera to observe the rebound of the projectile and the ejection of glass beads.

We observed the ejection of glass beads from the target surface. In the case of 0.1-mm bead target, the beads were ejected radially and the corn-shaped ejecta curtain was observed. In the case of 3-mm bead target, some intact beads were ejected at lower speed. In the case of four bead mixing target, some 0.1-mm beads were ejected like a smoke passing through other beads. Furthermore, the projectile rebounded from the target surface in most cases of 3-mm bead target and two mixing bead targets. When the projectile collided with a 10-mm bead, the amount of the ejected beads decreased drastically.

We applied our results to the crater scaling law showing as $\pi_R = a \cdot \pi_2^{-b}$, where π_R is the non-dimensional parameter related to the crater radius, π_2 is the non-dimensional parameter related to the gravity, the projectile size, and the impact velocity, and a and b are constants. As a result, the π_R of the 0.1-mm bead target was largest. The π_R of the 3-mm bead target and two mixing bead targets matched each other and a little smaller than that of the 0.1-mm bead target when the projectile did not collide with a 10 mm glass bead. Furthermore, the π_R of mixing bead targets was much smaller when the projectile collided with a 10-mm bead.

Finally, we revised the crater scaling law of mixing bead targets by using the scaling law of the 0.1-mm bead target (a=0.58 and b=0.21). In this study, we assumed that the projectile collided with a 3-mm or 10-mm bead and the momentum of the projectile was transferred to the impacted bead, then the bead penetrated into the target slowly and the cavity was formed. On this assumption, we constructed the revised crater scaling law by using the coefficient of the restitution of projectile, e, and the momentum conservation law. As a result, we could obtain e=0.5-1 to match our experimental results with the revised crater scaling law.

Enhancement of impact heating in strength-supported media

*Kosuke Kurosawa[1], Hidenori Genda[2], Shigeru Wakita[2], Thomas M Davison[3], Ryuki Hyodo[2], Tomoki Nakamura[4]

1. Planetary Exploration Research Center, Chiba Institute of Technology, 2. Earth-Life Science Institute, Tokyo Institute of Technology, 3. Department of Earth Science & Engineering, Imperial College London, 4. Department of Earth Science, Tohoku University

Hypervelocity mutual collisions between small bodies, which include the asteroid Ryugu,occur throughout the history of the solar system. A strong compression and thermal pulse caused by an impact can produce various unique features, such as a change in spectral properties, mosaicism, planer deformation features, high-pressure minerals, atomic diffusion, volatile loss, shock veins, impact melt, and so on. We can obtain these features in samples returned from Ryugu, collected by the Hayabusa2 spacecraft. When we have a reliable model connecting the degree of shock metamorphism with the impactor/target conditions, we can reveal the impact history of Ryugu more correctly.

Frequently, the table from Stöffler et al. (1991, 2018) is used to deduce the shock stage of meteorites using observed shock features, which are subsequently used to infer impact velocities on target bodies. Recently, Kurosawa and Genda (2018) reported that the degree of heating in low-velocity impacts (<10 km/s) is expected to be much higher than previously expected. This is caused by the irreversible heating during plastic deformation against material strength. Low-velocity impacts do not produce large-scale impact melting, but trigger a comminution of both impactor and target materials. Although the materials experiencing compression do not have a tensile strength, they still have a compressive one. Thus, the required impact velocities for producing the unique features produced mainly by the rise in temperature is greatly lowered as shown by Kurosawa and Genda (2018). Another work also confirmed the importance of plastic deformation during impacts to a target embedding hydrous minerals (Wakita and Genda 2019). The experienced temperature at a given shock stage defined by Stöffler’ s table would be revised to somewhat higher temperatures, which would mean that impact histories derived from shock features using the previous table would need to be revised. For example, the target bodies are likely to experience many fewer high-speed energetic impacts than previously expected.

We are planning to revise the Stöffler’ s table by using the state-of-the-art numerical shock physics code, iSALE, which includes both recent equation-of-state (EOS) models and various constitutive models. The Hayabusa2 spacecraft is planning to return to Earth with Ryugu samples in 2020. The revised table would largely help to reproduce the impact history of Ryugu.

In the presentation, we will introduce the work done by Kurosawa and Genda (2018) using the iSALE-2D model and will present some preliminary results from the three-dimensional (3D) model. We newly investigated the effects of impact obliquity using iSALE-3D. As a preliminary result, the enhancement of the impact heating in strength-supported media at oblique impacts becomes larger than the case at vertical impacts to the tangent plane. Although it is widely accepted that the degree of heating correlates well with the vertical component of the impact velocity, our preliminary results show that oblique impacts (45-degrees) produce nearly the same amount of heated volume as vertical impacts do. We are also going to discuss the strategy for reproducting Ryugu’ s impact history.

Global Thermal Inertia and Surface Roughness of Asteroid 162173 Ryugu by TIR on Hayabusa2

*Yuri Shimaki[1], Hiroki Senshu[2], Naoya Sakatani[1], Tatsuaki Okada[1,3], Tetsuya Fukuhara[4], Satoshi Tanaka[1], Makoto Taguchi[4], Takehiko Arai[5], Hirohide Demura[6], Yoshiko Ogawa[6], Kentaro Suko[6], Tomohiko Sekiguchi[7], Toru Kouyama[8], Jun Takita[9], Tsuneo Matsunaga[10], Takeshi Imamura[3], Takehiko Wada[1], Sunao Hasegawa[1]

National Institute for Environmental Studies

Thermal infrared imager TIR onboard the Hayabusa2 spacecraft acquired thermal images of the asteroid 162173 Ryugu for one asteroid rotation during Mid-altitude operation on August 1, 2018, with around 5 m/pixel resolution. The thermal images were converted to brightness temperature maps on a shape model based on the ground tests, then temperature profiles of the surface of Ryugu were obtained. For comparison, thermal calculations by a thermophysical model without roughness using the shape model (TPM1) and by one with roughness using fractal rough surfaces (TPM2) were carried out.

Thermal images by TIR reveled that the surface of Ryugu showed ubiquitously high temperature above 300 K, and its temperature profile showed flat pattern at noon. Thermal calculations by TPM1 did not reproduce observed temperature profiles. By comparing maximum temperatures by TIR with those by TPM1, thermal inertia of Ryugu was estimated to be around 160 in MKS unit and reached maximum at the equatorial ridge. By contrast, thermal calculations by TPM2 successfully created flat temperature profile at noon for various thermal inertia and surface roughness. The temperature profiles were fitted by 4-order function to characterize its pattern. A multi linear regression analysis was carried out to estimate thermal inertia and surface roughness from the fitting coefficients. From the regression equations and fitting coefficients by observed temperature profiles, thermal inertia and surface roughness of Ryugu were estimated. Since the estimation is strongly affected by surface tilt angle of a polygon on a shape model, we carried out tilt angle corrections. Finally, thermal inertia of Ryugu by TPM2 was estimated to be around 330 in MKS unit and showed little variation in latitude, and with moderate homogeneous surface roughness. Thermal inertia of Ryugu determined in this study by two TPMs are consistent with that determined by ground observations. Our results suggest that thermal inertia of Ryugu is consistent with that of boulders, indicating porous nature of the boulders widely distributed on Ryugu.

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Olivier Barnouin(Johns Hopkins University Applied Physics Laboratory)

In June 2018, the Hayabusa 2 spacecraft arrived at the target asteroid Ryugu after three and half years journey. In addition, another spacecraft, OSIRIS-REx will soon arrive at its destination Bennu. With these arrivals, the solar system research is about to enter a new era. We have organized this small bodies session since 2012 and had a broad range of discussions from viewpoints of laboratory experiments, observations, space explorations, theoretical modeling, and sample analyses. In particular, this time, we aim to hold this session to bring the latest research on solar system small bodies, focusing on the initial results of Hayabusa 2 and OSIRIS-REx. Presentations in the related fields other than these two asteroidal missions are also welcomed.

JAXA’s Hayabusa2 has conducted global observations of Ryugu and revealed many important properties of Ryugu, such as Cb-type average spectrum, the lack of a strong 0.7-um absorption, very low 0.55-um geometric albedo (4.5+/-0.2) %, and very young (< a few Myr) crater retention age for small craters (>10m).

The Cb-type spectrum of Ryugu is consistent with Eulalia and Polana families in the inner main belt, which are dynamically most probable source families. This agreement between the prediction from dynamic calculations and spectral observations suggests that one of the two asteroids is likely Ryugu’s parent body. These families are among the most widely dispersed C-complex families in the inner main belt, allowing to deliver family members at very high flux rate to the resonance zones (nue6 and 3:1) at both inner and outer boundaries of the inner main belt, which are the dominant source of near-Earth objects (NEOs).

Furthermore, high abundance of boulders are found on Ryugu. Evidence for mass wasting indicates mechanically unconsolidated surfaces, allowing surface boulders to move easily. The morphologies of impact craters on Ryugu are consistent with gravity-regime formation, in which impact events produce large ejecta masses. These suggest that large mass of boulders and pebbles can be ejected from Ryugu to space over time.

Consequently, a large mass of Ryugu-like macroscopic objects would enter Earth’s atmosphere, suggesting the presence of counterparts in our meteorite collection. Among such candidates is moderately dehydrated carbonaceous chondrites, which have both very low albedo and flat spectra. They are also found with high abundance in Antarctica, which may represent the long-term average flux of infalling meteorites on Earth. Another is interplanetary dust particles (IDPs), which also have low albedos and account for large influx of extraterrestrial materials to Earth. Although a decisive conclusion may not be obtained before the analysis of Ryugu samples returned to Earth, currently available observational evidence, such as high boulder abundance on Ryugu, favors that its composition may be similar to moderately dehydrated carbonaceous chondrites. This would further suggest that Ryugu’s relatively low abundance of hydrated minerals may be due to partial dehydration on Ryugu’s parent body.

The Hayabusa2 has acquired the high-resolution images and spectra of the Ryugu surface. Although the Ryugu surface has almost homogeneous reflectance and color at the macro scale, the regional variation in the spectral slope is observed by the telescopic optical navigation camera (ONC-T). The redder materials of the Ryugu surface seem to cover bluer materials. Some small craters excavate the red materials on the surface and penetrate the underlying blue materials, suggesting that the craters are younger than the reddening of the surface (space weathering or deposition of red materials). In this study, we performed the crater size-frequency measurements on the Ryugu surface using the ONC image data to constrain the surface age of the Ryugu and the age of reddening event or the timescale of reddening process of the Ryugu surface.

To identify the craters excavating the red materials we used the b-x slope images calculated from multi-band images obtained in the Mid-altitude operation. We identified 15 craters excavating the red materials. These craters have diameters from 10 to 50 m, suggesting that the thickness of the red material layer is less than 1 m.

The cratering chronology models of asteroids have been numerically calculated from the collision rate with other asteroids and scaling laws for crater formation. In this study, we used the intrinsic collision probabilities Pi for the main belt and the NEAs, the population models of the main belt asteroids and NEAs, the mean impact velocities for the main belt (5.3 km/s) and the NEAs (18 km/s), and the new Pi–scaling law developed by Tatsumi and Sugita to develop the cratering chronology model of Ryugu. Because little is known about the bulk strength of materials on Ryugu, we examined two cases (i) the strengthless target (Y = 0 MPa) and (ii) the strength for dry soil (Y = 0.18 MPa).

The density of large craters (D>100 m) on Ryugu is lower than the empirical saturation level and its slope is steeper than that of the saturated distribution, suggesting that craters larger than 100 m are not saturated and the size distribution reflects the crater production function. However, craters smaller than 100 m are significantly under-saturated, suggesting that some crater erasure processes such as seismic shaking and armoring effect are active on the Ryugu surface. Based on cratering chronology model for the main belt, the surface age of Ryugu is estimated to be 5–200 Ma from the size–frequency distribution of craters larger than 100 m.

The observed frequency of craters penetrating the underlying blue materials is ~1/50 of that of craters found on the whole Ryugu. The model age of the reddening is estimated to be 0.1–4 Ma based on the main-belt chronology model and 4–160 Ma based on the NEA chronology model. The NEA model age is roughly close to the median dynamical lifetime of NEAs (~10 Ma), suggesting that the reddening of the Ryugu surface may have some connect with the orbital transition from the main belt to near Earth orbit.

Chiba Institute of Technology, 11. Brown University, 12. Paris Observatory, 13. INAF, 14. Planetary Science Institute, 15. National Institute of Advanced Industrial Science and Technology

Preliminary result of global distribution of visible spectra of asteroid Ryugu derived from multi-band images obtained by ONC-T onboard Hayabuasa 2 is presented.
The ONC-T is a telescopic charge-coupled-device (CCD) camera with a 6.27˚ ×6.27˚ field of view (FOV) , having a 1024 pixels x 1024 pixels sensor and seven narrow band filters ranging from 395nm and 950nm and one wide-band filter. Images obtained by ONC-T are spatially aligned and converted into seven-band visible spectra (reflectance factor).

The spectra are clustered, and the obtained cluster id are shown on the global map. As the method of clustering, k-means++, x-means, gaussian mixture model via EM are tested for synthetized data and x-means is selected since this method is stable to obtain a suitable number of components.

The obtained spectra are divided into seven to nine groups depending the slope of the spectra. Flat spectrum group is distributed around the equatorial ridge, the redder and darker groups are in the southern hemisphere and the relatively bright and bluer spectra are observed at the polar region, in particular at Otohime Saxum. The distribution of these spectra groups appears to indicate the surface history such as space weathering and erosion and the supply from different sources.

Visible spectra of small bright spots on asteroid 162173 Ryugu

*Chiho Sugimoto[1], Eri Tatsumi[1], Yuichiro Cho[1], Kazuo Yoshioka[1], Hirotaka Sawada[2], Yasuhiro Yokota[2], Naoya Sakatani[2], Masahiko Hayakawa[2], Moe Matsuoka[2], Rie Honda[3], Tomokatsu Morota[4], Shingo Kameda[5], Manabu Yamada[6], Toru Kouyama[7], Hidehiko Suzuki[8], Chikatoshi Honda[9], Kazunori Ogawa[10], Deborah Domingue[11], Patrick Michel[12], Seiji Sugita[1]

1. University of Tokyo, 2. JAXA/ISAS, 3. Kochi University, 4. Nagoya University, 5. Rikkyo University, 6. Chiba Institute of Technology, 7. AIST, 8. Meiji University, 9. University of Aizu, 10. Kobe University, 11. Planetary Science Institute, 12. Nice Observatory

The Optical Navigation Camera (ONC) onboard the Hayabusa2 spacecraft has obversed asteroid 162173 Ryugu at various scales and found that Ryugu has a uniform spectrum in km-scale and that boulders exhibit a range of albedo (0.89 −1.3 times of the surface average) and spectra [1]. Higher resolution images taken during descent operations revealed the presence of bright spots, which are typically much brighter than the brightest large boulders. Brightness variation may reflect differences in composition, thermal alteration, or space weathering maturity. Such materials would follow spectral trends seen on other materials on Ryugu. In fact, brightest boulders are the end-members in reflectance/slope statistics and Principal Component Analysis (PCA) of boulders on Ryugu. If bright spots are fragments of the parent body at the origin of Ryugu, they may correspond to the fresher components of the boulder population constituting Ryugu, contributing to the spectral variety observed on the asteroid. In contrast, it is also possible that Ryugu contains materials of exogenous origin. In that case, the spectra of bright spots should not follow the spectral trends observed for other materials on Ryugu and should rather be consistent with the spectra of asteroids found in the inner main belt. In either case, bright spots will help us place important constraints on to the formation and evolution of Ryugu.

In this study, we analyzed the brightest spots whose reflectance is ≧ 1.7 times the reflectance global average. The dimensions of these sports are very small: ≦ 3 m. The spectra of these brightest spots were extracted from I/F images taken at altitudes of Hayabusa2 between 100 and 500 m (i.e., low-altitude descent observations) and 3 −4 km (hovering operation after MASCOT deployment) and were compared with meteorite spectra. As for low altitude images, we conducted a photometric correction because the rotation of Ryugu results in a several degrees phase angle gap between different filters. The spectra of meteorites include 250 carbonaceous chondrite spectra and 106 ordinary chondrite spectra from RELAB of Brown University and they are linearly interpolated to match the bands of ONC-T [2]. We searched for meteorite spectrum that gives minimum residual sum of squares (RSS) of spectra among the 356 samples.

Analysis results indicate that 5 out of 10 bright spots have spectra consistent with carbonaceous chondrites (CC), such as CM2 and CV3, and that the other half are consistent with ordinary chondrite (OC) such as LL6. Some of CC-like bright spot spectra are very similar to that of type3 (bright and molted) boulders found in [1], which was one of the end-members in reflectance/slope statistics and PCA of boulders. This suggests that these bright spots can be new members of this boulder group.

Because Ryugu most likely comes from the inner main bet, OC-like bright spots are consistent with exogenous origin. Preliminary results indicate that two types of spectra are present. One has a spectral peak at v-band (centered at 0.55 micron) and the other has a peak at w-band (0.86 micron). If this spectral variation is large enough to require the delivery of meteoritic materials from asteroids, it would reflect the variety in composition among many projectiles that collided with Ryugu after its formation. In

©2019. Japan Geoscience Union. All Right Reserved.

contrast, if the shift in spectral peak is consistent with spectral modification mechanisms within a large OC-like projectile, such as thermal metamorphism, these bright spots could be remnants of one projectile only. In either case, however, because the average impact velocity in the main belt is very high ~5km/s [3], the fact that we may observe remnants of projectiles impacting at such speeds on the surface of Ryugu has strong implications in our understanding of the impact process and in our interpretation of the compositional heterogeneity of small bodies and meteorites.

Geomorphological characteristics of asteroid Ryugu: implications to its evolutional history

Observations by Hayabusa 2 spacecraft indicate that Ryugu is a highly porous C-type asteroid. Ryugu’s surface is covered by numerous boulders. These are consistent with the idea that Ryugu is a rubble-pile asteroid. Interestingly, Itokawa, the only other similarly-sized rubble-pile asteroid closely observed by spacecraft, is different from Ryugu in many aspects. For example, while the shape of Ryugu is a top-shape, that of Itokawa is somehow elongated cigar-like. Though Ryugu is generally homogeneous in terms of roughness, Itokawa has two distinctive areas such as smooth and rough terrains. Ryugu has an almost continuous equatorial ridge, though Itokawa does not have such a large-scale topographic feature.

These differences may come from the difference in evolutional processes; a top-shape of rubble pile asteroid is believed to result of rotationally induced deformation or from re-accumulation. Another possibility is that the differences may come from variations in mechanical properties of asteroid forming materials. We are investigating geological characteristics of Ryugu, which may hold clues for these aspects. In this talk, we report initial results of geological investigations mostly using visible images obtained by the Optical Navigation Camera (ONC) onboard the Hayabusa2 spacecraft, and discuss about their implications to evolutional history of Ryugu..

The spacecraft Hayabusa2 arrived at a C-type asteroid Ryugu on June 27, 2018 and is currently conducting both global and high-resolution observations. These observations have revealed that Ryugu has a very high abundance of boulders; the number density of boulders >20m in diameter is about twice that on Itokawa. However, the sizes of boulders detected in global and regional observations are limited to several to ten meters because the image resolution is 0.5 –2 m in these observations.

In this study, in order to push the limits of boulder detetion, we developed a method that automatically evaluates the abundance of small boulders (sub-pixel to a few pixels in diameter) and applied it to both Ryugu and Itokawa.

The analysis results show that Ryugu has a relatively uniform distribution of boulders over its globe. More specifically, both the power-law index and the coefficient for the boulder cumulative size frequency distribution are very uniform over the entire surface. The power-law index average is -2.53 and the standard deviation due to regional scatter is 0.03 over the globe for boulders > 75 cm. This power-law index is consistent with the result (-2.65 ±0.05) of visual counting for boulders > 5 m [Michikami et al. 2019]. In contrast, Itokawa has a very heterogeneous boulder distribution. The power-law index average is -3.6, and the standard deviation due to regional scatter is 0.83 over the globe. This large regional variation of boulder size distribution on Itokawa strongly suggests the presence of size sorting on its surface, which may be induced by granular convection [Miyamoto et al. 2007].

More detailed analysis has revealed a large variation in boulder number density in both longitudinal and latitudinal directions. In the longitudinal direction, dichotomic contrast in boulder abundance is seen. The boulder density of the eastern hemisphere is ~1.4 times higher than that of the western hemisphere. A similar dichotomic pattern is seen in crater number density [Cho et al. 2019 LPSC] and v-band albedo distribution [Sugita et al. 2019]. Furthermore, the boulder number density is the lowest in troughs surrounding the western hemisphere. The troughs are bluer in the visible wavelengths, similar to the equatorial ridge and polar regions, where newer surfaces are expected to be exposed because of their high geopotential. These lines of evidence suggest that the western hemisphere may be separated from the eastern hemisphere by high mobility zones.

Global observations have revealed that Ryugu exhibits a small but significant latitudinal size sorting in boulders; a larger number of boulders is found at higher latitudes [Sugita et al. 2019]. Our new analysis found a more detailed trend in latitudinal direction. The top of the equatorial ridge exhibits a higher boulder number density, and both southern and northern slopes of the ridge have lower boulder density.

©2019. Japan Geoscience Union. All Right Reserved.

This trend is opposite from the general trend from the equator to the poles and is more pronounced in the eastern hemisphere. We found a significant correlation (R ~ -0.73) between the boulder abundance and the topographic slope with respect to the geopotential. This suggests that the observed boulder distribution is controlled by the current geopotential and not by the paleo-geopotential during a possible past high-spin-rate era.

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Masanao Abe(Institute of Space and Astronautical Science, JAXA)

In June 2018, the Hayabusa 2 spacecraft arrived at the target asteroid Ryugu after three and half years journey. In addition, another spacecraft, OSIRIS-REx will soon arrive at its destination Bennu. With these arrivals, the solar system research is about to enter a new era. We have organized this small bodies session since 2012 and had a broad range of discussions from viewpoints of laboratory experiments, observations, space explorations, theoretical modeling, and sample analyses. In particular, this time, we aim to hold this session to bring the latest research on solar system small bodies, focusing on the initial results of Hayabusa 2 and OSIRIS-REx. Presentations in the related fields other than these two asteroidal missions are also welcomed.

Hayabusa2 is the second sample return mission from an asteroid after Hayabusa which visited an S-type asteroid Itokawa. The target asteroid of Hayabusa2 is (162173)Ryugu (1999 JU3),which is a C-type asteroid. Since June 2018, Hayabusa2 observed Ryugu including several low altitude operations, where three surface rovers (MINERVA IIA, IIB, MASCOT) have been deployed successfully.

ONC(Optical Navigation Camera) on board Hayabusa2 captured tantalizing features of 162173 Ryugu, which is a top-shaped dark body with overall visible albedo is 4.6% and photometry standard reflectance is lower than 2%. Color Vis-NIR spectra are flat with little variation (close to B-Cb type, darker). Ryugu would be composed of dark CM meteorite.

Brightness Variation: There are brightness (and associated color u/v bands) variations on the surface. Ryugu’s surface is covered with numerous boulders/rocks whose number density is about twice as large as that of Itokawa. Bright, large boulders are on polar regions and smaller ones with similar brightness are scattered globally. Otohime Saxum is the largest boulder (~180m) on Ryugu; it has bright (and blue) smooth surface and darker surface. Around Otomime Saxum, there observed smooth bright boulders and dark rugged boulders.

The equatorial ridge (Ryujin Dorsum) and some of undulated crater rim zones are brighter. In high-resolution images, Ryugu‘s surface is covered with darker regolith materials (with various size particles >cm) that would cover and bury boulders. Ridge/crater brightness can be ascribed to movement of fine darker materials to potentially lower region, or to abundant brighter fragments. Bright crater rims could be explained by the former process, whereas Ryujin brightness could be also explained by the latter process.

©2019. Japan Geoscience Union. All Right Reserved.

The distinct characteristics of brighter and darker boulders are scale-invariant on Ryugu’ s surface. show brighter boulders with smooth and layered surface and darker boulders with rough (rugged/crumbling) surface. High resolution images obtained by MINERVA-II and MASCOT confirmed the characteristics of bright and dark rocks; MASCOT suggested the existence of bright rugged rocks. We do not observe pond-like deposits of relatively similar size grains as we saw on Eros and Itokawa.

Space Weathering: The brightness/color difference may not be due to compositional variation but to the differences of space weathering maturity. Usually bright boulders are a few 10 % brighter than dark boulders and regolith. Sometimes it is 50% and more brighter. We found the evidence that the interior of a dark small rock is 4 times brighter in v-band (550nm). It should be noted that (bi-directional) reflectance of the bright interior is about 8% (~4 x 2%) and still in the range of CM.

The darker boulders with rough (rugged/crumbling) surface, which would have experienced longer exposure and thus more erosion and weathering. Probably the darkening timescale is so short that usual brightness difference is smaller than a few 10 %.

Breccia A lot of rocks on Ryugu show brecciated structure with brightness variation. The breccia formation would take place by impacts on Ryugu’ s parent body, where the layered structure of boulders would be also formed.

Meridional Cracks: High resolution images show that more than 10 boulders/rocks have a crack in the meridional direction (north –south) on Ryugu. The size range of cracked rocks is a few 10cm to 10m. Boulders with a crack in the meridional direction suggest that thermal stress would play a role in the boulder disruption. Thermal fatigue is an advocated process where difference of thermal properties among minerals should cause disintegration of rocks and it is effective in a smaller scale. Actually thermal timescale of diurnal temperature change is as small as or smaller than 10cm.

In the terrestrial desert area, however, meridional fractures are frequently observed on rocks. Since Ryugu has a large orbital eccentricity 0.19, annual temperature change might bring about thermal stress in longer length scales.

Figure: Rocks with a crack in the meridional direction.

In LIDAR topography data, 3 circular depressions are recognized near the equatorial bulge. All of these circular depressions are identified as craters and have been given names approved by IAU, namely Urashima, Kolobok, and Brabo craters. After careful calibration for different passes, consistent and precise cross sections of the craters are derived.

For Urashima crater, topography data of 4 passes are merged. Because these passes are taken in different days of operation, altitude of the spacecraft and sampling rate vary widely from 6 to 21 km and from 1/32 Hz to 1 Hz, respectively. Nonetheless, the cross sections show a good match. Similarly, three passes are merged for Kolobok and Brabo craters, and the match among different passes is very good for these craters, too, except for topography over large boulders.

Depth-to-diameter ratios (d/D) of Urashima, Kolobok, and Brabo craters are 0.2, 0.14, and 0.155, respectively, and are consistent with previous in situ observations of asteroid topography, while there seems marked difference from craters on Itokawa and Bennu. Both Itokawa and Bennu are comparable in size and surface gravity to Ryugu, and these 3 asteroids are regarded as rubble pile bodies. On the contrary, the d/D of Itokawa craters, 0.08 +- 0.03, is significantly shallower than that of Ryugu and other asteroids. The d/D of Bennu is apparently shallower, too. In addition, craters on Ryugu have topographically distinctive raised rim while those on Itokawa do not.

The low d/D of Itokawa is regarded as a result of either an influence of curvature of small body, a lack of raised rim, or fine grains infilling the craters, but has been unsolved. On the other hand, craters of Mathilde have characteristics much alike to those on Ryugu; the d/D ranging from 0.12 to 0.25, prominent raised rim, and a lack of ejecta blanket. While Mathilde is 50 times larger than Ryugu, the bulk density of Mathilde is only 1.34 +- 0.2 g cm^{-3}. Such low density is likely suggesting that Mathilde is as porous as 50 %.

The shapes of the four craters are neither bowl-shaped like 951 Gaspra and Eros nor flat like Itokawa. It is notable that slopes of inner wall of Ryugu craters are linear rather than paraboloidal, and that Kolobok and Brabo craters are flat-bottomed. 3D topography model of Urashima crater shows a central cavity on Urashima crater indicating an agreement with impact cratering experiments into porous targets, while the d/D of Ryugu crates is lower than experimental results which is between 0.2 and 0.5. It is interesting that slopes of the 3 craters are almost identical. Such nearly identical conical shape indicates that either the crater shape is well relaxed, or in the contrary, is holding initial shape.

©2019. Japan Geoscience Union. All Right Reserved.

The slopes of inner walls are measured with respect to local gravity estimated by taking GM of 30.0 m^3 s^{-2} and assuming a constant density inside of Ryugu. The mode of the slopes of inner wall of Urahisma, Kolobok, and Breabo craters are between 16 and 20 degrees, 7 and 15 degrees, 16 and 18 degrees, respectively. The mode of slopes is shallower than the repose angle of regolith which is between 30 and 35 degrees. The shallow slopes and flat bottom may indicate that morphology of Ryugu craters is sufficiently relaxed. However, preservation of entire conical shape as well as central cavity of Urashima crater instead suggest that modification of crater topography on Ryugu is limited volumetrically and is less effective than Itokawa.

Observation of 1064 nm normal albedo around equator of the Ryugu using the Hayabusa2 LIDAR

*Ryuhei Yamada[1], Keiko Yamamoto[2], Hiroshi Araki[2], Hirotomo Noda[2], Hiroki Senshu[3], Noriyuki Namiki[2], Koji Matsumoto[2], Fumi Yoshida[3], Shinsuke Abe[4], Naru Hirata[1]

In June 2018, the Japanese asteroid explore Hayabusa2 has arrived to C-type asteroid 162173 Ryugu after three and half years journey. The Hayabusa2 has the laser altimeter (light detection and ranging: LIDAR) for navigation of the spacecraft and scientific uses. The main purpose of the LIDAR is to measure the distance between the spacecraft and the asteroid using time delay between the transmission and reception of the laser. In addition, the Hayabusa2 LIDAR has the function of measuring the intensities of a transmitted laser pulse and received laser pulse reflected from the asteroid surface. In this study, we have derived the normal albedo of the Ryugu at the laser wavelength of 1064 nm using the intensity data. The observation of normal albedo using the LIDAR has never been performed on C-type asteroid. Our observation will provide first knowledge of normal albedo variation at 1064 nm on C-type asteroid.

Usually, the Hayabusa2 spacecraft stands at home position (altitude of 20 km) and the intensity and ranging data are obtained with 1/32 Hz. As special operation, the spacecraft moves to latitudinal and longitudinal direction or descend to low altitude. Then, the LIDAR data are sampled at 1Hz. For analysis of normal albedo, we have selected the data obtained in altitude lower than 7 km. The size of the footprint become smaller with descent of the spacecraft, and mapping resolution is higher. Then, less size of footprint is effective to reduce effect of the surface terrain on the LIDAR return pulse. We have applied the data obtained at July 20, August 1, 6, 7, September 11, 20, 21, October 2, 3, 4, 15, 24, 31 and November 1, 2018 for normal albedo analysis. In these days, the spacecraft has been operated at low altitude, for example, rehearsal of touchdown for sample sampling has been performed in October 15 and 24. From the selected data, we have derived the normal albedo around equator of the Ryugu in range of about 10 degrees in latitude. The total data number is 37,5151.

For calculation of normal albedo, we applied some reflectance models; they are the Lambert, the Lommel-Seeliger and the Oren-Nayar models. The intensity of the reflected pulse calculated by the Oren-Nayar model depends on the applied value of roughness () in degree. We have applied 9 Oren-Nayar model changing the roughness from 10 to 90 degrees with interval of 10 degrees. On a footprint, 11 types of normal albedo have calculated for 11 reflectance models, respectively.

Firstly, we have found that the derived values of the 1064 nm normal albedo are different for each model. The lowest albedo is derived for the Lommel-Seeliger model, and the highest albedo is derived for the Oren-Nayar model with roughness of 90 degrees. Secondary, it has been found that values of normal albedo depend on the incident angle of the laser pulse for some reflectance models. Especially, the normal albedo using the Lambert model are evidently higher with increase in incident angle at many areas

©2019. Japan Geoscience Union. All Right Reserved.

around the equator. This is impossible phenomena for real material as rocks, and this means the Lambert model is inappropriate to represent reflectance of a lot of areas on the Ryugu. Therefore, we have investigated relation between the normal albedo and incident angle in each grid with resolution of 5 5 degrees. In the investigation, slope of normal albedo for incident angle were derived for 11 reflectance models in each grid, and the model which have the smallest slope would be appropriate in the area. From the results, we found that the Lommel-Seeliger model is dominant around equator of the Ryugu. When we apply the Lommel-Seeliger model, the average of normal albedo in the equator area is 0.042, and the deviation is 9.0 %. It corresponds to typical albedo of C-type asteroid (0.03-0.06) observed by ground telescope. In this presentation, we will also discuss regionality of the normal albedo on Ryugu and relation with surface terrain.

Improved Trajectory of Hayabusa2 by Combining LIDAR Data and a Shape Model

*Koji Matsumoto[1], Hirotomo Noda[1], Yoshiaki Ishihara[2], Hiroki Senshu[3], Keiko Yamamoto[1], Naru Hirata[4], Naoyuki Hirata[5], Noriyuki Namiki[1], Toshimichi Otsubo[6], Sei-ichiro WATANABE[7], Takahide Mizuno[8], Yukio Yamamoto[8], Hitoshi Ikeda[8], Naoko Ogawa[8], Shota Kikuchi[8], Takanao Saiki[8], Yuichi Tsuda[8]

1. RISE Project, National Astronomical Observatory of Japan, 2. National Institute for Environmental Studie, 3. Chiba Institute of Technology, 4. The University of Aizu, 5. Kobe University, 6. Hitotsubashi University, 7. Nagoya University, 8. JAXA

Hayabusa2 spacecraft successfully arrived at the target C-type asteroid 162173 Ryugu on 27 June, 2018, with its “home position” being about 20 km above the sub-Earth point. Soon after arrival, Hayabusa2’s remote sensing instruments started near-global observations. Because map products from these instruments depend on the spacecraft position with respect to the asteroid, it is necessary to provide precise spacecraft trajectory in a timely manner. The basic idea is to find a trajectory correction which makes “LIDAR-derived topography” fit to the reference shape model. The LIDAR-derived topography is, in other words, a sequence of LIDAR footprint positions expressed in asteroid-centered body-fixed rotating frame. The footprints can be computed by using the following information; spacecraft position with respect to the asteroid, spacecraft attitude, LIDAR range, rotational information of the asteroid (orientation and spin period). If all the information above was perfect, the collective footprints would delineate the shape of the asteroid. In reality, however, there are various errors affecting the footprint positions, among which the largest is generally the trajectory error, making the resultant LIDAR footprints deviate from the shape model. We call the deviation as residual. A shape model constructed by stereo photoclinometry (SPC) method is used as reference. We obtain trajectory correction by minimizing the residuals with polynomial functions. We made use of Markov chain Monte Carlo (MCMC) algorithm to explore better parameters. We compared the LIDAR-corrected trajectory with camera positions that are determined through SPC shape modeling. The two estimates agree with each other within about 40 m on 10 July 2018, and 20 m on 20 July 2018. LIDAR-derived topography with such an improved trajectory can be used for analysis of boulder height, crater shape, surface roughness, etc.

Hayabusa2 spacecraft had launched in Dec. 2014 and reached the C-type asteroid Ryugu in June 2018 [1]. It has been observing the asteroid with a series of remote-sensing instruments and plans to perform the first touchdown for sampling at the beginning of this year [1, 2]. It will depart from the asteroid at the end of 2019, and return its re-entry capsule encapsulating Ryugu's surface samples back to the Earth at the end of 2020 [1, 2].

In parallel with the spacecraft operation, JAXA has been preparing for the curation of the samples returned from the asteroid. A new class-1000 clean room for Hayabusa2-returned Ryugu samples was established in Sept. 2017. Installation of newly developed sample-handling clean chamber system (CCs) was accomplished by last Oct. The entire sample-handling system consists of five chambers (CC3-1, CC3-2, CC3-3, CC4-1 and CC4-2).

Because C-type asteroids are likely to be parent bodies of hydrated carbonaceous chondrites [3], volatile components such as water and organic matter are one of essential science target for sample analysis [4]. To return volatile-containing samples without contamination of terrestrial volatiles, a new metal sealing system was developed for the Hayabusa2 sample container [5, 6]. Although the sealing system using double Viton O-rings for the Hayabusa container could not prevent terrestrial air contamination [7], the metal sealing system can keep the air contamination less than 1 Pa for 100 hour in the air [5, 6].

After the recovery of re-entry capsule at the landing point, it will first be transferred to the quick look facility (QLC) nearby there. Following the securing processes to the capsule, the sample container will be extracted, cleaned up and connected to a gas sampling system in a clean booth to extract gaseous volatiles inside the container. After the gaseous volatile recovery from the container, the container will then be delivered to the JAXA's curation facility with being kept in a nitrogen atmosphere during the travel from the QLC to Japan. Then the parts of the container which should not be introduced into the CCs will be removed in the cleanroom. Finally, the sample container will be set to the container opening system and installed into CC3-1.

The container will be opened at the CC3-1 in vacuum condition to take out the sample catcher that encapsulates Ryugu grains. The extracted sample catcher will be transferred to CC3-2. The sample catcher has three chambers for keeping samples collected at different surface locations separately [5, 6], and a lid of the chamber for samples obtained at the first sampling location will be taken apart to pick up a small fraction of grains. The picked-up samples will be kept in CC3-2 for future generations under a vacuum condition. The catcher will be transferred from the CC3-2 to CC3-3 under a vacuum condition, and then CC3-3 will be purged with purified nitrogen. The catcher will be transported to CC4-1 and CC4-2 to take out grains from three chambers of the container. As the initial description called 'phase-1' curation work under purified nitrogen environment in CCs, the grains will be weighed, observed with a stereomicroscope, and examined with visible to near-infrared spectrometers in CC3-3

and CC4-2.

Functional checks of the sample handling system and rehearsals of receiving and handling samples will be initiated in April 2019. The sample handling system will be reconditioned in early 2020 based on feedbacks from the preparation activities to be ready for the sample return in late 2020.

Analysis of the grain from the asteroid Ryugu proposed by the Phase 2 curation “Team KOCHI”

*Motoo Ito[1], Naotaka Tomioka[1], Masayuki Uesugi[2], Kentaro Uesugi[2], Ohigashi Takuji[3], Akira Yamaguchi[4], Naoya Imae[4], Yuzuru Karouji[5], Naoki Shirai[6], Toru Yada[5], Masanao Abe[5]

1. Kochi Institute for Core Sample Research, JAMSTEC, 2. JASRI, 3. UVSOR Synchrotron Facility, Institute for Molecular Science, 4. National Institute Polar Research, 5. JAXA, 6. Tokyo Metropolitan University

Returned samples from asteroids and comets have provided unique characteristics to investigate their origin and nature of the Solar System [1-3]. For example, analytical studies of the S-type asteroid Itokawa by the Hayabusa mission provided new insights for the asteroid-meteorite connections, space weathering processes, small asteroidal body formation in the Solar System [e.g., 1, 3, 4]. JAXA Hayabusa2 and NASA Osiris-REx are both on-going sample return missions from the primitive asteroids, Ryugu (C-type) and Bennu (B-type), respectively [5, 6]. Both missions have complementary scientific goals that are to understand the Solar System evolution in the point of view of organics, water, and associated minerals (i.e., hydrous minerals).

Phase 2 curation teams will be acting under the scientific direction and strong ethic of the Astromaterial Science Research Group (ASRG) of JAXA and was authorized 2 institutes by the steering committee of the ASRG in 2017: (1) Kochi Institute for Core Sample Research (KOCHI), JAMSTEC in collaboration with JASRI/SPring-8, UVSOR Synchrotron Facility/National Institutes of Natural Sciences, Institute for Molecular Science, National Institute of Polar Research (NIPR) and Tokyo Metropolitan University, and (2) the Institute for Planetary Materials, Okayama University at Misasa. The JAXA Curation requested us to make an in-depth analysis of a few grains by the state-of-the-art instruments/techniques and nationwide collaborative research activities. We will conduct on analyses in parallel with the initial analysis team led by the Hayabusa2 project.

Recent reports by the Near-IR Spectrometer (NIRS3) on Hayabusa2 spacecraft presented that the asteroid Ryugu may consist of either CM chondritic materials [8] or shocked/heated carbonaceous chondrites [9]. Matsuoka et al. [9] pointed out that the low albedo of the asteroid Ryugu could be explained by a combination of C-rich material, grains size, porosity and space weathering effects on the asteroid surface materials. This implies that the avoiding terrestrial contaminations (i.e., atmospheric water/air, organics) during sample curation, transportation and analysis are important to obtain original chemical characteristics of Hayabusa2 returned samples.

We have developed novel and universal sample holders (KOCHI grid and KOCHI clamp) for a linkage analysis utilizing micro-analytical instruments of FIB, TEM, STXM and NanoSIMS minimizing terrestrial contaminations and sample lost or broken. We also made an additional sample holder (Okazaki cell) for STXM analysis (Ohigashi T. et al. in preparation), and a sample transport vessel (FFTC: facility to facility transfer container; Uesugi K. et al. in preparation) under vacuum or inert gas in parallel.

We have carried out the development of coordinated synchrotron based-CT (SPring-8) –XRD (SPring-8) –FIB (JAMSTEC KOCHI) –STXM (UVSOR Synchrotron Facility) –NanoSIMS (JAMSTEC KOCHI) –TEM (JAMSTEC KOCHI) analysis to obtain complex structure inside of the sample, light element/isotope images to obtain their spatial distributions, speciation of elements: type of bonding, chemical species, redox state and ultra-fine textural observation: mineralogy and crystallography in fine-grained mineral and

organic assemblages in few tens to hundreds of micrometer-scale Hayabusa2 samples. We, therefore, have chosen Antarctic micrometeorites provided by NIPR as analogues of Hayabusa2 sample because of their size (50 to 800 μm, as an example of small particle) and chemical characteristics.

We will report the current status, ethic and motivation of "Team KOCHI" of Phase2 Curation. In addition, we will present newly developed universal sample holders for FIB, TEM, NanoSIMS, STXM, and a sample transport vessel under vacuum or inert gas among nationwide/international universities and institutes.

The formation process of μm-sized dust grains into km-sized planetesimals in planet formation has several theories such as direct coalescence growth and concentration due to instability and has not yet been unraveled. It is difficult to verify the formation process because we cannot directly observe planetesimals forming in protoplanetary disks. Therefore, we focus on comets which are the most primitive bodies in our solar system and are thought to be leftover planetesimals. Comets are capable of detailed observation by spacecraft. In this work, we focused on the tensile strength of 67P/Churyumov-Gerasimenko, which is one of the comets in our solar system and was observed by the Rosetta mission.

In order to investigate whether or not the formation process of planetesimals can be restricted by their tensile strength, we conducted N-body simulations considering the interaction model of dust particles (Wada et al. 2007, ApJ, 661, 320) and investigated the tensile strength of porous dust aggregates. The initial dust aggregates were isotropically and statically compressed to simulate their formation process (Kataoka et al. 2013, A&A, 554, A4). As a result of our numerical simulations, we found that tensile stress gradually increases as tensile displacement increases, and then the tensile stress takes the maximum value. In other words, the tensile strength was obtained. We also confirmed that cutting of contacts between particles in the dust aggregates begins to occur near the maximum tensile stress. We obtained the relation that the tensile strength of dust aggregates is proportional to the 1.8 power of the initial volume filling factor, inversely proportional to the constituent particle radius, and proportional to the surface energy of the constituent material. Moreover, we succeeded in reproducing numerical simulation results by using a semi-analytical model that the tensile strength is determined by cutting of contacts between particles. It was also revealed that the constituent particle radius of comet 67P has to be about 3.3–220 μm to reproduce its tensile strength using our model. In the conventional planet formation theory, the constituent particle radius is assumed to be 0.1 μm same as the interstellar dust radius and is different from the value obtained from our model. It is necessary to reconsider theories such as the time evolution of the constituent particle radius.

Filling factor dependence of the thermal conductivity understood from the graph structure of dust aggregates

*Sota ARAKAWA[1], Masaki TAKEMOTO[1], Taishi NAKAMOTO[1]

1. Tokyo Institute of Technology

Previous studies (Arakawa *et al*. 2017; 2019) revealed that the thermal conductivity through the solid network of dust aggregates is proportional to the square of the filling factor. However, the reason why the thermal conductivity is given by the power-law function of the filling factor was still unclear. In order to understand the physical reason of this power-law dependence, we need to investigate the geometric structure of highly porous dust aggregates.
In this study, we study the graph structure of fractal aggregates called BCCA aggregates (e.g., Meakin 1991). The fractal dimension of BCCA aggregates is approximately 1.9 (e.g., Okuzumi *et al.* 2009) and the graph structure of BCCA aggregates is classified as a tree. Then the gyration radius r_g and the filling factor ϕ is connected by the following equation, $r_g \simeq \phi^{-1/(3-1.9)}$, and the number of the heat conduction path per unit area, σ, is given by $\sigma \simeq \phi^{2/(3-1.9)}$ for BCCA aggregates. In addition, we calculated the graph-theoretical distances of monomer grains within a BCCA aggregate. We found that the root mean square of the graph-theoretical distance d is given by $d \simeq r_g^{1.2}$. Therefore, the thermal conductivity of BCCA aggregates is proportional to $\sigma r_g / d \simeq \phi^2$.

Collisional disruption of planetesimals: dependence of material strength

*Ryo Suetsugu[1], Hidekazu Tanaka[2], Hiroshi Kobayashi[3], Hidenori Genda[4]

1. University of Occupational and Environmental Health, 2. Tohoku University, 3. Nagoya University, 4. Tokyo Institute of Technology

Collisions are one of the most important processes in planet formation because planetary bodies in the Solar System are thought to have experienced a lot of collisions during the accretion process. Thus, collisional processes have been examined extensively. Roughly speaking, collisional outcomes can be classified into disruptive collisions and erosive collisions by the specific impact energy Q_R. In particular, the specific impact energy required to disperse the largest body such that it has exactly half its total mass after the collision is called the critical specific impact energy Q_{RD}^*. In the case of $Q_R > Q_{RD}^*$, collisions between planetesimals are regarded as disruptive collisions, while they are non-disruptive collisions for $Q_R << Q_{RD}^*$, whose mass ejection is small. The values of Q_{RD}^* have been investigated by laboratory experiments and numerical simulations. When the target is small enough to neglect the effect of the target's gravity, the critical specific impact energy is mainly estimated by laboratory experiments. As target size increases, collision outcomes gradually become dominated by the gravity of the target. However, direct experimental measurements of a large scale collision are difficult to carry out in the laboratory. Thus, the values of Q_{RD}^* for large targets are estimated via shock-physics code calculations, which compute the propagation of the shock wave caused by a high velocity collision: Lagrangian hydrocode such as Smoothed Particle Hydrodynamics (SPH) methods, or a hybrid code of Eulerian hydrocode and N-body. These numerical simulations showed the dependence of the value of Q_{RD}^* on various impact conditions such as target size, impact velocity, material properties, impact angle, and numerical resolution. Recently, we performed impact simulation using the grid-based code (iSALE) in the gravity regime, because almost all high velocity collisions have been examined by the SPH method. We showed that collision outcomes of the iSALE simulation agree well with those of the SPH simulation.
As mentioned above, material properties of the target affect collisional outcomes. However, the dependence of Q_{RD}^* on material properties was not studied in detail. In this study, we perform impact simulations in the gravity regime by using shock-physics code, iSALE. We will discuss the dependence of Q_{RD}^* on material properties and impact conditions for a wide range of specific impact energy, and compare our results with previous studies.

Size and cooling rate of chondrules formed thorough collision between planetesimals containing volatile materials

*Sin-iti Sirono[1]

1. Department of Earth and Planetary Sciences, Nagoya University

Chondrite meteorite contains "chondrules", which are silicate spheres with sizes of 0.1-2 mm. Volume fraction of chondrules exceeds 80% in some chondrites. Its shape and high fraction indicate that chondrules were formed through common heating event in the solar nebula. Cooling rate of chondule has been estimated as 10-1000 K/h from laboratory experiments. The size and cooling rate are the most important quantities which characterize chondrules. Although many models have been proposed, the parameter range suitable for chondrule formation is limited in most models.

Collision of planetesimals has been studied as a chondrule forming mechanism. It requires high velocity collision > km/s which is difficult to attain in the solar nebula. However, the formation of Jupiter can excite the motion of planetesimals. Nagasawa et al. (2019) showed that the impact velocity between planetesimals can exceed 10 km/s due to the exitation. Moreover, the age of chondrules ranges between 1 and 3 Myr after CAI. This is consistent to the timing of Jupiter fomation and duration of excited motion of planetesimals.

In order to form chondrules of 0.1-2mm size, high gas dynamic pressure is necessary. The gas in the solar nebula is too rare to breakup silicate melt down to the size range. If a colliding plantesimal contains volatile materials, they evapolate quickly and expand because of the collisional heating. The velocity difference between silicate melt and gas can lead to breakup of silicate melt. The size of melt droplet is determined by Weber number, which is a ratio between gas dynamic pressure and surface tension. I conducted 1-D numerical simulation of expansion of gas-melt mixture. The simluation parameters are the thickness of the mixture L, mass fraction of volatile materials f, and initial temperature $T_{0.}$ I adopted physical parameters of H_2O, and ideal gas is assumed for simplicity.

Figure shows typical evolution of temperatrure. The temperature of the mixture decreases by the expansion of the gas. In this case, the cooling rate is ~1000 K/h. I conducted simluations with various parameter sets. The range of droplet size is 0.3-2mm. Cooling rate is 100-10000 K/h. These ranges are consistent to those of chondrules.

It is possible that the volatile material is not water but organics. If this is the case, the gas is reducing and Fe becomes Fe metal, not FeO. Then the variation of oxidation condition of Fe can explain by the variation of volatile materials. Moreover, if the inside of a planetesimal is melted due to heating by ^{26}Al, Fe migrates to the center of a planetesimal and avoid collision. Then the variation of Fe content (seen as H, L, LL chondrites) can be explained by the internal melting of a planetesimal.

From Dust to Planet via collisional growth

*Hiroshi Kobayashi[1], Hidekazu Tanaka[2]

1. Department of Physics, Nagoya University, 2. Tohoku University

We investigate collisional evolution from dust to planets in protoplanetary disks. For the collisional growth of dust, the bulk density evolution of dust aggregates is important. On the other hand, the random velocity evolution is needed to be considered for planetesimal growth. We take into account both effects consistently and then carry out the simulation for collisional growth from dust to planets. We show planets are possible to be formed via collisional growth of dust.

Impact Conditions for the Formation of the Extremely Elongated Shape of 1I/’Oumuamua

*Keisuke Sugiura[1], Hiroshi Kobayashi[1], Shu-ichiro Inutsuka[1]

1. NAGOYA UNIVERSITY Graduate School of Science

1I/’Oumuamua is considered to be the first interstellar object observed by the Pan-STARRS telescope on October 2017. The eccentricity of 1I/’Oumuamua is about 1.2, which corresponds to the relative velocity with respect to the sun at infinity of 26 km/s. This relative velocity at infinity is comparable to the relative velocity of solar neighborhoods, and thus we consider that 1I/’Oumuamua came from a nearby planetary system. The absolute magnitude of this object is about 22 magnitude, which corresponds to the size of about 100 m with the albedo of 0.04. This object shows large light curve amplitude of at most 2.5 magnitude, and the shape of 1I/’Oumuamua is estimated to be the extremely elongated one with the ratio of the intermediate to major axis lengths less than 0.3.

To examine whether asteroidal impacts can form the extremely elongated shape of 1I/’Oumuamua or not, we conduct numerical simulations of collisions between asteroids. We use a Smoothed Particle Hydrodynamics code for elastic dynamics with the self gravity, a fracture model for rocky material, and a friction model for completely damaged rocks. We assume that impacting bodies do not have tensile strength of monolith bodies but have frictional forces of granular material. The diameter of target bodies is fixed to 100 m. We conduct impact simulations with various ratios of the masses of two impacting bodies, friction angles, impact angles, and impact velocities, and then we investigate the impact conditions required for the formation of the extremely elongated objects with the ratio of the intermediate to major axis lengths less than 0.3.

As a result of the impact simulations, we find that the formation of the extremely elongated bodies requires the mass ratio larger than 0.5, the friction angle larger than 40 degrees, the impact angle less than 30 degrees, and the impact velocity less than 40 cm/s. The most difficult condition to be realized among these conditions is the impact velocity; the required impact velocity is much smaller than the average impact velocity in the main belt ~ 5 km/s.

The impact velocities less than 40 cm/s require dynamically cold environments in protoplanetary disks. However, turbulent scattering due to gas or gravitational scattering due to larger bodies increase the relative velocities. We estimate required turbulent strength and the size of larger bodies and find that the Shakura-Sunyaev alpha parameter less than $10^{-4}$and the size of larger bodies less than 7 km realize the relative velocities between 100-m sized bodies less than 40 cm/s. This turbulent strength is realized at the places where magnetorotational instability is not active. The size of bodies less than 7 km is realized only in extremely young protoplanetary disks. Therefore,1I/’Oumuamua might have been formed in such an extremely primordial protoplanetary disk, then might have been ejected from the planetary system due to, for example, a stellar encounter, and then visited our solar system.

The Study of Using SLR and GPS Observation Data to Estimate Geocenter Motion.

*Yih Jack Cheng[1], Fang-shii Ning[1]

1. National Chengchi University

Geocenter motion describes the difference of Center of Figure (CF) respect to Center of Mass of the Earth system (CM) due to the mass re-distribution and deformation of the Earth system. This is a factor that cannot be ignored in the maintenance of the high-precision terrestrial reference frame. As precision requirements and application demands in space geodesy increase, research on estimation of the geocenter motion become increasingly important as the key point to realize a reference frame with its origin fixed to the center of mass of the Earth system. In this study, GPS (Global Positioning System) observation data from IGS (International GNSS Service) and SLR (Satellite Laser Ranging) tracking data in the period of 2007 to 2016 are applied to estimate the coordinates of IGS sites on Earth’ s surface by using the GAMIT/GLOBK and Bernese software. Then, the Helmert transformation model is used to acquire seven parameters between the ITRF (International Terrestrial Reference Frame) reference frame and the CM reference frame. There are three parameters of them are related to the shift in three axes, which are the results of the geocenter motion. Afterwards, the geocenter motion time series are applied with the linear fitting method in order to obtain the amplitudes and phases along three axes of geocenter motion. The annual amplitude of X-, Y-, and Z- components between the years 2007and 2016 are 2.6± 0.2 mm, 4.1±0.2 mm, and 5.6±0.3mm respectively. The annual phase of X-, Y-, and Z- components are 72˚, 330˚, and 145˚ respectively. The accuracy of this study is significant improvement comparing to just using GPS or SLR technique only.

Evolution of Pluto's surface albedo due to sublimation and condensation of ice

*Hisashi Matsui[1], Jun Kimura[1]

1. Osaka University

Observation of the spacecraft New Horizons approached Pluto in 2015 revealed that H_2O, N_2, CH_4, CO ice coexists on the surface of Pluto and that the surface has a strong contrast of bright and dark due to a difference in the amount of ice. However, it is not cleared an origin of the bright and dark color distribution on the surface.
In previous researches about a temporal changing of albedo on the Jovian and Saturnian moons, it has been shown that sublimation of ice due to an insolation affects albedo changing on their surfaces. In addition, condensation of sublimated ice in the atmosphere also should affect Pluto’s surface albedo. Through these processes, ice behavior like sublimation and condensation possibly affects a change of albedo on Pluto’s surface. However, it has been not considered quantitatively so far.
In this study, we evaluate relationship between behavior such as sublimation and condensation of various ices and change of albedo with a numerical simulation, and investigate the origin of the albedo variation on Pluto.
In our model, we assume that bright ice and dark non-ice material exist uniformly mixed and the surface albedo can be modeled by the volume ratio. Subsequently, calculate the surface temperature with a change of insolation on each latitude and thermal inertia and then estimate the sublimation amount of ices from the difference between the vapor pressure at the temperature and the atmospheric pressure. Sublimated ices exist as the atmospheric gas, and these gas should be segregated and deposited on the surface if the surface temperature falls below the segregation temperature. We calculate albedo at the next time step from the volume ratio of ice and non-ice material contained in depth considered to be mixed by micrometeorite bombardment. Finally we examine temporal change of the Pluto’s surface albedo by repeating these cycle.
As a result, using the difference of insolation amount for each latitude caused by the large inclination of the obliquity, we found that a possibility to explain the overall trend of the albedo on current Pluto without special events like a giant impact.

Quantitative evaluation of the cumulus convection schemes for the implementation into the Paleo Martian Global Climate Model

*Katsushige Toriumi[1], Arihiro Kamada[1], Takeshi Kuroda[1,2], Naoki Terada[1], Yasumasa Kasaba[3], Isao Murata[1], Hiromu Nakagawa[1]

1. Tohoku university, Geophysics, Planetary Atmospheric Physics, 2. NICT, 3. Tohoku university, Geophysics, Planetary Plasma and Atmosperic Research Center

Current Mars has a lot of fluvial traces, which are supposed to be made during the late Noachian and early Hesperian boundary (3.85-3.6 Ga). If these traces are created by the fluvial activity, the climate of early Mars should be ‘warm and wet’ enough for the long-term existence of liquid water on its surface. However, solar luminosity at that time would be weaker by 20-30 % of today’s value, which would preclude early Mars from such ‘warm and wet’ climate (‘Faint young Sun paradox’). Previous studies using 3-dimensional Mars Global Climate Models (MGCMs) have revealed that pure CO_2atmosphere, even assuming 2~7 bars, was hard to reproduce the surface temperature above 273 K [e.g. *Kasting*, 1991; *Forget et al*. 2013].

We newly developed a 3-dimensional Paleo MGCM (PMGCM) with ancient ocean on its surface below a sea level of -2.54 km, including the absorptions of CO_2/ H_2O gases, CO_2/ H_2O ice clouds, thermodynamics of land / ocean, and hydrological processes [*Kamada et al*., submitting to Icarus]. This model reproduced a clement surface environment enough for liquid water on surface and could create most of fluvial channels by hydrological processes. However, the fluvial channels reproduced in our model were partly not consistent with observations on current Mars (e.g. *Sabaea Terra*). There are several explanations for the inconsistencies, such as 1) in Noachian and early Hesperian boundary the Tharsis rise had not finished or completed, which would enable wind system to transport water vapor towards the leeward regions such as Sabaea Terra, and/or 2) some of fluvial channels would have formed by glaciation.

Another possible reason is that our modelhad excluded the cumulus convection scheme, considering only the large-scale condensation process for the precipitation. This process could be crucial for resolving atmospheric instability and affect the distribution and the amount of precipitations on early Mars. Therefore, as the next step, we are newly introducing a cumulus convection scheme. One candidate is the Relaxed Arakawa-Schubert scheme [*Moorthi and Suarez*, 1991] which is often introduced to terrestrial GCMs. However, it is not clear whether this scheme could be adapted to early Mars, because it is a simplified scheme taking the empirical processes of the Earth into account for the calculations of the cloud mass flux, which may not be simply adopted to the CO_2/ H_2O atmosphere of early Mars. On the other hand, the Kain-Fritsch scheme [*Kain and Fritsch,* 1993], which is appropriate for middle resolution GCMs to reproduce the cumulus lifetime including creation, developing, declining, and deletion phases by one cumulusin a grid,is considered to be more suitable for PMGCM. It directly calculates the vertical structure of the cumulus without using the empirical assumption of the Earth.Though it is inferior to the Relaxed Arakawa-Schubert scheme in terms of ensemble, it is meaningful to introduce this scheme with high accuracy if we aim for high resolution in the future.Ultimately, we intend to calculate PMGCM with high resolution (both vertical and horizontal), verify the validity of the PMGCM introducing the cumulus convection model, and consider the influence on the running water topography.

In order to do the trade-off between those two schemes, we evaluated the differences of heat balance and

©2019. Japan Geoscience Union. All Right Reserved.

precipitation created by both schemes. First, we did the test under the present terrestrial condition (1bar, N_2/ O_2atmosphere, present solar flux at 1 AU). We supposed that both schemes would show the similar results in radiation balance and precipitation on the present terrestrial models. However, in the actual calculation results, the cloud structure had wider range of clouds in the low altitude with the Kain-Fritch scheme. That is because the characteristics of detrainment for each scheme are different. As the next step, we are changing parameters such as surface pressures (wet CO_2atmosphere of 0.5-2.0 bars), atmospheric compositions, solar flux, and terrain for early Mars as our PMGCM conditions. And we analyze the cloud structure generated by Kain-Fritsch scheme and qualitatively and quantitatively compare the change of water vapor transport with the case without cumulus convection scheme. In this paper, we plan to provide a first summary of those results.

Forced libration of Ganymede including the visco-elastic tidal deformation

*shinichiro kojima[1], Jun Kimura[1], Shunichi Kamata[2]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University, 2. Creative Research Institution, Hokkaido University

From spacecraft observations and interior thermal modeling, Ganymede has been expected to possess a global ocean beneath its ice shell. To confirm an existence of the ocean, the JUICE (JUpiter ICy moons Explorer) mission has been prepared by ESA (The European Space Agency) and the spacecraft will be launched in 2022. After arriving at Jupiter system, the JUICE spacecraft is going to make several flybys Europa and Callisto and finally will orbits around Ganymede. During orbiting around Ganymede, the spacecraft will obtain several kinds of scientific data, for instance, surface topography from GALA (GAnymede Laser Altimeter) and surface images from JANUS (camera system). These data will provide important information about the tidal responses of Ganymede.

The tidal responses, e.g., tidal deformation and rotational variation, are caused by the gravitational force of other bodies such as a mother planet. The rotational variation includes libration, obliquity variation, nutation, and precession. In this study, we focus on the libration which is a spin rate variation caused by a torque acted on the aspherical degree-2 order-0 shape of the satellite. The libration changes the centrifugal force of a satellite and affects the tidal deformation. Inversely, tidal deformation affects the aspherical shape of the satellite.

Although Van Hoolst et al. (2013) has modeled the interaction of the tidal deformation and the libration, their tidal deformation models were simplified. In order to estimate an actual libration, we model 5-layered Ganymede interior and use the visco-elastic tidal deformation model constructed by Kamata et al. (2016). Our interior model consists of five layers, which have a homogeneous density and rigidity in each layer. The viscosities of the ocean, the high-pressure ice mantle, the rock mantle and the metallic core are homogeneous in each layer, and the viscosity of the ice shell is not homogeneous and depends on a radial temperature variation.
As a typical case, we use interior parameters which are the ice shell thickness of 155 km, the ice shell density of 940 kg/m^3 , the ocean thickness of 1 km, and the ocean density of 1050 kg/m^3 . Then we also use the three sets of a shell rigidity and a shell viscosity (1) 0.1 GPa and 10^{12} Pas, (2) 0.1 GPa and 10^{17} Pas, and (3) 10 GPa and 10^{17} Pas, respectively. The results for the libration amplitude are 34.1 m, 34.1 m, and 37.5 m respectively. As a conclusion, our calculation of the visco-elastic libration infer that the reference viscosity of ice (temperature-dependent viscosity of ice at a melting point) doesn’ t affect the amplitude of the shell libration. The ice rigidity affects the amplitude of the shell libration of order of a few meters.

Experimental study on collision destruction simulating the primitive meteorite parent body

*Horikawa Kazuhiro[1], Masahiko Arakawa[1], Minami Yasui[1], Ryo Sugimura[1]

1. Kobe University Faculty of Science

We studied the impact strength of weak brittle materials changing the strength continuously from 40kPa to 800kPa, and found that the impact strength could be well scaled by using the non-dimensional impact strength.

Asteroids are believed to be constructed from various materials based on the long-term study related to meteorites. The components of S-type and C-type asteroids could be composed of chondrules and matrix; the chondrules are sub-mm size glass spherules and the matrix could be micron-size fine grained materials such as phyllosilicates and lithic fragments etc. Moreover, these components could have a wide range of porosity inside because they might be residual pore during the compaction process of planetesimals or relics of water ice or volatiles escaping from these bodies. Impact strength is one of the most important physical properties of asteroids because it could control the evolution of the size-frequency distribution of asteroids at the asteroid belt. The impact strength strongly depends on the asteroid size and it is dominated by the material strength at the size smaller than 100m, so that the impact strength should be determined by the laboratory experiments. Therefore, a lot of research have been conducted for rock, ice, and porous materials to investigate the material dependence, however the impact experiments using the target with the strength continuously changed have been hardly conducted so far. Then, we prepared the targets simulating asteroids composed of chondrules, matrix and pore and changed the internal structure of the target such as matrix ratio and porosity; the tensile strength was changed more than one order of magnitude, then we studied the relationship between the internal structure and the impact strength.

Impact experiments were conducted by using two-stage light gas gun at Kobe University, and we used a polycarbonate projectile with the size of 4.7mm and a nylon projectile with the size of 2mm and they were lunched at the velocity from 0.9km/s to 5.7km/s. The impact was conducted at a head-on collision. A spherical target with the size of 60mm were prepared by using quartz sands with the size of 100 μm and porous gypsum, and they are mixed with various mass ratio of quarts to gypsum from 2:1 to 8:1. The tensile strength of these materials (Y_t) was measured by using Brazilian test and it was found that the tensile strength changed from 40kPa to 800kPa with the increase of the gypsum mass ratio. The impact disruption was observed by a high-speed camera at 10^5fps.

The impact strength (Q*) was determined by using a largest fragment mass for each shot, and Q* was found to change from 400J/kg to 1900J/kg with the increase of the gypsum mass ratio. This means that the Q* is directly proportional to the tensile strength. However, the ejection velocity at an antipodal point (v_a), which was measured by using high-speed images, showed the almost similar results, irrespective of the tensile strength. A non-dimensional impact strength (P_I) is defined as the ratio of the target tensile strength to the antipodal pressure such as P_I=Y_t/P_a, where P_a is calculated by ρ C_b v_a/2. This P_I was proposed to scale the target with the different tensile strength. Then, the relationship between the largest fragment mass and P_I was examined to discuss the P_I scaling law for the catastrophic disruption. We found that P_I is able to scale the largest fragment data very well, and this might mean that P_I could be applicable to asteroid components composed of weak brittle materials.

Evolution of atmospheric composition in the early Martian atmosphere

*Ryosuke Yagi[1], Naoki Terada[1]

1. Planetary Atmospheric Physics Group, Tohoku University, Japan

The purpose of this study is to investigate the evolution of atmospheric composition in the early Martian atmosphere. Not only hydrogen and oxygen but also carbon escape to space is considered in this study. The early Martian atmosphere was influenced by a stronger Sun’ EUV radiation than today. The escape parameter, defined as the ratio of the gravitational potential to kinetic energy at a given altitude, could be small enough to allow massive escapes of these species under such a strong radiation. For example, the escape parameter of atomic carbon in the Martian atmosphere was estimated 0.8 times smaller than that of atomic oxygen and both densities at the exobase level were comparable at 4.1 Gyr ago (Tian et al., 2009). Hence, we consider that in early Mars, thermal escape of atomic carbon could be stronger than atomic oxygen, and oxygen dissociated from CO2 was left behind in the atmosphere. Assuming that the escape rates of atomic carbon and atomic oxygen were in the same proportion, we get results that carbon disappeared in 5 Myrs from 1 bar of CO2 atmosphere and only 0.4 bar of oxygen atmosphere remained around 4.2 Gyr ago. On the other hand, it was suggested that the Martian atmosphere about 3.5 Gyr ago could have several mbar or more of oxygen partial pressure(Noda et al., 2018). In the present study, we have developed a 1-D photochemical model of the early Martian atmosphere to investigate the evolution of the atmospheric composition, in particular from 4.2 to 3.5 Gyr ago. This model includes not only the effect of escapes of hydrogen, oxygen and carbon but also that of deposition to surface and degassing. In this presentation, we will show the influence of the atomic carbon escape to the evolution of oxygen partial pressure left behind in the early Martian atmosphere.

Observation of catastrophic destruction of two different targets using X Ray photography

*Takumi Nagano[1], Masahiko Arakawa[1], Minami Yasui[1], masato nakamura[1], Fumiya Nagatomo[1]

1. Faculty of Science Kobe University

We studied the dependence of physical properties of planetesimals on the impact strength in the gravity regime, then we made laboratory impact experiments by using a Flash X-ray for porous gypsum and dry clay simulating planetesimals in order to obtain the relationship between impact fragment masses and ejection velocities.

The impact strength of planetesimals is one of the most important physical properties to clarify the planetary accretion process and the formation process of proto-planets and asteroids. Thus, the impact strength in the strength regime applicable to planetary bodies smaller than 100 m has been mainly studied in laboratory experiments. However, the impact strength in the gravity regime applicable to planetary bodies larger than planetesimals has been studied only by numerical simulations, and their results are not consistent with each other. Furthermore, recent numerical results conducted by Jutzi (2016) showed us that the material properties such as friction, cohesion and porosity affected the impact strength in the gravity regime drastically. Then, we made laboratory impact experiments to elucidate the material dependence on the impact strength in the gravity regime.

In order to determine the impact strength in the gravity regime by the laboratory experiments, we should obtain the relationships between the impact fragment masses and the ejection velocities, and especially, the fragments ejected from the interior of the disrupted target must be observed to construct the velocity –mass relationship for all the fragments. Then, we introduced 3 sets of flash X-ray generators and imaging plates to take transmitted X-ray images of a target with 3 mm steel balls arranged in it. These steel balls were used as makers of the motion of impact fragments, and the time sequence of these balls were observed by using X-rays to analyze the local velocities of the target’ s interior.

Impact experiments were conducted by using a polycarbonate projectile with the size of 7mm at the velocity of 2 –5 km/s, and the projectile was impacted on a spherical target with the size of 6 cm in a head-on collision. We used porous gypsum targets with the porosity of 50% and the tensile strength from 1 to 2 MPa and dry clay targets with the porosity of 48 % and the tensile strength different from the porous gypsum. All the targets were catastrophically disrupted into the largest fragment mass less than 0.2. As a result, we determined an upper limit of ejection velocities having a half mass of the target for each experiment, and we defined this upper velocity as a median velocity of V*. So, we studied how V* depended on the energy density, tensile strength and porosity, then we found that V* increased with the energy density for both targets. Moreover, we found that it strongly depended on the target porosity when it was compared with the previous result for the frozen clay with the similar tensile strength but without porosity, the V* for porous gypsum reduced to be 1/3 for the frozen clay. The V* for the dry clay was almost similar to that for the porous gypsum, thus this might mean that the tensile strength does not affect the V* even for the porous target.

Charge transport between granular particles in an ejecta curtain produced by hypervelocity impacts

*Kosuke Kurosawa[1], Takanori Iwasawa[2], Satoshi Okuzumi[2], Sunao Hasegawa[3], Takayuki Muranushi[4]

1. Planetary Exploration Research Center, Chiba Institute of Technology, 2. Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 3. ISAS, JAXA, 4. AICS, RIKEN

We studied the charge transport between granular particles in an ejecta curtain produced by hypervelocity impacts to access the energy partitioning from the initial kinetic energy to the electrostatic one having the ejecta curtain. We conducted both hypervelocity impact experiments and numerical calculations. The impact experiments were done at ISAS/JAXA hypervelocity impact facility. A vertical gun was used to use granular materials as a target. High-speed video cameras for the visible and infrared were used to observed an impact-generated ejecta curtain. Any light sources were not used in this experiment. We constructed a numerical model by combining the iSALE shock physics code and the REBOUND N-body integrator. The processes of impact ejection under the conditions similar to the laboratory experiments were solved by the iSALE. The time at the ejection, ejection velocity, and the launch position of each particle was extracted as a txt file. Then, the txt file was imported in the REBOUND as a input file. At this time, we added random velocities to simulate the velocity dispersion. Although the dispersion would be inevitably added to each ejected particles in nature, it cannot be modeled in the hydrocode. The absolute magnitude of the random velocity was treated as a free parameter. Subsequent particle motions under the Earth’ s gravity field and the resistance force by the surrounding air were calculated. The decceleration due to inelastic collisions and charge transport between particles were included into the calculations. The restitution coefficient was also treated as a free parameter. The degree of charge separation was given by an empirical law proposed by the previous experiment. The results are summarized as follows; (1) We did not observe a large-scale discharge in an ejecta curtain under the experimental condition, (2) we observed a number of bright points along with an produced-ejection flow, (3) we observed a mesh pattern in the ejecta curtain as well as a previous study, (4) we reproduced the mesh pattern in the REBOUND when we chose the degree of the random velocity to be 5-15% of the ejection velocities at the restitution coefficient of 0.8, (5) mutual collisions between granular particles cease at the early stage of the growth of the ejecta curtain, (6) the end time of the mutual collisions depends on the atmospheric pressure, and (7) the empirical law pertaining to the charge separation yields an unphysically-high electrostatic energy. In the presentation, we will present the current status of our research development and discuss the future plans.

Acknowledgements:We thank the developers of iSALE, including G. Collins, K. Wün- nemann, B. Ivanov, J. Melosh, and D. Elbeshausen. We also appreciate the developers of REBOUND, including Hanno Rein, ShangfeiLiu, David S. Spiegel, Akihiko Fujii, and Dan Tamayo.

Nonlinear outcome of gravitational instability in irradiated protoplanetary disks

*Shigenobu Hirose[1], Jiming Shi[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Spotify USA Inc

Using local three dimensional radiation hydrodynamics simulations, the nonlinear outcome of gravitational instability in an irradiated protoplanetary disc is investigated in a parameter space of the surface density Σ and the radius r. Starting from laminar flow, axisymmetric self-gravitating density waves grow first. Their self-gravitating degree becomes larger when Σ is larger or the cooling time is shorter at larger radii. The density waves eventually collapse owing to non-axisymmetric instability, which results in either fragmentation or gravito-turbulence after a transient phase. The boundaries between the two are found at $r \sim 75$ AU as well as at the Σ that corresponds to the initial Toomre's parameter of ~ 0.2. The former boundary corresponds to the radius where the cooling time becomes short, approximating unity in terms of the inverse of the orbital frequency. Even when gravito-turbulence is established around the boundary radius, such a short cooling time inevitably makes the fluctuation of Σ large enough to trigger fragmentation. On the other hand, when Σ is beyond the latter boundary (i.e. the initial Toomre's parameter is less than $\sim$0.2), the initial laminar flow is so unstable against self-gravity that it evolves into fragmentation regardless of the radius or, equivalently, the cooling time. Runaway collapse follows fragmentation when the mass concentration at the centre of a bound object is high enough that the temperature exceeds the H_2 dissociation temperature.

Rheology of clay paste and application to the investigation of formation process of surface topography on the Mars

*Chihiro Uemura[1], Takahiro Iwata[1,2], Akio Nakahara[3], Yosuke Matsuo[3], Tomohiro Usui[2], Rina Noguchi[2]

1. SOKENDAI, 2. ISAS/JAXA, 3. Nihon Univ.

Mars is known to have many terrains formed by water, which is one of important candidates for future exploration places. For example, RSL (Reccuring Slope Lineae) is repeating disappearance and occurrence by seasonal variation, so it suggests that RSL was formed by water. However, there is a hypothesis that RSL is formed by sands, and formation process of RSL is still unclear.
Considering that flowing water is mixed with grain of sands and clay powders, and becomes pastes (colloidal suspension). It is valuable to understand properties of pastes. Since pastes have many unique properties, they are attracting widespread interest in various fields. Pastes are classified as attractive or repulsive according to a force among particles. Rheology of repulsive colloidal suspension has been studied so far. On the other hand, rheology of attractive colloidal suspension is still unknown. To understand the surface topography on Mars, it is important to study the rheology of clay paste, one of typical attractive colloidal suspension, because clay minerals are widely found on the surface of Mars. As the formation of some landforms, such as RSL, are considered to be dependent on temperature, we focused on the temperature dependence of their rheology, such as an yield stress and a viscosity, of attractive colloidal suspension.
We used paste of magnesium carbonate hydroxide because their properties are similar to clay minerals; their inter-particle force is attractive and makes a card house structure. We used rheometer (Anton Paar, Physica, MCR-301) for measuring. We measured rheology of paste at four different temperatures and five different solid volume fractions. We found that the yield stress of paste of magnesium carbonate hydroxide is an increasing function of a temperature. The yield stress of usual elastoplastic media is known to decrease as the temperature increases. However, our experimental study revealed that the yield stress of attractive colloidal suspension is an increasing function of the temperature, the result of which is an inverse behavior to that of usual elastoplastic media. The temperature dependence of the yield stress of attractive colloidal suspension is much more drastic when it is compared to the theoretical prediction for the repulsive colloidal suspension with the linear dependence to its absolute temperature.
As for the viscosity of attractive colloidal suspension, its behavior is similar to that of Newtonian viscous fluid with its viscosity a decreasing function of the temperature. We consider that this is because the viscosity of solvent, i. e., water, decreases as the temperature of an colloidal suspension increases.
These facts suggest that temperature dependence of rheology was caused by what kind of force is working among particles. As a mechanism of these results, we suggest that changing charge on the surface of particles or changing viscosity of water. In order to reveal why interaction is changed with increasing temperature, we need further verification.
In the future work, we will make use of these results for understanding the process of forming subsurface terrains on Mars.

An Explanation for Physical Mechanism of the Streaming Instability

*Hiroaki Kaneko[1]

1. Tokyo Institude of Technology

Planets are thought to be formed from planetesimals, which are 1-100 km in size, and planetesimals are formed by accumulating small dust particles. Dust particles of a size of 10 cm-1 m drift sunward at 1 au per a century. Dust particles must grow within a timescale faster than this sunward drift timescale limit, otherwise they cannot form planetesimals. Enhancement of the particle density leads to the self-gravitational instability if the density reaches the Roche density, and the dense dust particles form planetesimals. In this case, the dramatic radial drift of dust particles can be avoided. Youdin & Goodman (2005; YG05) discovered that dust and gas streams mutually interacting via drag force generate local linear instability and a particle clumping occurs. This instability is called the streaming instability (SI). A lot of linear and non-linear numerical simulations conducted and it has been confirmed that SI emerges under certain conditions. But the physical mechanism of SI is not clear yet, because the order of the dispersion relation is as high as 6 and the mechanism seems to be difficult to understand. Applying the terminal velocity approximation (YG05) to particle continuity equation and gas incompressibility, Jacquet, Balbus, & Latter (2011; JBL11) attempted to give a physical explanation about the SI mechanism. Their explanation was as follows:

1. The gas pressure maximum traps dust particles.

2. Dust particles drag the gas toward the gas pressure maximum.

3. The gas pressure maximum is strengthened. Though the gas pressure gradient tends to force out the gas from the maximum, the dust particle drag force on the gas and the Coriolis force make roles to keep the geostrophic balance.

JBL11 suggested the explanation of the mechanism in which all the motion takes place only in the midplane, however, YG05 emphasized that the vertical advection flows toward the density maximum and it dominates the flow in the midplane.

In this study, first, we conduct an analysis on the dispersion relation that employs the terminal velocity approximation (YG05) and calculate phase differences among the perturbed particle density, the perturbed gas pressure, and the perturbed particle velocities for an unstable mode. Then, we give an explanation about the mechanism of SI including the vertical motion unlike the explanation by JBL11.

Our explanation on the SI mechanism is as follows:

1. At the particle density maximum, the gas receives more angular momentum, while at the particle density minimum, the gas receives less. So, the gas radial velocity perturbation and the gas pressure fluctuation along the radial direction are generated.

©2019. Japan Geoscience Union. All Right Reserved.

2. Toward the gas pressure minimum, the gas flows in vertically with dragging dust particles. On the contrary, both gas and dust particles flow out vertically from the gas pressure maximum.

3. The phase velocity of the dust particle density maximum is negative so the particle density maximum moves radially inward. The density maximum encounters the dust particle input due to the vertical converging flow and the density maximum is enhanced.

This explanation is consistent with solutions of the linear stability analysis. In addition, the explanation seems physically reasonable and easy to understand.

Spatial motion of the Earth-Moon system and Earth pole oscillatory process

*Alexandra Sergeevna Filippova[1], Vadim Vladimirovich Perepelkin[1], Wai Yan Soe[1]

1. Moscow Aviation Institute

The variation of the Chandler and annual components of the polar motion are of a significant interest in the Earth pole oscillatory process research. Generally these variations are quasiperiodic. But some regular oscillations can be isolated from it that correspond with the basic periods of the lunar motion. Here we discuss the theoretical assumptions of the observed effect as well as the experimental rules that illustrate the relationship between the Earth pole oscillations and the lunar motion.
The complex process of the Earth pole oscillations includes components with frequency and amplitude that differ significantly from each other. Processing the pole motion observations over the last 100 years result in statistically convincing definition of the main characteristics in its oscillatory process. Basic components in the Earth pole motion are Chandler wobble, annual oscillation and also polar motion's trend. Observed Earth pole oscillations have a wobbling character. The trajectory of the pole on the Earth surface is a winding and unwinding spiral with a period of about six years.
Actual problem that was stated by P. Melchior (Melchior, 1972) about the instability in the basic components parameters of the Earth pole is still not sufficiently explored. This problem is connected with the exploring the celestial-mechanics' and geophysical causes of such behavior in the Chandler and annual components, and also with the construction of the refined models of the forecasting the Earth orientation parameters for long time intervals.
In this work along with the common methods of the separating the pole oscillation process into the Chandler and annual components we suggest an approach to the resulted Earth pole trajectory research. For the purpose of analyzing the nonstationary resulted pole motion a perturbed trajectory is isolated. For the unperturbed trajectory a “mean” one is chosen –the Earth pole trajectory where the Chandler and annual oscillation parameters have mean values.
The differential equations for the amplitude a and phase ψ of the Earth pole modulation motion can be derived from the dynamical Euler–Liouville equations of Earth motion around its center of mass (Markov, Perepelkin et al, Astronomy Reports, 2018 and Markov, Perepelkin at al, Doklady Physics, 2017).
It is shown that the significant impact into the variations of the basic pole oscillation components is given by the long-term perturbations from the lunar orbit. The analysis of these perturbations is held using the wavelet and Fourier transformations. On the long time interval it shows matching phases of the perturbed polar motion and the lunar orbit motion using the available series of observations C04 and C01 from the International Earth Rotation and Reference Systems Service. This feature can be used to refine the model of the forecasting the Earth pole oscillations. And taking into account these structural features of the oscillations the refined numerical-analytical model of the Earth pole motion is presented.
Thus the graphical correspondence between the Earth pole oscillations and the motion of the lunar orbit is presented. It is shown that the refined model gives a more accurate description of the Earth pole motion by comparing the model computation results with the observations made by the International Earth Rotation and Reference Systems Service.

Chondrule formation model by lightning in high dust density regions

*Chihiro Ikeda[1], Taishi Nakamoto[1]

1. Tokyo Institute of Technology

Chondrules are spherical objects of 0.1 - 1 mm in radius and are the main component of chondrite meteorites (Scott 2007). It is known that chondrules were formed early in the solar system. So, chondrules may have important information about early solar system nebula. It is believed that chondrules melt with dust particles heated within several minutes and have cooled and solidified at a rate of 1-1000 K/hour in the early solar nebula (Desch et al. 2012). Also, since chondrules contain volatile substances, it is considered that they are formed in a high dust density region (Alexander et al. 2008). Although the formation mechanism of chondrules have not been elucidated, formation theories include the shock wave model, astronomical collision model, X-wind model, and lightning model. In this study, we examine the chondrule formation by lightning from the viewpoint of thermal evolution of chondrules.

Thermal evolution of chondrules has been studied by Horanyi et al. (1995). In that study, assuming the occurrence of lightning in the solar nebula, they calculated the time evolution of the gas and dust in the lightning. As a result, the cooling rate of the chondrule became faster than the cooling inferred from observations of crystals in chondrules. On the other hand, according to studies on the occurrence of lightning, the mass ratio of dust to gas needs to be 100:1 or more for lightning generation (Muranushi 2010). However, Horanyi et al. (1995) considered the situation where only one dust particle is present inside the lightning.

In this study, we consider the occurrence of lightning in the high dust density region and calculate the thermal evolution of chondrules numerically. Especially, we investigate if the cooling rate condition for the chondrule formation is satisfied under the high dust density situation. As a result, it was found that there are circumstances suitable for chondrule formation. It is suggested that chondrule formation by lightning is possible in the solar nebula.

The transition to superrotation in stratospheric atmospheres

*Motoki Sumi[1]

1. Tokyo Institute of Technology

Titan is the only satellite with the developed atmosphere and the stable liquid on the ground surface in the solar system. The history of the observation begins with the suggestion of the existence of the atmosphere in 1908. In the 1970's, the temperature structure and atmospheric composition of the Titan atmosphere have been clarified thanks to the progress of observation technology. Also, in the Cassini-Huygens mission, it visited the Saturnian system, made Huygens probes into the Titan atmosphere, and made high-precision observations. Ground-based submillimeter wave observation by the ALMA telescope is currently being carried out, and it is possible to observe at high resolution.
Observations clearly show the existence of superrotation, which is a high-speed zonal wind oriented to overtake the rotation on a global scale as a characteristic of the Titan atmosphere. The wind speed reaches 100 m/s eastward at about 10 degrees south latitude where Huygens entered, but it is difficult to investigate its mechanism from the viewpoint of insufficient observation data and complexity of atmospheric structure. Also, the theory which unified the generation mechanism of superrotation is not established, and various theories are advocated. Representative examples are the Gierasch mechanism proposed by Gierasch or the mechanism by thermal tidal waves proposed by Fels and Lindzen.
In this research, I conducted numerical experiments to generate superrotation by changing only the planetary radius using the Earth model. We used the numerical simulation model DCPAM5 of the planetary atmospheric general circulation developed by GFD Dennou Club. Primitive equations were used as the basic equation system of the model assuming a dry atmosphere. We used the model of Williamson et al.(1998) which added the pressure dependency of stratosphere to the Newtonian cooling process in Held and Suarez (1994). The calculation time was 1080 days where sufficient stationarity was confirmed, and we analyzed the time average of the physical quantities in last 360 days.
First, I output the temperature field, the mass transport distribution, zonal-mean zonal wind speed field, compare the structure of the atmosphere in the meridional space, and investigate the location and the condition. where superrotation is occurring. In the Earth model, eastward jet streams occurred in the mid latitudes of the troposphere and the stratosphere, but on the equator the westward winds are blowing. If the planetary radius is small, in the troposphere even in the equator the eastward wind is accelerated and superrotation has occurred. In the stratosphere, equator superrotation occurred in the lower stratosphere, but in the upper stratosphere the jet occurred only in the middle and high latitudes, and the high-speed eastward wind did not appear in the equator.
Next, in order to investigate the mechanism of keeping the angular momentum in the upper layer of the equator, the dispersion of the band-like disturbance of the temperature, the band-shaped disturbance spectrum of the east-west wind speed field were output, and the structure of the wave existing in the atmosphere was summarized. In the troposphere in the Earth model, many waves with a wave number of 4 or more existed in the mid latitudes, and angular momentum in the east direction was accumulated in mid latitude. However, as the radius of the planet is decreased, the waves with large zonal wavenumbers decrease, and global waves with the wave number of around one dominate. The behavior is similar in the stratosphere, in the Earth model, waves with large wavenumbers are present, although the waves are weaker in the troposhere as the planetary radius is reduced, only waves with small wavenumbers remain. In the stratosphere the equator super rotation and the mid-high latitude jet occur in different altitude, and the mechanism for maintaining superrotation seems somewhat different from the mechanism in the troposphere.

ExPRES: a Tool to Simulate Exoplanetary and Planetary Radio Emissions

*Corentin LOUIS[1,2,3], Sebastien L. Hess[4], Baptiste Cecconi[2,3], Philippe Zarka[2,3], Laurent Lamy[2,3], Stéphane Aicardi[5], Alan Loh[2]

1. IRAP, Toulouse, 2. LESIA - Observatoire de Paris, 3. USN, Observatoire de Paris, 4. ONERA-The French Aerospace Lab, FR-31055 Toulouse, France, 5. DIO, Observatoire de Paris, PSL Research University, CNRS, Paris, France

All magnetized planets are known to produce intense non−thermal radio emissions through a mechanism known as Cyclotron Maser Instability (CMI), requiring the presence of accelerated electrons generally arising from magnetospheric current systems. In return, radio emissions are a good probe of these current systems and acceleration processes. The CMI generates highly anisotropic emissions and leads to important visibility effects, which have to be taken into account when interpreting the data. Several studies showed that modeling the radio source anisotropic beaming pattern can reveal a wealth of physical information about the planetary or exoplanetary magnetospheres that produce these emissions. We present a numerical tool, called ExPRES (Exoplanetary and Planetary Radio Emission Simulator), which is able to reproduce the occurrence in time−frequency plane of CMI−generated radio emissions from planetary magnetospheres, exoplanets or star−planet interacting systems. Special attention is given to the computation of the radio emission beaming at and near its source. We explain what physical information about the system can be drawn from such radio observations, and how it is obtained. These information may include the location and dynamics of the radio sources, the type of current system leading to electron acceleration and their energy and, for exoplanetary systems, the magnetic field strength, the orbital period of the emitting body and the rotation period, tilt and offset of the planetary magnetic field. Most of these parameters can be remotely measured only via radio observations. The ExPRES code provides the proper framework of analysis and interpretation for past (Cassini, Voyager, Galileo. . .), current (*Juno*, ground-based radiotelescopes) and future (BepiColombo, Juice) observations of planetary radio emissions, as well as for future detection of radio emissions from exoplanetary systems (or magnetic white dwarf−planet or white dwarf−brown dwarf systems). Our methodology can be easily adapted to simulate specific observations, once effective detection is achieved.

Crustal structures of major mercurian basins

*Qingyun Deng[1], Fei Li[1], Jianguo Yan[1], Zhiyong Xiao[2]

1. State Key Laboratory of Information Engineering in Surveying, Mapping and Remote Sensing, Wuhan University, 2. Planetary Science Institute, China University of Geoscience

Mercury is the innermost planet in the solar system. Its surface resembles to the Moon, which is characterized with large number of impact basins, indicating an intensive bombardment history. From the data acquired by previous Mercury missions, the spatial distribution, relative age, and morphology of impact basins on Mercury is studied. Gravity data from NASA MESSENGER mission revealed the crustal structures of mercurian basins, providing information about the crust properties of the early Mercury when those basins formed. In this work, the crustal thickness ratio for each basin is calculated from global crustal thickness model obtained by inverting gravity data. The relation between crustal thickness ratio, basin relaxation state, and relative age is investigated and some implication for the early evolution of Mercury is discussed.

Application of LiDAR Technique for the 3D Digital Documentation of Cultural Heritage Sites

*Sachchidanand -[1], Mayank Sharma[1], Rahul Dev Garg[1]

1. Indian Institute of Technology Roorkee

Now a day’ s remote sensing and geospatial techniques are gaining popularity as they offer correct and precise information of any object situated at a distant place. Advanced remote sensing techniques like terrestrial laser scanning (TLS), mobile laser scanner(MLS), close range photogrammetry(CRP), smart total station(STS) and GNSS are the useful techniques for creating a 3D (three-dimensional) documentation of complex engineering structures or cultural heritage sites. The integration of these techniques with other methods like topographic survey or physical measurement method also offer the potential to the user to perform a complete 3D documentation of any structure.

This paper presents a methodological framework for the 3D digital documentation of cultural heritage sites from laser scanned datasets. The framework includes acquisition of point cloud datasets through laser scanners and their conversion to 3D models. 3D models are useful for planning and surface detail measurements. Detailed planimetric and elevation information or plans could be easily extracted from developed 3D models. These planimetric informations and elevation plans are useful for the conservation and preservation of structure, and can help in restoration of these structures in case of any damage due to natural disasters or other seismic activities.

Tidal Interaction in the Earth-Moon System Treated as a Double Planet

*Aleksandr Aphanasievich Zlenko[1], Irina Michailovna Ryabikova[2]

1. Department of high mathematics, Moscow automobile and road construction state technical university, 2. Department of descriptive geometry, Moscow automobile and road construction state technical university

Our approach to the phenomenon of tides differs from the traditional one, in which an empirically tidal potential with Love numbers is introduced. We consider the motion of two viscoelastic bodies, the Earth and the Moon treated as a double planet, in the gravitational field of a massive point, the Sun.The deformations of the bodies are described by the classical theory of small deformations. The influence of viscous forces is described by the dissipative functional of the Kelvin-Voigt model. The quasi-static equation of the elasticity theory is solved for obtaining the displacements of body points. The method of averaging and separation of motion is used for solving of this equation. The displacements of each point of the deformable body consist of displacements caused by centrifugal forces, the forces due to body elasticity and dissipative forces due to body viscosity. Substituting these displacements in the potential formulae and integrating over the each body, we get the potential of the system and the moments of forces acting on the bodies.. Knowing the displacements, we determine the shape of deformable bodies, their moments of inertia and the lagging angle. The results of this approach are compared with the results of the traditional theory.

The consequences of Saturn’s “ring rain”

*James O Donoghue[1,2], Luke Moore[3], Jack Connerney[4,1], Henrik Melin[5], Tom Stallard[5], Sean Hsu[6], Steve Miller[7], Kevin Baines[8]

1. NASA Goddard Space Flight Center, USA, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency (ISAS; JAXA), Japan, 3. Boston University, USA, 4. Space Research Corporation, Maryland, USA, 5. University of Leicester, UK, 6. Laboratory for Atmospheric and Space Physics, University of Colorado–Boulder, CO, USA, 7. University College London, UK, 8. NASA Jet Propulsion Laboratory, California, USA

Saturn’s upper-atmospheric H3+ emissions have been previously studied using ground-based observations, and found to exhibit peaks in emissions at specific latitudes. The cause of these peaks is due to an influx of charged water products originating from Saturn’s rings known as 'ring rain'. Subsequent modeling using the Saturn Thermosphere Ionosphere Model (STIM) has indicated that these peaks in H3+ emissions are likely driven by an increase in H3+ density, rather than temperature, as a local reduction in electron density (due to charge exchange with water) lengthens the lifetime of H3+. However, a direct observation of the H3+ density is required to estimate the flow rate of material into Saturn with models. Calculation of ring rain’s flow rate into Saturn is a highly important input for determining the age, lifetime and evolution of Saturn’s rings.

Here we present the first ever derivation of H3+ density, temperature and radiance in the non-auroral regions of Saturn, using data taken from the 10-meter Keck telescope in 2011. H3+ density is enhanced near 45 degrees north planetocentric latitude and strongly reduced near 39 degrees south. When compared to STIM modeling results, these densities indicate a small ~50kg/sec water influx in the north and an enormous ~1500 kg/sec influx in the south. The charged grains are pulled in along the magnetic field by gravity, but the southward-inclination of the magnetic field (in the vicinity of the ring plane) means that the grains are preferentially drawn southwards into the planet. Assuming that our (Saturn northern Springtime) measurement represents all seasons, and that the rings are able to disperse over time, the ring rain mechanism alone will drain Saturn’s rings to the planet within 300 million years. If we also add the recent Cassini-spacecraft measured ring-material detected falling into Saturn’s equator (and assume it is constant), then the rings have less than 100 million years to live.

Recent measurements by Cassini again have estimated a ring age of ~50 million years, so it seems that Saturn’s rings are short-lived phenomena, perhaps lasting just 150 million years in total. A long time on human timescales, but compared to the 4.5 billion year age of Saturn, the rings are essentially temporary; i.e. if Saturn were 30 years old, the ring system would exist for just 1 year of its life! These recent findings indicate that ring systems in general are practically doomed to be removed as soon as they are formed. Indeed, the ring rain mechanism itself ought to be universal at any planet with both a ring system and a strong magnetic field. We might ask, did Jupiter, Uranus and Neptune, which have thin rings today, once have magnificent rings in the past that have eroded away?

Calculation of kinetic rate constants using high-level *ab initio* quantum chemical methods for planetary sciences and astrochemistry

*Shiblee Ratan Barua[1,2], Paul Romani[1]

1. NASA Goddard Space Flight Center, Greenbelt MD USA, 2. Universities Space Research Association (USRA), Columbia MD USA

Existing photochemical models for the atmospheres of planetary bodies suffer from large errors when predicting the mole fraction profiles of various compounds. Global sensitivity analyses show that a major source of these model errors can be attributed to inaccurate rate coefficients for “key” radical–radical and radical–neutral reactions in low-temperature conditions. Accurate rate coefficients for key reactions thus improve the accuracy of photochemical models. Unfortunately, accurate experimental rate constants for such low-*T* reactions are difficult, if not impossible, to measure, and the lab data are affected by uncertainties in determining the absolute concentrations of radical species. Currently, the most common theoretical approach involves uncertainty extrapolation technique in which uncertainties in room-temperature rate constants are extrapolated to low-temperature conditions, resulting in large errors in the theoretical low-*T* rate constant data. To solve this existing problem, we are employing the two-transition-state (2TS) model developed by Klippenstein and coworkers to calculate high-level *ab initio* rate-constants for key low-*T* (*i.e.* 10–200K) reactions relevant to planetary atmospheres like that of Titan. In particular, we are investigating key reactions that have not yet been studied in the lab, and for which accurate rate coefficients are still unknown. Our calculated *ab initio* rate coefficients will be made available to the astrochemistry community via well-established free online kinetic databases (*e.g.* KIDA). These rate coefficients will be used by scientists in photochemical models to make accurate predictions of mole fraction profiles for planetary atmospheres and improve our understanding of the diverse chemistry of these bodies.

How many conditions must be satisfied to produce a habitable planet?

*Shigenori Maruyama[1], Soichi Omori[2]

1. Earth-Life Science Institute, Tokyo Institute of Technology, 2. The Faculty of Liberal Arts, The Open University of Japan

<Purpose>

Concept of habitable zone (HZ below) is regarded as the presence of stability field of liquid water on the surface of planet. HZ is regarded as the most important condition to produce a habitable planet. However, we think the presence of liquid water is not enough to be habitable. We list up other necessary conditions (6+5=11) to produce a habitable planet in the Universe.

<Method>

The best studied habitable planet is the Earth. Therefore, based on the research results of the Earth, we consider necessary conditions. Key points are chemical composition of primordial atmosphere and biosphere.

<Result>

Based on the research of the Earth, I propose there are at least 6 conditions to be a habitable planet in case of the solar system. (1) a planet must be given totally 400 bars CO_2, 300 bars water, and 50-60 bars N_2 as minimum values. In addition, such an amount is given gradually with time (ABEL model) not to become Venus-state, (2) the presence of extremely small amount of ocean water (3km ±1km thickness), (3) the presence of huge landmass (continent above sea level) to finally provide habitable trinity condition to drive the material circulation to give nutrients through water-rock interaction to feed primordial life. (4) Initiation of plate tectonics to keep dynamic equilibria not to become Venus state. (5) selective transportation of CO_2 into mantle, while H_2O remains on the surface, and N_2 remains all in atmosphere, (6) the presence of biosphere, if not, fixation of atmospheric CO_2 is restricted only to inorganic carbonates that would be insufficient to prevent evolving into Venus-state.

<Discussion>

These six conditions are deduced from the history of the Earth. However, if we enlarge the concept to exoplanets based on the research of the solar system, the following five conditions are added; (7) the distance from the central star, (8) the abundance of atmosphere, (9) mass and composition of central star, (10) size and composition of planet, and (11) circular orbital path.

Quantitative Evaluations for Meteorite Impact Tsunami

*Naotaka YAMAMOTO CHIKASADA[1], Tetsuharu Fuse[2], Toshitaka Baba[3]

1. NIED, 2. NICT, 3. Tokushima University

Tsunami induced by earthquakes, submarine landslides, volcanic eruption in submarine and coastal area and meteorological phenomena is one of the most devastating natural disasters. A meteorite impact into the oceans spawn large tsunami depending on the size and velocity of the meteorite and the sea depth at the location of the impact as well. However, we do not have a numerical model to reproduce both of meteorite impacts and tsunami propagations. We have started to develop a new numerical model to simulate tsunamis generated by the meteorite impact combining iSALE (Wünnemann et al., 2006) for simulating impact phenomena and JAGURS (Baba et al., 2017) for simulating tsunami. The iSALE is a multi-material and multi-rheology shock physics code for simulating impact phenomena. JAGURS is a parallelized tsunami simulation code to solve two-dimensional non-linear long-wave equation with Boussinesq terms for representing observed tsunami waveforms, tsunami height and inundation. We set sea-floor deformation, sea-surface disturbance and velocity of gravity wave which is the output from iSALE to the input of JAGURS. We then calculate tsunami height along the coastlines in any place using ASTER GDEM version 2 (Fujisada et al., 2012) and GEBCO_2014 Grid. ASTER GDEM has one arcsecond (about 30 m) spatial resolution and covers land between 56S and 60N latitude as a topographic data. GEBCO’s gridded bathymetric data has thirty arcseconds (about 1 km) spatial resolution for the worldwide.
We first investigate the tsunami generation using iSALE code for creating tsunami source model depending on the meteor size, the velocity of impact, the size of cavity, the width and depth of crater and tsunami propagation speed. We also investigate probabilistic hazard of meteorite impact tsunami using simplified cavity curves with developed JAGURS built-in. Finally, we construct a new numerical model of meteorite impact tsunami combining iSALE and JAGURS. Additionally, we consider the way of automatic detection of meteorite impact using the recode of the highly sensitive seismograph network in real-time.
We gratefully acknowledge the developers of iSALE, including Gareth Collins, Kai Wünnemann, Boris Ivanov, H. Jay Melosh and Dirk Elbeshausen. Data analysis and visualizations of iSALE were carried out on PC cluster and the computers at Center for Computational Astrophysics, National Astronomical Observatory of Japan. This work was partially supported by JSPS KAKENHI Grant Number JP18K04674.

The Study of Using SLR and GPS Observation Data to Estimate Geocenter Motion.

*Yih Jack Cheng[1], Fang-shii Ning[1]

1. National Chengchi University

Geocenter motion describes the difference of Center of Figure (CF) respect to Center of Mass of the Earth system (CM) due to the mass re-distribution and deformation of the Earth system. This is a factor that cannot be ignored in the maintenance of the high-precision terrestrial reference frame. As precision requirements and application demands in space geodesy increase, research on estimation of the geocenter motion become increasingly important as the key point to realize a reference frame with its origin fixed to the center of mass of the Earth system. In this study, GPS (Global Positioning System) observation data from IGS (International GNSS Service) and SLR (Satellite Laser Ranging) tracking data in the period of 2007 to 2016 are applied to estimate the coordinates of IGS sites on Earth’ s surface by using the GAMIT/GLOBK and Bernese software. Then, the Helmert transformation model is used to acquire seven parameters between the ITRF (International Terrestrial Reference Frame) reference frame and the CM reference frame. There are three parameters of them are related to the shift in three axes, which are the results of the geocenter motion. Afterwards, the geocenter motion time series are applied with the linear fitting method in order to obtain the amplitudes and phases along three axes of geocenter motion. The annual amplitude of X-, Y-, and Z- components between the years 2007and 2016 are 2.6± 0.2 mm, 4.1±0.2 mm, and 5.6±0.3mm respectively. The annual phase of X-, Y-, and Z- components are 72˚, 330˚, and 145˚ respectively. The accuracy of this study is significant improvement comparing to just using GPS or SLR technique only.

Evolution of Pluto's surface albedo due to sublimation and condensation of ice

*Hisashi Matsui[1], Jun Kimura[1]

1. Osaka University

Observation of the spacecraft New Horizons approached Pluto in 2015 revealed that H_2O, N_2, CH_4, CO ice coexists on the surface of Pluto and that the surface has a strong contrast of bright and dark due to a difference in the amount of ice. However, it is not cleared an origin of the bright and dark color distribution on the surface.
In previous researches about a temporal changing of albedo on the Jovian and Saturnian moons, it has been shown that sublimation of ice due to an insolation affects albedo changing on their surfaces. In addition, condensation of sublimated ice in the atmosphere also should affect Pluto’s surface albedo. Through these processes, ice behavior like sublimation and condensation possibly affects a change of albedo on Pluto’s surface. However, it has been not considered quantitatively so far.
In this study, we evaluate relationship between behavior such as sublimation and condensation of various ices and change of albedo with a numerical simulation, and investigate the origin of the albedo variation on Pluto.
In our model, we assume that bright ice and dark non-ice material exist uniformly mixed and the surface albedo can be modeled by the volume ratio. Subsequently, calculate the surface temperature with a change of insolation on each latitude and thermal inertia and then estimate the sublimation amount of ices from the difference between the vapor pressure at the temperature and the atmospheric pressure. Sublimated ices exist as the atmospheric gas, and these gas should be segregated and deposited on the surface if the surface temperature falls below the segregation temperature. We calculate albedo at the next time step from the volume ratio of ice and non-ice material contained in depth considered to be mixed by micrometeorite bombardment. Finally we examine temporal change of the Pluto’s surface albedo by repeating these cycle.
As a result, using the difference of insolation amount for each latitude caused by the large inclination of the obliquity, we found that a possibility to explain the overall trend of the albedo on current Pluto without special events like a giant impact.

Origin of the moon, Reason why Moon is always facing to Earth, Origin of Moon Sea, reasons why there is no Ocean behind Moon

*Akira Taneko[1]

1. SEED SCIENCE Lab.

In Solar system, Way to verify Mystery of planet origin (evolution creative inference Abduction with Evolution),It is to be able to describe all Multiple results of evolution uniformly using physically meaningful hypothesis,It can be said that it is a verification using evolution that occurs only once.
Initial condition is also unknown, and from Present state where Reproduction experiment can not be done, there is a way that is Only way to infer **Missing Link** to Origin.
Origin of Moon **(2014 U 06 - P 24)**, described Theory of necessity of Moon formation in Model of Multi-Impact Hypothesis. In addition, Origin of Jupiter Large Red Spot, Origin of Asteroid Belt, Origin of Earth Differentiation Meteorite, Origin of Earth Deep Ocean Bottom, Origin of Plate Tectonics, Origin of Driving Force, Origin of Pluto, Origin of Diamond Pipe, Core Eccentricity Also Mentioned Origin.
Origin where Moon is always facing Earth, origin of Moon sea, reason why there is no ocean behind Moon, Earth mantle ejected as shown in Lower right figure has a higher inner density, Moon is biased Center of Moon sea was formed by collision with Meteorite crust which heavy basaltic rocks were heavily on Front side, and Same crustal material does not change even if Meteorite falls on Back side around Common center of gravity of Earth and Moon Rotate Heavy side always to Center (Earth) when Earth rotates each other from its birth, and it is further accelerated and rotating due to Collision.

Y. Toda and Y. Abe Hypothesis that a special mechanism is unnecessary and can be explained as Difference of **random collision number N** between Front side and Back side and **as a result** Tidal lock of Moon will occur after establishment of Crust deformation symmetry [2] . However, since it does not mention the cause of the N number difference, ***it is only a Result Theory.***

Moon Origin Hypothesis up to Present *was a Simulation Deformation in which Differentiated Mars was formed at an arbitrary angle and velocity by Accidental Collision and Moon of only Mantle was formed in the orbital position three times Earth Radius Re.*

In "Multi- Impact Hypothesis", CERRA which was flattened toward the near point side of Jupiter by the perturbation by the gravity of Jupiter formed on the outer side of the Mars sized Differentiated Protoplanet formed at the position of Asteroid Belt by Baudet's Law, And it breaks at Jupiter's gravitational equally dividing point and it revolves around a elliptical orbital with **Train Mantle Fragments** like **a comet of a shoe maker Levi collides** with Earth at the intersection of Earth orbit Time and angle at this time Mooon that is eccentric with **Pacific Ocean** in **the first collision** is formed at current **Moon orbit energy 60 ·Re.**Fragments that collided with Jupiter become **Large Rd Spots** and the mantle of the debris becomes the asteroid belt Origin became an isostasy and became **Origin of Deep Ocean Floor of depth 5 km**, and the multiple collisions became the origin of extinct species species **High Latitude Collision of Tethys Sea formation** is caused by **Earth's gradient** and **Sudden Change in Driving direction** And **Triggered the plate movement**. It can be explained by -Antarctica moving **Center of Shaft** became unchanged **Pacific Rim arc islands and back-arc basins** also **Aisosutashi.**
I can verify **the missing link** by using **the inevitable result of evolution** that I can explain about *the present condition of about 17 items* in **a single Hypothetical model** as **a result of only one Evolution.**

Quantitative evaluation of the cumulus convection schemes for the implementation into the Paleo Martian Global Climate Model

*Katsushige Toriumi[1], Arihiro Kamada[1], Takeshi Kuroda[1,2], Naoki Terada[1], Yasumasa Kasaba[3], Isao Murata[1], Hiromu Nakagawa[1]

1. Tohoku university, Geophysics, Planetary Atmospheric Physics, 2. NICT, 3. Tohoku university, Geophysics, Planetary Plasma and Atmosperic Research Center

Current Mars has a lot of fluvial traces, which are supposed to be made during the late Noachian and early Hesperian boundary (3.85-3.6 Ga). If these traces are created by the fluvial activity, the climate of early Mars should be ‘warm and wet’ enough for the long-term existence of liquid water on its surface. However, solar luminosity at that time would be weaker by 20-30 % of today’s value, which would preclude early Mars from such ‘warm and wet’ climate (‘Faint young Sun paradox’). Previous studies using 3-dimensional Mars Global Climate Models (MGCMs) have revealed that pure CO_2atmosphere, even assuming 2~7 bars, was hard to reproduce the surface temperature above 273 K [e.g. *Kasting*, 1991; *Forget et al*. 2013].

We newly developed a 3-dimensional Paleo MGCM (PMGCM) with ancient ocean on its surface below a sea level of -2.54 km, including the absorptions of CO_2/ H_2O gases, CO_2/ H_2O ice clouds, thermodynamics of land / ocean, and hydrological processes [*Kamada et al*., submitting to Icarus]. This model reproduced a clement surface environment enough for liquid water on surface and could create most of fluvial channels by hydrological processes. However, the fluvial channels reproduced in our model were partly not consistent with observations on current Mars (e.g. *Sabaea Terra*). There are several explanations for the inconsistencies, such as 1) in Noachian and early Hesperian boundary the Tharsis rise had not finished or completed, which would enable wind system to transport water vapor towards the leeward regions such as Sabaea Terra, and/or 2) some of fluvial channels would have formed by glaciation.

Another possible reason is that our modelhad excluded the cumulus convection scheme, considering only the large-scale condensation process for the precipitation. This process could be crucial for resolving atmospheric instability and affect the distribution and the amount of precipitations on early Mars. Therefore, as the next step, we are newly introducing a cumulus convection scheme. One candidate is the Relaxed Arakawa-Schubert scheme [*Moorthi and Suarez*, 1991] which is often introduced to terrestrial GCMs. However, it is not clear whether this scheme could be adapted to early Mars, because it is a simplified scheme taking the empirical processes of the Earth into account for the calculations of the cloud mass flux, which may not be simply adopted to the CO_2/ H_2O atmosphere of early Mars. On the other hand, the Kain-Fritsch scheme [*Kain and Fritsch,* 1993], which is appropriate for middle resolution GCMs to reproduce the cumulus lifetime including creation, developing, declining, and deletion phases by one cumulusin a grid,is considered to be more suitable for PMGCM. It directly calculates the vertical structure of the cumulus without using the empirical assumption of the Earth.Though it is inferior to the Relaxed Arakawa-Schubert scheme in terms of ensemble, it is meaningful to introduce this scheme with high accuracy if we aim for high resolution in the future.Ultimately, we intend to calculate PMGCM with high resolution (both vertical and horizontal), verify the validity of the PMGCM introducing the cumulus convection model, and consider the influence on the running water topography.

In order to do the trade-off between those two schemes, we evaluated the differences of heat balance and

©2019. Japan Geoscience Union. All Right Reserved.

precipitation created by both schemes. First, we did the test under the present terrestrial condition (1bar, N_2/ O_2atmosphere, present solar flux at 1 AU). We supposed that both schemes would show the similar results in radiation balance and precipitation on the present terrestrial models. However, in the actual calculation results, the cloud structure had wider range of clouds in the low altitude with the Kain-Fritch scheme. That is because the characteristics of detrainment for each scheme are different. As the next step, we are changing parameters such as surface pressures (wet CO_2atmosphere of 0.5-2.0 bars), atmospheric compositions, solar flux, and terrain for early Mars as our PMGCM conditions. And we analyze the cloud structure generated by Kain-Fritsch scheme and qualitatively and quantitatively compare the change of water vapor transport with the case without cumulus convection scheme. In this paper, we plan to provide a first summary of those results.

Forced libration of Ganymede including the visco-elastic tidal deformation

*shinichiro kojima[1], Jun Kimura[1], Shunichi Kamata[2]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University, 2. Creative Research Institution, Hokkaido University

From spacecraft observations and interior thermal modeling, Ganymede has been expected to possess a global ocean beneath its ice shell. To confirm an existence of the ocean, the JUICE (JUpiter ICy moons Explorer) mission has been prepared by ESA (The European Space Agency) and the spacecraft will be launched in 2022. After arriving at Jupiter system, the JUICE spacecraft is going to make several flybys Europa and Callisto and finally will orbits around Ganymede. During orbiting around Ganymede, the spacecraft will obtain several kinds of scientific data, for instance, surface topography from GALA (GAnymede Laser Altimeter) and surface images from JANUS (camera system). These data will provide important information about the tidal responses of Ganymede.

The tidal responses, e.g., tidal deformation and rotational variation, are caused by the gravitational force of other bodies such as a mother planet. The rotational variation includes libration, obliquity variation, nutation, and precession. In this study, we focus on the libration which is a spin rate variation caused by a torque acted on the aspherical degree-2 order-0 shape of the satellite. The libration changes the centrifugal force of a satellite and affects the tidal deformation. Inversely, tidal deformation affects the aspherical shape of the satellite.

Although Van Hoolst et al. (2013) has modeled the interaction of the tidal deformation and the libration, their tidal deformation models were simplified. In order to estimate an actual libration, we model 5-layered Ganymede interior and use the visco-elastic tidal deformation model constructed by Kamata et al. (2016). Our interior model consists of five layers, which have a homogeneous density and rigidity in each layer. The viscosities of the ocean, the high-pressure ice mantle, the rock mantle and the metallic core are homogeneous in each layer, and the viscosity of the ice shell is not homogeneous and depends on a radial temperature variation.
As a typical case, we use interior parameters which are the ice shell thickness of 155 km, the ice shell density of 940 kg/m^3 , the ocean thickness of 1 km, and the ocean density of 1050 kg/m^3 . Then we also use the three sets of a shell rigidity and a shell viscosity (1) 0.1 GPa and 10^{12} Pas, (2) 0.1 GPa and 10^{17} Pas, and (3) 10 GPa and 10^{17} Pas, respectively. The results for the libration amplitude are 34.1 m, 34.1 m, and 37.5 m respectively. As a conclusion, our calculation of the visco-elastic libration infer that the reference viscosity of ice (temperature-dependent viscosity of ice at a melting point) doesn’ t affect the amplitude of the shell libration. The ice rigidity affects the amplitude of the shell libration of order of a few meters.

Experimental study on collision destruction simulating the primitive meteorite parent body

*Horikawa Kazuhiro[1], Masahiko Arakawa[1], Minami Yasui[1], Ryo Sugimura[1]

1. Kobe University Faculty of Science

We studied the impact strength of weak brittle materials changing the strength continuously from 40kPa to 800kPa, and found that the impact strength could be well scaled by using the non-dimensional impact strength.

Asteroids are believed to be constructed from various materials based on the long-term study related to meteorites. The components of S-type and C-type asteroids could be composed of chondrules and matrix; the chondrules are sub-mm size glass spherules and the matrix could be micron-size fine grained materials such as phyllosilicates and lithic fragments etc. Moreover, these components could have a wide range of porosity inside because they might be residual pore during the compaction process of planetesimals or relics of water ice or volatiles escaping from these bodies. Impact strength is one of the most important physical properties of asteroids because it could control the evolution of the size-frequency distribution of asteroids at the asteroid belt. The impact strength strongly depends on the asteroid size and it is dominated by the material strength at the size smaller than 100m, so that the impact strength should be determined by the laboratory experiments. Therefore, a lot of research have been conducted for rock, ice, and porous materials to investigate the material dependence, however the impact experiments using the target with the strength continuously changed have been hardly conducted so far. Then, we prepared the targets simulating asteroids composed of chondrules, matrix and pore and changed the internal structure of the target such as matrix ratio and porosity; the tensile strength was changed more than one order of magnitude, then we studied the relationship between the internal structure and the impact strength.

Impact experiments were conducted by using two-stage light gas gun at Kobe University, and we used a polycarbonate projectile with the size of 4.7mm and a nylon projectile with the size of 2mm and they were lunched at the velocity from 0.9km/s to 5.7km/s. The impact was conducted at a head-on collision. A spherical target with the size of 60mm were prepared by using quartz sands with the size of 100 μm and porous gypsum, and they are mixed with various mass ratio of quarts to gypsum from 2:1 to 8:1. The tensile strength of these materials (Y_t) was measured by using Brazilian test and it was found that the tensile strength changed from 40kPa to 800kPa with the increase of the gypsum mass ratio. The impact disruption was observed by a high-speed camera at 10^5fps.

The impact strength (Q*) was determined by using a largest fragment mass for each shot, and Q* was found to change from 400J/kg to 1900J/kg with the increase of the gypsum mass ratio. This means that the Q* is directly proportional to the tensile strength. However, the ejection velocity at an antipodal point (v_a), which was measured by using high-speed images, showed the almost similar results, irrespective of the tensile strength. A non-dimensional impact strength (P_I) is defined as the ratio of the target tensile strength to the antipodal pressure such as P_I=Y_t/P_a, where P_a is calculated by ρ C_b v_a/2. This P_I was proposed to scale the target with the different tensile strength. Then, the relationship between the largest fragment mass and P_I was examined to discuss the P_I scaling law for the catastrophic disruption. We found that P_I is able to scale the largest fragment data very well, and this might mean that P_I could be applicable to asteroid components composed of weak brittle materials.

Evolution of atmospheric composition in the early Martian atmosphere

*Ryosuke Yagi[1], Naoki Terada[1]

1. Planetary Atmospheric Physics Group, Tohoku University, Japan

The purpose of this study is to investigate the evolution of atmospheric composition in the early Martian atmosphere. Not only hydrogen and oxygen but also carbon escape to space is considered in this study. The early Martian atmosphere was influenced by a stronger Sun’ EUV radiation than today. The escape parameter, defined as the ratio of the gravitational potential to kinetic energy at a given altitude, could be small enough to allow massive escapes of these species under such a strong radiation. For example, the escape parameter of atomic carbon in the Martian atmosphere was estimated 0.8 times smaller than that of atomic oxygen and both densities at the exobase level were comparable at 4.1 Gyr ago (Tian et al., 2009). Hence, we consider that in early Mars, thermal escape of atomic carbon could be stronger than atomic oxygen, and oxygen dissociated from CO2 was left behind in the atmosphere. Assuming that the escape rates of atomic carbon and atomic oxygen were in the same proportion, we get results that carbon disappeared in 5 Myrs from 1 bar of CO2 atmosphere and only 0.4 bar of oxygen atmosphere remained around 4.2 Gyr ago. On the other hand, it was suggested that the Martian atmosphere about 3.5 Gyr ago could have several mbar or more of oxygen partial pressure(Noda et al., 2018). In the present study, we have developed a 1-D photochemical model of the early Martian atmosphere to investigate the evolution of the atmospheric composition, in particular from 4.2 to 3.5 Gyr ago. This model includes not only the effect of escapes of hydrogen, oxygen and carbon but also that of deposition to surface and degassing. In this presentation, we will show the influence of the atomic carbon escape to the evolution of oxygen partial pressure left behind in the early Martian atmosphere.

Observation of catastrophic destruction of two different targets using X Ray photography

*Takumi Nagano[1], Masahiko Arakawa[1], Minami Yasui[1], masato nakamura[1], Fumiya Nagatomo[1]

1. Faculty of Science Kobe University

We studied the dependence of physical properties of planetesimals on the impact strength in the gravity regime, then we made laboratory impact experiments by using a Flash X-ray for porous gypsum and dry clay simulating planetesimals in order to obtain the relationship between impact fragment masses and ejection velocities.

The impact strength of planetesimals is one of the most important physical properties to clarify the planetary accretion process and the formation process of proto-planets and asteroids. Thus, the impact strength in the strength regime applicable to planetary bodies smaller than 100 m has been mainly studied in laboratory experiments. However, the impact strength in the gravity regime applicable to planetary bodies larger than planetesimals has been studied only by numerical simulations, and their results are not consistent with each other. Furthermore, recent numerical results conducted by Jutzi (2016) showed us that the material properties such as friction, cohesion and porosity affected the impact strength in the gravity regime drastically. Then, we made laboratory impact experiments to elucidate the material dependence on the impact strength in the gravity regime.

In order to determine the impact strength in the gravity regime by the laboratory experiments, we should obtain the relationships between the impact fragment masses and the ejection velocities, and especially, the fragments ejected from the interior of the disrupted target must be observed to construct the velocity –mass relationship for all the fragments. Then, we introduced 3 sets of flash X-ray generators and imaging plates to take transmitted X-ray images of a target with 3 mm steel balls arranged in it. These steel balls were used as makers of the motion of impact fragments, and the time sequence of these balls were observed by using X-rays to analyze the local velocities of the target’ s interior.

Impact experiments were conducted by using a polycarbonate projectile with the size of 7mm at the velocity of 2 –5 km/s, and the projectile was impacted on a spherical target with the size of 6 cm in a head-on collision. We used porous gypsum targets with the porosity of 50% and the tensile strength from 1 to 2 MPa and dry clay targets with the porosity of 48 % and the tensile strength different from the porous gypsum. All the targets were catastrophically disrupted into the largest fragment mass less than 0.2. As a result, we determined an upper limit of ejection velocities having a half mass of the target for each experiment, and we defined this upper velocity as a median velocity of V*. So, we studied how V* depended on the energy density, tensile strength and porosity, then we found that V* increased with the energy density for both targets. Moreover, we found that it strongly depended on the target porosity when it was compared with the previous result for the frozen clay with the similar tensile strength but without porosity, the V* for porous gypsum reduced to be 1/3 for the frozen clay. The V* for the dry clay was almost similar to that for the porous gypsum, thus this might mean that the tensile strength does not affect the V* even for the porous target.

Charge transport between granular particles in an ejecta curtain produced by hypervelocity impacts

*Kosuke Kurosawa[1], Takanori Iwasawa[2], Satoshi Okuzumi[2], Sunao Hasegawa[3], Takayuki Muranushi[4]

1. Planetary Exploration Research Center, Chiba Institute of Technology, 2. Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 3. ISAS, JAXA, 4. AICS, RIKEN

We studied the charge transport between granular particles in an ejecta curtain produced by hypervelocity impacts to access the energy partitioning from the initial kinetic energy to the electrostatic one having the ejecta curtain. We conducted both hypervelocity impact experiments and numerical calculations. The impact experiments were done at ISAS/JAXA hypervelocity impact facility. A vertical gun was used to use granular materials as a target. High-speed video cameras for the visible and infrared were used to observed an impact-generated ejecta curtain. Any light sources were not used in this experiment. We constructed a numerical model by combining the iSALE shock physics code and the REBOUND N-body integrator. The processes of impact ejection under the conditions similar to the laboratory experiments were solved by the iSALE. The time at the ejection, ejection velocity, and the launch position of each particle was extracted as a txt file. Then, the txt file was imported in the REBOUND as a input file. At this time, we added random velocities to simulate the velocity dispersion. Although the dispersion would be inevitably added to each ejected particles in nature, it cannot be modeled in the hydrocode. The absolute magnitude of the random velocity was treated as a free parameter. Subsequent particle motions under the Earth’ s gravity field and the resistance force by the surrounding air were calculated. The decceleration due to inelastic collisions and charge transport between particles were included into the calculations. The restitution coefficient was also treated as a free parameter. The degree of charge separation was given by an empirical law proposed by the previous experiment. The results are summarized as follows; (1) We did not observe a large-scale discharge in an ejecta curtain under the experimental condition, (2) we observed a number of bright points along with an produced-ejection flow, (3) we observed a mesh pattern in the ejecta curtain as well as a previous study, (4) we reproduced the mesh pattern in the REBOUND when we chose the degree of the random velocity to be 5-15% of the ejection velocities at the restitution coefficient of 0.8, (5) mutual collisions between granular particles cease at the early stage of the growth of the ejecta curtain, (6) the end time of the mutual collisions depends on the atmospheric pressure, and (7) the empirical law pertaining to the charge separation yields an unphysically-high electrostatic energy. In the presentation, we will present the current status of our research development and discuss the future plans.

Acknowledgements:We thank the developers of iSALE, including G. Collins, K. Wün- nemann, B. Ivanov, J. Melosh, and D. Elbeshausen. We also appreciate the developers of REBOUND, including Hanno Rein, ShangfeiLiu, David S. Spiegel, Akihiko Fujii, and Dan Tamayo.

Nonlinear outcome of gravitational instability in irradiated protoplanetary disks

*Shigenobu Hirose[1], Jiming Shi[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Spotify USA Inc

Using local three dimensional radiation hydrodynamics simulations, the nonlinear outcome of gravitational instability in an irradiated protoplanetary disc is investigated in a parameter space of the surface density Σ and the radius r. Starting from laminar flow, axisymmetric self-gravitating density waves grow first. Their self-gravitating degree becomes larger when Σ is larger or the cooling time is shorter at larger radii. The density waves eventually collapse owing to non-axisymmetric instability, which results in either fragmentation or gravito-turbulence after a transient phase. The boundaries between the two are found at $r \sim 75$ AU as well as at the Σ that corresponds to the initial Toomre's parameter of ~ 0.2. The former boundary corresponds to the radius where the cooling time becomes short, approximating unity in terms of the inverse of the orbital frequency. Even when gravito-turbulence is established around the boundary radius, such a short cooling time inevitably makes the fluctuation of Σ large enough to trigger fragmentation. On the other hand, when Σ is beyond the latter boundary (i.e. the initial Toomre's parameter is less than $\sim$0.2), the initial laminar flow is so unstable against self-gravity that it evolves into fragmentation regardless of the radius or, equivalently, the cooling time. Runaway collapse follows fragmentation when the mass concentration at the centre of a bound object is high enough that the temperature exceeds the H_2 dissociation temperature.

Rheology of clay paste and application to the investigation of formation process of surface topography on the Mars

*Chihiro Uemura[1], Takahiro Iwata[1,2], Akio Nakahara[3], Yosuke Matsuo[3], Tomohiro Usui[2], Rina Noguchi[2]

1. SOKENDAI, 2. ISAS/JAXA, 3. Nihon Univ.

Mars is known to have many terrains formed by water, which is one of important candidates for future exploration places. For example, RSL (Reccuring Slope Lineae) is repeating disappearance and occurrence by seasonal variation, so it suggests that RSL was formed by water. However, there is a hypothesis that RSL is formed by sands, and formation process of RSL is still unclear.
Considering that flowing water is mixed with grain of sands and clay powders, and becomes pastes (colloidal suspension). It is valuable to understand properties of pastes. Since pastes have many unique properties, they are attracting widespread interest in various fields. Pastes are classified as attractive or repulsive according to a force among particles. Rheology of repulsive colloidal suspension has been studied so far. On the other hand, rheology of attractive colloidal suspension is still unknown. To understand the surface topography on Mars, it is important to study the rheology of clay paste, one of typical attractive colloidal suspension, because clay minerals are widely found on the surface of Mars. As the formation of some landforms, such as RSL, are considered to be dependent on temperature, we focused on the temperature dependence of their rheology, such as an yield stress and a viscosity, of attractive colloidal suspension.
We used paste of magnesium carbonate hydroxide because their properties are similar to clay minerals; their inter-particle force is attractive and makes a card house structure. We used rheometer (Anton Paar, Physica, MCR-301) for measuring. We measured rheology of paste at four different temperatures and five different solid volume fractions. We found that the yield stress of paste of magnesium carbonate hydroxide is an increasing function of a temperature. The yield stress of usual elastoplastic media is known to decrease as the temperature increases. However, our experimental study revealed that the yield stress of attractive colloidal suspension is an increasing function of the temperature, the result of which is an inverse behavior to that of usual elastoplastic media. The temperature dependence of the yield stress of attractive colloidal suspension is much more drastic when it is compared to the theoretical prediction for the repulsive colloidal suspension with the linear dependence to its absolute temperature.
As for the viscosity of attractive colloidal suspension, its behavior is similar to that of Newtonian viscous fluid with its viscosity a decreasing function of the temperature. We consider that this is because the viscosity of solvent, i. e., water, decreases as the temperature of an colloidal suspension increases.
These facts suggest that temperature dependence of rheology was caused by what kind of force is working among particles. As a mechanism of these results, we suggest that changing charge on the surface of particles or changing viscosity of water. In order to reveal why interaction is changed with increasing temperature, we need further verification.
In the future work, we will make use of these results for understanding the process of forming subsurface terrains on Mars.

An Explanation for Physical Mechanism of the Streaming Instability

*Hiroaki Kaneko[1]

1. Tokyo Institude of Technology

Planets are thought to be formed from planetesimals, which are 1-100 km in size, and planetesimals are formed by accumulating small dust particles. Dust particles of a size of 10 cm-1 m drift sunward at 1 au per a century. Dust particles must grow within a timescale faster than this sunward drift timescale limit, otherwise they cannot form planetesimals. Enhancement of the particle density leads to the self-gravitational instability if the density reaches the Roche density, and the dense dust particles form planetesimals. In this case, the dramatic radial drift of dust particles can be avoided. Youdin & Goodman (2005; YG05) discovered that dust and gas streams mutually interacting via drag force generate local linear instability and a particle clumping occurs. This instability is called the streaming instability (SI). A lot of linear and non-linear numerical simulations conducted and it has been confirmed that SI emerges under certain conditions. But the physical mechanism of SI is not clear yet, because the order of the dispersion relation is as high as 6 and the mechanism seems to be difficult to understand. Applying the terminal velocity approximation (YG05) to particle continuity equation and gas incompressibility, Jacquet, Balbus, & Latter (2011; JBL11) attempted to give a physical explanation about the SI mechanism. Their explanation was as follows:

1. The gas pressure maximum traps dust particles.

2. Dust particles drag the gas toward the gas pressure maximum.

3. The gas pressure maximum is strengthened. Though the gas pressure gradient tends to force out the gas from the maximum, the dust particle drag force on the gas and the Coriolis force make roles to keep the geostrophic balance.

JBL11 suggested the explanation of the mechanism in which all the motion takes place only in the midplane, however, YG05 emphasized that the vertical advection flows toward the density maximum and it dominates the flow in the midplane.

In this study, first, we conduct an analysis on the dispersion relation that employs the terminal velocity approximation (YG05) and calculate phase differences among the perturbed particle density, the perturbed gas pressure, and the perturbed particle velocities for an unstable mode. Then, we give an explanation about the mechanism of SI including the vertical motion unlike the explanation by JBL11.

Our explanation on the SI mechanism is as follows:

1. At the particle density maximum, the gas receives more angular momentum, while at the particle density minimum, the gas receives less. So, the gas radial velocity perturbation and the gas pressure fluctuation along the radial direction are generated.

©2019. Japan Geoscience Union. All Right Reserved.

2. Toward the gas pressure minimum, the gas flows in vertically with dragging dust particles. On the contrary, both gas and dust particles flow out vertically from the gas pressure maximum.

3. The phase velocity of the dust particle density maximum is negative so the particle density maximum moves radially inward. The density maximum encounters the dust particle input due to the vertical converging flow and the density maximum is enhanced.

This explanation is consistent with solutions of the linear stability analysis. In addition, the explanation seems physically reasonable and easy to understand.

Spatial motion of the Earth-Moon system and Earth pole oscillatory process

*Alexandra Sergeevna Filippova[1], Vadim Vladimirovich Perepelkin[1], Wai Yan Soe[1]

1. Moscow Aviation Institute

The variation of the Chandler and annual components of the polar motion are of a significant interest in the Earth pole oscillatory process research. Generally these variations are quasiperiodic. But some regular oscillations can be isolated from it that correspond with the basic periods of the lunar motion. Here we discuss the theoretical assumptions of the observed effect as well as the experimental rules that illustrate the relationship between the Earth pole oscillations and the lunar motion.
The complex process of the Earth pole oscillations includes components with frequency and amplitude that differ significantly from each other. Processing the pole motion observations over the last 100 years result in statistically convincing definition of the main characteristics in its oscillatory process. Basic components in the Earth pole motion are Chandler wobble, annual oscillation and also polar motion's trend. Observed Earth pole oscillations have a wobbling character. The trajectory of the pole on the Earth surface is a winding and unwinding spiral with a period of about six years.
Actual problem that was stated by P. Melchior (Melchior, 1972) about the instability in the basic components parameters of the Earth pole is still not sufficiently explored. This problem is connected with the exploring the celestial-mechanics' and geophysical causes of such behavior in the Chandler and annual components, and also with the construction of the refined models of the forecasting the Earth orientation parameters for long time intervals.
In this work along with the common methods of the separating the pole oscillation process into the Chandler and annual components we suggest an approach to the resulted Earth pole trajectory research. For the purpose of analyzing the nonstationary resulted pole motion a perturbed trajectory is isolated. For the unperturbed trajectory a “mean” one is chosen –the Earth pole trajectory where the Chandler and annual oscillation parameters have mean values.
The differential equations for the amplitude a and phase ψ of the Earth pole modulation motion can be derived from the dynamical Euler–Liouville equations of Earth motion around its center of mass (Markov, Perepelkin et al, Astronomy Reports, 2018 and Markov, Perepelkin at al, Doklady Physics, 2017).
It is shown that the significant impact into the variations of the basic pole oscillation components is given by the long-term perturbations from the lunar orbit. The analysis of these perturbations is held using the wavelet and Fourier transformations. On the long time interval it shows matching phases of the perturbed polar motion and the lunar orbit motion using the available series of observations C04 and C01 from the International Earth Rotation and Reference Systems Service. This feature can be used to refine the model of the forecasting the Earth pole oscillations. And taking into account these structural features of the oscillations the refined numerical-analytical model of the Earth pole motion is presented.
Thus the graphical correspondence between the Earth pole oscillations and the motion of the lunar orbit is presented. It is shown that the refined model gives a more accurate description of the Earth pole motion by comparing the model computation results with the observations made by the International Earth Rotation and Reference Systems Service.

Chondrule formation model by lightning in high dust density regions

*Chihiro Ikeda[1], Taishi Nakamoto[1]

1. Tokyo Institute of Technology

Chondrules are spherical objects of 0.1 - 1 mm in radius and are the main component of chondrite meteorites (Scott 2007). It is known that chondrules were formed early in the solar system. So, chondrules may have important information about early solar system nebula. It is believed that chondrules melt with dust particles heated within several minutes and have cooled and solidified at a rate of 1-1000 K/hour in the early solar nebula (Desch et al. 2012). Also, since chondrules contain volatile substances, it is considered that they are formed in a high dust density region (Alexander et al. 2008). Although the formation mechanism of chondrules have not been elucidated, formation theories include the shock wave model, astronomical collision model, X-wind model, and lightning model. In this study, we examine the chondrule formation by lightning from the viewpoint of thermal evolution of chondrules.

Thermal evolution of chondrules has been studied by Horanyi et al. (1995). In that study, assuming the occurrence of lightning in the solar nebula, they calculated the time evolution of the gas and dust in the lightning. As a result, the cooling rate of the chondrule became faster than the cooling inferred from observations of crystals in chondrules. On the other hand, according to studies on the occurrence of lightning, the mass ratio of dust to gas needs to be 100:1 or more for lightning generation (Muranushi 2010). However, Horanyi et al. (1995) considered the situation where only one dust particle is present inside the lightning.

In this study, we consider the occurrence of lightning in the high dust density region and calculate the thermal evolution of chondrules numerically. Especially, we investigate if the cooling rate condition for the chondrule formation is satisfied under the high dust density situation. As a result, it was found that there are circumstances suitable for chondrule formation. It is suggested that chondrule formation by lightning is possible in the solar nebula.

The transition to superrotation in stratospheric atmospheres

*Motoki Sumi[1]

1. Tokyo Institute of Technology

Titan is the only satellite with the developed atmosphere and the stable liquid on the ground surface in the solar system. The history of the observation begins with the suggestion of the existence of the atmosphere in 1908. In the 1970's, the temperature structure and atmospheric composition of the Titan atmosphere have been clarified thanks to the progress of observation technology. Also, in the Cassini-Huygens mission, it visited the Saturnian system, made Huygens probes into the Titan atmosphere, and made high-precision observations. Ground-based submillimeter wave observation by the ALMA telescope is currently being carried out, and it is possible to observe at high resolution.
Observations clearly show the existence of superrotation, which is a high-speed zonal wind oriented to overtake the rotation on a global scale as a characteristic of the Titan atmosphere. The wind speed reaches 100 m/s eastward at about 10 degrees south latitude where Huygens entered, but it is difficult to investigate its mechanism from the viewpoint of insufficient observation data and complexity of atmospheric structure. Also, the theory which unified the generation mechanism of superrotation is not established, and various theories are advocated. Representative examples are the Gierasch mechanism proposed by Gierasch or the mechanism by thermal tidal waves proposed by Fels and Lindzen.
In this research, I conducted numerical experiments to generate superrotation by changing only the planetary radius using the Earth model. We used the numerical simulation model DCPAM5 of the planetary atmospheric general circulation developed by GFD Dennou Club. Primitive equations were used as the basic equation system of the model assuming a dry atmosphere. We used the model of Williamson et al.(1998) which added the pressure dependency of stratosphere to the Newtonian cooling process in Held and Suarez (1994). The calculation time was 1080 days where sufficient stationarity was confirmed, and we analyzed the time average of the physical quantities in last 360 days.
First, I output the temperature field, the mass transport distribution, zonal-mean zonal wind speed field, compare the structure of the atmosphere in the meridional space, and investigate the location and the condition. where superrotation is occurring. In the Earth model, eastward jet streams occurred in the mid latitudes of the troposphere and the stratosphere, but on the equator the westward winds are blowing. If the planetary radius is small, in the troposphere even in the equator the eastward wind is accelerated and superrotation has occurred. In the stratosphere, equator superrotation occurred in the lower stratosphere, but in the upper stratosphere the jet occurred only in the middle and high latitudes, and the high-speed eastward wind did not appear in the equator.
Next, in order to investigate the mechanism of keeping the angular momentum in the upper layer of the equator, the dispersion of the band-like disturbance of the temperature, the band-shaped disturbance spectrum of the east-west wind speed field were output, and the structure of the wave existing in the atmosphere was summarized. In the troposphere in the Earth model, many waves with a wave number of 4 or more existed in the mid latitudes, and angular momentum in the east direction was accumulated in mid latitude. However, as the radius of the planet is decreased, the waves with large zonal wavenumbers decrease, and global waves with the wave number of around one dominate. The behavior is similar in the stratosphere, in the Earth model, waves with large wavenumbers are present, although the waves are weaker in the troposhere as the planetary radius is reduced, only waves with small wavenumbers remain. In the stratosphere the equator super rotation and the mid-high latitude jet occur in different altitude, and the mechanism for maintaining superrotation seems somewhat different from the mechanism in the troposphere.

ExPRES: a Tool to Simulate Exoplanetary and Planetary Radio Emissions

*Corentin LOUIS[1,2,3], Sebastien L. Hess[4], Baptiste Cecconi[2,3], Philippe Zarka[2,3], Laurent Lamy[2,3], Stéphane Aicardi[5], Alan Loh[2]

1. IRAP, Toulouse, 2. LESIA - Observatoire de Paris, 3. USN, Observatoire de Paris, 4. ONERA-The French Aerospace Lab, FR-31055 Toulouse, France, 5. DIO, Observatoire de Paris, PSL Research University, CNRS, Paris, France

All magnetized planets are known to produce intense non−thermal radio emissions through a mechanism known as Cyclotron Maser Instability (CMI), requiring the presence of accelerated electrons generally arising from magnetospheric current systems. In return, radio emissions are a good probe of these current systems and acceleration processes. The CMI generates highly anisotropic emissions and leads to important visibility effects, which have to be taken into account when interpreting the data. Several studies showed that modeling the radio source anisotropic beaming pattern can reveal a wealth of physical information about the planetary or exoplanetary magnetospheres that produce these emissions. We present a numerical tool, called ExPRES (Exoplanetary and Planetary Radio Emission Simulator), which is able to reproduce the occurrence in time−frequency plane of CMI−generated radio emissions from planetary magnetospheres, exoplanets or star−planet interacting systems. Special attention is given to the computation of the radio emission beaming at and near its source. We explain what physical information about the system can be drawn from such radio observations, and how it is obtained. These information may include the location and dynamics of the radio sources, the type of current system leading to electron acceleration and their energy and, for exoplanetary systems, the magnetic field strength, the orbital period of the emitting body and the rotation period, tilt and offset of the planetary magnetic field. Most of these parameters can be remotely measured only via radio observations. The ExPRES code provides the proper framework of analysis and interpretation for past (Cassini, Voyager, Galileo. . .), current (*Juno*, ground-based radiotelescopes) and future (BepiColombo, Juice) observations of planetary radio emissions, as well as for future detection of radio emissions from exoplanetary systems (or magnetic white dwarf−planet or white dwarf−brown dwarf systems). Our methodology can be easily adapted to simulate specific observations, once effective detection is achieved.

Crustal structures of major mercurian basins

*Qingyun Deng[1], Fei Li[1], Jianguo Yan[1], Zhiyong Xiao[2]

1. State Key Laboratory of Information Engineering in Surveying, Mapping and Remote Sensing, Wuhan University, 2. Planetary Science Institute, China University of Geoscience

Mercury is the innermost planet in the solar system. Its surface resembles to the Moon, which is characterized with large number of impact basins, indicating an intensive bombardment history. From the data acquired by previous Mercury missions, the spatial distribution, relative age, and morphology of impact basins on Mercury is studied. Gravity data from NASA MESSENGER mission revealed the crustal structures of mercurian basins, providing information about the crust properties of the early Mercury when those basins formed. In this work, the crustal thickness ratio for each basin is calculated from global crustal thickness model obtained by inverting gravity data. The relation between crustal thickness ratio, basin relaxation state, and relative age is investigated and some implication for the early evolution of Mercury is discussed.

Application of LiDAR Technique for the 3D Digital Documentation of Cultural Heritage Sites

*Sachchidanand -[1], Mayank Sharma[1], Rahul Dev Garg[1]

1. Indian Institute of Technology Roorkee

Now a day’ s remote sensing and geospatial techniques are gaining popularity as they offer correct and precise information of any object situated at a distant place. Advanced remote sensing techniques like terrestrial laser scanning (TLS), mobile laser scanner(MLS), close range photogrammetry(CRP), smart total station(STS) and GNSS are the useful techniques for creating a 3D (three-dimensional) documentation of complex engineering structures or cultural heritage sites. The integration of these techniques with other methods like topographic survey or physical measurement method also offer the potential to the user to perform a complete 3D documentation of any structure.

This paper presents a methodological framework for the 3D digital documentation of cultural heritage sites from laser scanned datasets. The framework includes acquisition of point cloud datasets through laser scanners and their conversion to 3D models. 3D models are useful for planning and surface detail measurements. Detailed planimetric and elevation information or plans could be easily extracted from developed 3D models. These planimetric informations and elevation plans are useful for the conservation and preservation of structure, and can help in restoration of these structures in case of any damage due to natural disasters or other seismic activities.

Tidal Interaction in the Earth-Moon System Treated as a Double Planet

*Aleksandr Aphanasievich Zlenko[1], Irina Michailovna Ryabikova[2]

1. Department of high mathematics, Moscow automobile and road construction state technical university, 2. Department of descriptive geometry, Moscow automobile and road construction state technical university

Our approach to the phenomenon of tides differs from the traditional one, in which an empirically tidal potential with Love numbers is introduced. We consider the motion of two viscoelastic bodies, the Earth and the Moon treated as a double planet, in the gravitational field of a massive point, the Sun.The deformations of the bodies are described by the classical theory of small deformations. The influence of viscous forces is described by the dissipative functional of the Kelvin-Voigt model. The quasi-static equation of the elasticity theory is solved for obtaining the displacements of body points. The method of averaging and separation of motion is used for solving of this equation. The displacements of each point of the deformable body consist of displacements caused by centrifugal forces, the forces due to body elasticity and dissipative forces due to body viscosity. Substituting these displacements in the potential formulae and integrating over the each body, we get the potential of the system and the moments of forces acting on the bodies.. Knowing the displacements, we determine the shape of deformable bodies, their moments of inertia and the lagging angle. The results of this approach are compared with the results of the traditional theory.

The consequences of Saturn’s “ring rain”

*James O Donoghue[1,2], Luke Moore[3], Jack Connerney[4,1], Henrik Melin[5], Tom Stallard[5], Sean Hsu[6], Steve Miller[7], Kevin Baines[8]

University College London, UK, 8. NASA Jet Propulsion Laboratory, California, USA

Saturn’s upper-atmospheric H3+ emissions have been previously studied using ground-based observations, and found to exhibit peaks in emissions at specific latitudes. The cause of these peaks is due to an influx of charged water products originating from Saturn’s rings known as 'ring rain'. Subsequent modeling using the Saturn Thermosphere Ionosphere Model (STIM) has indicated that these peaks in H3+ emissions are likely driven by an increase in H3+ density, rather than temperature, as a local reduction in electron density (due to charge exchange with water) lengthens the lifetime of H3+. However, a direct observation of the H3+ density is required to estimate the flow rate of material into Saturn with models. Calculation of ring rain’s flow rate into Saturn is a highly important input for determining the age, lifetime and evolution of Saturn’s rings.

Here we present the first ever derivation of H3+ density, temperature and radiance in the non-auroral regions of Saturn, using data taken from the 10-meter Keck telescope in 2011. H3+ density is enhanced near 45 degrees north planetocentric latitude and strongly reduced near 39 degrees south. When compared to STIM modeling results, these densities indicate a small ~50kg/sec water influx in the north and an enormous ~1500 kg/sec influx in the south. The charged grains are pulled in along the magnetic field by gravity, but the southward-inclination of the magnetic field (in the vicinity of the ring plane) means that the grains are preferentially drawn southwards into the planet. Assuming that our (Saturn northern Springtime) measurement represents all seasons, and that the rings are able to disperse over time, the ring rain mechanism alone will drain Saturn’s rings to the planet within 300 million years. If we also add the recent Cassini-spacecraft measured ring-material detected falling into Saturn’s equator (and assume it is constant), then the rings have less than 100 million years to live.

Recent measurements by Cassini again have estimated a ring age of ~50 million years, so it seems that Saturn’s rings are short-lived phenomena, perhaps lasting just 150 million years in total. A long time on human timescales, but compared to the 4.5 billion year age of Saturn, the rings are essentially temporary; i.e. if Saturn were 30 years old, the ring system would exist for just 1 year of its life! These recent findings indicate that ring systems in general are practically doomed to be removed as soon as they are formed. Indeed, the ring rain mechanism itself ought to be universal at any planet with both a ring system and a strong magnetic field. We might ask, did Jupiter, Uranus and Neptune, which have thin rings today, once have magnificent rings in the past that have eroded away?

Calculation of kinetic rate constants using high-level *ab initio* quantum chemical methods for planetary sciences and astrochemistry

*Shiblee Ratan Barua[1,2], Paul Romani[1]

1. NASA Goddard Space Flight Center, Greenbelt MD USA, 2. Universities Space Research Association (USRA), Columbia MD USA

Existing photochemical models for the atmospheres of planetary bodies suffer from large errors when predicting the mole fraction profiles of various compounds. Global sensitivity analyses show that a major source of these model errors can be attributed to inaccurate rate coefficients for “key” radical–radical and radical–neutral reactions in low-temperature conditions. Accurate rate coefficients for key reactions thus improve the accuracy of photochemical models. Unfortunately, accurate experimental rate constants for such low-*T* reactions are difficult, if not impossible, to measure, and the lab data are affected by uncertainties in determining the absolute concentrations of radical species. Currently, the most common theoretical approach involves uncertainty extrapolation technique in which uncertainties in room-temperature rate constants are extrapolated to low-temperature conditions, resulting in large errors in the theoretical low-*T* rate constant data. To solve this existing problem, we are employing the two-transition-state (2TS) model developed by Klippenstein and coworkers to calculate high-level *ab initio* rate-constants for key low-*T* (*i.e.* 10–200K) reactions relevant to planetary atmospheres like that of Titan. In particular, we are investigating key reactions that have not yet been studied in the lab, and for which accurate rate coefficients are still unknown. Our calculated *ab initio* rate coefficients will be made available to the astrochemistry community via well-established free online kinetic databases (*e.g.* KIDA). These rate coefficients will be used by scientists in photochemical models to make accurate predictions of mole fraction profiles for planetary atmospheres and improve our understanding of the diverse chemistry of these bodies.

How many conditions must be satisfied to produce a habitable planet?

*Shigenori Maruyama[1], Soichi Omori[2]

1. Earth-Life Science Institute, Tokyo Institute of Technology, 2. The Faculty of Liberal Arts, The Open University of Japan

<Purpose>

Concept of habitable zone (HZ below) is regarded as the presence of stability field of liquid water on the surface of planet. HZ is regarded as the most important condition to produce a habitable planet. However, we think the presence of liquid water is not enough to be habitable. We list up other necessary conditions (6+5=11) to produce a habitable planet in the Universe.

<Method>

The best studied habitable planet is the Earth. Therefore, based on the research results of the Earth, we consider necessary conditions. Key points are chemical composition of primordial atmosphere and biosphere.

<Result>

Based on the research of the Earth, I propose there are at least 6 conditions to be a habitable planet in case of the solar system. (1) a planet must be given totally 400 bars CO_2, 300 bars water, and 50-60 bars N_2 as minimum values. In addition, such an amount is given gradually with time (ABEL model) not to become Venus-state, (2) the presence of extremely small amount of ocean water (3km ±1km thickness), (3) the presence of huge landmass (continent above sea level) to finally provide habitable trinity condition to drive the material circulation to give nutrients through water-rock interaction to feed primordial life. (4) Initiation of plate tectonics to keep dynamic equilibria not to become Venus state. (5) selective transportation of CO_2 into mantle, while H_2O remains on the surface, and N_2 remains all in atmosphere, (6) the presence of biosphere, if not, fixation of atmospheric CO_2 is restricted only to inorganic carbonates that would be insufficient to prevent evolving into Venus-state.

<Discussion>

These six conditions are deduced from the history of the Earth. However, if we enlarge the concept to exoplanets based on the research of the solar system, the following five conditions are added; (7) the distance from the central star, (8) the abundance of atmosphere, (9) mass and composition of central star, (10) size and composition of planet, and (11) circular orbital path.

Quantitative Evaluations for Meteorite Impact Tsunami

*Naotaka YAMAMOTO CHIKASADA[1], Tetsuharu Fuse[2], Toshitaka Baba[3]

1. NIED, 2. NICT, 3. Tokushima University

Tsunami induced by earthquakes, submarine landslides, volcanic eruption in submarine and coastal area and meteorological phenomena is one of the most devastating natural disasters. A meteorite impact into the oceans spawn large tsunami depending on the size and velocity of the meteorite and the sea depth at the location of the impact as well. However, we do not have a numerical model to reproduce both of meteorite impacts and tsunami propagations. We have started to develop a new numerical model to simulate tsunamis generated by the meteorite impact combining iSALE (Wünnemann et al., 2006) for simulating impact phenomena and JAGURS (Baba et al., 2017) for simulating tsunami. The iSALE is a multi-material and multi-rheology shock physics code for simulating impact phenomena. JAGURS is a parallelized tsunami simulation code to solve two-dimensional non-linear long-wave equation with Boussinesq terms for representing observed tsunami waveforms, tsunami height and inundation. We set sea-floor deformation, sea-surface disturbance and velocity of gravity wave which is the output from iSALE to the input of JAGURS. We then calculate tsunami height along the coastlines in any place using ASTER GDEM version 2 (Fujisada et al., 2012) and GEBCO_2014 Grid. ASTER GDEM has one arcsecond (about 30 m) spatial resolution and covers land between 56S and 60N latitude as a topographic data. GEBCO’s gridded bathymetric data has thirty arcseconds (about 1 km) spatial resolution for the worldwide.
We first investigate the tsunami generation using iSALE code for creating tsunami source model depending on the meteor size, the velocity of impact, the size of cavity, the width and depth of crater and tsunami propagation speed. We also investigate probabilistic hazard of meteorite impact tsunami using simplified cavity curves with developed JAGURS built-in. Finally, we construct a new numerical model of meteorite impact tsunami combining iSALE and JAGURS. Additionally, we consider the way of automatic detection of meteorite impact using the recode of the highly sensitive seismograph network in real-time.
We gratefully acknowledge the developers of iSALE, including Gareth Collins, Kai Wünnemann, Boris Ivanov, H. Jay Melosh and Dirk Elbeshausen. Data analysis and visualizations of iSALE were carried out on PC cluster and the computers at Center for Computational Astrophysics, National Astronomical Observatory of Japan. This work was partially supported by JSPS KAKENHI Grant Number JP18K04674.

Variation of carbon-14 in tree rings around the onset of the Spoerer Minimum

*Hiroko Miyahara[1], Fuyuki Tokanai[2], Toru Moriya[2], Motonari Ohyama[3], Masataka Hakozaki[4], Mirei Takeyama[2], Hirohisa Sakurai[2]

1. Musashino Art University, 2. Yamagata University, 3. Tohoku University, 4. Nagoya University

Solar activity in the past has been reconstructed using carbon-14 in tree rings and beryllium-10 in ice cores, and it has been indicated that the Sun has long-term activity cycles such as Gleissberg cycle (~88 yrs) and the de Vries cycle (~200 yrs). Long-term variations of solar activity sometimes bring the grand minima such as the Dalton Minimum (1800-1820 CE) and the Maunder Minimum (1645-1715 CE). The detailed mechanism of such grand minima, however, remain unsolved. Reconstruction of solar cycles around the onset of the grand minima may shed light on the process of the occurrence of grand minima. We therefore have been conducting high-precision measurement of carbon-14 in tree rings with annual resolution using the Accelerator Mass Spectrometer at the Yamagata University. In this paper, we present our recent results on the measurement of carbon-14 around the onset of the Spoerer Minimum.

Current Status of WASAVIES: Warning System for Aviation Exposure to Solar Energetic Particles

*Tatsuhiko Sato[1], Ryuho Kataoka[2,3], Daikou Shiota[4,5], Yuki Kubo[4], Mamoru Ishii[4], Hiroshi Yasuda[6], Shoko Miyake[7], InChun Park[5], Yoshizumi Miyoshi[5]

1. Japan Atomic Energy Agency, 2. National Institute of Polar Research, 3. SOKENDAI, 4. National Institute of Information and Communications Technology, 5. Nagoya University, 6. Hiroshima University, 7. National Institute of Technology, Ibaraki College

A physics-based warning system of aviation exposure to solar energetic particles, WASAVIES, is improved to be capable of real-time and automatic analysis. In the improved system, the count rates of several neutron monitors (NM) at the ground level, as well as the proton fluxes measured by the GOES satellite are continuously downloaded at intervals of 5 min and used for checking the occurrence of ground level enhancement (GLE). When a GLE event is detected, the system automatically determines the model parameters for characterizing the profiles of each GLE event, and nowcasts and forecasts the radiation dose rates all over the world up to 24 h after the flare onset. A web-interface of WASAVIES (see picture below) was also developed, which broadcasts radiation dose rates due to cosmic-ray exposure for all over the world as well as on 9 selected flight routes at intervals of 5 min and 1 day during GLE and the other periods, respectively. It is planned to be in operation from March 2019 through the public server of NICT.

Statistical analysis of solar energetic particle events

*Kosuke Kihara[1], Yuwei Huang[2], Nobuhiko Nishimura[3], Seiji Yashiro[4], Nariaki Nitta[5], Kiyoshi Ichimoto[2], Ayumi Asai[2]

1. Department of Astronomy, Kyoto University, 2. Astronomical Observatory, Kyoto University, 3. Institute for Space Earth Environmental Research, Nagoya University, 4. The Catholic University of America, 5. Lockheed Martin Advanced Technology Center

Solar energetic particles (SEPs), which originate in powerful eruptions in the solar corona, give rise to critical radiation hazards for astronauts and airline passengers, causing damages to satellites, which result in serious societal impacts. The SEP phenomenon encompasses many cross-disciplinary fields, so collaborative research is indispensable. As a part of the Japanese space weather project PSTEP (Project for Solar-Terrestrial Environment Prediction), a Coordinated Data Analysis Workshop (CDAW) was held at Kyoto University in August 2018. As a first step toward building the capabilities to predict SEP events, we need to better understand what solar eruptions lead to SEP events of varying magnitudes. One approach, as adopted by this CDAW, is to start from energetic coronal mass ejections (CMEs) regardless of SEP occurrences, rather than from the actual SEP events. We first identified 197 CMEs between 2006 and 2017 that were faster than 900 km/s and wider than 60 degrees, as determined using data from SOHO/LASCO.

Our first objective is to characterize the basic properties of SEP events, such as the occurrence, proton flux intensity, and their time variations. We examined proton peak intensity, duration, and onset time with respect to the extrapolated CME onset time, using GOES >10-MeV proton data. STEREO LET and HET data were also analyzed to study the longitudinal distribution of the SEPs. We investigated the correlations of these SEP properties with the source longitude and speed of the CMEs, and soft X-ray intensity of the associated solar flares. We found that the SEP onset time is correlated with the source longitude of the CMEs. There were correlations between other parameters that we found in our statistical analysis, which will also be discussed. Finally, we will present examples of peculiar SEP events that were found as outliers in some scatter plots.

Long-term variation of galactic cosmic ray intensity observed with the Nagoya multidirectional muon detector

*Kazuoki Munakata[1], Rafael Mendonca[2], Chihiro Kato[1], Munetoshi Tokumaru[3]

1. Department of Physics, Faculty of Science, Shinshu University, 2. INPE, Brazil, 3. ISEE, Nagoya University

We have recently developed a correction method of the atmospheric temperature effect on muon count rate by using the GMDN (Global Muon Detector Network) data (R. R. S. Mendonca et al., Astrophys. J., 830:88, 2016). This is a significant step, because it makes possible for the first time to analyze the long-term variation of ~50 GeV cosmic ray density (i.e. isotropic intensity) which has been nalyed only for cosmic ray below ~10 GeV using the neutron monitor data nearly free from the temperature effect. In this paper, we report the 11-year and 22-year variations of cosmic ray density observed with Nagoya muon detector in 1970-2016 and discuss the energy dependence of variations by comparing the observation with neutron monitors.

Solar modulation of galactic cosmic rays during grand minima: A hybrid simulation

*Shoko Miyake[1], Tomoaki Matsumoto[2,3], Ryuho Kataoka[4,5], Tatsuhiko Sato[6], Daikou Shiota[7], Hiroko Miyahara[8], Shinsuke Imada[9], Haruka Ueno[10]

In the current and next weak solar cycles, we expect higher flux of galactic cosmic rays than that in the previous solar cycles because of the decreasing trend of the solar activity. It is important to quantitatively evaluate the high flux of galactic cosmic rays because it leads to the increase in the radiation exposure of aircrews and the increasing rates of single event upset events at spacecraft. However, reliable prediction of the increasing galactic cosmic rays in upcoming weak solar cycles is a challenges topic in the field of space weather forecast. We introduce a new project called Grand Minimum 7 (Gm7) for developing a hybrid simulation of galactic cosmic rays in such a weak solar condition, solving the stochastic differential equations of energetic particles in the MHD solar wind resolved by adaptive mesh refinement technique. We also discuss the possible situation of galactic cosmic rays and the radiation dose during the grand minima such as Maunder Minimum.

Dated back to early 2016, the radio propagation subgroup was started in the A01 group (Space Weather Forecast System) of the PSTEP (Project for Solar-Terrestrial Environment Prediction). This subgroup has been working on clarifying of space weather (ionosphere is particular) effect on the radio propagation. Day-to-day variation of the bottom side of ionosphere has great influence on availability and integrity of radio waves in high frequency (HF, 3-30 MHz) band. HF is used as a backbone of communication systems for aviation during en-route phase and for amateur radio during disaster relief operation. We, therefore, focused on the HF band. The radio propagation simulator named HF-START (HF Simulator Targeting for All-users' Regional Telecommunications) has been developed. Availability and integrity of HF band are expected to be provided through HF-START interface after receiving users' input/ request. The HF-START project activity and its future operation plan will be overviewed in this talk.

Dynamic Spectral Characteristics of Equatorial Plasma Bubbles

*Tatsuhiro Yokoyama[1], Charles L Rino[2], Charles S Carrano[2]

1. Kyoto University, 2. Boston College

Equatorial plasma bubble (EPB) is a well-known phenomenon in the equatorial ionospheric F region. As it causes severe scintillation in the amplitude and phase of radio signals, it is important to understand and forecast the occurrence of EPB from a space weather point of view. In order to simulate the instability in the equatorial ionosphere, a 3D high-resolution bubble (HIRB) model with a grid spacing of as small as 200 m has been developed. It provides a unique opportunity to characterize intermediate-scale EPB structure, which was not well resolved until very recently. Estimation of altitude-dependent power law spectral density function parameters provides an altitude versus time history of the intermediate-scale structure development. Local structure onset is associated with successive bifurcation of rising EPBs. Developed structure characterized by a two-component power law spectral density function ultimately subtends several hundred kilometers in altitude. The EPB simulation data fully support the reported EPB diagnostics from previous in situ measurements. In the near future, HIRB model may be able to directly resolve Fresnel scale of GPS frequency band (300-400m), so that the effects of EPBs on radio wave propagation could be evaluated without any assumption.

Recent advances in space weather monitoring using the Super Dual Auroral Radar Network

*Evan G Thomas[1], Simon G Shepherd[1]

1. Dartmouth College

Over the last decade, the Super Dual Auroral Radar Network (SuperDARN) has undergone a dramatic expansion in the Northern Hemisphere with the addition of more than a dozen radars offering improved coverage at midlatitudes (50º–60º magnetic latitude) and in the polar cap (80º–90º magnetic latitude). This has led to the development of new empirical models which better describe both the regional and global morphology of ionospheric convection under a range of solar wind and geomagnetic activity conditions. In addition, real-time measurements of ionospheric plasma motion are once again being collected from more than 15 SuperDARN radar sites to produce nowcasts of the global convection pattern. In this presentation we discuss the operational challenges and space weather applications of these real-time SuperDARN products.

A Study of Solar Flare Effects on Radio Wave Propagation using SuperDARN & riometer

*Shibaji Chakraborty[1], Joseph Baker[1], John Michael Ruohoniemi[1], Nozomu Nishitani[2]

1. Virginia Tech, 2. Institute for Space-Earth Environmental Research, Nagoya University

A prolonged study is underway to improve the understanding of the lower ionospheric (D & lower E layer) response to solar flare and its effects on HF propagation. Over-the-Horizon communication is strongly dependent on the state of the ionosphere, which is fragile to solar X-ray flares. The Super Dual Auroral Radar Network (SuperDARN) is an active HF radio receiver, primarily used to probe ionosphere and upper atmosphere. SuperDARN has one common mode of operation which simulates a ground-to-ground communications link, commonly known as ground scatter. Riometers on the other side are passive HF radio receiver, provides information about HF absorption in the ionosphere by measuring variations in cosmic radio noise. Both instruments' observations get altered due to the well-known effects of Short-Wave Fadeout or SWF. During an SWF the number of SuperDARN ground-scatter echoes drops suddenly (≈1 min) and sharply followed by an apparent increase in Doppler velocity (also known as "Doppler Flash"), often to near zero, reflecting disruption. In addition to that, riometer observe an enhancement in cosmic noise absorption. Since decades, enhanced D and E region electron density are known to be the significant driver of HF radio wave absorption, and we have steadily developed a better understanding of the sources and driving processes of HF absorption. However, the picture is less clear when we talk about the influence of collision frequency in radio wave absorption and Doppler frequency anomaly during SWF. This study aims to propose a relatively newer semi-empirical model to provide insights into the physical significance of collision frequency in HF absorption effect which can be seen in the riometer data. In addition to that, the study also aims to provide physical insights to Doppler frequency anomaly seen in SuperDARN data. Furthermore, this study will help us to advance our understanding of the role of collision frequency in HF absorption and Doppler frequency anomaly, their sources and driving parameters.

Exploring the use of cell phone GNSS receivers for global monitoring of the ionosphere

*Dawn Kellogg Merriman[1], Omar A Nava[1], Jennifer L Meehan[2], Hsien-Liang R Tseng[1]

1. AFIT, 2. NOAA

Accurate characterization of the ionosphere in response to space weather events has important implications for the effective use of high-frequency (HF) communications in civilian and military operations, including, but not limited to, emergency services, amateur radio, aviation, and over-the-horizon radar. This study investigates the use of cell phone Global Navigation Satellite System (GNSS) technology to monitor and study highly variable phenomena in the ionosphere, such as the aurora at high-latitudes or scintillation at the equator. Field campaigns to high and mid-latitudes will be summarized here, emphasizing the sensitivity of cell phone GNSS receivers to pick up on space weather events such as traveling ionospheric disturbances. Preliminary analysis on the potential to combine data from various cell phone manufacturers (e.g. Hauwei, Samsung, Google, LG and Moto) to enhance data quality will also be presented. Based on this research the potential to collect data from millions of cell phones GNSS technology may allow for real-time monitoring and measuring of the ionosphere to occur on an unprecedented global scale.

Large enhancements of global GPS total electron content during a magnetic storm on 7-8 November 2004

*Sori Takuya[1], Yuichi Otsuka[1], Atsuki Shinbori[1], Takuya Tsugawa[2], Michi Nishioka[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. National Institute of Information and Communications Technology

Storm enhanced density (SED) with a latitudinally narrow structure is one of the storm-time ionospheric disturbances in the mid- and low-latitude regions. Foster and Rideout [2007] reported that the SED plume occurs in magnetically-conjugate regions in both northern and southern hemispheres. In this study, we analyzed geomagnetic storm events from 2000 to 2012 and found that a TEC enhancement over Japan on 8 November 2004 is the largest. Maruyama [2006] reported that the TEC enhancement appeared during this event, and pointed out that the mid-latitude TEC enhancement observed after the sunset is related to SED. However, since most of the previous studies focus on TEC variation in a specific region, the detail features of global TEC variation associated with the development and decay of the geomagnetic storm have not yet been clarified. The purpose of this study is to understand the generation mechanism of the TEC enhancement in the mid- and low-latitude ionosphere during the geomagnetic storm using global GPS-TEC data with high temporal and spatial resolutions provided by NICT. The GPS-TEC data have spatial and temporal resolutions of 0.5˚×0.5˚ in longitude and latitude and 5 minutes, respectively. Here, we first calculated a difference value (dTEC) between storm-time TEC and average TEC of 10 geomagnetically quiet days. In this calculation, we referred to a list of geomagnetically quiet and disturbed days provided by World Data Center for Kyoto University. Next, we created a two-dimensional map of rTEC (dTEC normalized by the average TEC of 10 geomagnetically quiet days), and analyzed the temporal and spatial variations of rTEC for a geomagnetic storm which occurred on 8 November 2004 with the minimum SYM-H value of -400 nT at 6:00 UT. As a result, the rTEC enhancement in Japan was maintained even after the onset of the recovery phase, and the maximum value reached ~17 (~90 TECU). The enhanced rTEC region in Japan propagates westward with a velocity of 317 m/s. In order to investigate the specific signature of rTEC in Japan in detail, we created the latitude-time plot of TEC at a longitude 142˚E. In this plot, two high TEC regions appear near 5:00 UT and 11:00 UT, and propagate from high to low latitudes. Furthermore, the ion drift meter data obtained from the DMSP satellite traveling over Japan show the westward flow with a velocity of 250 m/s, which is almost consistent with that of the enhanced rTEC velocity. In the two-dimensional global map of rTEC, the TEC enhancements over Japan and Australia occurred simultaneously with a magnetic conjugacy. The rTEC enhancements were larger in the northern hemisphere than that in the southern hemisphere. The rTEC enhancements started near 5:00 UT at magnetic latitude of 50˚ in both the hemispheres, and propagated from high to low latitudes. In order to investigate the global signature of rTEC over Japan and America, we created the magnetic latitude-time plot of rTEC. As a result, we found that the rTEC in Japan and America showed a large enhancement at 5:00 UT with the maximum values of more than 6. In the rTEC map at 5:00 UT, the enhanced rTEC region existed between America and Japan. This rTEC enhancement is thought as a cause of SED. SED is thought to be caused by the westward plasma transportation in the mid- and low-latitude ionosphere due to the storm-time enhanced SAPS [Tsurutani et al., 2004]. Assuming that the propagation velocity is 317 m/s, it takes 9.5 hours to move from America to Japan. However, the time difference of the onsets of the rTEC enhancement between America and Japan is 6 hours. Therefore, the rTEC enhancement cannot be explained by the above mechanism of the westward transportation. These results suggest that the enhanced TEC region associated with the TEC peak over Japan existed between America and Japan. Therefore, mechanism different from the SED generation can cause large TEC enhancement

Large scale traveling ionospheric disturbances origin and propagation

*Iurii Cherniak[1,2], Irina Zakharenkova[2,5], Paul Prikryl[3,4], William Schreiner[1]

1. COSMIC Program Office, University Corporation for Atmospheric Research, 2. University of Warmia and Mazury in Olsztyn, 3. Physics Department, University of New Brunswick, 4. Geomagnetic Laboratory, Natural Resources Canada, 5. West Department of IZMIRAN

We investigate an origin, occurrence, and propagation of large-scale traveling ionospheric disturbances (LSTIDs) with an analysis of the total electron content (TEC) perturbation component deduced from the ground-based GPS and GLONASS observations. The high spatio-temporal resolution mapping approach provides a very detailed specification of the ionospheric small- to large-scale disturbances associated with two major sources of the LSTIDs generation: the solar terminator passage during the quiet time and auroral activity caused by auroral particle precipitation and field-aligned currents (FACs) intensification during geomagnetic disturbances. For the first time, the joint analysis of the ionospheric plasma irregularities, FACs, and LSTIDs reveals that a zone with the intense FACs and ionospheric irregularities occurred at the same region that represent the most probable source of LSTIDs excitation. The COSMIC RO electron density profiles confirm the E layer plasma density enhancement within LSTIDs excitation area. Such density enhancement leads to an increase of ionospheric conductivity, intensification of currents in the ionosphere, and release of energy by Joule heating into the lower thermosphere.
This approach was demonstrated for the case of the 19-21 December 2015 geomagnetic storm, when LSTIDs propagated over the European region were detected. During the main phase of the storm, the LSTIDs propagated equatorward from European high latitudes to middle latitudes (35-40N) with the horizontal velocities of ~700-800 m/s. The LSTIDs as deduced from the TEC-disturbed component had a much larger magnitude and propagate much longer distances during the daytime (sunlit part) than in the night. We found that an equatorward expansion of the strong ionospheric irregularities zone and an increase of the FACs magnitude led to a simultaneous intensification of the LSTIDs occurrence at high latitudes. The GPS ROTI (rate of TEC index) technique, a sensitive one for detection of the rapid ionospheric gradients and irregularities, could not recognize any signatures of the TIDs structures.

The research is supported by the NSF CAS AGS-1033112, the NASA LWS grant NNX15AB83G, by the National Science Centre, Poland, through grants 2017/25/B/ST10/00479 and 2017/27/B/ST10/02190, and by RFBR Grant 19-05-00570A.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Tue. May 28, 2019 3:30 PM - 5:00 PM JST | Tue. May 28, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-EM12] Space Weather and Space Climate

convener:Ryuho Kataoka(National Institute of Polar Research), Antti A Pulkkinen(NASA Goddard Space Flight Center), Kanya Kusano(Institute for Space-Earth Environmental Research, Nagoya University), Kaori Sakaguchi(National Institute of Information and Communications Technology)

We share the latest scientific papers to understand how the solar-terrestrial environment changes in various time scales, and to discuss how we will react via international and interdisciplinary collaborations. More specifically, welcomed papers include space climate studies to reconstruct long-term variations from radio isotopes; cutting-edge observational and modeling studies of the ionosphere, geospace, heliosphere and the sun; simulation and statistical studies to predict the future space weather and space climate; applied science such as operational space weather forecast and mitigation of the social impact due to extreme space hazards.

Reconnection signatures in solar magnetograms during the solar storms of 4-10 September 2017

*Robert Dean Loper[1,2]

1. Air Force Institute of Technology, Department of Engineering Physics, 2. National Center for Atmospheric Research, High Altitude Observatory

Solar flare forecasting is limited to active region classification and historical correlation, due largely to our lack of understanding of magnetic reconnection as a driving mechanism for solar flares and coronal mass ejections. Photospheric observations indicate magnetic field changes during solar flares, brought about during magnetic reconnection and related to magnetic field helicity on the solar surface. While the neutral point of the reconnection event associated with a flare usually occurs in the solar corona, some signs of the magnetic field changes should manifest as low as the photosphere. This study utilizes data from SDO HMI and Space-Weather HMI Active Regions Patches (SHARPS) to analyze full vector field component data in the photospheric magnetic field during several magnetic reconnection events during the space weather events of 4-10 September 2017.

Statistical Relation between Solar Flares and Coronal Mass Ejections with Respect to Sigmoidal Structures in Active Regions

*Yusuke Kawabata[1,2], Yusuke Iida[3], Takafumi Doi, Sachiko Akiyama[4], Seiji Yashiro[4], Toshifumi Shimizu[2]

1. Earth and Planetary Science, The University of Tokyo, 2. Institute of Space and Astronautical Science, JAXA, 3. Kwansei Gakuin University, 4. The Catholic University of America

We will report statistical dependences among features of coronal mass ejections (CMEs), solar flares, and sigmoidal structures in soft-X-ray images (Kawabata et al. 2018). We applied analysis methods to all the features in the same way in order to investigate the reproducibility of the correlations among them, which may be found from previous statistical studies. Samples of 211 M-class and X-class flares, observed between 2006 and 2015 by the Hinode/X-ray telescope, Solar and Heliospheric Observatory/Large Angle and Spectrometric Coronagraph, and Geostationary Operational Environmental Satellite, were examined statistically. Five kinds of analysis were performed: Occurrence rate analysis, linear-correlation analysis, association analysis, the Kolmogorov–Smirnov test, and the Anderson–Darling test. These give three main results. First, the sigmoidal structure and long-duration events (LDEs) have a stronger dependence on CME occurrence than large X-ray-class events in on-disk events. Second, for the limb events, a significant dependence exists between LDEs and CME occurrence, and between X-ray-class events and CME occurrence. Third, 32.4% of on-disk flare events have sigmoidal structure and are not accompanied by CMEs. However, the occurrence probability of CMEs without sigmoidal structure is very small, 8.8%, in on-disk events. While the first and second results are consistent with previous studies, we provide for the first time a difference between the on-disk and limb events. The third result, that non-sigmoidal regions produce fewer eruptive events, is also different from previous results. We suggest that sigmoidal structures in soft X-ray images will be a helpful feature for CME prediction in on-disk flare events.

Multi-wavelength Observations of Pre-flare Quasi-periodic Pulsation in the C2.2 Flare on 2012 October 15

*Yung-Chi Yang[1], Ya-Hui Yang[1], Baolin Tan[2], Chengming Tan[2], Y.H. Yan[2]

1. Graduate Institute of Space Science National Central University, 2. Key Laboratory of Solar Activities, National Astronomical Observatories

Quasi-periodic pulsation (QPP) is thought to be the nature of solar flares, which can be observed during and before flares in various wavelengths, such as the radio, microwave, SXR, and EUV. In this study, we analyze a pre-flare QPP event on 2012 October 15 and its association with the following C2.2 flare based on the radio data in the ranges of 2.81-2.85 GHz and 2.91-2.95 GHz from Solar Broadband Radio Spectrometer (SBRS), EUV images from AIA multi-wavelength observations, and wavelet analysis. Our result show that the main period of the radio QPP is ~800 s which is similar to the period of ~13.5 min obtained in SXR by Tan et al. (2016). Moreover, we analyze several localized areas in the flare-eruptive AR 11593 to search for the possible regions responsible for the occurrence of pre-flare QPP. We find that the footpoints of brightening loops in 211 Åshow the quasi-periodic behavior of ~850 s. It is thus suggested that the pre-flare QPP with a period of 13-15 min can be manifested in both of the thermal (SXR, EUV) and nonthermal (radio) radiation processes. The relationship between the pre-flare QPP and the subsequent C2.2 flare will also be discussed.

Investigation of pre-flare type III solar radio bursts and their potential solar origins

*Shao-Fu Hsieh[1], Ya-Hui Yang[1], Baolin Tan[2], Chengming Tan[2], Y.H. Yan[2]

1. Graduate Institute of Space Science National Central University, 2. Key Laboratory of Solar Activities, National Astronomical Observatories, Chinese Academy of Sciences

Type III solar radio bursts are characterized as the fast-drifting radio emissions in a dynamic spectrogram, which is believed to be produced by the propagating electron beams and often accompanied with the solar flares or magnetic reconnection. Studying the type III radio bursts in high-frequency range before flares would be important for understanding the trigger of energy release although it is rarely reported previously. Here we present two pre-flare type III burst events found in the range of 2.6-3.8 GHz at Solar Broadband Radio Spectrometer (SBRS). By comparing with the SDO/AIA multi-wavelength observations in flare active regions, the pre-flare type III radio bursts have good temporal correlations with the increases of EUV emissions. Furthermore, we find that one event is related to the EUV brightening with 1-min delay, implying the existence of plasma heating before energy release. The other event has a simultaneous EUV jet with a speed of ~700 km/s indicating the occurrence of magnetic reconnection. We suppose both pre-flare events are associated with small-scale energy release via magnetic reconnection.

Statistical and observational research of solar flare for constructing total emission spectra prediction model

*Shohei Nishimoto[1], kyoko Watanabe[1], Shinsuke Imada[2], Tomoko Kawate[3], Kyoung-Sun Lee[4]

1. National Defense Academy, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Institute Of Space And Astronautical Science, Japan Aerospace Exploration Agency, 4. National Astronomical Observatory of Japan

Impulsive energy release phenomena such as solar flares, sometimes affect to the solar-terrestrial environment. Usually, we use soft X-ray flux (GOES class) as the index of flare scale. However, the magnitude of effect to the solar-terrestrial environment is not proportional to this scale. Therefore, it is considered that the GOES class is not optimal parameter for predicting the Sudden Ionospheric Disturbance (SID). To identify the relationship between solar flare phenomena and influence to the solar-terrestrial environment, we need to understand the full spectra of solar flares in detail.
There is the solar flare irradiance model named the Flare Irradiance Spectral Model (FISM) (Chamberlin et al., 2006, 2007, 2008). FISM is the most used model, and can estimate solar flare spectra with high wavelength and temporal resolution. However, this model can not express the time evolution of emitted plasma during the solar flare, and has low accuracy on short wavelength that might strongly affect to the total flare spectra. Therefore, individual SID phenomenon can not be reproduced.
In this work, in order to solve the problems of FISM, we performed statistical analysis on observational data during the solar flares. From This study, we tried to find the parameters that control the solar flare emission spectra. We selected solar flare events larger than M-class from the Hinode flare catalogue (Watanabe et al., 2012). First, we focused on the EUV emission observed by the SDO/EVE. We examined the intensities and time evolutions of five EUV lines (Fe XX, Fe XVIII, Fe XVI, Fe VIII, and He II) for 54 flare events. As a result, we found positive correlation between the “GOES class” and the “EUV peak flux” for all Fe lines. Moreover, we found that hotter lines peaked earlier than cooler lines. On the other hand, He II line data have poor correlation with GOES X-ray data. Furthermore, we considered that the geometrical features of solar flares effect to those time evolutions. We measured flare ribbon length for 33 flare events observed by SDO/AIA, and found positive correlation between the “flare duration” and the “ribbon length”. From the statistical research of these observational data, we found that the time evolution of EUV emission can be explained by the X-ray emission.
Then, we tried to identify parameters that determine the solar flare spectra by comparing the flare emissions derived from physical based numerical model of solar flare with the actual observational data. Consequently, we used numerical simulation same as Imada et al.(2015). This numerical model can reproduce the movement and ionization of the plasma in the flare loop.
In this presentation, we will show some results of numerical simulation, and discuss the parameters for total solar flare emission spectra by comparing of simulation results, observational data and FISM.

Modeling of solar active regions using local linear force-free fields to estimate magnetic twist

*Kento Nakatani[1], Kanya Kusano[1], Sung-Hong Park[1], Leka KD[2]

1. Institute for space-Earth Environmental Research, Nagoya University, 2. North West Reserch Associates

The prediction of solar flares is an important issue for space weather forecasting. Although solar flares are believed to be caused by the magnetohydrodynamic (MHD) instability in solar active regions, the method for accurately evaluating the stability of solar magnetic field is not yet established. Recently, Ishiguro & Kusano (2017) proposed that a new instability called the Double Arc Instability (DAI) plays a role of initial driver of solar flares and the critical parameter for this instability can be used to evaluate the stability of active regions. The parameter can be derived by the integration of the magnetic twist as the function of magnetic flux. One way for it is given by the nonlinear force-free field (NLFFF) extrapolation using the photospheric vector magnetic field data. However, the NLFFF extrapolation demands heavy computation and it sometimes cannot well work as a model of solar coronal magnetic field because the force-free condition is limited on the photosphere. Therefore, in order to improve the efficiency and applicability of the flare prediction using , it may be required to develop a method to approximately but much quickly capture the overall features of magnetic field in solar active regions, especially in the flare triggering region. From this point of view, we try to develop a method to extract the characteristic feature of magnetic field in solar active regions using the linear force-free field (LFFF) model. For this objective, we compare the several methods to accurately capture the structure of using LFFF. In this study, we report the result of the analysis for the solar active region NOAA 11429.

Magnetohydrodynamic Simulation of an Erupting Magnetic Flux Rope on February 13 2009: Journey to Coronal Mass Ejection

*Satoshi Inoue[1], Antonia Savcheva[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Harvard-Smithsonian Center for Astrophysics

We performed a magnetohydrodynamic (MHD) simulation of a solar eruption launched from solar active region 11012 on February 13, 2009. We in particular concentrated on the evolution of the magnetic flux rope (MFR) leading a coronal mass ejection. We first extrapolated the pre-eruptive magnetic flux ropes using a flux insertion method, in which the MFRs can be extrapolated from the normal component of the magnetic field (Bz) observed by SOHO/MDI and Extreme-Ultra Violet (EUV) images observed by the STEREO satellite. The extrapolated magnetic field reproduced the sigmoidal magnetic structure observed in EUV image well. Next we performed the MHD simulation using the extrapolated magnetic field.

The resulting simulation showed the dramatic eruption of the magnetic flux rope under which the current sheet and the post-flare loops are formed. This is well explained by the standard CSHKP flare model. The evolution of the MFR did not show simple dynamics, rather it showed very complicated dynamics through a magnetic reconnection. We found, during the eruption, that the coherent MFR is created through the reconnection of multiple pre-existing MFRs. Magnetic reconnection plays a role in producing the coherent, erupting MFR and supplying further twist into it. Furthermore we found that the footpoints of the erupting MFR moves along or away from the polarity inversion line, as seen in two-ribbon flares. The locations of both the footpoints of the MFR correspond to those of dimming regions observed in EUV images. Since the location and shape of the post-flare loops obtained from the simulation is reproduced in the observations, we can confirm the reliability of our simulation.

Investigation of flow structures in the solar interior through the surface magnetic elements' tracking

*Yusuke Iida[1]

1. Kwansei Gakuin University

We investigate the correlation of meridional flow and rotation velocity in the solar interior by tracking huge number of the surface magnetic elements.

As reported in JpGU2017 meeting, we found that the meridional flow velocity from the magnetic elements' tracking depends positively on their flux and size. We discussed that it may come from that the larger magnetic elements are rooted in the deeper solar interior. We further investigate this issue by correlating the meridional flow velocity and rotation velocity.

We use line-of-sight magnetograms obtained by SDO/HMI in July 2016. Time cadence is 45 seconds, in which the travel distance of magnetic element is smaller than 1 pixel. The magnetograms are transposed from the Earth-view coordinate to the Stonyhurst coordinate. We use the data within 75 degree from the disk center. Magnetic field strength is converted with an assumption that magnetic field is vertical to the surface and interpolated with a cubic spline interpolation.

We detected approximately 8,000 elements in each magnetogram and 4.5x108 displacements in our data set. The meridional flow and rotation velocity on magnetic flux are investigated. The rotation velocity shows negative dependence on the flux at the latitude within 45 degree while it shows weekly positive dependence at the latitude higher than 45 degree. This result is consistent with the depth dependence of rotation velocity obtained by previous helioseismology researches.

High-precision measurement of carbon-14 in tree rings around the onset of the Maunder Minimum

*Hiroko Miyahara[1], Fuyuki Tokanai[2], Toru Moriya[2], Hideyuki Hotta[3]

1. Musashino Art University, 2. Yamagata University, 3. Chiba University

It is well known that the Sun indicates long-term variations at time scales of a few hundred years to a few millennia. It sometimes brings the grand minima, at which period the sunspots disappear for more than several decades. The detailed process of such long-lasting disappearance of sunspots, however, remains unclear. We therefore have been trying to reconstruct solar cycles around the onset of grand minima based on high-precision measurement of carbon-14 in tree rings. In this paper, we report on our preliminary result on the measurement of carbon-14 around the onset of the Maunder Minimum.

Examination of ^{10}Be in travertine sediment as a possible tool to reconstruct past solar activity

*Hongyang Xu[1,2], Hiroko Miyahara[2], Kazuho Horiuchi[3], Hiroyuki Matsuzaki[4], Hailong Sun[5], Weijun Luo[5], Xiangmin Zheng[1], Yusuke Suganuma[6,7], Shijie Wang[5], Limin Zhou[1]

1. East China Normal University, 2. Musashino Art University, 3. Hirosaki University, 4. University of Tokyo, 5. Chinese Academy of Sciences, 6. National Institute of Polar Research, 7. The Graduate University for Advanced Studies (SOKENDAI)

In this study, we explore the possibility of using travertine sediment for reconstructing the past solar activity. We obtained an annual ^{10}Be record from travertine deposit from the modern period and compared with the neutron monitor data. We discuss a possible methodology to calibrate the climatological impact on ^{10}Be deposition and to obtain the signal of past solar and cosmic-ray variations.

1 year of CR observation at Syowa Station in the Antarctic.

*Chihiro Kato[1], Kazuoki Munakata[1], Akira Kadokura[2], Ryuho Kataoka[2], Paul Evenson[3]

1. Shinshu University, 2. National Institute of Polar Research, 3. University of Delaware

CR observation has been carried out for 1 year at Syowa Station in the Antarctic. There was no serious unavailability of data during the whole year. It is now concluded that this station can contribute to a space weather study as one of the CR monitoring station of Global Muon Detector Network (GMDN). We report observed data and its stability as GMDN.

Space weather forecast archives at NICT: handwritten solar activity charts

*Kaori Sakaguchi[1], Daikou Shiota[1], Kaori Fukunaga[1], Katsuhide Marubashi[1], Hiromitsu Ishibashi[1], Yuki Kubo[1], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology

About 40 years ago from 1978 to 1999, at Hiraiso Branch, Radio Research Laboratory; present Space Environment Laboratory of National Institute for Information and Communication Technology (NICT) in Japan, space environment data had been recorded in "solar activity chart" by hand for the operation of the radio wave warning service. The charts were created based on URSIgram codes, which were developed to facilitate the rapid exchange of information by telex in periods when internet was not available. Based on the exchanged codes, sunspots transitions and solar flare occurrences on the solar surface, these effects on shortwave propagation, geomagnetic disturbance, and cosmic ray flux over Japan were written in the solar activity charts together with comments and sketch by recorders. One chart was created for each Bertel’ s solar rotation number between No. 1974 and No. 2254, corresponding to sunspot cycles 21 and 22. We realized that the data exchange is almost only once a day from each observation point and charts was accumulation of the available data in real-time at that time.It might be quite difficult to decide future forecast from such a limited real-time data set. Currently, we are digitizing the solar activities charts and the data shown there. In this poster, we present examples of solar activity charts and possible real-time data set and time delay, as well as the verifying result of the solar flare / geomagnetism storm forecast at the time.

IMF dependence on solar wind parameters

*Tohru Araki, Yuki Harada[1]

1. Kyoto University

We studied IMF dependence upon solar wind parameters using OMNI hourly values.

Figure below is a plot of the total force (B), horizontal component (Bxy) in the ecliptic plane and vertical component (Bz) of IMF versus the solar wind density (Nsw). The IMF is averaged over 0.2/cc bin of Nsw. Data number in each bin is also plotted. The data period here is 1979-1981 (maximum SSN phase).

The figure shows (1) that B, Bxy and Bz slowly decrease with decreasing Nsw and (2) that when Nsw approaches further to zero. B and Bxy begin to increase and converges to the same finite value (about 10 nT here) while Bz converges to zero. The property (2) suggests that IMF converges to a typical spiral pattern when solar wind density converges to zero.

Two other data periods, 1999-2001 (SSN maximum) and 2007-2009 (SSN minimum) are examined. IMF observed by MAVEN orbiting Mars is also studied for the period, 2014-2018. The results of the analysis are roughly consistent with the description above. We also checked IMF dependence on solar wind velocity

Dipole Tilt Effect of Geomagnetic Activity from Low- to High-latitudes

*Nowada Motoharu[1]

1. Shandong University at Weihai

Geomagnetic activity is dominantly impacted by the orientation of the Interplanetary Magnetic Field (IMF). However, when trying to address why the variations of geomagnetic activity are “semi-annual”, and are greater at equinoxes than at solstices, only IMF control of geomagnetic activity is not enough. This is because these variations are strongly dependent on the Earth’s dipole tilt; the dipole tilt is smaller at the equinoxes than at the solstices. Primitive studies assumed that magnetic reconnection occurs only at the subsolar point of dayside magnetopause. In their studies, the dipole tilt effect was not considered, but only the magnetic field direction between the IMF and the magnetosphere at the subsolar point was discussed in their studies. After them, geomagnetic variations where both dipole tilt effect and IMF direction are taken into account have been investigated. Based on a large database of IMF and AL/AU, we examined the relationship between the IMF clock angle and AL/AU at various dipole tilts. For both positive and negative dipole tilts, geomagnetic activity decrease as the clock angle moves away from 180˚. The AL/AU indices also tend to become smaller for larger dipole tilts. This dipole tilt dependence enhances the semi-annual variation of high-latitude geomagnetic activity.
It also remains unclear how degree energy input rate from solar wind to ring current (dD_{st}^{*}/dt) depends on dipole tilt under various interplanetary magnetic field (IMF) orientation and whether or not ring current development also follows this dipole tilt dependence. We tried to statistically investigate the dependence of dipole tilt and IMF clock angles on low- and middle-latitude geomagnetic activity (D_{st}^{*}), which is a proxy of ring current development, and solar wind energy input rate to ring current (dD_{st}^{*}/dt) over one solar cycle (1978 - 1988). D_{st}^{*} was calculated with the solar wind dynamic pressure and original D_{st} index, and the dipole tilt angle was defined as function of the day of year and universal time. The (dD_{st}^{*}/dt) values were obtained based on the solar wind electric field under the southward IMF conditions. Under positive and negative dipole tilts, the (dD_{st}^{*}/dt) values under low dipole tilt are negatively larger than those in case of high dipole tilt. Further peaks at 180˚ of the IMF clock angle are seen in most of the dipole tilt cases. However, the D_{st}^{*} index shows neither a peak at 180˚ of the IMF clock angle nor particular dipole tilt dependence in case of negative dipole tilt angles. This result suggests that low- and middle latitude geomagnetic activity (ring current development) does not necessarily show dipole tilt dependence and a one-to-one correlation with solar wind energy input rate to ring current (dD_{st}^{*}/dt).

A New Prediction Model for Solar Wind-Triggered Magnetospheric Disturbances Based on Potential Learning (Neural Network)

*Ryozo Kitajima[1], Motoharu Nowada[2], Ryotaro Kamimura[3]

1. Seikei University, 2. Shandong University at Weihai, 3. Tokai University

Nowadays, it becomes so important in saving our economic activity, and preventing the disasters caused by terrestrial electromagnetic effects to predict a scale and the duration of the geomagnetic disturbances based on in-situ solar wind observations. Recently, one of the notable techniques for the predictions of the magnetospheric disturbances is Neural Network (NN). However, most of these studies are focused on the reproduction of the behaviors of the index values, which represent the geomagnetic disturbances (e.g, D_{st} and AE), by inputting the solar wind parameters measured by the satellites. In our study, we apply a novel neural network model of ‘Potential Learning (PL)’.
Basically, Neural Networks (NNs) are models which imitate the information processing in the nervous system of brain. The nerve is made of cells as referred to as “neurons”, which specializes the information processing. NNs consist of “artificial” neurons, and can process information by learning. Therefore, using NNs, we can obtain some characteristics of the data inputted. The PL is a new kind of the NNs. A feature of the PL is to make a network that can understand the input variables based on learning by “input potentialities”, which are indices as calculated with the variances derived from the input variables. If using this PL, we can specify what input variable(s) is (are) potentially important and influential for a phenomenon.
In this study, introducing the PL technique, we try to specify which solar wind parameter plays an essential role in causing the geomagnetic disturbances. Although the conventional PL, where we used, had automatically selected the variables of interest, we develop a “improved” PL in this study so that the variables can manually be selected. We benchmark this new algorithm using the 4 polar magnetic storm cases occurred under the southward Interplanetary Magnetic Field (IMF)-B_z conditions, and advisedly set the maximum potentiality for the IMF-B_z, so that the IMF-B_z component is the most possible solar wind parameter to cause the geomagnetic disturbances. We note “second” solar wind parameter(s) to possibly cause the magnetospheric disturbances, following the IMF-B_z component. After testing our new technique to actual storm events, we might distinguish the magnetospheric disturbances into two different types, that is, the geomagnetic disturbances driven by “IMF-dominant” and “combination of IMF with solar wind plasma (dynamic pressure)”. The advantages to adopt this new algorithm to space weather, and more detailed results will be discussed in this presentation.

Real-time magnetosphere simulator for space weather using REProduce Plasma Universe code

*Yasubumi Kubota[1], Aoi Nakamizo[1], Kaori Sakaguchi[1], Mitsue Den[1], Yuki Kubo[1], Tsutomu Nagatsuma[1], Takashi Tanaka[1,2]

1. National Institute of Information and Communications Technology, 2. Kyushu University

Surface charging of artificial satellite is one of risks caused by dynamical variations of space environment. It occurs when a satellite exposes high energy electrons around 10 keV created by plasma injection accompanied with substorm. Therefore we want to predict timing and electron energy of plasma injection using magnetosphere-ionosphere coupling global MHD simulation. Now we are developing a real-time numerical simulator for space weather forecast using magnetosphere-ionosphere coupling global MHD simulation called REPPU (REProduce Plasma Universe) code. The feature of the simulation code is highly robust to extreme solar wind parameters because the unstructured grid system has no singular point and is able to calculate in the uniform accuracy over the whole region. We use the real-time solar wind data formatted in the GSM coordinate system observed by DSCOVR spacecraft. Magnetic-dipole axis is fixed to z-direction in our simulation. Therefore daily variation of magnetic-dipole axis is not reproduced. Instead, we convert the input direction of the solar wind velocity and magnetic field into that which tilts including daily variation of magnetic dipole axis in x-z plane. In the method the solar wind structure is not exact. However we can relatively reproduce the magnetosphere response including daily variation of the magnetic-dipole axis against solar wind. The resolution is 7682 grids in the horizontal direction and 240 grids in the radial direction.
In this presentation, we compare the simulation results with the CPCP, AE index, and plasma variations observed by geostationary orbit satellites. Density and temperature of plasma injection derived from MHD simulation tends to estimate larger and smaller values than observation respectively because the MHD simulation does not include kinetic heating effects. We have to interpret MHD simulation results for prediction of electron density and temperature. We will discuss how to interpret electron density and temperature between observation and MHD simulation.

Simulation of GIC flowing through the power transmission network (187 kV-500 kV) in Japan

*Nishida Yuichiro[1,6], Yusuke Ebihara[1], Satoko Nakamura[1], Shinichi Watari[2], Kumiko Hashimoto[3], Kentaro Kitamura[4], Takashi Kikuchi[5]

1. Kyoto University Reserch Institute for Sustainable Humanosphere, 2. National Institute of Information and Communications Technology, 3. Kibi International University, 4. National Insutitute of Technology, Tokuyama College, 5. Nagoya University, 6. Kyoto University Department of Electrical Engineering

The energy released from the sun can enhance electric currents in Earth’ s magnetosphere, which induces an electric field on the ground surface. This electric field, called a geomagnetically induced electric field (GIE), gives rise to geomagnetically induced current (GIC) flowing in a transmission line. Japan is situated at geomagnetically low latitudes, but the potential risk is probably non-zero because a large-amplitude of GIC, as high as 129 A, was recorded in the Japanese power grid during the Halloween storm in October 2003. To evaluate the potential risk of the Japanese power grid properly, we modeled the Japanese power grid with high voltage class over 187 kV on the basis of publicly available data. The model consists of 602 nodes and 763 paths. The uniform GIE imposed on Japan was estimated on the basis of the geoelectric field observed in April 2018 at Kakioka Magnetic Observatory. We applied the uniform GIE on the model. The calculated GIC is roughly in agreement with that measured at 4 substations in Japan. For the westmost substation, a disagreement was found when we considered only the highest class of the power grid (500 kV), which may imply that the lower voltage class of the grid (<500 kV) may have some contribution to the GIC in Japan. We discuss the general tendency of the GIC flowing in the Japanese power grid, and prediction capability of the currently available model.

Abstract

The energy released from the sun can enhance electric currents in Earth's magnetosphere, which induces an electric field on the ground surface. This electric field, called a geomagnetically induced electric field (GIE), gives rise to geomagnetically induced current (GIC) flowing in a transmission line. Japan is situated at geomagnetically low latitudes, but the potential risk is probably non-zero because a large-amplitude of GIC, as high as 129 A, was recorded in the Japanese power grid during the Halloween storm in October 2003. To evaluate the potential risk of the Japanese power grid properly, we modeled the Japanese power grid with high voltage class over 187 kV on the basis of publicly available data. The model consists of 602 nodes and 763 paths. The uniform GIE imposed on Japan was estimated on the basis of the geoelectric field observed in April 2018 at Kakioka Magnetic Observatory. We applied the uniform GIE on the model. The calculated GIC is roughly in agreement with that measured at 4 substations in Japan. For the westmost substation, a disagreement was found when we considered only the highest class of the power grid (500 kV), which may imply that the lower voltage class of the grid (<500 kV) may have some contribution to the GIC in Japan. We discuss the general tendency of the GIC flowing in the Japanese power grid, and prediction capability of the currently available model.

Climatological features of the upper atmosphere reproduced by a revised version of a whole atmosphere-ionosphere coupled model GAIA

*Hidekatsu Jin[1], Yasunobu Miyoshi[2], Chihiro Tao[1], Hiroyuki Shinagawa[1], Hitoshi Fujiwara[3]

1. National Institude of Information and Communications Technology, 2. Kyushu University, 3. Seikei University

Temporal and spatial variations in the ionospheric electron density and thermospheric mass density could have significant impacts on radio communications between ground and space, and particle and atmospheric drag environments around satellites. Origins of such upper atmospheric variations are not only in the solar atmosphere through the emissions of solar radiation, high-speed plasma gas and high-energy particles, but also in the Earth’ s lower atmosphere, where meteorological phenomena could give rise to atmospheric waves propagating upward. In order to nowcast and forecast the upper atmospheric variations and disturbances, a whole atmospheric model, GAIA, has been developed, which combines a whole atmospheric GCM, an ionospheric model and an electrodynamics model in a self-consistent manner.

So far, for the purpose of its validation, we have compared climatological features of thermosphere and ionosphere reproduced by GAIA with those from ionospheric observation and observation-based empirical models. The comparison indicates that the model and observations are generally in good agreements, but in some condition such as at solar maximum there are significant disagreements in the ionospheric electron density distribution. In order to improve the accuracy of the model, we have made several updates such as ion chemical processes, energetics, parameterization, and so on. We also have introduced magnetospheric effects into the model, such as electrodynamics coupling with magnetosphere and particle precipitation. In this presentation, we discuss how the upper atmospheric model can improve its accuracy and how they can be validated.

Investigation of the thermospheric mass density variations below 200 km

*Hitoshi Fujiwara[1], Yasunobu Miyoshi[2], Masayoshi Utashima[1], Huixin Liu[2]

1. Faculty of Science and Technology, Seikei University, 2. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University

Since both the effects from the lower atmosphere and in-situ forcing are significant in the thermospheric region between 100 and 200 km altitude, the thermosphere in the region shows complex variations depending on various conditions. In addition, observations of the thermosphere (neutral atmosphere) between 100 and 200 km are very few compared to the upper thermosphere (above 300 km) and the ionosphere. These make it difficult to improve reliability of empirical and numerical models. Observations from Low Earth Orbit (LOE) satellites would be essential for building up available data sets in the thermospheric region between 100 and 200 km altitude. We will introduce our research project to investigate the thermospheric mass density variations in the 100-200 km altitude region with the LOE satellite, e.g., Tsubame (SLATS), data and a whole atmosphere GCM.

Low-latitude HF Doppler observations of magnetospheric electric fields during space weather disturbances

*Kumiko K. Hashimoto[1], Takashi Kikuchi[2], Ichiro Tomizawa[3], Keisuke Hosokawa[3], Jaroslav Chum[4]

1. Kibi International University, 2. Nagoya University, 3. University of Electro-Commnunications, 4. Institute of Atmospheric Physics, Prague

Ionospheric electric fields penetrated from the magnetosphere to the low latitude ionosphere have been observed as geomagnetic disturbances caused by ionospheric currents, such as the equatorial electrojet (EEJ) at the dayside equator. The ionospheric currents are too weak to be a detector of the electric field at low latitudes on the dayside and even at the equator on the nightside. The HF Doppler (HFD) sounder is another powerful tool for observations of the electric filed at low latitudes on both the day- and night-sides. We have shown that the electric fields of the geomagnetic sudden commencements (SC) are composed of the preliminary impulse followed by the main impulse, of which directions are opposite to each other and both electric fields are opposite on the day- to night-sides (Kikuchi et al. 2016 JGR). We have also shown that the substorm electric fields are composed of the growth phase followed by expansion phase overshielding electric fields, of which directions are opposite to each other (Hashimoto et al., 2017). In this paper, we show that the HFD sounder is capable of detecting stormtime electric fields and that the electric fields are found to decay rather rapidly over one hour during the main phase with the time scale of a few hours. Combining with the equatorial magnetometer data, we would be able to estimate the decaying rate of the HFD electric fields, which helps obtain the stormtime electric fields quantitatively from the HFD data. We discuss advantages of widely separated HFD sounder operations and cooperations with SuperDARN as well as with magnetometer networks.

Stratospheric ionization during magnetic storms

*Ryuho Kataoka[1]

1. National Institute of Polar Research

Transient mesospheric ionization was detected at an altitude of 65-70 km during the auroral breakup that occurred from 2220 to 2226 UT on June 30, 2017. During this event, the footprint of the Arase satellite was located within the field of view of the all-sky imagers at Syowa Station in the Antarctic. Auroral observations at Syowa Station revealed the dominant precipitation of relatively soft electrons during the auroral breakup. A corresponding spike in cosmic noise absorption was also observed at Syowa Station, while the Arase satellite observed a flux enhancement of >100 keV electrons and a broadband noise without detecting chorus waves or electromagnetic ion cyclotron waves. A general-purpose Monte Carlo particle transport simulation code was used to quantitatively evaluate the ionization in the middle atmosphere. Results of this study indicate that the precipitation of energetic electrons of >100 keV, rather than X-rays from the auroral electrons, played a dominant role in the transient and deep (65-70 km) mesospheric ionization during the observed auroral breakup. Based on the above results of Kataoka et al. (2019), we further discuss a possible role of X-rays to ionize the stratosphere during magnetic storms.

Calculating propagation time of HF radio wave using ray-tracing method and simple comparison with the observation.

*Ryo Nakao[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Kornyanat Hozumi[2], Takuya Tsugawa[2], Susumu Saito[3], Mamoru Ishii[2]

1. Graduate School of Engineering, Chiba University, 2. National Institute of imformation and Communications Technology, 3. Electronic Navigation Research Institute

To provide the information of nowcast of radio propagation, we have started a project, HF-START (HF simulator Targeting for All user's Regional Telecommunications). In this project, a simulator that is able to predict propagation of HF radio waves is constructed by ray-tracing calculation.
Using this simulator, we have examined whether HF radio wave travels between any two points. In this calculation, the electron density, which is necessary to calculate reflection index is determined by International Reference Ionosphere (IRI).In this project, HF receivers have been installed at Chiba University (Chiba, 35.62N, 140.10E), Sarobetu (Hokkaido, 45.16N, 141.74E), Numata (Gunma, 36.62N, 139.02E), Yamagawa (Kagoshima, 31.20N, 130.61), Ogimi (Okinawa, 26.68, 128.15E) for observing HF radio wave transmitted from radioNIKKEI (Nagara, Chiba, 35.46N, 140.20E) to confirm the results of the ray-tracing calculation. In the ray-tracing calculation, therefore, we set the same locations of the transmitter and receivers as the observatories of HF-START. As a result of simple comparison between the ray-tracing results and the observation, it is found that there was a difference of the propagation time between the ray-tracing results and the observations. It is possible that the radio wave propagation between radioNIKKEI and Ciba University is not ground wave but sky wave that is reflected by ionosphere. As for further calculation, we plan to use the electron density distributions determined by GAIA and GNSS tomography in the ray-tracing calculation.

Why do some probabilistic forecasts lack reliability?

*Yuki Kubo[1]

1. National Institute of Information and Communications Technology

One of the important attributes to be satisfied for the probabilistic forecast system is reliability. However, some probabilistic forecast systems lack reliability. Why do some probabilistic forecasts lack reliability? We investigate a condition for a probabilistic binary forecast to be reliable in this work. We mathematically prove that a necessary, but not sufficient, condition for achieving a reliable probabilistic forecast is maximizing the Peirce skill score (PSS) at the threshold probability of the climatological base rate. The condition is confirmed by using artificially synthesized forecast-outcome pair data and previously published probabilistic solar flare forecast models. The condition gives a partial answer as to why some probabilistic forecast systems lack reliability, because the system, which does not satisfy the proved condition, can never be reliable. The result implies that those who want to develop a reliable probabilistic forecast system must adjust or train the system so as to maximize PSS near the threshold probability of the climatological base rate.

An estimation method of GEO spacecraft surface charging for a real-time spacecraft risk assessment

*Masao Nakamura[1], Ryota Kawachi[1], Go Takahashi[1], Tsutomu Nagatsuma[2], Mamoru Ishii[2]

1. Osaka Prefecture University, 2. NICT

Spacecraft anomalies are often induced by electrostatic discharges due to surface charging. Some spacecraft charging simulation software is developed by space agencies and research institutes and used for spacecraft designs and charging analysis. However these simulations cannot be used for a real-time estimation because they need hours or days to calculate the surface potential for a given plasma environment. Therefore we develop a quick estimation method of GEO spacecraft surface charging for the Space Environment Customized Risk Estimation for Spacecraft (SECURES) of the space weather forecast Project for Solar-Terrestrial Environment Prediction (PSTEP). We estimate the surface potentials by interpolation using lookup tables of the pre-simulated surface potentials for combinations of plasma temperatures and densities. We study fitting functions used in the interpolation and how to make the lookup tables for the good estimation. Then we can real-time estimate the surface potentials of the target GEO spacecraft when the on-orbit plasma environment is predicted or observed. The spacecraft risk assessment can be accomplished by additional information about the experimental discharging differential potential of the surface materials.

A network of HF Doppler sounding systems in Japan

*Keisuke Hosokawa[1], Hiroyuki Nakata[2], Kumiko K. Hashimoto[3], Ichiro Tomizawa[1], Jun Sakai[1], Takashi Kikuchi[4]

1. University of Electro-Communications, 2. Chiba University, 3. Kibi International University, 4. ISEE, Nagoya University

Since 2003, a network observation of HF Doppler sounding has been conducted in Japan for remote-sensing the atmospheric, ionospheric and magnetospheric processes. Currently, 1 transmitting station (Tx) and 7 receiving stations (Rx) are operative by a collaborative effort of four difference universities. The main transmitting station is located at Chofu, Tokyo, Japan in the Campus of University of Electro-Communications (JG2XA). JG2XA transmits continuous waves at 5006 kHz and 8006 kHz with a transmitting power of 200 W. By receiving this JG2XA signal at 7 Rx stations (Sugadaira, Oarai, Kure, Kashima, Iitate, Fujisawa and Sugito) we derive the Doppler shift imposed during the propagation and reflection in the ionosphere. In particular, the Doppler shift data can be used to detect vertical motion of the ionospheric F region with a temporal resolution of 10 s. At some stations, we also have observed signals from Radio Nikkei 1 (JOZ at 3925 kHz, JOZ2 at 6055 kHz, and JOZ3 at 9595 kHz) transmitted from Nagara, Chiba, Japan, which allows us to observe the vertical motion of the ionosphere at several altitude levels. The data obtained from this experiment since 2003 are all available at http://gwave.cei.uec.ac.jp/~hfd. Not only quick-look plots but also several types of digital data (raw wave form and Doppler shift data) can be retrieved from this database. The experiment covers various ionospheric phenomena in the Magnetosphere-Ionospheric (M-I) coupling system, such as sporadic E-layer (Es), medium-scale traveling ionospheric disturbances (MSTIDs), large-scale traveling ionospheric disturbances (LSTIDs), global-scale electric field variation, geomagnetic pulsations, and sudden commencement (SC). The data can also be used for the studies of vertical coupling between the lower atmosphere and ionosphere, for example, observations of ionospheric variation after large earthquakes, volcanic eruptions and typhoons. To facilitate analyses of the phenomena listed above, it is desired to observe a wider area in latitude and longitude. For this purpose we plan to extend the network covering the entire ionosphere over Japan in the near future. In the presentation, we will give a brief introduction to the experiments and online database, and then discuss the future direction of the studies of atmosphere, ionosphere and magnetosphere using the HF Doppler sounding in a framework of international collaborations.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Tue. May 28, 2019 5:15 PM - 6:30 PM JST | Tue. May 28, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-EM12] Space Weather and Space Climate

convener:Ryuho Kataoka(National Institute of Polar Research), Antti A Pulkkinen(NASA Goddard Space Flight Center), Kanya Kusano(Institute for Space-Earth Environmental Research, Nagoya University), Kaori Sakaguchi(National Institute of Information and Communications Technology)

We share the latest scientific papers to understand how the solar-terrestrial environment changes in various time scales, and to discuss how we will react via international and interdisciplinary collaborations. More specifically, welcomed papers include space climate studies to reconstruct long-term variations from radio isotopes; cutting-edge observational and modeling studies of the ionosphere, geospace, heliosphere and the sun; simulation and statistical studies to predict the future space weather and space climate; applied science such as operational space weather forecast and mitigation of the social impact due to extreme space hazards.

Reconnection signatures in solar magnetograms during the solar storms of 4-10 September 2017

*Robert Dean Loper[1,2]

1. Air Force Institute of Technology, Department of Engineering Physics, 2. National Center for Atmospheric Research, High Altitude Observatory

Solar flare forecasting is limited to active region classification and historical correlation, due largely to our lack of understanding of magnetic reconnection as a driving mechanism for solar flares and coronal mass ejections. Photospheric observations indicate magnetic field changes during solar flares, brought about during magnetic reconnection and related to magnetic field helicity on the solar surface. While the neutral point of the reconnection event associated with a flare usually occurs in the solar corona, some signs of the magnetic field changes should manifest as low as the photosphere. This study utilizes data from SDO HMI and Space-Weather HMI Active Regions Patches (SHARPS) to analyze full vector field component data in the photospheric magnetic field during several magnetic reconnection events during the space weather events of 4-10 September 2017.

Statistical Relation between Solar Flares and Coronal Mass Ejections with Respect to Sigmoidal Structures in Active Regions

*Yusuke Kawabata[1,2], Yusuke Iida[3], Takafumi Doi, Sachiko Akiyama[4], Seiji Yashiro[4], Toshifumi Shimizu[2]

1. Earth and Planetary Science, The University of Tokyo, 2. Institute of Space and Astronautical Science, JAXA, 3. Kwansei Gakuin University, 4. The Catholic University of America

We will report statistical dependences among features of coronal mass ejections (CMEs), solar flares, and sigmoidal structures in soft-X-ray images (Kawabata et al. 2018). We applied analysis methods to all the features in the same way in order to investigate the reproducibility of the correlations among them, which may be found from previous statistical studies. Samples of 211 M-class and X-class flares, observed between 2006 and 2015 by the Hinode/X-ray telescope, Solar and Heliospheric Observatory/Large Angle and Spectrometric Coronagraph, and Geostationary Operational Environmental Satellite, were examined statistically. Five kinds of analysis were performed: Occurrence rate analysis, linear-correlation analysis, association analysis, the Kolmogorov–Smirnov test, and the Anderson–Darling test. These give three main results. First, the sigmoidal structure and long-duration events (LDEs) have a stronger dependence on CME occurrence than large X-ray-class events in on-disk events. Second, for the limb events, a significant dependence exists between LDEs and CME occurrence, and between X-ray-class events and CME occurrence. Third, 32.4% of on-disk flare events have sigmoidal structure and are not accompanied by CMEs. However, the occurrence probability of CMEs without sigmoidal structure is very small, 8.8%, in on-disk events. While the first and second results are consistent with previous studies, we provide for the first time a difference between the on-disk and limb events. The third result, that non-sigmoidal regions produce fewer eruptive events, is also different from previous results. We suggest that sigmoidal structures in soft X-ray images will be a helpful feature for CME prediction in on-disk flare events.

Multi-wavelength Observations of Pre-flare Quasi-periodic Pulsation in the C2.2 Flare on 2012 October 15

*Yung-Chi Yang[1], Ya-Hui Yang[1], Baolin Tan[2], Chengming Tan[2], Y.H. Yan[2]

1. Graduate Institute of Space Science National Central University, 2. Key Laboratory of Solar Activities, National Astronomical Observatories

Quasi-periodic pulsation (QPP) is thought to be the nature of solar flares, which can be observed during and before flares in various wavelengths, such as the radio, microwave, SXR, and EUV. In this study, we analyze a pre-flare QPP event on 2012 October 15 and its association with the following C2.2 flare based on the radio data in the ranges of 2.81-2.85 GHz and 2.91-2.95 GHz from Solar Broadband Radio Spectrometer (SBRS), EUV images from AIA multi-wavelength observations, and wavelet analysis. Our result show that the main period of the radio QPP is ~800 s which is similar to the period of ~13.5 min obtained in SXR by Tan et al. (2016). Moreover, we analyze several localized areas in the flare-eruptive AR 11593 to search for the possible regions responsible for the occurrence of pre-flare QPP. We find that the footpoints of brightening loops in 211 Åshow the quasi-periodic behavior of ~850 s. It is thus suggested that the pre-flare QPP with a period of 13-15 min can be manifested in both of the thermal (SXR, EUV) and nonthermal (radio) radiation processes. The relationship between the pre-flare QPP and the subsequent C2.2 flare will also be discussed.

Investigation of pre-flare type III solar radio bursts and their potential solar origins

*Shao-Fu Hsieh[1], Ya-Hui Yang[1], Baolin Tan[2], Chengming Tan[2], Y.H. Yan[2]

1. Graduate Institute of Space Science National Central University, 2. Key Laboratory of Solar Activities, National Astronomical Observatories, Chinese Academy of Sciences

Type III solar radio bursts are characterized as the fast-drifting radio emissions in a dynamic spectrogram, which is believed to be produced by the propagating electron beams and often accompanied with the solar flares or magnetic reconnection. Studying the type III radio bursts in high-frequency range before flares would be important for understanding the trigger of energy release although it is rarely reported previously. Here we present two pre-flare type III burst events found in the range of 2.6-3.8 GHz at Solar Broadband Radio Spectrometer (SBRS). By comparing with the SDO/AIA multi-wavelength observations in flare active regions, the pre-flare type III radio bursts have good temporal correlations with the increases of EUV emissions. Furthermore, we find that one event is related to the EUV brightening with 1-min delay, implying the existence of plasma heating before energy release. The other event has a simultaneous EUV jet with a speed of ~700 km/s indicating the occurrence of magnetic reconnection. We suppose both pre-flare events are associated with small-scale energy release via magnetic reconnection.

Statistical and observational research of solar flare for constructing total emission spectra prediction model

*Shohei Nishimoto[1], kyoko Watanabe[1], Shinsuke Imada[2], Tomoko Kawate[3], Kyoung-Sun Lee[4]

1. National Defense Academy, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Institute Of Space And Astronautical Science, Japan Aerospace Exploration Agency, 4. National Astronomical Observatory of Japan

Impulsive energy release phenomena such as solar flares, sometimes affect to the solar-terrestrial environment. Usually, we use soft X-ray flux (GOES class) as the index of flare scale. However, the magnitude of effect to the solar-terrestrial environment is not proportional to this scale. Therefore, it is considered that the GOES class is not optimal parameter for predicting the Sudden Ionospheric Disturbance (SID). To identify the relationship between solar flare phenomena and influence to the solar-terrestrial environment, we need to understand the full spectra of solar flares in detail.
There is the solar flare irradiance model named the Flare Irradiance Spectral Model (FISM) (Chamberlin et al., 2006, 2007, 2008). FISM is the most used model, and can estimate solar flare spectra with high wavelength and temporal resolution. However, this model can not express the time evolution of emitted plasma during the solar flare, and has low accuracy on short wavelength that might strongly affect to the total flare spectra. Therefore, individual SID phenomenon can not be reproduced.
In this work, in order to solve the problems of FISM, we performed statistical analysis on observational data during the solar flares. From This study, we tried to find the parameters that control the solar flare emission spectra. We selected solar flare events larger than M-class from the Hinode flare catalogue (Watanabe et al., 2012). First, we focused on the EUV emission observed by the SDO/EVE. We examined the intensities and time evolutions of five EUV lines (Fe XX, Fe XVIII, Fe XVI, Fe VIII, and He II) for 54 flare events. As a result, we found positive correlation between the “GOES class” and the “EUV peak flux” for all Fe lines. Moreover, we found that hotter lines peaked earlier than cooler lines. On the other hand, He II line data have poor correlation with GOES X-ray data. Furthermore, we considered that the geometrical features of solar flares effect to those time evolutions. We measured flare ribbon length for 33 flare events observed by SDO/AIA, and found positive correlation between the “flare duration” and the “ribbon length”. From the statistical research of these observational data, we found that the time evolution of EUV emission can be explained by the X-ray emission.
Then, we tried to identify parameters that determine the solar flare spectra by comparing the flare emissions derived from physical based numerical model of solar flare with the actual observational data. Consequently, we used numerical simulation same as Imada et al.(2015). This numerical model can reproduce the movement and ionization of the plasma in the flare loop.
In this presentation, we will show some results of numerical simulation, and discuss the parameters for total solar flare emission spectra by comparing of simulation results, observational data and FISM.

Modeling of solar active regions using local linear force-free fields to estimate magnetic twist

*Kento Nakatani[1], Kanya Kusano[1], Sung-Hong Park[1], Leka KD[2]

1. Institute for space-Earth Environmental Research, Nagoya University, 2. North West Reserch Associates

The prediction of solar flares is an important issue for space weather forecasting. Although solar flares are believed to be caused by the magnetohydrodynamic (MHD) instability in solar active regions, the method for accurately evaluating the stability of solar magnetic field is not yet established. Recently, Ishiguro & Kusano (2017) proposed that a new instability called the Double Arc Instability (DAI) plays a role of initial driver of solar flares and the critical parameter for this instability can be used to evaluate the stability of active regions. The parameter can be derived by the integration of the magnetic twist as the function of magnetic flux. One way for it is given by the nonlinear force-free field (NLFFF) extrapolation using the photospheric vector magnetic field data. However, the NLFFF extrapolation demands heavy computation and it sometimes cannot well work as a model of solar coronal magnetic field because the force-free condition is limited on the photosphere. Therefore, in order to improve the efficiency and applicability of the flare prediction using , it may be required to develop a method to approximately but much quickly capture the overall features of magnetic field in solar active regions, especially in the flare triggering region. From this point of view, we try to develop a method to extract the characteristic feature of magnetic field in solar active regions using the linear force-free field (LFFF) model. For this objective, we compare the several methods to accurately capture the structure of using LFFF. In this study, we report the result of the analysis for the solar active region NOAA 11429.

Magnetohydrodynamic Simulation of an Erupting Magnetic Flux Rope on February 13 2009: Journey to Coronal Mass Ejection

*Satoshi Inoue[1], Antonia Savcheva[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Harvard-Smithsonian Center for Astrophysics

We performed a magnetohydrodynamic (MHD) simulation of a solar eruption launched from solar active region 11012 on February 13, 2009. We in particular concentrated on the evolution of the magnetic flux rope (MFR) leading a coronal mass ejection. We first extrapolated the pre-eruptive magnetic flux ropes using a flux insertion method, in which the MFRs can be extrapolated from the normal component of the magnetic field (Bz) observed by SOHO/MDI and Extreme-Ultra Violet (EUV) images observed by the STEREO satellite. The extrapolated magnetic field reproduced the sigmoidal magnetic structure observed in EUV image well. Next we performed the MHD simulation using the extrapolated magnetic field.

The resulting simulation showed the dramatic eruption of the magnetic flux rope under which the current sheet and the post-flare loops are formed. This is well explained by the standard CSHKP flare model. The evolution of the MFR did not show simple dynamics, rather it showed very complicated dynamics through a magnetic reconnection. We found, during the eruption, that the coherent MFR is created through the reconnection of multiple pre-existing MFRs. Magnetic reconnection plays a role in producing the coherent, erupting MFR and supplying further twist into it. Furthermore we found that the footpoints of the erupting MFR moves along or away from the polarity inversion line, as seen in two-ribbon flares. The locations of both the footpoints of the MFR correspond to those of dimming regions observed in EUV images. Since the location and shape of the post-flare loops obtained from the simulation is reproduced in the observations, we can confirm the reliability of our simulation.

Investigation of flow structures in the solar interior through the surface magnetic elements' tracking

*Yusuke Iida[1]

1. Kwansei Gakuin University

We investigate the correlation of meridional flow and rotation velocity in the solar interior by tracking huge number of the surface magnetic elements.

As reported in JpGU2017 meeting, we found that the meridional flow velocity from the magnetic elements' tracking depends positively on their flux and size. We discussed that it may come from that the larger magnetic elements are rooted in the deeper solar interior. We further investigate this issue by correlating the meridional flow velocity and rotation velocity.

We use line-of-sight magnetograms obtained by SDO/HMI in July 2016. Time cadence is 45 seconds, in which the travel distance of magnetic element is smaller than 1 pixel. The magnetograms are transposed from the Earth-view coordinate to the Stonyhurst coordinate. We use the data within 75 degree from the disk center. Magnetic field strength is converted with an assumption that magnetic field is vertical to the surface and interpolated with a cubic spline interpolation.

We detected approximately 8,000 elements in each magnetogram and 4.5x108 displacements in our data set. The meridional flow and rotation velocity on magnetic flux are investigated. The rotation velocity shows negative dependence on the flux at the latitude within 45 degree while it shows weekly positive dependence at the latitude higher than 45 degree. This result is consistent with the depth dependence of rotation velocity obtained by previous helioseismology researches.

High-precision measurement of carbon-14 in tree rings around the onset of the Maunder Minimum

*Hiroko Miyahara[1], Fuyuki Tokanai[2], Toru Moriya[2], Hideyuki Hotta[3]

1. Musashino Art University, 2. Yamagata University, 3. Chiba University

It is well known that the Sun indicates long-term variations at time scales of a few hundred years to a few millennia. It sometimes brings the grand minima, at which period the sunspots disappear for more than several decades. The detailed process of such long-lasting disappearance of sunspots, however, remains unclear. We therefore have been trying to reconstruct solar cycles around the onset of grand minima based on high-precision measurement of carbon-14 in tree rings. In this paper, we report on our preliminary result on the measurement of carbon-14 around the onset of the Maunder Minimum.

Examination of ^{10}Be in travertine sediment as a possible tool to reconstruct past solar activity

*Hongyang Xu[1,2], Hiroko Miyahara[2], Kazuho Horiuchi[3], Hiroyuki Matsuzaki[4], Hailong Sun[5], Weijun Luo[5], Xiangmin Zheng[1], Yusuke Suganuma[6,7], Shijie Wang[5], Limin Zhou[1]

1. East China Normal University, 2. Musashino Art University, 3. Hirosaki University, 4. University of Tokyo, 5. Chinese Academy of Sciences, 6. National Institute of Polar Research, 7. The Graduate University for Advanced Studies (SOKENDAI)

In this study, we explore the possibility of using travertine sediment for reconstructing the past solar activity. We obtained an annual ^{10}Be record from travertine deposit from the modern period and compared with the neutron monitor data. We discuss a possible methodology to calibrate the climatological impact on ^{10}Be deposition and to obtain the signal of past solar and cosmic-ray variations.

We have been examining the potential of ^{10}Be in travertine sediment as a tool to reconstruct past solar and cosmic-ray variations. In this paper, we compare the ^{10}Be profile in the travertine layers from the rainy and dry seasons, and discuss the nature of ^{10}Be deposition at the two seasons.

1 year of CR observation at Syowa Station in the Antarctic.

*Chihiro Kato[1], Kazuoki Munakata[1], Akira Kadokura[2], Ryuho Kataoka[2], Paul Evenson[3]

1. Shinshu University, 2. National Institute of Polar Research, 3. University of Delaware

CR observation has been carried out for 1 year at Syowa Station in the Antarctic. There was no serious unavailability of data during the whole year. It is now concluded that this station can contribute to a space weather study as one of the CR monitoring station of Global Muon Detector Network (GMDN). We report observed data and its stability as GMDN.

Space weather forecast archives at NICT: handwritten solar activity charts

*Kaori Sakaguchi[1], Daikou Shiota[1], Kaori Fukunaga[1], Katsuhide Marubashi[1], Hiromitsu Ishibashi[1], Yuki Kubo[1], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology

About 40 years ago from 1978 to 1999, at Hiraiso Branch, Radio Research Laboratory; present Space Environment Laboratory of National Institute for Information and Communication Technology (NICT) in Japan, space environment data had been recorded in "solar activity chart" by hand for the operation of the radio wave warning service. The charts were created based on URSIgram codes, which were developed to facilitate the rapid exchange of information by telex in periods when internet was not available. Based on the exchanged codes, sunspots transitions and solar flare occurrences on the solar surface, these effects on shortwave propagation, geomagnetic disturbance, and cosmic ray flux over Japan were written in the solar activity charts together with comments and sketch by recorders. One chart was created for each Bertel’ s solar rotation number between No. 1974 and No. 2254, corresponding to sunspot cycles 21 and 22. We realized that the data exchange is almost only once a day from each observation point and charts was accumulation of the available data in real-time at that time.It might be quite difficult to decide future forecast from such a limited real-time data set. Currently, we are digitizing the solar activities charts and the data shown there. In this poster, we present examples of solar activity charts and possible real-time data set and time delay, as well as the verifying result of the solar flare / geomagnetism storm forecast at the time.

IMF dependence on solar wind parameters

*Tohru Araki, Yuki Harada[1]

1. Kyoto University

We studied IMF dependence upon solar wind parameters using OMNI hourly values.

Figure below is a plot of the total force (B), horizontal component (Bxy) in the ecliptic plane and vertical component (Bz) of IMF versus the solar wind density (Nsw). The IMF is averaged over 0.2/cc bin of Nsw. Data number in each bin is also plotted. The data period here is 1979-1981 (maximum SSN phase).

The figure shows (1) that B, Bxy and Bz slowly decrease with decreasing Nsw and (2) that when Nsw approaches further to zero. B and Bxy begin to increase and converges to the same finite value (about 10 nT here) while Bz converges to zero. The property (2) suggests that IMF converges to a typical spiral pattern when solar wind density converges to zero.

Two other data periods, 1999-2001 (SSN maximum) and 2007-2009 (SSN minimum) are examined. IMF observed by MAVEN orbiting Mars is also studied for the period, 2014-2018. The results of the analysis are roughly consistent with the description above. We also checked IMF dependence on solar wind velocity

Dipole Tilt Effect of Geomagnetic Activity from Low- to High-latitudes

*Nowada Motoharu[1]

1. Shandong University at Weihai

Geomagnetic activity is dominantly impacted by the orientation of the Interplanetary Magnetic Field (IMF). However, when trying to address why the variations of geomagnetic activity are “semi-annual”, and are greater at equinoxes than at solstices, only IMF control of geomagnetic activity is not enough. This is because these variations are strongly dependent on the Earth’s dipole tilt; the dipole tilt is smaller at the equinoxes than at the solstices. Primitive studies assumed that magnetic reconnection occurs only at the subsolar point of dayside magnetopause. In their studies, the dipole tilt effect was not considered, but only the magnetic field direction between the IMF and the magnetosphere at the subsolar point was discussed in their studies. After them, geomagnetic variations where both dipole tilt effect and IMF direction are taken into account have been investigated. Based on a large database of IMF and AL/AU, we examined the relationship between the IMF clock angle and AL/AU at various dipole tilts. For both positive and negative dipole tilts, geomagnetic activity decrease as the clock angle moves away from 180˚. The AL/AU indices also tend to become smaller for larger dipole tilts. This dipole tilt dependence enhances the semi-annual variation of high-latitude geomagnetic activity.
It also remains unclear how degree energy input rate from solar wind to ring current (dD_{st}^{*}/dt) depends on dipole tilt under various interplanetary magnetic field (IMF) orientation and whether or not ring current development also follows this dipole tilt dependence. We tried to statistically investigate the dependence of dipole tilt and IMF clock angles on low- and middle-latitude geomagnetic activity (D_{st}^{*}), which is a proxy of ring current development, and solar wind energy input rate to ring current (dD_{st}^{*}/dt) over one solar cycle (1978 - 1988). D_{st}^{*} was calculated with the solar wind dynamic pressure and original D_{st} index, and the dipole tilt angle was defined as function of the day of year and universal time. The (dD_{st}^{*}/dt) values were obtained based on the solar wind electric field under the southward IMF conditions. Under positive and negative dipole tilts, the (dD_{st}^{*}/dt) values under low dipole tilt are negatively larger than those in case of high dipole tilt. Further peaks at 180˚ of the IMF clock angle are seen in most of the dipole tilt cases. However, the D_{st}^{*} index shows neither a peak at 180˚ of the IMF clock angle nor particular dipole tilt dependence in case of negative dipole tilt angles. This result suggests that low- and middle latitude geomagnetic activity (ring current development) does not necessarily show dipole tilt dependence and a one-to-one correlation with solar wind energy input rate to ring current (dD_{st}^{*}/dt).

A New Prediction Model for Solar Wind-Triggered Magnetospheric Disturbances Based on Potential Learning (Neural Network)

*Ryozo Kitajima[1], Motoharu Nowada[2], Ryotaro Kamimura[3]

1. Seikei University, 2. Shandong University at Weihai, 3. Tokai University

Nowadays, it becomes so important in saving our economic activity, and preventing the disasters caused by terrestrial electromagnetic effects to predict a scale and the duration of the geomagnetic disturbances based on in-situ solar wind observations. Recently, one of the notable techniques for the predictions of the magnetospheric disturbances is Neural Network (NN). However, most of these studies are focused on the reproduction of the behaviors of the index values, which represent the geomagnetic disturbances (e.g, D_{st} and AE), by inputting the solar wind parameters measured by the satellites. In our study, we apply a novel neural network model of ‘Potential Learning (PL)’.
Basically, Neural Networks (NNs) are models which imitate the information processing in the nervous system of brain. The nerve is made of cells as referred to as “neurons”, which specializes the information processing. NNs consist of “artificial” neurons, and can process information by learning. Therefore, using NNs, we can obtain some characteristics of the data inputted. The PL is a new kind of the NNs. A feature of the PL is to make a network that can understand the input variables based on learning by “input potentialities”, which are indices as calculated with the variances derived from the input variables. If using this PL, we can specify what input variable(s) is (are) potentially important and influential for a phenomenon.
In this study, introducing the PL technique, we try to specify which solar wind parameter plays an essential role in causing the geomagnetic disturbances. Although the conventional PL, where we used, had automatically selected the variables of interest, we develop a “improved” PL in this study so that the variables can manually be selected. We benchmark this new algorithm using the 4 polar magnetic storm cases occurred under the southward Interplanetary Magnetic Field (IMF)-B_z conditions, and advisedly set the maximum potentiality for the IMF-B_z, so that the IMF-B_z component is the most possible solar wind parameter to cause the geomagnetic disturbances. We note “second” solar wind parameter(s) to possibly cause the magnetospheric disturbances, following the IMF-B_z component. After testing our new technique to actual storm events, we might distinguish the magnetospheric disturbances into two different types, that is, the geomagnetic disturbances driven by “IMF-dominant” and “combination of IMF with solar wind plasma (dynamic pressure)”. The advantages to adopt this new algorithm to space weather, and more detailed results will be discussed in this presentation.

Real-time magnetosphere simulator for space weather using REProduce Plasma Universe code

*Yasubumi Kubota[1], Aoi Nakamizo[1], Kaori Sakaguchi[1], Mitsue Den[1], Yuki Kubo[1], Tsutomu Nagatsuma[1], Takashi Tanaka[1,2]

1. National Institute of Information and Communications Technology, 2. Kyushu University

Surface charging of artificial satellite is one of risks caused by dynamical variations of space environment. It occurs when a satellite exposes high energy electrons around 10 keV created by plasma injection accompanied with substorm. Therefore we want to predict timing and electron energy of plasma injection using magnetosphere-ionosphere coupling global MHD simulation. Now we are developing a real-time numerical simulator for space weather forecast using magnetosphere-ionosphere coupling global MHD simulation called REPPU (REProduce Plasma Universe) code. The feature of the simulation code is highly robust to extreme solar wind parameters because the unstructured grid system has no singular point and is able to calculate in the uniform accuracy over the whole region. We use the real-time solar wind data formatted in the GSM coordinate system observed by DSCOVR spacecraft. Magnetic-dipole axis is fixed to z-direction in our simulation. Therefore daily variation of magnetic-dipole axis is not reproduced. Instead, we convert the input direction of the solar wind velocity and magnetic field into that which tilts including daily variation of magnetic dipole axis in x-z plane. In the method the solar wind structure is not exact. However we can relatively reproduce the magnetosphere response including daily variation of the magnetic-dipole axis against solar wind. The resolution is 7682 grids in the horizontal direction and 240 grids in the radial direction.
In this presentation, we compare the simulation results with the CPCP, AE index, and plasma variations observed by geostationary orbit satellites. Density and temperature of plasma injection derived from MHD simulation tends to estimate larger and smaller values than observation respectively because the MHD simulation does not include kinetic heating effects. We have to interpret MHD simulation results for prediction of electron density and temperature. We will discuss how to interpret electron density and temperature between observation and MHD simulation.

Simulation of GIC flowing through the power transmission network (187 kV-500 kV) in Japan

*Nishida Yuichiro[1,6], Yusuke Ebihara[1], Satoko Nakamura[1], Shinichi Watari[2], Kumiko Hashimoto[3], Kentaro Kitamura[4], Takashi Kikuchi[5]

1. Kyoto University Reserch Institute for Sustainable Humanosphere, 2. National Institute of Information and Communications Technology, 3. Kibi International University, 4. National Insutitute of Technology, Tokuyama College, 5. Nagoya University, 6. Kyoto University Department of Electrical Engineering

The energy released from the sun can enhance electric currents in Earth’ s magnetosphere, which induces an electric field on the ground surface. This electric field, called a geomagnetically induced electric field (GIE), gives rise to geomagnetically induced current (GIC) flowing in a transmission line. Japan is situated at geomagnetically low latitudes, but the potential risk is probably non-zero because a large-amplitude of GIC, as high as 129 A, was recorded in the Japanese power grid during the Halloween storm in October 2003. To evaluate the potential risk of the Japanese power grid properly, we modeled the Japanese power grid with high voltage class over 187 kV on the basis of publicly available data. The model consists of 602 nodes and 763 paths. The uniform GIE imposed on Japan was estimated on the basis of the geoelectric field observed in April 2018 at Kakioka Magnetic Observatory. We applied the uniform GIE on the model. The calculated GIC is roughly in agreement with that measured at 4 substations in Japan. For the westmost substation, a disagreement was found when we considered only the highest class of the power grid (500 kV), which may imply that the lower voltage class of the grid (<500 kV) may have some contribution to the GIC in Japan. We discuss the general tendency of the GIC flowing in the Japanese power grid, and prediction capability of the currently available model.

Abstract

The energy released from the sun can enhance electric currents in Earth's magnetosphere, which induces an electric field on the ground surface. This electric field, called a geomagnetically induced electric field (GIE), gives rise to geomagnetically induced current (GIC) flowing in a transmission line. Japan is situated at geomagnetically low latitudes, but the potential risk is probably non-zero because a large-amplitude of GIC, as high as 129 A, was recorded in the Japanese power grid during the Halloween storm in October 2003. To evaluate the potential risk of the Japanese power grid properly, we modeled the Japanese power grid with high voltage class over 187 kV on the basis of publicly available data. The model consists of 602 nodes and 763 paths. The uniform GIE imposed on Japan was estimated on the basis of the geoelectric field observed in April 2018 at Kakioka Magnetic Observatory. We applied the uniform GIE on the model. The calculated GIC is roughly in agreement with that measured at 4 substations in Japan. For the westmost substation, a disagreement was found when we considered only the highest class of the power grid (500 kV), which may imply that the lower voltage class of the grid (<500 kV) may have some contribution to the GIC in Japan. We discuss the general tendency of the GIC flowing in the Japanese power grid, and prediction capability of the currently available model.

Climatological features of the upper atmosphere reproduced by a revised version of a whole atmosphere-ionosphere coupled model GAIA

*Hidekatsu Jin[1], Yasunobu Miyoshi[2], Chihiro Tao[1], Hiroyuki Shinagawa[1], Hitoshi Fujiwara[3]

1. National Institude of Information and Communications Technology, 2. Kyushu University, 3. Seikei University

Temporal and spatial variations in the ionospheric electron density and thermospheric mass density could have significant impacts on radio communications between ground and space, and particle and atmospheric drag environments around satellites. Origins of such upper atmospheric variations are not only in the solar atmosphere through the emissions of solar radiation, high-speed plasma gas and high-energy particles, but also in the Earth’ s lower atmosphere, where meteorological phenomena could give rise to atmospheric waves propagating upward. In order to nowcast and forecast the upper atmospheric variations and disturbances, a whole atmospheric model, GAIA, has been developed, which combines a whole atmospheric GCM, an ionospheric model and an electrodynamics model in a self-consistent manner.

So far, for the purpose of its validation, we have compared climatological features of thermosphere and ionosphere reproduced by GAIA with those from ionospheric observation and observation-based empirical models. The comparison indicates that the model and observations are generally in good agreements, but in some condition such as at solar maximum there are significant disagreements in the ionospheric electron density distribution. In order to improve the accuracy of the model, we have made several updates such as ion chemical processes, energetics, parameterization, and so on. We also have introduced magnetospheric effects into the model, such as electrodynamics coupling with magnetosphere and particle precipitation. In this presentation, we discuss how the upper atmospheric model can improve its accuracy and how they can be validated.

Investigation of the thermospheric mass density variations below 200 km

*Hitoshi Fujiwara[1], Yasunobu Miyoshi[2], Masayoshi Utashima[1], Huixin Liu[2]

1. Faculty of Science and Technology, Seikei University, 2. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University

Since both the effects from the lower atmosphere and in-situ forcing are significant in the thermospheric region between 100 and 200 km altitude, the thermosphere in the region shows complex variations depending on various conditions. In addition, observations of the thermosphere (neutral atmosphere) between 100 and 200 km are very few compared to the upper thermosphere (above 300 km) and the ionosphere. These make it difficult to improve reliability of empirical and numerical models. Observations from Low Earth Orbit (LOE) satellites would be essential for building up available data sets in the thermospheric region between 100 and 200 km altitude. We will introduce our research project to investigate the thermospheric mass density variations in the 100-200 km altitude region with the LOE satellite, e.g., Tsubame (SLATS), data and a whole atmosphere GCM.

Low-latitude HF Doppler observations of magnetospheric electric fields during space weather disturbances

*Kumiko K. Hashimoto[1], Takashi Kikuchi[2], Ichiro Tomizawa[3], Keisuke Hosokawa[3], Jaroslav Chum[4]

1. Kibi International University, 2. Nagoya University, 3. University of Electro-Commnunications, 4. Institute of Atmospheric Physics, Prague

Ionospheric electric fields penetrated from the magnetosphere to the low latitude ionosphere have been observed as geomagnetic disturbances caused by ionospheric currents, such as the equatorial electrojet (EEJ) at the dayside equator. The ionospheric currents are too weak to be a detector of the electric field at low latitudes on the dayside and even at the equator on the nightside. The HF Doppler (HFD) sounder is another powerful tool for observations of the electric filed at low latitudes on both the day- and night-sides. We have shown that the electric fields of the geomagnetic sudden commencements (SC) are composed of the preliminary impulse followed by the main impulse, of which directions are opposite to each other and both electric fields are opposite on the day- to night-sides (Kikuchi et al. 2016 JGR). We have also shown that the substorm electric fields are composed of the growth phase followed by expansion phase overshielding electric fields, of which directions are opposite to each other (Hashimoto et al., 2017). In this paper, we show that the HFD sounder is capable of detecting stormtime electric fields and that the electric fields are found to decay rather rapidly over one hour during the main phase with the time scale of a few hours. Combining with the equatorial magnetometer data, we would be able to estimate the decaying rate of the HFD electric fields, which helps obtain the stormtime electric fields quantitatively from the HFD data. We discuss advantages of widely separated HFD sounder operations and cooperations with SuperDARN as well as with magnetometer networks.

Stratospheric ionization during magnetic storms

*Ryuho Kataoka[1]

1. National Institute of Polar Research

Transient mesospheric ionization was detected at an altitude of 65-70 km during the auroral breakup that occurred from 2220 to 2226 UT on June 30, 2017. During this event, the footprint of the Arase satellite was located within the field of view of the all-sky imagers at Syowa Station in the Antarctic. Auroral observations at Syowa Station revealed the dominant precipitation of relatively soft electrons during the auroral breakup. A corresponding spike in cosmic noise absorption was also observed at Syowa Station, while the Arase satellite observed a flux enhancement of >100 keV electrons and a broadband noise without detecting chorus waves or electromagnetic ion cyclotron waves. A general-purpose Monte Carlo particle transport simulation code was used to quantitatively evaluate the ionization in the middle atmosphere. Results of this study indicate that the precipitation of energetic electrons of >100 keV, rather than X-rays from the auroral electrons, played a dominant role in the transient and deep (65-70 km) mesospheric ionization during the observed auroral breakup. Based on the above results of Kataoka et al. (2019), we further discuss a possible role of X-rays to ionize the stratosphere during magnetic storms.

Calculating propagation time of HF radio wave using ray-tracing method and simple comparison with the observation.

*Ryo Nakao[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Kornyanat Hozumi[2], Takuya Tsugawa[2], Susumu Saito[3], Mamoru Ishii[2]

1. Graduate School of Engineering, Chiba University, 2. National Institute of imformation and Communications Technology, 3. Electronic Navigation Research Institute

To provide the information of nowcast of radio propagation, we have started a project, HF-START (HF simulator Targeting for All user's Regional Telecommunications). In this project, a simulator that is able to predict propagation of HF radio waves is constructed by ray-tracing calculation.
Using this simulator, we have examined whether HF radio wave travels between any two points. In this calculation, the electron density, which is necessary to calculate reflection index is determined by International Reference Ionosphere (IRI).In this project, HF receivers have been installed at Chiba University (Chiba, 35.62N, 140.10E), Sarobetu (Hokkaido, 45.16N, 141.74E), Numata (Gunma, 36.62N, 139.02E), Yamagawa (Kagoshima, 31.20N, 130.61), Ogimi (Okinawa, 26.68, 128.15E) for observing HF radio wave transmitted from radioNIKKEI (Nagara, Chiba, 35.46N, 140.20E) to confirm the results of the ray-tracing calculation. In the ray-tracing calculation, therefore, we set the same locations of the transmitter and receivers as the observatories of HF-START. As a result of simple comparison between the ray-tracing results and the observation, it is found that there was a difference of the propagation time between the ray-tracing results and the observations. It is possible that the radio wave propagation between radioNIKKEI and Ciba University is not ground wave but sky wave that is reflected by ionosphere. As for further calculation, we plan to use the electron density distributions determined by GAIA and GNSS tomography in the ray-tracing calculation.

Why do some probabilistic forecasts lack reliability?

*Yuki Kubo[1]

1. National Institute of Information and Communications Technology

One of the important attributes to be satisfied for the probabilistic forecast system is reliability. However, some probabilistic forecast systems lack reliability. Why do some probabilistic forecasts lack reliability? We investigate a condition for a probabilistic binary forecast to be reliable in this work. We mathematically prove that a necessary, but not sufficient, condition for achieving a reliable probabilistic forecast is maximizing the Peirce skill score (PSS) at the threshold probability of the climatological base rate. The condition is confirmed by using artificially synthesized forecast-outcome pair data and previously published probabilistic solar flare forecast models. The condition gives a partial answer as to why some probabilistic forecast systems lack reliability, because the system, which does not satisfy the proved condition, can never be reliable. The result implies that those who want to develop a reliable probabilistic forecast system must adjust or train the system so as to maximize PSS near the threshold probability of the climatological base rate.

An estimation method of GEO spacecraft surface charging for a real-time spacecraft risk assessment

*Masao Nakamura[1], Ryota Kawachi[1], Go Takahashi[1], Tsutomu Nagatsuma[2], Mamoru Ishii[2]

1. Osaka Prefecture University, 2. NICT

Spacecraft anomalies are often induced by electrostatic discharges due to surface charging. Some spacecraft charging simulation software is developed by space agencies and research institutes and used for spacecraft designs and charging analysis. However these simulations cannot be used for a real-time estimation because they need hours or days to calculate the surface potential for a given plasma environment. Therefore we develop a quick estimation method of GEO spacecraft surface charging for the Space Environment Customized Risk Estimation for Spacecraft (SECURES) of the space weather forecast Project for Solar-Terrestrial Environment Prediction (PSTEP). We estimate the surface potentials by interpolation using lookup tables of the pre-simulated surface potentials for combinations of plasma temperatures and densities. We study fitting functions used in the interpolation and how to make the lookup tables for the good estimation. Then we can real-time estimate the surface potentials of the target GEO spacecraft when the on-orbit plasma environment is predicted or observed. The spacecraft risk assessment can be accomplished by additional information about the experimental discharging differential potential of the surface materials.

A network of HF Doppler sounding systems in Japan

*Keisuke Hosokawa[1], Hiroyuki Nakata[2], Kumiko K. Hashimoto[3], Ichiro Tomizawa[1], Jun Sakai[1], Takashi Kikuchi[4]

1. University of Electro-Communications, 2. Chiba University, 3. Kibi International University, 4. ISEE, Nagoya University

Since 2003, a network observation of HF Doppler sounding has been conducted in Japan for remote-sensing the atmospheric, ionospheric and magnetospheric processes. Currently, 1 transmitting station (Tx) and 7 receiving stations (Rx) are operative by a collaborative effort of four difference universities. The main transmitting station is located at Chofu, Tokyo, Japan in the Campus of University of Electro-Communications (JG2XA). JG2XA transmits continuous waves at 5006 kHz and 8006 kHz with a transmitting power of 200 W. By receiving this JG2XA signal at 7 Rx stations (Sugadaira, Oarai, Kure, Kashima, Iitate, Fujisawa and Sugito) we derive the Doppler shift imposed during the propagation and reflection in the ionosphere. In particular, the Doppler shift data can be used to detect vertical motion of the ionospheric F region with a temporal resolution of 10 s. At some stations, we also have observed signals from Radio Nikkei 1 (JOZ at 3925 kHz, JOZ2 at 6055 kHz, and JOZ3 at 9595 kHz) transmitted from Nagara, Chiba, Japan, which allows us to observe the vertical motion of the ionosphere at several altitude levels. The data obtained from this experiment since 2003 are all available at http://gwave.cei.uec.ac.jp/~hfd. Not only quick-look plots but also several types of digital data (raw wave form and Doppler shift data) can be retrieved from this database. The experiment covers various ionospheric phenomena in the Magnetosphere-Ionospheric (M-I) coupling system, such as sporadic E-layer (Es), medium-scale traveling ionospheric disturbances (MSTIDs), large-scale traveling ionospheric disturbances (LSTIDs), global-scale electric field variation, geomagnetic pulsations, and sudden commencement (SC). The data can also be used for the studies of vertical coupling between the lower atmosphere and ionosphere, for example, observations of ionospheric variation after large earthquakes, volcanic eruptions and typhoons. To facilitate analyses of the phenomena listed above, it is desired to observe a wider area in latitude and longitude. For this purpose we plan to extend the network covering the entire ionosphere over Japan in the near future. In the presentation, we will give a brief introduction to the experiments and online database, and then discuss the future direction of the studies of atmosphere, ionosphere and magnetosphere using the HF Doppler sounding in a framework of international collaborations.

Tue. May 28, 2019 1:45 PM - 3:15 PM JST | Tue. May 28, 2019 4:45 AM - 6:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Danny Summers, Yoshizumi Miyoshi(ISEE, Nagoya University)

The inner magnetosphere is characterized by the dominance of intrinsic dipolar Earth's magnetic field. The dipolar magnetic field traps charged particles, resulting in the formation of unique particle environment known as the plasmasphere, the ring current, and the radiation belt. The inner magnetosphere is always changing because of incoming energy from the outer magnetosphere and the ionosphere in the forms of particles and electromagnetic fields. In the inner magnetosphere, the particle energy is transferred to the field energy, and vice versa. The mutual coupling between particles and fields also makes the inner magnetosphere unique. The outgoing energy to these regions is also known to be significant, such as precipitation into the upper atmosphere and sub-auroral disturbances. A number of satellites (e.g., DMSP, NOAA, Geotail, Cluster, THEMIS, Van Allen Probes, MMS, and Arase), ground-based instruments (e.g., SuperDARN and EISCAT radars, magnetometers, and cameras), and numerical simulations (e.g., global particle simulation, PIC simulation, and hybrid simulation) have successfully surveyed the inner magnetosphere, which deepen our knowledge significantly. USAF DSX, UCLA Elfin and NASA CeRES will be launched soon, being expected to provide important information. We solicit papers describing recent results on the inner magnetosphere and/or its coupling with the other regions, including the ionosphere and the outer magnetosphere.

Discussion

Developing an improved understanding of Earth's outer radiation belt electrons with combined observations from Van Allen Probes, MMS, and Arase

In this presentation, we focus on two aspects of Earth's outer radiation belt electrons: acceleration due to interactions with whistler-mode chorus waves and losses due to magnetopause incursions and outward radial transport. Using a combination of energetic electron intensities and wave data from NASA's Van Allen Probes and MMS missions plus JAXA's Arase (ERG) mission, we evaluate evidence of local acceleration and losses to outward radial transport based on phase space density and multipoint wave analysis. A telltale sign of local acceleration due to interactions between 100s of keV electrons and chorus waves within the heart of the outer radiation belt is a growing peak in electron phase space density for those energies and pitch angles affected by the acceleration. Sometimes that peak in phase space density might occur beyond the apogee of the Van Allen Probes orbit, but MMS and Arase data can be used to disambiguate dominant acceleration processes for such cases. Losses to the magnetopause and from outward radial transport also result in distinct features in the time history of radial distributions of electron phase space density. Again, with their apogees extending to higher L-shells (including into the magnetosheath for MMS), MMS and Arase can supplement the Van Allen Probes dataset by directly observing evidence of these processes beyond Van Allen Probes apogee. In this presentation, we showcase several examples of these processes using multipoint data from these missions.

The Van Allen Probes mission, since its launch in August 2012 has advanced our understanding of fundamental questions regarding the acceleration and loss of outer Van Allen belt electron populations. Electron dynamics in the outer radiation belt are driven by a number of physical processes, which affect low energy cold plasma to relativistic and ultra-relativistic particle populations. I will present recent results from Van Allen Probes mission focusing on the energetic electron dynamics. I will also discuss the significant role of CubeSats that may lead to a paradigm shift in the way space-based observations are carried out, e.g., by enabling multipoint observations. I am currently leading a CubeSat mission, CeREs, the Compact Radiation belt Explorer, CeREs that was launched December 2018 and is currently in the commissioning phase. CeREs will provide high quality measurements of radiation belt electrons, especially microbursts.

Optimal Use of Time Lags Between MMS Spacecraft : Application to the Estimation of Wave-Vectors

*Gerard Marcel CHANTEUR[1,2,3], Drew L. Turner, Olivier Le Contel[1,2,3], Alessandro Retino[1,2,3], Laurent Mirioni[1,2,3]

Turner et al. (2017) made use of cross-correlations of SCM quasi monochromatic data between pairs of MMS spacecraft to estimate phase lags and to derive wave vectors of whistler mode chorus elements in the inner magnetosphere. A new approach has been developped to revisite this study. For a cluster of four spacecraft there are six pairs of spacecraft, each one giving raise to a scalar equation relating the vector position **R** from the first to the second spacecraft, the wave vector **K** and the phase lag $\Delta\phi$: **R.K**=$\Delta\phi$. A positive weight is attributed to each equation (w_j, j=1 to 6). A statistical ensemble of 6-uplets is built and we look for the 6-uplet giving the lowest condition number of matrix **M**. This procedure warrants the best accuracy of the pseudo-inverse of **M** and hence the best estimate of the wave vector **K**. Adding random perturbations to M and $\Delta\phi$ the procedure allows to estimate the uncertainties on **K.**

We present a remarkable case study of strong EMIC wave emissions observed simultaneously by instruments on board the ARASE and RBSP-B satellites, as well as by ground-based observatories, during a period of significant geomagnetic activity. These waves coincided with strong substorm activity (AE>1000 nT) during a southward IMF Bz shift, corresponding to the initial phase of an intense geomagnetic storm (peak Dst < -170 nT). At the time of this observation, the ARASE and RBSP-B satellites were co-located in L and MLT, showing simultaneous observation of the same wave emission, but were significantly separated in magnetic latitude. This separation allows us to examine the evolution of the wave parameters as the wave propagates down the field-line to the Earth.

During this period of wave activity, we also see evidence of energetic electron precipitation into the ionosphere. At the time of the RBSP and ARASE observations, the POES METOP-02 satellite passed through the footprint of the source region and observed bursts of energetic ion and electron precipitation into the ionosphere, matching known signatures of EMIC-driven particle precipitation. This precipitation was then in turn observed from the ground as AARDDVARK-detected sub-ionospheric VLF perturbations. Through analysis of these ground-based observations, we are able to estimate the extent of the EMIC source region.

Pulsating aurora (PsA) is one of the major classes of aurora often seen in the lower latitude part of the auroral region in the morning side. PsAs are characterized by quasi-periodic variations in the optical intensity whose period typically ranges from a few to a few tens of second. Coordinated ground/satellite observations in the last decade demonstrated that the main optical pulsation well correlates with the intensity modulation of whistler mode chorus waves in the magnetosphere. Recent analyses of high time resolution ground-based optical observations have reported that the brightness of PsA decreases below the diffuse background immediately after the ON phase of the main pulsation. To date, however, the generation mechanism of such “over-darkening PsA” is still unclarified. In this paper, we investigate the characteristics of the over-darkening PsA by using simultaneous observations of PsA with an EMCCD all-sky camera in Sodankylä, Finland (67°N, 26°E, 64°MLAT) and the Arase satellite. The EMCCD all-sky camera captures auroral emission with a temporal resolution of 100 Hz. We make use of data from the PWE/OFA instrument to analyse the temporal variation of chorus wave as a source of PsA. During one of the conjunction events in Scandinavia on March 29, 2017, almost all the PsA pulses showed clear over-darkening characteristics. By analysing the 2D all-sky images at the times of over-darkening we identified that over-darkening areas appeared in the trailing edge of PsA patches and moved in tandem with the poleward propagating patches. It was also found that similar over-darkening characteristics were not seen in the chorus data from PWE/OFA onboard Arase located at the magnetospheric counterpart of PsA. These results indicate that the over-darkening PsA is not caused by a temporal variation of chorus at a fixed point, but is produced by a propagation of over-darkening area with PsA patches. That is, the over-darkening PsA is a spatial structure rather than a temporal variation. In the presentation, we discuss several possible scenarios that can explain the over-darkening along the edge of PsA patches.

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Yoshizumi Miyoshi(ISEE, Nagoya University), Danny Summers

The inner magnetosphere is characterized by the dominance of intrinsic dipolar Earth's magnetic field. The dipolar magnetic field traps charged particles, resulting in the formation of unique particle environment known as the plasmasphere, the ring current, and the radiation belt. The inner magnetosphere is always changing because of incoming energy from the outer magnetosphere and the ionosphere in the forms of particles and electromagnetic fields. In the inner magnetosphere, the particle energy is transferred to the field energy, and vice versa. The mutual coupling between particles and fields also makes the inner magnetosphere unique. The outgoing energy to these regions is also known to be significant, such as precipitation into the upper atmosphere and sub-auroral disturbances. A number of satellites (e.g., DMSP, NOAA, Geotail, Cluster, THEMIS, Van Allen Probes, MMS, and Arase), ground-based instruments (e.g., SuperDARN and EISCAT radars, magnetometers, and cameras), and numerical simulations (e.g., global particle simulation, PIC simulation, and hybrid simulation) have successfully surveyed the inner magnetosphere, which deepen our knowledge significantly. USAF DSX, UCLA Elfin and NASA CeRES will be launched soon, being expected to provide important information. We solicit papers describing recent results on the inner magnetosphere and/or its coupling with the other regions, including the ionosphere and the outer magnetosphere.

Discussion

Deformation of electron pitch angle distributions caused by chorus waves observed by the Arase satellite

*Satoshi Kurita[1], Yoshizumi Miyoshi[1], Satoshi Kasahara[2], Shoichiro Yokota[3], Yoshiya Kasahara[4], Shoya Matsuda[5], Ayako Matsuoka[5], Iku Shinohara[5]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. The University of Tokyo, 3. Graduate School of Science, Osaka University, 4. Information Media Center, Kanazawa University, 5. ISAS/JAXA

We report on deformation of electron pitch angle distributions associated with chorus waves observed by the Arase satellite. The deformation is characterized by flux increase of 17-30 keV electrons in a narrow and oblique pitch angle range and by flux decrease in 7-17 keV electron flux in the smaller pitch angle range than the flux increase. Comparison of change in electron pitch angle distributions with resonant ellipses of the upper band chorus shows that the deformation appears where effective wave-particle interaction is expected in the velocity space, and the flux increase takes place along the resonant ellipse of the upper frequency of the wave. This strongly suggests that the deformation is a consequence of wave-particle interactions between electrons and upper band chorus. The Arase observation demonstrates that the deformation occurs within 30 s, which is faster than expected from the quasi-linear diffusion theory.

Electron scattering by isolated chorus elements observed near the magnetospheric equator

*Satoshi Kasahara[1], Yoshizumi Miyoshi[2], Shoichiro Yokota[3], Yoshiya Kasahara[4], Shoya Matsuda[5], Ayako Matsuoka[5], Kunihiro Keika[1], Tomoaki Hori[2], Iku Shinohara[5]

1. The university of Tokyo, 2. Nagoya University, 3. Osaka University, 4. Kanazawa University, 5. Institute of Space and Astronautical Science

Theories have predicted significant pitch angle scattering of electron by chorus waves via cyclotron resonance, resulting in electron precipitation into the atmosphere and consequent auroral illumination. Recent observations of chorus waves at the equator, in conjunction with ground observations, have indicated that even a single chorus element can cause sufficient electron scattering causing auroral flashing. Here we report more direct, in-situ evidence that electrons are indeed scattered into the loss cone up to strong diffusion, by an isolated chorus element. We discuss the scattering rate based on the observed parameters.

Continuous precipitation of low-energy electrons associated with pulsating aurora obtained by the Reimei satellite

*Takeshi Sakanoi[1], Fukizawa Mizuki[1], Yoshizumi Miyoshi[2], Yusuke Ebihara[3], Kazushi Asamura[4], Masafumi Hirahara[2]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. ISEE, Nagoya University, 3. RISH, Kyoto University, 4. ISAS/JAXA

We report the results of event and statistical analyses on continuous precipitation of low-energy electrons associated with pulsating aurora using the data taken by the Reimei satellite. From recent data obtained with a magnetospheric satellite like Arase, it is widely supported that chorus waves interact with plasma sheet electrons that produce diffuse aurora mainly in the post-midnight to morning sectors. In addition, temporal (a few Hz) variation of lower band chorus waves cause modulation of pitch-angle scattering of keV-range electrons that generate pulsating aurora in the ionosphere. On the other hand, such temporal variation is not commonly seen in upper band chorus and electrostatic electron cyclotron harmonic (ECH) waves that expected to interact with lower-energy electrons. However, the characteristics of such low-energy electrons and their relationship to pulsating aurora are not understood.
Reimei is a polar-orbiting sun-synchronous satellite at an altitude of 650 km and obtained simultaneous image and particle data with high-time and spatial resolutions. Thanks to its orbit, Reimei covers wide L-value ranges and measures velocity-dispersed electrons travelling from magnetospheric source region to ionosphere. Miyoshi et al. [2015] showed an event that Reimei observed continuous precipitation of low-energy electrons (mainly in the energy range of hundreds eV) in addition to high energy (more than a few keV) temporal electrons that caused pulsating auroral emission. Here, we investigated the characteristics and generation mechanism of continuous low-energy electron precipitation using all of the electron data (5150 paths) taken by Reimei/ESA from November 2005 to August 2008, and compared the data with simulation results. Event selection criteria are 1) existence of continuous precipitation of low-energy electrons below a few keV range, and 2) high-energy (more than a few keV) electrons that distinguished from the continuous low-energy electrons. We also examined simultaneous auroral image data obtained with Reimei/MAC. Using the criteria, we found 155 events of continuous low-energy electron band. From statistical analysis, the continuous low-energy electron evens occurred in 11 % of total observation paths in the nightside sector, while temporal precipitation of high-energy electrons that produced pulsating aurora appeared in 36 % of total observation paths in the nightside sector. From event analysis for several cases, we found in most cases that energy of continuous low-energy electrons increased from ~200 eV to a few keV as the latitude decreased. However, the electron energy decreased near the lower boundary of plasma sheet. In some cases, multiple electron band structures were seen in the low-latitude region. To understand the characteristics and mechanisms of continuous precipitation of low-energy electrons, we carried out simulations of electron pitch angle scattering with chorus waves and ECH waves, respectively. For the simulation of ECH wave resonance, we calculated wavenumber at ECH wave frequency (e.g., 1.6 fce(cyclotron frequency)) based on the Bernstein mode dispersion relation, and estimated electron energy by the cyclotron resonance equation assuming the electron density with GCPM model and magnetic field with IGRF model. From the comparison between the Reimei data with simulation results, we suggest that latitudinal dependence of low-energy electrons can probably be explained with the chorus wave resonance. The decrease of electron energy near the low-latitude boundary is likely to be caused with decrease of plasma density outside of the plamsapause. On the other hand, we showed the possibility for some cases that low-energy electron precipitations were generated by ECH waves.

Origin of energetic electron precipitation with fast fluctuation: Data-driven simulations using the ERG plasma wave observations

*Shinji Saito[1], Yoshizumi Miyoshi[2], Shoya Matsuda[3], Satoshi Kurita[2], Yoshiya Kasahara[4], Atsushi Kumamoto[5], Fuminori Tsuchiya[5], Ayako Matsuoka[3]

1. Graduate School of Science, Nagoya University, 2. ISEE, Nagoya University , 3. ISAS/JAXA, 4. Kanazawa University, 5. Tohoku University

Bursty precipitation of keV electrons can be a source of pulsating aurora which has quasi-periodic on-off switching of luminosity. On the other hand, relativistic electrons also precipitate into the atmosphere with intermittent and bursty nature, which are observed as relativistic electron microbursts. A common cause of the electron bursty precipitation for the pulsating aurora and for the microbursts is expected to be whistler chorus waves propagating along a field line.
In this study, we demonstrate electron precipitation caused by realistic whistler chorus waves using our newly developed test-particle model, GEMSIS-RBW-II simulation code. Wave form data obtained from ERG satellite are applied to the simulation model as a boundary condition at the magnetic equator. The simulation shows that the whistler chorus waves propagating to high magnetic latitudes along the field line can precipitate electrons with energy from keV to MeV. We found that amplitude modulation of a whistler chorus burst observed by ERG causes over ten Hz modulation of keV electron precipitation. At relativistic energies fluctuation with higher frequencies and bursty/intermittent nature appear in time history of precipitation flux. It suggests that whistler chorus bursts can cause electron precipitation associated with pulsating aurora and relativistic electron microbursts.

Institute of Atmospheric Physics, Prague, Czech Republic, 7. Department of Physics and Astronomy, University of Iowa, USA

Extremely Low (ELF) and Very Low Frequency (VLF) emissions are naturally occurring magnetospheric plasma waves in the frequencies of 3 Hz to 30 kHz. They play a fundamental role in radiation belt dynamics, accelerating or scattering electrons through wave-particle interactions. We report the first quasi-periodic (QP) emission simultaneously observed by the Arase (ERG) satellite and both Van Allen Probes (RBSP). This is one of few known conjugated satellite events where the waves show very similar spectral and temporal features. The event was observed on November 29, 2018 from approximately 11 to 13:30 UT by both RBSP, while ERG observed it from 12 to 14 UT. Using wave analysis, propagation parameters, and intensities simultaneously measured at several locations we will discuss the approximate location of the source region. We will also discuss the eventual timing differences between QP periodicity at different locations. Some slight variation in the spectral shapes is observed. We will discuss possible relationships with the variations of plasma number density, magnetic field, and energetic electron distribution.

[P-CG22] Shock responses of planetary materials elucidated from meteorites and dynamic compression experiments

convener:Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Takuo Okuchi(Institute for Planetary Materials, Okayama University)

Impact phenomena had played essential roles in the process of planetary evolution. Recent analytical and experimental developments reveal a new prospective on the effects of shock-compression process for planetary materials. For deeper understanding of such shock effects, it is necessary to evaluate the detailed shock conditions from the observations of naturally-shocked planetary materials, and to compare them with the results on the planetary materials experienced a wide range of known shock conditions. Several metastable phases, that have not been known before, have recently been identified in shocked meteorites. They suggest that the shock state is often not in equilibrium and that it is more complicated process than ever thought. Experimental techniques including laser-driven shock compression and x-ray free electron laser diagnostics have been progressed to successfully simulate a wide range of shock conditions. The recent results indicate that shocked grains are fractured and rotated at relatively low pressures, and that they are subsequently transformed into denser phases or melts, or their mixtures at pressures of a few 100s GPa. Understanding of such shock dynamics requires another prospect, which is qualitatively different from the static high pressure and high temperature consensus. Therefore, it is timely to have an international symposium on dynamics of planetary materials.

discussion

*Takuo Okuchi[1], Toshimori Sekine[2]

1. Institute for Planetary Materials, Okayama University, 2. Center for High Pressure Science and Technology Advanced Research

We discuss natural and experimendal evidences on impact phenomena, which had played essential roles in the process of early planetary evolution. Recent analytical and experimenotal developments reveal a new prospective on the effects of shock-compression process of planetary materials. For deeper understanding of such shock effects, it is necessary to evaluate the detailed shock conditions from the observations of naturally-shocked planetary materials, as well as to compare them with the results of shock-compression experiments of these materials obtained at laboratory conditions.

We have conducted x-ray diffraction measurement (XRD) with femtosecond x-ray pulses generated by the x-ray free electron laser (XFEL) to observe lattice dynamics and phase transformation of single-crystal quartz under high strain-rate shock compression (~10^9 s^{-1}) and high pressure. Single-crystal quartz samples were shock-compressed by high-power short- and long-pulse lasers. In the short-pulse experiments, the lattice was reduced to 15% and 1.5% in the direction parallel and perpendicular to the compression axis, respectively. The sample was uniaxially compressed over its known Hugoniot elastic limit. In the long-pulse experiments, three different states were observed. Polycrystalline stishovite appeared at first, and elastically compressed state and a topotaxially transformed new phase were observed successively.

Laser-shock experiments of dense polymorphs of Mg_2SiO_4: technical developments using synthetic single crystals

*Narangoo Purevjav[1], Takuo Okuchi[1], Norimasa Ozaki[2], Takayoshi Sano[3], Yuhei Umeda[2], Shintaro Morioka[2], Nobuki Kamimura[2]

1. Institute for Planetary Materials, Okayama University, 2. Graduate School of Engineering, Osaka University, 3. Institute of Laser Engineering, Osaka University

Mg_2SiO_4 polymorphs (α-phase as forsterite, β-phase as wadsleyite, and γ-phase as ringwoodite) are the major constituents of our Earth's mantle and also for Earth-like planets. Thus studying these polymorphs at extreme pressure and temperature conditions will lead to understanding their changes of chemical and physical properties at extremely high pressure and temperature conditions, such as those occurring during the giant impacts phenomena of such planets at their final stage of accretion. Shock compression of forsterite has been studied up to ~ 1000 GPa by using polycrystalline and single crystal samples [1-3]. The studies have reported contradicting results for the shock compression of forsterite. Sekine et al (2016) reported that there are several phase transformations in the liquid state of Mg_2SiO_4 at > 270 GPa, while other two studies were reported no phase transformation [1, 3]. Thus it is interesting to see how the Hugonoit relations of Mg_2SiO_4 polymorphs will come up at different pressure and temperature conditions. However, Hugoniot relations of wadsleyite and ringwoodite have not been studied well. Especially, there is any data on the densest polymorph ringwoodite. Shock compression of wadsleyite was carried out up to 200 GPa by using polycrystalline samples [4]. In addition, there are no studies by using single crystal samples for both wadsleyite and ringwoodite. To newly conduct such studies, the denser polymorph of Mg_2SiO_4 are needed to be synthesized and grown at their relevant conditions of deep mantle corresponding to the 15 –21 GPa and 1000 –1500 ˚C in the laboratory. Most importantly, the synthesized minerals must be chemically, physically and optically homogenous and should have suitable sizes for the laser-shock experiments. Here, by utilizing the results of our previous efforts for growing such quality of single crystals, we made possible to obtain Hugoniot relation of wadsleyite and ringwoodite by laser-shock compression. Their crystals were synthesized and grown by using a scaled-up Kawai-type cell by together with applying our pre-established a slow-cooling method at their relevant conditions [5]. Recovered crystals were up to 1 mm in sizes and confirmed to be chemically homogenous and free from twinning, cracks, and inclusions. The crystals were then doubly polished separately down to 100 mm in thickness and with an area of > 500 mm. They were assembled to form targets which are optimized for the laser-shock experiments. laser-shock experiments at GEKKO XII were conducted at Institute of Laser Engineering, Osaka University. The crystals are optical to give very clean VISAR (Velocity Interferometer System for Any Reflector) images. The details of our technical developments will be discussed on the poster.

Richtmyer-Meshkov instability in inhomogeneous density materials and its application to planetary science

*Takayoshi Sano[1]

1. Institute of Laser Engineering, Osaka University

Richtmyer-Meshkov instability (RMI) is a hydrodynamic interfacial instability, which occurs by the interaction between a shock wave and corrugated density jump. Because of the corrugation of the interface, the surface profiles of the transmitted and reflected shocks are also rippled. The RMI is driven by the vorticity left by these rippled shocks at the interface and in the fluid. In this study, we consider shock propagation in inhomogeneous density materials (e.g., uniform density materials with small round voids) and the turbulent growth of the interface. For these cases, the vorticity distribution and turbulent motion are much more complicated than the standard RMI cases. Then the spatial fluctuation of pressure or temperature could be significantly large after the shock passage. Using two-dimensional hydrodynamic simulations, we will examine the dependence of the pressure fluctuation on the density inhomogeneity. As the application of this numerical study, we will discuss about the shock propagation in meteorites with large density fluctuation.

Impact-induced dehydration reactions of Fe- and Al-hydrates as potential storage, carrier and source of water

*Tsubasa Tobase[1], Toshimori Sekine[1], Ginga Kitahara[2], Makoto Tokuda[2], Akira Yoshiasa[2], Makoto Takafuji[2], Tsutomu Mashimo[2], Nobuaki Kawai[2]

1. HPSTAR, 2. Graduate School of Science and Technology, Kumamoto University

Hydrous minerals have been known to play an important role to preserve and carry water because a mechanism is required for water to reach the inner planets such as Earth far beyond the snow line that defines the boundary between water ice and vapor. In order to understand the detailes, we need to know the stability at high temperature and high pressure and impact resistance for possible hydrous minerals. Fe- and Al-hydrates (FeOOH and AlOOH) have been reported to be stable under static high temperature and static high pressure. In addition, they are observed in some meteorites and the surface on Mars. Although there are some data available on clay minerals and serpentine, those Fe- and Al-hydrates are considered to be present in the Earth’ s deep lower mantle according to the recent studies.

We have investigated the impact resistibility through shock recovery techniques. Our peak shock pressures are 24 GPa and 31 GPa for the recovered Fe- and Al-hydrates, respectively, where they displayed significant dehydration. We set various range of sample porosity and peak shock pressure to investing the dehydration reaction. These impact conditions correspond to impact velocities of 2.6 km/s and 4.9 km/s if we assume face to face impacts between carbonaceous chondrite such as Murchison. These are within a range of velocity for possible meteoritic collisions, and we need to know the relationship between impact condition and degree of dehydration. Using TG/DTA analyses of samples we estimated the relationship. The phase changes by impact dehydration are investigated by XRD, XAFS and Raman spectroscopy. We also try to understand dynamical void formation process by dehydration that can occur during adiabatic quenching through observation of void distribution in the recovered samples.

In our previous research for shock recovery experiments of hydrous minerals, we observed heterogenous temperature rise in dehydration process. We tried to confirm whether heterogeneous temperature rise occurs even in Fe- and Al-hydrates by comparison with the results between previously reported hydrous minerals. We will be able to select most possible candidate by comparing the thermal stability and impact resistibility among them.

Crystallization of amorphous $MgSiO_3$ by shock compression

*Akane Arasuna[1], Masayuki Okuno[1], Nobuaki Kawai[2]

1. Kanazawa University, 2. Kumamoto University

Structural change of synthesized amorphous $MgSiO_3$ by shock compression up to 22.2 GPa has been investigated using XRD and IR analyses. The obtained result provides information for elucidating of the collision behavior of $MgSiO_3$ contained in cosmic dust.

Amorphous $MgSiO_3$ sample was prepared by an aqueous solution of TEOS, Magnesium Nitrate Hexahydrate, and ethanol with ammonia as a catalyst. As-prepared sample was heated at 700 C˚ to dehydrate excess water. TG curve of this sample indicated that the sample contained about 8.8 wt% of water molecules and hydroxyl groups.

A powdered heated (original) sample was put in an aluminum tubes and pressed at 20 kN for 10 minutes to obtain samples for shock compression experiment. These samples were compressed at 13.6, 17.2, and 22.2 GPa using a single-stage propellant gun at Kumamoto University.

XRD pattern of the pressed sample showed no crystalline peak as same as the original sample. However, the XRD pattern of thesample compressed at 13.6 GPa showed the weak crystalline peaks at around 2θ = 28, 31, 35-36˚. These peaks became intense with increasing shock pressure. Crystalline peaks observed in the XRD pattern for the sample of 22.2 GPa were attributed to those of enstatite. However, some peaks was due to the formation of Mg_2SiO_4. IR spectra for the compressed samples showed the similar trend as the result of XRD analysis. But IR analysis indicated that the sample contains water molecules even after the shock compression at 22.2 GPa. Water molecules probably present in the remaining amorphous part. Crystallization of sample by shock compression has not been reported in shock experiments for other crystalline and non-crystalline silicates. The crystallization of our samples at low pressure may be due to the simple chain structure of enstatite. Also, high shock temperature which generated by friction due to the porosity of the sample may promote this crystallization.

First-principle study of the structural and electronic properties of N-doped $MgAl_2O_4$ spinel

*Chi Pui Tang[1], Pak Kin Leong[1], Toshimori Sekine[2,3]

1. State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology, 2. Center for High Pressure Science and Technology Advanced Research (HPSTAR) Shanghai Laboratory of HPSTAR, Shanghai, P.R. China, 3. Graduate School of Engineering, Osaka University

On basis of the first principle calculation, we report a possible nitrogen doped structure of $MgAl_2O_4$ spinel. The structural and electronic properties (include the band structure, density of states and phonon) of spinel ($MgAl_2O_4$) and N-doped spinel ($MgAl_2O_{3.5}N_{0.5}$) compounds are performed using density functional theory (DFT). The density and space group of two crystal cells are 3.47 g/cm^3 (Fd3m) for $MgAl_2O_4$ and 3.38 g/cm^3 (R3m) for $MgAl_2O_{3.5}N_{0.5}$, respectively. The calculated direct band gaps at the Γ-point are about 5.13 eV for $MgAl_2O_4$ and 4.24 eV for $MgAl_2O_{3.5}N_{0.5}$, respectively. The projected density of states (PDOS) shows that the tops of the valence bands are built up from ~93% of *p*(O) states and ~60% of *p*(N) + ~32% of *p*(O) states (for $MgAl_2O_4$ and $MgAl_2O_{3.5}N_{0.5}$, respectively). In the phonon analysis, the lowest frequency of $MgAl_2O_{3.5}N_{0.5}$ is redshifted to 36.6 cm^{-1} ($MgAl_2O_4$ is 39.8 cm^{-1}) caused by the N-doped. We also calculate their cohesive energy in the pressure range of 0-150 GPa. We found that the cohesive energy of $MgAl_2O_{3.5}N_{0.5}$ is lower than $MgAl_2O_4$ at the pressure higher than ~115 GPa, it implies that $MgAl_2O_{3.5}N_{0.5}$ is more stable than $MgAl_2O_4$ at high pressure. Finally, we suggest that nitrogen atom would replace the oxygen of spinel in the depths of the earth. The results imply the deep mantle may storage a considerable amount of nitrogen.

Transparency of shock-compressed single crystal diamond

*Kento Katagiri[1], Norimasa Ozaki[1,2], Kohei Miyanishi[2], Yuhei Umeda[1], Shintaro Morioka[1], Takayoshi Sano[2], Ryosuke Kodama[1,2]

1. Osaka University, 2. Institute of Laser Engineering, Osaka Unversity

Carbon is one of the most prominent elements in nature and it is abundant in the Earth and many other planets. Diamond, a metastable phase of carbon, is naturally synthesized in deep inside of the Earth where substances are isotropically pressured. Diamond is known for its many unique properties such as high hardness, low compressibility, small thermal expansion coefficient, and transparency. Since it is important to understand how substances behave under high pressure, properties of compressed diamond have been measured in a wide range of pressures up to 5 TPa. However, the transparency of diamond under pressure has not been fully elucidated. Here, we report the measurment of the pressure dependency of the absorption coefficient of laser shock compressed single crystalline diamond. A high-intensity laser was utilized to shock compress the diamond sample along its <100> direction, and velocity interferometer systems for any reflector (VISARs) were used to determine the absorption coefficient and pressure. It was found that single crystalline diamond remains largely transparent to the probe laser for VISAR (λ =532 nm) up to 140 GPa. The pressure dependence of the refractive index will also be discussed.

This experiment was conducted under the joint research of the Institute of Laser Engineering, Osaka University. This work was supported in part by JSPS KAKENHI grant No. 16H02246 and No. 16H01119. The part of work was also supported by Genesis Research Institute, Inc. (Konpon-ken, TOYOTA).

Pb-Pb dating of the NWA 7203 angrite and relationship to its shock metamorphism

*Hideyuki Hayashi[1], Takashi Mikouchi[1], Yuji Sano[1], Martin Bizzarro[2]

1. The university of Tokyo, 2. University of Copenhagen

Introduction: Angrite is one of the oldest basaltic achondrites in the early solar system which is depleted in volatile elements and enriched in refractory elements (e.g., Keil, 2012). Almost all angrites show either a quenched or slowly-cooled texture. The crystallization ages of quenched angrites are older (ca. 4564 Ma) than those of slowly-cooled samples (ca. 4558 Ma). One of the most striking mineralogical characteristics about angrites is the lack of shock metamorphism. Thus, quenched angrites can be good time anchors to connect absolute and relative ages, because the age differences between two systems can be ignored due to fast cooling and furthermore there is no chronological reset by shock metamorphism. However, NWA 1670 and NWA 7203 are known to show evidence for shock (Mikouchi et al., 2003; Hayashi et al., 2018), and especially we found that NWA 7203 exhibited remarkable shock metamorphic textures. The Pb-Pb dating of angrites has been done only for angrites without shock textures, indicating the obtained ages are crystallization ages. Pb-Pb age is relatively easy to be reset by shock heating. Therefore, Pb-Pb age of NWA 1670 or especially NWA 7203 may be reset by shock heating. However, there is no study which measured Pb-Pb dating of NWA 1670 or NWA 7203. In this study, we measured Pb isotopic ratios of silico-apatite in NWA 7203 by Nano-SIMS, and discussed the Pb-Pb age of NWA 7203.

Sample: We used NWA 7203 for this study. NWA 7203 is an angrite meteorite showing a quenched texture. NWA 7203 consists of a dendritic texture of olivine and anorthite, and pyroxene fills gaps of the dendrites. Grain size exhibits large variations from fine grains (~1 μm) to coarse grains (>100 μm). This is not a typical characteristic of quenched angrites. NWA 7203 is composed mainly of olivine, pyroxene and anorthite, and the accessory minerals are troilite, ulvospinel and silico-apatite.

Methods: Observation was carried out on thin sections by optical microscope and BSE images of FE-EPMA. Mineral phases were identified by micro-Raman spectroscopic analysis. Pb-Pb dating of NWA 7203 was carried out by measuring Pb isotope ratios of silico-apatites using Nano-SIMS at AORI, Univ. of Tokyo. Measurement conditions were 300 pA for primary ions and $^{16}O^-$ for ion sources. Pre-sputtering was performed for 8 minutes in the range of 10 x 10 μm. In the SIMS measurement, raster diameter of 3 x 3 μm and analysis time of 60 seconds were applied for two magnetic fields, respectively, and repeated for 30 cycles. For the standard, NIST SRM 610 was used.

Result and discussion: Pb isotopic ratios of silico-apatite in the NWA 7203 angrite were obtained. We obtained a weighted approximate straight line for each plot and found the Pb-Pb age to be 4551 ±17 Ma. These plots are relatively variable. This is probably because Pb isotopic ratios were disturbed by shock metamorphism. In fact, the Pb-Pb age of silico-apatite grains that are at least 200 μm away from the shock veins was found to be 4560 ±16 Ma. It is considered that the Pb isotopic ratios of these silico-apatite grains are relatively undisturbed as they are linearly aligned. This age coincides with the crystallization age of other quenched angrites within the error range. Takenouchi et al. (2019) measured the Ar-Ar ages of NWA 7203 and found that it has two plateau ages of 3800 ±440 Ma and 2300 ±140 Ma, and concluded that the shock metamorphism of NWA 7203 occurred at 2300 ±140 Ma. From this result, it is considered that the Pb-Pb age of NWA 7203 is not completely reset, but slightly disturbed.

Shock recovery of high-pressure phase of SiO_2 using high-power laser

*Tadashi Kondo[1], Hiromoto Kengo[1], Tatsuhiro Sakaiya[1], Hidenori Terasaki[1], Keisuke Shigemori[2], Youichiro Hironaka[2]

1. Department of Earth and Space Science, Graduate School of Science Osaka University, 2. Institute of Laser Engineering, Osaka University

High-pressure phases in meteorites provide us the important information of shock history in natural materials. Experimental approach to reproduce such high-pressure phase have been studied intensively mainly by light-gas gun so far, though shock condition with impact velocity beyond 10km/s is difficult. Recent technical progress of high-intensity laser as a tool of shock experiment realize the recovery of samples with shock condition above 10km/s(Nagaki et al.,2016). However, the limited shock duration time of about 10 nsec has been too short to drive structural conversion to high-pressure form in single crystal sample. In this study, we explored recovery condition of high-pressure phase of SiO_2 using finely ground samples of quartz, cristobalite and fused silica as starting materials. Laser shock experiments were performed using GXII hyper laser at Institute of Laser Engineering, Osaka University. The whole sample retaining relative locations in the recovered box made of aluminum was quenched without significant scattering in each run. The sectioned sample at shocked center were examined by optical microscope, micro-focused X-ray diffraction and SEM-EDS. We will report the characteristic feature of top portion of sample, which shows layered structure with different metamorphism, and distribution of grass and stishovite phase found in the samples shocked above 100GPa, which have still a residual stress to 10GPa in the ambient condition. We will discuss the dependence of the initial state of crystal to recover the high-pressure phase in shocked samples in nsec.

Hugoniot measurement of calcite under meteorite collision condition

*Fukui Keiya[1], Norimasa Ozaki[1,2], Yuhei Umeda[1], Kohei Miyanishi[3], Kento Katagiri[1], Shintaro Morioka[1], Takayoshi Sano[3], Ryosuke Kodama[1,2,3]

1. Graduate School of Engineering,Osaka univ., 2. PPC, Osaka Univ., 3. ILE, Osaka Univ.

Volatile substances inside planetary materialsare generated and released as gas under the extreme condition caused by collision phenomenon that is thought to contribute greatly to the formation of the planetary atmosphere [1]. Particularly the degassing reaction of carbonate, may generate CO or CO_2as greenhouse gas and affect the temperature of the planetary surface. A typical planetary mineral as carbonate of calcite ($CaCO_3$) is expected degassing above 3300 K at pressure of 150 GPa along the Hugoniot[2].
In the previous study, the experimental investigations for the shock-degassing reaction were carried out only below the impact pressure of 100 GPa. Also, we have not understood when the degassing reaction of calcite occur on a compressed state or a released state [3]
In natural, typical meteorite impacts exceed 10 km/s in impact velocity, and can generate at the pressure above 150 GPa. The purpose of this research is to understand the impact compression characteristics of calcite under the meteorite collision condition.

This experiment was conducted in Shock Drive Laser (Gekko XII) atInstitute for Laser Engineering, Osaka University. The target consists of polypropylene as an ablator aluminum as a piston, quartz as a standard material, and calcite as a sample from laser side. The impact pressures and temperatures were estimated by the measured shock wave velocity using Velocity interferometer system for any reflector (VISAR) and self-emission intensity using radiance thermometer (SOP).
As a result of this experiments, we obtained the Hugoniot date at the puressure from 200 GPa to 1 Tpa at the temperature above 5000 K. The detailed results will be shown as this presentation.
Acknowledgements

Direct observation of the transformation toughening of tetragonal stabilized zirconia under shock deformation condition by ns time-resolved XRD.

*Sota Takagi[1,2], Kouhei Ichiyanagi[2,3], Nobuaki Kawai[4], Ryo Fukaya[2], Shunsuke Nozawa[2], Atsushi Kyono[1], Nobumasa Funamori[2], Shin-ichi Adachi[2]

1. University of Tsukuba, 2. KEK PF, 3. Jichi Medical University, 4. Kumamoto University

The enhancement of strength and toughness was found in oxide-doped tetragonal stabilized zirconia, with the suggestion that the absorption of energy during the martensitic transformation contribute to the increment [Gravie et al., 1975; Gupta et al., 1977]. Using transmission electron microscopy (TEM), in recovery sample, it was observed that the stress-induced transformation from stabilized tetragonal phase to monoclinic phase can be occurred around the crack tip [Porter et al., 1977], and the transformation-toughening model were devised [McMeeking et al., 1982; Hannink et al., 2000]. In high-pressure experiments, the phase transformation behavior of tetragonal stabilized zirconia has not been clarified in both static and shock compression because a lack of in-situ observation [Ohtaka et al., 1988; Grady et al., 1992]. We tried to observe the behavior of tetragonal stabilized zirconia under shock compression condition using time-resolved XRD method.We performed the experiments at NW14A beamline at PF-AR (Photon Factory Advanced Ring), High Energy Accelerator Research Organization (KEK), Japan. Nd:glass laser with the wavelength of 1064 nm, pulse energy of 16 J, pulse width of 12 ns was used for shock-driving source. The laser beam was focused by optical lens to the size of 500 μm × 500 μm on the sample surface. For TR-XRD experiments, the synchrotron X-ray pulse of PF-AR was used as a probe source. The energy, the pulse width, and the size on the sample were 15.68 keV, about 100 ps, and 450 μm (H) ×250 μm (W), respectively. The irradiation timing between laser pulse and X-ray pulse on the sample surface were controlled by delay generator at ns time scale. The targets consisted of an 25 um PET film ablator with Al coated on the surface and 50 um polycrystalline 3 mol% yttria doped tetragonal stabilized zirconia.
The XRD change were observed up to 35 ns after shock compression started. Before shock, the (101), (002), (110), (102), (112), (200) diffraction of tetragonal phase were observed. 6.5 ns after shock, the diffraction from compression region appeared with maximum compression of 6%. No phase transition occurred at compression states. At release states (~11.4 ns), on the other hand, the (-111), (111), (022), (-221) diffraction peaks of monoclinic phase were appeared. We will discuss the detail of the experimental results and the transformation toughening mechanism.

[P-CG22] Shock responses of planetary materials elucidated from meteorites and dynamic compression experiments

convener:Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Takuo Okuchi(Institute for Planetary Materials, Okayama University)

Impact phenomena had played essential roles in the process of planetary evolution. Recent analytical and experimental developments reveal a new prospective on the effects of shock-compression process for planetary materials. For deeper understanding of such shock effects, it is necessary to evaluate the detailed shock conditions from the observations of naturally-shocked planetary materials, and to compare them with the results on the planetary materials experienced a wide range of known shock conditions. Several metastable phases, that have not been known before, have recently been identified in shocked meteorites. They suggest that the shock state is often not in equilibrium and that it is more complicated process than ever thought. Experimental techniques including laser-driven shock compression and x-ray free electron laser diagnostics have been progressed to successfully simulate a wide range of shock conditions. The recent results indicate that shocked grains are fractured and rotated at relatively low pressures, and that they are subsequently transformed into denser phases or melts, or their mixtures at pressures of a few 100s GPa. Understanding of such shock dynamics requires another prospect, which is qualitatively different from the static high pressure and high temperature consensus. Therefore, it is timely to have an international symposium on dynamics of planetary materials.

We have conducted x-ray diffraction measurement (XRD) with femtosecond x-ray pulses generated by the x-ray free electron laser (XFEL) to observe lattice dynamics and phase transformation of single-crystal quartz under high strain-rate shock compression (~10^9 s^{-1}) and high pressure. Single-crystal quartz samples were shock-compressed by high-power short- and long-pulse lasers. In the short-pulse experiments, the lattice was reduced to 15% and 1.5% in the direction parallel and perpendicular to the compression axis, respectively. The sample was uniaxially compressed over its known Hugoniot elastic limit. In the long-pulse experiments, three different states were observed. Polycrystalline stishovite appeared at first, and elastically compressed state and a topotaxially transformed new phase were observed successively.

Laser-shock experiments of dense polymorphs of Mg_2SiO_4: technical developments using synthetic single crystals

*Narangoo Purevjav[1], Takuo Okuchi[1], Norimasa Ozaki[2], Takayoshi Sano[3], Yuhei Umeda[2], Shintaro Morioka[2], Nobuki Kamimura[2]

1. Institute for Planetary Materials, Okayama University, 2. Graduate School of Engineering, Osaka University, 3. Institute of Laser Engineering, Osaka University

Mg_2SiO_4 polymorphs (α-phase as forsterite, β-phase as wadsleyite, and γ-phase as ringwoodite) are the major constituents of our Earth's mantle and also for Earth-like planets. Thus studying these polymorphs at extreme pressure and temperature conditions will lead to understanding their changes of chemical and physical properties at extremely high pressure and temperature conditions, such as those occurring during the giant impacts phenomena of such planets at their final stage of accretion. Shock compression of forsterite has been studied up to ~ 1000 GPa by using polycrystalline and single crystal samples [1-3]. The studies have reported contradicting results for the shock compression of forsterite. Sekine et al (2016) reported that there are several phase transformations in the liquid state of Mg_2SiO_4 at > 270 GPa, while other two studies were reported no phase transformation [1, 3]. Thus it is interesting to see how the Hugonoit relations of Mg_2SiO_4 polymorphs will come up at different pressure and temperature conditions. However, Hugoniot relations of wadsleyite and ringwoodite have not been studied well. Especially, there is any data on the densest polymorph ringwoodite. Shock compression of wadsleyite was carried out up to 200 GPa by using polycrystalline samples [4]. In addition, there are no studies by using single crystal samples for both wadsleyite and ringwoodite. To newly conduct such studies, the denser polymorph of Mg_2SiO_4 are needed to be synthesized and grown at their relevant conditions of deep mantle corresponding to the 15 –21 GPa and 1000 –1500 ˚C in the laboratory. Most importantly, the synthesized minerals must be chemically, physically and optically homogenous and should have suitable sizes for the laser-shock experiments. Here, by utilizing the results of our previous efforts for growing such quality of single crystals, we made possible to obtain Hugoniot relation of wadsleyite and ringwoodite by laser-shock compression. Their crystals were synthesized and grown by using a scaled-up Kawai-type cell by together with applying our pre-established a slow-cooling method at their relevant conditions [5]. Recovered crystals were up to 1 mm in sizes and confirmed to be chemically homogenous and free from twinning, cracks, and inclusions. The crystals were then doubly polished separately down to 100 mm in thickness and with an area of > 500 mm. They were assembled to form targets which are optimized for the laser-shock experiments. laser-shock experiments at GEKKO XII were conducted at Institute of Laser Engineering, Osaka University. The crystals are optical to give very clean VISAR (Velocity Interferometer System for Any Reflector) images. The details of our technical developments will be discussed on the poster.

Richtmyer-Meshkov instability in inhomogeneous density materials and its application to planetary science

*Takayoshi Sano[1]

1. Institute of Laser Engineering, Osaka University

Richtmyer-Meshkov instability (RMI) is a hydrodynamic interfacial instability, which occurs by the interaction between a shock wave and corrugated density jump. Because of the corrugation of the interface, the surface profiles of the transmitted and reflected shocks are also rippled. The RMI is driven by the vorticity left by these rippled shocks at the interface and in the fluid. In this study, we consider shock propagation in inhomogeneous density materials (e.g., uniform density materials with small round voids) and the turbulent growth of the interface. For these cases, the vorticity distribution and turbulent motion are much more complicated than the standard RMI cases. Then the spatial fluctuation of pressure or temperature could be significantly large after the shock passage. Using two-dimensional hydrodynamic simulations, we will examine the dependence of the pressure fluctuation on the density inhomogeneity. As the application of this numerical study, we will discuss about the shock propagation in meteorites with large density fluctuation.

Impact-induced dehydration reactions of Fe- and Al-hydrates as potential storage, carrier and source of water

*Tsubasa Tobase[1], Toshimori Sekine[1], Ginga Kitahara[2], Makoto Tokuda[2], Akira Yoshiasa[2], Makoto Takafuji[2], Tsutomu Mashimo[2], Nobuaki Kawai[2]

Hydrous minerals have been known to play an important role to preserve and carry water because a mechanism is required for water to reach the inner planets such as Earth far beyond the snow line that defines the boundary between water ice and vapor. In order to understand the detailes, we need to know the stability at high temperature and high pressure and impact resistance for possible hydrous minerals. Fe- and Al-hydrates (FeOOH and AlOOH) have been reported to be stable under static high temperature and static high pressure. In addition, they are observed in some meteorites and the surface on Mars. Although there are some data available on clay minerals and serpentine, those Fe- and Al-hydrates are considered to be present in the Earth’ s deep lower mantle according to the recent studies.

We have investigated the impact resistibility through shock recovery techniques. Our peak shock pressures are 24 GPa and 31 GPa for the recovered Fe- and Al-hydrates, respectively, where they displayed significant dehydration. We set various range of sample porosity and peak shock pressure to investing the dehydration reaction. These impact conditions correspond to impact velocities of 2.6 km/s and 4.9 km/s if we assume face to face impacts between carbonaceous chondrite such as Murchison. These are within a range of velocity for possible meteoritic collisions, and we need to know the relationship between impact condition and degree of dehydration. Using TG/DTA analyses of samples we estimated the relationship. The phase changes by impact dehydration are investigated by XRD, XAFS and Raman spectroscopy. We also try to understand dynamical void formation process by dehydration that can occur during adiabatic quenching through observation of void distribution in the recovered samples.

In our previous research for shock recovery experiments of hydrous minerals, we observed heterogenous temperature rise in dehydration process. We tried to confirm whether heterogeneous temperature rise occurs even in Fe- and Al-hydrates by comparison with the results between previously reported hydrous minerals. We will be able to select most possible candidate by comparing the thermal stability and impact resistibility among them.

Crystallization of amorphous $MgSiO_3$ by shock compression

*Akane Arasuna[1], Masayuki Okuno[1], Nobuaki Kawai[2]

1. Kanazawa University, 2. Kumamoto University

Structural change of synthesized amorphous $MgSiO_3$ by shock compression up to 22.2 GPa has been investigated using XRD and IR analyses. The obtained result provides information for elucidating of the collision behavior of $MgSiO_3$ contained in cosmic dust.

Amorphous $MgSiO_3$ sample was prepared by an aqueous solution of TEOS, Magnesium Nitrate Hexahydrate, and ethanol with ammonia as a catalyst. As-prepared sample was heated at 700 C˚ to dehydrate excess water. TG curve of this sample indicated that the sample contained about 8.8 wt% of water molecules and hydroxyl groups.

A powdered heated (original) sample was put in an aluminum tubes and pressed at 20 kN for 10 minutes to obtain samples for shock compression experiment. These samples were compressed at 13.6, 17.2, and 22.2 GPa using a single-stage propellant gun at Kumamoto University.

XRD pattern of the pressed sample showed no crystalline peak as same as the original sample. However, the XRD pattern of thesample compressed at 13.6 GPa showed the weak crystalline peaks at around 2θ = 28, 31, 35-36˚. These peaks became intense with increasing shock pressure. Crystalline peaks observed in the XRD pattern for the sample of 22.2 GPa were attributed to those of enstatite. However, some peaks was due to the formation of Mg_2SiO_4. IR spectra for the compressed samples showed the similar trend as the result of XRD analysis. But IR analysis indicated that the sample contains water molecules even after the shock compression at 22.2 GPa. Water molecules probably present in the remaining amorphous part. Crystallization of sample by shock compression has not been reported in shock experiments for other crystalline and non-crystalline silicates. The crystallization of our samples at low pressure may be due to the simple chain structure of enstatite. Also, high shock temperature which generated by friction due to the porosity of the sample may promote this crystallization.

First-principle study of the structural and electronic properties of N-doped $MgAl_2O_4$ spinel

*Chi Pui Tang[1], Pak Kin Leong[1], Toshimori Sekine[2,3]

1. State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology, 2. Center for High Pressure Science and Technology Advanced Research (HPSTAR) Shanghai Laboratory of HPSTAR, Shanghai, P.R. China, 3. Graduate School of Engineering, Osaka University

On basis of the first principle calculation, we report a possible nitrogen doped structure of $MgAl_2O_4$ spinel. The structural and electronic properties (include the band structure, density of states and phonon) of spinel ($MgAl_2O_4$) and N-doped spinel ($MgAl_2O_{3.5}N_{0.5}$) compounds are performed using density functional theory (DFT). The density and space group of two crystal cells are 3.47 g/cm^3 (Fd3m) for $MgAl_2O_4$ and 3.38 g/cm^3 (R3m) for $MgAl_2O_{3.5}N_{0.5}$, respectively. The calculated direct band gaps at the Γ-point are about 5.13 eV for $MgAl_2O_4$ and 4.24 eV for $MgAl_2O_{3.5}N_{0.5}$, respectively. The projected density of states (PDOS) shows that the tops of the valence bands are built up from ~93% of *p*(O) states and ~60% of *p*(N) + ~32% of *p*(O) states (for $MgAl_2O_4$ and $MgAl_2O_{3.5}N_{0.5}$, respectively). In the phonon analysis, the lowest frequency of $MgAl_2O_{3.5}N_{0.5}$ is redshifted to 36.6 cm^{-1} ($MgAl_2O_4$ is 39.8 cm^{-1}) caused by the N-doped. We also calculate their cohesive energy in the pressure range of 0-150 GPa. We found that the cohesive energy of $MgAl_2O_{3.5}N_{0.5}$ is lower than $MgAl_2O_4$ at the pressure higher than ~115 GPa, it implies that $MgAl_2O_{3.5}N_{0.5}$ is more stable than $MgAl_2O_4$ at high pressure. Finally, we suggest that nitrogen atom would replace the oxygen of spinel in the depths of the earth. The results imply the deep mantle may storage a considerable amount of nitrogen.

Transparency of shock-compressed single crystal diamond

*Kento Katagiri[1], Norimasa Ozaki[1,2], Kohei Miyanishi[2], Yuhei Umeda[1], Shintaro Morioka[1], Takayoshi Sano[2], Ryosuke Kodama[1,2]

1. Osaka University, 2. Institute of Laser Engineering, Osaka Unversity

Carbon is one of the most prominent elements in nature and it is abundant in the Earth and many other planets. Diamond, a metastable phase of carbon, is naturally synthesized in deep inside of the Earth where substances are isotropically pressured. Diamond is known for its many unique properties such as high hardness, low compressibility, small thermal expansion coefficient, and transparency. Since it is important to understand how substances behave under high pressure, properties of compressed diamond have been measured in a wide range of pressures up to 5 TPa. However, the transparency of diamond under pressure has not been fully elucidated. Here, we report the measurment of the pressure dependency of the absorption coefficient of laser shock compressed single crystalline diamond. A high-intensity laser was utilized to shock compress the diamond sample along its <100> direction, and velocity interferometer systems for any reflector (VISARs) were used to determine the absorption coefficient and pressure. It was found that single crystalline diamond remains largely transparent to the probe laser for VISAR (λ =532 nm) up to 140 GPa. The pressure dependence of the refractive index will also be discussed.

This experiment was conducted under the joint research of the Institute of Laser Engineering, Osaka University. This work was supported in part by JSPS KAKENHI grant No. 16H02246 and No. 16H01119. The part of work was also supported by Genesis Research Institute, Inc. (Konpon-ken, TOYOTA).

Pb-Pb dating of the NWA 7203 angrite and relationship to its shock metamorphism

*Hideyuki Hayashi[1], Takashi Mikouchi[1], Yuji Sano[1], Martin Bizzarro[2]

1. The university of Tokyo, 2. University of Copenhagen

Introduction: Angrite is one of the oldest basaltic achondrites in the early solar system which is depleted in volatile elements and enriched in refractory elements (e.g., Keil, 2012). Almost all angrites show either a quenched or slowly-cooled texture. The crystallization ages of quenched angrites are older (ca. 4564 Ma) than those of slowly-cooled samples (ca. 4558 Ma). One of the most striking mineralogical characteristics about angrites is the lack of shock metamorphism. Thus, quenched angrites can be good time anchors to connect absolute and relative ages, because the age differences between two systems can be ignored due to fast cooling and furthermore there is no chronological reset by shock metamorphism. However, NWA 1670 and NWA 7203 are known to show evidence for shock (Mikouchi et al., 2003; Hayashi et al., 2018), and especially we found that NWA 7203 exhibited remarkable shock metamorphic textures. The Pb-Pb dating of angrites has been done only for angrites without shock textures, indicating the obtained ages are crystallization ages. Pb-Pb age is relatively easy to be reset by shock heating. Therefore, Pb-Pb age of NWA 1670 or especially NWA 7203 may be reset by shock heating. However, there is no study which measured Pb-Pb dating of NWA 1670 or NWA 7203. In this study, we measured Pb isotopic ratios of silico-apatite in NWA 7203 by Nano-SIMS, and discussed the Pb-Pb age of NWA 7203.

Sample: We used NWA 7203 for this study. NWA 7203 is an angrite meteorite showing a quenched texture. NWA 7203 consists of a dendritic texture of olivine and anorthite, and pyroxene fills gaps of the dendrites. Grain size exhibits large variations from fine grains (~1 μm) to coarse grains (>100 μm). This is not a typical characteristic of quenched angrites. NWA 7203 is composed mainly of olivine, pyroxene and anorthite, and the accessory minerals are troilite, ulvospinel and silico-apatite.

Methods: Observation was carried out on thin sections by optical microscope and BSE images of FE-EPMA. Mineral phases were identified by micro-Raman spectroscopic analysis. Pb-Pb dating of NWA 7203 was carried out by measuring Pb isotope ratios of silico-apatites using Nano-SIMS at AORI, Univ. of Tokyo. Measurement conditions were 300 pA for primary ions and $^{16}O^-$ for ion sources. Pre-sputtering was performed for 8 minutes in the range of 10 x 10 μm. In the SIMS measurement, raster diameter of 3 x 3 μm and analysis time of 60 seconds were applied for two magnetic fields, respectively, and repeated for 30 cycles. For the standard, NIST SRM 610 was used.

Result and discussion: Pb isotopic ratios of silico-apatite in the NWA 7203 angrite were obtained. We obtained a weighted approximate straight line for each plot and found the Pb-Pb age to be 4551 ±17 Ma. These plots are relatively variable. This is probably because Pb isotopic ratios were disturbed by shock metamorphism. In fact, the Pb-Pb age of silico-apatite grains that are at least 200 μm away from the shock veins was found to be 4560 ±16 Ma. It is considered that the Pb isotopic ratios of these silico-apatite grains are relatively undisturbed as they are linearly aligned. This age coincides with the crystallization age of other quenched angrites within the error range. Takenouchi et al. (2019) measured the Ar-Ar ages of NWA 7203 and found that it has two plateau ages of 3800 ±440 Ma and 2300 ±140 Ma, and concluded that the shock metamorphism of NWA 7203 occurred at 2300 ±140 Ma. From this result, it is considered that the Pb-Pb age of NWA 7203 is not completely reset, but slightly disturbed.

Shock recovery of high-pressure phase of SiO_2 using high-power laser

*Tadashi Kondo[1], Hiromoto Kengo[1], Tatsuhiro Sakaiya[1], Hidenori Terasaki[1], Keisuke Shigemori[2], Youichiro Hironaka[2]

1. Department of Earth and Space Science, Graduate School of Science Osaka University, 2. Institute of Laser Engineering, Osaka University

High-pressure phases in meteorites provide us the important information of shock history in natural materials. Experimental approach to reproduce such high-pressure phase have been studied intensively mainly by light-gas gun so far, though shock condition with impact velocity beyond 10km/s is difficult. Recent technical progress of high-intensity laser as a tool of shock experiment realize the recovery of samples with shock condition above 10km/s(Nagaki et al.,2016). However, the limited shock duration time of about 10 nsec has been too short to drive structural conversion to high-pressure form in single crystal sample. In this study, we explored recovery condition of high-pressure phase of SiO_2 using finely ground samples of quartz, cristobalite and fused silica as starting materials. Laser shock experiments were performed using GXII hyper laser at Institute of Laser Engineering, Osaka University. The whole sample retaining relative locations in the recovered box made of aluminum was quenched without significant scattering in each run. The sectioned sample at shocked center were examined by optical microscope, micro-focused X-ray diffraction and SEM-EDS. We will report the characteristic feature of top portion of sample, which shows layered structure with different metamorphism, and distribution of grass and stishovite phase found in the samples shocked above 100GPa, which have still a residual stress to 10GPa in the ambient condition. We will discuss the dependence of the initial state of crystal to recover the high-pressure phase in shocked samples in nsec.

Hugoniot measurement of calcite under meteorite collision condition

*Fukui Keiya[1], Norimasa Ozaki[1,2], Yuhei Umeda[1], Kohei Miyanishi[3], Kento Katagiri[1], Shintaro Morioka[1], Takayoshi Sano[3], Ryosuke Kodama[1,2,3]

1. Graduate School of Engineering,Osaka univ., 2. PPC, Osaka Univ., 3. ILE, Osaka Univ.

Volatile substances inside planetary materialsare generated and released as gas under the extreme condition caused by collision phenomenon that is thought to contribute greatly to the formation of the planetary atmosphere [1]. Particularly the degassing reaction of carbonate, may generate CO or CO_2as greenhouse gas and affect the temperature of the planetary surface. A typical planetary mineral as carbonate of calcite ($CaCO_3$) is expected degassing above 3300 K at pressure of 150 GPa along the Hugoniot[2].
In the previous study, the experimental investigations for the shock-degassing reaction were carried out only below the impact pressure of 100 GPa. Also, we have not understood when the degassing reaction of calcite occur on a compressed state or a released state [3]
In natural, typical meteorite impacts exceed 10 km/s in impact velocity, and can generate at the pressure above 150 GPa. The purpose of this research is to understand the impact compression characteristics of calcite under the meteorite collision condition.

This experiment was conducted in Shock Drive Laser (Gekko XII) atInstitute for Laser Engineering, Osaka University. The target consists of polypropylene as an ablator aluminum as a piston, quartz as a standard material, and calcite as a sample from laser side. The impact pressures and temperatures were estimated by the measured shock wave velocity using Velocity interferometer system for any reflector (VISAR) and self-emission intensity using radiance thermometer (SOP).
As a result of this experiments, we obtained the Hugoniot date at the puressure from 200 GPa to 1 Tpa at the temperature above 5000 K. The detailed results will be shown as this presentation.

The enhancement of strength and toughness was found in oxide-doped tetragonal stabilized zirconia, with the suggestion that the absorption of energy during the martensitic transformation contribute to the increment [Gravie et al., 1975; Gupta et al., 1977]. Using transmission electron microscopy (TEM), in recovery sample, it was observed that the stress-induced transformation from stabilized tetragonal phase to monoclinic phase can be occurred around the crack tip [Porter et al., 1977], and the transformation-toughening model were devised [McMeeking et al., 1982; Hannink et al., 2000]. In high-pressure experiments, the phase transformation behavior of tetragonal stabilized zirconia has not been clarified in both static and shock compression because a lack of in-situ observation [Ohtaka et al., 1988; Grady et al., 1992]. We tried to observe the behavior of tetragonal stabilized zirconia under shock compression condition using time-resolved XRD method.We performed the experiments at NW14A beamline at PF-AR (Photon Factory Advanced Ring), High Energy Accelerator Research Organization (KEK), Japan. Nd:glass laser with the wavelength of 1064 nm, pulse energy of 16 J, pulse width of 12 ns was used for shock-driving source. The laser beam was focused by optical lens to the size of 500 μm × 500 μm on the sample surface. For TR-XRD experiments, the synchrotron X-ray pulse of PF-AR was used as a probe source. The energy, the pulse width, and the size on the sample were 15.68 keV, about 100 ps, and 450 μm (H) ×250 μm (W), respectively. The irradiation timing between laser pulse and X-ray pulse on the sample surface were controlled by delay generator at ns time scale. The targets consisted of an 25 um PET film ablator with Al coated on the surface and 50 um polycrystalline 3 mol% yttria doped tetragonal stabilized zirconia.
The XRD change were observed up to 35 ns after shock compression started. Before shock, the (101), (002), (110), (102), (112), (200) diffraction of tetragonal phase were observed. 6.5 ns after shock, the diffraction from compression region appeared with maximum compression of 6%. No phase transition occurred at compression states. At release states (~11.4 ns), on the other hand, the (-111), (111), (022), (-221) diffraction peaks of monoclinic phase were appeared. We will discuss the detail of the experimental results and the transformation toughening mechanism.

[P-CG22] Shock responses of planetary materials elucidated from meteorites and dynamic compression experiments

convener:Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Takuo Okuchi(Institute for Planetary Materials, Okayama University), Chairperson:Toshimori Sekine(HPSTAR & Osaka University), Ai-Cheng Zhang(Nanjing University)

Impact phenomena had played essential roles in the process of planetary evolution. Recent analytical and experimental developments reveal a new prospective on the effects of shock-compression process for planetary materials. For deeper understanding of such shock effects, it is necessary to evaluate the detailed shock conditions from the observations of naturally-shocked planetary materials, and to compare them with the results on the planetary materials experienced a wide range of known shock conditions. Several metastable phases, that have not been known before, have recently been identified in shocked meteorites. They suggest that the shock state is often not in equilibrium and that it is more complicated process than ever thought. Experimental techniques including laser-driven shock compression and x-ray free electron laser diagnostics have been progressed to successfully simulate a wide range of shock conditions. The recent results indicate that shocked grains are fractured and rotated at relatively low pressures, and that they are subsequently transformed into denser phases or melts, or their mixtures at pressures of a few 100s GPa. Understanding of such shock dynamics requires another prospect, which is qualitatively different from the static high pressure and high temperature consensus. Therefore, it is timely to have an international symposium on dynamics of planetary materials.

Shock-induced phase transformation in howardite-eucrite-diogenite meteorites

*Ai-Cheng Zhang[1,2], De-Liang Chen[1], Run-Lian Pang[1]

1. School of Earth Sciences and Engineering, Nanjing University, China, 2. CAS Center for Excellence in Comparative Planetary, China

Phase transformation is an important type of mineralogical respects to shock metamorphism in planets and asteroids. It has been widely used to constrain the dynamic conditions (pressure-temperature-time, P-T-*t*) of shock events and the mineral constituents in deep planets. In the past decades, shock-induced phase transformation has been extensively studied in shocked ordinary chondrites, martian and lunar meteorites. However, shock-induced phase transformation in howardite-eucrite-diogenite (HED) meteorites was less studied. In the past five years, a few high-pressure minerals (coesite, stishovite, tissintite, vacancy-rich clinopyroxene, super-silicic garnet, grossular, and a new mineral vestaite (TiFe)Ti_3O_9) have been reported in shocked eucrites (Miyahara et al., 2014; Pang et al., 2016, 2018; Fudge et al., 2017). In this study, we report a few new observations about shock-induced phase transformation in HED meteorites and discuss their potential implications for constraining the shock metamorphism of Vesta.

Four eucrite meteorites NWA 8003 (unbrecciated), NWA 2650 (brecciated), NWA 10245 (unbrecciated), and Dhofar 007 (brecciated) and two unbrecciated diogenite meteorites NWA 8321 and NWA 8326 were studied with scanning electron microscopy, Raman spectroscopy, Electron backscatter diffraction, and transmission electron microscopy.

The four eucrite meteorites NWA 8003, NWA 2650, NWA 10245, and Dhofar 007 have a few similar shock-induced features. All of them contain coesite, stishovite, vacancy-rich clinopyroxene, and tissintite. NWA 8003, NWA 2650, and Dhofar 007 also contain super-silicic garnet in shock-induced melt veins; however, no super-silicic garnet was observed in NWA 10245. In NWA 8003, unique Ti-rich melt pockets have been observed and contain ilmenite, vacancy-rich clinopyroxene, vestaite, corundum, and kyanite. In NWA 2650, an oval-shaped region in a super-silicic garnet-dominant shock-induced melt vein contains grossular, kyanite, and silica glass. Some kyanite crystals are present in the interstitial glass between surrounding super-silicic garnet grains. Some of the grossular grains occur as overgrowth on super-silicic garnet. These textures indicate that the grossular + kyanite + silica assemblage has formed through shock-induced melting of anorthite and recrystallization. Reidite was observed as irregular region and lamellae in zircon from NWA 2650. It might have formed through solid-state phase transformation at a pressure >20 GPa.

The two unbrecciated diogenite meteorites have different shock-induced features. NWA 8321 contains shock-induced melt veins which contain some mineral fragments of olivine, and pyroxene. No high-pressure minerals were detected within and adjacent to shock-induced melt veins. However, in NWA 8326, a few high-pressure minerals have been observed. They include stishovite, xieite, reidite, tuite, and tissintite. Stishovite was observed with two different textures. Xieite was observed as brighter lamellae in chromite adjacent to a thin shock-induced melt veins. Reidite mainly occurs as lamellar phase in zircon. The textures indicate that stishovite, xieite, and reidite have formed through solid-state phase transformation. Tissintite was also observed, closely adjacent to a shock-induced melt vein. It has probably formed through crystallization from high-pressure and high-temperature melt.

©2019. Japan Geoscience Union. All Right Reserved.

Our new observations reveal that shock-induced phase transformation in HED meteorites are more common than previous thought. Most of these HED meteorites have experienced a low to moderate degree of shock metamorphism. However, the presence of reidite and xieite indicates that some of the HED meteorites (NWA 2650 and NWA 8326 have experienced severe shock metamorphism. Generally, the diversity of high-pressure minerals in HED meteorites is consistent with the relatively low impact velocities in the main asteroid belt. In addition, compared to severe shock metamorphism in ordinary chondrites, martian and lunar meteorites, the high-pressure minerals in HED meteorites open a new window to study low to moderate shock metamorphism.

This work is financially supported by NSFC (grant 41673068) and NSF of Jiangsu Province of China (BK20170017).

Lattice-shear-induced metastable formation of high-pressure silicates in shocked meteorites

*Naotaka Tomioka[1], Takuo Okuchi[2], Masaaki Miyahara[3]

1. Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2. Institute for Planetary Materials, Okayama University, 3. Department of Earth and Planetary Systems Science, Hiroshima University

Heavily shocked meteorites contain various types of high-pressure polymorphs of silicate minerals. These high-pressure minerals are micron to submicron sized and occurred within and in the vicinity of shock-induced melt in stony meteorites. Their occurrence suggests two types of formation mechanisms: (1) solid-state high-pressure transformation of the host-rock minerals into monomineralic polycrystalline aggregates, and (2) crystallization of chondritic or monomineralic melts under high pressure [1]. In some cases of the former process, high-pressure minerals occur as coherent lamellae within grains of the host low-pressure minerals. A typical example is the (Mg,Fe)SiO_3pyroxene-akimotoite intergrowth in the Tenham meteorite [2]. The akimotoite has relatively high Fe content [Fe/(Mg+Fe)=0.21] but does not have its stability field at any P-T conditions [3]. Therefore, the akimotoite would have been formed metastably due to a rapidly-changing P-T history in the shock event. As another example, a new high-pressure polymorph of olivine, which has been defined as “ε-phase” with a spinelloid structure, was recently discovered as nano-scale lamellae in ringwoodite [$(Mg,Fe)_2SiO_4$-spinel] and wadsleyite [$(Mg,Fe)_2SiO_4$ -spinelloid] grains in Tenham and Miami meteorites, respectively [4]. The phase has never been observed in previous phase equilibrium studies. Both pyroxene-akimotoite and ringwoodite/wadsleyite-ε-phase intergrowths have topotaxy with preserving close-packed oxygen layers for their respective structures. The crystallographic relationships between these host and the product phases suggest that these polymorphic phase transformations are promoted by shear mechanism [5]. This process is achieved by shear deformation of oxygen sublattice associating movements of interstitial cations within single unit-cell dimension. Therefore, shear mechanism is considered to be a favorable mechanism under high differential stress, or under relatively low-temperatures, where atomic diffusion is kinetically hindered. Future experimental studies, which include ultrafast in-situ X-ray diffraction under laser shock compression, and high-resolution electron microscopy on recovered specimens of static high-pressure experiments, would contribute to better understanding of detailed structural changes in naturally shocked samples.

Can high-pressure polymorphs clarify an ordinary chondrite parent-body breakup?

*Masaaki Miyahara[1], Akira Yamaguchi[2], Masato Saitoh[1], Kanta Fukimoto[1], Takeshi Sakai[3], Hiroaki Ohfuji[3], Naotaka Tomioka[4], Yu Kodama[5], Eiji Ohtani[6]

An ordinary chondrite is the biggest clan in the meteorites. The ordinary chondrites are the building blocks of an ordinary chondrite parent-body that broke up by an impact in the solar nebula. The breakup process of the ordinary chondrite parent-body is one of the intriguing conundrums. Most ordinary chondrites have evidence for the impact event. Shock-induced melting textures and high-pressure polymorphs are the most distinct clues for the impact event. Chen et al. (1996) suggested that the high-pressure polymorphs occurring in the shock-induced melt can be a clue for clarifying the impact event occurred on the parent-body because we can constrain several parameters for the impact such as shock pressure and impact velocity based on the formation conditions of the high-pressure polymorph assemblage. Accordingly, many previous studies have worked on the high-pressure polymorphs in the ordinary chondrites for several decades. Most previous investigations have focused on the L6 chondrite because the meteorite type is abundantly recovered on the Earth. On the other hand, few previous studies have worked on other petrologic types such as L5 and L4. The inventories of the high-pressure polymorphs in shocked H- and LL-group ordinary chondrites have been barely described. The ordinary chondrite parent-body is expected to have an onion shell-like structure. H-, L-, and LL-group ordinary chondrites originate from their individual parent-bodies. We have to clarify the inventories of the high-pressure polymorphs included in all petrologic types and groups to elucidate the breakup processes of the ordinary chondrite parent-bodies. Accordingly, we initiated the systematic investigations of the high-pressure polymorphs included in the shocked ordinary chondrites. About sixty H-group, eighty L-group, and fifty LL-group ordinary chondrites with the shock-induced melting textures were systematically investigated by SEM and Raman spectrometer. There was the distinct difference in the modes of shock-induced melting between petrologic type 3–4 and type 5–6 in all groups. In the petrologic type 3–4, the melting occurred at the boundaries between the chondrules and surrounding matrices as a melt-pocket. In the petrologic type 5–6, melting occurred as isolated veins or networks. There was also a clear difference in abundance of the high-pressure polymorphs among H-, L-, and LL-groups: the high-pressure polymorphs are abundant in L- and LL-groups, whereas rare in H-group. The species and assemblages of the high-pressure polymorphs depended on the petrologic types. The abundance and assemblages of the high-pressure polymorphs in L- and LL-group were similar to each other, suggesting that both parent-bodies have similar impact histories. The shock-pressure conditions were estimated based on the identified high-pressure polymorph assemblages: from ~13 to ~24 GPa for L/LL6, from ~3 to ~12 GPa for L/LL4 and L/LL5, and less than ~3 GPa for L/LL3. When we adopted the estimations into the onion-shell-structured parent-body, the shock pressure condition on the parent-body surface is much lower than its interior, which is unlikely for a head-on impact. We cannot explain the parent-body breakup phenomenon based only on the estimation using the high-pressure polymorphs. There are clear differences on their petrographic structures between type 3–4 and type 5–6: the former consists of accumulated chondrules and the latter has equilibrated texture. It is also expected that type 3–4 and type 5–6 chondrites have different initial density and porosity. These differences will affect the

©2019. Japan Geoscience Union. All Right Reserved.

response to the shock metamorphism. Unless we take these factors into the estimation, we cannot clarify the parent-body breakup phenomenon by using the high-pressure polymorphs.

Linking occurrence and texture of dense silicate minerals in shocked meteorites with laser-shock experimental results of Mg_2SiO_4 analyzed by XFEL probe

*Takuo Okuchi[1], Narangoo Purevjav[1], Norimasa Ozaki[2], Takeshi Matsuoka[2], Yusuke Seto[3], Yoshinori Tange[4], Toshinori Yabuuchi[5], Naotaka Tomioka[6], Toshimori Sekine[7], Ryosuke Kodama[2]

Center for High Pressure Science and Technology Advanced Research

Primitive meteorites often show features of shock metamorphism, including occurrences of dense polymorphs of major mineral phases. By previous transmission electron microscopy studies it was demonstrated that olivine (alpha-Mg_2SiO_4) often had transformed into its denser polymorphs such as ringwoodite (gamma-Mg_2SiO_4), and as a recently-discovered new structure (epsilon-Mg_2SiO_4: Tomioka and Okuchi, Sci. Rep. 2017). The impact events that produced these polymorphs played essential roles in the history of early solar system evolution. Here we tried to reproduce such a dynamic transformation process starting from forsterite olivine single crystals by using very strong laser beam and x-ray free electron laser (XFEL) beam in combination at SACLA, SPring-8, Japan. A transformation process has been successfully observed with sub-nanosecond resolution by x-ray diffraction using femtosecond XFEL pulses. We discovered an ultrafast transformation process completing only within few nanoseconds, which was not expected to occur during shock metamorphism of meteorites. It can be a shear-induced fast lattice slipping proceeding without any atomic diffusion process. We conclude that formation processes and environments of some of dense Mg_2SiO_4 polymorphs in heavily shocked meteorites are needed to be reconsidered to involve this fast process.

Laser-shock evolution of organic molecules in carbonaceous meteorite

*Hikaru Yabuta[1], Hikaru Fujioka[2], Tatsuhiro Sakaiya[2], Tadashi Kondo[2], Sohsuke Ohno[3], Kosuke Kurosawa[3], Toshihiko Kadono[4], Keisuke Shigemori[5], Yoichiro Hironaka[5], Takamitsu Yamanaka[6]

Center for High Pressure Science & Technology Advanced Research, Shanghai, China

It has been hypothesized that extraterrestrial organic compounds were delivered to the early Earth by meteorites and comets during the Late Heavy Bombardment (LHB). There have been several experiments that simulated the shock synthesis of organic compounds during the LHB. However, in the past studies using gas guns, it is difficult to perform an open system experiment at higher impact velocities than Earth’ s escape velocity (> 17 km/s). In order to understand what compositions of meteoritic organic molecules were produced by the shock energy of LHB and delivered to the Earth, we carried out a high power laser compression experiment (up to 400 GPa) of carbonaceous chondritic meteorite, which contains 2wt% of organic carbon.

Pellets of Murchison carbonaceous meteorite was prepared by diamond anvil cell, respectively. Pellets of the meteorites in 3mm diameter and 1mm thickness were prepared. The titanium foil was located in front of the sample as the ablator for the laser and for preventing the sample from blowing out. The laser-shock experiment was carried using GEKKO XII/HIPER laser system, Institute of Laser Engineering, Osaka University. The laser wavelength, pulse width, and spot diameter were 1053 nm, ~20 ns, and ~0.4 mm, respectively. The shock pressures were 20, 50, and 400 GPa. The collected meteorite samples were extracted with dichloromethane and methanol. The extracts were concentrated and analyzed by a gas chromatography coupled with mass spectrometry (GCMS).

Molecular compositions of polycyclic aromatic hydrocarbons (PAHs) in Murchison meteorite are not changed before and after the shock experiment at 20 GPa, except that the concentration of naphthalene was depleted. At 50 and 400 GPa, the concentrations of pyrene and fluoranthene increased, while those of biphenyl, fluorenone, and anthracene decreased. Molecular compositions of *n*-alkanes (C_{14} –C_{24}) are not largely changed before and after the shock experiment at 20 GPa. However, at 50 GPa, the concentrations of short chain *n*-alkanes (C_{14} - C_{17}) decreased and those of long chain *n*-alkanes (C_{18} - C_{24}) relatively increased. These results indicate that impact processes promote aromatic ring condensation and elongation of carbon chains of *n*-alkanes.

Shock barometer using cathodoluminescence and synchrotron angle-dispersive x-ray diffraction analyses of minerals

*Masahiro KAYAMA[1]

1. Tohoku University

A part of meteorites record collisional history of asteroidal and cometary impacts. Impactites were created in impact craters by the shock event on the Earth. These materials provide vital information on collision and accumulation processes of asteroid and planet and ejection process from the parent body. The shock pressure is one of the most important parameters to interpret these impact history. Various techniques such as optical and electron microscopy and infrared adsorption and Raman spectrometry have been applied for minerals (e.g., feldspar and silica minerals) in meteorites and impactites to estimate the shock pressure that occurs on the Earth, Moon, and Mars. Although there are many works to evaluate the shock pressure using these techniques, quantitative estimation of a wider dynamic range of shock pressure has not been possible for a micrometer-sized grain to date. Here, cathodoluminescence (CL) and synchrotron angle-dispersive x-ray diffraction (SR-XRD) of experimentally shocked feldspars and quartz and these minerals in meteorite and impactite have been investigated to establish a new shock barometer.

Shock experiments were performed for single crystals of synthetic and terrestrial quartz and terrestrial feldspars at the National Institute for Material Science using a one stage propellant gun. Quartz in an impactite from the Chicxulub crater and alkali feldspar and plagioclase in martian meteorites (NWA 2975, Shergotty, Dhofar 019, and Zagami) were selected here. CL spectroscopy of these samples was conducted at Okayama University of Science. SR-XRD was measured for the powder samples at KEK Photon Factory (PF; beam line: PF BL-4B2).

CL spectra of unshocked feldspars (starting material for the shock recovery experiments) consist of blue, yellow, and/or red emission bands in the wavelength range from 300 to 800 nm. The ultraviolet (UV) to blue emission bands at 330 and 380 nm were obtained from CL spectra of only experimentally shocked feldspars at 20 to 40 GPa. The intensities of all UV-blue emissions correlate positively with the shock pressure. Similar UV-blue emission bands were recognized in CL spectra of the shock-induced feldspar glasses in the martian meteorites and impactites.

CL spectra of unshocked synthetic and terrestrial quartz show an extremely weak blue emission band at 400 nm. The blue emission band was also detected in CL spectra of the experimentally shock recovered samples at 5 to 40 GPa and quartz in the impactite, whereas their blue emission intensities are obviously higher than those of the unshocked quartz. The blue emission intensities increase with the pressure due to shock experiments gradually from 5 to 15 GPa and drastically from 20 to 40 GPa. These correlations obtained from CL spectra of experimentally shocked feldspar and quartz would give quantitative values of the shock pressures that the minerals in martian meteorites and impactite have experienced. Therefore, the CL intensity of feldspar has a potential for a shock barometer with high spatial resolution.

SR-XRD analyses of experimentally shocked quartz demonstrated that the diffraction peaks increase in the intensity and become broader with increasing the shock pressure in the range from 5 to 30 GPa. At the shock pressure above 35 GPa, diffraction peak of quartz was no longer undetectable from the pattern, implying its complete amorphization. Moreover, several crystal planes exhibit peak shifts with the pressure in the pressure range from 15 to 30 GPa. Furthermore, the shock experiments enhance micro strain and

©2019. Japan Geoscience Union. All Right Reserved.

reduce crystallite size. This fact indicates that the shock-induced amorphization was initiated by lattice distortion and structural defects induced by shock compression. The SR-XRD response to the shock pressure suggests the possibility of shock barometer using SR-XRD method, at least in the range from 15 to 30 GPa.

[P-CG22] Shock responses of planetary materials elucidated from meteorites and dynamic compression experiments

convener:Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Takuo Okuchi(Institute for Planetary Materials, Okayama University), Chairperson:Takuo Okuchi(Okayama University), Yongjae Lee(Yonsei University)

Impact phenomena had played essential roles in the process of planetary evolution. Recent analytical and experimental developments reveal a new prospective on the effects of shock-compression process for planetary materials. For deeper understanding of such shock effects, it is necessary to evaluate the detailed shock conditions from the observations of naturally-shocked planetary materials, and to compare them with the results on the planetary materials experienced a wide range of known shock conditions. Several metastable phases, that have not been known before, have recently been identified in shocked meteorites. They suggest that the shock state is often not in equilibrium and that it is more complicated process than ever thought. Experimental techniques including laser-driven shock compression and x-ray free electron laser diagnostics have been progressed to successfully simulate a wide range of shock conditions. The recent results indicate that shocked grains are fractured and rotated at relatively low pressures, and that they are subsequently transformed into denser phases or melts, or their mixtures at pressures of a few 100s GPa. Understanding of such shock dynamics requires another prospect, which is qualitatively different from the static high pressure and high temperature consensus. Therefore, it is timely to have an international symposium on dynamics of planetary materials.

Dynamic Compression at Pohang X-ray Free Electron Laser Facility (PAL-XFEL)

*Yongjae Lee[1]

1. Yonsei University, Seoul, Korea

We have successfully commissioned dynamic compression studies at the Pohang X-ray Free Electron Laser facility (PAL-XFEL) in Korea by utilizing instrumentations at FXS (Femtosecond X-ray Scattering) –XSS (X-ray Scattering and Spectroscopy) beamline. As the first experiment, a polycrystalline iron foil has been illuminated by an 800 nm wavelength uncompressed optical laser with ~6 mJ in 150 ps pulse length, focused onto a 100 mm FWHM spot. The shock-compressed sample has then been probed by ca. 50 fs quasi-monochromatic (bandwidth 0.4%) X-ray pulse at an energy of ~10 keV with 10^{11} photons per pulse, focused to ca. 30 mm diameter using a CRL optics. The sample is positioned normal to the X-ray pulse at a distance of ca. 12 cm from a Rayonix mx225 detector in a way to cover 2q angles up to ca. 65 degrees. Single-shot diffraction measurements were performed with ca. 100 ps. increment up to one nanosecond. We demonstrate that PAL-XFEL can provide a unique opportunity in probing ultrafast lattice dynamics with sufficient spatial and temporal resolution in intermediate pressure regime.

Two magnesium silicates of $MgSiO_3$(Enstatite) and Mg_2SiO_4(Forsterite) are primary mantle constitutions in the Earth and major components in Earth-type exoplanets.The ordinary chondrite, which accounts for about 90 % of all flying meteorites, consists of silicates as main components. The impacts at collision velocities exceeding 10 km/s are known as common events in the universe and such high energy phenomena could have played an important role to form planets or planetesimals and to evolve planetary environments. For example, a large-scale impact such as the giant impact related to the formation of moon was estimated to be at impact velocity of 15-20 km/s [Melosh, 1990].

In this study, Hugoniot equation of state (EOS) of enstatite has been determined at pressures of ~400 to 560 GPa by laser shock experiments. A coupling of both the present study and the previous data by Fratanduono et al. (2018) shows a discontinuity in the shock velocity-particle velocity at ~380-400 GPa. The measured reflectivity of shocked enstatite indicates three different trends relative to that of quartz; less steep slope at 300-345 GPa, parallel at 345-400 GPa, and a rapid increasing above ~400 GPa, suggesting different phases of enstatite melt, a mixture of metal-like liquid of $SiO_2$and crystalline MgO, and fluid-like enstatite melt above ~380 GPa. We also calculated the release state of thin enstatite using quartz on it as a reference. These results on enstatite imply that reactions in silicate magma occur at pressures of 300-400 GPa and that they may affect the current planet formation model in terms of the stratification of interior, the mantle convection, and the formation of magnetic field in Super-Earths.

An experimental design to determine iron melting at the Earth’s core conditions via in-situ X-ray diffraction technique at high power laser facility

*Hao Liu[1]

1. Laser fusion research center

Phase diagram of iron at the Earth’s core conditions is mandatory for determining the states at the core boundaries and the crystal structure of the solid core. Up to date, the iron phase diagram at high pressure has been investigated experimentally by both static compression (diamond-anvil cell) and dynamic compression (shock wave) techniques. However, the discrepancies among different researches on melting line of iron are still irreconciled. Combining in-situ transient X-ray diffraction and laser compression technique, we propose an investigation which could determine the melting line of iron or the high-pressure high-temperature phase from the lattice level. In this research, high power lasers are applied to drive the iron into melting state. X-ray diffraction pattern interpretation and the criteria for judging iron melting are of great importance. Traditionally, the existence of diffraction peak is used as the only criteria to determine if melting occurs. Nevertheless, this is not enough for shock loading with high heating rate, where the pre-melting or superheating phenomenon occurs. Under these conditions, the diffraction peaks could either disappear at temperature below the melting line or remain even above the melting line. This could lead to misinterpretation for melting temperature. However, the two-dimensional shape of diffraction pattern will change. When melting initiates, the shear modulus of the highly stressed material disappears and the diffraction pattern changes into an ideally circled shape. Therefore, with the information of two-dimensional diffraction pattern, we can make the melting criteria, from the lattice level, more sound and clear. This method could provide experimental judgment with higher precision, which might reconcile the discrepancies on melting temperature of iron at the Earth’s core conditions.

Information on the thermal and electrical transport properties of iron alloys under high-pressure and high-temperature conditions corresponding to the earth’ s outer core is necessary to clarify the convection phenomena of the earth and the cooling history. In particular, the transport properties in the outer core–mantle boundary condition strongly influence the mantle convection, the outer core convection generating the earth's magnetic field, the growth and inner flow of the inner core, and so on. However, there are very few experimental examples concerning high-pressure and high-temperature liquid iron/iron-alloy which correspond to the outer core conditions, and only a few cases have been reported for pure iron [1]. It is required to investigate transport coefficients of liquid iron alloys containing light elements to simulate actual outer core, experimentally. Laser shock compression technique has several advantages to exploring iron-alloys under high-pressure and high-temperature condition. As there is no mechanical restriction on pressure generation, producing the pressure of even TPa is easy, and high heating rate exceeding 10^{15}K / s is possible, and it is a closed system that is not affected by surroundings. Therefore the technique is effective for generation and observation of high-pressure and high-temperature liquid iron-alloys. In this research, we report optical reflectivity, pressure and temperature measurements of laser shock compressed iron and iron-silicon (Fe-Si) alloy at and above the earth's outer core conditions.

Target assemblies containing polypropylene (CH), aluminum, quartz, iron or iron-silicon alloy and magnesium oxide (MgO) window were shock compressed by laser ablation at the GEKKO XII laser facility, the Institute of Laser Engineering, Osaka University. Iron and iron-silicon alloy were formed by electron beam evaporation on the MgO window. Laser beams with a wavelength of 527 nm were focused onto the target. A focal spot was 1 mm in diameter with a flat-top spatial intensity distribution resulting in a planar shock front. Temporal shape of the laser pulse was approximately a flat-top with a full-width at half-maximum of 2.5 ns. The velocity interferometer system for any reflector (VISAR) measure a particle velocity and a reflectivity at the interface between iron or iron-silicon alloy and MgO. The Ppressure was evaluated using measured particle velocity and a known equation of state of MgO[2]. The optical pyrometer measures the temperature at the interface through the MgO window.

The pressures determined from the measurement results were from 200 to 400 GPa, and the temperatures were up to 15000 K. In the pressure range exceeding 200 GPa, in the case of iron, a decrease in reflectivity was observed as the pressure increased, whereas in the case of the iron-silicon alloy, a continuous increase following a discontinuous decrease in the reflectivity was observed. The decrease in reflectivity of iron suggests a decrease in electronic conductivity due to temperature rise with increasing pressure. On the other hand, the continuous rise seems to indicate an increase in the density of free electrons derived from silicon.

Laser shock compression in LFRC

*Liang Sun[1]

1. Laser Fusion Research Center, CAEP

Shock compression is a major technique used for achieving high pressures dynamically. High-powered lasers are increasingly being used for dynamic loading of materials, especially for extreme high pressure. Ramp loading, a series of weak compress waves, is an another advantage for laser-based dynamics, which can be realized easily by the laser pulse shape and can be applied to compress material in much lower temperature under exoplanetary condition. In this talk, we will present our shock loading and X-Ray diagnostics abilities in LFRC and our shock experiment results. Our research progress will also be mentioned, especially in laser shock compression of iron and ramp compression of Al to 420 GPa. Several problems in the mineralogy of Super-Earth planets will also be mentioned in the end of this talk.

Titan's atmosphere is characterized by the presence of the number of trace gases such as hydrocarbons and nitriles produced with complex photochemical processes. Cassini spacecraft, which completed its works in 2017, has played an important role to illustrate the dynamic variation of the trace gases. For example, on the high-latitudinal region of the southern hemisphere, both hydrogen cyanide (HCN) and benzene (C_6H_6) exhibited ~1000 times enhancement of their atmospheric abundances from 2011 to 2015 (Coustenis et al. 2016). For the understanding of complicated photochemical processes of Titan, long-term observation of the spatial distribution of such trace gases are crucial.

ALMA is a suitable tool for that purpose. We have constructed a large spectroscopic data-set of Titan's trace gases by converting ALMA's archival data obtained for the calibration purpose into the scientific data known as "FITS cube", which contains calibrated spectra in each 2-D image pixels. Extracted number of Titan's FITS data is more than 3000. Many trace gases such as carbon monoxide (CO), HCN, acetonitrile (CH_3CN), cyanoacetylene (HC_3N) and their isotopologues and other complex molecules are detected clearly. For the illustration of the time distribution, spectral intensity distribution maps of all detected species were produced.

From the analysis of the spectral intensity distribution map, from mid 2015, intensities of HC_3N measured on southern hemisphere is stronger than that of northern hemisphere. In turn, northern hemispheric CH_3CN and HCN intensities are still stronger than that of south in 2015 and 2017, respectively. Newly found difference of the time variation between the nitriles possibly reflects their photochemical production/destruction timescale against the seasonal variation of UV influx and atmospheric circulation. Currently, we are attempting to develop the semi-automated atmospheric retrieval code to reproduce the 3-D distribution of trace species to constrain the photochemical processes.

Transport and energization of planetary ions in the magnetospheric flanks of Mercury

*Sae Aizawa[1], Dominique Delcourt[2], Naoki Terada[1]

1. Graduate School of Science,Tohoku University, 2. LPC2E, CNRS

The transport and energization of planetary ions within Kelvin-Helmholtz (KH) vortices developing in the magnetospheric flanks of Mercury are investigated using both numerical methods and data analysis. Due to the presence of heavy ions of planetary origin (e.g., O^+, Na^+, and K^+) and the complicated field structure present during the KH vortex development, the scale of electric field variations can be comparable to that of the ion gyromotion. Therefore, ions may experience non-adiabatic energization as they drift across the magnetopause. In this study, we focus on the effects of the spatial/temporal variations of the electric field along the ion path. We show that the intensification, rather than the change in orientation, is responsible for large non-adiabatic energization of heavy ions of planetary origin. This energization systematically occurs for ions with low initial energies in the direction perpendicular to the magnetic field. The energy gain is of the order of the energy corresponding to the maximum *ExB* drift speed. It is also found that the ion transport across the magnetopause is controlled by the orientation of the magnetosheath electric field. Analyzing data from MESSENGER allow us to compare the observational facts with our numerical results. We find that the counts of Na^+-group detected by FIPS increase with the existence of KH waves, which is consistent with our numerical results. Although some differences in the energy distribution are expected in our numerical results, the data show no significant differences. This will be the subject of further studies using the newly developed BepiColombo instruments.

Exploring the real-time prediction of Mercury's magnetosphere

*Manabu Yagi[1], Kanako Seki[2], Yosuke Matsumoto[3], Dominique C. Delcourt[4], Francois Leblanc[4]

1. RIKEN Center for Computational Science, 2. Graduate School of Science, University of Tokyo, 3. Graduate School of Science, Chiba University, 4. The National Center for Scientific Research

Observations by MESSENGER found that Mercury's magnetosphere is analogous to the Earth's while there are several differences of the two. Big differences from the Earth's magnetosphere are strong IMF-Bx component and dipole offset which could affect to the global configuration of Mercury's magnetosphere. In this study, first we performed many cases of MHD simulation solving an interaction with solar wind plasma and offset dipole of Mercury. Solar wind densities are given betwenn nominal(35cm^{-3}), high(70cm^{-3}), and extreme(140cm^{-3}), with velocities for 400km/s to 800km/s, which are realistic values in the Mercury's orbit. When solar wind density is nominal and no IMF-Bx, the structure of Mercury’s magnetosphere is not far from ‘miniature’ of Earth’s magnetosphere, while north-south asymmetry is outstanding because of the offset dipole. In the realistic IMF case, global configurations of magnetosphere drastically change and become more complicated structures which include stronger north-south and dawn-dusk asymmetry. IMF-Bx also affects to the intensity ratio of north and south cusp pressure. IMF-By component “twist” the cusp region to longitudinal direction. The heavy ions’ trajectories basically obey the global structure of magnetic field, so that the ions’ precipitation concentrate on the ‘magnetic cusp’ defined from MHD simulations, but the precipitation region is wider and diffusive compared to the MHD cusp. In the presentation, we will discuss more details of heavy ion precipitation pattern. The identification of global structures and ions’ precipitation region especially the cusp is important not only on the understanding of magnetospheric physics itself, but also making a proposal to the observational plan of spacecraft such as Bepi-Colombo.

Model study on the contribution of various physical processes for generation and dissipation of Mercury's exosphere

*Yudai Suzuki[1], Kazuo Yoshioka[1]

1. University of Tokyo

Mercury has tenuous atmosphere (~1e-10 Pa), which escapes into space due to weak gravity and constant exposure to strong solar photo pressure and solar wind.Since exosphere directly connects with ground surface, the amount of generated and dissipated atmosphere drastically variesdepending on the environment.

Exosphere contains several elements such as Na, Mg, H, K, Ca, He. H and He are derived from solar wind, while other species are thought to be supplied owing to desorption from ground surface. For example, thermal desorption, charged particle sputtering (CPS), photon stimulated desorption (PSD) and meteorite impact vaporization (MIV) are suggested as desorption process. The amount of thermal desorption depends on the surface temperature, which is a function of the distance between the Sun and Mercury due to revolution. The amount of CPS changes owing to flares and the intensity of solar wind. Variation of PSD amount is due to fluctuation of solar radiation. MIV is dominated by the amount of dust around Mercury. Therefore, estimating how much each process contributes to generation of atmosphere encourages understanding the environment of inner solar system.

Velocity distribution of emitted particles is different from process to process. Thus, contribution of each process is often presumed by temperature of emitted particles which can be estimated by density profile obtained by the observation of MESSENGER spacecraft. However, the accuracy of estimating the abundance of high-temperature component gas is not enough, and besides it is hard to make an estimate of the dominant process in high latitudes in northern hemisphere and mid-latitudes owing to geometry of the spacecraft’ s orbit.

Thermal desorption dominates the distribution of sodium atoms on ground surface since particles emitted by thermal desorption has small energy and return to the surface only in a short time (~10min). CPS is thought to generate the majority of atmosphere in high latitudes of northern hemisphere and mid latitudes.

In this research, the behavior of neutral sodium particle from generation to escape focused on thermal desorption and CPS is simulated using Monte Carlo method. In addition, the contribution of those processes will be discussed by comparing with the MESSENGER/MASCS/UVVS observation.

The ESA-JAXA joint mission BepiColombo is now on the track to Mercury. Two spacecraft for BepiColombo, "MIO" (Mercury Magnetospheric Orbiter: MMO) and "Bepi" (Mercury Planetary Orbiter: MPO), were launched by Ariane-5 launch vehicle from Kourou in French Guiana on 20 October 2018. During the cruise to Mercury, in addition to two spacecraft MMO Sunshield and Interface Structure (MOSIF) and Mercury Transfer Module (MTM) are all integrated together. The critical phase just after launch and the near Earth commissioning phase were successfully finished in end of 2018, and the first electrical propulsion started from Decemeber 2018. The next activities are delta commissioning of high voltage instruments in mid 2019, and the first flyby around the Earth in April 2020. Here we report the updated status of BepiColombo mission and the overview of its science goals.

A Novel High-Moment Multifluid Model for Mercury: From the Planetary Conducting Core to the Dynamic Magnetosphere

*Chuanfei Dong[1], Liang Wang[1], Ammar Hakim[1], Amitava Bhattacharjee[1], James A Slavin[2], Gina A DiBraccio[3], Kai Germaschewski[4]

1. Princeton University, 2. University of Michigan, Ann Arbor, 3. NASA Goddard Space Flight Center, 4. University of New Hampshire

We have developed a novel three-dimensional ten-moment multifluid model and applied it to investigate the tightly coupled interior-magnetosphere system of Mercury. This new multifluid model self-consistently solves the continuity, momentum and pressure tensor equations of each species, together with the full Maxwell equations. As a result, non-ideal effects including the Hall effect, inertia, and tensorial pressures are self-consistently embedded without the need for explicitly solving a generalized Ohm's law.

Our simulation results from this new model are in good agreement with observations from MErcury Surface, Space ENvironment, GEochemistry, and Ranging (MESSENGER) spacecraft. The model is able to reproduce the magnetic field vectors, field-aligned currents and cross-tail current sheet asymmetry observed by MESSENGER. We also investigate collisionless magnetic reconnection in Mercury's magnetotail and at dayside magnetopause. In addition, we study the magnetospheric response of Mercury to a hypothetical extreme event with an enhanced solar wind dynamic pressure, which demonstrates the significance of electromagnetic induction effects resulting from the coupled interior. Moreover, two plasmoids (or flux ropes) are formed in Mercury's cross-tail current sheet during this hypothetical extreme event, indicating the extremely dynamic nature of Mercury's magnetotail. Thus, this novel high-moment, multifluid, interior-magnetosphere-coupled model is crucial for understanding Mercury's dynamic magnetosphere and has the potential to enhance the science returns of both the MESSENGER and BepiColombo missions.

DSMC simulation of slow hydrodynamic escape from terrestrial planets

Kaori Terada[1], *Naoki Terada[1], Hitoshi Fujiwara[2]

1. Graduate School of Science, Tohoku University, 2. Faculty of Science and Technology, Seikei University

Slow hydrodynamic escapes of atmospheric components from terrestrial planets subject to intense EUV radiation are investigated by DSMC simulations to understand the long-term evolution of planetary atmospheric composition.

Sun-like stars in earlier stages of their evolution emit intense EUV radiation. For example, the young sun of 4.5 billion years ago may have emitted 100 times stronger EUV radiation than today. After the formation of planets in a protoplanetary disk, planets get their atmospheres from the remnants of the disk gas and the outgassing due to impacts. The atmospheres were subject to the intense EUV radiation from a young central star, which caused significant heating and massive escape of planetary atmospheres.

The energy-limited escape rate is an upper limit of an atmospheric escape rate. The energy-limited escape is a category of the hydrodynamic escape. After an EUV radiation from a central star became weak, a planetary atmosphere was in hydrostatic equilibrium, and an escape rate became equal to the Jeans escape rate. While hydrodynamic escape and Jeans escape are understood well, there is an incomplete understanding of transition from hydrodynamic to Jeans escapes.

The thermal escape processes such as hydrodynamic escape and Jean escape depend on atmospheric composition. A previous study showed that the exobase temperature of Earth exceeded 10000 K and the atmosphere was well within the hydrodynamic regime when exposed to 20 times stronger EUV levels than present-day Earth. The exobase temperature of a CO2 dominated atmosphere like Mars was not heated as much as Earth’ s exobase because of efficient CO2 IR cooling. Nonetheless a previous simulation study using a fluid model showed that the exobase temperature reached about 2500 K and the Martian atmosphere was not in the hydrostatic equilibrium when exposed to 20 times stronger EUV levels.

In this study, escape rates from Earth-like and Mars-like planets for different EUV radiation intensities are estimated by DSMC simulations. Our full-particle upper thermosphere simulation model can solve the escape rates self-consistently. We show the escape rates of each species including the transition from hydrodynamic through slow hydrodynamic to Jeans escapes to understand the long-term evolution of planetary atmospheric composition.

The influence of Martian crustal magnetic fields on atmospheric escape

*Dave A Brain[1,2], Robin Ramstad[1], Yaxue Dong[1], Tristan Weber[1], Shogo Inui[2], Kanako Seki[2], Andrew Poppe[3], Riku Jarvinen[4], Jim McFadden[3], Jasper Halekas[5], Jared Espley[6], David Mitchell[3], Laila Andersson[1], Bruce Jakosky[1]

At present the influence of Martian crustal magnetic fields on atmospheric escape rates is debated. Since Mars lacks a significant global dynamo magnetic field, the presence of strong crustal fields over a significant fraction of the surface could shield portions of the atmosphere from the incident solar wind. The crustal fields could also allow or even enhance atmospheric escape through numerous cusp regions that are magnetically connected to the solar wind. This issue is of interest because the answer has implications for how atmospheric escape has operated on Mars over the history of the planet, including earlier times when Mars was more widely magnetized or even possessed a dynamo field. It is also relevant for assessing whether a global magnetic field is important for atmospheric retention. To this point, both modeling and observational studies appear to disagree on whether crustal fields significantly influence the escape of ions.

We will present the results of a new analysis of ion measurements from the Mars Atmosphere and Volatile EvolutioN (MAVEN) spacecraft mission made over four years. We examine how escape rates vary as Mars rotates and as a function of the solar zenith angle of strong crustal fields, including the dependence on ion energy and species. We also explore whether ion escape rates are larger, in a global sense, above crustal fields compared to non-magnetized regions. Finally, we introduce recent results relevant for evaluating ion escape from individual cusps, including from kinetic models of Martian cusp regions.

Effects of the IMF direction on atmospheric escape under a weak intrinsic magnetic field at Mars

*Shotaro Sakai[1], Kanako Seki[1], Naoki Terada[2], Hiroyuki Shinagawa[3], Ryoya Sakata[1], Takashi Tanaka[3,4], Yusuke Ebihara[5]

1. Graduate School of Science, The University of Tokyo, 2. Graduate School of Science, Tohoku University, 3. National Institute of Information and Communications Technology, 4. International Center for Space Weather Science and Education, Kyushu University, 5. Research Institute for Sustainable Humanosphere, Kyoto University

The planetary intrinsic magnetic field is significantly important in considering the atmospheric escape from planets. The strength of intrinsic field particularly affects the interaction between the solar wind and terrestrial-type planets (e.g., Seki et al., 2001), and it would change the escape mechanism. In contrast, Mars would have kept the warm and wet climate around 4 Ga. However, atmosphere and water are lost by certain processes, resulting in that present Mars only leave thin atmosphere. One candidate of the escape mechanism is the ion outflow from the upper atmosphere associated with the magnetic field. It is expected that ancient Mars had a global intrinsic magnetic field because there exists the crustal magnetic field in present Mars, and thus investigating the effect of intrinsic magnetic field on the ion escape leads to understanding the climate change of Mars from past through present.

Sakai et al. (2018) investigated the effect of an intrinsic magnetic field of 100 nT at the Martian equatorial surface on the escape mechanism. It was shown that the existence of the weak field results in an enhancement of the ion escape rate. A parker-spiral interplanetary magnetic field (IMF) was used in order to obtain the escape rate in this earlier study.

In this study, influences of the IMF direction on the ion escape mechanism under the intrinsic magnetic field of 100 nT at the equatorial surface are investigated based on global multispecies single-fluid magnetohydrodynamics simulations (Terada et al., 2009; Sakai et al., 2018). Ion escape processes from Mars under two IMF conditions, namely, a northward and southward cases, are compared to those of the parker-spiral case. For the parker-spiral case, heavy ions escape through the channel associated with the open field lines and another channel associated with a magnetic reconnection between the planetary and solar wind magnetic fields at the flank magnetopause (Sakai et al., 2018). For the north-IMF case, the heavy ions mainly escape through the open or draped field lines formed by double lobe reconnections. The escape rate of heavy ions is about one order of magnitude smaller than for the parker-spiral IMF case and it is even smaller than for the no-dipole case. On the other hand, the heavy ions escape by the mass loading of draped field lines in the ionosphere for the south-IMF case. The escape rate of heavy ions is about one order of magnitude greater than for the parker-spiral case. For the north-IMF case, the interaction of the weak intrinsic magnetic field and IMF forms the firm magnetosphere, resulting in suppressing the ion escape. In contrast, the erosion of IMF into the deep ionosphere yields the increment of the ion escape rate for the south-IMF case.

Solar disturbances release energetic charged particles that are expected to directly precipitate into the atmospheres of weakly magnetized planets like Mars. However, draped magnetic fields can influence the motion of energetic electrons. Using a test particle model of 1 keV - 100 keV electrons moving in magnetic fields from a multifluid magnetohydrodynamic simulation, we find that energetic electrons with steep pitch angles are affected by gradient drifts over the dayside of Mars. For an interplanetary magnetic field directed in the away sector, electrons will drift southwards, perpendicular to the direction of the draped magnetic field. Gradient drifts at Mars can facilitate increased precipitation by directing electrons towards the magnetized southern hemisphere and into magnetic field cusps. These findings suggest energetic electrons precipitate non-uniformly and are attenuated at low altitudes above the dayside northern hemisphere of Mars.

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University), Chairperson:Takeshi Imamura(Graduate School of Frontier Sciences, University of Tokyo), Naoki Terada(School of Science, Tohoku University)

Exploration of Moon, Venus, Mars, Mercury, Jupiter, Saturn, and beyond together with rapid developments of numerical simulations provides us new view of planetary environment. This session collects general contributions of new findings about planetary magnetosphere, ionosphere, and atmosphere. New methodology and technology development studies for future explorations are also welcome. In order to put the common knowledge at different planets into perspective, this session aims to facilitate discussions on comparative planetary environments.

Mars had a thick atmosphere before 4 Ga, but it lost most of them. Ion escape to space could play an important role in the atmosphere loss. The astronomical observations suggest that the solar XUV (X-ray and extreme ultra-violet) flux and the solar mass loss rate were more intense (Ribas et al., 2005; Wood et al., 2002). Previous studies pointed out that the ion loss was several orders of magnitude stronger under such intensified solar conditions (Terada et al., 2009a). On the other hand, the existence of the crustal magnetic field indicates that Mars had an intrinsic magnetic field before 4.1 Ga. The conventional idea is that the intrinsic magnetic field prevents the direct interaction between the solar wind and the atmosphere and thus restrains the ion loss (Lundin et al., 2007). On the contrary, some studies suggested that the existence of an intrinsic magnetic field promotes the ion loss (Sakai et al., 2018). Thus it is important to clarify the effect of the intrinsic magnetic field on the ion loss to understand the atmospheric evolution at Mars.

In this study, we investigated the ion loss processes from Mars under extreme solar conditions and the existence of an intrinsic magnetic field using a 3D multi-species MHD model (Terada et al., 2009b). The solar wind proton density, the solar wind velocity, and the solar XUV flux were assumed to be 1000 /cm^3, 2000 km/s, and 100 times higher than the present-day XUV flux, respectively. The interplanetary magnetic field was assumed to be in Parker spiral and its strength was 60 nT. These parameters are same as those used in Terada et al. (2009a). We conducted four cases of simulations with different intrinsic magnetic field conditions, i.e., dipole fields with the strength of 0 nT, 100 nT, 1000 nT, and 5000 nT on the equatorial surface.

In 0 nT case, there were two major ion loss processes: escape of O^+, O_2^+ and CO_2^+ from the polar region and pickup O^+ carried by the deflected solar wind. In 1000 nT case, O_2^+ and CO_2^+ mainly came from the dayside cusp region through open magnetic field lines. In 5000 nT case, O^+, O_2^+ and CO_2^+ fluxes had almost the same structure and originated from the dayside cusp region. In 0 nT, 100 nT, and 1000 nT cases, the loss rates of O_2^+ and CO_2^+ were higher under the existence of the stronger dipole field, while the O^+ loss rate was nearly the same in these three cases. In 5000 nT case, the loss rates of O_2^+ and CO_2^+ were about three orders of magnitude lower than those of the other weaker dipole cases, while the O^+ loss rate was five times lower. These results suggest that the existence of a weak intrinsic magnetic field facilitates the loss of heavier ions such as O_2^+ and CO_2^+, and there is a threshold strength of the intrinsic magnetic field for this facilitation effect.

Small-scale atmospheric waves, such as internal gravity waves, are recognized as an important part of the terrestrial climate system. They ubiquitously exist on the Earth's upper atmosphere and affect the dynamics, composition, and thermal structure of the terrestrial middle atmosphere and thermosphere. Global characteristics of gravity waves on Earth have been extensively investigated over decades. On Mars, large fluctuations in density and temperature with short vertical wavelengths were first detected in Viking, Opportunity, Spirit, and Mars Pathfinder entry profiles. Wave amplitudes in the Martian atmosphere are larger than those in the terrestrial atmosphere and the important role of gravity waves of tropospheric origin in the middle atmosphere has been appreciated in early modeling studies. Gravity waves strongly affect the large-scale winds, thermal balance, density in the mesosphere and lower thermosphere. Since October 2014, NASA's Mars Atmosphere and Volatile EvolutioN (MAVEN) mission have been performed comprehensive studies of the Martian atmosphere. In-situ measurements of the upper atmosphere, from 300 km down to 130 km, revealed that wavelike perturbations ubiquitously exist in ions and neutrals in the upper thermosphere. Wavelike perturbations have also been detected by remote sensing with the Imaging Ultraviolet Spectrograph (IUVS) onboard MAVEN at altitudes between 20 and 150 km. These IUVS measurements provide opportunities for investigating possible links between waves in the Martian troposphere and thermosphere.
In order to clarify a global characteristic of waves and its upward propagating processes, we use IUVS stellar occultation measurements to characterize a global distribution of waves in the middle atmosphere between 24 March 2015 and 12 April 2018 for two Martian Years. This study first revealed global characteristics of wave perturbations in the night side temperature profiles derived from MAVEN/IUVS stellar occultations at 20 - 160 km altitudes on Mars. The peak amplitudes of waves on Mars exceed 20 % which is larger than those in Earth's mesosphere/thermosphere (~5-13 %). Perturbations were found to be notably large in summer hemisphere at L_s = 0-180. These waves can be interpreted as resulting from superposed harmonics of internal gravity waves and thermal tides. The superposition of thermal-tides and small-scale perturbations generate extensive instability layer around 70 - 100 km, which potentially causes wave-breaking and turbulences. Vertical wavenumber spectral density in the Martian middle atmosphere shows a power-law dependence with the logarithmic spectral slope of -3. This is similar to the features seen in the Earth's atmosphere. The spectral density in southern hemisphere at L_s = 225-315 tends to follow the semi-empirical spectrum of saturated gravity waves on the high-wavenumber side. The spectral power at high-wavenumbers is lower at 80 - 160 km than that at 20 - 80 km. This suggests that the strong radiative damping by CO_2 15-micron could effectively dissipates shorter waves. Instead, the spectral power at low-wavenumbers suggests the amplitude growth with height of unsaturated waves toward upper thermosphere.

Seasonal variation of the dayside N_2/CO_2 at 140 km altitude derived from MAVEN/IUVS

*Nao Yoshida[1], Hiromu Nakagawa[1], Naoki Terada[1], Nicholas Schnider[2], Scott Evans[3], Sonal Jain[2], Hitoshi Fujiwara[4], Takeshi Imamura[5], Justin Deighan[2], Ian Stewart[2], Michael Stivens[6], Roger Yelle[7]

Naval Research Laboratory, Washington, USA, 7. Department of Planetary Sciences, University of Arizona

It is believed that liquid water was abundant on early Mars, despite Mars being too cold today to sustain significant amounts of liquid water. The most likely explanation is that early Mars had a more-effective greenhouse atmosphere and most part of atmosphere and water have lost to space. Mars Atmosphere and Volatile EvolutioN (MAVEN) mission was designed to explore the loss of gas to space at the present. MAVEN spacecraft revealed highly variable nature of upper atmosphere in density, temperature, and atmospheric compounds (e.g. Mahaffy et al., 2015; Elrod et al., 2017; Stone et al., 2018; Slipski et al., 2018). However, the controlling factor of the variations has yet to be fully characterized due to the limited spatial- and temporal- observing geometry by in-situ measurements. In addition to the effects by the external force, such as solar wind and solar EUV on the upper atmosphere, the effect of lower atmospheric phenomena is also required to account for the substantial variations of upper atmosphere. For instance, the homopause (~120 km altitude) influences the upper thermospheric composition, thereby the species escaping to space [Imamura et al., 2016]. The fractionation between the homopause and exobase determines the relative abundance of species to escape to space [Jakosky et al., 2017]. For this purpose, further investigation around atmospheric boundary from the middle atmosphere to lower thermosphere is crucial for understanding regional coupling between lower and upper atmosphere.
We have investigated the seasonal variation of the N_2/CO_2 ratio at 140 km altitude derived from ultraviolet spectroscopy remote-sensing measurements by Imaging Ultraviolet Spectrograph (IUVS) aboard MAVEN. We used the dataset of level 2 version 13 revision 1 data provided by the Planetary Data System, which includes retrieved CO_2 and N_2 number density profiles derived from dayglow emissions. We analyzed N_2 and CO_2 number densities observed from October 2014 to May 2018. Observations cover in the dayside from 7 to 19 hr. The observations covered almost all solar longitudes within the two Martian Years. The retrieved CO_2 density has small uncertainty but the retrieved N_2 density has relatively larger uncertainty in particular above ~170 km due to the dimmer emission intensity. For precise analysis of the N_2/CO_2 ratio, we confine our analysis to the data at 140 km altitude where N_2/CO_2 has uncertainty less than 50%. We found that the N_2/CO_2 ratio at 140 km altitude significantly varies in the range of 0.02 to 0.20, which shows an annual sinusoidal trend. The higher ratio appears during aphelion and the lower ratio appears during perihelion. CO_2 and N_2 number densities also have similar annual variations. It is noted that the CO_2 density varies by a factor of 100, while N_2 density by a factor of 10. This large CO_2 variation affects the N_2/CO_2 ratio at 140 km. The potential sources of the seasonal variation we found are variations (1) of the surface mixing ratio, (2) of the homopause altitude, and (3) of the thermospheric temperature. In this paper, the effect of surface mixing ratio is discussed using Mars Climate Database version 5.3 [Forget et al., 1999; Lewis et al., 1999]. We also address the effects of other sources by considering the seasonal variation of homopause altitude [Slipski et al., 2018] and background temperature [Bougher et al., 2017; Stone et al., 2018].

Automated segmentation of Martian dust storms in MGS/MOC images using a deep learning technique

*Kazunori Ogohara[1], Ryusei Gichu[2]

1. School of Engineering, University of Shiga Prefecture, 2. Graduate School of Engineering, University of Shiga Prefecture

The shape, texture, and size of dust storms and the climatology of these characteristics are important clues to understanding Martian dust storms. The relations between such characteristics and the phases of the variety of atmospheric waves as well as the frequency of textured/curvilinear dust storms and the spatial and seasonal variations of the cumulative area are also worth investigating (Wang 2007; Wang et al. 2011; Guzewich et al. 2015, 2017). However, it is time-consuming to detect all dust storms visually because of the vast number of images taken by just two instruments, the MGS/MOC and MRO/MARCI. It is also difficult to objectively define which features characterize dust storms. Even approximate categorization of dust events into textured dust storms, untextured yet discrete dust storms, and haze depends on the subjective experience of the human observer. For these reasons, visual detection and categorization of the three types of dust storm textures introduced by Kulowski et al. (2017) would not be exactly reproduced by another human viewing and characterizing the images. Furthermore, we perceive a need to update the criteria for detecting dust events, especially obscured ones such as untextured yet discrete dust storms and haze, via visual detection. Therefore, it would be useful to be able to automatically detect dust events, measure their shape, pattern, and size, and improve the objectivity and reproducibility of dust storm detection.
We have developed a novel algorithm for automated segmentation of Martian dust storms using a encoder-decoder type of Convolutional Neural Network. We can separate dust storm areas from the surface and cloud areas in subsets of the global swath images taken by MGS/MOC without any information from other instruments (e.g. MGS/TES). Assuming that segmentation based on authors' experience is the ground truth, 84% of the true dust storm areas in the Arabia Terra is recognized as dust strom. On the other hand, just 69% of the true dust storm areas in the Hellas Basin is correctly recognized as dust storm.

Investigation of variation mechanisms of the Jovian radiation belt using ALMA

*Hajime Kita[1], Hideo Sagawa[2], Takahiro Iino[3], Chihiro Tao[4], Takeshi Kuroda[4], Fuminori Tsuchiya[5], Hiroaki Misawa[5], Yasumasa Kasaba[5], Masaki Fujimoto[1]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency , 2. Faculty of Science, Kyoto Sangyo University, 3. Nature and Science Museum, Tokyo University of Agriculture and Technology, 4. National Institute of Information and Communications Technology, 5. Tohoku University

Jupiter is now considered as an archetype for gas giants widely exist in extrasolar systems. At the outermost layer of this giant planet, there is a 300 km-depth of the nearly isothermal atmospheric layer (stratosphere) above the massive troposphere. Jupiter is also known to be a fast rotator (with a period of 9.9 h) with an enormous magnetic field. High energy particles trapped in the magnetic field form a radiation belt around the planet, much stronger than the terrestrial Van Allen's belt. In the case of the Earth, the primary control factor of the radiation belt is the solar wind, while the solar wind is difficult to impact the Jovian radiation belt because of the intense magnetic field.

It is theoretically expected that the driving mechanism of Jovian radiation belt is due to the interaction between the radiation belt and the upper atmospheric dynamics: neutral wind perturbations and diurnal wind system control the radial diffusion and spatial distribution of the energetic particles, respectively. Therefore, precise measurements of Jovian wind field are essential for not only the dynamics of the stratosphere but also the magnetosphere.

ALMA's unprecedented high spatial-spectral resolution enables us to extract the limb emission of the trace gasses in the Jovian upper stratosphere with a few tens m/s sensitivity. It is well known that HCN and CS have been injected into Jupiter by the Shoemaker-Levy 9 impact and they distribute only in the upper atmosphere (p ~0.4-1mbar). Therefore, the Doppler shift of those molecular emission lines can be used to investigate the dynamics in the upper atmosphere particularly at the limb of the Jovian disk where the line-of-sight direction is equal to the horizontal direction of the atmosphere. Here we present the sensitivity of ALMA observation to measuring Jovian stratospheric winds, and discuss its capability of constraining the magnetosphere-atmosphere coupling. A test analysis is carried out using JVO ALMA archive data.

Jupiter's radio Riddle arcs observed by LWA and Juno

*Kazumasa Imai[1], Charles A. Higgins[2], Masafumi Imai[3], Tracy Clarke[4]

1. Department of Social Design Engineering, National Institute of Technology, Kochi College, 2. Middle Tennessee State University, 3. University of Iowa, 4. Naval Research Laboratory

The Riddle arcs were found in the dynamic spectrum of Jupiter's decametric radio emissions observed by the Voyager spacecraft [Riddle, 1983]. On a frequency time plot these Riddle arcs have the same slope at the same frequency and System III longitude. (The typical System III longitude is about 260 degrees at 20 MHz.) An isolated Riddle arc can be easily recognized inside of the Io-A arc structures. This emission of Riddle arcs was concluded to be from the instantaneous Io flux tube.

The modulation lane method [Imai et al., 1992,1997,2002] is based on the measurements of the slope of modulation lanes on the dynamic spectrum of Jupiter's decametric radio emissions. We usually measure the slope with a 1 MHz bandwidth and determine the most probable value of the lead angle between activated flux tubes to fit the value of the slope. The lead angle is the longitudinal angle between the instantaneous Io flux tube and the previously energized flux tube (real emitting region). The longitudinal location of the magnetic field line of the radio emitting sources can be calculated by this lead angle.

The Long Wavelength Array (LWA) is a low-frequency radio telescope designed to produce high-sensitivity, high-resolution spectra in the frequency range of 10-88 MHz. The sensitivity of the LWA, combined with the low radio frequency interference environment, allows us to observe wide band modulation lanes of Jupiter's decametric radio emissions [Clarke et al., 2014]. We have analyzed the modulation lane data including the Riddle arcs observed by LWA. We found almost all of the Riddle arcs correspond to a zero degree lead angle. This means that the radio sources related to the Riddle arcs are located along the instantaneous Io flux tube. This result is consistent with Riddle's conclusion.

The Juno spacecraft [Bolton et al., 2017] was inserted into polar orbit around Jupiter on 04 July 2016. Juno's highly eccentric orbits have a period of about 53 days with apojove near 113 Jovian radii and perijove near 1.06 Jovian radii. With the advantage of this unique orbit, Juno's Waves instrument [Kurth et al., 2017] is observing for the first time the polar beaming patterns and geometry of Jupiter's decametric radio emission sources. The dynamic spectra recorded by the Waves instrument show the Riddle arcs very clearly. We are continuing to analyze the Waves data to find the Riddle arcs in each Juno orbit. The Riddle arcs can be used as a reference point to understand the latitudinal beaming patterns of Jupiter's decametric radio emissions and the location of radio sources. We present the preliminary results of this study.

[J] Poster | P (Space and Planetary Sciences)：P-CG Complex & General

Tue. May 28, 2019 3:30 PM - 5:00 PM JST | Tue. May 28, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University)

Exploration of Moon, Venus, Mars, Mercury, Jupiter, Saturn, and beyond together with rapid developments of numerical simulations provides us new view of planetary environment. This session collects general contributions of new findings about planetary magnetosphere, ionosphere, and atmosphere. New methodology and technology development studies for future explorations are also welcome. In order to put the common knowledge at different planets into perspective, this session aims to facilitate discussions on comparative planetary environments.

By performing three-dimensional full particle-in-cell plasma simulations, we have been studying a small magnetosphere formed by the interaction between a weakly magnetized small body and the solar wind. In this study, we particularly focus on the electron dynamics at the dayside magnetopause in the equatorial plane. In the simulation model, a weakly magnetized small body is set in the center, and the solar wind having the southward IMF is injected from the boundary of the simulation domain. We define D_p as the distance between the dipole center and a position where the solar wind dynamics pressure balances the magnetic pressure at the dayside. We focus on a small-scale magnetosphere with $\lambda_i/D_p=1$ where we define λ_i as the ion inertia length in the solar wind. When we define R_b as the radius of the sphere, we set $R_b/D_p=0.6$ which implies a relatively large proportion of sphere in the magnetosphere. In the simulation results, we found dawn-dusk asymmetry characteristics of the plasma spatial distribution in the equatorial plane. It is also interesting to observe intense electron flux along the dayside magnetopause in the equator. We found that this intense flux is due to the electrons accelerated by the electric field enhanced at the magnetopause. They encounter the inner region where the southward IMF and the northward magnetic dipole field cancel each other, and they start making meandering motions toward the dawn side between the region of different orientations of the magnetic fields. We examined the mechanism of the intense electron flux in terms of electron trajectory as well electron velocity distribution in detail.

Mars is an important investigation target for understanding atmospheric environments, habitability, and resources of terrestrial planets. On Mars, methane has been detected, and research continues to study its origin and destruction processes by oxidation reaction networks in the atmosphere and on the surface. In order to understand the evolutionary processes of the Martian atmosphere, detailed and systematic observation of spatial and temporal variation of H_2O and oxidants such as HOx, altitude distribution of O_2 is still an important subject. Mars will also give us valuable information on the extent to which biomarkers O_2 and O_3 are formed abiotically in typical earth type planets with mainly CO_2 atmospheres.
Therefore, we are developing the Bread Board Model (BBM) of lightweight, low power consumption 0.48 THz band heterodyne remote sensing detectors for future Mars terahertz sensor missions with micro-satellites. THz/submillimeter-wave band heterodyne spectroscopy with high frequency resolution allows us to derive the altitude distribution of trace molecules of the planetary atmosphere, and this frequency band is less affected by the absorption and scattering by aerosol and dust because of its long wavelength. Also, regardless of the presence or absence of background light sources like the sun day- and night-side atmospheres are observable. In the BBM receiver system, subharmonic mixer (SHM) detectors with Schottky barrier diodes operating at room temperature were adopted and a circularly polarized wave separating device was united for the RF input port (manufactured by Virginia Diodes, USA), which enabled us to integrate two SHM detectors flatly and compactly. The equivalent noise temperature of the SHM mixers was 1400 - 1500 K (DSB) in the 1 - 6 GHz band. The power consumption and weight of the mixer receiver system are 11.2 W (1.66 A) and 0.6 kg. In the local oscillator system, 13 GHz band signals from the dielectric resonator oscillator with the phase locked to 99.9 MHz reference signal from an oven controlled crystal oscillator are multiplied and amplified with the integrated amplifier-multiplier chains (IAMC). For temperature fluctuations of about 3.5 degrees at room temperature, the frequency drift in the 0.48 THz band was about 100 kHz. Based on the performance of this front-end system, atmospheric radiative transfer simulation confirmed that atmospheric minor constituents such as O_3 and H_2O_2 as well as O_2 and H_2O can be sufficiently observed. In this presentation, we will report on these results.

Time response of the self-regulation of H and O escapes from Mars

*Shungo Koyama[1], Naoki Terada[1], Hiromu Nakagawa[1], Takeshi Kuroda[2]

1. Graduate School of Science, Tohoku University, 2. National Institute of Information and Communications Technology

Atmospheric loss from the Martian upper atmosphere plays an essential role in the evolution of the surface environment of Mars. Especially, water loss through the escapes of hydrogen and oxygen is crucial to determine the habitability. It was shown by McElroy. (1972) that Jeans escape flux of H and H2 and nonthermal escape flux of O were regulated to be in the ratio of 2:1 in a converged model, which is called “self-regulation”. However, it was only confirmed in the atmospheric condition of current Mars and time response of the self-regulation is not well understood.

Here we study time-dependent responses of self-regulation system on different atmospheric conditions. We use a 1D time-dependent photochemical model for various atmospheric conditions and parameters, such as atmospheric CO2 pressure, vertical temperature profile and O escape rate.

We find that timescale of the self-regulation is mainly determined by O escape flux and the CO2 pressure. The timescale is inversely proportional to O escape flux, whereas it increases nonlinearly as the CO2 pressure increases. Our calculations also show that when CO2 pressure drops from the current Martian converged condition, H escape flux increases on a timescale of several days and returns to the twice of O escape flux on a timescale of a hundred thousand years. It implies that seasonal drops of the atmospheric pressure due to the CO2 polar ice cap may contribute to the variation of H escape flux. The effect of vertical temperature profile on self-regulation will also be discussed.

Study of ion composition in the polar plume from Mars based on MAVEN observations

*Sakakura Kotaro[1], Kanako Seki[1], Shogo Inui[1], Shotaro Sakai[1], David A Brain[2], James P McFadden[3], Jasper S Halekas[4], Gina A Dibraccio[5], Bruce Jakosky[2]

1. Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo, Tokyo, Japan., 2. Laboratory for Atmospheric and Space Physics, University of Colorado Boulder, Boulder, Colorado, USA., 3. Space Sciences Laboratory, University of California, Berkeley, California, USA., 4. Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa, USA., 5. Solar System Exploration Division, NASA Goddard Space Flight Center, Greenbelt, MD, USA.

Mars climate was warm and had water on its surface about 4 billion years ago, but there are no liquid water on the surface at present. Escape of the atmosphere to space is considered as the main cause of this climate change. However, the mechanism of the large amount of atmospheric loss is far from understood. Ion escape is one of the important candidates of such mechanism. There are three channels of the ion escape, namely, tailward escape, pickup ion, and polar plume. Polar plume ions are accelerated by solar wind electric field and escape to +E hemisphere of the Mars-Sun-Electric field (MSE) coordinates. It is estimated by Dong et al., (2015) that the escape rate is 23% of the total ion escape. This is not negligible in order to understand ion escape from Mars. However, the composition of the plume is unknown. To fully understand the mechanism of polar plume, it is important to study the composition of the plume.
The purpose of this study is to assess the suggested mechanism of the polar plume based on MAVEN (Mars Atmosphere and Volatile EvolutioN) observations. Spatial distribution of the ion number density ratio can be the evidence that plume is accelerated by electric field because the trajectory of accelerated ions depends on the ion mass. Polar plume contains O^+, O_2^+, and CO_2^+ ions. We focused on molecular ions (O_2^+ and CO_2^+) originating from the ionosphere, since O^+ has corona as its source and its spatial distribution becomes complicated. We analyzed observation data by STATIC (Supra Thermal and Thermal Ion Composition) and MAG (magnetometer) onboard MAVEN. STATIC can measure ion distribution functions with mass discrimination. We selected 12 orbits, in which the plume is observed continuously, from two years of data (from December 2014 to December 2016). To derive CO_2^+ number density, we used fitting method invented by Inui et al., (2018). By fitting a log-normal distribution to O_2^+ count data, we eliminated O_2^+ contamination in the CO_2^+ mass range.
In the event on December 23, 2014, MAVEN moved from the dayside solar wind region to nightside induced magnetosphere in the +E hemisphere of the MSE coordinates. During this event, CO_2^+/O_2^+ number density ratio gradually decreased from ~50 % to ~0.2 %. This tendency is consistent with difference of the trajectories of O_2^+ and CO_2^+, when these ions are accelerated from the same position by the solar wind electric field. We also found high density CO_2^+ plume event in which the CO_2^+ number density is ~1 cm^{-3} and its ratio to O_2^+ is ~500 % at the maximum in the dayside solar wind. We will also report on the statistical tendency of the 12 plume events as well as their dependence on solar wind parameters.

Automated detection of Martian dust devils in multiframe images observed by the MER/Spirit rover.

*Kazuki Yajima[1], Kazunori Ogohara[2]

1. Graduate School of Engineering, The University of Shiga Prefecture, 2. School of Engineering, The University of Shiga Prefecture

Currently, on the surface of Mars the activity range of rovers has spread far more than before, and the Mars environment is gradually becoming clear. Dust devil on Mars is a phenomenon in which dust rolled up from the surface rises in a spiral shape.
Martian dust devils occur everywhere, especially in the middle and low latitudes, and there are various types ranging from small ones like the whirlwind commonly seen on the planet to huge ones much more than tornadoes. In addition, dust that dust devils wind up from the surface of the Martian ground may absorb and block sunlight, sometimes changing the global circulation of the Martian atmosphere. Therefore, in order to understand dynamics of the Mars atmosphere it is necessary to grasp the statistical nature of dust devils.
Previous studies were to count how many dust devils are present in a single image. However, in many cases, the same dust devil is seen in multiple images. Therefore, it was difficult to count the number of dust devil occurences accurately. The number of dust devils that actually occurred has been overestimated unless we detect and count dust devils visually. In this technological study, we propose an algorithm for automatically measuring the population of dust devils correctly by combining template matching and comparison of patch standard deviation.

Temperature change during the global dust storm period obtained by ground observation of the Martian mesosphere by infrared heterodyne spectroscopy

*Akiho Miyamoto[1], Hiromu Nakagawa[1], Kosuke Takami[1], Takeshi Kuroda[1,3], Isao Murata[2], Naoki Terada[1], Nao Yoshida[1], Katsushige Toriumi[1], Shohei Aoki[4], Yasumasa Kasaba[1]

1. Graduate School of Sciences in Tohoku University, 2. Graduate School of Environmental Sciences, 3. National Institute of Information and Communications Technology, 4. Royal Belgian Institute for Space Aeronomy(IASB-BIRA)

In the Martian atmosphere, it is revealed by Mars Express observation that the dust rises to the mesosphere (70-80 [km] in altitude) when dust storm occurs and water vaporis simultaneously transported to the same altitude [Maltagliati et al.,2013 , Heavens et al., 2018]. It leads to Hydrogen atom dissipation due to photodissociation of water vapor at high altitude. It is a new discovery that the phenomenon in the mesosphere can affect the evolution of the Martian environment, and the detailed understanding of the mesosphere is necessary. Therefore, we observed the non-LTE CO_2 emission of 10 μm band by ground observation using Tohoku University heterodyne spectrometer "MILAHI" with wavelength resolution of 10^7(velocity resolution 10 [m/s])to clarify the global mean temperature change during the dust storm period of the Martian mesosphere.
Observations were carried out at the summit of Haleakala, Hawaii from June 2018 (solar longitude Ls = 196, Southern Hemisphere Spring) in the global dust storm to November (Ls = 291 Southern Hemisphere Summer). The spatial resolution is 4 arcsec. (Mars: 19.1 arcsec in June, 10.7 arcsec in November). It is the first time continuous observation by infrared heterodyne spectrometer during the dust storm period at the altitude of 70-80 [km].
The temperature was derived for both kinetic temperature by Doppler width of emission and rotation temperature by line intensity [Sonnabend et al., 2008], and the obtained results were compared.
Kinetic temperature was 150 [K] (68% confidence interval -1sigma122/+1sigma 189 [K]) in June (Ls = 196) and 125 [K] (-1sigma 185/+1sigma 201 [K]) in Sptember(Ls=240), it turned out that the temperature decreased from the global dust storm period to the end.
Compared with the results of the general circulation model [Kuroda et al., 2005,2013,2015] in which dust is not transported at the same altitude, it indicated that 126-129 [K] (Ls = 196) and 132-135 [K] (Ls = 240) which was the opposite tendency to our result. It is thought that the temperature rises at Ls = 240, which is close to the perihelion (Ls = 270), because CO_2 radiation and absorption depend on sunlight. However, the observed higher temperature in Ls = 196 was considered to be caused by the heating by the uplifted dust.
For the rotational temperature, the decrease of line strength of about 1/2 was also detected from the dust storm period to the end. The tendency was similar to the kinetic temperature, and it is clear that absorption around emission was obstructed by dense dust in Ls = 196.
We will compare our results with the stellar occultation observation by MAVEN to validate our result. We will also discuss future prospects such as comparison with observation results at different altitudes in the presentation.

Observation of Neptune’ s storms with Pirka telescope

*Yuuki Sato[1], Yukihiro Takahashi[1], Seiko Takagi[1], Mitsuteru Sato[1], Ono Tatsuharu[1]

1. Graduate School of Science, Hokkaido University

A storm more than 4,000 km in diameter occurrs occasionally in Neptune. In previous study, Voyager 2 observed Neptune on May 24, 1989 and discovered a storm of 13,000 km in diameter called Great Dark Spot(GDS). GDS was located in southern hemisphere like Great Red Spot of Jupiter. But GDS became extinct when Hubble Space Telescope observed it in 1994. It is unknown whether it is a sudden thing or storms such as GDS always occur in Neptune. In addition, a huge storm of 9,000 km was observed on July 2 and June 26, 2017 by Keck observatory. It’ s considered that storms of Neptune occurs at mid latitude in the north and south that an ascending air occurs. However, this huge storm occured near the equator. A rotation axis of Neptune is 29.6 degrees, and the storm possibly occurred near the equator because of seasonal change.
Neptune is observed by large telescopes such as Keck observatory and the Hubble Space Telescope, but it is difficult to always use those telescopes for Neptune observation. Therefore Neptune is not observed for long term on a short time scale. I developed the technique to estimate the drift rate and intensity of storms by observing a whole spectrum of Neptune in this study. When seeing is bad, it’ s possible to observe and aquire the observation data of Neptune for a long term on a short time scale. The purpose is to deepen the understanding of the atmosphere convection structure of Neptune by chasing the detailed change of storms.
In this study, I observed Neptune by using 1.6 m Pirka telescope that Hokkaido University owned. The observation time is from August 7, 2017 to January 17, 2018 and from October 22, 2018 to November 26 2018. The wavelength is 650-1050 nm in 2017, and 890, 855 nm in 2018. In this study, I used methane absorption 890 nm. Storms look brighter at 890 nm because the altitude of storms is higher than that of other areas. In addition, the appearance size of storms from the observation point changes by the rotation of Neptune, so an 890 nm flux changes by the rotation. I took the ratio of an 890 nm flux and an 855 nm flux to correct the effect of the earth atmosphere and calculated the theoretical value of the 890 nm flux by the rotation, compared a relative intensity of the 890nm flux in observation with the theoretical value and estimated the drift rate and intensity of the storms.
I assumed storm's area and calculated the 890 nm reflectance of the storms and estimated the drift rete of storms is 24.9˚/day in 2017, and 47.5˚/day in 2018, 890 nm reflectance is 0.217 in 2018, and 0.105 in 2018. Edward Monlter et al. (2019) study shows that 2017 storm is located at 2˚N and the zonal drift speed is 237.4±0.2 m/s or 47.78±0.04 ˚/day. This drift rate is consistent with the drift rate estimated in my study.

The study of Jupiter’s zonal wind formation mechanism based on cumulonimbus observation

*Tatsuharu Ono[1], Yukihiro Takahashi[1], Shigeto Watanabe[1], Seiko Takagi[1]

1. Department of Cosmosciences, Graduate School of Science, Hokkaido University

From Galileo spacecraft observation, it is suggested that the zonal jet is created by the small-scale convection and coupling the small-scale eddies made by the vertical convection that involved cumulonimbus [Gierasch et al., 2000]. From the numerical simulation, the intermittency of cumulonimbus is from a few days to one hundred days. However, the observation period of the previous study by spacecraft is from a few days to one month. It is not enough observation period to reveal the relationship between the cumulonimbus and zonal wind. In our study, we observe the cumulonimbus’s time variation by using methane absorption band filters installed 1.6 m Pirka telescope and compare it with the zonal wind velocity variation to reveal this relationship.

In this presentation, we introduce the observational result by ground-based telescope from Jan to June in 2017. And we show the result that compares with the wind velocity time variation. We observed the 727 nm, 756 nm, and 889 nm filters installed at Multi-Spectral Imager (MSI) (pixel scale = 0.39 arcsec/pix) of the 1.6 m Pirka telescope. In our observation, we estimate the existence of cumulonimbus by using the relationship that high cloud top appears as a bright point because the sunlight reflected at cloud top before it is completely absorbed by Jupiter’s atmosphere. We operated the Gaussian High-Pass-Filtering to identify the position of cloud whose cloud top altitude is high like a cumulonimbus. For our observation data, the high cloud top altitude point is extracted in the resolution of one pixel. From the simulation, the intermittency of cumulonimbus would be about 5-100days [Sugiyama et al.,2014]. So, we tried to operate the observation once in a few days. We achieved to operate the observation total 61 times. The interval of observation ranged from successive days to over one week. The average seeing is about 3.0 arcsec. From these observation result,we find the high cloud top altitude point as a possible candidate of cumulonimbus at about latitude -12° and system III longitude 120° on April 20th, 2017. These observation conditions were 2.16 arcsec, equal to about 5000km spatial resolution on Jupiter, and observation covered region was from system III 90° to 180°. Compared with the amateur images that obtained the same day, it is confirmed that the white and bright pattern appeared at that same coordinate position. We observed Jupiter once in every three days from April 20th to the next couple of weeks. However, we couldn’t detect the bright point from data when observed April 23rd, 2017. Compared with the amateur images, we couldn’t confirm the bright and white point around that position. And on April 16th, 2017, from the amateur images, we couldn’t find the bright and white point at the same position. From these results, the lifetime of cumulonimbus at about latitude -12° and system III longitude 120° is about 6 days. We use amateur images to estimate the wind velocity. We compare the wind velocity variation about previous and late date of April 20. From this result, when cumulonimbus is generated, the wind velocity accelerates following the hypothesis. In the other hand, when cumulonimbus is disappeared, the wind velocity decelerates. In the other case, we couldn’t find this relationship. However, the number of data that can compare the wind and cumulonimbus time variation is few. And the accuracy of wind velocity estimated is not enough. So it is not enough to verify the hypothesis suggested by Gierasch and Ingersoll.

Development of a radial diffusion model of Jovian inner magnetospheric plasma aimed at comparison with HISAKI satellite observation

*Kazuki Yamaguchi[1], Takeshi Sakanoi[1], Fuminori Tsuchiya[1], Masato Kagitani[1], Ryoichi Koga[1], Tomoki Kimura[2]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. Frontier Research Institute for Interdisciplinary Sciences, Tohoku University

We focus on the development of a diffusion model that estimates interaction and radial transport of various ions and electron in Jovian inner magnetosphere to understand the balance of mass and energy of plasmas and their temporal changes. We also verify the model results with the data obtained by the extreme ultraviolet spectroscope satellite HISAKI.
Jovian first satellite Io has active volcanoes and releases the plasma of the volcanic gas origin to the inner magnetosphere. The plasma is distributed in donut shape along the revolution orbit of Io by co-rotating with Jupiter, and it is called Io plasma torus. 90% of the total mass of Jovian magnetosphere plasma is supplied from Io, and it is transported on the time scale of several tens of days in the radial direction while obtaining energy from the angular momentum of Jovian rotation. Revealing the mass and energy balance of plasma in Jovian inner magnetosphere is an important to understand the macroscopic physical phenomena of the magnetosphere.
The radial distribution model of steady state Jovian magnetospheric plasma was developed based on observation results of Voyager 1, Voyager 2, Cassini spacecrafts. However, there is no report on a model that explains time variation of radial distribution of ions and electrons.

In this study, we are developing a model with the Fokker-Planck equation that can track mass and energy balance of major heavy ions of Io origin (O^+,O^{2+},S^+,S^{2+},S^{3+}) and time evolution of radial transport. We modified the steady state model foe mass and energy transport in Jovian magnetosphere by Delamere *et al.* (2005) to estimate time variations by the Forward Time Central Space (FTCS) method. From Delamere & Bagenal (2003), considering the chemical interaction between ions and electrons by charge exchange, we cited coefficients of electron impact ionization, electron recombination, Coulomb interaction, and radiation due to electron collision excitation. Radiative rate is calculated from the CHIANTI database.The initial temperature and density values of each ion and thermal electron were adopted from HISAKI's observation data in November 2013 when the volcano activity was quiet [Yoshioka *et al.*, 2018]. We assumed that the distribution of neutral atoms (O, S) depends only on the radial direction. For inner boundary conditions, the spatial differentiation of the density was 0 and the ion temperature was 60 eV at 6 R_J. For outer boundary conditions, at 30 R_J, both density and temperature match with values calculated by the function obtained from HISAKI's observation. We compared the model results with the HISAKI's observation data in the region of 6-9 R_J under the steady state conditions. We obtained that the number density of ions with higher valence number tend to be greater than that of observation result. For example, the number density of O^{2+} was 1.2 to 2.0 times greater than observed value. The model estimated the electron temperature to be 6 to 8 eV that was several eV higher than observation value. We considered that the increase in number density of high valence number ions may be due to overestimation of electron impact ionization. We also estimated higher electron temperature than observed value. In addition, we obtained that the temperature with low valence ions was higher than observation value, for example, O^+ temperature was higher than 280 eV at 12 R_J. This discrepancy may be

©2019. Japan Geoscience Union. All Right Reserved.

caused by the heating of pick-up ion gained by high electron temperature. In this presentation, we give detailed comparison between model and observation and quantitative verification.

Pitch angle scattering due to elastic collisions between magnetospheric 500eV-50keV electrons and neutral H_2O originated from Enceladus: Test particle simulation

*Hiroyasu Tadokoro[1], Yuto Katoh[2]

1. Musashino University, 2. Tohoku University

Water group neutrals (H_2O, OH, and O) in Saturn’ s inner magnetosphere play the dominant role in loss of energetic electrons and ions because of abundance of the neutrals [e.g., *Paranicas et al.,* 2007; *Sittler et al.,* 2008]. The observations of injected plasmas in the inner magnetosphere suggest that these particles do not survive very long time due to the neutral cloud originated from Enceladus [e.g., Paranicas et al., 2007; 2008]. Thus, the previous studies suggested that the neutral cloud contributes to loss processes of plasma in the inner magnetosphere. However, little has been reported on a quantitative study of the electron loss process due to electron-neutral collisions.

In this study, we focus on the elastic collisional loss process with neutral H_2O originated from Enceladus. Conducting one dimensional test particle simulation, Tadokoro et al., [2014] examined the time variations of equatorial electron pitch angle distribution and electrons within loss cone through 1keV electron pitch angle scattering due to elastic collisions around Enceladus. The result showed that the electrons of 11.4 % are lost in ~380 sec. The time corresponds to the time scale of the co-rotation of the flux tube passing through the region of the dense H_2O in the vicinity of Enceladus. Assuming the uniform azimuth H2O density structure in the Enceladus torus, they estimated the electron loss rate of 33% during one co-rotation.

Next remaining issue is a calculation of energy dependent electron loss rate. We show the loss rates through pitch angle scattering of electrons with 500 eV –50keV and the comparison of the loss rates between the high (in the vicinity of Enceladus) and low (in the Enceladus torus) H_2O density regions. We also show the calculation errors by making several times calculations.

Study of Jovian atmosphere dynamics by a multi-band imaging observation

Hayate Ito[1], Sumito Hirota[2], Isshi Tabe[3], *Hidehiko Suzuki[1]

1. Meiji university, 2. Kawasaki municipal science museum, 3. Association of Lunar and Planetary Observers in Japan

There are various structures on the surface atmosphere of Jupiter. For example, ‘zones’ or ‘belts’ and vortex structures such as great red spot (GRS) are widely known as quasi-permanent features. Many observations from the ground have revealed dynamical variations both in spatial scale and in visual color for these structures. The changes in apparent color of these structures often occur accompanying dynamical processes such as deformation and change in vorticity. Therefore, it would be a key to understanding Jovian atmosphere dynamics to monitor the change in color of surface structures. The objective of this study is to reveal the mechanism of the variations in Jovian surface structures by a ground-based observation with a multi-band imaging system.
We have developed a multi-band imaging system which can simultaneously obtain both spectral data and spatiotemporal variations of structures. Seven bands in visible range have been selected for the routine observation based on the results from previous spectroscopic works. We have determined the relative sensitivity among these bands which is essential to synthesize a precise natural color image from 7 images. In this talk, we report the initial observation results obtained by the system. The results of the validation for these results by comparing with previous spectroscopic studies using Cassini spacecraft and Hubble space telescope are also shown.

Examination of the relation between Jupiter's inner magnetosphere and magnetic reconfiguration events

*Hiroaki Misawa[1]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University

It is known that Jupiter's synchrotron radiation (JSR) has information on dynamics of the deep inner magnetosphere. We have made JSR observations in the decimeter radio wavelength more than a decade, and has showed that JSR generally shows short term variations by more than several tens percent with the time scale of days to weeks. A plausible causality of such the short term variations is due to solar UV/EUV variations; i.e., the solar UV/EUV heating for Jupiter's upper atmosphere drives neutral wind perturbations, and the induced dynamo electric field leads to enhancement of radial diffusion of relativistic electrons in the inner magentosphere. and then JSR shows variations. This scenario was initially proposed by Brice and McDonough [1973] and observationally confirmed by Miyoshi et al. [1999], Tsuchiya et al. [2011] and Kita et al., [2013] which is so to speak, an externally driving process. However, this scenario cannot be always applicable to any short term JSR variations, particularly fast variations with the time scale within a few days, and any other processes are required (Kita, 2015; Tsuchiya et al., 2019).
As a process which might explain such a fast variation in Jupiter's magnetosphere, an internally driving process, so-called 'substorm like event', is known (see Louarn et al., 2014). This phenomena is interpreted as a magnetic reconfiguration event occurred in the Jupiter's magnetotail region. Although it is revealed that major magnetic reconfiguration events generally affect the whole magnesphere from 10 to 80-120 Rj (Jupiter's radii), however, it has not been known whether the events affect the inner magnetosphere within 2 Rj.
In order to reveal unknown dynamics of the fast variations in JSR, we have tried to examine relationship between the fast variations and magnetic reconfiguration events. In this study we have used the plasma data explored by the Galileo orbiter in Jupiter's magnetosphere and also Jupiter's particular radio wave component in the hectrometer wave range (see Misawa et al., 2018) for searching magnetic reconfiguration events, and we have compared them with the daily JSR monitoring data at 327MHz observed with the radio telescopes of ISEE, Nagoya University, Japan. In the presentation, we will show results of the examination and discuss a linkage possibility between Jupiter's inner magnetosphere and magnetotail region.

Effects of the charged particles of solar wind on planetary atmospheres

*Shinji Karasawa[1]

1. Miyagi National College of Technology Professor emeritus

The charged particle of H^+ is radiated at an average speed of about 450km/sec from the Sun. It has a rotating component (2km/sec) of the Sun’s rotation. There is no geomagnetic field caused from the inner core of Venus. The charged particles of solar-wind those possess large kinetic momentum. Those collide to the thick atmospheric molecules facing the Sun of Venus. The collisions of the solar wind with angular momentum of anti-clockwise direction causes super-rotation of Venus in the direction of clockwise.
Titan has a super-rotation of 120 m/s at an altitude of 120km. Radius 1.1 million km of the Titan's orbital passes through the stretched portion of the magnetosphere of Saturn at 1.2 million km. Titan's orbital is running through in a part of magnetosphere of Saturn. The rotation period of Titan is about 16 days that is the same as the revolution period of Titan by gravitational lock. So, the surface of Titan receives shower of the charged particle of H^+ in Saturn's magnetosphere at repeating period of 10.7 hours. The movement speed of the magnetosphere in the orbit of the Titan is 200 km/sec**.** The super-rotation of Titan is caused by the difference of moving speed of the H^+ shower on surface of Titan facing Saturn’s side and the backside. Maximum difference of moving speed of the shower is 843 m/sec in counter-clockwise direction. [Website by S. Karasawa,

[J] Poster | P (Space and Planetary Sciences)：P-CG Complex & General

Tue. May 28, 2019 5:15 PM - 6:30 PM JST | Tue. May 28, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University)

Exploration of Moon, Venus, Mars, Mercury, Jupiter, Saturn, and beyond together with rapid developments of numerical simulations provides us new view of planetary environment. This session collects general contributions of new findings about planetary magnetosphere, ionosphere, and atmosphere. New methodology and technology development studies for future explorations are also welcome. In order to put the common knowledge at different planets into perspective, this session aims to facilitate discussions on comparative planetary environments.

By performing three-dimensional full particle-in-cell plasma simulations, we have been studying a small magnetosphere formed by the interaction between a weakly magnetized small body and the solar wind. In this study, we particularly focus on the electron dynamics at the dayside magnetopause in the equatorial plane. In the simulation model, a weakly magnetized small body is set in the center, and the solar wind having the southward IMF is injected from the boundary of the simulation domain. We define D_p as the distance between the dipole center and a position where the solar wind dynamics pressure balances the magnetic pressure at the dayside. We focus on a small-scale magnetosphere with $\lambda_i/D_p=1$ where we define λ_i as the ion inertia length in the solar wind. When we define R_b as the radius of the sphere, we set $R_b/D_p=0.6$ which implies a relatively large proportion of sphere in the magnetosphere. In the simulation results, we found dawn-dusk asymmetry characteristics of the plasma spatial distribution in the equatorial plane. It is also interesting to observe intense electron flux along the dayside magnetopause in the equator. We found that this intense flux is due to the electrons accelerated by the electric field enhanced at the magnetopause. They encounter the inner region where the southward IMF and the northward magnetic dipole field cancel each other, and they start making meandering motions toward the dawn side between the region of different orientations of the magnetic fields. We examined the mechanism of the intense electron flux in terms of electron trajectory as well electron velocity distribution in detail.

Mars is an important investigation target for understanding atmospheric environments, habitability, and resources of terrestrial planets. On Mars, methane has been detected, and research continues to study its origin and destruction processes by oxidation reaction networks in the atmosphere and on the surface. In order to understand the evolutionary processes of the Martian atmosphere, detailed and systematic observation of spatial and temporal variation of H_2O and oxidants such as HOx, altitude distribution of O_2 is still an important subject. Mars will also give us valuable information on the extent to which biomarkers O_2 and O_3 are formed abiotically in typical earth type planets with mainly CO_2 atmospheres.
Therefore, we are developing the Bread Board Model (BBM) of lightweight, low power consumption 0.48 THz band heterodyne remote sensing detectors for future Mars terahertz sensor missions with micro-satellites. THz/submillimeter-wave band heterodyne spectroscopy with high frequency resolution allows us to derive the altitude distribution of trace molecules of the planetary atmosphere, and this frequency band is less affected by the absorption and scattering by aerosol and dust because of its long wavelength. Also, regardless of the presence or absence of background light sources like the sun day- and night-side atmospheres are observable. In the BBM receiver system, subharmonic mixer (SHM) detectors with Schottky barrier diodes operating at room temperature were adopted and a circularly polarized wave separating device was united for the RF input port (manufactured by Virginia Diodes, USA), which enabled us to integrate two SHM detectors flatly and compactly. The equivalent noise temperature of the SHM mixers was 1400 - 1500 K (DSB) in the 1 - 6 GHz band. The power consumption and weight of the mixer receiver system are 11.2 W (1.66 A) and 0.6 kg. In the local oscillator system, 13 GHz band signals from the dielectric resonator oscillator with the phase locked to 99.9 MHz reference signal from an oven controlled crystal oscillator are multiplied and amplified with the integrated amplifier-multiplier chains (IAMC). For temperature fluctuations of about 3.5 degrees at room temperature, the frequency drift in the 0.48 THz band was about 100 kHz. Based on the performance of this front-end system, atmospheric radiative transfer simulation confirmed that atmospheric minor constituents such as O_3 and H_2O_2 as well as O_2 and H_2O can be sufficiently observed. In this presentation, we will report on these results.

Time response of the self-regulation of H and O escapes from Mars

*Shungo Koyama[1], Naoki Terada[1], Hiromu Nakagawa[1], Takeshi Kuroda[2]

1. Graduate School of Science, Tohoku University, 2. National Institute of Information and Communications Technology

Atmospheric loss from the Martian upper atmosphere plays an essential role in the evolution of the surface environment of Mars. Especially, water loss through the escapes of hydrogen and oxygen is crucial to determine the habitability. It was shown by McElroy. (1972) that Jeans escape flux of H and H2 and nonthermal escape flux of O were regulated to be in the ratio of 2:1 in a converged model, which is called “self-regulation”. However, it was only confirmed in the atmospheric condition of current Mars and time response of the self-regulation is not well understood.

Here we study time-dependent responses of self-regulation system on different atmospheric conditions. We use a 1D time-dependent photochemical model for various atmospheric conditions and parameters, such as atmospheric CO2 pressure, vertical temperature profile and O escape rate.

We find that timescale of the self-regulation is mainly determined by O escape flux and the CO2 pressure. The timescale is inversely proportional to O escape flux, whereas it increases nonlinearly as the CO2 pressure increases. Our calculations also show that when CO2 pressure drops from the current Martian converged condition, H escape flux increases on a timescale of several days and returns to the twice of O escape flux on a timescale of a hundred thousand years. It implies that seasonal drops of the atmospheric pressure due to the CO2 polar ice cap may contribute to the variation of H escape flux. The effect of vertical temperature profile on self-regulation will also be discussed.

Study of ion composition in the polar plume from Mars based on MAVEN observations

*Sakakura Kotaro[1], Kanako Seki[1], Shogo Inui[1], Shotaro Sakai[1], David A Brain[2], James P McFadden[3], Jasper S Halekas[4], Gina A Dibraccio[5], Bruce Jakosky[2]

1. Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo, Tokyo, Japan., 2. Laboratory for Atmospheric and Space Physics, University of Colorado Boulder, Boulder, Colorado, USA., 3. Space Sciences Laboratory, University of California, Berkeley, California, USA., 4. Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa, USA., 5. Solar System Exploration Division, NASA Goddard Space Flight Center, Greenbelt, MD, USA.

Mars climate was warm and had water on its surface about 4 billion years ago, but there are no liquid water on the surface at present. Escape of the atmosphere to space is considered as the main cause of this climate change. However, the mechanism of the large amount of atmospheric loss is far from understood. Ion escape is one of the important candidates of such mechanism. There are three channels of the ion escape, namely, tailward escape, pickup ion, and polar plume. Polar plume ions are accelerated by solar wind electric field and escape to +E hemisphere of the Mars-Sun-Electric field (MSE) coordinates. It is estimated by Dong et al., (2015) that the escape rate is 23% of the total ion escape. This is not negligible in order to understand ion escape from Mars. However, the composition of the plume is unknown. To fully understand the mechanism of polar plume, it is important to study the composition of the plume.
The purpose of this study is to assess the suggested mechanism of the polar plume based on MAVEN (Mars Atmosphere and Volatile EvolutioN) observations. Spatial distribution of the ion number density ratio can be the evidence that plume is accelerated by electric field because the trajectory of accelerated ions depends on the ion mass. Polar plume contains O^+, O_2^+, and CO_2^+ ions. We focused on molecular ions (O_2^+ and CO_2^+) originating from the ionosphere, since O^+ has corona as its source and its spatial distribution becomes complicated. We analyzed observation data by STATIC (Supra Thermal and Thermal Ion Composition) and MAG (magnetometer) onboard MAVEN. STATIC can measure ion distribution functions with mass discrimination. We selected 12 orbits, in which the plume is observed continuously, from two years of data (from December 2014 to December 2016). To derive CO_2^+ number density, we used fitting method invented by Inui et al., (2018). By fitting a log-normal distribution to O_2^+ count data, we eliminated O_2^+ contamination in the CO_2^+ mass range.
In the event on December 23, 2014, MAVEN moved from the dayside solar wind region to nightside induced magnetosphere in the +E hemisphere of the MSE coordinates. During this event, CO_2^+/O_2^+ number density ratio gradually decreased from ~50 % to ~0.2 %. This tendency is consistent with difference of the trajectories of O_2^+ and CO_2^+, when these ions are accelerated from the same position by the solar wind electric field. We also found high density CO_2^+ plume event in which the CO_2^+ number density is ~1 cm^{-3} and its ratio to O_2^+ is ~500 % at the maximum in the dayside solar wind. We will also report on the statistical tendency of the 12 plume events as well as their dependence on solar wind parameters.

Automated detection of Martian dust devils in multiframe images observed by the MER/Spirit rover.

*Kazuki Yajima[1], Kazunori Ogohara[2]

1. Graduate School of Engineering, The University of Shiga Prefecture, 2. School of Engineering, The University of Shiga Prefecture

Currently, on the surface of Mars the activity range of rovers has spread far more than before, and the Mars environment is gradually becoming clear. Dust devil on Mars is a phenomenon in which dust rolled up from the surface rises in a spiral shape.
Martian dust devils occur everywhere, especially in the middle and low latitudes, and there are various types ranging from small ones like the whirlwind commonly seen on the planet to huge ones much more than tornadoes. In addition, dust that dust devils wind up from the surface of the Martian ground may absorb and block sunlight, sometimes changing the global circulation of the Martian atmosphere. Therefore, in order to understand dynamics of the Mars atmosphere it is necessary to grasp the statistical nature of dust devils.
Previous studies were to count how many dust devils are present in a single image. However, in many cases, the same dust devil is seen in multiple images. Therefore, it was difficult to count the number of dust devil occurences accurately. The number of dust devils that actually occurred has been overestimated unless we detect and count dust devils visually. In this technological study, we propose an algorithm for automatically measuring the population of dust devils correctly by combining template matching and comparison of patch standard deviation.

Temperature change during the global dust storm period obtained by ground observation of the Martian mesosphere by infrared heterodyne spectroscopy

*Akiho Miyamoto[1], Hiromu Nakagawa[1], Kosuke Takami[1], Takeshi Kuroda[1,3], Isao Murata[2], Naoki Terada[1], Nao Yoshida[1], Katsushige Toriumi[1], Shohei Aoki[4], Yasumasa Kasaba[1]

1. Graduate School of Sciences in Tohoku University, 2. Graduate School of Environmental Sciences, 3. National Institute of Information and Communications Technology, 4. Royal Belgian Institute for Space Aeronomy(IASB-BIRA)

In the Martian atmosphere, it is revealed by Mars Express observation that the dust rises to the mesosphere (70-80 [km] in altitude) when dust storm occurs and water vaporis simultaneously transported to the same altitude [Maltagliati et al.,2013 , Heavens et al., 2018]. It leads to Hydrogen atom dissipation due to photodissociation of water vapor at high altitude. It is a new discovery that the phenomenon in the mesosphere can affect the evolution of the Martian environment, and the detailed understanding of the mesosphere is necessary. Therefore, we observed the non-LTE CO_2 emission of 10 μm band by ground observation using Tohoku University heterodyne spectrometer "MILAHI" with wavelength resolution of 10^7(velocity resolution 10 [m/s])to clarify the global mean temperature change during the dust storm period of the Martian mesosphere.
Observations were carried out at the summit of Haleakala, Hawaii from June 2018 (solar longitude Ls = 196, Southern Hemisphere Spring) in the global dust storm to November (Ls = 291 Southern Hemisphere Summer). The spatial resolution is 4 arcsec. (Mars: 19.1 arcsec in June, 10.7 arcsec in November). It is the first time continuous observation by infrared heterodyne spectrometer during the dust storm period at the altitude of 70-80 [km].
The temperature was derived for both kinetic temperature by Doppler width of emission and rotation temperature by line intensity [Sonnabend et al., 2008], and the obtained results were compared.
Kinetic temperature was 150 [K] (68% confidence interval -1sigma122/+1sigma 189 [K]) in June (Ls = 196) and 125 [K] (-1sigma 185/+1sigma 201 [K]) in Sptember(Ls=240), it turned out that the temperature decreased from the global dust storm period to the end.
Compared with the results of the general circulation model [Kuroda et al., 2005,2013,2015] in which dust is not transported at the same altitude, it indicated that 126-129 [K] (Ls = 196) and 132-135 [K] (Ls = 240) which was the opposite tendency to our result. It is thought that the temperature rises at Ls = 240, which is close to the perihelion (Ls = 270), because CO_2 radiation and absorption depend on sunlight. However, the observed higher temperature in Ls = 196 was considered to be caused by the heating by the uplifted dust.
For the rotational temperature, the decrease of line strength of about 1/2 was also detected from the dust storm period to the end. The tendency was similar to the kinetic temperature, and it is clear that absorption around emission was obstructed by dense dust in Ls = 196.
We will compare our results with the stellar occultation observation by MAVEN to validate our result. We will also discuss future prospects such as comparison with observation results at different altitudes in the presentation.

Observation of Neptune’ s storms with Pirka telescope

*Yuuki Sato[1], Yukihiro Takahashi[1], Seiko Takagi[1], Mitsuteru Sato[1], Ono Tatsuharu[1]

1. Graduate School of Science, Hokkaido University

A storm more than 4,000 km in diameter occurrs occasionally in Neptune. In previous study, Voyager 2 observed Neptune on May 24, 1989 and discovered a storm of 13,000 km in diameter called Great Dark Spot(GDS). GDS was located in southern hemisphere like Great Red Spot of Jupiter. But GDS became extinct when Hubble Space Telescope observed it in 1994. It is unknown whether it is a sudden thing or storms such as GDS always occur in Neptune. In addition, a huge storm of 9,000 km was observed on July 2 and June 26, 2017 by Keck observatory. It’ s considered that storms of Neptune occurs at mid latitude in the north and south that an ascending air occurs. However, this huge storm occured near the equator. A rotation axis of Neptune is 29.6 degrees, and the storm possibly occurred near the equator because of seasonal change.
Neptune is observed by large telescopes such as Keck observatory and the Hubble Space Telescope, but it is difficult to always use those telescopes for Neptune observation. Therefore Neptune is not observed for long term on a short time scale. I developed the technique to estimate the drift rate and intensity of storms by observing a whole spectrum of Neptune in this study. When seeing is bad, it’ s possible to observe and aquire the observation data of Neptune for a long term on a short time scale. The purpose is to deepen the understanding of the atmosphere convection structure of Neptune by chasing the detailed change of storms.
In this study, I observed Neptune by using 1.6 m Pirka telescope that Hokkaido University owned. The observation time is from August 7, 2017 to January 17, 2018 and from October 22, 2018 to November 26 2018. The wavelength is 650-1050 nm in 2017, and 890, 855 nm in 2018. In this study, I used methane absorption 890 nm. Storms look brighter at 890 nm because the altitude of storms is higher than that of other areas. In addition, the appearance size of storms from the observation point changes by the rotation of Neptune, so an 890 nm flux changes by the rotation. I took the ratio of an 890 nm flux and an 855 nm flux to correct the effect of the earth atmosphere and calculated the theoretical value of the 890 nm flux by the rotation, compared a relative intensity of the 890nm flux in observation with the theoretical value and estimated the drift rate and intensity of the storms.
I assumed storm's area and calculated the 890 nm reflectance of the storms and estimated the drift rete of storms is 24.9˚/day in 2017, and 47.5˚/day in 2018, 890 nm reflectance is 0.217 in 2018, and 0.105 in 2018. Edward Monlter et al. (2019) study shows that 2017 storm is located at 2˚N and the zonal drift speed is 237.4±0.2 m/s or 47.78±0.04 ˚/day. This drift rate is consistent with the drift rate estimated in my study.

The study of Jupiter’s zonal wind formation mechanism based on cumulonimbus observation

*Tatsuharu Ono[1], Yukihiro Takahashi[1], Shigeto Watanabe[1], Seiko Takagi[1]

1. Department of Cosmosciences, Graduate School of Science, Hokkaido University

From Galileo spacecraft observation, it is suggested that the zonal jet is created by the small-scale convection and coupling the small-scale eddies made by the vertical convection that involved cumulonimbus [Gierasch et al., 2000]. From the numerical simulation, the intermittency of cumulonimbus is from a few days to one hundred days. However, the observation period of the previous study by spacecraft is from a few days to one month. It is not enough observation period to reveal the relationship between the cumulonimbus and zonal wind. In our study, we observe the cumulonimbus’s time variation by using methane absorption band filters installed 1.6 m Pirka telescope and compare it with the zonal wind velocity variation to reveal this relationship.

In this presentation, we introduce the observational result by ground-based telescope from Jan to June in 2017. And we show the result that compares with the wind velocity time variation. We observed the 727 nm, 756 nm, and 889 nm filters installed at Multi-Spectral Imager (MSI) (pixel scale = 0.39 arcsec/pix) of the 1.6 m Pirka telescope. In our observation, we estimate the existence of cumulonimbus by using the relationship that high cloud top appears as a bright point because the sunlight reflected at cloud top before it is completely absorbed by Jupiter’s atmosphere. We operated the Gaussian High-Pass-Filtering to identify the position of cloud whose cloud top altitude is high like a cumulonimbus. For our observation data, the high cloud top altitude point is extracted in the resolution of one pixel. From the simulation, the intermittency of cumulonimbus would be about 5-100days [Sugiyama et al.,2014]. So, we tried to operate the observation once in a few days. We achieved to operate the observation total 61 times. The interval of observation ranged from successive days to over one week. The average seeing is about 3.0 arcsec. From these observation result,we find the high cloud top altitude point as a possible candidate of cumulonimbus at about latitude -12° and system III longitude 120° on April 20th, 2017. These observation conditions were 2.16 arcsec, equal to about 5000km spatial resolution on Jupiter, and observation covered region was from system III 90° to 180°. Compared with the amateur images that obtained the same day, it is confirmed that the white and bright pattern appeared at that same coordinate position. We observed Jupiter once in every three days from April 20th to the next couple of weeks. However, we couldn’t detect the bright point from data when observed April 23rd, 2017. Compared with the amateur images, we couldn’t confirm the bright and white point around that position. And on April 16th, 2017, from the amateur images, we couldn’t find the bright and white point at the same position. From these results, the lifetime of cumulonimbus at about latitude -12° and system III longitude 120° is about 6 days. We use amateur images to estimate the wind velocity. We compare the wind velocity variation about previous and late date of April 20. From this result, when cumulonimbus is generated, the wind velocity accelerates following the hypothesis. In the other hand, when cumulonimbus is disappeared, the wind velocity decelerates. In the other case, we couldn’t find this relationship. However, the number of data that can compare the wind and cumulonimbus time variation is few. And the accuracy of wind velocity estimated is not enough. So it is not enough to verify the hypothesis suggested by Gierasch and Ingersoll.

Development of a radial diffusion model of Jovian inner magnetospheric plasma aimed at comparison with HISAKI satellite observation

*Kazuki Yamaguchi[1], Takeshi Sakanoi[1], Fuminori Tsuchiya[1], Masato Kagitani[1], Ryoichi Koga[1], Tomoki Kimura[2]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. Frontier Research Institute for Interdisciplinary Sciences, Tohoku University

We focus on the development of a diffusion model that estimates interaction and radial transport of various ions and electron in Jovian inner magnetosphere to understand the balance of mass and energy of plasmas and their temporal changes. We also verify the model results with the data obtained by the extreme ultraviolet spectroscope satellite HISAKI.
Jovian first satellite Io has active volcanoes and releases the plasma of the volcanic gas origin to the inner magnetosphere. The plasma is distributed in donut shape along the revolution orbit of Io by co-rotating with Jupiter, and it is called Io plasma torus. 90% of the total mass of Jovian magnetosphere plasma is supplied from Io, and it is transported on the time scale of several tens of days in the radial direction while obtaining energy from the angular momentum of Jovian rotation. Revealing the mass and energy balance of plasma in Jovian inner magnetosphere is an important to understand the macroscopic physical phenomena of the magnetosphere.
The radial distribution model of steady state Jovian magnetospheric plasma was developed based on observation results of Voyager 1, Voyager 2, Cassini spacecrafts. However, there is no report on a model that explains time variation of radial distribution of ions and electrons.

In this study, we are developing a model with the Fokker-Planck equation that can track mass and energy balance of major heavy ions of Io origin (O^+,O^{2+},S^+,S^{2+},S^{3+}) and time evolution of radial transport. We modified the steady state model foe mass and energy transport in Jovian magnetosphere by Delamere *et al.* (2005) to estimate time variations by the Forward Time Central Space (FTCS) method. From Delamere & Bagenal (2003), considering the chemical interaction between ions and electrons by charge exchange, we cited coefficients of electron impact ionization, electron recombination, Coulomb interaction, and radiation due to electron collision excitation. Radiative rate is calculated from the CHIANTI database.The initial temperature and density values of each ion and thermal electron were adopted from HISAKI's observation data in November 2013 when the volcano activity was quiet [Yoshioka *et al.*, 2018]. We assumed that the distribution of neutral atoms (O, S) depends only on the radial direction. For inner boundary conditions, the spatial differentiation of the density was 0 and the ion temperature was 60 eV at 6 R_J. For outer boundary conditions, at 30 R_J, both density and temperature match with values calculated by the function obtained from HISAKI's observation. We compared the model results with the HISAKI's observation data in the region of 6-9 R_J under the steady state conditions. We obtained that the number density of ions with higher valence number tend to be greater than that of observation result. For example, the number density of O^{2+} was 1.2 to 2.0 times greater than observed value. The model estimated the electron temperature to be 6 to 8 eV that was several eV higher than observation value. We considered that the increase in number density of high valence number ions may be due to overestimation of electron impact ionization. We also estimated higher electron temperature than observed value. In addition, we obtained that the temperature with low valence ions was higher than observation value, for example, O^+ temperature was higher than 280 eV at 12 R_J. This discrepancy may be

caused by the heating of pick-up ion gained by high electron temperature. In this presentation, we give detailed comparison between model and observation and quantitative verification.

Pitch angle scattering due to elastic collisions between magnetospheric 500eV-50keV electrons and neutral H_2O originated from Enceladus: Test particle simulation

*Hiroyasu Tadokoro[1], Yuto Katoh[2]

1. Musashino University, 2. Tohoku University

Water group neutrals (H_2O, OH, and O) in Saturn’ s inner magnetosphere play the dominant role in loss of energetic electrons and ions because of abundance of the neutrals [e.g., *Paranicas et al.,* 2007; *Sittler et al.,* 2008]. The observations of injected plasmas in the inner magnetosphere suggest that these particles do not survive very long time due to the neutral cloud originated from Enceladus [e.g., Paranicas et al., 2007; 2008]. Thus, the previous studies suggested that the neutral cloud contributes to loss processes of plasma in the inner magnetosphere. However, little has been reported on a quantitative study of the electron loss process due to electron-neutral collisions.

In this study, we focus on the elastic collisional loss process with neutral H_2O originated from Enceladus. Conducting one dimensional test particle simulation, Tadokoro et al., [2014] examined the time variations of equatorial electron pitch angle distribution and electrons within loss cone through 1keV electron pitch angle scattering due to elastic collisions around Enceladus. The result showed that the electrons of 11.4 % are lost in ~380 sec. The time corresponds to the time scale of the co-rotation of the flux tube passing through the region of the dense H_2O in the vicinity of Enceladus. Assuming the uniform azimuth H2O density structure in the Enceladus torus, they estimated the electron loss rate of 33% during one co-rotation.

Next remaining issue is a calculation of energy dependent electron loss rate. We show the loss rates through pitch angle scattering of electrons with 500 eV –50keV and the comparison of the loss rates between the high (in the vicinity of Enceladus) and low (in the Enceladus torus) H_2O density regions. We also show the calculation errors by making several times calculations.

Study of Jovian atmosphere dynamics by a multi-band imaging observation

Hayate Ito[1], Sumito Hirota[2], Isshi Tabe[3], *Hidehiko Suzuki[1]

1. Meiji university, 2. Kawasaki municipal science museum, 3. Association of Lunar and Planetary Observers in Japan

There are various structures on the surface atmosphere of Jupiter. For example, ‘zones’ or ‘belts’ and vortex structures such as great red spot (GRS) are widely known as quasi-permanent features. Many observations from the ground have revealed dynamical variations both in spatial scale and in visual color for these structures. The changes in apparent color of these structures often occur accompanying dynamical processes such as deformation and change in vorticity. Therefore, it would be a key to understanding Jovian atmosphere dynamics to monitor the change in color of surface structures. The objective of this study is to reveal the mechanism of the variations in Jovian surface structures by a ground-based observation with a multi-band imaging system.
We have developed a multi-band imaging system which can simultaneously obtain both spectral data and spatiotemporal variations of structures. Seven bands in visible range have been selected for the routine observation based on the results from previous spectroscopic works. We have determined the relative sensitivity among these bands which is essential to synthesize a precise natural color image from 7 images. In this talk, we report the initial observation results obtained by the system. The results of the validation for these results by comparing with previous spectroscopic studies using Cassini spacecraft and Hubble space telescope are also shown.

Examination of the relation between Jupiter's inner magnetosphere and magnetic reconfiguration events

*Hiroaki Misawa[1]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University

It is known that Jupiter's synchrotron radiation (JSR) has information on dynamics of the deep inner magnetosphere. We have made JSR observations in the decimeter radio wavelength more than a decade, and has showed that JSR generally shows short term variations by more than several tens percent with the time scale of days to weeks. A plausible causality of such the short term variations is due to solar UV/EUV variations; i.e., the solar UV/EUV heating for Jupiter's upper atmosphere drives neutral wind perturbations, and the induced dynamo electric field leads to enhancement of radial diffusion of relativistic electrons in the inner magentosphere. and then JSR shows variations. This scenario was initially proposed by Brice and McDonough [1973] and observationally confirmed by Miyoshi et al. [1999], Tsuchiya et al. [2011] and Kita et al., [2013] which is so to speak, an externally driving process. However, this scenario cannot be always applicable to any short term JSR variations, particularly fast variations with the time scale within a few days, and any other processes are required (Kita, 2015; Tsuchiya et al., 2019).
As a process which might explain such a fast variation in Jupiter's magnetosphere, an internally driving process, so-called 'substorm like event', is known (see Louarn et al., 2014). This phenomena is interpreted as a magnetic reconfiguration event occurred in the Jupiter's magnetotail region. Although it is revealed that major magnetic reconfiguration events generally affect the whole magnesphere from 10 to 80-120 Rj (Jupiter's radii), however, it has not been known whether the events affect the inner magnetosphere within 2 Rj.
In order to reveal unknown dynamics of the fast variations in JSR, we have tried to examine relationship between the fast variations and magnetic reconfiguration events. In this study we have used the plasma data explored by the Galileo orbiter in Jupiter's magnetosphere and also Jupiter's particular radio wave component in the hectrometer wave range (see Misawa et al., 2018) for searching magnetic reconfiguration events, and we have compared them with the daily JSR monitoring data at 327MHz observed with the radio telescopes of ISEE, Nagoya University, Japan. In the presentation, we will show results of the examination and discuss a linkage possibility between Jupiter's inner magnetosphere and magnetotail region.

Effects of the charged particles of solar wind on planetary atmospheres

*Shinji Karasawa[1]

1. Miyagi National College of Technology Professor emeritus

The charged particle of H^+ is radiated at an average speed of about 450km/sec from the Sun. It has a rotating component (2km/sec) of the Sun’s rotation. There is no geomagnetic field caused from the inner core of Venus. The charged particles of solar-wind those possess large kinetic momentum. Those collide to the thick atmospheric molecules facing the Sun of Venus. The collisions of the solar wind with angular momentum of anti-clockwise direction causes super-rotation of Venus in the direction of clockwise.
Titan has a super-rotation of 120 m/s at an altitude of 120km. Radius 1.1 million km of the Titan's orbital passes through the stretched portion of the magnetosphere of Saturn at 1.2 million km. Titan's orbital is running through in a part of magnetosphere of Saturn. The rotation period of Titan is about 16 days that is the same as the revolution period of Titan by gravitational lock. So, the surface of Titan receives shower of the charged particle of H^+ in Saturn's magnetosphere at repeating period of 10.7 hours. The movement speed of the magnetosphere in the orbit of the Titan is 200 km/sec**.** The super-rotation of Titan is caused by the difference of moving speed of the H^+ shower on surface of Titan facing Saturn’s side and the backside. Maximum difference of moving speed of the shower is 843 m/sec in counter-clockwise direction. [Website by S. Karasawa,

[A-AS03] Large-scale moisture and organized cloud systems

convener:Hiroaki Miura(The University of Tokyo), Atsushi Hamada(University of Toyama), Satoru Yokoi(Japan Agency for Marine-Earth Science and Technology), Masaki Satoh(Atmosphere and Ocean Research Institute, The University of Tokyo)

Water vapor plays a significant role in regulating the global atmospheric circulation, especially in the troposphere. The overturning circulation is directly driven by the longwave radiative cooling of water vapor and the latent heating/cooling through microphysical processes to balance it. This global circulation is composed of diverse atmospheric phenomena with various spatial and temporal scales. Developments of some significant turbulent motions such as 3D isotropic turbulence in clouds, stratocumulus and cumulus convection, squall lines and tropical cyclones, and the Madden-Julian oscillation, are essentially associated with moisture anomaly in each scale. Moisture is accumulated relatively slowly in larger horizontal scales, but is consumed relatively quickly in smaller ones. This significant scale gaps between the accumulation and consumption may be one of the causes of the long-lasting difficulty in developing the theory of the moist atmosphere. The aim of this session is to share the recent researches about the relationships between moisture and organized cloud systems in wider spatial and temporal scales to enhance collaborations between modeling, observational, and theoretical approaches in tackling this challenging task. Research results relating to the Years of the Maritime Continent (YMC) and Radiative-Convective Equilibrium Model Intercomparison Project (RCEMPI) are welcome.

Numerical investigation on the shape, terminal velocity, and drag coefficient of a small raindrop by the improved immersed boundary method

*Ong Chia Rui[1], Hiroaki Miura[1]

1. The University of Tokyo

The cloud microphysical processes play a crucial part in controlling the water cycle, cloud formation, and radiation transfer in the atmosphere. These process are parameterized in a numerical weather prediction model by empirical formulae. In particular, empirical formulae for the prediction of the terminal velocity, drag coefficient, and shape of a free-falling water droplet are used widely in the parameterizations. Despite that the model accuracy is sensitive to the microphysics parameterizations to a considerable extent, these formulae are only verified by experiments which are conducted at room temperature and standard atmospheric pressure or linear theories in an ideal condition. The validity of the parameterizations is therefore questionable under general conditions and the accuracy of the numerical prediction may be affected.
In this work, a new numerical tool, the immersed boundary method, is proposed as an alternative way to investigate the terminal velocity, drag coefficient, and shape of an axisymmetric free-falling raindrop. This improved immersed boundary method for water droplet simulations is applied to verify those commonly used empirical formulae under different conditions. The largest size of the free-falling raindrop in this work is 0.5 mm. To first verify the reliability and robustness of this new method the terminal velocity and drag coefficient obtained from axisymmetric raindrop simulations at standard pressure and temperature fit well with the experimental data. Further simulation results of an axisymmetric free-falling raindrop of diameters of 0.025, 0.01, and 0.5 mm at different altitudes assuming a fixed lapse rate show that the variation of the shape of the raindrop is negligibly small, and there is a significant discrepancy between the numerical results and some of the widely used empirical formulae. The discrepancy is larger at higher altitudes for small raindrops. This is because of the assumption of the fixed drag coefficient in the derivation of those empirical formulae. A new parameterization with better accuracy for terminal velocity aloft of raindrops with diameter smaller than 0.5 mm is proposed. A further sensitivity test of a 0.5 mm free-falling axisymmetric raindrop with different surface tension coefficients are performed and the numerical results suggest that the change in the shape and terminal velocity is negligible with respect to aerosols.

A diagnostic study of water vapor during an extreme precipitation event in Yili river valleyA diagnostic study of water vapor during an extreme precipitation event in Yili river valley

*Jing LiU[1], Yushu Zhou[2], Lianmei Yang[1]

1. Institute of Desert Meteorology,CMA, 2. Institute of Atmospheric Physics,CAS

An extreme precipitation events was happened during 31 July to 1 August, 2016 at Yili river valley which multi-stations breakthrough extreme precipitation’ s value. Based on calculation of water vapor transport stream function and the non-divergent (rotational) components, potential function and divergent (irrotational) components, the water vapor transport budget and water vapor transport trajectories for the Yili river valley using the conventional detection,1° x 1° NCEP/NCAR reanalysis, HYSPLIT model based on Lagrangian method, Ground-based GPS observation precipitable water vapor data(GPS-PWV) , the large-scale water vapor transport and convergence characteristics were analyzed during the heavy rainfall period. The results showed that: (1) The Indian, the Pacific and the Atlantic ocean all contributed to the water supply during the heavy rain period, and Indian summer monsoon circulation, the south China sea summer monsoon circulation at low latitudes and Atlantic ocean’ s east airflow at mid-latitude were constituted the water vapor transmission channel, which the Indian Ocean southwest water vapor transport mainly concentrated in the lower troposphere, and middle troposphere water vapor transport was given priority to the west flow of the Atlantic ocean and low trough itself; the valley was in the convergence area of water vapor flux during the heavy rain, and the convergence and uplift of the terrain to the West opening caused vertical motion development provided a favorable dynamic convergence mechanism for the occurrence of local heavy rain.(2) The 3000 m water vapor transmission trajectory included the westward and eastward path at bottom layer and the northward path at middle troposphere as complement of water vapor for the lower troposphere through the vertical motion, the southward path at lower troposphere which water vapor come from the Arabian sea,and the mid-latitude water vapor transport of the westward path was the most powerful ; The 5000 m water vapor transmission trajectory was dominated by the westward path and the low trough itself;(3) During the precipitation period, the water vapor was concentrated in the lower troposphere which transported to the upper level through vertical movement, and the water vapor was positive at the middle and upper layers contrasted with negative at the lower layer. south boundary of water vapor inflow was rapidly increasing at the lower layer while the middle and higher layer water vapor inflow derived from the western boundary during the heavy rainfall period;(4)Yili river valley GPS-PWV jumped caused by the southwest airflow front of low trough before the rainfall happened and steadily maintain the high value influenced by India southwest monsoon during the heavy rainfall period. The large-scale water vapor transport convergence enhancement corresponding local GPS-PWV increased, suggested that the water vapor supply in local heavy rain event was at least associated with the water vapor transport and convergence of hemisphere scale.

The Study on the Characteristics of Weather and Cloud Types in the Summer and Winter Seasons of the South China Sea

*Jou Ping Hou[1], Bo-Shiou Wei[1], Li-Zhen Su[1]

1. Chung Cheng Institute of Technology

The South China Sea is vast with a tropical maritime climate near the equator and a subtropical climate in the north. Therefore, although it is winter, there are still deep convective and strong precipitation systems in the South China Sea. In summer, thermal convection is strong, sometimes typhoons pass; Dongsha Island and Taiping Island are located in the north and south of the South China Sea. The weather in the region is bound to be significantly affected by various weather systems in the South China Sea. We selected the winter of December 2017 and the summer of June 2018 to study it. The Dongsha Island and Taiping Island areas were subjected to research on the northeast monsoon and tropical convection. The dual island observation and satellite data were combined with numerical models to analyze the mutual interaction between the thermal and dynamic processes in the South China Sea. To enhance the understanding of the weather evolution mechanism in the South China Sea, in order to further clarify the various cloud-phase characteristics of the monsoon circulation and thermal convection in the South China Sea. The results show that the change of northeast monsoon intensity obviously affects the interaction of air-sea in the South China Sea, enhances the intensity of precipitation, and changes the amount and height of the stratus cumulus in the sea. In addition, the northeast monsoon circulation may interact with the surrounding terrain of the South China Sea, thus induces local deep convection. In the summer, the southwest monsoon will be enhanced and thermal convection is very strong. The intensity and life cycle of the typhoon can be maintained when it passes this area.

Linkages between the South and East Asian Monsoon water vapor transport during boreal summer

*Yong Liu[1]

1. Institute of Atmospheric Physics, Beijing , China

This study provides a water vapor transport (WVT) perspective on the linkages between the South and East Asian summer monsoons (SASM and EASM) and indicates two robustly coupled modes of the vertical integrated WVT (VIWVT) over the two monsoons that accounts for above 90% of the total squared covariance fraction. The first coupled mode (SVD1 mode) depicts a meridional linkage between the meridional dipole VIWVT anomalies over both the SASM and EASM. While the second coupled mode (SVD2 mode) illustrates a zonal connection of an anomalous cyclonic/anticyclone VIWVT over the SASM and a zonal wave-like VIWVT over the EASM. The SVD1 mode is linked through the anomalous subtropical High over the western North Pacific (WNPSH) and primarily associated with the transition phase of El Niñ o/La Niña (ENSO) and simultaneous Indian Ocean Basin mode (IOBM) SST warming/cooling. The meridional connection of the VIWVT in the SVD1 mode experienced a clear intensification since the late-1970s that may be attributed to the strengthened impacts of the ENSO/IOBM on the EASM and SASM after the late-1970s. The SVD2 mode is connected by the Circumglobal teleconnection (CGT) pattern and related to the developing phase of ENSO and summer north Atlantic tripole (NAT) SST anomalies. The zonal VIWVT connection in SVD2 mode is strongly modulated by the SASM-CGT connections and reveals significant weakening since the late-1970s but re-intensifies after the early-1990s. This may be associated with the weakened ENSO-SASM relationship after the late-1970s and interdecadal decreasing of the all Indian summer rainfall since the early-1990s.

Interannual Modulation of the Local Hadley Circulation on Clouds, Radiation and Diagnostic Fields over the Western North Pacific

*Xinyue Wang[1], Hironobu Iwabuchi[1]

1. Tohoku Univ.

Variation of the local Hadley cell (HC) northern boundary over the western North Pacific, and its interannual imprints on the tropospheric clouds and atmospheric fields are examined with observation and reanalysis data for the winter season from December 1982 to February 2016. The poleward shift of the local HC subsiding edge is marked by anomalous rising motion, large-scale decreased static stability, and corresponding increases of the midlevel cloud amount over the climatological sinking zone around 30N. These responses primarily locate over the continental and coastal areas instead of the open oceans. Concomitant with the increasing cloud fraction, a net negative top-of-atmosphere radiation anomaly is identified, and the main contributor is suggested to be the cumulus congestus, whose top pressures are in a range of 440–680 hPa, and optical thicknesses in a range of 23–60. Interactions between this specific cloud type and the vertical moist instability, and their constrains on the precipitation field is further discussed.

Seasonal and Regional Variation of Diurnal Cycle of Rainfall over Java Island and the Surrounding Area

*Madam Taqiyya Maulana[1], Takeshi Yamazaki[1]

1. Tohoku University

The seasonality and regional variability of diurnal cycle of rainfall (DCR) over Java Island and the surrounding area (coastal region of the Java Sea and the Indian Ocean) are analyzed through satellite observations. This study focus on the area where the studies of the seasonality of DCR over Indonesian Maritime Continent (IMC) are still limited. The DCR is a prominent phenomenon over IMC which is important for aviation industry and related to heavy precipitation events that cause hydro-meteorological disasters.

In this study, **we investigate seasonal and regional variation of DCR (the phase and the amplitude)** through satellite observations. High resolution (spatial and temporal) rainfall estimate is needed to capture feature of DCR over the study area which is difficult to obtain from ground observation. We **mainly employ the high-resolution dataset of Global Satellite Mapping of Precipitation (GSMaP) reanalysis (GSMaP_RNL) and near real time (GSMaP_NRT).** The analysis of DCR seasonal variability is based on investigation throughout boreal winter (December-January-February), boreal spring (March-April-May), boreal summer (June-July-August), and boreal autumn (September-October-November) from 2008-2018 (GSMaP_NRT) and 2009-2014 (GSMaP_RNL).

The results show that hourly data of GSMaP_RNL and GSMaP_NRT with 0.1˚ spatial resolution are able to depict the detailed features of the seasonality and regional variability of DCRover Java Island and surrounding areas. **The comparison between GSMaP_RNL and GSMaP_NRT shows that GSMaP_NRT represents significant time lag of DCR phase over off shore region. GSMaP_NRT shows that the offshore region of the Java Sea is dominated by noon-afternoon rainfall while GSMaP_RNL shows morning rainfall.** However, both of GSMaP_RNL and GSMaP_NRT show similar pattern on phase and amplitude of DCR. Phase of DCR indicates the time when maximum rainfall occurs, while amplitudes indicates the magnitude of DCR. In general, both of GSMaP_RNL and GSMaP_NRT composites, show that the land region with wider landmass area (West Java and western part of East Java) is dominated by evening phase while narrow landmass area (Central Java and eastern part of Java Island) is dominated by late afternoon phase. A large magnitude of the DCR is concentrated inland. The Java Sea has a higher amplitude of DCR compared to the Indian Ocean and the coastal region. The amplitude over the coastal region of the Indian Ocean is higher than over the Indian Ocean and the coastal area of the Java Sea.

Both of rainfall estimates capture inhomogeneous seasonal shifting phase of DCR over this region. The remarkable seasonal shifting phase occurs along the coastal area of the Java Sea. Though, phase shifting over inland of a wide landmass area and the coastal region of the Indian Ocean is not significant. Inhomogeneous seasonal shifting phase of DCR indicated interactions between local circulations, which affected by the topography (e.g. terrain and shape of the coastline), and large circulations (background wind, synoptic conditions, etc.). The analysis of wind profile from reanalysis data confirms the seasonal change of interactions between large and small circulations that caused seasonal shifting phase of DCR.

Study on atmospheric circulation characteristics of precipitation anomalies in arid region of Central Asia

*Lianmei Yang[1], Xuefeng Guan[1]

1. Institute of Desert Meteorology, China Meteorological Administration,

As climate transition zone between Mediterranean climate region and East Asian monsoon region, arid region of Central Asia (including five Central Asian countries and Xinjiang province of China) which is influenced by high, middle and low latitude circulations has different synoptic-climatic characteristics from that of Europe and East Asia while its climate characteristics also varies greatly within the region. Central Asia has unique and complicated topography and ecosystem patterns like deserts, oasis, glaciers and basins, forming a highly representative meteorological disaster-breeding environment under the influence of multiple-background, multiple-factor and multiple-scale. This area has abundant solar-heat energy, large evaporation and dramatic temperature changes. Besides, its precipitation is scarce and has extremely uneven distribution with high value in the western and middle parts of Tianshan Mountains. Over the last one hundred years, Central Asia has experienced a warm and wet trend. Central Asia low value system together with the high, middle and low latitude circulation systems linked by West Asia westerly jet stream have contributed to the interdecadal and interannual variations of precipitation in Xinjiang. However, due to the insufficient construction of integrated meteorological observation network, the studies concerning regional featured circulation system, regularity and mechanism of disastrous weathers, high resolution regional numerical model, impacts of land-atmosphere interaction on regional weather and climate change prediction are still inadequate. Correspondingly, to carry out those studies has essential scientific significance and strategic value for the sustainable social and economic development in Silk Road Economic Belt.

Mechanisms for northward propagation of boreal summer intraseasonal oscillation

*Kanta Nakae[1], Masaki Satoh[1], Daisuke Takasuka[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

The 20-90-day Intraseasonal Oscillation (ISO) is one of the dominant modes of tropical variability. In boreal summer northward propagation (NP), which occurs on ISO time scales, originates near the equator and extends to India and western North Pacific Ocean. Understanding the NP of the boreal summer ISO (BSISO) is of vital importance to extended-range weather prediction. Hence, several mechanisms of the NP have been examined. However, they are still incompletely understood. The purpose of this study is to investigate the importance of vertical shear and sea surface temperature (SST) for the NP of the BSISO. In order to obtain a basic structure of the BSISO, we have conducted JJA-perpetual experiments using the Non-hydrostatic Icosahedral Atmospheric Model (NICAM) with a 56-km horizontal mesh.
Although the perpetual experiment has strong Indian monsoon over Arabian sea due to the bias of surface temperature on land, it is found that the NP of the BSISO from Indian Ocean (IO) has two abovementioned mechanisms. One warm SST anomaly north of convection destabilize the lower troposphere, while another tilted vertical shear can generate positive barotropic vorticity to the north of convection. In order to assess the effect of the former mechanism, we made an experiment using fix SST (SSTFIX) obtained from CTL experiment. SSTFIX experiment reproduces the NP of the BSISO from IO, although the amplitude became lower. Therefore, it suggests that the NP of the BSISO from IO doesn’t need warm SST anomaly. To Improve the bias related to basic state like vertical shear, we conducted an experiment using nudging method for surface temperature on land (LNDADJ). In LNDADJ experiment the NP of the BSISO from IO isn’t reproduced due to reduction of column water vapor over Bay of Bengal. Thus, tilted vertical shear can just begin the NP. On the other hand, it is suggested that the NP needs SST and column water vapor to maintain its strength.

Fractality in the perimeter of tropical clouds observed by Himawari-8 or simulated by a high-resolution model

*Takuya Jinno[1]

1. Graduate School of Science, The University of Tokyo

Cloud clusters show a wide variety of shape and size, and their spatial pattern is often taken up as a typical example of fractal. However, the methods of studying fractal are in an early stage of development. In this study, we conducted fractal analysis on the perimeter of tropical clouds using satellite observation and cloud-resolving simulation of sub-kilometer resolution. We evaluated fractal dimension as a function of spatial scale (transient fractal dimension) and quantified the characteristic spatial scale of the pattern from the scale where self-similarity breaks down. From the observational data from HIMAWARI-8, It is shown that the self-similarity of the cloud perimeter persists only in the spatial scale range from 2 km up to 30 km. The limit of the self-similarity is suggested to be the characteristic scale of the pattern formation of tropical clouds. The cloud-resolving simulation data with NICAM also shows finite-size self-similarity. However, the profile of the transient fractal dimension changed with integration time far more rapidly than HIMAWARI-8 observation, and it lost its self-similarity at the end of the 48-hour simulation. This process is suggested to reflect the increase of stratiform cloud in the upper-troposphere as an adjustment to the transition of spatial resolution.

Large-scale deformation of tropical cloud band in the ITCZ detected in NICAM simulations

*Noriyuki Nishi[1], Atsushi Hamada[4], Yohei Yamada[2], Tomoe Nasuno[2], Reona Satoh[5], Masaki Satoh[3]

1. Faculty of Science, Fukuoka Universtiy, 2. JAMSTEC, 3. AORI, University of Tokyo, 4. Graduate School of Science and Engineering for Education, University of Toyama, 5. Graduate School of Science, Fukuoka University

Over the central/eastern tropical Pacific, the Inter Tropical Convergence Zone (ITCZ) is detected in the northern side of the equator. In the ITCZ, we can sometimes observe drastic deformation of the cloud bands elongated zonally with several thousand-kilometer scale. The initial stage of the band, which is composed of deep convective systems, expands meridionally and separates into two or three parallel cirrus bands that keep alive one or two days (Hamada et al., 2013, JMSJ). These separation events cannot be well described in the objective analysis datasets, probably due to lack of the observations over the open ocean; investigation of their mechanism with the analysis data is difficult. In order to study their mechanism, we attempted to use the numerical simulation results of global cloud system resolving model NICAM (Satoh et al. 2014, Progress in Earth and Planetary Science) to find similar events in them. If we can find separation events in the results, we can examine the mechanism with many physical parameters including wind, various kinds of hydrometeors. We have already analyzed several numerical experiment results for different periods, resolution and physical schemes.

We found a similar separation event in an output of the simulation for one year from June 2004 and horizontal resolution 3.5 km. We examined the life cycle of the cirrus bands after separation. One interesting point is on the height of the cirrus clouds in the separated bands. The simulated cirrus clouds in the bands lie in the 13-14 km height level, while the height of the maximum meridional wind that contributes to the meridional movement of the cirrus bands is about 12 km. This difference of the heights means that the cirrus clouds were not just advected by meridional wind but were possibly developed in the course of the separation.

The trigger of zonally simultaneous separation of a long band is another our interest. Inertial instability may be a candidate since vertical exchange of zonal momentum by deep convection would occur in an original band and result in the large meridional shear of the zonal wind in the upper troposphere. We tried to confirm necessary condition for inertial instability by calculating geostrophic vorticity, following the general procedure. However, the position of the bands is too close to the equator (3-7N) to establish geostrophic relationship, and the spatial pattern of the geostrophic vorticity is too noisy to analyze. Therefore, we instead calculate simple absolute vorticity. We found that the absolute vorticity around the separated bands was almost negative. It suggests the possibility of the inertial (or similar kind of) instability.

We are now analyzing another numerical experiment including four kinds of runs using a cloud scheme with different cloud parameter settings. In the real atmosphere, a separation event occurred on 16-17 June 2008 at the just east of the date line. The event can be simulated in all of four runs at 36 hours from the initial time. It suggests that the basic mechanism of the separation is not sensitive to the detail of cloud systems. By analyzing the dynamical fields of these outputs, we are trying to find the key mechanisms to trigger the meridional separation of the cloud bands.

Improvement of single-moment bulk microphysics for super-cooled water clouds over the Southern Ocean in NICAM using Joint simulator and double-moment microphysics

*Woosub Roh[1], Tatsuya Seiki[2], Masaki Satoh[1], Tempei Hashino[3]

1. AORI, the university of Tokyo, 2. JAMSTEC, 3. Kochi university of technology

It is important to evaluate and improve the cloud properties in global non-hydrostatic models like a Nonhydrostatic ICosahedral Atmospheric Model (NICAM, Satoh et al. 2014) using observation data. One of the methods is a radiance-based evaluation using satellite data and a satellite simulator (here Joint simulator, Hashino et al. 2013), which avoids making different settings of the microphysics between retrieval algorithms and NICAM.

One of the challenging issues is an evaluation of mixed-phase clouds, which consist of water vapor, ice particles, and supercooled water droplets. It is known one of the main reasons why climate models reveal large errors about the reflection of solar radiation over the Southern Ocean and Arctic.

This study is an evaluation and improvement of mixed-phase clouds over the Southern Ocean in NICAM using a Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observation (CALIPSO) and a satellite simulator. We evaluated thermodynamics phase of mixed phases clouds over the Southern Ocean in a regional version of NICAM between 45˚S to 65˚S and 170˚E to 170˚W following Yoshida et al. (2010) method. We found underestimation of supercooled water clouds in our single moment scheme. We improved the single moment microphysics scheme using a double moment microphysics and a single column model. We also investigate the impact of microphysics scheme on moisture distributions and the size of cloud systems.

High-cloud property responses to SST change: sensitivity study using a global nonhydrostatic model

*Tomoki Ohno[1], Masaki Satoh[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Since it has been recognized that the uncertainty of cloud feedback is one of main contributors to the intermodel spread of climate sensitivity, the reduction of the uncertainties associated with cloud response to global warming has been one of central issues for robust projections and predictions of climate variability and change. High clouds have large impacts on the Earth’ s radiative energy budget, and the uncertainty of their response to climate change is known as one of large sources of the climate sensitivity spread although several possible hypotheses to predict the response have been proposed. As the radiation-cloud interaction plays a crucial role in the determination of life time of high clouds, the improvement of the understanding of cloud property responses to global warming helps the reduction of climate-sensitivity variability associated with the high-clouds feedback.

In order to investigate the cloud-property response to climate change, we conducted simulations with RCE configurations using a high-resolution nonhydrostatic global circulation model (the Nonhydrostatic Icosahedral Atmospheric Model; NICAM) with the earth-like sphere for simplifying the problem. Sea surface temperatures (SSTs) are fixed at 300K and 304K and a double-moment bulk scheme are used without cumulus parameterization scheme.

We found that high cloud amount increases with SST increase, as consistent with the previous NICAM studies. It was also determined that the change in particularly optically thin clouds whose optical thicknesses were <3 was dominant, and such thin clouds tended to have large particle sizes. These suggests that the slow evaporative property of ice phase clouds and their representability can play one of key roles in the uncertainty of the high-cloud amount change in global warming.

Effects of different cloud overlapping parameters on simulated total cloud fraction over the globe and East Asian region

*bo hai Wang[1], hua Zhang[2]

1. Institute of Atmospheric Physics, Chinese Academy of Sciences, 2. State Key Laboratory of Severe Weather, Chinese Academy of Meteorological Sciences

The cloud overlapping parameter (vertical decorrelation length, L_{cf}) from CloudSat/CALIPSO is implemented in Beijing Climate Center’ s GCM (BCC_AGCM2.0) to reduce the uncertainly in radiation field. Comparing the climate simulation results obtained by using the constant L_{cf} of 2 km with those using the above retrieved L_{cf}, it is found that the total cloud fraction simulation has been obviously improved by using the satellite-based L_{cf}. The error of global mean total cloud fraction between simulations and CERES (Clouds and the Earth's Radiant Energy System) satellite data is decreased by 1.6% in both the winter and summer, of which the positive deviation of total cloud amount at tropical convection area and the negative deviation in subtropical region both are significantly reduced. These improvements are helpful for better simulation of energy budget differences between different regions. In East Asia, using the satellite-based L_{cf} can decrease the error of average total cloud fraction (compared to the CERES) by 1.8% (1.4%) in the winter (summer).Overall, using L_{cf} from CloudSat/CALIPSO satellite data can improve the simulation of total cloud fraction and thus obtain more accurate simulation of radiation field.

[A-AS03] Large-scale moisture and organized cloud systems

convener:Hiroaki Miura(The University of Tokyo), Atsushi Hamada(University of Toyama), Satoru Yokoi(Japan Agency for Marine-Earth Science and Technology), Masaki Satoh(Atmosphere and Ocean Research Institute, The University of Tokyo)

Water vapor plays a significant role in regulating the global atmospheric circulation, especially in the troposphere. The overturning circulation is directly driven by the longwave radiative cooling of water vapor and the latent heating/cooling through microphysical processes to balance it. This global circulation is composed of diverse atmospheric phenomena with various spatial and temporal scales. Developments of some significant turbulent motions such as 3D isotropic turbulence in clouds, stratocumulus and cumulus convection, squall lines and tropical cyclones, and the Madden-Julian oscillation, are essentially associated with moisture anomaly in each scale. Moisture is accumulated relatively slowly in larger horizontal scales, but is consumed relatively quickly in smaller ones. This significant scale gaps between the accumulation and consumption may be one of the causes of the long-lasting difficulty in developing the theory of the moist atmosphere. The aim of this session is to share the recent researches about the relationships between moisture and organized cloud systems in wider spatial and temporal scales to enhance collaborations between modeling, observational, and theoretical approaches in tackling this challenging task. Research results relating to the Years of the Maritime Continent (YMC) and Radiative-Convective Equilibrium Model Intercomparison Project (RCEMPI) are welcome.

Numerical investigation on the shape, terminal velocity, and drag coefficient of a small raindrop by the improved immersed boundary method

*Ong Chia Rui[1], Hiroaki Miura[1]

1. The University of Tokyo

The cloud microphysical processes play a crucial part in controlling the water cycle, cloud formation, and radiation transfer in the atmosphere. These process are parameterized in a numerical weather prediction model by empirical formulae. In particular, empirical formulae for the prediction of the terminal velocity, drag coefficient, and shape of a free-falling water droplet are used widely in the parameterizations. Despite that the model accuracy is sensitive to the microphysics parameterizations to a considerable extent, these formulae are only verified by experiments which are conducted at room temperature and standard atmospheric pressure or linear theories in an ideal condition. The validity of the parameterizations is therefore questionable under general conditions and the accuracy of the numerical prediction may be affected.
In this work, a new numerical tool, the immersed boundary method, is proposed as an alternative way to investigate the terminal velocity, drag coefficient, and shape of an axisymmetric free-falling raindrop. This improved immersed boundary method for water droplet simulations is applied to verify those commonly used empirical formulae under different conditions. The largest size of the free-falling raindrop in this work is 0.5 mm. To first verify the reliability and robustness of this new method the terminal velocity and drag coefficient obtained from axisymmetric raindrop simulations at standard pressure and temperature fit well with the experimental data. Further simulation results of an axisymmetric free-falling raindrop of diameters of 0.025, 0.01, and 0.5 mm at different altitudes assuming a fixed lapse rate show that the variation of the shape of the raindrop is negligibly small, and there is a significant discrepancy between the numerical results and some of the widely used empirical formulae. The discrepancy is larger at higher altitudes for small raindrops. This is because of the assumption of the fixed drag coefficient in the derivation of those empirical formulae. A new parameterization with better accuracy for terminal velocity aloft of raindrops with diameter smaller than 0.5 mm is proposed. A further sensitivity test of a 0.5 mm free-falling axisymmetric raindrop with different surface tension coefficients are performed and the numerical results suggest that the change in the shape and terminal velocity is negligible with respect to aerosols.

A diagnostic study of water vapor during an extreme precipitation event in Yili river valleyA diagnostic study of water vapor during an extreme precipitation event in Yili river valley

*Jing LiU[1], Yushu Zhou[2], Lianmei Yang[1]

1. Institute of Desert Meteorology,CMA, 2. Institute of Atmospheric Physics,CAS

An extreme precipitation events was happened during 31 July to 1 August, 2016 at Yili river valley which multi-stations breakthrough extreme precipitation’ s value. Based on calculation of water vapor transport stream function and the non-divergent (rotational) components, potential function and divergent (irrotational) components, the water vapor transport budget and water vapor transport trajectories for the Yili river valley using the conventional detection,1° x 1° NCEP/NCAR reanalysis, HYSPLIT model based on Lagrangian method, Ground-based GPS observation precipitable water vapor data(GPS-PWV) , the large-scale water vapor transport and convergence characteristics were analyzed during the heavy rainfall period. The results showed that: (1) The Indian, the Pacific and the Atlantic ocean all contributed to the water supply during the heavy rain period, and Indian summer monsoon circulation, the south China sea summer monsoon circulation at low latitudes and Atlantic ocean’ s east airflow at mid-latitude were constituted the water vapor transmission channel, which the Indian Ocean southwest water vapor transport mainly concentrated in the lower troposphere, and middle troposphere water vapor transport was given priority to the west flow of the Atlantic ocean and low trough itself; the valley was in the convergence area of water vapor flux during the heavy rain, and the convergence and uplift of the terrain to the West opening caused vertical motion development provided a favorable dynamic convergence mechanism for the occurrence of local heavy rain.(2) The 3000 m water vapor transmission trajectory included the westward and eastward path at bottom layer and the northward path at middle troposphere as complement of water vapor for the lower troposphere through the vertical motion, the southward path at lower troposphere which water vapor come from the Arabian sea,and the mid-latitude water vapor transport of the westward path was the most powerful ; The 5000 m water vapor transmission trajectory was dominated by the westward path and the low trough itself;(3) During the precipitation period, the water vapor was concentrated in the lower troposphere which transported to the upper level through vertical movement, and the water vapor was positive at the middle and upper layers contrasted with negative at the lower layer. south boundary of water vapor inflow was rapidly increasing at the lower layer while the middle and higher layer water vapor inflow derived from the western boundary during the heavy rainfall period;(4)Yili river valley GPS-PWV jumped caused by the southwest airflow front of low trough before the rainfall happened and steadily maintain the high value influenced by India southwest monsoon during the heavy rainfall period. The large-scale water vapor transport convergence enhancement corresponding local GPS-PWV increased, suggested that the water vapor supply in local heavy rain event was at least associated with the water vapor transport and convergence of hemisphere scale.

The Study on the Characteristics of Weather and Cloud Types in the Summer and Winter Seasons of the South China Sea

*Jou Ping Hou[1], Bo-Shiou Wei[1], Li-Zhen Su[1]

1. Chung Cheng Institute of Technology

The South China Sea is vast with a tropical maritime climate near the equator and a subtropical climate in the north. Therefore, although it is winter, there are still deep convective and strong precipitation systems in the South China Sea. In summer, thermal convection is strong, sometimes typhoons pass; Dongsha Island and Taiping Island are located in the north and south of the South China Sea. The weather in the region is bound to be significantly affected by various weather systems in the South China Sea. We selected the winter of December 2017 and the summer of June 2018 to study it. The Dongsha Island and Taiping Island areas were subjected to research on the northeast monsoon and tropical convection. The dual island observation and satellite data were combined with numerical models to analyze the mutual interaction between the thermal and dynamic processes in the South China Sea. To enhance the understanding of the weather evolution mechanism in the South China Sea, in order to further clarify the various cloud-phase characteristics of the monsoon circulation and thermal convection in the South China Sea. The results show that the change of northeast monsoon intensity obviously affects the interaction of air-sea in the South China Sea, enhances the intensity of precipitation, and changes the amount and height of the stratus cumulus in the sea. In addition, the northeast monsoon circulation may interact with the surrounding terrain of the South China Sea, thus induces local deep convection. In the summer, the southwest monsoon will be enhanced and thermal convection is very strong. The intensity and life cycle of the typhoon can be maintained when it passes this area.

Linkages between the South and East Asian Monsoon water vapor transport during boreal summer

*Yong Liu[1]

1. Institute of Atmospheric Physics, Beijing , China

This study provides a water vapor transport (WVT) perspective on the linkages between the South and East Asian summer monsoons (SASM and EASM) and indicates two robustly coupled modes of the vertical integrated WVT (VIWVT) over the two monsoons that accounts for above 90% of the total squared covariance fraction. The first coupled mode (SVD1 mode) depicts a meridional linkage between the meridional dipole VIWVT anomalies over both the SASM and EASM. While the second coupled mode (SVD2 mode) illustrates a zonal connection of an anomalous cyclonic/anticyclone VIWVT over the SASM and a zonal wave-like VIWVT over the EASM. The SVD1 mode is linked through the anomalous subtropical High over the western North Pacific (WNPSH) and primarily associated with the transition phase of El Niñ o/La Niña (ENSO) and simultaneous Indian Ocean Basin mode (IOBM) SST warming/cooling. The meridional connection of the VIWVT in the SVD1 mode experienced a clear intensification since the late-1970s that may be attributed to the strengthened impacts of the ENSO/IOBM on the EASM and SASM after the late-1970s. The SVD2 mode is connected by the Circumglobal teleconnection (CGT) pattern and related to the developing phase of ENSO and summer north Atlantic tripole (NAT) SST anomalies. The zonal VIWVT connection in SVD2 mode is strongly modulated by the SASM-CGT connections and reveals significant weakening since the late-1970s but re-intensifies after the early-1990s. This may be associated with the weakened ENSO-SASM relationship after the late-1970s and interdecadal decreasing of the all Indian summer rainfall since the early-1990s.

Interannual Modulation of the Local Hadley Circulation on Clouds, Radiation and Diagnostic Fields over the Western North Pacific

*Xinyue Wang[1], Hironobu Iwabuchi[1]

1. Tohoku Univ.

Variation of the local Hadley cell (HC) northern boundary over the western North Pacific, and its interannual imprints on the tropospheric clouds and atmospheric fields are examined with observation and reanalysis data for the winter season from December 1982 to February 2016. The poleward shift of the local HC subsiding edge is marked by anomalous rising motion, large-scale decreased static stability, and corresponding increases of the midlevel cloud amount over the climatological sinking zone around 30N. These responses primarily locate over the continental and coastal areas instead of the open oceans. Concomitant with the increasing cloud fraction, a net negative top-of-atmosphere radiation anomaly is identified, and the main contributor is suggested to be the cumulus congestus, whose top pressures are in a range of 440–680 hPa, and optical thicknesses in a range of 23–60. Interactions between this specific cloud type and the vertical moist instability, and their constrains on the precipitation field is further discussed.

Seasonal and Regional Variation of Diurnal Cycle of Rainfall over Java Island and the Surrounding Area

*Madam Taqiyya Maulana[1], Takeshi Yamazaki[1]

1. Tohoku University

The seasonality and regional variability of diurnal cycle of rainfall (DCR) over Java Island and the surrounding area (coastal region of the Java Sea and the Indian Ocean) are analyzed through satellite observations. This study focus on the area where the studies of the seasonality of DCR over Indonesian Maritime Continent (IMC) are still limited. The DCR is a prominent phenomenon over IMC which is important for aviation industry and related to heavy precipitation events that cause hydro-meteorological disasters.

In this study, **we investigate seasonal and regional variation of DCR (the phase and the amplitude)** through satellite observations. High resolution (spatial and temporal) rainfall estimate is needed to capture feature of DCR over the study area which is difficult to obtain from ground observation. We **mainly employ the high-resolution dataset of Global Satellite Mapping of Precipitation (GSMaP) reanalysis (GSMaP_RNL) and near real time (GSMaP_NRT).** The analysis of DCR seasonal variability is based on investigation throughout boreal winter (December-January-February), boreal spring (March-April-May), boreal summer (June-July-August), and boreal autumn (September-October-November) from 2008-2018 (GSMaP_NRT) and 2009-2014 (GSMaP_RNL).

The results show that hourly data of GSMaP_RNL and GSMaP_NRT with 0.1˚ spatial resolution are able to depict the detailed features of the seasonality and regional variability of DCRover Java Island and surrounding areas. **The comparison between GSMaP_RNL and GSMaP_NRT shows that GSMaP_NRT represents significant time lag of DCR phase over off shore region. GSMaP_NRT shows that the offshore region of the Java Sea is dominated by noon-afternoon rainfall while GSMaP_RNL shows morning rainfall.** However, both of GSMaP_RNL and GSMaP_NRT show similar pattern on phase and amplitude of DCR. Phase of DCR indicates the time when maximum rainfall occurs, while amplitudes indicates the magnitude of DCR. In general, both of GSMaP_RNL and GSMaP_NRT composites, show that the land region with wider landmass area (West Java and western part of East Java) is dominated by evening phase while narrow landmass area (Central Java and eastern part of Java Island) is dominated by late afternoon phase. A large magnitude of the DCR is concentrated inland. The Java Sea has a higher amplitude of DCR compared to the Indian Ocean and the coastal region. The amplitude over the coastal region of the Indian Ocean is higher than over the Indian Ocean and the coastal area of the Java Sea.

Both of rainfall estimates capture inhomogeneous seasonal shifting phase of DCR over this region. The remarkable seasonal shifting phase occurs along the coastal area of the Java Sea. Though, phase shifting over inland of a wide landmass area and the coastal region of the Indian Ocean is not significant. Inhomogeneous seasonal shifting phase of DCR indicated interactions between local circulations, which affected by the topography (e.g. terrain and shape of the coastline), and large circulations (background wind, synoptic conditions, etc.). The analysis of wind profile from reanalysis data confirms the seasonal change of interactions between large and small circulations that caused seasonal shifting phase of DCR.

Study on atmospheric circulation characteristics of precipitation anomalies in arid region of Central Asia

*Lianmei Yang[1], Xuefeng Guan[1]

1. Institute of Desert Meteorology, China Meteorological Administration,

As climate transition zone between Mediterranean climate region and East Asian monsoon region, arid region of Central Asia (including five Central Asian countries and Xinjiang province of China) which is influenced by high, middle and low latitude circulations has different synoptic-climatic characteristics from that of Europe and East Asia while its climate characteristics also varies greatly within the region. Central Asia has unique and complicated topography and ecosystem patterns like deserts, oasis, glaciers and basins, forming a highly representative meteorological disaster-breeding environment under the influence of multiple-background, multiple-factor and multiple-scale. This area has abundant solar-heat energy, large evaporation and dramatic temperature changes. Besides, its precipitation is scarce and has extremely uneven distribution with high value in the western and middle parts of Tianshan Mountains. Over the last one hundred years, Central Asia has experienced a warm and wet trend. Central Asia low value system together with the high, middle and low latitude circulation systems linked by West Asia westerly jet stream have contributed to the interdecadal and interannual variations of precipitation in Xinjiang. However, due to the insufficient construction of integrated meteorological observation network, the studies concerning regional featured circulation system, regularity and mechanism of disastrous weathers, high resolution regional numerical model, impacts of land-atmosphere interaction on regional weather and climate change prediction are still inadequate. Correspondingly, to carry out those studies has essential scientific significance and strategic value for the sustainable social and economic development in Silk Road Economic Belt.

Mechanisms for northward propagation of boreal summer intraseasonal oscillation

*Kanta Nakae[1], Masaki Satoh[1], Daisuke Takasuka[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

The 20-90-day Intraseasonal Oscillation (ISO) is one of the dominant modes of tropical variability. In boreal summer northward propagation (NP), which occurs on ISO time scales, originates near the equator and extends to India and western North Pacific Ocean. Understanding the NP of the boreal summer ISO (BSISO) is of vital importance to extended-range weather prediction. Hence, several mechanisms of the NP have been examined. However, they are still incompletely understood. The purpose of this study is to investigate the importance of vertical shear and sea surface temperature (SST) for the NP of the BSISO. In order to obtain a basic structure of the BSISO, we have conducted JJA-perpetual experiments using the Non-hydrostatic Icosahedral Atmospheric Model (NICAM) with a 56-km horizontal mesh.
Although the perpetual experiment has strong Indian monsoon over Arabian sea due to the bias of surface temperature on land, it is found that the NP of the BSISO from Indian Ocean (IO) has two abovementioned mechanisms. One warm SST anomaly north of convection destabilize the lower troposphere, while another tilted vertical shear can generate positive barotropic vorticity to the north of convection. In order to assess the effect of the former mechanism, we made an experiment using fix SST (SSTFIX) obtained from CTL experiment. SSTFIX experiment reproduces the NP of the BSISO from IO, although the amplitude became lower. Therefore, it suggests that the NP of the BSISO from IO doesn’t need warm SST anomaly. To Improve the bias related to basic state like vertical shear, we conducted an experiment using nudging method for surface temperature on land (LNDADJ). In LNDADJ experiment the NP of the BSISO from IO isn’t reproduced due to reduction of column water vapor over Bay of Bengal. Thus, tilted vertical shear can just begin the NP. On the other hand, it is suggested that the NP needs SST and column water vapor to maintain its strength.

Fractality in the perimeter of tropical clouds observed by Himawari-8 or simulated by a high-resolution model

*Takuya Jinno[1]

1. Graduate School of Science, The University of Tokyo

Cloud clusters show a wide variety of shape and size, and their spatial pattern is often taken up as a typical example of fractal. However, the methods of studying fractal are in an early stage of development. In this study, we conducted fractal analysis on the perimeter of tropical clouds using satellite observation and cloud-resolving simulation of sub-kilometer resolution. We evaluated fractal dimension as a function of spatial scale (transient fractal dimension) and quantified the characteristic spatial scale of the pattern from the scale where self-similarity breaks down. From the observational data from HIMAWARI-8, It is shown that the self-similarity of the cloud perimeter persists only in the spatial scale range from 2 km up to 30 km. The limit of the self-similarity is suggested to be the characteristic scale of the pattern formation of tropical clouds. The cloud-resolving simulation data with NICAM also shows finite-size self-similarity. However, the profile of the transient fractal dimension changed with integration time far more rapidly than HIMAWARI-8 observation, and it lost its self-similarity at the end of the 48-hour simulation. This process is suggested to reflect the increase of stratiform cloud in the upper-troposphere as an adjustment to the transition of spatial resolution.

Large-scale deformation of tropical cloud band in the ITCZ detected in NICAM simulations

*Noriyuki Nishi[1], Atsushi Hamada[4], Yohei Yamada[2], Tomoe Nasuno[2], Reona Satoh[5], Masaki Satoh[3]

1. Faculty of Science, Fukuoka Universtiy, 2. JAMSTEC, 3. AORI, University of Tokyo, 4. Graduate School of Science and Engineering for Education, University of Toyama, 5. Graduate School of Science, Fukuoka University

Over the central/eastern tropical Pacific, the Inter Tropical Convergence Zone (ITCZ) is detected in the northern side of the equator. In the ITCZ, we can sometimes observe drastic deformation of the cloud bands elongated zonally with several thousand-kilometer scale. The initial stage of the band, which is composed of deep convective systems, expands meridionally and separates into two or three parallel cirrus bands that keep alive one or two days (Hamada et al., 2013, JMSJ). These separation events cannot be well described in the objective analysis datasets, probably due to lack of the observations over the open ocean; investigation of their mechanism with the analysis data is difficult. In order to study their mechanism, we attempted to use the numerical simulation results of global cloud system resolving model NICAM (Satoh et al. 2014, Progress in Earth and Planetary Science) to find similar events in them. If we can find separation events in the results, we can examine the mechanism with many physical parameters including wind, various kinds of hydrometeors. We have already analyzed several numerical experiment results for different periods, resolution and physical schemes.

We found a similar separation event in an output of the simulation for one year from June 2004 and horizontal resolution 3.5 km. We examined the life cycle of the cirrus bands after separation. One interesting point is on the height of the cirrus clouds in the separated bands. The simulated cirrus clouds in the bands lie in the 13-14 km height level, while the height of the maximum meridional wind that contributes to the meridional movement of the cirrus bands is about 12 km. This difference of the heights means that the cirrus clouds were not just advected by meridional wind but were possibly developed in the course of the separation.

The trigger of zonally simultaneous separation of a long band is another our interest. Inertial instability may be a candidate since vertical exchange of zonal momentum by deep convection would occur in an original band and result in the large meridional shear of the zonal wind in the upper troposphere. We tried to confirm necessary condition for inertial instability by calculating geostrophic vorticity, following the general procedure. However, the position of the bands is too close to the equator (3-7N) to establish geostrophic relationship, and the spatial pattern of the geostrophic vorticity is too noisy to analyze. Therefore, we instead calculate simple absolute vorticity. We found that the absolute vorticity around the separated bands was almost negative. It suggests the possibility of the inertial (or similar kind of) instability.

We are now analyzing another numerical experiment including four kinds of runs using a cloud scheme with different cloud parameter settings. In the real atmosphere, a separation event occurred on 16-17 June 2008 at the just east of the date line. The event can be simulated in all of four runs at 36 hours from the initial time. It suggests that the basic mechanism of the separation is not sensitive to the detail of cloud systems. By analyzing the dynamical fields of these outputs, we are trying to find the key mechanisms to trigger the meridional separation of the cloud bands.

Improvement of single-moment bulk microphysics for super-cooled water clouds over the Southern Ocean in NICAM using Joint simulator and double-moment microphysics

*Woosub Roh[1], Tatsuya Seiki[2], Masaki Satoh[1], Tempei Hashino[3]

1. AORI, the university of Tokyo, 2. JAMSTEC, 3. Kochi university of technology

It is important to evaluate and improve the cloud properties in global non-hydrostatic models like a Nonhydrostatic ICosahedral Atmospheric Model (NICAM, Satoh et al. 2014) using observation data. One of the methods is a radiance-based evaluation using satellite data and a satellite simulator (here Joint simulator, Hashino et al. 2013), which avoids making different settings of the microphysics between retrieval algorithms and NICAM.

One of the challenging issues is an evaluation of mixed-phase clouds, which consist of water vapor, ice particles, and supercooled water droplets. It is known one of the main reasons why climate models reveal large errors about the reflection of solar radiation over the Southern Ocean and Arctic.

This study is an evaluation and improvement of mixed-phase clouds over the Southern Ocean in NICAM using a Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observation (CALIPSO) and a satellite simulator. We evaluated thermodynamics phase of mixed phases clouds over the Southern Ocean in a regional version of NICAM between 45˚S to 65˚S and 170˚E to 170˚W following Yoshida et al. (2010) method. We found underestimation of supercooled water clouds in our single moment scheme. We improved the single moment microphysics scheme using a double moment microphysics and a single column model. We also investigate the impact of microphysics scheme on moisture distributions and the size of cloud systems.

High-cloud property responses to SST change: sensitivity study using a global nonhydrostatic model

*Tomoki Ohno[1], Masaki Satoh[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Since it has been recognized that the uncertainty of cloud feedback is one of main contributors to the intermodel spread of climate sensitivity, the reduction of the uncertainties associated with cloud response to global warming has been one of central issues for robust projections and predictions of climate variability and change. High clouds have large impacts on the Earth’ s radiative energy budget, and the uncertainty of their response to climate change is known as one of large sources of the climate sensitivity spread although several possible hypotheses to predict the response have been proposed. As the radiation-cloud interaction plays a crucial role in the determination of life time of high clouds, the improvement of the understanding of cloud property responses to global warming helps the reduction of climate-sensitivity variability associated with the high-clouds feedback.

In order to investigate the cloud-property response to climate change, we conducted simulations with RCE configurations using a high-resolution nonhydrostatic global circulation model (the Nonhydrostatic Icosahedral Atmospheric Model; NICAM) with the earth-like sphere for simplifying the problem. Sea surface temperatures (SSTs) are fixed at 300K and 304K and a double-moment bulk scheme are used without cumulus parameterization scheme.

We found that high cloud amount increases with SST increase, as consistent with the previous NICAM studies. It was also determined that the change in particularly optically thin clouds whose optical thicknesses were <3 was dominant, and such thin clouds tended to have large particle sizes. These suggests that the slow evaporative property of ice phase clouds and their representability can play one of key roles in the uncertainty of the high-cloud amount change in global warming.

Effects of different cloud overlapping parameters on simulated total cloud fraction over the globe and East Asian region

*bo hai Wang[1], hua Zhang[2]

1. Institute of Atmospheric Physics, Chinese Academy of Sciences, 2. State Key Laboratory of Severe Weather, Chinese Academy of Meteorological Sciences

The cloud overlapping parameter (vertical decorrelation length, L_{cf}) from CloudSat/CALIPSO is implemented in Beijing Climate Center’ s GCM (BCC_AGCM2.0) to reduce the uncertainly in radiation field. Comparing the climate simulation results obtained by using the constant L_{cf} of 2 km with those using the above retrieved L_{cf}, it is found that the total cloud fraction simulation has been obviously improved by using the satellite-based L_{cf}. The error of global mean total cloud fraction between simulations and CERES (Clouds and the Earth's Radiant Energy System) satellite data is decreased by 1.6% in both the winter and summer, of which the positive deviation of total cloud amount at tropical convection area and the negative deviation in subtropical region both are significantly reduced. These improvements are helpful for better simulation of energy budget differences between different regions. In East Asia, using the satellite-based L_{cf} can decrease the error of average total cloud fraction (compared to the CERES) by 1.8% (1.4%) in the winter (summer).Overall, using L_{cf} from CloudSat/CALIPSO satellite data can improve the simulation of total cloud fraction and thus obtain more accurate simulation of radiation field.

[A-AS03] Large-scale moisture and organized cloud systems

convener:Hiroaki Miura(The University of Tokyo), Atsushi Hamada(University of Toyama), Satoru Yokoi(Japan Agency for Marine-Earth Science and Technology), Masaki Satoh(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Hiroaki Miura

Water vapor plays a significant role in regulating the global atmospheric circulation, especially in the troposphere. The overturning circulation is directly driven by the longwave radiative cooling of water vapor and the latent heating/cooling through microphysical processes to balance it. This global circulation is composed of diverse atmospheric phenomena with various spatial and temporal scales. Developments of some significant turbulent motions such as 3D isotropic turbulence in clouds, stratocumulus and cumulus convection, squall lines and tropical cyclones, and the Madden-Julian oscillation, are essentially associated with moisture anomaly in each scale. Moisture is accumulated relatively slowly in larger horizontal scales, but is consumed relatively quickly in smaller ones. This significant scale gaps between the accumulation and consumption may be one of the causes of the long-lasting difficulty in developing the theory of the moist atmosphere. The aim of this session is to share the recent researches about the relationships between moisture and organized cloud systems in wider spatial and temporal scales to enhance collaborations between modeling, observational, and theoretical approaches in tackling this challenging task. Research results relating to the Years of the Maritime Continent (YMC) and Radiative-Convective Equilibrium Model Intercomparison Project (RCEMPI) are welcome.

Boundary-Layer Control on Convective Self-Aggregation

*Da YANG[1,2]

1. University of California, Davis, 2. Lawrence Berkeley National Laboratory

The atmosphere can self-organize into overturning circulations over an ocean surface with uniform temperature in cloud-resolving models. The upwelling branch is associated with humid air and deep convection; the downwelling branch is associated with dry air and clear sky. This phenomenon is referred to as convective self-aggregation, and understanding this phenomenon can advance our understanding of the Madden-Julian Oscillation (MJO). In this talk, I will introduce a boundary-layer centric framework for self-aggregation. This framework helps explain what leads to self-aggregation, and what sets the spatial scale of self-aggregation.

Statistical Properties of Cumulus Ensembles in High-Resolution Radiative-Convective Equilibrium Simulations

*Tomoro Yanase[1,2], Tetsuya Takemi[2]

1. Graduate School of Science, Kyoto University, 2. Disaster Prevention Research Institute, Kyoto University

This study investigates the statistical properties of cumulus ensembles in radiative-convective equilibrium states. Numerical experiments were conducted with the use of the non-hydrostatic Weather Research and Forecasting (WRF) model version 3.8.1 at horizontal grid spacing varied from 1600 m to 200 m in an area of $(200\ km)^2$, with an interactive radiative flux calculation scheme. The experiment with the horizontal grid spacing of 200 m successfully reproduced the diurnal variability of the trimodal characteristics of cumulus convection. With the decrease in the horizontal resolution, intermittent deep convection accompanied by the strong updraft and rainfall becomes dominant. The middle-to-upper troposphere appears to become stabler and drier with the decrease in the horizontal resolution. We further analyzed the cloud structures by using a three-dimensional cloud detection method. It is suggested that the vertical structure of in-cloud properties and the vertical development of cumulus ensembles are strongly affected by horizontal scales of microstructure which are constrained by horizontal resolution. Furthermore, it is suggested that the statistical properties of cumulus ensemble such as horizontal distances and size distribution are related to the horizontal heterogeneity of water vapor.

The role of interactive SST in the cloud-resolving simulations of aggregated convection

*Chien-Ming Wu[1], Yan-Ting Chen[1]

1. National Taiwan University

This study investigates the role of interactive SST in the early development of aggregated convection using a vector vorticity equation cloud-resolving model (VVM) coupled to a slab ocean. The simulations are initialized by a mock Walker circulation driven by initial SST gradient in the elongated x-axis, with an average of 300K and sinusoidal variation of amplitude ranging from 1.5K to 3K. According to large-scale perturbation strength, which is caused by SST variation, the results can be divided into two groups. Under weak perturbation, convection-SST feedback efficiently eliminates SST gradient and moisture anomaly. The large-scale environment is homogenized within two days. Even though SST in the group with stronger perturbation undergoes a similar process, significant moist static energy (MSE) advection in the boundary produces enough moisture difference to introduce virtual temperature effect and aggregation is triggered. Once dry zone starts to expand, radiative and convective effects regenerate SST gradient, which intensifies circulation and accelerates the process. We further show that the evolution of aggregation or not is captured by the trend of MSE-EIS variance. The results highlight the boundary layer processes on the formation of aggregated convection in the tropics.

Role of coastal convection to moisture buildup during the South China Sea summer monsoon onset

*Wei-Ting Chen[1], Wei-Ming Tsai[1,2], Chien-Ming Wu[1], Peng-Jen Chen[1]

1. National Taiwan University, 2. University of Miami

In this study, the climatological characteristics of object-based precipitation systems (OPS) and moisture development are analyzed over the South China Sea (SCS) during the sharp transition of summer monsoon onset. The satellite observed OPS statistics showed that during the pre-onset period, small (<100 km) to medium size (100-300 km) OPS are active over surrounding land, while convection over the ocean is mostly suppressed. During post-onset, large OPS develop over the coastal ocean and contribute to over 60% of the total precipitation. The results suggest that when the convection is strong over the surrounding islands, a local circulation with anomalous subsidence over the ocean can develop and suppress convection. The number of observed large OPS significantly increases along with the sharp moisture buildup during the SCS onset period. The moisture budgets suggested that local contribution from convection vertical mixing is the major moisture source during monsoon onset pentad, while large-scale moisture advection tends to be weak. The relationship between moisture buildup and convection organization is then examined using a set of idealized cloud-resolving model (CRM) experiments, with a land-ocean configuration approximating the SCS basin. The CRM appropriated represents the observed development of coastal convection. With a non-shear environment, the strong basin-scale circulation is formed, which suppresses the ocean moisture development. When large-scale vertical wind shear is imposed to represent the changes of large-scale circulation during the onset pentad, organized convection systems are increased over the coastal ocean and propagate toward the open ocean, accompanied by fast ocean moistening. We identified through the CRM simulations that the moistening time-scale by the transition of coastal convection organization is within 5-10 days.

Resolution dependencies of tropical convection in a global cloud/cloud-system resolving model

*Tomoki Miyakawa[1], Hiroaki Miura[2]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Graduate School of Science, The University of Tokyo

The properties of tropical convection are evaluated using one-month long simulation datasets produced by the non-hydrostatic icosahedral atmospheric model (NICAM) using 3.5-, 7-, and 14-km horizontal meshes with identical cloud-microphysics configurations. The simulations are targeted on the 2nd Madden-Julian oscillation (MJO) event observed in the CINDY2011/DYNAMO field campaign. An increase of high cloud fraction at 200 hPa level and a reduction of surface precipitation occur as the horizontal resolution increases, corresponding to the reduction of precipitation efficiency due to the shorter residence time inside stronger updrafts that occur at the higher resolution. The increase of high cloud fraction is followed by the warming of the troposphere, which results in an increase in the column water vapor and an elevation of the freezing level. The total water condensation is decreased at higher resolutions, which is likely due to a balance with the decreased outgoing longwave radiation (OLR). The reproduced MJOs, which accounted for a large portion of the tropical convections, were similar in the 3.5-km and 14-km simulations in terms of eastward propagation speeds and structures, including the characteristic westward tilt of the moisture anomaly with height. However, the amplitude of the anomalous MJO circulation was considerably smaller in the 3.5-km simulation. The robust resolution dependence and the interpretations presented in this study underline the necessity for a resolution-aware cloud-microphysics optimization method that will have value in the coming era of global cloud-resolving simulations.

Effects of the local convection over the western Maritime Continent on the large-scale: numerical study during the YMC Sumatra campaigns

*Tomoe Nasuno[1]

1. Japan Agency for Marine-Earth Science and Technology

The effects of the high-frequency variability on the large-scale, including the intraseasonal oscillation (ISO), over the western Maritime Continent (MC), was quantified using the global nonhydrostatic simulation datasets that marginally resolve mesoscale convective systems. Moisture transport during the Years of the Maritime Continent (YMC) winter field campaigns in 2015 and in 2017 were analyzed, focusing on the land-ocean contrast and their relationship with the ISO events.

The period-mean profiles indicate moistening by low-frequency upward motion in the deep troposphere and drying (moistening) in the lower (middle and upper) troposphere by high-frequency variability. The advection over ocean was greater in 2017 than in 2015, with the opposite occurring over land with smaller interannual differences. These can be related to the longer preconditioning period (rapid transition from the preconditioning to the active, and decaying phases) for the 2015 (2017) case, as well as the relatively suppressed (enhanced) upward motion over ocean under the strong El Niño (moderate La Niña) conditions during 2015 (2017).

The dependence of the land-ocean contrast on the ISO life cycle was more significant in 2015 than in 2017. In the 2015 simulation, moistening over land preceded the major convective period of the ISO, whereas that over ocean preceded the ISO convection not longer than 1 week, consistent with the arguments by previous studies based on precipitation observations. In this case, a nearly in-phase relationship between the moisture advection by high-frequency variability and by low-frequency variability was found over land. In the 2017 case, the land-ocean contrast was weak in low-frequency advection. The relationship between moisture advection by high-frequency variability and by low-frequency variability was indistinct over land, whereas clear relationship was seen over ocean: the high-frequency variability induced lower to middle tropospheric moistening (enhanced upward transport of moisture) during the preconditioning (active) phases of the ISO convection, in common with the 2015 case. These results highlight clear land-ocean contrasts in sensitivity of local convection to background states and its link with the ISO life cycle.

[A-AS03] Large-scale moisture and organized cloud systems

convener:Hiroaki Miura(The University of Tokyo), Atsushi Hamada(University of Toyama), Satoru Yokoi(Japan Agency for Marine-Earth Science and Technology), Masaki Satoh(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Satoru Yokoi

Water vapor plays a significant role in regulating the global atmospheric circulation, especially in the troposphere. The overturning circulation is directly driven by the longwave radiative cooling of water vapor and the latent heating/cooling through microphysical processes to balance it. This global circulation is composed of diverse atmospheric phenomena with various spatial and temporal scales. Developments of some significant turbulent motions such as 3D isotropic turbulence in clouds, stratocumulus and cumulus convection, squall lines and tropical cyclones, and the Madden-Julian oscillation, are essentially associated with moisture anomaly in each scale. Moisture is accumulated relatively slowly in larger horizontal scales, but is consumed relatively quickly in smaller ones. This significant scale gaps between the accumulation and consumption may be one of the causes of the long-lasting difficulty in developing the theory of the moist atmosphere. The aim of this session is to share the recent researches about the relationships between moisture and organized cloud systems in wider spatial and temporal scales to enhance collaborations between modeling, observational, and theoretical approaches in tackling this challenging task. Research results relating to the Years of the Maritime Continent (YMC) and Radiative-Convective Equilibrium Model Intercomparison Project (RCEMPI) are welcome.

A Mechanism for the Maintenance of Sharp Tropical Margins

*Hirohiko Masunaga[1], Brian Earle Mapes[2]

1. Nagoya University, 2. University of Miami

The deep tropics characterized by moist air and deep convection are separated from the dry, quiescent subtropics often by a sharp horizontal gradient of moisture only loosely tied to SST or other geographical constraints. Mapes et al. (GRL, 2018) showed that this margin of the moist tropics is a true PDF minimum (a regime separatrix), along a column water vapor (CWV) contour around 48 mm in instantaneous data. Quasi-meridional statistical composites of observations across the poleward-most excursion of this sinuous contour retain the sharpness of the margin while increasing signal to noise ratio. Observations primarily from a suite of the A-Train satellites show the meridional structure of thermodynamic state and budget terms across the margin of the moist tropics. Composites are computed around the PDF-minimum CWV value of 48 mm as well as a range of other thresholds from 35 mm to 60 mm for comparison. Major findings are summarized as follows. (1) CWV increases equatorward from the subtropics for all CWV thresholds but eventually converges to 48 mm deep into the tropical side. Precipitation abruptly intensifies on the tropical side of the margin but declines equatorward to 85 W/m2 regardless of the CWV thresholds. (2) The diabatic forcing to the atmosphere (radiative heating plus surface heat fluxes) changes its sign across the CWV=48 mm border, being positive on the tropical side and negative on the subtropics. This contrast is owing to the meridional gradient of radiative heating, principally the longwave effect of high clouds. (3) Vertical mode decomposition reveals a transition from bottom-heavy to top-heavy subsidence on the subtropical side of the margin. These observed features are interpreted in terms of a simple theory from the moisture and heat budget perspectives. The model explains the abrupt moistening at the margin as a singularity where the vertical displacement of air costs little energy within a column.

Observational Evidence of Mixed Rossby-Gravity Waves as a Driving Force for the MJO Convective Initiation and Propagation

*Daisuke Takasuka[1,2], Masaki Satoh[1], Satoru Yokoi[2]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology

The Madden-Julian Oscillation (MJO) is known to be the most dominant intraseasonal variability in the tropics, which features large-scale convective envelopes emergening and propagating eastward slowly (~5 m s^{-1}) over the warm pool region. Since its discovery, there have been dedicated efforts to clarify mechanisms about MJO initiation and propagation in terms of large-scale low-frequency dynamics and thermodynamics and a multi-scale interaction with synoptic disturbances. As for the latter standpoint, although some recent observational and idealized numerical studies suggested that mixed Rossby-gravity waves (MRGs) can play a significant role in MJO mechanics, more detailed evidence is necessary because the realistic relationship between MJO and MRGs has had little recognition.

In this study, we examine the contributions of MRGs to the MJO convective initation and propagation in the Indian Ocean during the YMC-Sumatra 2017 field campaign (YMC: Years of the Maritime Continent). The intensive observation captured mid-tropospheric wind variations associated with MRGs, and those signals propagated westward over the Indian Ocean in the MJO suppressed phase. The transition to the MJO active phase follows tight MRG-convection coupling, which is enhanced when the wavelength becomes shorter due to weak mid-level convergence in the western Indian Ocean. Basin-scale anomalous mid-tropospheric moistening caused by MRG shallow circulations is also recognized. These processes lead to the lower-tropospheric MRG wave packet formation and successive triggering of MJO convection, with the eastward MRG group velocity corresponding to MJO propagation. This study suggests that it is worth reconsidering the MJO with a focus on MRG activities at least in the Indian Ocean.

A characteristic of the MJO as a part of enhanced large-scale zonal circulation

*Tamaki Suematsu[1], Hiroaki Miura[2]

1. Atmosphere and Ocean Reaserch Institute, The University of Tokyo, 2. School of Science, The University of Tokyo

The Madden-Julian Oscillation (MJO) is known as the dominant mode of intraseasonal variability in the tropics, characterized a region of enhanced convective activities that propagate from the Indian Ocean (IO) to the Western Pacific(WP). However, our understanding of its fundamental role in the atmosphere, and explanation for why it exists is still limited. Taking this into consideration, this study examined how the MJO propagation speed and the intensity of their events were modulated by the background environment and sought for an intrinsic relationship of the MJO with the background atmospheric states. To build on our recent finding of MJO enhancement with background zonal sea surface temperature (SST) gradient, we examined how MJO propagation speed was influenced by the background SST. We constructed a tracking method of MJO convection and calculated the propagation speed of each event. We investigated how the characteristics of the MJO and the background SST states that they occur in varied depending on their propagation speed. The analysis revealed that the slower events were associated with a condition of low-frequency SST (> 60 days) distribution with a positive zonal gradient from the IO to WP. In contrast, high-frequency SST (20 –60 days) distributions associated with the MJO events were much the same between the fast and the slow groups with little zonal SST gradient across IO to WP. Furthermore, the extension of the analysis to rest of the events revealed that the relationship between zonal SST gradient and propagation speed was not a tendency restricted to the fastest and the slowest groups, but is an overall relationship that is displayed by all of the events. Taking note that the presence of zonal SST gradient in the low-frequency range has the potential to enhance large-scale zonal circulation, the component of the zonal wind associated with the background circulation was also analyzed. The analysis showed that there is a tendency for MJO to propagate slower when the background large-scale zonal circulation was stronger, implying that slower MJOs are embedded in enhanced large-scale zonal circulation.

The role of the moisture on the occurrences and distribution of the Amazonian mesoscale convective systems

*Amanda Rehbein[1,2], Masaki Satoh[2], Tercio Ambrizzi[1]

1. Univ. of Sao Paulo, 2. Univ. of Tokyo

The mesoscale convective systems (MCSs) are large and long-lived organized cloud systems, which have impacts on climate and weather. Studies on MCSs over the Amazon basin have been driven in recent years. They showed that MCSs occur spreadly during the Amazon’ s wet season (November to March) when the Intertropical Convergence Zone is toward northern South America. The MCSs occurrence during wet season months has variations very little known. For instance, during January and March, the MCSs occurrence is greater than in February, being March the month with most occurrences. A similar pattern occurs with the monthly precipitation. During the dry season (May to September), the number of MCSs decreases to a minimum in August, the same as precipitation. However, these MCSs are larger than those occurred in the wet season. Why these differences in the MCSs behavior and occurrence happens is an open question and very important for understanding and improving the MCSs simulations over the Amazon basin. Also, we know very few about the MCSs’ mechanism of genesis and maintenance over that region, mainly due to the lack of data on the Amazon capable of representing the convection time scale. Recently (Jan. 17th, 2019), the European Centre for Medium-Range Weather Forecasts (ECMWF) turn available the highest spatial and temporal reanalysis data (ERA5; hourly temporal and 0.5º spatial resolutions) for global range and long-term data (since 1979 to the present). Therefore, our objective is to use this dataset to investigate the moisture’ s role to the MCSs occurrences on the diurnal, seasonal and interannual scales. To achieve it, we will present temporal and spatial statistical analysis in the hourly, monthly, and annual scales, including vertical moisture profiles. The target period is 2000 to 2013 because of this is the same period of the available MCSs climatology by Rehbein et al. (2017). This investigation is complimentary for a major study where the Amazonian MCSs present and future climates are being investigated.

Interdecadal Change of the Impact of Eurasian Snow on Spring Precipitation Over Southern China

*Dingrui Cao[1]

1. Zhejiang University

In this study, the relationship between interdecadal and interannual changes of snow cover over Eurasia and precipitation over southern China are investigated. The results show that, the spring precipitation over southern China has experienced a change of positive to negative trend since the end of 1980s. The interannual change of spring precipitation over southern China has a significant positive correlation with the Eurasian snow cover (SCE) anomalies in northwest Lake Baikal. Baroclinic Atmosphere Model (LBM) was utilized in numerical simulation experiment. The results show that The SCE anomalies near northwest Lake Baikal can affect the spring precipitation over southern China by regulating the atmospheric circulation in East Asia and the Northwest Pacific. Further study indicates that the SCE anomalies near Lake Baikal have different contributions to the change of spring precipitation in south China around the end of 1980s. The whole dataset is divided into two periods, 1972-1987 (P1) and 1988-2009 (P2). During P1, the SCE anomalies around Lake Baikal contribute to the formation of regional mono-sign of spring precipitation over southern China. During P2, the SCE anomalies around Lake Baikal are conducive to the formation of north-south dipole modes of spring precipitation. Meanwhile, the SCE anomalies also have experienced an interdecadal change and contributes to precipitation mode over China. During P1, The SCE anomalies near Lake Baikal and its southeast side contribute to the formation of mono-sign of spring precipitation over southern China. During P2, the SCE anomalies near Lake Baikal and its northeast side are favorable for the south China spring precipitation to present the north-south dipole modes of spring precipitation.

Atmospheric Rivers and related atmospheric circulations associated with Japanese disastrous precipitation in warm season

Naho Suetou[1], *Akiyo Yatagai[1], Yukari Takayabu[2]

1. Graduate School of Science and Technology/Hirosaki University, 2. Atmosphere and Ocean Research Institute/The University of Tokyo

Atmospheric Rivers (ARs) refer to the flow of moisture like an elongated river that reach the mid-troposphere, and water vapor evaporated in the tropics is transported rapidly by subtropical jet streams and extends to mid-latitudes. ARs play an important role in the meridional moisture (i.e. energy) transport in the mid-latitudes; besides bringing down heavy rain on the west coast of North America and the western coast of Europe. Recently, it was found that ARs could emerge around Japan, and the AR occurrence in Hiroshima in August 2014 was reported as one of the factors of heavy rain. However, there are few studies about a relation between heavy precipitation and ARs occurred in Japan. However, previous studies counted the AR occurrence among the heavy precipitation events in entire Japan (longitude 123˚-146˚ and latitude 24˚-46˚). The result during the warm season (April-October) was approximately 70%, which was a high value. It was considered that it included the location of heavy rain did not coincide with the occurrence spot of ARs, because the AR occurrence rate was calculated over a wide range. Therefore, this study analyzed it by dividing Japan into sub-regions, calculating the rate of ARs for heavy rain days that cause disasters in each region, and clarifying the atmospheric circulation field of the day when ARs occurred on heavy rain days.

The target period was 35 years from 1980 to 2014, and a year was divided into two seasons, the warm season (April-October) and the cold season (November-March). This study extracted heavy rain days and detected ARs in the warm season after defined conditions for extracting heavy rain days that cause disasters and conditions for detecting ARs that pass through around Japan. Then, Japan was divided into 13 regions, and it was sorted out the extraction of heavy rain days and AR detection in each region. At this time, AR detection in each area was the detection area up to 100 km in four directions of the area targeted, considering the remote influence of ARs. Only the AR occurrence rate of the warm season was targeted to be analyzed.

The AR occurrence rate in each area was lower than the value calculated in entire Japan. The area with the highest AR occurrence rate was 64.6 % in North Kyushu Region, and the areas with many heavy rain days but a low AR occurrence rate were in Shikoku-Kii Peninsula Region (44.1 %) and South Kyushu Region (45.8%).
This study compared Shikoku-Kii Peninsula Region and North Kyushu Region, and investigated the circulation field. First, the monthly value of AR occurrence rate was the highest in September (61.9 %) in Shikoku-Kii Peninsula Region and in June (83.3 %) in North Kyushu Region. Although the month that took the highest value was different, what common for these two regions were that it was relatively low in July and August and high in rainy seasons.

Regarding the circulation field, the moisture flux in both regions converged on the target areas; however, it diverged over water in the east in Shikoku-Kii Peninsula Region and over water in the south in North Kyushu Region. Both moisture flow comes along the western periphery of the Pacific high where moisture diverges. It is found that there is a trough near the Korean Peninsula in Shikoku-Kii Peninsula Region.

©2019. Japan Geoscience Union. All Right Reserved.

Next, looking into the vertical cross section of the relative humidity and the wind field, the area with high specific humidity anomaly in both regions extended to the mid-troposphere. Also, looking into the specific humidity anomaly and the wind anomaly at the 2 pressure altitudes (500 hPa and 700 hPa) of the mid-troposphere, the areas with high in the specific humidity anomaly existed roughly at the same position as the moisture flux convergence, and the wind anomaly was similar to the flow of the moisture flux in the both regions. The flow of this wind and the moisture flux flown from the southwest to the northeast passing through the sea near Taiwan in Shikoku-Kii Peninsula Region, and from the west-southwest to the east-northeast passing through the mainland of China in North Kyushu Region.

Lastly, from the vertical cross section of the Omega (vertical p-velocity) anomaly, it was seen a strong ascending flow area that was narrow in the east and west and long in the north and south in Shikoku-Kii Peninsula Region, and that was wide in the east and west and narrow in the north and south.

[A-OS17] Kuroshio Large Meander

convener:Toru Miyama(Japan Agency for Marine-Earth Science and Technology, Application Laboratory), Norihisa Usui(Meteorological Research Institute), Takashi Setou(National Research Institute of Fisheries Science, Fisheries Research and Education Agency), Chairperson:Toru Miyama, Takashi Setou, Norihisa Usui

The Kuroshio has taken large meander path since the end of August 2017. Although it is unknown whether it is continuing at the time of the JpGU meeting, this notable event of the coastal area south of Japan after 12 years later from the last one has already attracted societal interests. In this session, behaviors, dynamics, influences, comparisons with past cases, etc. are discussed. Presentations from various perspectives of ocean physics, biology, chemistry, and meteorology are welcome.

1. Japan Meteorological Agency

Office of Marine Prediction (OMP) at Japan Meteorological Agency (JMA) has been routinely operating an ocean data assimilation and prediction system for the western North Pacific (MOVE/MRI.COM-WNP) since March 2008. This system aims to represent ocean characteristics such as the Kuroshio/Oyashio current and meso-scale eddies. Using MOVE/MRI.COM-WNP, OMP provides ocean state information of major currents around Japan (Kuroshio/Oyashio/Tsushima-Warm-Current) and water temperatures in the western North Pacific mainly through the JMA website.
In August 2017, the Kuroshio developed a large meander (LM) for the first time in 12 years. A small meander that developed southeast of Japan’ s Kyushu Island in late March 2017 and propagated eastward to waters off the country’ s Tokai region in August is considered to have induced the Kuroshio LM. In August, MOVE/MRI.COM-WNP successfully forecasted the generation of the Kuroshio LM and JMA published a press release about the probabilityof the Kuroshio LM.
This presentation shows the progress of the Kuroshio LM in and after 2017 as contrasted with the past cases.

Influences of the Kuroshio path variation south of Honshu on summer surface air temperature in Kanto district, Japan

*Shusaku Sugimoto[1]

1. Graduate School of Science, Tohoku University

In the Kuroshio and its extension (KE), the warm surface waters compared to the surrounding waters enhance upward heat release in winter, indicating that the ocean affects the atmosphere. On the other hand, in summer, atmospheric response to the Kuroshio/KE remains unclear because of a small difference between sea surface temperature (SST) and surface air temperature (SAT) over the Kuroshio/KE and of its-associated weak SST gradient. Here we investigated summertime (June-August) SST variations south of Japan, using high spatial resolution satellite-derived measurements of 2003–2018. The result showed that the variation is dominant in the region off Kanto-Tokai district, which was related to the Kuroshio path state; the SST increases off Kanto-Tokai district when the Kuroshio takes the meander path, which would reflect the following two points. In the meander period, (1) the Kuroshio shifted southward around Cape Shionomisaki, moves to the north around the Izu Islands, and then reaches very close to south coast of Kanto district, and (2) westward warm flow, which is a flow on the north edge of the anticlockwise eddy north of the Kuroshio, runs very close to the south coast of Tokai district. To reveal the extent to which the warm surface waters off Kanto-Tokai district influence the atmospheric fields, we conducted regional atmospheric model experiments using the high-resolution Japan Meteorological Agency nonhydrostatic model (JMA-NHM) with 5 km horizontal grid spacing. The experiment showed that, over the warm surface waters, evaporation increased considerably, and the northward water vapor transport by low-level wind caused an increase of moisture in Kanto district. The warm-water-induced moisture increase enhances downward longwave radiation at the surface in Kanto district, leading to the SAT increase. Actually, the SST off Kanto-Tokai district is significantly correlated with the SAT in Kanto district, from the Automated Meteorological Data Acquisition System (AMeDAS) of the Japan Meteorological Agency. Our results indicate that, in summer, the Kuroshio path state (meander or straight path) affect the overlying atmosphere and climate on Japan.

Bio-chemilcal difference between the large meander and the non case of the Kuroshio current

Since 2001, FRA has set up a regular monitoring line, called O-line north and south along 138E off Omaezaki south of Japan and has been conducting the monitoring four or five times a year until now. O-line, the monitoring line was named after Omaezaki City, which is near the starting point of the line. The line has been mainly conducted by the National Research Institute of Fisheries Science and has been carried out for the measure of water temperature, salinity, nutrient, some phytoplankton and zooplankton. In this presentation, the bio-chemical difference on the line between the large meandering case and the non case of the Kuroshio current has been focused on.

The late arrival of 2017-18 Japanese eel recruitment and its links to ocean circulation

*Yu-Lin Eda Chang[1], Yasumasa Miyazawa[1], Michael Miller[2], Katsumi Tsukamoto[2]

1. Application Laboratory, Japan Agency for Marine-Earth Science and Technology, 2. Department of Aquatic Bioscience, The University of Tokyo

In the year 2018, the Japanese eel (*Anguilla japonica*) recruitment almost vanished in Japan in the early recruitment season, and the eel catch peaked up in late recruitment period when the recruitment was usually small. Coincidently, the Kuroshio meander occurring south of Japan was revisiting since the previous event ends in 2005. The role of ocean circulation in 2018 unusual Japanese eel larvae recruitment was investigated using a three-dimensional particle tracking model, in which swimming behaviors of virtue larvae (v-larvae) was included in addition to passively drift by ocean currents. Similar results appeared in the simulation, showing none v-larvae arrival to the south of Japan in early recruitment period and increased substantially in the late recruitment period. The late arrival could be explained by the change of ocean circulation. The southward shifting and weak North Equatorial Current near spawning area, less Subtropical Countercurrent eddies, and weak Kuroshio during the early migration and recruitment period prevented v-larvae transport. In the late recruitment period, the Kuroshio was strengthened and strong near the East China Sea and south of Japan that transported v-larvae downstream efficiently. The maximum eel catch reduction in Tokai region where Kuroshio bifurcated offshore could be related to large meander. The Kuroshio large meander could potentially influence the local eel recruitment, but its actual role remained to be explored.

A probabilistic forecast of the Kuroshio current path variability using an 80-member ensemble simulation.

*Kunihiro Aoki[1], Yasumasa Miyazawa[1], Tsutomu Hihara[1]

1. JAMSTEC

This study aims to describe the probabilistic behavior of the Kuroshio current path variability using an 80-member ensemble simulation in a high-resolution numerical regional ocean model, JCOPE. This simulation provides the outputs for 4 months starting from the initial conditions optimized by the data assimilation (LETKF) for one months. All the members are found to predict the non-large meander path at first 2 months, but some members predict the large meander path after that. We propose a method of quantifying the occurrence/non-occurrence of the branch, the probabilities of each path, and a set of the mean and spread for each path by a machine learning method.

Long-term forecast of the Kuroshio large meander in 2017

*Norihisa Usui[1], Nariaki Hirose[1], Kei Sakamoto[1], Yosuke Fujii[1], Nadao Kohno[1]

1. Meteorological Research Institute

The Kuroshio large meander (KLM) occurred in the end of August 2017 for the first time in 12 years, and has maintained for more than a year. Changes in the oceanic condition south of Japan associated with the KLM have a large impact on various fields such as fisheries, marine transportation, and local weather. The KLM has, therefore, been received much attention. In this presentation, we discuss prospects of the KLM in 2017 on the basis of a long-term forecast experiment using an eddy-resolving ocean model. First, the actual Kuroshio state in the end of August 2018 is reproduced by applying data assimilation. We then conduct ensemble simulations with 40 members, in which atmospheric forcing data are replaced by those on the same day from 1975 to 2014 and the model is integrated for more than three years starting from 28 August 2018. In most cases, the KLM maintains for more than one and a half years (i.e. February 2020). After that, differences in the Kuroshio state among the ensemble members become large. As pointed out be former studies, these behaviors of the Kuroshio path are largely explained by the Sverdrup transport estimated from the wind stress field used in the experiment. In the presentation, we will evaluate the ensemble simulations results using the actual Kuroshio state in May 2019, and will show more detailed results.

[A-OS17] Kuroshio Large Meander

convener:Toru Miyama(Japan Agency for Marine-Earth Science and Technology, Application Laboratory), Norihisa Usui(Meteorological Research Institute), Takashi Setou(National Research Institute of Fisheries Science, Fisheries Research and Education Agency)

The Kuroshio has taken large meander path since the end of August 2017. Although it is unknown whether it is continuing at the time of the JpGU meeting, this notable event of the coastal area south of Japan after 12 years later from the last one has already attracted societal interests. In this session, behaviors, dynamics, influences, comparisons with past cases, etc. are discussed. Presentations from various perspectives of ocean physics, biology, chemistry, and meteorology are welcome.

Temporal and spacial changes in relative vorticity along the Kuroshio axis

*Yuya Hirano[1], Kazuyuki Uehara[1]

1. The Graduate School of Geo-environmental Science, Tokai University

The transition process of the Kuroshio path has been investigated by many previous studies. According to these studies, the transition from a non-large-meander path to a large-meander path is considerd to be caused by a eastward propagation of a "Kuroshio small meander" which occurs southeast of Kyushu (e.g. Solomon, 1978; Sekine, 1895; Kawabe, 2003). Not all small-meanders, however, form large-meander-paths. In many cases, magnitudes of small-meanders usually become smaller before reaching at Shionomisaki. In this study, we therefore calculate temporal and spacial changes along the Kuroshio axis in relative vorticities using maps of the absolute sea surface dynamic topography (MADT) providing from AVISO describe transition processes the Kuroshio meandering in detail. Here, we use MADT with weekly mean temporal resolution and 0.25 ×0.25 grid spatial resolution from January 4, 1993 to June 4, 2018. In addition, we also focus on the intensity of the Kuroshio recirculation gyre located stably at south of Shikoku.

The Kuroshio large meander in 2017 and its coastal impact reproduced by a 2-km resolution assimilation model

*Nariaki Hirose[1], Norihisa Usui[1], Kei Sakamoto[1], Goro Yamanaka[1], Nadao Kohno[1]

1. Meteorological Research Institute, Japan Meteorological Agency

The Kuroshio large meander (KLM) occurred in the end of August 2017 for the first time in 12 years. In order to reproduce this event and investigate its impact on coastal regions, we conducted assimilation and forecast experiments using a 2-km resolution assimilation model, which has been developed at the Meteorological Research Institute of Japan Meteorological Agency (MRI/JMA) for the purpose of operational use in JMA. The assimilation model succeeded in reproducing formation process of the KLM in 2017 as well as associated variations in sea level and water temperature in coastal regions. It is reported that sudden strong current so-called Kyusho occurred in the southeast coast of Shikoku in September 2017. The assimilation results show that this Kyucho event is caused as a result of propagation of a disturbance with cyclonic circulation along the Kuroshio. Besides, in the end of October, warm Kuroshio water was intruded into coastal regions in Shizuoka, Aichi and Mie prefectures in the central part of Japan. This warm water separates from a northward current in the eastern flank of the large meander. In the presentation, forecast results will also be shown to discuss more detailed process.

Reintesification of the Kuroshio Large Meander in Summer 2018

*Toru Miyama[1], Yasumasa Miyazawa[1]

1. Japan Agency for Marine-Earth Science and Technology, Application Laboratory

More than one year have passed since the Kuroshio large meander started in the end of August. It is already longer than the last event in 2004/2005 and the evert before the last in 1989/1990. If the strength of the cyclonic eddy that makes the large meander was defined with the minimum sea level height in 135-140ºE 30-35ºN of FRA-JCOPE 2 reanalysis (Miyazawa et al. 2009) (a smaller value means a stronger eddy), the cyclonic eddy was strengthened after the large meander started, and was weakened from spring in 2018. However, the eddy has been intensified since summer in 2018. The reintensification of the eddy was also found in the temperature field of the reanalysis. The same tendency can be confirmed by the observed absolute dynamic sea surface height (E.U. Copernicus Marine Service Information). Sekine (1985) reported that the spin-up of the cold eddy occurred from late spring to summer in the 1975-1980 Kuroshio large meander event. Therefore, the reintensification of the cold eddy in summer 2018 could play some role in that the current large meander event is becoming long one. In this talk, the situation and dynamics of the reintensification will be discussed.

Discussion

Real-Time Subsurface Moorings as a Promising Component of Global Ocean Monitoring System

*Jianing Wang[1], Fan Wang[1]

1. Institute of Oceanology, Chinese Academy of Sciences

Subsurface moorings have advantage in providing long term and full-depth ocean monitoring parameters. Traditional moorings normally release data once a year, which put constraints on the mooring data usage in the weather and short-term climate forecasts. Recently, the Institute of Oceanology, Chinese Academy of Sciences (IOCAS) has overcome difficulties in the long-term transmission of real-time data from subsurface moorings. Data from sensors up to 3000 m depth can be transmitted to the surface floating body through wireless acoustic communications and then to the shore through satellite. In 2016, the IOCAS had realized real-time transmission of three dimensional velocities over the upper 1000 m from one mooring for more than 280 days. In 2017, real-time transmission module was equipped on the majority of the moorings, and the depth range of data has been extended from 1000 to 3000 m; this real-time observing network has successfully been conducted for 300 days until now. The aim of this abstract is to make recommendation for Real-Time Subsurface Moorings (RTSMs) as a promising component of global ocean observing systems.

The present prediction skill of ENSO at short lead time still leaves much to be desired. Beyond surface ocean data delivered by moored buoys and satellites in real time, the RTSMs can provide the time-depth variations of temperature and velocity at the subsurface and intermediate layers (e.g., the Equatorial Undercurrent variability), which also play a crucial role in the evolution of ENSO. Assimilation of these data will further improve the ENSO prediction skill. Deep-sea data acquiring in real time are also useful to many marine applications, including shipping, fishing, ocean emergent search and rescue, and pollution monitoring. RTSMs will provide data without the need of the use of a ship. This reduces the cost of ship and the risk of data loss due to mooring damage, making the fixed observation system in a more cost-effective manner.

Seasonal Variation of the Mixed Layer Depth at 60°S and its governing dynamics

*Matheus Ferreira Azevedo[1], Yujiro Kitade[1], Shigeru Aoki[2]

1. Tokyo University of Marine Science and Technology, 2. Institute of Low Temperature Science, Hokkaido University

In this research, data from a yearlong M-TRITON type mooring system deployed in 2012 is used to study the seasonal variability of the dynamics governing the Southern Ocean and its influence on the mixed layer depth by measuring temperature, salinity and current velocity data. GHRSST Satellite data and reanalysis ERA-interim wind data were used to complement the mooring, identifying spatial variation in wind and sea surface temperature (SST). This is relevant in the context of coupling readily available surface information (via satellite) and punctual information from ship CTD casts with corresponding subsurface phenomena.

A major factor of mixing was identified as the work on upper-ocean inertial motions (period T =13.8186 hours) associated with variable wind forcing, corroborating with the work of Alford (2001, 2003), Watanabe & Hibiya (2002) and Furuichi et al. (2008). Strong wind peaks, were observed to break stability, parametrized as the Buoyancy frequency N^2, which varied from an order of 10^{-4} s^{-2} to 0 or negative values in the original mixed layer depth (MLD) at the period, while enhancing stability at deeper layers in the same proportion it decreases at the layer above. As a consequence, the MLD increases by around 25m during these events. Wind forcing was found to influence stability and MLD not only through the work of storm induced near-inertial motion but also through meso-scale meridional transport, modulating the frontal structure of the Antarctic Convergence. During winter, the system response to wind weakened as surface cooling induced large scale convection. In particular a cold front reached the mooring at May 28th, starting the convection process. MLD responded by deepening to as far as 150m, and upward salinity flux could be observed.

Strong shear could be observed, usually bellow the mixed layer and generally agreeing with other reports of momentum penetration beyond the scalar mixed layer (e.g. Johnston & Rudnick, 2009). Shear comparison could not be made throughout the year, however, as the mixed layer goes bellow the ADCP detection range during winter. The strong stratification at the base of the mixed layer was seen to generate a complex internal wave field, where shear instability dissipates through high frequency internal waves of period between 2 and 4 hours. These waves seem to become trapped at the stratified layer and evolve to inertial period oscillations, increasing in amplitude until they break, generating high frequency waves once again. This process was observed to repeat at every mixed layer deepening event, either in summer or winter. The relation between internal waves, mixing and MLD at the Southern Ocean is a step to understand nutrient availability and the formation of important water masses of global influence.

21st-Century Flood Hazards along the U.S. Atlantic Coast: Impacts of Sea Level Rise and Tropical Cyclone Climatology Change

*Reza Marsooli[1], Ning Lin[2], Kerry Emanuel[3]

1. Stevens Institute of Technology, 2. Princeton University, 3. Massachusetts Institute of Technology

Flooding due to tropical cyclones (TC) is among the most destructive coastal hazards along the U.S. Atlantic Coast. TC-induced coastal flooding will worsen under sea level rise (SLR) and climate change. To effectively adapt to these evolving hazards, it is essential to understand potential changes in future flood return levels. The present study investigates the impact of 21st-century sea level and TC climatology on flood return levels along the U.S. East and Gulf Coasts. We use extreme value theory and combine probabilistic estimates of sea level rise and TC storm tides to determine flood return levels for the historical period of 1980-2005 and the future period of 2070-2100 (under the emission scenario RCP8.5). A basin-scale hydrodynamic model is implemented to simulate storm tides for large numbers of synthetic TCs that are generated by a statistical-deterministic TC model under climate conditions observed during the historical period and projected by six climate models for the future period. We present and discuss flood return level projections and the contribution of sea level rise and TC climatology change to the projected changes in the return levels.

The Effect of Ocean Waves on an Explosive Cyclone Development: Investigation with a Coupled Model

*Yuki Kita[1], Takuji Waseda[1]

1. University of Tokyo

Violent ocean waves are generated by the explosive cyclone. Since ocean waves affect the development of tropical cyclones, the impacts of ocean waves on the development of explosive cyclones are expected. Ocean waves have several impacts on the atmospheric surface layer: surface friction, sea spray, and momentum flux. We implemented sensitivity experiments to clarify how much ocean waves affect the development of an explosive cyclone with an atmosphere-ocean-wave coupled model, especially focusing on surface friction affected by ocean waves. The test case is the explosive cyclone emerged in early January 2018 over the Northwestern Atlantic. The atmospheric model is Weather Research and Forecasting Model (WRF), the ocean model is Coastal and Regional Ocean COmmunity model (CROCO), and the ocean wave model is WAVEWATCH III (WW3). We compared the numerical simulation results between the WRF-CROCO model and the WRF-CROCO-WW3 model. In the WRF-CROCO-WW3 coupled model considering ocean wave impacts just on surface friction, it is found that the deepening of the explosive cyclone was intensified by about 2hPa in the central sea level pressure, and the center track slightly shifted. In the fully coupled model, the surface roughness reduced and the wind speed was intensified by and large. Compared with observation data above the ocean, the fully coupled model had more accurate wind speed and sea level pressure than the atmosphere-ocean coupled model. It is also revealed that the boundary surface layer scheme in the atmospheric model is critical for accurate reproduction of surface atmospheric process and ocean waves. To reproduce accurate wind speed and wave height, the YSU (Yonsei University) scheme had a better performance than the MYNN (Mellor-Yamada-Nakanishi-Niino) 3rd scheme. As the next step, it is necessary that a coupled model takes into account the turbulent momentum flux produced by ocean waves to reproduce complete accurate air-sea interactions.

Mathematical modeling for initial profile of tsunami by instantaneous- or slow-faulting

*Chi-Min Liu[1]

1. Chienkuo Technology University

Tsunami is one of the most catastrophic disasters in the world. Most of them are generated by the faultings. As the faulting speed is of several thousand meters per second, many tsunamis are generated instantaneously and therefore their initial profiles are assumed to be identical to the profiles of the uplifted sea bottom. This assumption is often adopted in numerical simulation for the sake of simplification. However, in some faulting cases, the speed is comparatively slow which results in the profile discrepancy between sea bottom and surface. To this end, present study aims to mathematically analyze the initial wave profiles generated by either the instantaneous or slow faulting. Results show that the initial profiles greatly differ from the variation of sea bottom for the slow-faulting scenarios.

Geoid height and sea surface changes due to the 2004 Sumatra-Andaman earthquake and the 2012 Indian-Ocean earthquake from satellite gravimetry and satellite altimetry

*Yusaku Tanaka[1]

1. Earthquake Research Institute

A research article about irreversible local geoid height changes on ocean area by the 2004 and 2012 Sumatra huge earthquakes is in press as of 18th February, 2019 (Tanaka et al., accepted by TAO in 2018). I hope to introduce the results in the session of ocean sciences. The abstract of the article is below.

We first report the results from analyzing the GRACE satellite data for the co-seismic and long-term post-seismic changes in the Earth’ s gravity field and geoid height induced by the 2004 Sumatra-Andaman earthquake (Mw9.2) and the 2012 Indian-Ocean earthquake (Mw8.6). The results suggest that the two earthquakes have changed the gravity field and geoid height irreversibly (as opposed to cyclically). We next use satellite ocean altimetry measurements to search for the geoid height change induced by the Sumatra-Andaman earthquake, employing an effective method of extracting coherent space-temporal signals, namely the empirical orthogonal functions (EOF) analysis. Our results demonstrate that the sea level variation in the studied (tropical) area during the studied (10-year) period is dominated by the strong steric changes related to ENSO, to the point that the earthquake-induced signals, even using EOF for the largest earthquakes, are obscured and thus undetectable by ocean altimetry. However, this also means that steric and non-steric changes can be observed separately from artificial satellites.

[Figure] (a) Coseismic geoid height changes induced by the 2004 Sumatra-Andaman earthquake (its rectangular faults are depicted). (b) The sum of short- and long-term post-seismic geoid height changes from the earthquake occurrences till May 2016. (c) The sum of (a) + (b), i.e. co- and post-seismic geoid height changes. (d, e, f) The same as (a, b, c) but for the 2012 Sumatra/Indian-Ocean earthquake. (g) The total geoid height changes by the two earthquakes. The fault mechanisms of the two earthquakes are shown at the epicenters. (h) The time series of geoid height changes at the red circles marked in (a)-(g). The overall mean and average seasonal changes have been removed. The black dots with error bars (assumed uniform in time and have been scaled with post-fit residuals) show monthly gravity data and the red curve is the least-squares fit. The two vertical green lines indicates the occurrences of the two earthquakes.

An irregularly shaped warm eddy observed by Chinese underwater gliders

*Huabin MAO[1]

1. South China Sea Institute of Oceanology

Mesoscale eddies are important for transporting oceanic energy and matter. We investigated the three-dimensional structure
of an irregularly shaped warm eddy using three Chinese underwater gliders and satellite data during May 2015 in the northern
South China Sea. The warm eddy lasted for 2 months, remained quasi-steady, and had a mean radius of ~ 70 km from May
10 to May 31. The heat contents observed along the two glider tracks differed markedly, by 2 ×109 J/m2, which reflected an
imbalance in the geostrophic and tangential velocity distributions of the eddy. The geostrophic/tangential velocity decreased/
increased with depth within the warm eddy. The maximum tangential velocities calculated using the datasets from the two
gliders were 0.8 and 0.25 m/s, respectively, confirming that the shape of the warm eddy was horizontally asymmetrical.
Large errors can arise when the heat, energy, and matter transport for an irregularly shaped eddy are estimated using a regular
circular model. We suggest that more intersecting glider tracks should be used to retrieve the three-dimensional eddy structure,
and that those tracks should be better designed. The irregular shape of the warm eddy was likely induced by oceanic
currents such as the wind-induced Ekman current. Further study is needed to elucidate the eddy–current interactions and
the mechanisms thereof.

sea surface cooling in the northern South China Sea observed using Chinese underwater glider

*Chunhua Qiu[1]

1. Sun Yat-sen University

Based on 26 days of Chinese Sea-wing underwater glider and satellite microwave data, we documented cooling of the upper mixed layer in response to changes in the wind in 9.19-10.15, 2014. The sea-wing underwater glider measured 177 profiles of temperature, salinity, and pressure. we estimated temperature tendencies using a mixed layer model. The entrainment rate and latent heat flux were the two major components that regulated cooling of the mixed layer, and that the Ekman advection and sensible heat flux were small.

Airborne SAR observation of dependence of ocean surface backscattering on wind direction

*Akitsugu Nadai[1]

1. NICT National Institute of Information and Communications Technology

Synthetic aperture radar (SAR) has attracted attention as an oceanwinds measurement technique in coastal areas where high spatial resolution is required.

Oceanwinds measurement by SAR requires the normalized radar cross section (NRCS) model of ocean surface backscattering. However, the NRCS models currently developed is statistically analyzed by combination of NRCS measured by spaceborne SAR and meteorological data. In this study, by carrying out airborne SAR observations with multiple illumination directions in a short time, direct measurement of wind direction dependence of the NRCS at a certain wind speed was tried.

Using a model function of NRCS with the same format as the NRCS models, the coefficients of oceanwinds dependence of NRCS are determined by the airborne SAR. The results determined by airborne SAR are compared with NRCS models and results of the airborne scatterometer.

Regarding the wind speed dependence, the results of the airborne SAR showed good agreement with that of the airborne scatterometer. On the other hand, two NRCS models give a fairly large NRCS. In addition, the change of wind speed dependence with incidence angle determined by the airborne SAR and the airborne scatterometer show different tendency with those of NRCS models.

Regarding the wind direction dependence, the results by airborne SAR shows significantly large wind direction dependence compared with the NRCS model at the incidence angle of 32 degrees. On the other hand, the wind direction dependence by the airborne SAR almost agrees with that of the airborne scatterometer at the incidence angle of 32 degrees.

Comparing the measured NRCS by the airborne SAR with that by the airborne scatterometer, the possibility of influence of the observation configuration on measurement accuracy of the wind direction dependence is suggested.

In addition, the influence of size of spatial averaging may be important on the accuracy of oceanwinds measurement using SAR. Though the high spatial resolution oceanwinds measurement is expected for SAR, ocean surface phenomena like swells and ship wakes may influence the oceanwinds measurement by SAR. Moreover, SAR data cannot be free from speckle noise. The influence of spatial averaging size has to be grasped.

[A-OS20] Global ocean observing systems, obtained results and system optimization: toward OceanObs19

convener:Shigeki Hosoda(Japan Marine-Earth Science and Technology), Shuhei Masuda(Japan Agency for Marine-Earth Science and Technology), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), Fujiki Tetsuichi(Japan Agency for Marine-Earth Science and Technology), Chairperson:Shigeki Hosoda(Japan Agency for Marine-Earth Science and Technology)

Almost twenty years have been passed since the beginning of Argo programme to construct global ocean observing system. The Argo observing system have been covering the global ocean with more than 3000 Argo floats with collaboration of many countries. The Argo is well known as one of the best practices of ocean observing systems, as lots of scientific results and social/industrial benefits have been gained based on indispensable huge amount of oceanic data which has never obtained before. Recently, the Argo observing system is rapidly expanded to monitor deeper ocean (Deep Argo; >4000m depth) and bio-geochemical parameters (Biogeochemical Argo) in addition to upper layer temperature and salinity (Core Argo; <2000m depth).
On the other hand, sustainability of the Argo is not guaranteed and its observing array is still developing as international infrastructure. For example, Argo float distribution recently tends to be inhomogeneous since a part of float deployment and operation is still conducted by voluntary works. Therefore, improving the observing systems to be more effective and sustainable is a mandatory task in the oceanographic community. In this background, various efforts are forwarded to evaluate impacts of ocean observations by the support of GODAE OceanView which is endorsing the Argo programme. In coming OceanObs19, development, expansion and enhancement of the sustainability of the Argo observing systems will be discussed based on scientific results and application researches.
In this session, current status, recent issues, future works on large-scale ocean observing systems are discussed in related to Argo and other research infrastructures such as GO-SHIP, OceanSITES etc., focusing on the global ocean observing system in coming next decade.

Global Ocean Observing System: The Past, the Present and the Future

*Toshio Suga[1,2]

1. Graduate School of Science, Tohoku University, 2. JAMSTEC

A global ocean observing system with the first letters capitalized is the name of the international program led by the Intergovernmental Oceanography Committee (IOC) of the UNESCO: the Global Ocean Observing System (GOOS). GOOS is responsible for coordinating global ocean observations for three critical themes: climate, operational services, and marine ecosystem health. GOOS was launched in 1991 by the IOC in response to calls from the Second World Climate Congress held in 1990. The ocean research community has been intrinsically involved in the subsequent development of GOOS. The two international conferences, OceanObs '99 and OceanObs' 09, were milestones both for GOOS as the international program and for the global ocean observation system as the system consisting of various observing networks. Focusing on the outcomes and significance of these two conferences, the history of GOOS will be briefly described. At the moment, preparation of OceanObs'19 to be held this coming September is going on. The objective of the conference is to "bring people from all over the planet together to communicate the decadal progress of ocean observing networks and to chart innovative solutions to society’ s growing needs for ocean information in the coming decade." The relevant and background information of OceanObs'19 will be presented and the role of the research community will be discussed.

Observed long-term change and variability in the global upper-ocean stratification

*Ryohei Yamaguchi[1], Toshio Suga[1,2]

1. Graduate School of Science, Tohoku University, 2. Japan Agency for Marine-Earth Science and Technology

With the progress of global warming, enhanced upper-ocean thermal stratification from the 1970s has been reported by IPCC AR5. Many studies on future climate projection using CMIP climate models also point out that upper-ocean stratification will strengthen in this century. The strengthened stratification will reduce vertical nutrient supply from the subsurface by futher stabilizing the upper-ocean water column, and then the primary production of the whole ocean is concerned to decrease.

However, large uncertainties in the observational estimate of the long-term change in the upper-ocean stratification still remain. Strengthening trend of the upper-ocean thermal stratification due to the surface intensification of the warming signals has been detected from estimation using globally-averaged sea surface and subsurface temperature time series. On the other hand, some observational studies focusing on some specific regions or using relatively short time series demonstrate that the upper-ocean stratifications are weakening in recent decades, rather than strengthening associated with global warming.

We investigated globally the long-term change and variability in the upper-ocean stratification defined here as the difference between the surface and subsurface density. To resolve spatial patterns of the trends and superposed decadal variability, we used temperature and salinity observations with as spatial and temporal coverage as wide as possible from World Ocean Database 2013. As a result, strengthening trends of the upper-ocean stratification associated with global warming were detected over the global ocean, except for the Arctic Ocean. In the global average, the increase in density stratification corresponds to a 6.6–11.8% of the mean stratification from the 1960s. In addition to the well-documented cause, that is the surface intensified warming, the subsurface temperature changes and haline stratification changes also have significant impacts on the long-term changes in the upper-ocean stratification. The decadal/interannual variabilities in the upper-ocean stratification associated with each particular climate mode are also detected in some ocean regions: The density stratification is correlated with the Niño 3.4 index in the tropical Pacific, negatively lagged correlated with the North Atlantic Oscillation (NAO) index in the North Atlantic, and shows correspondences with SST variations associated with the Pacific Decadal Oscillation (PDO) in the North Pacific.

Estimation of changes in salinity and dissolved oxygen based on observational networks

*Shinya Kouketsu[1]

1. JAMSTEC Japan Agency for Marine-Earth Science and Technology

Changes in temperature and salinity can be captured by Argo float networks more clearly than before the 2000s. For example, the global changes in ocean heat content can be comparable to the ones in sea surface height and net radiative flux into the earth system. Furthermore, various studies have been focusing on the changes in water masses, especially around surface layers. However, quantitative evaluation of regional changes has not been sufficiently clarified. For example, the salinity changes in the deeper layers cannot be easily captured by a float observation due to measurement uncertainty, and the changes in dissolved materials (ex. dissolved oxygen) remained not to be observed sufficiently. In this study, with the combination of autonomous observations and high accurate ship-based observations, we try to examine the possibility to capture and evaluate more accurately long-term changes with observation network.

As the first step, I will present the results based on the monthly salinity (temperature) distributions on the isopycnal surfaces obtained from Argo float observations. Based on the dataset, the long-term mean circulation with the spatial distribution of diffusivity coefficients was estimated, and the budgets for salinity (and temperature) changes in the recent decade were calculated. Especially, in the deeper layer (below 400m), the diapycnal diffusion effects were relatively large to the salinity (and temperature) increases. The salinity (and temperature) increases on the isopycnal surfaces might be consistent with the temperature increased on iso-depths. As the large-scale patterns of the changes revealed by the datasets were similar to the ones detected by twice occupations of the highest accurate observations, the salinity (and temperature) changes in this study were not so much influenced by biases in autonomous measurements (especially of salinity), and the present observation systems might be able to detect such small changes potentially.

The dissolved oxygen budgets were also estimated in the North Pacific with a long-term climatological distribution of the oxygen. The residuals of the budgets seemed to be consistent with the oxygen utilization estimation in previous studies. However, in some regions, temporal changes in oxygen, which included in temporal changes due to the changes in circulations and biological activities, were in the same order of magnitude of the residuals. Thus, spatial and temporal dense (and relatively high accurate) observation network will be needed to clarify the roles of mean biological activities on oxygen circulations as well as the temporal variabilities.

In the presentation, I will show some results of comparisons with assimilation or numerical models, and the other results (regional changes) appearing in the dataset.

Remotely forced decadal physical and biogeochemical variability of North Pacific Subtropical Mode Water over the last 40 years

*Daisuke Sasano[1], Eitarou Oka[2], Yudai Yamada[2], Enyo Kazutaka[1], Toshiya Nakano[1], Masao Ishii[3]

1. Japan Meteorological Agency, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Meteorological Research Institute

Half-century-long observations at the 137ºE hydrographic section across the western North Pacific have been analyzed to demonstrate remotely forced decadal physical and biogeochemical variability of Subtropical Mode Water (STMW) over the last 40 years. During unstable periods of the Kuroshio Extension (KE) that lagged the warm phase of the Pacific Decadal Oscillation by 3–4 years, high regional eddy activity reduced the formation rate and salinity of STMW in its main formation region south of the KE. At the 137ºE section south of Japan, decreasing advection of oxygen-rich STMW from the east resulted in decreases of dissolved oxygen and pH and increases of nutrients and dissolved inorganic carbon, accelerating acidification. Such changes reversed and acidification slowed down during stable-KE periods, especially in the current period since 2010 exhibiting a hiatus of acidification. These results indicate a new mechanism by which climate variability affects physical and biogeochemical structure in the ocean interior.

Asessing the impact of the global ocean observing system using ocean data assimilation systems

*Yosuke Fujii[1]

1. Meteorological Research Institute, Japan Meteorological Agency

Ocean and climate prediction systems are one of the important applications of the data observed by the global ocean observing system. In a prediction system, the oceanic field is estimated as accurately as possible through an ocean data assimilation system first, and then forecast integration of a numerical model is started using the estimated field as the oceanic initial condition. Data assimilation systems require ocean observation data for estimating the oceanic field, and the accuracy of the predictions, thus, severely depends on how much oceanic information effective for the predictions are included in the assimilated observation data, as well as the quality of the numerical model and the data assimilation scheme. Therefore, developing observing systems is an important factor of improving the prediction skills. Meanwhile, building up and maintenance of an observing system are conducted by public money or funds by stakeholders, and in order to sustain and to extend the observing system, we need to show that the system brings social benefits that is equivalent to or more than the investigation. Since observation data are exploited in the society mostly through the prediction systems, assessing impact of observation data on the accuracy of analysis and predictions in ocean data assimilation and prediction systems is an effective way to show the value of the observing system in the society.
GODAE OceanView (Its follow-on program “Oceanpredict” will take over the activity from May 2019) has established the Observing System Evaluation Task Team (OS-Eval TT) since the program was started, promotes data-impact assessments and information sharing for that, and builds up international collaboration for the relevant activities. These activities are also supported by CLIVAR Global Synthesis and Observation panel (GSOP). Operational centers, such as JMA and ECMWF, and research institutes, such as JAMSTEC and Scripps Institution of Oceanography, conducted observing system evaluation studies for various observations such as Argo, TAO-TRITON, and satellite altimetry under these supports. Those results are exploited in the evaluation of the TAO-TRIRON array for its reconstruction for example, but they have a limitation due to its system dependency and the importance of multi-system evaluation with common metrics is indicated. Achievements and resent challenges of observing system evaluation studies are summarized in a community white paper for OceanObs’19. This presentation will introduce some achievements of observing system evaluation studies and show a future perspective on this field.

Global ocean state estimation with new float observations

*Shuhei Masuda[1], Satoshi Osafune[1], Tadashi Hemmi[1]

1. Japan Agency for Marine-Earth Science and Technology

Argo floats are successfully contributing to global ocean state estimation. As the important roles of deep ocean to global changes has been recognized, sustainable deep ocean monitoring networks that use autonomous profiling floats have been widely proposed by the ocean observation community. An increasing number of deep-float deployment initiatives around the world. Deployed floats promise to provide unprecedented deep ocean information. Here we applied deep float data deployed by JAMSTEC to a deep ocean state estimation by using a four-dimensional variational approach. The results demonstrate that the available float data enables some corrections of the modeled ocean state locally for each float although the impact of the data on a basin-scale deep ocean state estimation was still limited in this study due to sparseness of used float data. This implies strategic deployments of deep float in the world’s ocean can immediately contribute to improvement of a current global deep ocean state estimation.

Long-term thermohaline variations in the North Pacific subtropical gyre observed by repeat hydrography along the 165°E meridian

*Yuma Kawakami[1,2], Yoshiteru Kitamura[1], Toshiya Nakano[1,2]

1. Japan Meteorological Agency, 2. Meteorological Research Institute

Recently, long-term thermohaline changes in the surface and subsurface of the world ocean, such as the global warming and the intensification of salinity contrast between basins or regions, are continuously reported. Since changes of temperature and salinity greatly influence not only the density-driven geostrophic ocean circulation but also the marine ecosystem, sea levels and climates, monitoring of the ocean variations and understandings of those mechanisms are important.

Numerous scientific knowledges about thermohaline variations in the subsurface and intermediate layers of the North Pacific subtropical gyre including significant freshening in the thermocline/halocline and fluctuation in a decadal timescale were given by previous researches. However, many of them described in the western part of the subtropical gyre, and studies in its central part have been more limited partially due to the lack of data even though large scale atmospheric forcing generates great long-term thermohaline variations in there. Since thermohaline anomalies in the central North Pacific are mostly transported to the west by the Rossby waves or subsurface water masses flowing along the anticyclonic geostrophic circulation, examinations in the central subtropical gyre may be helpful for better understandings of thermohaline variations in the whole North Pacific.

In this study, we analyzed the repeat hydrography along the 165°E meridian maintained by Japan Meteorological Agency since 1996 to examine long-term thermohaline variations in the North Pacific subtropical gyre. As a result, in the subsurface of the southern part of the subtropical gyre corresponding to North Pacific Tropical Water (NPTW) characterized as the salinity maximum, a significant incresing salinity trend was detected. In this region, potential temperature and salinity also performed an inter-annual variation. On the other hand, in the greater part of the main thermocline/halocline, a significant decreasing trend was observed. In addition, potential temperature and salinity clearly fluctuated in a decadal timescale.

Causes of these variations were further investigated. Then we confirmed that variations in the subsruface around NPTW were originated in the surface mixed layer in the western part of its formation region to the east of the 165°E meridian by temporal changes of freshwater flux and eddy diffusion, and anomalies were transported by the westward geostrophic flow, as demonstrated by previous studies. We also found that thermohaline anomalies in the intermediate layers around the main thermocline/halocline derived from variations of winter mixed layer properties in the central North Pacific. A long-term variation of mixed layer temperature caused by changes of winter atmospheric forcing induced meridional migrations of isopycnal outcrops and thermohaline anomalies on there. Such anomalies were widely distributed to the subtropical gyre by mode waters such as North Pacific Subtropical Mode Water (STMW) in a few years.

First detection of chlorofluorocarbons into bottom layer in the Melanesian Basin of the North Pacific

*Toshiya NAKANO[1], Kazutaka ENYO[1], Daisuke SASANO[1], Shogo URAKAWA[2], Hiroyuki TSUJINO[2], Hideyuki NAKANO[2], Masao ISHII[2]

1. Japan Meteorological Agency, 2. Meteorological Research Institute

Chlorofluorocarbons (CFCs) are a group of artificial chemical compounds that have no natural sources. The CFC concentrations in the ocean interior have been used to quantify the transit time distribution and transport time-scale since the water masses was ventilated from the formation region, and to estimate rates of formation for many water masses. In addition, the distribution of CFCs in the bottom layer indicates the pathway of the advection/diffusion of bottom waters. From 6 August to 27 September 2018, the Japan Meteorological Agency (JMA) conducted a Global Ocean Ship-based Hydrographic Investigation Program (GO-SHIP) revisit cruise at P13 section along the 165˚E meridian on board the R/V Ryofu Maru. In this cruise, JMA collected data of dissolved CFC-11, -12 and -113, and detected the concentration of CFC-11 greater than its detection limit (0.006±0.0011 pmol/kg) in bottom layer between 17˚N and 3˚S in the Melanesian Basin. This result demonstrates that the Lower Circumpolar Deep Water, i.e., a lower part of ventilated Southern Ocean water, formed after 1960s has already reached to the Melanesian Basin of the North Pacific through the Samoan Passage and across the Equator. From the high-quality historical WOCE and GO-SHIP cruise data in the South Pacific, we estimated that the advection speed of CFC-11 equivalent to current speed of bottom layer is about 1 cm/sec (315 km/year). This estimate is consistent with the results of the CMIP6/OMIP numerical modeling by the Meteorological Research Institute. Our results contribute to the understanding of the thermohaline circulation in the Pacific Ocean and the validation and upgrading of the Earth System Model for the future projection of the global warming.

Global grid mapping of temperature and salinity based on Argo float data

*Shigeki Hosoda[1]

1. Japan Marine-Earth Science and Technology

About twenty years have been passed since when Argo programme started in 1999, over 3500 active Argo floats are working to measure temperature and salinity in the upper ocean, accumulating over 2 million profiles. As the situation enables us to construct gridded temperature and salinity data set in the global ocean to be easier, variable kinds of 3-dimensional gridded data set based on purely Argo and Argo plus other observational data are produced from many institutes to investigate global changes in climate and ocean environment.

JAMSTEC produces quasi-real time gridded objective mappings of Argo, MOAA GPV for temperature and salinity fields, and MILA GPV for mixed layer depth every month or 10 days. Those data set are widely used not only to directly analyze the data set but also to validate the state estimate based on data assimilation. The data and its error from MOAA GPV are effectively informed to evaluate representation of temperature and salinity fields, which makes it possible to improve the data assimilation to be more elaborated for accurate analyses of changes in climate and ocean environment. While MILA GPV is produced with characteristics of Argo profiling float which has finer vertical resolution with horizontally homogeneous distribution. That enables us to capture detailed distribution of surface layer mixed layer depth, rapidly progressing physical and biogeochemical researches related to mixed layer variability.

In the future, the objective mapping will be more accurate and useful if the Core Argo array is sustained to obtain long-term statistical characteristics of the upper ocean temperature and salinity. Further, it is expected that improved mapping of physical and biogeochemical parameters will be developed when huge amount of measurement of temperature and salinity in deeper ocean than 2000 m and biogeochemical parameters, with the Deep and BGC Argo arrays.

Evolutions of water mass anomalies in the upper North Pacific based on Argo data, in STMW, ESTMW, and CMW.

*Tong Wang[1], Toshio Suga[1,2], Shinya Kouketsu[2]

1. Graduate School of Science, Tohoku University, 2. Research and Development Center for Global Change, JAMSTEC

Under the background of climate changes, long-term trends and interannual to decadal variations of water masses have been discovered in recent studies. However, how they evolved in space and time is still not fully investigated, partly due to the insufficiency of observation. With spatially and temporally unbiased data available through Argo floats recently, this study describes three-dimensional evolutions of water mass anomalies during 2004-2015, focusing on three typical water masses in the upper North Pacific: North Pacific Subtropical Mode Water (STMW), Eastern Subtropical Mode Water (ESTMW), and North Pacific Central Mode Water (CMW).

In order to preserve the water mass characteristics as much as possible, the analysis in this study is mainly on neutral density surfaces, along which the advection and mixing of water masses dominantly occur. Because of the compensation between temperature and salinity on isopycnal surfaces, this study mainly investigates salinity as a proxy of spiciness. The main results are listed as follows:

In STMW:
The temporal variations of spiciness are dominated by interannual or longer variations. There is a long-term freshening trend at 0.005/year generally as well as strong decadal variations. The former is related to global warming; the latter are caused by the decadal variations of Kuroshio Extension path stability. These anomalies show rapid southwestward propagations in STMW, and the directions can be explained by geostrophic currents, but the propagation speed are 2-3 times higher than geostrophic currents, which indicates other processes involved. The origins of anomalies are most likely to be the STMW formation region. Another possible origin is found in the subtropics of the central North Pacific through statistical analysis, which needs further verification and explanation. Strikingly, the Eulerian temporal changes of spiciness are preserved well during the large distance propagation, implying the existence and persistence of large-scale spiciness fronts.

In ESTMW:
The temporal variability of ESTMW is higher than STMW and CMW, and interannual or longer variations are dominant. The long-term trend in northeastern ESTMW shows freshening, while the southwestern ESTMW is in salinification. There is an obvious 5-6-year oscillation cycle. The anomalies shift between positive and negative rapidly at the ESTMW formation region, spread to the whole ESTMW along its subduction path in each period, and propagate southwestward to the central subtropics and the western tropics by geostrophic flow.

In CMW:
Both spiciness and its total variations are smaller than the other two water masses, but the seasonal variations are higher, being comparable with interannual or longer variations in the northern CMW. With regard to trends, the northern CMW is in salinification, with the anomalies propagating eastward on both monthly scale and annual mean. However, the majority of CMW shows freshening almost uniformly, with weak but recognizable southward propagations.

©2019. Japan Geoscience Union. All Right Reserved.

In conclusion, this study provides a comprehensive description of the evolutions of water mass anomalies in the upper North Pacific for the first time. The regional variations that have been found by limited observations are confirmed and complemented with three-dimensional presentations. The evolutions occurred in earlier years and documented by previous studies are updated by the present analysis. Furthermore, the new phenomena that should be investigated in future are also raised.

Impacts of temperature measurements from sea turtles on seasonal prediction around the Arafura Sea

*Takeshi Doi[1], Andrea Storto[2], Takuya Fukuoka[3], Hiroyuki Suganuma[4], Katsufumi Sato[3]

1. JAMSTEC, 2. CMRE, 3. The University of Tokyo, 4. ELNA

In this work, we add the assimilation of temperature measurements from sea turtles, which covered from surface to maximum depth of about 120m around the Arafura Sea during June-August 2017, into an operational seasonal prediction system. The impact of these new observations is explored by conducting so-called Ocean Observing System Experiments. We find that the prediction of sea surface temperature is significantly improved at 3-4 months lead-time. The results show that the addition of temperature measurements from sea turtles into the existing Global Ocean Observing System (including satellite, mooring buoys, ships, and profiling floats) may open a new door to improve regional seasonal prediction through better representation of the initial state of the upper ocean.

Physical and biogeochemical processes from winter to spring in the south of the Kuroshio Extension

*Chiho Sukigara[1], Ryuichiro Inoue[2], Takeyoshi Nagai[1], Andrea J Fassbender[3], Yuichiro Takeshita[3], Stuart P Bishop[4], Eitarou Oka[5]

1. Tokyo University of Marine Science and Technology, 2. Japan Agency for Marine-Earth Science and Technology, 3. Monterey Bay Aquarium Research Institute, 4. North Carolina State University, 5. The University of Tokyo

In a subtropical region south of the Kuroshio Extension (KE) in the Western North Pacific, large ocean heat loss in the surface layer during winter makes a deep mixed layer. Then, a part of CO_2 dissolved from air to surface ocean is transformed to particulate organic matters via photosynthesis using nutrients which are supplied from deeper layer. Eventually particulate organic matters are transported to deeper layer. In this oligotrophic region, winter mixing is a critical process to supply nutrients to the euphotic zone, which supports high chlorophyll concentrations in early spring are clearly seen by satellite observations. Therefore, it is important to understand effects of nutrient transports by physical processes on biogeochemical material transport and cycle in this period. However, there are few physical and biogeochemical data during winter in this region because of the difficult circumstances in observation.

In this study, we deployed two biogeochemical Argo (BGC-Argo) floats in 33°15’ N, 142°30’ E on January 28th, 2018 during the Shinsei-maru KS-18-1 cruise and recovered them in 35°31’ N, 143°11’ E and 35°43’ N, 143°29’ E on April 20th, 2018 during the Shinsei-maru KS-18-4 cruise. During these two cruises, CTD observations and water samplings were conducted to validate sensors (temperature, salinity, oxygen, chlorophyll, nitrate, and backscatter) attached to floats. BGC-Argos observed 82 profiles from 2000 m depth to the surface every day.

Those floats were kept staying around the deployment position for a month, then moved to southwestward in the middle of March, and were to northward near KE until the recovery. In the first half of the observation period, intermittent mixed layer deepening and subsequent restratification were repeated in the top 300 m depth. High chlorophyll concentrations and backscatter values were observed in the surface layer when upper layers were stratified. After March 17th, oxygen concentration increased, nitrate concentration decreased, and chlorophyll concentration and back scatter value were stable in the subsurface (100 to 300 m). After that, oxygen concentration, chlorophyll concentrations and back scatter values increased (nitrate decreased) coincided with stratification in the surface layer until April 2nd. In the subsurface layer, chlorophyll concentration and back scatter value decreased suddenly, which might mean that biogenic particulate organic matters transported by the deep mixing were quickly decomposed in the layer. Furthermore, a water with low oxygen and high nitrate intruded in the layer 50 to 100 m around March 30th. The origin of this water would be relative deeper layer because of low chlorophyll concentration and back scatter values.

The BGC-Argo observation in the south of KE for three months revealed that physical processes with various time scales in the surface layer from winter to spring affect the primary productivity of phytoplankton and the material distribution.

[A-OS20] Global ocean observing systems, obtained results and system optimization: toward OceanObs19

convener:Shigeki Hosoda(Japan Marine-Earth Science and Technology), Shuhei Masuda(Japan Agency for Marine-Earth Science and Technology), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), Fujiki Tetsuichi(Japan Agency for Marine-Earth Science and Technology)

Almost twenty years have been passed since the beginning of Argo programme to construct global ocean observing system. The Argo observing system have been covering the global ocean with more than 3000 Argo floats with collaboration of many countries. The Argo is well known as one of the best practices of ocean observing systems, as lots of scientific results and social/industrial benefits have been gained based on indispensable huge amount of oceanic data which has never obtained before. Recently, the Argo observing system is rapidly expanded to monitor deeper ocean (Deep Argo; >4000m depth) and bio-geochemical parameters (Biogeochemical Argo) in addition to upper layer temperature and salinity (Core Argo; <2000m depth).
On the other hand, sustainability of the Argo is not guaranteed and its observing array is still developing as international infrastructure. For example, Argo float distribution recently tends to be inhomogeneous since a part of float deployment and operation is still conducted by voluntary works. Therefore, improving the observing systems to be more effective and sustainable is a mandatory task in the oceanographic community. In this background, various efforts are forwarded to evaluate impacts of ocean observations by the support of GODAE OceanView which is endorsing the Argo programme. In coming OceanObs19, development, expansion and enhancement of the sustainability of the Argo observing systems will be discussed based on scientific results and application researches.
In this session, current status, recent issues, future works on large-scale ocean observing systems are discussed in related to Argo and other research infrastructures such as GO-SHIP, OceanSITES etc., focusing on the global ocean observing system in coming next decade.

Long-term thermohaline variations in the North Pacific subtropical gyre observed by repeat hydrography along the 165°E meridian

*Yuma Kawakami[1,2], Yoshiteru Kitamura[1], Toshiya Nakano[1,2]

1. Japan Meteorological Agency, 2. Meteorological Research Institute

Recently, long-term thermohaline changes in the surface and subsurface of the world ocean, such as the global warming and the intensification of salinity contrast between basins or regions, are continuously reported. Since changes of temperature and salinity greatly influence not only the density-driven geostrophic ocean circulation but also the marine ecosystem, sea levels and climates, monitoring of the ocean variations and understandings of those mechanisms are important.

Numerous scientific knowledges about thermohaline variations in the subsurface and intermediate layers of the North Pacific subtropical gyre including significant freshening in the thermocline/halocline and fluctuation in a decadal timescale were given by previous researches. However, many of them described in the western part of the subtropical gyre, and studies in its central part have been more limited partially due to the lack of data even though large scale atmospheric forcing generates great long-term thermohaline variations in there. Since thermohaline anomalies in the central North Pacific are mostly transported to the west by the Rossby waves or subsurface water masses flowing along the anticyclonic geostrophic circulation, examinations in the central subtropical gyre may be helpful for better understandings of thermohaline variations in the whole North Pacific.

In this study, we analyzed the repeat hydrography along the 165°E meridian maintained by Japan Meteorological Agency since 1996 to examine long-term thermohaline variations in the North Pacific subtropical gyre. As a result, in the subsurface of the southern part of the subtropical gyre corresponding to North Pacific Tropical Water (NPTW) characterized as the salinity maximum, a significant incresing salinity trend was detected. In this region, potential temperature and salinity also performed an inter-annual variation. On the other hand, in the greater part of the main thermocline/halocline, a significant decreasing trend was observed. In addition, potential temperature and salinity clearly fluctuated in a decadal timescale.

Causes of these variations were further investigated. Then we confirmed that variations in the subsruface around NPTW were originated in the surface mixed layer in the western part of its formation region to the east of the 165°E meridian by temporal changes of freshwater flux and eddy diffusion, and anomalies were transported by the westward geostrophic flow, as demonstrated by previous studies. We also found that thermohaline anomalies in the intermediate layers around the main thermocline/halocline derived from variations of winter mixed layer properties in the central North Pacific. A long-term variation of mixed layer temperature caused by changes of winter atmospheric forcing induced meridional migrations of isopycnal outcrops and thermohaline anomalies on there. Such anomalies were widely distributed to the subtropical gyre by mode waters such as North Pacific Subtropical Mode Water (STMW) in a few years.

First detection of chlorofluorocarbons into bottom layer in the Melanesian Basin of the North Pacific

*Toshiya NAKANO[1], Kazutaka ENYO[1], Daisuke SASANO[1], Shogo URAKAWA[2], Hiroyuki TSUJINO[2], Hideyuki NAKANO[2], Masao ISHII[2]

1. Japan Meteorological Agency, 2. Meteorological Research Institute

Chlorofluorocarbons (CFCs) are a group of artificial chemical compounds that have no natural sources. The CFC concentrations in the ocean interior have been used to quantify the transit time distribution and transport time-scale since the water masses was ventilated from the formation region, and to estimate rates of formation for many water masses. In addition, the distribution of CFCs in the bottom layer indicates the pathway of the advection/diffusion of bottom waters. From 6 August to 27 September 2018, the Japan Meteorological Agency (JMA) conducted a Global Ocean Ship-based Hydrographic Investigation Program (GO-SHIP) revisit cruise at P13 section along the 165˚E meridian on board the R/V Ryofu Maru. In this cruise, JMA collected data of dissolved CFC-11, -12 and -113, and detected the concentration of CFC-11 greater than its detection limit (0.006±0.0011 pmol/kg) in bottom layer between 17˚N and 3˚S in the Melanesian Basin. This result demonstrates that the Lower Circumpolar Deep Water, i.e., a lower part of ventilated Southern Ocean water, formed after 1960s has already reached to the Melanesian Basin of the North Pacific through the Samoan Passage and across the Equator. From the high-quality historical WOCE and GO-SHIP cruise data in the South Pacific, we estimated that the advection speed of CFC-11 equivalent to current speed of bottom layer is about 1 cm/sec (315 km/year). This estimate is consistent with the results of the CMIP6/OMIP numerical modeling by the Meteorological Research Institute. Our results contribute to the understanding of the thermohaline circulation in the Pacific Ocean and the validation and upgrading of the Earth System Model for the future projection of the global warming.

Global grid mapping of temperature and salinity based on Argo float data

*Shigeki Hosoda[1]

1. Japan Marine-Earth Science and Technology

About twenty years have been passed since when Argo programme started in 1999, over 3500 active Argo floats are working to measure temperature and salinity in the upper ocean, accumulating over 2 million profiles. As the situation enables us to construct gridded temperature and salinity data set in the global ocean to be easier, variable kinds of 3-dimensional gridded data set based on purely Argo and Argo plus other observational data are produced from many institutes to investigate global changes in climate and ocean environment.

JAMSTEC produces quasi-real time gridded objective mappings of Argo, MOAA GPV for temperature and salinity fields, and MILA GPV for mixed layer depth every month or 10 days. Those data set are widely used not only to directly analyze the data set but also to validate the state estimate based on data assimilation. The data and its error from MOAA GPV are effectively informed to evaluate representation of temperature and salinity fields, which makes it possible to improve the data assimilation to be more elaborated for accurate analyses of changes in climate and ocean environment. While MILA GPV is produced with characteristics of Argo profiling float which has finer vertical resolution with horizontally homogeneous distribution. That enables us to capture detailed distribution of surface layer mixed layer depth, rapidly progressing physical and biogeochemical researches related to mixed layer variability.

In the future, the objective mapping will be more accurate and useful if the Core Argo array is sustained to obtain long-term statistical characteristics of the upper ocean temperature and salinity. Further, it is expected that improved mapping of physical and biogeochemical parameters will be developed when huge amount of measurement of temperature and salinity in deeper ocean than 2000 m and biogeochemical parameters, with the Deep and BGC Argo arrays.

Evolutions of water mass anomalies in the upper North Pacific based on Argo data, in STMW, ESTMW, and CMW.

*Tong Wang[1], Toshio Suga[1,2], Shinya Kouketsu[2]

1. Graduate School of Science, Tohoku University, 2. Research and Development Center for Global Change, JAMSTEC

Under the background of climate changes, long-term trends and interannual to decadal variations of water masses have been discovered in recent studies. However, how they evolved in space and time is still not fully investigated, partly due to the insufficiency of observation. With spatially and temporally unbiased data available through Argo floats recently, this study describes three-dimensional evolutions of water mass anomalies during 2004-2015, focusing on three typical water masses in the upper North Pacific: North Pacific Subtropical Mode Water (STMW), Eastern Subtropical Mode Water (ESTMW), and North Pacific Central Mode Water (CMW).

In order to preserve the water mass characteristics as much as possible, the analysis in this study is mainly on neutral density surfaces, along which the advection and mixing of water masses dominantly occur. Because of the compensation between temperature and salinity on isopycnal surfaces, this study mainly investigates salinity as a proxy of spiciness. The main results are listed as follows:

In STMW:
The temporal variations of spiciness are dominated by interannual or longer variations. There is a long-term freshening trend at 0.005/year generally as well as strong decadal variations. The former is related to global warming; the latter are caused by the decadal variations of Kuroshio Extension path stability. These anomalies show rapid southwestward propagations in STMW, and the directions can be explained by geostrophic currents, but the propagation speed are 2-3 times higher than geostrophic currents, which indicates other processes involved. The origins of anomalies are most likely to be the STMW formation region. Another possible origin is found in the subtropics of the central North Pacific through statistical analysis, which needs further verification and explanation. Strikingly, the Eulerian temporal changes of spiciness are preserved well during the large distance propagation, implying the existence and persistence of large-scale spiciness fronts.

In ESTMW:
The temporal variability of ESTMW is higher than STMW and CMW, and interannual or longer variations are dominant. The long-term trend in northeastern ESTMW shows freshening, while the southwestern ESTMW is in salinification. There is an obvious 5-6-year oscillation cycle. The anomalies shift between positive and negative rapidly at the ESTMW formation region, spread to the whole ESTMW along its subduction path in each period, and propagate southwestward to the central subtropics and the western tropics by geostrophic flow.

In CMW:
Both spiciness and its total variations are smaller than the other two water masses, but the seasonal variations are higher, being comparable with interannual or longer variations in the northern CMW. With regard to trends, the northern CMW is in salinification, with the anomalies propagating eastward on both monthly scale and annual mean. However, the majority of CMW shows freshening almost uniformly, with weak but recognizable southward propagations.

Impacts of temperature measurements from sea turtles on seasonal prediction around the Arafura Sea

*Takeshi Doi[1], Andrea Storto[2], Takuya Fukuoka[3], Hiroyuki Suganuma[4], Katsufumi Sato[3]

1. JAMSTEC, 2. CMRE, 3. The University of Tokyo, 4. ELNA

In this work, we add the assimilation of temperature measurements from sea turtles, which covered from surface to maximum depth of about 120m around the Arafura Sea during June-August 2017, into an operational seasonal prediction system. The impact of these new observations is explored by conducting so-called Ocean Observing System Experiments. We find that the prediction of sea surface temperature is significantly improved at 3-4 months lead-time. The results show that the addition of temperature measurements from sea turtles into the existing Global Ocean Observing System (including satellite, mooring buoys, ships, and profiling floats) may open a new door to improve regional seasonal prediction through better representation of the initial state of the upper ocean.

Physical and biogeochemical processes from winter to spring in the south of the Kuroshio Extension

*Chiho Sukigara[1], Ryuichiro Inoue[2], Takeyoshi Nagai[1], Andrea J Fassbender[3], Yuichiro Takeshita[3], Stuart P Bishop[4], Eitarou Oka[5]

1. Tokyo University of Marine Science and Technology, 2. Japan Agency for Marine-Earth Science and Technology, 3. Monterey Bay Aquarium Research Institute, 4. North Carolina State University, 5. The University of Tokyo

In a subtropical region south of the Kuroshio Extension (KE) in the Western North Pacific, large ocean heat loss in the surface layer during winter makes a deep mixed layer. Then, a part of CO_2 dissolved from air to surface ocean is transformed to particulate organic matters via photosynthesis using nutrients which are supplied from deeper layer. Eventually particulate organic matters are transported to deeper layer. In this oligotrophic region, winter mixing is a critical process to supply nutrients to the euphotic zone, which supports high chlorophyll concentrations in early spring are clearly seen by satellite observations. Therefore, it is important to understand effects of nutrient transports by physical processes on biogeochemical material transport and cycle in this period. However, there are few physical and biogeochemical data during winter in this region because of the difficult circumstances in observation.

In this study, we deployed two biogeochemical Argo (BGC-Argo) floats in 33°15’ N, 142°30’ E on January 28th, 2018 during the Shinsei-maru KS-18-1 cruise and recovered them in 35°31’ N, 143°11’ E and 35°43’ N, 143°29’ E on April 20th, 2018 during the Shinsei-maru KS-18-4 cruise. During these two cruises, CTD observations and water samplings were conducted to validate sensors (temperature, salinity, oxygen, chlorophyll, nitrate, and backscatter) attached to floats. BGC-Argos observed 82 profiles from 2000 m depth to the surface every day.

Those floats were kept staying around the deployment position for a month, then moved to southwestward in the middle of March, and were to northward near KE until the recovery. In the first half of the observation period, intermittent mixed layer deepening and subsequent restratification were repeated in the top 300 m depth. High chlorophyll concentrations and backscatter values were observed in the surface layer when upper layers were stratified. After March 17th, oxygen concentration increased, nitrate concentration decreased, and chlorophyll concentration and back scatter value were stable in the subsurface (100 to 300 m). After that, oxygen concentration, chlorophyll concentrations and back scatter values increased (nitrate decreased) coincided with stratification in the surface layer until April 2nd. In the subsurface layer, chlorophyll concentration and back scatter value decreased suddenly, which might mean that biogenic particulate organic matters transported by the deep mixing were quickly decomposed in the layer. Furthermore, a water with low oxygen and high nitrate intruded in the layer 50 to 100 m around March 30th. The origin of this water would be relative deeper layer because of low chlorophyll concentration and back scatter values.

The BGC-Argo observation in the south of KE for three months revealed that physical processes with various time scales in the surface layer from winter to spring affect the primary productivity of phytoplankton and the material distribution.

Method for measuring the pore air pressure in the mountainous slope for rainfall-runoff processes research

*Sho Iwagami[1], Shoji Noguchi[1], Takanori Shimizu[1], Tayoko Kubota[1], Shin'ichi Iida[1], Makoto Araki[1]

1. Forestry and Forest Products Research Institute, Forest Research and Management Organization, National Research and Development Agency

Many researches have been conducted to clarify the mechanism of rainfall-runoff process in a forested catchment in humid warm-temperate regions. Some results obtained from hydrograph separation using isotopic tracer showed that stream discharge is mainly composed of pre-event old water rather than new water (rainwater). Since the 1980’s, the important issue in rainfall-runoff process studies has been solving how pre-event old water stored in the slope discharge in rapid response during rainstorm event. After 1990’s the role of bedrock groundwater contribution to rainfall-runoff process became to be illustrated. Iwagami et al. (2010) described the contribution of bedrock groundwater during rainfall events in a headwater catchment, however there were some large scale events which were not enough to be explain by the bedrock groundwater contribution. Further possible ideas to explain the rapid outflow of pre-event old water might be effect of pressure wave (Torres et al., 1998) and effect of entrapped air (Marui et al., 1993; Delfs et al., 2013).
Role of pore air effects (e.g., entrapped air and, pressure wave) on rainfall-runoff process are pointed out by previous studies however field evidence of pore air behavior or pore air pressure in the slope scale are still lacking. Also method for pore air pressure observation is not established and not discussed fully. In present study, in order to investigate the behavior of pore air under mountainous slopes, measurements of pore air pressure were conducted at two small headwater catchment in Hitachi Ohta Experimental Watershed and Tsukuba Experimental Watershed, Ibaraki Prefecture, Japan. We measured pore air pressure by detecting the inner pressure of borehole and piezometer. Focusing on the pressure difference between pore air and atmosphere (hereafter we call this as “pressure gap”), it is expected that during a dry period (not during rainfall and ground surface is unsaturated), shallow pore air pressure in the slope is almost at equilibrium state with the atmospheric pressure and the pressure gap might be zero. On the other hand, when the pressure gap was raised remarkably during the rainfall event, pore air is supposed to be entrapped and compressed by infiltrating rainwater (wetting front) and groundwater table (or underlying low permeability layer). During the observation from July 2018 to January 2019, pressure gap rising event have observed in both sites. Also negative pressure gap was observed after the pressure gap rising event. Further observation studies are needed for understanding the effect of entrapped air to rainfall-runoff process which could potentially contribute to the prediction of flash flood or corresponding slope instability.

A method to quantify the influence of total water storage change on climate elasticity of streamflow

*Yin Tang[1]

1. Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Science

Numerous studies documented the climate elasticity of streamflow (i.e., precipitation elasticity and potential evapotranspiration elasticity) without considering the total water storage change (dS) based on long-term Budyko framework. However, the values of dS have been found to be a significant component of water balance at short time scales (e.g., annual) and some specific watersheds (e.g., arid regions). The purpose of this paper is to develop a new approach based on the extended Budyko framework to quantify the climate elasticity of streamflow with the influence of dS . The available water under the extended Budyko framework is the effective precipitation (Pe), i.e. the difference between precipitation and dS. The climate elasticity of streamflow with the influence of dS are derived from one recent proposed Budyko-type equation based on proportionality relationship under the extended Budyko framework. The performance of this new approach at annual scale as an example is evaluated for 273 MOPEX watersheds in the United States. Results show that climate elasticity of streamflow with the influence of dS are generally larger than that without considering the influence of dS for study watersheds. Results also indicates that the modeled proportional changes in annual streamflow are significantly biased by using the methods without considering the influence of dS, especially for peak values. This study highlights the needs to consider the influence of dS on climate elasticity of streamflow and provides a framework to quantify the climate elasticity of streamflow with the influence of dS.

Trade-off analysis of discharge-desiltation-turbidity and sediment simulation of a combined reservoir–river system under multi-phase and multi-layer conjunctive releasing operation

*Chien-Lin Huang[1], Nien-Sheng Hsu[1], Gene Jiing-Yun You[1]

1. National Taiwan University, Taiwan

Multi-objective reservoir operation considering the trade-off of discharge-desiltation-turbidity during typhoons and sediment concentration simulation modeling are the vital components for sustainable reservoir management. The purpose of this study is to analyze the multi-layer release trade-offs between reservoir desiltation and intake turbidity of downstream purification plants and thus propose a superior conjunctive operation strategy. To this end, this study proposed a methodology to develop (1) a series of multi-phase and multi-layer sediment-flood conjunctive release modes and (2) a specialized sediment concentration numerical model for a combined reservoir–river system. The conjunctive release modes involve (1) an optimization model where the decision variables are multi-phase reduction/scaling ratios and the timings to generate a superior total release hydrograph for flood control (Phase I: phase prior to flood arrival, Phase II/III: phase prior to/subsequent to peak flow) and (2) a combination method with physical limitations regarding separation of the singular hydrograph into multi-layer release hydrographs for sediment control. This study employed the featured signals obtained from statistical quartiles/sediment duration curve in mesh segmentation, and an iterative optimization model with a sediment unit response matrix and corresponding geophysical-based acceleration factors, for efficient parameter calibration. This study applied the developed methodology to the Shihmen Reservoir watershed in Taiwan. The trade-off analytical results using Typhoons Sinlaku and Jangmi as case examples revealed that owing to gravity current and re-suspension effects, Phase I+II can de-silt safely without violating the intake's turbidity limitation before reservoir discharge reaches 2238 m^3/s; however, Phase III can only de-silt after the release at spillway reaches 827 m^3/s, and before reservoir discharge reaches 1924 m^3/s, with corresponding maximum desiltation ratio being 0.221 and 0.323, respectively.

Gradient change of soil moisture effect on next-day precipitation identified via a Random Forest-Granger causality model

*Lu Li[1], Wei ShangGuan[1], Shu Peng Zhang[1], Jin Jing Pan[1], Nan Wei[1], Yong Jiu Dai[1]

1. Guangdong Province Key Laboratory for Climate Change and Natural Disaster Studies, School of Atmospheric Sciences, Sun Yat-sen University

Surface soil moisture influences precipitation through its impact on water and energy cycles. Understanding of soil moisture-precipitation (SM-P) coupling on synoptic scale is important for improving short-term weather forecasting. However, the sign and pattern of SM-P feedback are still controversial, mainly caused by the difficulty to establish causal relationship. In this paper, we use empirical models to separate local land-atmosphere coupling effect from low frequency variation and persistence effects, and use Granger causality to identify the casual relationship between surface soil moisture and subsequent precipitation over China. Five experiments are designed to investigate the impact of the discrepancy of datasets and empirical models on SM-P feedback. Differences of SM-P feedback using different SM-P datasets are minor compared to those of empirical models. We improved the SM-P feedback model by using random forest to eliminate low frequency variation and persistence effects instead of generalized linear model. Moreover, we present a novel SM-P feedback framework by considering spatial impact of data, raising a new feature selection method and a new SM-P coupling index. The corresponding pattern of SM-P feedback shows that (1) positive SM-P feedback appears almost all over China. (2) The effect of surface soil moisture on next-day precipitation probability decreases from arid to humid regions over China. (3) The effect of low frequency variation and persistence on precipitation is larger than the effect of soil moisture, but we must emphasize that soil moisture also plays an important role in arid and semi-arid regions. Our finding statically supports the hypothesis that strong SM-P feedback locates in transition zones and SM-P coupling is higher during wet periods for dry regions.

Using data-driven methods to explore the predictability of surface soil moisture with FLUXNET site data

*jinjing Pan[1]

1. Guangdong Province Key Laboratory for Climate Change and Natural Disaster Studies, School of Atmospheric Sciences, Sun Yat-sen University.

Soil moisture (SM) is a key variable of land surface-atmosphere interactions. Data-driven methods have been widely used to predict SM, but the predictability of SM has not been well evaluated. This study investigated what variables and methods can be used to better predict SM for leading times of 7 days or longer with a global coverage of FLUXNET site data for the first time. Three machine-learning models, i.e., Bayesian linear regression, random forest and gradient boosting regression tree, are used for the prediction. Variables including atmospheric forcing, surface soil temperature, time variables (year, day of year (DOY) and hour), the Fourier transformation of time variables and lagged SM (7-14 day lagged) were sequentially added into models. A framework with five experiments is designed for factorial exploration of SM predictability. A stepwise method was used to build the best models for each site. The performance of regression models became better when adding more explaining variables in most cases. The results showed that from 47 % to 95% of variation of the best models can be explained. The important explaining variables are lagged surface SM, followed by DOY, year, soil temperature and atmospheric forcing. The predictability of SM depends highly on SM memory characteristics and the persistence of seasonality. The effect of SM memory characteristics on SM prediction as an initial condition question has been widely discussed in this paper. Our results also provide an insight that mechanisms of seasonality effects on SM should be also paid more attention to.

Keywords: A framework with five contrasting experiments is designed to investigate the factors affecting the predictability of soil moisture, The best models can explain between 47% and 95% of variation with different explaining variable combinations at different sites, The most important explaining variable is lagged surface soil moisture, followed by time variables, soil temperature and atmospheric forcing, The predictability of soil moisture depends highly on soil moisture memory characteristics and the persistence of seasonality

Global Analyis of the Hydrological Sensitivity to Climate Variability

*Marisol Dominguez[1], Hugo Alberto Gutierrez-Jurado[1]

1. University of Texas at El Paso

Projected climate changes in the 21st century is expected to have a profound impact in the functioning of Earth's water cycle. Therefore, identifying the components contributing to the sensitivity and resilience of water resources constitutes a research priority of global relevance. Here we present a practical approach to globally assess the hydrologic sensitivity of regions to climate variability. The aim is to identify the regions most vulnerable to changes in their hydrologic functioning as they experience external climatic shifts. For this purpose we present a new metric, the Hydrologic Sensitivity Index (HSI). HSI is calculated for any given location within 50 degrees North and South of the equator using annual values of Potential and Actual Evapotranspiration (PET and AET) obtained from the Moderate Resolution Imaging Spectrometer (MODIS), and Precipitation (P) from the Tropical Rainfall Measuring Mission (TRMM) for all continents for the last 16 years (2001-2016). The HSI defines the hydrologic behavior under a given climatic condition by calculating the change in the Evaporative Index (DAET/P) against the change in the Dryness Index (DPET/P) between consecutive years. For HSI values >=1, regions are classified as Sensitive and for values of <1, Resilient. We calculated the mean, frequency and intensity of the HSI and analyzed the distribution of sensitive areas (HSI >=1) against changes in latitude, elevation, slope and aspect conditions using a 90m elevation dataset from the Shuttle Radar Topography Mission (STRM), as well as according to land cover properties defined by different biome types. Our analysis show the most hydrologically sensitive regions to climate variability occur in Temperate Grasslands along the Great Plains in North American and the Great Dividing Range in Australia, in parts of eastern Asia, in European Temperate Forests, parts of Tropical and Subtropical pampas east of the Amazonian forest and Tropical and Subtropical African Savannas. We also observe a combined latitudinal-elevation control on the HSI that is particularly noticeable along equatorial regions of the globe.

Soil is an important regulator of Earth system processes, but remains one of the least well-described data layers in Earth System Models (ESMs). We reviewed global soil property maps from the perspective of ESMs, including soil physical and, chemical and biological properties. These soil datasets provide model inputs, initial variables and benchmark datasets. For modeling use, the dataset should be geographically continuous, scalable and with uncertainty estimates. The popular soil datasets used in ESMs are often based on limited soil profiles and coarse resolution soil type maps. Updated and comprehensive soil information needs to be incorporated in ESMs. New generation soil datasets derived by digital soil mapping with abundant, harmonized and quality controlled soil observations and environmental covariates are preferred to those by the taxotransfer rule-based method for ESMs. Because there is no universal pedotransfer function, an ensemble of them may be more suitable to provide derived soil properties to ESMs. Aggregation and upscaling of soil data are needed for model use but can be avoid by taking a subgrid method in ESMs at the cost of increases in model complexity. Uncertainty of soil data needs to be incorporated in ESMs.

Estimating near surface soil moisture at a high spatial resolution using an in-situ data based model

*Indishe Prabath Senanayake[1], In-Young Yeo[1,2], Natthachet Tangdamrongsub[3,4], Garry R Willgoose[1], Gregory R Hancock[5], Tony Wells[1], Bin Fang[6], Venkataraman Lakshmi[6], Jeffrey P Walker[7]

School of Earth Ocean and Environment, University of South Carolina, Columbia, SC 29223, United States., 7. Department of Civil Engineering, Monash University, Clayton, Victoria 3800, Australia.

Soil moisture is a key variable in the hydrologic cycle. Therefore, soil moisture information is important for hydrologic and climatic modelling, and for agricultural applications. However, the available point-scale in-situ observations and coarse resolution (10s of km) satellite soil moisture retrievals are unable to capture the spatial variability of soil moisture at high spatial resolutions as required by many of the local and regional scale applications. The lack of high resolution soil moisture data has resulted uncertainties in the model outcomes in these applications. Downscaling coarse spatial resolution L-band microwave satellite soil moisture products using high spatial resolution optical/thermal satellite data appears to be a feasible option to estimate near surface (~top 5 cm) soil moisture at a high spatial resolution. In this study a model was developed to estimate soil moisture at 1 km spatial resolution by downscaling coarse resolution satellite soil moisture products. This downscaling model was built by using in-situ observations from a long term monitoring network (2004-2015) over two sub-catchments, Krui and Merriwa River, located in the Upper Hunter Region of south-eastern Australia. The model was based on the soil thermal inertia relationship between the diurnal temperature difference (ΔT) and daily mean soil moisture (μSM). A regression tree (RT) was built between ΔT and μSM and classified based on the season, vegetation density and soil clay content. Moderate Resolution Imaging Spectroradiometer (MODIS) land surface temperature (LST) and Normalized Difference Vegetation Index (NDVI) values at 1 km spatial resolution were input to the model to estimate soil moisture at 1 km resolution. Subsequently, SMAP-Enhanced 9 km (L3SMP-E) and SMOS 25 km grid (SMOS CATDS L3 SM 3-DAY) soil moisture products over the study area were downscaled and then compared against in-situ observations. Further, the downscaling algorithm was applied to aggregated soil moisture observations from National Airborne Field Experiment 2005 (NAFE’05) over a 40 x 40 km land area over Krui and Merriwa River catchments. The downscaled products were validated using 1 km airborne data. The SMAP L3SMP-E and SMOS CATDS L3 SM 3-DAY products show unbiased root mean square errors (ubRMSEs) of 0.068 and 0.051 cm^3/cm^3 (R^2 values of 0.40 and 0.61), respectively, against in-situ observations. The downscaled airborne soil moisture data shows an RMSE of 0.07 cm^3/cm^3 (with R value of 0.4). The model performed well in dry conditions compared to wet conditions. This method shows a good potential in developing a long time series of high spatial resolution soil moisture information over arid and semi-arid regions using SMOS and SMAP soil moisture products.

Representation of dams in global flood inundation simulations by coupling the global hydrological model H08 and the global hydrodynamic model CaMa-Flood

*Julien Eric Boulange[1], Naota Hanasaki[1]

1. National Institute for Environmental Studies

Dams and reservoirs regulate the flow of rivers, storing and releasing water to maximize its availability for human and environmental needs[1]. While regulating water flow is beneficial regarding human water security, it was reported to have rather dire consequences for the environment such as aquatic biota[2,3]. Nevertheless, currently about half of the major global river systems are affected by dams[4].
Global hydrodynamic models have greatly improved in terms of accuracy and computational efficiency in reproducing flood inundation extent[5]. However, to this day, still few such models successfully simulated flood inundation considering the influence of dams.
In this research, the global hydrological model H08[6,7] is coupled to the global hydrodynamic model CaMa-Flood[8] for representing dams in global flood inundation simulation. The input meteorological dataset used in this study were provided by the ISIMIP2b project[9] and consisted of 4 GCMs and 4 scenarios.

The coupled model simulates river discharge and inundation globally at a daily interval, at a spatial resolution of 0.5˚ ×0.5˚. Discharge predicted with the original CaMa-Flood model were compared to those obtained with the coupled model. The seasonal discharge in rivers heavily affected by reservoir operation were very different between the two simulations. Generally, annual minimum (maximum) 7-day discharge was significantly higher (lower) for the simulation explicitly representing dams. In addition, timings of the discharge peaks were also different between the 2 simulations. We deeply investigated the results in several selected river basins.

An investigation into a potential long subglacial river beneath the Greenland ice sheet using SICOPOLIS simulations.

*Christopher Chambers[1], Ralf Greve[1], Bas Altena[2], Pierre-Marie Lefeuvre[2]

1. Hokkaido University, 2. University of Oslo

The Greenland ice sheet appears to be hiding large geographical features at its base that have the potential to affect ice sheet simulations to an unknown degree. One feature is a broken valley extending from Petermann Fjord far into the center of Greenland revealed by the widely used BedMachine basal topographic dataset. The valley appears to be blocked by topographic rises at many points along its route, however it will be demonstrated that these blockages are entirely artificial consequences of data interpolation and that all available data indicate that the valley is not blocked. To test whether opening up this valley could affect ice sheet sliding, SImulation COde for POLythermal Ice Sheets (SICOPOLIS) simulations are used. The simulations show that opening up this valley creates an uninterrupted potential subglacial water pathway from central Greenland to Petermann Fjord (Figure 1) suggesting that water could flow along its length. The reason this is possible is because the valley tracks down a gentle ice thickness gradient as it roughly follows the ice divide. The redistribution of water towards Petermann Glacier focuses increased sliding there. There is also a small reduction of sliding in central west Greenland. Other effects of this valley on the ice-sheet hydrology and dynamics will be presented. If confirmed with further radar bed observations, this would be a great world river the runs under ice for its entire length, a distance that could be up to 1600 km.

Changes in Annual Rainfall patterns in the Democratic Republic of Congo: Congo river basin

*Chetan Sharma[1], Chandra Shekhar Prasad Ojha[1]

1. Indian Institute of Technology Roorkee

This study focuses on the change detection in annual rainfall in the Democratic Republic of Congo (DRC) in the Congo river basin. High resolution gridded rainfall provided by Climate Research Unit (CRU) is used in this study. Trends in the annual rainfall patterns are calculated and the significance of the trends are found out using non-parametric Mann-Kendal test at 10% significance level. It is found that high negative trends are prevailing in Northern and Southern parts and high positive trends are in the Eastern and Western parts of the Congo river basin. Almost all of these locations show a significant trend. Central wetlands don’ t show a significant change in annual rainfall pattern. Change detection studies are carried out to detect year of change when annual rainfall starts showing deviation from its natural state. Mann-Whitney-Pettit method is used to detect year of change at 5% significance level in this study. Change is detected for almost all of the locations where the trend of annual rainfall is significant. Much earlier change is detected in the Eastern regions of the basin, i.e., the change year 1941-1960, while most of the Northern, Southern and Westerns shows change detection year from 1981-1995.
It is evident from this study that rainfall patterns in the Congo river basin are changing and the changes are non-uniform. There is no change detected in the central regions, while Northern and Southern areas show a significant decrease in rainfall and Eastern and Western regions are showing an increase in total annual rainfall. Change detection year also have non-uniform spatial patterns and Eastern regions are found to be affected much earlier by climate change.

Seasonality in the extreme precipitation events linked to temperature over Japan

*Sridhara Nayak[1], Tetsuya Takemi[1]

1. Disaster Prevention Research Institute, Kyoto University

The frequency of extreme precipitation events is expected to increase in future warmer climate according to the Clausius-Clapeyron (CC) equation which states that atmosphere can hold more moisture in warmer air temperature (about 7 percent per increase of 1ºC). In this study, the extreme precipitation intensities linked to temperature are investigated for different seasons over seven sub-regions of Japan by analyzing the d4PDF dataset at 20 km in present (1951-2010) and future climate (2051-2110). To do this we stratified the precipitation intensities of wet days (defined as excess of 1 mm per day) in different temperature bins at 1º intervals and computed the 99-percentile of the precipitation intensities from each temperature bin. We find that the extreme precipitation intensities linked to temperature is strongly influenced by the seasons and regions of Japan. The extreme precipitation intensities increase with temperature up to 21º over northern Japan, while the extreme precipitation intensities over Okinawa increase up to 24º. Intensities of extreme precipitation events over northern parts of Japan including Hokkaido and Tohoku regions are increased by about 10 mm per day in future warming climate, while over western regions of Japan it is increased by about 20 mm per day. Seasonal analysis indicates a super CC relationship in winter season and a sub CC relationship in summer. Overall results suggest that Japanese regions may experience more extreme precipitations in future warming climate.

Tue. May 28, 2019 9:00 AM - 10:30 AM JST | Tue. May 28, 2019 12:00 AM - 1:30 AM UTC | 201B 2F

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University), Chairperson:Ryu Uemura(University of the Ryukyus), Ikumi Oyabu(National Institute of Polar Research)

Analyses of ice cores from polar and mountain regions have contributed to the reconstruction and understanding of the past environmental changes on timescales from years to several hundred thousand years. In this session, we welcome paleoenvironmental studies using ice cores and paleoclimatic modeling. Studies on reconstruction methods, recording processes and new paleoenvironmental proxies, technical aspects of paleo-modeling are also welcomed. Studies with marine sediment cores, terrestrial sediment cores and tree-rings on similar timescales are also important and welcomed, in order to discuss past environmental changes from multidisciplinary viewpoints.

Atmospheric aerosols modify the global radiation budget directly through scattering and absorption of solar radiation and indirectly through modification of the microphysical properties of clouds. However, there remain large uncertainties in estimates of aerosol effects on the climate system because of the insufficient prediction of aerosols in the Arctic by previous climate models.
Meteorological Research Institute (MRI) has developed a new version of MRI Earth System Model (MRI-ESM2) for participating in the Coupled Model Intercomparison Project Phase 6 (CMIP6). MRI-ESM2 is an updated version of MRI-ESM1 and consists of four major component models; an atmospheric general circulation model with land processes (a horizontal resolution of approximately 120 km), an ocean-sea-ice general circulation model, an aerosol model (approximately 180 km), and an atmospheric chemistry model (approximately 280 km). The number of vertical levels of MRI-ESM2 is 80 (model top at 0.01 hPa). As MRI-ESM2 shows the improvement of prediction of aerosol variations in the recent Arctic, we estimate effects of aerosols on climate change in the Arctic from the pre-industrial to present conditions.
We conducted the CMIP6 historical experiment (1850-2014) by MRI-ESM2 and compared the model results with the ice core data in Greenland. In the comparisons, we used three types of model calculation results; the MRI-ESM2 calculation with the CMIP6 emission inventory, the MRI-ESM2 calculation with the CMIP5 emission inventory, and the previous MRI-ESM1 calculation with the CMIP5 emission inventory. The comparison with the Greenland SouthEastern Dome (SE-Dome) ice core data shows that the MRI-ESM2 calculations successfully reproduce the temporal variation of deposition flux of sulfate, although the previous MRI-ESM1 calculation largely underestimates the sulfate. The historical experiments by MRI-ESM2 show that sulfate at SE-Dome was mostly originating from anthropogenic sources in winter, but natural sources also played an important role in summer. The comparison with the ice core data at the D4 site shows that the MRI-ESM2 calculation with the CMIP6 emission could not reproduce the enhancement of black carbon concentrations in the early 20th century, but the MRI-ESM2 calculation with the CMIP5 emission could. This result suggests that there still remain large uncertainties in the emission inventory of black carbon. The CMIP6 historical experiments by MRI-ESM2 suggest that the aerosols play an important role for temperature changes in the Arctic. The predictions of the surface air temperature changes by MRI-ESM2 are improved from the previous model both in global and the Arctic. These results indicate the importance of analyses of ice cores for improvement of predictions of climate models and the usefulness of climate models for interpretation of ice core data.

Particles in ice layers of SIGMA-A ice core, northwestern Greenland

*Kaoru Kawakami[1,2], Yoshinori Iizuka[2], Sumito Matoba[2], Teruo Aoki[3], Shin Sugiyama[2], Takuto Ando[4]

Arctic atmospheric warming accelerates surface melting on the Greenland ice sheet. In the accumulation areas of the Greenland ice sheet, ice layers are formed by snowmelt and refreezing processes during summer. In the snowmelt water, chemical substances originated from atmospheric soluble aerosols exist as dissolved anion and cation species. After refreezing process, the ions are preserved in the state of acid or salt in the refrozen ice layer. However, the behavior of inclusions in refreezing ice layers is still unclear. In this study, we observed salt inclusions in ice layers of a Greenlandic ice core to understand how and where inclusions were formed along the snowmelt and refreezing process.
During spring 2017, a 60m ice core (hereinafter referred to as SIGMA-A core) was drilled on the northwestern Greenland (78º 03′06″N, 67º 37′42″W, 1490 m a.s.l), which covers the past 100 years. The SIGMA-A core has 243 ice layers (longer than 1mm in thickness), whose mean thickness is 13.8mm.Both the number and the thickness of ice layers have increased in recent 30 years. In a -20℃ cold room of Institute of Low Temperature Science, Hokkaido University, ice layers formed in 2006 and 2014 were selected from the SIGMA-A ice core. The two ice layers were cut to three sections of 40*6.56*25 mm(the 2014 sample), 40*5.45*75 mm(the bottom part of 2006 sample), 40*6*80 mm(the top part of 2006 sample) in the -20℃ cold room. Then, the size and location of inclusions in the sections were observed by a measuring microscope (OLYMPUS, STM-UM) in the cold room. The chemical composition of inclusions were identified by Raman spectroscopy in a cold chamber at -30℃ with the same method described in Ohno et al.[1].
The location of inclusions tends to be the bottom part of the both ice layers. The mean particle size is 17.6μm, which is larger than that in other dry ice cores. For example, the mean size of particles in Greenland NEEM core is about 1-4μm[2], and that in Dome Fuji core is 1-3 μm[1]. Also, inclusions are identified as $Na_2SO_4 \cdot 10H_2O$ and $CaSO_4 \cdot 2H_2O$ by the Raman measurements. The snowmelt and refreezing processes may produce huge salt inclusions at the last stage of refreezing due to ion redistribution.

Information of ice sheet albedo in the past is necessary for improving climatic models and future prediction. Snow grain size is indispensable property for evaluating surface albedo of ice sheets. The large parts of firn/ice core samples, however, have already lost information of initial snow grain size after densification. It is important to develop indicators to evaluate history of snow grain modification from firn/ice core samples. There is a correlation between specific surface area (SSA) and near-infrared reflectance (NIR). Continuous SSA values of core samples can be obtained by near-infrared reflectance analysis. We collected the firn core from SE-Dome, the southeastern Greenland in 2015. The SE-Dome firn core records the seasonal variations over the last 60 years due to their higher accumulation rate (~1m/year). In the present study, we focused on relationship between density and NIR and reconstructed the relationship between climate change and snow grain modification over the last 60 years.
Density and NIR data from the SE-Dome ice core are negatively correlated in the long-term trend. These negative correlations show SSA values basically decrease with snow densification. On the other hand, there is positive correlation between density and NIR data in the short-time trend. Both density and NIR of summer samples particularly tend to be lower value than those of samples deposited during other seasons in same year. Timing and number of the low-SSA and low-density layers are related to those of the periods in which air temperature reaching over -5 ℃ continued. This relationship shows the formation of low-SSA and low-density layers enhanced even though air temperature was less than 0℃. The low-SSA and low-density layers are caused by density reduction due to snow sublimation on the surface of ice sheet.

An ice core retrieved at the SIGMA-D site, Northwest Greenland, in 2014 was analyzed down to the depth of 113 m. Between 6 and 113 m depths, we used a Continuous Flow Analysis (CFA) system developed at the National Institute of Polar Research. The CFA system enabled us to obtain high resolution data of black carbon (BC), stable isotopes of water, microparticles and six elements (Na, K, Mg, Ca, Fe, and Al). The top 6 m of the core was cut at a ca 5 cm interval, melted and analyzed. For BC analysis, we used a recently developed Wide-range SP2 (Single Particle Soot Photometer). We dated the core by annual layer counting using mainly Na and water stable isotopes, with occasional use of other impurities. We divided a year into 12 months and calculated monthly averaged BC concentrations and size distributions.
Here we report the variability of monthly resolved BC concentrations and size distributions over the past 350 years. BC number and mass concentrations started to increase in the 1870s, reached its maximum in the 1920s - 1930s, and decreased again since then. The increases are likely due to anthropogenic input. The increases are most significant in fall and winter months. We find anthropogenic changes in seasonality of BC concentration: annual concentration peak shifted from summer to winter. We also find anthropogenic changes in size distribution of BC: the mode diameter of mass concentration and average mass of BC particles became larger. This suggests that anthropogenic BC particles are larger than natural ones in the snow deposited in Greenland. Apart from anthropogenic BC, BC concentration occasionally showed large spikes in summer. They are likely originated from biomass burnings. We will compare the results from the SIGMA-D core with those from other ice cores drilled in Greenland and discuss spatial variations of BC.

Dust (mineral particles) contained in the ice core has been used as a proxy of past atmospheric circulation or arid climate condition. Most of dust studies have just analyzed dust flux and size distribution, but little study focused the meteorological type and composition of dust. Since the type and composition of dust varies depending on its origin and transport process, they are potential to reveal detailed source of dust and atmospheric circulation fluctuation. In this study, we analyzed mineral composition of dust layers of a shallow ice core drilled in the Pamir Alay Mountains of Central Asia of Kyrgyz Republic in August 2016, using an optical microscope and a scanning electron microscope.
The depth profiles of dust differed between small size ($1<d\leqq15$ μm) and large size ($d>15$ μm). The dust layers consisting mainly of small size dust contained abundant yellow colored minerals, while those with large size dust contained more abundant red colored minerals. Furthermore, the dust layers of large size dust contained calcite originating from limestone, which is an unique geology of Pamir region, indicating they are originate from near the glacier. Results revealed that the mereological type and composition differed significantly among the dust layers of the ice core. In particular, they are possibly originated from two different sources, including a short distance consisting of calcite and red mineral, and a long-distance without them.

Estimation of snow surface patterns from the coast to the inland, Dome-Fuji Station, of Antarctica, using camera images

*Konosuke Sugiura[1], Kengo Watanabe[1], Naohiko Hirasawa[2], Kenji Kawamura[2], Fumio Nakazawa[2], Hiroshi Ohno[3], Shuji Fujita[2], Ikumi Oyabu[2], Takashi Yamanouchi[2], Hideaki Motoyama[2]

Snow surface patterns in Antarctica are of practical concern and are important from the standpoint of developing an optimum route in Antarctica. In this study, we estimate snow surface patterns from the coast to the inland of Antarctica using camera images during JARE-59. The interval camera was used to capture the image of snow surface. Snow surface was photographed from November 13, 2017 to December 9, 2017. The number of images from the southern latitude of 69 degrees to 77 degrees was about 14,000 sheets. One sheet was divided into eight zones to distinguish a small-scale snow surface pattern. The pattern of snow surface was classified in three kinds such as 1) deposition, 2) equilibrium, and 3) erosion. We judged the snow surface patterns by sight. When Snow dune/Snow barchan was observed, it was classified as a deposition pattern. When Sastrugi/Glazed surface was observed, it was classified as an erosion pattern. In addition, when snow ripples were observed, it was classified as an equilibrium pattern.
The result of our analysis shows that the frequency of the deposition pattern decreases as latitude rises to 73 degrees south (Katabatic wind region) and then it increases slightly. In contrast, the frequency of the erosion pattern increases as latitude rises to 73 degrees south above which it decreases slightly. On the other hand, there have been no outstanding changes in the equilibrium pattern. The analyzed results of latitude dependence agree with the previous research qualitatively. However, the dominant surface pattern in the inland plateau region was still the erosion pattern. Since we analyzed the data of the outward trip, it is necessary to analyze the data of the return trip from the inland to the coast and to investigate a time scale of the surface pattern changes.

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University), Chairperson:Nozomu Takeuchi(千葉大学), Kenji Kawamura(国立極地研究所)

Analyses of ice cores from polar and mountain regions have contributed to the reconstruction and understanding of the past environmental changes on timescales from years to several hundred thousand years. In this session, we welcome paleoenvironmental studies using ice cores and paleoclimatic modeling. Studies on reconstruction methods, recording processes and new paleoenvironmental proxies, technical aspects of paleo-modeling are also welcomed. Studies with marine sediment cores, terrestrial sediment cores and tree-rings on similar timescales are also important and welcomed, in order to discuss past environmental changes from multidisciplinary viewpoints.

Isolation of living fungi from Antarctic ice cores

*Masaharu Tsuji[1]

1. National Institute of Polar Research

15 million years ago, the temperature of Antarctica was about 11 ℃ higher than the current temperature [(1)]. Many of fungi reported from Antarctica have also been reported from a variety of extreme, perennial cold environments including the Arctic, Siberia, the Alps, Alaska, Patagonia. Since these fungi have only been reported from the environment like the polar desert, fungi currently inhabited in Antarctica are thought to have come after 15 million years ago. However, the origins of the fungi inhabiting Antarctica are unknown.

In this presentation, to elucidate the origin and evolution of Antarctic fungi, I would like to introduce the isolation of Antarctic fungi from Antarctic ice cores.

1. National Institute of Polar Research, 2. SOKENDAI (The Graduate University of Advanced Studies)

This study attempted to culture ancient fungi preserved in the polar ice cores dated from ~1000 to ~9000 years ago. The samples of several hundred grams of ice collected at depths of 97, 470 and 670 m from Mizuho station (70°42'S, 44°20'E; 2230 m a.s.l.) and at depths of 116, 141 and 169 m from Dome Fuji station (77°19'S, 39°42'E; 3810 m a.s.l.) in Antarctica (Fujii, 1985; Dome-F Deep Coring Group, 1998). The ages of these samples were estimated to be ~1000, ~5500 and ~9000 years for the Mizuho ice core (Nakawo et al., 1989) and ~3000, ~4000 and ~5000 years for the Dome Fuji deep ice core (Dome Fuji Ice Core Project Members, 2017) respectively. In addition, an ice core sample from Åsgardfonna in the northeastern part of Svalbard (79°27'N, 16°43'E; 1140 m a.s.l.) (Uchida et al., 1993) was used for the cultivation. The information on the sample depth and age were unclear. In this study, we successfully cultivated fungi from all the samples. The nucleotide sequences were obtained by DNA analyses of the strains. Many of these sequences showed low homology to those registered in the NCBI DNA database, therefore it was believed that ancient fungi were actually obtained. This suggested that the culture of ancient fungi and its DNA analysis enable to be done over time by using deep ice cores such as the Dome Fuji ice core. This allows to study the physiological ecology of ancient fungi and to use decomposition and fermentation characteristics of ancient fungi for industrial purposes. Also, DNA analyses of the ancient fungi may enable to examine the diversity of fungi with climate and environmental changes and to study the evolutionary history on fungi. In our presentation, we will introduce the results obtained and discuss the prospects and developments of the study using the ancient fungi preserved in the polar ice cores in the future.

We analyzed chemical compositions of dust and sea-salt particles in the EPICA Dome C (EDC) ice core between 26 and 7kyr BP by using an ice sublimation technique, and compared the results with existing data of the Dome Fuji (DF) ice core. Combining the results of non-sea-salt Na and sea-salt Na fractions in total Na from the sublimation measurement and Na^+concentrations from ion measurement, we estimated that sea-salt flux in the two cores are roughly the same, while dust flux in the EDC core is significantly lower than that in the DF core throughout the studied period. Al/Si ratio of dust particles in the EDC core increased since around 16 kyr BP, suggesting that the average mixing ratios of minerals, presumably from different source locations, are different before and after 16 kyr BP. The composition of calcic dust also changed around 16 kyr BP; the fraction of calcium sulfate (calcic dust sulfatized during transport through lower troposphere) decreased and that of calcium nitrate (calcic dust reacted with nitric acid during transport through the middle to upper troposphere) increased. Previous studies on the mineralogy of EDC dust have suggested that dominant dust source area was Patagonia before 16 kyr BP and that multiple dust sources may have contributed thereafter (Siggaard-Andersen et al., 2007; Marino et al., 2008; Vallelonga et al., 2010).On the other hand, atmospheric model simulations have suggested that Patagonian dust is transported via lower troposphere, while Australian dust is transported via middle to upper troposphere (Li et al., 2008; Krinner et al., 2010). Thus, our data collectively confirm the dominance of Patagonian dust during the LGM and support the hypothesis of increased Australian dust contribution during the Termination and Holocene. The Dome Fuji Al/Si ratios were lower than those in the EDC core, and the fraction of calcium sulfate in the DF core are higher than those in the EDC core after around 16 kyr BP. The results suggest that Patagonian dust continued to be the dominant contributor to the Dome Fuji region after 16 kyr BP.

Spatial variation of surface mass balance over the last few millennia in the Dome Fuji area from the analyses of shallow ice cores

*Kenji Kawamura[1], Ikumi Oyabu[1], Fumio Nakazawa[1,2], Shuji Fujita[1,2], Kyohei Yamada[1], Naoyuki Kurita[4], Shun Tsutaki[5], Hiroshi Ohno[6], Konosuke Sugiura[7], Kumiko Goto-Azuma[1,2], Hideaki Motoyama[1,2], Ayako Abe-Ouchi[5,3]

One of the main targets in the current Japanese Antarctic program is to identify the drilling site for the oldest ice around Dome Fuji. The site selection activities (during JARE 59 and 60 summer seasons) include national and international ice-penetrating radar surveys, four shallow ice corings, and firn air sampling at one site. In this presentation, we report the shallow drillings and their analytical results for DEP (dielectric profiling) for deducing spatial differences of accumulation rate among the shallow drill sites.

During the JARE 59 surveys (2017-2018), the first core was drilled at 55 km south of Dome Fuji (New Dome Fuji; NDF) to the depth of 151.9 m, second one was drilled at 40 km southeast of Dome Fuji (DFSE) to 41 m, and third one was drilled at 30 km northwest of Dome Fuji (DFNW) to 41 m. The DEP of these cores were analyzed in summer 2018 at the NIPR cold laboratory, and major volcanic signals were identified back to 13thcentury for all three cores. During the JARE 60 surveys (2018-2019), we set up one base camp 5 km north of NDF (~50 km south of Dome Fuji) (NDFN) and drilled a shallow core to 142 m. The DEP analyses will be conducted for detecting volcanic signals along the core.

We also found a visible 20-mm-thick volcanic ash layer at 118.9 m in the NDF core, and a 10-mm-thick layer at 122.18 m in the NDFN core. Visible ash layers from probably the same origin have also been found in the Dome C (< 1-mm-thick layer at 132.6 m) and Vostok (~30-mm-thick layer at 103.04 m) ice cores. These ash layers were dated at 3500–3600 years before present (Basile et al., 2001; Kohno et al., 2004). On the other hand, volcanic ash layer was not found in the first Dome Fuji deep ice core (Narcisi et al., 2005) but in the second Dome Fuji deep ice core at 133.6 m.

The DEP and in-situ density data are used to date the horizons by comparing the DEP peaks to published volcanic data sets from several ice cores including the WAIS Divide core (Sigl et al., 2014), and to deduce surface mass balance between the volcanic signals for the three cores from JARE 59.

We identified 6 volcanic signals to 40-m depth and 12 signals to ~150-m depth (from the DF and NDF cores). We also use the data from the previously drilled cores (e.g. one from 6-km south of DF drilled in JARE 52, and one from 195-km south of DF in JARE 54) to discuss spatial patterns of accumulation rate from the corings. In the near future, the data will be combined with shallow ice-radar data from the JARE

Sensitivity of global nonhydrostatic atmospheric model to changes in orbital forcing for the early Holocene

*Minoru Chikira[1], Ayako Abe-Ouchi[1], Masaki Satoh[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

Various types of geological records have extensively shown consistent patterns of warmer and moister areas over Asia and Africa during the early to mid-Holocene. Previous sensitivity simulations of many global climate models to the changes in the earth’s orbital parameters during this period have equally shown the enhancement of the Asian and African monsoons, providing a successful interpretation on the qualitative patterns of these records. This study aims to shed a new light on the climate of this period by running sensitivity simulations by a global nonhydrostatic atmospheric model which began to be available for climate studies in recent years. The model used in this study is Nonhydrostatic ICosahedoral Atmospheric Model (NICAM) developed by a Japanese meteorological community: a framework of a cloud resolving model which resolves cumulus convection when used with a proper resolution and does not adopt any cumulus parameterizations. Because of the limit of computational resources, we use NICAM with a horizontal resolution of 56km. Despite not resolving cumulus convection, previous studies confirmed that it behaved similarly to the one with much higher resolution and provided practically reasonable mean-states and variability. The simulations were run with a slab ocean model and orbital parameters of 9000 years B.P. (9kBP). The Integrations were continued for 5 years. The seasonal mean precipitation in the control run is largely overestimated, however, it shows very good spatial distributions in terms of the locations of the ITCZs and peak precipitation. In particular, because of the high resolution enough to represent the steep terrain of the Tibetan Plateau, the model successfully reproduces a narrow rain band along its southern edge. The boreal summer precipitation of the 9kBP simulation shows a well-known northward shift of the African ITCZ, consistent with previous studies. Over Asia, the narrow precipitation band at the south of the Tibetan Plateau is significantly enhanced. The precipitation also increases over the Indian ocean. In between, there is a band-like structure of the suppressed precipitation over the India and Indochinese Peninsula. Although the resolution is not sufficient to resolve cumulus convection, the global nonhydrostatic atmospheric model appears to have a potential to represent small structures of the earth’s topography and evaluate its effect on precipitation which had not been discussed in previous studies. It is expected to be useful in discussing regional scale patterns of the geological records.

Roles of sea ice–surface wind feedback in maintaining contrasting modes of glacial Atlantic meridional overturning circulation and climate

*Sam Sherriff-Tadano[1], Ayako Abe-Ouchi[1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo

During the glacial period, climate varied on millennial-time scale between two contrasting modes. These climate changes are often associated with drastic reorganizations of North Atlantic sea ice and Atlantic meridional overturning circulation (AMOC). However, processes affecting the periodicity of AMOC and climate variability remain unclear. Here, through performing simulations with a comprehensive climate model, we show that sea ice and associated changes in surface winds play a key role in maintaining the contrasting modes of AMOC and climate. Experiments highlights the importance of the suppression of atmosphere-ocean heat exchange by sea ice in inducing a weakening of surface winds. The surface wind anomaly then causes a reduction of salt transport and weakens AMOC, which triggers further expansion of sea ice. Our results show that sea ice–surface wind interactions over the North Atlantic plays an important role in inducing the long periodicity of the climate variability.

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University), Chairperson:Ayako Abe-Ouchi(東京大学大気海洋研究所), Sam Sherriff-Tadano(University of Tokyo)

Analyses of ice cores from polar and mountain regions have contributed to the reconstruction and understanding of the past environmental changes on timescales from years to several hundred thousand years. In this session, we welcome paleoenvironmental studies using ice cores and paleoclimatic modeling. Studies on reconstruction methods, recording processes and new paleoenvironmental proxies, technical aspects of paleo-modeling are also welcomed. Studies with marine sediment cores, terrestrial sediment cores and tree-rings on similar timescales are also important and welcomed, in order to discuss past environmental changes from multidisciplinary viewpoints.

During the last termination of ice age cycle (deglaciation), Heinrich event 1 as well as B/A, Antarctic Cold Reversal (ACR) and Younger Dryas occurred as millennial scale climate changes. On the other hand, millennial scale climate changes such as D-O cycles recorded in ice core and deep sea cores in both hemisphere seem to occur more frequently during the mid-glacial state than during the early or late glacial state. Here we ran several sensitivity experiments and deglaciation simulations using a coupled atmosphere and ocean GCM (MIROC4m AOGCM) developed in Japan and analyzed the stability of AMOC and climate. Many model experiments were run for longer than10000 years under many different conditions of constant Greenhouse Gas levels, obliquity with/without glacial ice sheet and with and without freshwater flux into North Atlantic region. The results show large self-sustained oscillation of AMOC and high latitude temperature change similar to D-O cycles, which are consistent with ice core data and deep-sea data in both low and high latitude. Furthurmore, the results imply that both Northern Atlantic ocean-atmosphere-sea ice coupled system and Southern Ocean are important to maintain the oscillation with periodicity longer than 2000 years, for which we propose “Bipolar thermohaline oscillation” as its mechanism. We show that the D-O like oscillation occur with Glacial ice sheets under limited range of CO2, obliquity, and freshwater forcing. Implication on the mechanism and the conditions of the millennial scale climate changes for the past time period is discussed.

The mode changes in the glacial cycle, smaller amplitudes with 20 kyr periods before 2.7 BP; medium amplitudes with 40 kyr periods between 2.70 and 1 Ma BP; greater amplitudes with around 100 kyr periods after 1 Ma BP, remain unanswered.

Carbon cycling is closely coupled with silicon cycling in the Earth surface. Oceanic silica is supplied from weathering of terrestrial matter, which depends on the atmospheric pCO_2. The atmospheric pCO_2, in turn, is influenced by the diatomaceous biological pump. Silicon can be a crucial driver of the Earth surface environment. Oceanic silica is removed by the burial of amorphous silica produced by diatoms. We have reported that the non-linear dissolution behavior of diatom frustules, where greater diatomaceous production tends to suppress dissolution of dissolved silica forming greater-sized frustule-aggregates.

Here we have developed a numerical model expressing the carbon and silicon cycling in the Earth surface, with diatomaceous biological pump and the non-linear dissolution behavior of diatom frustules being introduced.

The results of the model runs show interesting outcomes: when the amount of circulating carbon is reduced with time, both the amplitude and period of atmospheric pCO_2increase with time. When the insolation changes by Milankovitch forcing were loaded on the model temperature, the mode changes are successfully reproduced.

We propose that the glacial cycles may be understood by the coupling of ice-sheet dynamics and change in the oceanic Si inventory.

Development of an Ice Sheet Model coupled General Circulation Model and application of Energy Balance Model on the estimation of Ice Sheet mass balance

*Ryouta O'ishi[1], Ayako Abe-Ouchi[2,1], Fuyuki SAITO[2], Takashi Obase[1]

A sea level rise is an important topic in a future climate projection. In the past warm period known as the Last Interglacial (LIG), paleoevidences indicate sea level rise of several meters. Paleoclimate modeling community applies past GCM results on ice sheet models and tries to reproduce past sea level rises.
We designed a coupling procedure between an ice sheet model and a general circulation model and are planning to introduce a surface mass balance of ice sheet not only by a typicall empirical method called PDD (Positive Degree Days) but also surface mass balance on the ice sheet as an upper boundary condition. The PDD only refers the surface atmosphere temperature and snowfall. In the present study, we use a process-based land surface model MATSIRO to estimate surface mas balance forced not only by temperature and snowfall but also by other surface variables including shortwave and longwave radiation. We compare the characteristics of resultant ice melt amount from PDD and MATSIRO to evaluate the inclusion of process-based heat and water balance instead of empirical equation.
We apply this procedure on the estimation of Grennland mass balance in the LIG.

Institute of Low Temperature Science, Hokkaido University

The recovery of a new Antarctic ice core to cover one million years will advance our understandings of the Quaternary climate. Previous ice flow modeling studies indicate that such old ice may exist in inland areas of the Antarctic continent, where horizontal ice flow is slow, the ice is thick, accumulation rate is low, basal temperature is well below the pressure melting point (Pattyn 2010; Fischer et al. 2013). We have been analyzing the field data taken by 59th Japanese Antarctic Research Expedition (JARE 59, 2017-2018) and conducting ice flow modelings as the essential parts of the site selection activities. In the present study, we show results of ice flow modeling to estimate the temperature and age of ice, and age resolution of the ice near the bed at a dome of the ice sheet. We use an one-dimensional ice flow-thermodynamic model, in which the vertical velocity of the ice is parameterized with empirical functions applied to the area near ice sheet domes. At first, the calculated age and temperature profiles of the ice are compared with depth-age profile of the Dome Fuji ice core and borehole temperature at Dome Fuji to assess the model performance for our purposes. Next, we investigate the influence of parameters (ice thickness, accumulation rate, geothermal heat flux, profile of vertical velocity of the ice) on the age of ice especially in the lowest few hundred meters. The results indicate that a fine resolution of oldest ice (~age of 1.0 Ma before present) is expected from a thick ice and a low accumulation, but the thick ice increases the chance of basal melting. The one-dimensional model is applied to the vicinity of Dome Fuji along the transect of JARE 59 surveys, using estimated ice thickness and simplified pattern of surface mass balance and geothermal heat flux. The calculated distribution of the age of ice are compared with internal layers of the ice (isochrone) derived from ground radar surveys. The calculated age of ice roughly follows observed internal layers of ice, and a smaller accumulation near NDF compared to Dome Fuji increases the agreement between calculated age of ice and internal layers of ice.

Climatic histories from about 800 kyr BP up to present have been studied using very deep ice cores drilled at dome summits in East Antarctica at Dome Fuji and Dome C. Knowledge gained from ice cores studies are crucial to understand the past and present climate and to predict the impacts of future climate changes. International Partnership for Ice Core Sciences (IPICS) identified that ice cores covering ages of the mid-Pleistocene Transition are necessary step to better understand climate dynamics. Multiple ice cores older than 1 M yrs BP are necessary. Dome Fuji area in East Antarctica is one of the candidate areas where we may be able to find very old ice core near the bottom of the ice sheet. Japanese Antarctic Research Expedition (JARE) has conducted deep ice coring at Dome Fuji twice in the past decade. They recovered ice cores covering ages up to about 720 kyr BP. At the same time, they have accumulated radar sounding data in this area. Alfred Wegener Institute (AWI), Germany, made an extensive airborne radar survey in 2016/2017 season covering Dom Fuji with a basic survey line spacing of 10 km. In the following season of 2017/2018, JARE also made ground-based radar surveys over a distance of 2950 km with a line spacing of 5 km or less. Based on results of these surveys, we conducted a more detailed radar surveys at Dome Fuji in 2018/2019 season as a collaborative research between University of Alabama, the University of Kansas, National Institute of Polar Research under Research Organization of Information and Systems (Japan), and Norwegian Polar Institute. Norwegian Polar Institute joined also collaborating on these efforts with the European framework of Beyond EPICA - Oldest Ice (BE-OI). We used two state-of-the-art radars: A wideband radar ice sounder developed by CReSIS, University of Kansas and ultra-wideband radar developed by University of Alabama. In addition, we used a classical pulse-modulated VHF radar of JARE with high gain antennas. Using a traverse team of JARE and its snow vehicles, we investigated along 2,700 km in an area of about 1,000 km^2. Final spacing between survey lines varied between 0.5 km and 0.25 km. The surveys were completed by the end of December, 2018. We will present preliminary results from these surveys. Preliminary quick-look results indicate that we collected an excellent radar data set with very good layering information including the bottom 10% of the ice. The data will be examined to identify candidate locations to drill very old ice.

Deformation mechanism of coarse-grained polycrystalline ice is well investigated by various experiments. However, the deformation of ice-sheet ice is complicated by various factors such as local distributions of impurities and mechanical anisotropies. Detailed analyses of ice cores have revealed that ice from glacial periods (ice-age ice) that has highly-concentrated impurities and small grains deforms rapidly compared with ice from Holocene. Although the causes of the rapid deformation in ice-age ice have been discussed in various studies, the detailed mechanism remains unclear.
The deformation rate in ice sheets is extremely slow; therefore, ice-sheet ice deforms under low dislocation density state. To replicate such deformation mechanism in laboratory experiments, we prepared fine-grained ice which has much grain boundaries. Since grain boundaries can act as sinks of dislocations, a low dislocation density state is kept during deformation like ice sheets.
To investigate the cause of rapid deformation of ice-age ice, we conducted deformation experiments and microstructural observations using artificial ice, with focusing on the influences of microparticles and grain size (grain boundaries). We made pure ice, and silica-dispersed ice with particle diameters of 0.3 μm and mass concentrations of 0.1 and 0.01 %. For the investigation of grain-size-sensitivity of deformation, various-sized ice (mean grain size with 30 μm –2 mm) was prepared.
Our experimental results revealed different trends for softening and hardening effect due to microparticles dispersion, grain-size-sensitivity, and microstructural evolutions during deformation in fine- and coarse-grained ice. Silica-dispersed ice with coarse grains indicated a hardening trend compared with pure ice, while little direct effect on the deformation in fine-grained ice. Grain-size-sensitivity was appeared only in fine-grained ice: the strain rates become larger at finer grains.
In this presentation, we discuss the possible cause for the rapid deformation of ice-age ice based on systematic deformation experiments and microstructural observations.

Ice cores drilled from mountain glaciers usually contains abundant pollen grains supplied from vegetation around the glaciers. Pollen grains have been used in ice core studies as markers of annual layer boundary since they are supplied on the glacier in a certain season of a year. Furthermore, they have been used as a proxy of vegetation in the surrounding area since their composition reflects relative abundance of each species in the source area. An ice core from the surface to the bottom was drilled on a glacier in Pamir Arai Mountains in central Asia in 2016. In this study, pollen grains in a part of the ice core and snow pit were analyzed. Annual layers of the ice core, which were determined based on a seasonality of stable isotope, were compared with the variations of pollen grains concentration, and the seasonality of pollen supplies was examined.
Ice cores were recovered at two sites (sites 1 and 2 at 5300 m and 5208 m, respectively) on the glacier. Oxygen stable isotope in the 7 m deep ice cores at both sites showed significant fluctuations. We assumed that they are periodic seasonal signals and determined the annual layers. As a result, the ice cores of Sites 1 and 2 includes layers for 8 years and 9 years, respectively. Microscopic analysis revealed that 6 types of pollen grains, which were identified as Cupressaceae, Artemisia, Chenopodiaceae, Pinaceae, Betulaceae, and Ephedra, were contained in the ice cores. Mean concentration of the pollen grains was highest for Cupressaceae at both sites (2.20, 2.62 grains/ml (74, 67%)), was second highest for Artemisia (0.65, 1.06 grains/ml (22, 27%)). The depth profile of the pollen grain concentrations showed several spikes in the ice cores. The depth of peaks differed between species. The peaks of Artemisia and Chenopodiaceae appeared at the same depth while the peaks of Cupressaceae appeared just below the depth of their peaks. The peak depths of Artemisia and Chenopodiaceae roughly agreed with the depth of the maximum value of the isotope ratio, indicating that these pollens were supplied in the summer or autumn. On the other hand, Cupressaceae found in the layer below is likely to be supplied in spring or summer. There are exceptional annual layers, in which the peaks of all species were not present, and the flux of pollen grains did not agree between two sites. These inconsistencies were likely due to the influence of the melting of the glacier surface. Results shows that the ice cores contain sufficient pollen grains for analysis and pollen profiles can be used to annual layer counting.

Snow and ice on glaciers and the ice sheet in the Arctic contain windblown mineral dust derived from local sediments as well as distant deserts. Dust deposited on the ice sheet in the past can be obtained by ice core drilling, and the variations in its sources and transportation processes can be reconstructed by particle analysis of ice cores. In this study, we analyzed morphology and surface chemistry of mineral dust particles in an ice core drilled in Northwest Greenland with Scanning Electron Microscope (SEM, QUANTA FEG 450) and Energy Dispersive X-ray Spectrometer (EDS).
The ice core was drilled at the SIGMA-D site (N77°64’, W59°12’ [1]) of 2100 m a.s.l. in 2014. The length is 222.72 m and the estimated age at 113 m depth is 350 years before present . The ice samples were collected every five years in plastic bottles and freeze dried on a polycarbonate filter to concentrate micro-particles. Then, the filter was coated with platinum (Pt) for SEM analysis. Here we report the temporal variations in size distributions and compositions of the minerals during the past 100 years (A.D 1920-2013).
The SEM observation revealed that the mean size of mineral dust in the SIGMA-D ice core ranged from 1-3 μm, which is similar to that of the other Greenland ice core dust that seems to be derived from distant areas. This suggests that the SIGMA-D ice core contained mainly long–range transported wind-blown mineral dust.
The EDS analysis revealed the ice core contained mainly silicate minerals, especially clay minerals that showed compositional variation among the samples. For example, the mineralogical composition varied in every 10-15 years and showed a negative correlation between minerals formed by chemical and physical weathering (kaolinite vs illite/micas and chlorite). This indicates that minerals in the ice core were derived from multiple geological sources and the source areas might have varied temporally. Furthermore, quartz and feldspar, which had larger particles than clay minerals and thus were generally used as a short-distant transport, were higher in 1920-1945 and 1990-2013 compared with the other periods. Based on the past temperature record in Greenland, the warming occurred from 1910 to 1945 and after 1990. This may suggest that the minerals were derived not only from distant areas but also from local sources, such as moraine around the ice sheet margin in warmer periods. This is likely due to exposure of ground surface without snow cover.

Size and shape of solid particles in a Greenland ice core

*Wataru Shigeyama[1,2], Kumiko Goto-Azuma[2,1], Kaori Fukuda[2], Fumio Nakazawa[2,1], Morimasa Takata[3], Tomoyuki Homma[3], Nobuhiko Azuma[3], Dorthe Dahl-Jensen[4]

Concentrations and size distributions of insoluble solid particles in ice cores provide us with information on the changes in provenance, aridity, atmospheric circulation, etc. Most of the previous studies have focused on concentrations and size distributions. However, several studies (e.g., Barnes et al., 2002; Lambert et al., 2008; Simonsen et al., 2018) reported that particles formed aggregates and had various shapes. For a better environmental reconstruction, we need to study shapes and aggregation processes of the particles together with concentrations and size distributions.

Using a cryogenic scanning electron microscope (cryo-SEM), we carried out in-situ observations of solid particles in ice core samples without melting them. From the observations on selected ice samples (124 m depth in the present interglacial period, 1548 m depth in the last glacial period and 2406 m in the last interglacial period) retrieved by North Greenland Eemian Ice Drilling (NEEM), we found that many particles formed aggregates, and that individual particles (particles forming the aggregates) had elongated shapes (aspect ratio: 0.4-0.8). We also found that the sizes of the aggregate and individual particles showed log-normal distribution. The aggregates were larger in the interglacial periods than those in the glacial period (median diameter: 4.5 μm in the present interglacial period, 5.9 μm in the last interglacial period, and 2.2 μm in the last glacial period). These results need to be taken into account to interpret the size distribution data obtained by analyses on melted ice cores.

At the National Institute of Polar Research (NIPR), Continuous Flow Analyses (CFA) system has been developed. In addition to the measurements of melt water (e.g. water isotopes, micro-particles and major ions), the enclosed air is extracted from the water stream and measured for methane (CH_4) concentration by a customized Cavity Ring-Down Spectrometer (CRDS) (Picarro G2301). The CFA system provides data at much higher resolution than classic discrete measurements, which can improve our knowledge and understanding of past climatic variations.

The CH_4 concentration measured by CFA is affected by several factors, impacting precision, accuracy and resolution. The factors include dissolution of CH_4 in meltwater and its imperfect extraction, sample mixing and smoothing in sample lines, and contamination by room air intrusion into the system at the interface between ice samples. The magnitudes of these effects have been investigated, and the data are corrected accordingly. Here, we report the results of various tests for assessing the performance of our CFA for CH_4 measurement. Furthermore, the results of the measurement campaigns of the Dome Fuji ice core, covering the 8.2-kyr cooling event and a part of the last deglaciation, will also be presented.

Drilling a deep ice core extending 1.5 million years (Ma) back in time is crucial to better understand the transition in the periodicity of the glacial cycles changed from 40 kilo year (ka) to the current 100 ka during the mid-Pleistocene transition (0.9–1.2 Ma). However, continuous ice core records more than 1 Ma have not been retrieved in the Antarctic ice sheet. Sufficient knowledge of the basal topography is crucial to modify numerical experiments that may provide a continuous record of past mechanisms of climate change. A ground-based radar survey was conducted over an area of 20000 km^2 with a line spacing of 5 km in the Dome Fuji area in the 59th Japanese Antarctic Research Expedition (JARE 59, 2017–2018 Antarctic summer). In this study, we analyze the JARE 59 radar data to construct an improved map of basal topography in the Dome Fuji region to progress the identification of a suitable drilling site at the region.

Performance of RCIP scheme on 1-d age computation of ice sheet.

*Fuyuki SAITO[1], Takashi Obase[2], Ayako Abe-Ouchi[2,1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere and Ocean Research Institute, University of Tokyo

Generally the evolution of ice-sheet thickness, temperature and age in an ice-sheet model are formulated using the transport or advection equation. There are many variation of the formulation, which differ in numerical aspects such as stability, accuracy, numerical diffusivity, conservation and/or computational costs.
Rational Constrained Interpolation Profile scheme (RCIP, Xiao et al. 1996) is a variation of semi-Lagrangian scheme, which has properties in suppressing numerical oscillation and diffusion near large gradients.
In this study, RCIP scheme is implemented on 1d age computation of ice sheet, which is a typical numerical study of ice-core related topics. Comparison with the results of RCIP scheme and those of classical upwind scheme shows that the former keeps fine information (i.e., surface mass balance) recorded at the deposit.

Climate changes of the last deglaciation simulated by MIROC AOGCM

*Takashi Obase[1], Ayako Abe-Ouchi[1,2], Sam Sherriff-Tadano[1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology

During the last deglaciation, a major global warming was punctuated by abrupt climate changes related to Atlantic Meridional Overturning Circulation (AMOC). However, abrupt climate change associated with a rapid increase in the AMOC during Bølling-Allerød (BA) transition was reproduced only by applying a reduction in glacial meltwater, which is not inferred from reconstructions. Here we show that an abrupt increase in the AMOC during the BA transition can occur without reduction in glacial meltwater, from a transient simulation of the last deglaciation using an atmosphere-ocean general circulation model. The abrupt increase in the AMOC accompanied with drastic retreat of sea ice in the North Atlantic, abrupt warming in Greenland, cooling of the Southern Hemisphere, that are consistent with proxies and previous modeling studies. Model-data comparison at specific sites will be presented to evaluate simulated climate changes of the last deglaciation.

A Last Glacial Maximum experiment using MIROC-ES2L earth system model in comparison with ice core and the other paleo-proxy data

*Rumi Ohgaito[1], Tomohiro Hajima[1], Akitomo Yamamoto[1], Hiroaki Tatebe[1], Michio Kawamiya[1], Ayako Abe-Ouchi[2,1]

1. Japan Agency for Marine-Earth Science and Technology, 2. AORI, Univ. Tokyo

We are performing numerical experiments targeting distinctive time period of the past, Last Glacial Maximum (LGM, 21,000 years before present), using MIROC-ES2L. MIROC-ES2L is a newly developed earth system model (ESM) (Hajima et al. in prep.) including atmosphere, ocean, land, and ocean and land biogeochemical cycles in order to contribute Coupled Model Intercomparison Project phase 6 and Intergovernmental Panel on Climate Change 6th assessment report.
Testing climate models using paleoclimate experiments is an irreplaceable opportunity on evaluation of models to simulate climate change significantly different from the present day. In this presentation, we describe how we simulate the LGM experiment, compare with paleo-proxy data and discuss which component contributed for the realization of the LGM climate.
Following protocol of Paleoclimate Modelling Intercomparison Project phase 4 (Kageyama et al. 2017), we are performing a LGM experiment. Because the LGM condition is significantly different from the present day, long spin-up is essential. Hence, before the model development is finalized, we started spin-up using the physical core (Atmosphere-Ocean coupled general circulation model) of MIROC-ES2L. Firstly, an experiment is branched from pre-industrial control (PI) experiment and the greenhouse gas levels are reduced to the LGM values. After integration for 2640 model years, land-sea mask and ice sheets, altitude, river path, orbit of the earth, salinity of ocean, and an erodibility map (concerning dust) of the LGM conditions are applied step by step and the total spin-up reached 6760 model years. Since MIROC-ES2L is ready during this procedure, the initial conditions at the 6760th model year of the spin-up experiment are used to initiate LGM experiment using MIROC-ES2L. In this conversion procedure, the initial conditions for land and ocean biogeochemical cycles were prepared respectively using offline modules to obtain quasi-stabilized states. Global mean temperature drawdown of the last 60 year climatology after 540 years integration with the ESM is -4.4 degree Celsius. Borehole thermometry suggested the cooling over the Eastern Antarctica at LGM was -7 to -10 degree Celsius (Stenni et al. 2010, Uemura et al. 2012). The modelled temperature anomaly is about -6.0 degree Celsius, which suggests weaker cooling compared to the ice core data. For the central Greenland, borehole thermometry suggested -21 to -25 degree Celsius (Cuffey et al. 1995, Johnsen et al. 1995, Dahl-Jensen et al. 1998), whereas the LGM experiment resulted -11.1 degree Celsius. This large discrepancy would be attributed to realization of ocean thermohaline state in the model experiment. The modelled peak value of the Atlantic Meridional Overturning Circulation (AMOC) is 21.0 Sverdrup for LGM and 15.3 Sverdrup for PI. On the other hand, AMOC is thought to be weaker than the present day from paleo proxy data (Lynch-Stieglitz et al. 2007, Hesse et al. 2011). We continue the experiment and analyze which component contributes global cooling and the cooling over the polar regions.

On the possible bifurcation mechanisms and associated dynamical properties of Dansgaard-Oeschger oscillations

*Takahito Mitsui[1], Ayako Abe-Ouchi[1], Wing-Le Chan[1], Sam Sherriff-Tadano[1]

1. The University of Tokyo

Dansgaard-Oeschger (DO) oscillations are millennial-scale abrupt climate changes in the last glacial period (Dansgaard et al. 1993; Johnsen et al. 1992). In particular, they are frequent in the mid-glacial and less frequent at the beginning of the glacial and in the Last Glacial Maximum (McManus et al. 1999; Kawamura et al. 2017). Since its discovery, DO oscillations have been intensively studied, but its detailed mechanisms are still a subject of debate. Our recent modeling study (Abe-Ouchi et al. in prep) with MIROC4m Atmosphere-Ocean general circulation model (Hasumi and Emori 2004) suggests that DO oscillations are spontaneous oscillations which arise from global-scale interactions between the atmosphere and ocean (see also studies in [12] and Brown and Galbraith, 2016). Our simulated oscillations are likely to appear in a certain region of background climate conditions directly related to factors such as ice sheets, orbital elements, and greenhouse gases (Abe-Ouchi et al. in prep; Sam Sherriff-Tadano et al. 2017). This result is consistent with the observations that DO oscillations were most frequent in the mid-glacial.

The bifurcation theory is a field of mathematics which studies qualitative changes of dynamical systems depending on the changes in parameters. In general, we can consider numerous types of dynamical systems, but their bifurcation phenomena are classified into only several types (Strogatz, Nonlinear Dynamics And Chaos, 2000). Identifying bifurcation mechanisms may help us to understand the emergence mechanism of the oscillation and its associated properties like the period or the amplitude. For example, when oscillations emerge/vanish via a Homoclinic bifurcation, the period of oscillations diverges to infinity as the parameter approaches the bifurcation point. On the other hand, when oscillations emerge via a Hopf bifurcation, such divergence of the period does not occur. On the basis of such scaling properties of the period, previous studies [7, 9] suggested onset mechanisms for the oscillations.

In this study, we survey bifurcation mechanisms reported in previous models of DO oscillations [1-12]. We also performed a bifurcation analysis of an extended version of the Winton (1993) 3-box halocline oscillator [2], which has a parameter dependence similar to that of MIROC AOCGM. It is found that, in many models, DO-like oscillations emerge via a Hopf-type bifurcation [1,2,4,5,6,7,10,11] and/or via a Homoclinic-type bifurcation [1,2,3,5,6,7,8,9,11]. The Welander (1982) model [1] and the extended Winton model may generate oscillations via both a Hopf-type bifurcation and a Homoclinic-type bifurcation depending on their parameters, but these bifurcations become identical at a parameter limit. This implies that the oscillation period may increase rapidly even near the Hopf bifurcation points (though it does not diverge). Therefore, identifying onset mechanisms of oscillations on the basis of scaling properties of the period may have a subtle problem. The extended Winton's model has a phase space structure like Homoclinic orbit even near the Hopf bifurcation point, and this phase space structure induces a long oscillation period. In MIROC AOGCM, the onset of oscillation may be related to either a Hopf-type bifurcation or a Homoclinic-type bifurcation, or to both of them. The determination of the bifurcation type in MIROC AOGCM is still difficult because of limited computational time and inherent natural variability. Nevertheless, we observe that noisy 'limit cycles' near bifurcation points show characteristics similar to Homoclinic orbit and have relatively long periods.

The role of climate-vegetation feedback in climate changes driven by orbital parameter changes: the Arctic land surfaces and seasonality

*Kanon Kino[1], Ayako Abe-Ouchi[1,2], Ryouta O'ishi[1], Fuyuki SAITO[2], Masakazu Yoshimori[1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology

Periodic summer insolation change accompanying Earth’s orbital parameter changes is widely known as a main driver of the glacial cycles. Realistic orbital parameters are prescribed with climate models and ice-sheet models to reproduce and explain the characteristic of the glacial cycles in past several hundred thousand years(e.g. Abe-Ouchi et al., 2007; 2013). On the other way, radiative feedback analyses at the top of the atmosphere enable to understand the Earth’s climate response to the orbital forcing (Mantsis et al., 2011; Erb et al., 2013). In this study, we investigate the surface climate responses to the orbital forcing, by using MIROC-GCM and a surface climate feedback analyses method. We focus on the relationship between summer insolation and summer temperature on the land in the northern high latitude, since the former is a major index and the later is important for the ice-sheets melt.

We use a coupled atmosphere-vegetation GCM with slab ocean of MIROC-GCM (O’ishi and Abe-Ouchi, 2011) and performed numerous experiments by systematically changing the combinations of orbital parameters (maximum, minimum and present values of each parameter). A seasonal surface feedback analysis method (Lu and Cai, 2009) is also applied.

Results show that summer temperature change over the Arctic land due to obliquity change can be larger than that due to precession-eccentricity change, when the summer insolation maxima are the same. The results also show that the different efficiency is mainly caused by vegetation feedback with a meridional shift of a tundra-boreal forest boundary. In the northern high latitude, insolation change due to the summer solstice at the perihelion has a typical pattern of seasonality (increased in the mid-summer decreased in the spring and autumn) with no annual-mean component. This seasonality is unfavorable for snow melt in the spring (hence delay the melt) and surface albedo feedback, which accompany cooling in the spring and prevent boreal forests from growing. On the other hand, insolation change due to large obliquity has the other pattern of seasonality (increased the insolation in half a year) with increased annual mean insolation. This seasonality is favorable for the snow melt (hence promote the melt) and surface albedo feedback, which accompany warming throughout the year and assist the growing. These differences cause that obliquity changes promote vegetation-snow-albedo feedback stronger than precession-eccentricity changes.

Tue. May 28, 2019 5:15 PM - 6:30 PM JST | Tue. May 28, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[A-CC26] Ice cores and paleoenvironmental modeling

convener:Ryu Uemura(University of the Ryukyus), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Nozomu Takeuchi(Chiba University)

Analyses of ice cores from polar and mountain regions have contributed to the reconstruction and understanding of the past environmental changes on timescales from years to several hundred thousand years. In this session, we welcome paleoenvironmental studies using ice cores and paleoclimatic modeling. Studies on reconstruction methods, recording processes and new paleoenvironmental proxies, technical aspects of paleo-modeling are also welcomed. Studies with marine sediment cores, terrestrial sediment cores and tree-rings on similar timescales are also important and welcomed, in order to discuss past environmental changes from multidisciplinary viewpoints.

Ice cores drilled from mountain glaciers usually contains abundant pollen grains supplied from vegetation around the glaciers. Pollen grains have been used in ice core studies as markers of annual layer boundary since they are supplied on the glacier in a certain season of a year. Furthermore, they have been used as a proxy of vegetation in the surrounding area since their composition reflects relative abundance of each species in the source area. An ice core from the surface to the bottom was drilled on a glacier in Pamir Arai Mountains in central Asia in 2016. In this study, pollen grains in a part of the ice core and snow pit were analyzed. Annual layers of the ice core, which were determined based on a seasonality of stable isotope, were compared with the variations of pollen grains concentration, and the seasonality of pollen supplies was examined.
Ice cores were recovered at two sites (sites 1 and 2 at 5300 m and 5208 m, respectively) on the glacier. Oxygen stable isotope in the 7 m deep ice cores at both sites showed significant fluctuations. We assumed that they are periodic seasonal signals and determined the annual layers. As a result, the ice cores of Sites 1 and 2 includes layers for 8 years and 9 years, respectively. Microscopic analysis revealed that 6 types of pollen grains, which were identified as Cupressaceae, Artemisia, Chenopodiaceae, Pinaceae, Betulaceae, and Ephedra, were contained in the ice cores. Mean concentration of the pollen grains was highest for Cupressaceae at both sites (2.20, 2.62 grains/ml (74, 67%)), was second highest for Artemisia (0.65, 1.06 grains/ml (22, 27%)). The depth profile of the pollen grain concentrations showed several spikes in the ice cores. The depth of peaks differed between species. The peaks of Artemisia and Chenopodiaceae appeared at the same depth while the peaks of Cupressaceae appeared just below the depth of their peaks. The peak depths of Artemisia and Chenopodiaceae roughly agreed with the depth of the maximum value of the isotope ratio, indicating that these pollens were supplied in the summer or autumn. On the other hand, Cupressaceae found in the layer below is likely to be supplied in spring or summer. There are exceptional annual layers, in which the peaks of all species were not present, and the flux of pollen grains did not agree between two sites. These inconsistencies were likely due to the influence of the melting of the glacier surface. Results shows that the ice cores contain sufficient pollen grains for analysis and pollen profiles can be used to annual layer counting.

Variations in mineralogy of dust in the Greenland SIGMA-D ice core over the past 100 years using SEM

*Naoko Nagatsuka[1], Kumiko Goto-Azuma[1,2], Akane Tsushima, Hideaki Motoyama[1,2], Sumito Matoba[3], Koji Fujita[4], Tetsuhide Yamasaki[5], Yukihiko Onuma[6], Masahiro Minowa[7], Teruo Aoki[8], Motohiro Hirabayashi[1]

Snow and ice on glaciers and the ice sheet in the Arctic contain windblown mineral dust derived from local sediments as well as distant deserts. Dust deposited on the ice sheet in the past can be obtained by ice core drilling, and the variations in its sources and transportation processes can be reconstructed by particle analysis of ice cores. In this study, we analyzed morphology and surface chemistry of mineral dust particles in an ice core drilled in Northwest Greenland with Scanning Electron Microscope (SEM, QUANTA FEG 450) and Energy Dispersive X-ray Spectrometer (EDS).
The ice core was drilled at the SIGMA-D site (N77°64’, W59°12’ [1]) of 2100 m a.s.l. in 2014. The length is 222.72 m and the estimated age at 113 m depth is 350 years before present . The ice samples were collected every five years in plastic bottles and freeze dried on a polycarbonate filter to concentrate micro-particles. Then, the filter was coated with platinum (Pt) for SEM analysis. Here we report the temporal variations in size distributions and compositions of the minerals during the past 100 years (A.D 1920-2013).
The SEM observation revealed that the mean size of mineral dust in the SIGMA-D ice core ranged from 1-3 μm, which is similar to that of the other Greenland ice core dust that seems to be derived from distant areas. This suggests that the SIGMA-D ice core contained mainly long–range transported wind-blown mineral dust.
The EDS analysis revealed the ice core contained mainly silicate minerals, especially clay minerals that showed compositional variation among the samples. For example, the mineralogical composition varied in every 10-15 years and showed a negative correlation between minerals formed by chemical and physical weathering (kaolinite vs illite/micas and chlorite). This indicates that minerals in the ice core were derived from multiple geological sources and the source areas might have varied temporally. Furthermore, quartz and feldspar, which had larger particles than clay minerals and thus were generally used as a short-distant transport, were higher in 1920-1945 and 1990-2013 compared with the other periods. Based on the past temperature record in Greenland, the warming occurred from 1910 to 1945 and after 1990. This may suggest that the minerals were derived not only from distant areas but also from local sources, such as moraine around the ice sheet margin in warmer periods. This is likely due to exposure of ground surface without snow cover.

Concentrations and size distributions of insoluble solid particles in ice cores provide us with information on the changes in provenance, aridity, atmospheric circulation, etc. Most of the previous studies have focused on concentrations and size distributions. However, several studies (e.g., Barnes et al., 2002; Lambert et al., 2008; Simonsen et al., 2018) reported that particles formed aggregates and had various shapes. For a better environmental reconstruction, we need to study shapes and aggregation processes of the particles together with concentrations and size distributions.

Using a cryogenic scanning electron microscope (cryo-SEM), we carried out in-situ observations of solid particles in ice core samples without melting them. From the observations on selected ice samples (124 m depth in the present interglacial period, 1548 m depth in the last glacial period and 2406 m in the last interglacial period) retrieved by North Greenland Eemian Ice Drilling (NEEM), we found that many particles formed aggregates, and that individual particles (particles forming the aggregates) had elongated shapes (aspect ratio: 0.4-0.8). We also found that the sizes of the aggregate and individual particles showed log-normal distribution. The aggregates were larger in the interglacial periods than those in the glacial period (median diameter: 4.5 μm in the present interglacial period, 5.9 μm in the last interglacial period, and 2.2 μm in the last glacial period). These results need to be taken into account to interpret the size distribution data obtained by analyses on melted ice cores.

At the National Institute of Polar Research (NIPR), Continuous Flow Analyses (CFA) system has been developed. In addition to the measurements of melt water (e.g. water isotopes, micro-particles and major ions), the enclosed air is extracted from the water stream and measured for methane (CH_4) concentration by a customized Cavity Ring-Down Spectrometer (CRDS) (Picarro G2301). The CFA system provides data at much higher resolution than classic discrete measurements, which can improve our knowledge and understanding of past climatic variations.

The CH_4 concentration measured by CFA is affected by several factors, impacting precision, accuracy and resolution. The factors include dissolution of CH_4 in meltwater and its imperfect extraction, sample mixing and smoothing in sample lines, and contamination by room air intrusion into the system at the interface between ice samples. The magnitudes of these effects have been investigated, and the data are corrected accordingly. Here, we report the results of various tests for assessing the performance of our CFA for CH_4 measurement. Furthermore, the results of the measurement campaigns of the Dome Fuji ice core, covering the 8.2-kyr cooling event and a part of the last deglaciation, will also be presented.

Drilling a deep ice core extending 1.5 million years (Ma) back in time is crucial to better understand the transition in the periodicity of the glacial cycles changed from 40 kilo year (ka) to the current 100 ka during the mid-Pleistocene transition (0.9–1.2 Ma). However, continuous ice core records more than 1 Ma have not been retrieved in the Antarctic ice sheet. Sufficient knowledge of the basal topography is crucial to modify numerical experiments that may provide a continuous record of past mechanisms of climate change. A ground-based radar survey was conducted over an area of 20000 km^2 with a line spacing of 5 km in the Dome Fuji area in the 59th Japanese Antarctic Research Expedition (JARE 59, 2017–2018 Antarctic summer). In this study, we analyze the JARE 59 radar data to construct an improved map of basal topography in the Dome Fuji region to progress the identification of a suitable drilling site at the region.

Performance of RCIP scheme on 1-d age computation of ice sheet.

*Fuyuki SAITO[1], Takashi Obase[2], Ayako Abe-Ouchi[2,1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere and Ocean Research Institute, University of Tokyo

Generally the evolution of ice-sheet thickness, temperature and age in an ice-sheet model are formulated using the transport or advection equation. There are many variation of the formulation, which differ in numerical aspects such as stability, accuracy, numerical diffusivity, conservation and/or computational costs.
Rational Constrained Interpolation Profile scheme (RCIP, Xiao et al. 1996) is a variation of semi-Lagrangian scheme, which has properties in suppressing numerical oscillation and diffusion near large gradients.
In this study, RCIP scheme is implemented on 1d age computation of ice sheet, which is a typical numerical study of ice-core related topics. Comparison with the results of RCIP scheme and those of classical upwind scheme shows that the former keeps fine information (i.e., surface mass balance) recorded at the deposit.

Climate changes of the last deglaciation simulated by MIROC AOGCM

*Takashi Obase[1], Ayako Abe-Ouchi[1,2], Sam Sherriff-Tadano[1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology

During the last deglaciation, a major global warming was punctuated by abrupt climate changes related to Atlantic Meridional Overturning Circulation (AMOC). However, abrupt climate change associated with a rapid increase in the AMOC during Bølling-Allerød (BA) transition was reproduced only by applying a reduction in glacial meltwater, which is not inferred from reconstructions. Here we show that an abrupt increase in the AMOC during the BA transition can occur without reduction in glacial meltwater, from a transient simulation of the last deglaciation using an atmosphere-ocean general circulation model. The abrupt increase in the AMOC accompanied with drastic retreat of sea ice in the North Atlantic, abrupt warming in Greenland, cooling of the Southern Hemisphere, that are consistent with proxies and previous modeling studies. Model-data comparison at specific sites will be presented to evaluate simulated climate changes of the last deglaciation.

A Last Glacial Maximum experiment using MIROC-ES2L earth system model in comparison with ice core and the other paleo-proxy data

*Rumi Ohgaito[1], Tomohiro Hajima[1], Akitomo Yamamoto[1], Hiroaki Tatebe[1], Michio Kawamiya[1], Ayako Abe-Ouchi[2,1]

1. Japan Agency for Marine-Earth Science and Technology, 2. AORI, Univ. Tokyo

We are performing numerical experiments targeting distinctive time period of the past, Last Glacial Maximum (LGM, 21,000 years before present), using MIROC-ES2L. MIROC-ES2L is a newly developed earth system model (ESM) (Hajima et al. in prep.) including atmosphere, ocean, land, and ocean and land biogeochemical cycles in order to contribute Coupled Model Intercomparison Project phase 6 and Intergovernmental Panel on Climate Change 6th assessment report.
Testing climate models using paleoclimate experiments is an irreplaceable opportunity on evaluation of models to simulate climate change significantly different from the present day. In this presentation, we describe how we simulate the LGM experiment, compare with paleo-proxy data and discuss which component contributed for the realization of the LGM climate.
Following protocol of Paleoclimate Modelling Intercomparison Project phase 4 (Kageyama et al. 2017), we are performing a LGM experiment. Because the LGM condition is significantly different from the present day, long spin-up is essential. Hence, before the model development is finalized, we started spin-up using the physical core (Atmosphere-Ocean coupled general circulation model) of MIROC-ES2L. Firstly, an experiment is branched from pre-industrial control (PI) experiment and the greenhouse gas levels are reduced to the LGM values. After integration for 2640 model years, land-sea mask and ice sheets, altitude, river path, orbit of the earth, salinity of ocean, and an erodibility map (concerning dust) of the LGM conditions are applied step by step and the total spin-up reached 6760 model years. Since MIROC-ES2L is ready during this procedure, the initial conditions at the 6760th model year of the spin-up experiment are used to initiate LGM experiment using MIROC-ES2L. In this conversion procedure, the initial conditions for land and ocean biogeochemical cycles were prepared respectively using offline modules to obtain quasi-stabilized states. Global mean temperature drawdown of the last 60 year climatology after 540 years integration with the ESM is -4.4 degree Celsius. Borehole thermometry suggested the cooling over the Eastern Antarctica at LGM was -7 to -10 degree Celsius (Stenni et al. 2010, Uemura et al. 2012). The modelled temperature anomaly is about -6.0 degree Celsius, which suggests weaker cooling compared to the ice core data. For the central Greenland, borehole thermometry suggested -21 to -25 degree Celsius (Cuffey et al. 1995, Johnsen et al. 1995, Dahl-Jensen et al. 1998), whereas the LGM experiment resulted -11.1 degree Celsius. This large discrepancy would be attributed to realization of ocean thermohaline state in the model experiment. The modelled peak value of the Atlantic Meridional Overturning Circulation (AMOC) is 21.0 Sverdrup for LGM and 15.3 Sverdrup for PI. On the other hand, AMOC is thought to be weaker than the present day from paleo proxy data (Lynch-Stieglitz et al. 2007, Hesse et al. 2011). We continue the experiment and analyze which component contributes global cooling and the cooling over the polar regions.

On the possible bifurcation mechanisms and associated dynamical properties of Dansgaard-Oeschger oscillations

*Takahito Mitsui[1], Ayako Abe-Ouchi[1], Wing-Le Chan[1], Sam Sherriff-Tadano[1]

1. The University of Tokyo

Dansgaard-Oeschger (DO) oscillations are millennial-scale abrupt climate changes in the last glacial period (Dansgaard et al. 1993; Johnsen et al. 1992). In particular, they are frequent in the mid-glacial and less frequent at the beginning of the glacial and in the Last Glacial Maximum (McManus et al. 1999; Kawamura et al. 2017). Since its discovery, DO oscillations have been intensively studied, but its detailed mechanisms are still a subject of debate. Our recent modeling study (Abe-Ouchi et al. in prep) with MIROC4m Atmosphere-Ocean general circulation model (Hasumi and Emori 2004) suggests that DO oscillations are spontaneous oscillations which arise from global-scale interactions between the atmosphere and ocean (see also studies in [12] and Brown and Galbraith, 2016). Our simulated oscillations are likely to appear in a certain region of background climate conditions directly related to factors such as ice sheets, orbital elements, and greenhouse gases (Abe-Ouchi et al. in prep; Sam Sherriff-Tadano et al. 2017). This result is consistent with the observations that DO oscillations were most frequent in the mid-glacial.

The bifurcation theory is a field of mathematics which studies qualitative changes of dynamical systems depending on the changes in parameters. In general, we can consider numerous types of dynamical systems, but their bifurcation phenomena are classified into only several types (Strogatz, Nonlinear Dynamics And Chaos, 2000). Identifying bifurcation mechanisms may help us to understand the emergence mechanism of the oscillation and its associated properties like the period or the amplitude. For example, when oscillations emerge/vanish via a Homoclinic bifurcation, the period of oscillations diverges to infinity as the parameter approaches the bifurcation point. On the other hand, when oscillations emerge via a Hopf bifurcation, such divergence of the period does not occur. On the basis of such scaling properties of the period, previous studies [7, 9] suggested onset mechanisms for the oscillations.

In this study, we survey bifurcation mechanisms reported in previous models of DO oscillations [1-12]. We also performed a bifurcation analysis of an extended version of the Winton (1993) 3-box halocline oscillator [2], which has a parameter dependence similar to that of MIROC AOCGM. It is found that, in many models, DO-like oscillations emerge via a Hopf-type bifurcation [1,2,4,5,6,7,10,11] and/or via a Homoclinic-type bifurcation [1,2,3,5,6,7,8,9,11]. The Welander (1982) model [1] and the extended Winton model may generate oscillations via both a Hopf-type bifurcation and a Homoclinic-type bifurcation depending on their parameters, but these bifurcations become identical at a parameter limit. This implies that the oscillation period may increase rapidly even near the Hopf bifurcation points (though it does not diverge). Therefore, identifying onset mechanisms of oscillations on the basis of scaling properties of the period may have a subtle problem. The extended Winton's model has a phase space structure like Homoclinic orbit even near the Hopf bifurcation point, and this phase space structure induces a long oscillation period. In MIROC AOGCM, the onset of oscillation may be related to either a Hopf-type bifurcation or a Homoclinic-type bifurcation, or to both of them. The determination of the bifurcation type in MIROC AOGCM is still difficult because of limited computational time and inherent natural variability. Nevertheless, we observe that noisy 'limit cycles' near bifurcation points show characteristics similar to Homoclinic orbit and have relatively long periods.

The role of climate-vegetation feedback in climate changes driven by orbital parameter changes: the Arctic land surfaces and seasonality

*Kanon Kino[1], Ayako Abe-Ouchi[1,2], Ryouta O'ishi[1], Fuyuki SAITO[2], Masakazu Yoshimori[1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology

Periodic summer insolation change accompanying Earth’s orbital parameter changes is widely known as a main driver of the glacial cycles. Realistic orbital parameters are prescribed with climate models and ice-sheet models to reproduce and explain the characteristic of the glacial cycles in past several hundred thousand years(e.g. Abe-Ouchi et al., 2007; 2013). On the other way, radiative feedback analyses at the top of the atmosphere enable to understand the Earth’s climate response to the orbital forcing (Mantsis et al., 2011; Erb et al., 2013). In this study, we investigate the surface climate responses to the orbital forcing, by using MIROC-GCM and a surface climate feedback analyses method. We focus on the relationship between summer insolation and summer temperature on the land in the northern high latitude, since the former is a major index and the later is important for the ice-sheets melt.

We use a coupled atmosphere-vegetation GCM with slab ocean of MIROC-GCM (O’ishi and Abe-Ouchi, 2011) and performed numerous experiments by systematically changing the combinations of orbital parameters (maximum, minimum and present values of each parameter). A seasonal surface feedback analysis method (Lu and Cai, 2009) is also applied.

Results show that summer temperature change over the Arctic land due to obliquity change can be larger than that due to precession-eccentricity change, when the summer insolation maxima are the same. The results also show that the different efficiency is mainly caused by vegetation feedback with a meridional shift of a tundra-boreal forest boundary. In the northern high latitude, insolation change due to the summer solstice at the perihelion has a typical pattern of seasonality (increased in the mid-summer decreased in the spring and autumn) with no annual-mean component. This seasonality is unfavorable for snow melt in the spring (hence delay the melt) and surface albedo feedback, which accompany cooling in the spring and prevent boreal forests from growing. On the other hand, insolation change due to large obliquity has the other pattern of seasonality (increased the insolation in half a year) with increased annual mean insolation. This seasonality is favorable for the snow melt (hence promote the melt) and surface albedo feedback, which accompany warming throughout the year and assist the growing. These differences cause that obliquity changes promote vegetation-snow-albedo feedback stronger than precession-eccentricity changes.

[A-GE30] Conservation and Restoration of Soil Environment at Terrestrial Surface

convener:Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University), Chairperson:Yasushi Mori(Okayama University)

Soil is the largest store of carbon of all terrestrial media. Soils also have important functions such as water storage and plant support roles. However, at present, these characteristics do not fully function, because of mismanagement of the field or climate-change-induced heavy rainfall would wash away the organic-rich surface soils. In this session, soil environment research, from soil conservation to restoration technique for degraded soils are welcomed.

Soil Organic Cabon Contents Estimation using Neural Network System

Ikumi Kaida[1], *Yasushi Mori[1], Takayuki Shuku[1]

1. Graduate School of Environmental and Life Science, Okayama University

Dynamics of organic matter in soil greatly affects the material circulation of the outermost layer of the earth and since it has the largest storage capacity in the terrestrial area, its accumulation and disappearance attracts high attention on global warming. Previous studies showed some achievements on the estimation of soil organic matter. However, since natural process is very complicated, the parameters are extracted from the accumulation of individual research, and are not estimated while considering mutual relationships based on a sufficient amount of data. Therefore, it is going to be waste of time or not realistic to tackle the problem for relating huge sets of soil parameters without understanding functional relationship. With the development of computers in recent years, machine learning and neural networks, which are rapidly becoming to be applied to realistic tasks, read huge amounts of data and learn individual relationships while estimating the target value.

Therefore, in this study, we tried to find deeply related soil parameters using 11000 sets of 16 parameters (limited only in Europe) obtained from Harmonized World Soil Database (FAO, IIASA). Recursive Feature Elimination (RFE method) eliminated the weakly related parameters, and then the deeply related parameters are used to estimate organic carbon using neural network. Among the verifications, the neural network showed the best performance when the parameter selection was set to seven. Clay content, dry bulk density, clay CEC, total CEC, base saturation, exchangeable base, and ESP are evaluated as having high relevance. Interestingly, uncommon parameters were also included in the selection. 70% of the models constructed with these seven parameters estimated the amount of soil organic matter very well, 30% resulted in extremely bad results. In addition, although the selected parameter is deeply related to soil organic matter contents, it is not clear whether each parameter works positive or negative for estimation in the non-linear function. Since the derived relation is nonlinear and very complicated, it is difficult to understand the calculation process. But since the model function is obtained without giving a functional system from the human side, it is going to be a powerful tool in extracting necessary parameters from huge data sets which seems to have unknown relationships. In addition, the research will be more effective, and will greatly contribute to elucidation of environmental dynamics involving complex factors.

The effects of trenching and insertion of crop residue on infiltration and soil erosion in a farmland

*Kazutoshi Osawa[1], Yasushi Mori[2], Akira Hoshikawa

1. Utsunomiya University, 2. Graduate school of Environmental and Life Science, Okayama University

It has been recognized that dynamics of water and the associated materials such as sediment and nutrients are important to conserve ecosystem existing in a watershed. Among others, excess soil and nutrients transports toward the coastal zones and deposition on corals are one of the major environmental problems in Okinawa, Japan, in which agricultural area is the major source of sediment yield. In this study, we focused on effects of trenching and insertion of crop residue on infiltration and soil erosion in a sugarcane field.

In the term of fallow period, water discharge in the trenching plot was 69% smaller than that in the control plot because the rainwater was infiltrated at the trenches on the surface. However, sediment yield in the trenching plot increased 57% over that in the control prot because soil surface was distubed by subsoiler to make trenches.

In the term of cropping period, water discharge in the plot of trenching and insertion of crop residue was 39% smaller than that in the control plot. The effect of increasing infiltration was continued because trenches did not fill with soil due to insertion of crop residue. Sediment yield in the plot of trenching and insertion of crop residue decreased 64% over that in the control prot. Then, from the view of preventing soil erosion, trenching and insertion of crop residue are effective practice during cropping period.

Measuring wide-range soil water content using GPS signals

*Kosuke Noborio[1], Natsumi Naganuma[1]

1. Meiji University

For prediction of the amount of irrigation water during a crop growing period, estimation of groundwater recharge amount, landslide forecast, and others, measurement of a wide range of soil moisture content is indispensable. Since the introduction of TDR moisture meter by Topp et al. in 1980, measurement of soil water content at a certain point has become possible with high precision, and remote automatic data acquisition. However, when measuring a wide range of soil moisture content as conventional measurements using satellites or cosmic rays, there are concerns on resolution and measurement accuracy so that it has not been applied to routine observation. In 2008 Larson and colleagues reported that there is a significant relationship between the ground reflected wave intensity contained in the GPS signal and the soil moisture content around the GPS antenna. Since GPS satellites are operated to be observed at any location on the earth for 24 hours a day, if we could measure soil moisture content using GPS signals, applicability of this method would be immeasurable. In this report, we outline the principle and examples of wide area soil moisture content measurement using GPS signals.

[A-GE30] Conservation and Restoration of Soil Environment at Terrestrial Surface

convener:Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University)

Soil is the largest store of carbon of all terrestrial media. Soils also have important functions such as water storage and plant support roles. However, at present, these characteristics do not fully function, because of mismanagement of the field or climate-change-induced heavy rainfall would wash away the organic-rich surface soils. In this session, soil environment research, from soil conservation to restoration technique for degraded soils are welcomed.

Analysis of soil erosion on cropland considering future climate change in Okinawa

*Gen Machida[1], Kazutoshi Osawa[1], Hiroyuki Matsui[1]

1. Utsunomiya University

In Okinawa Prefecture, excessive red soil runoff due to soil erosion (water erosion) is a problem, and development of prediction method of erosion amount in cropland is required. In previous studies, analysis using a process based model "Water Erosion Prediction Project, WEPP" has been tried. However, methods for assessing soil erosion risk considering future climate change, which are necessary for long-term project for measures to reduce soil erosion, have not been studied yet. In this study, we made climate input data considering future climate change in Okinawa Prefecture using weather simulator "MarkSim" and applied it to WEPP.

In the climate input data created from MarkSim, precipitation tended to increase with the rise in temperature due to global warming. However, in the WEPP analysis under bare soil condition and under sugarcane farming condition, no increase in risk of erosion due to climate change could be confirmed. This is because the infiltration amount in the cropland increased with excessive drying of surface soil due to increasing evaporation. From the above, it is suggested that the increase in precipitation due to future climate change may not necessarily lead to an increase in erosion amount.

Linear-Macropore Installation to Reduce Surface Flow at Subtropical Farmland.

Masaki Kiyohiro, Yasushi Mori, Kazutoshi Osawa, and Akira Hoshikawa

Key words: Soil erosion, Macro pore, Surface flow

Fields in Okinawa is suffering from surface flow which causes soil erosion. Soil erosion affects not only farming but also marine resources such as coral reef. The mechanism of the surface flow is as follows. First, rain drops hit the ground, and soil particles are separated from surface. Second, small soil particles filled the soil pores and crust layer is formed. Finally, surface flow increases. Farmland is the main sources of the soil erosion. Therefore, it’ s important to reduce surface flow with soil particles in farmland. Linear-macropore is one of the countermeasures for soil runoff. Linear-macropore is artificial ditch filling with plant residue which keep its structure. It can be installed easily by using agricultural machine. Furthermore, we can obtain plant residue easily in farmland. The objective of this study was to examine whether surface flow can be reduced by installation of linear macro pore by laboratory experiment.

We setup the lysimeter with soil which taken from sugarcane field in Ishigaki island, Okinawa and we examined 4 treatments (i.e., control, mulching, subsoiler (empty linear macro pore) and linear macro pore (subsoiling with filling gap by sugarcane residue). The soil was sieved through a 2 mm screen, and packed with the bulk density of 1.2 gcm^{-3}. Infiltration experiments with artificial rainfall were conducted in the laboratory at 25℃. Simulated rainfall with intensity of 20 mmh^{-1} was applied 4 hours to the surface, and 24 hours later after the first rainfall, the next rainfall was applied. In each experiment, we measured surface flow, soil moisture, and soil runoff.

As a result, crust layer was formed in all sections, and the ditch was collapsed in the subsoiler treatment. There was more surface flow in control section than mulching section, and no surface flow was confirmed in linear-macropore plot. Soil moisture increased the most in linear macropore. This is because linear-macropore can enhance infiltration and decrease surface flow. As we mentioned above, our research suggest that linear macro pore can increase infiltration and it can reduce soil erosion. It can be one of the countermeasures for surface flow and soil runoff.

Rice terraces of the Philippine Cordilleras in northern Luzon have been damaged seriously. They need proper and efficient agricultural management. In slope failure area including rice terraces, reports said that the infiltration from paddy field surface strongly affected to the short -time ground water level changes. In that situation, the chance of land collapse would be higher when the water infiltration becomes larger. Therefore, in this study, the relationship between soil properties and vertical infiltration was examined. Cone-penetrometer test and infiltration test with ponded paddy was carried out at the site, and soil analysis (C,N and mineral) were at the laboratory. Results showed that both hardpan formation and clogging with organic matter (OM) were considered as factors that control infiltration. At the site, the rice terraces with no-hard pan stored more OM and exchangeable cations had been leached out. Although infiltration control has two patterns, hard pan formation is preferable from the perspective of soil fertility.

In the northern part of Luzon island of the Philippines, the Cordillera terraced paddy fields were registered as a World Heritage site in 1995, and cultivation of paddy rice has been carried out for many years. However, in recent years, maintenance and management of rice paddy fields have become difficult due to lack of personnel and shortage of budget. In addition, some farmers complain about a declining rice yield year by year. In this research, we study methods for stabilizing of crop production, through managing agricultural activities such as irrigation and fertilizer applications, with consideration of environmental conservation. We selected Bangaan village within the Cordillera rice paddy area, and will analyze water and substances dynamics by a simulation model. As results of our preliminary survey, the target area had approximately 11 ha of paddy fields, and the water catchment area flowing into the uppermost paddy field had almost the same area size. Also, using ASTER GDEM, the average slope in the east-west direction was calculated and found to be steep as about 20%. Furthermore, the paddy fields were traced as accurately as possible using the satellite image, and found that more than 130 paddy fields were existed. The largest paddy field in the area was roughly 0.3 ha, with smaller rice paddy fields occupying the majority. As next, we are going to understand the transfer of irrigation water and substances, especially between paddy fields, for modeling analyses.

Life search on Mars by Life Detection Microscope (LDM)

*Yoshitaka Yoshimura[1]

1. College of Agriculture, Tamagawa University

Recent findings on Mars tend to support the possible presence of living microbes near the surface of Mars. MSL Curiosity has found organic compounds [1], the temporal increase of methane concentration in Martian atmosphere [2] and reduced sulfur compounds such as pyrite in Martian soil [3]. Methane and reduced sulfur compounds can be energy sources to support the growth of chemoautotrophic microbes [4]. The detection of hydrated salts suggested the possible presence of liquid water at Recurring Slope Lineae [5]. Although present Martian environments are hostile to life, terrestrial microorganisms inhabit a wide range of environmental conditions, suggesting some microorganisms may survive near the surface [4]. Though UV radiation is harmful, it would be shielded by thin layers (less than a millimeter) of dust or regolith [6]. A depth of several centimeters from the surface, therefore, could provide sufficient covering for microorganisms to survive.

The Viking mission in 1970’ s did not find evidence for life [7], however, the sensitivity of the GC-MS (mass spectrometer) onboard the Viking mission was found not to be very high, and it was not able to detect 10^6 microbial cells in 1 gram soil [8, 9], indicating that another life detection program is necessary.

The Life Detection Microscope (LDM) that we have proposed [6, 10] has the potential sensitivity much higher than the Viking instrument. Microscopes directly image life forms and identify their shapes, sizes, and other morphological structures and have the potential to detect a single cell in field of view. Therefore, the sensitivity can be as high as desired just by increasing the volume of sample to be scanned in a reasonable duration of experiment. LDM scans about 1 mm^3 and detects less than 10^4 cells in 1 gram soil at a spatial resolution of 1 μm [10]. LDM differentiates among organic compounds surrounded by membranes or with enzyme activity by staining the samples with fluorescent pigments. This technique is especially useful for the detection of living microorganisms.

Our investigation goals are the followings. 1) Identify cell-like structure in which organic compounds are enveloped by membrane, which may represent Martian life. 2) Search for organic compounds in Mars surface samples. The compounds include cells, other biological materials, and abiotic polycyclic aromatic hydrocarbon (PAH). 3) High-resolution characterization of regolith and dust particles. The search for living microorganisms is important not only for scientific interest but for planetary protection. Before future human missions begin, surveys investigating the presence of living microorganisms should be conducted to mitigate the risk of human contact with Martian microorganisms, which may be harmful to human health. The LDM would be also an effective tool for this purpose.

Moisture movement in sand during evaporation under reduced pressure

*Masaru Mizoguchi[1]

1. Graduate school of Agricultural and Life Sciences, The University of Tokyo

In order to investigate the mechanism of moisture transfer in the basement of Mars, experiments were conducted to measure the moisture, temperature, and salt distribution in the sand column during the vacuum evaporation process. As a result, it was found that the sample freezes at low salt concentration while it does not freeze at high concentration. In addition, we found that the salt moves to the surface layer with liquid water movement, and that the higher the salt concentration, the higher the evaporation amount. These results may relate to phenomena such as drying accompanied by evaporation under reduced pressure, freezing due to latent heat loss, crust formation due to salt concentration and freezing point depression.

In recent years, evidence of the existence of water has been found on the moon and Mars. The water resources on the moon or Mars are expected to be utilized as an in situ resource for future manned exploration. It is necessary to elucidate how the water exists in the porous media and how we can extract it. Under the 1G condition, water flow in porous media is expressed by Richards' equation. According to Richards' equation, water moves by a matric potential gradient and a gravity gradient. It was reported that water movement by a matric potential gradient, however, changed under microgravity. Therefore, water movement under low gravity might be different from estimation by conventional water movement theory. In this study, we observed water movement in porous media made of glass beads under microgravity and evaluated the effects of gravity on liquid behavior in porous media. We conducted infiltration experiments using porous media of 0.4 mm grass beads under microgravity conditions created by parabolic flight. The advances of the gas-liquid interface were captured by a video camera and the infiltration rate was calculated. We also conducted a horizontal infiltration experiment under 1G and compared the infiltration rate under each gravity conditions. The infiltration rate under microgravity was slightly lower than the horizontal infiltration rate under 1G. The decrease of infiltration rate, however, was smaller than the decrease in the previous study using 1.5 mm glass beads.

Effects of changes in viscosity under low gravity on infiltration rate

*Kento Nogawa[1], Naoto Sato[2], Yuichi Maruo[1], Natsumi Naganuma[1], Kosuke Noborio[2]

1. Graduate School of Agriculture, Meiji University, 2. School of Agriculture, Meiji University

It is important to clarify water behavior in the porous media to realize cultivation of crops in spacecraft, on Mars or on the Moon. However, Jones et al. (1999) revealed that infiltration rate in porous media under microgravity (μG) is lower than that under 1G. In addition, Maruo (2018) revealed that infiltration rate in the capillary tube under μG is lower than that under 1G. Infiltration in porous media under μG depends on capillary force, so that the decrease infiltration rate in the capillary tube might be a cause of the decrease in infiltration rate in the porous media under μG. It is thought that the decrease of infiltration rate in capillary tube under μG was caused by a decrease in surface tension, an increase in contact angle, and/or an increase in viscosity. Naganuma et al. (2019) reported that the surface tension of water does not vary with gravity. In addition, it was revealed that the contact angle of water droplets under μG does not change compared to under 1G (Naganuma et al., 2018). However, there are few studies that evaluated the gravitational dependence of the viscosity of water. In this research, we evaluated the gravity dependence of the viscosity of water and estimated the influence of viscosity change on infiltration rate. In this experiment, low gravity experiment using parabolic flight was carried out for 2 days using MU-300 (Diamond Air Service Inc., Nagoya, Japan) as an aircraft. The gravity condition was μG (1st day: 3 times, 2nd day: 3 times), 1/6G (1st day: 3 times, 2nd day: 6 times), 1/3G (1st day: 5 times, 2nd: 3 times), and each low gravity duration was 20 to 30 seconds. Changes in gravity were acquired from the accelerometer installed in the aircraft. For the acrylic column with an inner diameter of 64 mm and a height of 41 mm used for the experiment, water repellent treatment was performed on the upper 14 mm of the inner wall of the column, and the water level was adjusted so that the boundary between the processed part and the unprocessed part became the water surface. Degassed water was used as the sample to be filled in the column. For measurement of viscosity, a viscometer (Tuning Fork Vibro Viscometers SV-10, A & D Co., Ltd.) was used. The water temperature was measured by a temperature sensor built in the viscometer. The measurement interval of viscosity and temperature was 2 seconds on the 1st day and 1 second at the 2nd day. I photographed the state of the surface with a video camera (GoPro Hero 4, GoPro Inc.). Experimental results showed a negative correlation between viscosity and gravity in the range of 0G to 1G (Fig. 1). In the range of 1 G to 2 G, the measured values varied due to vibration, and reliable data could not be obtained. Since it is known that the surface tension and the contact angle do not change under μG, it is considered that the decrease infiltration rate in the capillary tube was brought about only by the increase in viscosity. From this, we consider the effect of increase in viscosity under μG on decrease of capillary invasion rate. Maruo (2018) defines the rate of change of infiltration rate in the capillary tube under μG compared to under 1G as a coefficient of delay α and is expressed by equation (1) (Fig. 2). Postulate that values other than viscosity do not change with 1G and μG in equation (1), it is considered that equation (2) holds. Therefore, $1/\alpha^2$ in capillary infiltration experiment by Maruo (2018) is compared with $\eta_{\mu G}/\eta_{1G}$ in this experiment. $1/\alpha^2$ is 2.49 at the capillary diameter of 0.8 mm, 2.78 at 2.37 mm, 3.19 at 5.5 mm, $\eta_{\mu G}/\eta_{1G}$ is at 2.66 on the 1st day and 2.70 on the 2nd day, $1/\alpha^2$ and $\eta_{\mu G}/\eta_{1G}$ are nearly the same value. From this, it is considered that the decrease infiltration rate in the capillary tube under μG was caused by the increase in viscosity.

Differences in infiltration process on the planets under different gravity.

*Yasushi Mori[1]

1. Graduate School of Environmental and Life Science, Okayama University

These days, we are trying to conduct the long-term stay in the space station, the various experiments under microgravity by the parabolic flight, and the research to explore the possibility of our stay on the other planets. In addition, we are exploring the existence of water and traces of living things on the other planets and satellites. If such an approach has become realistic, the next approach would be the earth, soil or regolith, where we need to consider how liquid flows and behaves. Here we consider the penetration phenomenon of solution when gravity is different. In the parabolic flight, they report that water in a vessel is sucked into noodles when it becomes zero gravity. When the influence of gravity becomes small, the influence of the capillary force by the porous body becomes relatively large, and the downward movement by the inertial force is restricted. Indeed, preliminary experiments showed that the downward reach of the solution increased as pseudo gravity increased. When we are trying to use regolith as planting on a planet with small gravity, the solution such as water might not move downward as we are estimating.

Liquid and solid water has recently been deiscovered in the moon, Mars, and other meterorites. Although people talk building bases on the moon and Mars and grow vegetables there, water transport in porous media in such conditions has little attention. Soil physics may play important roles even in extraterestrials as well as on the earth having 1G condition. Overview of water move in spce will be duscussed.

Characterization of Soil Organic Matter using Fourier Transform Infrared Spectrometer

*Iwasaki Masayoshi[1], Yasushi Mori[1]

1. okayama university graduate school environmental and life science

Combustion method is usually used to measure total carbon (TC). However, the total amount of carbon does not tell the contents such as fresh biomass or old humin. Therefore, detailed organic matter analysis was attempted using Fourier transform infrared spectrometer (FTIR), which could obtain unique spectrum of absorption or emission of soils. First, calibration curve was obtained using a mixture of cellulose and KCl. KCl was newly introduced as a diluent to avoid saturation of the emission peak. Furthermore, in order to extract individual organic matter, heavy liquids were used to select them by specific weight. Then, a total of 12 field soil samples were analyzed to figure out the organic matter differences affected by land management. As a result, the amount of cellulose was successfully measured. In field soils, cellulose was the most abundant organic matter in the surface layer, and the amount was more at the cultivated field than at the no-tillage field. When comparing this result with the result of the total carbon analysis, we estimated that there are much readily decomposable organic matter on the tillage field and much hardly decomposable organic matter on the no-tillage field. This is consistent with the previous reports. However, we should note, in the experiment using heavy liquids for specific gravity fractionation selection, sufficient accuracy was not obtained. So far, quantitative analysis was challenging to examine the organic matter of field soil, but we obtained the possibility that it can be done by specific gravity fractionation. Currently, accurate quantification has not been achieved, but comparison was possible.

The international deep space gateway is going to be built on the moon orbit from early 2020s. As manned space missions may get farther and longer, the importance of food production in space increases. For food production by growing crops in space, water by the crops plays an important role; however, few workers have conducted research on water movement in porous media under microgravity. It was reported that a water infiltration rate in porous media was slower under microgravity than under 1G. The objective of this study is to reveal what makes water move slower in porous media under microgravity. Capillary rises in capillary tubes, which were simpler pores, were observed under microgravity induced by a free-fall tower. The measured rates of capillary rise were slower than theoretical values calculated by Lucas-Washburn equation for 1G condition. The slower rates could be explained if either surface tension, contact angle, or viscosity are the function of gravity. Previous research reported that larger viscosity was observed under microgravity than under 1G although surface tension and contact angle were not changed by gravity. Slower water flows in capillary tubes under microgravity may be explained by changes in viscosity as a function of gravity.

Challenges to measuring of the contact angle and the surface tension of water under reduced gravity

Matric potential gradient is one of the driving forces of water movement in porous media. It has been reported that water movement in porous media under microgravity was slower than that under 1G, and hydraulic characteristic curve changed. Therefore, there is a possibility that the matric potential changes under reduced gravity. Capillary pressure is the main factor of dominating the matric potential value in porous media with a relatively large pore size. In this study we investigated the dependence of capillary force on gravity. Capillary forces are governed by the surface tension and contact angle that the liquid makes with the solid surfaces. We measured the contact angle of droplets on glass plate under microgravity condition to reveal the dependence of the contact angle on gravity. For large droplets, the contact angle under microgravity was larger than that under 1G, but the difference in contact angle between 1G and μG reduced with smaller droplets. We also conducted parabolic experiments to measure the surface tension of water under reduced gravity (μG, 1/6G, 1/3G, 1G). The maximum bubble pressure method which is one of the methods measuring surface tension was used. The bubble pressure greatly changed due to dynamically change of the inboard air pressure during parabolic flight. Evaluation of the surface tension by removing air pressure and hydraulic pressure from bubble pressure will be discussed.

[A-CG32] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies)

The landmark Paris Agreement under the United Nations Framework Convention on Climate Change (UNFCCC) aims at reduction of greenhouse gases (GHGs) emission to keep the global warming below 2 degC. As per the agreement the nationally determined commitments (NDCs) and their progresses should be carefully monitored and verified by international bodies. The emission verification will be based on observation of the time evolution of greenhouse gases and model-based estimations of emissions from time to time.

In recent years, the number of observations and new techniques to monitor GHGs budget have been increasing. The improvements includes observational platforms for monitoring atmospheric GHGs, national or regional emission inventories, top-down models (e.g. atmospheric inverse models), and bottom-up models (e.g. process-based models). However, due to uncertainties in modeling and sparse observation network, high uncertainty exists in GHGs sources/sinks estimations at global and regional scales. These uncertainties lead to large variations in future projection of GHG budgets and climate changes.

The purpose of the session is to discuss state-of-the-art techniques for estimations of GHGs (e.g. CO2, CH4, N2O) budget at global and regional scales. The topic includes natural and anthropogenic processes, various methodologies (e.g. in-situ observation, aircraft monitoring, remote sensing, modeling), and various targets (e.g. atmosphere, terrestrial, and ocean), various spatial and temporal coverage (e.g. regional to global scales and past-present-future). Improved estimates of emissions from land use change, forest fires, and other anthropogenic sources (urban developments and thermal power station etc.) are also of interest. We also welcome discussions for designs and plans for future studies targeting city and country scale emission estimations using sophisticated modeling tools.

Atmospheric observations of greenhouse gases provide accurate record the changes in their abundance in the Earth's environments, and it has now been well established that the increase in greenhouse gases concentrations is causing the rise in the mean surface air temperature. Using atmospheric chemistry-transport models (ACTM), along with the concentration measurements, we can estimate the sources and sinks of the chemical species. Using MIROC4-ACTM at JAMSTEC, we estimated regional sources and sinks of carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O) over the period of 1996 to 2016. This will help global stocktake every 5 years, as a independent estimate, when the coutries report their progress on nationally determined contributions (NDCs) under the Paris Agreement and their ammendments, overseen by the UNFCCC.

Analysis of hot summer in 2018

*Kazutaka Murakami[1], Kazuhito Ichii[1,2], Yukio Yoshida[1], Haruki Oshio[1], Makoto Saito[1]

1. National Institute for Environmental Studies, 2. Chiba University

Global averaged temperature in 2018 was considerably higher than normal year. Probably it is the fourth highest in the past. Especially, it was memorable that East Asia, Europe, and the southwestern part of the United States were hit by record heat waves in this summer. It is important for the ecological resilience to investigate how much such extreme weather damages the terrestrial ecosystem and how will it change after that. In this study, we analyzed the effect of this extremely high temperature on terrestrial vegetation using satellite remote sensing data. First, we investigated the high temperature area using MODIS land surface temperature (LST) product. Then, focusing on these high LST areas, we analyzed the impact to satellite observed Solar Induced Fluorescence (SIF) that closely related to a photosynthetic activity. As a result, it was found that the LST of 2018 in the East Asia (Japan, Korea and North Korea) was the highest during 2002 - 2018 years. And it also indicated abnormal high LST regions from Germany to northern Europe. Analysis of SIF data showed a positive decline in Europe but did not show a clear trend in Asia. In addition, similar trends were seen from other satellite vegetation indices, and it was found that the terrestrial vegetation shows different responses in both areas affected by the same hot summer.

Abstract

Data-driven approach is effective for understanding and up-scaling observation network data of terrestrial carbon fluxes. Recently, the expansion of observation network, the improvement of remote sensing products and more application of machine learning on natural science make it more possible. In this study, we estimated two important parameters of terrestrial ecosystem, terrestrial gross primary productivity (GPP) and net ecosystem exchange (NEE) through re-assessment of previous approaches [Ichii et al. 2017; Kondo et al. 2015]. We tested multiple combinations of input parameters with lagged effect, additional new input parameters and the updated MODIS datasets (Collection C6). Besides, we selected 3 typical machine learning methods (Random Forest, RF; Support Vector Regression, SVR; Artificial Neural Network, ANN) as data-driven method and compare the estimation from 3 different types of machine learning model. The site-level analysis shows that use of the new version data and the time-lagged improved the model performance. Finally, we compared our new estimation of GPP and NEE with several terrestrial models output and other available datasets and we found our new results show better consistency with them. This shows our estimation provides a good benchmark for understanding spatio-temporal variability in terrestrial GPP and NEE.

Institute for Space-Earth Environmental Research, Nagoya University, 4. Faculty of Agriculture, University of the Ryukyus, 5. Faculty of Agriculture, Kyushu University, 6. Forest Research and Management Organization

Tropical rainforests belong to the most important biomes, as they are one of the largest terrestrial carbon sink and also a consequent source of latent energy. Furthermore, they will be among the first ecosystems to undergo climatic changes in the near future. Understanding how they will response to those changes is essential. El Niño-Southern Oscillation (ENSO) is an opportunity to study ecosystem response under real climatic change conditions.

Transpiration (Tr), net ecosystem exchange (NEE) and heat fluxes were measured with an eddy covariance system in a natural rainforest in Sarawak, Malaysia. Meteorological and soil moisture observations were also conducted. This region does not have phase-locked dry periods, and seasonal variations of both air temperature and solar radiation are small. However, it is directly impacted by ENSO events. During the study period, from November 2009 to December 2016, two events were selected : La Niña 2010-2011 and El Niño 2014-2016. Normal conditions were assumed as a third "neutral" period. Comparisons of measured flux and meteorological drivers between the three periods were carried out, and analysis of environmental controls, as canopy conductance (g_c) were made.

Precipitation and air temperature were significantly different between the three periods. While the water cycle (latent heat flux, Tr, g_c) responded immediately to the changes imposed by La Niña, the enhancement of the ecosystem respiration balanced the gross primary production gain, resulting into a NEE similar to neutral conditions. Conversely, the NEE during El Niño was significantly smaller than during neutral, when the water cycle seemed not impacted. However, further observations of this late rainforest response evolution showed that, during the first part of El Niño, Tr and g_c increased while CO_2 flux reduced. Then, during the second part, the trend reversed : CO_2 flux increased and Tr, as well as g_c, reduced. This may indicate a time lag between the meteorological drivers (precipitation and air temperature) changes imposed by El Niño and the ecosystem response (H_2O and CO_2 fluxes). The response delay may be caused by the rainforest tendency to poorly regulate its water use, being a particular moist environment. As for the response itself, it may be triggered by the depletion of the soil water content.

Those results imply that considering the length of El Niño and the ecosystem response trigger are important to understand and model bornean rainforest fluxes under future climatic scenario.

For verification of data products of the Greenhouse Gas Observing Satellite (GOSAT), in this study, we monitored and evaluated CO2 flux, that is, the absorption and emission of CO2 by ecosystems in the grasslands of Mongolia by the eddy correlation method. Two flux towers were established in 2015 at the Nalaikh site near Ulaanbaatar City and the Hustai site with less influence of cities, respectively. The CO2 analyzers installed on the towers were calibrated every year by using the standard gas imported from Japan. Up to now, about 4-year monitoring data have been accumulated since 2015. The data analysis shows that the CO2 absorption was larger than emissions at both sites, which indicated that the ecosystem at both sites are carbon sinks. The annual mean value of the CO2 absorption at the Nalaikh site was about 2.66 μmol m^{-2} s^{-1} and the emission was about 1.53 μmol m^{-2} s^{-1}, but the absorption at the Hustai site was about 2.11 μmol m^{-2} s^{-1}, and the emission was about 1.37 μmol m^{-2} s^{-1} (Figure 1). Generally, the net CO2 absorption at the Nalaikh site (0.76 μmol m^{-2} s^{-1}) was found to be larger than that at the Hustai site (0.36 μmol m^{-2} s^{-1}).

To compare the GOSAT L4B data with the ground observation at both sites, we extracted the monthly mean value of CO2 absorption/emission from the grid data of GOSAT during 2009-2015 and compared with the observed data. We found that although the seasonal changing pattern and fluctuation range are similar, the CO2 emission derived by GOSAT were larger than absorption, which suggested that the steppe ecosystems at both sites are the carbon sources. However, the ground observations showed that the CO2 absorption at both sites was larger than emission, which suggested that the grassland ecosystems at both sites are carbon sinks (Figure 2). It is essential for us to find the reasons of this difference in the future.

Finally, to evaluate the spatiotemporal distribution of carbon absorption and emission in the whole country, we have developed a carbon budget model considering the influence of grazing density. The primary simulation results showed that the percentage of carbon loss by grazing (CLG) accounted for 19-38% of the net ecosystem production (NEP) in the Nalaikh area around the city of Ulaanbaatar, where the grazing density was 1.5-2.3 sheep/ha during 2012-2016. On the other hand, CLG accounted for only 7-20% of NEP in the Hustai area away from the city, where the grazing density was only 0.4-0.6 sheep/ha (Figure 3). The result implied that the carbon budget was greatly influenced by animal husbandry near cities, where the grazing density is large. The monitoring cameras installed at both sites show that the biomass inside and outside the fence was greatly influenced by the ingestion of livestock.

This study was funded by “the Project to implement MRV and related technological improvements contributing to the Joint Crediting Mechanism (JCM) in Mongolia”, Ministry of the Environment, Japan.

Data-driven monitoring of terrestrial carbon cycle in Mongolia

*ZAYA MART[1], Zhiyan Liu[1], Riku Kawase[1], Kazuhito Ichii[1]

1. Chiba University

Mongolia has been experiencing both climate changes and anthropogenic environmental changes. Therefore, it is important to monitor environmental changes. In particular, more and more observation-based data sets are available, and synthesis analysis using these multiple observation-based data sets are essential.

We analyzed changes in the terrestrial environmental environment in Mongolia from the 1980s to 2010s. We focused on two different temporal periods, the 1980s to 2010s and 2000 to 2015. As for the first period (1980s to 2010s), we used NOAA AVHRR data sets, observed climate data sets for the analysis. As for the second period (1980s to 2010s), we used multiple remote sensing data sets (e.g. Terra MODIS), empirically upscaled CO2 flux products, and outputs from terrestrial ecosystem models. We will show and discuss the estimated terrestrial environmental changes in Mongolia at the conference.

[A-CG32] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies)

The landmark Paris Agreement under the United Nations Framework Convention on Climate Change (UNFCCC) aims at reduction of greenhouse gases (GHGs) emission to keep the global warming below 2 degC. As per the agreement the nationally determined commitments (NDCs) and their progresses should be carefully monitored and verified by international bodies. The emission verification will be based on observation of the time evolution of greenhouse gases and model-based estimations of emissions from time to time.

In recent years, the number of observations and new techniques to monitor GHGs budget have been increasing. The improvements includes observational platforms for monitoring atmospheric GHGs, national or regional emission inventories, top-down models (e.g. atmospheric inverse models), and bottom-up models (e.g. process-based models). However, due to uncertainties in modeling and sparse observation network, high uncertainty exists in GHGs sources/sinks estimations at global and regional scales. These uncertainties lead to large variations in future projection of GHG budgets and climate changes.

The purpose of the session is to discuss state-of-the-art techniques for estimations of GHGs (e.g. CO2, CH4, N2O) budget at global and regional scales. The topic includes natural and anthropogenic processes, various methodologies (e.g. in-situ observation, aircraft monitoring, remote sensing, modeling), and various targets (e.g. atmosphere, terrestrial, and ocean), various spatial and temporal coverage (e.g. regional to global scales and past-present-future). Improved estimates of emissions from land use change, forest fires, and other anthropogenic sources (urban developments and thermal power station etc.) are also of interest. We also welcome discussions for designs and plans for future studies targeting city and country scale emission estimations using sophisticated modeling tools.

Regional budgets of 3 major greenhouse gases using inverse modelling of atmospheric data

*Prabir Patra[1], Naveen Chandra[1], Jagat Bisht[1]

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC)

Atmospheric observations of greenhouse gases provide accurate record the changes in their abundance in the Earth's environments, and it has now been well established that the increase in greenhouse gases concentrations is causing the rise in the mean surface air temperature. Using atmospheric chemistry-transport models (ACTM), along with the concentration measurements, we can estimate the sources and sinks of the chemical species. Using MIROC4-ACTM at JAMSTEC, we estimated regional sources and sinks of carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O) over the period of 1996 to 2016. This will help global stocktake every 5 years, as a independent estimate, when the coutries report their progress on nationally determined contributions (NDCs) under the Paris Agreement and their ammendments, overseen by the UNFCCC.

Analysis of hot summer in 2018

*Kazutaka Murakami[1], Kazuhito Ichii[1,2], Yukio Yoshida[1], Haruki Oshio[1], Makoto Saito[1]

1. National Institute for Environmental Studies, 2. Chiba University

Global averaged temperature in 2018 was considerably higher than normal year. Probably it is the fourth highest in the past. Especially, it was memorable that East Asia, Europe, and the southwestern part of the United States were hit by record heat waves in this summer. It is important for the ecological resilience to investigate how much such extreme weather damages the terrestrial ecosystem and how will it change after that. In this study, we analyzed the effect of this extremely high temperature on terrestrial vegetation using satellite remote sensing data. First, we investigated the high temperature area using MODIS land surface temperature (LST) product. Then, focusing on these high LST areas, we analyzed the impact to satellite observed Solar Induced Fluorescence (SIF) that closely related to a photosynthetic activity. As a result, it was found that the LST of 2018 in the East Asia (Japan, Korea and North Korea) was the highest during 2002 - 2018 years. And it also indicated abnormal high LST regions from Germany to northern Europe. Analysis of SIF data showed a positive decline in Europe but did not show a clear trend in Asia. In addition, similar trends were seen from other satellite vegetation indices, and it was found that the terrestrial vegetation shows different responses in both areas affected by the same hot summer.

Abstract

Data-driven approach is effective for understanding and up-scaling observation network data of terrestrial carbon fluxes. Recently, the expansion of observation network, the improvement of remote sensing products and more application of machine learning on natural science make it more possible. In this study, we estimated two important parameters of terrestrial ecosystem, terrestrial gross primary productivity (GPP) and net ecosystem exchange (NEE) through re-assessment of previous approaches [Ichii et al. 2017; Kondo et al. 2015]. We tested multiple combinations of input parameters with lagged effect, additional new input parameters and the updated MODIS datasets (Collection C6). Besides, we selected 3 typical machine learning methods (Random Forest, RF; Support Vector Regression, SVR; Artificial Neural Network, ANN) as data-driven method and compare the estimation from 3 different types of machine learning model. The site-level analysis shows that use of the new version data and the time-lagged improved the model performance. Finally, we compared our new estimation of GPP and NEE with several terrestrial models output and other available datasets and we found our new results show better consistency with them. This shows our estimation provides a good benchmark for understanding spatio-temporal variability in terrestrial GPP and NEE.

Response of a Bornean Rainforest to the Climatic Changes imposed by ENSO during 2009-2016

Forest Research and Management Organization

Tropical rainforests belong to the most important biomes, as they are one of the largest terrestrial carbon sink and also a consequent source of latent energy. Furthermore, they will be among the first ecosystems to undergo climatic changes in the near future. Understanding how they will response to those changes is essential. El Niño-Southern Oscillation (ENSO) is an opportunity to study ecosystem response under real climatic change conditions.

Transpiration (Tr), net ecosystem exchange (NEE) and heat fluxes were measured with an eddy covariance system in a natural rainforest in Sarawak, Malaysia. Meteorological and soil moisture observations were also conducted. This region does not have phase-locked dry periods, and seasonal variations of both air temperature and solar radiation are small. However, it is directly impacted by ENSO events. During the study period, from November 2009 to December 2016, two events were selected : La Niña 2010-2011 and El Niño 2014-2016. Normal conditions were assumed as a third "neutral" period. Comparisons of measured flux and meteorological drivers between the three periods were carried out, and analysis of environmental controls, as canopy conductance (g_c) were made.

Precipitation and air temperature were significantly different between the three periods. While the water cycle (latent heat flux, Tr, g_c) responded immediately to the changes imposed by La Niña, the enhancement of the ecosystem respiration balanced the gross primary production gain, resulting into a NEE similar to neutral conditions. Conversely, the NEE during El Niño was significantly smaller than during neutral, when the water cycle seemed not impacted. However, further observations of this late rainforest response evolution showed that, during the first part of El Niño, Tr and g_c increased while CO_2 flux reduced. Then, during the second part, the trend reversed : CO_2 flux increased and Tr, as well as g_c, reduced. This may indicate a time lag between the meteorological drivers (precipitation and air temperature) changes imposed by El Niño and the ecosystem response (H_2O and CO_2 fluxes). The response delay may be caused by the rainforest tendency to poorly regulate its water use, being a particular moist environment. As for the response itself, it may be triggered by the depletion of the soil water content.

Those results imply that considering the length of El Niño and the ecosystem response trigger are important to understand and model bornean rainforest fluxes under future climatic scenario.

Carbon dioxide (CO_2) emissions from fossil fuel combustion (Fossil fuel CO_2, FFCO2) is the largest input to the global carbon cycle over the decadal time scales. FFCO2 needs to be accurately quantified and monitored in order to deduce the carbon uptakes by natural sinks from atmospheric measurements as well as support the emission reduction and management. The Open-source Data Inventory for Anthropogenic CO_2 (ODIAC) is a global, high-spatial resolution (1x1km) gridded FFCO2 emission data product. We first pioneered the combined use of the point source information and satellite-observed nighttime lights data for emission downscaling in order to achieve global 1×1 km spatial resolution emission fields. The use of nightlight data allows us to observe dynamic changes in emissions spatial distributions in a timely manner and incorporate these into the emission field. Since its establishment in 2009, ODIAC has been extensively used in global and regional flux inversions especially with CO_2 data collected by carbon observing satellites, such as the Japanese Greenhouse gas Observing SATellite (GOSAT) and NASA’s Orbiting Carbon Observatory 2 (OCO-2). ODIAC has been also successfully applied to studies for localized emissions point sources such as power plants and cities. In order to further improve the accuracy of the emission downscaling, we have examined NASA’s new Visible Infrared Imaging Spectrometer Suite (VIIRS) Nighttime Environmental Product. An accurate global emission disaggregation is one of the key elements of future Monitoring and Verification Support (MVS) scientific systems that consist of the carbon modeling and data assimilation. Our advanced satellite-based emission downscaling model holds the promise of playing a critical role in such future systems.

Towards Decreasing the Uncertainty in Global Carbon Dioxide Emission Inventory

*Richao Cong[1], Makoto Saito[1], Ryuichi Hirata[1], Akihiko Ito[1]

1. Center for Global Environmental Research, National Institute for Environmental Studies

Global carbon dioxide (CO_2) emission inventory are considered as containing large uncertainty. To decrease the uncertainty, we corrected the emissions reported by some famous orgainzations to make a new global CO_2 emission map by top-down approach and to analyze the temporary variation of emissions at global, regional, and national scale. For that purpose, 133 nations across 10 databases which included the values from 2000 to 2010 were picked up for analysis. Then, the emissions are corrected by averaging of the values in the range of 25% to 75% quartile. To visualize the temporary variation for the emissions, we linked the emissions for 133 nations with global boundary map of nations by Geographic Information System (GIS). As our summarization, the total CO_2 emissions for 133 nations in 2010 are about 31,595 Tg CO_2 yr^{-1} which are inside the values reported by IEA (30,434 Tg only from fuel combustion) and CDIAC (33,469 Tg from fuel combustion, cement manufacture, and gas flaring), occupying about 94% of the emissions reported by EDGAR (33,588 Tg). In addition, we also combined the emissions with population, GDP, and area of each nation reported by world bank to summarize the emissions per capita and analyze the trends of them from 2000 to 2010.

Evaluation of MIROC4-ACTM reanalysis of GHGs concentrations using aircraft

*Jagat Bisht[1], Prabir Patra[1], Naveen Chandra[1], Sergey Gromov[2], Taku Umezawa[3], Andreas Zahn[4], cARL A. M. Brenninkmeijer[5]

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Yokohama, Japan, 2. Max Planck Institute for Chemistry, Mainz, Germany, 3. National Institute for Environmental Studies, Tsukuba, Japan, 4. Karlsruhe Institute of Technology (KIT), Institute for Meteorology and Climate Research, Karlsruhe, Germany, 5. Max Planck Institute for Chemistry, Air Chemistry Division, Mainz, Germany

Using the “Atmospheric Chemistry Transport Model” being part of the “Model for Interdisciplinary Research On Climate Earth System Model, version 4” (MIROC4-ACTM), simulations of several important greenhouse gases, such as CH_4, CO_2, SF_6, and N_2O, have been conducted using optimized emissions by inverse modelling of surface measurements for the period 1996-2016 (referred to as “reanalysis data”). Aircraft observations, conducted on board passenger aircraft (projects: CARIBIC and CONTRAIL) over diverse latitude and longitude regions offer independent constraints for evaluating the quality of reanalysis data. MIROC4-ACTM captures the variations in CO_2 and SF_6 observed by CARIBIC and CONTRAIL very well, with a correlation coefficient of above 0.96 and a slope of 0.92 at all atmospheric conditions. However, for CH_4 and N_2O the agreement was worse, with correlation coefficients (slopes) between CONTRAIL observations and model simulations of 0.80(0.49)-0.87(0.66) and 0.74(0.55)-0.77(0.75), respectively, at 0-140°E and poleward of 40°N. Further south, that is between 30° S-40°N latitude (for the Tokyo-Australia flights), the correlation coefficients (slopes) was 0.76(0.83)-0.88(0.89) and 0.92(0.87)-0.98(1.05), respectively. Similarly, the agreement with the CARIBIC observations was moderate for CH_4 and N_2O, with correlation coefficients (slopes) of 0.81(0.55) and 0.88(0.65), respectively.

Carbon flux estimation using NICAM-TM 4D-Var and GOSAT data towards GOSAT-2 Level 4 product

*Tazu Saeki[1], Yosuke Niwa[1], Makoto Saito[1]

1. National Institute for Environmental Studies

Greenhouse gases (GHG) observations from satellites have contributed to expanding spatial coverage of observational networks for GHGs over the globe. Greenhouse gases Observing SATellite (GOSAT) has been monitoring the column-averaged dry-air mole fractions of atmospheric carbon dioxide (XCO_2) and methane (XCH_4) from space since its launch in January 2009. Its successor GOSAT-2 was successfully launched on 29 October 2018, and the observational data are being processed at GOSAT-2 ground systems. The GOSAT-2 mission aims to continue and enhance spaceborne measurement of GHGs started by GOSAT, and to monitor the impacts of climate change and human activities on the carbon cycle. Both satellites are jointly developed and operated by Ministry of the Environment, Japan Aerospace Exploration Agency (JAXA), and National Institute for Environmental Studies (NIES). NIES is responsible for producing and distributing higher level data products, such as Level 2 products (XCO_2 and XCH_4 etc.) and Level 4 products (surface fluxes of CO_2 and CH_4 and three-dimensional global distributions of CO_2 and CH_4 concentrations) (http://www.gosat-2.nies.go.jp).

We are currently developing an inversion system for operational use to produce GOSAT-2 L4 products. The Non-hydrostatic ICosahedral Atmospheric Model (NICAM)-based Transport Model (NICAM-TM; Niwa et al., 2011) is used for simulating atmospheric CO_2 and CH_4 concentrations, and an inversion system based on the four-dimensional variational (4D-Var) method with NICAM-TM (NICAM-TM 4D-Var; Niwa et al., 2017a,b) is adopted to estimate global surface CO_2 and CH_4 fluxes. In this presentation, we will present test results of CO_2 flux estimation with NICAM-TM 4D-Var using GOSAT data (not GOSAT-2 data), ground-based data, prior fluxes, and their error covariances. NICAM-TM is operated with a horizontal resolution of glevel-5 (an average grid resolution of 223 km) and 40 vertical layers, and its meteorological fields are nudged with JRA-55 data to simulate real atmospheric transport. NICAM-TM 4D-Var is run with stored meteorological data, which successfully reduces computational cost. CO_2 surface fluxes have been estimated at every 223 km grid resolution and at monthly time resolution. Preliminary test results with single-year GOSAT data showed that flux differences between the prior fluxes and estimated fluxes from the GOSAT data inversion appear over a broad area of land regions, even over Siberia and South America where ground sites are sparse, while the ocean regions showed relatively fewer flux changes after the inversion. Our ongoing work includes inversions with multi-year data, the inclusion of other data, and tuning model parameters. The details will be presented at the meeting.

Acknowledgments. The model simulations are performed with the NIES supercomputer system and the Research Computation Facility for GOSAT-2 (RCF2). This research is partly supported by the Environment Research and Technology Development Fund (2-1701) of the Environmental Restoration and Conservation Agency of Japan.

Attribution of the ambiguity in methane’s growth rate shifts during 1988-2016.

*Naveen Chandra[1], Prabir Patra[1]

1. Japan Agency for Marine Earth Science and Technology

Atmospheric (CH_4) is an important greenhouse gas for mitigating climate change in the decadal scale due to its shorter atmospheric lifetime and about 30 times higher warming potential than carbon dioxide. The remarkable shift in CH_4 growth rate (decrease since early 1990s, quasi-stationary state during 1999-2005 and resume increase after 2006) has observed in past three decades (1990s-2010s). However, the attribution of these fluctuations remained highly conflicting. We have used a global inverse modeling system for constraining CH_4 emissions from 53 land regions for the period 1988–2016 using measurements from 19 sites and forward simulation by MIROC4-ACTM. The ACTM realistically represent inter-hemispheric transport and stratospheric age of air, and methyl chloroform concentration decay (proxy for loss OH concentration level) which are key elements for modelling CH4 in atmosphere. A set of 2 inversions is performed for different combinations of a priori emissions due to the wetlands and rice cultivation. We have shown that slowing down of emissions from oil and gas industry in the 1980s and Mt. Pinatubo volcanic eruption in 1991 led to a stabilization in emissions and thus the quasi-stationary state of CH4 concentration. The CH_4 growth after 2006 is attributed to increases in emissions mainly from coal industry and ruminant farming. The climatic variation due to ENSO caused significant interannual variation in the CH_4 growth rate. The role of CH_4 loss by hydroxyl (OH) reaction in CH4 growth rate variability is proposed to be not significant from inter-site differences.

Ocean uptake and land use change emissions suppressed atmospheric CO_2 growth in the 2015/16 El Niño

*Masayuki Kondo[1], Peter Landschützer[2], Yousuke Iida[3], Richard Houghton[4], Stephen Sitch[5]

1. Center for Environmental Remote Sensing, Chiba University, 2. Max Planck Institute for Meteorology, 3. Global Environment and Marine Department, Japan Meteorological Agency, 4. Woods Hole Research Center, 5. University of Exeter

Large variability in El Niño-Southern Oscillation (ENSO) induces anomalous CO_2 fluxes both in biosphere and hydrosphere. In the negative phase of ENSO (i.e., El Niño), dryer climate over lower latitudes decreases productivity of land vegetation and increases vulnerability to biomass burning. At the same time, suppressed upwelling of carbon-rich water near the Pacific South America reduces outgassing of oceanic CO_2 to atmosphere. In years of a strong El Niño, anomalous land and ocean CO_2 fluxes account for a large part of interannual variability of the total net CO_2 flux of the Earth surface. Thus, anomalously large atmospheric CO_2 growth rates co-occur with periods of El Niño events.

Biomass burning is believed to be the dominant component of variability in atmospheric CO_2 growth rate during El Niño. The 1997/98 El Niño induced the most significant anomalous CO_2 release on record, largely due to forest and peat fires in Southeast Asia. Likewise, a massive fire haze over Southeast Asia was found during the recent 2015/16 El Niño. Despite the seemingly large impact of biomass burning in the two events, the 2015/16 El Niño accompanied substantially less atmospheric CO_2 growth compared with that in the 1997/98 El Niño. It turns out that CO_2 emission from biomass burning in 2015 was substantially less than that in 1997 because precipitation before the peak of fire emission (Sept-Oct) shortened the drought length of 2015.

However, it is still arguable that the insignificant biomass burning is the dominate cause behind no obvious signs of large CO_2 release in the 2015/16 El Niño. In the recent decades, both biospheric and hydrospheric CO_2 fluxes has shown trends towards a net sink of CO_2, which suggest a possibility of that increasing CO_2 uptake has suppressed the atmospheric CO_2 growth in the 2015/16 El Niño. To evaluate this possibility, a synthesis of land-ocean CO_2 flux over the period of the two El Niño events is necessary. Here, we explore mechanisms behind differences in the atmospheric CO_2 growth in the 1997/98 and 2015/16 El Niño. The aim of this study is to fully characterize the causes for insignificant atmospheric CO_2 growth in 2015/16 through analyzing types (anomaly/trend) of relative contributions of land-ocean fluxes to atmospheric CO_2 growth between the two El Niño events. Through the analysis, we discuss about components that would likely continue to mitigate atmospheric CO_2 growth in future El Niño.

[A-CG32] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies), Chairperson:Prabir Patra

The landmark Paris Agreement under the United Nations Framework Convention on Climate Change (UNFCCC) aims at reduction of greenhouse gases (GHGs) emission to keep the global warming below 2 degC. As per the agreement the nationally determined commitments (NDCs) and their progresses should be carefully monitored and verified by international bodies. The emission verification will be based on observation of the time evolution of greenhouse gases and model-based estimations of emissions from time to time.

In recent years, the number of observations and new techniques to monitor GHGs budget have been increasing. The improvements includes observational platforms for monitoring atmospheric GHGs, national or regional emission inventories, top-down models (e.g. atmospheric inverse models), and bottom-up models (e.g. process-based models). However, due to uncertainties in modeling and sparse observation network, high uncertainty exists in GHGs sources/sinks estimations at global and regional scales. These uncertainties lead to large variations in future projection of GHG budgets and climate changes.

The purpose of the session is to discuss state-of-the-art techniques for estimations of GHGs (e.g. CO2, CH4, N2O) budget at global and regional scales. The topic includes natural and anthropogenic processes, various methodologies (e.g. in-situ observation, aircraft monitoring, remote sensing, modeling), and various targets (e.g. atmosphere, terrestrial, and ocean), various spatial and temporal coverage (e.g. regional to global scales and past-present-future). Improved estimates of emissions from land use change, forest fires, and other anthropogenic sources (urban developments and thermal power station etc.) are also of interest. We also welcome discussions for designs and plans for future studies targeting city and country scale emission estimations using sophisticated modeling tools.

Spectral vegetation index (VI) time series data derived from moderate resolution, polar-orbiting satellite sensors, have been used to monitor and characterize the Earth’ s vegetative cover and its dynamics in regional to global scales. Unities of these VI time series data are, however, constrained by frequent cloud covers. That is, the derived VI products from these sensor data are at a weekly or bi-weekly temporal resolution due to the availability of cloud-free observations, resulting in relatively high uncertainties in their seasonal dynamics characterization. A new generation of geostationary satellite sensors equipped with spectral bands suitable for VIs, such as Himawari-8/9, have been launched during the last decade. As they are on geostationary orbit, they can image an Earth’ s hemisphere at 10-15 min intervals, potentially serving as another significant data source for the studies of vegetation dynamics.

In this study, we assessed the utilities of Himawari-8 “hypertemporal” NDVI data for characterizing seasonal dynamics of vegetation and land cover conditions. We compared Himawari NDVI temporal signatures to those derived from a new generation polar-orbiting satellite sensor, Visible Infrared Imaging Radiometer Suite (VIIRS), at select sites in Japan. Our analysis showed that cloud-free observations were available for ~24 days during the 45-day green-up period with Himawari, but ~12 days with VIIRS. In other words, the number of days with cloud-free observations could double with Himawari data compared to VIIRS data. These results indicate the potential of Himawari data for providing higher temporal resolution NDVI time series data and, thus, improved monitoring and characterization of vegetation dynamics in Japan compared to the current polar-orbiting satellite data. One potential drawback would be the fixed view zenith and azimuth angles which might become problematic when one is interested in analyzing vegetation dynamics across space. Validation of Himawari-observed NDVI temporal profiles with ground observational NDVI and carbon flux data will be one required step.

Carbon and Water Fluxes at High spatial Resolutions through Down-Scaling

*Jiquan Chen[1], Pietro Sciusco[1], Ranjeet John[1], Zutao Ouyang[1]

1. Michigan State University

We propose an innovative top-down modeling approach to estimate high resolution (30 m) net primary production (NPP), evapotranspiration (ET) and *albedo* from MODIS products by integrating accurately classified land cover from Landsat/Sentinel and MODIS. Assuming that a measure of ecosystem ET in a landscape is a linear sum of ET of cover type (i), MODIS ET of a pixel can be expressed as:

$ET = sum(a_i * ET_i) + e$ [1]

where a_i is the compositional portion of cover type i within a MODIS pixel (where $sum(\alpha_i) = 1$) that can be calculated from classified land cover for the year; ET_i is the ET value of cover type i and can be estimated through multi-linear regression analysis with a zero intercept; and e is the residuals from the empirical model [1] and will be further examined for the potential influences of biophysical and socioeconomic driving forces. MODIS products of NPP, ET, and *albedo* of a landscape are estimated for their monthly and annual values by assuming that land cover during an individual year remains unchanged. This downscaling approach, currently tested for the Kalamazoo watershed in the southwestern Michigan, is only valid at a scale where similar climate, soil, and landforms exist (i.e. value of the same cover type in isolated patches are the same). To assure the validity of this approach, a multilinear regression analysis is performed with external factors such as soil type, climatic zone, and/or disturbance regime. Estimated ecosystem functions is then scaled up based on the 30 m resolution land cover of Landsat imagery for their high resolution spatiotemporal changes.

Connecting Satellite Based Spectral Modelling Approach and Forest Inventory to Model Biomass and Carbon Stocks in Natural and Planted Forest over part of Semi-arid zone, India

*SWATI UNIYAL[1], Siti Raju Rao

1. Andhra University

Forests have been recognized as having important mitigation potential because of their critical role in the global carbon cycle and significant potential to capture and hold carbon. Biomass is an important parameter to assess the atmospheric carbon that is harvested by trees.

This study describes an effort to estimate regional level Above Ground Biomass (AGB) and carbon from plot to point from multi-season MODIS data for a part of semi-arid zone i.e. Madhya Pradesh state by establishing a correlation with field observed data. Using clustered sampling approach a total number of 1200 plots were laid on ground for natural forests and planted forests/tress. Stand biomass for each plot was computed from ground inventory using diameter, height, generalized species and interspecies allometric equations.

Spectral modelling was done with red, infra-red and NDVI of different seasons with observed AGB using statistical functions like linear, logarithmic, power and exponential. Various linear and multiple regression models were tested among all seasons and bands, and the best fit model from those was used for predicting biomass and carbon at regional level.

Red band and NDVI spectral reflectance combined with logarithmic function in multiple regression was found to be the best model (r^2=0.5784) for model Y= a +b1* ln (NDVI) + b2 *1/x*(Red) +b3 *sqrt (NDVI) for predicting biomass and Carbon. Predicted biomass value is in the range of 0-134.836t/ha, while total biomass of the area is 5950Tg. Similarly Predicted Carbon content is in the range of 0-64.04tC/ha and total carbon content in the range of 2690TgC.

Results were validated using 50 random points. The observed ABG of these 50 points validated with predicted AGB, a correlation R^2= 0.6003 was obtained indicating biomass and carbon obtained through spectral modelling has given good estimation at regional level.

Comparing biomass and carbon value for natural forest and plantation study explicitly noted that planted forest/trees sequester more carbon because results from a combination of site factors and adaptation of good silvicultural practices, while for natural forest wide variation in stand structure, tree growth, different stages of forest growth cycle, and varying tree density resulted in lower carbon content.

Allocation of forest net primary production varies by forest age and air temperature

*Xiang Song[1], Xiaodong Zeng[1], Dongxiao Tian[2]

1. IAP, CAS, 2. Beijing Meteorological Information Center

Carbon partition among plant parts has a vital influence not only on the growth of individual plants but also on decomposition, carbon and nitrogen sequestration, and plant-atmosphere water exchange. Although many studies have tried to reveal plant growth mechanisms using observational living biomass or the biomass ratio among different organs, knowledge and understanding about carbon partition is still scarce and exists much uncertainty. In this work, a dataset from the Chinese Ecosystem Research Network (CERN) was used to explore the dependences of net primary production (NPP) partition among foliage, stem and branch, and root on forest age, and mean annual temperature (MAT). The results found that (1) younger plants usually allocated a higher proportion of the NPP to stems, branches, and roots; (2) MAT was negatively correlated with the proportions of the NPP allocated to foliage (F_{leaf}; %) and roots (F_{root}; %), while proportions of the NPP allocated to stems and branches (F_{stbr}; %) were positively dependent on MAT; (3) forest age had a larger direct influence on F_{leaf} and F_{root}, while MAT was relatively important for F_{stbr}. This work not only is important for understanding the contribution of climatic factor and forest age on forest NPP partition, but also provides valuable ideas for developing ecological models.

Analyzing Model Biases in Terrestrial Carbon Cycle Submodels in Earth System Models and Offline Models

*Kazuhito Ichii[1], Kazutaka Murakami[2], Hiroaki Takayama[3], Tomohiro Hajima[3], Kaoru Tachiiri[3]

1. Chiba University, 2. National Institute for Environmental Studies, 3. Japan Agency for Marine-Earth Science and Technology

Improvement of terrestrial models in earth system models (ESMs) is important to reduce uncertainties in future projections of global carbon cycle and climate. Toward an improvement of ESMs, we need to evaluate current performance of terrestrial components in current ESMs and analyze their causes of biases. Therefore, using available observation based products (e.g. satellite-based products), offline ecosystem model outputs, and CMIP-5 ESM outputs, we attempted to characterize causes of biases of modeled terrestrial carbon flux and pools. We found that key climate variables, such as precipitation, is one of the causes of biases in ESM-based carbon fluxes. For example, positive precipitation biases in Africa and Oceania results in positive biases of gross primary productivity (GPP), biomass, and net biome productivity (NBP). Negative precipitation bias in tropical South America leads to negative GPP, biomass and NBP biases. Therefore, improvement of spatial patterns are one of the important next step toward ESM, in particular toward realistic simulations of sub-continental scale terrestrial variations.

Assessing terrestrial biogeochemical feedbacks in a strategically geoengineered climate

*Forrest M. Hoffman[1,2], Cheng-En Yang[2,1], Joshua S. Fu[2,1], Simone Tilmes[3], Lili Xia[4], Douglas G. MacMartin[5], Jadwiga H. Richter[3], Michael Mills[3], Ben Kravitz[6]

1. Oak Ridge National Laboratory, 2. University of Tennessee, 3. National Center for Atmospheric Research, 4. Rutgers University, 5. Cornell University, 6. Pacific Northwest National Laboratory

Stratospheric geoengineering by injecting sulfur dioxide into the lower stratosphere has been suggested as a possible means of reducing anthropogenic warming. While the impacts of stratospheric aerosol geoengineering on climate change have been investigated in the past few decades, only a few studies have considered the terrestrial biogeochemical feedbacks resulting from such treatment. These feedbacks can alter the atmospheric carbon dioxide concentration by storing or releasing additional carbon in terrestrial and marine ecosystems, thus, changing the climate trajectory and aerosol injection strategy for geoengineering. In this study, we analyzed model output from the recent Stratospheric Aerosol Geoengineering Large Ensemble project to assess the changes in terrestrial biogeochemical feedbacks on climate, particularly the carbon sink strength (CSS), in response to stratospheric aerosol geoengineering. Our results showed that the terrestrial CSS increased globally by 5.2 Pg C during 2070–2089 compared to that during the first twenty years of geoengineering starting from 2020, *i.e.*, an additional 11 ppm CO_2 -equivalent amount of carbon in the atmosphere would be stored on land. Among seven latitude bands, the midlatitudes in the Northern Hemisphere (35˚N–60˚N) had the largest CSS increase (+8.0 Pg C) whereas the Tropics (23.5˚S–23.5˚N) released carbon back to the atmosphere (–2.9 Pg C). Hypotheses regarding the causes of the variations in the differences in regional responses will be presented.
