Wed. May 29, 2019

[J] Poster | U (Union)：Union

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute)

[U04-P01] Present status of time resolved measurement using X-ray absorption spectroscopy at SPring-8

*Kiyofumi Nitta[1], Oki Sekizawa[1], Kazuo Kato[1], Hitoshi Osawa[1] (1.Japan Synchrotron Radiation Research Institute)

[U04-P02] Ultrafast time-resolved XFEL diffraction study on shock-compressed corundum

*Yoshinori Tange[1] (1.Japan Synchrotron Radiation Research Institute)

[J] Poster | U (Union)：Union

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute)

[U04-P01] Present status of time resolved measurement using X-ray absorption spectroscopy at SPring-8

*Kiyofumi Nitta[1], Oki Sekizawa[1], Kazuo Kato[1], Hitoshi Osawa[1] (1.Japan Synchrotron Radiation Research Institute)

[U04-P02] Ultrafast time-resolved XFEL diffraction study on shock-compressed corundum

*Yoshinori Tange[1] (1.Japan Synchrotron Radiation Research Institute)

[J] Oral | U (Union)：Union

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 103 1F

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute), Chairperson:Takashi Yoshino(Okayama University), Yoshio Kono(愛媛大学地球深部ダイナミクスセンター), Yoshinori Tange

1:48 PM - 2:00 PM JST | 4:48 AM - 5:00 AM UTC

[U04-01] Toward organization of a new field on fast process in Earth and planetary science

★Invited Papers

*Takashi Yoshino[1] (1.Institute for Planetary Materials, Okayama University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[U04-02] Fractal particle size distribution of pulverized fault rocks and dynamic fragmentation of rocks

★Invited Papers

*Jun Muto[1], Osamu Nishikawa[2], Hiroyuki Nagahama[1] (1.Department of Earth Sciences, Tohoku University, 2.Graduate School of Engineering and Resource Sciences, Akita University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[U04-03] Universal aspects of acceleration process toward unstable fast rupture

★Invited Papers

*Takahiro Hatano[1] (1.Earthquake Research Institute, University of Tokyo)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[U04-04] Semi-brittle flow in dunite and harzburgite at upper mantle pressures

★Invited Papers

*Tomohiro Ohuchi[1], Xinglin Lei[2], Yuji Higo[3], Yoshinori Tange[3] (1.Geodynamics Research Center, Ehime University, 2.National Institute of Advanced Industrial Science and Technology, 3.Japan Synchrotron Radiation Research Institute)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[U04-05] A mechanism of magma fracturing revealed by in-situ X-ray imaging and diffraction

★Invited Papers

*Satoshi Okumura[1], Kentaro Uesugi[2], Tatsuya Sakamaki[1], Akio Goto[3] (1.Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University, 2.SPring-8/JASRI, 3.Center for Northeast Asian Studies, Tohoku University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[U04-06] Estimation of physical parameters of volcanic eruptions based on analysis of eruptive products –Toward understanding of eruption dynamics–

★Invited Papers

*Fukashi Maeno[1] (1.Earthquake Research Institute, University of Tokyo)

[J] Oral | U (Union)：Union

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 103 1F

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute), Chairperson:Takashi Yoshino(Okayama University), Yoshio Kono(愛媛大学地球深部ダイナミクスセンター), Yoshinori Tange

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[U04-07] Chemical reaction processes bridge between asteroid Ryugu and early evolution of Earth

★Invited Papers

*Seiji Sugita[1,3], Hideharu Kuwahara[2], Kosuke Kurosawa[3] (1.Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo, 2.Ehime University, 3.Chiba Institute of Technology)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[U04-08] Time-resolved synchrotron X-ray observations of mineral transformations under static pressures: applications to non-equilibrium behaviors in shocked meteorites

★Invited Papers

*Tomoaki Kubo[1], Masaaki Miyahara[2] (1.Kyushu University, 2.Hiroshima University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[U04-09] Ultrafast pump-probe experiemnts for planetary materials using high-power lasers and XFEL

★Invited Papers

*Norimasa Ozaki[1] (1.Osaka University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[U04-10] Tracking dynamical phenomena with X-ray free-electron lasers

★Invited Papers

*Tetsuo Katayama[1] (1.Japan Synchrotron Radiation Research Institute)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[U04-11] High speed measurement with synchrotron radiation X-ray.

★Invited Papers

*Kentaro Uesugi[1] (1.Japan Synchrotron Radiation Research Institute)

4:45 PM - 4:58 PM JST | 7:45 AM - 7:58 AM UTC

[U04-12] Recent advances in high-pressure synchrotron X-ray experiments on magmas under pressure at the beamline 16-BM-B in Advanced Photon Source

★Invited Papers

*Yoshio Kono[1] (1.Geodynamics Research Center, Ehime University)

[J] Oral | U (Union)：Union

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Convention Hall A 2F

[U-07] How JpGU will manage environment and disaster from the impacts of unforeseen geo-hazards

convener:Koji Okumura(Graduate School of Letters, Hiroshima University), Jun Matsumoto(Deaprtment of Geography, Tokyo Metropolitan University), Daisaku Kawabata(Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Masaki Matsushima(Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology), Chairperson:Daisaku Kawabata, Koji Okumura(Hiroshima University)

10:45 AM - 10:55 AM JST | 1:45 AM - 1:55 AM UTC

[U07-01] Seismotectonic environments and landscape as keys to mitigate the impacts from unexpected hazards

*Koji Okumura[1] (1.Graduate School of Letters, Hiroshima University)

10:55 AM - 11:10 AM JST | 1:55 AM - 2:10 AM UTC

[U07-02] Activities related with the eruption at Kusatsu-Shiranesan (Motoshiranesan) volcano on 23 Jan,2018 - Focusing on JMA's activities -

*Junichi Miyamura[1] (1.Japan Meteorological Agency)

11:10 AM - 11:25 AM JST | 2:10 AM - 2:25 AM UTC

[U07-03] Correspondences to society events at emergency disaster – In case of the Annual Meeting of the Geological Society of Japan -

*Matsuda Hiroki[1,2] (1.Kumamoto University, 2.the Geological Society of Japan)

11:25 AM - 11:40 AM JST | 2:25 AM - 2:40 AM UTC

[U07-04] Aftershock and microtremor array observation around the source area of the 2018 Hokkaido Eastern Iburi earthquake

*Masayuki Yoshimi[1], Kahori Iiyama[2], Hitoshi Morikawa[2], Hiroyuki Goto[3] (1.Geological Survey of Japan, AIST, 2.Tokyo Institute of Technology, 3.DPRI, Kyoto Univ.)

11:40 AM - 11:55 AM JST | 2:40 AM - 2:55 AM UTC

[U07-05] Effect of non-linear site response on earthquake hazard map

*Takao Kagawa[1] (1.Tottori University Graduate School of Engineering)

11:55 AM - 12:10 PM JST | 2:55 AM - 3:10 AM UTC

[U07-06] Evolution of catastrofic landslides due to rapid valley incision and filling since Last Glacial Age in central Nepal Himalayas

★Invited Papers

*Hiroshi YAGI[1] (1.Faculty of Art, Science and Education, Yamagata University)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder)

[PPS02-P01] Abrasion experiments of mineral and meteorite grains: Dependence of particle size and vibration rate on abrasion rate and its application to Itokawa and lunar regolith particles.

*Hirotaka Yamaguchi[1], Akira Tsuchiyama[1], Akiko Nakamura[2] (1.National University Corporation, Kyoto University, 2.National University Corporation,Kobe University)

[PPS02-P02] Measurements of adhesive force of meteorite powders using centrifugal method

*Yuuya Nagaashi[1], Akiko Nakamura[1] (1.Kobe University)

[PPS02-P03] Laboratory impact penetration experiments conducted at simulated reduced gravity

*Akiko Nakamura[1], Kana Morizono[2], Yuuya Nagaashi[1] (1.Graduate School of Science, Kobe University, 2.Faculty of Science, Kobe University)

[PPS02-P04] MARAUDERS: Using instrumented nano-impactors to probe the icy properties of Lunar permanently shadowed regions

*Ronald Ballouz[1], Sarah T Crites[2], Naoya Ozaki[2], Shun Arahata[3], Nicola Baresi[2], Ralf Bolden, Onur Celik[4,2], Yu Himeno[3], Lucie Riu[2], Kevin J Walsh[5] (1.Lunar and Planetary Lab, University of Arizona, Tucson, AZ, USA, 2.Institute of Space and Astronautical Science, Sagamihara, Japan, 3.University of Tokyo, Tokyo, Japan, 4.Sokendai Graduate University, Japan, 5.Southwest Research Institute, Boulder, CO, USA)

[PPS02-P05] Surface size-frequency distribution of accumulating boulders using discrete element simulations of spherical particles in 3D

*Hiroshi Kikuchi[1], Hideaki Miyamoto[1] (1.The University of Tokyo)

[PPS02-P06] Experimental Study to Determine the Best Compression Ratio of High-Resolution Images of Small Bodies for the Martian Moons eXploration (MMX) Mission

*Yuta Shimizu[1], Hiroaki Kamiyoshihara[1], Takafumi Niihara[1], Hideaki Miyamoto[1] (1.University of Tokyo)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder)

[PPS02-P01] Abrasion experiments of mineral and meteorite grains: Dependence of particle size and vibration rate on abrasion rate and its application to Itokawa and lunar regolith particles.

*Hirotaka Yamaguchi[1], Akira Tsuchiyama[1], Akiko Nakamura[2] (1.National University Corporation, Kyoto University, 2.National University Corporation,Kobe University)

[PPS02-P02] Measurements of adhesive force of meteorite powders using centrifugal method

*Yuuya Nagaashi[1], Akiko Nakamura[1] (1.Kobe University)

[PPS02-P03] Laboratory impact penetration experiments conducted at simulated reduced gravity

*Akiko Nakamura[1], Kana Morizono[2], Yuuya Nagaashi[1] (1.Graduate School of Science, Kobe University, 2.Faculty of Science, Kobe University)

[PPS02-P04] MARAUDERS: Using instrumented nano-impactors to probe the icy properties of Lunar permanently shadowed regions

*Ronald Ballouz[1], Sarah T Crites[2], Naoya Ozaki[2], Shun Arahata[3], Nicola Baresi[2], Ralf Bolden, Onur Celik[4,2], Yu Himeno[3], Lucie Riu[2], Kevin J Walsh[5] (1.Lunar and Planetary Lab, University of Arizona, Tucson, AZ, USA, 2.Institute of Space and Astronautical Science, Sagamihara, Japan, 3.University of Tokyo, Tokyo, Japan, 4.Sokendai Graduate University, Japan, 5.Southwest Research Institute, Boulder, CO, USA)

[PPS02-P05] Surface size-frequency distribution of accumulating boulders using discrete element simulations of spherical particles in 3D

*Hiroshi Kikuchi[1], Hideaki Miyamoto[1] (1.The University of Tokyo)

[PPS02-P06] Experimental Study to Determine the Best Compression Ratio of High-Resolution Images of Small Bodies for the Martian Moons eXploration (MMX) Mission

*Yuta Shimizu[1], Hiroaki Kamiyoshihara[1], Takafumi Niihara[1], Hideaki Miyamoto[1] (1.University of Tokyo)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder), Chairperson:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PPS02-01] Moganite in a lunar meteorite as a trace of H_2O ice in the lunar regolith

★Invited Papers

*Masahiro KAYAMA[1] (1.Tohoku University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PPS02-02] Simulating the Lunar Soil: a Japanese Lunar Soil Simulant FJS-1 and Its Properties

★Invited Papers

*Naohiro Uyama[1], Hiroshi Kanamori[1], Shigeru Aoki[1] (1.Shimizu Corporation)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PPS02-03] Experimental estimation of regolith scattering behavior when a space lander touches on a planetary body

★Invited Papers

*Mitsuhisa Baba[1], Ronald Louis Ballouz[2], Masatsugu Otsuki[1] (1.Japan Aerospace Exploration Agency, 2.The University of Arizona)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PPS02-04] Ray systems in granular cratering

*Tapan Sabuwala[1], Christian Butcher[1], Gustavo Gioia[1], Pinaki Chakraborty[1] (1.Okinawa Institute of Science and Technology Graduate University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PPS02-05] Scaling of oblique impact cratering onto inclined granular layer

Shinta Takizawa[1], *Hiroaki Katsuragi[1] (1.Graduate School of Environmental Studies, Nagoya University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PPS02-06] Experimental study on gravitational effects on crater size formed by low-velocity impacts into granular media

*Masato Kiuchi[1], Akiko M Nakamura[2], Koji Wada[3] (1.Japan aerospace exploration agency, Institute of space and astronautical science, 2.Department of Planetology, Kobe University, 3.Planetary Exploration Research Center, Chiba Institute of Technology)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder), Chairperson:Akiko Nakamura(Graduate School of Science, Kobe University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PPS02-07] Impact Ejecta Environment of an Eccentric Asteroid: 3200 Phaethon

*Jamey Szalay[1], Peter Pokorny[2], Mihaly Horanyi[3], Diego Janches[2], Menelaos Sarantos[2], Ralf Srama[4] (1.Princeton University, 2.NASA/GSFC, 3.University of Colorado Boulder, 4.University of Stuttgart)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PPS02-08] On the Detection of an Ejecta Dust Cloud Around Asteroid (3200) Phaethon by the DESTINY$^+$ Dust Analyzer

*Hiroshi Kimura[1], Masanori Kobayashi[1], Koji Wada[1], Tomoko Arai[1], Hiroki Senshu[1], Masateru Ishiguro[2], Hidekazu Hanayama[3], Ko Ishibashi[1], Takayuki Hirai[1], Fumi Yoshida[1], Peng Hong[1] (1.Planetary Exploration Research Center, 2.Seoul National University, 3.Ishigakijima Astronomical Observatory)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PPS02-09] Close-up thermal and optical observation of asteroid Ryugu

★Invited Papers

*Naoya Sakatani[1], Tatsuaki Okada[1], Satoshi Tanaka[1], Hiroki Senshu[2], Yuri Shimaki[1], Takehiko Arai[3], Toru Kouyama[5], Hirohide Demura[6], Kentaro Suko[6], Tomohiko Sekiguchi[4], Jun Takita[15], Tetsuya Fukuhara[4], Makoto Taguchi[4], Thomas Müller[7], Axel Hargermann[8], Jens Biele[9], Matthias Grott[9], Marco Delbo[10], Seiji Sugita[13], Rie Honda[12], Tomokatsu Morota[11], Manabu Yamada[2], Shingo Kameda[4], ERI TATSUMI[13], Yasuhiro Yokota[1], Hidehiko Suzuki[14], Chikatoshi Honda[6], Kazunori Ogawa[16], Masahiko Hayakawa[1], Moe Matsuoka[1], Yuichiro Cho[13], Hirotaka Sawada[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Chiba Institute of Technology, 3.Ashikaga University, 4.Rikkyo University, 5.National Institute of Advanced Industrial Science and Technology, 6.University of Aizu, 7.Max-Planck Institute for Extraterrestrial Physics, 8.University of Stirling, 9.German Aerospace Center, 10.Observatoire de la Côte d'Azur, CNRS, 11.Nagoya University, 12.Kochi University, 13.University of Tokyo, 14.Meiji University, 15.Hokkaido University for Education, 16.Kobe University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PPS02-10] In-Situ Investigation of Asteroid (162173) Ryugu by the Hayabusa2 MASCOT Lander

★Invited Papers

*Hajime Yano[1], Tra-Mi Ho[2], Ralf Jaumann[3], Jean-Pierre Bibring[4], Karl-Heinz Glassmeier[5], Matthias Grott[3], David Hercik[5], Jens Biele[6], Maximilian Hamm[3], Nicole Schmitz[3], Stefanus Schröder[3], Katharina Otto[3], Christian Krause[6], Laurence Lorda[7], Aurelie Moussi-Soffys[7], Cedric Pilorget[4], Vincent Hamm[4], Lucie Riu[1], Tatsuaki Okada[1], Naoya Sakatani[1], Josef Reill[8], Kaname Sasaki[2], Markus Schlotterer[2], Yuichi Tsuda[1], Stephan Ulamec[6], Friederike Wolff[8], Patrick Michel[9], Marco Delbo[9], Kazunori Ogawa[10], Hiroki Senshu[11], Tetsuo Yoshimitsu[1], Frank Preusker[3], Frank Scholten[3], Stephan Elgner[3], Stefano Mottola[3], Ekkehard Kührt[3], Takanao Saiki[1], Yuya Mimasu[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Sagamihara, Japan, , 2.German Aerospace Center DLR Bremen, Bremen, Germany, 3.German Aerospace Center, Berlin, Germany, 4.Univ. de Paris Sud-Orsay, IAS, Orsay, France, 5.TU Braunschweig, Braunschweig, Germany, 6.German Aerospace Center DLR Cologne, Cologne, Germany, 7.National Centre for Space Studies, CNES, Toulouse, France, 8.German Aerospace Center, DLR, Oberpfaffenhofen, Germany, 9.Université Côte d'Azur, Observatoire de la Côte d'Azur, CNRS, Laboratoire Lagrange, Nice, France, 10.Department of Planetology, Graduate School of Science, Kobe University, Kobe, Japan, 11.Planetary Exploration Research Center, Chiba Institute of Technology, Narashino, Japan)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PPS02-11] Evidence of Mass Movement and Boulder Transport on Bennu from NASA's OSIRIS-REx Space Mission

★Invited Papers

*Erica R Jawin[1], Kevin J Walsh[2], Tim McCoy[1], Harold C Connolly[3], Dante S Lauretta[4], Ron L Ballouz[4], Jamie L Molaro[5], Olivier S Barnouin[6], Mike Nolan[4] (1.Smithsonian National Institute, Washington, DC, USA, 2.Southwest Research Institute, Boulder, CO, USA, 3.Dept. of Geology, Rowan University, Glassboro, NJ, USA, 4.Lunar and

Planetary Laboratory, University of Arizona, Tucson, AZ, USA , 5.Planetary Science Institute, Tucson, AZ, USA, 6.The Applied Physics Laboratory, Johns Hopkins University, Laurel, MD, USA)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PPS02-12] Resurfacing processes on small asteroids constrained by crater size distributions on Ryugu, Itokawa, and Eros

*Naofumi Takaki[1], Yuichiro Cho[1], Tomokatsu Morota[3], ERI TATSUMI[1], Kazuo Yoshioka[1], Hirotaka Sawada[5], yokota yasuhiro[2,5], Naoya Sakatani[5], Masahiko Hayakawa[5], Moe Matsuoka[5], Rie Honda[2], Shingo Kameda[4], Manabu Yamada[6], Toru Kouyama[8], Hidehiko Suzuki[10], Chikatoshi Honda[7], Kazunori Ogawa[9], Hideaki Miyamoto[1], Olivier Barnouin[11], Patrick Michel[12], Carolyn Ernst[11], Seiji Sugita[1,6] (1.University of Tokyo, 2.Kochi University, 3.Nagoya University, 4.Rikkyo University, 5.JAXA, 6.Chiba Institute of Technology, Planetary Exploration Res. Center, 7.University of Aizu, 8.AIST, 9.Kobe University, 10.Meiji University, 11.Johns Hopkins University Applied Physics Laboratory, 12.Nice Observatory)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Taishi Nakamoto(Tokyo Institute of Technology)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PPS03-19] The shape of Bennu: Implications for internal structure.

★Invited Papers

*Olivier S Barnouin[1], Micheal G. Daly[2], Eric E Palmer[3], Robert W Gaskell[3], John R. Weirich[3], Catherine L Johnson[4], Manar Al Asad[4], James H Roberts[1], Mark E. Perry[1], Hannah C.M. Sursorney[4], R. Terik Daly[1], Edward B. Bierhaus[5], Jeff A Seabrook[2], Raymond C. Espiritu[1], A. Hari Nair[1], Lilian Nguyen[1], Gregory A Neumann[6], Carolyn M Ernst[1], William V Boynton[7], Micheal C. Nolan[7], Coralie D. Adams[9], Micheal C. Moreau[6], Bashar Rizk[7], Christian Drouet D'Aubigny[7], Erica R. Jawin[8], Kevin J Walsh[10], Patrick Michel[11], Stephen R. Schwartz[7], Ronald L. Ballouz[7], Erwan M Mazarico[6], Daniel J. Scheeres[12], Jay W. McMahon[12], W Bottke[10], Seiji Sugita[13], Naru Hirata[14], Noayuki Hirata[15], Sei-ichiro Watanbe[16], Keara N. Burke[7], Daniella N. DellaGuistina[7], Carinna A. Bennet[7], Dante Lauretta[7] (1.Johns Hopkins University Applied Physics Laboratory, 2.The Centre for Research in Earth and Space Science, York University, Toronto, Ontario, Canada., 3.Planetary Science Institute, Tucson, AZ, USA, 4.Department of Earth, Ocean and Atmospheric Sciences, University of British Columbia, Vancouver, Canada., 5.Lockheed Martin Space Systems Company, Denver, CO, USA., 6.NASA Goddard Space Flight Center, Greenbelt, MD, USA., 7.Lunar Planetary Laboratory, University of Arizona, Tucson, AZ, USA., 8.Smithsonian Institution National Museum of Natural History, Washington, DC, USA., 9.KinetX Aerospace, Inc. Simi Valley, CA, USA, 10.Southwest Research Institute, Boulder, CO, USA., 11.Université Côte d'Azur, Observatoire de la Côte d'Azur, CNRS, Laboratoire Lagrange, Nice, France., 12.Department of Aerospace Engineering Sciences, University of Colorado, Boulder, CO, USA., 13.University of Tokyo, Tokyo, Japan., 14.Aizu University, Aizu-Wakamatsu, Japan., 15.Kobe University, Kobe, Japan., 16.Nagoya University, Nagoya, Japan.)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PPS03-20] Global Geology of Bennu from NASA's OSIRIS-REx Space Mission

★Invited Papers

*Erica R Jawin[1], Kevin J Walsh[2], Tim McCoy[1], Harold C Connolly[3], Dante S Lauretta[4], Ron L Ballouz[4], Olivier S Barnouin[5], C Beddingfield[6], Carina A Bennett[4], Edward B Bierhaus[7], Keara N Burke[4], Ben Clark[8], Michael G Daly[9], Marco Delbo[10], Daniella DellaGiustina[4], Jason P Dworkin[11], Christine Hartzell[12], John Marshall[6], Patrick Michel[10], Jamie L. Molaro[13], Mike Nolan[4], Maurizio Pajola[14], Mark Perry[5], Bashar Rizk[4], Scott Sandford[15], Dan J Scheeres[16], Stephen R Schwartz[4], David Trang[17] (1.Smithsonian National Institute, Washington, DC, USA, 2.Southwest Research Institute, Boulder, CO, USA, 3.Dept. of Geology, Rowan University, Glassboro, NJ, USA, 4.Lunar and Planetary Laboratory, University of Arizona, Tucson, AZ, USA , 5.The Applied Physics Laboratory, Johns Hopkins University, Laurel, MD, USA, 6.SETI Institute, Mountain View, CA, USA, 7.Lockheed Martin Space Systems Company, USA, 8.Space Science Institute, Boulder CO, USA, 9.York University, Canada, 10.Laboratoire Lagrange, Université Côte d'Azur, Observatoire de la Côte d'Azur, CNRS, Laboratoire Lagrange, Nice, France, 11.NASA Goddard Space Flight Center, Greenbelt, MD, USA, 12.Department of Aerospace Engineering, University of Maryland, College Park MD, USA, 13.Planetary Science Institute, Tucson, AZ, USA, 14.INAF - Astronomical Observatory of Padova, Italy, 15.NASA Ames Research Center, USA, 16.Dept. of Aerospace Engineering Sciences, University of Colorado, Boulder, CO, USA, 17.HIGP/University of Hawaii at Manoa, USA)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PPS03-21] Modeling surface mobility mechanisms on a top-shaped near-Earth asteroid

★Invited Papers

*Ronald Ballouz[1], Nicola Baresi[2], Olivier S Barnouin[3], Carina A Bennet[1], Edward B Bierhaus[4], Keara N Burke[1], Harold C Connolly[5], Sarah T Crites[2], Daniella DellaGiustitna[1], Erica Jawin[6], Dante S Lauretta[1], Patrick Michel[7], Derek C Richardson[8], Dan J Scheeres[9], Stephen Schwartz[1], Seiji Sugita[10], Eri Tatsumi[10], Florian Thuillet[7], Kevin Walsh[11] (1.Lunar and Planetary Lab, University of Arizona, Tucson, AZ, USA, 2.Institute of Space and Astronautical Science, Sagamihara, Japan, 3.The Applied Physics Laboratory, Johns Hopkins University, Laurel, MD, USA, 4.Lockheed Martin, Boulder, CO, USA, 5.Department of Geology, Rowan University, Glassboro, NJ, USA, 6.Smithsonian National Museum of Natural History, Washington, DC, USA, 7.UCA-OCA-CNRS, Lagrange Laboratory, Nice, France, 8.Dept. of Astronomy, University of Maryland, College Park, MD, USA, 9.Dept. of Aerospace Engineering Sciences, University of Colorado, Boulder, CO, USA, 10.University of Tokyo, Tokyo, Japan, 11.Southwest Research Institute, Boulder, CO, USA)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PPS03-22] **Visualization and Analysis of Solar System Small Bodies with NASA's Solar System Treks Project**

*Brian Hamilton Day[1], Emily Law[2] (1.NASA Solar System Exploration Research Virtual Institute, NASA Ames Research Center, 2.NASA Jet Propulsion Laboratory, California Institute of Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PPS03-23] Density Distribution within Small Solar System Bodies Based on Smooth Terrain Shape: Asteroid 25143 Itokawa and Comet 67P/Churyumov-Gerasimenko

*Masanori Kanamaru[1], Sho Sasaki[1], Mark Wieczorek[2] (1.Osaka University, 2.Côte d'Azur Observatory)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PPS03-24] Low temperature hydration experiments of cometary analog materials towards the Comet Astrobiology Exploration Sample Return (CAESAR) mission

*Aki Takigawa[1,4], Yuki Kimura[1], Yoshihiro Furukawa[2], Tomoki Nakamura[3] (1.Graduate School of Science, Kyoto University, 2.Institute of Low Temperature Science, 3.Graduate School of Science, Tohoku University, 4.The Hakubi Center for Advanced Research)

[E] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Masateru Ishiguro(Seoul National University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PPS03-25] Overview and current status of DESTINY$^+$ mission

★Invited Papers

*Tomoko Arai[1], Masanori Kobayashi[1], Ko Ishibashi[1], Fumi Yoshida[1], Hiroshi Kimura[1], Takayuki Hirai[1], Hong Peng[1], Manabu Yamada[1], Hiroki Senshu[1], Koji Wada[1], Ralf Srama[2], Harald Kruger[3], Jun-ichi Watanabe[4], Takashi Ito[4], Masateru Ishiguro[5], Tomoki Nakamura[6], Hikaru Yabuta[7], Shogo Tachibana[8], Takashi Mikouchi[8], Shinsuke Abe[9], Katsuhito Ohtsuka[10], Seitaro Urakawa[11], Keiko Nakamura-Messenger[12], Mutsumi Komatsu[13], Shingo Kameda[14], Masato Kagitani[6], Naru Hirata[15], Hirohide Demura[15], Sho Sasaki[16], Takahiro Hiroi[17], Goro Komatsu[18], Hidehiro Kaneda[19], Takaya Inamori[19], Takaya Okamoto[20], Toshifumi Yanagisawa[20], Makoto Yoshikawa[20], Hajime Yano[20], Tatsuaki Okada[20], Takahiro Iwata[20], Takafumi Ootsubo[20], Yasuhiro Kawakatsu[20], Hiroyuki Toyota[20], Kazutaka Nishiyama[20], Takeshi Takashima[20] (1.Planetary Exploration Research Center, Chiba Institute of Technology, 2.University of Stuttgart, 3.Max Planck Institute, 4.National Astronomical Observatory of Japan , 5.Seoul National Universtiy, 6.Tohoku University, 7.Hiroshima University, 8.The University of Tokyo, 9.Nihon University, 10.Tokyo Meteor Network, 11.Japan Spaceguard Association, 12.NASA , 13.The Graduate University for Advanced Studies, 14.Rikkyo University, 15.Aizu University, 16.Osaka University, 17.Brown University, 18.D'Annunzio University, 19.Nagoya University, 20.JAXA)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PPS03-26] Observational campaign of (3200) Phaethon and (155140) 2005UD in 2017-2018

*Fumi Yoshida[1], Tomoko Arai[1], Ko Ishibashi[1], Peng Hong[1], Ryo Ishimaru[1], DESTINY+ International observation collaborators (1.Planetary Exploration Research Center, Chiba Institute of Technology)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PPS03-27] Rotationally-resolved spectroscopic observations of Phaethon - 2005 UD, and their fragments detected by lunar impact flashes.

*Shinsuke Abe[1], Nicholas Moskovitz[2], Fumi Yoshida[3], Katsutoshi Ohtsuka[4], Ito Takashi[5], Ryota Fuse[1], Masahisa Yanagisawa[6], Ryuhei Yamada[7] (1.Department of Aerospace Engineering, College of Science and Technology, Nihon University, 2.Lowell Observatory, 3.Planetary Exploration Research Center, Chiba Institute of Technology, 4.Tokyo Meteor Network, 5.National Astronomical Observatory of Japan, 6.The University of Electro-Communications, 7.The University of Aizu, Department of Computer Science and Engineering)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PPS03-28] Thermal Radiation Pressure Force on Regolith Particles of Atmosphereless Bodies

*Yoonsoo P. Bach[1], Masateru Ishiguro[1] (1.Department of Physics and Astronomy, Seoul National University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PPS03-29] A kilometre-sized Kuiper belt object revealed by OASES stellar occultation observations

*Ko Arimatsu[1,2], Kohji Tsumura[3], Fumihiko Usui[4], Shinnaka Yoshiharu[5], Kohei Ichikawa[3,6,7], Takafumi Ootsubo[8], Takayuki Kotani[2,9], Takehiko Wada[8], Koichi Nagase[8], Jun-ichi Watanabe[2] (1.Astronomical Observatory, Graduate School of Science, Kyoto University, 2.National Astronomical Observatory of Japan, 3.Frontier Research Institute for Interdisciplinary Science, Tohoku University, 4.Center for Planetary Science, Graduate School of Science, Kobe University, 5.Laboratory of Infrared High-resolution Spectroscopy, Koyama Astronomical Observatory, Kyoto Sangyo University, 6.Department of Astronomy, Columbia University, 7.Department of Physics and Astronomy, University of Texas at San Antonio, 8.Department of Space Astronomy and Astrophysics, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 9.Astrobiology Center, National Institutes of Natural Sciences)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PPS03-30] AKARI/IRC near-infrared asteroid spectroscopic survey: AcuA-spec

*Fumihiko Usui[1], Sunao Hasegawa[2], Takafumi Ootsubo[2], Takashi Onaka[3,4] (1.Kobe University, 2.ISAS/JAXA, 3.The University of Tokyo, 4.Meisei University)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory)

[PPS03-P01] Impact experiments on low strength coarse-grained regolith simulating surface materials on asteroid Ryugu

*Yuya Yamamoto[1], Masahiko Arakawa[1], Minami Yasui[1], Sunao Hasegawa[2], Ryo Sugimura[1] (1.Graduate School of Science, Kobe University, 2.ISAS, JAXA)

[PPS03-P02] Reflectance estimation of asteroid Ryugu using MASCOT

*Marika Ishida[1], Koto Amano[1], Keiichi Moroi[1], ERI TATSUMI[2], Tra-Mi Ho[10], Shingo Kameda[1], Seiji Sugita[2], Rie Honda[3], Tomokatsu Morota[4], yokota yasuhiro[5], Toru Kouyama[6], Hidehiko Suzuki[7], Manabu Yamada[8], Naoya Sakatani[5], Chikatoshi Honda[9], Masahiko Hayakawa[5], Kazuo Yoshioka[2], Moe Matsuoka[5], Yuichiro Cho[2], Hirotaka Sawada[5] (1.Rikkyo Univ., 2.Univ. of Tokyo, 3.Kochi Univ., 4.Nagoya Univ., 5.JAXA/ISAS, 6.AIST, 7.Meiji Univ., 8.Chiba Inst. Tech, 9.Univ. of Aizu, 10.DLR)

[PPS03-P03] Flyby observation of Asteroid (3200) Phaethon by DESTINY$^+$ onboard cameras

*Ko Ishibashi[1], Shingo Kameda[2], Masato Kagitani[3], Peng Hong[1], Manabu Yamada[1], Osamu Okudaira[1], Tomoko Arai[1], Fumi Yoshida[1], Shunsuke Sato[4], Takahiro Ishimaru[4], Takaya Okamoto[4], Takahiro Iwata[4], Tatsuaki Okada[4], Takeshi Takashima[4] (1.Chiba Institute of Technology, 2.Rikkyo University, 3.Tohoku Universtiy, 4.Japan Aerospace Exploration Agency)

[PPS03-P04] Polarimetric Study of Asteroids in Comet-Like Orbits (ACOs)

*Jooyeon Geem[1], Masateru Ishiguro[1], Yoonsoo P. Bach[1], Daisuke Kuroda[2], Hiroyuki Naito[3], Hidekazu Hanayama[4], yoonyoung kim[10], Yuna G. Kwon[1], Sunho Jin[1], Tomohiko Sekiguchi[5], Ryo Okazaki[5], Jeremie J. Vaubaillon[6], Masataka Imai[7], Tatsuharu Oono[8], Yuki Futamuts[8], Seiko Takagi[8], Mitsuteru Sato[8], Kiyoshi Kuramoto[8], Makoto Watanabe[9] (1.Astronomy program, Dept of Physics and Astronomy, Seoul National University, 2.Okayama Observatory, Kyoto University, 3.Nayoro Observatory, 4.Ishigakijima Astronomical Observatory, National Astronomical Observatory of Japan, 5.Hokkaido University of Education, 6.Observatoire de Paris, I.M.C.C.E., 7.National Institute of Advanced Industrial Science and Technology, 8.Department of Cosmosciences, Graduate School of Science, Hokkaido University, 9.Department of Applied Physics, Okayama University of Science, 10.Max Planck Institute for Solar System Research)

[PPS03-P05] Dynamical lifetime of the Oort Cloud new comets under planetary perturbation

*Ito Takashi[1], Arika Higuchi[1] (1.National Astronomical Observatory of Japan)

[PPS03-P06] Thermal Infrared Imaging of C-type Asteroid 162173 Ryugu with Porous Surfaces

*Tatsuaki Okada[1,2], Tetsuya Fukuhara[3], Satoshi Tanaka[1], Makoto Taguchi[3], Takehiko Arai[4], Naoya Sakatani[1], Yuri Shimaki[1], Hiroki Senshu[5], Yoshiko Ogawa[6], Hirohide Demura[6], Kentaro Suko[6], Kohei Kitazato[6], Toru Kouyama[7], Tomohiko Sekiguchi[8], Jun Takita[9], Sunao Hasegawa[1], Tsuneo Matsunaga[10], Takehiko Wada[1], Takeshi Imamura[2], Jorn Helbert[11], Thomas G. Mueller[12], Axel Hagermann[13], Jens Biele[11], Matthias Grott[11], Maximiliam Hamm[11], Marco Delbo[14], Yukio Yamamoto[1], Naru Hirata[6], Naoyuki Hirata[15], Fuyuto Terui[1], Takanao Saiki[1], Satoru Nakazawa[1], Makoto Yoshikawa[1], Sei-ichiro WATANABE[1,16], Yuichi Tuda[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.University of Tokyo, 3.Rikkyo University, 4.Ashikaga University, 5.Chiba Institute of Technology, 6.University of Aizu, 7.National Institute of Advanced Industrial Science and Technology, 8.Hokkaido University of Education, 9.Hokkaido Kitami-Hokuto High School, 10.National Institute for Environmental Studies, 11.German Aerospace Center, 12.Max-Planck Institute for Extraterrestrial Physics, 13.University of Stirling, 14.Observatoire de la Côte d'Azur, 15.Kobe University, 16.Nagoya University)

[PPS03-P07] Data Release of Asteroid 162173 Ryugu by Observation of Thermal Infrared Imager onboard Hayabusa2

*Takehiko Arai[1], Hirohide Demura[2], Toru Kouyama[7], Naoya Sakatani[3], Kentaro Suko[2], Yuri Shimaki[3], Hiroki Senshu[5], Tomohiko Sekiguchi[6], Yoshiko Ogawa[2], Sunao Hasegawa[3], Takehiko Wada[3], Takeshi Imamura[10], Tsuneo Matsunaga[9], Jun Takita[8], Kohei Kitazato[2], Makoto Taguchi[4], Tetsuya Fukuhara[4], Satoshi Tanaka[3], Tatsuaki Okada[3] (1.Ashikaga University, 2.The University of Aizu, 3.Japan Aerospace Exploration Agency (JAXA), 4.Rikkyo University,

5.Chiba Institute of Technology, 6.Hokkaido University of Education, 7.National Institute of Advanced Industrial Science and Technology (AIST), 8.Hokkaido Kitami Hokuto High School, 9.National Institute for Environmental Studies (NIES), 10.The University of Tokyo)

[PPS03-P08] Multi-mission capability of HARMONICS

*Shintaro Tsunoda[1], Hirohide Demura[1], Naru Hirata[1] (1.The University of Aizu)

[PPS03-P09] New interface of verification for calibration and conversion in HEAT : Hayabusa2 Exploration Assistant for TIR

*Tatsuro Kobayashi[1], Kentaro Suko[1], Hirohide Demura[1], Yoshiko Ogawa[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4] (1.The University of Aizu, 2.Ashikaga University, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4.Rikkyo University)

[PPS03-P10] **Dust particle evolution of a near-Earth object 252P/LINEAR from near-infrared polarimetric observations in 2016**

*Yuna G Kwon[1], Masateru Ishiguro[1], Jungmi Kwon[2], Daisuke Kuroda[3], Myungshin Im[1], Changsu Choi[1], Motohide Tamura[4], Takahiro Nagayama[5], Nobuyuki Kawai[6], Jun-ichi Watanabe[7] (1.Seoul National Univ., 2.ISAS/Japan Aerospace Exploration Agency, 3.Okayama Astrophysical Observatory, 4.The Univ. of Tokyo, 5.Kagoshima Univ., 6.Tokyo Institute of Technology, 7.National Astronomical Observatory of Japan)

[PPS03-P11] **Performance Evaluation of TRIPOL on the 61-cm Telescope at Seoul National University for Polarimetric Observations of Solar System Small Bodies**

*Sunho Jin[1], Masateru Ishiguro[1], Yuna G Kwon[1], Jooyeon Geem[1], Yoonsoo P. Bach[1], Jinguk Seo[1], Hiroshi Sasago[2], Shuji Sato[3] (1.Seoul National University, 2.Sasago Co.,Ltd, 3.Nagoya University)

[PPS03-P12] Smart Interface of HEAT: Hayabusa2 Exploration Assistant for TIR

*Kentaro Suko[1], Tatsuro Kobayashi[1], Hirohide Demura[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4] (1.The University of Aizu, 2.Ashikaga University, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4.Rikkyo University)

[PPS03-P13] Experimental Study on Collision Crater Formed on Bulge Geography

*Yusaku Yokota[1], Yuya Yamamoto[2], Minami Yasui[2], Masahiko Arakawa[2] (1.Faculty of Science, Kobe University, 2.Graduate School of Science, Kobe University)

[PPS03-P14] Initial analysis plan of soluble organic compounds for the Hayabusa2 sample from asteroid Ryugu

*Hiroshi Naraoka[1], Yoshinori Takano[2], Jason P. Dworkin[3], SOM Analysis Team (1.Department of Earth and Planetary Sciences, Research Center for Planetary Trace Organic Compounds, Kyushu University, 2.Japan Agency for Marine-Earth Science and Technology, 3.Astrochemistry Laboratory NASA Goddard Space Flight Center, Greenbelt, MD 20771 USA)

[PPS03-P15] Radar and optical simultaneous observations of faint meteors with MU radar and Tomo-e Gozen

*Ryou Ohsawa[1], Akira Hirota[2], Shinsuke Abe[2], Daniel Kastinen[3], Kero Johan[3], yasunori Fujiwara[4], Takuji Nakamura[5], Shigeyuki Sako[1], Yuto Kojima[1], Jun-ichi Watanabe[6] (1.Institute of Astronomy, Graduate School of Science, The University of Tokyo, 2.Department of Aerospace Engineering, College of Science & Technology, Nihon University, 3.Swedish Institute of Space Physics, 4.SOKENDAI (The Graduate University for Advanced Studies), 5.National Institute of Polar Research, 6.National Astronomical Observatory of Japan)

[PPS03-P16] Global distribution and spectral characteristics of bright spots on asteroid Ryugu

*Masanori Suemitsu[1], Tomokatsu Morota[1], Rie Honda[2], Singo Kameda[15], Eri Tatsumi[3], Manabu Yamada[4], Naoya Sakatani[5], Toru Kouyama[6], Yokota Yasuhiro[7], Yuichiro Cho[8], Hidehiko Suzuki[9], Masahiko Hayakawa[10], Moe Matsuoka[10], Chikatoshi Honda[11], Tatsuhiro Michikami[12], Kazuo Yoshioka[13], Kazunori Ogawa[14], Hirotaka Sawada[5], Seiji Sugita[3] (1.Graduate School of Environmental Studies, Nagoya University, 2.Department of Science and Technology, System of Natural Science, Kochi Unicversity, 3.Graduate School of Earth and Planetary Science, Tokyo Unicversity, 4.Planetary Exploration Reserch Center, Chiba Institute of Technology, 5.Institute of Space and Astoronautical Science, Japan Aerospace Exploration Agency, 6.National Institute of Advanced Industrial Science and Technology, 7.Kochi University, 8.Department of Earth and Planetary Science, Tokyo University, 9.Depertment of physics, Meiji University , 10.Department of Solar System Science, Institute of Space and Astoronautical Science, Japan Aerospace Exploration Agency, 11.Aizu University, 12.Faculty of Engineering, Kindai University, 13.Graduate School of frontier Science, Tokyo University, 14.Kobe University, 15.Rikkyo University)

[PPS03-P17] Polarimetry of (155140) 2005 UD: the Dynamical Association with (3200) Phaethon

*Masateru Ishiguro[1], Jooyeon Geem[1], Hiroyuki Naito[2], Yoonsoo P. Bach[1], Daisuke Kuroda[3], Tatsuharu Ono[4], Seiko Takagi[4], Mitsuteru Sato[4], Kiyoshi Kuramoto[4], Tomohiko Sekiguchi[5], Masataka Imai[6], Makoto Watanabe[7], Katsuhito Ohtsuka[8], Sunao Hasegawa[9], Takashi Ito[10], Fumi Yoshida[11], Tomoko Arai[11] (1.Department of Physics and Astronomy, Seoul National University, 2.Nayoro Observatory, 3.Okayama Observatory, Kyoto University, 4.Department of Cosmosciences, Graduate School of Science, Hokkaido University, 5.Hokkaido University of Education, 6.National Institute of Advanced Industrial Science and Technology, 7.Department of Applied Physics, Okayama University of Science, 8.Tokyo Meteor Network, 9.Japan Aerospace Exploration Agency, 10.National Astronomical Observatory of Japan, 11.Planetary Exploration Research Center, Chiba Institute of Technology)

[PPS03-P18] **Follow-up observations for AKARI/IRC near-infrared asteroid spectroscopic survey (AcuA-spec)**

*Sunao Hasegawa[1], Daisuke KURODA[2], Kenshi YANAGISAWA[3], Fumihiko Usui[4] (1.Japan Aerospace Exploration Agency, 2.Kyoto University, 3.National Astronomical Observatory of Japan, 4.Kobe University)

[PPS03-P19] Amino acids on witness coupons collected from the ISAS/JAXA curation facility for the assessment and quality control of the Hayabusa2 sampling procedure

*Haruna Sugahara[1,2], Yoshinori Takano[1], Yuzuru Karouji[3], Kazuya Kumagai[4], Toru Yada[3], Naohiko Ohkouchi[1], Masanao Abe[3], Hayabusa2 project team (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Institut de Chimie de Nice, Universite Cote dAzur, 3.Japan Aerospace Exploration Agency (JAXA), 4.Marine Works Japan Ltd.)

[PPS03-P20] Hayabusa2 orbit determination using c5++ software

*Keiko Yamamoto[1], Toshimichi Otsubo[2], Koji Matsumoto[1], Hirotomo Noda[1], Noriyuki Namiki[1], Hiroki Senshu[3], Takahide Mizuno[4], Naoko Ogawa[4], Go Ono[4], Yuya Mimasu[4], Kent Yoshikawa[4], Tadateru Takahashi[4], Yuto Takei[4], Atsushi Fujii[4], Fuyuto Terui[4], Takanao Saiki[4], Satoru Nakazawa[4], Makoto Yoshikawa[4], Yuichi Tsuda[4] (1.National Astronomical Observatory of Japan, 2.Hitotsubashi University, 3.Chiba Institute of Technology, 4.Japan Aerospace Exploration Agency)

[PPS03-P21] **Landing Site Selection for Hayabusa2: Scientific Evaluation of the Candidate Sites on Asteroid (162173) Ryugu**

*Hikaru Yabuta[1], Sei-ichiro WATANABE[2], Tomoki Nakamura[3], Naru Hirata[4], Seiji Sugita[5], Tatsuaki Okada[6], Kohei Kitazato[4], Yoshiaki Ishihara[7], Tomokatsu Morota[2], Naoya Sakatani[6], Koji Matsumoto[8], Koji Wada[9], Shogo Tachibana[5], Mutsumi Komatsu[10], ERI TATSUMI[5], Moe Matsuoka[6], Chikatoshi Honda[4], Takahiro Hiroi[11], Hiroki Senshu[9], Rie Honda[12], Yasuhiro Yokota[6], Rina Noguchi[6], Yuri Shimaki[6], Deborah Lorin Domingue[13], Lucille Le Corre[13], Antonella Barucci[14], Ernest Palomba[15], Shota Kikuchi[6], Akira Miura[6], Tomohiro Yamaguchi[6], Yukio Yamamoto[6], Takanao Saiki[6], Satoshi Tanaka[6], Makoto Yoshikawa[6], Yuichi Tsuda[6] (1.Hiroshima University, Department of Earth and Planetary Systems Science, 2.Nagoya University, 3.Tohoku University, 4.University of Aizu, 5.The University of Tokyo, 6.ISAS/JAXA, 7.NIES, 8.NAOJ, 9.Chiba Institute of Technology, Planetary Exploration Research Center (PERC), 10.Sokendai, 11.Brown University, 12.Kochi University, 13.Planetary Science Institute, USA, 14.Observatoire Paris-Site de Meudon, LESIA, France, 15.INAF-IAPS, Italy.)

[PPS03-P22] Visible Photometric, Spectroscopic and Polarimetric observations of an inactive comet, P/2016 BA14 with the 1.6m Pirka Telescope

*Ryo Yamagata[1], Tomohiko Sekiguchi[1], Ryo Okazaki[1], Kazuya Doi[1], Daisuke Kuroda[2], Masateru Ishiguro[3], Hiroyuki Naito[4] (1.Hokkaido University of Education, 2.Kyoto University, 3.Seoul National University, 4.Nayoro Observatory)

[PPS03-P23] **Polycyclic aromatic hydrocarbons and aliphatic hydrocarbons in Jbilet Winselwan carbonaceous chondrite : Attempt to evaluate the thermal metamorphism degree on the parent body**

Hiroki Kato[1], *Hikaru Yabuta[1] (1.Hiroshima University, Department of Earth and Planetary Systems Science)

[PPS03-P24] Disk-Resolved Photometry Analysis of the Asteroid Ryugu Images Obtained by Hayabusa2 Visible Camera ONC

*yokota yasuhiro[1,2], Rie Honda[1], ERI TATSUMI[3], Deborah Domingue[4], Stefanus E. Schroeder[5], Moe Matsuoka[2], Seiji Sugita[3], Tomokatsu Morota[6], Shingo Kameda[7], Toru Kouyama[8], Hidehiko Suzuki[9], Manabu Yamada[10], Naoya Sakatani[2], Chikatoshi Honda[11], Masahiko Hayakawa[2], Kazuo Yoshioka[3], Yuichiro Cho[3], Hirotaka Sawada[2] (1.Kochi University, 2.ISAS/JAXA, 3.Univ. of Tokyo, 4.Planetary Science Institute, 5.DLR, 6.Nagoya Univ., 7.Rikkyo Univ., 8.AIST, 9.Meiji Univ., 10.Chiba Institute od Technology, 11.Aizu Univ.)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory)

[PPS03-P01] Impact experiments on low strength coarse-grained regolith simulating surface materials on asteroid Ryugu

*Yuya Yamamoto[1], Masahiko Arakawa[1], Minami Yasui[1], Sunao Hasegawa[2], Ryo Sugimura[1] (1.Graduate School of Science, Kobe University, 2.ISAS, JAXA)

[PPS03-P02] Reflectance estimation of asteroid Ryugu using MASCOT

*Marika Ishida[1], Koto Amano[1], Keiichi Moroi[1], ERI TATSUMI[2], Tra-Mi Ho[10], Shingo Kameda[1], Seiji Sugita[2], Rie Honda[3], Tomokatsu Morota[4], yokota yasuhiro[5], Toru Kouyama[6], Hidehiko Suzuki[7], Manabu Yamada[8], Naoya Sakatani[5], Chikatoshi Honda[9], Masahiko Hayakawa[5], Kazuo Yoshioka[2], Moe Matsuoka[5], Yuichiro Cho[2], Hirotaka Sawada[5] (1.Rikkyo Univ., 2.Univ. of Tokyo, 3.Kochi Univ., 4.Nagoya Univ., 5.JAXA/ISAS, 6.AIST, 7.Meiji Univ., 8.Chiba Inst. Tech, 9.Univ. of Aizu, 10.DLR)

[PPS03-P03] Flyby observation of Asteroid (3200) Phaethon by DESTINY$^+$ onboard cameras

*Ko Ishibashi[1], Shingo Kameda[2], Masato Kagitani[3], Peng Hong[1], Manabu Yamada[1], Osamu Okudaira[1], Tomoko Arai[1], Fumi Yoshida[1], Shunsuke Sato[4], Takahiro Ishimaru[4], Takaya Okamoto[4], Takahiro Iwata[4], Tatsuaki Okada[4], Takeshi Takashima[4] (1.Chiba Institute of Technology, 2.Rikkyo University, 3.Tohoku Universtiy, 4.Japan Aerospace Exploration Agency)

[PPS03-P04] Polarimetric Study of Asteroids in Comet-Like Orbits (ACOs)

*Jooyeon Geem[1], Masateru Ishiguro[1], Yoonsoo P. Bach[1], Daisuke Kuroda[2], Hiroyuki Naito[3], Hidekazu Hanayama[4], yoonyoung kim[10], Yuna G. Kwon[1], Sunho Jin[1], Tomohiko Sekiguchi[5], Ryo Okazaki[5], Jeremie J. Vaubaillon[6], Masataka Imai[7], Tatsuharu Oono[8], Yuki Futamuts[8], Seiko Takagi[8], Mitsuteru Sato[8], Kiyoshi Kuramoto[8], Makoto Watanabe[9] (1.Astronomy program, Dept of Physics and Astronomy, Seoul National University, 2.Okayama Observatory, Kyoto University, 3.Nayoro Observatory, 4.Ishigakijima Astronomical Observatory, National Astronomical Observatory of Japan, 5.Hokkaido University of Education, 6.Observatoire de Paris, I.M.C.C.E., 7.National Institute of Advanced Industrial Science and Technology, 8.Department of Cosmosciences, Graduate School of Science, Hokkaido University, 9.Department of Applied Physics, Okayama University of Science, 10.Max Planck Institute for Solar System Research)

[PPS03-P05] Dynamical lifetime of the Oort Cloud new comets under planetary perturbation

*Ito Takashi[1], Arika Higuchi[1] (1.National Astronomical Observatory of Japan)

[PPS03-P06] Thermal Infrared Imaging of C-type Asteroid 162173 Ryugu with Porous Surfaces

*Tatsuaki Okada[1,2], Tetsuya Fukuhara[3], Satoshi Tanaka[1], Makoto Taguchi[3], Takehiko Arai[4], Naoya Sakatani[1], Yuri Shimaki[1], Hiroki Senshu[5], Yoshiko Ogawa[6], Hirohide Demura[6], Kentaro Suko[6], Kohei Kitazato[6], Toru Kouyama[7], Tomohiko Sekiguchi[8], Jun Takita[9], Sunao Hasegawa[1], Tsuneo Matsunaga[10], Takehiko Wada[1], Takeshi Imamura[2], Jorn Helbert[11], Thomas G. Mueller[12], Axel Hagermann[13], Jens Biele[11], Matthias Grott[11], Maximiliam Hamm[11], Marco Delbo[14], Yukio Yamamoto[1], Naru Hirata[6], Naoyuki Hirata[15], Fuyuto Terui[1], Takanao Saiki[1], Satoru Nakazawa[1], Makoto Yoshikawa[1], Sei-ichiro WATANABE[1,16], Yuichi Tuda[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.University of Tokyo, 3.Rikkyo University, 4.Ashikaga University, 5.Chiba Institute of Technology, 6.University of Aizu, 7.National Institute of Advanced Industrial Science and Technology, 8.Hokkaido University of Education, 9.Hokkaido Kitami-Hokuto High School, 10.National Institute for Environmental Studies, 11.German Aerospace Center, 12.Max-Planck Institute for Extraterrestrial Physics, 13.University of Stirling, 14.Observatoire de la Côte d'Azur, 15.Kobe University, 16.Nagoya University)

[PPS03-P07] Data Release of Asteroid 162173 Ryugu by Observation of Thermal Infrared Imager onboard Hayabusa2

*Takehiko Arai[1], Hirohide Demura[2], Toru Kouyama[7], Naoya Sakatani[3], Kentaro Suko[2], Yuri Shimaki[3], Hiroki Senshu[5], Tomohiko Sekiguchi[6], Yoshiko Ogawa[2], Sunao Hasegawa[3], Takehiko Wada[3], Takeshi Imamura[10], Tsuneo Matsunaga[9], Jun Takita[8], Kohei Kitazato[2], Makoto Taguchi[4], Tetsuya Fukuhara[4], Satoshi Tanaka[3], Tatsuaki Okada[3] (1.Ashikaga University, 2.The University of Aizu, 3.Japan Aerospace Exploration Agency (JAXA), 4.Rikkyo University,

5.Chiba Institute of Technology, 6.Hokkaido University of Education, 7.National Institute of Advanced Industrial Science and Technology (AIST), 8.Hokkaido Kitami Hokuto High School, 9.National Institute for Environmental Studies (NIES), 10.The University of Tokyo)

[PPS03-P08] Multi-mission capability of HARMONICS

*Shintaro Tsunoda[1], Hirohide Demura[1], Naru Hirata[1] (1.The University of Aizu)

[PPS03-P09] New interface of verification for calibration and conversion in HEAT : Hayabusa2 Exploration Assistant for TIR

*Tatsuro Kobayashi[1], Kentaro Suko[1], Hirohide Demura[1], Yoshiko Ogawa[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4] (1.The University of Aizu, 2.Ashikaga University, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4.Rikkyo University)

[PPS03-P10] **Dust particle evolution of a near-Earth object 252P/LINEAR from near-infrared polarimetric observations in 2016**

*Yuna G Kwon[1], Masateru Ishiguro[1], Jungmi Kwon[2], Daisuke Kuroda[3], Myungshin Im[1], Changsu Choi[1], Motohide Tamura[4], Takahiro Nagayama[5], Nobuyuki Kawai[6], Jun-ichi Watanabe[7] (1.Seoul National Univ., 2.ISAS/Japan Aerospace Exploration Agency, 3.Okayama Astrophysical Observatory, 4.The Univ. of Tokyo, 5.Kagoshima Univ., 6.Tokyo Institute of Technology, 7.National Astronomical Observatory of Japan)

[PPS03-P11] **Performance Evaluation of TRIPOL on the 61-cm Telescope at Seoul National University for Polarimetric Observations of Solar System Small Bodies**

*Sunho Jin[1], Masateru Ishiguro[1], Yuna G Kwon[1], Jooyeon Geem[1], Yoonsoo P. Bach[1], Jinguk Seo[1], Hiroshi Sasago[2], Shuji Sato[3] (1.Seoul National University, 2.Sasago Co.,Ltd, 3.Nagoya University)

[PPS03-P12] Smart Interface of HEAT: Hayabusa2 Exploration Assistant for TIR

*Kentaro Suko[1], Tatsuro Kobayashi[1], Hirohide Demura[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4] (1.The University of Aizu, 2.Ashikaga University, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4.Rikkyo University)

[PPS03-P13] Experimental Study on Collision Crater Formed on Bulge Geography

*Yusaku Yokota[1], Yuya Yamamoto[2], Minami Yasui[2], Masahiko Arakawa[2] (1.Faculty of Science, Kobe University, 2.Graduate School of Science, Kobe University)

[PPS03-P14] Initial analysis plan of soluble organic compounds for the Hayabusa2 sample from asteroid Ryugu

*Hiroshi Naraoka[1], Yoshinori Takano[2], Jason P. Dworkin[3], SOM Analysis Team (1.Department of Earth and Planetary Sciences, Research Center for Planetary Trace Organic Compounds, Kyushu University, 2.Japan Agency for Marine-Earth Science and Technology, 3.Astrochemistry Laboratory NASA Goddard Space Flight Center, Greenbelt, MD 20771 USA)

[PPS03-P15] Radar and optical simultaneous observations of faint meteors with MU radar and Tomo-e Gozen

*Ryou Ohsawa[1], Akira Hirota[2], Shinsuke Abe[2], Daniel Kastinen[3], Kero Johan[3], yasunori Fujiwara[4], Takuji Nakamura[5], Shigeyuki Sako[1], Yuto Kojima[1], Jun-ichi Watanabe[6] (1.Institute of Astronomy, Graduate School of Science, The University of Tokyo, 2.Department of Aerospace Engineering, College of Science & Technology, Nihon University, 3.Swedish Institute of Space Physics, 4.SOKENDAI (The Graduate University for Advanced Studies), 5.National Institute of Polar Research, 6.National Astronomical Observatory of Japan)

[PPS03-P16] Global distribution and spectral characteristics of bright spots on asteroid Ryugu

*Masanori Suemitsu[1], Tomokatsu Morota[1], Rie Honda[2], Singo Kameda[15], Eri Tatsumi[3], Manabu Yamada[4], Naoya Sakatani[5], Toru Kouyama[6], Yokota Yasuhiro[7], Yuichiro Cho[8], Hidehiko Suzuki[9], Masahiko Hayakawa[10], Moe Matsuoka[10], Chikatoshi Honda[11], Tatsuhiro Michikami[12], Kazuo Yoshioka[13], Kazunori Ogawa[14], Hirotaka Sawada[5], Seiji Sugita[3] (1.Graduate School of Environmental Studies, Nagoya University, 2.Department of Science and Technology, System of Natural Science, Kochi Unicversity, 3.Graduate School of Earth and Planetary Science, Tokyo Unicversity, 4.Planetary Exploration Reserch Center, Chiba Institute of Technology, 5.Institute of Space and Astoronautical Science, Japan Aerospace Exploration Agency, 6.National Institute of Advanced Industrial Science and Technology, 7.Kochi University, 8.Department of Earth and Planetary Science, Tokyo University, 9.Depertment of physics, Meiji University , 10.Department of Solar System Science, Institute of Space and Astoronautical Science, Japan Aerospace Exploration Agency, 11.Aizu University, 12.Faculty of Engineering, Kindai University, 13.Graduate School of frontier Science, Tokyo University, 14.Kobe University, 15.Rikkyo University)

[PPS03-P17] Polarimetry of (155140) 2005 UD: the Dynamical Association with (3200) Phaethon

*Masateru Ishiguro[1], Jooyeon Geem[1], Hiroyuki Naito[2], Yoonsoo P. Bach[1], Daisuke Kuroda[3], Tatsuharu Ono[4], Seiko Takagi[4], Mitsuteru Sato[4], Kiyoshi Kuramoto[4], Tomohiko Sekiguchi[5], Masataka Imai[6], Makoto Watanabe[7], Katsuhito Ohtsuka[8], Sunao Hasegawa[9], Takashi Ito[10], Fumi Yoshida[11], Tomoko Arai[11] (1.Department of Physics and Astronomy, Seoul National University, 2.Nayoro Observatory, 3.Okayama Observatory, Kyoto University, 4.Department of Cosmosciences, Graduate School of Science, Hokkaido University, 5.Hokkaido University of Education, 6.National Institute of Advanced Industrial Science and Technology, 7.Department of Applied Physics, Okayama University of Science, 8.Tokyo Meteor Network, 9.Japan Aerospace Exploration Agency, 10.National Astronomical Observatory of Japan, 11.Planetary Exploration Research Center, Chiba Institute of Technology)

[PPS03-P18] **Follow-up observations for AKARI/IRC near-infrared asteroid spectroscopic survey (AcuA-spec)**

*Sunao Hasegawa[1], Daisuke KURODA[2], Kenshi YANAGISAWA[3], Fumihiko Usui[4] (1.Japan Aerospace Exploration Agency, 2.Kyoto University, 3.National Astronomical Observatory of Japan, 4.Kobe University)

[PPS03-P19] Amino acids on witness coupons collected from the ISAS/JAXA curation facility for the assessment and quality control of the Hayabusa2 sampling procedure

*Haruna Sugahara[1,2], Yoshinori Takano[1], Yuzuru Karouji[3], Kazuya Kumagai[4], Toru Yada[3], Naohiko Ohkouchi[1], Masanao Abe[3], Hayabusa2 project team (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Institut de Chimie de Nice, Universite Cote dAzur, 3.Japan Aerospace Exploration Agency (JAXA), 4.Marine Works Japan Ltd.)

[PPS03-P20] Hayabusa2 orbit determination using c5++ software

*Keiko Yamamoto[1], Toshimichi Otsubo[2], Koji Matsumoto[1], Hirotomo Noda[1], Noriyuki Namiki[1], Hiroki Senshu[3], Takahide Mizuno[4], Naoko Ogawa[4], Go Ono[4], Yuya Mimasu[4], Kent Yoshikawa[4], Tadateru Takahashi[4], Yuto Takei[4], Atsushi Fujii[4], Fuyuto Terui[4], Takanao Saiki[4], Satoru Nakazawa[4], Makoto Yoshikawa[4], Yuichi Tsuda[4] (1.National Astronomical Observatory of Japan, 2.Hitotsubashi University, 3.Chiba Institute of Technology, 4.Japan Aerospace Exploration Agency)

[PPS03-P21] **Landing Site Selection for Hayabusa2: Scientific Evaluation of the Candidate Sites on Asteroid (162173) Ryugu**

*Hikaru Yabuta[1], Sei-ichiro WATANABE[2], Tomoki Nakamura[3], Naru Hirata[4], Seiji Sugita[5], Tatsuaki Okada[6], Kohei Kitazato[4], Yoshiaki Ishihara[7], Tomokatsu Morota[2], Naoya Sakatani[6], Koji Matsumoto[8], Koji Wada[9], Shogo Tachibana[5], Mutsumi Komatsu[10], ERI TATSUMI[5], Moe Matsuoka[6], Chikatoshi Honda[4], Takahiro Hiroi[11], Hiroki Senshu[9], Rie Honda[12], Yasuhiro Yokota[6], Rina Noguchi[6], Yuri Shimaki[6], Deborah Lorin Domingue[13], Lucille Le Corre[13], Antonella Barucci[14], Ernest Palomba[15], Shota Kikuchi[6], Akira Miura[6], Tomohiro Yamaguchi[6], Yukio Yamamoto[6], Takanao Saiki[6], Satoshi Tanaka[6], Makoto Yoshikawa[6], Yuichi Tsuda[6] (1.Hiroshima University, Department of Earth and Planetary Systems Science, 2.Nagoya University, 3.Tohoku University, 4.University of Aizu, 5.The University of Tokyo, 6.ISAS/JAXA, 7.NIES, 8.NAOJ, 9.Chiba Institute of Technology, Planetary Exploration Research Center (PERC), 10.Sokendai, 11.Brown University, 12.Kochi University, 13.Planetary Science Institute, USA, 14.Observatoire Paris-Site de Meudon, LESIA, France, 15.INAF-IAPS, Italy.)

[PPS03-P22] Visible Photometric, Spectroscopic and Polarimetric observations of an inactive comet, P/2016 BA14 with the 1.6m Pirka Telescope

*Ryo Yamagata[1], Tomohiko Sekiguchi[1], Ryo Okazaki[1], Kazuya Doi[1], Daisuke Kuroda[2], Masateru Ishiguro[3], Hiroyuki Naito[4] (1.Hokkaido University of Education, 2.Kyoto University, 3.Seoul National University, 4.Nayoro Observatory)

[PPS03-P23] **Polycyclic aromatic hydrocarbons and aliphatic hydrocarbons in Jbilet Winselwan carbonaceous chondrite : Attempt to evaluate the thermal metamorphism degree on the parent body**

Hiroki Kato[1], *Hikaru Yabuta[1] (1.Hiroshima University, Department of Earth and Planetary Systems Science)

[PPS03-P24] Disk-Resolved Photometry Analysis of the Asteroid Ryugu Images Obtained by Hayabusa2 Visible Camera ONC

*yokota yasuhiro[1,2], Rie Honda[1], ERI TATSUMI[3], Deborah Domingue[4], Stefanus E. Schroeder[5], Moe Matsuoka[2], Seiji Sugita[3], Tomokatsu Morota[6], Shingo Kameda[7], Toru Kouyama[8], Hidehiko Suzuki[9], Manabu Yamada[10], Naoya Sakatani[2], Chikatoshi Honda[11], Masahiko Hayakawa[2], Kazuo Yoshioka[3], Yuichiro Cho[3], Hirotaka Sawada[2] (1.Kochi University, 2.ISAS/JAXA, 3.Univ. of Tokyo, 4.Planetary Science Institute, 5.DLR, 6.Nagoya Univ., 7.Rikkyo Univ., 8.AIST, 9.Meiji Univ., 10.Chiba Institute od Technology, 11.Aizu Univ.)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University)

[PEM09-P01] Local-time Variabilities of SABER CO_2 in the Mesosphere and Lower Thermosphere Region

*Cornelius Csar Jude Salinas[1], Loren Chang[1], Danie Liang[2], Jia Yue[3], Liying Qian[4], Quan Gan[5], James Russel III[3], Martin G Mlynczak[6] (1.Institute of Space Science, National Central University, 2.Institute of Earth Science, Academia Sinica, 3.Department of Atmospheric Sciences, Hampton University, 4.High Altitude Observatory, National Center for Atmospheric Research, 5.Department of Physics and Astronomy, Clemson University, 6.NASA Langley Research Center)

[PEM09-P02] Enhanced dynamo electric field as a possible cause of ionosphere disturbance before Large Earthquake

*Koichiro Oyama[1,2,3] (1.Institute of Plasma and Space Sciences,National Cheng Kung Univ., Taiwan, 2.International Ceneter for Space Weather Sudy and Education, Kyushu Univ.,, 3.CoLtd. Asia Space Environment Research Consortium, Japan)

[PEM09-P03] Morphology of E1 and E2 Kelvin waves from ECMWF reanalysis

*Chen-Jeih Pan[1], Wei-Sheng Chen[1], Uma Das[2] (1.Institute of Space Science, National Central University, 2.Department of Physics, Indian Institute of Information Technology, Kalyani, India)

[PEM09-P04] Impact of strong ENSO on TEC activity disturbed by ultra-fast Kelvin waves

*Wei-Sheng Chen[1], C.J. Pan[1], Uma Das[2], Chian-Chiau Lin[3] (1.Institute of Space Science, National Central University, Taiwan, 2.Department of Physics, Indian Institute of Information Technology, Kalyani, India, 3.Environmental Research and Information Center, Chang Jung Christian University, Taiwan)

[PEM09-P05] Observation and simulation of propagation of coseismic infrasound to the ionosphere

*Jaroslav Chum[1] (1.Institute of Atmospheric Physics of the Czech Academy of Sciences)

[PEM09-P06] Solar wind influence on tropical cyclones mediated by atmospheric gravity waves

*Paul Prikryl[1,2], Iurii Cherniak[3], Irina Zakharenkova[4,5], James M. Weygand[6], Bharat S. R. Kunduri[7] (1.Physics Department, University of New Brunswick, Fredericton, NB, Canada, 2.Geomagnetic Laboratory, Natural Resources Canada, Ottawa, ON, Canada, 3.COSMIC Program Office, University Corporation for Atmospheric Research, Boulder, CO, USA, 4.West Department of IZMIRAN, Kaliningrad, Russia, 5.University of Warmia and Mazury in Olsztyn, Poland, 6.Earth Planetary and Space Sciences, University of California, Los Angeles, CA, USA, 7.Bradley Dept. of Electrical and Computer Engineering, Virginia Tech, Blacksburg, VA, USA)

[PEM09-P07] VIPIR ionospheric observations in Japan

*Takuya Tsugawa[1], Hideo Maeno[1], Michi Nishioka[1], Takumi Kondo[1], Mamoru Ishii[1] (1.National Institute of Information and Communications Technology)

[PEM09-P08] Simulation Results and Performance Analysis of Phase Velocity Spectral Analysis Software (M-Transform) for Airglow Imaging Data

*Septi Perwitasari[1], Takuji Nakamura[2], Masaru Kogure[2], Yoshihiro Tomikawa[2], Mitsumu K. Ejiri[2] (1.LAPAN, 2.NIPR)

[PEM09-P09] Comparisons of Co-incident Ionospheric Plasma Observations Between FORMOSAT-5/AIP and Millstone Hill Incoherent Scatter Radar

*Yi-Wun Chen[1], Chi-Kuang Chao[1] (1.Graduate Institute of Space Science, National Central University, Taiwan)

[PEM09-P10] Sub-ionospheric effects of volcano eruptions using VLF/LF standard radio waves

*Kei Maruyama[1], Hiroyo Ohya[1], Fuminori Tsuchiya[2], Kenro Nozaki[5], Kozo Yamashita[3], Yukihiro Takahashi[4], Hiroyuki Nakata[1], Toshiaki Takano[1] (1.Chiba University, 2.Tohoku University, 3.Ashikaga University, 4.Hokkaido University, 5.National Institute of Information and Communications Technology)

[PEM09-P11] Observations of ionospheric and mesospheric wave structures by a low-cost airglow imaging system

*Keisuke Hosokawa[1], Nanami Kusuyama[1], Yuta Hozumi[1], Kohei Takami[1], Susumu Saito[2], Yasunobu Ogawa[3], Mamoru Ishii[4], Yuichi Otsuka[5], Takuya Tsugawa[4] (1.University of Electro-Communications, 2.ENRI, 3.NIPR, 4.NICT, 5.ISEE, Nagoya University)

[PEM09-P12] Analysis of characteristics of ionospheric parameters, Sq index and neutral winds over Taiwan

*Yu-Jung Chuo[1] (1.Department of Information Technology, Ling Tung University)

[PEM09-P13] Statistical study on daytime Es observed by ground-ionosonde and RO-COSMIC in magnetic Equator region in 2010

*Zheng Wang [1,2], Huixin Liu[1] (1.Department of Earth and Planetary Sciences, School of Science, Kyushu University, Japan. , 2.National Space Science Center, Chinese Academy of Sciences, China.)

[PEM09-P14] The statistical study of the growth rates of Medium-Scale Traveling Ionospheric Disturbances observed with GPS-TEC

*Takafumi Ikeda[1], Akinori Saito[1], Takuya Tsugawa[2], Hiroyuki Shinagawa[2] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.National Institutes of Information and Communications Technology)

[PEM09-P15] Comparison of Gravity Wave Activity in the Mesosphere Observed by OH Airglow Imagers and MF Radars over the Antarctic (Syowa & Davis).

*Masaru Kogure[1], Takuji Nakamura[1,2], Yoshihiro Tomikawa[1,2], Mitsumu K. Ejiri[1,2], Takanori Nishiyama[2,1], Masaki Tsutsumi[1,2], Michael J. Taylor[3], Yucheng Zhao[3], P.-Dominique Pautet[3], Damian Murphy[4] (1.National Institute of Polar Research, 2.Department of Polar Science, Sokendai, 3.Physics Department, Utah State University, 4.Australian Antarctic Division)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Patrick Espy(Norwegian University of Science and Technology), Astrid Maute(National Center for Atmospheric Research, US)

1:45 PM - 2:05 PM JST | 4:45 AM - 5:05 AM UTC

[PEM09-01] **Vertical Coupling from the Atmosphere to Geospace at Arrival Heights in Antarctica**

★Invited Papers

*Xinzhao Chu[1] (1.University of Colorado Boulder)

2:05 PM - 2:20 PM JST | 5:05 AM - 5:20 AM UTC

[PEM09-02] Vertical structure of terdiurnal tides in the Antarctic MLT region: 15 years observation over Syowa

*Huixin Liu[1], Masaki Tsutsumi[2], Hanli Liu[3] (1.Earth and Planetary Science Division, Kyushu University, Japan, 2.National Institute for Polar Research, Japan, 3.National Center for Atmospheric Research, US)

2:20 PM - 2:35 PM JST | 5:20 AM - 5:35 AM UTC

[PEM09-03] **3D Investigation of gravity waves propagation by Continuous Doppler sounding**

*Jaroslav Chum[1], Katerina Podolska[1] (1.Institute of Atmospheric Physics of the Czech Academy of Sciences)

2:35 PM - 2:55 PM JST | 5:35 AM - 5:55 AM UTC

[PEM09-04] **Observations of MLT dynamics using meteor radars and meteor radar networks**

★Invited Papers

*Gunter Stober[1], Vivien Matthias[2], Sven Wilhelm[1], Dimitry Pokhotelov[1], Alexander Kozlovsky[3], Evgenia Belova[4], Johan Kero[4], Chris Hall[5], Masaki Tsutsumi[6] (1.Leibniz Institute of Atmospheric Physics, 2.Potsdam Institute for Climate Impact Research, Earth System Analysis - Research Domain 1, Potsdam, Germany, 3.Sodankylä Geophysical Observatory, Sodankylä, FIN-99600, Finland, 4.Swedish Institute of Space Physics, Box 812, 98128 Kiruna, Sweden, 5.Tromsø Geophysical Observatory UiT-the Arctic University of Norway, Tromsø, Norway, 6.National Institute of Polar Research, Tokyo, Japan)

2:55 PM - 3:15 PM JST | 5:55 AM - 6:15 AM UTC

[PEM09-05] Ionospheric Variability Associated with the Quasi-6-day Planetary Wave

★Invited Papers

*Yosuke Yamazaki[1] (1.GFZ German Research Centre for Geosciences)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Yuichi Otsuka, Yosuke Yosuke Yamazaki(GFZ Potsdam, Germany)

3:30 PM - 3:50 PM JST | 6:30 AM - 6:50 AM UTC

[PEM09-06] Results of FORMOSAT-3/COSMIC to the most recent developments on FORMOSAT-7/COSMIC-2

★Invited Papers

*JANN-YENQ Liu[1] (1.Center for Astronautical Physics and Engineering; Graduate Institute of Space Science, National Central University, Taiwan)

3:50 PM - 4:05 PM JST | 6:50 AM - 7:05 AM UTC

[PEM09-07] A morphological study on the relationship between electron density fluctuations and magnetic fluctuations observed by low altitude satellites in low and middle latitudes

*Toshihiko Iyemori[1], Tadashi Aoyama[1], Yoshihiro Yokoyama[1] (1.Kyoto University)

4:05 PM - 4:25 PM JST | 7:05 AM - 7:25 AM UTC

[PEM09-08] Observations of the Thermosphere and Ionosphere by the NASA GOLD Mission

★Invited Papers

*Stanley C Solomon[1], Alan G. Burns[1], Richard W. Eastes[2], William E. McClintock[2] (1.National Center for Atmospheric Research, 2.University of Colorado)

4:25 PM - 4:40 PM JST | 7:25 AM - 7:40 AM UTC

[PEM09-09] Temporal and spatial evolutions of storm enhanced density in the mid- and low-latitude regions as seen in the variation of global total electron content

*Atsuki Shinbori[1], Takuya Sori[1], Yuichi Otsuka[1], Takuya Tsugawa[2], Michi Nishioka[2] (1.Institute for Space-Earth Environment Research (ISEE), Nagoya University, 2.National Institute of Information and Communications Technology (NICT))

4:40 PM - 4:55 PM JST | 7:40 AM - 7:55 AM UTC

[PEM09-10] **Tidal Forcing Effects on the Zonal Variation of Solstice Equatorial Plasma Bubbles**

*Loren Chang[1], Jude Salinas[1], Yi-Chung Chiu[1], Pei-yun Chiu[1], Charles Lin[2] (1.Institute of Space Science and Engineering, Center for Astronautical Physics and Engineering, National Central University, Taiwan, 2.Department of Earth Science, National Cheng Kung University, Taiwan)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University)

[PEM11-P01] Effects of Inclination/Rotation of Earth's Magnetic Axis on Magnetosphere Simulated by Global MHD Model

*Aoi Nakamizo[1] (1.Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology)

[PEM11-P02] Asymmetric deformation of the magnetosphere under low-density solar wind

*Masaki N Nishino[1,2], Yoshifumi Saito[2], Kazuo Shiokawa[1], Masaki Fujimoto[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.JAXA/ISAS)

[PEM11-P03] New perspectives on coupling processes in solar-terrestrial system obtained by comprehensive data analysis

*Yoshimasa Tanaka[1], Norio Umemura[2], Shuji Abe[3], Satoru UeNo[4], Masahito Nose[2], Yumi Nakagawa[5] (1.National Institute of Polar Research, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.International Center for Space Weather Science and Education, 4.Kwasan & Hida Observatories, School of Science, Kyoto University, 5.Ibaraki University)

[PEM11-P04] The interaction between the magnetosphere-ionosphere compound system and the magnetic field topology

*Shigeru Fujita[1], Takashi Tanaka[2], Masakazu Watanabe[2] (1.Meteorological College, Japan Meteorological Agency/ Nationa Institute of Polar Research, 2.Kyushu University)

[PEM11-P05] Effects of the dipole tilt and the interplanetary magnetic field Bx component on the dawn-dusk and interhemispheric asymmetries of the interchange convection cycle

*Masakazu Watanabe[1,2], Takashi Tanaka[2], Shigeru Fujita[3,4] (1.Graduate School of Science, Kyushu University, 2.International Center for Space Weather Science and Education, Kyushu University, 3.Meteorological College, 4.National Institute of Polar Research)

[PEM11-P06] Transient polar ionospheric convection response to negative dynamic pressure pulse

*Jianjun Liu[1] (1.Polar Research Institute of China)

[PEM11-P07] An active ionosphere: a new perspective of field line dipolarization

*Osuke Saka[1] (1.Office Geophysik)

[PEM11-P08] Toward the automatic identification of FLR signals in the SuperDARN data by using the gradient method

*Hideaki Kawano[1,2], Akira Sessai Yukimatu[3,4], Nozomu Nishitani[5], Yoshimasa Tanaka[3,4], Satoko Saita[6], Tomoaki Hori[5] (1.Dept. Earth Planet. Sci., Kyushu Univ., 2.ICSWSE, Kyushu University, 3.National Institute of Polar Research, 4.SOKENDAI, 5.ISEE, Nagoya University, 6.Kitakyushu College)

[PEM11-P09] A statistical study of Pi2 pulsations observed in the upper ionosphere using Swarm magnetic field data

*Park Jaehee[1], Khan-Hyuk Kim[1], Junga Hwang[2] (1.School of Space Research, Kyung Hee University, Gyeonggi, South Korea, 2.Korea Astronomy and Space Science Institute, Daejeon,South Korea)

[PEM11-P10] Study on the global distribution characteristics of Pc 1-2 geomagnetic pulsation with the 10Hz data of the MAGDAS system

*Taisei Kabasawa[1], Akimasa Yoshikawa[1], Teiji Uozumi[1], Akiko Fujimoto[1], Shuji Abe[1] (1.Kyushu University)

[PEM11-P11] In-situ Observations of Reconnection Separatrix Regions in the near-Earth Magnetotail

*Mizuho Araki[1], Masahiro Hoshino[1], Kunihiro Keika[1], Yoshifumi Saito[2] (1.Graduate School of Science, The University of Tokyo, 2.Institude of Space and Astronautical Science)

[PEM11-P12] Flow speed dependence of ion temperature, electron temperature, and their ratio in the near-Earth magnetotail reconnection region

*Kaori Watanabe[1], Masahiro Hoshino[1], Kunihiro Keika[1], Yoshifumi Saito[2], Naritoshi Kitamura[1] (1.Univ. of Tokyo, 2.ISAS/JAXA)

[PEM11-P13] **Examining Minimum Cyclotron Resonant Electron Energy of EMIC Waves with MMS**

*Si Liu[1] (1.Changsha University of Science and Technology)

[PEM11-P14] Small scale whistler mode waves near the magnetic field intensity minimum in the magnetosheath

*Naritoshi Kitamura[1], Takanobu Amano[1], Yoshiharu Omura[2], Satoko Nakamura[2], Chika Umegaki[1], Scott A Boardsen[3,4], Narges Ahmadi[5], Robert E Ergun[5], Olivier Le Contel[6], Per-Arne Lindqvist[7], Yoshifumi Saito[8], Shoichiro Yokota[9], Daniel J Gershman[3], Barbara L Giles[3], Thomas E Moore[3], William R Paterson[3], Craig J Pollock[10], Christopher T Russell[11], Robert J Strangeway[11], James L Burch[12] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Research Institute for Sustainable Humanosphere, Kyoto University, 3.NASA Goddard Space Flight Center, 4.University of Maryland, 5.Laboratory for Atmospheric and Space Physics, University of Colorado, 6.Laboratoire de Physique des Plasmas, UMR7648 CNRS/Ecole Polytechnique/UPMC/Université Paris-Sud/Observatoire de Paris, 7.Royal Institute of Technology, 8.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 9.Department of Earth and Space Science, Graduate School of Science, Osaka University, 10.Denali Scientific, 11.Institute of Geophysics and Planetary Physics, University of California, Los Angeles, 12.Southwest Research Institute)

[PEM11-P15] Spatial characteristics of the internal modulation of pulsating aurora: multi-point high-speed optical observations in Scandinavia

*Yuki Kawamura[1], Keisuke Hosokawa[1], Shin-ichiro Oyama[2,3], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Satoshi Kurita[2], Satoshi Ebukuro[1], Ryoichi Fujii[4] (1.Department of Communication Engineering and Informatics, University of Electro-Communications, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.National Institute of Polar Research, 4.Research Organization of Information and Systems)

[PEM11-P16] **Large-scale characteristics of pulsating aurora periodicities:multi-point high-speed optical observations in Scandinavia**

*Satoshi Ebukuro[1], Keisuke Hosokawa[1], Shin-ichiro Oyama[2,3,5], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Satoshi Kurita[2], Yuki Kawamura[1], Ryoichi Fujii[4] (1.Department of Communication Engineering and Informatics, University of Electro-Communications, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.National Institute of Polar Research, 4.Research Organization of Information and Systems, 5.University of Oulu)

[PEM11-P17] Variations of cosmic noise absorption (CNA) by energetic electron precipitation (EEP) and changes of the auroral morphology

*Miyamoto Taishiro[1], Shin-ichiro Oyama[1,4,5], Yasunobu Ogawa[2], Keisuke Hosokawa[3], Satoshi Kurita[1], Yoshizumi Miyoshi[1], Ryuho Kataoka[2], Hiroshi Miyaoka[2], Tero Raita[4] (1. Institute for Space-Earth Environmental Research,Nagoya University, 2.National Institute of Polar Research, 3.Department of Communication Engineering and Informatics, University of Electro-Communications, 4.Sodankylä Geophysical Observatory, University of Oulu, 5.Ionosphere Research Unit, University of Oulu)

[PEM11-P18] Spatiotemporal characteristics on the source region of flash aurora using ray tracing analysis

*Tomohiro Inoue[1], Mitsunori Ozaki[1], Yoshitaka Goto[1], Satoshi Yagitani[1], Yoshiya Kasahara[1], Kazuo Shiokawa[2], Yoshizumi Miyoshi[2], Ryuho Kataoka[3], Yusuke Ebihara[4] (1.Kanazawa University , 2.Nagoya University, 3.National Institute of Polar Research, 4.Kyoto University)

[PEM11-P19] Molecular ion supply mechanisms from the low-altitude ionosphere to magnetosphere observed by EISCAT and Arase(ERG)

*Masayoshi Takada[1], Kanako Seki[1], Yasunobu Ogawa[2], Kunihiro Keika[3], Satoshi Kasahara[4], Shoichiro Yokota[5], Tomoaki Hori[7], Kazushi Asamura[6], Yoshizumi Miyoshi[7] (1.Graduate School of Science, Tokyo University, 2.National Institute of Polar Research, 3.Department of Earth and Planetary Science, Graduate School of Science, Tokyo University, 4.The University of Tokyo, 5.Graduate School of Science, Osaka University, 6.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 7.Institute for Space-Earth Environmental Research, Nagoya University)

[PEM11-P20] Optical and radar observation of the dynamic auroral forms

*Yunosuke Nagafusa[1], Tima Sergienko[2], Satoshi Taguchi[1], Urban Braendstroem[2], Masatoshi Yamauchi[2] (1.Graduate School of Science, Kyoto University, 2.Swedish Institute of Space Physics, Kiruna)

[PEM11-P21] Observations of MF/HF auroral radio emissions at three ground-based stations

*Yuka Sato[1], Atsushi Kumamoto[2], Yuto Katoh[2], Akira Kadokura[3,4], Yasunobu Ogawa[3,4], Atsuki Shinbori[5] (1.Nippon Institute of Technology (NIT), 2.Graduate School of Science, Tohoku University, 3.National Institute of Polar Research (NIPR), 4.The Graduate University for Advanced Studies, 5.Institute for Space-Earth Environmental Research (ISEE), Nagoya University)

[PEM11-P22] **Ionospheric F-region Drift Measurements Derived from DPS-4D at Zhongshan Station, Antarctic**

*Xiangcai Chen[1] (1.Polar Research Institute of China)

[PEM11-P23] PARM-HEP Observation of Precipitating High Energy Electrons over Pulsating Aurora

*Taku Namekawa[1], Takefumi Mitani[2], Kazushi Asamura[2], Yoshifumi Saito[2] (1.Department of Earth and Planetary Science, Graduate school of Science, The University of Tokyo, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PEM11-P24] Development of the medium-energy electron detector with hemispherical field-of-view and the flight test in the PARM (Pulsating AuRora and Microburst) mission

*Shin Sugo[1], Oya Kawashima[1], Kazushi Asamura[2], Reiko Nomura[3], Yasunobu Ogawa[4], Keisuke Hosokawa[5], Yoshizumi Miyoshi[6], Takefumi Mitani[2], Taku Namekawa[1,2], Takeshi Sakanoi[7], Mizuki Fukizawa[7], Naoshi Yagi[7], Satoshi Kasahara[1] (1.The University of Tokyo, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.National Astronomical Observatory of Japan, 4.National Institute of Polar Research, 5.The University of Electro-Communications, 6.Institute for Space-Earth Environmental Research, Nagoya University, 7.Tohoku University)

[PEM11-P25] Auroral substorm onset in satellite-based global images and ground-based all-sky images

*Akimasa Ieda[1], Kirsti Kauristie[2], Yukitoshi Nishimura[3], Yukinaga Miyashita[4], Harald U Frey[5], Liisa Juusola[2], Daniel Whiter[6], Masahito Nose[7], Matthew O Fillingim[5], Farideh Honary[8], Neil C Rogers[8], Yoshizumi Miyoshi[1], Shinobu Machida[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Finnish Meteorological Institute, 3.Boston university, 4.Korea Astronomy and Space Science Institute, 5.University of California Berkeley, 6.University of Southampton, 7.Graduate School of Science, Kyoto University, 8.Lancaster University)

[PEM11-P26] Automatic Classification of Auroral images using optical flow feature

*Naoto Kashiwagi[1], Akiko Fujimoto[1], Terumasa Tokunaga[1], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Keisuke Hosokawa[4] (1.Kyushu Institute of Technology, 2.Nagoya University, 3.National Institute of Polar Research, 4.The University of Electro-Communications)

[PEM11-P27] Fine-scale visualization of aurora in a wide area using color digital camera images from the International Space Station

*Sota Nanjo[1], Yuta Hozumi[1], Keisuke Hosokawa[1] (1.The University of Electro-Communications)

[PEM11-P28] Geospace Imaging via the soft X-ray imager: GEO-X mission

*Yoshizumi Miyoshi[1], Yuichiro Ezoe[2], Satoshi Kasahara[3], Yosuke Matsumoto[4], Kumi Ishikawa[5], Ryuho Kataoka[6], Hiroki Ito[1], Daiki Ishi[2], Masaki Numazawa[2], Atsushi Yamazaki[5], Hiroshi Hasegawa[5], Masaki Fujimoto[5], Kazuhisa Mitsuda[5] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Tokyo Metropolitan University, 3.University of Tokyo, 4.Chiba University, 5.ISAS/JAXA, 6.NIPR)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University)

[PEM11-P01] Effects of Inclination/Rotation of Earth's Magnetic Axis on Magnetosphere Simulated by Global MHD Model

*Aoi Nakamizo[1] (1.Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology)

[PEM11-P02] Asymmetric deformation of the magnetosphere under low-density solar wind

*Masaki N Nishino[1,2], Yoshifumi Saito[2], Kazuo Shiokawa[1], Masaki Fujimoto[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.JAXA/ISAS)

[PEM11-P03] New perspectives on coupling processes in solar-terrestrial system obtained by comprehensive data analysis

*Yoshimasa Tanaka[1], Norio Umemura[2], Shuji Abe[3], Satoru UeNo[4], Masahito Nose[2], Yumi Nakagawa[5] (1.National Institute of Polar Research, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.International Center for Space Weather Science and Education, 4.Kwasan & Hida Observatories, School of Science, Kyoto University, 5.Ibaraki University)

[PEM11-P04] The interaction between the magnetosphere-ionosphere compound system and the magnetic field topology

*Shigeru Fujita[1], Takashi Tanaka[2], Masakazu Watanabe[2] (1.Meteorological College, Japan Meteorological Agency/ Nationa Institute of Polar Research, 2.Kyushu University)

[PEM11-P05] Effects of the dipole tilt and the interplanetary magnetic field Bx component on the dawn-dusk and interhemispheric asymmetries of the interchange convection cycle

*Masakazu Watanabe[1,2], Takashi Tanaka[2], Shigeru Fujita[3,4] (1.Graduate School of Science, Kyushu University, 2.International Center for Space Weather Science and Education, Kyushu University, 3.Meteorological College, 4.National Institute of Polar Research)

[PEM11-P06] Transient polar ionospheric convection response to negative dynamic pressure pulse

*Jianjun Liu[1] (1.Polar Research Institute of China)

[PEM11-P07] An active ionosphere: a new perspective of field line dipolarization

*Osuke Saka[1] (1.Office Geophysik)

[PEM11-P28] Geospace Imaging via the soft X-ray imager: GEO-X mission

*Yoshizumi Miyoshi[1], Yuichiro Ezoe[2], Satoshi Kasahara[3], Yosuke Matsumoto[4], Kumi Ishikawa[5], Ryuho Kataoka[6], Hiroki Ito[1], Daiki Ishi[2], Masaki Numazawa[2], Atsushi Yamazaki[5], Hiroshi Hasegawa[5], Masaki Fujimoto[5], Kazuhisa Mitsuda[5] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Tokyo Metropolitan University, 3.University of Tokyo, 4.Chiba University, 5.ISAS/JAXA, 6.NIPR)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Hiroshi Hasegawa(Institute of Space and Astronautical Science, JAXA)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PEM11-01] **A Case Study Based on Ground Observations of the Conjugate Ionospheric Response to Interplanetary Shock in Polar Regions**

*He Fang[1], Zejun HU[1], Hongqiao HU[1] (1.Polar Research Institute of China)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PEM11-02] **Effects of Solar Illumination on the Auroral Electrojet Intensity**

*Shinichi Ohtani[1], Jesper W Gjerloev[1] (1.The Johns Hopkins University Applied Physics Laboratory)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PEM11-03] Quasi-persistent multiple mesoscale field-aligned currents in the duskside auroral oval

*Yoshihiro Yokoyama[1], Satoshi Taguchi[1], Toshihiko Iyemori[2], Keisuke Hosokawa[3] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Kyoto University, 3.Department of Communication Engineering and Informatics, University of Electro-Communications)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PEM11-04] Generation of dispersive Alfvenic turbulence in magnetosphere-ionosphere feedback coupling

*Tomo-Hiko Watanabe[1], Masatoshi Kaneyama[1], Shinya Maeyama[1] (1.Graduate School of Science, Nagoya University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PEM11-05] Aspects of simulating magnetosphere-ionosphere coupling via field-aligned current

*Astrid I Maute[1], Arthur D Richmond[1], Gang Lu[1] (1.High Altitude Observatory, National Center for Atmospheric Research, Boulder CO, 80301, USA)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PEM11-06] **Revisiting the energy conversion process of Birkeland current generation**

*Akimasa Yoshikawa[1] (1.Department of Earth and Planetary Sciences, Kyushu University)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Shinji Saito(ISEE, Nagoya University), Yusuke Ebihara(RISH, Kyoto University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PEM13-11] Nonlinear Damping of Oblique Whistler Mode Waves Via Landau Resonance

*Yikai HSIEH[1], Yoshiharu Omura[1] (1.Reserach Institute for Sustainable Humanosphere, Kyoto University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PEM13-12] Instantaneous Frequency Analysis on Nonlinear EMIC Emissions: Arase Observation

*Masafumi Shoji[1], Yoshizumi Miyoshi[1], Yoshiharu Omura[2], Lynn M Kistler[1,3], Yasumasa Kasaba[4], Shoya Matsuda[5], Yoshiya Kasahara[6], Ayako Matsuoka[5], Reiko Nomura[7], Keigo Ishisaka[8], Atsushi Kumamoto[4], Fuminori Tsuchiya[4], Satoshi Yagitani[6], Mariko Teramoto[1], Kazushi Asamura[5], Takeshi Takashima[5], Iku Shinohara[5] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Research Institute for Sustainable Humanosphere, Kyoto University, 3.Institute for the Study of Earth Oceans and Space, University of New Hampshire, 4.Tohoku University, 5.Institute of Space and Astronautical Science, 6.Kanazawa University, 7.National Astronomical Observatory of Japan, 8.Toyama Prefecture University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PEM13-13] Rapid Precipitation by EMIC Rising-tone Emissions of Relativistic Electrons Observed by the Van Allen Probes Mission

*Satoko Nakamura[1], Yoshiharu Omura[1], Craig Kletzing[2], Daniel Baker[3] (1.Research Institute for Sustainable Humanosphere, Kyoto University., 2.Department of Physics and Astronomy University of Iowa , 3.The Laboratory for Atmospheric and Space Physics (LASP) at the University of Colorado)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PEM13-14] Plasmaspheric EMIC waves excited through mode conversion from equatorial noise under existence of M/Q=2 ions

*Yoshizumi Miyoshi[1], Shoya Matsuda[2], Satoshi Kurita[1], koji nomura[1], Kunihiro Keika[3], Masafumi Shoji[1], Naritoshi Kitamura[3], Yoshiya Kasahara[4], Ayako Matsuoka[2], Iku Shinohara[2], Kazuo Shiokawa[1], Shinobu Machida[1], Ondrej Santolik[5], Scott Boardsen[6], Richard Horne[7], Wygant John[8] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.JAXA, 3.University of Tokyo, 4.Kanazawa University, 5.CAS, 6.NASA, 7.British Antarctic Survey, 8.University of Minnesota)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PEM13-15] Generation Mechanism of Non-thermal Continuum Radiation

*Yoshiharu Omura[1], Miroslav Horky[1,2] (1.Reserach Institute for Sustainable Humanosphere, Kyoto University, 2.Department of Space Physics, Institute of Atmospheric Physics, Czech Academy of Sciences)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PEM13-16] Influence of kappa distributions on the sweep rate of whistler mode chorus waves

*Danny Summers[1] (1.Memorial University of Newfoundland)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Yusuke Ebihara(RISH, Kyoto University), Shinji Saito(ISEE, Nagoya University)

10:45 AM - 11:05 AM JST | 1:45 AM - 2:05 AM UTC

[PEM13-17] The Impacts of Substorms on the Ring Current

★Invited Papers

*Jasmine Kaur Sandhu[1], I. J. Rae[1], M. Gkioulidou[2], C. Forsyth[1], G. D. Reeves[3], M. P. Freeman[4], K. R. Murphy[5], M.-T. Walach[6], H. E. Spence[7] (1.Mullard Space Science Laboratory, University College London, UK., 2.Applied Physics Laboratory, John Hopkins University, USA., 3.Los Alamos National Laboratory, USA., 4.British Antarctic Survey, UK., 5.University of Maryland, USA., 6.Lancaster University, UK., 7.University of New Hampshire, USA.)

11:05 AM - 11:25 AM JST | 2:05 AM - 2:25 AM UTC

[PEM13-18] Dipolarization in the Inner Magnetosphere: Comparison between Geosynchronous Orbit and Further Inside

★Invited Papers

*Shinichi Ohtani[1], Tetsuo Motoba[1], Matina Gkioulidou[1], Kazue Takahashi[1] (1.The Johns Hopkins University Applied Physics Laboratory)

11:25 AM - 11:40 AM JST | 2:25 AM - 2:40 AM UTC

[PEM13-19] Substorm-associated particle injection near/at geosynchronous orbit: Observations from ERG and GOES

*Tzu-Fang Chang[1,2], Chio-Zong Cheng[2], Sunny Wing-Yee Tam[2], Chih-Yu Chiang[2], Yoshizumi Miyoshi[1], Tomoaki Hori[1], Takefumi Mitani[3], Takeshi Takashima[3], Ayako Matsuoka[3], Mariko Teramoto[1], Iku Shinohara[3] (1.Institute for Space-Earth Environmental Research, Nagoya University, Japan, 2.Institute of Space and Plasma Sciences, National Cheng Kung University, Tainan, Taiwan, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Japan)

11:40 AM - 11:55 AM JST | 2:40 AM - 2:55 AM UTC

[PEM13-20] Substorm -like energetic electron injection observed at the plasma sheet boundary in the inner magnetosphere

*Iku Shinohara[1], Nagai Tsugunobu[1], Takefumi Mitani[1], Nana Higashio[2], Satoshi Kasahara[3], Yoichi Kazama[4], Shiang-Yu Wang[4], Sunny Tam[5], Ayako Matsuoka[1], Kazushi Asamura[1], Shoichiro Yokota[6], Takeshi Takashima[1], Yoshizumi Miyoshi[7] (1.Japan Aerospace Exploration Agency/Institute of Space and Astronautical Science, 2.Japan Aerospace Exploration Agency, 3.The University of Tokyo, 4.Academia Sinica/Institute of Astronomy and Astrophysics, 5.National Cheng Kung University, 6.Osaka University, 7.Nagoya University/Institute for Space-Earth Einvironment Research)

11:55 AM - 12:10 PM JST | 2:55 AM - 3:10 AM UTC

[PEM13-21] Magnetic field disturbances associated with the magnetic dipolarization observed by Arase (ERG) in the inner magnetosphere

*Ayako Matsuoka[1], Masahito Nose[2], Yoshizumi Miyoshi[2], Iku Shinohara[1], Mariko Teramoto[2], Reiko Nomura[3], Akiko Fujimoto[4], Yoshimasa Tanaka[5], Manabu Shinohara[6], Yoshiya Kasahara[7], Yasumasa Kasaba[8], Keigo Ishisaka[9], Shoya Matsuda[1], Masafumi Shoji[2], Tomoko Nakagawa[10], Yoichi Kazama[11], Shiang-Yu Wang[11], Satoshi Kasahara[12], Shoichiro Yokota[13], Takefumi Mitani[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.RISE, National Astronomical Observatory of Japan, 4.School of Computer Science and Systems Engineering, Kyushu Institute of Technology, 5.National Institute of Polar Research, 6.National Institute of Technology, Kagoshima College, 7.Information Media Center, Kanazawa University, 8.Planetary Plasma and Atmospheric Research Center, Tohoku University, 9.Faculty of Engineering, Toyama Prefectural University, 10.Faculty of Engineering, Tohoku Institute of Technology, 11.Academia Sinica Institute of Astronomy and Astrophysics, 12.School of Science, The University of Tokyo, 13.School of Science, Osaka University)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Yoshizumi Miyoshi(ISEE, Nagoya University), Yusuke Ebihara(RISH, Kyoto University)

1:45 PM - 2:05 PM JST | 4:45 AM - 5:05 AM UTC

[PEM13-22] Statistical Property of Long Lasting Poloidal Pc 4-5 Waves and Relation with Particle Dynamics in the Inner Magnetosphere: Van Allen Probes Observations

★Invited Papers

*Kazuhiro Yamamoto[1], Masahito Nose[2], Kunihiro Keika[3], Charles W. Smith[4], Robert J. MacDowall[5], Donald G. Mitchell[6], Hyomin Kim[7], John Wygant[8] (1.Graduate School of Science, Kyoto University, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Graduate School of Science, the University of Tokyo, 4.Institute for the Study of Earth, Oceans, and Space, University of New Hampshire, 5.Solar System Exploration Division, Goddard Space Flight Center, 6.The Johns Hopkins University Applied Physics Laboratory, 7.Center for Solar Terrestrial Research, New Jersey Institute of Technology, 8.School of Physics and Astronomy, University of Minnesota)

2:05 PM - 2:25 PM JST | 5:05 AM - 5:25 AM UTC

[PEM13-23] Subauroral Polarization Streams: Indication of Magnetosphere–Ionosphere Coupling

★Invited Papers

*Fei He[1,2,3], Xiao-Xin Zhang[4], Wenbin Wang[5], Zhonghua Yao[1,2,3], Yong Wei[1,2,3], Zhi-Peng Ren[1,2,3], Xinan Yue[1,2,3], Weixing Wan[1,2,3] (1.Institute of Geology & Geophysics, CAS, 2.Institutions of Earth Science, CAS, 3.College of Earth and Planetary Sciences, UCAS, 4.National Center for Space Weather, CMA, 5.High Altitude Observatory, NCAR)

2:25 PM - 2:40 PM JST | 5:25 AM - 5:40 AM UTC

[PEM13-24] Simultaneous Arase-ground observations of a purple and green auroral arc

*Kazuo Shiokawa[1], Masahito Nose[1], Satoshi Tsuchiya[1], Yuki Takagi[1], Shun Imajo[1], Yoshimasa Tanaka[2], Yoshizumi Miyoshi[1], Keisuke Hosokawa[3], Yoichi Kazama[4], Shiang-Yu Wang[4], Sunny W.Y. Tam[4], Kazushi Asamura[5], Satoshi Kasahara[6], Shoichiro Yokota[7], Tomoaki Hori[1], Kunihiro Keika[6], Ayako Matsuoka[5] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.National Institute of Polar Research, 3.The University of Electro-Communications, 4.National Cheng Kung University, 5.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 6.University of Tokyo, 7.Osaka University)

2:40 PM - 2:55 PM JST | 5:40 AM - 5:55 AM UTC

[PEM13-25] Multiple Satellite Observations of Oxygen Torus in the Inner Magnetosphere

*Masahito Nose[1], Ayako Matsuoka[2], Atsushi Kumamoto[3], Yoshiya Kasahara[4], J Goldstein[5,6], Mariko Teramoto[1], Fuminori Tsuchiya[3], Shoya Matsuda[2], Masafumi Shoji[1], Shun Imajo[1], Oimatsu Satoshi[7], Kazuhiro Yamamoto[7], Yuki Obana[8], Reiko Nomura[9], Akiko Fujimoto[10], Iku Shinohara[2], Yoshizumi Miyoshi[1], W S Kurth[11], C A Kletzing[11], C W Smith[12], R J MacDowall[13] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Graduate School of Science, Tohoku University, 4.Information Media Center, Kanazawa University, 5.Space Science and Engineering Division, Southwest Research Institute, 6.University of Texas at San Antonio, 7.Graduate School of Science, Kyoto University, 8.Faculty of Engineering, Osaka Electro-Communication University, 9.National Astronomical Observatory of Japan, 10.Kyushu Institute of Technology, 11.Department of Physics and Astronomy, University of Iowa, 12.Institute for the Study of Earth, Oceans, and Space, University of New Hampshire, 13.Solar System Exploration Division, Goddard Space Flight Center)

2:55 PM - 3:10 PM JST | 5:55 AM - 6:10 AM UTC

[PEM13-26] Study of characteristics of storm-time Pc5 ULF waves excited by the drift-bounce resonance with ring current ions based on the global drift-kinetic simulation

*Tomotsugu Yamakawa[1], Kanako Seki[1], Takanobu Amano[1], Yoshizumi Miyoshi[2], Naoko Takahashi[1] (1.Department of Earth and Planetary Science, School of Science, The University of Tokyo, 2.ISEE, Nagoya University)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University)

[PEM13-P01] Evaluation of wave normal and Poynting vector analyses for whistler mode waves observed by the waveform capture (WFC) on board the Arase

*Yoshiya Kasahara[1], Satoshi Ikarashi[1], Hiroyuki Nishizawa[1], Shoya Matsuda[2], Fuminori Tsuchiya[3], Atsushi Kumamoto[3], Yasumasa Kasaba[3], Mitsunori Ozaki[1], Ayako Matsuoka[2] (1.Kanazawa University, 2.ISAS/JAXA, 3.Tohoku University)

[PEM13-P02] Calibration of electric fields dedicated to the measurement of the S-WPIA of the Arase Satellite

*Miki Jumpei[1], Hirotsugu Kojima[2], Yuto Katoh[3], Shoya Matsuda[4], Yoshiya Kasahara[5], Mitsuru Hikishima[4], Satoshi Kurita[6], Masahiro Kitahara[3], Satoshi Kasahara[7], Yoshizumi Miyoshi[6], Atsushi Kumamoto[3], Ayako Matsuoka[4], Shoichiro Yokota[8], Tomoaki Hori[6], Kunihiro Keika[7] (1.Space Radio Engineering Laboratory, Division of Electrical Engineering, Kyoto University Graduated School, 2.Research Institute for Sustainable Humanosphere, Kyoto University, 3.Graduate School of Science and Faculty of Science, Tohoku University, 4.Institute of Space and Astronautical Science, JAXA, 5.Information Media Center, Kanazawa University, 6.Institute for Space-Earth Environmental Research, Nagoya University, 7.School of Science, The University of Tokyo, 8.School of Science, Osaka University)

[PEM13-P03] Enhancement of whistler-mode chorus in association with Pc 4-5 ULF waves and related variation of high energy electrons

*Atsuhiro Ono[1], Yuto Katoh[1], Atsushi Kumamoto[1], Fuminori Tsuchiya[1], Mariko Teramoto[2], Yoshiya Kasahara[3], Shoya Matsuda[4], Ayako Matsuoka[4], Takefumi Mitani[4], Tomoaki Hori[2], Satoshi Kasahara[5], Shoichiro Yokota[6], Kunihiro Keika[5], Yoshizumi Miyoshi[2], Iku Shinohara[4] (1.Tohoku University, 2.Nagoya University, 3.Kanazawa University, 4.ISAS/JAXA, 5.The University of Tokyo, 6.Osaka University)

[PEM13-P04] Sudden enhancements of electron cyclotron harmonic waves observed by the Arase satellite

*Shinjo Airi[1], Hirotsugu Kojima[1], Yoshiya Kasahara[2], Yoichi Kazama[3], Hideyuki Usui[4], Yoshizumi Miyoshi[5], Yasumasa Kasaba[6], Shoya Matsuda[7], Tomoaki Hori[5], S. -Y. Wang[8], Sunny W.Y. Tam[9], Atsushi Kumamoto[10], Ayako Matsuoka[11] (1.Research institute for sustainable humanosphere, Kyoto University, 2.Information Media Center, Kanazawa University, 3.ASIAA, 4.Graduate school of system informatics Kobe University, 5.Institute for Space-Earth Environmental Research, Nagoya University, 6.Planetary Plasma and Atmospheric Research Center, Tohoku University, 7.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 8.ASIAA, Taiwan, 9.ISAPS, NCKU, Taiwan, 10.Department of Geophysics, Graduate School of Science, Tohoku University, 11.Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PEM13-P05] Correlation between pulsating aurora and electrostatic electron cyclotron harmonic waves obtained from coordinated Arase and ground data

*Mizuki Fukizawa[1], Takeshi Sakanoi[1], Yoshizumi Miyoshi[2], Keisuke Hosokawa[3], Yoichi Kazama[4], Yoshiya Kasahara[5], Shoya Matsuda[6], Ayako Matsuoka[7], Wang Shiang-Yu[4], Sunny Wing-Yee Tam[8], Ryuho Kataoka[9] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Department of Communication Engineering and Informatics, University of Electro-Communications, 4.Academia Sinica Institute of Astronomy and Astrophysics, 5.Information Media Center, Kanazawa University, 6.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 7.Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 8.Institute of Space and Plasma Sciences, College of Sciences, National Cheng Kung University , 9.National Institute of Polar Research)

[PEM13-P06] Automatic determination of Upper Hybrid Resonance Frequencies by Convolutional Neural Network.

*Shoya Matsuda[1], Tatsuhito Hasegawa[2], Atsushi Kumamoto[3], Fuminori Tsuchiya[3], Yoshiya Kasahara[4], Yoshizumi Miyoshi[5], Yasumasa Kasaba[3], Ayako Matsuoka[1] (1.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 2.University of Fukui, 3.Tohoku University, 4.Kanazawa University, 5.ISEE, Nagoya University)

[PEM13-P07] Amplitude dependence of whistler wave motion on electron scattering process

*Yoshiki Ito[1], Yoshizumi Miyoshi[1], Shinji Saito[1] (1.Nagoya University, ISEE)

[PEM13-P08] Two-dimensional simulation of whistler mode wave packets interacting with energetic electrons

*Takeshi Nogi[1], Yoshiharu Omura[1] (1.Reserch Institute for Sustainable Humanosphere, Kyoto University)

[PEM13-P09] Relativistic electron acceleration by whistler-mode chorus waves in 1D, 2D, and 3D magnetic field models.

*Keita Takahashi[1], Yoshiharu Omura[1], Yikai HSIEH[1], Danny Summers[2] (1.Research Institute for Sustainable Humanosphere, Kyoto University , 2.Department of Mathematics and Statistics, Memorial University of Newfoundland)

[PEM13-P10] Study of global spatio-temporal development of magnetospheric ELF/VLF waves for the 26-30 March 2017 storm based on ground and satellite observations and the RAM simulations

*Yuhei Takeshita[1], Kazuo Shiokawa[1], Yoshizumi Miyoshi[1], Mitsunori Ozaki[2], Yoshiya Kasahara[2], Martine Connors[3], Jyrki Manninen[4], Craig Kletzing[5], Vania Jordanova[6] (1.Nagoya University, Institute for Space-Earth Environmental Resarch, 2.Kanazawa University, 3.Athabasca University, 4.Sodankylä Geophysical Observatory, 5.The University of Iowa, 6.Los Alamos National Laboratory)

[PEM13-P11] Flux decrease of outer radiation belt electrons associated with solar wind pressure pulse: A Code coupling simulation of GEMSIS-RB and GEMSIS-GM

*Ito Hiroki[1], Yoshizumi Miyoshi[1], Shinji Saito[2], Yosuke Matsumoto[3], Takanobu Amano[4] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School of Science, Nagoya University, 3. Graduate School of Science, Chiba University, 4.Department of Earth and Planetary Science, University of Tokyo)

[PEM13-P12] Non-diffusive response of outer belt electrons on interplanetary shock

Takuma Toishi[1], *Yusuke Ebihara[1], Takashi Tanaka[2] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.Kyushu University)

[PEM13-P13] PARM: Initial result of the auroral camera on the G-CHASER (RockSat-XN) rocket and status of the development of auroral cameras for the LAMP rocket experiment

*Naoshi Yagi[1], Takeshi Sakanoi[1], Fukizawa Mizuki[1], Kazushi Asamura[2], Yoshizumi Miyoshi[3], Keisuke Hosokawa[4], Genki Ishizawa[5] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Department of Communication Engineering and Informatics, University of Electro-Communications, 5.Space & terrestrial plasma pyhsics)

[PEM13-P14] First simultaneous observation of a SAR arc at subauroral latitudes using a ground all-sky camera and the Arase satellite in the inner magnetosphere

*Yudai Inaba[1], Kazuo Shiokawa[1], Shin-ichiro Oyama[1,8,9], Yuichi Otsuka[1], Atsuki Shinbori[1], Yoichi Kazama[2], Shiang-Yu Wang[2], Sunny W. Y. Tam[2], Shoichiro Yokota[3], Satoshi Kasahara[4], Kunihiro Keika[4], Tomoaki Hori[1], Ayako Matsuoka[5], Yoshiya Kasahara[6], Atsushi Kumamoto[7], Yasumasa Kasaba[7], Yoshizumi Miyoshi[1], Iku Shinohara[5], Arto Oksanen[10] (1.Institute for Space-Earth Environmental Research, 2.Academia Sinica, 3.Osaka Univ, 4.Tokyo Univ, 5.JAXA, 6.Kanazawa University, 7.Tohoku University, 8.University of Oulu, Finland, 9.National Institute of Polar Research, 10.Jyväskylän Sirius ry, Finland)

[PEM13-P15] Pi2 pulsations observed by the Arase satellite inside and outside the plasmapause

*Mariko Teramoto[1], Ayako Matsuoka[2], Reiko Nomura[5], Yoshiya Kasahara[3], Yasumasa Kasaba[4], Atsushi Kumamoto[4], Fuminori Tsuchiya[4], Shoya Matsuda[2], Masahito Nose[1], Masafumi Shoji[1], Yasunori Tsugawa[1], Shun Imajo[1], Yoshizumi Miyoshi[1], Iku Shinohara[2] (1.Institute for Space-Earth Environmental Research Nagoya University, 2.Institute of Space and Astronautical Science, Japan Aerospace eXploration Agency, 3.Kanazawa University, 4.Tohoku University, 5.National Astronomical Observatory of Japan)

[PEM13-P16] An extreme erosion of the plasmasphere during the 7–10 September 2017 storm

*Yuki Obana[1], Naomi Maruyama[2,3], Atsuki Shinbori[4], Kumiko K. Hashimoto[5], Mariangel Fedrizzi[2,3], Masahito Nose[4], Yuichi Otsuka[4], Nozomu Nishitani[4], Tomoaki Hori[4], Atsushi Kumamoto[6], Fuminori Tsuchiya[6], Shoya Matsuda[7], Ayako Matsuoka[7], Yoshiya Kasahara[8], Akimasa Yoshikawa[9], Yoshizumi Miyoshi[4], Iku Shinohara[7] (1.Osaka Electro-Communication University, 2.University of Colorado Boulder, 3.NOAA Space Weather Prediction Center, 4.Nagoya

University, 5.Kibi International University, 6.Tohoku University, 7.Japan Aerospace Exploration Agency, 8.Kanazawa University, 9.Kyushu University)

[PEM13-P17] Relative contribution of ULF and chorus waves to the radiation belt variation: Comparison between multi-point observations and BATSRUS + CRCM simulation

*Naoko Takahashi[1], Kanako Seki[1], Mei-Ching Fok[2], Yihua Zheng[2], Yoshizumi Miyoshi[3], David Hartley[4], Ayako Matsuoka[5], Yoshiya Kasahara[6], Yasumasa Kasaba[7], Nana Higashio[8] (1.Graduate School of Science, University of Tokyo, 2.NASA Goddard Space Flight Center, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Department of Physics and Astronomy, University of Iowa, 5.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 6.Information Media Center, Kanazawa University, 7.Planetary Plasma and Atmospheric Research Center, Tohoku University, 8.Japan Aerospace Exploration Agency)

[PEM13-P18] Modulation of the D-region ionosphere by Pc5 waves observed by VLF/LF standard radio waves

*Miyashita Takuya[1], Hiroyo Ohya[1], Fuminori Tsuchiya[2], Hiroyuki Nakata[1], Toshiaki Takano[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3] (1.Chiba University, 2.Tohoku University, 3.Nagoya University)

[PEM13-P19] Oxygen-proton differences in ion energies dominating plasma pressure: Dependence on storm phases and solar wind drivers

*Kunihiro Keika[1], Satoshi Kasahara[1], Shoichiro Yokota[2], Masahiro Hoshino[1], Kanako Seki[1], Masahito Nose[3], Yoshizumi Miyoshi[3], Iku Shinohara[4] (1.Graduate School of Science, The University of Tokyo , 2.Graduate School of Science, Osaka University, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PEM13-P20] Mass dependence of penetration depth of multi-energy ions in the inner magnetosphere during magnetic storms: Arase observations

*Ryosuke Fujii[1], Yoshizumi Miyoshi[1], Masafumi Shoji[1], Kazushi Asamura[2], Lynn Kistler[1,8], Vania Jordanova[9], Tomoaki Hori[1], Satoshi Kurita[1], Mariko Teramoto[1], Yasunori Tsugawa[1], Yoshiya Kasahara[3], Yasumasa Kasaba[4], Atsushi Kumamoto[5], Fuminori Tsuchiya[4], Shoichiro Yokota[6], Kunihiro Keika[7], Ayako Matsuoka[2], Iku Shinohara[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Information Media Center, Kanazawa University, 4.Planetary Plasma and Atmospheric Research Center, Tohoku University, 5.Department of Geophysics, Graduate School of Science, Tohoku University, 6.Graduate School of Science, Osaka University, 7.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 8.University of New Hampshire, 9.Los Alamos National Laboratory)

[PEM13-P21] Relativistic Acceleration of Energetic Protons by Electromagnetic Ion Cyclotron Waves in the Jovian Magnetosphere

*Tomohiro Sekine[1], Yoshiharu Omura[1], Danny Summers[2], Yikai HSIEH[1], Satoko Nakamura[1] (1.Reserach Institute for Sustainable Humanosphere, Kyoto University, 2.Memorial University of Newfoundland)

[PEM13-P22] Statistical study of IPDP type EMIC wave-related electron precipitation at subauroral latitude

*Asuka Hirai[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Yasumasa Kasaba[1], Yuto Katoh[2], Hiroaki Misawa[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3], Satoshi Kurita[3], Martin G Connors[4] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku Univ. , 2.Department of Geophysics, Graduate School of Science, Tohoku University, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Athabasca University)

[PEM13-P23] Meridional distributions of proton plasma and pressure-driven currents in the nightside inner magnetosphere: Arase observations

*Shun Imajo[1], Masahito Nose[1], Satoshi Kasahara[2], Shoichiro Yokota[3], Ayako Matsuoka[4], Kunihiro Keika[2], Tomoaki Hori[1], Mariko Teramoto[1], Kazuhiro Yamamoto[5], Oimatsu Satoshi[5], Reiko Nomura[6], Akiko Fujimoto[7], Iku Shinohara[4], Yoshizumi Miyoshi[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Graduate School of Science, The University of Tokyo, 3.Graduate School of Science, Osaka University, 4.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 5.Graduate School of Science, Kyoto University, 6.National Astronomical Observatory of Japan, 7.Kyushu Institute of Technology)

[PEM13-P24] Space Weather Effects on Energetic Proton Flux Response in South Atlantic Anomaly

*Kirolosse Mina GIRGIS[1,2], Tohru Hada[1], Shuichi Matsukiyo[1] (1.Earth System Science and Technology (ESST) Department, Interdisciplinary Graduate School of Engineering Sciences (IGSES), Kyushu University, Japan, 2.Aerospace Engineering Department, Faculty of Engineering, Cairo University, Egypt)

[PEM13-P25] Solar-cycle variations of >30 keV electron flux enhancements under the inner radiation belt

*ALLA SUVOROVA[1] (1.National Central University)

[PEM13-P26] Energy spectra variations of high energy electrons in the inner magnetosphere observed by HEP/XEP on ARASE and SEDA-e on HIMAWARI

*Takeshi Takashima[1], Takefumi Mitani[1], Nana Higashio[2], Tsutomu Nagatsuma[3] (1. ISAS/JAXA, 2.Research and Development Directorate/JAXA, 3.NiCT)

[PEM13-P27] Inter-channel calibration of the high-energy electron experiments (HEP) instrument onboard the Arase satellite

*Tomoaki Hori[1], Takefumi Mitani[2], Takeshi Takashima[2], Park Inchun[1], Satoshi Kurita[1], Mariko Teramoto[1], Nana Higashio[3], Satoshi Kasahara[4], Shoichiro Yokota[5], Yoshizumi Miyoshi[1], Iku Shinohara[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science, 3.Japan Aerospace Exploration Agency, 4.Graduate School of Science, The University of Tokyo, 5.Graduate School of Science, Osaka University)

[PEM13-P28] Particle simulation for calibrating the HEP data onboard the ARASE satellite

*PARK INCHUN[1], Yoshizumi Miyoshi[1], Takefumi Mitani[2], Tomoaki Hori[1], Satoshi Kurita[1], Mariko Teramoto[1], Takeshi Takashima[2], Nana Higashio[3], Iku Shinohara[2] (1.Nagoya University Institute for Space-Earth Environmental Research, 2.Japan Aerospace Exploration Agency Institute of Space and Astronautical Science , 3.Japan Aerospace Exploration Agency)

[PEM13-P29] Geant4 model calculation and energetic particle observation with HEP/Arase in the inner radiation belt

*Honoka Toda[1], Wataru Miyake[1], Takefumi Mitani[3], Takeshi Takashima[3], Yoshizumi Miyoshi[2], PARK INCHUN[2], Tomoaki Hori[2] (1.Tokai University, 2.ISEE/Nagoya University, 3.ISAS/JAXA)

[PEM13-P30] Validation of High-energy electron detector simulator for the HEP instruments onboard Arase

*Takefumi Mitani[1], PARK INCHUN[2], Tomoaki Hori[2], Taku Namekawa[1,3], Kazushi Asamura[1], Takeshi Takashima[1], Satoshi Kasahara[3], Satoshi Kurita[2], Mariko Teramoto[2], Nana Higashio[1], Yoshizumi Miyoshi[2], Iku Shinohara[1] (1.Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science, 2.Institute for Space-Earth Environmental Research, Nagoya Univ., 3.The university of Tokyo)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University)

[PEM13-P01] Evaluation of wave normal and Poynting vector analyses for whistler mode waves observed by the waveform capture (WFC) on board the Arase

*Yoshiya Kasahara[1], Satoshi Ikarashi[1], Hiroyuki Nishizawa[1], Shoya Matsuda[2], Fuminori Tsuchiya[3], Atsushi Kumamoto[3], Yasumasa Kasaba[3], Mitsunori Ozaki[1], Ayako Matsuoka[2] (1.Kanazawa University, 2.ISAS/JAXA, 3.Tohoku University)

[PEM13-P02] Calibration of electric fields dedicated to the measurement of the S-WPIA of the Arase Satellite

*Miki Jumpei[1], Hirotsugu Kojima[2], Yuto Katoh[3], Shoya Matsuda[4], Yoshiya Kasahara[5], Mitsuru Hikishima[4], Satoshi Kurita[6], Masahiro Kitahara[3], Satoshi Kasahara[7], Yoshizumi Miyoshi[6], Atsushi Kumamoto[3], Ayako Matsuoka[4], Shoichiro Yokota[8], Tomoaki Hori[6], Kunihiro Keika[7] (1.Space Radio Engineering Laboratory, Division of Electrical Engineering, Kyoto University Graduated School, 2.Research Institute for Sustainable Humanosphere, Kyoto University, 3.Graduate School of Science and Faculty of Science, Tohoku University, 4.Institute of Space and Astronautical Science, JAXA, 5.Information Media Center, Kanazawa University, 6.Institute for Space-Earth Environmental Research, Nagoya University, 7.School of Science, The University of Tokyo, 8.School of Science, Osaka University)

[PEM13-P03] Enhancement of whistler-mode chorus in association with Pc 4-5 ULF waves and related variation of high energy electrons

*Atsuhiro Ono[1], Yuto Katoh[1], Atsushi Kumamoto[1], Fuminori Tsuchiya[1], Mariko Teramoto[2], Yoshiya Kasahara[3], Shoya Matsuda[4], Ayako Matsuoka[4], Takefumi Mitani[4], Tomoaki Hori[2], Satoshi Kasahara[5], Shoichiro Yokota[6], Kunihiro Keika[5], Yoshizumi Miyoshi[2], Iku Shinohara[4] (1.Tohoku University, 2.Nagoya University, 3.Kanazawa University, 4.ISAS/JAXA, 5.The University of Tokyo, 6.Osaka University)

[PEM13-P04] Sudden enhancements of electron cyclotron harmonic waves observed by the Arase satellite

*Shinjo Airi[1], Hirotsugu Kojima[1], Yoshiya Kasahara[2], Yoichi Kazama[3], Hideyuki Usui[4], Yoshizumi Miyoshi[5], Yasumasa Kasaba[6], Shoya Matsuda[7], Tomoaki Hori[5], S. -Y. Wang[8], Sunny W.Y. Tam[9], Atsushi Kumamoto[10], Ayako Matsuoka[11] (1.Research institute for sustainable humanosphere, Kyoto University, 2.Information Media Center, Kanazawa University, 3.ASIAA, 4.Graduate school of system informatics Kobe University, 5.Institute for Space-Earth Environmental Research, Nagoya University, 6.Planetary Plasma and Atmospheric Research Center, Tohoku University, 7.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 8.ASIAA, Taiwan, 9.ISAPS, NCKU, Taiwan, 10.Department of Geophysics, Graduate School of Science, Tohoku University, 11.Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PEM13-P05] Correlation between pulsating aurora and electrostatic electron cyclotron harmonic waves obtained from coordinated Arase and ground data

*Mizuki Fukizawa[1], Takeshi Sakanoi[1], Yoshizumi Miyoshi[2], Keisuke Hosokawa[3], Yoichi Kazama[4], Yoshiya Kasahara[5], Shoya Matsuda[6], Ayako Matsuoka[7], Wang Shiang-Yu[4], Sunny Wing-Yee Tam[8], Ryuho Kataoka[9] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Department of Communication Engineering and Informatics, University of Electro-Communications, 4.Academia Sinica Institute of Astronomy and Astrophysics, 5.Information Media Center, Kanazawa University, 6.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 7.Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 8.Institute of Space and Plasma Sciences, College of Sciences, National Cheng Kung University , 9.National Institute of Polar Research)

[PEM13-P06] Automatic determination of Upper Hybrid Resonance Frequencies by Convolutional Neural Network.

*Shoya Matsuda[1], Tatsuhito Hasegawa[2], Atsushi Kumamoto[3], Fuminori Tsuchiya[3], Yoshiya Kasahara[4], Yoshizumi Miyoshi[5], Yasumasa Kasaba[3], Ayako Matsuoka[1] (1.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 2.University of Fukui, 3.Tohoku University, 4.Kanazawa University, 5.ISEE, Nagoya University)

[PEM13-P07] Amplitude dependence of whistler wave motion on electron scattering process

*Yoshiki Ito[1], Yoshizumi Miyoshi[1], Shinji Saito[1] (1.Nagoya University, ISEE)

[PEM13-P08] Two-dimensional simulation of whistler mode wave packets interacting with energetic electrons

*Takeshi Nogi[1], Yoshiharu Omura[1] (1.Reserch Institute for Sustainable Humanosphere, Kyoto University)

[PEM13-P09] Relativistic electron acceleration by whistler-mode chorus waves in 1D, 2D, and 3D magnetic field models.

*Keita Takahashi[1], Yoshiharu Omura[1], Yikai HSIEH[1], Danny Summers[2] (1.Research Institute for Sustainable Humanosphere, Kyoto University , 2.Department of Mathematics and Statistics, Memorial University of Newfoundland)

[PEM13-P10] Study of global spatio-temporal development of magnetospheric ELF/VLF waves for the 26-30 March 2017 storm based on ground and satellite observations and the RAM simulations

*Yuhei Takeshita[1], Kazuo Shiokawa[1], Yoshizumi Miyoshi[1], Mitsunori Ozaki[2], Yoshiya Kasahara[2], Martine Connors[3], Jyrki Manninen[4], Craig Kletzing[5], Vania Jordanova[6] (1.Nagoya University, Institute for Space-Earth Environmental Resarch, 2.Kanazawa University, 3.Athabasca University, 4.Sodankylä Geophysical Observatory, 5.The University of Iowa, 6.Los Alamos National Laboratory)

[PEM13-P11] Flux decrease of outer radiation belt electrons associated with solar wind pressure pulse: A Code coupling simulation of GEMSIS-RB and GEMSIS-GM

*Ito Hiroki[1], Yoshizumi Miyoshi[1], Shinji Saito[2], Yosuke Matsumoto[3], Takanobu Amano[4] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School of Science, Nagoya University, 3. Graduate School of Science, Chiba University, 4.Department of Earth and Planetary Science, University of Tokyo)

[PEM13-P12] Non-diffusive response of outer belt electrons on interplanetary shock

Takuma Toishi[1], *Yusuke Ebihara[1], Takashi Tanaka[2] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.Kyushu University)

[PEM13-P13] PARM: Initial result of the auroral camera on the G-CHASER (RockSat-XN) rocket and status of the development of auroral cameras for the LAMP rocket experiment

*Naoshi Yagi[1], Takeshi Sakanoi[1], Fukizawa Mizuki[1], Kazushi Asamura[2], Yoshizumi Miyoshi[3], Keisuke Hosokawa[4], Genki Ishizawa[5] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Department of Communication Engineering and Informatics, University of Electro-Communications, 5.Space & terrestrial plasma pyhsics)

[PEM13-P14] First simultaneous observation of a SAR arc at subauroral latitudes using a ground all-sky camera and the Arase satellite in the inner magnetosphere

*Yudai Inaba[1], Kazuo Shiokawa[1], Shin-ichiro Oyama[1,8,9], Yuichi Otsuka[1], Atsuki Shinbori[1], Yoichi Kazama[2], Shiang-Yu Wang[2], Sunny W. Y. Tam[2], Shoichiro Yokota[3], Satoshi Kasahara[4], Kunihiro Keika[4], Tomoaki Hori[1], Ayako Matsuoka[5], Yoshiya Kasahara[6], Atsushi Kumamoto[7], Yasumasa Kasaba[7], Yoshizumi Miyoshi[1], Iku Shinohara[5], Arto Oksanen[10] (1.Institute for Space-Earth Environmental Research, 2.Academia Sinica, 3.Osaka Univ, 4.Tokyo Univ, 5.JAXA, 6.Kanazawa University, 7.Tohoku University, 8.University of Oulu, Finland, 9.National Institute of Polar Research, 10.Jyväskylän Sirius ry, Finland)

[PEM13-P15] Pi2 pulsations observed by the Arase satellite inside and outside the plasmapause

*Mariko Teramoto[1], Ayako Matsuoka[2], Reiko Nomura[5], Yoshiya Kasahara[3], Yasumasa Kasaba[4], Atsushi Kumamoto[4], Fuminori Tsuchiya[4], Shoya Matsuda[2], Masahito Nose[1], Masafumi Shoji[1], Yasunori Tsugawa[1], Shun Imajo[1], Yoshizumi Miyoshi[1], Iku Shinohara[2] (1.Institute for Space-Earth Environmental Research Nagoya University, 2.Institute of Space and Astronautical Science, Japan Aerospace eXploration Agency, 3.Kanazawa University, 4.Tohoku University, 5.National Astronomical Observatory of Japan)

[PEM13-P16] An extreme erosion of the plasmasphere during the 7–10 September 2017 storm

*Yuki Obana[1], Naomi Maruyama[2,3], Atsuki Shinbori[4], Kumiko K. Hashimoto[5], Mariangel Fedrizzi[2,3], Masahito Nose[4], Yuichi Otsuka[4], Nozomu Nishitani[4], Tomoaki Hori[4], Atsushi Kumamoto[6], Fuminori Tsuchiya[6], Shoya Matsuda[7], Ayako Matsuoka[7], Yoshiya Kasahara[8], Akimasa Yoshikawa[9], Yoshizumi Miyoshi[4], Iku Shinohara[7] (1.Osaka Electro-Communication University, 2.University of Colorado Boulder, 3.NOAA Space Weather Prediction Center, 4.Nagoya

University, 5.Kibi International University, 6.Tohoku University, 7.Japan Aerospace Exploration Agency, 8.Kanazawa University, 9.Kyushu University)

[PEM13-P17] Relative contribution of ULF and chorus waves to the radiation belt variation: Comparison between multi-point observations and BATSRUS + CRCM simulation

*Naoko Takahashi[1], Kanako Seki[1], Mei-Ching Fok[2], Yihua Zheng[2], Yoshizumi Miyoshi[3], David Hartley[4], Ayako Matsuoka[5], Yoshiya Kasahara[6], Yasumasa Kasaba[7], Nana Higashio[8] (1.Graduate School of Science, University of Tokyo, 2.NASA Goddard Space Flight Center, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Department of Physics and Astronomy, University of Iowa, 5.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 6.Information Media Center, Kanazawa University, 7.Planetary Plasma and Atmospheric Research Center, Tohoku University, 8.Japan Aerospace Exploration Agency)

[PEM13-P18] Modulation of the D-region ionosphere by Pc5 waves observed by VLF/LF standard radio waves

*Miyashita Takuya[1], Hiroyo Ohya[1], Fuminori Tsuchiya[2], Hiroyuki Nakata[1], Toshiaki Takano[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3] (1.Chiba University, 2.Tohoku University, 3.Nagoya University)

[PEM13-P19] Oxygen-proton differences in ion energies dominating plasma pressure: Dependence on storm phases and solar wind drivers

*Kunihiro Keika[1], Satoshi Kasahara[1], Shoichiro Yokota[2], Masahiro Hoshino[1], Kanako Seki[1], Masahito Nose[3], Yoshizumi Miyoshi[3], Iku Shinohara[4] (1.Graduate School of Science, The University of Tokyo , 2.Graduate School of Science, Osaka University, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PEM13-P20] Mass dependence of penetration depth of multi-energy ions in the inner magnetosphere during magnetic storms: Arase observations

*Ryosuke Fujii[1], Yoshizumi Miyoshi[1], Masafumi Shoji[1], Kazushi Asamura[2], Lynn Kistler[1,8], Vania Jordanova[9], Tomoaki Hori[1], Satoshi Kurita[1], Mariko Teramoto[1], Yasunori Tsugawa[1], Yoshiya Kasahara[3], Yasumasa Kasaba[4], Atsushi Kumamoto[5], Fuminori Tsuchiya[4], Shoichiro Yokota[6], Kunihiro Keika[7], Ayako Matsuoka[2], Iku Shinohara[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Information Media Center, Kanazawa University, 4.Planetary Plasma and Atmospheric Research Center, Tohoku University, 5.Department of Geophysics, Graduate School of Science, Tohoku University, 6.Graduate School of Science, Osaka University, 7.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 8.University of New Hampshire, 9.Los Alamos National Laboratory)

[PEM13-P21] Relativistic Acceleration of Energetic Protons by Electromagnetic Ion Cyclotron Waves in the Jovian Magnetosphere

*Tomohiro Sekine[1], Yoshiharu Omura[1], Danny Summers[2], Yikai HSIEH[1], Satoko Nakamura[1] (1.Reserach Institute for Sustainable Humanosphere, Kyoto University, 2.Memorial University of Newfoundland)

[PEM13-P22] Statistical study of IPDP type EMIC wave-related electron precipitation at subauroral latitude

*Asuka Hirai[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Yasumasa Kasaba[1], Yuto Katoh[2], Hiroaki Misawa[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3], Satoshi Kurita[3], Martin G Connors[4] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku Univ. , 2.Department of Geophysics, Graduate School of Science, Tohoku University, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Athabasca University)

[PEM13-P23] Meridional distributions of proton plasma and pressure-driven currents in the nightside inner magnetosphere: Arase observations

*Shun Imajo[1], Masahito Nose[1], Satoshi Kasahara[2], Shoichiro Yokota[3], Ayako Matsuoka[4], Kunihiro Keika[2], Tomoaki Hori[1], Mariko Teramoto[1], Kazuhiro Yamamoto[5], Oimatsu Satoshi[5], Reiko Nomura[6], Akiko Fujimoto[7], Iku Shinohara[4], Yoshizumi Miyoshi[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Graduate School of Science, The University of Tokyo, 3.Graduate School of Science, Osaka University, 4.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 5.Graduate School of Science, Kyoto University, 6.National Astronomical Observatory of Japan, 7.Kyushu Institute of Technology)

[PEM13-P24] Space Weather Effects on Energetic Proton Flux Response in South Atlantic Anomaly

*Kirolosse Mina GIRGIS[1,2], Tohru Hada[1], Shuichi Matsukiyo[1] (1.Earth System Science and Technology (ESST) Department, Interdisciplinary Graduate School of Engineering Sciences (IGSES), Kyushu University, Japan, 2.Aerospace Engineering Department, Faculty of Engineering, Cairo University, Egypt)

[PEM13-P25] Solar-cycle variations of >30 keV electron flux enhancements under the inner radiation belt

*ALLA SUVOROVA[1] (1.National Central University)

[PEM13-P26] Energy spectra variations of high energy electrons in the inner magnetosphere observed by HEP/XEP on ARASE and SEDA-e on HIMAWARI

*Takeshi Takashima[1], Takefumi Mitani[1], Nana Higashio[2], Tsutomu Nagatsuma[3] (1. ISAS/JAXA, 2.Research and Development Directorate/JAXA, 3.NiCT)

[PEM13-P27] Inter-channel calibration of the high-energy electron experiments (HEP) instrument onboard the Arase satellite

*Tomoaki Hori[1], Takefumi Mitani[2], Takeshi Takashima[2], Park Inchun[1], Satoshi Kurita[1], Mariko Teramoto[1], Nana Higashio[3], Satoshi Kasahara[4], Shoichiro Yokota[5], Yoshizumi Miyoshi[1], Iku Shinohara[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science, 3.Japan Aerospace Exploration Agency, 4.Graduate School of Science, The University of Tokyo, 5.Graduate School of Science, Osaka University)

[PEM13-P28] Particle simulation for calibrating the HEP data onboard the ARASE satellite

*PARK INCHUN[1], Yoshizumi Miyoshi[1], Takefumi Mitani[2], Tomoaki Hori[1], Satoshi Kurita[1], Mariko Teramoto[1], Takeshi Takashima[2], Nana Higashio[3], Iku Shinohara[2] (1.Nagoya University Institute for Space-Earth Environmental Research, 2.Japan Aerospace Exploration Agency Institute of Space and Astronautical Science , 3.Japan Aerospace Exploration Agency)

[PEM13-P29] Geant4 model calculation and energetic particle observation with HEP/Arase in the inner radiation belt

*Honoka Toda[1], Wataru Miyake[1], Takefumi Mitani[3], Takeshi Takashima[3], Yoshizumi Miyoshi[2], PARK INCHUN[2], Tomoaki Hori[2] (1.Tokai University, 2.ISEE/Nagoya University, 3.ISAS/JAXA)

[PEM13-P30] Validation of High-energy electron detector simulator for the HEP instruments onboard Arase

*Takefumi Mitani[1], PARK INCHUN[2], Tomoaki Hori[2], Taku Namekawa[1,3], Kazushi Asamura[1], Takeshi Takashima[1], Satoshi Kasahara[3], Satoshi Kurita[2], Mariko Teramoto[2], Nana Higashio[1], Yoshizumi Miyoshi[2], Iku Shinohara[1] (1.Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science, 2.Institute for Space-Earth Environmental Research, Nagoya Univ., 3.The university of Tokyo)

[J] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-EM16] Physics and Chemistry in the Atmosphere and Ionosphere

convener:Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Takuya Tsugawa(National Institute of Information and Communications Technology), Seiji Kawamura(National Institute of Information and Communications Technology), Chairperson:Mitsumu Ejiri(国立極地研究所), Yuichi Otsuka

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PEM16-01] The model study of ionospheric variations during the solar eclipse event by assimulating the GNSS TEC observations

*Chia-Hung Chen[1], Charles Lin[1], Tomoko Matsuo[2] (1.Department of Earth Sciences, National Cheng Kung University, 2.Department of Aerospace Engineering Sciences, University of Colorado at Boulder, CO)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PEM16-02] Characteristics of mesoscale thermospheric-ionospheric dynamics associated with heating in the auroral region

*Tomokazu Oigawa[1], Hiroyuki Shinagawa[2], Satoshi Taguchi[1] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.National Institute of Information and Communications Technology)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PEM16-03] Spatial distribution of the polar thermospheric wind acceleration and importance of the 2D measurement

*Shin-ichiro Oyama[1,2,3], Anita Aikio[2], Mark G Conde[4], Heikki Vanhamaki[2], Ilkka Virtanen[2], Thomas Ulich[5], Urban Brandstrom[6], Pekka Verronen[7], Monika Andersson[7], Niilo Kalakoski[7], Lassi Roininen[8], Sari Lasanen[8], Abiyot Workayehu[2], Kazuo Shiokawa[1], Heqiucen XU[1], Mamoru Ishii[9], Masafumi Hirahara[1], Takeshi Sakanoi[10], Masato Kagitani[10], Juha Sorri[5], Tomi Teppo[5], Yoshimasa Tanaka[3], Christopher Fallen[4], Brenton J Watkins[4], Mikko Orispaa[5], Yasunobu Ogawa[3], Lei Cai[11], Esa Turunen[5], Kirsti Kauristie[7], Takuo T. Tsuda[12], Junichi Kurihara[13] (1.Institute for Space-Earth Environmental Research, Nagoya University, Japan, 2.University of Oulu, Finland, 3.National Institute of Polar Research, Japan, 4.Geophysical Institute, University of Alaska Fairbanks, US, 5.Sodankyla Geophysical Observatory, University of Oulu, Finland, 6.The Swedish Institute of Space Physics (IRF), Sweden, 7.Finnish Meteorological Institute, Finland, 8.Lappeenranta-Lahti University of Technology, Finland, 9.National Institute of Information and Communications Technology, Japan, 10.Tohoku University, Japan, 11.KTH Royal Institute of Technology, Sweden, 12.The University of Electro-Communications, 13.Hokkaido University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PEM16-04] Analysis of the thermospheric neutral wind vector using observed images of *Trimethylaluminium* (*C6H18Al2*) released from sounding rocket in the upper atmosphere

*Yuki Otsuka[1], Masa-yuki Yamamoto[1], Hiroaki Saito[1] (1.Kochi University of Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PEM16-05] Establishment of real-time analysis method in a new HRO interferometer system and operation test of comprehensive meteor observation

*Takumi Sato[1], Seiya Takeda[2], Masa-yuki Yamamoto[1] (1.KOCHI UNIVERSITY OF TECHNOLOGY, 2.Inc.Bascule)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PEM16-06] Solar flare effects of the D-region ionosphere using daytime tweek atmospherics

*Kodai Yamanobe[1], Hiroyo Ohya[2], Hiroyuki Nakata[2], Toshiaki Takano[2], Kazuo Shiokawa[3] (1.Graduate School of Science and Engineering, Chiba University , 2.Graduate School of Science and Engineering, Chiba University, 3.Institute for Space-Earth Environmental Research, Nagoya University)

[J] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A03 TOKYO BAY MAKUHARI HALL

[P-EM16] Physics and Chemistry in the Atmosphere and Ionosphere

convener:Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Takuya Tsugawa(National Institute of Information and Communications Technology), Seiji Kawamura(National Institute of Information and Communications Technology), Chairperson:Yuichi Otsuka, Mitsumu Ejiri(国立極地研究所)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PEM16-07] Toward a detection of sporadic-E episodes by ALOS2 ScaSAR InSAR

*Masato Furuya[1], Jun Maeda[2], Kosuke Heki[1] (1.Department of Earth and Planetary Sciences Hokkaido University, 2.Hokkaido University Library)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PEM16-08] Vertical fine structure and time evolution of plasma irregularities in the E_s layer, observed by a high resolution Ca^+ lidar

*Mitsumu K. Ejiri[1,2], Takuji Nakamura[1,2], Takuo T. Tsuda[3], Takanori Nishiyama[1,2], Makoto Abo[4], Toru Takahashi[1], Katsuhiko Tsuno[5], Takuya Kawahara[6], Takayo Ogawa[5], Satoshi Wada[5] (1.National Institute of Polar Research, 2.SOKENDAI (Department of Polar Science, The Graduate University for Advanced Studies), 3.The University of Electro-Communications, 4.Tokyo Metropolitan University, 5.RIKEN, RAP, 6.Shinshu University Faculty of Engineering)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PEM16-09] Study of Effects of Stratospheric Sudden Warming on Medium-Scale Traveling Ionospheric Disturbances Using Total Electron Content Data Obtained from World-Wide GPS Receiver Networks

*Yuichi Otsuka[1], Atsuki Shinbori[1], Prayitno Abadi[2], Takuya Tsugawa[3], Michi Nishioka[3] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.LAPAN, 3.National Institute of Information and Communications Technology)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PEM16-10] Tsunami-generated ionospheric currents inferred from geomagnetic observations at ground level: Case for the 2011 Tohoku Earthquake

*Takuto Minami[1], Masashi Kamogawa[2], Tsutomu Ogawa[1], Makoto Uyeshima[1], Toru Mogi[3], Hiroshi Ichihara[4] (1.Earthquake Research Institute,The University of Tokyo, 2.Department of Physics, Tokyo Gakugei University, 3.Graduate School of Engineering, Hokkaido University, 4.Graduate School of Environmental Studies, Nagoya University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PEM16-11] Relationship between the magnitude of Sakurajima eruptions and the disturbance of GPS-TEC

*Kiyoto Shoji[1], Hiroyuki Nakata[1], Toshiaki Takano[1], Hiroyo Ohya[1], Takuya Tsugawa[2], Michi Nishioka[2] (1.Graduate School of Science and Engineering, Chiba University, 2.National Institute of Information and Communications Technology)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PEM16-12] Water vapor estimation using digital terrestriall broadcasting waves - Simultaneous observation with microwave radiometer -

*Hiroshi HANADO[1], Seiji Kawamura[1], Hironori Iwai[1], Shinsuke Satoh[1], Katsuhiro Nakagawa[1], Takuya Tajiri[2], Narihiro Orikasa[2], Yoshinori Shoji[2], Kentaro Araki[2], Hiromu Seko[2] (1.National Institute of Information and Communications Technology, 2.Meteorological Research Institute)

[J] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 201A 2F

[P-EM18] Heliosphere and Interplanetary Space

convener:Ken Tsubouchi(University of Electro-Communications), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Kazumasa Iwai(Institute for Space?Earth Environmental Research (ISEE), Nagoya University), Chairperson:Yasuhiro Nariyuki, Kazumasa Iwai

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PEM18-01] Problems in determining structures of interplanetary magnetic flux ropes

*Katsuhide Marubashi[1], Yuki Kubo[1], Nobuhiko Nishimura[2], Munetoshi Tokumaru[2], Nada Al-Haddad[3] (1.National Institute of Information and Communications Technology , 2.ISEE, Nagoya University, 3.IACS, Catholic University of America)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PEM18-02] Validation of estimated interplanetary flux rope axial direction using internal plasma motions: benchmark test

*Nobuhiko Nishimura[1], Munetoshi Tokumaru[1], Katsuhide Marubashi[2] (1.Institute for Space Earth Environmental Research, 2.National Institute of Information and Communications Technology)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PEM18-03] Effect of line-of-sight integration on locations of coronal mass ejection in the sky projection map of interplanetary scintillation observations

*Munetoshi Tokumaru[1], Ken'ichi Fujiki[1], Kazumasa Iwai[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PEM18-04] Estimation of spatial structure of whistler mode wave packets in Earth’s bow shock by multiple spacecraft analysis

*Chika Umegaki[1], Takanobu Amano[1], Naritoshi Kitamura[1] (1.The university of tokyo)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PEM18-05] Experimental Test for Stochastic Shock Drift Acceleration Theory

*Takanobu Amano[1], Takuma Katou[1], Naritoshi Kitamura[1], Mitsuo Oka[2], Yosuke Matsumoto[3], Masahiro Hoshino[1] (1.Department of Earth and Planetary Science, University of Tokyo, 2.Space Sciences Laboratory, University of California, Berkeley, 3.Department of Physics, Chiba University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PEM18-06] Radial structure of heliospheric boundary region

*Shuichi Matsukiyo[1], Gary P. Zank[2], Haruichi Washimi[3], Tohru Hada[1] (1.Faculty of Engineering Sciences, Kyushu University, 2.The Center for Space Plasma and Aeronomic Research, University of Alabama in Huntsville, 3.International Center for Space Weather Science and Education, Kyushu University)

[J] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-EM18] Heliosphere and Interplanetary Space

convener:Ken Tsubouchi(University of Electro-Communications), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Kazumasa Iwai(Institute for Space?Earth Environmental Research (ISEE), Nagoya University)

[PEM18-P01] Study of the contribution of electric field to the acceleration of cometary ions around comet 67P/Churyumov-Gerasimenko

*Kazuki Yamagishi[1], Yuto Katoh[1], Tomoki Kimura[1], Atsushi Kumamoto[1] (1.Department of Geophysics, Graduate School of Science, Tohoku University)

[PEM18-P02] Energy conversion process at the lunar wake boundary

*Tomoko Nakagawa[1], Hideo Tsunakawa[2], Yoshifumi Saito[3] (1.Information and Communication Engineering, Tohoku Institute of Technology, 2.Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology , 3.JAXA,ISAS)

[PEM18-P03] Electron acceleration at quasi-perpendicular collisionless shock: One-dimensional PIC simulation

*Fumiko Otsuka[1], Shuichi Matsukiyo[2], Mitsuo Oka[3] (1.NIT, Kurume College, 2.ESST, Kyushu Univ., 3.UC Berkeley)

[PEM18-P04] 4-season's optical observation of neutral helium distribution in interplanetary space by Hisaki

*Atsushi Yamazaki[1], Go Murakami[1], Kazuo Yoshioka[2], Tomoki Kimura[3], Fuminori Tsuchiya[4], Masato Kagitani[4], Takeshi Sakanoi[4], Naoki Terada[5], Yasumasa Kasaba[4], Ichiro Yoshikawa[6], Hisaki (SPRINT-A) Project team (1.Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science , 2.The University of Tokyo, Graduate School of Frontier Sciences, 3.Tohoku University, 4.Tohoku University, Planetary Plasma and Atmospheric Research Center , 5.Tohoku University, Graduate School of Sciense, 6.The University of Tokyo)

[PEM18-P05] Structural variations in the pickup ion density associated with magnetic reconnection at the heliopause

*Ken Tsubouchi[1] (1.University of Electro-Communications)

[J] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

[P-EM18] Heliosphere and Interplanetary Space

convener:Ken Tsubouchi(University of Electro-Communications), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Kazumasa Iwai(Institute for Space?Earth Environmental Research (ISEE), Nagoya University)

[PEM18-P01] Study of the contribution of electric field to the acceleration of cometary ions around comet 67P/Churyumov-Gerasimenko

*Kazuki Yamagishi[1], Yuto Katoh[1], Tomoki Kimura[1], Atsushi Kumamoto[1] (1.Department of Geophysics, Graduate School of Science, Tohoku University)

[PEM18-P02] Energy conversion process at the lunar wake boundary

*Tomoko Nakagawa[1], Hideo Tsunakawa[2], Yoshifumi Saito[3] (1.Information and Communication Engineering, Tohoku Institute of Technology, 2.Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology , 3.JAXA,ISAS)

[PEM18-P03] Electron acceleration at quasi-perpendicular collisionless shock: One-dimensional PIC simulation

*Fumiko Otsuka[1], Shuichi Matsukiyo[2], Mitsuo Oka[3] (1.NIT, Kurume College, 2.ESST, Kyushu Univ., 3.UC Berkeley)

[PEM18-P04] 4-season's optical observation of neutral helium distribution in interplanetary space by Hisaki

*Atsushi Yamazaki[1], Go Murakami[1], Kazuo Yoshioka[2], Tomoki Kimura[3], Fuminori Tsuchiya[4], Masato Kagitani[4], Takeshi Sakanoi[4], Naoki Terada[5], Yasumasa Kasaba[4], Ichiro Yoshikawa[6], Hisaki (SPRINT-A) Project team (1.Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science , 2.The University of Tokyo, Graduate School of Frontier Sciences, 3.Tohoku University, 4.Tohoku University, Planetary Plasma and Atmospheric Research Center , 5.Tohoku University, Graduate School of Sciense, 6.The University of Tokyo)

[PEM18-P05] Structural variations in the pickup ion density associated with magnetic reconnection at the heliopause

*Ken Tsubouchi[1] (1.University of Electro-Communications)

[J] Oral | P (Space and Planetary Sciences)：P-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 105 1F

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan), Chairperson:Takayuki Muto

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PCG24-01] Understanding solar atmosphere by ALMA observations

★Invited Papers

*Tomoko Kawate[1], Takenori J Okamoto[2], Kazumasa Iwai[3], Satoshi Masuda[3], Masumi Shimojo[2] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.National Astronomical Observatory of Japan, 3.Nagoya University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PCG24-02] **Multi-thermal structures in a spicule observed with ALMA, IRIS, and AIA/SDO**

*Masumi Shimojo[1], Tomoko Kawate[2], Takenori Okamoto[1], Takaaki Yokoyama[3] (1.National Astronomical Observatory of Japan, 2. Institute of Space and Astronautical Science , 3.University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PCG24-03] Observing the 2018 global dust storm on Mars with ALMA

Shohei Aoki[2], *Hideo Sagawa[1], Kazi Rigl[3], Geronimo L. Villanueva[4], Bill Dent[5], Hiroyuki Maezawa[6], Severine Robert[2], Hiromu Nakagawa[7], Frank Daerden[2], Takeshi Kuroda[8], Marco Giuranna[10], Kazuya Saigo[9], Michael J. Mumma[4], Yasumasa Kasaba[7], Ann Carine Vandaele[2] (1.Kyoto Sangyo University, 2.Royal Belgian Institute for Space Aeronomy, 3.Italian ALMA Regional Centre, INAF-Istituto di Radioastronomia, 4.NASA Goddard Space Flight Center, USA, 5.ESO ALMA, Chile, 6.Osaka Prefecture University, 7.Tohoku University, 8.NICT Big Data Integration Research Center, 9.NAOJ Chile Observatory, 10.Istituto di Astrofisica e Planetologia Spaziali, Italy)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PCG24-04] Atmospheric observation of submillimeter wave and the thermal evolution of ice giants

★Invited Papers

*Kenji Kurosaki[1], Masahiro Ikoma[2] (1.Department of Physics, Nagoya University , 2.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

10:00 AM - 10:30 AM JST | 1:00 AM - 1:30 AM UTC

[PCG24-05] Planetary-system formation revealed with ALMA

★Invited Papers

*Misato Fukagawa[1] (1.National Astronomical Observatory of Japan)

[J] Oral | P (Space and Planetary Sciences)：P-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 105 1F

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan), Chairperson:Munetake MOMOSE(Ibaraki University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PCG24-06] Probing dust aggregate structure in protoplanetary disks by millimeter-wave polarization

*Ryo Tazaki[1], Hidekazu Tanaka[1], Takayuki Muto[2], Akimasa Kataoka[3], Satoshi Okuzumi[4] (1.Tohoku University, 2.Kogakuin University, 3.NAOJ, 4.Tokyo Institute of Technology)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PCG24-07] A CONSTRAINT ON THE AMOUNT OF HYDROGEN FROM THE CO CHEMISTRY IN DEBRIS DISKS

*Hiroshi Kobayashi[1], Kazunari Iwasaki[2,4], Aya Higuchi[3] (1.Department of Physics, Nagoya University, 2.NAOJ, 3.RIKEN, 4.Osaka University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PCG24-08] Structure of the protoplanetary disk around V1094 Sco obtained from dust continuum emission and SED

*Sanemichi Takahashi[1,2], Takayuki Muto[1], Takashi Tsukagoshi[2], Jun Hashimoto[2] (1.Kogakuin University, 2.NAOJ)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PCG24-09] The Synthetic ALMA Multiband Analysis of the Dust Properties of the TW Hya Protoplanetary Disk

*Seongjoong Kim[1], Hideko Nomura[1], Takashi Tsukagoshi[2], Ryohei Kawabe[2,3,4], Takayuki Muto[5] (1.Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 2.National Astronomical Observatory of Japan, 3.The Graduate University for Advanced Studies (SOKENDAI), 4.Department of Astronomy, School of Science, University of Tokyo, 5.Division of Liberal Arts, Kogakuin University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PCG24-10] Dust evolution in the protoplanetary disk around TW Hya

*Takayuki Matsuura[1], Satoshi Okuzumi[1] (1.Tokyo Institute of Technology)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PCG24-11] Discovery of a localized excess in the millimeter emission of the protoplanetary disk around TW Hya

*Takashi Tsukagoshi[1], Takayuki Muto[2], Hideko Nomura[3], Ryohei Kawabe[1,4,5], Kazuhiro Kanagawa[9], Satoshi Okuzumi[3], Shigeru Ida[10], Catherine Walsh[6], Tom J Millar[7], Sanemichi Takahashi[2,1], Jun Hashimoto[8], Taichi Uyama[5], Motohide Tamura[5,8] (1.Division of Radio Astronomy, National Astronomical Observatory of Japan, 2.Division of Liberal Arts, Kogakuin University, 3.Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 4.The Graduate University for Adnvanced Studies, 5.School of Science, University of Tokyo, 6.School of Physics and Astronomy, University of Leeds, 7.Astrophysics Research Centre, Queen's University Belfast, 8.Astrobiology Center, National Institutes of Natural Sciences, 9.Research Center for the Early Universe, University of Tokyo, 10.Earth-Life Science Institute, Tokyo Institute of Technology)

[J] Poster | P (Space and Planetary Sciences)：P-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan)

[PCG24-P01] Nitrogen isotopic fractionation on Titan atmosphere: An analysis of ALMA archive data

*Hideo Sagawa[1], Takahiro Iino[2], Takashi Tsukagoshi[3] (1.Kyoto Sangyo University, 2.Tokyo University of Agriculture and Technology, 3.National Astronomical Observatory of Japan)

[PCG24-P02] Investigating the gas-to-dust ratio in the protoplanetary disk of HD 142527

*Soon Kang-Lou[1], Munetake Momose[1], Takayuki Muto[2], Takashi Tsukagoshi[3], Akimasa Kataoka[3], Tomoyuki Hanawa[4], Misato Fukagawa[3], Kazuya Saigo[3], Hiroshi Shibai[5] (1.Ibaraki University, 2.Kogakuin University, 3.National Astronomical Observatory of Japan, 4.Chiba University, 5.Osaka University)

[PCG24-P03] Super-resolution Imaging of the Protoplanetary Disk HD 142527 Using Sparse Modeling

*Masayuki Yamaguchi[1,2], Kazunori Akiyama[3,2], Akimasa Kataoka[2,6], Takashi Tsukagoshi[2], Takayuki Muto[4], Shiro Ikeda[5], Misato Fukagawa[2], Mareki Honma[2,6], Ryohei Kawabe[2,1,6] (1.The University of Tokyo, 2.National Astronomical Observatory of Japan, 3.Massachusetts Institute of Technology, Haystack Observatory, 4.Kogakuin University, 5.The Institute of Statistical Mathematics, 6. Graduate University for Advanced Studies)

[PCG24-P04] Detail Structures of Dust Disk around T-Tauri star RY Tau in ALMA High-Spatial Resolution Imaging

*Mihoko Konishi[1,2], Jun Hashimoto[1,2], Hauyu Liu[3], Ruobing Dong[4], Takayuki Muto[5] (1.Astrobiology Center, National Institute of Natural Science, 2.National Astronomical Observatory of Japan, 3.Institute of Astronomy and Astrophysics, Academia Sinica, 4.University of Victoria, 5.Kogakuin University)

[PCG24-P05] Possible inclined inner protoplanetary disk

*Jun Hashimoto[1], Mihoko Konishi[1], Taichi Uyama[2], Christian Ginski[3], Matthias Samland[4] (1.AstroBiology Center, National Institutes of Natural Sciences, 2.University of Tokyo, 3.University of Amsterdam, 4.Max Planck Institute for Astronomy)

[PCG24-P06] Search for the Inner Disk Structures in "Transitional" Disks

*Takayuki Muto[1], Jun Hashimoto[2], Takashi Tsukagoshi[3], Mihoko Konishi[3], Tomoyuki Kudo[3] (1.Division of Liberal Arts, Kogakuin University, 2.Astrobiology Center, 3.NAOJ)

[J] Poster | P (Space and Planetary Sciences)：P-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 104 1F

[A-AS01] High performance computing for next generation weather, climate, and environmental sc iences

convener:Hiromu Seko(Meteorological Research Institute), Takemasa Miyoshi(RIKEN), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology), Masayuki Takigawa(Japan Agency for Marine-Earth Science and Technology), Chairperson:Hiromu Seko(Meteorological Research Institute), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AAS01-01] Data Assimilation Studies using Big Observation Data in the Projects of Post K and BDA

*Hiromu Seko[1], Masaru Kunii[2], Yohei Sawada[1], Kozo Okamoto[1], Sho Yokota[1], Kosuke Ito[3], Kazuki Shimoji[2] (1.Meteorological Research Institute, 2.Japan Meteorological Agency, 3.University of the Ryukyus)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AAS01-02] **High-resolution Numerical Weather Simulation with a Large Domain for Extreme Heavy Rainfall Events**

*Tsutao OIZUMI[1,2], Kazuo Saito[4,3], le duc[1], Junshi Ito[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.Meteorological Research Institute, 3.The Atmosphere and Ocean Research Institute, 4.Japan Meteorological Business Support Center)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AAS01-03] A Numerical Case Study on a Tornado that Formed in a Quasi Linear Convective System

★Invited Papers

*Eigo Tochimoto[1], Hiroshi Niino[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AAS01-04] Improving the observation operator for Phased Array Weather Radar in the SCALE-LETKF system

*Arata Amemiya[1], Takumi Honda[1], Takemasa Miyoshi[1] (1.RIKEN Center for Computational Science)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AAS01-05] Data assimilation and forecast experiments for the record-breaking rainfall event in Japan in July 2018 with NICAM-LETKF at 112-km and 28-km resolution

*Koji Terasaki[1], Takemasa Miyoshi[1] (1.RIKEN Center for Computational Science)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AAS01-06] Model Parameter Estimation with Data Assimilation Using NICAM-LETKF

★Invited Papers

*Shunji Kotsuki[1], Yousuke Sato[2], Koji Terasaki[1], Hasashi Yashiro[1], Hirofumi Tomita[1], Masaki Satoh[3], Takemasa Miyoshi[1] (1.RIKEN Center for Computational Science, 2.Graduate School of Engineering, Nagoya University, 3.Atmosphere and Ocean Research Institute, the University of Tokyo)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 104 1F

[A-AS01] High performance computing for next generation weather, climate, and environmental sc iences

convener:Hiromu Seko(Meteorological Research Institute), Takemasa Miyoshi(RIKEN), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology), Masayuki Takigawa(Japan Agency for Marine-Earth Science and Technology), Chairperson:Masayuki Takigawa(Japan Agency for Marine-Earth Science and Technology), Takemasa Miyoshi(RIKEN Advanced Institute for Computational Science)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AAS01-07] 3D debris flow simulations by using smoothed particle hydrodynamics (SPH) method

*Shoji Ueta[1], Natsuki Hosono[2], Yosuke Alexandre Yamashiki[1] (1.Kyoto University, 2.JAMSTEC)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AAS01-08] **Regional atmospheric data assimilation coupled with an ocean mixed layer model: a case of typhoon Soudelor (2015)**

*Kohei Takatama[1], Takumi Honda[1], Takemasa Miyoshi[1] (1.RIKEN)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AAS01-09] Effective Radiative Forcing and Climate Response to Short-Lived Climate Pollutants Under Different Scenarios

Hua Zhang[1], *Bing Xie[1], Zhili Wang[1] (1.China Meteorological Administration)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AAS01-10] **The NICAM–SPRINTARS simulation of the long-range transport of black carbon using the K computer**

★Invited Papers

*Yousuke Yamashita[1], Masayuki Takigawa[1], Daisuke Goto[2], Hisashi Yashiro[3], Masaki Satoh[4,1], Yugo Kanaya[1], Fumikazu Taketani[1], Takuma Miyakawa[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute for Environmental Studies, 3.RIKEN Advanced Institute for Computational Science (AICS), 4.Atmosphere and Ocean Research Institute, The University of Tokyo)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AAS01-11] High-resolution, ensemble simulations of intense tropical cyclones and their stochasticity during the El Niños of 1997 and 2015

*Yohei Yamada[1], Chihiro Kodama[1], Masaki Satoh[1,2], Masuo Nakano[1], Tomoe Nasuno[1], Masato Sugi[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere and Ocean Research Institute, The university of Tokyo, 3.Meteorological Research Institute, Japan Meteorological Agency)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AAS01-12] **NICAM results of the project DYAMOND for global storm-resolving model intercomparison**

★Invited Papers

*Masaki Satoh[1], Ryosuke Shibuya[2], Chihiro Kodama[2] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.JAMSTEC)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[A-AS01] High performance computing for next generation weather, climate, and environmental sc iences

convener:Hiromu Seko(Meteorological Research Institute), Takemasa Miyoshi(RIKEN), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology), Masayuki Takigawa(Japan Agency for Marine-Earth Science and Technology)

[AAS01-P01] **Categorized correction forecast for accumulative precipitation of heavy rainfall processes based on optimal probability (OPPF) in medium-extended-range forecast time**

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 102 1F

[A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Fumiko Nakagawa(名古屋大学)

9:00 AM - 9:30 AM JST | 12:00 AM - 12:30 AM UTC

[AAS04-01] Reconstruction and fluctuation mechanism of past aerosols preserved in ice cores

★Invited Papers

*Iizuka Yoshinori[1], Ryu Uemura[2], Koji Fujita[3], Shohei Hattori[4], Osamu Seki[1], Naga Oshima[5], Hiroshi Ohno[6], Sumito Matoba[1] (1.Institite of Low Temperature Science, Hokkaido University, 2.Department of Chemistry, Biology, and Marine Science, Faculty of Science, University of the Ryukyus, 3.Graduate School of Environmental Studies, Nagoya University, 4.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology,, 5.Meteorological Research Institute, 6.Kitami Institute of Technology)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AAS04-02] The 60 years history of atmospheric formation pathways responsible for sulfate based on triple oxygen isotopic composition of sulfate preserved in SE-Dome ice core

*Shohei Hattori[1], Iizuka Yoshinori[2], Koji Fujita[3], Ryu Uemura[4], Sakiko Ishino[1], Naga Oshima[5], Nozomi Suzuki[1], Sumito Matoba[2], Asuka Tsuruta[1], Joel Savarino[6], Naohiro Yoshida[1] (1.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 2.Institute of Low Temperature Science, Hokkaido University, 3.Graduate School of Environmental Studies, Nagoya University, Nagoya, Japan., 4.Department of Chemistry, Biology, and Marine Science, Faculty of Science, University of the Ryukyus, 5.Meteorological Research Institute, 6.Institut des Geoscience de l'Environnement, Universite Grenoble Alpes/CNRS)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AAS04-03] Estimation of high sulfate aerosol sources in 2012 spring at Cape Hedo, Okinawa

*Syuichi Itahashi[1], Shiro Hatakeyama[2], Kojiro Shimada[3], Akinori Takami[4] (1.Central Research Institute of Electric Power Industry, 2.Center for Environmental Science in SaitamaCenter for Environmental Science in Saitama, 3.School of Creative Science and Engineering, Waseda University, 4.National Institute for Environmental Studies)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AAS04-04] Isotopic constrains on sources and formation pathways of atmospheric nitrate in Mt. Everest

*Kun Wang[1,2,4], Shohei Hattori[2], Shichang Kang[1,3,4], Mang Lin[2], Naohiro Yoshida[2,5] (1.Northwest Institute of Eco-Environment and Resources, Chinese Academy of Sciences , 2.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 3.CAS Center for Excellence in Tibetan Plateau Earth Sciences, 4.University of Chinese Academy of Sciences, 5. Earth-Life Science Institute, Tokyo Institute of Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AAS04-05] Development of a large volume sampling system for measuring stable isotope analysis of carbonyl sulfide and field observation

*Kazuki Kamezaki[1], Shohei Hattori[1], Naohiro Yoshida[1,2] (1.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 4259 Nagatsuta-cho, Midori-ku, Yokohama, Kanagawa 226-8502, Japan, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 2-12-1-IE-1 Ookayama, Meguro-ku, Tokyo 152-8550, Japan)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 102 1F

[A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Takashi Maki(気象研究所)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[AAS04-06] Observations of aerosol optical properties by sky radiometers at SKYNET Southeast and South Asian sites

*Al Mashroor Fatmi[1], Hitoshi Irie[1], Hossain Mohammed Syedul Hoque[1], Alessandro Damiani[1], Pradeep Khatri[2], Tamio Takamura[1], Thanawat Jurupongsaku[3], Govindan Pandithurai[4] (1.Center for Environmental Remote Sensing Chiba University , 2.Tohoku University, 3.Chulalongkorn University, 4.Indian Institute of Tropical Metereology)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[AAS04-07] Analysis of factors causing variations in the absorption Ångström exponent of aerosols in Japan using skyradiometers

*Kodai Yamaguchi[1], Hitoshi Irie[1], Pradeep Khatri[2], Toshihiko Takemura[3], Hirokazu Yamamoto[4] (1.Chiba University, 2.Tohoku University, 3.Kyushu University, 4.National Institute of Advanced Industrial Science and Technology)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[AAS04-08] Sources of atmospheric black carbon and related carbonaceous components at Rishiri Island, Japan

*Chunmao Zhu[1], Yugo Kanaya[1], Hisayuki Yoshikawa[2], Tomohisa Irino[2], Osamu Seki[2], Yasunori Tohjima[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.Hokkaido University, 3.National Institute for Environmental Studies)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[AAS04-09] Black Carbon and Inorganic Aerosols in Snowpack over the Arctic

*Tatsuhiro Mori[1], Kumiko Goto-Azuma[2,3], Yutaka Kondo[2], Yoshimi Ogawa-Tsukagawa[2], Kazuhiko Miura[1], Motohiro Hirabayashi[2], Naga Oshima[4], Makoto Koike[5], Kaarle Kupiainen[6], Nobuhiro Moteki[5], Sho Ohata[7], Sinha Puna Ram[8], Konosuke Sugiura[9], Teruo Aoki[10], Martin Schneebeli[11], Konrad Steffen[11], Atsushi Sato[12], Akane Tsushima[13], Vladimir Makarov[14], Satoshi Omiya[15,16], Atsuko Sugimoto[17], Shinya Takano[17] (1.Tokyo University of Science, 2.National Institute of Polar Research, 3.The Graduate University for Advanced Studies, 4.Meteorological Research Institute, 5.Depertment of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 6.Environmental Protection Department Ministry of the Environment, 7.Institute for Space–Earth Environmental Research (ISEE), Nagoya University, 8.Department of Space Indian Space Research Organization, 9.University of Toyama, 10.Okayama University, 11.WSL Institute for Snow and Avalanche Research, 12.former Snow and Ice Research Center, 13.Reserach Institute for Humanity and Nature, 14.Melnikov's Permafrost Institute, 15.Institute of Low Temperature Science, Hokkaido University, 16.Civil Engineering Research Institute for Cold Region, 17.Graduate School of Environmental Science, Hokkaido University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[AAS04-10] The single-particle extinction and scattering method for online characterization of submicron particles: Principles and applications to aerosol research

*Nobuhiro Moteki[1] (1.The Univerisity of Tokyo)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[AAS04-11] High spatial resolution vehicular emissions inventory for China using VEIN model

*Sergio Ibarra Espinosa[1], Xuelei Zhang[1], Aijun Xiu[1], Edmilson Dias de Freitas[2] (1.Research Group of Regional Atmospheric Environment, Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, P. R. China, 2.Department of Atmospheric Sciences, University of São Paulo, Brazil.)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 102 1F

[A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Kentaro Ishijima(気象研究所)

3:30 PM - 4:00 PM JST | 6:30 AM - 7:00 AM UTC

[AAS04-12] Effect of land use change on GHG fluxes of tropical peat forests in Borneo island

★Invited Papers

*Ryuichi Hirata[1], Habura Borjigin[1], Tomohiro Shiraishi[1], Takashi Hirano[2], Lulie Melling[3] (1.National Institute for Environmental Studies, 2.Hokkaido University, 3.Sarawak Tropical Peat Research Institute)

4:00 PM - 4:30 PM JST | 7:00 AM - 7:30 AM UTC

[AAS04-13] Remote sensing of carbon assimilation function of terrestrial ecosystem by Earth-observation satellite

★Invited Papers

*Hibiki M Noda[1], Yukio Yoshida[1], Haruki Oshio[1], Tomoki Kiyono[1], Tatsuya Miyauchi[1], Tsuneo Matsunaga[1] (1.NIES National Institute of Environmental Studies)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AAS04-14] Analysis of the carbon dioxide in the upper troposphere and lower stratosphere by the data from GOSAT TANSO-FTS TIR

*Nawo Eguchi[1], Akihiro Honda[1], Naoko Saitoh[2], Yosuke Niwa[3] (1.Kyushu University, 2.Chiba University, 3.National Institute for Environmental Studies)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AAS04-15] Seasonal and interannual variations of the Atmospheric Potential Oxygen over the Western North Pacific observed by using a cargo aircraft C-130H

*Shigeyuki Ishidoya[1], Kazuhiro Tsuboi[2], Yosuke Niwa[3], Shohei Murayama[1], Hidekazu Matsueda[2], Yousuke Sawa[2], Nobuyuki Aoki[1], Kentaro Ishijima[2], Kentaro Kozumi[4], Genta Umezawa[4], Kazuya Yukita[4], Shigeharu Nishida[4], Megumi Yamamoto[4] (1.National Institute of Advanced Industrial Science and Technology (AIST), 2.Meteorological Research Institute, 3.National Institute for Environmental Studies, 4.Japan Meteorological Agency)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 201B 2F

[A-AS05] Stratosphere-troposphere Processes And their Role in Climate

convener:Yoshio Kawatani(Japan Agency for Marine-Earth Science and Technology), Shingo Watanabe(Japan Agency for Marine-Earth Science and Technology), Takashi Sekiya(Japan Agency for Marine-Earth Science and Technology), Kaoru Sato(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Chairperson:Watanabe Shingo(海洋研究開発機構)

9:10 AM - 9:40 AM JST | 12:10 AM - 12:40 AM UTC

[AAS05-01] Turbulent kinetic energy dissipation rates depending on the polar vortex and on synoptic-scale disturbances in the UTLS region in the Antarctic

★Invited Papers

*Masashi Kohma[1], Kaoru Sato[1], Koji Nishimura[2], Masaki Tsutsumi[2] (1.Department of Earth and Planet Science, Graduate School of Science, The University of Tokyo, 2.National Institute of Polar Research and The Graduate University for Advanced Studies (SOKENDAI))

9:40 AM - 9:55 AM JST | 12:40 AM - 12:55 AM UTC

[AAS05-02] Momentum budget of semiannual oscillation around the tropical stratopause

*Yoshihiro Tomikawa[1,2], V. Lynn Harvey[3], John A. Knox[4], Masatomo Fujiwara[5] (1.National Institute of Polar Research, 2.SOKENDAI, 3.University of Colorado Boulder, 4.University of Georgia, 5.Hokkaido University)

9:55 AM - 10:10 AM JST | 12:55 AM - 1:10 AM UTC

[AAS05-03] A study on sources of gravity waves that reach the summer stratosphere and mesosphere based on high-resolution radiosonde data

*Haruka Okui[1], Masashi Kohma[1], Kaoru Sato[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

10:10 AM - 10:25 AM JST | 1:10 AM - 1:25 AM UTC

[AAS05-04] Stratospheric initial conditions provide seasonal predictability of the North Atlantic and Arctic Oscillations

*Yu Nie[1], Adam Scaife[2,3], Hong-Li Ren[1,4], Ruth Comer[2], Martin Andrews[2] (1.Laboratory for Climate Studies, National Climate Center, China Meteorological Administration, Beijing, China, 2.Met Office Hadley Centre, Exeter, UK, 3.College of Engineering, Mathematics and Physical Sciences, University of Exeter, Exeter, UK, 4.Department of Atmospheric Science, School of Environmental Studies, China University of Geoscience, Wuhan, China)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 201B 2F

[A-AS05] Stratosphere-troposphere Processes And their Role in Climate

convener:Yoshio Kawatani(Japan Agency for Marine-Earth Science and Technology), Shingo Watanabe(Japan Agency for Marine-Earth Science and Technology), Takashi Sekiya(Japan Agency for Marine-Earth Science and Technology), Kaoru Sato(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Chairperson:Takashi Sekiya

10:45 AM - 11:15 AM JST | 1:45 AM - 2:15 AM UTC

[AAS05-05] Transport of trace gases into the extratropical upper troposphere/lower stratosphere

★Invited Papers

*Yoichi Inai[1], Ryo Fujita[2,1], Toshinobu Machida[3], Hidekazu Matsueda[4], Yousuke Sawa[4], Kazuhiro Tsuboi[4], Keiichi Katsumata[3,5], Shinji Morimoto[1], Shuji Aoki[1], Takakiyo Nakazawa[1] (1.Tohoku Univ., 2.Imperial College London, 3.NIES, 4.MRI, 5.Takachiho Chem. Industrial)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AAS05-06] Possible impacts of stratospheric ozone on circulation changes in the tropical tropposphere following a stratospheric sudden warming event

*Makoto Deushi[1] (1.Department of Atmospheric Environment and Applied Meteorology, Meteorological Research Institute)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AAS05-07] **Stratosphere-troposphere exchange of ozone and carbon monoxide over the northern Pacific Ocean in northern winter using two chemical reanalysis data sets**

*Haosen Xi[1], Masatomo Fujiwara[1], Kazuyuki Miyazaki[2] (1.Graduate School of Environmental Science, Hokkaido University, 2.NASA Jet Propulsion Laboratory, California Institute of Technology, USA)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AAS05-08] **Inter-comparison of Upper Air Temperature in China between Satellite MSU and Radiosonde Datasts**

*Yanjun GUO[1], Cheng-zhi Zou[2], Panmao Zhai[3], Guofu Wang[1] (1.National Climate Center(NCC), China Meteorological Administration(CMA) , 2.Center for Satellite Applications and Research, NOAA/NESDIS, 3.Chinese Academy of Meteorolgical Sciences (CAMS), China Meteorological Administration (CMA))

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AAS05-09] Environmental Characterization of the Atmosphere Using WACCM-X

*Rose Tseng[1], Michelle Kanipe[1], Brian Urbancic[1], Robert Tournay[1], Omar Nava[1], Daniel Emmons[1], Robert Loper[1], Charlton Lewis[1] (1.Air Force Institute of Technology)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 201B 2F

[A-AS05] Stratosphere-troposphere Processes And their Role in Climate

convener:Yoshio Kawatani(Japan Agency for Marine-Earth Science and Technology), Shingo Watanabe(Japan Agency for Marine-Earth Science and Technology), Takashi Sekiya(Japan Agency for Marine-Earth Science and Technology), Kaoru Sato(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Chairperson:Yoshio Kawatani

1:45 PM - 2:15 PM JST | 4:45 AM - 5:15 AM UTC

[AAS05-10] Diagnostics of a WN2-type major sudden stratospheric warming event in February 2018 using a new three-dimensional wave activity flux

★Invited Papers

*Yayoi Harada[1], Kaoru Sato[2], Takenari Kinoshita[3], Ryosuke Yasui[2], Toshihiko Hirooka[4], Hiroaki Naoe[1] (1.Meteorological Research Institute, 2.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 3.Japan Agency for Marine-Earth Science and Technology, 4.Department of Earth and Planetary Sciences, Kyushu University)

2:15 PM - 2:45 PM JST | 5:15 AM - 5:45 AM UTC

[AAS05-11] Response of the Southern Hemisphere atmosphere to the QBO from winter to early summer

★Invited Papers

*Yousuke Yamashita[1], Hiroaki Naoe[2], Makoto Inoue[3], Masaaki Takahashi[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.Meteorological Research Institute, 3.Akita Prefectural University, 4.National Institute for Environmental Studies)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[AAS05-12] Influence of QBO-like Oscillation on Tropical Convective Systems in a Three-Dimensional Minimal Model Framework of the Stratosphere-Troposphere Coupled System

*Shigeo Yoden[1], Hai Bui[2], Takahiro Banno[1] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2.Geophysical Institute, University of Bergen)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[AAS05-13] Downward Propagation of Planetary Wave Packets from the Stratosphere to the Troposphere During Northern Hemisphere Winter

*Matsuyama Yuya[1], Toshihiko Hirooka[2] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

[A-AS05] Stratosphere-troposphere Processes And their Role in Climate

convener:Yoshio Kawatani(Japan Agency for Marine-Earth Science and Technology), Shingo Watanabe(Japan Agency for Marine-Earth Science and Technology), Takashi Sekiya(Japan Agency for Marine-Earth Science and Technology), Kaoru Sato(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

[AAS05-P01] **An advanced impact of Arctic stratospheric ozone changes on spring precipitation in China**

*Fei Xie[1] (1.Beijing Normal University)

[AAS05-P02] Global Cooling System installed on the beach by means of Artificial Convection and Artificial Rain

*Murakami Hideyo[1] (1.Ii Ecology Development)

[AAS05-P03] Stratospheric front-like temperature structure and gravity wave activity during a stratospheric sudden warming event in 2016

*Yukari Sumi[1], Kaoru Sato[1] (1.University of Tokyo)

[AAS05-P04] The effects of a well-resolved stratosphere on the simulated boreal winter circulation in a climate model

*Yoshio Kawatani[1], Kevin Hamilton[2], Lesley J. Gray[3], Scott M. Osprey[3], Shingo Watanabe[1], Yousuke Yamashita[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.International Pacific Research Center, University of Hawaii, 3.Atmospheric, Oceanic and Planetary Physics, Department of Physics, University of Oxford)

[AAS05-P05] On the relation between three-dimensional wave activity flux and pseudo momentum without using intrinsic phase velocities

★Invited Papers

*Takenari Kinoshita[1] (1.Japan Agency for Marine-Earth Science and Technology)

[AAS05-P06] Hindcasts of the 2016 Disruption of the Stratospheric Quasi-biennial Oscillation

*Shingo Watanabe[1], Kevin Hamilton[2], Scott Osprey[3], Yoshio Kawatani[1], Eriko Nishimoto (1.Japan Agency for Marine-Earth Science and Technology, 2.International Pacific Research Center, University of Hawaii at Manoa, 3.NCAS-Climate, University of Oxford)

[AAS05-P07] Selection bias of quasi-fixed-point observations in the ExUTLS and its impact on the seasonal record

*Yoichi Inai[1], Toshinobu Machida[2], Hidekazu Matsueda[3], Yousuke Sawa[3], Kazuhiro Tsuboi[3], Keiichi Katsumata[2,4], Shinji Morimoto[1], Shuji Aoki[1], Takakiyo Nakazawa[1], Ryo Fujita[5,1] (1.Tohoku Univ., 2.NIES, 3.MRI, 4.Takachiho Chem. Industrial, 5.Imperial College London)

[AAS05-P08] Varying Rossby Wave Trains from the Developing to Decaying Period of the Upper Atmospheric Heat Source over the Tibetan Plateau in Boreal Summer

*Chuandong Zhu[1,2], Rongcai Ren[1] (1.Institute of Atmospheric Physics, Chinese Academy of Sciences, 2.University of Chinese Academy of Sciences)

[AAS05-P09] **Equilibrium Climate Responses of the East Asian Summer Monsoon to Various Anthropogenic Aerosol Species**

*Qiuyan Wang[2,1], Zhili Wang[1,2], Hua Zhang[3,2] (1.State Key Laboratory of Severe Weather & Key Laboratory of Atmospheric Chemistry of CMA, Chinese Academy of Meteorological Sciences, Beijing, 2.Collaborative Innovation Center on Forecast and Evaluation of Meteorological Disasters, Nanjing University of Information Science and Technology, Nanjing, 3.Laboratory for Climate Studies, National Climate Center, China Meteorological Administration, Beijing)

[AAS05-P10] Analysis of specific energy in zonal currents focusing on the analogy between jet stream and open channel flow

*Yoshikazu Kitano[1], Tomohito J. Yamada[2] (1.Central Research Institute of Electric Power Industry, 2.Faculty of Engineering, Hokkaido University)

[AAS05-P11] Analysis of the ozone reduction event over the southern tip of South America in November 2009

*Hideharu Akiyoshi[1], Masanao Kadowaki[2], Haruna Nakamura[3], Takafumi Sugita[1], Toshihiko Hirooka[4], Yayoi Harada[5], Akira Mizuno[6] (1.National Institute for Environmental Studies, 2.Japan Atomic Energy Agency, 3.Fujitsu FIP Corporation, 4.Department of Earth and Planetary Sciences, Kyushu University, 5.Meteorological Research Institute, 6.Institute for Space-Earth Environmental Research, Nagoya University)

[AAS05-P12] **Analysis of relatively low ozone in Arctic spring during the QBO-westerly and solar-minimum years**

*Yousuke Yamashita[1,2], Hideharu Akiyoshi[2], Masaaki Takahashi[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute for Environmental Studies)

[AAS05-P13] Evaluation of ozone in the upper troposphere and lower stratosphere derived from multi-species satellite data assimilation

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Koji Ogochi[1], Kengo Sudo[3,1], Masayuki Takigawa[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Jet Propulsion Laboratory/California Institute for Technology, 3.Graduate School of Environmental Studies, Nagoya University)

[AAS05-P14] Characteristics of Initial Perturbation of JMA GEPS during Sudden Stratospheric Warmings

★Invited Papers

*Shunsuke Noguchi[1,2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Meteorological Research institute, Japan Meteorological Agency)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[A-AS05] Stratosphere-troposphere Processes And their Role in Climate

convener:Yoshio Kawatani(Japan Agency for Marine-Earth Science and Technology), Shingo Watanabe(Japan Agency for Marine-Earth Science and Technology), Takashi Sekiya(Japan Agency for Marine-Earth Science and Technology), Kaoru Sato(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

[AAS05-P01] **An advanced impact of Arctic stratospheric ozone changes on spring precipitation in China**

*Fei Xie[1] (1.Beijing Normal University)

[AAS05-P02] Global Cooling System installed on the beach by means of Artificial Convection and Artificial Rain

*Murakami Hideyo[1] (1.Ii Ecology Development)

[AAS05-P03] Stratospheric front-like temperature structure and gravity wave activity during a stratospheric sudden warming event in 2016

*Yukari Sumi[1], Kaoru Sato[1] (1.University of Tokyo)

[AAS05-P04] The effects of a well-resolved stratosphere on the simulated boreal winter circulation in a climate model

*Yoshio Kawatani[1], Kevin Hamilton[2], Lesley J. Gray[3], Scott M. Osprey[3], Shingo Watanabe[1], Yousuke Yamashita[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.International Pacific Research Center, University of Hawaii, 3.Atmospheric, Oceanic and Planetary Physics, Department of Physics, University of Oxford)

[AAS05-P05] On the relation between three-dimensional wave activity flux and pseudo momentum without using intrinsic phase velocities

★Invited Papers

*Takenari Kinoshita[1] (1.Japan Agency for Marine-Earth Science and Technology)

[AAS05-P06] Hindcasts of the 2016 Disruption of the Stratospheric Quasi-biennial Oscillation

*Shingo Watanabe[1], Kevin Hamilton[2], Scott Osprey[3], Yoshio Kawatani[1], Eriko Nishimoto (1.Japan Agency for Marine-Earth Science and Technology, 2.International Pacific Research Center, University of Hawaii at Manoa, 3.NCAS-Climate, University of Oxford)

[AAS05-P07] Selection bias of quasi-fixed-point observations in the ExUTLS and its impact on the seasonal record

*Yoichi Inai[1], Toshinobu Machida[2], Hidekazu Matsueda[3], Yousuke Sawa[3], Kazuhiro Tsuboi[3], Keiichi Katsumata[2,4], Shinji Morimoto[1], Shuji Aoki[1], Takakiyo Nakazawa[1], Ryo Fujita[5,1] (1.Tohoku Univ., 2.NIES, 3.MRI, 4.Takachiho Chem. Industrial, 5.Imperial College London)

[AAS05-P08] Varying Rossby Wave Trains from the Developing to Decaying Period of the Upper Atmospheric Heat Source over the Tibetan Plateau in Boreal Summer

*Chuandong Zhu[1,2], Rongcai Ren[1] (1.Institute of Atmospheric Physics, Chinese Academy of Sciences, 2.University of Chinese Academy of Sciences)

[AAS05-P09] **Equilibrium Climate Responses of the East Asian Summer Monsoon to Various Anthropogenic Aerosol Species**

*Qiuyan Wang[2,1], Zhili Wang[1,2], Hua Zhang[3,2] (1.State Key Laboratory of Severe Weather & Key Laboratory of Atmospheric Chemistry of CMA, Chinese Academy of Meteorological Sciences, Beijing, 2.Collaborative Innovation Center on Forecast and Evaluation of Meteorological Disasters, Nanjing University of Information Science and Technology, Nanjing, 3.Laboratory for Climate Studies, National Climate Center, China Meteorological Administration, Beijing)

[AAS05-P10] Analysis of specific energy in zonal currents focusing on the analogy between jet stream and open channel flow

*Yoshikazu Kitano[1], Tomohito J. Yamada[2] (1.Central Research Institute of Electric Power Industry, 2.Faculty of Engineering, Hokkaido University)

[AAS05-P11] Analysis of the ozone reduction event over the southern tip of South America in November 2009

[AAS05-P13] Evaluation of ozone in the upper troposphere and lower stratosphere derived from multi-species satellite data assimilation

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Koji Ogochi[1], Kengo Sudo[3,1], Masayuki Takigawa[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Jet Propulsion Laboratory/California Institute for Technology, 3.Graduate School of Environmental Studies, Nagoya University)

[AAS05-P14] Characteristics of Initial Perturbation of JMA GEPS during Sudden Stratospheric Warmings

★Invited Papers

*Shunsuke Noguchi[1,2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Meteorological Research institute, Japan Meteorological Agency)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[A-OS08] ECS-Kuroshio and Ryukyu Current System -Observation, modeling and theory-

convener:Hirohiko Nakamura(Kagoshima University, Faculy of Fisheries), Xiao-Hua Zhu(Second Institute of Oceanography)

[AOS08-P01] **Impact of the mesosacle eddies on the western boundary current over the entire western North Pacific**

*Kako Shinichiro[1], Hirohiko Nakamura[2] (1.Graduate School of Science and Engineering, Kagoshima University, 2.Faculty of Fisheries, Kagoshima University)

[AOS08-P02] Glider observations of interleaving layers in the Kuroshio

*Sen Jan[1], Shih-Hong Wang[1], Kai-Chieh Yang[1], Yiing Jang Yang[1], Ming-Huei Chang[1] (1.Institute of Oceanography, National Taiwan Univ.)

[AOS08-P03] Bottom Pressure in the East China Sea -Observation and modeling

*Hua Zheng[1], Xiao-Hua Zhu[1], Hirohiko Nakamura[2], Jae-Hun Park[3], Chanhyung Jeon[4], Ruixiang Zhao[1], Ayako Nishina[2], Chuanzheng Zhang[1], Hanna Na[5], Ze-Nan Zhu[1], Hong Sik Min[6] (1.Second Institute of Oceanography, Ministry of Natural Resources, China, 2.Faculty of Fisheries, Kagoshima University, Kagoshima, Japan, 3.Department of Ocean Sciences, Inha University, Incheon, South Kore, 4.Department of Marine Science and Biological Engineering, Inha University, Incheon, Korea, 5.School of Earth and Environmental Sciences, Seoul National University, Seoul, Korea, 6.Ocean Circulation and Climate Research Center, Korea Institute of Ocean Science and Technology, Busan, Korea)

[AOS08-P04] A numerical study on the dynamics of seasonal velocity variation in the East China Sea

*ZHENLONG ZHANG[1], Nakamura Hirohiko[1], Xiao-Hua Zhu[2] (1.Kagoshima University, 2.Ministry of Natural Resources, CHINA.)

[AOS08-P05] Temporal and spatial velocity variations over the Kuroshio Extension, Kuroshio and Ryukyu Current System in 1982-2014

*YUXIANG QIAO[1], Hirohiko Nakamura[2], AYAKO NISHINA[2] (1.Kagoshima University, Graduate School of Fisheries, 2.Kagoshima University, Faculty of Fishries)

[AOS08-P06] Characteristics of water in the southern Okinawa Trough.

*Ayako Nishina[1], Hirohiko Nakamura[1], Jae-Hun Park[2], Xiao-Hua Zhu[3], Hong Sik Min[4], Hanna Na[5] (1.Kagoshima University, 2.Inha University, 3.Second Institute of Oceanography, 4.Korea Institute of Ocean Science and Technology, 5.Seoul National University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_11

[A-OS08] ECS-Kuroshio and Ryukyu Current System -Observation, modeling and theory-

convener:Hirohiko Nakamura(Kagoshima University, Faculy of Fisheries), Xiao-Hua Zhu(Second Institute of Oceanography)

[AOS08-P01] Impact of the mesosacle eddies on the western boundary current over the entire western North Pacific

*Kako Shinichiro[1], Hirohiko Nakamura[2] (1.Graduate School of Science and Engineering, Kagoshima University, 2.Faculty of Fisheries, Kagoshima University)

[AOS08-P02] Glider observations of interleaving layers in the Kuroshio

*Sen Jan[1], Shih-Hong Wang[1], Kai-Chieh Yang[1], Yiing Jang Yang[1], Ming-Huei Chang[1] (1.Institute of Oceanography, National Taiwan Univ.)

[AOS08-P03] Bottom Pressure in the East China Sea -Observation and modeling

*Hua Zheng[1], Xiao-Hua Zhu[1], Hirohiko Nakamura[2], Jae-Hun Park[3], Chanhyung Jeon[4], Ruixiang Zhao[1], Ayako Nishina[2], Chuanzheng Zhang[1], Hanna Na[5], Ze-Nan Zhu[1], Hong Sik Min[6] (1.Second Institute of Oceanography, Ministry of Natural Resources, China, 2.Faculty of Fisheries, Kagoshima University, Kagoshima, Japan, 3.Department of Ocean Sciences, Inha University, Incheon, South Kore, 4.Department of Marine Science and Biological Engineering, Inha University, Incheon, Korea, 5.School of Earth and Environmental Sciences, Seoul National University, Seoul, Korea, 6.Ocean Circulation and Climate Research Center, Korea Institute of Ocean Science and Technology, Busan, Korea)

[AOS08-P04] A numerical study on the dynamics of seasonal velocity variation in the East China Sea

*ZHENLONG ZHANG[1], Nakamura Hirohiko[1], Xiao-Hua Zhu[2] (1.Kagoshima University, 2.Ministry of Natural Resources, CHINA.)

[AOS08-P05] Temporal and spatial velocity variations over the Kuroshio Extension, Kuroshio and Ryukyu Current System in 1982-2014

*YUXIANG QIAO[1], Hirohiko Nakamura[2], AYAKO NISHINA[2] (1.Kagoshima University, Graduate School of Fisheries, 2.Kagoshima University, Faculty of Fishries)

[AOS08-P06] Characteristics of water in the southern Okinawa Trough.

*Ayako Nishina[1], Hirohiko Nakamura[1], Jae-Hun Park[2], Xiao-Hua Zhu[3], Hong Sik Min[4], Hanna Na[5] (1.Kagoshima University, 2.Inha University, 3.Second Institute of Oceanography, 4.Korea Institute of Ocean Science and Technology, 5.Seoul National University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 105 1F

[A-OS08] ECS-Kuroshio and Ryukyu Current System -Observation, modeling and theory-

convener:Hirohiko Nakamura(Kagoshima University, Faculy of Fisheries), Xiao-Hua Zhu(Second Institute of Oceanography), Chairperson:Hirohiko Nakamura(Kagoshima University), Jae-Hun Park(Inha University)

1:50 PM - 2:10 PM JST | 4:50 AM - 5:10 AM UTC

[AOS08-01] Downstream Evolution of the Kuroshio Velocity Structure and Transport

★Invited Papers

*Magdalena Andres[1], Sen Jan[2] (1.Woods Hole Oceanographic Institution, 2.National Taiwan University)

2:10 PM - 2:25 PM JST | 5:10 AM - 5:25 AM UTC

[AOS08-02] **Non-seasonal variability of the Kuroshio shelf intrusion and its associated changes in the ocean environment over the East China Sea during 1993-2017**

*Jiwon Kang[1], Hanna Na[1] (1.School of Earth and Environmental Sciences, Seoul National University, Republic of Korea)

2:25 PM - 2:40 PM JST | 5:25 AM - 5:40 AM UTC

[AOS08-03] The temporal and spatial variability of the Kuroshio in the East China Sea and its associated mechanisms

*Yanzhou Wei[1] (1.State Key Laboratory of Satellite Ocean Environment Dynamics, Second Institute of Oceanography, Ministry of Natural Resources, Hangzhou, China)

2:40 PM - 2:55 PM JST | 5:40 AM - 5:55 AM UTC

[AOS08-04] The Joint Kuroshio–Ryukyu Current System Study and a rapid report about mooring observations southeast of Miyakojima

*Xiao-Hua Zhu[1], Hirohiko Nakamura[2], Jae-Hun Park[3], Ruixiang Zhao[1], Ayako Nishina[2], Chuanzheng Zhang[1], Chanhyung Jeon[4], Hanna Na[5], Ze-Nan Zhu[1], Hong Sik Min[6] (1.State Key Laboratory of Satellite Ocean Environment Dynamics, Second Institute of Oceanography, Ministry of Natural Resources, Hangzhou, China, 2.Faculty of Fisheries, Kagoshima University, Kagoshima, Japan, 3.Department of Ocean Sciences, Inha University, Incheon, South Korea, 4.Department of Marine Science and Biological Engineering, Inha University, Incheon, Korea, 5.School of Earth and Environmental Sciences, Seoul National University, Seoul, Korea, 6.Ocean Circulation and Climate Research Center, Korea Institute of Ocean Science and Technology, Busan, Korea)

2:55 PM - 3:10 PM JST | 5:55 AM - 6:10 AM UTC

[AOS08-05] Relationship of the Kuroshio with the current fields in the East China Sea from observations and model results

*Hong Sik Min[1], Chorong Hwang[1], Dong Guk Kim[1], Hirohiko Nakamura[2], Ayako Nishina[2], Xiao-Hua Zhu[3], Jae-Hun Park[4], Chanhyung Jeon[4], Hanna Na[5], Naoki Hirose[6] (1.Korea Institute of Ocean Science & Technology, 2.Kagoshima University, 3.Second Institute of Oceanography, 4.Inha University, 5.Seoul National University, 6.Kyushu University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 105 1F

[A-OS08] ECS-Kuroshio and Ryukyu Current System -Observation, modeling and theory-

convener:Hirohiko Nakamura(Kagoshima University, Faculy of Fisheries), Xiao-Hua Zhu(Second Institute of Oceanography), Chairperson:Jae-Hun Park(Inha University), Hirohiko Nakamura(Kagoshima University)

3:35 PM - 3:55 PM JST | 6:35 AM - 6:55 AM UTC

[AOS08-06] Separating Small-Scale Oceanic Internal Waves and Vortical Motions

★Invited Papers

*Ren-Chieh Lien[1] (1.University of Washington, Seattle, WA, USA)

3:55 PM - 4:10 PM JST | 6:55 AM - 7:10 AM UTC

[AOS08-07] Structure and variability of the Kuroshio current in the Tokara Strait

*Zhao-Jun Liu[1], Hirohiko Nakamura[2], Xiao-Hua Zhu[1], Ayako Nishina[2], Xinyu Guo[3], Menghong Dong[1] (1.Second Institute of Oceanography, China, 2.Kagoshima University, Japan, 3.Ehime University, Japan)

4:10 PM - 4:25 PM JST | 7:10 AM - 7:25 AM UTC

[AOS08-08] **Near-inertial waves advected by the Kuroshio from observation and simulation**

*CHANHYUNG JEON[1], Jae-Hun Park[1], Hirohiko Nakamura[2], Ayako Nishina[2], Xiao-Hua Zhu[3], Dong Guk Kim[4], Hong Sik Min[4], Sok Kuh Kang[4], Hanna Na[5], Naoki Hirose[6], Youngseok Choi[1] (1.Inha University, 2.Kagoshima University, 3.Second Institute of Oceanography, 4.Korea Institute of Ocean Science and Technology, 5.Seoul National University, 6.Kyushu University)

4:25 PM - 4:40 PM JST | 7:25 AM - 7:40 AM UTC

[AOS08-09] Turbulent mixing and near-inertial internal waves induced by the Kuroshio over seamounts in the Tokara Strait

*Takeyoshi Nagai[1], Daisuke Hasegawa[2], Eisuke Tsutsumi[3], Hirohiko Nakamura[4], Ayako Nishina[4], Tomoharu Senjyu[3], Takahiro Endoh[3], Takeshi Matsuno[3], Ryuichiro Inoue[5], Amit Tandon[6] (1.Department of Ocean Sciences, Tokyo University of Marine Science and Technology, 2.Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 3.Kyushu University, Research Institute for Applied Mechanics, 4.Faculty of Fisheries Kagoshima University, 5.Ocean Circulation Research Group, Japan Agency for Marine-Earth Science and Technology, 6.Mechanical Engineering Department & SMAST, University of Massachusetts Dartmouth)

4:40 PM - 4:55 PM JST | 7:40 AM - 7:55 AM UTC

[AOS08-10] Microstructure and mooring observations of enhanced mixing in the Kerama Gap

*Ryuichiro Inoue[1], Hirohiko Nakamura[2], Takahiro Tanaka[3], Shinzou Fujio[4], Daigo Yanagimoto[4], Ichiro Yasuda[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kagoshima University, Faculy of Fisheries, 3.Tohoku National Fisheries Research Institute, Japan Fisheries Research and Education Agency, 4.The University of Tokyo, Atmosphere and Ocean Research Institute)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 301A 3F

[A-OS11] Continental-Oceanic Mutual Interaction: Planetary scale Material Circulation

convener:Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Yukio Masumoto(Graduate School of Science, The University of Tokyo), Swadhin Behera(Climate Variation Predictability and Applicability Research Group, Application Laboratory, JAMSTEC, 3173-25 Showa-machi, Yokohama 236-0001), Takanori Sasaki(Department of Astronomy, Kyoto University), Chairperson:Yukio Masumoto, Behera Swadhin(JAMSTEC)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AOS11-01] Explorations and current understandings for subsurface ocean of icy bodies

★Invited Papers

*Jun Kimura[1] (1.Osaka University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AOS11-02] **Climate predictability for societal applications including AI/ML**

*Swadhin Behera[1], Manali Pal[2], J.V. Ratnam[1], Rajib Maity[2], Takeshi Doi[1], Yushi Morioka[1], Masami Nonaka[1] (1.Application Laboratory, JAMSTEC, 3173-25 Showa-machi, Yokohama 236-0001, 2.Indian Institute of Technology, Kharagpur, India)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AOS11-03] Re-entry of giant-impact fragments and early evolution of the Earth's ocean

*Takanori Sasaki[1] (1.Department of Astronomy, Kyoto University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AOS11-04] Modeling of Extreme Freshwater Discharge and influence from Japanese First-Class Rivers to Coastal zones

*Ryusuke Kuroki, Yosuke Alexandre Yamashiki[1], Sergey Varlamov[2], Yasumasa Miyazawa[2], Racault Fanny Marie[3], Hoshin Vijai Gupta[4] (1.Kyoto University, 2.Application Laboratory, Japan Agency for Marine-Earth Science and Technology, Japan, 3.Plymouth Marine Laboratory, Plymouth, United Kingdom, 4.University of Arizona)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AOS11-05] Establishment of new curriculum at Biosphere 2

*Kenji Miki[1], Takao Doi[2], Yosuke Yamashiki[3], Masahiro Terada[2] (1.Kyoto University Graduate School of Agriculture, 2.Kyoto University Unit of Synergetic Studies for Space, 3.Graduate School of Advanced Integrated Studies in Human Survivability)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AOS11-06] Development of the highly precise high-speed photometry technique with the photometer mounted with PIRKA telescope

*Nami Kimura[1] (1.Hokkaido University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 301A 3F

[A-OS11] Continental-Oceanic Mutual Interaction: Planetary scale Material Circulation

convener:Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Yukio Masumoto(Graduate School of Science, The University of Tokyo), Swadhin Behera(Climate Variation Predictability and Applicability Research Group, Application Laboratory, JAMSTEC, 3173-25 Showa-machi, Yokohama 236-0001), Takanori Sasaki(Department of Astronomy, Kyoto University), Chairperson:Yosuke Yamashiki(GSAIS Kyoto University), Takanori Sasaki(Department of Astronomy, Kyoto University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AOS11-07] **The Drivers of early Archean Earth's Hydrology: Resolving the Faint Young Sun's Paradox**

★Invited Papers

*Vladimir Airapetian[1], Guillaume Gronoff[2], Michael Way[3], Meng Jin[4] (1.NASA Goddard Space Flight Center/SEEC and American University, 2.NASA LaRC/SSAI, 3.NASA GISS/SEEC, 4.SETI)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AOS11-08] Experimental study on elementary hydrological process of rainfall in a forested continental hinterland

*Shigeki Murakami[1] (1.Kyushu Research Cente, Forestry and Forest Products Research Institute)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AOS11-09] Radiological Assessment of Martian and Terrestrial Surface during Young Sun

*Yosuke Alexandre Yamashiki[1], Hiroyuki Maehara[6], Yuta Notsu[3], Tatsuhiko Sato[2], Airapetian Vladimir[7], Shota Notsu[3], Ryusuke Kuroki[1], keiya murashima[5], Hiroaki Sato[4], Hina Bando[5], Kosuke Namekata[3], Takanori Sasaki[3], Scott Thomas[8], Nogami Daisaku[3], Kazunari Shibata[9] (1.Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University, 2.Japan Atomic Energy Agency, 3.Graduate School of Science, Kyoto University, 4.School of Engineering, 5.School of Science, 6.National Astronomical Observatory of Japan, 7.NASA / Goddard Space Flight Center, 8.University of Bristol , 9.Kwasan Astronomical Observatory, Kyoto University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AOS11-10] **Evaluation of scintillator detection materials for application within environmental radiation monitoring**

*Peter George Martin[1], D. Connor[1], M. Lowden[1], T. B. Scott[1] (1.School of Physics, University of Bristol, Bristol, UK)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AOS11-11] The important factors for future human space activity in terms of space medicine

*Masahiro Terada[1], Yosuke Yamashiki[1], Kenji Miki[1], Satoko Tsujihiro[1], Takao Doi[1] (1.Kyoto University, Unit of Synergetic Studies for Space)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AOS11-12] Storm Surge Response to Freshwater Outflow from Typhoons on the Ibaraki Coast

*Josko Troselj[1], Nobuhito Mori[1] (1.Coastal Engineering Laboratory, Disaster Prevention Research Institute, Kyoto University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

[A-OS11] Continental-Oceanic Mutual Interaction: Planetary scale Material Circulation

convener:Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Yukio Masumoto(Graduate School of Science, The University of Tokyo), Swadhin Behera(Climate Variation Predictability and Applicability Research Group, Application Laboratory, JAMSTEC, 3173-25 Showa-machi, Yokohama 236-0001), Takanori Sasaki(Department of Astronomy, Kyoto University)

[AOS11-P01] Remote Sensing of Chlorophyll-a and Submerged Aquatic Vegetation for a Freshwater Lake in Japan

*Shweta Yadav[1], Yamashiki Yosuke[1], Junichi Susaki[1], Kanako Ishikawa[2] (1.Kyoto University, 2.Lake Biwa Environmental Research Institute)

[AOS11-P02] Hydrological and Debris-flow simulation of Martian Surface in Hesperian & early Amazonian epoch

*Hiroaki Sato[2], Yosuke Alexandre Yamashiki[1], Ryusuke Kuroki[1], Hideaki Miyamoto[3], Ryodo Hemmi[3] (1.Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University, 2.Faculty of Engineering, Kyoto University, 3.Graduate School of Engineering, The University of Tokyo)

[AOS11-P03] Global Lakes & reservoirs Repository and their application for terrestrial surface environment

*Yosuke Alexandre Yamashiki[1], Ryusuke Kuroki[1], Botong Gao[1], Hina Bando[2], Fuka Takagi[3], Shweta Yadav[4] (1.Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University, 2.Faculty of Science, Kyoto University, 3.Faculty of Agriculture, Kyoto University, 4.Educational Unit for Studies on Connectivity of Hills, Humans and Ocean, Kyoto University)

[AOS11-P04] Numerical simulation of Tidal Heating using SPH and its application to inner sea formation

*keiya murashima[1], Yosuke Alexandre Yamashiki[1], Natsuki Hosono[2] (1.Kyoto University, 2.Japan Agency for Marine-Earth Science and Technology)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_12

[A-OS11] Continental-Oceanic Mutual Interaction: Planetary scale Material Circulation

convener:Yosuke Alexandre Yamashiki(Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University), Yukio Masumoto(Graduate School of Science, The University of Tokyo), Swadhin Behera(Climate Variation Predictability and Applicability Research Group, Application Laboratory, JAMSTEC, 3173-25 Showa-machi, Yokohama 236-0001), Takanori Sasaki(Department of Astronomy, Kyoto University)

[AOS11-P01] **Remote Sensing of Chlorophyll-a and Submerged Aquatic Vegetation for a Freshwater Lake in Japan**

*Shweta Yadav[1], Yamashiki Yosuke[1], Junichi Susaki[1], Kanako Ishikawa[2] (1.Kyoto University, 2.Lake Biwa Environmental Research Institute)

[AOS11-P02] Hydrological and Debris-flow simulation of Martian Surface in Hesperian & early Amazonian epoch

*Hiroaki Sato[2], Yosuke Alexandre Yamashiki[1], Ryusuke Kuroki[1], Hideaki Miyamoto[3], Ryodo Hemmi[3] (1.Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University, 2.Faculty of Engineering, Kyoto University, 3.Graduate School of Engineering, The University of Tokyo)

[AOS11-P03] Global Lakes & reservoirs Repository and their application for terrestrial surface environment

*Yosuke Alexandre Yamashiki[1], Ryusuke Kuroki[1], Botong Gao[1], Hina Bando[2], Fuka Takagi[3], Shweta Yadav[4] (1.Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University, 2.Faculty of Science, Kyoto University, 3.Faculty of Agriculture, Kyoto University, 4.Educational Unit for Studies on Connectivity of Hills, Humans and Ocean, Kyoto University)

[AOS11-P04] Numerical simulation of Tidal Heating using SPH and its application to inner sea formation

*keiya murashima[1], Yosuke Alexandre Yamashiki[1], Natsuki Hosono[2] (1.Kyoto University, 2.Japan Agency for Marine-Earth Science and Technology)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[A-OS14] Coastal physical processes associated with mixing, eddies, internal waves

convener:Eiji Masunaga(Ibaraki University), Taira Nagai(Graduate School of Science, The University of Tokyo), TSUTSUMI EISUKE(Atmosphere and Ocean Research Institute, The University of Tokyo)

[AOS14-P01] **Development of methods and systems for vertical mixing and observations (OMIX-A01-1)**

*Ichiro Yasuda[1], Koenjong Lee[1], Shinzo Fujio[1], Daigo Yanagimoto[1], Maki Nagasawa[1], Yusuke Kawaguchi[1], Eitarou Oka[1], Shuo Zhai[1], Shino Kimura[1], Ryuichiro Inoue[2], Daisuke Hasegawa[3], Takahiro Tanaka[3], Masao Ishii[4], Toshiya Nakano[4], Yasutaka Goto[4] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Japan Agency of Marine-Earth Science and Technology, 3.Fisheries Research Agency, 4.Japan Meteorological Agency)

[AOS14-P02] **Observation of enhanced nonlinear interactions after the passage of typhoon in the western South China Sea**

*gui ying Chen, chang rong Liang, xiao dong Shang

[AOS14-P03] Investigating vertical mixing in estuarine pycnocline: a case study in the Ariake Sea, Japan

*Takeshi Matsuno[1], Eisuke Tsutsumi[1] (1.Kyushu University)

[AOS14-P04] Possibility of interactions between the coastal and offshore branch of Tsushima Warm Current over the submarine canyon in the Sea of Japan.

*Yosuke Igeta[1], Alexander Yankovsky [2], Mizuki Kuga[1], Naoki Hirose[3], Kenichi Fukudome[4] (1.Japan Sea National Fishseries Research Institute, 2.University of South Carolina, 3.RIAM Kyushu Univ., 4.National Institute of Technology, Toyama College)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_13

[A-OS14] Coastal physical processes associated with mixing, eddies, internal waves

convener:Eiji Masunaga(Ibaraki University), Taira Nagai(Graduate School of Science, The University of Tokyo), TSUTSUMI EISUKE(Atmosphere and Ocean Research Institute, The University of Tokyo)

[AOS14-P01] Development of methods and systems for vertical mixing and observations (OMIX-A01-1)

*Ichiro Yasuda[1], Koenjong Lee[1], Shinzo Fujio[1], Daigo Yanagimoto[1], Maki Nagasawa[1], Yusuke Kawaguchi[1], Eitarou Oka[1], Shuo Zhai[1], Shino Kimura[1], Ryuichiro Inoue[2], Daisuke Hasegawa[3], Takahiro Tanaka[3], Masao Ishii[4], Toshiya Nakano[4], Yasutaka Goto[4] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Japan Agency of Marine-Earth Science and Technology, 3.Fisheries Research Agency, 4.Japan Meteorological Agency)

[AOS14-P02] Observation of enhanced nonlinear interactions after the passage of typhoon in the western South China Sea

*gui ying Chen, chang rong Liang, xiao dong Shang

[AOS14-P03] Investigating vertical mixing in estuarine pycnocline: a case study in the Ariake Sea, Japan

*Takeshi Matsuno[1], Eisuke Tsutsumi[1] (1.Kyushu University)

[AOS14-P04] Possibility of interactions between the coastal and offshore branch of Tsushima Warm Current over the submarine canyon in the Sea of Japan.

*Yosuke Igeta[1], Alexander Yankovsky [2], Mizuki Kuga[1], Naoki Hirose[3], Kenichi Fukudome[4] (1.Japan Sea National Fishseries Research Institute, 2.University of South Carolina, 3.RIAM Kyushu Univ., 4.National Institute of Technology, Toyama College)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 301A 3F

[A-OS14] Coastal physical processes associated with mixing, eddies, internal waves

convener:Eiji Masunaga(Ibaraki University), Taira Nagai(Graduate School of Science, The University of Tokyo), TSUTSUMI EISUKE(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Eiji Masunaga, Eisuke Tsutsumi

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[AOS14-01] The cooling of sea surface temperature in the southern Indonesian Seas due to a combination of the Ekman transport and tidal mixing in narrow straits

*Taira Nagai[1], Toshiyuki Hibiya[1] (1.Graduate School of Science, The University of Tokyo)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[AOS14-02] A reanalysis of regional circulations in the Southern South China Sea using a HYCOM-ROMS downscaling ocean model

*Naru Takaura[1], Yusuke Uchiyama[1], Nizamani Zafarullah[2], Akihiko Nakayama[2] (1.Kobe Univ, 2.Tunku Abdul Rahman University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[AOS14-03] Nutrient and phytoplankton dynamics in the continental slope region of the East China Sea associated with the Kuroshio frontal eddy

*Naoki Yoshie[1], Anri Kabe[1], Kazuki Ohgi[1], Eisuke Tsutsumi[2], Shigenobu Takeda[3], Joji Ishizaka[4], Xinyu Guo[1] (1.Center for Marine Environmental Studies, Ehime University, 2.Research Institute for Applied Mechanics, Kyushu University, 3.Faculty of Fisheries, Nagasaki University, 4.Institute for Space-Earth Environmental Research, Nagoya University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[AOS14-04] Dissipation and transport due to internal tides generated by multiple submarine canyons

*Qiang Li[1], Xianzhong Mao[1], Ran Liao[1] (1.Tsinghua University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[AOS14-05] Measurement of Physical structure in Kasumigaura using high resolution tow-yo instrument

*Daiki Asaoka[1], Eiji Masunaga[1], Shunsuke Komuro[2], Shunichi Matsumoto[2], Masahiko Ono[3], Hiroaki Banba[3] (1.Ibaraki University, 2.Ibaraki Kasumigaura Environmental Science Center, 3.Ministry of Land, Infrastructure, Transport and Tourism)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[AOS14-06] Mixing and baroclinic structure in a stratified shallow lake, Lake Kasumigaura, Japan

*Eiji Masunaga[1], Daiki Asaoka[1], Shunsuke Komuro[2], Shunichi Matsumoto[2], Masahiko Ono[3], Hiroaki Banba[3] (1.Ibaraki University, 2.Ibaraki Kasumigaura Environmental Science Center, 3.Ministry of Land, Infrastructure, Transport and Tourism)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 301A 3F

[A-OS14] Coastal physical processes associated with mixing, eddies, internal waves

convener:Eiji Masunaga(Ibaraki University), Taira Nagai(Graduate School of Science, The University of Tokyo), TSUTSUMI EISUKE(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Eiji Masunaga, Taira Nagai

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[AOS14-07] Turbulent mixing and vertical nitrate flux in the Bungo Channel, Japan

*TSUTSUMI EISUKE[1], Naoki Yoshie[2], Takashi Mano[3], Kanda Taisei[3], Naoki Fujii[4], Xinyu Guo[2] (1.Research Institute for Applied Mechanics, Kyushu University, 2.Center for Marine Environmental Studies, Ehime Univeristy, 3.Graduate School for Science and Engineering, Ehime University, 4.Faculty of Agriculture, Saga Univerisity)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AOS14-08] Numerical Analysis of Submerged Turbulent Buoyant Jet in River Mouth

*Yen-Chen Mou[1], Gene You[1], Chih-Chieh Young[2] (1.National Taiwan University, 2.National Taiwan Ocean University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AOS14-09] Implementing regional downscaling capability in the STEAMER radionuclide dispersion prediction system based on multi-nested ROMS model

*Kamidaira Yuki[1], Hideyuki Kawamura[1], Takuya Kobayashi[1], Yusuke Uchiyama[2] (1.Japan Atomic Energy Agency, 2.Kobe University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AOS14-10] Transport processes around the Izu-chain islands investigated with a Lagrangian particle tracking model

*Waku Kimura[1], Eiji Masunaga[1], Taichi Kosako[2], Yusuke Uchiyama[3] (1.Ibaraki University, 2.Port and Airport Research Institute, 3.Kobe University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AOS14-11] Fates and dynamical roles of pinch-off mesoscale eddies originated from the Kuroshio Extension Jet

*Yusuke Uchiyama[1], Nobue Okada[1], Changming Dong[2] (1.Graduate School of Engineering, Kobe University, 2.Nanjing University of Information Science & Technology)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 201B 2F

[A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz), Chairperson:Noboru Okuda(Research Institute for Humanity and Nature)

3:40 PM - 4:00 PM JST | 6:40 AM - 7:00 AM UTC

[AHW22-01] **Coral Skeleton $\delta^{15}N$ as a Tracer of Historic Nutrient Loading to a Coral Reef in Maui, Hawaii**

★Invited Papers

*Adina Paytan[1] (1.University of California Santa Cruz)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AHW22-02] **The Use of Ammonium and Trace Metals in Identifying Low Redox Environment Zone at Indonesian Coastal Alluvial Groundwater**

*Anna Fadliah Rusydi[1,4], Mitsuyo - Saito[2], Seiichiro - Ioka[3], Shin-ichi - Onodera[1] (1.Graduate School of Integrated Arts and Sciences, Hiroshima University, Japan, 2.Graduate School of Environmental and Life Sciences, Okayama University, Japan, 3.Institute of Regional Innovation, Hirosaki University, Japan, 4.Research Center for Geotechnology, Indonesian Institute of Sciences, Indonesia)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AHW22-03] Spatial and temporal variation in submarine groundwater discharge (SGD) on a beach scale in a temperate coastal island: a multi-tracer approach

*Mitsuyo Saito[1], Shin-ichi Onodera[2], Yusuke Tomozawa[2], Kazuyoshi Asai[3] (1.Graduate School of Environmental and Life Science, Okayama University, 2.Graduate School of Integrated Arts and Sciences, Hiroshima University, 3.Geo Science Laboratory)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AHW22-04] **Phosphorus discharge via groundwater into the lake, based on lacustrine groundwater discharge (LGD) and alluvial plain sediment**

*Shin-ichi Onodera[1], Mitsuyo Saito[2], Guangzhe Jin[3], Anna Fadliah Rusydi[1], Yusuke Tomozawa[1], Kunyang Wang[1], Syuhei Ban[4], Noboru Okuda[5] (1.Graduate School of Integrated and Arts Sciences, Hiroshima University, 2. Graduate School of Environmental and Life Science, Okayama University, 3.Guangdong Ocean University, 4.The University of Shiga Prefecture, 5.Research Institute for Humanity and Nature)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AHW22-05] **Geochemical controls and health implications of water chemistry in Benoue River Basin, North Cameroon: Insights from Major ions**

*Sharon Bih Kimbi[1,2], Wilson Y Fantong[3], Samuel N Ayonghe[2], Robert Kringel[4], Shin-ichi Onodera[1] (1.Graduate School of Integrate Arts and Sciences, Hiroshima University, 2.Department of Environmental Science, Faculty of science, University of Buea, 3.Institute of Mining and Geological Research (IRGM), 4.Federal Institute for Geoscience and Natural Resources Bundesanstalt fur Geowissenschaften und Rohstoffe (BGR) PRESS NO & SW)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 103 1F

[A-HW23] Hydrology & Water Environment

convener:Isao Machida(Geological Survey of Japan), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Takeshi Hayashi(Faculty of Education and Human Studies, Akita University), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Chairperson:Takeshi Hayashi(Faculty of Education and Human Studies, Akita University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AHW23-12] Drought Analysis based on Copulas and Poisson Process

*Pei-Yu Wu[1], Gene Jiing-yun You[1] (1.National Taiwan University, Department of Civil Engineering)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AHW23-13] **Snow melt dynamics in snowfall dominated mountain regions in Shonai**

*Alexander Brandt[1,3], Muhammad Fraz Ismail[2], Larry Maximo Lopez Caceres[1], Wolfgang Bogacki[2] (1.Yamagata University, 2.Hochschule Koblenz, 3.UGAS)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AHW23-14] Study on transport of particulate organic matter in a small river with forest and paddy filed by using carbon isotopes ($\delta^{13}C$ and $\Delta^{14}C$)

*Seiya Nagao[1], Ryunosuke Tahara[2], Shinya Ochiai[1], Akiko Goto[3], Takashi Hasegawa[3] (1.Institute of Nature and Environmental Technology, Kanazawa University, 2.Graduate School of Natural Science and Technology, Kanazawa University, 3.Institute of Science and Engineering, Kanazawa University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AHW23-15] **Sources of Shallow Groundwater Salinity in the Ganges Delta of Bangladesh**

*Masudur Rahman[1,2], Tomochika Tokunaga[1] (1.Department of Environment Systems, Graduate School of Frontier Sciences, The University of Tokyo, 5-1-5, Kashiwa-no-ha, Kashiwa-shi, Chiba 277-8563, Japan, 2.Environmental Science Discipline, Life Science School, Khulna University, Khulna 9208, Bangladesh)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AHW23-16] **Groundwater chemistry in the Gunii Khooloi basin, Southern Gobi Region of Mongolia using multivariate analysis**

*Batdemberel BAYANZUL[1,2], Isao Machida[3], Kengo Nakamura[2], Noriaki Watanabe[2], Takeshi Komai[2] (1.School of Geology and Mining Engineering, Mongolian University of Science and Technology, 2.Graduate School of Environmental Studies, Tohoku University, 3.Groundwater research group, Advanced Industrial Science and Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AHW23-17] **Temporal observation of molybdenum concentrations in rivers from Erdenet mining area, Mongolia**

*Solongo Tsetsgee[1], Keisuke Fukushi[1], Altansukh Ochir[2], Takahashi Yoshio[3], Ariuntungalag Yunden[2], Enkhjin Odgerel[2], Noriko Hasebe[1] (1.Kanazawa University, 2.National University of Mongolia, 3.The University of Toyko)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 103 1F

[A-HW23] Hydrology & Water Environment

convener:Isao Machida(Geological Survey of Japan), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Takeshi Hayashi(Faculty of Education and Human Studies, Akita University), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Chairperson:Keisuke Fukushi

10:45 AM - 11:05 AM JST | 1:45 AM - 2:05 AM UTC

[AHW23-18] Solid-water interaction of Mn and As near the bottom of Lake Biwa. –Implications for the spatio-temporal change of these elements for past 40 years-

★Invited Papers

*TAKAAKI ITAI[1], SACHIKA NATORI[1] (1.Department of Earth and Planetary Science, The University of Tokyo)

11:05 AM - 11:20 AM JST | 2:05 AM - 2:20 AM UTC

[AHW23-19] **Sources, pathways and treatment of contaminants in surface water: Applicability in developing countries**

*Mst. Shamsun Nahar[1] (1.Earth Consultant Co. Ltd, Toyama, Japan)

11:20 AM - 11:35 AM JST | 2:20 AM - 2:35 AM UTC

[AHW23-20] **Numerical simulations (COMSOL) of γ-Fe_2O_3 nanohybrids for transport (3D) and arsenic removal in homogeneous porous media**

*Ajay Kumar[1], Himanshu Joshi[1], Anil Kumar[1] (1.INDIAN INSTITUTE OF TECHNOLOGY ROORKEE, INDIA)

11:35 AM - 11:50 AM JST | 2:35 AM - 2:50 AM UTC

[AHW23-21] **Transport processes of suspended solids in the Kumaki River inferred from atmospheric radionuclides**

*Shinya Ochiai[1], Ryunosuke Tahara[2], Tetsuya Matsunaka[1], Seiya Nagao[1] (1.Institute of Nature and Environmental Technology, Kanazawa University, 2.Graduate School of Natural Science and Technology, Kanazawa University)

11:50 AM - 12:05 PM JST | 2:50 AM - 3:05 AM UTC

[AHW23-22] Using tritium in Japanese precipitation for tritium-tracer transit time studies across Asia

*Maksym Gusyev[1], Yoshito Kikumori[1], Terumasa Nishihara[2], Takeshi Hayashi[3], Kimpei Ichiyanagi[4], Naofumi Akata[5], Tomoki Oda[6], Uwe Morgenstern[7], Michael Stewart[7] (1.International Centre for Water Hazard and Risk Management (ICHARM), Public Works Research Institute (PWRI), 2.Civil Engineering Research Institute for Cold Region, PWRI, 3.Akita University, 4.Kumamoto University, 5.National Institute for Fusion Science (NIFS), 6.University of Tokyo, 7.GNS Science, New Zealand)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[A-HW23] Hydrology & Water Environment

convener:Isao Machida(Geological Survey of Japan), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Takeshi Hayashi(Faculty of Education and Human Studies, Akita University), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University)

[AHW23-P01] **A multiobjective risk management model for real-time reservoir flood control operation**

*Juan Chen[1,2], Ping-An Zhong[2], XinYu Wan[2], Yu Zhang[2] (1.College of Earth Sciences and Engineering, Hohai University, 2.College of Hydrology and Water Resources, Hohai University)

[AHW23-P02] **Assessment of the Flow Regime of Roanoke River due to Climatic and Anthropogenic Activities**

*Rahul Kumar Singh[1], Dr. Manoj Kumar Jain[1] (1.Indian Institute of Technology, Roorkee, India)

[AHW23-P03] Predictive Analysis of Climate, Water, Health and the Environment Nexus

*Abhishek [1], Deepika [2] (1.Technical University Dresden, GERMANY, 2.BPS Government Medical College for Women, Sonepat, INDIA)

[AHW23-P05] Severe droughts provide huge fuel for widespread wildfires in California in USA

*Linghua Qiu[1], Ji Chen[1], Haiyun Shi[2], Liqun Sun[3], Jun Niu[4] (1.the University of Hong Kong, 2.Southern University of Science and Technology, 3.Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, 4.China Agricultural University)

[AHW23-P06] A comprehensive evaluation of MODIS-based water use efficiency with global eddy covariance flux data and a process model

*Shanshan YANG[1,2], Jiahua ZHANG[1], Sha ZHANG[1,2], Jingwen WANG[1,2], Yun BAI[1,2], Fengmei YAO[2], Huadong GUO[1] (1.Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, 2.University of Chinese Academy of Sciences, Beijing, China)

[AHW23-P07] Impact of variability and anisotropy in the correlation decay distance for precipitation spatial interpolation in China

*yingxian zhang[1] (1.National Climate Center, China Meteorological Administration)

[AHW23-P08] New Record-Breaking Frequency of Annual Maximum Daily Precipitation of 58 stations in the whole Japan, an increasing of extreme values.

*Chhay Ngorn SEANG[1], Tomohito YAMADA[1] (1.Hokkaido University)

[AHW23-P09] Quantifying stemflow to better express its ecohydrological significance

*Shin'ichi Iida[1], Darryl E. Carlye-Moses[2], Sonja Germer[3], Pilar Llorens[4], Beate Michalzik[5], Kazuki Nanko[1], Alexander Tischer[5], Delphis F. Levia[6] (1.Department of Disaster Prevention, Meteorology and Hydrology, Forestry and Forest Products Research Institute, 2.Department of Geography and Environmental Studies, Thompson Rivers University, Kamloops, British Columbia, Canada, 3.Department of Bioengineering, Leibniz Institute for Agricultural Engineering and Bioeconomy, Potsdam, Germany, 4.Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain, 5.Soil Science, Institute of Geography, Friedrich Schiller University Jena, Jena, Germany, 6.Department of Geography and Department of Plant and Soil Sciences, University of Delaware, Newark, DE, USA)

[AHW23-P10] **Hydraulic analysis of overland flow caused by temporally varying rainfall**

*PING-CHENG HSIEH[1], Ming-Chang Wu[1] (1.National Chung Hsing University)

[AHW23-P11] A comparative Study on Water Environment of Isolated Islands - Focusing on Islands in Nagasaki Prefecture - (3)

*Go Yamaki[1], Koji Kodera[2], Kazuki Asami[1], Yoshihiro IGARI[1], Masaki Horiuchi[1] (1.Grad. Student, Hosei Univ., 2.Dep. of Geography, Hosei Univ.)

[AHW23-P12] **Water environment around Kusatsu-Shirane volcano and consideration of the effect of eruption in January 2018**

*Igari Yoshihiro[1], Koji Kodera[2], Kazuki Asami[1] (1.Grad.Student,Hosei Univ., 2.Dep.of Geography Hosei Univ.)

[AHW23-P13] Re-consideration of discharge rate of spring water in Lake Ezu, Kumamoto

*Kimpei Ichiyanagi[1], Kiyoshi Ide[1], Jun Shimada[1], Tsutomu Ichikawa[2] (1.Kumamoto University, 2.Tokai University)

[AHW23-P14] **Evaluating the efficacy of hydrologically and hydrodynamically driven methods of e-flow assessment for Upper Godavari River Basin, India**

*GAURAV KALIDAS PAKHALE[1], Jyoti Punjahari Nale[2], Ashvin Kumar Gosain[3], Rakesh Khosa[3] (1.PhD Research Scholar, Civil Engineering Department, Indian Institute of Technology, Delhi, 2.Project Advisor, IEWP, GIZ India, New Delhi, India, 3.Professor, Civil Engineering Department, Indian Institute of Technology, Delhi)

[AHW23-P15] Presence of pharmaceutical compounds in freshwater lakes and their impact on phytoplankton

*Nandakumar Kanavillil[1], Cassandra Fligg[1], Sreekumari Kurissery[1] (1.Lakehead University, Canada)

[AHW23-P16] **Novel approximate solutions for solute transport due to injections: considering the scale-dependent dispersion and non-integer flow dimension**

*Ye-Chen Lin[1], Hund-Der Yeh[1] (1.National Chiao Tung Univ.)

[AHW23-P17] Experimemtal study on the residual saturation of Porous Media using Pore Doublets Micromodel

*Chun-Wei Peng[1] (1.Taiwan National Chiao Tung University)

[AHW23-P18] Assessment of Synergy between Biomedical Waste and Shallow Groundwater Pollution

*Deepika [1], Abhishek [2] (1.BPS Government Medical College for Women, Sonepat, INDIA, 2.Technical University Dresden, GERMANY)

[AHW23-P19] Erosion and transport processes of earth surface materials in a reservoir-catchment system inferred from atmospheric radionuclides ^{7}Be and ^{210}Pb

*Mikiya Tsuruoka[1], Shinya Ochiai[2], Atsushi Matsuki[2], Seiya Nagao[2] (1.Graduate School of Natural Science and Technology, Kanazawa University, 2.Institute of Nature and Environmental Technology, Kanazawa University)

[AHW23-P20] Fluctuation of groundwater level in a sloping unconfined aquifer due to time varying recharge

*Ming-Chang Wu[1], Ping-Cheng Hsieh[1] (1.National Chung Hsing University)

[AHW23-P21] **Effect of cutoff wall on recharge water storage volume**

*Pei-hsun Tsai[1], Jung-hsing Tai[1] (1.Chaoyang University of Technology)

[AHW23-P22] **Studying Operation Parameters on Flat-Plate Membrane Bioreactor for Sewage Treatment**

*Jen Hung Chiu[1], Wen Chin Chen[1] (1.Studying Operation Parameters on Flat-Plate Membrane Bioreactor for Sewage Treatment)

[AHW23-P23] **Mine-water quality at a tertiary coalfield in India: Characterisation and treatment using novel polyvinyl alcohol (PVA) gel bioreactor**

*Aparna Dutta[1], Sudipta Sarkar[1] (1.Indian Institute of Technology Roorkee)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_14

[A-HW23] Hydrology & Water Environment

convener:Isao Machida(Geological Survey of Japan), Dai Yamazaki(Institute of Industrial Sciences, The University of Tokyo), Takeshi Hayashi(Faculty of Education and Human Studies, Akita University), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University)

[AHW23-P01] **A multiobjective risk management model for real-time reservoir flood control operation**

*Juan Chen[1,2], Ping-An Zhong[2], XinYu Wan[2], Yu Zhang[2] (1.College of Earth Sciences and Engineering, Hohai University, 2.College of Hydrology and Water Resources, Hohai University)

[AHW23-P02] **Assessment of the Flow Regime of Roanoke River due to Climatic and Anthropogenic Activities**

*Rahul Kumar Singh[1], Dr. Manoj Kumar Jain[1] (1.Indian Institute of Technology, Roorkee, India)

[AHW23-P03] Predictive Analysis of Climate, Water, Health and the Environment Nexus

[ACG35-P07] A global simulation of bioenergy crop yield

*Zhipin Ai[1], Naota Hanasaki[1] (1.National Institute for Environmental Studies)

[ACG35-P08] Integrated Research Program for Advancing Climate Models - Theme B: national research program in Japan on earth system modeling

*Michio Kawamiya[1], Tomohiro Hajima[1], Kaoru Tachiiri[1], Jun'ichi Tsutsui[2], Tokuta Yokohata[3], Takashi Arakawa[4], Takahiro Inoue[4] (1.Japan Agency for Marine-Earth Science and Technology, 2.Central Research Institute of Electric Power Industry, 3.National Institute for Environmental Studies, 4.Research Organization for Information Science and Technology)

[ACG35-P09] Towards probabilistic climate projections based on the CMIP6 multi-model ensemble

*Junichi Tsutsui[1] (1.Central Research Institute of Electric Power Industry)

[ACG35-P10] Effect on the earth system of realizing 1.5 degree climate target by overshooting after reaching 2 degree level

*Kaoru Tachiiri[1], Herran Diego Silva[2], Xuanming Su[1], Michio Kawamiya[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Institute for Global Environmental Strategies)

[ACG35-P11] **Historical regional and sectoral contributions to climate change**

*Xuanming Su[1], Kaoru Tachiiri[1], Katsumasa TANAKA[2], Michio Watanabe[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute for Environmental Studies)

[ACG35-P12] **Future projection of global climate, water, food, bio-energy, and land investigated with MIROC-INTEG: a global bio-geophysical land surface model with human components**

*Tokuta Yokohata[1], Yusuke Satoh[1], Tsuguki Kinoshita[2], Gen Sakurai[3], Yadu Pokhrel[4], Akihiko Ito[1], Etsushi Kato[5], Masashi Okada[1], Naota Hanasaki[1], Tomoko Nitta[6], Seita Emori[1] (1.National Institute for Environmental Studies, 2.Ibaraki University, 3.National Agriculture and Food Research Organization, 4.Michigan State University, 5.The Institute of Applied Energy, 6.University of Tokyo)

[ACG35-P13] **Downscaling a global agricultural land use model to country level for national SSP analysis**

*Wenchao Wu[1], Tomoko Hasegawa[1], Kiyoshi Takahashi[1], Shinichiro Fujimori[2] (1.National Institute for Environmental Studies, 2.Kyoto Univ.)

[ACG35-P14] Extreme Events and Emergent Trends in Marine Ecosystem Stressors under a historical/RCP8.5 Climate Change Pathway

*Keith Bradley Rodgers[1,2], Sarah Schlunegger[3], Richard Slater[3], Burke Hales[4], Axel Timmermann[1,2] (1.IBS Center for Climate Physics, Busan, South Korea, 2.Pusan National University, Busan, South Korea, 3.AOS Program, Princeton University, Princeton NJ, USA, 4.College of Ocean and Atmospheric Sciences, Oregon State Universitym, Corvallis, OR, USA)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 303 3F

[A-CG35] Projection and detection of global environmental change

convener:Michio Kawamiya(Japan Agency for Marine-Earth Science and Technology), Hiroaki Tatebe(Japan Agency for Marine-Earth Science and Technology), Kaoru Tachiiri(Japan Agency for Marine-Earth Science and Technology), Chairperson:Hiroaki Tatebe

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[ACG35-01] **Sour and anoxic Sea of Japan in the near future**

*Chen-Tung Arthur Chen[1], Hon-Kit Lui[1], Masao Ishii[2] (1.National Sun Yat Sen University, 2.Japan Meteorological Agency)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[ACG35-02] **Decadal predictions of the variable ocean carbon uptake**

★Invited Papers

*Hongmei Li[1], Tatiana Ilyina[1], Wolfgang A. Müller[1,2], Peter Landschützer[1] (1.Max Planck Institute for Meteorology, Bundesstraße 53, 20146 Hamburg, Germany, 2.Deutscher Wetterdienst, Bernhard-Nocht-Straße 76, 20359 Hamburg, Germany)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[ACG35-03] Air-sea CO_2 flux variations in the tropical Pacific simulated with two ESMs embedded an ocean data assimilation system

*Michio Watanabe[1], Hiroaki Tatebe[1], Hiroshi Koyama[1], Tomohiro Hajima[1], Masahiro Watanabe[2], Michio Kawamiya[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[ACG35-04] **A Study of Decadal Ocean Deoxygenation and Heat Uptake from a suite of OMIP Simulations**

*Yohei Takano[1], Jerry Tjiputra[2], Jörg Schwinger[2], Matthias Gröger[3], Sarah Berthet[4], Roland Séférian[4], Andrew Yool[5], Julien Palmieri[5], Michio Watanabe[6], Irene Stemmler[1], Tatiana Ilyina[1] (1.Max Planck Institute for Meteorology, 2.Norwegian Research Centre, 3.Swedish Meteorological and Hydrological Institute, 4.Centre National de Recherche Météorologique, Unite mixte de recherche 3589 Météo-France/CNRS, 5. National Oceanography Centre, 6.Japan Agency for Marine-Earth Science and Technology)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[ACG35-05] **Role of large-scale environmental variability in changing storm climate**

*Nilima Aditya Natoo[1] (1.University of Bremen, Germany)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[ACG35-06] The forced response of the climate system: The case of climatic teleconnections

*Tamas Bodai[1], Matyas Herein[2], Gabor Drotos[3] (1.University of Reading, 2.Eotvos University Budapest, 3.Universitat de les Illes Balears)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 303 3F

[A-CG35] Projection and detection of global environmental change

convener:Michio Kawamiya(Japan Agency for Marine-Earth Science and Technology), Hiroaki Tatebe(Japan Agency for Marine-Earth Science and Technology), Kaoru Tachiiri(Japan Agency for Marine-Earth Science and Technology), Chairperson:Kaoru Tachiiri(Japan Agency for Marine-Earth Science and Technology), Michio Kawamiya(JAMSTEC)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[ACG35-07] Guiding Mother Earth: taking stock of progress to a long-term temperature goal

★Invited Papers

*Myles Robert Allen[1] (1.Environmental Change Institute, School of Geography and the Environment and Department of Physics, University of Oxford)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[ACG35-08] **Uneven distributions of four hazard indicators of climate change with the Paris Agreement's goals**

*Hideo Shiogama[1] (1.Center for Global Environmental Research, National Institute for Environmental Studies)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[ACG35-09] Understanding the centennial-scale human-natural interactions using an integrated terrestrial model MIROC-INTEG under ISIMIP2 project

*Yusuke Satoh[1], Julien Boulange[1], Naota Hanasaki[1], Kumiko Takata[1], Yadu Pokhrel[3], Ted Veldkamp[2,4], Peter Burek[2], Tokuta Yokohata[1] (1.National Institute for Environmental Studies, 2.International Institute for Applied Systems Analysis, 3.Department of Civil and Environmental Engineering, Michigan State University, 4.Institute for Environmental Studies (IVM), VU Amsterdam)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[ACG35-10] Radiative forcing of the physiological CO_2 response

*Victor Brovkin[1], Veronika Gayler[1], Sonia I Seneviratne[2], Pierre Gentine[3] (1.Max Planck Institute for Meteorology, Hamburg, Germany, 2.ETH, Institute for Atmospheric and Climate Science, Zurich, Switzerland, 3.Columbia University, Earth and Environmental Engineering, New York, USA)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[ACG35-11] Progress of MIROC-ES2 simulations in CMIP6 and the analysis of the biogeochemical feedbacks

*Tomohiro Hajima[1], Shingo Watanabe[1], Michio Kawamiya[1], Kaoru Tachiiri[1], Hiroaki Tatebe[1], Akihiko Ito[2], Kumiko TAKATA[2], Michio Watanabe[1], Maki Noguchi[1], Akitomo Yamamoto[1], Akinori Ito[1], Manabu Abe[1], Rumi Ohgaito[1], Dai Yamazaki[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute for Environmental Studies, 3.Institute of Industrial Science, the University of Tokyo)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[ACG35-12] The impact of long-term historical warming on the global terrestrial gross primary production

*Irina Melnikova[1], Takahiro Sasai[1] (1.Tohoku University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 102 1F

[A-CG42] Biogeochemical linkages between the surface ocean and atmosphere

convener:Yuzo Miyazaki(Institute of Low Temperature Science, Hokkaido University), Jun Nishioka(Hokkaido University, Institute of low temperature sciences), Koji Suzuki(Hokkaido University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Chairperson:Yuzo Miyazaki(Institute of low temperature science, Hokkaido University), Jun Nishioka(Institute of low temperature science, Hokkaido University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACG42-01] Production of bromoform in sea ice and emission to the atmosphere

*Daiki Nomura[1], Atsushi Ooki[1], Ellen Damm[2], Gerhard Dieckmann[2], Bruno Delille[3], Markus Frey[4], Mats Granskog[5], Klaus Meiners[6,7], Anna Silyakova[8], Takeshi Tamura[9], Jean-Louis Tison[10], Youhei Yamashita[11] (1.Faculty of Fisheries Sciences, Hokkaido University, 2.Alfred Wegener Institute for Polar and Marine Research, Bremerhaven, Germany, 3.Université de Liège, Liège, Belgium., 4.British Antarctic Survey, Cambridge, United Kingdom., 5.Norwegian Polar Institute, Tromsø, Norway., 6.Antarctic Climate andEcosystems Cooperative Research Centre, University of Tasmania, Hobart, Australia., 7.Australian Antarctic Division, Kingston, Australia., 8.Centre for Arctic Gas Hydrate, Environment and Climate, Tromsø, Norway., 9.National Institute of Polar Research, Tokyo, Japan., 10.Université Libre de Bruxelles, Bruxelles, Belgium., 11.Graduate School of Environmental Sceince, Hokkaido University, Sapporo, Japan.)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACG42-02] Accumulation processes of trace metals into arctic sea ice: distribution of Fe, Mn and Cd associated with ice structure

*La Kenya Evans[1], Jun Nishioka[1] (1.Institute of Low Temperature Sciences, Hokkaido University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACG42-03] Is halogen chemistry responsible for low ozone levels observed over western Pacific equatorial region? - From observations on R/V Mirai

*Yugo Kanaya[1], Kazuyuki Miyazaki[1], Fumikazu Taketani[1], Takuma Miyakawa[1], Hisahiro Takashima[1,2], Yuichi Komazaki[1], Xiaole PAN[3,1], Saki Kato[2], Kengo Sudo[4,1] (1.Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology, 2.Fukuoka University, 3.Institute of Atmospheric Physics, Chinese Academy of Sciences, China, 4.Nagoya University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACG42-04] Very low $\delta^{15}N$ of atmospheric nitrate found in the earstern equatorial Pacific and its implication to dynamic nitrogen recycle between ocean and lower atmosphere

*Shohei Hattori[1], Kazuki Kamezaki[1], Yoko Iwamoto[2], Sakiko Ishino[1], Mitsuo Uematsu[3], Kazuhiko Miura[4], Naohiro Yoshida[1] (1.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 2.Hiroshima University, 3.University of Tokyo, 4.Tokyo University of Science)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[ACG42-05] Origin of water-soluble organic nitrogen in marine atmospheric aerosols in the subtropical North Pacific

*Tsukasa Dobashi[1,2], Yuzo Miyazaki[1], Eri Tachibana[1], Yoko Iwamoto[3], Kazutaka Takahashi[4], Sachiko Horii[4], Shu-Kuan Wong[5], Koji Hamasaki[5] (1.Institute of Low Temperature Science, Hokkaido Univ., 2.Graduate School of Env. Sci., Hokkaido Univ., 3.Graduate School of Biosphere Science, Hiroshima Univ., 4.Graduate School of Agricultural and Life Sciences, Univ. of Tokyo, 5.Atmosphere and Ocean Research Institute, Univ. of Tokyo)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[ACG42-06] Impacts of ammonia on gas-particle partition and AWC during the 2016 APHH-Beijing campaign: inducing effects of nitrate ammonium

*baozhu Ge[1], Xiaobin Xu[2], Zhiqiang Ma[3], Xiaole PAN[1], Zhe WANG[1,4], Weili Lin[5], Bin Ouyang[6], Danhui Xu[1], James Lee[7], Mei Zheng[8], Dongsheng Ji[1], Yele Sun[1], Huabin Dong[8], Freya Anne Squires[7], Pingqing Fu[1], Zifa Wang[1] (1.State Key Laboratory of Atmospheric Boundary Layer Physics and Atmospheric Chemistry, Institute of Atmospheric Physics, Chinese Academy of Sciences, Beijing 100029, China, 2.State Key Laboratory of Severe Weather & Key Laboratory for Atmospheric Chemistry of China Meteorological Administration, Chinese Academy of Meteorological Sciences, Beijing 100081, China, 3.Institute of Urban Meteorology, China Meteorological Administration, Beijing, China, 4.Research Institute for Applied Mechanics (RIAM), Kyushu University, Fukuoka, Japan, 5.College of Life and Environmental Sciences, Minzu University of China, Beijing 100081, China, 6.Lancaster Environment Centre,

Lancaster University, Lancaster, LA1 4YQ, UK, 7.National Centre for Atmospheric Science Department of Chemistry, University of York, York, YO10 5DD, UK, 8.State Key Joint Laboratory of Environmental Simulation and Pollution Control, College of Environmental Sciences and Engineering, Peking University, Beijing, 100871, China)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[A-CG42] Biogeochemical linkages between the surface ocean and atmosphere

convener:Yuzo Miyazaki(Institute of Low Temperature Science, Hokkaido University), Jun Nishioka(Hokkaido University, Institute of low temperature sciences), Koji Suzuki(Hokkaido University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University)

[ACG42-P01] Mixing States of Aged Black Carbon Collected over the Western North Pacific Ocean

*Momoka Yoshizue[1], Masahiro Momoi[1], Kouji Adachi[2], Masanori Yabuki[3], Tatsuhiro Mori[1], Akiho Suizu[4], Shinichi Kodama[1,4], Kazuhiko Miura[1], Mitsuo Uematsu[4] (1.Tokyo University of Science, 2.Meteorological Research Institute, 3.Kyoto University, 4.The University of Tokyo)

[ACG42-P02] Influence of Deposition of Atmospheric Inorganic Nitrogen Compounds to Marine Ecosystem at Bay of Bengal

*Fumikazu Taketani[1], Maki Noguchi Aita[1], Kazuyo Yamaji[1,2], Takashi Sekiya[1], Kohei Ikeda[3], Taketo Hashioka[1], Makio Honda[1], Kazuhiko Matsumoto[1], Yugo Kanaya[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kobe University, 3.National Institute for Environmental Studies)

[ACG42-P03] Carbon isotopic characterization of organic aerosols in tropical marine atmosphere at the Maïdo high-altitude observatory, Reunion Island

Sharmine Akter Simu[1], *Yuzo Miyazaki[1], OCTAVE Science Team (1.Institute of Low Temperature Science, Hokkaido University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_17

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 101 1F

[H-GM04] Geomorphology

convener:Tsuyoshi Hattanji(Faculty of Life and Environmental Sciences, University of Tsukuba), Masayuki Seto(Fukushima Future Center for Regional Revitalization, Fukushima University), Chairperson:Masayuki Seto, Hiroshi Shimazu

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[HGM04-06] The landform and flood characteristics of the Iron Gate on the ancient road from Samarkand to Bamian, south Uzbekistan

*Hiroshi Shimazu[1] (1.Department of Geography, Faculty of Geo-Environmental Science, Rissho University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[HGM04-07] OSL dating of sediment core in Olgoi lake, Mongolia

*Yudai Igarashi[1], Noriko Hasebe[1], Nagayoshi Katsuta[2], Hitoshi Hasegawa[3], Davaadorj Davaasuren[4], Yukiya Tanaka[5], Uyangaa Udaanjargal[1], Keisuke Fukushi[1], Ichinnorov Niiden[6] (1.Kanazawa University, 2.Gihu University, 3.Kochi University, 4.National University of Mongolia, 5.Kyunghee University, 6.Mongolian Academy of Science)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HGM04-08] Paleo Lake level change in southern part of Mongolia

*Noriko Hasebe[1], Makoto Sambo[2], Uyangaa Udaanjargal[2,3], Shuukaaz Ganbat[3], Keisuke Fukushi[1], Yukiya Tanaka[4], Davaadorj Davaasuren[3] (1.Institute of Nature and Environmental Technology, Kanazawa University, 2.Department of Earth Sciences, Kanazawa University, 3.National University of Mongolia, 4.Kyunghee University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HGM04-09] Numerical modeling of wave propagation on the coral reef based on high resolution 3D topography

*Kenta Minamidate[1], Kazuhisa Goto[2], Masashi Watanabe[3,4], Volker Roeber[5,6], Ken Toguchi[7], Masami Sannoh[8], Yosuke Nakashima[9], Hironobu Kan[10] (1.Graduate School of Science, Tohoku University, 2.International Research Institute of Disaster Science (IRIDeS), Tohoku University, 3.Graduate School of Engineering, Tohoku University, 4.Graduate School of Science and Engineering, Chuo University, 5.Hawaii University, 6.Université de Pau et des Pays de l'Adour, 7.Ryukyu University, 8.Mikuniya Corporation, 9.NIT, Ariake College, 10.Graduate School of Integrated Sciences for Global Society, Kyushu University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HGM04-10] Coastal Seafloor Geomorphology: launching of a new field and perspectives

*Hironobu Kan[1], Nobuyuki Hori[2], Tatsuro Nakai[3], Yusuke Yokoyama[4], Kazuhiko Fujita[5], Hitoshi Hasegawa[3], Yosuke Nakashima[6], Kensaku Urata[1], Atsushi Suzuki[7], Masayuki Nagao[7], Kazuhisa Goto[8] (1.Graduate School of Integrated Sciences for Global Society, Kyushu University, 2.Emeritus Professor, Department of Geography, Tokyo Metropolitan University, 3.Department of Geography and Environmental Studies, Kokushikan University, 4.AORI, University of Tokyo, 5.Department of Physics and Earth Sciences, Faculty of Science, University of the Ryukyus, 6.National Institute of Technology, Ariake College, 7.Research Institute of Geology and Geoinformation, AIST, 8.IRIDeS, Tohoku University)

[J] Poster | H (Human Geosciences)：H-GM Geomorphology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_12

[H-GM04] Geomorphology

convener:Tsuyoshi Hattanji(Faculty of Life and Environmental Sciences, University of Tsukuba), Masayuki Seto(Fukushima Future Center for Regional Revitalization, Fukushima University)

[HGM04-P01] Automatic landform classification using Self-Organizing Map (SOM) by geomorphological features calculated from DEM

*Ito Yoshiki[1], Yoshiya Oda[1], Toshifumi Matsuoka[2] (1.Tokyo Metropolitan University, 2.Fukada Geological Institute)

[HGM04-P02] **Functionalization of the Average Erosion of Drainage Basin Using DEM**

*Rei Yamanaka[1], Tatsuto Aoki[1] (1.Kanazawa University)

[HGM04-P03] The Movement of Sediment and Development of Gullies Inside of Landslide area

*Yasuhiro Horikawa[1], Tatsuto Aoki[2] (1.Tsukuba University, 2.Kanazawa University)

[HGM04-P04] Detailed topographic survey of valley head in hill by terrestrial laser scanning

*KIYOSHI SAIJO[1], Takahisa Furuichi[2], Asaka Konno[3] (1.Miyagi University of Education, 2.Graduate School of Agriculture, Hokkaido University, 3.Tokoha University)

[HGM04-P05] Preliminary application of electrical resistivity tomography to estimate subsurface structure of unchanneled valley: A case at granitic hillslope near Mt. Tsukuba, Japan

*Naoyuki Yoshihara[1], Tsuyoshi Hattanji[2] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Faculty of Life and Environmental Sciences, University of Tsukuba)

[HGM04-P06] Estimating distribution of soil thickness in doline from electrical resistivity tomography:A case study in the Akiyoshi-dai Karst Plateau, Japan

*Naoya Hiramoto[1], Tsuyoshi Hattanji[2] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Faculty of Life and Environmental Sciences, University of Tsukuba)

[HGM04-P07] Occurrence and origin of potholes developed on the eastern slope of Miharayama in Hachijojima, Izu Islands, Tokyo Prefecture, Japan

*Takashi Ishibashi[1], Tomoaki Mastumi[2], Ren Higuchi[2], Yuki Yamatmoto[2], Keigo Shimada[2], Hirotomo Morimoto[2], Tsutomu Shimada[3], Kenji Asakura[4] (1.Masutomi Museum of Geocience, 2.Ritsumeikan University Explorers Club, 3.Pothole Survey Team, 4.Kyoto University Graduate School of Science)

[HGM04-P08] Temporal and spatial changes of sediment supply processes from tributaries since the last glacial period in the upper valleys of the Tama and Ara rivers, central Japan

*Takayuki Takahashi[1], Toshihiko Sugai[1] (1.Graduate School of Frontier Sciences, The University of Tokyo)

[HGM04-P09] Landform evolution and active tectonics in the eastern part of Oiso Hills inferred by characteristics of gravels composing Kissawa Formation, Japan

*Masahiro Muraki[1], Toshihiko Sugai[1] (1.Graduate School of Frontier Science, The University of Tokyo)

[HGM04-P10] Sediment movement and collapse of bank protections by a series of large flood events at the Sendai River, Tottori, southwest Japan

*Yoshinori Kodama[1], Kento Takemoto[2] (1.Faculty of Agriculture, 2.Hyogo Prefecture)

[HGM04-P11] Channel incision history with knickpoint retreat in the Kushira River after the deposition of Ata pyroclastic flow, Osumi Peninsula, Kyushu, Japan

*Shintaro Takanami[1] (1.Meiji University)

[HGM04-P12] **Implications of the distribution of marine terraces and submerged terraces in Japanese Island**

*Tetsuya Komatsu[1], Hiura Yuki[1], Takayuki Takahashi[2], Taro Funatsu[2], Masahiro Muraki[2], Taiga Kimori[2], Toshihiko Sugai[2] (1.Japan Atomic Energy Agency, 2.Graduate School of Frontier Sciences, The University of Tokyo)

[HGM04-P13] Marine erosional landforms along the southern coast of Yonaguni Island, Ryukyus

*Hayate Kimura[1], Kensaku Urata[2], HASEGAWA Hitoshi[3], Toshihiko Ichihara[4], Atsushi Suzuki[5], Nobuyuki Hori[6], Hironobu Kan[2] (1.Graduate school of integrated sciences for global society, 2.Graduate School of Integrated Sciences for Global Society, Kyushu University, 3.Kokushikan University, 4.Sedimentary Environments Research, 5.Geological Survey of Japan National Institute of Advanced Industrial Science and Technology (AIST), 6.Department of Geography, Nara University)

[HGM04-P14] Seafloor topography of Amami Sumiyo Bay -Visualization of Seafloor derived from multibeam bathymetric survey-

*Miho Tanaka[1], Ken Toguchi[2], Nobuyuki Hori[3], Hayate Kimura[4], Yukihiko Imai[5], Yosuke Nakashima[6], Yayoi Najima[7], Hironobu Kan[8] (1.Graduate School of Integrated Sciences for Global Society, 2.University of the Ryukyus, 3.Tokyo Metropolitan University, 4.School of Engineering, Kyushu University, 5.Faculty of science, Okayama University, 6.National Institute of Technology, Ariake College, 7.The Graduate University for Advanced Studies, 8.Kyushu University)

[J] Poster | H (Human Geosciences)：H-GM Geomorphology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_19

[J] Oral | H (Human Geosciences)：H-SC Social Earth Sciences & Civil/Urban System Sciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 301B 3F

[H-SC07] CCUS (Carbon Dioxide Capture, Utilization, and Storage) for Climate Mitigation

convener:Masao Sorai(Institute for Geo-Resources and Environment, National Institute of Advanced Industrial Science and Technology), Ziqiu Xue(Research Institute of Innovative Tech for the Earth), Masaatsu Aichi(Graduate School of Frontier Sciences, University of Tokyo), Chairperson:Masao Sorai(National Institute of Advanced Industrial Science and Technology)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[HSC07-01] Numerical simulation of variational pore pressure response to ocean tidal loading during CO2 injection

*Toshifumi Akaki[1], Hajime Yamamoto[1] (1.Taisei Corporation)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[HSC07-02] Relationship between rock deformation and permeability evolution during fracturing in rocks for CCUS technology

*Takashi Fujii[1], Xinglin Lei[1], Masao Sorai[1] (1.National Institute of Advanced Industrial Science and Technology)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[HSC07-03] Comparison of Optical Fiber Sensing Technique and Strain Gauge in a Measurement of Rock Deformation Caused by Chemical Osmosis

*Shogo Hirota[1], Tomochika Tokunaga[1], Ziqiu Xue[2], Hyuck Park[2] (1.Department of Environmental Systems, Graduate School of Frontier Science, the University of Tokyo, 2.Research Institute of Innovative Technology for the Earth)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[HSC07-04] Experiment of precipitation of salt for dry-out condition caused by CO_2 storage in saline aquifer

*Hayato Morigaki[1,2], Masaatsu Aichi[1] (1.University of Tokyo, 2.Toshiba Energy Systems & Solution Corporation)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[HSC07-05] Thermodynamic Approach to Wettability of CO_2/Brine/Mineral System by Augmented Young Laplace Equation

*Masashige Shiga[1,2], Masao Sorai[1], Masaatsu Aichi[2], Hiromi Honda[2] (1.AIST, 2.The University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[HSC07-06] A proposal of CO2 underground storage using hydrate

*Takaomi Tobase[1] (1.Electric Power Development Co., Ltd.)

[J] Oral | H (Human Geosciences)：H-SC Social Earth Sciences & Civil/Urban System Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 301B 3F

[H-SC07] CCUS (Carbon Dioxide Capture, Utilization, and Storage) for Climate Mitigation

convener:Masao Sorai(Institute for Geo-Resources and Environment, National Institute of Advanced Industrial Science and Technology), Ziqiu Xue(Research Institute of Innovative Tech for the Earth), Masaatsu Aichi(Graduate School of Frontier Sciences, University of Tokyo), Chairperson:Ziqiu Xue(Research Institute of Innovative Technology for the Earth)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[HSC07-07] CO_2 behavior simulation using large scale geological model

*Yuuki Shigeoka[1], Haruki Nishiyama[1], Hiroshi Kinoto[1], Takaomi Tobase[2], Takahiro Nakajima[3], Ziqiu Xue[3] (1.JP Business Survice Corporation, 2.Electric Power Development Co., Ltd., 3.Research Institute of Innovative Technology for the Earth)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[HSC07-08] **Monitoring hydromechanical responses in aquifer by distributed fiber-optic strain sensing: From lab to field**

*Yi Zhang[1,2], Ziqiu Xue[1,2], Tsutomu Hashimoto[1,2], Hyuck Park[1,2] (1.Geological Carbon dioxide Storage Technology Research Association, 2.Research Institute of Innovative Tech for the Earth)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HSC07-09] **Field Testing of Hybrid Brillouin-Rayleigh Distributed Sensing System for Subsurface Water Injection Monitoring**

*Yankun Sun[1,2], Ziqiu Xue[1,2], Tsutomu Hashimoto[1,2], Xinglin Lei[3], Yi Zhang[1,2] (1.Geological Carbon Dioxide Storage Technology Research Association, 2.Research Institute of Innovative Technology for the Earth, 3.National Institute of Advanced Industrial Science and Technology)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HSC07-10] Gravity monitoring using superconducting gravimeters near the seashore at the Tomakomai CCS demonstration site

*Hiroki Goto[1,2], Mituhiko Sugihara[1,2], Hiroshi Ikeda[3], Yuji Nishi[1,2], Tsuneo Ishido[1,2], Masao Sorai[1,2] (1.Geological Carbon Dioxide Storage Technology Research Association, 2.National Institute of Advanced Industrial Science and Technology, 3.University of Tsukuba)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HSC07-11] Pilot test for microbubble CO_2 injection to reservoir in oil field - Test planning and preparation -

*Kazunori Nakagawa[1], Ryo Ueda[1], Masanori Nakano[1], Ziqiu Xue[2] (1.Japan Petroleum Exploration Co., Ltd., 2.Research Institute of Innovative Technology for the Earth)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[HSC07-12] Mechanisms inducing anomalously high pCO_2 without CO_2 leakage in coastal environment

*Yuji Watanabe[1,2], Keisuke Uchimoto[1,2], Makoto Nishimura[1,2], Saeko Mito[1,2], Ziqiu Xue[1,2] (1.Geological CO2 Storage Technology Research Association, 2.RITE)

[J] Poster | H (Human Geosciences)：H-SC Social Earth Sciences & Civil/Urban System Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_13

[H-SC07] CCUS (Carbon Dioxide Capture, Utilization, and Storage) for Climate Mitigation

convener:Masao Sorai(Institute for Geo-Resources and Environment, National Institute of Advanced Industrial Science and Technology), Ziqiu Xue(Research Institute of Innovative Tech for the Earth), Masaatsu Aichi(Graduate School of Frontier Sciences, University of Tokyo)

[HSC07-P01] Evaluation of seismic event location accuracy of Tomakomai CO2 injection site: a numerical simulation case study

*Luchen Wang[1], Takahiro Nakajima[1], Ziqiu Xue[1] (1.RITE, Research Institute of Innovative Technology for the Earth)

[HSC07-P02] Technical Challenges of Machine Learning Approach for Porosity Estimation in Nagaoka CCS site

*Takayuki Miyoshi[1], Takahiro Nakajima[1], Ziqiu Xue[1] (1.Research Institute of Innovative Technology for the Earth)

[HSC07-P03] Utilization of wave attenuation in time-lapse sonic logging data to evaluate the effect of super-critical CO_2 in the reservoir

*Takahiro Nakajima[2,1], Luchen Wang[2,1], Ziqiu Xue[2,1] (1.Research Institute of Innovative Technology for the Earth, 2.Geological Carbon Dioxide Storage Technology Research Association)

[HSC07-P04] **Geological sequestration in saline carbonate formations: CO_2-brine-rock interaction**

*Shachi Shachi[1], Brijesh Kumar Yadav[1], Mohammad Azizur Rahman[2], Mayur Pal[3] (1.Indian Institute of Technology Roorkee, 2.Texas A&M University Qatar, 3.North Oil Company, Qatar)

[HSC07-P05] **Changes in sealing performance of artificial caprocks caused by carbonate reactions**

*Masao Sorai[1] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[HSC07-P06] **CO_2 migration characteristics of microbubble and conventional sequestration in Berea sandstone revealed by X-ray CT imaging**

*Hongyu Zhai[1,2], Yi Zhang[1,2], Hyuck Park[1,2], Ziqiu Xue[1,2] (1.Geological Carbon dioxide Storage Technology Research Association,9-2, Kizugawadai, Kizugawa Shi, Kyoto, 6190292 Japan, 2.Research Institute of Innovative Technology for the Earth (RITE),9-2, Kizugawadai, Kizugawa Shi, Kyoto, 6190292 Japan)

[HSC07-P07] Strain detection by optical fiber for CO_2 injected core specimen

*Hyuck Park[1], Yankun Sun[1], Ziqiu Xue[1] (1.Research Institute of Innovative Technology for the Earth)

[HSC07-P08] Bed deformation measured by distributed optical fiber and its sedimentological interpretation: alternated sandstone and mudstone aquifer, Boso Peninsula, Japan

*Takuma Ito[1,2], Tsutomu Hashimoto[1,2], Ziqiu Xue[1,2] (1.Research Institute of Innovative Technology for the Earth, 2.Geological Carbon Dioxide Storage Technology Research Association)

[HSC07-P09] How many data are necessary to make a suitable threshold for anomalous pCO_2 owing to CO_2 leakage?

*Keisuke Uchimoto[1,2], Yuji Watanabe[1,2], Makoto Nishimura[1,2], Ziqiu Xue[1,2] (1.Geological Carbon dioxide Storage Technology Research Association , 2.Research Institute of Innovative Technology for the Earth)

[J] Poster | H (Human Geosciences)：H-SC Social Earth Sciences & Civil/Urban System Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

[H-DS10] Natural hazards impacts on human society, economics and technological systems

convener:ELENA PETROVA(Lomonosov Moscow State University, Faculty of Geography), Hajime Matsushima(Research Faculty of Agriculture, Hokkaido University)

[HDS10-P01] **The 2018 Activity of Kamchatka Volcanoes and Danger to Aviation**

*Olga Girina[1], Dmitry Melnikov[1], Alexander Manevich[1], Anton Nuzhdaev[1], Elena Petrova[2] (1.Institute of Volcanology and Seismology, Far East Division, Russian Academy of Sciences, 2.M.V. Lomonosov Moscow State University)

[HDS10-P02] Planning Methodology on the Effective Use of Green Infrastructure for Disaster Risk Reduction

★Invited Papers

*Keita Aragane[1], Satoshi Funakubo[1] (1.National Institute for Land Infrastructure Management)

[HDS10-P03] EMERGENCY CALL PATTERN IN PETROZAVODSK

*Boris Zalmanovich Belashev[1], Natalia Vladimirovna Krutskikh[1], Anna Aleksandrovna Gerasimova[1] (1.Karelian research center of Russian academy of science)

[HDS10-P04] IDENTIFYING “REGIMES” IN THE TIME SEQUENCES OF PROCESSES

*Boris Zalmanovich Belashev[1] (1.Karelian research center of Russian academy of science)

[HDS10-P05] **Investigation of status and demand on public service of earthquake disaster mitigation in China**

*Lina Dong[1], Weiping Lian[1], Weitao Chen[1] (1.Development Research Center, China Earthquake Administration)

[HDS10-P06] Analysis of Eco-DRR and Ecological Services using InVEST at the Disaster Areas of Kumamoto Earthquake

*Minghui Tang[1], Naoko Fujita[1] (1.Kyushu University)

[HDS10-P07] Transformation as praxis: Exploring socially just and transdisciplinary pathways to sustainability in marginal environments (TAPESTRY)

*Nobuhito Ohte[1], Lyla Mehta[2], Synne Movik[3], Devanathan Parthasarathy[4] (1.Department of Social Informatics, Graduate School of Informatics, Kyoto University, 2.Institute of Development Studies at the University of Sussex, 3.Department of Urban and Regional Planning, Norwegian University of Life Sciences, 4.Department of Humanities and Social Sciences, Indian Institute of Technology)

[HDS10-P08] Study for the Establishment of the Design for Disaster prevention through the survey of Recognition of tsunami disaster prevention from the viewpoint of green infrastructure in the coastal area of Kyushu-Pacific region.

*Shanshan Xu[1], Naoko Fujita[1], Minghui Tang[1] (1.Kyushu University)

[HDS10-P09] Design for Green Infrastructure: Analysis of Landscape change in the Kumamoto earthquake area

★Invited Papers

*Naoko Fujita[1] (1.Kyushu University)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_21

[H-DS10] Natural hazards impacts on human society, economics and technological systems

convener:ELENA PETROVA(Lomonosov Moscow State University, Faculty of Geography), Hajime Matsushima(Research Faculty of Agriculture, Hokkaido University)

[HDS10-P01] **The 2018 Activity of Kamchatka Volcanoes and Danger to Aviation**

*Olga Girina[1], Dmitry Melnikov[1], Alexander Manevich[1], Anton Nuzhdaev[1], Elena Petrova[2] (1.Institute of Volcanology and Seismology, Far East Division, Russian Academy of Sciences, 2.M.V. Lomonosov Moscow State University)

[HDS10-P02] Planning Methodology on the Effective Use of Green Infrastructure for Disaster Risk Reduction

★Invited Papers

*Keita Aragane[1], Satoshi Funakubo[1] (1.National Institute for Land Infrastructure Management)

[HDS10-P03] EMERGENCY CALL PATTERN IN PETROZAVODSK

*Boris Zalmanovich Belashev[1], Natalia Vladimirovna Krutskikh[1], Anna Aleksandrovna Gerasimova[1] (1.Karelian research center of Russian academy of science)

[HDS10-P04] IDENTIFYING “REGIMES” IN THE TIME SEQUENCES OF PROCESSES

*Boris Zalmanovich Belashev[1] (1.Karelian research center of Russian academy of science)

[HDS10-P05] **Investigation of status and demand on public service of earthquake disaster mitigation in China**

*Lina Dong[1], Weiping Lian[1], Weitao Chen[1] (1.Development Research Center, China Earthquake Administration)

[HDS10-P06] Analysis of Eco-DRR and Ecological Services using InVEST at the Disaster Areas of Kumamoto Earthquake

*Minghui Tang[1], Naoko Fujita[1] (1.Kyushu University)

[HDS10-P07] Transformation as praxis: Exploring socially just and transdisciplinary pathways to sustainability in marginal environments (TAPESTRY)

*Nobuhito Ohte[1], Lyla Mehta[2], Synne Movik[3], Devanathan Parthasarathy[4] (1.Department of Social Informatics, Graduate School of Informatics, Kyoto University, 2.Institute of Development Studies at the University of Sussex, 3.Department of Urban and Regional Planning, Norwegian University of Life Sciences, 4.Department of Humanities and Social Sciences, Indian Institute of Technology)

[HDS10-P08] Study for the Establishment of the Design for Disaster prevention through the survey of Recognition of tsunami disaster prevention from the viewpoint of green infrastructure in the coastal area of Kyushu-Pacific region.

*Shanshan Xu[1], Naoko Fujita[1], Minghui Tang[1] (1.Kyushu University)

[HDS10-P09] Design for Green Infrastructure: Analysis of Landscape change in the Kumamoto earthquake area

★Invited Papers

*Naoko Fujita[1] (1.Kyushu University)

[E] Oral | H (Human Geosciences)：H-DS Disaster geosciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 301B 3F

[H-DS10] Natural hazards impacts on human society, economics and technological systems

convener:ELENA PETROVA(Lomonosov Moscow State University, Faculty of Geography), Hajime Matsushima(Research Faculty of Agriculture, Hokkaido University), Chairperson:Hajime Matsushima, Elena Petrova

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[HDS10-07] **Seasonal variations of atmospheric hazard impacts on infrastructure**

★Invited Papers

*ELENA PETROVA[1] (1.Lomonosov Moscow State University, Faculty of Geography)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[HDS10-08] Assessment of water supply function and measures for chemical release accidents triggered by major earthquakes

*Lisa Ito[1], Toyohiko Nakakubo[2], Naoya Kojima[1], Akihiro Tokai[1] (1.Graduate School of Engineering, Osaka University, 2.Faculty of Core Research, Ochanomizu University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[HDS10-09] Development of disaster risk management plan of a thermal power plant: Spearheading the paradigm shift from disaster management to disaster risk management of NATECH in India

*Repaul Kanji[1], Madan Mohan Rout[2], Ankur Srivastava[3] (1.Gujarat Institute of Disaster Management, Gandhinagar, Gujarat, India, 2.Institute of Seismological Research, Gandhinagar, India, 3.Indian Institute of Technology Delhi, India)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[HDS10-10] **Applying Transfer Learning to Improve Machine Learning Impact Model at Extremes**

*Peter Lawrence Watson[1], Manos Anagnostou[1], David Wanik[1] (1.University of Connecticut)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[HDS10-11] rescEU, the European Union Civil Protection System UCPM and the future role of Geosciences in natural disaster reduction

*Andreas Nikolaus Kueppers[1] (1.GFZ - Deutsches Geoforschungszentrum - Helmholtz Zentrum Potsdam)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[HDS10-12] The Probability of Satellite Anomalies by a Disastrous Solar Flare

*Daikichi SEKI[1,2,3] (1.Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University, 2.Centre for the Study of Existential Risk, University of Cambridge, 3.Astronomical Observatory, Kyoto University)

[E] Oral | H (Human Geosciences)：H-DS Disaster geosciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 301B 3F

[H-DS10] Natural hazards impacts on human society, economics and technological systems

convener:ELENA PETROVA(Lomonosov Moscow State University, Faculty of Geography), Hajime Matsushima(Research Faculty of Agriculture, Hokkaido University), Chairperson:Elena Petrova, Hajime Matsushima

3:30 PM - 3:50 PM JST | 6:30 AM - 6:50 AM UTC

[HDS10-13] Management and Maintenance for Disaster prevention park in Tokyo Metropolitan Government

★Invited Papers

*Masayshi Kikuchi[1] (1.Tokyo Metropolitan Park Association)

3:50 PM - 4:05 PM JST | 6:50 AM - 7:05 AM UTC

[HDS10-14] Rebuilding Tourism after the Great East Japan Earthquake and Examining Post-Disaster Tourism in Kamaishi City

*Satoshi Sasaki[1], Kiyotatsu Yamamoto[2], Kaoruko Sasaki[3] (1.Iwate University, 2.The University of Tokyo, 3.Hokkaido University)

4:05 PM - 4:20 PM JST | 7:05 AM - 7:20 AM UTC

[HDS10-15] Population Change in Ishinomaki City, Miyagi Prefecture, with a Focus on the Area around the Earthquake Ruins

*Ryo Nishisaka[1], Katsunori Furuya[1] (1.Chiba University)

4:20 PM - 4:35 PM JST | 7:20 AM - 7:35 AM UTC

[HDS10-16] The Way of Seeing the Atomic Bomb Dome and the Relationship with Viewers' Attributes

*yasuhara arisa[1], Kiyotatsu Yamamoto[1], Akio Shimomura[1] (1.Graduate School of Agricultural and Life Sciences, The University of Tokyo)

4:35 PM - 4:50 PM JST | 7:35 AM - 7:50 AM UTC

[HDS10-17] Flood Disaster Risk Analysis at Ratnapura in Sri Lanka

*Tsuchida Ryo[1], Kaoru Takara[1] (1.Graduate School of Advanced Integrated Studies in Human Survivability, Kyoto University)

[J] Oral | H (Human Geosciences)：H-DS Disaster geosciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | Convention Hall B 2F

[H-DS13] Tsunami and Tsunami Forecast

convener:Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Hiroaki Tsushima(Japan Meteorological Agency), Tatsuya Kubota(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Masaaki Minami(気象研究所), Naotaka Chikasada(National Res. Inst. for Earth Science and Disaster Resilience)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[HDS13-07] Functions of Real-time Tsunami Inundation Forecast System Using S-net Pressure Data

*Wataru Suzuki[1], Naotaka YAMAMOTO CHIKASADA[1], Takayuki Miyoshi[1], Shin Aoi[1] (1.National Research Institute for Earth Science and Disaster Resilience)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[HDS13-08] Improvement of Real-time Tsunami Forecast System for Outer-rise Earthquake

*Naotaka YAMAMOTO CHIKASADA[1], Toshitaka Baba[2] (1.NIED, 2.Tokushima University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[HDS13-09] Maximum tsunami height prediction using Ocean-Bottom Pressure Values based on Gaussian Process Regression

*Kotaro Takahashi[1], Kenjiro Kashiwabara[1], Yasuhiko Igarashi[1,2], Toshitaka Baba[3], Takane Hori[4], Masato Okada[1] (1.Graduate School of Frontier Sciences, The University of Tokyo, 2.Japan Science and Technology Agency PRESTO, 3.Institute of Technology and Science, The University of Tokushima, 4.Research and Development Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[HDS13-10] Improvement for Finite-Difference Formula of Non-Linear Longwave Equations to Express Tsunami Decay

*Masaaki MINAMI[1] (1.Meteorological Research Institute)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[HDS13-11] **Real time tsunami inundation forecast method developed for Central America Region**

*Yuichiro Tanioka[1], Ulbert Gleb Grillo[2], Greyving Jose Argrello[2], Amilcar Cabrera[2] (1.Hokkaido University, Institute of Seismology and Volcanology, 2.Nicaraguan Institute of Territorial Studies, Nicaragua)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[HDS13-12] Near-fault observations of an offshore earthquake by DONET: Comparison of ocean bottom pressure gauges and strong-motion accelerometers

*Ayumu Mizutani[1], Kiyoshi Yomogida[1] (1.Natural History Science, Graduate School of Science, Hokkaido University, Earth and Planetary Dynamics)

[J] Oral | H (Human Geosciences)：H-DS Disaster geosciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Convention Hall B 2F

[H-DS13] Tsunami and Tsunami Forecast

convener:Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Hiroaki Tsushima(Japan Meteorological Agency), Tatsuya Kubota(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Kentaro Imai, Toshitaka Baba(Graduate School of Science and Technology, Tokushima University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[HDS13-13] **Investigation of variation in multiple tsunami inundation modelling**

*Yoshinori Shigihara[1], Kentaro Imai[2], Hiroyuki Iwase[3], Koji Kawasaki[4], Makoto Nemoto[5], Toshitaka Baba[6], Naotaka YAMAMOTO CHIKASADA[7], Yu Chida[8], Taro Arikawa[9] (1.Department of Civil and Environmental Engineering, National Dedense Academy, 2.Japan Agency for Marine-Earth Science and Technology, 3.Ecoh Corporation, 4.Hydro Technology Institute, Co., Ltd., 5.OYO Corporation, 6.Graduate School of Science and Technology, Tokushima University, 7.National Research Institute for Earth Science and Disaster Resilience, 8.Port and Airport Research Institute, 9.Civil and Environmental Engineering, Faculty of Science and Engineering, Chuo University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[HDS13-14] **Numerical Modeling of Tsunami Inundation in Urban Area using Sub-Grid Scale Drag Force Model**

*Nobuki Fukui[1], Nobuhito Mori[2] (1.Graduate School of Engineering, Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HDS13-15] Numerical experiment of tsunami deposits related to fault parameters by sediment transport model

*Ako YAMAMOTO[1], Tomoyuki Takahashi[2], Kenji Harada[3] (1.Forest of Research and Management Organization Forestry and Forest Products Research Institute, 2.Kansai University, 3.Shizuoka University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HDS13-16] Evaluation of potential impact of tsunami-induced sediment transport in Kochi Prefecture during the Nankai Trough megathrust earthquake and tsunami

*Kei Yamashita[1], Daisuke Sugawara[2], Shuji Seto[1], Taro Arikawa[3], Tomoyuki Takahashi[4], Fumihiko Imamura[1] (1.International Research Institute of Disaster Science, Tohoku University, 2.Museum of Natural and Environmental History, Shizuoka, 3.Faculty of Science and Engineering , Chuo University, 4.Faculty of Societal Safety Sciences, Kansai University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HDS13-17] Tsunami damage of the Keicho Earthquake of February 3rd, 1605 on the coasts of Tokai, Shikoku, and Kyushu Districts

*Yoshinobu Tsuji[1], Kentaro Imai[2], Yuuichi Ebina[3], Hiroyuki Iwase[4], Ryoko Oobayashi[2] (1.Shimanto City, 2.JAMSTEC, 3.IRIDeS, 4.Ecoh co. LTD)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[HDS13-18] Re-examination of tsunami heights distribution during the 1854 Ansei Tokai Earthquake

*Kentaro Imai[1], ebina yuichi[2], Yoshinobu Tsuji[3], Hiroyuki Iwase[4], Takane Hori[1], Narumi Takahashi[1,5], Takashi Furumura[6] (1.Japan Agency for Marine-Earth Science and Technology, 2.International Research Institute of Disaster Science, 3.Shimanto City, 4.ECOH CORPORATION, 5.National Research Institute for Earth Science and Disaster Resilience, 6.Earthquake Research Institute The University of Tokyo)

[J] Oral | H (Human Geosciences)：H-RE Resource and Engineering Geology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 106 1F

[H-RE16] Resource Geology

convener:Tsubasa Otake(Division of Sustainable Resources Engineering, Faculty of Engineering, Hokkaido University), Daisuke Araoka(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Ryohei Takahashi(Graduate School of International Resource Sciences, Akita University), Tatsuo Nozaki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Chairperson:Tsubasa Otake(Faculty of Engineering, Hokkaido University), Daisuke Araoka

10:45 AM - 11:15 AM JST | 1:45 AM - 2:15 AM UTC

[HRE16-01] The role of water in the concentration of Cr

★Invited Papers

*Shoji Arai[1] (1.Department of Earth Sciences, Faculty of Science, Kanazawa University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HRE16-02] Mineralogical Features of Silver-Bearing Minerals in Chimney Ore from Myojinsho Caldera, Myojin Knoll and Bayonnaise Knoll Seafloor Hydrothermal Area, Izu-Bonin Arc

Shinji Kawaguchi[1], *Kotaro Yonezu[1], Thomas Tindell[1], Jun-ichiro Ishibashi[2], Tatsuo Nozaki[3], Yoko Ohtomo[4], Koichiro Watanabe[1] (1.Deaprtment of Earth Resources Engineering, Faculty of Engineering, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 3.Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology, 4.Faculty of Engineering, Hokkaido University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HRE16-03] Organic matters and acid-sulfate alteration in Itomuka Mine, Hokkaido, Japan: implications for the transportation and deposition mechanisms of mercury

*Takuya Echigo[1], Mitsuyoshi Kimata[2], Masahiro Shimizu[2] (1.Graduate School of International Resource Sciences, Akita University, 2.Graduate School of Life and Environmental Sciences, University of Tsukuba)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HRE16-04] **Significances of 12 Ma manganese ores in the Hokuroku district, Akita: unique Mn accumulation and interaction with organic matter during submarine hydrothermal activities**

*Yuya Tsukamoto[1], Takeshi Kakegawa[1] (1.Tohoku Univ.)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[HRE16-05] Microbial communities around ca. 2.7 Ga submarine hydrothermal fields at the Potterdoal deposit in Abitibi Greenstone Belt, Canada

*Takeru Osato[1], Akizumi Ishida[1], Takeshi Kakegawa[1] (1.Tohoku University)

[J] Oral | H (Human Geosciences)：H-RE Resource and Engineering Geology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 106 1F

[H-RE16] Resource Geology

convener:Tsubasa Otake(Division of Sustainable Resources Engineering, Faculty of Engineering, Hokkaido University), Daisuke Araoka(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Ryohei Takahashi(Graduate School of International Resource Sciences, Akita University), Tatsuo Nozaki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Chairperson:Tatsuo Nozaki(JAMSTEC), Ryohei Takahashi(Faculty of International Resource Sciences, Akita University)

1:45 PM - 2:15 PM JST | 4:45 AM - 5:15 AM UTC

[HRE16-06] Development of nano-fabrication and high-resolution electron microscopy techniques: their possible applications to resource geology

★Invited Papers

*Naotaka Tomioka[1], Satoko Motai[1], Yu Kodama[2], Motoo Ito[1] (1.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2.Marine Works Japan)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[HRE16-07] Microscopic study on rare earth elements in ion-adsorption type ore of China

*Hiroki Mukai[1], Yoshiaki Kon[1], Kenzo Sanematsu[1], Yoshio Takahashi[2], Motoo Ito[3] (1.National Institute of Advanced Industrial Science and Technology, 2.Graduate School of Science, the University of Tokyo, 3.Kochi Institute for Core Sample Research JAMSTEC)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[HRE16-08] Geochemical features of “invisible gold” in pyrites from the Akeshi and Kasuga deposits, Kagoshima, Japan

*Mizuki Ishida[1], Rurik Romeo[2,3], Mathieu Leisen[2,3], Junji Torimoto[4], Tatsuo Nozaki[4,5,6,7], Kazutaka Yasukawa[1,6], Koichiro Fujinaga[6,1], Kentaro Nakamura[1], Martin Reich[2,3], Yasuhiro Kato[1,6,5] (1.Department of Systems Innovation, School of Engineering, The University of Tokyo, 2.Department of Geology and Andean Geothermal Center of Excellence (CEGA), FCFM, 3.Millennium Nucleus for Metal Tracing Along Subduction, FCFM, Universidad de Chile, FCFM, 4.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 5.Frontier Research Center for Energy and Resources, School of Engineering, The University of Tokyo, 6.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 7.Department of Planetology, Graduate School of Science, Kobe University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[HRE16-09] Hydrothermal Mineral Assemblage of the Southwest Prospect, in the Vicinity Sto. Tomas II (Philex) Porphyry Cu-Au Deposit, Baguio District, Philippines

*Avriel Venis Literal Cirineo[1], Akira Imai[2], Ryohei Takahashi[1], Noel C. Oliveros[3], Redempta P. Baluda[3], Victor B. Maglambayan[3], Roy Ronald C. Luis[3], Maria Lourdes M. Faustino[3] (1.Graduate School of International Resource Sciences, Akita University, 2.Faculty of Engineering, Kyushu University, 3.Philex Mining Corporation)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[HRE16-10] Characteristics and genesis of weathering REE deposits

★Invited Papers

*Kenzo Sanematsu[1] (1.Mineral Resource Research Group, Institute for Geo-Resources and Environment, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[J] Poster | H (Human Geosciences)：H-RE Resource and Engineering Geology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_14

[H-RE16] Resource Geology

convener:Tsubasa Otake(Division of Sustainable Resources Engineering, Faculty of Engineering, Hokkaido University), Daisuke Araoka(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Ryohei Takahashi(Graduate School of International Resource Sciences, Akita University), Tatsuo Nozaki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology)

[HRE16-P01] Mineral Chemistry and Petrogenesis of the Mazua Ultramafic Massif, Northern Mozambique: Constraints on the Associated Fe-Ti Oxides Deposit

*David Augusto Bene Unganai[1], Akira Imai[2], Ryohei Takahashi[1], Daud Liace Jamal[3], Takashi Hoshide[1] (1.Akita University, 2.Kyushu University, 3.Eduardo Mondlane University)

[HRE16-P02] **Ni-Cu-PGM Mineralisation in the Bastard Reef and Merensky Reef of the Flatreef section, Turfspruit Farm, Northern Limb, Bushveld Igneous Complex, South Africa.**

*MOKHIRI MALESELA MAKHAFOLA[1], Tsubasa Otake[1], Tsutomu Sato[1], Danie Grobler[2] (1.Hokkaido University, 2.Ivanplats Pty. Ltd)

[HRE16-P03] Characteristics of Porphyry Copper-Gold Mineralization in the Grasberg Mine, Papua, Indonesia

*Kanehiko Kawasaki[1], Kotaro Yonezu[2], Reza Al Furqan[3], Benny Bensaman[4], Mega Fatimah Rosana[4] (1.Kyushu University Facurity of Engineering, 2.Deaprtment of Earth Resources Engineering, Faculty of Engineering, Kyushu University, 3.PT Freeport Indonesia, 4.Department of Geology, Padjadjaran University)

[HRE16-P04] Formation of Ni-bearing minerals during chemical weathering of ultramafic rocks in Myanmar

*Ayaka Murofushi[1], Akane Ito[1], Tsubasa Otake[2], Kenzo Sanematsu[3], Kyaw Zay Ya[1,4], Tsutomu Sato[2] (1.Graduate school of Engineering, Hokkaido University, 2.Facility of Engineering, Hokkaido University, 3.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 4.Department of Geological Survey and Mineral Exploration)

[HRE16-P05] Geological Characteristics and Mineralogy of the Makorungo and Nalia Gold Prospects, Northeastern Mozambique

*Manuel Augusto Manuel Nopeia[1], Ryohei Takahashi[1], Akira Imai[2], Daud Liace Jamal[3] (1.Akita University, 2.Kyushu University, 3.Eduardo Mondlane University)

[HRE16-P06] Geochemical features of the Hishikari epithermal gold deposit based on simultaneous multi-element analysis

*Sota Nishida[1], Mizuki Ishida[1], Kazutaka Yasukawa[1,2], Kentaro Nakamura[1], Koichiro Fujinaga[2,1], Yasuhiro Kato[3,1,2] (1.Department of Systems Innovation, School of Engineering, The University of Tokyo, 2.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 3.Frontier Research Center for Energy and Resources, School of Engineering, The University of Tokyo)

[HRE16-P07] Transformation of ore minerals and their geochemical signatures in submarine hydrothermal ore deposits in Izena Hole, Okinawa Trough

*IKESHIMA TAKURO[1], Tsubasa Otake[1], Tsutomu Sato[1], Akane Ito[1], Shuji Ono[1], Jun-ichiro Ishibashi[2], Tatsuo Nozaki[3], Hidenori Kumagai[3], Lena Maeda[3] (1.Hokkaido University, 2.Kyushu University, 3.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

[HRE16-P08] Geochemical behavior of heavy metals during wastewater treatment in Chingola Stream of the Zambia Copperbelt

*Cryton Phiri[1], Daiki Shimazui[2], Tsutomu Sato[2], Tsubasa Otake[2] (1.University of Zambia, 2.Hokkaido University)

[J] Poster | H (Human Geosciences)：H-RE Resource and Engineering Geology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_22

[H-RE16] Resource Geology

convener:Tsubasa Otake(Division of Sustainable Resources Engineering, Faculty of Engineering, Hokkaido University), Daisuke Araoka(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Ryohei Takahashi(Graduate School of International Resource Sciences, Akita University), Tatsuo Nozaki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology)

[HRE16-P01] Mineral Chemistry and Petrogenesis of the Mazua Ultramafic Massif, Northern Mozambique: Constraints on the Associated Fe-Ti Oxides Deposit

*David Augusto Bene Unganai[1], Akira Imai[2], Ryohei Takahashi[1], Daud Liace Jamal[3], Takashi Hoshide[1] (1.Akita University, 2.Kyushu University, 3.Eduardo Mondlane University)

[HRE16-P02] **Ni-Cu-PGM Mineralisation in the Bastard Reef and Merensky Reef of the Flatreef section, Turfspruit Farm, Northern Limb, Bushveld Igneous Complex, South Africa.**

*MOKHIRI MALESELA MAKHAFOLA[1], Tsubasa Otake[1], Tsutomu Sato[1], Danie Grobler[2] (1.Hokkaido University, 2.Ivanplats Pty. Ltd)

[HRE16-P03] Characteristics of Porphyry Copper-Gold Mineralization in the Grasberg Mine, Papua, Indonesia

*Kanehiko Kawasaki[1], Kotaro Yonezu[2], Reza Al Furqan[3], Benny Bensaman[4], Mega Fatimah Rosana[4] (1.Kyushu University Facurity of Engineering, 2.Deaprtment of Earth Resources Engineering, Faculty of Engineering, Kyushu University, 3.PT Freeport Indonesia, 4.Department of Geology, Padjadjaran University)

[HRE16-P04] Formation of Ni-bearing minerals during chemical weathering of ultramafic rocks in Myanmar

*Ayaka Murofushi[1], Akane Ito[1], Tsubasa Otake[2], Kenzo Sanematsu[3], Kyaw Zay Ya[1,4], Tsutomu Sato[2] (1.Graduate school of Engineering, Hokkaido University, 2.Facility of Engineering, Hokkaido University, 3.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 4.Department of Geological Survey and Mineral Exploration)

[HRE16-P05] Geological Characteristics and Mineralogy of the Makorungo and Nalia Gold Prospects, Northeastern Mozambique

*Manuel Augusto Manuel Nopeia[1], Ryohei Takahashi[1], Akira Imai[2], Daud Liace Jamal[3] (1.Akita University, 2.Kyushu University, 3.Eduardo Mondlane University)

[HRE16-P06] Geochemical features of the Hishikari epithermal gold deposit based on simultaneous multi-element analysis

*Sota Nishida[1], Mizuki Ishida[1], Kazutaka Yasukawa[1,2], Kentaro Nakamura[1], Koichiro Fujinaga[2,1], Yasuhiro Kato[3,1,2] (1.Department of Systems Innovation, School of Engineering, The University of Tokyo, 2.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 3.Frontier Research Center for Energy and Resources, School of Engineering, The University of Tokyo)

[HRE16-P07] Transformation of ore minerals and their geochemical signatures in submarine hydrothermal ore deposits in Izena Hole, Okinawa Trough

*IKESHIMA TAKURO[1], Tsubasa Otake[1], Tsutomu Sato[1], Akane Ito[1], Shuji Ono[1], Jun-ichiro Ishibashi[2], Tatsuo Nozaki[3], Hidenori Kumagai[3], Lena Maeda[3] (1.Hokkaido University, 2.Kyushu University, 3.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

[HRE16-P08] Geochemical behavior of heavy metals during wastewater treatment in Chingola Stream of the Zambia Copperbelt

*Cryton Phiri[1], Daiki Shimazui[2], Tsutomu Sato[2], Tsubasa Otake[2] (1.University of Zambia, 2.Hokkaido University)

[E] Poster | H (Human Geosciences)：H-TT Technology & Techniques

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[H-TT21] Non-destructive techniques applied to stone cultural heritage

convener:Chiaki T. Oguchi(Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University), Celine Elise Thomachot-Schneider(Groupe d'etude des environnements naturels, anthropiques et archeologiques - Universite de Reims-Champagne-Ardenne (France)), Wonsuh Song(Waseda University), Miguel Gomez-Heras(Universidad Autonoma de Madrid)

[HTT21-P01] **Comparison and Analysis of GNSS-RTK Combined with 3D LiDAR Technology on Monument Maintenance Project**

*Lih-Shinn Hwang[1], Chien-Hua Chiu[1], Chien-Wen Wang[1], Hsiao-Hung Chen[1] (1.National Defense Univ.)

[HTT21-P02] Non-destructive field measurement for investigation of deteriorated parts of an artificial cave

Kaisei Sakane[1], *Chiaki T. Oguchi[1], Yasuhiko TAMURA[2] (1.Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University, 2.The Exective Committee for the Preservation of Taya Cavern)

[HTT21-P03] Ultra-portable thermal cameras for moisture detection

*Miguel Gomez-Heras[1], Laura Lopez-Gonzalez[2], Maria Teresa Gil-Muñoz[3] (1.Universidad Autonoma de Madrid, 2.Artfabrik, 3.Universidad Complutense de Madrid)

[HTT21-P04] A laboratory experiment on stone decay by combination of salt and ice crystallization

*Masato Sato[1], Tsuyoshi Hattanji[2] (1.Graduate School of Life and environmental Sciences, 2.Faculty of Life and EnvironmentalSciences, University of Tsukuba)

[HTT21-P05] Study of the micro-climatic monitoring on the Saint-Remi Basilica (Rheims, France)

*Emilie Huby[1], Celine Elise Thomachot-Schneider[1], Patricia Vazquez[1], Gilles Fronteau[1] (1.Universite de Reims-Champagne-Ardenne)

[S-SS09] Earthquake prediction and forecast

convener:Masayuki Obayashi(Japan Agency for Marine-Earth Science and Technology), Toshitaka Baba(Graduate School of Science and Technology, Tokushima University), Chairperson:Sumio Yoshikawa(気象研究所), Mamoru Kato(Graduate School of Human and Environmental Studies Kyoto University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SSS09-01] **Objective evaluationof precursory seismic quiescence and activation phenomenon in wide area**

*Sumio Yoshikawa[1] (1.Meteorological Research Institute)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SSS09-02] Long-term Probability of a Great Earthquake along the Kurile Trench, Hokkaido Japan (2)

*Masajiro Imoto[1], Morilkawa Nobuyuki[1], Fujiwara Hiroyuki[1] (1.National Research Institute for Earth Science and Disaster Resilience)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SSS09-03] Parallel and Focused Increase Trends in Time Series (M-T Diagram) of Earthquake Occurrences

*Satoshi Hashimoto[1] (1.none)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SSS09-04] Revisiting a simple method for short-term earthquake probabilities derived from past Seismicity

*Mamoru Kato[1] (1.Graduate School of Human and Environmental Studies Kyoto University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SSS09-05] Recent anomalous groundwater temperature and water level changes at the frontier land zone of Nanki region for impending great earthquakes at the Nankai trough

*Tameshige Tsukuda[1] (1.none)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SSS09-06] What happen on the East Japan Megaquake; answer to sufferers

*Nobuaki Niitsuma[1] (1.Institute of Geosciences,Shizuoka University)

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[S-SS14] Fault Rheology and Earthquake Physics

convener:Keishi Okazaki(Japan Agency for Marine-Earth Science and Technology), Hideki Mukoyoshi(Department of Geoscience Interdisciplinary Graduate School of Science and Engineering, Shimane University), Hiroyuki Noda(Kyoto University, Disaster Prevention Research Institute), Keisuke Yoshida(Tohoku University), Chairperson:Hideki Mukoyoshi, Shunya Kaneki(Osaka University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SSS14-07] Effect of slickenside on the crustal strength

*Jun-ichi Ando[1], Takayoshi Nagaoka[1], Naotaka Tomioka[2], Hiroyuki Kagi[3], Kaushik Das[1] (1.Department of Earth and Planetary Systems Science, Hiroshima University, 2.Kochi Institute for core sample research, Japan Agency for Marine-Earth Science and Technology, 3.Geochemical Research Center, Graduate School of Science, University of Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SSS14-08] Dehydroxylation kinetics of clay minerals and its application to friction heating along an imbricate thrust in an accretionary prism

★Invited Papers

*Hirokazu Masumoto[1], Jun Kameda[1] (1.Faculty of Science, Hokkaido University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SSS14-09] Origin of frictional melt in the Jurassic accretionary complex of the Mino Belt on the basis of trace element and isotope analysis

*Chizuru Ozawa[1], Tsuyoshi Ishikawa[2], Kohtaro Ujiie[1] (1.University of Tsukuba, 2.JAMSTEC)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SSS14-10] Geochemical constraint on the origin of albite-bearing black fault rocks in the Kodiak accretionary complex

*Tsuyoshi Ishikawa[1], Asuka Yamaguchi[2] (1.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 2.AORI, The University of Tokyo)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SSS14-11] Importance of initial maturity and reaction kinetics on maturation of carbonaceous material and its implications for thermal maturity as a proxy for temperature in estimation of coseismic slip parameters

*Shunya Kaneki[1], Ichiba Tatsuya[1], Shuhei Yamashita[1], Tetsuro Hirono[1] (1.Graduate School of Science, Osaka University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SSS14-12] Experimental investigation of cumulative effect on thermal maturation of carbonaceous material as a proxy for earthquake slip

*Tetsuro Hirono[1], Yuhtaro Shimamura[1], Shunya Kaneki[2] (1.Department of Earth and Space Science, Graduate School of Science, Osaka University, 2.Disaster Prevention Research Institute, Kyoto University)

convener:Keishi Okazaki(Japan Agency for Marine-Earth Science and Technology), Hideki Mukoyoshi(Department of Geoscience Interdisciplinary Graduate School of Science and Engineering, Shimane University), Hiroyuki Noda(Kyoto University, Disaster Prevention Research Institute), Keisuke Yoshida(Tohoku University), Chairperson:Hiroyuki Noda(DPRI, Kyoto University), Keishi Okazaki(JAMSTEC)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SSS14-13] **Fault rheology at the depth limits of the seismogenic zone**

★Invited Papers

*Berend Antonie Verberne[1] (1.Geological Survey of Japan, National Institute of Industrial Science and Technology)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SSS14-14] Fault models revisited based on friction to flow law

*Toshihiko Shimamoto[1] (1.State Key Laboratory of Earthquake Dynamics, Institute of Geology, China Earthquake Administration)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SSS14-15] Timing of Earthquakes on Intraplate Active Faults Subjected to Stress Perturbation by Megathrust Earthquakes: Insights from Earthquake Sequence Simulation

*Hiroyuki Noda[1] (1.Kyoto University, Disaster Prevention Research Institute)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SSS14-16] Physics of earthquake triggering: effect of stress perturbation to slip acceleration

★Invited Papers

*Takahiro Hatano[1] (1.Earthquake Research Institute, University of Tokyo)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SSS14-17] Foreshock activities controlled by slip rate on a 4-meter-long laboratory fault

*Futoshi Yamashita[1], Eiichi Fukuyama[1], Shiqing Xu[1] (1.National Research Institute for Earth Science and Disaster Resilience)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SSS14-18] Supersonic propagation of slow slip rupture during rock friction experiments

*Eiichi Fukuyama[1], Futoshi Yamashita[1], Shiqing Xu[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[J] Oral | S (Solid Earth Sciences)：S-SS Seismology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A05 TOKYO BAY MAKUHARI HALL

[S-SS14] Fault Rheology and Earthquake Physics

convener:Keishi Okazaki(Japan Agency for Marine-Earth Science and Technology), Hideki Mukoyoshi(Department of Geoscience Interdisciplinary Graduate School of Science and Engineering, Shimane University), Hiroyuki Noda(Kyoto University, Disaster Prevention Research Institute), Keisuke Yoshida(Tohoku University), Chairperson:Hiroyuki Noda(DPRI, Kyoto University), Keisuke Yoshida(東北大学大学院理学研究科 地球物理学専攻)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SSS14-19] The role of fault damage zone in the supershear rupture of the 2018 Mw 7.5 Palu earthquake

*Lingsen Meng[1], Han Bao[1], Jean-Paul Ampuero[2], Eric Fielding[3], Cunren Liang[4], Christopher Milliner [3], Tian Feng[1], Hui Huang[1] (1.University of California Los Angeles, 2.Université Côte d'Azur and IRD, 3.Jet Propulsion Laboratory , 4.California Institute of Technology)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SSS14-20] The role of curvature in earthquake mechanics

*Pierre Romanet[1], Daisuke Sato[2], Ryosuke Ando[1] (1.Earth and Planetary Science Department, University of Tokyo, 2.Disaster Prevention Research Institute, Kyoto University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SSS14-21] **Heterogeneous source modelling by the fully dynamic simulations of earthquake cycles on a strike-slip fault and scaling relations.**

*Percy Galvez[1,5], Anatoly Petukhin[2], Paul Somerville[3], Ken Miyakoshi[2], Kojiro Irikura[4] (1.KAUST University, Saudi Arabia, 2.Geo-Research Institute, Osaka Japan, 3.AECOM, Los Angeles, USA., 4.Aichi Institute of Technology, Japan, 5.ETH Zurich, Switzerland)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SSS14-22] **Strain energy released by an earthquake: Contributions of random slip fluctuations**

*Tatsuhiko Saito[1], Akemi Noda[1] (1.National Research Institute for Earth Science and Disaster Resilience)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SSS14-23] The change in the elastic strain energy due to the 1992 Landers earthquake and triggering mechanisms of aftershock activity

*Toshiko Terakawa[1], Mitsuhiro Matsu'ura[2], Akemi Noda[3] (1.Graduate School of Environmental Studies, Nagoya University, 2.Institute of Statistical Mathematics, 3.National Research Institute for Earth Science and Disaster Resilience)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SSS14-24] Toward understanding generation mechanism of crustal earthquakes based on accumulation/release of elastic strain energy

★Invited Papers

*Akemi Noda[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[J] Poster | S (Solid Earth Sciences)：S-SS Seismology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_16

[S-SS14] Fault Rheology and Earthquake Physics

convener:Keishi Okazaki(Japan Agency for Marine-Earth Science and Technology), Hideki Mukoyoshi(Department of Geoscience Interdisciplinary Graduate School of Science and Engineering, Shimane University), Hiroyuki Noda(Kyoto University, Disaster Prevention Research Institute), Keisuke Yoshida(Tohoku University)

[SSS14-P01] Measurement of shear-wave polarization anisotropy in crack-bearing Aji granite during shear experiment

*Jinki Tanaka[1], Ikuo Katayama[1] (1.Hiroshima University)

[SSS14-P02] Effects of talc content on frictional properties of quartz gouge

Risako Shirahige[1], Inori Tatara[1], *Ken-ichi Hirauchi[1], Takato Takemura[2] (1.Department of Geosciences, Faculty of Science, Shizuoka University, 2.Department of Earth and Environmental Sciences, College of Humanities and Sciences, Nihon University)

[S-SS17] Seismic evidence of volcanic roots

convener:Naofumi Aso(Tokyo Institute of Technology), Yohei Yukutake(Hot Springs Research Institute of Kanagawa Prefecture)

[SSS17-P01] S-wave reflectors beneath the earthquake swarm in the Yonezawa-Kitakata area, NE Japan

*Manami Suzuki [1], Akiko Hasemi[1], Tomomi Okada[1], Toru Matsuzawa[1], Norihito Umino[1], Takashi Nakayama[1], Noriko Tsumura[2], Tadashi Yamashina[3], Group for the aftershock observations of the 2011 off the Pacific of Tohoku Earthquake (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 2.Graduate School of Science, Chiba University, 3.Faculty of Science and Technology, Kochi University)

[SSS17-P02] Imaging of the magma pathway beneath Kirishima volcanoes by seismic interferometry

*Yutaka Nagaoka[1], Kiwamu Nishida[2], Yosuke Aoki[2], Minoru Takeo[2], Takahiro Ohkura[3], Shin Yoshikawa[3] (1.Volcanology Research Department, Meteorological Research Institute, 2.Earthquake Research Institute, The University of Tokyo, 3.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

[SSS17-P03] Finite element three-dimensional seismic waveform calculations of volcanic deep low frequency earthquake including true topographic effects of Hakone volcano

*Lina Yamaya[1], Kimihiro Mochizuki[1], Tsuyoshi Ichimura[1], Kohei Fujita[1], Takeshi Akuhara[1], Takane Hori[2], Ryou Honda[3], Yohei Yukutake[3] (1.Earthquake Research Institute, Univ. of Tokyo, 2.JAMSTEC, 3.Hot Springs Research Institute of Kanagawa)

[SSS17-P04] Magma transport system beneath Hakone volcano inferred from deep low frequency earthquakes

*Yohei Yukutake[1], Yuki Abe[1] (1.Hot Springs Research Institute of Kanagawa Prefecture)

[SSS17-P05] Hypocenter and waveform characteristics of deep low-frequency earthquakes beneath Zao volcano

*Takuma Ikegaya[1], Mare Yamamoto[1] (1.Graduate School of Science, Tohoku University)

[SSS17-P06] Mechanisms transition of LFEs beneath Zao volcano due to the stress change induced by the 2011 Tohoku earthquake

*Genki Oikawa[1], Naofumi Aso[1], Junichi Nakajima[1], Toru Matsuzawa[2] (1.Tokyo Institute of Technology, 2.Tohoku University)

[SSS17-P07] Magma/gas intrusion process of Shinmoedake Eruption in 2017 suggested by volcanic tremors location with ASL method

Shoya Imamura[1], *Makoto OKUBO[2] (1.Faculty of Science, Kochi University, 2.Natural Science Cluster, Kochi University)

[SSS17-P08] Source depth estimation of a magmatic inflation in 2008-2010 at Mt. Fuji, Japan, based on sparsity-promoting L1 inversion of GNSS data

*Yuta Mitsui[1], Takahiro Kato[2] (1.Department of Geosciences, Shizuoka University, 2.formerly at Department of Geosciences, Shizuoka University)

[J] Poster | S (Solid Earth Sciences)：S-SS Seismology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_27

[S-SS17] Seismic evidence of volcanic roots

convener:Naofumi Aso(Tokyo Institute of Technology), Yohei Yukutake(Hot Springs Research Institute of Kanagawa Prefecture)

[SSS17-P01] S-wave reflectors beneath the earthquake swarm in the Yonezawa-Kitakata area, NE Japan

*Manami Suzuki [1], Akiko Hasemi[1], Tomomi Okada[1], Toru Matsuzawa[1], Norihito Umino[1], Takashi Nakayama[1], Noriko Tsumura[2], Tadashi Yamashina[3], Group for the aftershock observations of the 2011 off the Pacific of Tohoku Earthquake (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 2.Graduate School of Science, Chiba University, 3.Faculty of Science and Technology, Kochi University)

[SSS17-P02] Imaging of the magma pathway beneath Kirishima volcanoes by seismic interferometry

*Yutaka Nagaoka[1], Kiwamu Nishida[2], Yosuke Aoki[2], Minoru Takeo[2], Takahiro Ohkura[3], Shin Yoshikawa[3] (1.Volcanology Research Department, Meteorological Research Institute, 2.Earthquake Research Institute, The University of Tokyo, 3.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

[SSS17-P03] Finite element three-dimensional seismic waveform calculations of volcanic deep low frequency earthquake including true topographic effects of Hakone volcano

*Lina Yamaya[1], Kimihiro Mochizuki[1], Tsuyoshi Ichimura[1], Kohei Fujita[1], Takeshi Akuhara[1], Takane Hori[2], Ryou Honda[3], Yohei Yukutake[3] (1.Earthquake Research Institute, Univ. of Tokyo, 2.JAMSTEC, 3.Hot Springs Research Institute of Kanagawa)

[SSS17-P04] Magma transport system beneath Hakone volcano inferred from deep low frequency earthquakes

*Yohei Yukutake[1], Yuki Abe[1] (1.Hot Springs Research Institute of Kanagawa Prefecture)

[SSS17-P05] Hypocenter and waveform characteristics of deep low-frequency earthquakes beneath Zao volcano

*Takuma Ikegaya[1], Mare Yamamoto[1] (1.Graduate School of Science, Tohoku University)

[SSS17-P06] Mechanisms transition of LFEs beneath Zao volcano due to the stress change induced by the 2011 Tohoku earthquake

*Genki Oikawa[1], Naofumi Aso[1], Junichi Nakajima[1], Toru Matsuzawa[2] (1.Tokyo Institute of Technology, 2.Tohoku University)

Shoya Imamura[1], *Makoto OKUBO[2] (1.Faculty of Science, Kochi University, 2.Natural Science Cluster, Kochi University)

[SSS17-P08] Source depth estimation of a magmatic inflation in 2008-2010 at Mt. Fuji, Japan, based on sparsity-promoting L1 inversion of GNSS data

*Yuta Mitsui[1], Takahiro Kato[2] (1.Department of Geosciences, Shizuoka University, 2.formerly at Department of Geosciences, Shizuoka University)

[E] Poster | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

[S-IT26] New perspectives on the geodynamics of East Asia

convener:Timothy B Byrne(University of Connecticut), Asuka Yamaguchi(Atomosphere and Ocean Research Institute, The University of Tokyo), Jonny Wu(University of Houston), Kyoko Okino(Atmosphere and Ocean Research Institute, The University of Tokyo)

[SIT26-P01] Geochemical characteristics of effusive rocks (greenstones) in the Hidaka Belt, Hokkaido, Japan

*Toru Yamasaki[1], Futoshi Nanayama[1] (1.Geol. Survey of Japan (AIST))

[SIT26-P02] Large gas reservoir in continental back-arc basin, revealed by automatic seismic velocity analysis in the Okinawa Trough

*Kota Mukumoto[1], Takeshi Tsuji[1], Andri Hendriyana[1] (1.Kyushu University)

[SIT26-P03] Characterize coseismic deformation of Mw 7.5 Palu earthquake in a triple junction in Sulawesi, Indonesia

*MIN-CHIEN TSAI[1], Ying-Hui Yang[2], Chun-Ying Chiu[3], Jyr-Ching Hu[3] (1.Seismological center, Central Weather Bureau, Taipei, Taiwan, R.O.C., 2.School of Civil Engineering and Architecture, Southwest Petroleum University, Chengdu, China, 3.Department of Geosciences, National Taiwan University, Taipei, Taiwan, R.O.C.)

[E] Poster | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_28

[S-IT26] New perspectives on the geodynamics of East Asia

convener:Timothy B Byrne(University of Connecticut), Asuka Yamaguchi(Atomosphere and Ocean Research Institute, The University of Tokyo), Jonny Wu(University of Houston), Kyoko Okino(Atmosphere and Ocean Research Institute, The University of Tokyo)

[SIT26-P01] Geochemical characteristics of effusive rocks (greenstones) in the Hidaka Belt, Hokkaido, Japan

*Toru Yamasaki[1], Futoshi Nanayama[1] (1.Geol. Survey of Japan (AIST))

[SIT26-P02] Large gas reservoir in continental back-arc basin, revealed by automatic seismic velocity analysis in the Okinawa Trough

*Kota Mukumoto[1], Takeshi Tsuji[1], Andri Hendriyana[1] (1.Kyushu University)

[SIT26-P03] Characterize coseismic deformation of Mw 7.5 Palu earthquake in a triple junction in Sulawesi, Indonesia

*MIN-CHIEN TSAI[1], Ying-Hui Yang[2], Chun-Ying Chiu[3], Jyr-Ching Hu[3] (1.Seismological center, Central Weather Bureau, Taipei, Taiwan, R.O.C., 2.School of Civil Engineering and Architecture, Southwest Petroleum University, Chengdu, China, 3.Department of Geosciences, National Taiwan University, Taipei, Taiwan, R.O.C.)

[E] Oral | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A09 TOKYO BAY MAKUHARI HALL

[S-IT26] New perspectives on the geodynamics of East Asia

convener:Timothy B Byrne(University of Connecticut), Asuka Yamaguchi(Atomosphere and Ocean Research Institute, The University of Tokyo), Jonny Wu(University of Houston), Kyoko Okino(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Jonny Wu, Okino Kyoko

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SIT26-01] How to solve controversies in Cenozoic tectonics in western Pacific margin

*Gaku Kimura[1] (1.Tokyo University of Marine Science and Technology)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SIT26-02] Plio-Pleistocene plate interactions associated the Philippine Sea Plate

*Timothy B Byrne[1], Gaku Kimura[3], Jonny Wu[2] (1.University of Connecticut, 2.University of Houston, 3.Tokyo University of Science and Technology)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SIT26-03] A regional mylonite zone between the Mesozoic metamorphic basement and the subducted Miocene covered schists in eastern Range of Taiwan: A possible Plio-Pleistocene transform fault between Eurasia and the Philippine Sea plate

*Gong-Ruei Ho[1], Jian-Cheng Lee[1], Timothy B Byrne[2], En-Chao Yeh[3] (1.Institute of Earth Sciences, Academia Sinica, 2.Department of Geography, University of Connecticut, 3.Department of Earth Sciences, National Taiwan Normal University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SIT26-04] **Coeval exhumation or subduction channel extrusion of the high pressure Yuli belt? Insights from the Shoufeng fault in eastern Taiwan**

*Jian-Cheng Lee[1,5], Gong-Ruei Ho[1,5], Timothy B Byrne[2], Yuan Hsi Lee[3,5], En-Chao Yeh[4,5] (1.Academia Sinica, 2.Univerity of Connecticut, 3.National Chung Cheng University, 4.National Taiwan Normal University, 5.The Yuli Exhumation Study team (YES Team))

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SIT26-05] Metamorphic temperature variation across the Yuli belt: a clue about exhumation of high-pressure rocks?

*Chin-Ho Tsai[1], Chih-Ying Yeh[1], Yui Kouketsu[2], Masaki Enami[3] (1.Department of Natural Resources & Environmental Studies, National Dong Hwa Univ., 2.Department of Earth & Planetary Sciences, Nagoya Univ., 3.Institute for Space-Earth Environmental Research, Nagoya Univ.)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SIT26-06] **Thermal state, slab metamorphism and interface seismicity in Mariana based on 3-D modeling**

*Yingfeng Ji[1,2,3], Shoichi Yoshioka[3,4] (1.Center of Excellence in Tibetan Plateau Earth Science, Chinese Academy of Sciences, 2.Key laboratory of continental collision and plateau uplift, Institute of Tibetan Plateau, Chinese Academy of Sciences, 3.Research Center for Urban Safety and Security, Kobe University, 4.Graduate School of Science, Kobe University)

[E] Oral | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A09 TOKYO BAY MAKUHARI HALL

[S-IT26] New perspectives on the geodynamics of East Asia

convener:Timothy B Byrne(University of Connecticut), Asuka Yamaguchi(Atomosphere and Ocean Research Institute, The University of Tokyo), Jonny Wu(University of Houston), Kyoko Okino(Atmosphere and Ocean Research Institute, The University of Tokyo), Chairperson:Asuka Yamaguchi(Atomosphere and Ocean Research Institute, The University of Tokyo), Tim Byrne

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SIT26-07] **A tomography-led plate reconstruction of NE Asia during the late Cretaceous**

*Jonny Wu[1], Yi-An Lin[1], Nicolas Flament[2], Tsung-Jui Wu[1], Yiduo Liu[1] (1.University of Houston, 2.University of Wollongong)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SIT26-08] Geodynamic models of late Mesozoic intraoceanic subduction offshore NE Asia caused by growing Izanagi plate

*Lorenzo Colli[1], Jonny Wu[1], Yi-An Lin[1] (1.University of Houston)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SIT26-09] **Early Cretaceous to Paleocene magmatism in the Sikhote-Alin area and their implications for Paleo-Pacific plate subduction and continental evolution**

*Tsung-Jui Wu[1], Jonny Wu[1], Igor Alexandrov[2], Thomas Lapen[1] (1.Department of Earth and Atmospheric sciences, University of Houston, Houston, U.S., 2.Far East Geological Institute, Russian Academy of Sciences, Vladivostok, Russia)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SIT26-10] Processes of subduction initiation revealed by P-T paths of amphibolite and blueschist tectonic blocks in serpentinite mélange: An example from the Kamuikotan high-P/T metamorphic rocks in Hokkaido, northern Japan

*Toru Takeshita[1], Ayumi S. Okamoto, Wonji Shin[1], Mizuho Ando[1] (1.Department of Natural History Sciences, Graduate School of Science, Hokkaido University)

4:30 PM - 4:50 PM JST | 7:30 AM - 7:50 AM UTC

[SIT26-11] Metamorphism in the Sanbagawa belt of SW Japan as a record of subduction processes

★Invited Papers

*Simon Richard Wallis[1] (1.University of Tokyo)

4:50 PM - 5:00 PM JST | 7:50 AM - 8:00 AM UTC

[SIT26-12] Subduction and exhumation of the high pressure metamorphic rocks: What we know and what we need to know.

*Timothy B Byrne[1] (1.University of Connecticut)

[J] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A08 TOKYO BAY MAKUHARI HALL

[S-MP32] Deformed rocks, Metamorphic rocks and Tectonics

convener:Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Yoshihiro Nakamura(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Yoshihiro Nakamura(産総研), Yumiko Harigane(産総研)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SMP32-01] Argon release mechanism of deformed phengite

*Tetsumaru Itaya[1] (1.Engineering Geology Center, Hiruzen Institute for Geology and Chronology)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SMP32-02] Detrital zircons from a traverse along the Asemi River (Sanbagawa Metamorphic Belt, Shikoku, Japan): U-Pb geochronology and Hf isotopic composition

*Ulrich Knittel[1], Shigeyuki Suzuki[2], Monika Walia[3], Juan-Hsi Lee[4], Hao-Yang Lee[5] (1.RWTH Aachen University, 2.Okayama University, 3.Nat. Taiwan University , 4.Chung Cheng University, 5.Academia Sinica)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SMP32-03] Tectonic process of the Sanbagawa eclogite: zircon U–Pb and REE composition analyses

*Shogo Aoki[1], Kazumasa Aoki[2], Tatsuki Tsujimori[3], Yuta Tsuchiya[1], Daichi Kato[2] (1.Department of Biosphere-Geosphere Science, Okayama University of Science, 2.Department of Applied Science, Okayama University of Science, 3.Center for Northeast Asian Studies, Tohoku University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SMP32-04] Petrological implications of a new occurrence of retrogressed eclogite from the Sanbagawa belt of southwest Japan

*Tomoki Taguchi[1], Shunsuke Endo[2], Yohei Igami[1,3], Akira Miyake[1] (1.Graduate School of Science, Kyoto University, 2.Interdisciplinary Faculty of Science and Engineering, Shimane University, 3.Institute of Materials and Systems for Sustainability, Nagoya University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SMP32-05] *P-T* estimations of Kashio mylonite in Oshika, Nagano, Japan: Constraints on the amalgamation of Ryoke and Sambagawa belts

*Yoshihiro Nakamura[1], Yutaka Takahasi[1], Tohru Danhara[2], Hideki Iwano[2], Takehumi Hirata[3] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 2.Kyoto Fission-Track Co., Ltd., 3.Geochemical Research Center, The University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SMP32-06] Static phenomena retained by garnet during exhumation of metamorphic rocks

*Masaki Enami[1], Yui Kouketsu[2] (1.Institute for Space–Earth Environmental Research, Nagoya University, 2. Nagoya University)

[J] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A08 TOKYO BAY MAKUHARI HALL

[S-MP32] Deformed rocks, Metamorphic rocks and Tectonics

convener:Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Yoshihiro Nakamura(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Tomoki Taguchi(京都大学　大学院理学研究科), Kenta Yoshida(JAMSTEC)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SMP32-07] Garnet zoning suggesting the correlation between the Higo and Abukuma metamorphic rocks

*Tadao Nishiyama[1], Yuto Wakida[1] (1.Department of Earth and Environmental Sciences, School of Science, Graduate School of Science and Technology, Kumamoto University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SMP32-08] $FeAlO_3$ phase at ultrahigh-temperature metamorphic conditions: Evidences from the sillimanite—Fe_2O_3 and sillimanite—Fe_3O_4 systems at 9 kbar and 1050 °C

*Toshisuke Kawasaki[1], Tatsuro Adachi[2], Hiroaki Ohfuji[1], Yasuhito Osanai[2] (1.Ehime University, 2.Kyushu University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SMP32-09] **Halogens in nanogranitoids entrapped during granulite facies to ultrahigh-temperature metamorphism in the lower crust**

*Fumiko Higashino[1], Tetsuo Kawakami[2] (1. Graduate School of Environmental Studies, Tohoku University, 2.Graduate School of Science, Kyoto University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SMP32-10] Significance of high-Ti biotite and anatectic conditions of paragneiss in the Oki-Dogo Island, Japan

Hiroshi Yoshida[1], *Shunsuke Endo[1], Mai Fujiwara[1], Atsushi Kamei[1] (1.Department of Earth Science, Interdisciplinary Faculty of Science and Engineering, Shimane University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SMP32-11] Eclogite-to-granulite transition in the Ufipa Complex (Tanzania): the time-lag between collision and the granulitization

*Morita Isamu[1], Tatsuki Tsujimori[1], Nelson Boniface[2], Shogo Aoki[3], Kazumasa Aoki[3] (1.Tohoku University, 2.University of Dar es Salaam, 3.Okayama University of Science)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SMP32-12] **Switching of metamorphic growth kinetics due to volume fraction of metamorphic fluid**

*Kazuhiro Miyazaki[1] (1.Orogenic Processes Research Group, Institute of Geology and Geoinformation, Geological Survey of Japan/National Institute of Advanced Industrial Science and Technology)

[J] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[S-MP32] Deformed rocks, Metamorphic rocks and Tectonics

convener:Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Yoshihiro Nakamura(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SMP32-P01] Pressure-temperature estimates of the Lützow-Holm Complex utilizing distributions of trace elements and inclusions in garnet porphyroblasts in pelitic gneisses

*Kota Suzuki[1], Tetsuo Kawakami[1], Yohei Igami[2] (1.Department of Geology and Mineralogy, Graduate School of Science, Kyoto University, 2.Institute of Materials and Systems for Sustainability, Nagoya University)

[SMP32-P02] Microstructures and pressure-temperature condition in pelitic gneisses from the Lützow-Holm Complex at Akarui Point, East Antarctica

*Hayato Yodoya[1], Takeshi Ikeda[2] (1.Department of Earth and Planetary Sciences, Graduate School of Scinece, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of School of Scinece, Kyushu University)

[SMP32-P03] Long-lived (>90 Myr) granulite-facies metamorphism in the Trivandrum Block, southern India.

*Hikaru Kadowaki[1], Toshiaki Tsunogae[2], Santosh M.[3], Shaji E.[4], Yusuke Takamura[5], Yukiyasu Tsutsumi[6] (1.College of Geoscience, Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Faculty of Life and Environmental Sciences, University of Tsukuba, 3.School of Earth Sciences and Resources, China University of Geosciences Beijing, 4.Department of Geology, University of Kerala, 5. Doctoral Program in Earth Evolution Sciences, Graduate School of Life and Environmental Sciences, University of Tsukuba, 6.Department of Geology and Paleontology, National Museum of Nature and Science)

[SMP32-P04] Dislocation microstructures in garnet: Thermal effect during deeper crustal seismic slip in orogen-boundary shear zone

*Kaushik Das[1], Naotaka Tomioka[2], Proloy Ganguly[3], Jun-ichi Ando[1], Gautam Ghosh[3], Sankar Bose[3] (1.Hiroshima University, 2.Kochi Institute for Core Sample Research, JAMSTEC, 3.Presidency University, India)

[SMP32-P05] U-Pb zircon ages of migmatitic rocks from the Ryoke belt in the Mikawa and eastern Sanuki areas

*Keiichi Kazuratachi[1], Tetsuo Kawakami[1], Etienne Skrzypek[1], Shuhei Sakata[2], Takafumi Hirata[3] (1.Kyoto University, 2.Gakushuin University, 3.The University of Tokyo)

[SMP32-P06] Structural geology of Hidaka metamorphic belt in the Mt.Nozuka area, Hokkaido, Japan - Growth and formation process of the Cenozoic continental crust by island arc/arc join and its mechanism-

*Moeko Kanno[1], Tsuyoshi Toyoshima[2] (1.Graduate school of Science and Technology, Niigata University , 2.Department of Geology,Faculty of Science,Niigata University)

[SMP32-P07] THE PRESSURE-TEMPERATURE PATH AND MINERAL ASSEMBLAGE OF THE KHONICHIIN OVOO AREA, SOUTHEASTERN MONGOLIA.

*Undarmaa Batsaikhan[1], Noriyoshi Tsuchiya[1], Masaoki Uno[1], Yukio Isozaki[2], Uyanga Bold[2], OTGONBAYAR DANDAR[1], Hikaru Sawada[2] (1.Graduate School of Environmental Studies, Tohoku University, 2.Graduate School of Arts and Sciences the University of Tokyo)

[SMP32-P08] **Pressure-temperature conditions of contact metamorphism in Nokita area, Itoshima Peninsula, northwest Kyushu**

*Takeshi Ikeda[1], Kento Ota[2] (1.Department of Earth and Planetary Sciences,Faculty of Scinece, Kyushu University, 2.Department of Earth and Planetary Sciences,Graduate School of Scinece, Kyushu University)

[SMP32-P09] Evidence of Partial Melting of Migmatitic Felsic Gneiss from Nagasaki Metamorphic Complex in Amakusa-Shimoshima, western Kyushu, Japan

*Yuki Mori[1], Takeshi Ikeda[2], Kazuhiro Miyazaki[3] (1.Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 3.Research Institute of Geology and Geoinformation, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SMP32-P10] **Microstructural Analysis of Quartz grains in Monomineralic and Polyphase domains: A case study from Main Central Thrust (MCT) Zone Mylonites, western Himalaya, India**

*Shivaji Saha[1], Toru Takeshita[1], Subhajit Ghosh[2], Hari Bahadur Srivastava[3] (1.Department of Natural History Sciences, Hokkaido University, 2.Earthquake Research Institute, The University of Tokyo, 3.Department of Geology, Banaras Hindu University)

[SMP32-P11] **Tectono-thermal evolution of the Main Central Thrust (MCT) zone rocks of the Himalayan Crystalline Complex (*HCC*), Darjeeling-Sikkim Himalaya**

*Subhajit Ghosh[1,2], Santanu Bose[2,3], Nibir Mandal[4], Arijit Laik[2] (1.Earthquake Research Institute, The University of Tokyo, 1-1-1 Yayoi, Bunkyo-Ku, Tokyo 113-0032, 2.Department of Geology, University of Calcutta, 35, Ballygunge Circular Road, Kolkata 700019, India, 3.Department of Geology, Presidency University, 86/1 College Street, Kolkata 700073, India, 4.Department of Geological Sciences, Jadavpur University, Kolkata 700032, India)

[SMP32-P12] Thermal structure and deformation history of the low-grade Sanbagawa belt in the central of Kii Peninsula and tectonic implications

*Ken Yamaoka[1,2], Simon Wallis[1], Hiroshi Mori[2] (1.University of Tokyo, 2.Shinshu University)

[SMP32-P13] Antigorite Raman spectrum: a case study in Shiraga region of the central Shikoku, Sanbagawa metamorphic belt, SW Japan

*Kota Ando[1], Yui Kouketsu[1], Katsuyoshi Michibayashi[1] (1.Nagoya University)

[SMP32-P14] A fluid inclusion study from the late Paleozoic retrograde eclogite from the Yunotani Valley of the Omi area, Hida-Gaien Belt, Japan

*Yuzuki Shinji[1], Tatsuki Tsujimori[1], Tatsuhiko Kawamoto[2] (1.Tohoku University, 2.Shizuoka University)

[SMP32-P15] Development of reaction-induced stress and permeability in MgO-H_2O system

*Hisamu Kasahara[1], Masaoki Uno[1], Atsushi Okamoto[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University)

[SMP32-P16] Crystal orientation analysis of olivine in ultra-mylonite using TKD method: progress in spatial resolution from EBSD

*Yohei Igami[1], Katsuyoshi Michibayashi[2], Kakihata Yuki[2], Yui Kouketsu[2] (1.Institute of Materials and Systems for Sustainability, Nagoya University, 2.Graduate School of Environmental Studies, Nagoya University)

[SMP32-P17] Elucidation of effective diffusion coefficient along grain boundaries by hydrothermal experiment using low porosity rocks

*Naoki Sugisawa[1], Masaoki Uno[1], Noriyoshi Tsuchiya[1] (1.Graduate school of environmental studies Tohoku university)

[SMP32-P18] **Seismic slipping events recorded in a fault gouge zone: evidence from the Nojima Fault drill holes, SW Japan**

*Aiming Lin[1], Takafumi Nishiwaki[1] (1.Department of Geophysics, Graduate School of Science, Kyoto University)

[SMP32-P19] Evolution of fluid chemistry during basalt-water and basalt-seawater interactions revealed by hydrothermal flow-through experiments

*Yusuke Netsu[1], Atsushi Okamoto[1], Nobuo Hirano[1], Masaoki Uno[1], Noriyoshi Tsuchiya[1] (1.Tohoku University, Graduate School of Environment Studies)

[SMP32-P20] **3D microstructural analyses of fault rocks using CT and μCT scanning techniques**

*Bingcheng Liu[1], Aiming Lin[1], Takafumi Nishiwaki[1] (1.Kyoto University)

[SMP32-P21] **Dissolution kinetics of forsterite olivine at >200 °C: implication for the kinetics of serpentinization.**

*Ryosuke Oyanagi[1], Tatsu Kuwatani[1], Katsuhiko Suzuki[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_29

[S-MP32] Deformed rocks, Metamorphic rocks and Tectonics

convener:Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Yoshihiro Nakamura(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SMP32-P01] Pressure-temperature estimates of the Lützow-Holm Complex utilizing distributions of trace elements and inclusions in garnet porphyroblasts in pelitic gneisses

*Kota Suzuki[1], Tetsuo Kawakami[1], Yohei Igami[2] (1.Department of Geology and Mineralogy, Graduate School of Science, Kyoto University, 2.Institute of Materials and Systems for Sustainability, Nagoya University)

[SMP32-P02] Microstructures and pressure-temperature condition in pelitic gneisses from the Lützow-Holm Complex at Akarui Point, East Antarctica

*Hayato Yodoya[1], Takeshi Ikeda[2] (1.Department of Earth and Planetary Sciences, Graduate School of Scinece, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of School of Scinece, Kyushu University)

[SMP32-P03] Long-lived (>90 Myr) granulite-facies metamorphism in the Trivandrum Block, southern India.

*Hikaru Kadowaki[1], Toshiaki Tsunogae[2], Santosh M.[3], Shaji E.[4], Yusuke Takamura[5], Yukiyasu Tsutsumi[6] (1.College of Geoscience, Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Faculty of Life and Environmental Sciences, University of Tsukuba, 3.School of Earth Sciences and Resources, China University of Geosciences Beijing, 4.Department of Geology, University of Kerala, 5. Doctoral Program in Earth Evolution Sciences, Graduate School of Life and Environmental Sciences, University of Tsukuba, 6.Department of Geology and Paleontology, National Museum of Nature and Science)

[SMP32-P04] Dislocation microstructures in garnet: Thermal effect during deeper crustal seismic slip in orogen-boundary shear zone

*Kaushik Das[1], Naotaka Tomioka[2], Proloy Ganguly[3], Jun-ichi Ando[1], Gautam Ghosh[3], Sankar Bose[3] (1.Hiroshima University, 2.Kochi Institute for Core Sample Research, JAMSTEC, 3.Presidency University, India)

[SMP32-P05] U-Pb zircon ages of migmatitic rocks from the Ryoke belt in the Mikawa and eastern Sanuki areas

*Keiichi Kazuratachi[1], Tetsuo Kawakami[1], Etienne Skrzypek[1], Shuhei Sakata[2], Takafumi Hirata[3] (1.Kyoto University, 2.Gakushuin University, 3.The University of Tokyo)

[SMP32-P06] Structural geology of Hidaka metamorphic belt in the Mt.Nozuka area, Hokkaido, Japan - Growth and formation process of the Cenozoic continental crust by island arc/arc join and its mechanism-

*Moeko Kanno[1], Tsuyoshi Toyoshima[2] (1.Graduate school of Science and Technology, Niigata University , 2.Department of Geology,Faculty of Science,Niigata University)

[SMP32-P07] THE PRESSURE-TEMPERATURE PATH AND MINERAL ASSEMBLAGE OF THE KHONICHIIN OVOO AREA, SOUTHEASTERN MONGOLIA.

*Undarmaa Batsaikhan[1], Noriyoshi Tsuchiya[1], Masaoki Uno[1], Yukio Isozaki[2], Uyanga Bold[2], OTGONBAYAR DANDAR[1], Hikaru Sawada[2] (1.Graduate School of Environmental Studies, Tohoku University, 2.Graduate School of Arts and Sciences the University of Tokyo)

[SMP32-P08] **Pressure-temperature conditions of contact metamorphism in Nokita area, Itoshima Peninsula, northwest Kyushu**

*Takeshi Ikeda[1], Kento Ota[2] (1.Department of Earth and Planetary Sciences,Faculty of Scinece, Kyushu University, 2.Department of Earth and Planetary Sciences,Graduate School of Scinece, Kyushu University)

[SMP32-P09] Evidence of Partial Melting of Migmatitic Felsic Gneiss from Nagasaki Metamorphic Complex in Amakusa-Shimoshima, western Kyushu, Japan

*Yuki Mori[1], Takeshi Ikeda[2], Kazuhiro Miyazaki[3] (1.Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 3.Research Institute of Geology and Geoinformation, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SMP32-P10] **Microstructural Analysis of Quartz grains in Monomineralic and Polyphase domains: A case study from Main Central Thrust (MCT) Zone Mylonites, western Himalaya, India**

*Shivaji Saha[1], Toru Takeshita[1], Subhajit Ghosh[2], Hari Bahadur Srivastava[3] (1.Department of Natural History Sciences, Hokkaido University, 2.Earthquake Research Institute, The University of Tokyo, 3.Department of Geology, Banaras Hindu University)

[SMP32-P11] **Tectono-thermal evolution of the Main Central Thrust (MCT) zone rocks of the Himalayan Crystalline Complex (*HCC*), Darjeeling-Sikkim Himalaya**

*Subhajit Ghosh[1,2], Santanu Bose[2,3], Nibir Mandal[4], Arijit Laik[2] (1.Earthquake Research Institute, The University of Tokyo, 1-1-1 Yayoi, Bunkyo-Ku, Tokyo 113-0032, 2.Department of Geology, University of Calcutta, 35, Ballygunge Circular Road, Kolkata 700019, India, 3.Department of Geology, Presidency University, 86/1 College Street, Kolkata 700073, India, 4.Department of Geological Sciences, Jadavpur University, Kolkata 700032, India)

[SMP32-P12] Thermal structure and deformation history of the low-grade Sanbagawa belt in the central of Kii Peninsula and tectonic implications

*Ken Yamaoka[1,2], Simon Wallis[1], Hiroshi Mori[2] (1.University of Tokyo, 2.Shinshu University)

[SMP32-P13] Antigorite Raman spectrum: a case study in Shiraga region of the central Shikoku, Sanbagawa metamorphic belt, SW Japan

*Kota Ando[1], Yui Kouketsu[1], Katsuyoshi Michibayashi[1] (1.Nagoya University)

[SMP32-P14] A fluid inclusion study from the late Paleozoic retrograde eclogite from the Yunotani Valley of the Omi area, Hida-Gaien Belt, Japan

*Yuzuki Shinji[1], Tatsuki Tsujimori[1], Tatsuhiko Kawamoto[2] (1.Tohoku University, 2.Shizuoka University)

[SMP32-P15] Development of reaction-induced stress and permeability in MgO-H_2O system

*Hisamu Kasahara[1], Masaoki Uno[1], Atsushi Okamoto[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University)

[SMP32-P16] Crystal orientation analysis of olivine in ultra-mylonite using TKD method: progress in spatial resolution from EBSD

*Yohei Igami[1], Katsuyoshi Michibayashi[2], Kakihata Yuki[2], Yui Kouketsu[2] (1.Institute of Materials and Systems for Sustainability, Nagoya University, 2.Graduate School of Environmental Studies, Nagoya University)

[SMP32-P17] Elucidation of effective diffusion coefficient along grain boundaries by hydrothermal experiment using low porosity rocks

*Naoki Sugisawa[1], Masaoki Uno[1], Noriyoshi Tsuchiya[1] (1.Graduate school of environmental studies Tohoku university)

[SMP32-P18] **Seismic slipping events recorded in a fault gouge zone: evidence from the Nojima Fault drill holes, SW Japan**

*Aiming Lin[1], Takafumi Nishiwaki[1] (1.Department of Geophysics, Graduate School of Science, Kyoto University)

[SMP32-P19] Evolution of fluid chemistry during basalt-water and basalt-seawater interactions revealed by hydrothermal flow-through experiments

*Yusuke Netsu[1], Atsushi Okamoto[1], Nobuo Hirano[1], Masaoki Uno[1], Noriyoshi Tsuchiya[1] (1.Tohoku University, Graduate School of Environment Studies)

[SMP32-P20] **3D microstructural analyses of fault rocks using CT and μCT scanning techniques**

*Bingcheng Liu[1], Aiming Lin[1], Takafumi Nishiwaki[1] (1.Kyoto University)

[SMP32-P21] **Dissolution kinetics of forsterite olivine at >200 °C: implication for the kinetics of serpentinization.**

*Ryosuke Oyanagi[1], Tatsu Kuwatani[1], Katsuhiko Suzuki[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A08 TOKYO BAY MAKUHARI HALL

[S-MP32] Deformed rocks, Metamorphic rocks and Tectonics

convener:Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Yoshihiro Nakamura(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Shunsuke Endo(島根大学 総合理工学部 地球科学科), Ryosuke Oyanagi(国立研究開発法人 海洋研究開発機構 地球内部物質循環研究分野)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SMP32-13] Early Paleozoic subduction-zone metamorphism in Japan: A geochronological reappraisal of Kitomyo Schists

*Shota Matsunaga [1], Tatsuki Tsujimori[1], Atsushi MIYASHITA[2], Shogo Aoki[3], Kazumasa Aoki[3] (1.Tohoku University, 2.Seikei University, 3. Okayama University of Science)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SMP32-14] Dating a 'princess': U–Pb age determination of 'nunakawaite' (strontio-orthojoaquinite)

*Tatsuki Tsujimori[1], Tomomi Hara[1], Yuzuki Shinji[1], Tomohiro Ishizaka[1], Hiroshi Miyajima[2], Jun-Ichi Kimura[3], Shogo Aoki[4], Kazumasa Aoki[4] (1.Tohoku University, 2.Fossa Magna Museum, 3.JAMSTEC, 4.Okayama University of Science)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SMP32-15] Modeling of the progressive evolution of subducting slab composition by sparse modeling

*Kenta Yoshida[1], Tatsu Kuwatani[1,2], Kenta Ueki[1], Ryosuke Oyanagi[1], Shotaro Akaho[3] (1.Japan Agency for Marine-earth Science and Technology (JAMSTEC), 2.PRESTO, Japan Science and Technology Agency, 3.National Institute of Advanced Industrial Science and Technology (AIST))

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SMP32-16] Bayesian statistical evaluation method for detrital zircon geochronology: Applications

*Tan Furukawa[1], Tatsuki Tsujimori[2], Shogo Aoki[3], Kazumasa Aoki[4] (1.Tohoku University, Department of Earth Science, 2.Tohoku University, 3.Faculty of Biosphere-Geosphere Science, Okayama University of Science, 4.Department of Applied Science Okayama University of Science)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SMP32-17] 3D structural analysis using X-ray Computed Tomography technique: a case study for fault rocks from the Nojima Fault, southwest Japan

*Takafumi Nishiwaki[1], Aiming Lin[1], Bingcheng Liu[1] (1.Kyoto University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SMP32-18] High- and low-stress subduction zones recognized in the rock record

*Kazuhiko Ishii[1], Simon Richard Wallis[2] (1.Department of Physical Science, Graduate School of Sciences, Osaka Prefecture University, 2.Department of Earth and Planetary Science, Faculty of Science, The University of Tokyo)

[J] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-MP33] Physics and Chemistry of Minerals

convener:Seiji Kamada(Frontier Research Institute for Interdisciplinary Sciences, Tohoku University), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Chairperson:Seiji Kamada(FRIS, Tohoku Univ.)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SMP33-01] High-temperature Raman spectroscopic study of CO_2-containing melanophlogite

*Masami Kanzaki[1] (1.Institute for Planetary Matereials, Okayama University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SMP33-02] Synthesis of barium carbonate with calcite structure and rotational disorder of carbonate ions

*Hiroyuki Kagi[1], Ayaka Saito[1], Kazuki Komatsu[1], Jun Kawano[2] (1.Geochemical Research Center, Graduate School of Science, University of Tokyo, 2.Fuculty of Science, Hokkaido University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SMP33-03] In-situ Raman spectroscopy of ε-FeOOH under high pressures

*Osamu Ikeda[1], Tatsuya Sakamaki[1], Akio Suzuki[1] (1.Department of Earth Science, Graduate School of Science, Tohoku University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SMP33-04] **Strong hydrogen-bond generation in dense hydrous magnesium silicate phase E observed by single-crystal neutron diffraction**

*Narangoo Purevjav[1], Takuo Okuchi[1], Christina Hoffmann[2] (1.Institute for Planetary Materials, Okayama University, 2.Neutron Scattering Division, Neutron Sciences Directorate, Oak Ridge National Laboratory)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SMP33-05] **Water partitioning between upper mantle minerals and melts**

*Dmitry Bondar[1], Hongzhan Fei[1], Tony Withers[1], Tomoo Katsura[1] (1.Bayerisches Geoinstitut, University of Bayreuth, 95440 Bayreuth, Germany)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SMP33-06] Drop-solution enthalpy measurement of $MgSiO_3$ majorite

*Hiroshi Kojitani[1], Masamichi Noda[2], Toru Inoue[2,3], Masaki Akaogi[1] (1.Department of Chemistry, Faculty of Science, Gakushuin University, 2.GRC, Ehime University, 3.Dept. of Earth and Planetary systems Science, Hiroshima University)

[J] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-MP33] Physics and Chemistry of Minerals

convener:Seiji Kamada(Frontier Research Institute for Interdisciplinary Sciences, Tohoku University), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Chairperson:Masahiro Kayama(東北大学)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SMP33-07] High-pressure phase transitions of minerals in the system MgO-TiO_2

*Masaki Akaogi[1], Tetsuya Fujimura[1], Shunto Arai[1], Masaki Okano[1], Hiroshi Kojitani[1] (1.Department of Chemistry, Faculty of Science, Gakushuin University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SMP33-08] Phase change process of iron sulfide nanoparticle from amorphous to crystalline with grain growth

*Yoshinari Sano[1], Atsushi Kyono[2], Yasuhiro Yoneda[3], Gen-ichiro Yamamoto[1] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Faculty of Life and Environmental Sciences, University of Tsukuba, 3.Japan Atomic Energy Agency)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SMP33-09] Texture formation in quenching of Fe-S-O micro melt spherules

*Hiroshi Isobe[1] (1.Department of Earth and Environmental Sciences, Faculty of Advanced Science and Technology, Kumamoto University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SMP33-10] Development of a software for electron diffraction simulation based on dynamical theory and its application to mineralogy

*Yusuke Seto[1], Masahiro Ohtuka[3], Akira Miyake[2] (1.Graduate School of Science, Kobe University, 2.Graduate School of Science, Kyoto University, 3.Graduate School of Technology, Nagoya University)

11:45 AM - 12:15 PM JST | 2:45 AM - 3:15 AM UTC

[SMP33-11] Site occupation analysis for cation in minerals by analytical electron microscopy: application of TEM-ALCHEMI for earth and planetary science

★Invited Papers

*Yohei Igami[1], Shunsuke Muto[1], Masahiro Ohtsuka[3], Akira Miyake[2], Takahiro Kuribayashi[4], Shoichi Toh[5] (1.Institute of Materials and Systems for Sustainability, Nagoya University, 2.Graduate School of Science, Kyoto University, 3.Graduate School of Engineering, Nagoya University, 4.Graduate School of Science, Tohoku University, 5.Faculty of Science, Fukuoka University)

[J] Oral | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[S-MP33] Physics and Chemistry of Minerals

convener:Seiji Kamada(Frontier Research Institute for Interdisciplinary Sciences, Tohoku University), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Chairperson:Fumiya Noritake(Materials Science, Faculty of Engineering, Graduate Faculty of Interdisciplinary Research, UNIVERSITY OF YAMANASHI), Seiji Kamada(FRIS, Tohoku Univ.)

1:45 PM - 2:15 PM JST | 4:45 AM - 5:15 AM UTC

[SMP33-12] Molecular Dynamics Study of Soret Effect in Silicate Liquids

★Invited Papers

*Fumiya Noritake[1] (1.Graduate Faculty of interdisciplinary Research, University of Yamanashi)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SMP33-13] Seebeck coefficient of olivine: Implausible Mercury's thermoelectric dynamo

*Hitoshi Gomi[1], Takashi Yoshino[1], Akira Yoneda[1] (1.Okayama University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SMP33-14] Density measurement of liquid gallium using externally heated diamond anvil cell

*Ryo Tsuruoka[1], Hidenori Terasaki[1], Seiji Kamada[2], Iori Yamada[1], Fumiya Maeda[3], Tadashi Kondo[1], Satoru Urakawa[4], Naohisa Hirao[5], Akihiko Machida[6] (1.Department of Earth and Space Science, Graduate School of Science Osaka University, 2.Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, 3.Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University, 4.Department of Earth Science, Okayama University, 5.Japan Synchrotron Radiation Research Institute, 6.National Institutes for Quantum and Radiological Science and Technology)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SMP33-15] Density measurements of crystalline Fe and amorphous materials at high pressure

*Seiji Kamada[1,2], Hidenori Terasaki[3], Yusaku Takubo[3], Ryo Tsuruoka[3], Fumiya Maeda[2], Rui Yamada[1], Saori Kawaguchi[4], Naohisa Hirao[4], Akihiko Machida[5] (1.Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, 2.Department of Earth Science, Graduate School of Science, Tohoku University, 3.Department of Earth and Space Science, Graduate School of Science, Osaka University, 4.JASRI, 5.QST)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SMP33-16] DAC-GHz ultrasonic P wave velocity measurement on KCl and natural olivine

*Akira Yoneda[1], Shinichiro Kobayashi[2], Seiji Kamada[3] (1.Institute for planetary materials, Okayama University, 2.Department of Earth Science, Graduate school of Science, Tohoku Univ., 3.Frontier Research Institute for Interdisciplinary Sciences, Tohoku Univ.)

[J] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_18

[S-MP33] Physics and Chemistry of Minerals

convener:Seiji Kamada(Frontier Research Institute for Interdisciplinary Sciences, Tohoku University), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University)

[SMP33-P01] Raman spectroscopy of seifertite

*Masahiro KAYAMA[1], Eiji Ohtani[1], Masaaki Miyahara[2], Shohei Kaneko[1], Toshimori Sekine[3], Shin Ozawa[1], Naohisa Hirao[4] (1.Tohoku University, 2.Hiroshima University, 3.HPSTAR, 4.Japan Synchrotron Radiation Research Institute)

[SMP33-P02] Microtexture and crystallization process of impact diamonds

*Hiroaki Ohfuji[1], Motosuke Nakaya[1] (1.Geodynamics Research Center, Ehime University)

[SMP33-P03] **Metamorphic temperature analysis of H chondrites: Using revised Lindsley's pyroxene thermometer**

*Ryo Uehara[1], Yoshihiro Kuwahara[1], Kazuhiko Shimada[1], Yoshihiro Nakamuta[1], Seiichiro Uehara[1], Tatsuro Adachi[1] (1.Kyushu university)

[SMP33-P04] The occurrence combinations of Zeolites at Chichijima, Ogasawara Islands

Michiharu Ito[1], *Yuki Inoue[1], Mana Yasui[2], Atsushi Yamazaki[2], Hiroshi Hagiya[1] (1. Tokyo City University, 2.Waseda research institute for science and engineering)

[SMP33-P05] Title: Single-crystal X-ray diffraction study of mirabilite ($Na_2SO_4 \cdot 10H_2O$) from 213 to 303 K

*Ryutaro Ikeda[1] (1.University of tsukuba)

[SMP33-P06] Elastic constants of single-crystal topaz studied via sphere-resonance method

*Kako Aradachi[1], Tohru Watanabe[1], Morihisa Hamada[2] (1.University of Toyama, 2.JAMSTEC)

[SMP33-P07] Verification of damage by polishing of sheet-like minerals

*Yui Kouketsu[1], Kota Ando[1], Katsuyoshi Michibayashi[1] (1.Department of Earth & Planetary Sciences, Graduate School of Environmental Studies, Nagoya University)

[SMP33-P08] Description of Zebra Rock and the pattern formation model

*Kaoru Yoshimura[1], Atsushi Toramaru[2], Mie Ichihara[3], Takaaki Noguchi[4], Toru Matsumoto[5] (1.Department of Earth and Planetary Science, Graduate School of Science, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 3.Earthquake Research Institute, University of Tokyu, 4.Department of Arts and Science, Kyushu University, 5.Japan Aerospace Exploration Agency/ Institute of Space and Astronautical Science)

[SMP33-P09] Thermal conductivity anomaly of (Mg,Fe)CO_3 solid solution across the spin transition

*Keng-Hsien Chao[1], Wen-Pin Hsieh[1,2] (1.Institute of Earth Sciences, Academia Sinica, Taiwan, 2.Department of Geosciences, National Taiwan University, Taiwan)

[SMP33-P10] **Melting experiments in the $MgSiO_3$ – SiO_2 system under high pressures**

*Takuya Moriguti[1], Akira Yoneda[1], Eiji Ito[1] (1.Institute for Planetary Materials, Okayama University)

[SMP33-P11] Melting relations of the Fe-Ni-S-C system and the formation of superdeep diamonds

*Yu Itami[1], Satoru Urakawa[1] (1.Okayama University)

[SMP33-P12] Effect of ammonia on the stability of methane hydrate under high-pressure and high-temperature

*Hirokazu Kadobayashi[1], Hisako Hirai[2], Hiroaki Ohfuji[1], Hideaki Kawamura[1], Michika Ohtake[3], Yoshitaka Yamamoto[3] (1.Geodynamics Research Center, Ehime University, 2.Department of Environment System, Faculty of Geo-environmental Science, Rissho University, 3.National Institute of Advanced Industrial Science and Technology)

[SMP33-P13] Study on magnetite-maghemite-hematite transformation

*Ibuki Kinebuchi[1], Atsushi Kyono[1], Yoshinari Sano[1] (1.University of Tsukuba)

[SMP33-P14] The Effects of Temperature and Pressure on Hydromagnesite

*Gen-ichiro Yamamoto[1], Atsushi Kyono[1], Jun Abe[2], Takanori Hattori[3], Yoshitaka Matsushita[4], Yasuhiro Yoneda[3] (1.University of Tsukuba, 2.CROSS, 3.JAEA, 4.NIMS)

[SMP33-P15] Synthesis and crystal structure of Mg-bearing Fe_9O_{11}: New insight in the complexity of Fe-Mg oxides at conditions of the deep upper mantle

*Takayuki Ishii[1], Uenver-Thiele Laura[2], Alan B Woodland[2], Edith Alig[3], Tiziana Boffa Ballaran[1] (1.Bavarian Research Institute, University of Bayreuth, 2.Institut für Geowissenschaften, Goethe-Universität Frankfurt, 3.Institut für Anorganische und Analytische Chemie, Goethe-Universität Frankfurt)

[SMP33-P16] **Changes in specific surface area and morphology of kaolin group minerals with pressure treatment**

*Soyeon Kwon[1], Yongjae Lee[1] (1.YONSEI University)

[J] Poster | S (Solid Earth Sciences)：S-MP Mineralogy & Petrology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_30

[S-MP33] Physics and Chemistry of Minerals

convener:Seiji Kamada(Frontier Research Institute for Interdisciplinary Sciences, Tohoku University), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University)

[SMP33-P01] Raman spectroscopy of seifertite

*Masahiro KAYAMA[1], Eiji Ohtani[1], Masaaki Miyahara[2], Shohei Kaneko[1], Toshimori Sekine[3], Shin Ozawa[1], Naohisa Hirao[4] (1.Tohoku University, 2.Hiroshima University, 3.HPSTAR, 4.Japan Synchrotron Radiation Research Institute)

[E] Oral | S (Solid Earth Sciences)：S-GC Geochemistry

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A10 TOKYO BAY MAKUHARI HALL

[S-GC40] Volatile Cycles in the Deep Earth - from Subduction Zone to Hot Spot

convener:Hirochika Sumino(Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo), Takeshi Hanyu(Japan Agency for Marine-Earth Science and Technology, Department of Solid Earth Geochemistry), Yuji Sano(Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo), Gray E Bebout(Lehigh University), Chairperson:Takeshi Hanyu, Gray Bebout(Lehigh University), Yuji Sano, Hirochika Sumino

1:45 PM - 2:15 PM JST | 4:45 AM - 5:15 AM UTC

[SGC40-01] Continental growth, crustal recycling, and global water cycle

★Invited Papers

*Jun Korenaga[1] (1.Department of Geology and Geophysics, Yale University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SGC40-02] Role of volatiles in magma genesis of ascending mantle plume

*Eiichi Takahashi[1], Jintuan Wang[1], Li Li[1] (1.Guangzhou Institute of Geochemistry, Chinese Academy of Science)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SGC40-03] DH partitioning experiment among high-pressure polymorph of olivine

*Asami Sano-Furukawa[1], Shoichi Itoh[2], Toru Inoue[3], Masamichi Noda[3] (1.J-PARC center, Japan Atomic Energy Agency, 2.Kyoto University, 3.Hiroshima University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SGC40-04] **Formation of Fe-rich volatile-bearing phases in the deep lower mantle and the implications for deep Earth volatile cycles**

*Li Zhang[1], Hongsheng Yuan[1], Eiji Ohtani[2], Lianjie Man[1], Duck Young Kim[1], Dmitry Popov[3], Yue Meng[3], Eran Greenberg[4], Vitali Prakapenka[4] (1.Center for High Pressure Science and Technology Advanced Research (HPSTAR), 2.Department of Earth Science, Graduate School of Science, Tohoku University, 3.HPCAT, X-ray Science Division, Argonne National Laboratory, 4.GeoSoilEnviroCARS, University of Chicago)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SGC40-05] Estimation of the origin of Pitcairn Island OIB by Independent Component Analysis

*Takahiro Ozawa[1], Hikaru Iwamori[1,2,3], Takeshi Hanyu[2], Morihisa Hamada[2], Kenji Shimizu[4], Ushikubo Takayuki[4], Jun-Ichi Kimura[2], Q. Chang[2], Hitomi Nakamura[5], Motoo Ito[4] (1.Tokyo Institute of Tokyo, 2.Geochemical Evolution Research Program, Japan Agency for Marine-Earth Science and Technology, 3.Earthquake Research Institute, The University Tokyo, 4.Kochi Core Center, Japan Agency for Marine-Earth Science and Technology, 5.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[E] Oral | S (Solid Earth Sciences)：S-GC Geochemistry

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A10 TOKYO BAY MAKUHARI HALL

[S-GC40] Volatile Cycles in the Deep Earth - from Subduction Zone to Hot Spot

convener:Hirochika Sumino(Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo), Takeshi Hanyu(Japan Agency for Marine-Earth Science and Technology, Department of Solid Earth Geochemistry), Yuji Sano(Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo), Gray E Bebout(Lehigh University), Chairperson:Takeshi Hanyu, Gray Bebout(Lehigh University), Yuji Sano, Hirochika Sumino

3:30 PM - 4:00 PM JST | 6:30 AM - 7:00 AM UTC

[SGC40-06] Tracing recycled volatiles in MORB with halogens

★Invited Papers

*Ray Burgess[1], Lorraine Ruzie-Hamilton[1], Patricia Clay[1], Bastian Joachim[2], Christopher Ballentine[3] (1.School of Earth and Environmental Sciences, University of Manchester, Manchester, M13 9PL UK, 2.Institute for Mineralogy and Petrography, University of Innsbruck, Innrain, 52A-6020, Innsbruck, Austria, 3.Department of Earth Sciences, University of Oxford, South Parks Road, Oxford, OX1 3AN UK)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SGC40-07] Volatile composition in ocean island basalts

*Takeshi Hanyu[1] (1.Japan Agency for Marine-Earth Science and Technology, Department of Solid Earth Geochemistry)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SGC40-08] Halogen heterogeneity in the subcontinental lithospheric mantle

*Hirochika Sumino[1], Masahiro Kobayashi[2], Ray Burgess[3], Chris J Ballentine[4] (1.Department of Basic Science, Graduate School of Arts and Sciences, University of Tokyo, 2.Tokyo Metropolitan Industrial Technology Research Institute, 3.School of Earth and Environmental Sciences, University of Manchester, 4.Department of Earth Sciences, University of Oxford)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SGC40-09] Efficiency of Deep Carbon Subduction: Input, Metamorphic Records, and Bearing on Estimated Sources of Arc Volcanic Gases

*Gray E Bebout[1,2], Gabe S Epstein[2], Brian M House[3] (1.Institute for Planetary Materials, Okayama University, 2.Lehigh University, 3.University of California, San Diego)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SGC40-10] Helium isotope variations in subduction-type volcanic hydrothermal systems

*Yuji Sano[1], Takanori Kagoshima[1], Naoto Takahata[1], Tetsuji Onoue[2], Tomo Shibata[3], Tobias P Fischer[4] (1.Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo, 2.Department of Earth and Environmental Sciences, Kumamoto University, 3.Institute for Geothermal Sciences, Kyoto University, 4.Department of Earth and Planetary Sciences, University of New Mexico)

[J] Poster | S (Solid Earth Sciences)：S-GC Geochemistry

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_19

[S-GC41] Solid Earth Geochemistry, Cosmochemistry

convener:Gen Shimoda(Geological Survey of Japan, AIST), Katsuhiko Suzuki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Katsuyuki Yamashita(Graduate School of Natural Science and Technology, Okayama University), Akira Ishikawa(Department of Earth and Planetary Sciences, Tokyo Institute of Technology)

[SGC41-P01] Experimental and Simulation Study on the Migration Rule of Arsenic in the Soil of Surface Karst Zone in Southwest China

*bin zeng[1] (1.China University of Geosciences)

[SGC41-P02] H_2 production and CO_2 storage during peridotite serpentinization under CO_2-rich hydrothermal conditions: Influence of pyroxene

*Jiajie Wang[1], Noriaki Watanabe[1], Atsushi Okamoto[1], Kengo Nakamura[1], Takeshi Komai[1] (1.Tohoku Univ.)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | IC 2F

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Nobukazu Seama, Tetsuo Matsuno

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SVC38-30] Summary of Kikai submarine caldera researches conducted by KOBEC (Kobe Ocean-Bottom Exploration Center)

*Nobukazu Seama[1,2], Tetsuo Matsuno[2,1], Koji Kiyosugi[3,2], Satoshi Shimizu[2], Reina Nakaoka[2], Keiko Suzuki-Kamata[2,1], Yasutomo Seto[1], Mamoru Sano[2], Yuiko Morita[4], Hikaru Iwamaru[2], Haruhisa Morozumi[2], Misaki Horiuchi[1], Kimihiro Nishimura[1], Hiroshi Ichihara[5], Kazuki Hayashi[1], Toki Hirose[1], Katsuya Kaneko[1,2], Hiroto Yamaguchi[4], Yuki Okizono[4], Hiroko Sugioka[1,2], Kazuo Nakahigashi[6,2], Yojiro Yamamoto[7], Tatsuya KODA[2], Shuichi Kodaira[7,2], Yoshiyuki Tatsumi[2,1], Scientific party of T/S Fukae-maru Kikai caldera research cruises (1.Department of Planetology, Graduate School of Science, Kobe University, 2.Kobe Ocean Bottom Exploration Center, Kobe University, 3.Organization of Advanced Science and Technology, Kobe University, 4.Department of Planetology, Faculty of Science, Kobe University, 5.Graduate school of environmental studies, Nagoya University, 6.Tokyo University of Marine Science and Technology, 7.Japan Agency for Marine-Earth Science and Technology)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SVC38-31] Distribution of submarine pyroclastic-flow deposits of Akahoya eruption, Kikai caldera

*Satoshi Shimizu[1,2], Nobukazu Seama[3,1], Reina NAKAOKA[1], Tetsuo Matsuno[1,3], Koji Kiyosugi[5], Hikaru Iwamaru[1,2], Mamoru Sano[1,2], Kimihiro Nishimura[3], Keiko Suzuki-Kamata[1,3], Katsuya Kaneko[3], hiroto yamaguchi[4], Misaki Horiuchi[3], Toki Hirose[3], Kazuki Hayashi[3], Yoshiyuki Tatsumi[1,3] (1.Ocean Bottom Exploraiton Center, Kobe University, 2.Nippon Marine Enterprises, Ltd., 3.Department of Planetology, Graduate School of Science, Kobe University, 4.Department of Planetology, Faculty of Science, Kobe University, 5.Organization of Advanced Science and Technology, Kobe University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SVC38-32] Identification of submarine volcanic ash around the Kikai caldera with the Koya pyroclastic flow deposit inferred from glass composition

*Reina NAKAOKA[1], Keiko Suzuki-Kamata[1,2], Satoshi Shimizu[1], Yoshiyuki Tatsumi[1,2], Katsuya Kaneko[2,1], Koji Kiyosugi[3,1], Nobukazu Seama[2,1], Tetsuo Matsuno[1,2], Kimihiro Nishimura[2], Kazuki Hayashi[2] (1.Kobe Ocean-Bottom Exploration Center, Kobe University, 2.Department of Planetology, Graduate School ofScience, Kobe University, 3.Organization of Advanced Science and Technology, Kobe University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SVC38-33] Preliminary report of the sea floor survey by a remotely operated vehicle (ROV) at the Kikai caldera, SW Japan

*Koji Kiyosugi[1], Keiko Suzuki-Kamata[2], Haruhisa Morozumi[2,4], Yoshiyuki Tatsumi[2], Katsuya Kaneko[3], Reina NAKAOKA[2], Mamoru Sano[2], Satoshi Shimizu[2], Hikaru Iwamaru[2], Nobukazu Seama[3], Tetsuo Matsuno[2], Kimihiro Nishimura[3], Kazuki Hayashi[3], Misaki Horiuchi[3] (1.Organization for Advanced and Integrated Research, Kobe University, 2.Kobe Ocean-Bottom Exploration Center, Kobe University, 3.Department of Planetology, Graduate School of Science, Kobe University, 4.Japan Oil, Gas and Metals National Corporation)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SVC38-34] Seismic activity beneath Kikai Caldera by using Ocean Bottom Observation

*Yasutomo Seto[1], Hiroko Sugioka[2], Yojiro Yamamoto[3], Tsutomu Takahashi[4] (1.Department of Planetology, Graduate School of Science, Kobe University, 2.Department of Planetology, Kobe University, 3.Japan Agency for Marine-Earth Science and Technology, 4.Research and Developement Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SVC38-35] An investigation of three-dimensional electrical resistivity structure under Kikai Caldera

*Tetsuo Matsuno[1,2], Toki Hirose[2], Yuuki Okizono[3], Nobukazu Seama[2,1], Hiroshi Ichihara[4], Hiroko Sugioka[2,1], Yoshiyuki Tatsumi[1,2] (1.Kobe Ocean Bottom Exploration Center, Kobe University, 2.Department of Planetology, Graduate School of Science, Kobe University, 3.Department of Planetology, Faculty of Science, Kobe University, 4.Graduate school of environmental studies, Nagoya University)

[J] Oral | S (Solid Earth Sciences)：S-VC Volcanology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | IC 2F

[S-VC38] Active Volcanism

convener:Yuta Maeda(Nagoya University), Takahiro Miwa(National research institute for earth science and disaster prevention), Takeshi Nishimura(Department of Geophysics, Graduate School of Science, Tohoku University), Chairperson:Takeshi Ohba, Akihiko Terada

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SVC38-36] Time variation in the chemical and isotopic composition of fumarolic gases at Hakone volcano Japan

*Takeshi Ohba[1], Muga Yaguchi[2], Kana NISHINO[1], Nozomi Numanami[1], Yasushi DAITA[3], Urumu Tsunogai[4], Masanori Ito[4], Chiho Sukigara[4] (1.Department of chemistry, School of Science, Tokia University, 2.Meteorological Research Institute, JMA, 3.Kanagawa Environmental Research Center, 4.Nagoya University Graduate School of Environmental Studies)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SVC38-37] Chemical and isotopic composition of volcanic gases at Mt Kirishima Iwoyama, Japan

*Takeshi Ohba[1], Muga Yaguchi[2], Kotaro Toyama[3], Hirochika Sumino[3], Urumu Tsunogai[4], Masanori Ito[4], Ryo Shingubara[4] (1.Department of chemistry, School of Science, Tokia University, 2.Meteorological Research Institute, 3.The University of Tokyo Graduate School of Arts and Sciences Department of Basic Science, 4.Nagoya University Graduate School of Environmental Studies)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SVC38-38] Temporal and spatial variations of helium isotope ratios in volcanic gases in Kirishima volcanic group, Japan

*Kotaro Toyama[1], Hirochika Sumino[1], Kaori Kawana[1], Takeshi Ohba[2], Muga Yaguchi[3], Yoshihide Akiyama[1], Koki Aizawa[4], Kaori Tsukamoto[4] (1.Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo, 2.Department of chemistry, School of Science, Tokia University, 3.Meteorological Research Institute, 4.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SVC38-39] Emission regions of gaseous elemental mercury around Yugama crater lake at Kusatsu-Shirane volcano, Japan

*Akihiko Terada[1], Noriaki Mizutani[1] (1.Volcanic Fluid Research Center, Faculty of Science, Tokyo Institute of Technology)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SVC38-40] Magnetotelluric images of Kusatsu-Shirane volcano, revisited by 3-D modeling with tetrahedral elements considered topography effect

*Kuo Hsuan Tseng[1], Yasuo Ogawa[1], Nurhassan .[2], Sabri Bulent Tank[3], Akihiko Terada[1], Wataru Kanda[1], Masato Fukai[1] (1.Tokyo Institute of Technology, 2.Bandung Institute of Technology, Indonesia, 3.Bogazici University, Turkey)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SVC38-41] Magma conduit and associated hydrothermal systems of Aso volcano as revealed by broadband magnetotelluric data

*Nobuo Matsushima[1], Mitsuru Utsugi[2], Shinichi Takakura[1], Tadashi Yamasaki[1], Maki Hata[3], Takeshi Hashimoto[4], Makoto Uyeshima[3] (1.Geological Survey of Japan,AIST, 2.Kyoto University, 3.The University of Tokyo, 4.Hokkaido University)

[E] Oral | S (Solid Earth Sciences)：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | IC 2F

[S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo), Chairperson:Hitoshi Hirose, Yoshiyuki Tanaka

9:00 AM - 9:30 AM JST | 12:00 AM - 12:30 AM UTC

[SCG48-01] Variability of the space-time evolution of slow slip events off the Boso Peninsula, central Japan, from 1996 to 2018

★Invited Papers

*Jun'ichi Fukuda[1] (1.Earthquake Research Institute, University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SCG48-02] Cumulative slip distribution of short-term slow slip events in the western Shikoku area, southwest Japan based on tilt change measurements

*Hitoshi Hirose[1,2], Wakako Tamura[2], Takeshi Kimura[3] (1.Research Center for Urban Safety and Security, Kobe University, 2.Graduate School of Science, Kobe University, 3.National Research Institute for Earth Science and Disaster Resilience)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SCG48-03] Shallow undersea SSEs off the western Japan monitored by the GNSS-A

*Yusuke Yokota[1], Tadashi Ishikawa[2] (1.Institute of Industrial Science, The University of Tokyo, 2.Hydrographic and Oceanographic department, Japan Coast Guard)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SCG48-04] Co- and Post-seismic deformation due to the 2016 moderate earthquake sequence at the Chaman fault

*Fumiko Matsumoto[1], Masato Furuya[1] (1.Hokkaido University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SCG48-05] An attempt to quantify transient fluid flow during slow slip event using GNSS and gravity data-1st report

*Yusuke Umemiya[1], Yoshiyuki Tanaka[1] (1.The University of Tokyo)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

[S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo)

[SCG48-P01] Off the Kii Peninsula Shallow Low Frequency Earthquake in 2004 revealed by Ocean Bottom Seismometer

*Koji Tamaribuchi[1], Akio Kobayashi[1], Takahito Nishimiya[1], Satoshi Annoura[2] (1.Meteorological Research Institute, 2.Japan Meteorological Agency)

[SCG48-P02] The development of pressure vessel on gouges for rock deformation at seismic rates under water-saturated conditions

*Wei-Ting Lin[1], Li-Wei Kuo[1], Wen-Jie Wu[1], Jia-Jyun Dong[1], Yi-Hung Huang[2] (1.National Central University, 2.MATSUKI HYDRAULIC INDUSTRIAL CO. LTD)

[SCG48-P03] Spatial variations of shallow very low-frequency earthquake activity along the Nankai Trough based on CMT inversion using the 3D heterogeneous model

*Shunsuke Takemura[1], Takanori Matsuzawa[1], Akemi Noda[1], Takashi Tonegawa[2], Youichi Asano[1], Takeshi Kimura[1], Katsuhiko Shiomi[1] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Japan Agency for Marine-Earth Science and Technology)

[SCG48-P04] Evaluation of Magnitude and Characteristics of Seismicity of Low Frequency Earthquakes in Parkfield

*Miki Aso[1,3], Naofumi Aso[2], Satoshi Ide[1] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Tokyo Institute of Technology, School of Science, 3.OYO RMS Corporation)

[SCG48-P05] Tectonic tremor catalog in the Tohoku-Hokkaido-Oki region using S-net

*Satoshi Ide[1], Tomoaki Nishikawa[2], Takanori Matsuzawa[3], Kazuaki Ohta[2], Naoki Uchida[4], Takuya NISHIMURA[2] (1.Department of Earth an Planetary Science, University of Tokyo, 2.Disaster Prevention Research Institute, Kyoto University, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Graduate School of Science and International Research Institute of Disaster Science, Tohoku University)

[SCG48-P06] Spontaneous Slow Slip and Runaway Slip in Laboratory

*Miki Takahashi[1] (1.Institute of Earthquake and Volcano Geology, Geological Survey of Japan, AIST)

[SCG48-P07] Hydration and amorphization of quartz rocks during high-velocity frictional sliding: An examination of fault gouge from friction experiments of synthetic quartz

*Yuko Onoe[1], Hirotaka Iida[2], Akito Tsutsumi[1], Aki Takigawa[1] (1.Graduate School of Science, Kyoto University, 2.Geothermal Engineering Co., Ltd.)

[SCG48-P08] Constraining S Wave Velocity of the Source Region of Shallow Very Low-Frequency Earthquakes

*Takeshi Akuhara[1], Takashi Tonegawa[2] (1.Earthquake Research Institute, The University of Tokyo, 2.Research and Development center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology)

[SCG48-P09] Quantitative relationship between aseismic slip propagation speed and frictional properties

*Keisuke Ariyoshi[1], Jean-Paul Ampuero[2,3], Roland Burgmann[4], Toru Matsuzawa[5], Akira Hasegawa[5], Ryota Hino[5], Takane Hori[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Université Côte d'Azur, 3.California Institute of Technology, 4.University of California, Berkeley, 5.Graduate School of Science, Tohoku University)

[SCG48-P10] Comprehensive detection of very low frequency earthquakes off the Pacific coasts of Hokkaido and Tohoku, northeastern Japan

*Satoru Baba[1], Akiko Takeo[1], Kazushige Obara[1], Takanori Matsuzawa[2], Takuto Maeda[3] (1.Earthquake Research Institute, University of Tokyo, 2.National Research Institute for Earth Science and Disaster Resilience, 3.Graduate School of Science and Technology, Hirosaki University)

[SCG48-P11] **Spatio-temporal evolution of long- and short-term slow slip events in the Tokai region, central Japan estimated from a very dense GNSS network, during 1997-2017**

*Hiromu Sakaue[1], Takuya NISHIMURA[2], Jun'ichi Fukuda[3], Teruyuki Kato[4] (1.Graduate School of Science, Kyoto University, 2.Disaster Prevention Research Institute Kyoto University, 3.Earthquake Research Institute,The University of Tokyo, 4.Hot Springs Research Institute of Kanagawa Prefecture)

[SCG48-P12] Broadband excitation of acoustic emission in granular stick-slip : experiments and spectral analyses

*Hidekazu Fukumizu[1], Ikuro Sumita[2] (1.Earth and Environmental Science Course, Division of Natural System, Graduate school of Natural Science and Technology, Kanazawa University, 2.School of Geosciences and Civil Engineering, Kanazawa University)

[SCG48-P13] Episodic tremor and slip silently invades strongly locked megathrust in the Nankai Trough

*Masayuki Kano[1], Aitaro Kato[2], Kazushige Obara[2] (1.Graduate school of science, Tohoku University, 2.Earthquake Research Institute, The University of Tokyo)

[SCG48-P14] Spatial distribution of the electrical resistivity beneath western part of Shikoku Island where long-term SSE events have repeatedly occurred

*Makoto Uyeshima[1], Maki Hata[1], Hiroshi Ichihara[2], Ryokei Yoshimura[3], Koki Aizawa[4] (1.Earthquake Research Institute, The University of Tokyo, 2.Graduate School of Environmental Studies, Nagoya University, 3.Disaster Prevention Research Institute, Kyoto University, 4.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University)

[SCG48-P15] Variations of scaling relationships for shallow tremor observed along the Nankai trough

*Masaru Nakano[1], Suguru Yabe[1] (1.Japan Agency for Marine-Earth Science and Technology)

[SCG48-P16] Low-frequency earthquakes triggered by teleseismic surface waves by Ryukyu subduction zone.

Ayumi Kinjo[1], *Mamoru Nakamura[1] (1.Faculty of Science, University of the Ryukyus)

[SCG48-P17] Detection of small surface displacement accompanying deep low-frequency tremor in Shikoku region, southwest Japan

*Yutaro Okada[1], Takao Tabei[2] (1.Faculty of Science, Kochi University, 2.Faculty of Science and Technology, Kochi University)

[SCG48-P18] Long-term temporal change in crustal resistivity beneath western Shikoku

*Futoshi Yamashita[1], Yoshimori Honkura[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SCG48-P19] Slow decay of postseismic deformation compared with aftershocks following the 2011 Tohoku-oki Earthquake

*Yuta Mitsui[1], Shunsuke Morikami[2] (1.Department of Geosciences, Shizuoka University, 2.Formerly at Graduate School of Science and Technology, Shizuoka University)

[SCG48-P20] Serpentinite dehydration in subduction shear zones formed at source depths of slow earthquakes

*Yasushi Mori[1], Miki Shigeno[1], Kohtaro Ujiie[2], Kazuya Noro[2], Tadao Nishiyama[3] (1.Kitakyushu Museum of Natural History and Human History, 2.University of Tsukuba, 3.Kumamoto University)

[SCG48-P21] Earthquake swarms following very low-frequency earthquakes in the central Ryukyu Trench

*Mamoru Nakamura[1] (1.Faculty of Science, University of the Ryukyus)

[SCG48-P22] Seismic imaging in the central Nankai trough, off Shionomisaki to Kii channel

*Yasuyuki Nakamura[1], Shuichi Kodaira[1], Tetsuo No[1], Yuka Kaiho[1], Gou Fujie[1], Seiichi Miura[1], Kazuya Shiraishi[1] (1.Japan Agency for Marine Earth Science and Technology)

[SCG48-P23] Attempt to Detect Intra-plate SSEs Based on F3 Solution of GEONET

*Yusaku Tanaka[1] (1.Earthquake Research Institute)

[SCG48-P24] A new hydrothermal, low to high speed rotary-shearing apparatus: Reproduction of slow/megathrust earthquakes in laboratory

*Takehiro Hirose[1], Wataru Tanikawa[1], Yohei Hamada[1], Keishi Okazaki[1] (1.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology)

[SCG48-P25] Very low-frequency earthquakes in western Shikoku remotely triggered by the 2016 Mw5.9 off-Kii Peninsula earthquake

*Masatoshi Miyazawa[1] (1.Disaster Prevention Research Institute, Kyoto University)

[SCG48-P26] **Underground structure around source region of slow earthquakes in western Shikoku obtained by receiver function analysis**

Akira Hikita[1], Aitaro Kato[1], *Kazushige Obara[1], Akiko Takeo[1], Takeshi Akuhara[1] (1.Earthquake Research Institute, The University of Tokyo)

[SCG48-P27] Hypocenter determination of deep low frequency tremors beneath the Kii Peninsula by backprojection of seismic array data

*Kodai Sagae[1], Hisashi Nakahara[1], Takeshi Nishimura[1], Kazutoshi Imanishi[2] (1.Graduate School of Science,Tohoku University, 2.National Institute of Advanced Industrial Science and Technology (AIST))

[SCG48-P28] Triggered tremors and stress perturbations due to surface waves

*Ryohei Ikeda[1], Naoki Suda[1] (1.Hiroshima University)

[SCG48-P29] Numerical modeling of long- and shallow slow slip events including shallow region in Hyuganada and western Nankai, Japan

*Takanori Matsuzawa[1], Bunichiro Shibazaki[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Building Research Institute)

[SCG48-P30] Further evidence for the influence of a subducting-ridge on the spatial strain accumulation and release pattern in the shallow eastern Nankai Trough, based on VLFE distribution

*Akiko Toh[1], Chen Wan-Jou [2], Doug Dreger[3], Wu-Cheng Chi[2], Satoshi Ide[1] (1.University of Tokyo, 2.Institute of Earth Sciences, Academia Sinica, 3.UC Berkeley)

[SCG48-P31] Evidence for semi-brittle flow in mantle-wedge serpentinites under high pore fluid pressure and their implications for deep low frequency earthquakes

Kengo Kataoka[1], Yurina Nagata[1], *Ken-ichi Hirauchi[1], Ryosuke Oyanagi[2], Atsushi Okamoto[3], Katsuyoshi Michibayashi[4] (1.Department of Geosciences, Faculty of Science, Shizuoka University, 2.Japan Agency for Marine-Earth Science and Technology, 3.Graduate School of Environmental studies, Tohoku University, 4.Department of Earth and Planetary Sciences, Nagoya University)

[SCG48-P32] Spatial distribution of slow slip events off the Boso peninsula from 1996 to 2018 under sparsity constraints

*Ryoko Nakata[1], Hideitsu Hino[2], Tatsu Kuwatani[3,4], Takahiro Akiyama[5], Shoichi Yoshioka[6], Masato Okada[7], Takane Hori[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.The Institute of Statistical Mathematics, 3.Department of Solid Earth Geochemistry, Japan Agency for Marine-Earth Science and Technology, 4.PRESTO, Japan Science and Technology Agency, 5.Graduate School of Science, Kobe University, 6.Research Center for Urban Safety and Security, Kobe University, 7.Graduate School of Frontier Sciences, The University of Tokyo)

[SCG48-P33] Marine electromagnetic observations around a slow earthquake region in the western Nankai trough

*Hiroshi Ichihara[1], Tada-nori Goto[2], Tetsuo Matsuno[3], Noriko Tada[4], Shinya Sato[2] (1.Earthquake and Volcano Research Center, Nagoya University, 2.Graduate School of Engineering, Kyoto University, 3.Ocean Bottom Exploration Center, Kobe University, 4.JAMSTEC)

[SCG48-P34] Dynamics of precipitating injection fronts inside of structured medium

*Yutaka Sumino[1], Shunsuke Tanaka[1], Miyuki Kunihiro[1] (1.Tokyo University of Science)

[SCG48-P35] Permeability changes of simulated low permeable fault rocks induced by intermediate velocity friction test

*Wataru Tanikawa[1] (1.Japan Agency for Marine-Earth Science and Technology, Kochi Instutute for Core Sample Research)

[SCG48-P36] Modified relation between the coupling and tremor rates around the Shikoku region

*Tadafumi Ochi[1] (1.Institute of Earthquake and Volcano Geology, Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology)

[SCG48-P37] Spatiotemporal distribution of regular and very low-frequency earthquakes in the northern part of the Ryukyu subduction zone

*Youichi Asano[1], Kazuhiko Goto[2], Hiroshi Yakiwara[3], Shuichiro Hirano[3] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Association for the development of earthquake prediction, 3.Nansei-toko Observatory for Earthquakes and Volcanoes, Kagoshima University)

[SCG48-P38] Possible tectonic tremor activities near the VLFE epicenters in the Sanriku-Oki region in 2011

*Hidenobu Takahashi[1], Ryota Hino[1], Yusaku Ohta[1], Naoki Uchida[1], Syuichi Suzuki[1], Masanao Shinohara[2], Takanori Matsuzawa[3] (1.Graduate school of Science Tohoku University , 2.Earthquake Research Institute, University of Tokyo, 3.National Research Institute for Earth Science and Disaster Resilience)

[SCG48-P39] Heterogeneous structure around a region of slow earthquake activity off Ibaraki prefecture along the Japan Trench

*Kimihiro Mochizuki[1], Tomoaki Yamada[1], Masanao Shinohara[1], Ryota Hino[2], Ryosuke Azuma[2], Yoshihiro Ito[3], Yoshio Murai[4], Kenji Uehira[5], Toshinori Sato[6] (1.ERI, Univ. of Tokyo, 2.Graduate School of Science, Tohoku Univ., 3.DPRI, Kyoto Univ., 4.Faculty of Science, Hokkaido Univ., 5.NIED, 6.Graduate School of Science, Chiba Univ.)

[SCG48-P40] Shallow low-frequency tremor triggered by nearby moderate earthquakes off Sanriku

*Sachiko Tanaka[1], Takanori Matsuzawa[1], Youichi Asano[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SCG48-P41] Slow slip events in the Bungo Channel over 15 years as inferred from GNSS data (1996-2011)

Takatoshi Yokoi[1], *SHINICHI MIYAZAKI[1], Hiromu Sakaue[1], Jun'ichi Fukuda[2] (1.Graduate School of Science, Kyoto University, 2.Earthquake Research Institute, The University of Tokyo)

[SCG48-P42] Investigations of sensor orientation and a possibility of detecting crustal deformation based on accelerometer records of S-net

*Ryota Takagi[1], Naoki Uchida[1], Takashi NAKAYAMA[1], Ryosuke Azuma[1], Akira Ishigami[1], Tomomi Okada[1], Yusaku Ohta[1], Ryota Hino[1] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University)

[SCG48-P43] Spatiotemporal variation of released seismic energy from shallow low-frequency tremor in Hyuga-nada, revealed by ocean bottom seismological observation

*Yusuke Yamashita[1], Saki Watanabe[2], Tomoaki Yamada[3], Masanao Shinohara[3], Takeshi Matsushima[2] (1.Disaster Prevention Research Institute, Kyoto University, 2.Institute of Seismology and Volcanology, Kyushu University, 3.Earthquake Research Institute, The University of Tokyo)

[SCG48-P44] Unified description of fast and slow earthquakes using velocity strengthening patches

*So Ozawa[1], Takahiro Hatano[1] (1.Earthquake Research Institute, the University of Tokyo)

[SCG48-P45] The b-value of the earthquake swarm activities accompanied by the Boso slow slip events

*Yuki Noda[1], Hitoshi Hirose[2,1] (1.Department of Planetology, Faculty of Science, Kobe University , 2.Research Center for Urban Safety and Security, Kobe University)

[SCG48-P46] **Three-dimensional thermal modeling associated with subduction of the Philippine Sea plate at the Ryukyu Trench, and its relation to the occurrence of interplate seismic events**

*Nobuaki Suenaga[1], Shoichi Yoshioka[2,1], Yinfeng Ji[3] (1.Graduate School of Science, Kobe University, Japan, 2.Research Center for Urban Safety and Security, Kobe University, Japan, 3.Chinese Academy of Science, Beijin, China)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_33

[S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo)

[SCG48-P01] Off the Kii Peninsula Shallow Low Frequency Earthquake in 2004 revealed by Ocean Bottom Seismometer

*Koji Tamaribuchi[1], Akio Kobayashi[1], Takahito Nishimiya[1], Satoshi Annoura[2] (1.Meteorological Research Institute, 2.Japan Meteorological Agency)

[SCG48-P02] The development of pressure vessel on gouges for rock deformation at seismic rates under water-saturated conditions

*Wei-Ting Lin[1], Li-Wei Kuo[1], Wen-Jie Wu[1], Jia-Jyun Dong[1], Yi-Hung Huang[2] (1.National Central University, 2.MATSUKI HYDRAULIC INDUSTRIAL CO. LTD)

[SCG48-P03] Spatial variations of shallow very low-frequency earthquake activity along the Nankai Trough based on CMT inversion using the 3D heterogeneous model

*Shunsuke Takemura[1], Takanori Matsuzawa[1], Akemi Noda[1], Takashi Tonegawa[2], Youichi Asano[1], Takeshi Kimura[1], Katsuhiko Shiomi[1] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Japan Agency for Marine-Earth Science and Technology)

[SCG48-P04] Evaluation of Magnitude and Characteristics of Seismicity of Low Frequency Earthquakes in Parkfield

*Miki Aso[1,3], Naofumi Aso[2], Satoshi Ide[1] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Tokyo Institute of Technology, School of Science, 3.OYO RMS Corporation)

[SCG48-P05] Tectonic tremor catalog in the Tohoku-Hokkaido-Oki region using S-net

*Satoshi Ide[1], Tomoaki Nishikawa[2], Takanori Matsuzawa[3], Kazuaki Ohta[2], Naoki Uchida[4], Takuya NISHIMURA[2] (1.Department of Earth an Planetary Science, University of Tokyo, 2.Disaster Prevention Research Institute, Kyoto University, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Graduate School of Science and International Research Institute of Disaster Science, Tohoku University)

*Hiroshi Ichihara[1], Tada-nori Goto[2], Tetsuo Matsuno[3], Noriko Tada[4], Shinya Sato[2] (1.Earthquake and Volcano Research Center, Nagoya University, 2.Graduate School of Engineering, Kyoto University, 3.Ocean Bottom Exploration Center, Kobe University, 4.JAMSTEC)

[SCG48-P34] Dynamics of precipitating injection fronts inside of structured medium

*Yutaka Sumino[1], Shunsuke Tanaka[1], Miyuki Kunihiro[1] (1.Tokyo University of Science)

[SCG48-P35] Permeability changes of simulated low permeable fault rocks induced by intermediate velocity friction test

*Wataru Tanikawa[1] (1.Japan Agency for Marine-Earth Science and Technology, Kochi Instutute for Core Sample Research)

[SCG48-P36] Modified relation between the coupling and tremor rates around the Shikoku region

*Tadafumi Ochi[1] (1.Institute of Earthquake and Volcano Geology, Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology)

[SCG48-P37] Spatiotemporal distribution of regular and very low-frequency earthquakes in the northern part of the Ryukyu subduction zone

*Youichi Asano[1], Kazuhiko Goto[2], Hiroshi Yakiwara[3], Shuichiro Hirano[3] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Association for the development of earthquake prediction, 3.Nansei-toko Observatory for Earthquakes and Volcanoes, Kagoshima University)

[SCG48-P38] Possible tectonic tremor activities near the VLFE epicenters in the Sanriku-Oki region in 2011

*Hidenobu Takahashi[1], Ryota Hino[1], Yusaku Ohta[1], Naoki Uchida[1], Syuichi Suzuki[1], Masanao Shinohara[2], Takanori Matsuzawa[3] (1.Graduate school of Science Tohoku University , 2.Earthquake Research Institute, University of Tokyo, 3.National Research Institute for Earth Science and Disaster Resilience)

[SCG48-P39] Heterogeneous structure around a region of slow earthquake activity off Ibaraki prefecture along the Japan Trench

*Kimihiro Mochizuki[1], Tomoaki Yamada[1], Masanao Shinohara[1], Ryota Hino[2], Ryosuke Azuma[2], Yoshihiro Ito[3], Yoshio Murai[4], Kenji Uehira[5], Toshinori Sato[6] (1.ERI, Univ. of Tokyo, 2.Graduate School of Science, Tohoku Univ., 3.DPRI, Kyoto Univ., 4.Faculty of Science, Hokkaido Univ., 5.NIED, 6.Graduate School of Science, Chiba Univ.)

[SCG48-P40] Shallow low-frequency tremor triggered by nearby moderate earthquakes off Sanriku

*Sachiko Tanaka[1], Takanori Matsuzawa[1], Youichi Asano[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SCG48-P41] Slow slip events in the Bungo Channel over 15 years as inferred from GNSS data (1996-2011)

Takatoshi Yokoi[1], *SHINICHI MIYAZAKI[1], Hiromu Sakaue[1], Jun'ichi Fukuda[2] (1.Graduate School of Science, Kyoto University, 2.Earthquake Research Institute, The University of Tokyo)

[SCG48-P42] Investigations of sensor orientation and a possibility of detecting crustal deformation based on accelerometer records of S-net

*Ryota Takagi[1], Naoki Uchida[1], Takashi NAKAYAMA[1], Ryosuke Azuma[1], Akira Ishigami[1], Tomomi Okada[1], Yusaku Ohta[1], Ryota Hino[1] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University)

[SCG48-P43] Spatiotemporal variation of released seismic energy from shallow low-frequency tremor in Hyuga-nada, revealed by ocean bottom seismological observation

*Yusuke Yamashita[1], Saki Watanabe[2], Tomoaki Yamada[3], Masanao Shinohara[3], Takeshi Matsushima[2] (1.Disaster Prevention Research Institute, Kyoto University, 2.Institute of Seismology and Volcanology, Kyushu University, 3.Earthquake Research Institute, The University of Tokyo)

[SCG48-P44] Unified description of fast and slow earthquakes using velocity strengthening patches

*So Ozawa[1], Takahiro Hatano[1] (1.Earthquake Research Institute, the University of Tokyo)

[SCG48-P45] The b-value of the earthquake swarm activities accompanied by the Boso slow slip events

*Yuki Noda[1], Hitoshi Hirose[2,1] (1.Department of Planetology, Faculty of Science, Kobe University , 2.Research Center for Urban Safety and Security, Kobe University)

[SCG48-P46] **Three-dimensional thermal modeling associated with subduction of the Philippine Sea plate at the Ryukyu Trench, and its relation to the occurrence of interplate seismic events**

*Nobuaki Suenaga[1], Shoichi Yoshioka[2,1], Yinfeng Ji[3] (1.Graduate School of Science, Kobe University, Japan, 2.Research Center for Urban Safety and Security, Kobe University, Japan, 3.Chinese Academy of Science, Beijin, China)

[E] Oral | S (Solid Earth Sciences)：S-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Convention Hall A 2F

[S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo), Chairperson:Kazushige Obara(Earthquake Research Institute, University of Tokyo), Aitaro Kato(Earthquake Research Institute, University of Tokyo)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SCG48-06] Interplay between long-term SSE and ETS facilitated by different underground environment

*Kazushige Obara[1] (1.Earthquake Research Institute, The University of Tokyo)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SCG48-07] **Determination of sVLFE epicenters around the subducted Kyushu-Palau Ridge from coda interferometry**

*Takashi Tonegawa[1], Yusuke Yamashita[2], Aki Ito[1], Masanao Shinohara[3], Daisuke Suetsugu[1], Tsutomu Takahashi[1], Yasushi Ishihara[1], Shuichi Kodaira[1], Yoshiyuki Kaneda[4] (1.JAMSTEC, 2.DPRI, Kyoto University, 3.ERI, The University of Tokyo, 4.Kagawa University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SCG48-08] Detection of slow earthquakes in the microseism frequency band (0.05–1.0 Hz) by large-scale waveform stacking

*Koki Masuda[1], Satoshi Ide[1], Kazuaki Ohta[2] (1.Department of Earth an Planetary Science, University of Tokyo, 2.Disaster Prevention Research Institute, Kyoto University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SCG48-09] Source characteristics of low-frequency earthquakes in Nankai subduction zone inferred from analysis of large event dataset

*Natalia Poiata[1], Mariano Supino[1,2], Gaetano Festa[2], Jean-Pierre Vilotte[1], Kazushige Obara[3] (1.Institut de Physique du Globe de Paris, 2.Università degli Studi di Napoli “ Federico II ”, Napoli, Italy, 3.Earthquake Research Institute, University of Tokyo, Japan)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SCG48-10] **High-frequency radiation prior to semi-volcanic low-frequency earthquake in Eastern Shimane, SW Japan, illuminated by “0.1 manten” Hyper Dense Seismic Observation**

*Aitaro Kato[1], Shin'ichi Sakai[1], Satoshi Matsumoto[2], Yoshihisa Iio[3] (1.Earthquake Research Institute, the University of Tokyo, 2.Kyushu University, 3.Kyoto University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SCG48-11] Variation of Focal Mechanisms of Low Frequency Earthquakes in Parkfield

*Miki Aso[1,3], Naofumi Aso[2], Satoshi Ide[1] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Tokyo Institute of Technology, School of Science , 3.OYO RMS Corporation)

[E] Oral | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Convention Hall A 2F

[S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo), Chairperson:Satoshi Ide(Graduate School of Science, University of Tokyo), Kazuaki Ohta

3:30 PM - 4:00 PM JST | 6:30 AM - 7:00 AM UTC

[SCG48-12] Mapping seismic data to slow slip using machine learning

★Invited Papers

*Bertrand Rouet-Leduc[1], Claudia Hulbert[2], Ian McBrearty[1], Paul Johnson[1] (1.Los Alamos National Laboratory, USA, 2.Ecole Normale Superieure, France)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SCG48-13] Revealing the slow earthquake activity in the Japan Trench and its relation to the 2011 Tohoku-Oki earthquake

*Tomoaki Nishikawa[1], Takanori Matsuzawa[2], Kazuaki Ohta[1], Naoki Uchida[3], Takuya NISHIMURA[1], Satoshi Ide[4] (1.Disaster Prevention Research Institute, Kyoto University, 2.National Research Institute for Earth Science and Disaster Resilience, 3.Graduate School of Science, Tohoku University, 4.Graduate School of Science, The University of Tokyo)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SCG48-14] Tremor and slow slip associated with afterslip of the 2011 Tohoku earthquake

*Kazuaki Ohta[1], Yoshihiro Ito[1], Ryota Hino[2], Shukei Ohyanagi[1], Takanori Matsuzawa[3], Masanao Shinohara[4], Hajime Shiobara[4] (1.Disaster Prevention Research Institute, Kyoto University, 2.Graduate School of Science, Tohoku University, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Earthquake Research Institute, the University of Tokyo)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SCG48-15] High definition imaging of the Japan Trench by OBS Array of Arrays: Does shallow tectonic tremor occur in the plate interface?

*Shukei Ohyanagi[1], Kazuaki Ohta[2], Yoshihiro Ito[2], Ryota Hino[3], Yusaku Ohta[3], Ryosuke Azuma[3], Masanao Shinohara[4], Kimihiro Mochizuki[4], Toshinori Sato[5], Yoshio Murai[6] (1.Kyoto University, Graduate School of Science, 2.Kyoto University, Disaster Prevention Research Institute, 3.Tohoku University, 4.Tokyo University, Earthquake Research Institute, 5.Chiba University, 6.Hokkaido University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SCG48-16] The activity of small repeating earthquakes after the 2011 Tohoku-oki earthquake: an examination based on the S-net and land networks

*Naoki Uchida[1], Ryota Takagi[1], Satoshi Hirahara[1], Takashi NAKAYAMA[1], Toru Matsuzawa[1], Sachiko Tanaka[2], Youichi Asano[2] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions Graduate School of Science, Tohoku University, 2.National Research Institute for Earth Science and Disaster Resilience)

[J] Oral | S (Solid Earth Sciences)：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A09 TOKYO BAY MAKUHARI HALL

[S-CG57] Structure and evolution of Japanese islands - Formation of island arc systems and earthquake cycles

convener:Hiroshi Sato(Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo), Masanao Shinohara(Earthquake Research Institute, University of Tokyo), Masahiro Ishikawa(Graduate School of Environment and Information Sciences Yokohama National University), Makoto MATSUBARA(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Masanao Shinohara(Earthquake Research Institute, The University of Tokyo), Tatsuya Ishiyama(Earthquake Research Institute, University of Tokyo)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SCG57-01] Recent Earthquake Activity in Northern Hokkaido, Japan

Cancelled

*Tetsuo Takanami[1,2] (1.Carnegie Institution for Science, 2.Hokkaido Research Center of Geology)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SCG57-02] Seismic constraints on the crustal structure off the southwestern coast of Hokkaido, Japan Sea

*Tetsuo No[1], Takeshi Sato[1], Shuichi Kodaira[1], Hiroshi Sato[2], Tatsuya Ishiyama[2] (1.JAMSTEC, 2.ERI, University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SCG57-03] Deep seismic reflection profiling across the Oshima Peninsula, SW Hokkaido, Japan

*Hiroshi Sato[1], Tatsuya Ishiyama[1], Naoko Kato[1], Hidehiko Shimizu[2], Takeshi Sato[3], Shinji Kawasaki[2], Tetsuo No[3], Shuichi Kodaira[3], Seiichi Miura[3] (1.Earthquake Research Institute, The University of Tokyo, 2.JGI Inc, 3.Japan Agency for Marine-Earth Acience and Technology)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SCG57-04] Crustal deformation and stress accumulation on source faults around Hokkaido, Japan, due to coupling at the Kuril trench

*Akinori Hashima[1], Hiroshi Sato[1], Tatsuya Ishiyama[1], Andrew M. Freed[2] (1.Earthquake Research Institute, The University of Tokyo, 2.Purdue University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SCG57-05] Structural Heterogeneity in and around the Source Region of the 2018 Hokkaido Eastern Iburi Earthquake, Central Hokkaido, Japan

*Takaya Iwasaki[1], Noriko Tsumura[2], Tanio Ito[3], Kazunori Arita[4], Makoto Matsubara[5], Hiroshi Sato[1], Eiji Kurashimo[1], Naoshi Hirata[1], Susumu Abe[6], Katsuya Noda[7], Akira Fujiwara[8], Shinsuke Kikuchi[9], Kazuko Suzuki[10] (1.Eathquake Research Institute, the University of Tokyo, 2.Graduate School of Science, Chiba University, 3.Association for the Development of Earthquake Prediction, 4.Hokkaido Research Center of Geology, 5.National Research Institute for Earth Science and Disaster Resilience, 6.JAPEX, 7.GEOSYS Inc., 8.JOGMEC, 9.JGI Inc., 10.Schlumberger Ltd.)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SCG57-06] Electrical resistivity distribution around the middle axis of Hokkaido Island: constraint for tectonics of ultra-mafic rocks

*Hiroshi Ichihara[1], Toru Mogi[1], Yusuke Yamaya[2] (1.Earthquake and Volcano Research Center, Nagoya University, 2.AIST)

[J] Oral | S (Solid Earth Sciences)：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A09 TOKYO BAY MAKUHARI HALL

[S-CG57] Structure and evolution of Japanese islands - Formation of island arc systems and earthquake cycles

convener:Hiroshi Sato(Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo), Masanao Shinohara(Earthquake Research Institute, University of Tokyo), Masahiro Ishikawa(Graduate School of Environment and Information Sciences Yokohama National University), Makoto MATSUBARA(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Hiroshi Sato(Earthquake Research Institute, Tokyo University), Masahiro Ishikawa(Yokohama National University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SCG57-07] Three-dimensional seismic velocity structure beneath and around Japanese Islands including beneath the Pacific Ocean using NIED S-net data

*Makoto MATSUBARA[1], Hiroshi Sato[2], Kenji Uehira[1], Masashi Mochizuki[4], Toshihiko Kanazawa[5], Narumi Takahashi[1], Kensuke Suzuki[3], Shinichiro Kamiya[1] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Earthquake Research Institute, the University of Tokyo, 3.Japan Agency for Marine-Earth Science and Technology, 4.Ministry of Education, Culture, Sports, Science and Technology, Japan , 5.Association for the Development of Earthquake Prediction)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SCG57-08] Spatio-temporal extent of Cretaceous fore-arc basin in Japan

*Yukio Isozaki[1], Ryo Hasegawa[1], Yukiyasu Tsutsumi[1] (1.Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SCG57-09] Geotectonic identities of dismembered ancient fore-arc clastics: U-Pb dating of detrital zircons in Cretaceous-Paleogene shallow marine/fluvial sandstones sporadically found in Kanto, central Japan

*Ryo Hasegawa[1], Yukio Isozaki[1], Yukiyasu Tsutsumi[2] (1.Department of Earth Science and Astronomy, The University of Tokyo, 2.Department of Geology and Paleontology, National Museum of Nature and Science)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SCG57-10] Laboratory Measurements of Vp, Vs and Vp/Vs for polycrystalline labradorite up to 800°C and 1GPa

*Satoko Honda[1], Masahiro Ishikawa[1] (1.Graduate School of Environment and Information Sciences, Yokohama National University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SCG57-11] Shallow to deeper structures of the Median Tectonic Line active fault system in Shikoku illuminated by new hi-resolution seismic reflection profiling, southwest Japan

*Tatsuya Ishiyama[1], Naoko Kato[1], Shin Koshiya[2], Hiroshi Sato[1], Makoto MATSUBARA[3], Tomoko Elizabeth Yano[3], Taro Koike[4], Katsuya Noda[4] (1.Earthquake Research Institute, University of Tokyo, 2.Department of Civil and Environmental Engineering, Faculty of Science and Engineering, Iwate University, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Geosys, Inc.)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SCG57-12] **Cenozoic evolution of the Tsushima Strait and the Fukue Basin, southern Sea of Japan: an interplay of tectonics, palaeo-environment, and volcanism**

*Johan S. Claringbould[1], Hiroshi Sato[1], Tatsuya Ishiyama[1], Anne Van Horne[1,2], Shinji Kawasaki[3], Susume Abe[4] (1.Earthquake Research Institute, The University of Tokyo, 2.Department of Geology and Geophysics, University of Wyoming, 3.JGI, Inc., 4.JAPEX)

[J] Poster | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_20

[S-CG57] Structure and evolution of Japanese islands - Formation of island arc systems and earthquake cycles

convener:Hiroshi Sato(Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo), Masanao Shinohara(Earthquake Research Institute, University of Tokyo), Masahiro Ishikawa(Graduate School of Environment and Information Sciences Yokohama National University), Makoto MATSUBARA(National Research Institute for Earth Science and Disaster Resilience)

[SCG57-P01] Crustal structure from the Japan Sea back-arc basin to the margin off SW Hokkaido deduced from the seismic survey

*Takeshi Sato[1], Tetsuo No[1], Shuichi Kodaira[1], Seiichi Miura[1], Tatsuya Ishiyama[2], Hiroshi Sato[2] (1.Research and Development Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology, 2.ERI, Univ. of Tokyo)

[SCG57-P02] Three-dimensional plate geometry model from the Nankai to the Ryukyu subduction zone

*Ayako Nakanishi[1], Tsutomu Takahashi[1], Yojiro Yamamoto[1], Mikiya Yamashita[1], Minako KATSUYAMA[1], Seiichi Miura[1], Narumi Takahashi[3,1], Hiromi Kamata[1], Shuichi Kodaira[1], Yoshiyuki Kaneda[2,1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Kagawa University, 3.National Research Institute for Earth Science and Disaster Resilience)

[SCG57-P03] Trace elements and Sr-Nd-Hf-Pb isotopic composition of Miocene Tomari volcanic rocks, Shimokita Peninsula, Aomori, NE Japan

*Masataka Aizawa[1], Mitsuru Inaba[2], Satoshi Okamura[3,4], Ryuichi Shinjo[5] (1.Graduate School of Engineering and Sience, University of Ryukyus, 2.GeoPuck Association, 3.Hokkaido Education University, 4.Hokkaido Soil Research Co-op., 5.Faculty of Science, University of Ryukyus)

[SCG57-P04] Acceleration of oceanic plate following megathrust earthquakes

*Mohammad Yuzariyadi[1], Kosuke Heki[1] (1.Hokkaido University)

[SCG57-P05] 3D velocity model in the region of Nankai Trough

*Minako KATSUYAMA[1], Ayako Nakanishi[1], Rei Arai[1], Shigeyoshi Tanaka[1], Narumi Takahashi[2], Hiromi Kamata[1], Yoshiyuki Kaneda[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Research Institute for Earth Science and Disaster Resilience, 3.Kagawa University)

[J] Oral | B (Biogeosciences)：B-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 201A 2F

[B-CG07] Decoding the history of Earth: From Hadean to the present

convener:Tsuyoshi Komiya(Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo), Yasuhiro Kato(Department of Systems Innovation, Graduate School of Engineering, University of Tokyo), Katsuhiko Suzuki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Chairperson:Tomohiko Sato(Earth-Life Science Institute, Tokyo Institute of Technology)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[BCG07-01] Iron-oxidizing bacteria and stromatolites in the Ediacaran hydrothermal carbonate

*Akihiro Kano[1], Aya Miyazaki[1], Jumpei Yoshioka[1], Ibtissam Chraiki[2], Abdelhafed Barzouk[2], Nasrrddine Youbi[2,3], Hassan Admou[2], Moulay Ahmed Boumehdi[2,3], Lhou Maacha[4], Hsaine Baoutoul[4], Ismail Bouskri[4] (1.Graduate School of Science, The University of Tokyo, 2.Department of Geology, Faculty of Sciences-Semlalia, Cadi Ayyad University, 3.Instituto Dom Luiz, Faculdade de Ciências, Universidade de Lisboa, 4.Managem-ONA Group)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[BCG07-02] Carbonate carbon isotope stratigraphy of the Paleoproterozoic Francevillian Group in Gabon

★Invited Papers

*Tomohiko Sato[1], Yusuke Sawaki[2], Hisashi Asanuma[2], Hisahiro Ueda[1], Shigenori Maruyama[1] (1.Tokyo Institute of Technology, 2.The University of Tokyo)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[BCG07-03] The redox condition of late Paleoproterozoic shallow marine environment: The Cape Smith Belt, Canada

*Kento Motomura[1], Shoichi Kiyokawa[1], Minoru Ikehara[2], Takashi Sano[4], Kentaro Tanaka[3], Tsubasa Miki[3], Yuji Sano[3] (1.Kyushu University, 2.Kochi University, 3.University of Tokyo, 4.National Museum of Nature and Science)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[BCG07-04] Paleovegetation changes reconstructed by terrestrial plant biomarker analyses in the sediments deposited across the Cenomanian/Turonian boundary in the Tomamae area, Hokkaido, Japan

*Masashi A. Ikeda[1], Ken Sawada[2], Takuto Ando[3], Hideto Nakamura[4], Reishi Takashima[5], Hiroshi Nishi[5] (1.Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 3.Arctic Research Center, Hokkaido University, 4.Faculty of Science, Osaka City University, 5.The Center for Academic Resources and Archives, The Tohoku University Museum, Tohoku University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[BCG07-05] A general overview of the research progress on REY-rich mud

*Yasuhiro Kato[1,2], Kentaro Nakamura[1], Koichiro Fujinaga[2,1], Kazutaka Yasukawa[1,2], Yutaro Takaya[3,1,2], Junichiro Ohta[2,1], Erika Tanaka[1], Kazuhide Mimura[1], Koichi Iijima[4,1], Shiki Machida[2,1], Tatsuo Nozaki[4,1,2,5], Jun-Ichi Kimura[4], Hikaru Iwamori[1,4,6] (1.The University of Tokyo, 2.ORCeNG, Chiba Institute of Technology, 3.Waseda University, 4.JAMSTEC, 5.Kobe University, 6.Tokyo Institute of Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[BCG07-06] A cold and alkaline Hadean ocean caused by impact ejecta weathering

*Shintaro Kadoya[1], David C Catling[1] (1.University of Washington)

[J] Oral | B (Biogeosciences) : B-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 201A 2F

[B-CG07] Decoding the history of Earth: From Hadean to the present

convener:Tsuyoshi Komiya(Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo), Yasuhiro Kato(Department of Systems Innovation, Graduate School of Engineering, University of Tokyo), Katsuhiko Suzuki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Chairperson:Satoshi Yoshida(Department of Earth Science & Astronomy, Graduate School of Arts and Sciences, The University of Tokyo)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[BCG07-07] **Impact-induced magmatism on early Earth**

*Hiroshi Ohmoto[1], Uschi M. Graham[2], Yuya Tsukamoto[3], Yumiko Watanabe[3], Takeshi Kakegawa[3], Hiroshi Hamasaki[4], Andrew Chorney[5], Katherine Crispin[1], Zi-Kui Liu[1] (1.The Pennsylvania State University, 2.Univ. of Kentucky, 3.Tohoku Univ., 4.Tokyo Gas, 5.Temple Univ.)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[BCG07-08] An evaluation of impact dating for shocked zircons with planar features (PFs) in the Vredefort dome by LA-ICP-MS multi-spot analysis

*Shinji Yamamoto[1], Taiga Kato[1] (1.Graduate School of Environment and Information Sciences, Yohohama National University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[BCG07-09] **Application of acid-washing to trace element and tungsten isotope analyses of Eoarchean rocks from the Isua Supracrustal Belt**

★Invited Papers

*Hatsuki Enomoto[1], Tsuyoshi Iizuka[1], Yoshitaka Homma[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[BCG07-10] Limited primary production in the early Archean oceans and its biogeochemical consequenses

★Invited Papers

*Kazumi Ozaki[1] (1.Toho University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[BCG07-11] Behaviors of carbon cycle system and inevitability of the hot climate in the Archean Earth

★Invited Papers

*Yasuto Watanabe[1], Eiichi Tajika[1], Kazumi Ozaki[2], Peng Hong[3] (1.The University of Tokyo, 2.Toho University, 3.Chiba Institute of Technology)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[BCG07-12] Occurrence and chemical composition of metamorphic carbonate rocks in the Isua supracrustal belt, West Greenland: Implications for the origin of carbonate rocks and compositions of the Eoarchean seawater.

*Yoshida Satoshi[1], Kazutaka Yasukawa[2], Yasuhiro Kato[2], Yusuke Sawaki[3], Tsuyoshi Komiya[3] (1.Department of Earth & Planetary Science, Graduate School of Science, The University of Tokyo, 2.Department of Systems Innovation, Graduate School of Engineering, University of Tokyo, 3.Department of Earth Science & Astronomy Graduate School of Arts and Sciences, The University of Tokyo)

[J] Poster | B (Biogeosciences)：B-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_21

[B-CG07] Decoding the history of Earth: From Hadean to the present

convener:Tsuyoshi Komiya(Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo), Yasuhiro Kato(Department of Systems Innovation, Graduate School of Engineering, University of Tokyo), Katsuhiko Suzuki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology)

[BCG07-P01] Geology of the Eoarchean Nuvvuagittuq supracrustal belt, northeastern Canada: Reappraisal of Protoliths and ages of the sedimentary rocks

*Tsuyoshi Komiya[1], Shinji Yamamoto[2], Hiroki Uehara[1], Yoshida Satoshi[1], Aoi Murakami[1], Yuki Ishihara[1] (1.Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo, 2.Graduate School of Environment and Information Sciences, Yohohama National University)

[BCG07-P02] Behavior of phosphorus during hydrothermal alteration of basalt under CO_2-rich condition

*Aoi Murakami[1], Yusuke Sawaki[2], Hisahiro Ueda[3], Yuji Orihashi[4], Shiki Machida[5], Tsuyoshi Komiya[2] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.The University of Tokyo, 3.Tokyo Institute of Technology, 4.Hirosaki University, 5.Chiba Institute of Technology)

[BCG07-P03] Origin of chromitites in the Akulleq terrane, southern West Greenland

*Kanta Takahashi[1], Tomoaki Morishita[1], Juan Miguel Ramirez Guotana[1], Kenichiro Tani[2], Yumiko Harigane[3], Ikuya Nishio[1], Kristoffer Szilas[4], Akihiro Tamura[1] (1.Kanazawa University, 2.Department of Geology and Paleontology, National Museum of Nature and Science, 3.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST), 4.University of Copenhagen)

[BCG07-P04] Metamorphic P–T condition of the Inyoni shear zone rocks in the Barberton Greenstone Belt, South Africa and its significance

*Daichi Kato[1], Kazumasa Aoki[1], Yuta Tsuchiya[2], Shogo Aoki[2], Tsuyoshi Komiya[3] (1.Department of Applied Science,Okayama University of Science, 2.Department of Biosphere-Geosphere Science,Okayama University of Science, 3.Department of Earth Science and Astronomy,University of Tokyo)

[BCG07-P05] Discovery of possible traces of asteroid impact within the fossil-bearing carbonaceous chert from the 3.4 Ga Strelley Pool Formation, Pilbara Craton of Western Australia - a preliminary study

*Kenichirio Sugitani[1], Ryoko Senda[3], Tsuyoshi Iizuka[2], Simon Wallis[2] (1.Nagoya University, 2.The University of Tokyo, 3.Kyushu University)

[BCG07-P06] High-resolution stable isotopes and chemical analyses on laminations of the early Proterozoic stromatolite

Yuta Miyanishi[1], Kazuki Takamura[1], *Nagayoshi Katsuta[1], Maki Morimoto[1], ATSUSHI YASUDA[2], Shin-ichi Kawakami[3] (1.Faculty of Education, Gifu University, 2.Earthquake Research Institute, University of Tokyo, 3.Faculty of Education, Gifu Shotoku Gakuen University)

[BCG07-P07] Biogeochemical dynamics in during the Great Oxidation Event constrained by a biogeochemical cycle model

*Yuna Miura[1], Kazumi Ozaki[1] (1.Toho University)

[BCG07-P08] Composition of seawater before the Sturtian Snowball Earth estimated by the occurrence of late Tonian evaporitic magnesite

*Aya Miyazaki[1], Akihiro Kano[1], Fumito Shiraishi[2] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Department of Earth and Planetary Systen Sciences, Hiroshima University)

[BCG07-P09] Geochemical characteristics of black shales in the Japanese accretionary complex across the Permian-Triassic boundary extracted by independent component analysis

*Moei Yano[1], Kazutaka Yasukawa[1,3], Koichiro Fujinaga[3,2], Kentaro Nakamura[1], Yasuhiro Kato[2,1,3] (1.Department of Systems Innvation, School of Engineering, The University of Tokyo, 2.Frontier Research Center for Energy and Resources, School of Engineering, The University of Tokyo, 3.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology)

[BCG07-P10] The Distribution of the Ejecta Deposit derived from Australasian Tektite Event: Implication for the Location of the Impact

*Toshihiro Tada[1], Ryuji Tada[1,2], Paul Carling[3], Wickanet Songtham[4], Le Xuan Thuyen[5], Yu Chang, Eiichi Tajika[1]
(1.Department of Earth and Planetary Science, 2.Yunnan University, 3.Geography and Environment, University of Southampton, 4.Northeastern Research institute of Petrified Wood and Mineral Resources, Nakhon Ratchasima Rajabhat University, 5.Ho Chi Minh City University of Science)

[BCG07-P11] Tectonic-sedimentation reconstruction of Neoproterozoic metavolcanic sequences; the El-Dabbah area, Central Eastern Desert, Egypt

*Shoichi Kiyokawa[1], TAISHI SUZUKI[1], Maher Dawoud[3], El-Hasan Mohamed[3], Kenji Horie[2], Mami Takehara[2]
(1.Department of Earth and Planetary Sciences Faculty of sciences, Kyuushu University, 2.National Institute of Polar Research, 3.Department of Geology, Faculty of Science, Menoufiya University,)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 201A 2F

[M-IS07] Astrobiology

convener:Hikaru Yabuta(Hiroshima University, Department of Earth and Planetary Systems Science), Seiji Sugita(Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo), Misato Fukagawa(National Astronomical Observatory of Japan), Fujishima Kosuke(Tokyo Institute of Technology, Earth-Life Science Institute), Chairperson:Misato Fukagawa(名古屋大学大学院 理学研究科), Kosuke Fujishima(ELSI 地球生命研究所)

3:35 PM - 3:50 PM JST | 6:35 AM - 6:50 AM UTC

[MIS07-01] METEOROID AND DEBRIS IMPACT FLUX IN LOW EARTH ORBIT WITNESSED BY THE TANPOPO CAPTURE PANELS ONBOARD THE ISS IN 2015-2017

*Hajime Yano[1], K. Yamamoto[2], E. Minakami[2], M. Eitel[1,3], S. Sasaki[4], J. Imani[5], K. Okudaira[6], M. Higashide[7], E. Imai[8], Y. Kawaguchi[9], Yoko Kebukawa[10], H. Mita[11], M. Nishi[12], T. Noguchi[13], Makoto Tabata[14], A. Tsuchiyama[12], Hikaru Yabuta[15], K. Arai[8], H. Hashimoto[1], Kensei Kobayashi[10], A. Yamagishi[16] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Hosei University, 3.University of Stuttgart, 4.Tokyo University of Technology, 5.Yuki Seimitsu, Co. Ltd., 6.University of Aizu, 7.JAXA/Aerospace Research and Development Directorate, 8.Nagaoka University of Technology, 9.Chiba Institute of Technology, 10.Yokohama National University, 11.Fukuoka Institute of Technology, 12.Kyoto University, 13.Kyushu University, 14.Chiba University, 15.Hiroshima University, 16.Tokyo University of Pharmacy and Life Science)

3:50 PM - 4:10 PM JST | 6:50 AM - 7:10 AM UTC

[MIS07-02] Growth and transport of dust, ice, and organics in the inner part of protoplanetary disks

★Invited Papers

*Satoshi Okuzumi[1] (1.Department of Earth and Planetary Sciences, Tokyo Institute of Technology)

4:10 PM - 4:25 PM JST | 7:10 AM - 7:25 AM UTC

[MIS07-03] Model Prediction of Complex Organic Molecules in Protoplanetary Disks

*Hideko Nomura[1], Catherine Walsh[2], Tom J. Millar[3] (1.Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 2.School of Physics and Astronomy, University of Leeds, 3.School of Mathematics and Physics, Queen’s University Belfast)

4:25 PM - 4:40 PM JST | 7:25 AM - 7:40 AM UTC

[MIS07-04] Abiotic synthesis of organic matters in environments simulating asteroids and the catalytic effect of minerals on amino acid formation

*Walaa Elmasry[1], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.Yokohama National University)

4:40 PM - 4:55 PM JST | 7:40 AM - 7:55 AM UTC

[MIS07-05] Peptide Formation from amino acid precursors under simulated submarine hydrothermal environments

*Kensei Kobayashi[1], Keisuke Naito[1], Koki Naito[1], Soushi Kuramoto[1], Ei-ichi Imai[2], MITA Hajime[3], Yoko Kebukawa[1] (1.Yokohama National University, 2.Nagaoka University of Technology, 3.Fukuoka Institute of Technology)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 304 3F

[M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Yusuke Okazaki

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS19-01] Development of Longitudinal dunes under the Pangean atmospheric circulation

*Hiroki Shozaki[1], Hitoshi Hasegawa[2] (1.Faculty of Science, Kochi University, 2.Faculty of Science and Technology, Kochi University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS19-02] Response of primary producers in the ocean anoxic events during the Cretaceous

*Haga Mayuko[1], Eiichi Tajika[1], Kazumi Ozaki[2] (1.The University of Tokyo, 2.Toho University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS19-03] The linkage between desertification and tectonism inferred from the provenance change of the terrestrial sediments in the Tarim basin

*Aki Sakuma[1], Ryuji Tada[1], Tomohiro Yoshida[1], Hitoshi Hasegawa[2], Naomi Sugiura[1], Akinori Karasuda[1], Ke WANG[1], Hongbo Zheng[3] (1.Department of Earth and Planetary Science, School of Science, the University of Tokyo, 2.Faculty of Science and Technology, Kochi University, 3.School of Resource Environment and Earth Science, Yunnan University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS19-04] Paleoceanographic reconstruction in the northwestern Pacific during MIS 19 using ultra-high temporal resolution oxygen isotope profiles and planktonic foraminiferal assemblage

*Yuki Haneda[1], Nanako Yokokawa[1], Makoto Okada[1], Hiroki Hayashi[2], Yoshimi Kubota[3], Yusuke Suganuma[4] (1.College of Science, Ibaraki University, 2.Interdisciplinary Factulty of Science and Engineering, Shimane University, 3.National Museum of Nature and Science, 4.National Institute of Polar Research)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS19-05] Paleoclimate reconstruction using fossil pollen analyses from a sedimentary sequence around the Matuyama-Brunhes polarity transition in the Chiba composite section

*Makoto Okada[1], Hitomi Takizawa[1], Yuki Haneda[2], Yusuke Suganuma[3,4], Quentin Simon[5] (1.Department of Earth Sciences, College of Science, Ibaraki University, 2.Graduate school of Science and Technology, Ibaraki University, 3.National Institute of Polar Research, 4.Graduate University for Advanced Studies, 5.Aix-Marseille University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[MIS19-06] Reconstruction of vertical thermal structure in the western Pacific warm pool over the last 1 Myr

*Fumito Mizuno[1], Takuya Sagawa[2], Keisuke Mukaida[3], Yoshimi Kubota[4], Toshitsugu Yamazaki[5], Junichiro Kuroda[5] (1.Graduate School of Natural Science and Technology. Kanazawa University, 2.Institute of Science & Engineering. Kanazawa University, 3.Collage of Science & Engineering. Kanazawa University, 4.National Museum of Nature & Science, 5.Atmosphere and Ocean Research Institute. The University of Tokyo)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 304 3F

[M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Michinobu Kuwae(愛媛大学沿岸環境科学研究センター)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS19-07] Future perspective on the response of marine calcifiers to “evil twins” of climate change due to increased PCO2

*Hodaka Kawahata[1] (1.Atmosphere Ocean Research Institute, the University of Tokyo)

2:00 PM - 2:22 PM JST | 5:00 AM - 5:22 AM UTC

[MIS19-08] Reconstruction of seawater pH and atmospheric CO_2 concentration based on boron isotopic composition of biogenic calcium carbonate

★Invited Papers

*Kaoru Kubota[1] (1.Kochi Institute for Core Sample Research, JAMSTEC)

2:22 PM - 2:37 PM JST | 5:22 AM - 5:37 AM UTC

[MIS19-09] A 70 years changes of the Java Sea surface condition based on geochemical analyses of a coral core

*Ai Genda[1], Atsushi Suzuki[2], Toyoho Ishimura[3], Minoru Ikehara[4], Mayuri Inoue[1] (1.Graduate School of National Science and Technology, Okayama University, 2.Geological Survey of Japan Natinal Institute of Advanced Industrial Science and Technology, 3.National Institute of Technology, Ibaraki College, 4.Center for Advanced Marine Core Research, Kochi University)

2:37 PM - 2:52 PM JST | 5:37 AM - 5:52 AM UTC

[MIS19-10] Reconstruction of paleoenvironments in the western Pacific for the last 220 years

Mutsumi Chihara[1], Ayaka Fukushima[2], Minoru Ikehara[3], Hodaka Kawahata[2], Atsushi Suzuki[4], *Mayuri Inoue[1] (1.Department of Earth Sciences, Okayama University, 2.Atmosphere and Ocean Research Institute, the University of Tokyo, 3.Center for Advanced Marine Core Research, Kochi University, 4.Geological Survey of Japan, AIST)

2:52 PM - 3:15 PM JST | 5:52 AM - 6:15 AM UTC

[MIS19-11] Ocean deoxygenation from the Last Glacial Maximum to the future global warming: inshight from model simulations

★Invited Papers

*Akitomo Yamamoto[1], Ayako Abe-Ouchi[2,1], Rumi Ohgaito[1], Akinori Ito[1], Masahito Shigemitsu[1], Yasuhiro Yamanaka[3], Akira Oka[2] (1.Japan Agency for Marine-Earth Science and TechnologyAtmosphere and Ocean Research Institute, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Faculty of Environmental Earth Science, Hokkaido University)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 304 3F

[M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Akira Oka

3:30 PM - 3:52 PM JST | 6:30 AM - 6:52 AM UTC

[MIS19-12] Extraction of high-quality ^{14}C data from terrestrial sediments containing pollen fossils

★Invited Papers

*Takayuki Omori[1], Keitaro Yamada[2], Ikuko Kitaba[2], Takeshi Nakagawa[2] (1.The University Museum, The University of Tokyo, 2.Research Centre for Palaeoclimatology, Ritsumeikan University)

3:52 PM - 4:07 PM JST | 6:52 AM - 7:07 AM UTC

[MIS19-13] Oxygen isotope fluctuations of pollen fossils from Lake Suigetsu, Japan

*Keitaro Yamada[1], Takayuki Omori[2], Ikuko Kitaba[1], Takeshi Nakagawa[1] (1.Research Organization of Science and Technology, Ritsumeikan University, 2.The University museum, The University of Tokyo)

4:07 PM - 4:22 PM JST | 7:07 AM - 7:22 AM UTC

[MIS19-14] Reconstruction of lake-level changes during the last glaciation based on fossil diatom record in Lake Biwa

*Takashi Suzuki[1], Yoshio Inouchi[2], Keisuke Otsuka[1], Kaoru Kawakami[3] (1.Graduate School of Human Science, Waseda University, 2.Faculty of Human Sciences, Waseda University, 3.Graduate School of Environmental Science, Hokkaido University)

4:22 PM - 4:45 PM JST | 7:22 AM - 7:45 AM UTC

[MIS19-15] An estimation of microplatcis sedimentation flux in a coastal sea

★Invited Papers

*Hirofumi Hinata[1], Michinobu Kuwae[1], Issei Masumoto[1], Hayato Kawamata[1] (1.Ehime University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MIS19-16] Beppu Bay sediments: Potential palaeoenvironmental archives for a candidate auxiliary stratotype for Anthropocene-Holocene boundary

*Michinobu Kuwae[1], Yoshiaki Suzuki[2] (1.Center for Marine Environmental Studies, Ehime Univ., 2.Department of Eearth Scieces, Fuculty of Education and Integrated Arts and Sciences, Waseda Univ.)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[M-IS22] Electromagnetic phenomena associated with seismic and volcanic activities

convener:Tetsuya Kodama(Research Unit I, Research and Development Directorate, Japan Space Exploration Agency), Toshiyasu Nagao(Institute of Oceanic Research and development, Tokai University)

[MIS22-P01] Ionospheric TEC changes immediately before large earthquakes: Derivation of the standard curve and discussion on the physical mechanisms

*Yuki Takasaka [1], Kosuke Heki[1] (1.Department of Earth and Planetary Science, Faculty of Science, Hokkaido University)

[MIS22-P02] Examination of ionospheric disturbances at different altitudes associated with Tohoku earthquake using HF Doppler sounding

*Natsuki Ono[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Ichiro Tomizawa[2], Keisuke Hosokawa[2], Takuya Tsugawa[3], Michi Nishioka[3] (1.Department of Electrical and Electronic Engineering, Graduate School of Science and Engineering, Chiba University, 2.The University of Electro-Communications, 3.NICT)

[MIS22-P03] **Electromagnetic observation addressed to the short-term earthquake prediction research in VLF band**

*Toshiyasu Nagao[1], Jun Izutsu[2], Masashi Kamogawa[3], Yoshiaki Orihara[1], Shigeki Sugiura[4], Hitoshi Kondo[4] (1.Institute of Oceanic Research and development, Tokai University, 2.Intl. Digital Earth Applied Sci. Res. Ctr, Chubu Inst. for Advanced Studies, Chubu Univ., 3.Department of Physics, Tokyo Gakugei University, 4.Genesis Research Institute, Inc.)

[MIS22-P04] ELF electric field intensity at the time of VLF precursor in the DEMETER data

*Masashi Kamogawa[1], Tetsuya Kodama[2], Toshiyasu Nagao[3] (1.Department of Physics, Tokyo Gakugei University, 2.Japan Space Exploration Agency, 3.Tokai University)

[MIS22-P01] Ionospheric TEC changes immediately before large earthquakes: Derivation of the standard curve and discussion on the physical mechanisms

*Yuki Takasaka [1], Kosuke Heki[1] (1.Department of Earth and Planetary Science, Faculty of Science, Hokkaido University)

[MIS22-P02] Examination of ionospheric disturbances at different altitudes associated with Tohoku earthquake using HF Doppler sounding

*Natsuki Ono[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Ichiro Tomizawa[2], Keisuke Hosokawa[2], Takuya Tsugawa[3], Michi Nishioka[3] (1.Department of Electrical and Electronic Engineering, Graduate School of Science and Engineering, Chiba University, 2.The University of Electro-Communications, 3.NICT)

[MIS22-P03] **Electromagnetic observation addressed to the short-term earthquake prediction research in VLF band**

*Toshiyasu Nagao[1], Jun Izutsu[2], Masashi Kamogawa[3], Yoshiaki Orihara[1], Shigeki Sugiura[4], Hitoshi Kondo[4] (1.Institute of Oceanic Research and development, Tokai University, 2.Intl. Digital Earth Applied Sci. Res. Ctr, Chubu Inst. for Advanced Studies, Chubu Univ., 3.Department of Physics, Tokyo Gakugei University, 4.Genesis Research Institute, Inc.)

[MIS22-P04] ELF electric field intensity at the time of VLF precursor in the DEMETER data

*Masashi Kamogawa[1], Tetsuya Kodama[2], Toshiyasu Nagao[3] (1.Department of Physics, Tokyo Gakugei University, 2.Japan Space Exploration Agency, 3.Tokai University)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A07 TOKYO BAY MAKUHARI HALL

[M-IS22] Electromagnetic phenomena associated with seismic and volcanic activities

convener:Tetsuya Kodama(Research Unit I, Research and Development Directorate, Japan Space Exploration Agency), Toshiyasu Nagao(Institute of Oceanic Research and development, Tokai University), Chairperson:Tetsuya Kodama, Toshiyasu Nagao

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MIS22-01] Stress-induced charges in gabbro at high temperature

*Chihiro Yamanaka[1], Daiki Maezono[1] (1.Graduate School of Science, Osaka University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MIS22-02] Evaluation of ULF seismo-magnetic precursor phenomena at Kakioka, Japan over 1983 – 2018 by using SEA and Molchan's error diagram

*Katsumi Hattori[1], Kei Takahashi[2], Peng Han[3] (1.Department of Earth Sciences, Graduate School of Science, Chiba University, 2.Department of Earth Sciences, Faculty of Science, Chiba University, 3.Southern University of Science and Technology, China)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MIS22-03] On the tsunami and electromagnetic pulses appeared abound 10min. after the 2011 Tohoku earthquake

*Yuji Enomoto[1], Tsuneaki Yamabe[1], Shigeki Sugiura[2], Hitoshi Kondo[2] (1.Shinshu Univeristy, Ueda Campus Fii, 2.Genesis Reserach Institute, Inc.)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MIS22-04] Reinvestigation of correlation between groundwater anomalies and earthquakes carried out by an amateur network in Japan

*Yoshiaki Orihara[1], Masashi Kamogawa[2], Toshiyasu Nagao[1] (1.Institute of Oceanic Research and Development, Tokai University, 2.Dpt. of Phys., Tokyo Gakugei Univ.)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MIS22-05] Participation Report of S-Booster 2018

*Tetsuya Kodama[1] (1.Research Unit I, Research and Development Directorate, Japan Space Exploration Agency)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MIS22-06] The future direction of EMSEV, IUGG International Working Group

*Toshiyasu Nagao[1] (1.Institute of Oceanic Research and development, Tokai University)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-GI General Geosciences, Information Geosciences & Simulations

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_11

[M-GI30] Data assimilation: A fundamental approach in geosciences

convener:Shin ya Nakano(The Institute of Statistical Mathematics), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), SHINICHI MIYAZAKI(Graduate School of Science, Kyoto University), Takemasa Miyoshi(RIKEN)

[MGI30-P01] Superposition of atmospheric states using information redundancy for Numerical Weather Prediction

*Toshiyuki Ishibashi[1] (1.Meteorological Research Institute/Japan Meteorological Agency)

[MGI30-P02] **Numerical Weather Prediction Experiments using a Coupled Atmosphere-Ocean Data Assimilation System in JMA/MRI** (3)

*Toshiyuki Ishibashi[1], Takeshi Iriguchi[1], Yosuke Fujii[1], Tamaki Yasuda[1], Yuhei Takaya[1], Naoki Saito[1], Toshikazu Onogi[1] (1.Meteorological Research Institute/Japan Meteorological Agency)

[MGI30-P03] **Accurate estimation of posterior error covariance in a 4D-Var inverse analysis**

*Yosuke Niwa[1,2], Yosuke Fujii[2,3] (1.National Institute for Environmental Studies, 2.Meteorological Research Institute, Japan Meteorological Agency, 3.The Institute of Statistical Mathematics)

[MGI30-P04] Assimilation CO_2 concentration data in the Kanto region using AIST-MM model and for the estimation of CO_2 emissions

*Yutaka Arai[1], Ryoichi Imasu[1], Hiroaki Kondo[2], Yosuke Niwa[3] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.National Institute of Advanced Industrial Science and Technology, 3.National Institute for Environmental Studies, Independent Administrative Institutions)

[MGI30-P05] **Application of data assimilation method on parameter estimation of flow and nutrient behavior in watershed model**

*Yosuke Horie[1] (1.Nippon Koei Co., Ltd.)

[MGI30-P06] Bayesian inference of grain growth prediction via multi-phase-field models

*Shin-ichi Ito[1], Hiromichi Nagao[1], Takashi Kurokawa[1], Tadashi Kasuya[1], Junya Inoue[1] (1.The University of Tokyo)

[MGI30-P07] GNSS data assimilation for the Bungo channel Long-term SSEs using Ensemble Kalman Filter (EnKF)

*Megumi Fujita[1], Takuya NISHIMURA[2], Kazuro Hirahara[3], SHINICHI MIYAZAKI[1] (1.Graduate School of Science , Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University, 3.Institute of Education, Research and Regional Cooperation for crisis Management Shikoku, Kagawa University)

[MGI30-P08] A data assimilation library with Python for parallel computing

*Shin ya Nakano[1], Yuya Ariyoshi[2], Tomoyuki Higuchi[1] (1.The Institute of Statistical Mathematics, 2.Faculty of Engineering, Nippon Bunri University)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-GI General Geosciences, Information Geosciences & Simulations

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_37

[M-GI30] Data assimilation: A fundamental approach in geosciences

convener:Shin ya Nakano(The Institute of Statistical Mathematics), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), SHINICHI MIYAZAKI(Graduate School of Science, Kyoto University), Takemasa Miyoshi(RIKEN)

*Shin-ichi Ito[1], Hiromichi Nagao[1], Takashi Kurokawa[1], Tadashi Kasuya[1], Junya Inoue[1] (1.The University of Tokyo)

[MGI30-P07] GNSS data assimilation for the Bungo channel Long-term SSEs using Ensemble Kalman Filter (EnKF)

*Megumi Fujita[1], Takuya NISHIMURA[2], Kazuro Hirahara[3], SHINICHI MIYAZAKI[1] (1.Graduate School of Science , Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University, 3.Institute of Education, Research and Regional Cooperation for crisis Management Shikoku, Kagawa University)

[MGI30-P08] A data assimilation library with Python for parallel computing

*Shin ya Nakano[1], Yuya Ariyoshi[2], Tomoyuki Higuchi[1] (1.The Institute of Statistical Mathematics, 2.Faculty of Engineering, Nippon Bunri University)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-GI General Geosciences, Information Geosciences & Simulations

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 104 1F

[M-GI30] Data assimilation: A fundamental approach in geosciences

convener:Shin ya Nakano(The Institute of Statistical Mathematics), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), SHINICHI MIYAZAKI(Graduate School of Science, Kyoto University), Takemasa Miyoshi(RIKEN), Chairperson:Takemasa Miyoshi(RIKEN Advanced Institute for Computational Science), Shin'ya Nakano(情報・システム研究機構 統計数理研究所)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MGI30-01] Recent progresses and applications of geomagnetic data assimilation

★Invited Papers

*Julien Aubert[1], Vincent Lesur[1], Alexandre Fournier[1], Gauthier Hulot[1] (1.Institut de Physique du Globe de Paris, France)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MGI30-02] Accounting for non-locality of vertical error correlation within ETKF through eigen-spectral localization

★Invited Papers

*Daisuke Hotta[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MGI30-03] Data assimilation experiments with MODIS LAI observations and the dynamic global vegetation model SEIB-DGVM over Siberia

★Invited Papers

*Hazuki Arakida[1], Shunji Kotsuki[1], Shigenori Otsuka[1], Yohei Sawada[1,2], Takemasa Miyoshi[1] (1.RIKEN Center for Computational Science, 2.Meteorological Research Institute)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MGI30-04] Inversion of the ocean vertical diffusivity from steady-state tracer distributions by using an adjoint method

★Invited Papers

*Akira Oka[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MGI30-05] Nonlinear data assimilation with 4DEnVar using iterative weather forecast model

*Sho Yokota[1], Ko Koizumi[1], Masaru Kunii[2,1], Kosuke Ito[3,1] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Numerical Prediction Division, Forecast Department, Japan Meteorological Agency, 3.University of the Ryukyus)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MGI30-06] Development of Data Assimilation System for Atmospheric Density to Improve Satellite's Orbit Prediction Accuracy

*Hiroshi Kato[1], Hideaki Hinagawa[1], Kyohei Akiyama[1], Yuki Akiyama[1], Masaya Nakano[2], Daichi Obinata[2], Shinichi Nakamura[1] (1.Japan Aerospace Exploration Agency, 2.FUJITSU LIMITED)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-GI General Geosciences, Information Geosciences & Simulations

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 104 1F

[M-GI30] Data assimilation: A fundamental approach in geosciences

convener:Shin ya Nakano(The Institute of Statistical Mathematics), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), SHINICHI MIYAZAKI(Graduate School of Science, Kyoto University), Takemasa Miyoshi(RIKEN), Chairperson:Shinichi Miyazaki(Kyoto University), Yosuke Fujii

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MGI30-07] An LETKF-based ocean reanalysis for the Asia-Oceania region using Himawari-8 SSTs and SMOS/SMAP SSS

★Invited Papers

*Shun Ohishi[1], Tsutomu Hihara[2], Hidenori AIKI[1], Joji Ishizaka[1], Yasumasa Miyazawa[2], Misako Kachi[3] (1.Nagoya University, 2.JAMSTEC, 3.JAXA)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MGI30-08] Validation of JCOPE-T DA ocean assimilation product

*Tsutomu Hihara[1], Sergey Varlamov[1], Yasumasa Miyazawa[1], Toru Miyama[1], Misako Kachi[2], Hiroshi Murakami[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Japan Aerospace Exploration Agency)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MGI30-09] **Do surface lateral flows matter for land data assimilation?: Implication for hyper-resolution land modeling and observation**

*Yohei Sawada[1] (1.Meteorological Research Institute)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MGI30-10] Geodynamo data assimilation for candidate models of IGRF13-SV from Japan team

*Takuto Minami[1], Shin ya Nakano[2], Futoshi Takahashi[3], Masaki Matsushima[4], Hisayoshi Shimizu[1], Hiroaki TOH[5] (1.Ocean Hemisphere Research Institute, Earthquake Research Institute,The University of Tokyo, 2.The Institute of Statistical Mathematics, 3.Faculty of Science, Kyushu University, 4.School of Science, Tokyo Institute of Technology, 5.Graduate School of Science, Kyoto University)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MGI30-11] A pilot study of geomagnetic data assimilation into a geodynamo model

*Shin ya Nakano[1], Takuto Minami[2], Futoshi Takahashi[3], Masaki Matsushima[4], Hiroaki TOH[5], Hisayoshi Shimizu[2] (1.The Institute of Statistical Mathematics, 2.Earthquake Research Institute, the University of Tokyo, 3.Faculty of Science, Kyushu University, 4.School of Science, Tokyo Institute of Technology, 5.Data Analysis Center for Geomagnetism and Space Magnetism, Graduate School of Science, Kyoto University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MGI30-12] Bayesian parameter estimation of a physics-based model of postseismic crustal deformation

★Invited Papers

*Jun'ichi Fukuda[1], Kaj Johnson[2] (1.Earthquake Research Institute, University of Tokyo, 2.Department of Earth and Atmospheric Sciences, Indiana University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-GI General Geosciences, Information Geosciences & Simulations

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_22

[M-GI36] Social media and earth and planetary sciences

convener:Kazuo Amano(Department of Environmental Sciences,Ibaraki University), Takashi Oguchi(Center for Spatial Information Science, The University of Tokyo), Masaki Ito(Institute of Industrial Science, the University of Tokyo), Kayoko Yamamoto(University of Elctro-Communications)

[MGI36-P01] Research and Development on Chatbot for Disaster Response

*Hiroki Azuma[1], Masatsugu Hangyo[2], Kiyonori Ohtake[3] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Weathernews Inc., 3.National Institute of Information and Communications Technology)

[MGI36-P02] Collaboration between NIPR image platform service and social media

*Takeshi Terui[1], Yasuyuki Minamiyama[2], Masaki Hidano[3] (1.National Institute of Polar Research, 2.Tokyo Foundation for Policy Research, 3.Info Lounge Corporation)

[MGI36-P03] Twitter account of the Association of Japanese Geographers: History of establishment and operation

*Takashi Oguchi[1], Yuichiro Nishimura[2], Daichi Kohmoto[3], Atsuko Niina[4], Hitoshi Saito[5] (1.Center for Spatial Information Science, The University of Tokyo, 2.Division of Humanities and Social Sciences, Nara Women's University, 3.Nara University of Education, 4.Izu Peninsula Geopark Promotion Council, 5.College of Economics, Kanto Gakuin University)

[MGI36-P04] Utilization of SNS for the North-Ibaraki Geopark Plan after canceling the certification of JGC

*Kazuo Amano[1], Jun Hosoi[2] (1.The Institute of Natural Sciences, College of Humanities and Sciences, Nihon Univ., 2.Institute of Geology and Geoinformation, Geological Survey of Japan, AIST)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-GI General Geosciences, Information Geosciences & Simulations

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_38

[M-GI36] Social media and earth and planetary sciences

convener:Kazuo Amano(Department of Environmental Sciences,Ibaraki University), Takashi Oguchi(Center for Spatial Information Science, The University of Tokyo), Masaki Ito(Institute of Industrial Science, the University of Tokyo), Kayoko Yamamoto(University of Elctro-Communications)

[MGI36-P01] Research and Development on Chatbot for Disaster Response

*Hiroki Azuma[1], Masatsugu Hangyo[2], Kiyonori Ohtake[3] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Weathernews Inc., 3.National Institute of Information and Communications Technology)

*Kazuo Amano[1], Jun Hosoi[2] (1.The Institute of Natural Sciences, College of Humanities and Sciences, Nihon Univ., 2.Institute of Geology and Geoinformation, Geological Survey of Japan, AIST)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-SD Space Development & Earth Observation from Space

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 302 3F

[M-SD44] Future Missions of Satellite Earth Observation

convener:Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Shinichi Sobue(Japan Aerospace Exploration Agency), Yuki Kaneko(Japan Aerospace Exploration Agency), Chairperson:Yoshiaki Honda

9:05 AM - 9:20 AM JST | 12:05 AM - 12:20 AM UTC

[MSD44-01] Experimental platform for design and advance evaluation of frequent satellite observations to innovate weather, ocean and land surface predictions

*Takemasa Miyoshi[1], Shunji Kotsuki[1], Koji Terasaki[1], Shigenori Otsuka[1], Takumi Honda[1], Atsushi Okazaki[1], Kohei Takatama[1] (1.RIKEN)

9:20 AM - 9:35 AM JST | 12:20 AM - 12:35 AM UTC

[MSD44-02] Technology demonstration mission for next generation precipitation observation radars

*Tomoo Ushio[1], Toshio Iguchi[2], Kenji Nakamura[4], Kinji Furukawa[3], Riko Oki[3], Daisuke Jodoi[3] (1.Tokyo Metropolitan University, 2.NICT, 3.JAXA, 4.Dokkyo University)

9:35 AM - 9:50 AM JST | 12:35 AM - 12:50 AM UTC

[MSD44-03] Mission of creating base maps as public infrastructures for disaster and monitoring

*ISHITSUKA Naoki[1] (1.The Remote Sensing Society of Japan)

9:50 AM - 10:05 AM JST | 12:50 AM - 1:05 AM UTC

[MSD44-04] Aerosol monitoring, forecasting and estimate of its impacts with multispectral imager data

*Keiya Yumimoto[1,2], Takashi Maki[2], Taichu Y Tanaka[2], Thomas Sekiyama[2], Toshihiko Takemura[1] (1.Kyushu University, 2.Meteorological Research Institute)

10:05 AM - 10:20 AM JST | 1:05 AM - 1:20 AM UTC

[MSD44-05] Global aerosol and cloud observation by space-borne multi-wavelength polarization high-spectral-resolution lidar

*Tomoaki Nishizawa[1], Hajime Okamoto[2], Syoken Ishii[3], Yoshitaka Jin[1] (1.National Institute for Environmental Studies, 2.Kyushu University, 3.National Institute of Information and Communication Technology)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-SD Space Development & Earth Observation from Space

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 302 3F

[M-SD44] Future Missions of Satellite Earth Observation

convener:Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Shinichi Sobue(Japan Aerospace Exploration Agency), Yuki Kaneko(Japan Aerospace Exploration Agency), Chairperson:Kazuhiro Asai(東北工業大学), Toshiyoshi Kimura(宇宙航空研究開発機構)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MSD44-06] Dual-Doppler-velocity-mission using cloud radar and lidar

*Okamoto Hajime[1], Kentaroh Suzuki[2], Tomoaki Nishizawa[3], Shoken Ishii[4] (1.Kyushu University, 2.The university of Tokyo, 3.National Instuitute for Environmental Studies, 4.National Institute of Information and Communications Technology)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MSD44-07] Global wind profiling with space-based Doppler wind lidar for improvement of numerical weather prediction

*Shoken Ishii[1], Kozo Okaoto[2,1], Takuji Kubota[3], Atsushi Sato[4,1], Daisuke Sakaizaw[3], Tomoaki Nishizawa[5], Ayako Matsumoto[6], Tetsuya Tugami[6], Toshiyuki Ishibashi[2], Taichu Y Tanaka[2], Philippe Baron[1], Makoto Aoki[1], Riko Oki[3], Masaki Satoh[7], Toshiki Iwasaki[8] (1.National Institute of Information and Communications Technology, 2.JMA/MRI, 3.JAXA, 4.TIT, 5.NIES, 6.ANA, 7.University of Tokyo, 8.Tohoku University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MSD44-08] Technology demonstration of space-borne water vapor DIAL

*Makoto Abo[1], Chikao Nagasawa[1], Yasukuni Shibata[1], Osamu Uchino[2], Takashi Shibata[3] (1.Graduate School of System Design, Tokyo Metropolitan University, 2.National Institute for Environmental Studies, 3.Nagoya University)

11:30 AM - 12:00 PM JST | 2:30 AM - 3:00 AM UTC

[MSD44-09] Short presentation of poster session

*Yoshiaki HONDA[1] (1.Center for Environmental Remote Sensing, Chiba University)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-SD Space Development & Earth Observation from Space

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 302 3F

[M-SD44] Future Missions of Satellite Earth Observation

convener:Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Shinichi Sobue(Japan Aerospace Exploration Agency), Yuki Kaneko(Japan Aerospace Exploration Agency), Chairperson:Riko Oki(宇宙航空研究開発機構)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MSD44-10] **Himawari-8/9 follow-on satellites program**

*BESSHO Kotaro[1] (1.Japan Meteorological Agency)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MSD44-11] Impact assessment of hyperspectral infrared sounders toward Himawari-8/9 follow-on satellites

*Kozo OKAMOTO[1], Hiromi Owada[2], Masahiro Kazumori[2], Michiko Otsuka[1], Yoshifumi Ota[2], Naotaka Uekiyo[1], Hiromu Seko[1], Akiyoshi Ando[2], Ryo Yoshida[2], Hiroshi Ishimoto[1], Masahiro Hayashi[1], Haruma Ishida[3], Yoshiaki Sato[2], Hiroshi Kunimatsu[2], Kotaro Bessho[2], Hironobu Yokota[2] (1.Meteorological Research Institute, 2.Japan Meteolological Agency, 3.Meteorological Satellite Center)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MSD44-12] Observation system simulation experiments for a hyperspectral infrared sounder onboard geostationary satellite

*HIROMI OWADA[1], Kozo OKAMOTO[2], Masahiro Kazumori[1], NAOTAKA UEKIYO[2], Hiroshi Ishimoto[2], Masahiro Hayashi[2] (1.Japan Meteorological Agency, 2.Meteorological Research Institute)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MSD44-13] Realization of pseudo high frequency high resolution observation by geostationary satellite and orbiting satellite combined observation

*Yoshiaki HONDA[1] (1.Center for Environmental Remote Sensing, Chiba University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MSD44-14] **Geostationary Optical Earth Observation Satellite**

*Kazuo Oki[1], Toshiyoshi Kimura[2], Tadahito Mizutani[2], Takeo Tadono[2] (1.The University of Tokyo, 2.JAXA)

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute)

Phenomena such as destruction, eruption and collision are catastrophic phenomena, which is different from geological phenomena like mantle convection. However, global phenomena such as meteorite collisions characterised by extinction of dinosaurs were caused not only by long-term fluctuations but also by such a dramatic high-speed phenomenon. It is also important to understand the high-speed dynamics in order to consider evolution of the Earth and disaster prevention. Now it has become possible to capture fast phenomena from femtosecond to several minutes scale under the extreme condition with progress of synchrotron radiation technology. The purpose of this session is that comprehensively understand high-speed dynamics from many methods such as material science / observation / numerical model.

X-ray Absorption Fine Structure (XAFS) is powerful tool to investigate electric structure and local structure around X-ray absorption atom. Time resolved XAFS measurement developed from appearance of synchrotron radiation and have been applied to many fields. For example, time-resolved XAFS is applied for the catalytic reaction at the in-situ condition and give us the information about how the chemical reaction progresses. We will introduce three representative time-resolved XAFS measurement.

(Super) Quick XAFS (QXAFS),
In QXAFS, the monochromator sweeps quickly (or oscillates at high frequency in Super QXAFS) and it measures the incident X-ray and transmission/fluorescence X-ray intensity continuously. The time resolution depends on the sweep speed of monochromator and the flux of X-ray. The fastest time-resolution of QXAFS in SPring-8 is 800 μs/spectrum which using galvano motor driven monochromator and very compact Si channel-cut crystal without cooling system.

Energy Dispersive XAFS (DXAFS)
DXAFS is a method of measuring the XAFS spectrum by one-shot acquisition. DXAFS measurement is done by converting the energy of X rays into position information using a polychromator and monitoring the position and intensity using a position sensitive detector. So DXAFS has higher time-resolution than QXAFS and the time-resolution is about few ms as usual.

Pump-probe XAFS
Pump-probe XAFS is a method that uses bunch structures of synchrotron radiation. X-ray from the synchrotron facility has a time width. For example at SPring-8, the time width of each X-ray is about 50ps and interval between each X-ray is about 100nsec. Pump-probe XAFS use such time-structure and achieve high time-resolution. However, this method can only apply for repeated reactions.

Ultrafast time-resolved XFEL diffraction study on shock-compressed corundum

*Yoshinori Tange[1]

1. Japan Synchrotron Radiation Research Institute

X-ray Free Electron Lasers (XFEL) allow us ultrafast observations due to its quite short X-ray exposure time of <10 fs (10^{-14} s) with extremely high peak brilliance of >10^{30} photons/sec·mm^2·mrad^2·0.1%b.w., which corresponds to 10^9-times higher compared to synchrotron radiation X-rays made by undulators in third-generation radiation facility such as SPring-8 in general. These extremely-intense and ultrashort-pulsed X-ray flash lamps made it possible to probe samples before the samples are damaged by external forces, conditions, and also XFEL itself.

In an XFEL facility SACLA, constructed at next to SPring-8, laser-driven shock-compression experiments are available with a high-power long-pulse laser system installed by Dr. N. Ozaki' s group and the Photon Pioneers Center in Osaka university. Using the high-power laser system (Nd:YAG, 532 nm, Hamamatsu Photonics K.K.) with the maximum energy of 50 J and pulse width of <10 ns (10^{-8} s), now we are able to reproduce ultrahigh-pressure and ultrahigh-temperature conditions to 1000 GPa (1 TPa) and >10,000 K regime. Here we show a result of in situ observation of shock-compressed polycrystalline corundum utilizing the high-power ns-pulsed pump laser with fs-pulsed intense probe X-ray based on pump-probe techniques.

The pump-probe measurements were carried out varying delay times of XFEL-probe exposure after flashing pump laser to generate shock wave on the surface of targets, which were composed of polypropylene ablator and corundum sample. After series of the pump-probe measurements, pseudo time-resolved profiles were obtained as a function of elapsed time after shock wave arrival to the sample through the ablator. As a result of the pump-probe laser-shock experiments, elastic/plastic compression, uniaxial/quasi-hydrostatic compression, and dynamic recrystallization were observed during shock-wave propagation in the corundum sample with the passing time in the maximum time-resolution of 0.2 ns. In the presentation, we will show the experimental setups and features of XRD profiles of the shock-compressed material in detail.

Toward organization of a new field on fast process in Earth and planetary science

*Takashi Yoshino[1]

1. Institute for Planetary Materials, Okayama University

In the evolution of the Earth and the planet, it is necessary to consider that the event occurred on a short scale, which is different from the evolution on the geological time scale, gives a global impact on the evolution of the planetary scale and its surface environment.In order to understand such events, it is indispensable to understand high-speed processes such as destructive processes as typified by seismic activity, eruption processes in volcanic activities, and huge meteorite collision processes. Since these phenomena are events that can occur anytime even now, it is also an important research topic in terms of disaster prevention. In this presentation, we propose to combine the research on the elementary processes of these phenomena and the research on the influence of these phenomena from various types of research fields, and aim to construct an interdisciplinary research organization.
In recent years, with the progress of measurement experiment technology in large synchrotron radiation facility and X-ray free electron laser facility, It has been possible to detect the short time scale catastrophic phenomenon occurring in extreme environments in a wide range time interval extending from several minutes ($> 10^2$ s) to femtosecond (10^{-15} s). Studies combining synchrotron radiation with high pressure experiments is shifting from the observation of static processes to monitoring of dynamic processes such as deformation, attenuation, and destruction. It is becoming possible to capture phenomena on the millisecond scale.Situations are being developed that can detect the high-speed process. In studies using X-ray free electron laser, a situation where the collision process can be tracked in detail at 100 picosecond scale has been realized during impact compression experiment using high intensity laser. Furthermore, in the field of computer science using supercomputers, the progress of high-speed process reproduction experiments has been remarkable, and it is time to be able to oversee seamless research on capturing high-speed processes from atomic scale to huge meteorite collision.Research on high-speed processes has been studied independently in each event, but there are many aspects that common phenomena in the method of grasping the high-speed process and its elementary process are common. This session was planned with the goal of forming a research network that can efficiently operate "knowledge" by incorporating numerous methods such as material science, geophysical observation and numerical model. By establishing and utilizing this network, it is expected that we will comprehensively understand the high speed dynamics in Earth and planetary science, and at the same time obtain new knowledge about the impact on the global scale and cause a new paradigm shift.

Fractal particle size distribution of pulverized fault rocks and dynamic fragmentation of rocks

*Jun Muto[1], Osamu Nishikawa[2], Hiroyuki Nagahama[1]

1. Department of Earth Sciences, Tohoku University, 2. Graduate School of Engineering and Resource Sciences, Akita University

Earthquake is a catastrophic phenomenon caused by the rapid slip on fault. Development of high-speed rotary shear apparatus enables us to conduct friction experiments of various rocks at seismic slip rates to investigate dynamic fault behaviors [1]. The nominal strain rate at the seismic slip reaches 100 /s under the slip rate of 1 m/s occurring across the 1 cm width of the slip zone. On the other hand, the field observations along large-scale strike-slip faults reported the peculiar fault rocks with in-situ shattered microstructures [2]. The rocks are called pulverized fault rocks and characterized by a lack of shear deformation and intense fragmentation. These intensive damage zones have been suggested to form dynamically during earthquake rupture propagation. Theoretical calculation of the rupture propagation predicts much higher strain-rate deformation exceeding 10000 /s near the rupture tip [3]. However, because such high strain rate can be achieved only along the very close to the tip, several models have also been proposed to explain the wide distribution (~ 100 m from the fault core) of the pulverized rocks along the fault [2,4,5]. From the microstructural analysis of pulverized rocks, we reported the measurements of size distributions of fractured particles [6]. Fragments in those rocks in both fault zones show a fractal size (power-law) distribution down to the micron scale. Fractal dimensions of fragments, dependent on mineral types, reaches 2.92 near the fault cores. The value exceeds a theoretical upper fractal limit of confined comminution (~2.58 [7]) and experimentally created gouges by high-speed friction experiment (~2.6 [8]). Fractal dimensions close to 3.0 have been reported in high-speed impact loading experiments. The observed fractal properties imply that pulverization is likely to have occurred by a dynamic stress pulse with instantaneous volumetric expansion, possibly during seismic rupture propagation similar to impact loading. The obtained results from fractal properties of the pulverized rocks are consistent with laboratory experiments for dynamic fragmentation of rocks using Split-Hopkinson Pressure Bar (SHPB or Kolsky Bar) apparatus [5, 9]. SHPB is a loading apparatus that transmits planar elastic compressive waves into a sample under strain rates of 10 ~ 1000/s. Using the apparatus, Doan and Gary [5] clearly showed that the high strain rate exceeds 150 /s is required to cause pulverization of granite. Moreover, from the analysis of grain size distribution of fragments created by SHPB experiments of fine-grained novaculite, Barber and Griffith [9] showed that energy dissipation by fragmentation is not trivial than previously considered (10 % to as much as 40 %). According to dynamic fragmentation model by Hild [10], strength of rocks in multiple fragmentation regime dramatically increases with strain rate. This implies that the significant strain-rate hardening accompanying pulverization may be the responsible for the significant energy sink of the earthquake [9]. In the presentation, we review the dynamic fragmentation phenomena based on field evidence, theoretical models and laboratory experiments using SHPB apparatus to shed light on the dynamic fault behavior.

Universal aspects of acceleration process toward unstable fast rupture

*Takahiro Hatano[1]

1. Earthquake Research Institute, University of Tokyo

In this talk, we will elaborate the acceleration process of unstable slip on a model of earthquake fault. based on an empirical friction law that has been verified in the lab scale, it is shown that slip velocity increases in a power law manner resembling the inverse Omori law. This acceleration process has been known empirically, and is derivable theoretically for a class of simple systems. We will show that this power-law acceleration is realized in a wider class of systems including non-planer faults and random brittle media. Analysis on a mean-field model indicates saddle node bifurcation is responsible for the power law behavior.

The mechanism of intraslab earthquakes (> 40 km depth) is fundamentally different from those of shallower ones. This is because the frictional strength is much higher and fracture process associates ductile flow (i.e., semi-brittle flow) at deeper parts. The location of the double seismic zone in the subducting Pacific slab corresponds to the main dehydration field in the pressure-temperature diagram of the hydrous peridotite (Omori et al., 2002). The cause of intraslab seismicity at intermediate depths has been attributed to breakdown of hydrous minerals such as serpentinite (e.g., Ferrand et al., 2017) and lawsonite (Okazaki et al., 2016) because it causes unstable fault slip or shear localization. However, the role of aqueous fluid in fracturing at high pressures is still unclear.

To evaluate the effect of water on semi-brittle behavior of dunite and harzburgite, we conducted in-situ uniaxial deformation experiments on as-is/water-saturated dunite and harzburgite at pressures 1-3 GPa and temperatures 670-1250 K with a constant displacement rate using a deformation-DIA apparatus. Pressure, stress, and strain were measured in situ by using x-ray diffraction patterns and radiographs. Radiographs were taken at each several minutes in most of deformation experiments, though radiographs were continuously taken (each 5 seconds) during a deformation run (at 2 GPa and 860 K). Acoustic emissions (AEs) were also recorded continuously on six sensors, and three-dimensional AE source location were determined.

Formation of throughgoing faults was observed in water-saturated dunite and harzburgite at 860 K and lower temperatures. Fault slip rate is between 3E-5 and 4E-4 s^{-1} which are comparable to the background strain rate just before a faulting (1E-5 and 3E-4 s^{-1}), showing that shear localization is ineffective under water-saturated conditions. Addition of the aqueous fluid resulted in the reduction in the number of AE events in the faulted sample (i.e., aseismic faulting). A high time-resolution strain monitoring revealed that fault slip rate fluctuate within several ten seconds (i.e., stick-slip phenomena). Because the high time-resolution strain monitoring is a preliminary experiment, the relationship between stick-slip phenomena and aqueous fluid is unclear. We will investigate that point in near future.

A mechanism of magma fracturing revealed by in-situ X-ray imaging and diffraction

*Satoshi Okumura[1], Kentaro Uesugi[2], Tatsuya Sakamaki[1], Akio Goto[3]

1. Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University, 2. SPring-8/JASRI, 3. Center for Northeast Asian Studies, Tohoku University

Explosive volcanism is one of the most spectacular phenomena on Earth. Explosive volcanism is characterized by the vigorous release of magma fragments and volcanic gases to the surface. In such cases, the magma is the continuum in the crust but becomes fragmented during its ascent. In particular, brittle fragmentation of silicic (relatively SiO2-rich) magma results in explosive eruptions. Therefore, the cause of brittle fragmentation of magma determines whether the eruption will be explosive or effusive.

The viscoelasticity of magma and the relaxation timescale of its structure are currently thought to control fragmentation (Dingwell, 1996 Science). Under rapid deformation rates, magma exhibits elastic behaviour, while viscous magma behaviour is dominant when the deformation rate is slow. Fiber elongation experiments for magmas clearly demonstrate the transition from viscous elongation to brittle fracturing with increased elongation rates. This transition is empirically formulated and can be applied to the modelling of volcanic eruptions (Gonnermann and Manga, 2003 Nature). In contrast, the atomic- to nano-scale structure of melt across this transition is poorly understood. For example, magma exhibits shear thinning (viscosity decreases as shear rate increases) behaviour when the shear rate is close to the conditions at which magma fracturing occurs. No explanation for the relationship between shear thinning and brittle fracturing has yet been proposed. Understanding the atomic- to nano-scale structures across viscous to brittle transition will provide important information for clarifying the mechanism of magma fragmentation. We have investigated magma fracturing by using in-situ X-ray imaging and diffraction techniques. Some preliminary results of our work will be introduced in this presentation.

Estimation of physical parameters of volcanic eruptions based on analysis of eruptive products –Toward understanding of eruption dynamics–

*Fukashi Maeno[1]

1. Earthquake Research Institute, University of Tokyo

'Volume' and 'mass discharge rate' of volcanic eruptions are fundamental parameters in understanding the spatiotemporal scale of magma accumulation and migration in the shallow crust and the type and nature of the surface phenomena accompanying the eruption. 'Volume' of one volcanic eruption is the most fundamental physical parameter for determining the scale of the eruption. Its mid- to long-term transition is related to the accumulation process of magma and the frequency of the eruption, as well as the entire volcanic activity. On the other hand, 'discharge rate' of magma is closely related to magma ascending process, and it is a parameter that controls diversity and transition of eruption styles, eruption intensity, and plume height, etc. The elucidation of 'volume' and 'discharge rate' of magma (physical parameter of eruption) is a key in understanding various volcanic phenomena occurring in the crust and the earth surface as the magma rises. The improvement of the estimation accuracy is indispensable to promote the understanding of the causes of diversity of volcanic activities and eruption phenomena, and the magma reservoir-conduit system. Also the magma discharge rate, which is one of the factors that dominates the diversity of the eruption, greatly influences the characteristics of the eruptive products caused by magma ascent and decompression such as the microstructure and texture, and the chemical composition heterogeneity. The elucidation of the relationship between such physical parameters of eruption and the characteristics of the products may enhance the understanding of volcanic eruptions. On the other hand, in recent eruptions, by comparing ejecta/deposit data with various remote observation data from the ground and satellites, it is possible to grasp the process from magma extrusion to deposition at high resolution. The knowledge obtained therefrom is expected to be an important constraint in the reconstruction of past volcanic events. Estimation of the eruption physical parameters is important not only for understanding the dynamics of volcanic eruption but also for predicting volcanic disasters and future eruptions. In this presentation, we will introduce the estimation of physical parameters of eruption in recent volcanic eruptions and the past gigantic caldera-forming eruptions and also describe the issues.

[U-04] Capture the fast process in Earth and planetary science

convener:Takashi Yoshino(Institute for Planetary Materials, Okayama University), Yoshinori Tange(Japan Synchrotron Radiation Research Institute), Chairperson:Takashi Yoshino(Okayama University), Yoshio Kono(愛媛大学地球深部ダイナミクスセンター), Yoshinori Tange

Phenomena such as destruction, eruption and collision are catastrophic phenomena, which is different from geological phenomena like mantle convection. However, global phenomena such as meteorite collisions characterised by extinction of dinosaurs were caused not only by long-term fluctuations but also by such a dramatic high-speed phenomenon. It is also important to understand the high-speed dynamics in order to consider evolution of the Earth and disaster prevention. Now it has become possible to capture fast phenomena from femtosecond to several minutes scale under the extreme condition with progress of synchrotron radiation technology. The purpose of this session is that comprehensively understand high-speed dynamics from many methods such as material science / observation / numerical model.

Discussion

Chemical reaction processes bridge between asteroid Ryugu and early evolution of Earth

*Seiji Sugita[1,3], Hideharu Kuwahara[2], Kosuke Kurosawa[3]

1. Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo, 2. Ehime University, 3. Chiba Institute of Technology

JAXA's Hayabusa2 has arrived at asteroid Ryugu and is uncovering many new aspects of the primitive asteroid, such as extremly low albedo (4.5+/- 0.1%), flat spectra (Cb type), young resurfacing age (<10^6 yr for the top 1 m layer), high boulder number dentity (x2 of Itokawa) and low abundance of hydrated minerals. These pieces of information is very importance for understanding the early evolution of inner solar system and Earth's surface environment. In particular, what happens upon hypervelocity impacts of such bodies is important for understading the atmospheric chemistry of early Earth. In this study, we review atmospheric entry processes, high-temperature chemistry processes, and discuss the implications of recent results on asteroid missions, such as Hayabusa2 and OSIRIS-REx, for Earth's early evolution.

Time-resolved synchrotron X-ray observations of mineral transformations under static pressures: applications to non-equilibrium behaviors in shocked meteorites

*Tomoaki Kubo[1], Masaaki Miyahara[2]

1. Kyushu University, 2. Hiroshima University

High-pressure transformations occur on timescales of ~0.01 to a few seconds in shocked meteorites. Reactions in such short timescales often remain incomplete and/or metastable state, which is usually problematic for the interpretation, but can be good information for shock durations if the kinetics is experimentally known. Here we present some experimental results on curious kinetic behaviors in seifertite and lingunite, those presences in shocked meteorites have been difficult to explain based on phase equilibrium. A conventional method combining multi-anvil high-pressure apparatus with synchrotron white X-ray was routinely used to observe non-equilibrium behaviors and their kinetics in minerals at pressures up to ~30 GPa by collecting time-resolved X-ray diffraction data every 10 sec with energy dispersive method. By using this system, we found that seifertite and lingunite are metastably formed at high pressures from silica and plagioclase, respectively. The problematic presence of these phases in shocked meteorites can be reasonably explained as metastable phases. Extrapolations of kinetic data obtained to shorter timescales at higher temperatures of shock events uniquely constrain the critical shock durations and the size of the impactor. Similar strategy has also been applied to the back-transformation recorded in shocked meteorites. Time-resolved X-ray observations have revealed that some high-pressure phases such as bridgmanite and lingunite do not directly transform to their low-pressure phases, but through the amorphous state. This may explain the presence of amorphous phases with enstatite and plagioclase compositions in shocked meteorites. Our studies demonstrate that the conventional 10-second time-resolved synchrotron X-ray observations under static pressures capture the critical processes of solid-state reactions during shock events. On the other hand, crystallization of high-pressure phases from shock-induced melt is another important process to be solved. Improvement of the system with better time resolution and grain observations by 2D detector are required to detect the rapid melt crystallization processes.

Ultrafast pump-probe experiemnts for planetary materials using high-power lasers and XFEL

*Norimasa Ozaki[1]

1. Osaka University

Materials at high pressures and temperatures are of great current interest for warm dense matter (WDM) physics, planetary sciences, and inertial fusion energy research. At the high-energy density (HED) conditions, the micro-structures of material significantly influence the behavior and properties. Ultra-short X-ray pulse, *i.e.*, X-ray free electron laser (XFEL), is a unique and powerful tool to directly observe a structure and to reveal the time scale of the structural change under the dynamic high pressures. Here we present recent experimental results on shock-compressed planetary materials using high-power laser and XFEL.

Tracking dynamical phenomena with X-ray free-electron lasers

*Tetsuo Katayama[1]

1. Japan Synchrotron Radiation Research Institute

X-ray free-electron lasers (XFELs) provide brilliant X-ray pulses with femtosecond duration and are utilized to track dynamics, which is difficult to capture using synchrotron radiation. In the femtosecond time domain, one can achieve "molecular movie"[1-3] with an atomic spatio-temporal resolution by combining XFEL and synchronized optical laser pulses. On the other hand, in the nanosecond time domain, XFELs are utilized to observe irreversible dynamic processes[4,5] with the single-shot measurement scheme that can not be performed with synchrotron radiation.
In this presentation, I will talk XFEL properties and research examples at SACLA to discuss the XFEL potentials in Earth and planetary science.

High speed measurement with synchrotron radiation X-ray.

*Kentaro Uesugi[1]

1. Japan Synchrotron Radiation Research Institute

X-ray is suitable for a probe for investigation of materials inside because of its deep penetration depth. For examples, X-ray transmission images show the internal structure of materials, the X-ray energy spectrums show the chemical characteristics and mineral phase of the materials can be obtained from X-ray diffraction.

Synchrotron radiation X-ray has continuum spectrum and is highly collimated basically. Therefore, the X-ray condition such as energy, beam size and intensity could be tuned for the purpose of the measurement and materials. A lot of insertion devices such as in-vacuum type undulator have been installed in a storage ring of third-generation synchrotron radiation facility to obtain ultra-high flux density (photons / sec / mm^2) or brilliance (photons / sec / mm^2 / $(mrad)^2$ / 0.1%b.w.) X-ray at the sample. The highest brilliance of X-ray is about 10^9 time higher than the laboratory-based X-ray source. The high brilliant X-ray enable us to do ultra-high speed, spatial resolution and energy resolution measurement comparing to laboratory-based system.
At the SPring-8 the following experiments could be possible, X-ray imaging with more than 1kHz frame rate (liquid flow), X-ray diffraction with several kHz (insect flapping) and dispersive XAFS with 100Hz. These are essential technique for capturing various non-equilibrium or dynamic phenomena. At the conference, some examples of high speed measurement will be shown.

Recent advances in high-pressure synchrotron X-ray experiments on magmas under pressure at the beamline 16-BM-B in Advanced Photon Source

*Yoshio Kono[1]

1. Geodynamics Research Center, Ehime University

High-pressure synchrotron X-ray experiments using large volume press is one of the most useful tools to investigate structure and properties of Earth’ s materials under high pressure and high temperature conditions. However, in contrast to extensive studies on high-pressure mineralogy and mineral physics, experimental investigation of structure and properties of magmas under pressure has been limited, due to experimental difficulties. In the past decade, new developments in high-pressure experiments, particularly combined with synchrotron X-ray techniques, have advanced the study of magmas under pressure. The new experiments have revealed significant changes to the structure and physical properties of magmas under pressure. In this talk, I will introduce recent advances in high-pressure synchrotron X-ray experiments for studying magmas at high pressures, developed at the beamline 16-BM-B, HPCAT in Advanced Photon Source, USA.

[U-07] How JpGU will manage environment and disaster from the impacts of unforeseen geo-hazards

convener:Koji Okumura(Graduate School of Letters, Hiroshima University), Jun Matsumoto(Deaprtment of Geography, Tokyo Metropolitan University), Daisaku Kawabata(Institute of Geology and Geoinformation, Geological Survey of Japan, AIST), Masaki Matsushima(Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology), Chairperson:Daisaku Kawabata, Koji Okumura(Hiroshima University)

Japan Geoscience Union has established the Environment and Disaster Coping Committee in 2008 to cope with various environmental and natural hazard issues. Those issues are among the most urgent and important geoscientific issues for the society. The enormous extent and severity of the disasters caused by the 2011 Tohoku earthquake and tsunamis urged collaboration of many scientific associations to know the effects of the extreme natural hazards. A number of severe meteorological, volcanic, and earthquake hazards demanded interdisciplinary collaboration to respond to the emergencies. The occurrence and consequence of severe disasters were clearly controlled by the combined effect of environments and hazards. In this session, we share our activities related with recent unforseen disasters, and discuss how Japan Geoscience Union sets up the framework to enhance the real cooperation among scientific associations to prepare the impacts of unexpected hazards.

Seismotectonic environments and landscape as keys to mitigate the impacts from unexpected hazards

*Koji Okumura[1]

1. Graduate School of Letters, Hiroshima University

Even if we know little about the hazards that may occur at certain location, the geologic envieonments and landscape may tell us the risks. They are seismotectonic enveironments and landscapes. Since people contact with geologic and geomorphic environments and landscapes very often, they will be useful keys to understand the risks from natural hazards in that location. The environments and landscapes of the 2018 June 16 Osaka-hokub earthquakes and 2018 September 6 Hokkaido Iburi Tobu earthquakes will be discussed.

Activities related with the eruption at Kusatsu-Shiranesan (Motoshiranesan) volcano on 23 Jan,2018 - Focusing on JMA’s activities -

*Junichi Miyamura[1]

1. Japan Meteorological Agency

Japan is one of the world's leading volcanic country with 111 active volcanoes, and so many volcanic disasters have been repeated. But after the early 20th century, no large eruptions occurred and volcanic activity in Japan has been quiet.
On the other hand, the eruption at Ontakesan volcano on 2014 sacrificed many mountaineers who were near the crater and caused the greatest volcanic disaster after the war. One of the features of eruptive disasters is that even a small eruption could lead to a great disaster if encountered near the crater. In the latest case, the eruption at Kusatsu-Shiranesan volcano on January 23, 2018 suddenly occurred at Motoshiranesan where there was no record of historical eruption and caused human damage at the ski resort near the eruption point.
The Volcanological Society of Japan was established as the world's first academic conference on volcanoes in 1932 and re-established as a specified nonprofit corporation in 2002 for the purpose of advance and disseminate volcanology and related science. The institution to which the member belongs is not only universities and research institutes, but also local municipalities, disaster prevention organizations, high schools and geological consultants. Recently, in order to lead to the reduction of volcanic disaster by volcanology research, we also focus on public awareness raising, such as opening lectures and symposiums targeting the general public.
In this presentation, we will introduce the activities related with the 2018 Motoshiranesan eruption by each institution, mainly on the correspondence of Japan Meteorological Agency.

Aftershock and microtremor array observation around the source area of the 2018 Hokkaido Eastern Iburi earthquake

*Masayuki Yoshimi[1], Kahori Iiyama[2], Hitoshi Morikawa[2], Hiroyuki Goto[3]

1. Geological Survey of Japan, AIST, 2. Tokyo Institute of Technology, 3. DPRI, Kyoto Univ.

The 2018 Hokkaido Eastern Iburi earthquake (Mw 6.6, depth=37 km) is a shallow to moderate depth earthquake. Strong ground motions were widely observed around the source area and in the Ishikari-Yufutsu sedimentary basin, culminated with the maximum seismic intensity VII of the JMA scale at JMA Atsuma seismic station. Waveforms with clear velocity pulse, having 1 to 3 dominant period, were observed along the west of the source area: K-NET Mukawa (HKD126), JMA Atsuma, KiK-net Atsuma (IBUH03), and Atsuma city hall. Velocity response spectra of these pulse waveforms are comparable to that of the Takatori station record, located close to the heavy damage area, during the 1995 Kobe earthquake. Therefore, we need to resolve the reason why such strong ground motions were developed during the 2018 earthquake although the magnitude was moderate (Mw 6.6) and focal depth was not shallow.

Four seismic station, where the strong pulse waveform was observed, are commonly located along the basin edge of the Yufutsu sedimentary basin. The subsurface velocity structure around the source area is considered to responsible for producing the ground motions. Thus, we conducted temporal observation of aftershocks and microtremor array measurements around the source area to investigate spatial variation of the site amplification and subsurface velocity structure. We deployed 14 temporal seismic station during 16th-21st Sep., 2018 to record around 20 aftershocks with magnitude larger than M2. We also conducted microtremor array survey at 13 locations with array aperture of several to 30 meters. Site amplification and subsurface velocity structures will be shown.

Effect of non-linear site response on earthquake hazard map

*Takao Kagawa[1]

1. Tottori University Graduate School of Engineering

Various earthquake hazard maps are published by country and municipalities in Japan. It is better to consider non-linear site response for the hazard maps, however, simple frequency independent amplification of ground motion is frequently adopted. The site responses are generally evaluated from the data of microtremor or stationary earthquake observations; i.e. weak motion, therefore rigidity reduction and damping increase under strong ground motion are not considered in the responses. It is suspected that prolonged predominant period by non-linear site response and synchronized prolongation of residential natural period cause heavy building damages by the 2016 Kumamoto earthquake. It is also suspected that non-linear site response was one of triggers of slope failures and fill ground disaster through the 2018 Hokkaido eastern Iburi earthquake. The non-linear site response is an important issue to consider earthquake disaster by strong ground motion and also ground disaster.

Seismological community has noticed the effect from 1990s, however, evaluation methodology; i.e. program SHAKE, has been proposed in 1970s in engineering community. Latest methodologies have been introduced for modeling subsurface structures in seismological community such as microtremor survey, seismic interferometry, diffuse wave field theory and so on. Joint study across research fields beyond earth and planetary science is required for providing further realistic earthquake hazard map.

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder)

Recent planetary explorations have revealed that almost all solid bodies in the solar system are covered with small particles, called regolith. The surface geology, especially regolith behavior on the surfaces of solid bodies, becomes increasingly more important as represented by Hayabusa mission and other on-going and planned sample-return missions such as Hayabusa2, OSIRIS-REx, and MMX.

For fully understanding the regolith science, it is required to know and compare the regolith conditions on various celestial bodies, from asteroids to planets, with various methods.

Therefore, this session welcomes broad topics related to regolith on various celestial bodies, such as asteroids, comets, the Moon, the martian moons, Mars, etc. Papers on the formation, evolution, and alteration processes of regolith particles and regolith systems on the surface of planetary bodies, remote and in-situ observational results and techniques, analyses and results of returned samples, and laboratory, numerical, and theoretical studies on the fundamental physical and chemical processes are all welcome.

Note that what we call regolith is not just fine grains: all kinds of materials (more or less loose) that lie on the surface, from cobbles to finer grains, are our targets.

Abrasion experiments of mineral and meteorite grains: Dependence of particle size and vibration rate on abrasion rate and its application to Itokawa and lunar regolith particles.

*Hirotaka Yamaguchi[1], Akira Tsuchiyama[1], Akiko Nakamura[2]

1. National University Corporation, Kyoto University, 2. National University Corporation,Kobe University

Rounded edges were found in some regolith particles collected from asteroid Itokawa [1] and Moon [2]. These particles should be formed by mechanical abrasion [1]. Seismic-induced grain motion by micrometeoroid impacts [1] and YORP effect [3] were proposed for the abrasion process on Itokawa. However, it is not clear how these processes actually work on the surfaces of the airless celestial bodies.

In order to understand detailed process of the abrasion, our research group have carried out abrasion experiments using mineral, rock and meteorite grains (grain size: 1-2 mm) [4]. Samples used were quartz, olivine, corundum, marble, L5 chondrite meteorite (Sayh al Uhaymir 001) and CM chondrite meteorite (Murchison). These particles were put into a vessel of 10 mL with the filling ratio of ~50 % and the sample was vibrated with the rate from 1000 to 3000 rpm using a multi-beads-shocker (YASUIKIKAI Co.). The proportion of powder (<250 μm) produced by vibration at first 1 min., ΔP_1, was adopted as the measure of abrasion and its dependence of the vibration rate and the sample strength was examined. However, the particle size used in the experiments (1-2 mm) is larger than Itokawa particles (< a few hundred μm). In addition, the vibration rates used in the experiments are larger than those estimated for Itokawa(~100 rpm) and Moon (~700 rpm) by considering the maximum seismic acceleration due to micrometeoroidimpacts onto their surface [5]. In the present study, therefore, we conducted new experiments with different parameters such as particle size and vibration rate using the same experimental procedure as [4]. In the present experiments, we used quartz grains for examining the effect of packing ratio in the vessel (Exp-1), particle size (Exp-2), mixing ratio of large and small particles (Exp-3). The effect of lower vibration rate (100 - 1000 rpm) was examined using olivine and basalt as well as quartz (Exp-4). Experiments using basalt at higher vibration rates were also made.

We obtained following results. Exp-1: $\Delta P_1$was constant in a wide range of the filling rate except for the filling rate of 2/3, where ΔP_1showed a peak value. Exp-2: $\Delta P_1$is proportional to the particle size. Exp-3: When the proportion of large particles is larger than 25%, $\Delta P_1$is almost constant and the same as $\Delta P_1$for the large particles. Exp-4: In the previous experiments, ΔP_1increases with the vibration rate with the power of 1.1-2.9 for large vibration rates (>~1000 rpm) [4] while the power becomes smaller (0.67-0.77) for smaller vibration rates (<~1000 rpm). This result shows that the abrasion mode changed at ~1000 rpm. In order to understand abrasion modes, SEM observation of powder particles produced in the abrasion experiments were also made. It was found that chipping of particle edges occurred at low vibration rate (~100 rpm) and the proportion of gradual wearing on the whole particle surface gradually increased as the vibration rate increased.

We estimated the amount of abrasion of Itokawa and lunar regolith particles in a regolith layer by impact based on the present experiments. ΔP_1values of basalt at 100 and 700 rpm, which corresponding to Itokawa and Moon [4], are ~0.1 %and ~1 %, respectively (Exp-4). If we consider the size of Itokawa and Moon particle (~100 μm), ΔP_1on Itokawa and Moon should be ~0.01%and ~0.1%, respectively(Exp-2). These values are larger than those estimated from the previous experiments [4] by the order of about 1.

Measurements of adhesive force of meteorite powders using centrifugal method

*Yuuya Nagaashi[1], Akiko Nakamura[1]

1. Kobe University

Introduction: Layer of fine particles in the laboratory shows fluffy structure owing to interparticle force (e.g., Kiuchi and Nakamura, 2014). On small bodies, interparticle forces are thought to be dominant compared to gravitational force for small particles. Fast rotators spin in excess of what gravity alone could hold together were shown to be explained by cohesive force between constituent particles (Sánchez & Scheeres, 2016). Measurements of cohesive force between micron-size spherical silica particles using an atomic force microscope cantilever (Heim et al., 1999) showed that the results agree with predictions of the JKR model (Johnson et al., 1971). On the other hand, measurements of cohesive force between 50 or 100 μm glass beads and a glass plate using centrifugal method showed that the results are by several orders of magnitude smaller than predictions of the JKR theory (Nagaashi et al., 2018). In addition, it was also shown that ~ 70 μm irregularly-shaped silica and alumina grains have the range of adhesive force similar to the glass beads, indicating that the adhesive force of the spherical and the irregular particles used in the measurement is dependent not on the macroscopic shape but on the microscopic surface roughness. However, it is not clear whether the adhesive force of the particles that actually form the asteroids is similar to those of silica grains. Measurements of adhesive force of meteorite powders will bring important knowledge of adhesive force of the asteroid-forming particles for understanding physical processes occurring on asteroids.

Experimental method: In this study, we used centrifugal method as in our previous study (Nagaashi et al., 2018) in order to measure cohesive or adhesive force between a particle and a plate. This method can directly measure the cohesive or adhesive force of many particles at the same time, which enables us to statistically analyze the results. Additionally, it can also deal with irregularly shaped particles. The measurements were conducted for carbonaceous chondrite (CV3: Allende, CM2: Murchison), ordinary chondrite (LL3.5: NWA 539, LL5: NWA 1794, LL6: NWA 542), and Eucrite (Millbillillie) powders of median diameter ~ 50 μm. We discretely increased the centrifugal acceleration from 10g to 5000g (g: the Earth's gravitational acceleration) and took optical microscope images of the same location of the plate before and after applying centrifugal force at each centrifugal acceleration. We determined the range of centrifugal acceleration within which the particle separated from the plate based on the microscope images and estimated the cohesive or adhesive force between the particle and the plate. More detail description of the procedure is described in Nagaashi et al. (2018).

Results: As compared with the JKR adhesion force $F_{ad} = 3\pi\gamma R$ (γ: surface energy, R: reduced radius of particle) for a spherical particle of silica composition, we calculated the effective surface energy of particles which reproduces the measurement value, and compared the results of each type of meteorite powders. Similar to the previous results described in the above (Nagaashi et al., 2018), the measurements of meteorite powders showed a wide range of adhesive force distributions over several orders of magnitude for all measured meteorite types. In addition, we found that the effective surface energy of Allende and Murchison meteorite particles were several times smaller than those for the particles of the other meteorite types. There is no difference in the axial ratio of each type of meteorite powders, and therefore this is likely due to differences in material composition or micro-topography of the particles.

Laboratory impact penetration experiments conducted at simulated reduced gravity

*Akiko Nakamura[1], Kana Morizono[2], Yuuya Nagaashi[1]

1. Graduate School of Science, Kobe University, 2. Faculty of Science, Kobe University

Small bodies are covered with a layer of regolith made up of particles of various sizes. It is important to understand the interactions that occur with surface regolith when a spacecraft lands on or when a block secondarily collide with the regolith layer at low velocity. Penetration depth of an impactor in granular layer was investigated under Earth’ s gravity and an empirical relationship between the drop height and penetration depth was shown to reproduce the experimental results for various granular materials (Uehara et al., 2013). Deceleration of spherical impactor in granular layer was experimentally and theoretically investigated and deceleration formulae were proposed (Katsuragi and Durian 2007, Nakamura et al., 2013; Katsuragi and Durian 2013). On the other hand, interactions of spheres with simulated regolith have been studied at reduced gravity and micro-gravity conditions (Murdoch et al., 2016; Brisset et al., 2018). However, more data of penetration depth of impactor are required to establish quantitative understanding of the penetration process in regolith under low gravity.

We conducted laboratory low-velocity impact experiments of a sphere into granular layer at reduced gravity. Impactor was a glass sphere with a diameter of 16.7 mm and granular layer consisted of glass beads with a diameter of 1 mm. The glass beads were packed in a bucket having a diameter of 15 cm and a depth of 15 cm. The bucket was hung with three constant load springs. The bucket was fixed with two electromagnets, and when the electromagnet was switched off, it dropped vertically downward with the gravity reduced. The simulated reduced gravity level was monitored by an accelerometer placed in a bucket and found to be on average 0.26 G. A plastic straw with horizontal line drawing was glued to the glass sphere. The glass sphere collided with the glass bead layer at a relative velocity between 2 and 4 ms $^{-1}$. The penetration process of the glass sphere with the straw was imaged at 240 fps by a camera attached to the bucket. The final depth of the glass sphere was found to be systematically deeper than the depth found in the experiment conducted at 1 G.

MARAUDERS: Using instrumented nano-impactors to probe the icy properties of Lunar permanently shadowed regions

*Ronald Ballouz[1], Sarah T Crites[2], Naoya Ozaki[2], Shun Arahata[3], Nicola Baresi[2], Ralf Bolden, Onur Celik[4,2], Yu Himeno[3], Lucie Riu[2], Kevin J Walsh[5]

The Mini lAndeRs And boUncers Deployed for Exploration and Regolith Science (MARAUDERS) is a small satellite concept that aims to characterize the surface and volatile properties of regolith in permanently shadowed regions (PSRs) around the Moon's poles. Large PSRs are cold enough to trap scientifically and economically valuable volatiles such as water ice. However, despite ongoing studies, the distribution, abundance, and physical phase of volatiles at the Moon's poles remains elusive [1]. *In-situ* measurements are required to conclusively determine the geotechnical and physical properties of lunar polar volatiles. To address these needs, the MARAUDERS team is currently developing a technique using instrumented nano-impactors to determine the mechanical properties of regolith at the impact point.

Small spacecraft equipped with penetrators or inertial measurement units (IMU) can characterize the strength and structure of the planetary surface that they impact. Early space exploration used penetrometers to determine the surface properties of the Moon and Mars before the arrival of astronauts and rovers. In recent decades, spacecraft equipped with IMUs characterized the surface of Titan [1], and determined the sub-surface stratification of ice and rock on the comet 67P/C-G [2]. While this technique is unable to relay the detailed mineralogical and elemental composition at the impact point, it obtains a first-order structural knowledge of potentially hazardous surfaces and sub-surfaces that cannot be obtained through remote sensing. This is highly relevant for PSRs due to extreme environmental conditions such as the lack of solar illumination, cold temperatures, and challenging communications.

Here, we present preliminary analysis on the instrument capabilities based on the potential deployment scenarios to PSRs, and the possible mechanical properties of the regolith found within these regions (Fig. 1). We present a computational study of the varying response of an instrumented impactor impacting regolith with variable i) water ice content (0-10%), ii) impactor speeds (50-250 m/s], and iii) impact angles (45-90˚), using a discrete element method code [4]. Furthermore, we analyse the ejecta properties and resulting crater morphology in order to gain a better understanding of impact processes on icy bodies. Our next steps will be to conduct laboratory impact experiments using prototypes of our instrumented impactors to calibrate the impact response on lunar simulant with variable water-ice content.

Surface size-frequency distribution of accumulating boulders using discrete element simulations of spherical particles in 3D

*Hiroshi Kikuchi[1], Hideaki Miyamoto[1]

1. The University of Tokyo

Several spacecraft have revealed new detail about small bodies such as asteroids, comets, and small satellites. Images from Hayabusa, Hayabusa2, and OSIRIS-REx showed more boulders on the surfaces than originally expected. Owing to the high resolution at which images were taken, a number of boulders could often be observed in clusters. In future explorations, because we expect to observe more cases of boulder-rich surfaces, the characterization of the size-frequency distribution (SFD) will be important especially for the missions involving a lander such as MMX. Basically, measuring the SFD of boulders on a surface is expected to represent that of the interior. However, considering that surface boulders can hide the underlying boulder, it is not clear that the SFD in a volume can adequately be represented by its surface. Therefore, in this work, we focus on how accumulating boulders with a known SFD appear from above.
In order to compare the SFD on a surface with that of a volume, the initial SFD has to be known. For the initial study, numerical simulations are convenient, because they can easily prepare the suitable conditions. In the previous studies, spherical boulders were randomly distributed in three-dimensional space, and only those on the surface were automatically extracted and measured (Tancredi et al., 2015). It was found that the particle distribution on the surface well reproduces the overall particle distribution. We consider that there is room for improvement in the arrangement of particles and the measurement of particles. Thus, we implement a three-dimensional discrete element method using rigid spherical particles to simulate the accumulation of a boulder-rich regolith. We then measure particles one by one manually when viewed from above the surface. For initial conditions, we set the size and the number of boulders randomly as specified by the power law index of -3. During a simulation, particles are not initially adjacent to each other and are instead dropped from the height of 30 m above the 54 x 54 m planar surface. The total number of particles is changed from 3000 to 7000 in 1000 increments. After the simulation, the size and number of the particles are measured manually when viewing the surface from the vertical direction. Then we refer to Clauset et al. (2009) for fitting and evaluating the data using the p-value metric.
We find that the power law index of the SFD is low when the number of particles is 3000. This may be because the larger particles are not buried in the smaller particles, resulting in only the number of smaller particles being reduced when viewed from above. When the total number is 4000 or more in a volume and p-value is high, the surface power law index from the multiple simulations is consistent with the specified value of -3 for some cases.
The SFD observed on the surface corresponds to the SFD in the interior of the body for the following conditions: the thickness of the deposited particles is larger than the largest particle and the p-value is high. For more detailed analyses, investigating the effects of the number of simulations, the complicated shapes of boulders, and parameter studies are needed. In addition, for a deeper understanding of the problem, experiments in a similar condition to the airless bodies using simulated regolith particles such as UTPS-TB and UTPS-IB (Miyamoto et al., 2018) are also required.

Experimental Study to Determine the Best Compression Ratio of High-Resolution Images of Small Bodies for the Martian Moons eXploration (MMX) Mission

*Yuta Shimizu[1], Hiroaki Kamiyoshihara[1], Takafumi Niihara[1], Hideaki Miyamoto[1]

1. University of Tokyo

Data transmission rate becomes one of the biggest limiting factors in space explorations; technological advance in increasing pixel numbers of camera images dominates the improvement of the data transmission rate. Yet, high demand exists for high-resolution images especially in geological studies, and thus there is a tradeoff between the spatial resolutions (or pixel numbers) and the number of images to be transmitted to Earth. The telecommunications issue is critical for Martian Moons eXploration (MMX) mission that explore either/both Phobos and Deimos and return samples. Especially, timely transmission of high-resolution images is required for the selection of sampling site both in terms of scientific impacts and of the landing safety. The highest image resolution of the current camera configuration is as good as several tens of centimeters per pixel and the size of image is 3296 x 2472 pixels, which means 7 color (3 bands) images can be up to 1 GB if no compression is considered. During the landing phase, such large data have to be sent at the limited bitrate (< 32 kbps) to select landing and sampling sites, while the landing duration is about 4 hours. Thus, considering the best compression scheme of images is a big issue for landing operation. Lossy compression can significantly reduce the sizes of images, though images can be scientifically worthless when compressed too much. The best compression ratio should make the sizes of images as small as possible without losing scientific importance.

Here, we develop a method of rapidly determining the best compression ratio of high-resolution images of the surface of small bodies. For preparing the image studied in this research, we take an experimental scheme, where we develop a simulated Phobos surface by using a high-quality simulant of Phobos regolith (UTPS-TB) and take simulated images of the surface of Phobos in somehow similar condition with the camera of the MMX mission. The images are compressed by JPEG2000, which is planned to be used in MMX mission, and the influence of the compression is analyzed by objective methods such as Structural SIMilarity (SSIM) and entropy of image. The results shows that they are able to rapidly detect the exact ratio, in which the quality of the images started to be diminished.

Moreover, by defining scientific value of images as detectability of rock gravel on the surface of celestial bodies and showing that the loss of scientific value can be expressed by the change in the value of slope of Cumulative Size-Frequency Distribution (CSFD) of gravel, we carefully confirm whether the decrease in the image quality is truly connected with the loss of scientific information such as for landing operations and conclude that those objective methods can determine the best compression ratio. By using those methods, the spacecraft can autonomously complete the process of finding the best compression ratio, compressing images and sending it to the ground within a few minutes even if it has only a limited transmission rate.

Wed. May 29, 2019 5:15 PM - 6:30 PM JST | Wed. May 29, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder)

Recent planetary explorations have revealed that almost all solid bodies in the solar system are covered with small particles, called regolith. The surface geology, especially regolith behavior on the surfaces of solid bodies, becomes increasingly more important as represented by Hayabusa mission and other on-going and planned sample-return missions such as Hayabusa2, OSIRIS-REx, and MMX.

For fully understanding the regolith science, it is required to know and compare the regolith conditions on various celestial bodies, from asteroids to planets, with various methods.

Therefore, this session welcomes broad topics related to regolith on various celestial bodies, such as asteroids, comets, the Moon, the martian moons, Mars, etc. Papers on the formation, evolution, and alteration processes of regolith particles and regolith systems on the surface of planetary bodies, remote and in-situ observational results and techniques, analyses and results of returned samples, and laboratory, numerical, and theoretical studies on the fundamental physical and chemical processes are all welcome.

Note that what we call regolith is not just fine grains: all kinds of materials (more or less loose) that lie on the surface, from cobbles to finer grains, are our targets.

Measurements of adhesive force of meteorite powders using centrifugal method

*Yuuya Nagaashi[1], Akiko Nakamura[1]

1. Kobe University

Introduction: Layer of fine particles in the laboratory shows fluffy structure owing to interparticle force (e.g., Kiuchi and Nakamura, 2014). On small bodies, interparticle forces are thought to be dominant compared to gravitational force for small particles. Fast rotators spin in excess of what gravity alone could hold together were shown to be explained by cohesive force between constituent particles (Sánchez & Scheeres, 2016). Measurements of cohesive force between micron-size spherical silica particles using an atomic force microscope cantilever (Heim et al., 1999) showed that the results agree with predictions of the JKR model (Johnson et al., 1971). On the other hand, measurements of cohesive force between 50 or 100 μm glass beads and a glass plate using centrifugal method showed that the results are by several orders of magnitude smaller than predictions of the JKR theory (Nagaashi et al., 2018). In addition, it was also shown that ~ 70 μm irregularly-shaped silica and alumina grains have the range of adhesive force similar to the glass beads, indicating that the adhesive force of the spherical and the irregular particles used in the measurement is dependent not on the macroscopic shape but on the microscopic surface roughness. However, it is not clear whether the adhesive force of the particles that actually form the asteroids is similar to those of silica grains. Measurements of adhesive force of meteorite powders will bring important knowledge of adhesive force of the asteroid-forming particles for understanding physical processes occurring on asteroids.

Experimental method: In this study, we used centrifugal method as in our previous study (Nagaashi et al., 2018) in order to measure cohesive or adhesive force between a particle and a plate. This method can directly measure the cohesive or adhesive force of many particles at the same time, which enables us to statistically analyze the results. Additionally, it can also deal with irregularly shaped particles. The measurements were conducted for carbonaceous chondrite (CV3: Allende, CM2: Murchison), ordinary chondrite (LL3.5: NWA 539, LL5: NWA 1794, LL6: NWA 542), and Eucrite (Millbillillie) powders of median diameter ~ 50 μm. We discretely increased the centrifugal acceleration from 10g to 5000g (g: the Earth's gravitational acceleration) and took optical microscope images of the same location of the plate before and after applying centrifugal force at each centrifugal acceleration. We determined the range of centrifugal acceleration within which the particle separated from the plate based on the microscope images and estimated the cohesive or adhesive force between the particle and the plate. More detail description of the procedure is described in Nagaashi et al. (2018).

Results: As compared with the JKR adhesion force $F_{ad} = 3\pi\gamma R$ (γ: surface energy, R: reduced radius of particle) for a spherical particle of silica composition, we calculated the effective surface energy of particles which reproduces the measurement value, and compared the results of each type of meteorite powders. Similar to the previous results described in the above (Nagaashi et al., 2018), the measurements of meteorite powders showed a wide range of adhesive force distributions over several orders of magnitude for all measured meteorite types. In addition, we found that the effective surface energy of Allende and Murchison meteorite particles were several times smaller than those for the particles of the other meteorite types. There is no difference in the axial ratio of each type of meteorite powders, and therefore this is likely due to differences in material composition or micro-topography of the particles.

Laboratory impact penetration experiments conducted at simulated reduced gravity

*Akiko Nakamura[1], Kana Morizono[2], Yuuya Nagaashi[1]

1. Graduate School of Science, Kobe University, 2. Faculty of Science, Kobe University

Small bodies are covered with a layer of regolith made up of particles of various sizes. It is important to understand the interactions that occur with surface regolith when a spacecraft lands on or when a block secondarily collide with the regolith layer at low velocity. Penetration depth of an impactor in granular layer was investigated under Earth’ s gravity and an empirical relationship between the drop height and penetration depth was shown to reproduce the experimental results for various granular materials (Uehara et al., 2013). Deceleration of spherical impactor in granular layer was experimentally and theoretically investigated and deceleration formulae were proposed (Katsuragi and Durian 2007, Nakamura et al., 2013; Katsuragi and Durian 2013). On the other hand, interactions of spheres with simulated regolith have been studied at reduced gravity and micro-gravity conditions (Murdoch et al., 2016; Brisset et al., 2018). However, more data of penetration depth of impactor are required to establish quantitative understanding of the penetration process in regolith under low gravity.

We conducted laboratory low-velocity impact experiments of a sphere into granular layer at reduced gravity. Impactor was a glass sphere with a diameter of 16.7 mm and granular layer consisted of glass beads with a diameter of 1 mm. The glass beads were packed in a bucket having a diameter of 15 cm and a depth of 15 cm. The bucket was hung with three constant load springs. The bucket was fixed with two electromagnets, and when the electromagnet was switched off, it dropped vertically downward with the gravity reduced. The simulated reduced gravity level was monitored by an accelerometer placed in a bucket and found to be on average 0.26 G. A plastic straw with horizontal line drawing was glued to the glass sphere. The glass sphere collided with the glass bead layer at a relative velocity between 2 and 4 ms $^{-1}$. The penetration process of the glass sphere with the straw was imaged at 240 fps by a camera attached to the bucket. The final depth of the glass sphere was found to be systematically deeper than the depth found in the experiment conducted at 1 G.

MARAUDERS: Using instrumented nano-impactors to probe the icy properties of Lunar permanently shadowed regions

*Ronald Ballouz[1], Sarah T Crites[2], Naoya Ozaki[2], Shun Arahata[3], Nicola Baresi[2], Ralf Bolden, Onur Celik[4,2], Yu Himeno[3], Lucie Riu[2], Kevin J Walsh[5]

1. Lunar and Planetary Lab, University of Arizona, Tucson, AZ, USA, 2. Institute of Space and Astronautical Science, Sagamihara, Japan, 3. University of Tokyo, Tokyo, Japan, 4. Sokendai Graduate University, Japan, 5. Southwest Research Institute, Boulder, CO, USA

The Mini lAndeRs And boUncers Deployed for Exploration and Regolith Science (MARAUDERS) is a small satellite concept that aims to characterize the surface and volatile properties of regolith in permanently shadowed regions (PSRs) around the Moon's poles. Large PSRs are cold enough to trap scientifically and economically valuable volatiles such as water ice. However, despite ongoing studies, the distribution, abundance, and physical phase of volatiles at the Moon's poles remains elusive [1]. *In-situ* measurements are required to conclusively determine the geotechnical and physical properties of lunar polar volatiles. To address these needs, the MARAUDERS team is currently developing a technique using instrumented nano-impactors to determine the mechanical properties of regolith at the impact point.

Small spacecraft equipped with penetrators or inertial measurement units (IMU) can characterize the strength and structure of the planetary surface that they impact. Early space exploration used penetrometers to determine the surface properties of the Moon and Mars before the arrival of astronauts and rovers. In recent decades, spacecraft equipped with IMUs characterized the surface of Titan [1], and determined the sub-surface stratification of ice and rock on the comet 67P/C-G [2]. While this technique is unable to relay the detailed mineralogical and elemental composition at the impact point, it obtains a first-order structural knowledge of potentially hazardous surfaces and sub-surfaces that cannot be obtained through remote sensing. This is highly relevant for PSRs due to extreme environmental conditions such as the lack of solar illumination, cold temperatures, and challenging communications.

Here, we present preliminary analysis on the instrument capabilities based on the potential deployment scenarios to PSRs, and the possible mechanical properties of the regolith found within these regions (Fig. 1). We present a computational study of the varying response of an instrumented impactor impacting regolith with variable i) water ice content (0-10%), ii) impactor speeds (50-250 m/s], and iii) impact angles (45-90˚), using a discrete element method code [4]. Furthermore, we analyse the ejecta properties and resulting crater morphology in order to gain a better understanding of impact processes on icy bodies. Our next steps will be to conduct laboratory impact experiments using prototypes of our instrumented impactors to calibrate the impact response on lunar simulant with variable water-ice content.

Surface size-frequency distribution of accumulating boulders using discrete element simulations of spherical particles in 3D

*Hiroshi Kikuchi[1], Hideaki Miyamoto[1]

1. The University of Tokyo

Several spacecraft have revealed new detail about small bodies such as asteroids, comets, and small satellites. Images from Hayabusa, Hayabusa2, and OSIRIS-REx showed more boulders on the surfaces than originally expected. Owing to the high resolution at which images were taken, a number of boulders could often be observed in clusters. In future explorations, because we expect to observe more cases of boulder-rich surfaces, the characterization of the size-frequency distribution (SFD) will be important especially for the missions involving a lander such as MMX. Basically, measuring the SFD of boulders on a surface is expected to represent that of the interior. However, considering that surface boulders can hide the underlying boulder, it is not clear that the SFD in a volume can adequately be represented by its surface. Therefore, in this work, we focus on how accumulating boulders with a known SFD appear from above.
In order to compare the SFD on a surface with that of a volume, the initial SFD has to be known. For the initial study, numerical simulations are convenient, because they can easily prepare the suitable conditions. In the previous studies, spherical boulders were randomly distributed in three-dimensional space, and only those on the surface were automatically extracted and measured (Tancredi et al., 2015). It was found that the particle distribution on the surface well reproduces the overall particle distribution. We consider that there is room for improvement in the arrangement of particles and the measurement of particles. Thus, we implement a three-dimensional discrete element method using rigid spherical particles to simulate the accumulation of a boulder-rich regolith. We then measure particles one by one manually when viewed from above the surface. For initial conditions, we set the size and the number of boulders randomly as specified by the power law index of -3. During a simulation, particles are not initially adjacent to each other and are instead dropped from the height of 30 m above the 54 x 54 m planar surface. The total number of particles is changed from 3000 to 7000 in 1000 increments. After the simulation, the size and number of the particles are measured manually when viewing the surface from the vertical direction. Then we refer to Clauset et al. (2009) for fitting and evaluating the data using the p-value metric.
We find that the power law index of the SFD is low when the number of particles is 3000. This may be because the larger particles are not buried in the smaller particles, resulting in only the number of smaller particles being reduced when viewed from above. When the total number is 4000 or more in a volume and p-value is high, the surface power law index from the multiple simulations is consistent with the specified value of -3 for some cases.
The SFD observed on the surface corresponds to the SFD in the interior of the body for the following conditions: the thickness of the deposited particles is larger than the largest particle and the p-value is high. For more detailed analyses, investigating the effects of the number of simulations, the complicated shapes of boulders, and parameter studies are needed. In addition, for a deeper understanding of the problem, experiments in a similar condition to the airless bodies using simulated regolith particles such as UTPS-TB and UTPS-IB (Miyamoto et al., 2018) are also required.

Experimental Study to Determine the Best Compression Ratio of High-Resolution Images of Small Bodies for the Martian Moons eXploration (MMX) Mission

*Yuta Shimizu[1], Hiroaki Kamiyoshihara[1], Takafumi Niihara[1], Hideaki Miyamoto[1]

1. University of Tokyo

Data transmission rate becomes one of the biggest limiting factors in space explorations; technological advance in increasing pixel numbers of camera images dominates the improvement of the data transmission rate. Yet, high demand exists for high-resolution images especially in geological studies, and thus there is a tradeoff between the spatial resolutions (or pixel numbers) and the number of images to be transmitted to Earth. The telecommunications issue is critical for Martian Moons eXploration (MMX) mission that explore either/both Phobos and Deimos and return samples. Especially, timely transmission of high-resolution images is required for the selection of sampling site both in terms of scientific impacts and of the landing safety. The highest image resolution of the current camera configuration is as good as several tens of centimeters per pixel and the size of image is 3296 x 2472 pixels, which means 7 color (3 bands) images can be up to 1 GB if no compression is considered. During the landing phase, such large data have to be sent at the limited bitrate (< 32 kbps) to select landing and sampling sites, while the landing duration is about 4 hours. Thus, considering the best compression scheme of images is a big issue for landing operation. Lossy compression can significantly reduce the sizes of images, though images can be scientifically worthless when compressed too much. The best compression ratio should make the sizes of images as small as possible without losing scientific importance.

Here, we develop a method of rapidly determining the best compression ratio of high-resolution images of the surface of small bodies. For preparing the image studied in this research, we take an experimental scheme, where we develop a simulated Phobos surface by using a high-quality simulant of Phobos regolith (UTPS-TB) and take simulated images of the surface of Phobos in somehow similar condition with the camera of the MMX mission. The images are compressed by JPEG2000, which is planned to be used in MMX mission, and the influence of the compression is analyzed by objective methods such as Structural SIMilarity (SSIM) and entropy of image. The results shows that they are able to rapidly detect the exact ratio, in which the quality of the images started to be diminished.

Moreover, by defining scientific value of images as detectability of rock gravel on the surface of celestial bodies and showing that the loss of scientific value can be expressed by the change in the value of slope of Cumulative Size-Frequency Distribution (CSFD) of gravel, we carefully confirm whether the decrease in the image quality is truly connected with the loss of scientific information such as for landing operations and conclude that those objective methods can determine the best compression ratio. By using those methods, the spacecraft can autonomously complete the process of finding the best compression ratio, compressing images and sending it to the ground within a few minutes even if it has only a limited transmission rate.

Wed. May 29, 2019 1:45 PM - 3:15 PM JST | Wed. May 29, 2019 4:45 AM - 6:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder), Chairperson:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology)

Recent planetary explorations have revealed that almost all solid bodies in the solar system are covered with small particles, called regolith. The surface geology, especially regolith behavior on the surfaces of solid bodies, becomes increasingly more important as represented by Hayabusa mission and other on-going and planned sample-return missions such as Hayabusa2, OSIRIS-REx, and MMX.

For fully understanding the regolith science, it is required to know and compare the regolith conditions on various celestial bodies, from asteroids to planets, with various methods.

Therefore, this session welcomes broad topics related to regolith on various celestial bodies, such as asteroids, comets, the Moon, the martian moons, Mars, etc. Papers on the formation, evolution, and alteration processes of regolith particles and regolith systems on the surface of planetary bodies, remote and in-situ observational results and techniques, analyses and results of returned samples, and laboratory, numerical, and theoretical studies on the fundamental physical and chemical processes are all welcome.

Note that what we call regolith is not just fine grains: all kinds of materials (more or less loose) that lie on the surface, from cobbles to finer grains, are our targets.

Moganite in a lunar meteorite as a trace of H_2O ice in the lunar regolith

*Masahiro KAYAMA[1]

1. Tohoku University

A large amount of H_2O ice has been observed on the regolith surface near the lunar poles by remote sensing spacecraft. However, only sparse evidence for H_2O ice beneath the top few millimeters of the regolith exists because neutron spectrometers cannot distinguish forms of H and near-infrared spectrometers are only sensitive to the optical surface. Furthermore, traces of H_2O ice have not yet been found from the lunar samples. Here, 13 different lunar meteorites with various lithologies have been investigated using micro-Raman spectrometry, electron microscopy, and synchrotron angle-dispersive x-ray diffraction (SR-XRD) to find a trace of H_2O ice in the subsurface. Consequently, moganite has been discovered from the KREEP (high potassium, rare-earth element, and phosphorous)-like gabbroic-basaltic brecciated meteorite NWA 2727 that may originate from the local crater sites within the Procellarum terranes.

Moganite (monoclinic SiO_2 phase that belongs to the *I2/a* space group) coexisting with coesite and stishovite (high-pressure SiO_2 polymorphs) was discovered only in NWA2727 by the micro-Raman spectrometry. NWA 2727 is mainly composed of gabbroic and basaltic clasts containing their breccia matrix, where only the breccia matrix contain moganite-bearing silica micrograins (2 to 13 mm in radius) between the constituent minerals (olivine, pyroxene and plagioclase). The SR-XRD analyses of these silica micrograins in the breccia matrix indicate a characteristic diffraction pattern that is in good agreement with the structure of moganite. However, no moganite was discovered from the basaltic and gabbroic clasts of NWA 2727 as well as in the other lunar meteorites selected here. Transmission electron microscopy of the silica micrograins demonstrates the aggregates of numerous euhedral or subhedral moganite nanoparticles (average radius of 4.5 nm).

Moganite was discovered in only one of those 13 samples. If terrestrial weathering had produced moganite in the lunar meteorites, there should be moganite present in all the samples, especially lunar meteorites fell to Earth around the same time (NWA 2977, 3333, and 6950 as measured here), but this was not the case. Furthermore, many previous researches on natural occurrences and laboratory experiments conclude that moganite is restricted to formation by precipitating from alkaline silicic acid (H_4SiO_4) water under high-pressure consolidation at >100 MPa, which is distinctly different environment from the desert that NWA 2727 found. A part of the moganite had changed into the coesite and stishovite, indicating their formation through heavy impact collisions on the Moon. These facts confirm our theory that it could not have formed in the desert.

Formation of lunar moganite can be interpreted based on the present and previous works as follows. Alkaline water-bearing carbonaceous chondrite collisions delivered abundant alkaline water to the lunar surface at <2.67 Ga. After the collisions, the delivered water was captured as fluid inside the breccia during the shock-induced consolidation. On the sunlit surface, lunar moganite precipitated from this captured alkaline water. Simultaneously, such captured water got cold-trapped at the lunar regolith in the subsurface and may still remain as ice underneath the local crater sites within the Procellarum terranes. Lunar moganite coexists with coesite and stishovite, thereby implying that a trace of the subsurface water ice was brought from the Moon by the recent impact at <1–30 Ma. Our moganite-precipitation simulation

©2019. Japan Geoscience Union. All Right Reserved.

modeling concludes a subsurface H_2O concentration higher than the estimated bulk content of 0.6 wt % is expected to still remain as ice. This value is in excellent agreement with the concentrations of H_2O ice on the poles by remote sensing spacecraft observation. Thus, the subsurface is expected to be the abundant and available water resource for future lunar explorations.

Simulating the Lunar Soil: a Japanese Lunar Soil Simulant FJS-1 and Its Properties

*Naohiro Uyama[1], Hiroshi Kanamori[1], Shigeru Aoki[1]

1. Shimizu Corporation

Going back to the Moon is a world-wide trend of space exploration based on the international cooperation as the Global Exploration Roadmap (GER3) stated. JAXA also proposed future human exploration missions around 2030 within the international cooperation. All scenarios have their bases on the scientific observation that a plenty of water (hydrogen) is trapped in the polar regions, especially inside the craters of permanent shadow. In order to investigate those water and other existing volatiles, however, many engineering challenges wait for human and robotic missions even only from the view of lunar soil, such as traversing the soft soil, drilling and/or excavating the soil, and handling the soil for desired sample collections and scientific processes, and more for the in-situ resource utilization and human missions. Thus, the ground tests prior to launches are of great importance to increase the possibility of mission success.

In order to offer opportunities for the community to perform ground tests, we have manufactured a lunar soil simulant, called FJS-1. The investigation of FJS-1 shows that many properties of FJS-1 lies close to the data collected from Apollo samples. For instance, the particle size distribution lies below 2 [mm]; the median particle size is between 70 and 75 [micro-m]; the shear strength, i.e. cohesion c, is 0 to 10 [kN/m2]; and the internal friction angle, phi, is 30 to 50 [deg]. The chemical composition is also close to Apollo samples with slight difference that FJS-1 contains more ferric oxide and Alkaline components than Apollo samples.

In addition to the basic properties, we started investigating the strength of frozen lunar soil using FJS-1. Determining the optimized configuration of a sampler such as a drill or an excavator needs the information of actual lunar soil; however, nobody knows the actual state, in other words, the ground truth of lunar water/ice yet. We therefore decided to investigate the strength of frozen soil, utilizing FJS-1, for the future use for drill or excavator designs. The qualitative observation from our first experiment is that the frozen FJS-1 at temperature below 0 [degC] became slightly loose when FJS-1 contained 0.5 to 1.0 [wt%] of water, and that the strength drastically increased above 2 [wt%]. We will conduct more experiments to collect a set of frozen soil strength to offer the estimates of the strength of lunar soil for future lunar exploration missions.

Experimental estimation of regolith scattering behavior when a space lander touches on a planetary body

*Mitsuhisa Baba[1], Ronald Louis Ballouz[2], Masatsugu Otsuki[1]

1. Japan Aerospace Exploration Agency, 2. The University of Arizona

A planetary lander, which needs to land on and lift up from a planetary surface, needs to be concerned with levitated regolith. Regolith scattered by the landing foot pad might attach to or damage on-board instruments, such as the spacecraft’ s camera suite. To design the landing probe, it is necessary to estimate the expected area of the regolith that the probe may scatter. Here we show an experimental approach that was developed to study the behavior of scattered regolith under a vacuum environment. For the probe design, it is necessary to precisely measure the initial ejection angle, ejection velocity, and the amount of regolith that the landing foot pad scatters.

In order to characterize scattered-particle behavior, drop tests in a large vacuum chamber were conducted. A cylindrical mass projectile, mimicking the lander foot pad, fell freely from various heights in the vacuum chamber. The mass lands in a sandbox filled with silica sand and forms a crater with scattered sand particles. During silica sand scattering, a high-speed camera detected particle highlighted by a line laser. Initial ejection velocities and the ejection angles were estimated by processing the images of the impact site, captured by the high-speed camera.

The result of our study revealed that the ejection angle of scattered grains is not sensitive to the impact kinetic energy of the projectile. Our results are consistent with previous studies that showed a similar relationship between impact kinetic energy and ejection angle, but for lower impact energies. Moreover, we find that for impact speeds of ~ 4 m/s, the initial ejection velocity of a majority of the silica sand particle is distributed around 1 m/s.

Our experimental approach can be applied to various kinds of planetary regolith, such as Phobos simulant for the Martian Moons eXploration(MMX). These results help us to understand how to determine the optimal design conditions for a landing probe. Further studies that account for the effect of microgravity and changes to the bulk density and porosity of the regolith need to be undertaken based on drop tower test and numerical simulation.

Ray systems in granular cratering

*Tapan Sabuwala[1], Christian Butcher[1], Gustavo Gioia[1], Pinaki Chakraborty[1]

1. Okinawa Institute of Science and Technology Graduate University

In classical experiments of granular cratering, a ball dropped on a smooth bed of grains ends up within a crater surrounded by a uniform blanket of ejecta. We show that such a uniform blanket of ejecta changes to a ray system, or set of radial streaks of ejecta, where the surface of the granular bed includes undulations. By carrying out numerous experiments and computational simulations thereof, we ascertain that the number of rays in a ray system $\propto D/\lambda$, where D is the diameter of the ball and λ the wavelength of the undulations. Further, we show that the ejecta in a ray system originates from valleys located in a narrow annulus of diameter D with center at the site of impact. The impacting ball creates a hemispherical shockwave, whose interaction with the surficial valleys engenders the ray system. Our findings may help shed light on the enigmatic ray systems that ring many impact craters on the Moon and other planetary bodies.

Scaling of oblique impact cratering onto inclined granular layer

Shinta Takizawa[1], *Hiroaki Katsuragi[1]

1. Graduate School of Environmental Studies, Nagoya University

Empirical (Pi-group) scaling laws for craters created on an inclined granular layer by an oblique impact of a spherical projectile were experimentally obtained. In the experiment, inclination angle and incident angle were systematically (and independently) varied in the ranges of 0 to 33 degree and 10 to 170 degree, respectively. A spherical projectile (diameter 6 mm) was impacted onto a surface of inclined granular layer with an impact speed 10 - 100 m/s. Two high-speed cameras and laser profilometry system were used to measure the impact speed, angle, and final crater shape. From the experimental results, we found following behaviors. When the incident angle is small, almost symmetric craters were observed. However, the collapse of the upper crater wall was triggered when the inclination angle is large enough. The scale of the collapse grows as the inclination angle is increased. In addition, the crater volume strongly depends on inclination angle. By combining these experimental findings, we developed the empirical scaling for crater dimensions and aspect ratios. The obtained scaling is consistent with previous works on the normal impact to horizontal granular surface with high impact speed. We also discuss a possible way to evaluate the impact conditions from the actual astronomical impact craters.

Experimental study on gravitational effects on crater size formed by low-velocity impacts into granular media

*Masato Kiuchi[1], Akiko M Nakamura[2], Koji Wada[3]

1. Japan aerospace exploration agency, Institute of space and astronautical science, 2. Department of Planetology, Kobe University, 3. Planetary Exploration Research Center, Chiba Institute of Technology

Craters on regolith surface can be formed at various impact velocities. When secondary craters form on the surface of small bodies, such as asteroids and comets, the impactors have very low-velocities of several m s^{-1} or less due to the small escape velocity of the bodies. These secondary collisions can increase the number of small craters on the surface and will affect the surface topography of small bodies. Therefore, it is important to investigate low-velocity impacts on granular materials that simulate regolith particles to understand the low-velocity cratering process on the surface of small bodies.

Low-velocity impact experiments with velocities in the range of several m s^{-1} and granular targets have been conducted to investigate crater size and develop empirical relationships between impact conditions and crater size under 1 G (e.g., Uehara et al., 2003; Walsh et al., 2003). However, it was found that the impact velocity dependence of crater diameter was inconsistent between the hypervelocity impact experiments conducted at low and high-gravity conditions (Gault and Wedekind, 1977; Schmidt and Housen, 1987) and the low-velocity impact experiments conducted under 1 G (Kiuchi et al., 2018, JpGU meeting).

We collected data of crater diameter on granular materials with impact velocities ranging from 1 to 4.6 m s^{-1} under a gravity range of 0.20 to 1 G to investigate the effects of gravity on crater diameter using a drop system developed for reduced gravity impact experiments (Kiuchi and Nakamura, 2015 JPGU meeting). Most of our experiments were conducted under 10^5 Pa for comparison with the low-velocity experiments under 1 G reported in previous studies, but we also conducted several experiments under 7 Pa according to the atmosphere-less condition of small bodies.

This time we newly organized our experimental results in which the gravity was changed using the atmospheric pressure dependence. As a result, the exponent values of gravity became close to that obtained by the high-velocity experiment (Gault and Wedekind, 1977). We compared our results with high-velocity experiments reported in previous studies. Our results for the glass projectile and the sand target almost agreed with the previous high-velocity crater-size scaling- law (Housen and Holsapple, 2011) when the atmospheric effect was taken into account, but the crater diameter for the steel projectile and the sand target was lower than that for the glass projectile. This result shows that the crater-size scaling- law obtained for high-velocity impact can be applied to low-velocity impacts of several m s^{-1} under reduced pressure when the density ratio of the projectile to the target is close to unity. The same scaling applies over a very wide range of impact velocities.

[P-PS02] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Observatoire De La Cote D'Azur), Kevin John Walsh(Southwest Research Institute Boulder), Chairperson:Akiko Nakamura(Graduate School of Science, Kobe University)

Recent planetary explorations have revealed that almost all solid bodies in the solar system are covered with small particles, called regolith. The surface geology, especially regolith behavior on the surfaces of solid bodies, becomes increasingly more important as represented by Hayabusa mission and other on-going and planned sample-return missions such as Hayabusa2, OSIRIS-REx, and MMX.

For fully understanding the regolith science, it is required to know and compare the regolith conditions on various celestial bodies, from asteroids to planets, with various methods.

Therefore, this session welcomes broad topics related to regolith on various celestial bodies, such as asteroids, comets, the Moon, the martian moons, Mars, etc. Papers on the formation, evolution, and alteration processes of regolith particles and regolith systems on the surface of planetary bodies, remote and in-situ observational results and techniques, analyses and results of returned samples, and laboratory, numerical, and theoretical studies on the fundamental physical and chemical processes are all welcome.

Note that what we call regolith is not just fine grains: all kinds of materials (more or less loose) that lie on the surface, from cobbles to finer grains, are our targets.

Airless regolith bodies in the solar system are continually bombarded by meteoroids, modifying their surfaces and sustaining impact ejecta clouds. While large bodies like the Moon retain a significant fraction of ejected regolith, small asteroids shed this material into the interplanetary dust complex. Measurements of the lunar impact ejecta cloud found it was sustained by the known sporadic meteoroid sources. Here, we extend lunar ejecta measurements using a model of the meteoroid environment at 1 au to investigate the structure of an ejecta cloud at an eccentric airless body, asteroid 3200 Phaethon: the target of JAXA’ s DESTINY+ mission.

Due to Phaethon's large eccentricity, Phaethon's peak ejecta density at 1 au is approximately 30 times higher compared to a body in a circular orbit at 1 au, largely due to enhanced ejecta production from meteoroids shed from Jupiter Family Comets. Such asymmetric ejecta production suggests Phaethon experiences significantly different meteoroid-specific space weathering processes than a body with a similar semi-major axis on a circular orbit. We estimate impact ejecta processes at Phaethon shed approximately 1 ton per year, which is not sufficient to appreciably contribute to the Geminids meteoroid complex, yet provides ample ejecta densities to measure with an in-situ dust detector aboard DESTINY+. These results suggest eccentric asteroids shed more material than those on near-circular orbits, and are suitable candidates for in-situ dust detection and chemical characterization due to their amplified asymmetric ejecta production.

In this presentation, we will summarize recent efforts to constrain the evolution and ejection of asteroid regolith for 3200 Phaethon. We will present predicted impact counts for a dust detector on close flybys of Phaethon in preparation for JAXA’ s DESTINY+ mission and discuss how such measurements would provide critical insight into Phaethon’ s origin and evolution in a manner unique to dust detection data.

We will provide the most recent report on the detectability of an ejecta cloud around Asteroid (3200) Phaethon by the DESTINY$^+$ Dust Analyzer (DDA), based on a model of dust dynamics in the cloud. We demonstrate that solar radiation pressure plays a vital role in shaping the spatial distribution of dust particles in Phaethon's ejecta cloud, because small particles, albeit the majority, are expelled from the sunward direction. We find that the DDA will have an opportunity of detecting dust particles in the ejecta cloud of Phaethon during a flyby, depending on the closest approach to the asteroid, heliocentric distance, and the initial velocity of ejecta. There are no hazard from impacts of 100 μm-sized ejecta particles that potentially could make tiny holes on the surface of the spacecraft during a flyby.

In 2018, the Hayabusa2 spacecraft successfully carried out four descend operations toward Ryugu’s surface. During these operations, we acquired highly resolved optical and thermal images from altitudes below several hundred meters, using Hayabusa2’s Optical Navigation Camera (ONC-T) and Thermal Infrared Imager (TIR), respectively. Close-up thermal images by TIR indicate thermophysical properties of the surface materials and its regional difference, which cannot be resolved by higher altitude observations (e.g., home-position observations from 20 km altitude). The temperature depends mainly on the thermal inertia of the observed medium; higher thermal inertia materials have lower daytime temperatures. Optical images by ONC-T show detailed physical conditions of the surface materials, such as particle size distribution of pebbles, surface morphology of small boulders and craters. At the spacecraft altitude of 100 m, for example, TIR and ONC-T have pixel resolutions of 8.9 cm/pix and 1.1 cm/pix, respectively. In this study, we report on a comparison of TIR and ONC images, especially for boulders and craters.

BOULDERS: TIR close-up observations showed various boulders with different daytime temperatures, or different thermal inertia. Typical thermal inertia of boulders is about 300 J m^{-2} K^{-1} $s^{-0.5}$, but there are a few boulders with thermal inertia up to 1000 J m^{-2} K^{-1} $s^{-0.5}$. The thermal inertia of rocks is mainly controlled by porosity, and porous rock has lower thermal inertia. Therefore, TIR observations show that the porosity of boulders is variable. Furthermore, boulders with high thermal inertia (low porosity) observed by ONC-T were found to be relatively brighter and had a smooth surface. Such variation in porosity, optical brightness, and surface morphology of boulders on Ryugu’s surface might reflect the degree of thermal metamorphism (depth of the source) in the parent body. If the constituents of Ryugu originate from variable depths inside the parent body, this supports the idea of a rubble pile formation of Ryugu after the catastrophic disruption of the parent body. This will place important constraints on the thermal evolution of the parent body.

CRATERS: During the MINERVA descend operations at 21st Sep., we acquired highly resolved images of two craters with diameter of less than 35 m by TIR, but both craters exhibit different thermal characteristics. One crater has a hot spot close to the center of crater, where the thermal inertia is estimated to be less than 150 J m^{-2} K^{-1} $s^{-0.5}$. On the other hand, there seems to be no hot spot in the other crater. The difference in thermophysical properties between these craters might be attributed to formation age or original surface conditions. Our finding of a hot spot with low thermal inertia indicates the presence of a fine-particle deposit in the crater and regolith generation related to the cratering process on this low-gravity asteroid.

After a journey of almost four years to the C-type asteroid (162173) Ryugu, the MASCOT lander of the Hayabusa2 mission was delivered to the asteroid’s surface on October 3rd in 2018 and successfully performed in situ investigations. MASCOT was released from the mother spacecraft at an altitude of 41 m and came to rest on the surface at a site located at 22.31±0.05°S, 317.16±0.05°E. MASCOT observed the surface for a full day-night cycle using its four science instruments until batteries ran out after 17h and 7min. The payload consisting of a wide angle camera (MASCAM), an imaging IR spectrometer (MicrOmega), a multi-channel radiometer (MARA), and a magnetometer (MasMAG) provided a wealth of data which helped to characterize the asteroid’s surface down to millimeter scale. MasCAM images revealed a surface dominated by rocks and boulders without showing fine-grained material. Boulders appeared either bright with smooth faces and sharp edges or dark with cauliflower-like crumbly surfaces. Inclusions observed in high-resolution images showed that rocks had strong similarities with carbonaceous chondrites. Temperatures of a ~60 cm diameter rock that have been measured in situ, were found to be consistent with a thermal inertia of 282(+93, -35) J m^{-2} K^{-1} $s^{-1/2}$, much lower than anticipated when compared to samples in our meteorite collections. This indicated that rocks on Ryugu were highly porous and likely very friable. The remnant magnetization of Ryugu's surface material on scales larger than 1 m was estimated to be lower than $3 \cdot 10^{-6}$ Am^2/kg (the measurement limit of MasMAG). A preliminary analysis of the induction effect in Ryugu caused by the variation in the solar wind magnetic field revealed significantly high electrical conductivity (of the order 1 S/m).

The near-Earth Asteroid (101955) Bennu is currently being studied by the NASA OSIRIS-REx mission. This small, top-shaped asteroid has evidence of a diverse suite of geologic units, including impact craters, linear features, and abundant boulders at a range of sizes, geometric albedos, and morphologies. The surface of the asteroid appears to be old; however localized evidence of mass movement has been detected in various locations that suggests the surface is dynamic. The abundance of boulders on the surface varies widely with location, with concentrations of boulders located in local topographic lows (e.g. the interior of candidate impact craters, between linear ridges), suggesting that boulders travelled across the surface to result in these concentrations. Several locations that are abundant in boulders show evidence of imbrication in the local downslope direction, but evidence of imbrication is more localized than on other asteroids such as Itokawa. Evidence of mass movement at smaller particles sizes is also evident by burial of boulders: evidence of largescale W-E movement of material and burial of rocks has been identified, as well as pileup of boulders at locations downslope of scarps. In addition, the largest boulder on Bennu (~95 m diameter) appears to be partly buried, with a portion of the boulder of unknown size remaining in the subsurface. This boulder has an exposed face that extends vertically off the surface by ~20 m, suggesting that several tens of meters of finer-grained material could have accumulated to bury part of the boulder. The direction that material would have traveled to bury this boulder follows the regional slopes. As a comparison, the second largest boulder on Bennu (~50 m diameter) that is nearby albeit at a slightly higher latitude (45 S latitude, versus the buried boulder at 25 S latitude) is not buried –rather, this boulder appears to be perched on the surface. The variation in very large boulder burial suggests the surface of Bennu has potentially experienced large-scale material transport.

Recent ion irradiation experiments in laboratories suggest that space weathering may take place very rapidly [1], but telescopic observations of asteroids support much slower space weathering [2]. The spectral rejuvenation process on asteroid surfaces may hold a key for bridging the gap between the two opposite conclusions [3]. However, the nature of the spectral rejuvenation process has not been understood well yet. One approach for understanding the spectral rejuvenation process is to constrain the depth-age relation of surface layers on asteroids. In fact, imaging observations by Hayabusa2 revealed that smaller craters are highly depleted on the surface of the asteroid Ryugu [4], strongly suggesting that resurfacing is acting efficiently on near-surface layers. This depletion was already observed on Eros and Itokawa [5]. In this study, we analyze this depletion in small craters to constrain the resurfacing mechanism on small asteroids, such as Ryugu, Itokawa, and Eros. More specifically, we estimate the resurfacing age of Ryugu, Itokawa and Eros based on crater counting and crater production functions. Then we compare the analysis results with theoretical models for resurfacing mechanisms on such small asteroids.

Crater retention age can be estimated by using both the crater size frequency distribution (CSFD) and the crater production function (CPF). The CSFD on Ryugu shows that the large craters distribution (≧100m in diameter) is close to saturation level, but the number density of small craters (~10 m) is reduced by a factor of 100 [4]. Similar depletion in small craters is also observed on Itokawa [5]. We calculated crater retention ages for different size craters and derived the relation between crater retention ages and excavation depth of craters.

The CPFs on Ryugu, Itokawa, and Eros are estimated based on a classical main belt collisional evolution model and a scaling relation for crater formation. We used a scaling relation including armoring effect [6] for Ryugu and Itokawa to account for the high abundance of boulders on them. In this analysis, we used larger craters than ~10m in diameter. Finally, we derived the relation between crater retention age, t, and depth, d, of crater, $t \sim d^a$, where a is found to be 1.8±0.4 on Ryugu, 1.1±0.3 on Itokawa, and 1.9±0.3 on Eros, respectively. If crater degradation is controlled by a diffusion process, the relation between crater retention age t is proportional to the square of crater depth d, i.e., $t \sim d^2$. Ryugu's and Eros's power-law indices (a ~1.8-1.9) are consistent with diffusion (a = 2), which is not the case of Itokawa's power-law index. However, Itokawa's power-law index a increase to 1.9 if we include smaller craters than ~10m in

©2019. Japan Geoscience Union. All Right Reserved.

diameter in this analysis. This value is consistent with diffusion (a = 2). Actually, Michel et al. 2009 suggests that the depletion of small craters on Itokawa is reproduced by a seismic shaking model without taking an armoring effect into account [7]. The efficiency of an armoring effect for small craters on asteroids is uncertain, but an armoring effect may change the interpretation of CSFDs. In order to understand crater scaling for smaller craters, Small Carry-on Impactor (SCI) experiment on Hayabusa2 is important.

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Taishi Nakamoto(Tokyo Institute of Technology)

In June 2018, the Hayabusa 2 spacecraft arrived at the target asteroid Ryugu after three and half years journey. In addition, another spacecraft, OSIRIS-REx will soon arrive at its destination Bennu. With these arrivals, the solar system research is about to enter a new era. We have organized this small bodies session since 2012 and had a broad range of discussions from viewpoints of laboratory experiments, observations, space explorations, theoretical modeling, and sample analyses. In particular, this time, we aim to hold this session to bring the latest research on solar system small bodies, focusing on the initial results of Hayabusa 2 and OSIRIS-REx. Presentations in the related fields other than these two asteroidal missions are also welcomed.

Introduction: We used data collected by the Origins, Spectral Interpretation, Resource Identification, and Security–Regolith Explorer (OSIRIS-REx) spacecraft since November 1, 2018 to develop a global digital terrain model (DTM) of Bennu. The DTM is developed from images collected by the OSIRIS-REx Camera Suite using stereophotoclinometry (SPC). We validated the DTM independently using limb data and by the identification of keypoints between actual images and synthetic images rendered from the DTM. The results are also compared to an independent model derived from range measurements collected by the OSIRIS-REx Laser Altimeter (OLA). While developing the global model, we also refine the pole orientation and rotational state of the asteroid. The characteristics of the resulting global digital terrain model provide constraints on the factors responsible for the origin and evolution of Bennu’s shape and surface.

Digital Terrain Model Construction from Imaging: About 1500 OCAMS images with ground sample distance ranging from 30 to 200 m were used to develop the global DTM of Bennu. We used distant limb data of Bennu to construct an initial DTM of Bennu. Then a combination of geometric stereo data and surface lighting conditions (or photoclinometry) modeled small patches (or maplets) of terrain across the asteroid. Geometric stereo typically defines the location of the center of each maplet, while the surface tilts across the maplet are estimated by best fitting the brightness variations of images that contain some portion of the maplet. These maplets are then combined to build a global model. The model increases in detail, accuracy, and precision as higher-resolution images and images with different viewing conditions are incorporated.

©2019. Japan Geoscience Union. All Right Reserved.

Digital Terrain Model Construction from Laser Altimetry: We collated several six-hour linear scans obtained by OLA during orbit around Bennu to make an independent shape model of Bennu at a resolution equivalent to the one derived from imaging. This DTM is improved relative to the SPC-derived model because OLA better resolves the heights, and extent of 1 to 3m boulders across the surface of the asteroid.

Bennu’ s Geomorphological and Structural Properties: The evaluation of the both models shows that the average size of the asteroid is 490.06 ±0.16 m.

The model shows the presence of several features:
-An equatorial ridge that is muted, and is diamond-shaped when viewed from the pole;
-Topographic north-south ridges that extend in some instances from pole to pole. The ridges influence the distribution of boulders, which are frequently concentrated between the ridges;
-Large craters that influence some of the attributes of the shape, primarily along the equator;
-A few large protruding boulders >40 m in diameter and >10 m high, mostly in the southern hemisphere;
-Grooves, scarps, and troughs that in some instances extend several 10s to 100s of meters, with depths ranging from 2–10 m.

Conclusion: The initial shape characteristics suggest that Bennu has some interior stiffness. Considering past modeling efforts investigating deformation due to spin-up, the lack of a circular equatorial ridge with a pronounced bulge, and the presence of high standing north-south ridges indicate that in spite of an abundance of evidence for material moving towards the equator, Bennu has interior structure that resists deformation.

NASA’s OSIRIS-REx sample return mission has been observing the near-Earth Asteroid (101955) Bennu since December 2018 and will be collecting a sample of the surface in the summer of 2020, to be returned to Earth in 2023. Preliminary and ongoing observations have yielded much information about Bennu’s formation, evolution, and ongoing geologic activity. Here we report on the global geology of Bennu based on analyses of images combined with shape, mass, and slope measurements. Initial results suggest that Bennu is a rubble-pile asteroid, formed from a parent body that was collisionally disrupted and reaccumulated. The asteroid has a “top” shape which is spherical with an equatorial bulge, similar to other near-Earth asteroids including Ryugu as observed by the Hayabusa2 sample return space mission. Candidate impact craters have been observed at a range of diameters between ~10-150 m across the surface of Bennu, leading to a crater retention age of 100 million to 1 billion years. An apparent concentration of large crater candidates at low latitudes suggest that the equatorial ridge is stratigraphically old, and may have formed early in Bennu’s history or been inherited from the reaccumulation event which created the asteroid. Several linear features have been identified on Bennu, the largest of which are topographic highs that extend longitudinally from the northern polar regions to the equator. Boulders are concentrated between several of these linear ridges, as well as in the interior of large candidate craters. Boulders on Bennu appear to be geologically diverse. Boulder sizes range from < 3 m to ~95 m in diameter with large variations in geometric albedo, morphology, degree of burial, and state of degradation. Fractured boulders have been identified with various numbers, orientations, and widths of fractures. Distinct clasts within several boulders indicate they may be breccias, while piles of boulders may represent disaggregated polymict or brecciated boulders. Current imaging resolution cannot resolve centimeter-sized particles, so direct detections of regolith or other sub-cm sized particles have not been made. However, several small candidate craters (< 20 m diameter) have a significant lack of boulders relative to the surrounding terrain, and additional datasets suggest the presence of a component of fine-grained particles. Improved image resolution will aid in the identification of regolith deposits on Bennu.

The advent of near-Earth asteroid (NEA) encounters with spacecraft has provided a view of planetary surfaces evolving on the smallest objects yet explored. The arrival of OSIRIS-REx and Hayabusa2 at their target asteroids (101955) Bennu, with average diameter (d) = 0.49 km, and (162173) Ryugu (d = 0.90 km), revealed cratered top-shaped worlds with signs of surface mobility [1, 2]. Compared to larger planetary bodies, Bennu and Ryugu’s small sizes and gravities challenge the conventional understanding of surface modification mechanisms, such as the redistribution of boulders on the surface or the erasure of craters.

On the larger NEA (433) Eros (d = 16.8 km), boulders were spatially correlated with impact craters, which degrade through impact-induced seismic shaking [3]. However, our poor understanding of rubble-pile interiors [4], combined with processes that operate more efficiently on smaller NEAs (such as thermal re-radiation torques, i.e., the YORP effect [5]), introduces new complexities to understanding surface mobility on Bennu and Ryugu.

Here, we first present evidence of a dynamic surface on Bennu and Ryugu. Then, we present an analysis of the dynamical processes that may dominate the surface modification of small top-shaped NEAs. We model the redistribution of material on the surface due to different input energy sources: i) impact-induced seismic shaking, ii) YORP spin-up, iii) impact cratering, and iv) planetary encounters. We use a combination of techniques that allows us to approach the problem at multiple length and time scales. The first step models the global effect of the energy sources using analytical techniques. In the second step, we model the fine grain scale interactions in a microgravity environment in short timescales using a particle dynamics code [6,7]. Finally, we propagate the accumulated effect of the fine-scale interactions by integrating individual surface modifications over the typical timescale of each individual process. The results are used to assess which of the above listed mechanisms are the most effective at transforming small NEA surfaces.

Visualization and Analysis of Solar System Small Bodies with NASA's Solar System Treks Project

*Brian Hamilton Day[1], Emily Law[2]

1. NASA Solar System Exploration Research Virtual Institute, NASA Ames Research Center, 2. NASA Jet Propulsion Laboratory, California Institute of Technology

In its investigations of Vesta and Ceres, NASA's Dawn mission has returned spectacular data detailing the surfaces of these two prominent small bodies in our Solar System's asteroid belt. In order to greatly facilitate dissemination, visualization, and analysis of this data, and public understanding of the mission, the Dawn mission has partnered with NASA's Solar System Treks Project (SSTP). SSTP has recently released an update to the Vesta Trek online portal (https://trek.nasa.gov/vesta/) and has released a new Ceres Trek portal (https://trek.nasa.gov/ceres/).

This presentation will showcase the use of the Ceres Trek and Vesta Trek portals and demonstrate how they can be used to visualize and analyze particularly interesting landforms such as the pitted terrain on Vesta and relic cryovolcanoes on Ceres. We will also demonstrate the new VR capability that has been added to the portals, allowing users to generate their own virtual reality flyovers for any user-defined paths along the bodies' surfaces. In addition to highlighting the portals for Ceres and Vesta, the presentation will preview additional portals being planned/developed for other small bodies. NASA and JAXA have requested the development of a portal for the asteroid Ryugu to facilitate dissemination, visualization, and analysis of data from Japan's Hayabusa2 mission, and a portal for Mars' moon Phobos in support of mission planning for Japan's MMX mission. We are also planning a portal for the asteroid Bennu with data from the OSIRIS-Rex mission.

All of these products are efforts in the NASA Solar System Treks Project (SSTP), available at https://trek.nasa.gov. NASA's Solar System Trek online portals provide web-based suites of interactive data visualization and analysis tools to enable mission planners, planetary scientists, students, and the general public to access mapped data products from past and current missions for a growing number of planetary bodies including the Moon, Mars, Vesta, etc. These portals are being used for site selection and analysis by NASA and a number of its international partners, supporting upcoming missions. In addition to demonstrating the capabilities of selected portals in this presentation, we will solicit input from the community for ideas for future enhancements to the portals.

Density Distribution within Small Solar System Bodies Based on Smooth Terrain Shape: Asteroid 25143 Itokawa and Comet 67P/Churyumov-Gerasimenko

*Masanori Kanamaru[1], Sho Sasaki[1], Mark Wieczorek[2]

1. Osaka University, 2. Côte d'Azur Observatory

Small solar system bodies are the remnants of the early stage of the solar system formation. Shapes and interior structures of small bodies tell us about how they formed and evolved. Particularly, the interior density distribution of small bodies is an important clue for better understanding of planetesimal collisions and subsequent accumulation processes. However, we have much less information about their interiors than their surface properties, partly because it is difficult to measure the exterior gravity precisely in a small body mission. We have investigated a method to estimate density distribution within a small body based on combining spacecraft imagery and the simulated gravity field on the surface of the small body (Kanamaru and Sasaki, 2019; Kanamaru, Sasaki and Wieczorek, in prep.).

If a small body possesses loose regolith sufficiently, over geologic time, impact-induced seismic shaking or cometary activity may have triggered mass movement from a high standing region to a low standing region (Richardson and Bowling, 2014). Our inversion of density distribution assumes that a very flat region on a small body, which is covered with fine gravels and associated with the low standing area in gravitational potential, might approximate an equi-potential surface. Therefore, the inversion processes include (1) mapping a smooth terrain on a 3D shape model of the small body using the Small Body Mapping Tool, and (2) computing dynamic elevations above a reference potential surface given ununiform density distribution (as shown in the upper left panel in Figure). As a criteria for mapping the smooth terrain, we also used a surface roughness defined as the standard deviation of the dynamic elevations within a circle of a specific scale (upper right panel in Figure). The misfit between the smooth terrains and the equi-potential surface is characterized by the standard deviation of the surface elevations within the flat region. On the above assumption of the topographic erosion process, the minimum misfit gives a best fitting density. We applied this method to asteroid Itokawa and comet 67P/Churyumov-Gerasimenko to investigate whether each of their lobes has a different density from the other or not.

There exists three major smooth terrains on Itokawa, named MUSES-C Regio, Sagamihara Regio and Uchinoura Regio. Given different densities to the two lobes of Itokawa (the head and body), the misfit for the smooth terrains is minimized where the head of Itokawa has a higher density than the mean bulk density. Based on the consideration of the systematic errors that arise from the uncertainty of the shape model itself and the calculation error of the gravity field, the allowable range of the head density is estimated to be 2,450 (2,220-2,670) kg/m^3 in contrast to the body density of 1,930 (1,976-1,879) kg/m^3 . Such a great contrast in density between the two lobes is consistent with the independent estimate of the center-of-mass/center-of-figure offset of Itokawa based on the YORP spin-up observation (Lowry et al., 2014).

The comet nucleus of 67P also has a smooth terrain called Hapi, which is likely to be covered with particles falling from other regions. In the density inversion for the two lobes of 67P, the head and body (see the middle left panel in Figure), the best fitting density of the head is similar to the mean bulk density unlike the case of Itokawa (lower panel in Figure). This result indicates a global scaled homogeneity of

©2019. Japan Geoscience Union. All Right Reserved.

67P, which is consistent with the gravity measurement by Patzold et al. (2016). If the bi-lobed shape of the comet was formed by a sub-catastrophic disruption of its parent body and merger of two main fragments (Jutzi and Benz, 2017), it is possible for the two lobes to have the same density.

Low temperature hydration experiments of cometary analog materials towards the Comet Astrobiology Exploration Sample Return (CAESAR) mission

*Aki Takigawa[1,4], Yuki Kimura[1], Yoshihiro Furukawa[2], Tomoki Nakamura[3]

1. Graduate School of Science, Kyoto University, 2. Institute of Low Temperature Science, 3. Graduate School of Science, Tohoku University, 4. The Hakubi Center for Advanced Research

The Comet Astrobiology Exploration Sample Return (CAESAR) mission is a final candidate for selection as the fourth mission in NASA’s New Frontiers Program. CAESARaims to acquire and return to Earth for laboratory analysis a minimum of 80 g of surface material from the nucleus of comet 67P/Churyumov-Gerasimenko (67P) (Squyres et al. 2018).Near-infrared spectra of a short-period comet 67P taken by the spectrometer onboard Rosseta spacecraft also indicate the absence of phyllosilicates in this comet (Capaccioni et al. 2015). In order to return anhydrated samples from 67P, optimal conditions for sampling should be determined because cometary dust particles especially amorphous silicates are highly reactive. Hydration process of anhydrous crystalline silicates such as olivine is already well-characterized, whereas reaction of water vapor or ice with amorphous silicates and organic matters at temperatures below H_2O freezing points has been poorly understood. In this study, we performed incubation experiments of amorphous silicates and organic matters under low temperature conditions with ice or vapor of D_2O/NH_3.

Amorphous silicate nanoparticles with three different chemical compositions and textures (S1, S2, and S3), and commercial glycine and ribose powder were used in the experiments. S1 is composed of ~100 nm particles having $MgSi_2O_5$composition prepared with sol-gel processing. S2 and S3 are condensates from high temperature gases. S2 is amorphous Mg_2SiO_4nanoparticles of ~80 nm in size synthesized in a Radio Frequency plasma system (Koike et al. 2010). S3 is 30-100 nm sized amorphous silicate with Mg/Si~0.93 embedded with metallic Fe-Ni particles condensed from a high temperature vapor of the CI chondritic ratios of Mg, Al, Ca, Fe, and Nito Si in an induction thermal plasma system (Kim et al. 2017).

Two types of ice were used in the experiments to evaluate the effects of corrosive gases in 67P; (A) Pure D_2O ice (99.90% purity) and (B) Mixture D_2O ice with 0.3% H_2O and 0.15% NH_3. Experiments with different ices were performed in different vacuum containers placed in a cryogenic box. About 5 mg of three silicate and glycine samples were put in different open-top glass bottles (2 ml). Approximately 50 mg of chipped ice fragments were put in the glass bottles and directly contact with the silicate and glycine samples. Roughly ~500 mg of the same ice fragments were put in the vacuum containers as a vapor source. The temperature of the cryogenic box sets at -17 or -27˚C. The samples were exposed with saturated vapor of ices for 10-120 days. As a comparison, exposure experiments of amorphous silicate samples (S1, S2, and S3) to H_2O vapor were also conducted at 25 and 50˚C for 10 days.

The exposed silicate samples were analyzed with a powder X-ray diffraction (XRD, Rigaku SmartLab) and Fourier-transform infrared spectroscopy (FT-IR; JASCO MFT-680, Thermo Nicolet iS5). The recovery rate of glycine (i.e., molar ratio of recovered glycine over starting glycine) and ribose were obtained by liquid chromatography tandem mass spectrometer (LC/MSMS; Shimadzu LCMS-8040).

No clear change of the XRD patterns and FT-IR spectra for S1, S2, and S3 was confirmed after the

©2019. Japan Geoscience Union. All Right Reserved.

experiments for <120 days at -17 and -27˚C. The recovery of glycine exposed to D_2O ice and NH_3 -containing D_2O ice for 10 days was 108±8 mol% and 105±8 mol%, respectively. The recovery of ribose exposed to D_2O ice and NH_3-containing D_2O ice for 10 days was 108±12 mol% and 105±12 mol%, respectively. Bicause the ice sublimation timescale is very short at the exoerimental temperatures, the present results indicate that cometary silicates at <-20˚C in comets are pristine even if they have high surface to volume ratio and amorphous structures as GEMS grains in anhydrous CP-IDPs.

Wed. May 29, 2019 10:45 AM - 12:15 PM JST | Wed. May 29, 2019 1:45 AM - 3:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory), Chairperson:Masateru Ishiguro(Seoul National University)

In June 2018, the Hayabusa 2 spacecraft arrived at the target asteroid Ryugu after three and half years journey. In addition, another spacecraft, OSIRIS-REx will soon arrive at its destination Bennu. With these arrivals, the solar system research is about to enter a new era. We have organized this small bodies session since 2012 and had a broad range of discussions from viewpoints of laboratory experiments, observations, space explorations, theoretical modeling, and sample analyses. In particular, this time, we aim to hold this session to bring the latest research on solar system small bodies, focusing on the initial results of Hayabusa 2 and OSIRIS-REx. Presentations in the related fields other than these two asteroidal missions are also welcomed.

DESTINY^{+} (Demonstration and Experiment of Space Technology for INterplanetary voYage, Phaethon fLyby and dUst Science) was selected in 2017 as a mission for JAXA/ISAS small-class program. It is a joint mission of technology demonstration and scientific observation. It will test high performance electric propelled vehicle technology and high-speed flyby of asteroid (3200) Phaethon and possibly asteroid 2005UD, which a break-up body from Phaethon as an extended mission. Engineering challenges include an up-close encounter at a distance of 500 km from Phaethon with radio-optical hybrid navigation guidance and control, and autonomous imaging based on optical information for target tracking during a high-speed flyby of 33km/sec. The science goal is to understand the nature and origin of cosmic dust brought onto the Earth, in the context of exogenous contribution of carbon and organics for possible prebiotic seeds of the terrestrial life. Phaethon is a parent body of Geminid meteor shower, and thus a known source to periodically provide dust to the Earth, via the dust stream. The science objectives are two folded: (1) in-situ analyses of velocity, arrival direction, mass and chemical composition of interplanetary and interstellar dust particles around 1 au, the dust trail, and nearby Phaethon, and (2) flyby imaging of Phaethon to study its geology, for understanding dust ejection mechanism of active asteroid and the surface compositional variation. High-spatial-resolution images of less than 5 meter per pixel are obtained with Telescopic camera (TCAP), and VIS-NIR spectral images of less than 100 meter per pixel are taken with multiband camera (MCAP). Mass, speed, arrival direction and chemical composition for each dust particle are analyzed with dust analyzer (DDA). Here, we present an overview and the current status of DESTINY^{+} mission.

Observational campaign of (3200) Phaethon and (155140) 2005UD in 2017-2018

*Fumi Yoshida[1], Tomoko Arai[1], Ko Ishibashi[1], Peng Hong[1], Ryo Ishimaru[1], DESTINY+ International observation collaborators

1. Planetary Exploration Research Center, Chiba Institute of Technology

(3200) Phaethon is the flyby target and (155140) 2005UD is a second flyby candidate of the DESTINY+ mission. Each asteroid approached to the Earth and became bright in 2017-2018. We utilize this opportunity and organized an observation campaign for both asteroids with international collaborators. The following people participated to the observational campaign : F. Yoshida, R. Ishimaru, K. Ishibashi, P. Hong, T. Arai (PERC/ChiTech), R. Okazaki, T. Sekiguchi, H. Naito, M. Imai, T. Ono (Hokkaido University of Education), S. Urakawa (Japan Spaceguard Association, Bisei Spaceguard Center), Y. Shinnaka (Kyoto Sanyo Univ.), T. Tanigawa (Sumoto high school), T. Yanagisawa, H. Kurosaki (JAXA), S. Abe, R. Kato (Nihon Univ.), N. Natira, T. Nishiumi (Univ. of Tokyo), M. Ishiguro (Seoul National University), M.-J. Kim, Y.-J. Choi, H.-K. Moon (KASI), D.-H. Kim, H.-J. Lee, S.-M. Lee (Chungbuk National University), Zhong-Yi Lin (Institute of Astronomy, National Central University), Xiaobin Wang (Yunnan Observatories, CAS), A. Serebryanskiy, M. Krugov, I. Reva (Fesenkov Astrophysical Institute), O. Burkhonov, E. Kamoliddin (UBAI), A. Peyrot, J-P. Teng (Les Makes Observatory), Y. Krugly (Institute of Astronomy of V.N. Karazin Kharkiv National University), I. M. Volkov (SAI MSU, INASAN), I. V. Nikolenko, S. I. Barabanov (INASAN), M. Kaplan, O. Erece (Akdeniz university), A. Sonka, S. Anghel (Astronomical Institute of Romanian Academy, Bucharest University), M. Birlan, F. Vachier, J. Berthier (Observatoire de Paris, IMCCE, CNRS), A. Klotz (CNRS-OMP-IRAP), P. Thierry (Auragne Observatory), O. Ivanova, M. Husarik (Astronomical Institute of the Slovak Academy of Sciences), E. Kuznetsov, D. Glamazda, G. Kaiser, E. Koren, V. Krushinsky, A. Popov, A. Shagabutdinov, Y. Vibe (Ural Federal University), M. Lazzarin, V. Petropoulou, I. Bertini, F. La Forgia (University of Padova), E. Palomba, E. D'aversa, A. Migliorini (INAF-IAPS), J. Vaubaillon (Observatoire de Paris), T. G. Wilson (University College London, Isaac Newton Group), O. Vaduvescu (Isaac Newton Group, Instituto de Astrofísica de Canarias), M. Popescu, Julia de Leon (Instituto de Astrofísica de Canarias), V. Lorenzi (Fundación Galileo Galilei - INAF, Instituto de Astrofísica de Canarias), M. Granvik (University of Helsinki / Luleå University of Technology), A. Penttilä (University of Helsinki), K. O. Muinonen (University of Helsinki / National Land Survey of Finland), T. Kareta, V. Reddy, D. S. Lauretta, B. Sharkey, C. Hergenrother (LPL, University of Arizona), J. A. Sanchez (PSI), T. Linder (Astronomical Research Institute), O. Kuhn, A. Conrad (Large Binocular Telescope Observatory), N. Moskovitz (Lowell Observatory), J. Masiero, A. Mainzer, L. Benner, M. Brozovic, S. Naidu, J. Giorgini (NASA JPL), E.L. Wright, D. Jewitt (UCLA), P. Taylor, E. Rivera-Valentin, S. Bhiravarasu, B. Aponte-Hernandez (Lunar and Planetary Institute), S. Marshall, F. Venditti, A. Virkki, L. Zambrano-Marin (Arecibo Observatory & University of Central Florida), C. R. Sanchez-Vahamonde (University of Western Ontario) (in the order from east to west in Fig.1).

Most of results obtained from the campaign were presented in IDP2019, which was held at Tokyo Skytree Town Campus of CIT, Japan, on February 12-14, 2019 (Fig. 2). So far, for both asteroids, rotation period, average colors, absolute magnitudes, spectra (0.4-2.5 μm) were obtained by photometry and spectroscopy during this observation campaign. Radar observation were done for Phaethon, and polarimetric observations were done for both asteroids. As preliminary results, the following properties were reported. Rotation periods: 5.2 hr (or 7.85 hr) for 2005UD, 3.6hr for Phaethon. Average colors : B-V=0.71, V-R=0.37, V-I=0.32 for 2005UD, B-V=0.73, V-R=0.36 for Phaethon. Absolute magnitude is 17.25 mag for 2005UD. No significant variation of rotationally resolved VIS-NIR spectra were seen for

©2019. Japan Geoscience Union. All Right Reserved.

both asteroids. However, a slight variation of visual spectra of Phaethon taken in 2017 was reported. Both asteroids are in C-complex. Interestingly, in the NIR spectra, both asteroids show totally different spectra each other: concave-up and blue for Phaethon, linear and red for 2005UD. The results from polarimetric observation show both asteroids are very similar. As for Phaethon, rotational variation in polarization was reported. Lightcurve observations revealed Phethon has top shape. Radar observation estimated the Phaethon's diameter is about 6km, and revealed no coma, no satellite. Possible craters (D>1km below 30 deg latitude, D=1.5km near equator), 600m wide dark spot (likely a flattened region) were discovered.

3200 Phaethon is an Apollo type near-Earth asteroid (NEA) categorized as a B-type asteroid which has been associated with the most intense meteor shower, Geminids. Cometary activity of Phaethon has been observed during its perihelion passage, ~0.140 AU, that motivates us to do direct exploration by the spacecraft, DESTINY+. It is also suggested that (155140) 2005 UD is a break-up pair of Phaethon because of dynamically similarity and same B-type spectrum type which is only ~5 % in NEA population. We examined the spectral properties of this asteroid pair to find the surface heterogeneity. Rotationally-resolved spectroscopic observations of Phaethon were carried out using 1.0-m telescopes at Lulin/Taiwan, and Kawabe/Wakayama, observatories in 2007 and 2017 apparitions, respectively. While Rotationally-resolved spectroscopic observation of 2005 UD was performed by using 4.1-m SOAR telescope at Cerro Tololo, Chili in 2018. It is presumably revealed that the surface heterogeneity, C-type like red slope surface area, of Phaethon was clearly seen from 2017 data, while no-existing surface heterogeneity was observed for 2005 UD.

When a meteoroid impacts the moon at several 10s of km/s, a brilliant flash at the point of impact can be observed as a flash in visible and near-infrared light. Lunar impact monitoring has a great advantage to detect large meteoroids in the mass range between 10s of grams and few kilograms corresponding to centimeters and tens of centimeters, which is as a bridge between visual meteors and small asteroids. We observed lunar impact flashes during Geminids maximum in 2018. 11 events were simultaneously detected from 2 locations at Nihon university and UEC, suggesting existence of relativity large fragments, several cm to several tens of cm in diameter, in the Geminid meteor stream.

In order to understand the Phaethon-Geminid stream Complex (PGC), ground-based telescopic observations of Geminids meteoroids and its parent splitting-bodies will be presented.

Thermal Radiation Pressure Force on Regolith Particles of Atmosphereless Bodies

*Yoonsoo P. Bach[1], Masateru Ishiguro[1]

1. Department of Physics and Astronomy, Seoul National University

It is suggested that thermal fracture near the perihelion is a possible mechanism to produce the dust trail of the near-Earth asteroid, (3200) Phaethon (Jewitt and Li, 2013, ApJ 771, L36). For this scenario to be true, generated dust particles should have been ejected from the surface before its next apparition to show the detectable activities (Li and Jewitt, 2013, ApJ, 145, 154). It is, however, not well understood how these particles were escalated from the regolith against the asteroid's gravity. In this study, we hypothesize that the thermal radiation pressure around the perihelion passage would exert substantial force on dust grains to be lifted up and contributes the dust tail formation with further help of solar radiation pressure. As a result, we find that roughly ~1-10 micron size dust grains can be ejected from Phaethon by the mechanism, while a detailed model of gravitational field is required for accurate range of the particle sizes. Our idea is not necessarily limited to Phaethon case, but is applicable to any atmosphereless bodies. We will explain how the thermal radiation pressure is effective at different distances from the sun.

Department of Physics and Astronomy, University of Texas at San Antonio, 8. Department of Space Astronomy and Astrophysics, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 9. Astrobiology Center, National Institutes of Natural Sciences

We will report the first detection of a single stellar occultation event candidate by a kilometer-sized (radius= 1-10 km) Kuiper belt object (KBO). Since the kilometer-sized KBOs are too faint to be detected directly, the monitoring of stellar occultation events is one possible way to discover them. With the aim of detecting the stellar occultation events, we launched an optical observation project named Organized Autotelescopes for Serendipitous Event Survey (OASES). We installed two low-cost OASES observation systems in different positions on the rooftop of the Miyako open-air school on Miyako Island, Miyakojima-shi, Okinawa Prefecture, Japan, and monitored up to 2000 stars simultaneously with a sampling cadence of 15.4Hz. In the 60-hour dataset obtained with the two-year OASES observations, we discovered one occultation candidate event by a KBO with a radius of approximately 1.3 km. Our present detection yields a surface number density of KBOs with radii exceeding 1.2 km is approximately 6×10^5 deg^{-2}. This surface number density favors a theoretical size distribution model with an excess signature at a radius of 1–2 km. The present results suggest that planetesimals before their runaway growth phase grew into kilometer-sized objects in the primordial outer Solar System and remain as one of the major populations in the present-day Kuiper belt.

AKARI/IRC near-infrared asteroid spectroscopic survey: AcuA-spec

*Fumihiko Usui[1], Sunao Hasegawa[2], Takafumi Ootsubo[2], Takashi Onaka[3,4]

Water is found in various forms in our solar system and is one of the most important ingredients in the origin of life. It provides evidence for the evolution of the solar system, especially its thermal history. Hydrated minerals are formed in environments where anhydrous rock and liquid water exist together, resulting from aqueous alteration. Because hydrated minerals are stable even above the sublimation temperature of water ice, they become an important reservoir to trace the water present in the history of the solar system unless they were reset by a temperature change after formation. Asteroids are considered to record the initial conditions of our solar nebula of 4.6 Ga ago. To explore the existence of water in the present solar system, it is indispensable to investigate the presence of hydrated minerals and water ice on various types of asteroids. Hydrated minerals and water ice exhibit diagnostic absorption features in the so-called 3 micron band (approximately 2.5-3.5 micron wavelength range). Many spectroscopic surveys have been conducted in the 3 micron band using ground-based observatories, which are severely affected by telluric absorption at around 2.8 micron. Space-borne observations, free from the effect, therefore, offer an excellent opportunity to study and identify the mineral species in asteroids.

The Infrared Camera (IRC) on board the AKARI satellite has a unique spectroscopic capability covering 2.5-5 microns continuously with a spectral resolution of R~100, which provides valuable data thanks to its high sensitivity and unique wavelength coverage. We conducted a spectroscopic survey of asteroids in the 3 micron band using IRC. In the warm mission period of AKARI, 147 pointed observations were performed for 66 asteroids in the grism mode in 2.5-5 microns. According to our observations, it is found that most C-complex asteroids, especially all Ch-, Cgh-, B-, and Cb-type asteroids, have obvious absorption features in the reflectance spectra at around 2.75 micron, which is attributed to OH-stretch in hydrated minerals. The peak wavelength of the 2.7 micron band feature is concentrated at around 2.75 micron: in particular, there is a correlation between the peak wavelength and the band depth among 13 C-complex asteroids. This trend can be understood in terms of the process where hydrated minerals are being heated up and gradually losing water, that is, the dehydration process.

In this talk, we present the spectroscopic survey of asteroids with AKARI for detecting the 2.7 micron absorption features and discuss scenarios for the formation and evolution of C-complex asteroids.

Impact experiments on low strength coarse-grained regolith simulating surface materials on asteroid Ryugu

*Yuya Yamamoto[1], Masahiko Arakawa[1], Minami Yasui[1], Sunao Hasegawa[2], Ryo Sugimura[1]

1. Graduate School of Science, Kobe University, 2. ISAS, JAXA

Impact cratering is one of the most important physical processes, then we study crater scaling laws and impact induced seismic waves in order to elucidate various flow processes on asteroids caused by impacts. The conventional crater scaling laws are categorized into two regions according to the controlling physics for the crater growth: they are gravity and material strength. A crater formed on regolith layer is surely controlled by the gravity, however when the regolith layer was filled with coarse particles with low mechanical strength, then the several coarse grains might be disrupted to consume the Ek. Thus, the crater size could be affected by the disruptions of the coarse grains. We speculate that not only the gravity but also the grain strength could affect the final crater size. Then, we made cratering experiments by using the target made of weak particles, and studied the effects of the particle strength on the crater scaling law and the impact induced seismic wave.

Experiments: Cratering experiments were conducted by using a gas gun set at Kobe University and ISAS. Granular targets were prepared by using weathered tuff granules with the size of 1 to 4mm (small particle) and the size of 1 to 4cm (large particle). The crush strength of these tuff particles was measured to be about 60 kPa. A spherical projectile with the size of 3mm which is made of iron, zirconia, alumina, glass, and nylon) was lunched at the impact velocity from 40 to 200m/s, and a spherical Al projectile with the size of 2mm was impacted at the impact velocity from 1.2 to 4.5km/s, then these two types of the projectile were impacted on the target surface at the normal direction. Impact cratering process and ejecta curtain growth were observed by a high-speed camera at 10^3-10^5 fps, and the video images were used to analyze ejecta particles to reconstruct the trajectories. After the shot, the crater morphology was recorded and the diameter and the depth were measured. Impact induced seismic waves were measured by using 3 accelerometers (specific frequency is 30kHz) set at different positions from the impact point, and a data logger was used to record the seismic data through charge amplifiers (data acquisition rate is 100kHz) connecting to the accelerometer.

Results: The crater size was found to increase with the projectile kinetic energy (Ek) at lower than 0.14J and at higher than 0.63J, so that the crater size was almost constant among them, and more the crater size obtained at very high Ek was almost on the extrapolated line from the relationship given by the low Ek data. The pi-scaling law was used to construct the relationship between normalized radius (πR) and normalized gravity (π2), and πR at small π2 was found to be rather smaller than that obtained for sand and glass beads targets, and more πR at large π2 was found to be consistent with that for sand and glass beads. More detail analysis tells us that all the data separated into two trends with large offset according to the impact velocity and the projectile material. This offset might be caused by the disruption of several tuff particles. The ejection velocities of each tuff particle were so scattered, then the distinctive relationship between initial position of particle and the ejection velocity was not derived in the low velocity range. The propagation velocity of the impact induced seismic wave was about 30 m/s, and it is 1/3 of that for glass beads. Furthermore, we found that the relationship between the maximum acceleration and the distance from the impact point was about 1/10 of that obtained for glass beads: the seismic wave in the tuff granules attenuated so quickly compared to the glass beads. But, when the distance is normalized by the crater radius, these relationships almost consistent each other, so that the

normalized distance could be a good parameter for the scaling of the acceleration of seismic wave.

Hayabusa2 is a sample-return mission for the C-type asteroid 162173 Ryugu. Hayabusa2 arrived at Ryugu on 27 June 2018, and various observations are still being conducted. Hayabusa2 performs multiband spectral observation by employing the optical navigation camera telescope (ONC-T)and can thereby obtain spectral map of Ryugu, which enables the study of material distribution and degree of space weathering of Ryugu. However, the sensitivity of ONC-T has been previously calibrated by incorporating the inflight data of stars with significant uncertainty. Hence, the authors aim to estimate the reflectance of Ryugu by employing Mobile Asteroid Surface Scout (MASCOT).
MASCOT comprises four instruments (MASCAM, MicrOmega, MARA, and MASMAG) that are employed for analyzing the soil of Ryugu. The upper side of the MASCOT landeris coated with white paint, and its spectral image was captured by ONC-T after its release from Hayabusa2 to Ryugu. The authors conducted on-ground reflectance measurement of a white plate whose white paint is identical to that of MASCOT. Hence, the primary objective of the proposed study is to estimate the reflectance of Ryugu by comparing MASCOT’ s white side’ s spectrum captured by ONC-T with the on-ground reflectance measurement of the white plate that has identical paint as MASCOT, and thus evaluate the validity.

DESTINY$^+$ (Demonstration and Experiment of Space Technology for INterplanetary voYage, Phaethon fLy-by and dUst Science) is a mission proposed for JAXA/ISAS Epsilon class small program, currently in the pre-project phase (Phase-A) with a launch targeted for 2023. DESTINY$^+$ is a joint mission of technology demonstration and scientific observation. The near-Earth asteroid (3200) Phaethon, the flyby target, is known as a parent body of the Geminid meteor shower, the size of which is approximately 5 to 6 km in diameter.

In this mission, spatially resolved images of Phaethon will be taken by two onboard cameras, the Telescopic CAmera for Phaethon (TCAP) and the Multiband CAmera for Phaethon (MCAP) during the flyby, in order to understand the nature of a meteor shower's parent body, which is one of the sources of interplanetary dust particles that are thought to be an important transport medium of organic matter to the Earth. The spacecraft flybys Phaethon with a relative speed of 30 to 40 km/s. Despite such a high flyby speed, the cameras are required to take un-blurred images of Phaethon.

The main purposes of the DESTINY$^+$ flyby observation of Phaethon is to understand the geology of a parent body of a meteor shower, and in particular constrain the dust ejection mechanisms from active (i.e., dust-ejecting) asteroids. The specific objectives of the camera observation are taking images for (1) obtaining the light curve of Phaethon in order to estimate the rotational period, (2) measuring the outline shape of Phaeton, (3) making a 3D shape model of Phaethon, (4) observing the surface geological features of Phaethon including dust ejection features, and (5) observing the surface material distribution of Phaethon. The observations (1) to (4) will be conducted by TCAP, and (5) by MCAP.

TCAP is a telescopic panchromatic camera for high spatial resolution imaging of the surface of Phaethon and have a rotational mirror for asteroid tracking during flyby. The rotational mirror can change the direction of the line of sight from 0 deg to 180 deg. This enables to observe Phaethon throughout the flyby with wide solar phase angles, which is extremely important to image and understand the surfaces of planetary bodies because the solar phase angle affects significantly the appearance of geological features in taken images.

MCAP is a multiband camera, the wavelengths of which are 400, 480, 550, 700, 850, and 950 nm (480 and 950 nm are optional bands) and has multiple optical systems and sensors in order to take all band images simultaneously. This is because there is not enough time to take each band image in turn with changing bandpass filters using such as a filter wheel in this high speed flyby mission. MCAP does not have a tracking mirror due to the weight limitation, and the line of sight of MCAP is fixed to the spacecraft with 40 deg off the relative velocity vector of the spacecraft.

We will explain the flyby imaging sequence of DESTINY$^+$, and show the conceptual designs of TCAP and MCAP.

It is important to determine the taxonomic types of small bodies in the solar system and further to study the spatial distribution of the planetary system. Among the small bodies, it is considered that there should be dormant comets that have lost a significant fraction of volatile materials in their subsurface layers. As a result, they are unable to produce any detectable coma and recognized as asteroids. It has been challenging to find out such dormant comet population from a list of known asteroids because of the asteroidal appearances. There are several attempts to find the dormant comet nuclei from asteroidal catalogs, for example, by using their reflectance spectra or orbital elements. However, little has been studied via polarimetry.
We conduct a polarimetric study of three candidates of dormant comet nuclei, (331471) 1984 QY1, (3552) Don Quixote and (944) Hidalgo, by using the 1.6-m Pirka Telescope at the Nayoro observatory (operated by Hokkaido University, Japan). We chose these asteroids in comet-like orbits (ACOs) based on the orbital elements (i.e., the Tisserand parameter with respect to Jupiter $T_J < 3$). We found that 1984 QY1 has a polarimetric albedo (geometric albedo determined via polarimetry) $p_V = 0.16 \pm 0.06$ while both Don Quixote and Hidalgo have Rc-band polarimetric albedo $p_R < 0.05$. Based on the polarimetric result together with a dynamical analysis, we conjectured that 1984 QY1 could be an S-type asteroid transported into the current orbit via 3:1 mean motion resonance with Jupiter. From the previous spectroscopic study, Don Quixote and Hidalgo are classified into D-type taxonomic group, which are typical of comet nuclei. In this presentation, we will introduce our polarimetric observations of ACOs and emphasize that polarimetry is a powerful tool for discriminating the asteroidal and cometary origins.

Dynamical lifetime of the Oort Cloud new comets under planetary perturbation

*Ito Takashi[1], Arika Higuchi[1]

1. National Astronomical Observatory of Japan

Nearly isotropic comets with very long orbital period are supposed to come from the Oort Cloud. Recent observational and theoretical studies have greatly revealed the dynamical nature of this cloud and its evolutionally history, but many issues are yet to be known. Our goal is to trace the dynamical evolution of the Oort Cloud new comets (OCNCs) produced by evolving comet cloud, hopefully estimating the fraction of OCNCs embedded in the current populations of the solar system small bodies. We combine two models to follow the dynamical evolution of OCNCs beginning from their production until their ejection out of the solar system, obtaining statistics of the dynamical lifetime of OCNCs: The first model is a semi-analytical one about the OCNC production in an evolving comet cloud under the perturbation of the galactic tide and stellar encounters. The second model numerically deals with planetary perturbation over OCNCs' dynamics in planetary region. The main results of the present study are: (1) Typical dynamical lifetime of OCNCs in our models turned out to be O(10^7) years. Once entering into the planetary region, most OCNCs stay there just for this timespan, then get ejected out of the solar system on hyperbolic orbits. (2) While averaged orbital inclination of OCNCs is small, the so-called "planet barrier" works rather effectively, preventing some OCNCs from penetrating into the terrestrial planetary region.

Thermal images from global to close-up scales taken by the Thermal Infrared Imager TIR [1] on Hayabusa2 [2] have revealed thermophysical properties of the C-type Near-Earth Asteroid 162173 Ryugu. On 27 June 2018, Hayabusa2 arrived at Ryugu and started remote sensing to characterize the nature of the asteroid and find the proper landing sites. *In situ* surface experiments were conducted using the robotic landers Minerva-II and Mascot [3]. *In situ* radiometry was conducted by MARA on MASCOT during a day-night cycle to derive the thermal inertia of a single boulder [4]. Ground-based observations [5] have been informed that the averaged thermal inertia of the asteroid is from 150 to 300 [tiu = J m^{-2} $s^{-0.5}$ K^{-1}] [5,6], corresponding to the surface covered with cm-sized granules.

TIR is the same design as the LIR on Akatsuki Venus climate orbiter [6], with 8 to 12 μm wavelength range, 328 x 248 effective pixels, and the FOV and IFOV of 16.7˚ x 12.7˚ and 0.051˚ per pixel, respectively. The first image of Ryugu detected by TIR was a point source on 6 June 2018, as was previously predicted [7]. Disc-resolved thermal images of Ryugu was taken from the HP on 30 June. The surface temperature was measured at 300 to 370K at about 1AU from the Sun, and gradually decreased with the solar distance. Comparison of the results with modeling [8] shows that the surface of Ryugu is not like fine regolith nor base rocks. Most of large boulders on Ryugu show temperatures almost the same as the surrounding surfaces. Diurnal temperature profiles of Ryugu are rather flatter than expected for a smooth terrain. Apparent thermal inertia is ~300 tiu or larger, but probably lower than the value when the surface roughness is considered. All these facts are consistent with a very rough and porous surface with low porosity (~35 ±10 %) [9] and the surrounding surface is dominated by porous rocks larger than several centimeters. Macro porosity should be 30 to 50 % to account for the bulk density of Ryugu ~1200 kg m^{-3}.

During the descent operations for the release of landers and the touchdowns for sample collection, TIR has taken close-up thermal images of the local sites, continually from the altitude of 500 m until the start of final descent at 10 or 20 m altitude. Close-up thermal images show the surface physical state and a variety of boulders. Most of the boulders in close-up images have temperatures similar to the surroundings but with more variety. A small number of boulders are remarkably colder than the surroundings, indicating dense rocks with lower porosity.

©2019. Japan Geoscience Union. All Right Reserved.

These facts indicate that Ryugu is probably a rubble pile of loosely-bound porous rocks, which might originate from the outer layer of parent body where compaction did not occur effectively, while the dense boulders might originate the compacted center region of parent body or from the different parent body. A different composition (e.g., organic rich materials) cannot be ruled out so far to account for such a low thermal inertia (and low density) of Ryugu.

Acknowledgments: The authors appreciate all the members of the Hayabusa2 Project and supporting staff for their technical assistance and scientific discussions. The thermal infrared imager (TIR) onboard the Hayabusa2 spacecraft performed thermography of the asteroid 162173 Ryugu through in-situ observations from 2018 to 2019. The primary purpose of TIR is to determine the global thermophysical properties of the asteroid and to reveal the evolutional history such as physical properties of the coalesced bodies, orbital changes due to radiation force, and the thermal evolution. This study introduces observed data of TIR and public data for scientists. The data are released by JAXA data archives (DARTS) and NASA PDS.

Multi-mission capability of HARMONICS

*Shintaro Tsunoda[1], Hirohide Demura[1], Naru Hirata[1]

1. The University of Aizu

This research has updated HARMONICS from a viewpoint of multi-mission capability, such as the Martian satellite exploration mission MMX in 2020s. Newly additional function is Switching on the shape model interface.
Bird view and visualization of FOV is important in robotics control. This technology is also used for deep space explorer missions.
HARMONICS is visualization tool of FOV(Field Of View) of scientific instruments and spacecraft’s position for HAYABUSA mission. The software has been updated by University of Aizu students of the past. The original HARMONICS had been developed by Nemoto(2006). GUI of HARMONICS had been replaced GUI library from GKT to Qt and added new functions, such as interactive modification of input mission plan by Ueno+(2017). The software had been add FOV frustum function by Aoki(2017). HARMONICS has tried to manage data for each project based on preference file in 2018.
HARMONICS should improved scalability to be compatible for ongoing mission. HARMONICS had been used to decide shutter chance by Camera Science Team in the asteroid Itokawa rendezvous of HAYABUSA. This software has not used in the asteroid Ryugu rendezvous of HAYABUSA2. The proven software should be use for future ongoing missions other than HAYABUSA. This research is development to HARMONICS adapt to ongoing missions.
I separated the designation of the data set from the source code and clarified the part edited by the user and the part edited by the developer.
HARMONICS has the function to switch and display data of different missions by this research. When users extend HARMONICS for multiple missions, users don’t need edit source code. User needs only kernel and the shape model of spacecraft and target asteroid. User do not need tough coding. User can use easily HARMONICS by editing preference file and kernel.

New interface of verification for calibration and conversion in HEAT : Hayabusa2 Exploration Assistant for TIR

*Tatsuro Kobayashi[1], Kentaro Suko[1], Hirohide Demura[1], Yoshiko Ogawa[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4]

1. The University of Aizu, 2. Ashikaga University, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Rikkyo University

Hayabusa2 is an ongoing mission for sample return from the asteroid Ryugu.
Candidates of sampling sites are selected based on surface mapping by optical instruments such as Thermal Camera (TIR). TIR observes surface infrared radiation from the asteroid. A software package peculiar to TIR is HEAT: Hayabusa2 Exploration Assistant for TIR. The software has four functions; Database for ground tests, calibration of flight data based on the ground tests, conversion from raw data to temperature one, and analysis for verifying the calibration and conversion. The converted data products are divided into some levels: Lv1 Raw data [DN], Lv2a Temperature [K], Lv2b is Brightness [W/m2], and higher thermal model with VTK format [K]. This research implements new interface of verification for calibration and conversion based on hearing and survey for requirements from TIR science team. The environment of implementation is following tool. OS: macOS Mojave 10.14.2. Computing language: C++, OpenGL. Frameworks: Qt5.4. Tools: Fits, Qt creator, SPICE toolkit, Visualization Toolkit, QcustomPlot, Xcode10.1.

Dust particle evolution of a near-Earth object 252P/LINEAR from near-infrared polarimetric observations in 2016

*Yuna G Kwon[1], Masateru Ishiguro[1], Jungmi Kwon[2], Daisuke Kuroda[3], Myungshin Im[1], Changsu Choi[1], Motohide Tamura[4], Takahiro Nagayama[5], Nobuyuki Kawai[6], Jun-ichi Watanabe[7]

1. Seoul National Univ., 2. ISAS/Japan Aerospace Exploration Agency, 3. Okayama Astrophysical Observatory, 4. The Univ. of Tokyo, 5. Kagoshima Univ., 6. Tokyo Institute of Technology, 7. National Astronomical Observatory of Japan

Comets, one of the least-altered leftovers from the early solar system, have probably preserved the primitive structure inside, whereas their surfaces become differentiated from initial states after repetitive orbital revolutions around the sun. Resurfacing makes the surface drier and more consolidated than the bulk nuclei, creating inert refractory dust layer (so-called “dust mantle”). Near-Infrared (NIR) polarimetry is theoretically expected to maximize the contrast of the porosity between inner fresh and evolved dust particles, by harboring more dust constituents in the single wavelength than the optical, and thus intensifying electromagnetic interference in dust agglomerates. Despite the advantage, only few studies have been conducted in this approach at multiple observation epochs. Herein, we present our new multi-band NIR polarimetric (1.25—2.25 microns) study of near-Earth object 252P/LINEAR over 12 days near perihelion; alongside broadband optical photometric (0.48—0.80 microns) data over four months in 2016 and a subsidiary dynamical simulation over 1000 year backward in time. 252P/LINEAR drew attention due to (1) its close approach to the Earth (~0.036 au on 2016 March 16), (2) its possible pairing to a comet P/2016 BA14 (PanSTARRS), and (3) its very low activity level despite its relatively young dynamical age. In this study, we detected two discontinuous brightness enhancements of 252P/LINEAR, particularly, the former of which accompanied a significant increase of NIR polarization degree of the comet (by ~13 % at most) with unusual blue polarimetric color. We will discuss the most probable scenario of the observed results, together with the orbital evolution of the comet and a dynamical association with its pair.

Performance Evaluation of TRIPOL on the 61-cm Telescope at Seoul National University for Polarimetric Observations of Solar System Small Bodies

*Sunho Jin[1], Masateru Ishiguro[1], Yuna G Kwon[1], Jooyeon Geem[1], Yoonsoo P. Bach[1], Jinguk Seo[1], Hiroshi Sasago[2], Shuji Sato[3]

1. Seoul National University, 2. Sasago Co.,Ltd, 3. Nagoya University

Polarimetry of solar system small bodies is a powerful technique for investigating their physical properties, such as albedos, particle sizes, and porosities of these bodies. Observational opportunities arise sometimes suddenly, that is, just after unforeseeable activations of comets and discoveries of near-miss asteroids. Here, we introduce our activity to install the polarimetric instrument, TRIPOL (Triple-Range Imager and POLarimeter) on the 61-cm telescope (a Ritchey-Chretien reflector with f/7.0) at the Center for Astronomy and Space Science, Seoul National University, and report an observational result of three comets. This combination provides an 8.0’ ´8.0’ field of view and pixel resolution of 0.94” pixel^{-1}. Throughout photometric observations, we determined the limiting magnitudes (defined as magnitudes for S/N=5) of 15.17±0.06 (g’-band), 15.68±0.01 (r’-band), 16.24±0.03 (I’-band), respectively, with total 240-seconds exposure (four 60-seconds exposure images, each was taken at different rotation angle for the half-wave plate). We also found that the instrumental polarizations are negligibly small, that is, -0.32±0.04% (g’-band), -0.36±0.05% (r’-band) and -0.21±0.04% (I’-band), while the polarization efficiencies are large enough to maximize the performance, that is, 97.52±0.03% (g’-band), 98.83±0.02% (r’-band) and 99.15±0.02% (I’-band).

With this instrument, we conducted polarimetric observations of three Jupiter-family comets, 21P/Giacobini-Zinner, 38P/Stephan-Oterma, and 46P/Wirtanen on a trial basis. It is known from a recent study that the polarization degrees of cometary dust particles are significantly influenced by gas emissions [1] With multiband data taken with TRIPOL, we eliminated an influence of gas contaminations and found that the dust polarization degrees of these three comets coincide with those of so-called ‘dust-rich comets’. From this result, we conjecture that the polarimetric property of Jupiter-family comets is broadly homogeneous, unlike asteroids. We plan to describe our future plan using the polarimetric system.

Smart Interface of HEAT: Hayabusa2 Exploration Assistant for TIR

*Kentaro Suko[1], Tatsuro Kobayashi[1], Hirohide Demura[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4]

1. The University of Aizu, 2. Ashikaga University, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Rikkyo University

The Hayabusa2 project is a sample return mission to the asteroid Ryugu. It was launched on Dec. 3, 2014, and it has been at Ryugu since June 27, 2018. Hayabusa2 has optical instrument called Thermal Infrared Imager (TIR). These main functions are to know natures of the asteroid and to select the candidate of safe landing sites for sampling based on thermos-physical properties of the surface. TIR records infrared radiation from the target as a digital number (DN). The infrared signal is affected by sensor-surrounding objects; lens, shutter, package, and case. TIR requires consideration about this effect when converts DN images to temperature one. This study improved conversion system to increase conversion efficiency.

Hayabusa2 TIR Science Team has developed an analysis supporting tool called Hayabusa2 Exploration Assistant for TIR (HEAT). HEAT is used to search TIR data interactively, display TIR images, and visualize thermal models. We receive TIR raw images (Product Level 1) from ISAS/JAXA and convert them to brightness temperature images (Level 2a) and radiance images (Level 2b) using HEAT at Univ. of Aizu. The converted images are provided to the Hayabusa2 project data server.

This part introduces a concept model. The spectral radiance emitted from a blackbody B(λ ,T) (W s r-1m-2) is given by the Planck function based on wavelength λ (m) and temperature T(K) as follows:

$$B(\lambda,T) = (2hc2/\lambda 5)^* (1/(\exp(\lambda kBT)-1))$$

H = 6.63*1034 (m2 kg s-2 s-1) is the Planck constant, c=2.9972*108(ms-1) is the speed of light, and KB= 1.38*10-23 (m2 kg s-2K-1) is the Boltzmann constant. The observed radiance L(T) (W sr−1 m−2) is as follows:

$$L(T)= \varepsilon \int BR(\lambda)d\lambda$$

ε is the spectral thermal emissivity, and R(λ) is the response function such as the detection efficiency of the bolometer, the measured transmittance of optics including the band-pass filter and the germanium lens. The calibration formula with two regressed parameters A and B is written as follows:

$$DN=A * L(T) + B$$

The converted temperatures of the Moon were lower than expected because each pixel did not cover the sunlit area entirely or due to roughness effect of the cratered terrain. TIR has been observing Ryugu in approach and rendezvous phases. The altitudes of TIR observations during the rendezvous phase range from 20 km to less than 10 m. This study has processed about 3000 Ryugu images observed by TIR since June 2018.

©2019. Japan Geoscience Union. All Right Reserved.

This study improved conversion system. Previous conversion system converts a TIR image one by one, but current conversion system converts TIR images in selected directory at once.

Experimental Study on Collision Crater Formed on Bulge Geography

*Yusaku Yokota[1], Yuya Yamamoto[2], Minami Yasui[2], Masahiko Arakawa[2]

1. Faculty of Science, Kobe University, 2. Graduate School of Science, Kobe University

An equatorial bulge was found on the surface of asteroid Ryugu and Bennu by recent spacecrafts of Hayabusa2 and OSIRIS-Rex, and ridge structures with various scales originated by geological activities have been recognized on icy satellites. Impact craters are dominant geological features on solid planets such as asteroids and satellites, and a crater rim are also recognized as a ridge or bulge with a circular shape. These bulges and ridges are shown to be erased with time because small scale impacts excavate and disrupt these topographies. It is well known that old craters gradually degraded by small impacts to get blurred and could be completely erased. We can expect the similar degradation process on large bulges and ridge structures, so that the life time of these structures by small impacts is a good indicator of the formation age of these structure by geologic activities. So far, the effect of small impacts on the degradation is estimated by using the results on the flat surface, but actually the surface of the bulge is curved and there is a summit on the bulge. Therefore, if we estimate the life time of the bulge structure, we should consider the effect of the topography such as a summit and curvature. Then, the impacts on the bulge structure was studied to clarify how the bulge structure affected the crater formation efficiency. In this study, we suppose the bulge made from regolith and boulders, such as an equatorial bulge of Ryugu and assume the crater formation process dominated by not the strength but the gravity.

We prepared a triangular prism target to simulate the bilge structure, and set it like that the base of this prism is rectangle, then it looks triangle when we look it at the horizontal direction, and we can look at the linear summit from the top view. Quartz sands with the size of 100μm was used to build the target and the angle of repose for this quartz sand is about 30 degree. The slope of the prism was measured from the base, and we set the angle from 20 to 30 degree. The quartz sands were filled into a transparent water tank with the depth of 20 cm to prepare the bulge structure. Impact experiments were conducted by using a vertical type gas gun, and the water tank was set in the chamber to evacuate below 1000 Pa. A alumina sphere projectile with the size of 3mm was launched at the velocity from 70 to 200 m/s, and it was impacted on the bulge in the vertical direction: the impact angle measured from the target surface was about 60 degree when the slope was 30 degree. The distance from the impact pint to the summit (deviation distance, d_d) was changed from 0 to 20mm.

We found that the crater shape strongly depended on the d_d, so the crater shape was an ellipsoid when the impact point was near the summit. Th major axis appeared along the linear summit and the minor axis appeared across the summit. The aspect ratio of the major axis to the minor axis gradually changed toward 1 with the increase of d_d. Moreover, the aspect ratio becomes large at the same d_d when the impact velocity increased. The major axis of the ellipsoid crater formed on the bulge was slightly larger than the crater diameter formed on the flat surface, and the slope angle might affect the size of the ellipsoid because we found that the crater formed on the slope of 30 degree was systematically larger than that formed on the slope of 20 degree. We also observed an asymmetric ejecta curtain from the impact point on the bulge, moreover the ejecta curtain was notice to be deformed so much at the impact point near the summit because of the effect of curvature of the bulge on the crater flow.

Initial analysis plan of soluble organic compounds for the Hayabusa2 sample from asteroid Ryugu

*Hiroshi Naraoka[1], Yoshinori Takano[2], Jason P. Dworkin[3], SOM Analysis Team

1. Department of Earth and Planetary Sciences, Research Center for Planetary Trace Organic Compounds, Kyushu University, 2. Japan Agency for Marine-Earth Science and Technology, 3. Astrochemistry Laboratory NASA Goddard Space Flight Center, Greenbelt, MD 20771 USA

The spectra of asteroid 162173 Ryugu taken by Near-Infrared Spectrometer (NIRS3) onboard Hayabusa2 are nearly featureless and consistent with carbonaceous chondrites (Matsuoka et al., 2018). The Hayabusa2 spacecraft will collect surface samples of Ryugu and deliver to the Earth during late 2020. The initial analysis of the Ryugu samples will focus on (1) detailed chemical and mineralogical characterization of the samples and (2) understanding the history of Ryugu and the Solar System in order to maximize the scientific achievement of the project and (3) to prove the scientific potential of the samples to the community for the analytical opportunity (Tachibana et al., 2014). We have organized an international team, consisting of 24 members currently, for the initial analysis of soluble organic matter (SOM) for the returned samples.
The primitive asteroidal materials are expected to contain diverse and complex (e.g. elemental, structural, and optical) organic matter all at low concentrations. The occurrence of SOM will provide clues to the origins of organic compounds as well as prebiotic molecules of potential relevance to origins of life on Earth and possibly elsewhere in the Solar System. We propose the comprehensive SOM analyses to reveal the chemical evolution of Ryugu using high-sensitive and high-resolution analytical methods as follows:

1) High-resolution mass spectrometry (HRMS) of various solvent extracts with electrospray ionization (ESI) coupled with or without nano-liquid chromatography.
2) Enantiomerically resolved amino acid analysis using high-resolution column chromatography with high-sensitive fluorescence spectroscopy coupled with HRMS.
3) *In situ* organic compound analysis and molecular imaging using desorption electrospray ionization (DESI) and/or direct analysis in real time (DART) equipped with HRMS.
4) Spatial resolution imaging of organic compounds using time of flight-secondary ion mass spectrometry (ToF-SIMS; Naraoka et al., 2015).

In addition, if the sample is available, we will also perform the following additional analyses:

5) Compound-specific isotope analysis using gas chromatography/combustion or pyrolysis /isotope ratio mass spectrometry (GC/C or pyrolysis/IRMS).
6) Bulk chemical and isotopic analysis of organic matter (C, H, N and S) using nano-EA/IRMS system and laser-tunable FT-IR spectroscopy.

Depending to the sample size available to the initial analysis, we will perform preliminary analytical tests using 30 mg, 10 mg, and 1 mg samples of the Murchison meteorite (CM2, positive SOM-rich), Yamato 793321 meteorite (heated CM2, positive SOM-depleted), and baked serpentine (negative SOM-depleted) as well as procedural blank. The analytical protocol will be discussed in the meeting.

Swedish Institute of Space Physics, 4. SOKENDAI (The Graduate University for Advanced Studies), 5. National Institute of Polar Research, 6. National Astronomical Observatory of Japan

The Earth is surrounded by small dust grains produced by comets and asteroids. Tons of such grains plunge into the Earth's atmosphere hourly. Part of their kinetic energy excites and ionizes the surrounding atmosphere, which is observed as a meteor phenomenon. A simultaneous radar and optical observation is promising to constrain the motion and mass of a meteor at a time. We launched a project to observe faint meteors with Middle and Upper Atmosphere Radar (MU radar) and a wide-field CMOS mosaic camera Tomo-e Gozen installed on the 105 cm Kiso Schmidt telescope. The observations were carried out in 18--21, April, 2018. From tons of the detected meteors, the simultaneous detections were extracted in terms of the times, loci, and directions of the meteors. Finally, we identified the 894 meteor events simultaneously detected in the both sites. The optical brightness of the simultaneous meteors ranged from about 3--11 mag. in the V-band, which is about 5 magnitude fainter than in previous studies. We confirmed a clear correlation between the meteor brightnesses and the radar cross sections.

On June 27, 2018, the asteroid explorer Hayabusa2 arrived at the target C-type asteroid 162173 Ryugu. The telescopic optical navigation camera (ONC-T) on-board Hayabusa2 has acquired the multiband image data for the entire surface of Ryugu with spatial resolutions better than 2 m/pixel. These data show that the Ryugu surface has the very low surface reflectance, flat spectra, and its spatial homogeneity [Sugita et al. 2019]. However, more detailed observations on Ryugu have revealed that many boulders exhibit different spectral properties and that a number of spots with distinctively brighter than the surroundings [Sugita et al. 2019]. Although larger boulders have been analyzed to show that they form two distinctive spectral trends, no substantial spectral analyses on bright spots have been conducted. Determining whether or not these bright spots are one of the materials that originate from the parent body of Ryugu is important to understand the differentiation and geologic processes on the parent body. In this study, in order to understand origins of the bright spots, we investigated spectral characteristics of the bright spots and compared those of the boulders on Ryugu. We used the ONC-T multiband images obtained in Box-A (20 km altitude) and mid-altitude (5 km altitude) operations.

We found seven meter-sized bright spots that have radiance factor 1.3 to 2.0 times higher than that of the surrounding area. The spectra of these bright spots were classified into two types, one being a flat spectrum type and another being a convex spectrum type. The former type has spectrum similar to but flatter and brighter than the mean spectra of the whole Ryugu and boulders, suggesting that the bright spots originate from parent body of Ryugu. The latter type has spectrum similar to those of S-type asteroids, suggesting their exogenous origin.

Department of Applied Physics, Okayama University of Science, 8. Tokyo Meteor Network, 9. Japan Aerospace Exploration Agency, 10. National Astronomical Observatory of Japan, 11. Planetary Exploration Research Center, Chiba Institute of Technology

An Apollo-type near--Earth asteroid, (155140) 2005 UD, is considered as a possible fragment from (3200) Phaethon, suggesting that Phaethon precursor body might undergo a catastrophic disruption in the past. Here we present our new observational evidence for supporting these two are common origin. We thus conducted a polarimetric observation in 2018 September-October and found that 2005 UD exhibited a polarimetric property significantly different from those of major taxonomic classes of NEAs (i.e., S- and C-type) but similar to that of Phaethon at a wide range of the solar phase angles. Using the polarimetric data, we derived the geometric albedo of ~0.1. In addition, we made a photometric observation at the opposition (the zero phase angle), and determined the mean absolute magnitude of 17.2, the synodic rotational period 5.23 hr, and the effective diameter 1.5 km in combination with the derived geometric albedo. From these evidence, we found that the Phaethon precursor body might have lost more than a few percents of the mass via a disruption if 2005 UD was indeed ejected from the Phaethon precursor.

Follow-up observations for AKARI/IRC near-infrared asteroid spectroscopic survey (AcuA-spec)

*Sunao Hasegawa[1], Daisuke KURODA[2], Kenshi YANAGISAWA[3], Fumihiko Usui[4]

1. Japan Aerospace Exploration Agency, 2. Kyoto University, 3. National Astronomical Observatory of Japan, 4. Kobe University

In the range from 1 to 2.5 μm, we made the spectroscopic observations of the AcuA-spec asteroids (Hasegawa et al. 2017, PASJ, 69, 9), whose spectra were obtained in continuous covered between 2.5 and 5.0 μm by NIR/IRC/AKARI (Usui et al. 2019, PASJ, 71, 1). Candidates of AcuA-spec asteroids were selected from only main-belt asteroids classified based on visible spectrophotometric and spectroscopic observations (Tholen 1984, PhD thesis, Arizona University; Bus & Binzel 2002, Icarus, 158, 146; Lazzaro et al. 2004, Icarus, 172, 179). About 200 classified asteroids were raised as observational candidates. Spectroscopic observations for 65 AcuA-spec asteroids which were selected among the AcuA-spec candidate catalogue in taking account of signal-noise ratio and target opportunity by AKARI were executed.
Section work of the AcuA-spec candidate catalogue was done around 2005, yet there were not many spectroscopic observations of asteroids in the near-infrared wavelength range. As a result of survey of published paper for near-infrared spectroscopic observations of asteroids, howevwer, it was found that spectroscopic observations in the near-infrared region of 1–2.5 μm for most AcuA-spec asteroids are performed except for several asteroids.
If data in near-infrared wavelength range of the lacked AcuA-spec asteroids were acquired, all AcuA-spec asteroids will have 0.35–5 μm of data available. Obtaining continuous reflectance of asteroids is essential data to compare with those such as meteorites. Based on the Bus-DeMeo taxonomy (DeMeo et al. 2009, Icarus, 202, 160), we conducted classification of all AcuA-spec asteroids using published and our observational data.

Amino acids on witness coupons collected from the ISAS/JAXA curation facility for the assessment and quality control of the Hayabusa2 sampling procedure

*Haruna Sugahara[1,2], Yoshinori Takano[1], Yuzuru Karouji[3], Kazuya Kumagai[4], Toru Yada[3], Naohiko Ohkouchi[1], Masanao Abe[3], Hayabusa2 project team

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Institut de Chimie de Nice, Universite Cote dAzur, 3. Japan Aerospace Exploration Agency (JAXA), 4. Marine Works Japan Ltd.

The Hayabusa2 spacecraft is visiting a near-Earth carbonaceous type (C-type) asteroid, 162173 Ryugu, and planning to return the pristine samples to the Earth. C-type asteroids are considered to be related with carbonaceous chondrites that are enriched in organic and volatile materials. The one of the scientific goals of Hayabusa2 mission is to understand the origin and evolution of organic materials through interactions with water and minerals in the early solar system [e.g., 1]. Thus, the characterization of organic materials in the returned sample has great importance for this purpose. However, the analysis of small quantities of extraterrestrial organic materials in the returned samples requires a great care to avoid the introduction of terrestrial contaminants and any artifact materials to the pristine samples. Thus, the assessment of the degrees of the terrestrial contaminants to the samples as well as the comprehensive and specific managements to minimize the terrestrial contamination throughout the mission is essential.

The purpose of the study is to investigate the potential terrestrial organic contamination in a clean chamber for the Hayabusa2 returned samples in an Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency (ISAS/JAXA) curation room [2-4]. As the indicator of the terrestrial organic contaminants, we selected amino acids that ubiquitously exist in the terrestrial environments and are also the target molecules in the Hayabusa2 mission. In the study, we used witness coupons made of aluminum foil to collect the contaminants in the clean chamber. The witness coupons were collected at different exposure times, ranging from 1 day to 1 month to examine the accumulation rate of the contaminants. After the collection, amino acids on the witness coupons were extracted in hot water, hydrolysed with HCl, and then converted to *N*-pivaloyl isopropyl (Pv/iPr) ester derivatives for gas chromatographic (GC) analysis [5].

On the witness coupons, eight terrestrially common amino acids (glycine, alanine, valine, leucine, isoleucine, proline, aspartic acid and glutamic acid) were detected and seven of them, except valine due to the under quantification limit, were quantified. Among them, glycine was the most abundant species with the highest concentration of 10 pmol/cm^2. A time-dependent profile of the four major amino acids (glycine, alanine, aspartic acid and glutamic acid) showed the increasing trend between 1 to 7 days. The average accumulation rates are 1.2 pmol/cm^2/day for glycine, 0.6 pmol/cm^2/day for alanine, 0.1 pmol/cm^2/day for aspartic acid and 0.2 pmol/cm^2/day for glutamic acid. The species and the concentrations of amino acids on our witness coupons are similar to those reported by the National Aeronautics and Space Administration/Johnson Space Center (NASA/JSC) OSIRIS-REx team [6]. Thus, the quality control against terrestrial contaminants in ISAS/JAXA curation facility is at the same quantitative level as in their facility. This inter-laboratory evaluation [7] about the terrestrial organic contamination will provide important information for the curation procedure of the Hayabusa2-returned samples.

Hayabusa2 orbit determination using c5++ software

*Keiko Yamamoto[1], Toshimichi Otsubo[2], Koji Matsumoto[1], Hirotomo Noda[1], Noriyuki Namiki[1], Hiroki Senshu[3], Takahide Mizuno[4], Naoko Ogawa[4], Go Ono[4], Yuya Mimasu[4], Kent Yoshikawa[4], Tadateru Takahashi[4], Yuto Takei[4], Atsushi Fujii[4], Fuyuto Terui[4], Takanao Saiki[4], Satoru Nakazawa[4], Makoto Yoshikawa[4], Yuichi Tsuda[4]

1. National Astronomical Observatory of Japan, 2. Hitotsubashi University, 3. Chiba Institute of Technology, 4. Japan Aerospace Exploration Agency

Hayabusa2 arrived at the target asteroid Ryugu in June 2018 and is currently conducting remote sensing observations with various onboard instruments. So far, we have improved orbit determination software c5++, originally developed for the analysis of satellite laser ranging (SLR) data of the Earth, so that it can be used for the analysis of laser ranging data between Hayabusa2 and Ryugu obtained by Hayabusa2 LIDAR. Then we used it for the estimation of Hayabusa2 trajectory and the GM value of Ryugu. However, in the case of Hayabusa2, it is difficult to determine all of the 6 components of the initial state vector precisely if only LIDAR range data was used, and the simultaneously estimated GM value also had large uncertainty. To overcome this problem, in addition to LIDAR ranging data, we used Automated-Image-Tracking (AIT) data obtained by wide-angle optical navigation camera (ONC-W1) for the estimation of Hayabusa2 trajectory. In principle, LIDAR data gives information on the radial direction and AIT data give the ones on the across and along track directions. Thus, both data sets are complementary and help to improve the precision of the trajectory estimation. For this purpose, we improved c5 ++ so that it can deal with AIT data as observation data. In the presentation, we will show the results of trajectory and GM estimations using LIDAR and AIT data, and show how much the precision and accuracy are improved compared to the case using LIDAR data only.

Observatoire Paris-Site de Meudon, LESIA, France, 15. INAF-IAPS, Italy.

On June 27, 2018, JAXA’s Hayabusa2 spacecraft arrived at its target C-type asteroid Ryugu. Immediately after arrival, remote-sensing observations were carried out with the Optical Navigation Camera (ONC), the Near Infrared Spectrometer (NIRS3), the Thermal Infrared Imager (TIR), and the Laser Altimeter (LIDAR). Based on data from this suite of instruments, we carried out the landing site selection for the first touch-down (TD1). Since the mission aims to understand i) the origin and chemical evolution of the solar system and ii) the formation process and structure of the asteroid, we have set the most scientifically valuable TD1 site as the least altered region where water and/or carbon are potentially abundant.

Landing candidate sites were first selected by engineering evaluation for operational safety followed by scientific evaluations based on criteria such as science and samplability for the most interesting sites. The process was repeated using the observations from the altitudes of 20 km, 6 km, and 5 km.

Scientific evaluations of the landing site candidates were conducted based on the data products from ONC, NIRS3, TIR, and LIDAR. The shape modeling team produced two different shape models. ONC produced multiband images and reflectance spectra, as well as maps of spectral indices and X-means clustering analysis. Measurements of boulder size-frequency and Hapke parameters in the candidate landing areas were examined. NIRS3 produced four types of spectral feature maps. TIR provided maps of maximum temperature from the October 22, 2018 TD1 practice operations, apparent thermal inertia, and typical grain size determinations. LIDAR provided time series ranging data, topography, and corrected spacecraft trajectory.

Engineering evaluation: The possible landing site candidates were selected from the engineering safety score map evaluated based on the sub-Earth distance, local solar angle, local slope and elevation maximum difference. Thermal prediction results for TD1 were obtained by TIR. Temperatures of each site are < 350 K, confirming the safe conditions. The regions that satisfied all the conditions were, L05, L07, L08, L12, M01, M03 and M04.

Scientific evaluation:
1) Boulders. Based on the distribution of boulders with a diameter larger than 3 m for each potential landing site, regions L07, L08, and M04 show smaller percentages of boulder coverage than other areas, and are regarded as safer sites for landing.

©2019. Japan Geoscience Union. All Right Reserved.

2) Geology. Ryugu exhibits a variety of topographic features and geologic settings. From a scientific perspective, it is of interest to be able to study various materials representing the evolution of Ryugu.
3) Hydrous minerals. The NIR spectral properties are nearly homogeneous across Ryugu’ s surface, especially between the candidate sites. The near-infrared reflectance spectra of Ryugu is similar to experimentally heated Murchison meteorite at 400˚C.
4) Carbon contents. It is likely that visible reflectance at 0.55 μm (R(0.55)) is influenced mostly by carbon content. R(0.55) is almost homogeneous across the surface with a low value, regardless of the candidate sites.
5) Secondary processes. Although the surface of Ryugu is almost homogeneous at the macro scale in the map of spectral slope from 0.48 to 0.86 μm, a slight heterogeneity is observed across the candidate regions. L-regions are relatively bluish and M-regions are reddish. Considering that spectral reddening is observed by laser irradiation of dehydrated carbonaceous chondrites, L regions are probably less altered and preferable for sampling.

In the total evaluation, L08, L07 and M04 were selected as the TD1 candidates on August 17, 2018. In September 2018, many boulders > 50 cm were additionally found for the sites during the rehearsal of TD1. Thus, the originally scheduled TD1 in October was postponed. Further search for a flat and safe site continued, and L08-E1 was determined as the TD1 site. The TD1 will be scheduled on Feb 22, 2019.

Visible Photometric, Spectroscopic and Polarimetric observations of an inactive comet, P/2016 BA14 with the 1.6m Pirka Telescope

*Ryo Yamagata[1], Tomohiko Sekiguchi[1], Ryo Okazaki[1], Kazuya Doi[1], Daisuke Kuroda[2], Masateru Ishiguro[3], Hiroyuki Naito[4]

1. Hokkaido University of Education, 2. Kyoto University, 3. Seoul National University, 4. Nayoro Observatory

We performed photometric, spectroscopic and polarimetric observations of an inactive comet, P/2016 BA14 with the 1.6m Pirka Telescope, Hokkaido.

P/2016 BA14 (a=3.02 au, e=0.67, i=18.9 deg.) was discovered as an unusual asteroid with a cometary orbit by the PANSTAARS on 2016 January 21.Since Knight et al. 2016 detected its cometary tail when the object close to sun(r=1.018au). It was classified into a Jupiter Family Comets. It can be regarded as a bare nucleus invisible coma because very weak comet activity that is different from general comet. There is a remarkable similarity between the orbits of 252P/LINEAR (a=3.05au, e=0.67, i=10.4deg) and P/2016 BA14. Jupiter Tisserand parameter is 252P/LINEAR and that of P/2016 BA14 are 2.82. P/2016 BA14 and 252P/LINEAR is division comet that is originally same comet (Jian-Yang.2017).

In this study, surface reflection properties of P/2016 BA14 classify D-type asteroids (Bus-DeMeo taxonomy) from result of visible spectroscopy (435-820nm). Color of surface is little red as D-type asteroid, but very blue as comet nucleus from result of BVRI photometry. The linear polarization Pr=10.46.±0.11% (α=46°) is in close accord with that of D-type asteroids and comet nucleus.

Polycyclic aromatic hydrocarbons and aliphatic hydrocarbons in Jbilet Winselwan carbonaceous chondrite : Attempt to evaluate the thermal metamorphism degree on the parent body

Hiroki Kato[1], *Hikaru Yabuta[1]

1. Hiroshima University, Department of Earth and Planetary Systems Science

Introduction: On June 27, 2018, Hayabusa2 spacecraft arrived at the C-type asteroid Ryugu. The surface of Ryugu has been thought to have experienced dehydration at least partially, according to the grand-based observation (Vilas et al. 2008; Hiroi et al. 1993). Therefore, it is important to investigate the chemical compositions of dehydrated carbonaceous CM chondrites for understanding the surface process of asteroid Ryugu. Although the extents of thermal metamorphism of CM chondrites have been evaluated by mineralogical compositions (e.g., Nakamura et al. 2006) and elemental and molecular compositions of insoluble organic matter (IOM) (e.g., Naraoka et al. 2004; Yabuta et al. 2005), the estimated temperature varies widely. On the other hand, soluble organic molecules from the dehydrated CM chondrites have not been quantified or below detection (e.g. Shimoyama et al. 1989), and there has been no study which evaluated thermal metamorphism based on the compositions of soluble organic molecules. Therefore, in this study, we analyzed aliphatic hydrocarbons and polycyclic aromatic hydrocarbons (PAHs) in Jbilet Winselwan CM chondrite, which is a dehydrated CM chondrite (Zolensky et al 2016) and show similar reflectance spectrum to that of asteroid Ryugu (Kameda et al. 2015), for precise evaluation of parent body thermal metamorphism. The relative abundances of the hydrocarbons were compared with those of Murray meteorite, which is a primitive CM chondrite.

Samples and Methods: Powdered samples of Jbilet Winselwan meteorite and Murray meteorite (0.2 - 0.4g) were extracted with dichloromethane/methanol (9:1) by sonication. The extracts were applied to a silica gel column. From the column, aliphatic hydrocarbons were eluated with hexane and then PAHs were eluated with dichloromethane. The hexane and dichloromethane eluates were concentrated to 100 μl individually under a nitrogen flow for analysis by a gas chromatography coupled with mass spectrometry (GC-MS). Identification and quantification of compounds were made by comparison of peak retention times on mass chromatograms and mass spectra, and peak areas, respectively, with those of standard compounds. For compounds without standard compounds, identification was made by comparison of mass spectra with library data.

Results and discussion: Total concentration of *n*-alkanes from Jbilet Winselwan meteorite (1.85 μg/g meteorite) was 40 times lower than those from Murray meteorite (80.7 μg/g meteorite). Relative abundances of short-chain *n*-alkanes (C_{15}-C_{16}) were dominant in Jbilet Winselwan meteorite, while those of long-chain *n*-alkanes (C_{17}-C_{21}) were dominant in Murray meteorite. This difference implies that short-chain *n*-alkanes were resulted from cracking of long-chain *n*-alkanes and/or IOM during thermal metamorphism of the parent body of Jbilet Winselwan meteorite. Total concentration of PAHs from Jbilet Winselwan meteorite (0.05 μg/ meteorite) was 1000 times lower than those from Murray meteorite (62.0 μg/g meteorite). Dimethylnaphthalene, fluorine, phenanthrene, pyrene, fluoranthene, methylbiphenyl (0.003-0.039 μg/g meteorite) were identified, while low molecular weight PAHs, such as naphthalene, methylnaphthalene, and acenaphthene, were not detected. The results suggest that PAHs with high volatility in Jbilet Winselwan meteorite were lost or involved in further aromatization during thermal metamorphism. Distributions of dimethylnaphthalene and methylbiphenyl isomers in Jbilet Winselwan

©2019. Japan Geoscience Union. All Right Reserved.

and Murray meteorites were similar, respectively, which indicates that the parent body of Jbilet Winselwan meteorite experienced relatively mild thermal metamorphism.

Since June 2018, the Optical Navigation Camera (ONC) onboard Hayabusa2, has observed the C-type asteroid 162173 Ryugu at a distance below 20 km. ONC-T and ONC-W1 are used for surface imaging operations, and their images allow us to investigate the disk-resolved photometric properties of the surface. A narrow-angle camera ONC-T has 7 broad-band filters ranging in wavelength from 0.39–0.95 μm. ONC-W1 is a wide-angle (> 65˚) pan-chromatic camera mainly used for optical navigation during cruise and low-altitude (< 20km) operations. We are proceeding the analysis of both dataset, ONC-T and ONC-W1.

Since Hayabusa2’s position is nominally fixed on the line connecting Ryugu and the Earth, the available solar phase angle range by ONC-T changes seasonally with the orbits of Earth and Ryugu around the sun. Therefore, we are collecting a large number of ONC-T images over a long period of time to cover a wide phase angle range.

ONC-W1 data has a strong point that it covers a wide phase angle range within a single frame during the descent operations, because of its wide field of view. One of our current challenges is deriving a precise viewing geometries (incidence angle, emission angle, and phase angle) at each pixel. Additionally, comparison of the absolute brightness value (radiance factor) with ONC-T is an ongoing issue.

[P-PS03] Solar System Small Bodies: A New Frontier Arising Hayabusa 2, OSIRIS-REx and Other Projects

convener:Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University), Taishi Nakamoto(Tokyo Institute of Technology), Masanao Abe(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Olivier S Barnouin(Johns Hopkins University Applied Physics Laboratory)

In June 2018, the Hayabusa 2 spacecraft arrived at the target asteroid Ryugu after three and half years journey. In addition, another spacecraft, OSIRIS-REx will soon arrive at its destination Bennu. With these arrivals, the solar system research is about to enter a new era. We have organized this small bodies session since 2012 and had a broad range of discussions from viewpoints of laboratory experiments, observations, space explorations, theoretical modeling, and sample analyses. In particular, this time, we aim to hold this session to bring the latest research on solar system small bodies, focusing on the initial results of Hayabusa 2 and OSIRIS-REx. Presentations in the related fields other than these two asteroidal missions are also welcomed.

Impact experiments on low strength coarse-grained regolith simulating surface materials on asteroid Ryugu

*Yuya Yamamoto[1], Masahiko Arakawa[1], Minami Yasui[1], Sunao Hasegawa[2], Ryo Sugimura[1]

1. Graduate School of Science, Kobe University, 2. ISAS, JAXA

Impact cratering is one of the most important physical processes, then we study crater scaling laws and impact induced seismic waves in order to elucidate various flow processes on asteroids caused by impacts. The conventional crater scaling laws are categorized into two regions according to the controlling physics for the crater growth: they are gravity and material strength. A crater formed on regolith layer is surely controlled by the gravity, however when the regolith layer was filled with coarse particles with low mechanical strength, then the several coarse grains might be disrupted to consume the Ek. Thus, the crater size could be affected by the disruptions of the coarse grains. We speculate that not only the gravity but also the grain strength could affect the final crater size. Then, we made cratering experiments by using the target made of weak particles, and studied the effects of the particle strength on the crater scaling law and the impact induced seismic wave.

Experiments: Cratering experiments were conducted by using a gas gun set at Kobe University and ISAS. Granular targets were prepared by using weathered tuff granules with the size of 1 to 4mm (small particle) and the size of 1 to 4cm (large particle). The crush strength of these tuff particles was measured to be about 60 kPa. A spherical projectile with the size of 3mm which is made of iron, zirconia, alumina, glass, and nylon) was lunched at the impact velocity from 40 to 200m/s, and a spherical Al projectile with the size of 2mm was impacted at the impact velocity from 1.2 to 4.5km/s, then these two types of the projectile were impacted on the target surface at the normal direction. Impact cratering process and ejecta curtain growth were observed by a high-speed camera at 10^3-10^5 fps, and the video images were used to analyze ejecta particles to reconstruct the trajectories. After the shot, the crater morphology was recorded and the diameter and the depth were measured. Impact induced seismic waves were measured by using 3 accelerometers (specific frequency is 30kHz) set at different positions from the impact point, and a data logger was used to record the seismic data through charge amplifiers (data acquisition rate is 100kHz) connecting to the accelerometer.

Results: The crater size was found to increase with the projectile kinetic energy (Ek) at lower than 0.14J and at higher than 0.63J, so that the crater size was almost constant among them, and more the crater size obtained at very high Ek was almost on the extrapolated line from the relationship given by the low Ek data. The pi-scaling law was used to construct the relationship between normalized radius (πR) and normalized gravity (π2), and πR at small π2 was found to be rather smaller than that obtained for sand and glass beads targets, and more πR at large π2 was found to be consistent with that for sand and glass beads. More detail analysis tells us that all the data separated into two trends with large offset according to the impact velocity and the projectile material. This offset might be caused by the disruption of several tuff particles. The ejection velocities of each tuff particle were so scattered, then the distinctive relationship between initial position of particle and the ejection velocity was not derived in the low velocity range. The propagation velocity of the impact induced seismic wave was about 30 m/s, and it is 1/3 of that for glass beads. Furthermore, we found that the relationship between the maximum acceleration and the distance from the impact point was about 1/10 of that obtained for glass beads: the seismic wave in the tuff granules attenuated so quickly compared to the glass beads. But, when the distance is normalized by the crater radius, these relationships almost consistent each other, so that the

normalized distance could be a good parameter for the scaling of the acceleration of seismic wave.

Hayabusa2 is a sample-return mission for the C-type asteroid 162173 Ryugu. Hayabusa2 arrived at Ryugu on 27 June 2018, and various observations are still being conducted. Hayabusa2 performs multiband spectral observation by employing the optical navigation camera telescope (ONC-T)and can thereby obtain spectral map of Ryugu, which enables the study of material distribution and degree of space weathering of Ryugu. However, the sensitivity of ONC-T has been previously calibrated by incorporating the inflight data of stars with significant uncertainty. Hence, the authors aim to estimate the reflectance of Ryugu by employing Mobile Asteroid Surface Scout (MASCOT).
MASCOT comprises four instruments (MASCAM, MicrOmega, MARA, and MASMAG) that are employed for analyzing the soil of Ryugu. The upper side of the MASCOT landeris coated with white paint, and its spectral image was captured by ONC-T after its release from Hayabusa2 to Ryugu. The authors conducted on-ground reflectance measurement of a white plate whose white paint is identical to that of MASCOT. Hence, the primary objective of the proposed study is to estimate the reflectance of Ryugu by comparing MASCOT’ s white side’ s spectrum captured by ONC-T with the on-ground reflectance measurement of the white plate that has identical paint as MASCOT, and thus evaluate the validity.

DESTINY$^+$ (Demonstration and Experiment of Space Technology for INterplanetary voYage, Phaethon fLy-by and dUst Science) is a mission proposed for JAXA/ISAS Epsilon class small program, currently in the pre-project phase (Phase-A) with a launch targeted for 2023. DESTINY$^+$ is a joint mission of technology demonstration and scientific observation. The near-Earth asteroid (3200) Phaethon, the flyby target, is known as a parent body of the Geminid meteor shower, the size of which is approximately 5 to 6 km in diameter.

In this mission, spatially resolved images of Phaethon will be taken by two onboard cameras, the Telescopic CAmera for Phaethon (TCAP) and the Multiband CAmera for Phaethon (MCAP) during the flyby, in order to understand the nature of a meteor shower's parent body, which is one of the sources of interplanetary dust particles that are thought to be an important transport medium of organic matter to the Earth. The spacecraft flybys Phaethon with a relative speed of 30 to 40 km/s. Despite such a high flyby speed, the cameras are required to take un-blurred images of Phaethon.

The main purposes of the DESTINY$^+$ flyby observation of Phaethon is to understand the geology of a parent body of a meteor shower, and in particular constrain the dust ejection mechanisms from active (i.e., dust-ejecting) asteroids. The specific objectives of the camera observation are taking images for (1) obtaining the light curve of Phaethon in order to estimate the rotational period, (2) measuring the outline shape of Phaeton, (3) making a 3D shape model of Phaethon, (4) observing the surface geological features of Phaethon including dust ejection features, and (5) observing the surface material distribution of Phaethon. The observations (1) to (4) will be conducted by TCAP, and (5) by MCAP.

TCAP is a telescopic panchromatic camera for high spatial resolution imaging of the surface of Phaethon and have a rotational mirror for asteroid tracking during flyby. The rotational mirror can change the direction of the line of sight from 0 deg to 180 deg. This enables to observe Phaethon throughout the flyby with wide solar phase angles, which is extremely important to image and understand the surfaces of planetary bodies because the solar phase angle affects significantly the appearance of geological features in taken images.

MCAP is a multiband camera, the wavelengths of which are 400, 480, 550, 700, 850, and 950 nm (480 and 950 nm are optional bands) and has multiple optical systems and sensors in order to take all band images simultaneously. This is because there is not enough time to take each band image in turn with changing bandpass filters using such as a filter wheel in this high speed flyby mission. MCAP does not have a tracking mirror due to the weight limitation, and the line of sight of MCAP is fixed to the spacecraft with 40 deg off the relative velocity vector of the spacecraft.

We will explain the flyby imaging sequence of DESTINY$^+$, and show the conceptual designs of TCAP and MCAP.

It is important to determine the taxonomic types of small bodies in the solar system and further to study the spatial distribution of the planetary system. Among the small bodies, it is considered that there should be dormant comets that have lost a significant fraction of volatile materials in their subsurface layers. As a result, they are unable to produce any detectable coma and recognized as asteroids. It has been challenging to find out such dormant comet population from a list of known asteroids because of the asteroidal appearances. There are several attempts to find the dormant comet nuclei from asteroidal catalogs, for example, by using their reflectance spectra or orbital elements. However, little has been studied via polarimetry.
We conduct a polarimetric study of three candidates of dormant comet nuclei, (331471) 1984 QY1, (3552) Don Quixote and (944) Hidalgo, by using the 1.6-m Pirka Telescope at the Nayoro observatory (operated by Hokkaido University, Japan). We chose these asteroids in comet-like orbits (ACOs) based on the orbital elements (i.e., the Tisserand parameter with respect to Jupiter $T_J < 3$). We found that 1984 QY1 has a polarimetric albedo (geometric albedo determined via polarimetry) $p_V = 0.16 \pm 0.06$ while both Don Quixote and Hidalgo have Rc-band polarimetric albedo $p_R < 0.05$. Based on the polarimetric result together with a dynamical analysis, we conjectured that 1984 QY1 could be an S-type asteroid transported into the current orbit via 3:1 mean motion resonance with Jupiter. From the previous spectroscopic study, Don Quixote and Hidalgo are classified into D-type taxonomic group, which are typical of comet nuclei. In this presentation, we will introduce our polarimetric observations of ACOs and emphasize that polarimetry is a powerful tool for discriminating the asteroidal and cometary origins.

Dynamical lifetime of the Oort Cloud new comets under planetary perturbation

*Ito Takashi[1], Arika Higuchi[1]

1. National Astronomical Observatory of Japan

Nearly isotropic comets with very long orbital period are supposed to come from the Oort Cloud. Recent observational and theoretical studies have greatly revealed the dynamical nature of this cloud and its evolutionally history, but many issues are yet to be known. Our goal is to trace the dynamical evolution of the Oort Cloud new comets (OCNCs) produced by evolving comet cloud, hopefully estimating the fraction of OCNCs embedded in the current populations of the solar system small bodies. We combine two models to follow the dynamical evolution of OCNCs beginning from their production until their ejection out of the solar system, obtaining statistics of the dynamical lifetime of OCNCs: The first model is a semi-analytical one about the OCNC production in an evolving comet cloud under the perturbation of the galactic tide and stellar encounters. The second model numerically deals with planetary perturbation over OCNCs' dynamics in planetary region. The main results of the present study are: (1) Typical dynamical lifetime of OCNCs in our models turned out to be O(10^7) years. Once entering into the planetary region, most OCNCs stay there just for this timespan, then get ejected out of the solar system on hyperbolic orbits. (2) While averaged orbital inclination of OCNCs is small, the so-called "planet barrier" works rather effectively, preventing some OCNCs from penetrating into the terrestrial planetary region.

Thermal images from global to close-up scales taken by the Thermal Infrared Imager TIR [1] on Hayabusa2 [2] have revealed thermophysical properties of the C-type Near-Earth Asteroid 162173 Ryugu. On 27 June 2018, Hayabusa2 arrived at Ryugu and started remote sensing to characterize the nature of the asteroid and find the proper landing sites. *In situ* surface experiments were conducted using the robotic landers Minerva-II and Mascot [3]. *In situ* radiometry was conducted by MARA on MASCOT during a day-night cycle to derive the thermal inertia of a single boulder [4]. Ground-based observations [5] have been informed that the averaged thermal inertia of the asteroid is from 150 to 300 [tiu = J m^{-2} $s^{-0.5}$ K^{-1}] [5,6], corresponding to the surface covered with cm-sized granules.

TIR is the same design as the LIR on Akatsuki Venus climate orbiter [6], with 8 to 12 μm wavelength range, 328 x 248 effective pixels, and the FOV and IFOV of 16.7˚ x 12.7˚ and 0.051˚ per pixel, respectively. The first image of Ryugu detected by TIR was a point source on 6 June 2018, as was previously predicted [7]. Disc-resolved thermal images of Ryugu was taken from the HP on 30 June. The surface temperature was measured at 300 to 370K at about 1AU from the Sun, and gradually decreased with the solar distance. Comparison of the results with modeling [8] shows that the surface of Ryugu is not like fine regolith nor base rocks. Most of large boulders on Ryugu show temperatures almost the same as the surrounding surfaces. Diurnal temperature profiles of Ryugu are rather flatter than expected for a smooth terrain. Apparent thermal inertia is ~300 tiu or larger, but probably lower than the value when the surface roughness is considered. All these facts are consistent with a very rough and porous surface with low porosity (~35 ±10 %) [9] and the surrounding surface is dominated by porous rocks larger than several centimeters. Macro porosity should be 30 to 50 % to account for the bulk density of Ryugu ~1200 kg m^{-3}.

During the descent operations for the release of landers and the touchdowns for sample collection, TIR has taken close-up thermal images of the local sites, continually from the altitude of 500 m until the start of final descent at 10 or 20 m altitude. Close-up thermal images show the surface physical state and a variety of boulders. Most of the boulders in close-up images have temperatures similar to the surroundings but with more variety. A small number of boulders are remarkably colder than the surroundings, indicating dense rocks with lower porosity.

©2019. Japan Geoscience Union. All Right Reserved.

These facts indicate that Ryugu is probably a rubble pile of loosely-bound porous rocks, which might originate from the outer layer of parent body where compaction did not occur effectively, while the dense boulders might originate the compacted center region of parent body or from the different parent body. A different composition (e.g., organic rich materials) cannot be ruled out so far to account for such a low thermal inertia (and low density) of Ryugu.

Acknowledgments: The authors appreciate all the members of the Hayabusa2 Project and supporting staff for their technical assistance and scientific discussions. The thermal infrared imager (TIR) onboard the Hayabusa2 spacecraft performed thermography of the asteroid 162173 Ryugu through in-situ observations from 2018 to 2019. The primary purpose of TIR is to determine the global thermophysical properties of the asteroid and to reveal the evolutional history such as physical properties of the coalesced bodies, orbital changes due to radiation force, and the thermal evolution. This study introduces observed data of TIR and public data for scientists. The data are released by JAXA data archives (DARTS) and NASA PDS.

Multi-mission capability of HARMONICS

*Shintaro Tsunoda[1], Hirohide Demura[1], Naru Hirata[1]

1. The University of Aizu

This research has updated HARMONICS from a viewpoint of multi-mission capability, such as the Martian satellite exploration mission MMX in 2020s. Newly additional function is Switching on the shape model interface.
Bird view and visualization of FOV is important in robotics control. This technology is also used for deep space explorer missions.
HARMONICS is visualization tool of FOV(Field Of View) of scientific instruments and spacecraft’s position for HAYABUSA mission. The software has been updated by University of Aizu students of the past. The original HARMONICS had been developed by Nemoto(2006). GUI of HARMONICS had been replaced GUI library from GKT to Qt and added new functions, such as interactive modification of input mission plan by Ueno+(2017). The software had been add FOV frustum function by Aoki(2017). HARMONICS has tried to manage data for each project based on preference file in 2018.
HARMONICS should improved scalability to be compatible for ongoing mission. HARMONICS had been used to decide shutter chance by Camera Science Team in the asteroid Itokawa rendezvous of HAYABUSA. This software has not used in the asteroid Ryugu rendezvous of HAYABUSA2. The proven software should be use for future ongoing missions other than HAYABUSA. This research is development to HARMONICS adapt to ongoing missions.
I separated the designation of the data set from the source code and clarified the part edited by the user and the part edited by the developer.
HARMONICS has the function to switch and display data of different missions by this research. When users extend HARMONICS for multiple missions, users don’t need edit source code. User needs only kernel and the shape model of spacecraft and target asteroid. User do not need tough coding. User can use easily HARMONICS by editing preference file and kernel.

New interface of verification for calibration and conversion in HEAT : Hayabusa2 Exploration Assistant for TIR

*Tatsuro Kobayashi[1], Kentaro Suko[1], Hirohide Demura[1], Yoshiko Ogawa[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4]

1. The University of Aizu, 2. Ashikaga University, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Rikkyo University

Hayabusa2 is an ongoing mission for sample return from the asteroid Ryugu.
Candidates of sampling sites are selected based on surface mapping by optical instruments such as Thermal Camera (TIR). TIR observes surface infrared radiation from the asteroid. A software package peculiar to TIR is HEAT: Hayabusa2 Exploration Assistant for TIR. The software has four functions; Database for ground tests, calibration of flight data based on the ground tests, conversion from raw data to temperature one, and analysis for verifying the calibration and conversion. The converted data products are divided into some levels: Lv1 Raw data [DN], Lv2a Temperature [K], Lv2b is Brightness [W/m2], and higher thermal model with VTK format [K]. This research implements new interface of verification for calibration and conversion based on hearing and survey for requirements from TIR science team. The environment of implementation is following tool. OS: macOS Mojave 10.14.2. Computing language: C++, OpenGL. Frameworks: Qt5.4. Tools: Fits, Qt creator, SPICE toolkit, Visualization Toolkit, QcustomPlot, Xcode10.1.

Dust particle evolution of a near-Earth object 252P/LINEAR from near-infrared polarimetric observations in 2016

*Yuna G Kwon[1], Masateru Ishiguro[1], Jungmi Kwon[2], Daisuke Kuroda[3], Myungshin Im[1], Changsu Choi[1], Motohide Tamura[4], Takahiro Nagayama[5], Nobuyuki Kawai[6], Jun-ichi Watanabe[7]

1. Seoul National Univ., 2. ISAS/Japan Aerospace Exploration Agency, 3. Okayama Astrophysical Observatory, 4. The Univ. of Tokyo, 5. Kagoshima Univ., 6. Tokyo Institute of Technology, 7. National Astronomical Observatory of Japan

Comets, one of the least-altered leftovers from the early solar system, have probably preserved the primitive structure inside, whereas their surfaces become differentiated from initial states after repetitive orbital revolutions around the sun. Resurfacing makes the surface drier and more consolidated than the bulk nuclei, creating inert refractory dust layer (so-called “dust mantle”). Near-Infrared (NIR) polarimetry is theoretically expected to maximize the contrast of the porosity between inner fresh and evolved dust particles, by harboring more dust constituents in the single wavelength than the optical, and thus intensifying electromagnetic interference in dust agglomerates. Despite the advantage, only few studies have been conducted in this approach at multiple observation epochs. Herein, we present our new multi-band NIR polarimetric (1.25—2.25 microns) study of near-Earth object 252P/LINEAR over 12 days near perihelion; alongside broadband optical photometric (0.48—0.80 microns) data over four months in 2016 and a subsidiary dynamical simulation over 1000 year backward in time. 252P/LINEAR drew attention due to (1) its close approach to the Earth (~0.036 au on 2016 March 16), (2) its possible pairing to a comet P/2016 BA14 (PanSTARRS), and (3) its very low activity level despite its relatively young dynamical age. In this study, we detected two discontinuous brightness enhancements of 252P/LINEAR, particularly, the former of which accompanied a significant increase of NIR polarization degree of the comet (by ~13 % at most) with unusual blue polarimetric color. We will discuss the most probable scenario of the observed results, together with the orbital evolution of the comet and a dynamical association with its pair.

Performance Evaluation of TRIPOL on the 61-cm Telescope at Seoul National University for Polarimetric Observations of Solar System Small Bodies

*Sunho Jin[1], Masateru Ishiguro[1], Yuna G Kwon[1], Jooyeon Geem[1], Yoonsoo P. Bach[1], Jinguk Seo[1], Hiroshi Sasago[2], Shuji Sato[3]

1. Seoul National University, 2. Sasago Co.,Ltd, 3. Nagoya University

Polarimetry of solar system small bodies is a powerful technique for investigating their physical properties, such as albedos, particle sizes, and porosities of these bodies. Observational opportunities arise sometimes suddenly, that is, just after unforeseeable activations of comets and discoveries of near-miss asteroids. Here, we introduce our activity to install the polarimetric instrument, TRIPOL (Triple-Range Imager and POLarimeter) on the 61-cm telescope (a Ritchey-Chretien reflector with f/7.0) at the Center for Astronomy and Space Science, Seoul National University, and report an observational result of three comets. This combination provides an 8.0’ ´8.0’ field of view and pixel resolution of 0.94” pixel^{-1}. Throughout photometric observations, we determined the limiting magnitudes (defined as magnitudes for S/N=5) of 15.17±0.06 (g’-band), 15.68±0.01 (r’-band), 16.24±0.03 (I’-band), respectively, with total 240-seconds exposure (four 60-seconds exposure images, each was taken at different rotation angle for the half-wave plate). We also found that the instrumental polarizations are negligibly small, that is, -0.32±0.04% (g’-band), -0.36±0.05% (r’-band) and -0.21±0.04% (I’-band), while the polarization efficiencies are large enough to maximize the performance, that is, 97.52±0.03% (g’-band), 98.83±0.02% (r’-band) and 99.15±0.02% (I’-band).

With this instrument, we conducted polarimetric observations of three Jupiter-family comets, 21P/Giacobini-Zinner, 38P/Stephan-Oterma, and 46P/Wirtanen on a trial basis. It is known from a recent study that the polarization degrees of cometary dust particles are significantly influenced by gas emissions [1] With multiband data taken with TRIPOL, we eliminated an influence of gas contaminations and found that the dust polarization degrees of these three comets coincide with those of so-called ‘dust-rich comets’. From this result, we conjecture that the polarimetric property of Jupiter-family comets is broadly homogeneous, unlike asteroids. We plan to describe our future plan using the polarimetric system.

Smart Interface of HEAT: Hayabusa2 Exploration Assistant for TIR

*Kentaro Suko[1], Tatsuro Kobayashi[1], Hirohide Demura[1], Takehiko Arai[2], Naoya Sakatani[3], Tatsuaki Okada[3], Satoshi Tanaka[3], Tetsuya Fukuhara[4]

1. The University of Aizu, 2. Ashikaga University, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Rikkyo University

The Hayabusa2 project is a sample return mission to the asteroid Ryugu. It was launched on Dec. 3, 2014, and it has been at Ryugu since June 27, 2018. Hayabusa2 has optical instrument called Thermal Infrared Imager (TIR). These main functions are to know natures of the asteroid and to select the candidate of safe landing sites for sampling based on thermos-physical properties of the surface. TIR records infrared radiation from the target as a digital number (DN). The infrared signal is affected by sensor-surrounding objects; lens, shutter, package, and case. TIR requires consideration about this effect when converts DN images to temperature one. This study improved conversion system to increase conversion efficiency.

Hayabusa2 TIR Science Team has developed an analysis supporting tool called Hayabusa2 Exploration Assistant for TIR (HEAT). HEAT is used to search TIR data interactively, display TIR images, and visualize thermal models. We receive TIR raw images (Product Level 1) from ISAS/JAXA and convert them to brightness temperature images (Level 2a) and radiance images (Level 2b) using HEAT at Univ. of Aizu. The converted images are provided to the Hayabusa2 project data server.

This part introduces a concept model. The spectral radiance emitted from a blackbody B(λ ,T) (W s r-1m-2) is given by the Planck function based on wavelength λ (m) and temperature T(K) as follows:

$$B(\lambda,T) = (2hc2/\lambda 5)^* (1/(\exp(\lambda kBT)-1))$$

H = 6.63*1034 (m2 kg s-2 s-1) is the Planck constant, c=2.9972*108(ms-1) is the speed of light, and KB= 1.38*10-23 (m2 kg s-2K-1) is the Boltzmann constant. The observed radiance L(T) (W sr−1 m−2) is as follows:

$$L(T)= \varepsilon \int BR(\lambda)d\lambda$$

ε is the spectral thermal emissivity, and R(λ) is the response function such as the detection efficiency of the bolometer, the measured transmittance of optics including the band-pass filter and the germanium lens. The calibration formula with two regressed parameters A and B is written as follows:

$$DN=A * L(T) + B$$

The converted temperatures of the Moon were lower than expected because each pixel did not cover the sunlit area entirely or due to roughness effect of the cratered terrain. TIR has been observing Ryugu in approach and rendezvous phases. The altitudes of TIR observations during the rendezvous phase range from 20 km to less than 10 m. This study has processed about 3000 Ryugu images observed by TIR since June 2018.

©2019. Japan Geoscience Union. All Right Reserved.

This study improved conversion system. Previous conversion system converts a TIR image one by one, but current conversion system converts TIR images in selected directory at once.

Experimental Study on Collision Crater Formed on Bulge Geography

*Yusaku Yokota[1], Yuya Yamamoto[2], Minami Yasui[2], Masahiko Arakawa[2]

1. Faculty of Science, Kobe University, 2. Graduate School of Science, Kobe University

An equatorial bulge was found on the surface of asteroid Ryugu and Bennu by recent spacecrafts of Hayabusa2 and OSIRIS-Rex, and ridge structures with various scales originated by geological activities have been recognized on icy satellites. Impact craters are dominant geological features on solid planets such as asteroids and satellites, and a crater rim are also recognized as a ridge or bulge with a circular shape. These bulges and ridges are shown to be erased with time because small scale impacts excavate and disrupt these topographies. It is well known that old craters gradually degraded by small impacts to get blurred and could be completely erased. We can expect the similar degradation process on large bulges and ridge structures, so that the life time of these structures by small impacts is a good indicator of the formation age of these structure by geologic activities. So far, the effect of small impacts on the degradation is estimated by using the results on the flat surface, but actually the surface of the bulge is curved and there is a summit on the bulge. Therefore, if we estimate the life time of the bulge structure, we should consider the effect of the topography such as a summit and curvature. Then, the impacts on the bulge structure was studied to clarify how the bulge structure affected the crater formation efficiency. In this study, we suppose the bulge made from regolith and boulders, such as an equatorial bulge of Ryugu and assume the crater formation process dominated by not the strength but the gravity.

We prepared a triangular prism target to simulate the bilge structure, and set it like that the base of this prism is rectangle, then it looks triangle when we look it at the horizontal direction, and we can look at the linear summit from the top view. Quartz sands with the size of 100μm was used to build the target and the angle of repose for this quartz sand is about 30 degree. The slope of the prism was measured from the base, and we set the angle from 20 to 30 degree. The quartz sands were filled into a transparent water tank with the depth of 20 cm to prepare the bulge structure. Impact experiments were conducted by using a vertical type gas gun, and the water tank was set in the chamber to evacuate below 1000 Pa. A alumina sphere projectile with the size of 3mm was launched at the velocity from 70 to 200 m/s, and it was impacted on the bulge in the vertical direction: the impact angle measured from the target surface was about 60 degree when the slope was 30 degree. The distance from the impact pint to the summit (deviation distance, d_d) was changed from 0 to 20mm.

We found that the crater shape strongly depended on the d_d, so the crater shape was an ellipsoid when the impact point was near the summit. Th major axis appeared along the linear summit and the minor axis appeared across the summit. The aspect ratio of the major axis to the minor axis gradually changed toward 1 with the increase of d_d. Moreover, the aspect ratio becomes large at the same d_d when the impact velocity increased. The major axis of the ellipsoid crater formed on the bulge was slightly larger than the crater diameter formed on the flat surface, and the slope angle might affect the size of the ellipsoid because we found that the crater formed on the slope of 30 degree was systematically larger than that formed on the slope of 20 degree. We also observed an asymmetric ejecta curtain from the impact point on the bulge, moreover the ejecta curtain was notice to be deformed so much at the impact point near the summit because of the effect of curvature of the bulge on the crater flow.

Initial analysis plan of soluble organic compounds for the Hayabusa2 sample from asteroid Ryugu

*Hiroshi Naraoka[1], Yoshinori Takano[2], Jason P. Dworkin[3], SOM Analysis Team

1. Department of Earth and Planetary Sciences, Research Center for Planetary Trace Organic Compounds, Kyushu University, 2. Japan Agency for Marine-Earth Science and Technology, 3. Astrochemistry Laboratory NASA Goddard Space Flight Center, Greenbelt, MD 20771 USA

The spectra of asteroid 162173 Ryugu taken by Near-Infrared Spectrometer (NIRS3) onboard Hayabusa2 are nearly featureless and consistent with carbonaceous chondrites (Matsuoka et al., 2018). The Hayabusa2 spacecraft will collect surface samples of Ryugu and deliver to the Earth during late 2020. The initial analysis of the Ryugu samples will focus on (1) detailed chemical and mineralogical characterization of the samples and (2) understanding the history of Ryugu and the Solar System in order to maximize the scientific achievement of the project and (3) to prove the scientific potential of the samples to the community for the analytical opportunity (Tachibana et al., 2014). We have organized an international team, consisting of 24 members currently, for the initial analysis of soluble organic matter (SOM) for the returned samples.
The primitive asteroidal materials are expected to contain diverse and complex (e.g. elemental, structural, and optical) organic matter all at low concentrations. The occurrence of SOM will provide clues to the origins of organic compounds as well as prebiotic molecules of potential relevance to origins of life on Earth and possibly elsewhere in the Solar System. We propose the comprehensive SOM analyses to reveal the chemical evolution of Ryugu using high-sensitive and high-resolution analytical methods as follows:

1) High-resolution mass spectrometry (HRMS) of various solvent extracts with electrospray ionization (ESI) coupled with or without nano-liquid chromatography.
2) Enantiomerically resolved amino acid analysis using high-resolution column chromatography with high-sensitive fluorescence spectroscopy coupled with HRMS.
3) *In situ* organic compound analysis and molecular imaging using desorption electrospray ionization (DESI) and/or direct analysis in real time (DART) equipped with HRMS.
4) Spatial resolution imaging of organic compounds using time of flight-secondary ion mass spectrometry (ToF-SIMS; Naraoka et al., 2015).

In addition, if the sample is available, we will also perform the following additional analyses:

5) Compound-specific isotope analysis using gas chromatography/combustion or pyrolysis /isotope ratio mass spectrometry (GC/C or pyrolysis/IRMS).
6) Bulk chemical and isotopic analysis of organic matter (C, H, N and S) using nano-EA/IRMS system and laser-tunable FT-IR spectroscopy.

Depending to the sample size available to the initial analysis, we will perform preliminary analytical tests using 30 mg, 10 mg, and 1 mg samples of the Murchison meteorite (CM2, positive SOM-rich), Yamato 793321 meteorite (heated CM2, positive SOM-depleted), and baked serpentine (negative SOM-depleted) as well as procedural blank. The analytical protocol will be discussed in the meeting.

Swedish Institute of Space Physics, 4. SOKENDAI (The Graduate University for Advanced Studies), 5. National Institute of Polar Research, 6. National Astronomical Observatory of Japan

The Earth is surrounded by small dust grains produced by comets and asteroids. Tons of such grains plunge into the Earth's atmosphere hourly. Part of their kinetic energy excites and ionizes the surrounding atmosphere, which is observed as a meteor phenomenon. A simultaneous radar and optical observation is promising to constrain the motion and mass of a meteor at a time. We launched a project to observe faint meteors with Middle and Upper Atmosphere Radar (MU radar) and a wide-field CMOS mosaic camera Tomo-e Gozen installed on the 105 cm Kiso Schmidt telescope. The observations were carried out in 18--21, April, 2018. From tons of the detected meteors, the simultaneous detections were extracted in terms of the times, loci, and directions of the meteors. Finally, we identified the 894 meteor events simultaneously detected in the both sites. The optical brightness of the simultaneous meteors ranged from about 3--11 mag. in the V-band, which is about 5 magnitude fainter than in previous studies. We confirmed a clear correlation between the meteor brightnesses and the radar cross sections.

On June 27, 2018, the asteroid explorer Hayabusa2 arrived at the target C-type asteroid 162173 Ryugu. The telescopic optical navigation camera (ONC-T) on-board Hayabusa2 has acquired the multiband image data for the entire surface of Ryugu with spatial resolutions better than 2 m/pixel. These data show that the Ryugu surface has the very low surface reflectance, flat spectra, and its spatial homogeneity [Sugita et al. 2019]. However, more detailed observations on Ryugu have revealed that many boulders exhibit different spectral properties and that a number of spots with distinctively brighter than the surroundings [Sugita et al. 2019]. Although larger boulders have been analyzed to show that they form two distinctive spectral trends, no substantial spectral analyses on bright spots have been conducted. Determining whether or not these bright spots are one of the materials that originate from the parent body of Ryugu is important to understand the differentiation and geologic processes on the parent body. In this study, in order to understand origins of the bright spots, we investigated spectral characteristics of the bright spots and compared those of the boulders on Ryugu. We used the ONC-T multiband images obtained in Box-A (20 km altitude) and mid-altitude (5 km altitude) operations.

We found seven meter-sized bright spots that have radiance factor 1.3 to 2.0 times higher than that of the surrounding area. The spectra of these bright spots were classified into two types, one being a flat spectrum type and another being a convex spectrum type. The former type has spectrum similar to but flatter and brighter than the mean spectra of the whole Ryugu and boulders, suggesting that the bright spots originate from parent body of Ryugu. The latter type has spectrum similar to those of S-type asteroids, suggesting their exogenous origin.

Planetary Exploration Research Center, Chiba Institute of Technology

An Apollo-type near--Earth asteroid, (155140) 2005 UD, is considered as a possible fragment from (3200) Phaethon, suggesting that Phaethon precursor body might undergo a catastrophic disruption in the past. Here we present our new observational evidence for supporting these two are common origin. We thus conducted a polarimetric observation in 2018 September-October and found that 2005 UD exhibited a polarimetric property significantly different from those of major taxonomic classes of NEAs (i.e., S- and C-type) but similar to that of Phaethon at a wide range of the solar phase angles. Using the polarimetric data, we derived the geometric albedo of ~0.1. In addition, we made a photometric observation at the opposition (the zero phase angle), and determined the mean absolute magnitude of 17.2, the synodic rotational period 5.23 hr, and the effective diameter 1.5 km in combination with the derived geometric albedo. From these evidence, we found that the Phaethon precursor body might have lost more than a few percents of the mass via a disruption if 2005 UD was indeed ejected from the Phaethon precursor.

Follow-up observations for AKARI/IRC near-infrared asteroid spectroscopic survey (AcuA-spec)

*Sunao Hasegawa[1], Daisuke KURODA[2], Kenshi YANAGISAWA[3], Fumihiko Usui[4]

1. Japan Aerospace Exploration Agency, 2. Kyoto University, 3. National Astronomical Observatory of Japan, 4. Kobe University

In the range from 1 to 2.5 μm, we made the spectroscopic observations of the AcuA-spec asteroids (Hasegawa et al. 2017, PASJ, 69, 9), whose spectra were obtained in continuous covered between 2.5 and 5.0 μm by NIR/IRC/AKARI (Usui et al. 2019, PASJ, 71, 1). Candidates of AcuA-spec asteroids were selected from only main-belt asteroids classified based on visible spectrophotometric and spectroscopic observations (Tholen 1984, PhD thesis, Arizona University; Bus & Binzel 2002, Icarus, 158, 146; Lazzaro et al. 2004, Icarus, 172, 179). About 200 classified asteroids were raised as observational candidates. Spectroscopic observations for 65 AcuA-spec asteroids which were selected among the AcuA-spec candidate catalogue in taking account of signal-noise ratio and target opportunity by AKARI were executed.
Section work of the AcuA-spec candidate catalogue was done around 2005, yet there were not many spectroscopic observations of asteroids in the near-infrared wavelength range. As a result of survey of published paper for near-infrared spectroscopic observations of asteroids, howevwer, it was found that spectroscopic observations in the near-infrared region of 1–2.5 μm for most AcuA-spec asteroids are performed except for several asteroids.
If data in near-infrared wavelength range of the lacked AcuA-spec asteroids were acquired, all AcuA-spec asteroids will have 0.35–5 μm of data available. Obtaining continuous reflectance of asteroids is essential data to compare with those such as meteorites. Based on the Bus-DeMeo taxonomy (DeMeo et al. 2009, Icarus, 202, 160), we conducted classification of all AcuA-spec asteroids using published and our observational data.

Amino acids on witness coupons collected from the ISAS/JAXA curation facility for the assessment and quality control of the Hayabusa2 sampling procedure

*Haruna Sugahara[1,2], Yoshinori Takano[1], Yuzuru Karouji[3], Kazuya Kumagai[4], Toru Yada[3], Naohiko Ohkouchi[1], Masanao Abe[3], Hayabusa2 project team

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Institut de Chimie de Nice, Universite Cote dAzur, 3. Japan Aerospace Exploration Agency (JAXA), 4. Marine Works Japan Ltd.

The Hayabusa2 spacecraft is visiting a near-Earth carbonaceous type (C-type) asteroid, 162173 Ryugu, and planning to return the pristine samples to the Earth. C-type asteroids are considered to be related with carbonaceous chondrites that are enriched in organic and volatile materials. The one of the scientific goals of Hayabusa2 mission is to understand the origin and evolution of organic materials through interactions with water and minerals in the early solar system [e.g., 1]. Thus, the characterization of organic materials in the returned sample has great importance for this purpose. However, the analysis of small quantities of extraterrestrial organic materials in the returned samples requires a great care to avoid the introduction of terrestrial contaminants and any artifact materials to the pristine samples. Thus, the assessment of the degrees of the terrestrial contaminants to the samples as well as the comprehensive and specific managements to minimize the terrestrial contamination throughout the mission is essential.

The purpose of the study is to investigate the potential terrestrial organic contamination in a clean chamber for the Hayabusa2 returned samples in an Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency (ISAS/JAXA) curation room [2-4]. As the indicator of the terrestrial organic contaminants, we selected amino acids that ubiquitously exist in the terrestrial environments and are also the target molecules in the Hayabusa2 mission. In the study, we used witness coupons made of aluminum foil to collect the contaminants in the clean chamber. The witness coupons were collected at different exposure times, ranging from 1 day to 1 month to examine the accumulation rate of the contaminants. After the collection, amino acids on the witness coupons were extracted in hot water, hydrolysed with HCl, and then converted to *N*-pivaloyl isopropyl (Pv/iPr) ester derivatives for gas chromatographic (GC) analysis [5].

On the witness coupons, eight terrestrially common amino acids (glycine, alanine, valine, leucine, isoleucine, proline, aspartic acid and glutamic acid) were detected and seven of them, except valine due to the under quantification limit, were quantified. Among them, glycine was the most abundant species with the highest concentration of 10 pmol/cm^2. A time-dependent profile of the four major amino acids (glycine, alanine, aspartic acid and glutamic acid) showed the increasing trend between 1 to 7 days. The average accumulation rates are 1.2 pmol/cm^2/day for glycine, 0.6 pmol/cm^2/day for alanine, 0.1 pmol/cm^2/day for aspartic acid and 0.2 pmol/cm^2/day for glutamic acid. The species and the concentrations of amino acids on our witness coupons are similar to those reported by the National Aeronautics and Space Administration/Johnson Space Center (NASA/JSC) OSIRIS-REx team [6]. Thus, the quality control against terrestrial contaminants in ISAS/JAXA curation facility is at the same quantitative level as in their facility. This inter-laboratory evaluation [7] about the terrestrial organic contamination will provide important information for the curation procedure of the Hayabusa2-returned samples.

Hayabusa2 orbit determination using c5++ software

*Keiko Yamamoto[1], Toshimichi Otsubo[2], Koji Matsumoto[1], Hirotomo Noda[1], Noriyuki Namiki[1], Hiroki Senshu[3], Takahide Mizuno[4], Naoko Ogawa[4], Go Ono[4], Yuya Mimasu[4], Kent Yoshikawa[4], Tadateru Takahashi[4], Yuto Takei[4], Atsushi Fujii[4], Fuyuto Terui[4], Takanao Saiki[4], Satoru Nakazawa[4], Makoto Yoshikawa[4], Yuichi Tsuda[4]

1. National Astronomical Observatory of Japan, 2. Hitotsubashi University, 3. Chiba Institute of Technology, 4. Japan Aerospace Exploration Agency

Hayabusa2 arrived at the target asteroid Ryugu in June 2018 and is currently conducting remote sensing observations with various onboard instruments. So far, we have improved orbit determination software c5++, originally developed for the analysis of satellite laser ranging (SLR) data of the Earth, so that it can be used for the analysis of laser ranging data between Hayabusa2 and Ryugu obtained by Hayabusa2 LIDAR. Then we used it for the estimation of Hayabusa2 trajectory and the GM value of Ryugu. However, in the case of Hayabusa2, it is difficult to determine all of the 6 components of the initial state vector precisely if only LIDAR range data was used, and the simultaneously estimated GM value also had large uncertainty. To overcome this problem, in addition to LIDAR ranging data, we used Automated-Image-Tracking (AIT) data obtained by wide-angle optical navigation camera (ONC-W1) for the estimation of Hayabusa2 trajectory. In principle, LIDAR data gives information on the radial direction and AIT data give the ones on the across and along track directions. Thus, both data sets are complementary and help to improve the precision of the trajectory estimation. For this purpose, we improved c5 ++ so that it can deal with AIT data as observation data. In the presentation, we will show the results of trajectory and GM estimations using LIDAR and AIT data, and show how much the precision and accuracy are improved compared to the case using LIDAR data only.

Observatoire Paris-Site de Meudon, LESIA, France, 15. INAF-IAPS, Italy.

On June 27, 2018, JAXA’s Hayabusa2 spacecraft arrived at its target C-type asteroid Ryugu. Immediately after arrival, remote-sensing observations were carried out with the Optical Navigation Camera (ONC), the Near Infrared Spectrometer (NIRS3), the Thermal Infrared Imager (TIR), and the Laser Altimeter (LIDAR). Based on data from this suite of instruments, we carried out the landing site selection for the first touch-down (TD1). Since the mission aims to understand i) the origin and chemical evolution of the solar system and ii) the formation process and structure of the asteroid, we have set the most scientifically valuable TD1 site as the least altered region where water and/or carbon are potentially abundant.

Landing candidate sites were first selected by engineering evaluation for operational safety followed by scientific evaluations based on criteria such as science and samplability for the most interesting sites. The process was repeated using the observations from the altitudes of 20 km, 6 km, and 5 km.

Scientific evaluations of the landing site candidates were conducted based on the data products from ONC, NIRS3, TIR, and LIDAR. The shape modeling team produced two different shape models. ONC produced multiband images and reflectance spectra, as well as maps of spectral indices and X-means clustering analysis. Measurements of boulder size-frequency and Hapke parameters in the candidate landing areas were examined. NIRS3 produced four types of spectral feature maps. TIR provided maps of maximum temperature from the October 22, 2018 TD1 practice operations, apparent thermal inertia, and typical grain size determinations. LIDAR provided time series ranging data, topography, and corrected spacecraft trajectory.

Engineering evaluation: The possible landing site candidates were selected from the engineering safety score map evaluated based on the sub-Earth distance, local solar angle, local slope and elevation maximum difference. Thermal prediction results for TD1 were obtained by TIR. Temperatures of each site are < 350 K, confirming the safe conditions. The regions that satisfied all the conditions were, L05, L07, L08, L12, M01, M03 and M04.

Scientific evaluation:
1) Boulders. Based on the distribution of boulders with a diameter larger than 3 m for each potential landing site, regions L07, L08, and M04 show smaller percentages of boulder coverage than other areas, and are regarded as safer sites for landing.

©2019. Japan Geoscience Union. All Right Reserved.

2) Geology. Ryugu exhibits a variety of topographic features and geologic settings. From a scientific perspective, it is of interest to be able to study various materials representing the evolution of Ryugu.
3) Hydrous minerals. The NIR spectral properties are nearly homogeneous across Ryugu’ s surface, especially between the candidate sites. The near-infrared reflectance spectra of Ryugu is similar to experimentally heated Murchison meteorite at 400˚C.
4) Carbon contents. It is likely that visible reflectance at 0.55 μm (R(0.55)) is influenced mostly by carbon content. R(0.55) is almost homogeneous across the surface with a low value, regardless of the candidate sites.
5) Secondary processes. Although the surface of Ryugu is almost homogeneous at the macro scale in the map of spectral slope from 0.48 to 0.86 μm, a slight heterogeneity is observed across the candidate regions. L-regions are relatively bluish and M-regions are reddish. Considering that spectral reddening is observed by laser irradiation of dehydrated carbonaceous chondrites, L regions are probably less altered and preferable for sampling.

In the total evaluation, L08, L07 and M04 were selected as the TD1 candidates on August 17, 2018. In September 2018, many boulders > 50 cm were additionally found for the sites during the rehearsal of TD1. Thus, the originally scheduled TD1 in October was postponed. Further search for a flat and safe site continued, and L08-E1 was determined as the TD1 site. The TD1 will be scheduled on Feb 22, 2019.

Visible Photometric, Spectroscopic and Polarimetric observations of an inactive comet, P/2016 BA14 with the 1.6m Pirka Telescope

*Ryo Yamagata[1], Tomohiko Sekiguchi[1], Ryo Okazaki[1], Kazuya Doi[1], Daisuke Kuroda[2], Masateru Ishiguro[3], Hiroyuki Naito[4]

1. Hokkaido University of Education, 2. Kyoto University, 3. Seoul National University, 4. Nayoro Observatory

We performed photometric, spectroscopic and polarimetric observations of an inactive comet, P/2016 BA14 with the 1.6m Pirka Telescope, Hokkaido.

P/2016 BA14 (a=3.02 au, e=0.67, i=18.9 deg.) was discovered as an unusual asteroid with a cometary orbit by the PANSTAARS on 2016 January 21.Since Knight et al. 2016 detected its cometary tail when the object close to sun(r=1.018au). It was classified into a Jupiter Family Comets. It can be regarded as a bare nucleus invisible coma because very weak comet activity that is different from general comet. There is a remarkable similarity between the orbits of 252P/LINEAR (a=3.05au, e=0.67, i=10.4deg) and P/2016 BA14. Jupiter Tisserand parameter is 252P/LINEAR and that of P/2016 BA14 are 2.82. P/2016 BA14 and 252P/LINEAR is division comet that is originally same comet (Jian-Yang.2017).

In this study, surface reflection properties of P/2016 BA14 classify D-type asteroids (Bus-DeMeo taxonomy) from result of visible spectroscopy (435-820nm). Color of surface is little red as D-type asteroid, but very blue as comet nucleus from result of BVRI photometry. The linear polarization Pr=10.46.±0.11% (α=46°) is in close accord with that of D-type asteroids and comet nucleus.

Polycyclic aromatic hydrocarbons and aliphatic hydrocarbons in Jbilet Winselwan carbonaceous chondrite : Attempt to evaluate the thermal metamorphism degree on the parent body

Hiroki Kato[1], *Hikaru Yabuta[1]

1. Hiroshima University, Department of Earth and Planetary Systems Science

Introduction: On June 27, 2018, Hayabusa2 spacecraft arrived at the C-type asteroid Ryugu. The surface of Ryugu has been thought to have experienced dehydration at least partially, according to the grand-based observation (Vilas et al. 2008; Hiroi et al. 1993). Therefore, it is important to investigate the chemical compositions of dehydrated carbonaceous CM chondrites for understanding the surface process of asteroid Ryugu. Although the extents of thermal metamorphism of CM chondrites have been evaluated by mineralogical compositions (e.g., Nakamura et al. 2006) and elemental and molecular compositions of insoluble organic matter (IOM) (e.g., Naraoka et al. 2004; Yabuta et al. 2005), the estimated temperature varies widely. On the other hand, soluble organic molecules from the dehydrated CM chondrites have not been quantified or below detection (e.g. Shimoyama et al. 1989), and there has been no study which evaluated thermal metamorphism based on the compositions of soluble organic molecules. Therefore, in this study, we analyzed aliphatic hydrocarbons and polycyclic aromatic hydrocarbons (PAHs) in Jbilet Winselwan CM chondrite, which is a dehydrated CM chondrite (Zolensky et al 2016) and show similar reflectance spectrum to that of asteroid Ryugu (Kameda et al. 2015), for precise evaluation of parent body thermal metamorphism. The relative abundances of the hydrocarbons were compared with those of Murray meteorite, which is a primitive CM chondrite.

Samples and Methods: Powdered samples of Jbilet Winselwan meteorite and Murray meteorite (0.2 - 0.4g) were extracted with dichloromethane/methanol (9:1) by sonication. The extracts were applied to a silica gel column. From the column, aliphatic hydrocarbons were eluated with hexane and then PAHs were eluated with dichloromethane. The hexane and dichloromethane eluates were concentrated to 100 μl individually under a nitrogen flow for analysis by a gas chromatography coupled with mass spectrometry (GC-MS). Identification and quantification of compounds were made by comparison of peak retention times on mass chromatograms and mass spectra, and peak areas, respectively, with those of standard compounds. For compounds without standard compounds, identification was made by comparison of mass spectra with library data.

Results and discussion: Total concentration of *n*-alkanes from Jbilet Winselwan meteorite (1.85 μg/g meteorite) was 40 times lower than those from Murray meteorite (80.7 μg/g meteorite). Relative abundances of short-chain *n*-alkanes (C_{15}-C_{16}) were dominant in Jbilet Winselwan meteorite, while those of long-chain *n*-alkanes (C_{17}-C_{21}) were dominant in Murray meteorite. This difference implies that short-chain *n*-alkanes were resulted from cracking of long-chain *n*-alkanes and/or IOM during thermal metamorphism of the parent body of Jbilet Winselwan meteorite. Total concentration of PAHs from Jbilet Winselwan meteorite (0.05 μg/ meteorite) was 1000 times lower than those from Murray meteorite (62.0 μg/g meteorite). Dimethylnaphthalene, fluorine, phenanthrene, pyrene, fluoranthene, methylbiphenyl (0.003-0.039 μg/g meteorite) were identified, while low molecular weight PAHs, such as naphthalene, methylnaphthalene, and acenaphthene, were not detected. The results suggest that PAHs with high volatility in Jbilet Winselwan meteorite were lost or involved in further aromatization during thermal metamorphism. Distributions of dimethylnaphthalene and methylbiphenyl isomers in Jbilet Winselwan

©2019. Japan Geoscience Union. All Right Reserved.

and Murray meteorites were similar, respectively, which indicates that the parent body of Jbilet Winselwan meteorite experienced relatively mild thermal metamorphism.

Since June 2018, the Optical Navigation Camera (ONC) onboard Hayabusa2, has observed the C-type asteroid 162173 Ryugu at a distance below 20 km. ONC-T and ONC-W1 are used for surface imaging operations, and their images allow us to investigate the disk-resolved photometric properties of the surface. A narrow-angle camera ONC-T has 7 broad-band filters ranging in wavelength from 0.39–0.95 μm. ONC-W1 is a wide-angle (> 65˚) pan-chromatic camera mainly used for optical navigation during cruise and low-altitude (< 20km) operations. We are proceeding the analysis of both dataset, ONC-T and ONC-W1.

Since Hayabusa2’s position is nominally fixed on the line connecting Ryugu and the Earth, the available solar phase angle range by ONC-T changes seasonally with the orbits of Earth and Ryugu around the sun. Therefore, we are collecting a large number of ONC-T images over a long period of time to cover a wide phase angle range.

ONC-W1 data has a strong point that it covers a wide phase angle range within a single frame during the descent operations, because of its wide field of view. One of our current challenges is deriving a precise viewing geometries (incidence angle, emission angle, and phase angle) at each pixel. Additionally, comparison of the absolute brightness value (radiance factor) with ONC-T is an ongoing issue.

Wed. May 29, 2019 10:45 AM - 12:15 PM JST | Wed. May 29, 2019 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University)

Vertical coupling mechanisms throughout the whole atmosphere are critical to understanding the near Earth space environment, as well as its sensitivity to the solar, geomagnetic, and atmospheric drivers. This international session focuses on physical/chemical processes occurring in the mesosphere, thermosphere, and ionosphere (MTI). Both quiet and disturbed states in response to lower atmospheric forcing or solar forcing are important for understanding the MTI system and its coupling to other regions. We invite presentations of observations and observational concepts with ground-based and/or space-borne instruments, theoretical studies, numerical simulations, and development of data analysis systems for various kinds of temporal and spatial variations in atmosphere-ionosphere coupled system.

Local-time Variabilities of SABER CO_2 in the Mesosphere and Lower Thermosphere Region

*Cornelius Csar Jude Salinas[1], Loren Chang[1], Danie Liang[2], Jia Yue[3], Liying Qian[4], Quan Gan[5], James Russel III[3], Martin G Mlynczak[6]

1. Institute of Space Science, National Central University, 2. Institute of Earth Science, Academia Sinica, 3. Department of Atmospheric Sciences, Hampton University, 4. High Altitude Observatory, National Center for Atmospheric Research, 5. Department of Physics and Astronomy, Clemson University, 6. NASA Langley Research Center

This work presents the local-time variabilities of CO_2 in the Mesosphere and Lower Thermosphere region (MLT region) as observed by the Sounding of the Atmosphere using Broadband Emission Radiometry (SABER) onboard the Thermosphere Ionosphere Mesosphere Energetics and Dynamics Satellite (TIMED Satellite). These are then compared to CO_2 as modeled by the Whole Atmosphere Community Climate Model –eXtended (WACCM-X). Also using WACCM-X, a tendency analysis using the continuity equation is done to explain the local-time variabilities of CO_2 in the MLT region. Finally, consequences of including a significant local-time variability in CO_2 when retrieving SABER temperature profiles are determined.

Enhanced dynamo electric field as a possible cause of ionosphere disturbance before Large Earthquake

*Koichiro Oyama[1,2,3]

1. Institute of Plasma and Space Sciences,National Cheng Kung Univ., Taiwan, 2. International Ceneter for Space Weather Sudy and Education, Kyushu Univ.,, 3. CoLtd. Asia Space Environment Research Consortium, Japan

Disturbance of ionosphere before large earthquakes has been very often reported. One of the possible disturbing drivers is electric field, which explains most of the ionosphere features we reported so far. However, the origin of the electric field is still in the darkness. One idea of electric field generation exists inside earth interior (Freund et a., 2006). We propose here that the electric field is dynamo field at the height of ≈100 km, which simply intensified before earthquake; intensified eastward (westward)electric field during daytime(nighttime). This idea explains satellite data (Oyama et al.,2008; Oyama et al.,2011; Ryu et al., 2014; Ryu et al., 2016; Oyama et al.,2016; Oyama et al., 2019).

Next question on the electric field generation is the mechanism which modifies the dynamo field. We speculate that modification of E field is a result of modification of neutral wind system, which is originally caused by internal gravity waves which propagate from below. Then again next question is on the origin of the internal gravity waves. The waves might be originally caused by the ground motion, and these waves which propagate upward might interact with planetary wave, and amplified. We show several side evidence of ground motions before earthquakes.

Morphology of E1 and E2 Kelvin waves from ECMWF reanalysis

*Chen-Jeih Pan[1], Wei-Sheng Chen[1], Uma Das[2]

1. Institute of Space Science, National Central University, 2. Department of Physics, Indian Institute of Information Technology, Kalyani, India

Kelvin waves are planetary waves traveling eastwards and confined in the equatorial latitudes. The waves play an important role in middle atmosphere dynamics because they transfer energy and momentum from lower to higher altitudes, which contributes to the quasi-biennial oscillation (QBO) and further influences the global climate. Kelvin waves have been studied for many decades, and the most of studies were focused on the waves of wavenumber 1 (E1). On the other hand, the wavenumber-2 Kelvin waves (E2) are also an important part of Kelvin wave activities although their amplitude less than the E1. In this study, we analyzed the long-term European Centre for Medium-Range Weather Forecasts (ECMWF) reanalysis data and reported the morphology of E1 and E2 Kelvin waves in the stratospheric altitudes individually. The temperature from ECMWF reanalysis was used to extract the wave properties. Temperatures between latitudes of 10S and 10N were firstly gridded into the structure of day-altitude-longitude, and then subtract background (longitudinal means) to get equatorial temperature fluctuations. For each altitude, the two-dimensional fast Fourier transform was applied to each 96-day data segment and stepped forward in time by 1 day. The output spectra were then analyzed to get primary wave periods and amplitude variations. From spectra, the E1 amplitude is 1.5 to 2.0 times larger than the E2 in average. The E1 primary periods are 12 to 25 days and are restricted under the 20-km altitude. The periods of 8 to 14 days are the secondary group. They can propagate upward to the 40-km altitude. Regarding the E2, the primary periods are 7 to 12 days and are also restricted under the 20-km altitude. Its secondary group is the periods of 5 to 8 days, which also can propagate upward to the 40-km altitude. Furthermore, the altitude-time-amplitude variation show that the E2 waves are influenced strictly by the QBO westerly. Finally, the cross correlation between E1 and E2 show that the E1 and E2 have high correlation at altitudes close to the tropopause, which implies they are excited simultaneously.

Impact of strong ENSO on TEC activity disturbed by ultra-fast Kelvin waves

*Wei-Sheng Chen[1], C.J. Pan[1], Uma Das[2], Chian-Chiau Lin[3]

1. Institute of Space Science, National Central University, Taiwan, 2. Department of Physics, Indian Institute of Information Technology, Kalyani, India, 3. Environmental Research and Information Center, Chang Jung Christian University, Taiwan

Ultra-fast Kelvin waves (UFKW) are a subclass of Kelvin waves that they have the shortest periods (2-5 days) and thus can propagate into the ionosphere. UFKW relate to ionospheric variations have been reported, which include ionospheric minimum virtual height (h'F), F2 maximum critical frequency (foF2), total electron content (TEC), S4 scintillations, etc. In the study, we analyzed the UFKW activities using SABER (Sounding of the Atmosphere using Broadband Emission Radiometry) temperatures and GIM (Global Ionospheric Maps) TEC from 2009 to 2011 to see how UFKW influence the ionosphere. The period 2009-2011 belongs to the strong ENSO period. Previous studies have shown that Kelvin waves were highly active in this period, especially in the early of 2010. Therefore, this study can implicitly reveal how the ionosphere responds to the ENSO. The wave signatures in SABER temperatures were extracted using the fast Fourier transform (FFT). Temperatures in the geographic equatorial latitudes were gridded into the day-altitude-longitude structure and then removed background to get temperature fluctuations. The two-dimensional FFT was applied to each 96-day data segment for each altitude and stepped forward in time by one day. Regarding TEC, the Lomb-Scargle periodogram was used to extract UFKW signatures. Because TEC has a strong local time variation and constrains by the geomagnetic configuration, TEC at 16 local time and low geomagnetic latitudes were selected. The background was removed firstly from the data and then fed TEC fluctuations into the Lomb-Scargle process, which also stepped forward in time by one day. The FFT and Lomb-Scargle process both outputted spectra, which revealed UFKW activities in the mesosphere and lower thermosphere (MLT) region (90-100 km) and the ionosphere (about 150-600 km). The results show that UFKW activities at two equatorial ionization anomalies (EIA) were almost identical, and both were higher than that at geomagnetic equator. Most of wave activities in the temperature field in the MLT region have corresponding activities in TEC. However, there are a lot of small amplitude activities only in TEC.

Observation and simulation of propagation of coseismic infrasound to the ionosphere

*Jaroslav Chum[1]

1. Institute of Atmospheric Physics of the Czech Academy of Sciences

Vertical motion of the ground surface caused by seismic waves generates acoustic waves that propagate nearly vertically upward owing to supersonic speed of seismic waves. As the air density decreases with height, the amplitude of acoustic waves increases to conserve the energy flux up to the altitudes where the air is so rarefied that it cannot sustain the propagation and the waves start dissipating. For distances up to about 1500 km from the epicenter of the strong earthquakes (M>7), the amplitude (oscillation velocity) of infrasound waves reaches significant values in the upper atmosphere. Consequently, the nonlinear phenomena start to play an important role. Spectral content of the wave packet is changed and the energy is transferred to lower frequencies, which can cause the formation of roughly bipolar N-shaped pulse. The simulation results are compared with observation for selected examples. It is also shown that only infrasound with periods larger than about 10 s (generated by long period seismic waves) can reach the ionospheric heights, namely the F layer where it can be easily detected.

Solar wind influence on tropical cyclones mediated by atmospheric gravity waves

*Paul Prikryl[1,2], Iurii Cherniak[3], Irina Zakharenkova[4,5], James M. Weygand[6], Bharat S. R. Kunduri[7]

Solar wind coupling to the magnetosphere-ionosphere-atmosphere (MIA) system generates medium- and large-scale atmospheric gravity waves (AGWs) propagating globally from sources in the lower thermosphere at high latitudes. The AGWs propagate globally [1,2] upward and downward, are observed in the ionosphere as traveling ionospheric disturbances [3], can be ducted in lower atmosphere over long distances and reach troposphere. At the reflection point in the troposphere they can trigger moist instabilities to initiate convective bursts, with the latent heat release leading to intensification of storms [4]. In the follow-up studies [5,6,7] it was shown that explosive extratropical cyclones and rapid intensification of tropical cyclones tend to follow arrivals of solar wind high-speed streams (HSS) and/or interplanetary coronal mass ejections (ICMEs). The coupling of solar wind to MIA is most intense during the arrivals of co-rotating interaction regions (CIRs) and/or interplanetary shocks at the leading edges of HSSs and ICMEs when the amplitudes of aurorally-generated AGWs are largest. Ray tracing of AGWs in a model atmosphere show that they can reach tropical cyclones. Spiral gravity waves in typhoons were observed and simulated to propagate radially outward from the typhoon core [8]. The spectra of waves in surface pressure and surface wind measured by the Impacts of Typhoons on the Ocean in the Pacific (ITOP) buoy during the nearby passages of intense typhoons are similar to those of incoming aurorally-generated AGWs. It is suggested that the interaction of aurorally-generated gravity waves with the tropical cyclone vortex and the inner primary eyewall plays a role in the intensification process.

VIPIR ionospheric observations in Japan

*Takuya Tsugawa[1], Hideo Maeno[1], Michi Nishioka[1], Takumi Kondo[1], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology

National Institute of Information and Communications Technology (NICT) has observed ionosphere by ionosondes more than 70 years in Japan. At present, four ionosondes at Wakkanai (Sarobetsu), Kokubunji, Yamagawa, Okinawa (Ogimi) are automatically operated and controlled from Tokyo. Major ionospheric parameters such as foF2 and foEs are scaled from the ionograms automatically on a realtime basis and scaled manually for the final values. These scaled parameters are provided through our web site (http://wdc.nict.go.jp/IONO/). In 2017, we replaced the 10C ionosondes with Vertical Incidence Pulsed Ionospheric Radar 2 (VIPIR2) which can separate the O- and X-modes of ionospheric echoes which have improved the availability of automatic scaling of the ionogram. Our automatic scaling method has been improved using new O- and X-modes separated ionograms. As for future plans, we try to expand observation area by oblique sounding observations with VIPIRs in Japan and neighboring countries. We have also tried to detect arrival directions of ionospheric echo by using the 8ch receiving data as a interferometry. In this presentation, we will introduce current status and future plans of ionospheric observation in NICT.

Simulation Results and Performance Analysis of Phase Velocity Spectral Analysis Software (M-Transform) for Airglow Imaging Data

*Septi Perwitasari[1], Takuji Nakamura[2], Masaru Kogure[2], Yoshihiro Tomikawa[2], Mitsumu K. Ejiri[2]

1. LAPAN, 2. NIPR

We have developed a user-friendly software based on *Matsuda et al.*, 2014's 3D-FFT method (M-Transform) for airglow data analysis as a function on Interactive Data Language (IDL). Input of this function is 3-D array of a time series of airglow image that have already been converted to geographical coordinate (*x*, *y*, *t*). The user can customize the wave parameters (e.g. horizontal wavelength (λ_h), wave period (τ), phase speed (*c*), image resolution in space (*dx*,*dy*) and time (*dt*)) in one-line command when executing the program, which depends on their analysis purpose. In order to exhibit this new function's performance and the characteristics/interpretation of the spectral analysis, we have run several test cases using artificial wave. The first case is artificial wave with constant speed (40 m/s) and different wave period (8, 15, 30 min) and horizontal wavelength. In second case, we applied Gaussian shape wave-packet with different FWHM (50, 100, 200 km). For the third test case, with a fixed wave packet size (100 km), we changed the wave packet duration (30, 60, 120 min). The results from the various simulations showed reasonable characteristics of the spectral analysis for different scenarios. We showed that the increase of wave period and horizontal wavelength lead to the wider spectrum with total power difference of ~10%. By changing the wave packet size, we showed that the bigger the wave packet size, the sharper and narrower the spectrum became with the total power increase 2x of the increase size of the wave packet. The result of changing the wave packet duration showed that the longer the duration of wave packet, the spectrum becomes sharper and the total power is proportional to the wave packet length. We also examined the aliasing and zero padding effect on the spectral analysis. In order to avoid the aliasing effect, it is recommended to set the period minimum to at least 2 x image interval (*dt*). More detailed analysis will be discussed during the presentation.

Comparisons of Co-incident Ionospheric Plasma Observations Between FORMOSAT-5/AIP and Millstone Hill Incoherent Scatter Radar

*Yi-Wun Chen[1], Chi-Kuang Chao[1]

1. Graduate Institute of Space Science, National Central University, Taiwan

Advanced Ionospheric Probe (AIP) onboard FORMOSAT-5 satellite has routinely measured ionospheric plasma parameters, like ion concentration, velocity, and temperature in a sun-synchronous circular orbit at 720 km altitude along 2230 local-time sector since November 2017. AIP has found that the satellite has a much lower potential with respective to environmental plasma from measured current-voltage curves. A comparison study shall be performed to identify possible bias on the derived AIP parameters. Co-incident observations have been scheduled with Millstone Hill incoherent scatter radar during 30 January to 1 February 2019. In this poster, preliminary comparison results will be outlined and will be used to improve accuracy of the AIP measurement in the future.

Keywords: FORMOSAT-5, AIP, ionosphere

Sub-ionospheric effects of volcano eruptions using VLF/LF standard radio waves

*Kei Maruyama[1], Hiroyo Ohya[1], Fuminori Tsuchiya[2], Kenro Nozaki[5], Kozo Yamashita[3], Yukihiro Takahashi[4], Hiroyuki Nakata[1], Toshiaki Takano[1]

1. Chiba University, 2. Tohoku University, 3. Ashikaga University, 4. Hokkaido University, 5. National Institute of Information and Communications Technology

Several studies for the F-region ionosphere associated with volcano eruptions based on GPS-TEC data have been reported so far (e.g., Heki, 2006; Dautermann et al., 2009; Heki et al., 2010). These studies reported that acoustic waves excited by volcano eruptions reach up to the F-region ionosphere, and caused F-region perturbations. After eruption of the Kelud Volcano, Indonesia, in February 2014, acoustic resonance between the Earth’ s surface and lower thermosphere was reported based on TEC data and the seismic wave data (Nakashima et al., 2015). However, little studies on the D-region ionosphere associated with volcano eruptions have been reported. In this study, we investigate the D-region effects of eruptions of Sakurajima volcano (31.59N, 130.66E), Japan, at 04:11 UT on June 6, 2014, using intensity perturbation of VLF/LF transmitter signals. The VLF/LF propagation paths use in this study are JJY (JJY 60 kHz) - Tainan (TNN, Taiwan), and JJI (22.2 kHz) - TNN. Based on wavelet spectra, the perturbation of both transmitter signals had a frequency of 2-6 mHz during 04:12-04:30 UT after the eruptions (04:11 UT).We compared the perturbations with atmospheric pressure data obtained by an infrasonic meter observed by Sakurajima Volcano Research Center, Kyoto University, and seismic waves in the NIED F-net data (FUK, STM, and SBR) located close to the JJY-TNN path. The atmospheric pressure and vertical velocity of the seismic waves had the similar frequencies of 2-10 mHz during 04:12-04:47 UT. These similar frequencies suggest that the perturbations would be caused by acoustic resonance between the Earth's surface and lower thermosphere, or by acoustic and atmospheric gravity waves generated by volcanic eruptions. In the presentation, we will discuss the cause of the VLF/LF perturbations in more detail.

Observations of ionospheric and mesospheric wave structures by a low-cost airglow imaging system

*Keisuke Hosokawa[1], Nanami Kusuyama[1], Yuta Hozumi[1], Kohei Takami[1], Susumu Saito[2], Yasunobu Ogawa[3], Mamoru Ishii[4], Yuichi Otsuka[5], Takuya Tsugawa[4]

1. University of Electro-Communications, 2. ENRI, 3. NIPR, 4. NICT, 5. ISEE, Nagoya University

In the last two decades, all-sky airglow imagers with cooled CCD cameras have widely been used to observe large-scale wave structures in the F-region ionosphere, for example medium-scale traveling ionospheric disturbances (MSTIDs). Such wavy features are seen in the oxygen emission at 630.0 nm from altitudes slightly below the F-region peak. Similar optical observations of OH band emission have also enabled us to visualize atmospheric gravity waves at the mesospheric height. Deploying airglow imagers in multiple places is one of the cost-effective ways to visualize the large-scale structure of these wave structures at both the F-region ionosphere and mesosphere [e.g., Kubota et al., 2001; Suzuki et al., 2013]. However, ground-based airglow imagers equipped with a cooled CCD camera is still expensive; thus, it is rather difficult to deploy such systems in a wide area and carry out a network observation. To overcome this limitation, we recently developed a low-cost airglow imaging system (Low-Cost Airglow imaging System: LCAS) which consists of a small camera (WAT-910HX), fisheye lens and optical filter. We then confirmed its capability of imaging the spatial structure of polar cap patches and plasma bubble in the 630.0 nm emission from the F-region. But, still, it is unclarified if the system is also capable of detecting the two-dimensional structure of MSTIDs. On the night of May 12, 2018, we identified a weak wavy signature in the 630.0 nm airglow images from one of our LCAS stations in Ishigaki Island, Japan. The wave structure in the 630.0 nm images was smoothly connected to the structure of MSTIDs in the GPS-TEC data, which confirmed the ability of LCAS for detecting MSTIDs. We also identified smaller scale wave structures in the 630.0 nm images, showing characteristic concentric wave fronts. We speculate that gravity waves in the mesosphere were captured in the 630.0 nm images as a contamination of the OH airglow. This is mainly because we make use of an optical filter having 10 nm FWHM, which enables us to detect several spectral peaks of OH emission near the 630.0 nm oxygen emission. We have estimated the center of the concentric wave structures by using the curvature of the wave fronts, and then confirmed that active rain fall took place in a localized area close to the estimated center of the concentric waves. This result supports our hypothesis that the OH emission containing signatures of mesospheric gravity waves were detected in the 630.0 nm images. In summary, the 630.0 nm airglow observation of LCAS is able to observe MSTIDs and mesospheric gravity waves. This will allow us to monitor such wavy structures at two different altitudes by distributing the similar system in a wide area.

Analysis of characteristics of ionospheric parameters, Sq index and neutral winds over Taiwan

*Yu-Jung Chuo[1]

1. Department of Information Technology, Ling Tung University

In this paper, we examine the variation of thermospheric neutral winds and solar quiet (Sq) current of the geomagnetic fields for the equatorial ionospheric anomaly area (EIA) during the solar activity period in 1999. The thermospheric neutral winds are derived from the ionospheric F_2-layer peak height, hmF_2, by using the servo model method. The variability of the amplitude ofSq fields is derived from the ground geomagnetic fields in the components H and Z, respectively. Theresults of the current system show a same diurnal variation, which that peaks / valleys in the local noon time for Sq(H) / Sq(Z) in the low latitudes, respectively.The results also indicate a weak seasonal variation that peaks appear at the local summer of the Sq currents in H and Z components, respectively. The Sq current system is associated with the change of the equatorial electrojet (EEJ). Further, the variability is probably attributed to local thermospheric winds. The study also shows that the zonal and meridional components of the neutral winds at the EIA over Taiwan area. Furthermore, the study examines the variations of Sq(H), Sq(Z), neutral winds, and ionospheric parameters foE_s, NmF_2, and hmF_2during the disturbed geophysical conditions such as geomagnetic storm and earthquake. The result shows the variationsof ionospheric Sq(H), Sq(Z) and thermospheric neutral winds are different between the seismo-ionospheric and solar-terrestrial disturbed periods, even they lead the same decreasing electron density reaction in the ionosphere at the EIA over Taiwan area.

Statistical study on daytime Es observed by ground-ionosonde and RO-COSMIC in magnetic Equator region in 2010

*Zheng Wang [1,2], Huixin Liu[1]

1. Department of Earth and Planetary Sciences, School of Science, Kyushu University, Japan. , 2. National Space Science Center, Chinese Academy of Sciences, China.

Scintillations under 150 km height shown by radio occultation (RO) of COSMIC are considered to be associated with ionospheric sporadic E (Es) layer. In this paper, we make a Statistical study on daytime Es observed by ground-ionosonde at five stations in magnetic Equator region in 2010, and make a comparison with S4 index from RO-COSMIC within 6 degree of each station. The results show that: At each station the diurnal variation of foEs from ionosonde decrease a little around LT 0600 and then increase, having maximum around LT 1200, decrease around LT 1800 and then increase near LT 2000-2200; All the S4>=0.3 observations during daytime come from RO-COSMIC under 150 km height; The diurnal variation of S4 index under 150 km height from RO-COSMIC over each station has similar trend with that of foEs at the same station; S4 index over 150 km height from RO-COSMIC is only high during nighttime; For the stations at different longitudes, Es occurrences from ionosonde are positively associated with S4>=0.3 from RO-COSMIC. The comparison shows that the S4 index from RO-COSMIC could show some features of daytime Es layer in magnetic Equator region without the location limitation of ground stations.

The statistical study of the growth rates of Medium-Scale Traveling Ionospheric Disturbances observed with GPS-TEC

*Takafumi Ikeda[1], Akinori Saito[1], Takuya Tsugawa[2], Hiroyuki Shinagawa[2]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institutes of Information and Communications Technology

We think two mechanism, E-F coupling and Perkins Instability, will relate to growth for nighttime-MSTID in mid-latitude [Tsunoda and Cosgrove., 2001 ; Perkins., 1973]. Linear growth rate of perturbation intensity of Pedersen conductivity expected from E-F coupling is around 15 minutes [Yokoyama et al., 2009], which is far shorter than one expected from Perkins Instability [Fukao and Kelley, 1991 ; Miller et al., 1997 ; Shiokawa et al., 2003]. However, Es layer’ s spatial and temporal scale is less than 100km and 15min [Maeda et al., 2013 ; S.Saito et al., 2007]. They are different from MSTID’ s ones, which are 200-400 km and around 2hours [Otsuka et al., 2011]. To decide which instability is responsible for growth of nighttime MSTID, the growth rate of MSTID was observationally determined with ground-based GPS network data.

We statistically investigated the growth rate of nighttime-MSTID in Japan in 2014 observed with GPS-TEC. The growth rate of nighttime -MSTID observed was 1.0 - 6.0 $\times 10^{-4}$ s^{-1} during 1800LT-2400LT in summer.Linear growth rate of Perkins instability in summer was 1.0 - 6.0 $\times 10^{-4}$ s^{-1} during 1800LT - 2400LT, so they were less than one of the E-F coupling instability. Also,Seasonal distribution of observed growth rate before midnight was similar to that of linear growth rate.U×B derived by GAIA model was high in spring - summer and seasonal distribution of U×B was similar to that of linear growth rate. Therefore, the growth of MSTID when propagating is not determined by E-F coupling instability but Perkins instability and neutral wind.

Comparison of Gravity Wave Activity in the Mesosphere Observed by OH Airglow Imagers and MF Radars over the Antarctic (Syowa & Davis).

*Masaru Kogure[1], Takuji Nakamura[1,2], Yoshihiro Tomikawa[1,2], Mitsumu K. Ejiri[1,2], Takanori Nishiyama[2,1], Masaki Tsutsumi[1,2], Michael J. Taylor[3], Yucheng Zhao[3], P.-Dominique Pautet[3], Damian Murphy[4]

1. National Institute of Polar Research, 2. Department of Polar Science, Sokendai, 3. Physics Department, Utah State University, 4. Australian Antarctic Division

Gravity waves transport momentum and energy from the lower atmosphere to the upper atmosphere and drive the general circulation, which significantly changes the temperature in the middle atmosphere [Fritts and Alexander, 2003]. To understand this role quantitatively will improve the modern general circulation models [Garcia et al., 2017].

The polar night jet region is known to have high gravity-wave activity. However, sources of gravity waves, their propagation, and their spectra are poorly understood because of a lack of observations. In particular, little is known about the dependence of their characteristics on their spectra (i.e., wavenumber and frequency) and on interactions among waves with several wavenumbers and frequencies [Fritts and Alexander, 2003]. To understand these, our group has observed gravity waves at different sites over the Antarctic.

Observation techniques have limitations due to the breadth of the gravity wave spectrum and the target and physical parameter sensed by the observing system [Alexander et al., 1998]. In this study an OH imager and an MF radar are used. Both instruments cover the OH layer (~87 km altitude), but both cover quite different ranges of the wave spectrum. The OH imager can observe waves with shorter ground-based periods (8-60 min) and shorter horizontal wavelengths (2-100 km) [Matsuda et al., 2017]. On the other hand, the MF radar can observe waves with the longer ground-based periods (>~30 min). It also has a preference for the waves with longer horizontal wavelength because of its observational volume.

This study derives gravity-wave perturbations, over Syowa and Davis, from the OH imager data based on Matsuda et al. [2014] and the MF radar data based on Murphy et al. [2007], respectively. In this presentation, we would like to show the gravity wave activity, over Syowa and Davis, with the shorter horizontal wavelength (i.e., observed by the OH imagers) and with the longer horizontal wavelength (i.e., observed by the MF radars). The correlation and relationship between both wave activities will be discussed. Also, we would like to discuss the local variation of that relationship.

Keywords: Gravity Wave, Middle Atmosphere, OH Imager

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Wed. May 29, 2019 5:15 PM - 6:30 PM JST | Wed. May 29, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

[P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University)

Vertical coupling mechanisms throughout the whole atmosphere are critical to understanding the near Earth space environment, as well as its sensitivity to the solar, geomagnetic, and atmospheric drivers. This international session focuses on physical/chemical processes occurring in the mesosphere, thermosphere, and ionosphere (MTI). Both quiet and disturbed states in response to lower atmospheric forcing or solar forcing are important for understanding the MTI system and its coupling to other regions. We invite presentations of observations and observational concepts with ground-based and/or space-borne instruments, theoretical studies, numerical simulations, and development of data analysis systems for various kinds of temporal and spatial variations in atmosphere-ionosphere coupled system.

High Altitude Observatory, National Center for Atmospheric Research, 5. Department of Physics and Astronomy, Clemson University, 6. NASA Langley Research Center

This work presents the local-time variabilities of CO_2 in the Mesosphere and Lower Thermosphere region (MLT region) as observed by the Sounding of the Atmosphere using Broadband Emission Radiometry (SABER) onboard the Thermosphere Ionosphere Mesosphere Energetics and Dynamics Satellite (TIMED Satellite). These are then compared to CO_2 as modeled by the Whole Atmosphere Community Climate Model –eXtended (WACCM-X). Also using WACCM-X, a tendency analysis using the continuity equation is done to explain the local-time variabilities of CO_2 in the MLT region. Finally, consequences of including a significant local-time variability in CO_2 when retrieving SABER temperature profiles are determined.

Enhanced dynamo electric field as a possible cause of ionosphere disturbance before Large Earthquake

*Koichiro Oyama[1,2,3]

1. Institute of Plasma and Space Sciences,National Cheng Kung Univ., Taiwan, 2. International Ceneter for Space Weather Sudy and Education, Kyushu Univ.,, 3. CoLtd. Asia Space Environment Research Consortium, Japan

Disturbance of ionosphere before large earthquakes has been very often reported. One of the possible disturbing drivers is electric field, which explains most of the ionosphere features we reported so far. However, the origin of the electric field is still in the darkness. One idea of electric field generation exists inside earth interior (Freund et a., 2006). We propose here that the electric field is dynamo field at the height of ≈100 km, which simply intensified before earthquake; intensified eastward (westward)electric field during daytime(nighttime). This idea explains satellite data (Oyama et al.,2008; Oyama et al.,2011; Ryu et al., 2014; Ryu et al., 2016; Oyama et al.,2016; Oyama et al., 2019).

Next question on the electric field generation is the mechanism which modifies the dynamo field. We speculate that modification of E field is a result of modification of neutral wind system, which is originally caused by internal gravity waves which propagate from below. Then again next question is on the origin of the internal gravity waves. The waves might be originally caused by the ground motion, and these waves which propagate upward might interact with planetary wave, and amplified. We show several side evidence of ground motions before earthquakes.

Morphology of E1 and E2 Kelvin waves from ECMWF reanalysis

*Chen-Jeih Pan[1], Wei-Sheng Chen[1], Uma Das[2]

1. Institute of Space Science, National Central University, 2. Department of Physics, Indian Institute of Information Technology, Kalyani, India

Kelvin waves are planetary waves traveling eastwards and confined in the equatorial latitudes. The waves play an important role in middle atmosphere dynamics because they transfer energy and momentum from lower to higher altitudes, which contributes to the quasi-biennial oscillation (QBO) and further influences the global climate. Kelvin waves have been studied for many decades, and the most of studies were focused on the waves of wavenumber 1 (E1). On the other hand, the wavenumber-2 Kelvin waves (E2) are also an important part of Kelvin wave activities although their amplitude less than the E1. In this study, we analyzed the long-term European Centre for Medium-Range Weather Forecasts (ECMWF) reanalysis data and reported the morphology of E1 and E2 Kelvin waves in the stratospheric altitudes individually. The temperature from ECMWF reanalysis was used to extract the wave properties. Temperatures between latitudes of 10S and 10N were firstly gridded into the structure of day-altitude-longitude, and then subtract background (longitudinal means) to get equatorial temperature fluctuations. For each altitude, the two-dimensional fast Fourier transform was applied to each 96-day data segment and stepped forward in time by 1 day. The output spectra were then analyzed to get primary wave periods and amplitude variations. From spectra, the E1 amplitude is 1.5 to 2.0 times larger than the E2 in average. The E1 primary periods are 12 to 25 days and are restricted under the 20-km altitude. The periods of 8 to 14 days are the secondary group. They can propagate upward to the 40-km altitude. Regarding the E2, the primary periods are 7 to 12 days and are also restricted under the 20-km altitude. Its secondary group is the periods of 5 to 8 days, which also can propagate upward to the 40-km altitude. Furthermore, the altitude-time-amplitude variation show that the E2 waves are influenced strictly by the QBO westerly. Finally, the cross correlation between E1 and E2 show that the E1 and E2 have high correlation at altitudes close to the tropopause, which implies they are excited simultaneously.

Impact of strong ENSO on TEC activity disturbed by ultra-fast Kelvin waves

*Wei-Sheng Chen[1], C.J. Pan[1], Uma Das[2], Chian-Chiau Lin[3]

1. Institute of Space Science, National Central University, Taiwan, 2. Department of Physics, Indian Institute of Information Technology, Kalyani, India, 3. Environmental Research and Information Center, Chang Jung Christian University, Taiwan

Ultra-fast Kelvin waves (UFKW) are a subclass of Kelvin waves that they have the shortest periods (2-5 days) and thus can propagate into the ionosphere. UFKW relate to ionospheric variations have been reported, which include ionospheric minimum virtual height (h'F), F2 maximum critical frequency (foF2), total electron content (TEC), S4 scintillations, etc. In the study, we analyzed the UFKW activities using SABER (Sounding of the Atmosphere using Broadband Emission Radiometry) temperatures and GIM (Global Ionospheric Maps) TEC from 2009 to 2011 to see how UFKW influence the ionosphere. The period 2009-2011 belongs to the strong ENSO period. Previous studies have shown that Kelvin waves were highly active in this period, especially in the early of 2010. Therefore, this study can implicitly reveal how the ionosphere responds to the ENSO. The wave signatures in SABER temperatures were extracted using the fast Fourier transform (FFT). Temperatures in the geographic equatorial latitudes were gridded into the day-altitude-longitude structure and then removed background to get temperature fluctuations. The two-dimensional FFT was applied to each 96-day data segment for each altitude and stepped forward in time by one day. Regarding TEC, the Lomb-Scargle periodogram was used to extract UFKW signatures. Because TEC has a strong local time variation and constrains by the geomagnetic configuration, TEC at 16 local time and low geomagnetic latitudes were selected. The background was removed firstly from the data and then fed TEC fluctuations into the Lomb-Scargle process, which also stepped forward in time by one day. The FFT and Lomb-Scargle process both outputted spectra, which revealed UFKW activities in the mesosphere and lower thermosphere (MLT) region (90-100 km) and the ionosphere (about 150-600 km). The results show that UFKW activities at two equatorial ionization anomalies (EIA) were almost identical, and both were higher than that at geomagnetic equator. Most of wave activities in the temperature field in the MLT region have corresponding activities in TEC. However, there are a lot of small amplitude activities only in TEC.

Observation and simulation of propagation of coseismic infrasound to the ionosphere

*Jaroslav Chum[1]

1. Institute of Atmospheric Physics of the Czech Academy of Sciences

Vertical motion of the ground surface caused by seismic waves generates acoustic waves that propagate nearly vertically upward owing to supersonic speed of seismic waves. As the air density decreases with height, the amplitude of acoustic waves increases to conserve the energy flux up to the altitudes where the air is so rarefied that it cannot sustain the propagation and the waves start dissipating. For distances up to about 1500 km from the epicenter of the strong earthquakes (M>7), the amplitude (oscillation velocity) of infrasound waves reaches significant values in the upper atmosphere. Consequently, the nonlinear phenomena start to play an important role. Spectral content of the wave packet is changed and the energy is transferred to lower frequencies, which can cause the formation of roughly bipolar N-shaped pulse. The simulation results are compared with observation for selected examples. It is also shown that only infrasound with periods larger than about 10 s (generated by long period seismic waves) can reach the ionospheric heights, namely the F layer where it can be easily detected.

Solar wind coupling to the magnetosphere-ionosphere-atmosphere (MIA) system generates medium- and large-scale atmospheric gravity waves (AGWs) propagating globally from sources in the lower thermosphere at high latitudes. The AGWs propagate globally [1,2] upward and downward, are observed in the ionosphere as traveling ionospheric disturbances [3], can be ducted in lower atmosphere over long distances and reach troposphere. At the reflection point in the troposphere they can trigger moist instabilities to initiate convective bursts, with the latent heat release leading to intensification of storms [4]. In the follow-up studies [5,6,7] it was shown that explosive extratropical cyclones and rapid intensification of tropical cyclones tend to follow arrivals of solar wind high-speed streams (HSS) and/or interplanetary coronal mass ejections (ICMEs). The coupling of solar wind to MIA is most intense during the arrivals of co-rotating interaction regions (CIRs) and/or interplanetary shocks at the leading edges of HSSs and ICMEs when the amplitudes of aurorally-generated AGWs are largest. Ray tracing of AGWs in a model atmosphere show that they can reach tropical cyclones. Spiral gravity waves in typhoons were observed and simulated to propagate radially outward from the typhoon core [8]. The spectra of waves in surface pressure and surface wind measured by the Impacts of Typhoons on the Ocean in the Pacific (ITOP) buoy during the nearby passages of intense typhoons are similar to those of incoming aurorally-generated AGWs. It is suggested that the interaction of aurorally-generated gravity waves with the tropical cyclone vortex and the inner primary eyewall plays a role in the intensification process.

VIPIR ionospheric observations in Japan

*Takuya Tsugawa[1], Hideo Maeno[1], Michi Nishioka[1], Takumi Kondo[1], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology

National Institute of Information and Communications Technology (NICT) has observed ionosphere by ionosondes more than 70 years in Japan. At present, four ionosondes at Wakkanai (Sarobetsu), Kokubunji, Yamagawa, Okinawa (Ogimi) are automatically operated and controlled from Tokyo. Major ionospheric parameters such as foF2 and foEs are scaled from the ionograms automatically on a realtime basis and scaled manually for the final values. These scaled parameters are provided through our web site (http://wdc.nict.go.jp/IONO/). In 2017, we replaced the 10C ionosondes with Vertical Incidence Pulsed Ionospheric Radar 2 (VIPIR2) which can separate the O- and X-modes of ionospheric echoes which have improved the availability of automatic scaling of the ionogram. Our automatic scaling method has been improved using new O- and X-modes separated ionograms. As for future plans, we try to expand observation area by oblique sounding observations with VIPIRs in Japan and neighboring countries. We have also tried to detect arrival directions of ionospheric echo by using the 8ch receiving data as a interferometry. In this presentation, we will introduce current status and future plans of ionospheric observation in NICT.

Simulation Results and Performance Analysis of Phase Velocity Spectral Analysis Software (M-Transform) for Airglow Imaging Data

*Septi Perwitasari[1], Takuji Nakamura[2], Masaru Kogure[2], Yoshihiro Tomikawa[2], Mitsumu K. Ejiri[2]

1. LAPAN, 2. NIPR

We have developed a user-friendly software based on *Matsuda et al.*, 2014's 3D-FFT method (M-Transform) for airglow data analysis as a function on Interactive Data Language (IDL). Input of this function is 3-D array of a time series of airglow image that have already been converted to geographical coordinate (*x*, *y*, *t*). The user can customize the wave parameters (e.g. horizontal wavelength (λ_h), wave period (τ), phase speed (*c*), image resolution in space (*dx*,*dy*) and time (*dt*)) in one-line command when executing the program, which depends on their analysis purpose. In order to exhibit this new function's performance and the characteristics/interpretation of the spectral analysis, we have run several test cases using artificial wave. The first case is artificial wave with constant speed (40 m/s) and different wave period (8, 15, 30 min) and horizontal wavelength. In second case, we applied Gaussian shape wave-packet with different FWHM (50, 100, 200 km). For the third test case, with a fixed wave packet size (100 km), we changed the wave packet duration (30, 60, 120 min). The results from the various simulations showed reasonable characteristics of the spectral analysis for different scenarios. We showed that the increase of wave period and horizontal wavelength lead to the wider spectrum with total power difference of ~10%. By changing the wave packet size, we showed that the bigger the wave packet size, the sharper and narrower the spectrum became with the total power increase 2x of the increase size of the wave packet. The result of changing the wave packet duration showed that the longer the duration of wave packet, the spectrum becomes sharper and the total power is proportional to the wave packet length. We also examined the aliasing and zero padding effect on the spectral analysis. In order to avoid the aliasing effect, it is recommended to set the period minimum to at least 2 x image interval (*dt*). More detailed analysis will be discussed during the presentation.

Comparisons of Co-incident Ionospheric Plasma Observations Between FORMOSAT-5/AIP and Millstone Hill Incoherent Scatter Radar

*Yi-Wun Chen[1], Chi-Kuang Chao[1]

1. Graduate Institute of Space Science, National Central University, Taiwan

Advanced Ionospheric Probe (AIP) onboard FORMOSAT-5 satellite has routinely measured ionospheric plasma parameters, like ion concentration, velocity, and temperature in a sun-synchronous circular orbit at 720 km altitude along 2230 local-time sector since November 2017. AIP has found that the satellite has a much lower potential with respective to environmental plasma from measured current-voltage curves. A comparison study shall be performed to identify possible bias on the derived AIP parameters. Co-incident observations have been scheduled with Millstone Hill incoherent scatter radar during 30 January to 1 February 2019. In this poster, preliminary comparison results will be outlined and will be used to improve accuracy of the AIP measurement in the future.

Keywords: FORMOSAT-5, AIP, ionosphere

Sub-ionospheric effects of volcano eruptions using VLF/LF standard radio waves

*Kei Maruyama[1], Hiroyo Ohya[1], Fuminori Tsuchiya[2], Kenro Nozaki[5], Kozo Yamashita[3], Yukihiro Takahashi[4], Hiroyuki Nakata[1], Toshiaki Takano[1]

1. Chiba University, 2. Tohoku University, 3. Ashikaga University, 4. Hokkaido University, 5. National Institute of Information and Communications Technology

Several studies for the F-region ionosphere associated with volcano eruptions based on GPS-TEC data have been reported so far (e.g., Heki, 2006; Dautermann et al., 2009; Heki et al., 2010). These studies reported that acoustic waves excited by volcano eruptions reach up to the F-region ionosphere, and caused F-region perturbations. After eruption of the Kelud Volcano, Indonesia, in February 2014, acoustic resonance between the Earth’ s surface and lower thermosphere was reported based on TEC data and the seismic wave data (Nakashima et al., 2015). However, little studies on the D-region ionosphere associated with volcano eruptions have been reported. In this study, we investigate the D-region effects of eruptions of Sakurajima volcano (31.59N, 130.66E), Japan, at 04:11 UT on June 6, 2014, using intensity perturbation of VLF/LF transmitter signals. The VLF/LF propagation paths use in this study are JJY (JJY 60 kHz) - Tainan (TNN, Taiwan), and JJI (22.2 kHz) - TNN. Based on wavelet spectra, the perturbation of both transmitter signals had a frequency of 2-6 mHz during 04:12-04:30 UT after the eruptions (04:11 UT).We compared the perturbations with atmospheric pressure data obtained by an infrasonic meter observed by Sakurajima Volcano Research Center, Kyoto University, and seismic waves in the NIED F-net data (FUK, STM, and SBR) located close to the JJY-TNN path. The atmospheric pressure and vertical velocity of the seismic waves had the similar frequencies of 2-10 mHz during 04:12-04:47 UT. These similar frequencies suggest that the perturbations would be caused by acoustic resonance between the Earth's surface and lower thermosphere, or by acoustic and atmospheric gravity waves generated by volcanic eruptions. In the presentation, we will discuss the cause of the VLF/LF perturbations in more detail.

Observations of ionospheric and mesospheric wave structures by a low-cost airglow imaging system

*Keisuke Hosokawa[1], Nanami Kusuyama[1], Yuta Hozumi[1], Kohei Takami[1], Susumu Saito[2], Yasunobu Ogawa[3], Mamoru Ishii[4], Yuichi Otsuka[5], Takuya Tsugawa[4]

1. University of Electro-Communications, 2. ENRI, 3. NIPR, 4. NICT, 5. ISEE, Nagoya University

In the last two decades, all-sky airglow imagers with cooled CCD cameras have widely been used to observe large-scale wave structures in the F-region ionosphere, for example medium-scale traveling ionospheric disturbances (MSTIDs). Such wavy features are seen in the oxygen emission at 630.0 nm from altitudes slightly below the F-region peak. Similar optical observations of OH band emission have also enabled us to visualize atmospheric gravity waves at the mesospheric height. Deploying airglow imagers in multiple places is one of the cost-effective ways to visualize the large-scale structure of these wave structures at both the F-region ionosphere and mesosphere [e.g., Kubota et al., 2001; Suzuki et al., 2013]. However, ground-based airglow imagers equipped with a cooled CCD camera is still expensive; thus, it is rather difficult to deploy such systems in a wide area and carry out a network observation. To overcome this limitation, we recently developed a low-cost airglow imaging system (Low-Cost Airglow imaging System: LCAS) which consists of a small camera (WAT-910HX), fisheye lens and optical filter. We then confirmed its capability of imaging the spatial structure of polar cap patches and plasma bubble in the 630.0 nm emission from the F-region. But, still, it is unclarified if the system is also capable of detecting the two-dimensional structure of MSTIDs. On the night of May 12, 2018, we identified a weak wavy signature in the 630.0 nm airglow images from one of our LCAS stations in Ishigaki Island, Japan. The wave structure in the 630.0 nm images was smoothly connected to the structure of MSTIDs in the GPS-TEC data, which confirmed the ability of LCAS for detecting MSTIDs. We also identified smaller scale wave structures in the 630.0 nm images, showing characteristic concentric wave fronts. We speculate that gravity waves in the mesosphere were captured in the 630.0 nm images as a contamination of the OH airglow. This is mainly because we make use of an optical filter having 10 nm FWHM, which enables us to detect several spectral peaks of OH emission near the 630.0 nm oxygen emission. We have estimated the center of the concentric wave structures by using the curvature of the wave fronts, and then confirmed that active rain fall took place in a localized area close to the estimated center of the concentric waves. This result supports our hypothesis that the OH emission containing signatures of mesospheric gravity waves were detected in the 630.0 nm images. In summary, the 630.0 nm airglow observation of LCAS is able to observe MSTIDs and mesospheric gravity waves. This will allow us to monitor such wavy structures at two different altitudes by distributing the similar system in a wide area.

Analysis of characteristics of ionospheric parameters, Sq index and neutral winds over Taiwan

*Yu-Jung Chuo[1]

1. Department of Information Technology, Ling Tung University

In this paper, we examine the variation of thermospheric neutral winds and solar quiet (Sq) current of the geomagnetic fields for the equatorial ionospheric anomaly area (EIA) during the solar activity period in 1999. The thermospheric neutral winds are derived from the ionospheric F_2-layer peak height, hmF_2, by using the servo model method. The variability of the amplitude ofSq fields is derived from the ground geomagnetic fields in the components H and Z, respectively. Theresults of the current system show a same diurnal variation, which that peaks / valleys in the local noon time for Sq(H) / Sq(Z) in the low latitudes, respectively.The results also indicate a weak seasonal variation that peaks appear at the local summer of the Sq currents in H and Z components, respectively. The Sq current system is associated with the change of the equatorial electrojet (EEJ). Further, the variability is probably attributed to local thermospheric winds. The study also shows that the zonal and meridional components of the neutral winds at the EIA over Taiwan area. Furthermore, the study examines the variations of Sq(H), Sq(Z), neutral winds, and ionospheric parameters foE_s, NmF_2, and hmF_2during the disturbed geophysical conditions such as geomagnetic storm and earthquake. The result shows the variationsof ionospheric Sq(H), Sq(Z) and thermospheric neutral winds are different between the seismo-ionospheric and solar-terrestrial disturbed periods, even they lead the same decreasing electron density reaction in the ionosphere at the EIA over Taiwan area.

Statistical study on daytime Es observed by ground-ionosonde and RO-COSMIC in magnetic Equator region in 2010

*Zheng Wang [1,2], Huixin Liu[1]

1. Department of Earth and Planetary Sciences, School of Science, Kyushu University, Japan. , 2. National Space Science Center, Chinese Academy of Sciences, China.

Scintillations under 150 km height shown by radio occultation (RO) of COSMIC are considered to be associated with ionospheric sporadic E (Es) layer. In this paper, we make a Statistical study on daytime Es observed by ground-ionosonde at five stations in magnetic Equator region in 2010, and make a comparison with S4 index from RO-COSMIC within 6 degree of each station. The results show that: At each station the diurnal variation of foEs from ionosonde decrease a little around LT 0600 and then increase, having maximum around LT 1200, decrease around LT 1800 and then increase near LT 2000-2200; All the S4>=0.3 observations during daytime come from RO-COSMIC under 150 km height; The diurnal variation of S4 index under 150 km height from RO-COSMIC over each station has similar trend with that of foEs at the same station; S4 index over 150 km height from RO-COSMIC is only high during nighttime; For the stations at different longitudes, Es occurrences from ionosonde are positively associated with S4>=0.3 from RO-COSMIC. The comparison shows that the S4 index from RO-COSMIC could show some features of daytime Es layer in magnetic Equator region without the location limitation of ground stations.

The statistical study of the growth rates of Medium-Scale Traveling Ionospheric Disturbances observed with GPS-TEC

*Takafumi Ikeda[1], Akinori Saito[1], Takuya Tsugawa[2], Hiroyuki Shinagawa[2]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institutes of Information and Communications Technology

We think two mechanism, E-F coupling and Perkins Instability, will relate to growth for nighttime-MSTID in mid-latitude [Tsunoda and Cosgrove., 2001 ; Perkins., 1973]. Linear growth rate of perturbation intensity of Pedersen conductivity expected from E-F coupling is around 15 minutes [Yokoyama et al., 2009], which is far shorter than one expected from Perkins Instability [Fukao and Kelley, 1991 ; Miller et al., 1997 ; Shiokawa et al., 2003]. However, Es layer’ s spatial and temporal scale is less than 100km and 15min [Maeda et al., 2013 ; S.Saito et al., 2007]. They are different from MSTID’ s ones, which are 200-400 km and around 2hours [Otsuka et al., 2011]. To decide which instability is responsible for growth of nighttime MSTID, the growth rate of MSTID was observationally determined with ground-based GPS network data.

We statistically investigated the growth rate of nighttime-MSTID in Japan in 2014 observed with GPS-TEC. The growth rate of nighttime -MSTID observed was 1.0 - 6.0 $\times 10^{-4}$ s^{-1} during 1800LT-2400LT in summer.Linear growth rate of Perkins instability in summer was 1.0 - 6.0 $\times 10^{-4}$ s^{-1} during 1800LT - 2400LT, so they were less than one of the E-F coupling instability. Also,Seasonal distribution of observed growth rate before midnight was similar to that of linear growth rate.U×B derived by GAIA model was high in spring - summer and seasonal distribution of U×B was similar to that of linear growth rate. Therefore, the growth of MSTID when propagating is not determined by E-F coupling instability but Perkins instability and neutral wind.

Comparison of Gravity Wave Activity in the Mesosphere Observed by OH Airglow Imagers and MF Radars over the Antarctic (Syowa & Davis).

*Masaru Kogure[1], Takuji Nakamura[1,2], Yoshihiro Tomikawa[1,2], Mitsumu K. Ejiri[1,2], Takanori Nishiyama[2,1], Masaki Tsutsumi[1,2], Michael J. Taylor[3], Yucheng Zhao[3], P.-Dominique Pautet[3], Damian Murphy[4]

1. National Institute of Polar Research, 2. Department of Polar Science, Sokendai, 3. Physics Department, Utah State University, 4. Australian Antarctic Division

Gravity waves transport momentum and energy from the lower atmosphere to the upper atmosphere and drive the general circulation, which significantly changes the temperature in the middle atmosphere [Fritts and Alexander, 2003]. To understand this role quantitatively will improve the modern general circulation models [Garcia et al., 2017].

The polar night jet region is known to have high gravity-wave activity. However, sources of gravity waves, their propagation, and their spectra are poorly understood because of a lack of observations. In particular, little is known about the dependence of their characteristics on their spectra (i.e., wavenumber and frequency) and on interactions among waves with several wavenumbers and frequencies [Fritts and Alexander, 2003]. To understand these, our group has observed gravity waves at different sites over the Antarctic.

Observation techniques have limitations due to the breadth of the gravity wave spectrum and the target and physical parameter sensed by the observing system [Alexander et al., 1998]. In this study an OH imager and an MF radar are used. Both instruments cover the OH layer (~87 km altitude), but both cover quite different ranges of the wave spectrum. The OH imager can observe waves with shorter ground-based periods (8-60 min) and shorter horizontal wavelengths (2-100 km) [Matsuda et al., 2017]. On the other hand, the MF radar can observe waves with the longer ground-based periods (>~30 min). It also has a preference for the waves with longer horizontal wavelength because of its observational volume.

This study derives gravity-wave perturbations, over Syowa and Davis, from the OH imager data based on Matsuda et al. [2014] and the MF radar data based on Murphy et al. [2007], respectively. In this presentation, we would like to show the gravity wave activity, over Syowa and Davis, with the shorter horizontal wavelength (i.e., observed by the OH imagers) and with the longer horizontal wavelength (i.e., observed by the MF radars). The correlation and relationship between both wave activities will be discussed. Also, we would like to discuss the local variation of that relationship.

[P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Patrick Espy(Norwegian University of Science and Technology), Astrid Maute(National Center for Atmospheric Research, US)

Vertical coupling mechanisms throughout the whole atmosphere are critical to understanding the near Earth space environment, as well as its sensitivity to the solar, geomagnetic, and atmospheric drivers. This international session focuses on physical/chemical processes occurring in the mesosphere, thermosphere, and ionosphere (MTI). Both quiet and disturbed states in response to lower atmospheric forcing or solar forcing are important for understanding the MTI system and its coupling to other regions. We invite presentations of observations and observational concepts with ground-based and/or space-borne instruments, theoretical studies, numerical simulations, and development of data analysis systems for various kinds of temporal and spatial variations in atmosphere-ionosphere coupled system.

Vertical Coupling from the Atmosphere to Geospace at Arrival Heights in Antarctica

*Xinzhao Chu[1]

1. University of Colorado Boulder

The observational campaign with Fe Boltzmann and Na Doppler lidars has entered its 9th year at Arrival Heights near McMurdo (77.8S, 166.7E), Antarctica. The unique datasets have opened an exceptional window for exploration in the vertical coupling from the lower atmosphere to the thermosphere, and vertical coupling among the neutral atmosphere, ionosphere, and magnetosphere. Collaborating with theoreticians and modelers, we are attempting to establish a vertical picture of gravity waves in Antarctica from near the surface to the thermosphere, and a key concept is the secondary gravity wave generation initially hypothesized by Dr. Sharon Vadas. Combining observations with numerical modeling, we are also trying to understand how metal layers with cosmic dust origins are formed high in the thermosphere and ionosphere F-region via a complex atmosphere-ionosphere-magnetosphere (AIM) coupling and even correlating with solar wind activity. In this paper we will report a few studies that may be intriguing for advancing the understandings of vertical coupling from the atmosphere to the geospace at Arrival Heights that is a gravity-wave hotspot and by the edge of polar cap and auroral zone.

Vertical structure of terdiurnal tides in the Antarctic MLT region: 15 years observation over Syowa

*Huixin Liu[1], Masaki Tsutsumi[2], Hanli Liu[3]

1. Earth and Planetary Science Division, Kyushu University, Japan, 2. National Institute for Polar Research, Japan, 3. National Center for Atmospheric Research, US

The terdiurnal tide (TDT) in the Antarctica mesosphere and lower thermosphere (MLT) region is poorly known. In this study, we examine its characteristics using long-term neutral wind observations at Syowa (69S, 39E) between January 2004 and July 2018. The analysis reveals TDT being a significant tidal component in the Antarctica with distinct vertical structures and seasonal evolution. (1) It shows a prominent height-dependent seasonal variation, being in opposite phase above and below 94 km altitude, with peak amplitude in June –July at altitudes below 94 km, but in November –December above it. (2) The zonal wind component is 90 phase shifted from the meridional, with its amplitude of comparable or larger values than the meridional in all seasons except for November –December. (3) The vertical wavelength is shortest (50 –65 km) in local summer (Nov.–Jan.) and longes (80 –110 km) in local winter (Jun.–Aug.). Most of these features differ from those reported in the Arctic, indicating hemispheric asymmetry. Furthermore, the phase structure reveals a dominant upward propagating mode in local summer, but superposition of more than one mode in other seasons. Especially in local winter, a downward propagating mode above 95 km suggests Joule heating/ion drag as likely tidal sources from above, in addition to those from lower atmosphere. The nearly 15 years Syowa observations provide new constrains and benchmark for model simulations that seek to understan terdiurnal tidal forcing mechanisms in polar regions.

3D Investigation of gravity waves propagation by Continuous Doppler sounding

*Jaroslav Chum[1], Katerina Podolska[1]

1. Institute of Atmospheric Physics of the Czech Academy of Sciences

Multi-point continuous Doppler sounding is a useful tool to investigate short-time fluctuations in the ionosphere. We present analysis of GW propagation in the upper atmosphere and ionosphere in 3D. It is based on multi-point continuous Doppler sounding at three different frequencies; sounding radio waves of various frequencies reflect at different altitudes. The advantage of this analysis is information about the GW propagation in 3D and about the attenuation of wave power with height. The disadvantage is a relatively small number of events that can be analyzed as critical frequency of the ionosphere foF2 has to be larger than the highest sounding frequency and also significant cross-correlation between signals reflecting at different altitudes is necessary.

The winter 2015/16 was characterized by an unusually strong polar vortex with values up to 2 standard deviations guiding the mid-latitude planetary waves into the subtropical mesosphere. This exceptionally strong wave activity in the subtropical mesosphere led to a regionally reversed meridional temperature gradient resulting in a zonal wind reversal between 70 and 80 km at polar latitudes due to the thermal wind relation. This regional wind reversal changes the propagation conditions for waves propagating upward from the mesosphere into the thermosphere/ionosphere. The variability of the thermosphere/ionosphere is influenced by forcing from below and thus by gravity waves and atmospheric tides propagating upward from the mesosphere into the thermosphere.
To investigate the change in propagation characteristics of gravity waves and tides in the upper mesosphere/ lower thermosphere (MLT) during this unusual zonal wind reversal in winter 2015/16 we use data from a meteor radar network in Scandinavia. With this network we are able to apply tomographic wind field analysis obtaining horizontally resolved wind fields and horizontal wavelength spectra. Further, we are able to assess the spatial and temporal day-to-day variability of tides.

Ionospheric Variability Associated with the Quasi-6-day Planetary Wave

*Yosuke Yamazaki[1]

1. GFZ German Research Centre for Geosciences

The state of the ionosphere varies from day to day. This is partly due to atmospheric waves that propagate to the upper atmosphere from below. The present study investigates the ionospheric variability associated with the quasi-6-day wave (Q6DW), which is a westward-traveling planetary wave with zonal wave number s=1 and period around t=6d. First, the Q6DW effect on the equatorial ionospheric electric field is examined using the equatorial electrojet measurements from CHAMP and Swarm satellites, as well as ground-based magnetometer and radar observations. Case studies are presented where westward-propagating disturbances with s=1 and t~6d are observed in the daytime equatorial ionospheric electric field. Geopotential height measurements from the Aura satellite confirm the presence of the Q6DW in the lower thermosphere during those events. Next, the impact of the Q6DW on the equatorial ionization anomaly (EIA) is assessed using global maps of total electron content (TEC) from Global Positioning System data. It is shown that the amplitude of the Q6DW in TEC is largest at the EIA crest latitudes and its intra-annual variability closely follows the Q6DW variability in the lower thermosphere.

Discussion

Results of FORMOSAT-3/COSMIC to the most recent developments on FORMOSAT-7/COSMIC-2

*JANN-YENQ Liu[1]

1. Center for Astronautical Physics and Engineering; Graduate Institute of Space Science, National Central University, Taiwan

The FORMOSAT-3 Project is also named Constellation Observing System for Meteorology, Ionosphere and Climate (COSMIC), or FORMOSAT-3/COSMIC (F3/C) for short. The project is targeted to place six micro-satellites into six different orbits with 72-deg inclination at 700~800 kilometer above the earth ground. These satellites orbit around the earth to form a low-earth-orbit constellation that conduct radio occultation (RO) by receiving signals transmitted by the 24 US GPS satellites. The satellite observation covers the entire global ionosphere, providing over 2,500 global RO sounding data (electron density and S4 scintillation profiles) per day since 15 April 2006. This for the first time allows scientists observing the 3D ionospheric electron density structure and dynamics. Simultaneous F3/C RO observations and ground-based receiver measurements of International GNSS (global navigation satellite system) Service (IGS) further initiate constructing three different models for monitoring (near real-time), nowcasting (few minutes to hours), and forecasting (few hours to days) the ionospheric weather resulted from the space weather (solar disturbances, solar winds, magnetic storms, etc.); the atmospheric severe weathers (typhoons, fronts, volcano eruptions, etc.); and the lithosphere weather (earthquakes, tsunami, etc.). The monitoring model is combining the total electron content (TEC) or the GNSS satellite signal scintillations of F3/C and ground-based IGS observations to construct an advanced GIM (global ionospheric map) to report the ionospheric bias and develop L-band scintillation models for communication, positioning, and navigation applications. The nowcast model is a global 3D ionospheric data assimilation model based on the Gauss-Markov Kalman filter with an existing background model to assimilate the TEC observations from the ground-based IGS receivers and space-based F3/C to output the global electron density for coming few minutes to hours. On the other hand, to carry out a long-term forecast, the neutral compositions in the atmosphere should be taken into consideration. Therefore, to develop a forecast model assimilating the observations of F3/C and IGS ground-based receivers into a neutral-ion coupled model. Following the F3/C, FORMOSAT-7/COSMIC (F7/C2) consists of six small-satellites with 24-deg inclination and about 500 km altitude will be launched in 2019. The developed models with F7/C2 RO by receiving signals transmitted by the GPS/GLONASS satellites and IVM (ionospheric velocity meter) plasma measurements as well as ground-based IGS GNSS data shall significantly improve the space weather monitoring/nowcast/forecast in the near future.

A morphological study on the relationship between electron density fluctuations and magnetic fluctuations observed by low altitude satellites in low and middle latitudes

*Toshihiko Iyemori[1], Tadashi Aoyama[1], Yoshihiro Yokoyama[1]

1. Kyoto University

Polar orbiting low-altitude satellites such as the Swarm satellites observe magnetic and electron density fluctuations in low and middle latitudes along satellite orbit. The magnetic fluctuations typically have the period about 10-30seconds along satellite orbit and they are mostly small-scale field-aligned current effects and named as 'magnetic ripples'. They are supposed to be generated in lower ionosphere by dynamo mechanism caused by neutral atmospheric waves from lower atmosphere. On the nightside, they still exist with smaller amplitude because of lower ionospheric conductivity. Plasma bubbles also exist on the nightside and they normally accompany magnetic fluctuations to keep pressure balance. If we trace down to the dynamo layer around 120km altitude from magnetic ripples and compare the electron density fluctuations, they correspond better than the correspondence on the orbit. This indicates vertical propagation of atmospheric waves which causes both magnetic ripples and electron density fluctuations. On the other hand, in well-developed plasma bubbles, plasma density fluctuation and magnetic fluctuation occur at the same location on the orbit. In this study, we present morphological relationship between the two phenomena. That is, we investigate how magnetic ripples relate to plasma bubbles.

Observations of the Thermosphere and Ionosphere by the NASA GOLD Mission

*Stanley C Solomon[1], Alan G. Burns[1], Richard W. Eastes[2], William E. McClintock[2]

1. National Center for Atmospheric Research, 2. University of Colorado

The new Global-scale Observations of the Limb and Disk (GOLD) mission is an imaging spectrograph deployed in geostationary orbit on the SES-14 communications satellite. GOLD measures airglow emitted by the Earth in the far-ultraviolet region of the spectrum from 132 to 164 nm, notably including the 135.6 nm doublet of atomic oxygen (O), and most of the LBH bands of molecular nitrogen (N_2). During the day, the ratios of the oxygen to nitrogen emissions indicate the relative column densities of O and N_2, and temperature can be inferred from the spectral shape of the LBH bands. During the night, radiative recombination emissions by the O doublet indicate the density of the ionosphere, particularly the equatorial ionization anomalies and the structured instabilities that form within them. GOLD also measures exospheric temperatures on the limb, it infers molecular oxygen densities from stellar occultations, and it can also see northern hemisphere aurora. SES-14 was launched in January 2018, the satellite achieved geostationary orbit in, and GOLD observations commenced in October. We will give an overview of the GOLD mission and show preliminary results from its first months of operations. Despite the recent quiet conditions with low solar activity, composition images reveal daily and seasonal variations, indicative of global vertical wind patterns. The equatorial ionization anomalies are seen to be surprisingly variable and dynamic, with instabilities forming on most nights, even at solar minimum. We will compare GOLD results with global general circulation models and airglow emissions modeling, and discuss how these data could be used in assimilation models of the upper atmosphere and ionosphere.

Temporal and spatial evolutions of storm enhanced density in the mid- and low-latitude regions as seen in the variation of global total electron content

*Atsuki Shinbori[1], Takuya Sori[1], Yuichi Otsuka[1], Takuya Tsugawa[2], Michi Nishioka[2]

1. Institute for Space-Earth Environment Research (ISEE), Nagoya University, 2. National Institute of Information and Communications Technology (NICT)

The global electron density distribution in the ionosphere depends strongly on geographical latitude, longitude, and local time. The structure changes severely from the high-latitude to the equatorial regions associated with geomagnetic storms. The storm-time prominent ionospheric phenomena are tongue of ionization (TOI), storm-enhanced density (SED), and equatorial ionization anomaly (EIA). These phenomena are very dynamic because ionospheric electric fields and particle precipitation from the magnetosphere vary significantly during the development and decay of the geomagnetic storms. The generation mechanism of SED has been thought as local upward **E**x**B** drifts [e.g., Huang et al., 2005, Liu et al., 2016], westward plasma transportation from the nightside to the dayside by sub-auroral polarization stream (SAPS) [Foster et al., 2007], equatorward neutral winds [Anderson, 1976], and latitudinal expansion of the EIA [e.g., Kelley et al., 2004]. However, since such different mechanisms of the formation of SED have been proposed by many researchers, a comprehensive understanding of the cause of SED formation has not yet been done. In this study, we investigate the temporal and spatial evolutions of SED during the development and decay of geomagnetic storms using Global Navigation Satellite System (GNSS) Total Electron Content (TEC) data with high time and spatial resolutions, to identify the main mechanism responsible for SED. We also use solar wind data and geomagnetic indices to see the interplanetary condition and geomagnetic activity during geomagnetic storms. In the present analysis, we first calculate the average absolute TEC (ATEC) of 10 geomagnetically quiet days every month, referring to the list of quiet and disturbed days provided by GFZ. Next, we subtract the storm-time ATEC from the average ATEC and create global maps of the difference ATEC in geographical and geomagnetic coordinates. Several hours after the onset of the main phase of the geomagnetic storms, the enhanced TEC region with a narrow latitudinal width (5-10 degrees) appears at high latitudes (60-70 degrees in geomagnetic latitude (GMLAT)) of the afternoon sector (12-16 h, MLT: magnetic local time). The enhanced TEC region is located at a lower latitude of the equatorward wall of the midlatitude trough. As the geomagnetic storms grow, the enhanced TEC region expands to the nightside (~20 h, MLT) within a time scale of 20-30 minutes, and the region moves equatorward within several hours. After that, apart from the midlatitude enhanced TEC phenomena, another TEC enhancement takes place in the low-latitude region (15-30 degrees, GMLAT) on both sides of the dip equator. This observational fact cannot be explained by the latitudinal expansion of the EIA and westward transportation of a part of the higher latitude EIA by SAPS [Kelley et al., 2004; Foster et al., 2007]. As already proposed by Liu et al. [2016], the midlatitude enhanced TEC signature may be caused by upward **E**x**B** drifts that lift the ionosphere in the sunlit region to higher altitudes. In future study, we verify the effect of the localized **E**x**B** drifts on the formation of SED from a comparison between the global TEC and ionospheric plasma flow observed by the SuperDARN radars.

Tidal Forcing Effects on the Zonal Variation of Solstice Equatorial Plasma Bubbles

*Loren Chang[1], Jude Salinas[1], Yi-Chung Chiu[1], Pei-yun Chiu[1], Charles Lin[2]

1. Institute of Space Science and Engineering, Center for Astronautical Physics and Engineering, National Central University, Taiwan, 2. Department of Earth Science, National Cheng Kung University, Taiwan

Equatorial plasma bubbles are elongated plasma depletions that can occur in the nighttime ionospheric F region, causing scintillation in satellite navigation and communications signals, and manifesting in ionograms as spread F. Equatorial plasma bubbles are believed to be Rayleigh-Taylor instabilities seeded by vertically propagating gravity waves. A necessary pre-condition for plasma bubble formation is believed to be a threshold vertical ion drift from the E region, which is required to produce the vertical plasma gradients conducive to such an instability. Factors affecting the zonal and seasonal variation of equatorial plasma bubbles therefore include magnetic declination, as well as the strength of the equatorial electojet, and neutral winds in the lower thermosphere controlling vertical plasma drifts via the wind dynamo. In most longitude zones, the above factors result in elevated occurrence rates of equatorial plasma bubbles during the equinoxes. The notable exception is over the central Pacific and African sectors, where equatorial plasma bubble activity maximizes during solstice. As the zonal separation of the two sectors is roughly half the Earth’ s circumference, *Tsunoda et al.* (2015) hypothesized that the solstice maxima in these two sectors could be driven by a zonal wavenumber 2 atmospheric tidal component in the mesosphere and lower thermosphere (MLT). In this study, we find that the post-sunset electron density observed by FORMOSAT-3/COSMIC during the boreal summer does indeed exhibit a wave-2 zonal distribution in both the equatorial and northern mid latitude regions. The equatorial wave-2 is consistent with results expected from elevated vertical ion drift over the Central Pacific and African sectors, while the mid- latitude wave-2 is consistent with the Mid-Summer Nighttime Anomaly. Using COSMIC, the seasonal, longitudinal, and local time variation of ionospheric tidal and stationary planetary wave (SPW) components that produce zonal wavenumber 2 disturbances when viewed in a constant local time frame is examined. Numerical experiments are also carried out using the Thermosphere Ionosphere Electrodynamics General Circulation Model (TIE-GCM) to determine the effect of the aforementioned tidal and SPW components on vertical ion drift, showing a clear wave-2 modulation of vertical ion drift when subject to forcing from wave-2 atmospheric tidal components in the mesosphere and lower thermosphere. The aforementioned results are consistent with the solstice maxima hypothesis.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Wed. May 29, 2019 1:45 PM - 3:15 PM JST | Wed. May 29, 2019 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

[P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University)

This session provides an opportunity to present recent results from satellite and ground-based observations and theoretical and simulation studies on the magnetosphere, ionosphere, and their coupling processes. We invite talks and posters discussing various phenomena related to the magnetosphere-ionosphere system: solar wind-magnetosphere interaction, magnetosphere-ionosphere convection, field-aligned current, magnetic storms/substorms, neutral-plasma interaction, ionospheric ion inflow and outflow, aurora phenomena, and so forth. Discussions on planetary and satellite ionosphere and magnetospheres, future missions and instrument developments are also welcome.

Effects of Inclination/Rotation of Earth’s Magnetic Axis on Magnetosphere Simulated by Global MHD Model

*Aoi Nakamizo[1]

1. Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology

Recently, we have shown that the ionospheric Hall conductance distribution, owing to the polarization field generated by its nonuniformity, largely control the magnetospheric configuration and dynamics by using a global MHD model. The effects of the ionospheric conductance on the magnetosphere were also reported by previous studies based on other global models; for example, the current-voltage relationship in the solar wind-magnetosphere-ionosphere [Fedder and Lyon, 1987] and the plasma pressure distribution in the near-Earth region [Ridley et al., 2004]. These studies indicate that the ionospheric conductance is one of the most important settings in the global models to accurately simulate the magnetosphere.

On the other hand, in the development/improvement of the global MHD model in NICT, which was originally developed by Tanaka [1994] and Tanaka et al. [2010], introducing the inclination and rotation of Earth’s magnetic axis with respect to the rotation axis has been remained as one of the most difficult problems. In other words, in the present model, the precession between the magnetic axis and the rotation axis is not included. This means that the simulated magnetosphere will show a different structure and temporal development than the actual magnetosphere.

We, for the first time, equivalently introduce the precession by rotating the background conductance distribution due to solar illumination (i.e., depending on the geographic coordinate) with respect to the geomagnetic coordinate. (Improvement of the conductance setting in the auroral region is the next challenge.) In this paper, we will show how the simulated magnetosphere is changed by this improvement, focusing on the near-Earth plasma environment.

Asymmetric deformation of the magnetosphere under low-density solar wind

*Masaki N Nishino[1,2], Yoshifumi Saito[2], Kazuo Shiokawa[1], Masaki Fujimoto[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. JAXA/ISAS

The density of the solar wind around the Earth's magnetosphere sometimes decreases to only several percent of the usual value, and such density extrema results in a significant reduction of dynamic pressure and Alfvenic Mach number of the solar wind flow. While simple expansion of the Earth's magnetosphere by the low dynamic pressure was assumed in previous studies, a global-MHD simulation study predicted a remarkable dawn-dusk asymmetry of the magnetosphere in shape under low-density solar wind and Parker-spiral IMF configuration. Here we present evidence of asymmetric deformation of the magnetosphere under low-density solar wind and Parker-spiral IMF conditions, based on several events of GEOTAIL observations. As predicted by the global-MHD simulation, the magnetosphere on the dawnside expands much further than the magnetopause location of simple (symmetric) expansion, while no significant expansion is detected in the dusk tail flank. Fast ion beams detected at the flank magnetopause suggest that magnetic reconnection frequently occurs due to the low-beta environment of the magnetosheath.

New perspectives on coupling processes in solar-terrestrial system obtained by comprehensive data analysis

*Yoshimasa Tanaka[1], Norio Umemura[2], Shuji Abe[3], Satoru UeNo[4], Masahito Nose[2], Yumi Nakagawa[5]

1. National Institute of Polar Research, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. International Center for Space Weather Science and Education, 4. Kwasan & Hida Observatories, School of Science, Kyoto University, 5. Ibaraki University

In the Earth’ s upper atmosphere above 60 km, including magnetosphere and ionosphere, various phenomena are generated by energy inputs from solar radiation (including solar wind) and atmospheric waves propagating from the lower atmosphere. Thus, comprehensive analysis of various kinds of satellite and ground-based observational data using advanced methods is required to understand physical mechanism of the phenomena. For such interdisciplinary studies, it is important to share data distributed across many universities and institutes and use advanced tools, such as metadata database for cross-searching a variety of datasets and analysis software for analyzing various types of data in an integrated fashion. In fact, many scientific papers on the upper atmosphere have recently been obtained by comprehensive analysis of various data with such analysis tools.
We present some examples of scientific results achieved by comprehensively analyzing data from multiple regions. These examples include the effect of solar coronal holes on the Earth’ s geomagnetic activity and the interaction between solar wind, magnetosphere, ionosphere and neutral atmosphere. The former study investigated long-term trends of coronal boles, solar wind parameters, and Earth’ s geomagnetic indices during two solar cycles. It showed the possibility that the solar wind speed and geomagnetic activities may be controlled by the size and latitudinal distribution of coronal holes. The latter analyzed multi-instrument data simultaneously obtained from interplanetary space, magnetosphere, and ionosphere and mesosphere in both northern and southern hemispheres. They newly found that the polar mesosphere is affected by relativistic electron precipitation caused by the interaction with magnetospheric plasma waves during the high-speed solar wind stream. These studies demonstrate that sharing and comprehensive analysis of long-term, multiple-sphere, and multi-instrument data using sophisticated tools are very effective to produce scientific outcomes. At present there are data gap areas in the Asia and African regions. Therefore, we believe that filling in the data gap by international collaborations could be a breakthrough for unsolved issues in the upper atmosphere.

The interaction between the magnetosphere-ionosphere compound system and the magnetic field topology

*Shigeru Fujita[1], Takashi Tanaka[2], Masakazu Watanabe[2]

1. Meteorological College, Japan Meteorological Agency/ Nationa Institute of Polar Research, 2. Kyushu University

The steady convection in the magnetosphere-ionosphere coupling system is composed of the following self-consistent elementary processes; dynamo in the cusp-mantle region, the field-perpendicular current system in the magnetosphere, the field-aligned current system connecting the ionosphere, the ionospheric electric field, the magnetospheric convection corresponding to the ionospheric electric field, and the high plasma pressure distribution in the cusp region [Tanaka, 2007].

The energy of the convection is transported from the solar wind across the magnetopause where the magnetic field configures the null-separator structure. Since the magnetic field configuration of the null-separator structure is originally derived from the superposition of two scalar fields [Stern, 1973], say, the dipole field and the uniform field, the magnetic field of the null-separator would not have free energy necessary for plasma acceleration. However, the simulation reveals that the magnetic field has a tension force near the null point. Therefore, we need a mechanism that transports the energy to this region.

It is revealed from the simulation that the bow shock supplies the energy. Indeed, the current from the bow shock deforms the magnetic field of the null-separator structure. In addition, it is noted that the Chapman-Ferraro current also deforms the magnetic field configuration in the magnetopause. This fact indicates that the convection system in the magnetosphere contributes to deformation of the null-separator structure. That is to say, energy transport from the solar wind to the magnetosphere-ionosphere compound system is affected by the physical processes in the convection. Therefore, as a result of the interaction between the magnetosphere-ionosphere convection and the null-separator structure, the magnetosphere-ionosphere compound system can be extended to the solar wind-magnetosphere-ionosphere compound system.

Effects of the dipole tilt and the interplanetary magnetic field Bx component on the dawn-dusk and interhemispheric asymmetries of the interchange convection cycle

*Masakazu Watanabe[1,2], Takashi Tanaka[2], Shigeru Fujita[3,4]

1. Graduate School of Science, Kyushu University, 2. International Center for Space Weather Science and Education, Kyushu University, 3. Meteorological College, 4. National Institute of Polar Research

The interchange cycle is a mode of magnetic flux circulation that appears for periods of northward interplanetary magnetic field (IMF). It is made up of IMF-to-open reconnection in one hemisphere and open-to-closed reconnection in the other hemisphere. The two reconnection processes have the same topological nature in that the roles of the two reconnecting field lines interchange at the time of reconnection. The interchange cycle is characterized by reciprocation of open magnetic flux between the two hemispheres. One observable signature of the interchange cycle is an appearance of a reverse cell circulating in the closed field line region of the ionosphere, which is named the “reciprocal cell.” The reciprocal cell appears in the open-to-closed reconnection hemisphere, whereas in the opposite IMF-to-open reconnection hemisphere, there appears a lobe cell circulating exclusively on open field lines. For given (1) IMF By, (2) IMF Bx, and (3) dipole tilt conditions, two interchange cycles concur, one on the dawnside and the other on the duskside. For an ideal case, one can easily expect the mode of the interchange cycles to occur. For example, for the case of due northward IMF with significant dipole tilt, the twin reverse cells in the summer hemisphere are both lobe cells, while in the winter hemisphere the twin reverse cells are both reciprocal cells. For the general case, however, one cannot predict the mode of the interchange cycles without quantitative modeling. The purpose of this study is to examine how the presence of dipole tilt or IMF Bx alters the dawn-dusk and north-south pattern of the twin reverse cells. For this purpose, we perform numerical magnetohydrodynamic simulations using the REPPU (Reproduce Plasma Universe) code developed by T. Tanaka. In the presentation, we discuss the dipole tilt and IMF Bx effects revealed by the numerical modeling.

Transient polar ionospheric convection response to negative dynamic pressure pulse

*Jianjun Liu[1]

1. Polar Research Institute of China

The response of the high latitude ionospheric convection to a sudden decrease in solar wind dynamic pressure provides a unique opportunity to investigate how the solar wind couples to the dayside magnetosphere and ionosphere. Here, the event shows three IMF components do not have prominent changes, but the solar wind plasma went down to near zero magnitude, which leads to very weak solar wind driving during northward IMF. However, ionospheric convection observed by SuperDARN radars showed enhanced plasma flow speed in the central polar cap region just after the negative pressure pulse arrival to the magnetosphere. Simultaneous convection map generated by SuperDARN measurement presents enlarged convection cell with obvious equatorward moving Heppner-Maynard boundary. It is noted that cross polar cap potential enhanced instantly and this enhanced feature continued almost 10 min. The distribution of total electron content (TEC) exhibited typical auroral oval signature especially on dayside ionosphere, TEC density in auroral oval showed a noticeable decrease after the arrival of the negative pressure pulse. Both ionospheric convection and TEC distribution reveal that negative pressure pulse impacts the magnetosphere-ionosphere coupling system directly and dramatically. Moreover, the TIEGCM model also showed an enhanced polar potential pattern.

An active ionosphere: a new perspective of field line dipolarization

*Osuke Saka[1]

1. Office Geophysik

Transient westward electric fields from the magnetosphere generate equatorward plasma drifts of the order of kilometers per second in the auroral ionosphere. This flow channel extends in north-south directions and is produced in the initial pulse of Pi2 pulsations associated with the filed line dipolarization. Drifts in the ionosphere of the order of kilometers per second that accumulated plasmas at the low latitude end of the flow channel are of such large degree that possible vertical transport effects (including precipitation) along the field lines may be ignored. We suggest that plasma compression in the ionosphere implemented the ionosphere to be active. Active ionosphere generates field-aligned currents to satisfy the quasi-neutrality of the ionosphere, ion acoustic wave for ion outflows and the inverted-V type electron precipitations in the topside ionosphere, and poleward expansion of auroras due to a nonlinear evolution of the ionosphere. We will study auroral expansion in this acoustic regime.

Toward the automatic identification of FLR signals in the SuperDARN data by using the gradient method

*Hideaki Kawano[1,2], Akira Sessai Yukimatu[3,4], Nozomu Nishitani[5], Yoshimasa Tanaka[3,4], Satoko Saita[6], Tomoaki Hori[5]

1. Dept. Earth Planet. Sci., Kyushu Univ., 2. ICSWSE, Kyushu University, 3. National Institute of Polar Research, 4. SOKENDAI, 5. ISEE, Nagoya University, 6. Kitakyushu College

The FLR (Field Line Resonance) takes place where the frequency of an incoming wave matches the eigen-frequency of magnetospheric magnetic field lines, and excites the eigen-oscillation of the field lines. The FLR can be identified by using the unique manner of change in the amplitude and the phase of thus excited eigen-oscillation across the resonant point. That is, the amplitude is maximum at the resonant point, and the phase changes the most steeply across the resonance point. The FLR-generated eigen-oscillations can be identified in the ground magnetic field data and the ionospheric plasma velocity data. From thus identified eigen-frequency ("FLR frequency" below) one can estimate the magnetospheric plasma density along the field line which passes through the ground/ionospheric observation point.

In this study we use the SuperDARN radar data to identify FLR: For each radar beam from each SuperDARN radar, the velocity of the ionospheric plasma flow along the line of sight (VLOS) of the beam is obtained; we use the VLOS data to identify the FLR and estimate the magnetospheric plasma density. Unlike the ground magnetometer data, the SuperDARN data is two-dimensional, enabling two-dimensional estimates of the magnetospheric equatorial plasma density and magnetospheric region identification.

To achieve that, it is important to identify as many FLR events as possible. Overwrapping of non-FLR waves/perturbations hides FLR events. As a countermeasure to this problem, the so-called gradient method has been applied to the ground magnetometer data; this method cancels out the overwrapping signals by dividing the data from a magnetometer by the data from another magnetometer having an adequate latitudinal distance from the other. The division yields the amplitude ratio and the phase difference. The gradient method is effective since the FLR frequency tends to depend on the latitude more strongly than the overwrapping signals.

The gradient method is also applicable to the SuperDARN VLOS data. The field of view of each beam is divided into Range Gates (RGs below) having the same length along the beam. The identification number of the RGs increases with increasing distance from the radar. The VLOS is obtained for each RG. Thus, each RG can be regarded as a "virtual observatory."

As an initial study, we have selected an FLR event which was identified in the VLOS data of a radar (at Hankasalmi) without the use of the gradient method, selected a beam, and selected a few pairs of RGs of the beam. We then have manually applied the gradient method to the VLOS data of the above-selected RG pairs, and successfully identified the FLR. In more detail, the identification has been successful only for two paired RGs whose RG numbers differs by two. This suggest that, since the length of the RG, mapped to the meridional plane, was about 40km for this event, about 80km distance was the best (with the resolution of 40km) for this event. This distance reflects the resonance width, which is an important quantity reflecting the diffusion and dissipation of the FLR energy.

©2019. Japan Geoscience Union. All Right Reserved.

In order to identify as many FLR events as possible, it is also important to automatically identify the FLR events, since visual identification is time-consuming. The gradient method enables automatic identification more easily than analyses of VLOS itself, since the gradient method yields peaks in both the amplitude ratio and the phase difference. We have started making a program for automatic identification by applying the gradient method to VLOS; the version at the time of this abstract has successfully identified FLRs for all of the above-stated pairs of RGs.

A statistical study of Pi2 pulsations observed in the upper ionosphere using Swarm magnetic field data

*Park Jaehee[1], Khan-Hyuk Kim[1], Junga Hwang[2]

1. School of Space Research, Kyung Hee University, Gyeonggi, South Korea, 2. Korea Astronomy and Space Science Institute, Daejeon,South Korea

The properties of Pi2 pulsations observed in the upper ionosphere are studied using magnetic field data acquired by the Swarm-A spacecraft in low Earth orbit (LEO) and at the low-latitude Bohyun ground station (BOH, L = 1,3) for January 2014-Jun 2015. From time intervals when Swarm-A was on the nightside (magnetic local time (MLT) = 1800-0600 hrs) and the BOH station was near midnight (MLT = 2100-0300 hrs), we identified 623 Pi2 events in the horizontal H component of the BOH data. For each event we examine the coherence between the horizontal H component on the ground and the B_x (radial) azimuthal B_y (azimuthal), or B_z (compressional) components at Swarm-A. Out of 623 events, the B_x-H high coherence (> 0.7) events are ~6%, the B_y-H high coherence events are ~4%, and the B_z-H high coherence events are ~25%. The ground-satellite high coherence events occurred when the spacecraft was located within a magnetic latitude range of ±50°. Using the ground-satellite high coherence events, we examined the latitudinal structure of the relative amplitude and phase of the ionospheric Pi2 pulsations detected at Swarm-A. Confirming previous observations at LEO, we found that the ionospheric Pi2 pulsations are characterized by symmetric odd mode standing oscillations in the north-south direction, having a node for B_x oscillation and an antinode for B_z oscillation, respectively, at the equator. This indicates that the source of ionospheric Pi2 pulsations is the plasmaspheric resonance.

Study on the global distribution characteristics of Pc 1-2 geomagnetic pulsation with the 10Hz data of the MAGDAS system

*Taisei Kabasawa[1], Akimasa Yoshikawa[1], Teiji Uozumi[1], Akiko Fujimoto[1], Shuji Abe[1]

1. Kyushu University

The magnetic field observed on the ground is affected by the space weather phenomena such as magnetic storms and auroral storms.

The Pc1 geomagnetic pulsation (frequency range of 0.2-5.0 seconds) activated mainly around a high-latitude region is understood as a phenomenon accompanied by the excitation of EMIC waves to cause the particle acceleration in the equatorial region of the magnetosphere. Also, it is well known that Pc1 waves propagate horizontally in the ionospheric at the F layer. However, it is not clarified about the global occurrence and propagation properties of Pc1 geomagnetic pulsation on the ground. Moreover, although induction magnetometers are used to observe the high-frequency magnetic field disturbance phenomenon like Pc1 and Pc2 (frequency range of 5.0-10.0 seconds) geomagnetic pulsation, the global observation network with induction magnetometers covering from high-latitude to low-latitude area and equator domain does not exist at this stage. On the other hand, although it is common to use Fluxgate magnetometers for the observation of global space weather phenomenon, it is considered to be unsuitable for analysis of the high-frequency Pc1-2 geomagnetic pulsation because its time accuracy is usually one second value.

The ground multipoint magnetic field observation network which Kyushu University has developed (MAGDAS-9 magnetometer) acquire a 250Hz sampling and 10Hz mean data. Also, it is the only geomagnetic observation network that can investigate the global aspects of Pc1-2 geomagnetic pulsation.

In this study, we investigated the global distribution of Pc1-2 pulsation from polar region to equatorial region with magnetic field data provided by MAGDAS and Dst/AE index provided by the WDC for Geomagnetism, Kyoto. As a result, when the substorm have occurred during a magnetic storm time, generation of Pc1-2 pulsation from high-latitude to middle-and-low latitude region and further arrival of Pc2 pulsation to the dip-equator are identified. The elucidation of occurrence characteristic of the Pc1-2 pulsation on the ground with the EMIC waves excitation is very important not only for space weather application to be able to monitor particle energization process via EMIC excitation but also the elucidation of the super global coupling process from inner magnetosphere to the global ionosphere from polar to equatorial region. In this presentation, we will report the preliminary results of observational analysis of Pc1-2 pulsation by using MAGDAS network. We also discuss the comprehensive approach for understanding global coupling process among inner magnetosphere and high-middle-low latitude to the equatorial region by using FM-CW radar data, PWING induction magnetometer data, and the geo-space environment data from the ERG satellite.

In-situ Observations of Reconnection Separatrix Regions in the near-Earth Magnetotail

*Mizuho Araki[1], Masahiro Hoshino[1], Kunihiro Keika[1], Yoshifumi Saito[2]

1. Graduate School of Science, The University of Tokyo, 2. Institude of Space and Astronautical Science

Magnetic reconnection which converts magnetic energy into thermal and kinetic energy of plasmas is an important physical mechanism of plasma heating and acceleration. Particularly in the Petschek-type reconnection, plasma acceleration and heating in the slow-mode shocks formed at the separatrices must be taken into consideration. The structure of the slow-mode shocks in the distant tail of the Earth’s magnetosphere was investigated with in-situ observations made by the GEOTAIL satellite (Saito et.al, 1995). It is observationally suggested that about 10% of the plasma sheet boundary layer (PSBL) is slow-mode shocks. It is, however, not fully understood what determines this percentage and what is the difference in the ion and electron temperature changes between slow-mode shocks and others separatrix regions.
In this study, we utilized multi-spacecraft in-situ observations of separatrix regions at magnetic reconnection in the near-Earth magnetotail (GSM-X is between ~13 and ~25RE). We used data obtained from FPI (Fast Plasma Investigation) and FGM (Fluxgate Magnetometer) on board the MMS satellite from June 1, 2017to August 31, 2017. We examined occurrence locations, ion flow directions and velocity of ion flow in downstream regions of observed events. We also examined changes in ion and electron temperatures and the ion-to-electron temperature ratio.

We classified their events into 2 types according to plasma beta in the in-flow regions: below 0.1 or around 1. We term them “lobe reconnection” and “plasma sheet reconnection”, respectively. In the former type, plasmas in the in-flow regions are cold and tenuous. In the latter type, plasmas in the in-flow regions are hot and dense. In both types, we observed increases in ion and electron temperatures increase, but their characteristics are different. In the lobe reconnection, ion temperatures increase from several hundred eV to several keV. In the plasma sheet reconnection, ion temperatures also increase from about 1 keV to several keV. The increase rate of the electron temperature is less than one order of magnitude for both types, smaller than that of the ion temperature; the electron temperature increases up to at most 1 keV. The ion-to-electron temperature ratio in the out-flow regions in both types is about 5 for both types. We then examined changes of the ion-to-electron temperature ratio and found that the changes are consistent with the result reported by Wang et al. (2012).

In this presentation, we will show the results of separatrix crossing events (both lobe and plasma sheet reconnection events) that occur in 2017 and 2018. We will identify whether each of the separatrices is a slow shock or not and how the separatrix conditions affect ion and electron heating. These characteristics will provide insights into heating mechanisms and energy conversion through separatrix regions.

Flow speed dependence of ion temperature, electron temperature, and their ratio in the near-Earth magnetotail reconnection region

*Kaori Watanabe[1], Masahiro Hoshino[1], Kunihiro Keika[1], Yoshifumi Saito[2], Naritoshi Kitamura[1]

1. Univ. of Tokyo, 2. ISAS/JAXA

Plasma in the Earth's magnetotail are heated up to 1-10 keV and stored in the plasma sheet. One of the heating or acceleration mechanisms is the magnetic reconnection. Heated or accelerated plasma are transported both earthward and tailward as fast flow with a speed of several hundred kilometers per second. However, what determines the partition among ion and electron thermal energy and kinetic energy is an unresolved problem. It has been reported that ion temperature T_i, electron temperature T_e, and their ratio T_i/T_e vary spatially and depend on the conditions of fast flows [Wang et al., 2012, Runov et al., 2018] but there are few studies which focus on macroscopic profiles of them in reconnection regions in the magnetotail.

In this study, we examine the relation between flow speed and average profiles of T_i, T_e, and T_i/T_e in the magnetotail reconnection region by using data obtained from FPI and FGM on board the MMS spacecraft. We use the observations for a period from May to August 2017 and take out the data in the region of $X_{GSM} < -15$ Re, -10 Re $< Y_{GSM} < 10$ Re, and beta > 0.1. We then divide them into different groups according to flow speed normalized by alfven speed and show B_z/B_{lobe}– B_x/B_{lobe} maps of T_i, T_e, and T_i/T_e of each group. The results show that ion temperature increase with increasing flow speed while electron temperature decrease. Ion temperature are hotter around the X-point. The structure of inflow and outflow regions is pronounced in the profile of electron temperature. T_i/T_e in inflow region are greater than in outflow region, which means that ion and electron temperatures become comparable by passing through the diffusion region. The results suggest that electron get less energy when more energy is partitioned into plasma kinetic energy. We will discuss about the profiles of anisotropy of plasma temperatures to know more details about the heating mechanisms.

Examining Minimum Cyclotron Resonant Electron Energy of EMIC Waves with MMS

*Si Liu[1]

1. Changsha University of Science and Technology

Electromagnetic ion cyclotron (EMIC) waves can be in cyclotron resonance with relativistic electrons, causing relativistic electron precipitation. The four ideal Magnetospheric Multiscale (MMS) spacecraft provide great opportunity to directly calculate the wave vector ***k*** of EMIC waves by phase differencing technique and hence estimate the minimum resonant energy by the resonance condition. Deriving a simplified analytic solution, we find that the phase differencing method can still provide an estimate of the dominant wave number when a finite wave number spread or a finite frequency spread is present. Numerical calculations indicate that quasi-antiparallel propagation dominates the EMIC event on 20 November 2015, which is consistent with the FFT spectral analysis results. We also find that obtained wave vectors, roughly agreeing with the validity of cold plasma theory, might significantly vary from wave packet to wave packet. Moreover, minimum resonant electron energies gradually increase from 0.5 MeV to tens of MeV with a decreasing parallel componet of ***k***. Current results provide evidence that EMIC waves can be in resonance with the electrons of energies down to hundreds of keV. It further demonstrates that EMIC waves in a narrow frequency band can effectively interact with the relativistic electrons with a broad energy range.

Wave-particle interactions are thought to play a crucial role in energy transfer in collisionless space plasmas in which the motion of charged particles is controlled by electromagnetic fields. In the terrestrial magnetosheath, intense whistler mode waves, called 'Lion roars', are often detected by spacecraft around minima of semi-periodic fluctuations of magnetic field intensity due to mirror mode structures and motion of the structures. It is expected that whistler mode waves are efficiently generated near a local minimum of magnetic field intensity due to the smallest cyclotron resonance velocity. We report the detailed characteristics of such whistler mode waves using the data obtained by the four MMS (Magnetospheric Multiscale) spacecraft. Because reversals of field-aligned component of Poynting flux around minima in mirror mode structures correspond to reversals of gradient of magnetic field intensity along the magnetic field, whistler mode events with reversals of the field-aligned component of Poynting flux are good candidates of observations of effective wave generation regions along field lines. Even in such events, phase difference and change of amplitude of whistler mode waves observed by the four spacecraft do not have a clear correlation in cases of ~40 km separation, which is much smaller than the spatial scale of magnetic field depression due to mirror mode structures and is even smaller than the local thermal ion gyro scale. This result indicates that the coherent whistler wave generation in mirror mode structures has very limited spatial scale across field lines and is probably affected by any electron scale process. A plane wave approximation can be usable only in a very small scale. Because some events in cases of ~7 km separation showed good correlation among four spacecraft, the typical scale of coherent whistler wave across field lines can be at least an order of 10 km in mirror mode structures in the terrestrial magnetosheath. The whistler mode waves observed by a spacecraft in a mirror mode structure are a cluster of waves from multiple spatially small sources.

Spatial characteristics of the internal modulation of pulsating aurora: multi-point high-speed optical observations in Scandinavia

*Yuki Kawamura[1], Keisuke Hosokawa[1], Shin-ichiro Oyama[2,3], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Satoshi Kurita[2], Satoshi Ebukuro[1], Ryoichi Fujii[4]

1. Department of Communication Engineering and Informatics, University of Electro-Communications, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. National Institute of Polar Research, 4. Research Organization of Information and Systems

Pulsating aurora (PsA) is a kind of diffuse aurora which almost always appears in the morning side during the recovery phase of auroral substorm. PsA typically has two characteristic temporal variations. One is so-called main pulsation whose period ranges from a few to a few tens of seconds. The other is a few Hz brightness modulation (internal modulation) which is often seen during the ON time of the main pulsation. Previous studies have suggested that the temporal variation of PsA is characterized by wave-particle interaction between whistler-mode chorus waves and high energy electrons in the magnetosphere. Especially, it has been indicated that there is one to one correspondence between the amplitude variation of chorus waves and the luminosity modulation of PsA.
Recent studies revealed the occurrence distribution of the frequency of the internal modulation. However, there have been no studies which analyzed the spatial distribution of the internal modulation.

To reveal the spatial characteristics of the internal modulation, we need to perform a frequency analysis of the internal modulation by using data from high speed optical instruments having wide spatial coverage. For this purpose, we make use of highly sensitive EMCCD cameras which have been operated in Sodankylä and Kevo in Finland, Tromsø in Norway, and Tjautjas in Sweden. In these observations, all-sky images are taken with a sampling rate of 100 Hz, which is sufficient to identify temporal variations of the internal modulation.

In the frequency analysis, we have employed all-sky images taken on March 15, 2018 (00:00 –01:30 UT) in Sodankylä, Kevo, Tromsø, and Tjautjas. We computed the average frequency of the internal modulation from each pixel of the EMCCD cameras and derived the spatial distribution of their dominant frequencies. Regardless of the latitude, each pulsating patch was fluctuating at a similar frequency. We also derived the frequency spectrum of several pulsating patches existing at different positions in the north-south direction and found that those frequency spectrums of pulsating patches have peaks at about 3 Hz. These results indicate that the frequency of the internal modulation does not depend on the magnetic latitude, and the frequency of the internal modulation is collimated on 3 Hz.
In the presentation, we discuss why the frequency of the internal modulation concentrate on 3 Hz by taking into account the time of flight of PsA electrons.

Large-scale characteristics of pulsating aurora periodicities: multi-point high-speed optical observations in Scandinavia

*Satoshi Ebukuro[1], Keisuke Hosokawa[1], Shin-ichiro Oyama[2,3,5], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Satoshi Kurita[2], Yuki Kawamura[1], Ryoichi Fujii[4]

1. Department of Communication Engineering and Informatics, University of Electro-Communications, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. National Institute of Polar Research, 4. Research Organization of Information and Systems, 5. University of Oulu

It has been known that most of diffuse aurorae in the morning side are composed of luminous patches whose brightness modulates quasi-periodically. Such aurorae are termed as pulsating aurora (PsA) and have been studied extensively in the last decade. PsA patches have a scale size of a few hundreds of km and are usually observed during the late recovery phase of substorms. The entire temporal variation of PsA consists of two individual modulations: main pulsation and internal modulation. The periodicity of the main pulsation ranges from a few to a few tens of seconds and the internal modulation, showing a few Hz scintillating luminosity changes, is often embedded within the ON time of the main pulsation. Previous studies using satellites indicated one-to-one correlation between PsA and chorus wave near the equatorial plane of the magnetosphere, suggesting that ground-based observations of PsA can be used for mapping the activity of chorus in the magnetosphere in 2D fashion. In the past, the spatial characteristics of chorus wave have not visualized in detail because satellite observations only cover a single point in the magnetosphere. To overcome this limitation, we derive the spatial distribution of chorus waves by using ground-based optical observations of PsA and discuss the ambient parameters which characterize the nature of chorus.
For this purpose, we have employed data from electron multiplying charge-coupled device (EMCCD) cameras deployed at multiple sites in Scandinavia to derive the large-scale characteristics of PsA. EMCCD cameras have been operative in Kevo and Sodankyla in Finland, Tromsoe in Norway, and Tjautjas in Sweden and their temporal resolution is 100 Hz. We conducted a frequency analysis for a PsA event on March 28, 2017 (23:30 to 24:10 UT). During the event studied, there existed three different regions of PsA, regions A, B and C, showing different modulation periods. It was also found that the boundaries between these three regions were sharp. We derived the 2D frequency map by using data from all the available stations. As a result, it became clear that the higher latitude region (region C) showed faster internal modulation than the lower latitude region (region A). In addition, region B, which was sandwiched by regions A and C, did not show any internal modulations (i.e., main pulsation without internal modulation). In the presentation, we discuss why the three regions showed different modulation periods with sharp boundaries. In particular, we address what ambient conditions can control the absence of internal modulation in region B. We also derived similar frequency maps of chorus waves by tracing the PsA modulation with the Tsyganenko 04 magnetic field model, which could be used to estimate the spatial extent of chorus wave generation region.

Variations of cosmic noise absorption (CNA) by energetic electron precipitation (EEP) and changes of the auroral morphology

*Miyamoto Taishiro[1], Shin-ichiro Oyama[1,4,5], Yasunobu Ogawa[2], Keisuke Hosokawa[3], Satoshi Kurita[1], Yoshizumi Miyoshi[1], Ryuho Kataoka[2], Hiroshi Miyaoka[2], Tero Raita[4]

1. Institute for Space-Earth Environmental Research,Nagoya University, 2. National Institute of Polar Research, 3. Department of Communication Engineering and Informatics, University of Electro-Communications, 4. Sodankylä Geophysical Observatory, University of Oulu, 5. Ionosphere Research Unit, University of Oulu

Temporal and spatial variations of aurora morphology in association with substorm have been studied for more than half a century. Various types of aurora are known, such as discrete arc emitting at relatively high intensity and elongating along the zonal direction, and diffuse aurora with darker but more widely spreading in the sky. Pulsating aurora, which is characterized by quasi-periodic oscillations in the emission intensity at periods of a few to tens seconds, and auroral patches observed embedding in the pulsating aurora tend to appear at the recovery phase of substorm, especially from midnight to dawn. It is known that these types of aurora are accompanied by energetic electron precipitation exceeding several hundreds keV. Elucidation of the causality to produce pulsating aurora and energetic electron precipitation is an important theme to understand relationships between the radiation belt and upper-middle atmosphere of the earth. Analyzing measurements from satellite observations (e.g., Arase) and ground-based optical/radio technique observations, the generation mechanism is thought to be mainly attributed to wave particle interactions due to plasma wave and electrons in the magnetosphere. In this study, we focus on relationships between auroral morphological changes, in particular spatiotemporal evolutions to patches and coinciding precipitations of the energetic electron.

Some previous studies have presented changes in morphology from pulsating aurora to patch structures [e.g., Shiokawa et al., 2014] and temporal variations of energetic electron precipitation [e.g., Hosokawa and Ogawa, 2015]. As mentioned above, the wave-particle interaction has been widely accepted with experimental evidences to support generation of pulsating aurora and energetic electron precipitation. However, our understanding has not yet reached its maturity of presenting spatiotemporal evolutions of auroral morphology and associated electron precipitation. Oyama et al. [2017] presented enhancements of CNA (cosmic noise absorption) coinciding with appearance of the patch structure but with only two events. Furthermore, due to measurements with intensive diagnostic instruments, the result was based on information of a part of the auroral ionosphere. In this study, we conducted observations to capture simultaneously time evolutions and spatial distributions of auroral morphology and energetic electron precipitation by utilizing a network of EMCCD (Electron Multiplying Charge Coupled Device) cameras and riometers deployed in Northern Europe.

This study will present three events (February 19-20, 2018, March 6-7, 2017, and March 29-30, 2017). On the way of all events, after substorm onsets twice near Northern Europe, another onset occurred again at more west side (near Iceland or Greenland area) but at dawn in the Northern Europe. In this study, we have focused on the aurora and CNA associated with the latter onset, and at that time, the aurora spatially and temporally shifted from diffuse to pulsation and patch structures. This suggests that substorm activities occurred in the distance can induce these auroral morphological changes seen in the Northern Europe. CNA at that time is characterized by gradual variations with time scale of several hours. This trend cannot be seen at substorm onset near the Northern Europe. Moreover, in the latitude distribution, the feature was confirmed that CNA increases at the latitude where patch structure is seen, and CNA keeps

©2019. Japan Geoscience Union. All Right Reserved.

constant value at the latitude where patch structure is not seen. In the presentation, based on these observations, we will discuss physical mechanisms to cause changes in the auroral morphology and energetic electron precipitation, which can be seen as increases of CNA.

Whistler mode waves cause precipitation of high-energy electrons via wave-particle interactions in the magnetosphere. The scattered particles precipitate to the ground along the geomagnetic field line. Then, flush aurora, which is a rapid (less than 1 s) auroral phenomenon, is happened. Flash aurora is important for understanding the spatial evolution of wave-particle interaction region in the magnetosphere. We observed the mainly southward spread of flush aurora. In order to understand the spatial-time variation of wave-particle interaction region, we analyze the propagation effects of whistler mode waves near the magnetic equator region using ray tracing analysis. We calculated the ray paths of whistler mode waves (0.2 fce and 0.4 fce) near the magnetic equator (-10 to +10 degrees of geographic latitude), where fce is the electron cyclotron frequency at the magnetic equator. The initial ray paths put in the assumption of a spatial spread with the wave normal angles of tens of degrees along the magnetic field line at the magnetic equator (a point source). Then, we traced the magnetic field lines from the ray paths of whistler mode waves and estimated the precipitation area of electrons in the ionosphere using the IGRF model. The calculation results showed the precipitation area was not mainly spread southward, but evolved northward in the preliminary study.
In this presentation, we will present the spatiotemporal characteristics of flash aurora and the analysis results of ray tracing in detail.

Molecular ion supply mechanisms from the low-altitude ionosphere to magnetosphere observed by EISCAT and Arase(ERG)

*Masayoshi Takada[1], Kanako Seki[1], Yasunobu Ogawa[2], Kunihiro Keika[3], Satoshi Kasahara[4], Shoichiro Yokota[5], Tomoaki Hori[7], Kazushi Asamura[6], Yoshizumi Miyoshi[7]

Institute for Space-Earth Environmental Research, Nagoya University

Molecular ions ($O_2^+/NO^+/N_2^+$) in the magnetosphere have been observed during magnetic storms [Peterson et al., 1994; Klecker et al., 1986]. These molecular ions are considered to originate from the Earth’ s ionosphere. It is considered that they have been transported upward by some heating processes in the ionosphere. However, due to the larger mass than atomic ions (O^+), the molecular ions usually exist only in the low-altitude ionosphere below 300 km altitude. It is hence difficult to transport these molecular ions by overcoming loss by chemical reactions to the high-altitude ionosphere where the ion upflow and outflows usually take place [Peterson et al., 1994]. Therefore, it is necessary to reveal what mechanism causes molecular ion upflow during the magnetic storms. In this study, we aim at the observational assessments of the supply processes of the molecular ions from the low-altitude ionosphere to the magnetosphere based on conjugate observations by EISCAT radar and the Arase (ERG) satellite.

The EISCAT radar and the Arase (ERG) satellite have the conjunction event during the large magnetic storm with the minimum Dst of -124 nT on September 8, 2017. During the event, the Arase satellite was located in the dusk-side inner magnetosphere and observed molecular ions in the energy range of 12-180 keV/q. The EISCAT radar simultaneously observed the ion upflow (with the upward velocity of ~50-150 m/s) from the low-altitude ionosphere (~250-400 km) together with strong ion heating (>2000 K). The convective electric field was also enhanced by a factor of 2 in the same region. We estimated each term in the equation of motion for ions. The result indicates that the ion upflow reached stable equilibrium because the upward ion and electron pressure gradients are balanced with the downward gravitational force. It is suggested that the ion upflow can take place from the low-altitude ionosphere due to strong ion pressure gradient. We also estimated the flux decrease of molecular ions due to dissociative recombination. The flux decreased to ~1 % at 350 km compared with 280 km. The estimated upflow flux of molecular ions at 350 km is $>10^{10}$ m^{-2} s^{-1} . Comparison between distribution functions observed by Arase satellite and EISCAT radar suggests that acceleration by 3 orders of magnitudes is necessary during the outflow process. These results indicate that the strong ion frictional heating during magnetic storms enabled molecular ions to be transported upward from the low-altitude ionosphere and provide a source of molecular ion outflows into the magnetosphere.

Ionosphere disturbances caused by the auroral electron precipitations are studied using auroral images taken by Auroral Large Imaging System (ALIS) and ionospheric parameters measured by EISCAT UHF radar that were conjugate with ALIS field-of-view. ALIS consists of several remote controlled stations located in northern Scandinavia, separated by approximately 50 km. Each station is equipped with a high-resolution CCD detector with 1024×1024 pixels, and a filter wheel with six positions for narrow-band interference filters. In this study we use the data obtained with the 557.7 nm filter, which show the auroral emission originated from the atomic oxygen. EISCAT UHF radar located in northern Norway near Tromsø operating in the BEATA program provides the ionospheric electron density, electron and ion temperatures, and ion velocity with the time resolution of 5 s and the spatial resolution of 1.5 km. The auroral images from the different ALIS stations were used for triangulation of the auroral forms in order to determine the aurora position in relation to the radar beam. For each auroral arc, the electron density, the electron and ion temperatures measured inside and in the vicinity of the auroral forms were analyzed with the aim of understanding the ionospheric response to the different types of auroral electron precipitations.

We started ground-based observations of MF/HF auroral radio emissions about 10 years ago at two stations (The Husafell Station, Iceland, September 2005; The Kjell Henriksen Observatory, Svalbard, September 2008) and found multiple unknown properties of MF/HF auroral radio emissions, e.g. polarization features [*Sato et al.*, 2008, 2015] and existence of a higher frequency component [*Sato et al.*, 2012]. To make a next siginificant step for a futher understanding of MF/HF auroral radio emissions, we installed a new dedicated instrumentation at the KAIRA (Kilpisjärvi Atmospheric Imaging Receiver Array) site in Kilpisjärvi, Finland (Latitude: 60.07 N, Longitude: 20.76 E) in the summer of 2018. It is a passive receiving system designed to realize a high-resolution spectral, interferometric and polarization measurements using 4 loop antennas and a software-defined radio (SDR) receiver. This SDR receiver can implement high-speed, flexible digital signal processing of RF signals and obtain high-resolution spectra pauselessly throughout the night in a wide frequency range up to 6 MHz. One of the main research subjects of this project is radio emission spontaneously emitted from aurora. There are long-known three types of MF/HF auroral radio emissions identified at ground level: auroral hiss, medium frequency burst (MFB), and auroral roar. Investigation into the generation of these emissions not only offers a tool of great promise for remote sensing of ionospheric plasma processes and parameters but also gives the foundation for understanding various radiation mechanisms that occur in planetary magnetospheres and plasma in space. In combination with the long-term continuous observations in Iceland and Svalbard and future EISCAT_3D experiments, observation with this new instrumentation will provide a first-time opportunity to reveal spatiotemporal variations of macro and fine structures of MF/HF auroral radio emissions associated with substorm evolution. In this presentation, we show detailed specification of this new instrumentation and some initial results.

Ionospheric F-region Drift Measurements Derived from DPS-4D at Zhongshan Station, Antarctic

*Xiangcai Chen[1]

1. Polar Research Institute of China

By means of high-frequency radio sounding, the ionospheric plasma drift can be measured by the Doppler frequency shift of signal. In this paper we analyze the ionospheric F-region plasma motion performed by Digisonde Portable Sounder (DPS-4D) at cusp latitude over Zhongshan Station in Antarctic. By restricting the echo arrival angle, and selecting the reflection height range at 175 –475 km, we present the variation of the F-region plasma drift measurements by setting limits on the Doppler frequency shift. Base on the 7.5 min interval Digisonde drift data from November 2011 to February 2012, we considered the variations of the plasma drift in F-region under the different geomagnetic activity (Kp) and magnetic local time, as well as it correlation with interplanetary magnetic field (IMF). The results indicate that properly restricting the Doppler frequency shift of the echo has a strong effect that contributes to the accurate and robust measurements of the ionospheric plasma drift. The mean value of horizontal drift mostly leveled off to about 600 m/s at altitude around of 230 km, while the field-aligned component of drift showed mean values of -25 m/s near pre-noon and +40 m/s during the night. These strong diurnal variations have dependence on the sign and strength of the IMF B_y and B_z components. It implies that the contraction and expansion of the polar cap with Kp and the convection in the proximity of the throat with different IMF conditions have a profound influence on the observed drift velocities.

PARM-HEP Observation of Precipitating High Energy Electrons over Pulsating Aurora

*Taku Namekawa[1], Takefumi Mitani[2], Kazushi Asamura[2], Yoshifumi Saito[2]

1. Department of Earth and Planetary Science, Graduate school of Science, The University of Tokyo, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The phenomenon called microbursts that radiation belt particles precipitate to the Earth’ s atmosphere is thought to be largely related to the dissipation of high energy electrons in radiation belt. It is suggested that this phenomenon is caused by pitch angle scattering of the magnetospheric particles by plasma waves, which is a mechanism similar to the cause of the pulsating aurora observed in the Earth’ s polar region. There is a possibility that the origin of microburst can be clarified by proving simultaneous occurrence of microburst and pulsating aurora, but observational verification has not been made yet. For that purpose, we have developed a high-energy electron detector (HEP) for the observation of sub-relativistic - relativistic energy electrons that make up the microburst. HEP is designed to measure electrons between 300 keV and 2 MeV with energy resolution of 20% or less and with signal processing time of ~ 5 μs. Energy analysis is performed by the detection part of this instrument using SSD (Solid State Detector). Performance tests of this instrument are carried out using a sealed radiation source and a high energy electron beam line. This instrument is installed as one of the core instruments of the PARM instrument package developed for the simultaneous observation of the pulsating aurora and microburst by an international student sounding rocket experiment RockSat-XN and LAMP (Loss through Auroral Microburst Pulsation) sounding rocket experiment. We have succeeded in obtaining the flight data on 13 January 2019 from RockSat-XN sounding rocket experiment. In parallel, we are now preparing HEP analyzer for LAMP sounding rocket experiment. In this presentation, we will show the outline and observation results of RockSat-XN-HEP as well as the LAMP-HEP development status.

Energetic electrons significantly affect ionospheric dynamics and the long-term evolution of surfaces and atmospheres of planets and moons. Since the energetic electron flux is not necessarily isotropic, it is important to cover the broad solid angle to quantitatively evaluate the effects on solar system bodies. With future planetary explorations in mind, we developed the medium-energy (20 - 100 keV) electron detector (MED) which can cover almost 2-pi steradian without the spacecraft spin. In order to test the performance of this analyzer in the relevant environment, we participated in the PARM mission, which aimed to measure electron precipitation using NASA’s sounding rocket RockSat-XN. In this presentation we report on MED observation results obtained through the flight on 13 January 2019.

Auroral substorm onset in satellite-based global images and ground-based all-sky images

*Akimasa Ieda[1], Kirsti Kauristie[2], Yukitoshi Nishimura[3], Yukinaga Miyashita[4], Harald U Frey[5], Liisa Juusola[2], Daniel Whiter[6], Masahito Nose[7], Matthew O Fillingim[5], Farideh Honary[8], Neil C Rogers[8], Yoshizumi Miyoshi[1], Shinobu Machida[1]

University of California Berkeley, 6. University of Southampton, 7. Graduate School of Science, Kyoto University, 8. Lancaster University

Substorm onset has originally been defined as a longitudinally extended sudden auroral brightening (Akasofu initial brightening: AIB) followed a few minutes later by an auroral poleward expansion in ground-based all-sky images (ASIs). In contrast, such clearly marked two-stage development has not been evident in satellite-based global images (GIs). Instead, substorm onsets have been identified as localized sudden brightenings that expand immediately poleward.
To resolve these differences, optical substorm onset signatures in GIs and ASIs are compared in this study for a substorm that occurred on December 7, 1999. For this substorm, the Polar satellite ultraviolet global imager was operated with a fixed-filter (170 nm) mode, enabling a higher time resolution (37 s) than usual to resolve the possible two-stage development. These data were compared with 20-s resolution green-line (557.7 nm) ASIs at Muonio in Finland. The ASIs revealed the AIB at 2124:50 UT and the subsequent poleward expansion at 2127:50 UT, whereas the GIs revealed only an onset brightening that started at 2127:49 UT.
Thus, the onset in the GIs was delayed relative to the AIB and in fact agreed with the poleward expansion in the ASIs. The fact that the AIB was not evident in the GIs may be attributed to the limited spatial resolution of GIs for thin auroral arc brightenings. The implications of these results for the definition of substorm onset are discussed herein.

Automatic Classification of Auroral images using optical flow feature

*Naoto Kashiwagi[1], Akiko Fujimoto[1], Terumasa Tokunaga[1], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Keisuke Hosokawa[4]

1. Kyushu Institute of Technology, 2. Nagoya University, 3. National Institute of Polar Research, 4. The University of Electro-Communications

The machine learning technique including the deep learning has been developed and the practical uses have increased on various field. On the study of auroral detection, the concern over the automatic image classification has risen using the approach of machine learning technique for the large statistical analysis of auroral images. The automatic auroral image classification has tried to use some techniques from computer vision, machine vision and pattern recognition. There are roughly two kinds of the selected feature: the color of image and the motion of aurora image sequences. The works based on the color feature of aurora image have been performed by Rao et al. (2014) and Tanaka et al. (2015). Rao et al. (2014) performed Support Vector Machines (SVM) classification with several local feature extraction techniques, and found that Scale Invariant Feature Transform (SIFT), OpponentSIFT, is the most effective feature for the automated classification of color aurora images. Tanaka et al. (2015) used the aurora area using the HSV model. They mentioned that it is difficult to classify the images including the diffuse aurora and cloud area. The color feature work well for the color auroral image, while the gray-scale (optically filtered) auroral images need other features on the automated classification. Blixt et al. (2006) applied the optical flow estimation to auroral image sequences. Their case study showed the useful tool for representing the motion of the aurora. In this study, we validate the optical flow estimation to extract the feature of auroral image, and automatically classify the large gray-scale auroral images using the machine learning with Convolution Neural Network (CNN). We use 63,486 gray-scale aurora images in total and use five categories for the preparation of supervised learning data, 1) aurora, 2) aurora and cloudy, 3) aurora and moon, 4) aurora, cloudy and moon, 5) noaurora. We perform the Hold-out and the Cross Validation to evaluate our classification performance. We obtained 98.58% of the classification accuracy based on Hold-out and 98.47% of the classification accuracy based on Cross Validation.

Fine-scale visualization of aurora in a wide area using color digital camera images from the International Space Station

*Sota Nanjo[1], Yuta Hozumi[1], Keisuke Hosokawa[1]

1. The University of Electro-Communications

Various ground-based and space-based imagers have been used to observe aurora borealis and australis. So far, however, it has been difficult to observe the detailed spatial structure of auroras in a wide area with sufficient spatial and temporal resolution. Since the photographs taken from the International Space Station (ISS) have sufficient spatial and temporal resolution, it is possible to visualize the fine-scale structures of aurora in a wide area. A calibration of imaging parameters of the photographs using star lights was proposed by a previous research. The accuracy in the timestamp was not guaranteed by the method based on the star lights because the position of the star lights in the image did not change with elapsed time. Thus, it is still difficult to use the mapped data for studying fast variations of aurora, for example pulsating aurora (PsA). Therefore, in this study, we calibrated the images from the ISS using city lights which change their apparent positions with elapsed time. In order to validate the calibration method using city light positions, we mapped two PsA events in the photographs to the geographical coordinate, and compared with those from ground-based all-sky imagers in Alaska and Canada. We found that the approximate shape of discrete aurora and the temporal variation of PsA derived from the ISS images are consistent with those from the ground-based observation. The accuracy in the timestamp is less than 0.5 sec and that in space in the direction perpendicular to the line of sight of the camera is within 5 km. In the presentation, we will also address how the mapped full-color images can be used for studies of PsA in the future work.

PARM: Investigation of precipitating high-energy electrons into the auroral ionosphere with sounding rockets

*Kazushi Asamura[1], Yoshizumi Miyoshi[2], Keisuke Hosokawa[3], Takefumi Mitani[1], Taku Namekawa[1,5], Takeshi Sakanoi[4], Naoshi Yagi[4], Mizuki Fukizawa[4], Genki Ishizawa[4], Satoshi Kasahara[5], Shin Sugo[5], Oya Kawashima[5], Reiko Nomura[6], Masahito Nose[2], Mariko Teramoto[2], Yasunobu Ogawa[7], Shinji Saito[2], Ryoichi Fujii[8]

1. ISAS / JAXA, 2. ISEE, Nagoya University, 3. The University of Electro-Communications, 4. Tohoku University, 5. The University of Tokyo, 6. NAOJ / NINS, 7. NiPR / ROIS, 8. ROIS

Bursty precipitations of high-energy electrons into the polar ionopshere have been observed by low-altitude satellite, for example, SAMPEX and FIREBIRD II. These precipitations, called microburst, may contribute to the loss of the terrestrial radiation belt through the collisional energy loss with the dense, cold atmospheric particles. Recent numerical simulations successfully reproduce these microburst precipitations with a few Hz modulations by taking into account the pitch angle scattering with the whistler chorus elements at off-equator regions in the inner magnetosphere. Therefore, one can expect that the miscroburst precipitations have properties depending on auroral activities especially the pulsating auroras. In order to investigate the mechanisms of the microburst precipitations by in-situ observations, we are developing two instrument packages: PARM (Pulsating AuRora and Microbursts; already developed) and PARM-2 (being developed), both of which are designed suitable for sounding rocket experiments. PARM consists of four sensors; HEP (high-energy electron energy spectrometer), MED (medium-energy electron detector), AIC (auroral camera), and AFG (ASIC-based fluxgate magnetometer). PARM was onboard the NASA's RockSat-XN sounding rocket, and launched from Andoya, Norway at 09:13UT, Jan 13, 2019. On the other hand, PARM-2 is under development. It consists of HEP, two AICs, and MIM (magneto-impedance magnetometer). PARM-2 is to be onboard the NASA's LAMP sounding rocket which will fly from Poker Flat, Alaska in the period between the end of 2019 and the beginning of 2020.

We will present the overview of PARM missions including the initial results of RockSat-XN/PARM with ground-based observations and preparation status of LAMP/PARM-2.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Wed. May 29, 2019 5:15 PM - 6:30 PM JST | Wed. May 29, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

[P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University)

This session provides an opportunity to present recent results from satellite and ground-based observations and theoretical and simulation studies on the magnetosphere, ionosphere, and their coupling processes. We invite talks and posters discussing various phenomena related to the magnetosphere-ionosphere system: solar wind-magnetosphere interaction, magnetosphere-ionosphere convection, field-aligned current, magnetic storms/substorms, neutral-plasma interaction, ionospheric ion inflow and outflow, aurora phenomena, and so forth. Discussions on planetary and satellite ionosphere and magnetospheres, future missions and instrument developments are also welcome.

Recently, we have shown that the ionospheric Hall conductance distribution, owing to the polarization field generated by its nonuniformity, largely control the magnetospheric configuration and dynamics by using a global MHD model. The effects of the ionospheric conductance on the magnetosphere were also reported by previous studies based on other global models; for example, the current-voltage relationship in the solar wind-magnetosphere-ionosphere [Fedder and Lyon, 1987] and the plasma pressure distribution in the near-Earth region [Ridley et al., 2004]. These studies indicate that the ionospheric conductance is one of the most important settings in the global models to accurately simulate the magnetosphere.

On the other hand, in the development/improvement of the global MHD model in NICT, which was originally developed by Tanaka [1994] and Tanaka et al. [2010], introducing the inclination and rotation of Earth’s magnetic axis with respect to the rotation axis has been remained as one of the most difficult problems. In other words, in the present model, the precession between the magnetic axis and the rotation axis is not included. This means that the simulated magnetosphere will show a different structure and temporal development than the actual magnetosphere.

We, for the first time, equivalently introduce the precession by rotating the background conductance distribution due to solar illumination (i.e., depending on the geographic coordinate) with respect to the geomagnetic coordinate. (Improvement of the conductance setting in the auroral region is the next challenge.) In this paper, we will show how the simulated magnetosphere is changed by this improvement, focusing on the near-Earth plasma environment.

Asymmetric deformation of the magnetosphere under low-density solar wind

*Masaki N Nishino[1,2], Yoshifumi Saito[2], Kazuo Shiokawa[1], Masaki Fujimoto[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. JAXA/ISAS

The density of the solar wind around the Earth's magnetosphere sometimes decreases to only several percent of the usual value, and such density extrema results in a significant reduction of dynamic pressure and Alfvenic Mach number of the solar wind flow. While simple expansion of the Earth's magnetosphere by the low dynamic pressure was assumed in previous studies, a global-MHD simulation study predicted a remarkable dawn-dusk asymmetry of the magnetosphere in shape under low-density solar wind and Parker-spiral IMF configuration. Here we present evidence of asymmetric deformation of the magnetosphere under low-density solar wind and Parker-spiral IMF conditions, based on several events of GEOTAIL observations. As predicted by the global-MHD simulation, the magnetosphere on the dawnside expands much further than the magnetopause location of simple (symmetric) expansion, while no significant expansion is detected in the dusk tail flank. Fast ion beams detected at the flank magnetopause suggest that magnetic reconnection frequently occurs due to the low-beta environment of the magnetosheath.

New perspectives on coupling processes in solar-terrestrial system obtained by comprehensive data analysis

*Yoshimasa Tanaka[1], Norio Umemura[2], Shuji Abe[3], Satoru UeNo[4], Masahito Nose[2], Yumi Nakagawa[5]

1. National Institute of Polar Research, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. International Center for Space Weather Science and Education, 4. Kwasan & Hida Observatories, School of Science, Kyoto University, 5. Ibaraki University

In the Earth’ s upper atmosphere above 60 km, including magnetosphere and ionosphere, various phenomena are generated by energy inputs from solar radiation (including solar wind) and atmospheric waves propagating from the lower atmosphere. Thus, comprehensive analysis of various kinds of satellite and ground-based observational data using advanced methods is required to understand physical mechanism of the phenomena. For such interdisciplinary studies, it is important to share data distributed across many universities and institutes and use advanced tools, such as metadata database for cross-searching a variety of datasets and analysis software for analyzing various types of data in an integrated fashion. In fact, many scientific papers on the upper atmosphere have recently been obtained by comprehensive analysis of various data with such analysis tools.
We present some examples of scientific results achieved by comprehensively analyzing data from multiple regions. These examples include the effect of solar coronal holes on the Earth’ s geomagnetic activity and the interaction between solar wind, magnetosphere, ionosphere and neutral atmosphere. The former study investigated long-term trends of coronal boles, solar wind parameters, and Earth’ s geomagnetic indices during two solar cycles. It showed the possibility that the solar wind speed and geomagnetic activities may be controlled by the size and latitudinal distribution of coronal holes. The latter analyzed multi-instrument data simultaneously obtained from interplanetary space, magnetosphere, and ionosphere and mesosphere in both northern and southern hemispheres. They newly found that the polar mesosphere is affected by relativistic electron precipitation caused by the interaction with magnetospheric plasma waves during the high-speed solar wind stream. These studies demonstrate that sharing and comprehensive analysis of long-term, multiple-sphere, and multi-instrument data using sophisticated tools are very effective to produce scientific outcomes. At present there are data gap areas in the Asia and African regions. Therefore, we believe that filling in the data gap by international collaborations could be a breakthrough for unsolved issues in the upper atmosphere.

The interaction between the magnetosphere-ionosphere compound system and the magnetic field topology

*Shigeru Fujita[1], Takashi Tanaka[2], Masakazu Watanabe[2]

1. Meteorological College, Japan Meteorological Agency/ Nationa Institute of Polar Research, 2. Kyushu University

The steady convection in the magnetosphere-ionosphere coupling system is composed of the following self-consistent elementary processes; dynamo in the cusp-mantle region, the field-perpendicular current system in the magnetosphere, the field-aligned current system connecting the ionosphere, the ionospheric electric field, the magnetospheric convection corresponding to the ionospheric electric field, and the high plasma pressure distribution in the cusp region [Tanaka, 2007].

The energy of the convection is transported from the solar wind across the magnetopause where the magnetic field configures the null-separator structure. Since the magnetic field configuration of the null-separator structure is originally derived from the superposition of two scalar fields [Stern, 1973], say, the dipole field and the uniform field, the magnetic field of the null-separator would not have free energy necessary for plasma acceleration. However, the simulation reveals that the magnetic field has a tension force near the null point. Therefore, we need a mechanism that transports the energy to this region.

It is revealed from the simulation that the bow shock supplies the energy. Indeed, the current from the bow shock deforms the magnetic field of the null-separator structure. In addition, it is noted that the Chapman-Ferraro current also deforms the magnetic field configuration in the magnetopause. This fact indicates that the convection system in the magnetosphere contributes to deformation of the null-separator structure. That is to say, energy transport from the solar wind to the magnetosphere-ionosphere compound system is affected by the physical processes in the convection. Therefore, as a result of the interaction between the magnetosphere-ionosphere convection and the null-separator structure, the magnetosphere-ionosphere compound system can be extended to the solar wind-magnetosphere-ionosphere compound system.

Effects of the dipole tilt and the interplanetary magnetic field Bx component on the dawn-dusk and interhemispheric asymmetries of the interchange convection cycle

*Masakazu Watanabe[1,2], Takashi Tanaka[2], Shigeru Fujita[3,4]

1. Graduate School of Science, Kyushu University, 2. International Center for Space Weather Science and Education, Kyushu University, 3. Meteorological College, 4. National Institute of Polar Research

The interchange cycle is a mode of magnetic flux circulation that appears for periods of northward interplanetary magnetic field (IMF). It is made up of IMF-to-open reconnection in one hemisphere and open-to-closed reconnection in the other hemisphere. The two reconnection processes have the same topological nature in that the roles of the two reconnecting field lines interchange at the time of reconnection. The interchange cycle is characterized by reciprocation of open magnetic flux between the two hemispheres. One observable signature of the interchange cycle is an appearance of a reverse cell circulating in the closed field line region of the ionosphere, which is named the “reciprocal cell.” The reciprocal cell appears in the open-to-closed reconnection hemisphere, whereas in the opposite IMF-to-open reconnection hemisphere, there appears a lobe cell circulating exclusively on open field lines. For given (1) IMF By, (2) IMF Bx, and (3) dipole tilt conditions, two interchange cycles concur, one on the dawnside and the other on the duskside. For an ideal case, one can easily expect the mode of the interchange cycles to occur. For example, for the case of due northward IMF with significant dipole tilt, the twin reverse cells in the summer hemisphere are both lobe cells, while in the winter hemisphere the twin reverse cells are both reciprocal cells. For the general case, however, one cannot predict the mode of the interchange cycles without quantitative modeling. The purpose of this study is to examine how the presence of dipole tilt or IMF Bx alters the dawn-dusk and north-south pattern of the twin reverse cells. For this purpose, we perform numerical magnetohydrodynamic simulations using the REPPU (Reproduce Plasma Universe) code developed by T. Tanaka. In the presentation, we discuss the dipole tilt and IMF Bx effects revealed by the numerical modeling.

Transient polar ionospheric convection response to negative dynamic pressure pulse

*Jianjun Liu[1]

1. Polar Research Institute of China

The response of the high latitude ionospheric convection to a sudden decrease in solar wind dynamic pressure provides a unique opportunity to investigate how the solar wind couples to the dayside magnetosphere and ionosphere. Here, the event shows three IMF components do not have prominent changes, but the solar wind plasma went down to near zero magnitude, which leads to very weak solar wind driving during northward IMF. However, ionospheric convection observed by SuperDARN radars showed enhanced plasma flow speed in the central polar cap region just after the negative pressure pulse arrival to the magnetosphere. Simultaneous convection map generated by SuperDARN measurement presents enlarged convection cell with obvious equatorward moving Heppner-Maynard boundary. It is noted that cross polar cap potential enhanced instantly and this enhanced feature continued almost 10 min. The distribution of total electron content (TEC) exhibited typical auroral oval signature especially on dayside ionosphere, TEC density in auroral oval showed a noticeable decrease after the arrival of the negative pressure pulse. Both ionospheric convection and TEC distribution reveal that negative pressure pulse impacts the magnetosphere-ionosphere coupling system directly and dramatically. Moreover, the TIEGCM model also showed an enhanced polar potential pattern.

An active ionosphere: a new perspective of field line dipolarization

*Osuke Saka[1]

1. Office Geophysik

Transient westward electric fields from the magnetosphere generate equatorward plasma drifts of the order of kilometers per second in the auroral ionosphere. This flow channel extends in north-south directions and is produced in the initial pulse of Pi2 pulsations associated with the filed line dipolarization. Drifts in the ionosphere of the order of kilometers per second that accumulated plasmas at the low latitude end of the flow channel are of such large degree that possible vertical transport effects (including precipitation) along the field lines may be ignored. We suggest that plasma compression in the ionosphere implemented the ionosphere to be active. Active ionosphere generates field-aligned currents to satisfy the quasi-neutrality of the ionosphere, ion acoustic wave for ion outflows and the inverted-V type electron precipitations in the topside ionosphere, and poleward expansion of auroras due to a nonlinear evolution of the ionosphere. We will study auroral expansion in this acoustic regime.

Toward the automatic identification of FLR signals in the SuperDARN data by using the gradient method

*Hideaki Kawano[1,2], Akira Sessai Yukimatu[3,4], Nozomu Nishitani[5], Yoshimasa Tanaka[3,4], Satoko Saita[6], Tomoaki Hori[5]

1. Dept. Earth Planet. Sci., Kyushu Univ., 2. ICSWSE, Kyushu University, 3. National Institute of Polar Research, 4. SOKENDAI, 5. ISEE, Nagoya University, 6. Kitakyushu College

The FLR (Field Line Resonance) takes place where the frequency of an incoming wave matches the eigen-frequency of magnetospheric magnetic field lines, and excites the eigen-oscillation of the field lines. The FLR can be identified by using the unique manner of change in the amplitude and the phase of thus excited eigen-oscillation across the resonant point. That is, the amplitude is maximum at the resonant point, and the phase changes the most steeply across the resonance point. The FLR-generated eigen-oscillations can be identified in the ground magnetic field data and the ionospheric plasma velocity data. From thus identified eigen-frequency ("FLR frequency" below) one can estimate the magnetospheric plasma density along the field line which passes through the ground/ionospheric observation point.

In this study we use the SuperDARN radar data to identify FLR: For each radar beam from each SuperDARN radar, the velocity of the ionospheric plasma flow along the line of sight (VLOS) of the beam is obtained; we use the VLOS data to identify the FLR and estimate the magnetospheric plasma density. Unlike the ground magnetometer data, the SuperDARN data is two-dimensional, enabling two-dimensional estimates of the magnetospheric equatorial plasma density and magnetospheric region identification.

To achieve that, it is important to identify as many FLR events as possible. Overwrapping of non-FLR waves/perturbations hides FLR events. As a countermeasure to this problem, the so-called gradient method has been applied to the ground magnetometer data; this method cancels out the overwrapping signals by dividing the data from a magnetometer by the data from another magnetometer having an adequate latitudinal distance from the other. The division yields the amplitude ratio and the phase difference. The gradient method is effective since the FLR frequency tends to depend on the latitude more strongly than the overwrapping signals.

The gradient method is also applicable to the SuperDARN VLOS data. The field of view of each beam is divided into Range Gates (RGs below) having the same length along the beam. The identification number of the RGs increases with increasing distance from the radar. The VLOS is obtained for each RG. Thus, each RG can be regarded as a "virtual observatory."

As an initial study, we have selected an FLR event which was identified in the VLOS data of a radar (at Hankasalmi) without the use of the gradient method, selected a beam, and selected a few pairs of RGs of the beam. We then have manually applied the gradient method to the VLOS data of the above-selected RG pairs, and successfully identified the FLR. In more detail, the identification has been successful only for two paired RGs whose RG numbers differs by two. This suggest that, since the length of the RG, mapped to the meridional plane, was about 40km for this event, about 80km distance was the best (with the resolution of 40km) for this event. This distance reflects the resonance width, which is an important quantity reflecting the diffusion and dissipation of the FLR energy.

©2019. Japan Geoscience Union. All Right Reserved.

In order to identify as many FLR events as possible, it is also important to automatically identify the FLR events, since visual identification is time-consuming. The gradient method enables automatic identification more easily than analyses of VLOS itself, since the gradient method yields peaks in both the amplitude ratio and the phase difference. We have started making a program for automatic identification by applying the gradient method to VLOS; the version at the time of this abstract has successfully identified FLRs for all of the above-stated pairs of RGs.

A statistical study of Pi2 pulsations observed in the upper ionosphere using Swarm magnetic field data

*Park Jaehee[1], Khan-Hyuk Kim[1], Junga Hwang[2]

1. School of Space Research, Kyung Hee University, Gyeonggi, South Korea, 2. Korea Astronomy and Space Science Institute, Daejeon,South Korea

The properties of Pi2 pulsations observed in the upper ionosphere are studied using magnetic field data acquired by the Swarm-A spacecraft in low Earth orbit (LEO) and at the low-latitude Bohyun ground station (BOH, L = 1,3) for January 2014-Jun 2015. From time intervals when Swarm-A was on the nightside (magnetic local time (MLT) = 1800-0600 hrs) and the BOH station was near midnight (MLT = 2100-0300 hrs), we identified 623 Pi2 events in the horizontal H component of the BOH data. For each event we examine the coherence between the horizontal H component on the ground and the B_x (radial) azimuthal B_y (azimuthal), or B_z (compressional) components at Swarm-A. Out of 623 events, the B_x-H high coherence (> 0.7) events are ~6%, the B_y-H high coherence events are ~4%, and the B_z-H high coherence events are ~25%. The ground-satellite high coherence events occurred when the spacecraft was located within a magnetic latitude range of ±50°. Using the ground-satellite high coherence events, we examined the latitudinal structure of the relative amplitude and phase of the ionospheric Pi2 pulsations detected at Swarm-A. Confirming previous observations at LEO, we found that the ionospheric Pi2 pulsations are characterized by symmetric odd mode standing oscillations in the north-south direction, having a node for B_x oscillation and an antinode for B_z oscillation, respectively, at the equator. This indicates that the source of ionospheric Pi2 pulsations is the plasmaspheric resonance.

Study on the global distribution characteristics of Pc 1-2 geomagnetic pulsation with the 10Hz data of the MAGDAS system

*Taisei Kabasawa[1], Akimasa Yoshikawa[1], Teiji Uozumi[1], Akiko Fujimoto[1], Shuji Abe[1]

1. Kyushu University

The magnetic field observed on the ground is affected by the space weather phenomena such as magnetic storms and auroral storms.

The Pc1 geomagnetic pulsation (frequency range of 0.2-5.0 seconds) activated mainly around a high-latitude region is understood as a phenomenon accompanied by the excitation of EMIC waves to cause the particle acceleration in the equatorial region of the magnetosphere. Also, it is well known that Pc1 waves propagate horizontally in the ionospheric at the F layer. However, it is not clarified about the global occurrence and propagation properties of Pc1 geomagnetic pulsation on the ground. Moreover, although induction magnetometers are used to observe the high-frequency magnetic field disturbance phenomenon like Pc1 and Pc2 (frequency range of 5.0-10.0 seconds) geomagnetic pulsation, the global observation network with induction magnetometers covering from high-latitude to low-latitude area and equator domain does not exist at this stage. On the other hand, although it is common to use Fluxgate magnetometers for the observation of global space weather phenomenon, it is considered to be unsuitable for analysis of the high-frequency Pc1-2 geomagnetic pulsation because its time accuracy is usually one second value.

The ground multipoint magnetic field observation network which Kyushu University has developed (MAGDAS-9 magnetometer) acquire a 250Hz sampling and 10Hz mean data. Also, it is the only geomagnetic observation network that can investigate the global aspects of Pc1-2 geomagnetic pulsation.

In this study, we investigated the global distribution of Pc1-2 pulsation from polar region to equatorial region with magnetic field data provided by MAGDAS and Dst/AE index provided by the WDC for Geomagnetism, Kyoto. As a result, when the substorm have occurred during a magnetic storm time, generation of Pc1-2 pulsation from high-latitude to middle-and-low latitude region and further arrival of Pc2 pulsation to the dip-equator are identified. The elucidation of occurrence characteristic of the Pc1-2 pulsation on the ground with the EMIC waves excitation is very important not only for space weather application to be able to monitor particle energization process via EMIC excitation but also the elucidation of the super global coupling process from inner magnetosphere to the global ionosphere from polar to equatorial region. In this presentation, we will report the preliminary results of observational analysis of Pc1-2 pulsation by using MAGDAS network. We also discuss the comprehensive approach for understanding global coupling process among inner magnetosphere and high-middle-low latitude to the equatorial region by using FM-CW radar data, PWING induction magnetometer data, and the geo-space environment data from the ERG satellite.

In-situ Observations of Reconnection Separatrix Regions in the near-Earth Magnetotail

*Mizuho Araki[1], Masahiro Hoshino[1], Kunihiro Keika[1], Yoshifumi Saito[2]

1. Graduate School of Science, The University of Tokyo, 2. Institude of Space and Astronautical Science

Magnetic reconnection which converts magnetic energy into thermal and kinetic energy of plasmas is an important physical mechanism of plasma heating and acceleration. Particularly in the Petschek-type reconnection, plasma acceleration and heating in the slow-mode shocks formed at the separatrices must be taken into consideration. The structure of the slow-mode shocks in the distant tail of the Earth’s magnetosphere was investigated with in-situ observations made by the GEOTAIL satellite (Saito et.al, 1995). It is observationally suggested that about 10% of the plasma sheet boundary layer (PSBL) is slow-mode shocks. It is, however, not fully understood what determines this percentage and what is the difference in the ion and electron temperature changes between slow-mode shocks and others separatrix regions.
In this study, we utilized multi-spacecraft in-situ observations of separatrix regions at magnetic reconnection in the near-Earth magnetotail (GSM-X is between ~13 and ~25RE). We used data obtained from FPI (Fast Plasma Investigation) and FGM (Fluxgate Magnetometer) on board the MMS satellite from June 1, 2017to August 31, 2017. We examined occurrence locations, ion flow directions and velocity of ion flow in downstream regions of observed events. We also examined changes in ion and electron temperatures and the ion-to-electron temperature ratio.

We classified their events into 2 types according to plasma beta in the in-flow regions: below 0.1 or around 1. We term them “lobe reconnection” and “plasma sheet reconnection”, respectively. In the former type, plasmas in the in-flow regions are cold and tenuous. In the latter type, plasmas in the in-flow regions are hot and dense. In both types, we observed increases in ion and electron temperatures increase, but their characteristics are different. In the lobe reconnection, ion temperatures increase from several hundred eV to several keV. In the plasma sheet reconnection, ion temperatures also increase from about 1 keV to several keV. The increase rate of the electron temperature is less than one order of magnitude for both types, smaller than that of the ion temperature; the electron temperature increases up to at most 1 keV. The ion-to-electron temperature ratio in the out-flow regions in both types is about 5 for both types. We then examined changes of the ion-to-electron temperature ratio and found that the changes are consistent with the result reported by Wang et al. (2012).

In this presentation, we will show the results of separatrix crossing events (both lobe and plasma sheet reconnection events) that occur in 2017 and 2018. We will identify whether each of the separatrices is a slow shock or not and how the separatrix conditions affect ion and electron heating. These characteristics will provide insights into heating mechanisms and energy conversion through separatrix regions.

Flow speed dependence of ion temperature, electron temperature, and their ratio in the near-Earth magnetotail reconnection region

*Kaori Watanabe[1], Masahiro Hoshino[1], Kunihiro Keika[1], Yoshifumi Saito[2], Naritoshi Kitamura[1]

1. Univ. of Tokyo, 2. ISAS/JAXA

Plasma in the Earth's magnetotail are heated up to 1-10 keV and stored in the plasma sheet. One of the heating or acceleration mechanisms is the magnetic reconnection. Heated or accelerated plasma are transported both earthward and tailward as fast flow with a speed of several hundred kilometers per second. However, what determines the partition among ion and electron thermal energy and kinetic energy is an unresolved problem. It has been reported that ion temperature T_i, electron temperature T_e, and their ratio T_i/T_e vary spatially and depend on the conditions of fast flows [Wang et al., 2012, Runov et al., 2018] but there are few studies which focus on macroscopic profiles of them in reconnection regions in the magnetotail.

In this study, we examine the relation between flow speed and average profiles of T_i, T_e, and T_i/T_e in the magnetotail reconnection region by using data obtained from FPI and FGM on board the MMS spacecraft. We use the observations for a period from May to August 2017 and take out the data in the region of $X_{GSM} < -15$ Re, -10 Re $< Y_{GSM} < 10$ Re, and beta > 0.1. We then divide them into different groups according to flow speed normalized by alfven speed and show B_z/B_{lobe}– B_x/B_{lobe} maps of T_i, T_e, and T_i/T_e of each group. The results show that ion temperature increase with increasing flow speed while electron temperature decrease. Ion temperature are hotter around the X-point. The structure of inflow and outflow regions is pronounced in the profile of electron temperature. T_i/T_e in inflow region are greater than in outflow region, which means that ion and electron temperatures become comparable by passing through the diffusion region. The results suggest that electron get less energy when more energy is partitioned into plasma kinetic energy. We will discuss about the profiles of anisotropy of plasma temperatures to know more details about the heating mechanisms.

Examining Minimum Cyclotron Resonant Electron Energy of EMIC Waves with MMS

*Si Liu[1]

1. Changsha University of Science and Technology

Electromagnetic ion cyclotron (EMIC) waves can be in cyclotron resonance with relativistic electrons, causing relativistic electron precipitation. The four ideal Magnetospheric Multiscale (MMS) spacecraft provide great opportunity to directly calculate the wave vector ***k*** of EMIC waves by phase differencing technique and hence estimate the minimum resonant energy by the resonance condition. Deriving a simplified analytic solution, we find that the phase differencing method can still provide an estimate of the dominant wave number when a finite wave number spread or a finite frequency spread is present. Numerical calculations indicate that quasi-antiparallel propagation dominates the EMIC event on 20 November 2015, which is consistent with the FFT spectral analysis results. We also find that obtained wave vectors, roughly agreeing with the validity of cold plasma theory, might significantly vary from wave packet to wave packet. Moreover, minimum resonant electron energies gradually increase from 0.5 MeV to tens of MeV with a decreasing parallel componet of ***k***. Current results provide evidence that EMIC waves can be in resonance with the electrons of energies down to hundreds of keV. It further demonstrates that EMIC waves in a narrow frequency band can effectively interact with the relativistic electrons with a broad energy range.

Wave-particle interactions are thought to play a crucial role in energy transfer in collisionless space plasmas in which the motion of charged particles is controlled by electromagnetic fields. In the terrestrial magnetosheath, intense whistler mode waves, called 'Lion roars', are often detected by spacecraft around minima of semi-periodic fluctuations of magnetic field intensity due to mirror mode structures and motion of the structures. It is expected that whistler mode waves are efficiently generated near a local minimum of magnetic field intensity due to the smallest cyclotron resonance velocity. We report the detailed characteristics of such whistler mode waves using the data obtained by the four MMS (Magnetospheric Multiscale) spacecraft. Because reversals of field-aligned component of Poynting flux around minima in mirror mode structures correspond to reversals of gradient of magnetic field intensity along the magnetic field, whistler mode events with reversals of the field-aligned component of Poynting flux are good candidates of observations of effective wave generation regions along field lines. Even in such events, phase difference and change of amplitude of whistler mode waves observed by the four spacecraft do not have a clear correlation in cases of ~40 km separation, which is much smaller than the spatial scale of magnetic field depression due to mirror mode structures and is even smaller than the local thermal ion gyro scale. This result indicates that the coherent whistler wave generation in mirror mode structures has very limited spatial scale across field lines and is probably affected by any electron scale process. A plane wave approximation can be usable only in a very small scale. Because some events in cases of ~7 km separation showed good correlation among four spacecraft, the typical scale of coherent whistler wave across field lines can be at least an order of 10 km in mirror mode structures in the terrestrial magnetosheath. The whistler mode waves observed by a spacecraft in a mirror mode structure are a cluster of waves from multiple spatially small sources.

Spatial characteristics of the internal modulation of pulsating aurora: multi-point high-speed optical observations in Scandinavia

*Yuki Kawamura[1], Keisuke Hosokawa[1], Shin-ichiro Oyama[2,3], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Satoshi Kurita[2], Satoshi Ebukuro[1], Ryoichi Fujii[4]

1. Department of Communication Engineering and Informatics, University of Electro-Communications, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. National Institute of Polar Research, 4. Research Organization of Information and Systems

Pulsating aurora (PsA) is a kind of diffuse aurora which almost always appears in the morning side during the recovery phase of auroral substorm. PsA typically has two characteristic temporal variations. One is so-called main pulsation whose period ranges from a few to a few tens of seconds. The other is a few Hz brightness modulation (internal modulation) which is often seen during the ON time of the main pulsation. Previous studies have suggested that the temporal variation of PsA is characterized by wave-particle interaction between whistler-mode chorus waves and high energy electrons in the magnetosphere. Especially, it has been indicated that there is one to one correspondence between the amplitude variation of chorus waves and the luminosity modulation of PsA.
Recent studies revealed the occurrence distribution of the frequency of the internal modulation. However, there have been no studies which analyzed the spatial distribution of the internal modulation.

To reveal the spatial characteristics of the internal modulation, we need to perform a frequency analysis of the internal modulation by using data from high speed optical instruments having wide spatial coverage. For this purpose, we make use of highly sensitive EMCCD cameras which have been operated in Sodankylä and Kevo in Finland, Tromsø in Norway, and Tjautjas in Sweden. In these observations, all-sky images are taken with a sampling rate of 100 Hz, which is sufficient to identify temporal variations of the internal modulation.

In the frequency analysis, we have employed all-sky images taken on March 15, 2018 (00:00 –01:30 UT) in Sodankylä, Kevo, Tromsø, and Tjautjas. We computed the average frequency of the internal modulation from each pixel of the EMCCD cameras and derived the spatial distribution of their dominant frequencies. Regardless of the latitude, each pulsating patch was fluctuating at a similar frequency. We also derived the frequency spectrum of several pulsating patches existing at different positions in the north-south direction and found that those frequency spectrums of pulsating patches have peaks at about 3 Hz. These results indicate that the frequency of the internal modulation does not depend on the magnetic latitude, and the frequency of the internal modulation is collimated on 3 Hz.
In the presentation, we discuss why the frequency of the internal modulation concentrate on 3 Hz by taking into account the time of flight of PsA electrons.

Large-scale characteristics of pulsating aurora periodicities: multi-point high-speed optical observations in Scandinavia

*Satoshi Ebukuro[1], Keisuke Hosokawa[1], Shin-ichiro Oyama[2,3,5], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Satoshi Kurita[2], Yuki Kawamura[1], Ryoichi Fujii[4]

1. Department of Communication Engineering and Informatics, University of Electro-Communications, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. National Institute of Polar Research, 4. Research Organization of Information and Systems, 5. University of Oulu

It has been known that most of diffuse aurorae in the morning side are composed of luminous patches whose brightness modulates quasi-periodically. Such aurorae are termed as pulsating aurora (PsA) and have been studied extensively in the last decade. PsA patches have a scale size of a few hundreds of km and are usually observed during the late recovery phase of substorms. The entire temporal variation of PsA consists of two individual modulations: main pulsation and internal modulation. The periodicity of the main pulsation ranges from a few to a few tens of seconds and the internal modulation, showing a few Hz scintillating luminosity changes, is often embedded within the ON time of the main pulsation. Previous studies using satellites indicated one-to-one correlation between PsA and chorus wave near the equatorial plane of the magnetosphere, suggesting that ground-based observations of PsA can be used for mapping the activity of chorus in the magnetosphere in 2D fashion. In the past, the spatial characteristics of chorus wave have not visualized in detail because satellite observations only cover a single point in the magnetosphere. To overcome this limitation, we derive the spatial distribution of chorus waves by using ground-based optical observations of PsA and discuss the ambient parameters which characterize the nature of chorus.
For this purpose, we have employed data from electron multiplying charge-coupled device (EMCCD) cameras deployed at multiple sites in Scandinavia to derive the large-scale characteristics of PsA. EMCCD cameras have been operative in Kevo and Sodankyla in Finland, Tromsoe in Norway, and Tjautjas in Sweden and their temporal resolution is 100 Hz. We conducted a frequency analysis for a PsA event on March 28, 2017 (23:30 to 24:10 UT). During the event studied, there existed three different regions of PsA, regions A, B and C, showing different modulation periods. It was also found that the boundaries between these three regions were sharp. We derived the 2D frequency map by using data from all the available stations. As a result, it became clear that the higher latitude region (region C) showed faster internal modulation than the lower latitude region (region A). In addition, region B, which was sandwiched by regions A and C, did not show any internal modulations (i.e., main pulsation without internal modulation). In the presentation, we discuss why the three regions showed different modulation periods with sharp boundaries. In particular, we address what ambient conditions can control the absence of internal modulation in region B. We also derived similar frequency maps of chorus waves by tracing the PsA modulation with the Tsyganenko 04 magnetic field model, which could be used to estimate the spatial extent of chorus wave generation region.

Department of Communication Engineering and Informatics, University of Electro-Communications, 4. Sodankylä Geophysical Observatory, University of Oulu, 5. Ionosphere Research Unit, University of Oulu

Temporal and spatial variations of aurora morphology in association with substorm have been studied for more than half a century. Various types of aurora are known, such as discrete arc emitting at relatively high intensity and elongating along the zonal direction, and diffuse aurora with darker but more widely spreading in the sky. Pulsating aurora, which is characterized by quasi-periodic oscillations in the emission intensity at periods of a few to tens seconds, and auroral patches observed embedding in the pulsating aurora tend to appear at the recovery phase of substorm, especially from midnight to dawn. It is known that these types of aurora are accompanied by energetic electron precipitation exceeding several hundreds keV. Elucidation of the causality to produce pulsating aurora and energetic electron precipitation is an important theme to understand relationships between the radiation belt and upper-middle atmosphere of the earth. Analyzing measurements from satellite observations (e.g., Arase) and ground-based optical/radio technique observations, the generation mechanism is thought to be mainly attributed to wave particle interactions due to plasma wave and electrons in the magnetosphere. In this study, we focus on relationships between auroral morphological changes, in particular spatiotemporal evolutions to patches and coinciding precipitations of the energetic electron.

Some previous studies have presented changes in morphology from pulsating aurora to patch structures [e.g., Shiokawa et al., 2014] and temporal variations of energetic electron precipitation [e.g., Hosokawa and Ogawa, 2015]. As mentioned above, the wave-particle interaction has been widely accepted with experimental evidences to support generation of pulsating aurora and energetic electron precipitation. However, our understanding has not yet reached its maturity of presenting spatiotemporal evolutions of auroral morphology and associated electron precipitation. Oyama et al. [2017] presented enhancements of CNA (cosmic noise absorption) coinciding with appearance of the patch structure but with only two events. Furthermore, due to measurements with intensive diagnostic instruments, the result was based on information of a part of the auroral ionosphere. In this study, we conducted observations to capture simultaneously time evolutions and spatial distributions of auroral morphology and energetic electron precipitation by utilizing a network of EMCCD (Electron Multiplying Charge Coupled Device) cameras and riometers deployed in Northern Europe.

This study will present three events (February 19-20, 2018, March 6-7, 2017, and March 29-30, 2017). On the way of all events, after substorm onsets twice near Northern Europe, another onset occurred again at more west side (near Iceland or Greenland area) but at dawn in the Northern Europe. In this study, we have focused on the aurora and CNA associated with the latter onset, and at that time, the aurora spatially and temporally shifted from diffuse to pulsation and patch structures. This suggests that substorm activities occurred in the distance can induce these auroral morphological changes seen in the Northern Europe. CNA at that time is characterized by gradual variations with time scale of several hours. This trend cannot be seen at substorm onset near the Northern Europe. Moreover, in the latitude distribution, the feature was confirmed that CNA increases at the latitude where patch structure is seen, and CNA keeps

©2019. Japan Geoscience Union. All Right Reserved.

constant value at the latitude where patch structure is not seen. In the presentation, based on these observations, we will discuss physical mechanisms to cause changes in the auroral morphology and energetic electron precipitation, which can be seen as increases of CNA.

Whistler mode waves cause precipitation of high-energy electrons via wave-particle interactions in the magnetosphere. The scattered particles precipitate to the ground along the geomagnetic field line. Then, flush aurora, which is a rapid (less than 1 s) auroral phenomenon, is happened. Flash aurora is important for understanding the spatial evolution of wave-particle interaction region in the magnetosphere. We observed the mainly southward spread of flush aurora. In order to understand the spatial-time variation of wave-particle interaction region, we analyze the propagation effects of whistler mode waves near the magnetic equator region using ray tracing analysis. We calculated the ray paths of whistler mode waves (0.2 fce and 0.4 fce) near the magnetic equator (-10 to +10 degrees of geographic latitude), where fce is the electron cyclotron frequency at the magnetic equator. The initial ray paths put in the assumption of a spatial spread with the wave normal angles of tens of degrees along the magnetic field line at the magnetic equator (a point source). Then, we traced the magnetic field lines from the ray paths of whistler mode waves and estimated the precipitation area of electrons in the ionosphere using the IGRF model. The calculation results showed the precipitation area was not mainly spread southward, but evolved northward in the preliminary study.
In this presentation, we will present the spatiotemporal characteristics of flash aurora and the analysis results of ray tracing in detail.

Institute for Space-Earth Environmental Research, Nagoya University

Molecular ions ($O_2^+/NO^+/N_2^+$) in the magnetosphere have been observed during magnetic storms [Peterson et al., 1994; Klecker et al., 1986]. These molecular ions are considered to originate from the Earth’ s ionosphere. It is considered that they have been transported upward by some heating processes in the ionosphere. However, due to the larger mass than atomic ions (O^+), the molecular ions usually exist only in the low-altitude ionosphere below 300 km altitude. It is hence difficult to transport these molecular ions by overcoming loss by chemical reactions to the high-altitude ionosphere where the ion upflow and outflows usually take place [Peterson et al., 1994]. Therefore, it is necessary to reveal what mechanism causes molecular ion upflow during the magnetic storms. In this study, we aim at the observational assessments of the supply processes of the molecular ions from the low-altitude ionosphere to the magnetosphere based on conjugate observations by EISCAT radar and the Arase (ERG) satellite.

The EISCAT radar and the Arase (ERG) satellite have the conjunction event during the large magnetic storm with the minimum Dst of -124 nT on September 8, 2017. During the event, the Arase satellite was located in the dusk-side inner magnetosphere and observed molecular ions in the energy range of 12-180 keV/q. The EISCAT radar simultaneously observed the ion upflow (with the upward velocity of ~50-150 m/s) from the low-altitude ionosphere (~250-400 km) together with strong ion heating (>2000 K). The convective electric field was also enhanced by a factor of 2 in the same region. We estimated each term in the equation of motion for ions. The result indicates that the ion upflow reached stable equilibrium because the upward ion and electron pressure gradients are balanced with the downward gravitational force. It is suggested that the ion upflow can take place from the low-altitude ionosphere due to strong ion pressure gradient. We also estimated the flux decrease of molecular ions due to dissociative recombination. The flux decreased to ~1 % at 350 km compared with 280 km. The estimated upflow flux of molecular ions at 350 km is $>10^{10}$ m^{-2} s^{-1} . Comparison between distribution functions observed by Arase satellite and EISCAT radar suggests that acceleration by 3 orders of magnitudes is necessary during the outflow process. These results indicate that the strong ion frictional heating during magnetic storms enabled molecular ions to be transported upward from the low-altitude ionosphere and provide a source of molecular ion outflows into the magnetosphere.

Optical and radar observation of the dynamic auroral forms

*Yunosuke Nagafusa[1], Tima Sergienko[2], Satoshi Taguchi[1], Urban Braendstroem[2], Masatoshi Yamauchi[2]

1. Graduate School of Science, Kyoto University, 2. Swedish Institute of Space Physics, Kiruna

Ionosphere disturbances caused by the auroral electron precipitations are studied using auroral images taken by Auroral Large Imaging System (ALIS) and ionospheric parameters measured by EISCAT UHF radar that were conjugate with ALIS field-of-view. ALIS consists of several remote controlled stations located in northern Scandinavia, separated by approximately 50 km. Each station is equipped with a high-resolution CCD detector with 1024×1024 pixels, and a filter wheel with six positions for narrow-band interference filters. In this study we use the data obtained with the 557.7 nm filter, which show the auroral emission originated from the atomic oxygen. EISCAT UHF radar located in northern Norway near Tromsø operating in the BEATA program provides the ionospheric electron density, electron and ion temperatures, and ion velocity with the time resolution of 5 s and the spatial resolution of 1.5 km. The auroral images from the different ALIS stations were used for triangulation of the auroral forms in order to determine the aurora position in relation to the radar beam. For each auroral arc, the electron density, the electron and ion temperatures measured inside and in the vicinity of the auroral forms were analyzed with the aim of understanding the ionospheric response to the different types of auroral electron precipitations.

Observations of MF/HF auroral radio emissions at three ground-based stations

*Yuka Sato[1], Atsushi Kumamoto[2], Yuto Katoh[2], Akira Kadokura[3,4], Yasunobu Ogawa[3,4], Atsuki Shinbori[5]

1. Nippon Institute of Technology (NIT), 2. Graduate School of Science, Tohoku University, 3. National Institute of Polar Research (NIPR), 4. The Graduate University for Advanced Studies, 5. Institute for Space-Earth Environmental Research (ISEE), Nagoya University

We started ground-based observations of MF/HF auroral radio emissions about 10 years ago at two stations (The Husafell Station, Iceland, September 2005; The Kjell Henriksen Observatory, Svalbard, September 2008) and found multiple unknown properties of MF/HF auroral radio emissions, e.g. polarization features [*Sato et al.*, 2008, 2015] and existence of a higher frequency component [*Sato et al.*, 2012]. To make a next siginificant step for a futher understanding of MF/HF auroral radio emissions, we installed a new dedicated instrumentation at the KAIRA (Kilpisjärvi Atmospheric Imaging Receiver Array) site in Kilpisjärvi, Finland (Latitude: 60.07 N, Longitude: 20.76 E) in the summer of 2018. It is a passive receiving system designed to realize a high-resolution spectral, interferometric and polarization measurements using 4 loop antennas and a software-defined radio (SDR) receiver. This SDR receiver can implement high-speed, flexible digital signal processing of RF signals and obtain high-resolution spectra pauselessly throughout the night in a wide frequency range up to 6 MHz. One of the main research subjects of this project is radio emission spontaneously emitted from aurora. There are long-known three types of MF/HF auroral radio emissions identified at ground level: auroral hiss, medium frequency burst (MFB), and auroral roar. Investigation into the generation of these emissions not only offers a tool of great promise for remote sensing of ionospheric plasma processes and parameters but also gives the foundation for understanding various radiation mechanisms that occur in planetary magnetospheres and plasma in space. In combination with the long-term continuous observations in Iceland and Svalbard and future EISCAT_3D experiments, observation with this new instrumentation will provide a first-time opportunity to reveal spatiotemporal variations of macro and fine structures of MF/HF auroral radio emissions associated with substorm evolution. In this presentation, we show detailed specification of this new instrumentation and some initial results.

Ionospheric F-region Drift Measurements Derived from DPS-4D at Zhongshan Station, Antarctic

*Xiangcai Chen[1]

1. Polar Research Institute of China

By means of high-frequency radio sounding, the ionospheric plasma drift can be measured by the Doppler frequency shift of signal. In this paper we analyze the ionospheric F-region plasma motion performed by Digisonde Portable Sounder (DPS-4D) at cusp latitude over Zhongshan Station in Antarctic. By restricting the echo arrival angle, and selecting the reflection height range at 175 –475 km, we present the variation of the F-region plasma drift measurements by setting limits on the Doppler frequency shift. Base on the 7.5 min interval Digisonde drift data from November 2011 to February 2012, we considered the variations of the plasma drift in F-region under the different geomagnetic activity (Kp) and magnetic local time, as well as it correlation with interplanetary magnetic field (IMF). The results indicate that properly restricting the Doppler frequency shift of the echo has a strong effect that contributes to the accurate and robust measurements of the ionospheric plasma drift. The mean value of horizontal drift mostly leveled off to about 600 m/s at altitude around of 230 km, while the field-aligned component of drift showed mean values of -25 m/s near pre-noon and +40 m/s during the night. These strong diurnal variations have dependence on the sign and strength of the IMF B_y and B_z components. It implies that the contraction and expansion of the polar cap with Kp and the convection in the proximity of the throat with different IMF conditions have a profound influence on the observed drift velocities.

PARM-HEP Observation of Precipitating High Energy Electrons over Pulsating Aurora

*Taku Namekawa[1], Takefumi Mitani[2], Kazushi Asamura[2], Yoshifumi Saito[2]

1. Department of Earth and Planetary Science, Graduate school of Science, The University of Tokyo, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The phenomenon called microbursts that radiation belt particles precipitate to the Earth’ s atmosphere is thought to be largely related to the dissipation of high energy electrons in radiation belt. It is suggested that this phenomenon is caused by pitch angle scattering of the magnetospheric particles by plasma waves, which is a mechanism similar to the cause of the pulsating aurora observed in the Earth’ s polar region. There is a possibility that the origin of microburst can be clarified by proving simultaneous occurrence of microburst and pulsating aurora, but observational verification has not been made yet. For that purpose, we have developed a high-energy electron detector (HEP) for the observation of sub-relativistic - relativistic energy electrons that make up the microburst. HEP is designed to measure electrons between 300 keV and 2 MeV with energy resolution of 20% or less and with signal processing time of ~ 5 μs. Energy analysis is performed by the detection part of this instrument using SSD (Solid State Detector). Performance tests of this instrument are carried out using a sealed radiation source and a high energy electron beam line. This instrument is installed as one of the core instruments of the PARM instrument package developed for the simultaneous observation of the pulsating aurora and microburst by an international student sounding rocket experiment RockSat-XN and LAMP (Loss through Auroral Microburst Pulsation) sounding rocket experiment. We have succeeded in obtaining the flight data on 13 January 2019 from RockSat-XN sounding rocket experiment. In parallel, we are now preparing HEP analyzer for LAMP sounding rocket experiment. In this presentation, we will show the outline and observation results of RockSat-XN-HEP as well as the LAMP-HEP development status.

National Institute of Polar Research, 5. The University of Electro-Communications, 6. Institute for Space-Earth Environmental Research, Nagoya University, 7. Tohoku University

Energetic electrons significantly affect ionospheric dynamics and the long-term evolution of surfaces and atmospheres of planets and moons. Since the energetic electron flux is not necessarily isotropic, it is important to cover the broad solid angle to quantitatively evaluate the effects on solar system bodies. With future planetary explorations in mind, we developed the medium-energy (20 - 100 keV) electron detector (MED) which can cover almost 2-pi steradian without the spacecraft spin. In order to test the performance of this analyzer in the relevant environment, we participated in the PARM mission, which aimed to measure electron precipitation using NASA’s sounding rocket RockSat-XN. In this presentation we report on MED observation results obtained through the flight on 13 January 2019.

Auroral substorm onset in satellite-based global images and ground-based all-sky images

*Akimasa Ieda[1], Kirsti Kauristie[2], Yukitoshi Nishimura[3], Yukinaga Miyashita[4], Harald U Frey[5], Liisa Juusola[2], Daniel Whiter[6], Masahito Nose[7], Matthew O Fillingim[5], Farideh Honary[8], Neil C Rogers[8], Yoshizumi Miyoshi[1], Shinobu Machida[1]

University of California Berkeley, 6. University of Southampton, 7. Graduate School of Science, Kyoto University, 8. Lancaster University

Substorm onset has originally been defined as a longitudinally extended sudden auroral brightening (Akasofu initial brightening: AIB) followed a few minutes later by an auroral poleward expansion in ground-based all-sky images (ASIs). In contrast, such clearly marked two-stage development has not been evident in satellite-based global images (GIs). Instead, substorm onsets have been identified as localized sudden brightenings that expand immediately poleward.
To resolve these differences, optical substorm onset signatures in GIs and ASIs are compared in this study for a substorm that occurred on December 7, 1999. For this substorm, the Polar satellite ultraviolet global imager was operated with a fixed-filter (170 nm) mode, enabling a higher time resolution (37 s) than usual to resolve the possible two-stage development. These data were compared with 20-s resolution green-line (557.7 nm) ASIs at Muonio in Finland. The ASIs revealed the AIB at 2124:50 UT and the subsequent poleward expansion at 2127:50 UT, whereas the GIs revealed only an onset brightening that started at 2127:49 UT.
Thus, the onset in the GIs was delayed relative to the AIB and in fact agreed with the poleward expansion in the ASIs. The fact that the AIB was not evident in the GIs may be attributed to the limited spatial resolution of GIs for thin auroral arc brightenings. The implications of these results for the definition of substorm onset are discussed herein.

Automatic Classification of Auroral images using optical flow feature

*Naoto Kashiwagi[1], Akiko Fujimoto[1], Terumasa Tokunaga[1], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Keisuke Hosokawa[4]

1. Kyushu Institute of Technology, 2. Nagoya University, 3. National Institute of Polar Research, 4. The University of Electro-Communications

The machine learning technique including the deep learning has been developed and the practical uses have increased on various field. On the study of auroral detection, the concern over the automatic image classification has risen using the approach of machine learning technique for the large statistical analysis of auroral images. The automatic auroral image classification has tried to use some techniques from computer vision, machine vision and pattern recognition. There are roughly two kinds of the selected feature: the color of image and the motion of aurora image sequences. The works based on the color feature of aurora image have been performed by Rao et al. (2014) and Tanaka et al. (2015). Rao et al. (2014) performed Support Vector Machines (SVM) classification with several local feature extraction techniques, and found that Scale Invariant Feature Transform (SIFT), OpponentSIFT, is the most effective feature for the automated classification of color aurora images. Tanaka et al. (2015) used the aurora area using the HSV model. They mentioned that it is difficult to classify the images including the diffuse aurora and cloud area. The color feature work well for the color auroral image, while the gray-scale (optically filtered) auroral images need other features on the automated classification. Blixt et al. (2006) applied the optical flow estimation to auroral image sequences. Their case study showed the useful tool for representing the motion of the aurora. In this study, we validate the optical flow estimation to extract the feature of auroral image, and automatically classify the large gray-scale auroral images using the machine learning with Convolution Neural Network (CNN). We use 63,486 gray-scale aurora images in total and use five categories for the preparation of supervised learning data, 1) aurora, 2) aurora and cloudy, 3) aurora and moon, 4) aurora, cloudy and moon, 5) noaurora. We perform the Hold-out and the Cross Validation to evaluate our classification performance. We obtained 98.58% of the classification accuracy based on Hold-out and 98.47% of the classification accuracy based on Cross Validation.

Fine-scale visualization of aurora in a wide area using color digital camera images from the International Space Station

*Sota Nanjo[1], Yuta Hozumi[1], Keisuke Hosokawa[1]

1. The University of Electro-Communications

Various ground-based and space-based imagers have been used to observe aurora borealis and australis. So far, however, it has been difficult to observe the detailed spatial structure of auroras in a wide area with sufficient spatial and temporal resolution. Since the photographs taken from the International Space Station (ISS) have sufficient spatial and temporal resolution, it is possible to visualize the fine-scale structures of aurora in a wide area. A calibration of imaging parameters of the photographs using star lights was proposed by a previous research. The accuracy in the timestamp was not guaranteed by the method based on the star lights because the position of the star lights in the image did not change with elapsed time. Thus, it is still difficult to use the mapped data for studying fast variations of aurora, for example pulsating aurora (PsA). Therefore, in this study, we calibrated the images from the ISS using city lights which change their apparent positions with elapsed time. In order to validate the calibration method using city light positions, we mapped two PsA events in the photographs to the geographical coordinate, and compared with those from ground-based all-sky imagers in Alaska and Canada. We found that the approximate shape of discrete aurora and the temporal variation of PsA derived from the ISS images are consistent with those from the ground-based observation. The accuracy in the timestamp is less than 0.5 sec and that in space in the direction perpendicular to the line of sight of the camera is within 5 km. In the presentation, we will also address how the mapped full-color images can be used for studies of PsA in the future work.

PARM: Investigation of precipitating high-energy electrons into the auroral ionosphere with sounding rockets

*Kazushi Asamura[1], Yoshizumi Miyoshi[2], Keisuke Hosokawa[3], Takefumi Mitani[1], Taku Namekawa[1,5], Takeshi Sakanoi[4], Naoshi Yagi[4], Mizuki Fukizawa[4], Genki Ishizawa[4], Satoshi Kasahara[5], Shin Sugo[5], Oya Kawashima[5], Reiko Nomura[6], Masahito Nose[2], Mariko Teramoto[2], Yasunobu Ogawa[7], Shinji Saito[2], Ryoichi Fujii[8]

1. ISAS / JAXA, 2. ISEE, Nagoya University, 3. The University of Electro-Communications, 4. Tohoku University, 5. The University of Tokyo, 6. NAOJ / NINS, 7. NiPR / ROIS, 8. ROIS

Bursty precipitations of high-energy electrons into the polar ionopshere have been observed by low-altitude satellite, for example, SAMPEX and FIREBIRD II. These precipitations, called microburst, may contribute to the loss of the terrestrial radiation belt through the collisional energy loss with the dense, cold atmospheric particles. Recent numerical simulations successfully reproduce these microburst precipitations with a few Hz modulations by taking into account the pitch angle scattering with the whistler chorus elements at off-equator regions in the inner magnetosphere. Therefore, one can expect that the miscroburst precipitations have properties depending on auroral activities especially the pulsating auroras. In order to investigate the mechanisms of the microburst precipitations by in-situ observations, we are developing two instrument packages: PARM (Pulsating AuRora and Microbursts; already developed) and PARM-2 (being developed), both of which are designed suitable for sounding rocket experiments. PARM consists of four sensors; HEP (high-energy electron energy spectrometer), MED (medium-energy electron detector), AIC (auroral camera), and AFG (ASIC-based fluxgate magnetometer). PARM was onboard the NASA's RockSat-XN sounding rocket, and launched from Andoya, Norway at 09:13UT, Jan 13, 2019. On the other hand, PARM-2 is under development. It consists of HEP, two AICs, and MIM (magneto-impedance magnetometer). PARM-2 is to be onboard the NASA's LAMP sounding rocket which will fly from Poker Flat, Alaska in the period between the end of 2019 and the beginning of 2020.

We will present the overview of PARM missions including the initial results of RockSat-XN/PARM with ground-based observations and preparation status of LAMP/PARM-2.

Wed. May 29, 2019 3:30 PM - 5:00 PM JST | Wed. May 29, 2019 6:30 AM - 8:00 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Hiroshi Hasegawa(Institute of Space and Astronautical Science, JAXA)

This session provides an opportunity to present recent results from satellite and ground-based observations and theoretical and simulation studies on the magnetosphere, ionosphere, and their coupling processes. We invite talks and posters discussing various phenomena related to the magnetosphere-ionosphere system: solar wind-magnetosphere interaction, magnetosphere-ionosphere convection, field-aligned current, magnetic storms/substorms, neutral-plasma interaction, ionospheric ion inflow and outflow, aurora phenomena, and so forth. Discussions on planetary and satellite ionosphere and magnetospheres, future missions and instrument developments are also welcome.

A Case Study Based on Ground Observations of the Conjugate Ionospheric Response to Interplanetary Shock in Polar Regions

*He Fang[1], Zejun HU[1], Hongqiao HU[1]

1. Polar Research Institute of China

This study uses data acquired by an imaging riometer, an ionosphere total electron content (TEC) monitor, and three specific wavelength auroral imagers at the conjugate Antarctic Zhongshan (ZHS) and Arctic Yellow River (YRS) stations to investigate the response of the polar ionosphere to a space weather event induced by solar flare activity on July 14, 2012. After the geomagnetic storm suddenly commenced and a magnetospheric substorm was triggered by the arrival of an interplanetary shock wave and its interaction with the magnetosphere at 18:10 UT, significantly enhanced auroral activity was observed by the auroral imagers at the ZHS. Meanwhile, the polar conjugate observation stations in the two hemispheres recorded notable growth of the two-dimensional cosmic noise adsorption and similar motion tendencies. According to our analysis and comparison of the ionospheric TEC data acquired by the conjugate stations, the TEC at both locations presented a considerable growth tendency after the interplanetary shock wave arrived, although the two stations experienced different sunlight conditions (polar night in the Antarctic region and polar day in the Arctic region). However, a comparison with high-frequency radar data demonstrated that different sources were responsible for the electron density enhancement of the ionosphere. In the Arctic polar day region, the increased electron density may have been caused by anti-sunward convection of the plasma irregularity, whereas in the Antarctic polar night region, the increased electron density may have been caused by energetic particle precipitation at the magnetospheric tail. Different physical processes might be the cause of the differential responses of the ionosphere at the two studied geomagnetic conjugate stations in the same solar activity event due to different local photoionization conditions.

Effects of Solar Illumination on the Auroral Electrojet Intensity

*Shinichi Ohtani[1], Jesper W Gjerloev[1]

1. The Johns Hopkins University Applied Physics Laboratory

The present study investigates the dependence of the local auroral electrojet (AEJ) intensity on the solar illumination by statistically examining the northward geomagnetic disturbance in terms of the solar zenith angle (SZA) χ. It is found that on the day side, both westward and eastward electrojets (WEJ and EEJ) are more intense for smaller χ suggesting that the solar EUV-induced conductance is the dominant factor for the AEJ intensity. On the night side, in contrast, the χ dependence of the AEJ intensity, if sorted solely by the magnetic local time (MLT), is apparently different for stations at different longitudes and in different hemispheres. However, if additionally sorted by the dipole tilt angle ϕ, a consistent pattern emerges. It is therefore suggested that although ϕ and χ are correlated, the dipole tilt angle and SZA have physically different effects on the local AEJ intensity. The nightside AEJ, especially the WEJ, tends to be more intense for small $|\phi|$. Moreover, whereas the WEJ is statistically more intense when the ionosphere is dark, the EEJ is more intense when sunlit. The preference of the WEJ for the dark ionosphere extends widely in MLT from premidnight to dawn, and therefore, it cannot be linked exclusively with the substorms or be attributed to the previously proposed processes of the preferred auroral precipitation in the dark ionosphere. Instead, it may be explained at least morphologically in terms of the conductance enhancement due to the diffuse auroral precipitation, which is also prevalent from premidnight to dawn and is more intense in the dark hemisphere.

Quasi-persistent multiple mesoscale field-aligned currents in the duskside auroral oval

*Yoshihiro Yokoyama[1], Satoshi Taguchi[1], Toshihiko Iyemori[2], Keisuke Hosokawa[3]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. Kyoto University, 3. Department of Communication Engineering and Informatics, University of Electro-Communications

Within a large-scale field-aligned current, whose latitudinal width is a few hundred kilometers in the ionosphere, smaller-scale current structures are often embedded. Previous studies have shown that a mesoscale upward field-aligned current with widths of order 10 km generally agree with auroral arcs. However, we still do not understand how this relation forms. In this study, using multispacecraft Swarm data and aurora data from a ground-based all-sky imager at Longyearbyen, Svalbard, we have examined mesoscale features of the field-aligned current and auroral arcs in the duskside auroral oval. We focused on the situation when the large-scale Region 1 current diminishes so that mesoscale features can stand out. Through the cross-correlation analysis of the magnetic perturbations observed by Swarm A and Swarm C, we took events in which the observed magnetic perturbations represent the spatial structure of multiple pairs of upward/downward mesoscale field-aligned currents, not Alfven wave. Conjugate observations between Swarm satellites and the all-sky imager have shown that auroral arcs actually occur in the region of the upward field-aligned current. The result of the analysis of the all-sky image data obtained before and after the conjunction event has shown that the auroral arcs have quasi-persistent features, and also indicated when the auroral arcs appear and disappear. From these results, we discuss how the mesoscale field-aligned current can form.

Generation of dispersive Alfvenic turbulence in magnetosphere-ionosphere feedback coupling

*Tomo-Hiko Watanabe[1], Masatoshi Kaneyama[1], Shinya Maeyama[1]

1. Graduate School of Science, Nagoya University

Magnetosphere-ionosphere (M-I) feedback coupling is considered to provide possible explanations to self-excitatation of auroral arc structures with enhancements of the ionospheric density and the field-aligned current. Recent theoretical and numerical studies have revealed generation of Alfvenic turbulence in the nonlinear evolution of the feedback instability, following the Kelvin-Helmholtz instability accompanied with curl structures of the ionospheric density.
Our recent study has extented to include effects of the electron intertia in the magnetospheric dynamics, where the dispersive Alfven waves with the parallel electric field play a key role in the M-I coupling. The linear stability analysis incuding the electron inertia term has shown the stabilization effect while the mean parallel acceleration of electrons is self-consistently included in the model of auroral arc growth. Nonlinear simulations of the feedback instability have also demonstrated generation of the Alfvenic turbulence with finite parallel electric fields, where a power law energy spectra are obtained for the parallel and perpendicular wavenumbers. The physical picture of Alfvenic turbulence obtained in the persent study is consistent to FAST spacecraft observations of the dispersive Alfven waves and the electron acceleration in the Alfvenic aurora.

Aspects of simulating magnetosphere-ionosphere coupling via field-aligned current

*Astrid I Maute[1], Arthur D Richmond[1], Gang Lu[1]

1. High Altitude Observatory, National Center for Atmospheric Research, Boulder CO, 80301, USA

Magnetosphere-ionosphere (MI) coupling is crucial in modeling the thermosphere-ionosphere (TI) response to geomagnetic activity. In general circulation models (GCMs) the MI coupling is frequently realized by specifying the ion convection and auroral particle precipitation patterns from, e.g., empirical models or assimilative models. Using assimilative models, such as the Assimilative Model of Ionospheric Electrodynamics (AMIE), has the advantage that the ion convection and auroral particle precipitation patterns are self-consistent and based on available observations. However, assimilating data can be time consuming and requires expert knowledge, and therefore it is so far not the standard way of MI coupling in GCMs. With the availability of AMPERE data, there is an increased interest of employing field-aligned currents (FAC) in GCMs to represent the MI coupling. The FAC from AMPERE captures interhemispheric differences in the MI coupling not represented by empirical ion convection models. However, since GCMs mostly employ prescribed high latitude ion convection patterns little is known about differences in the TI response to high latitude forcing by prescribed FACs.

In this study, we will compare with the help of a simulated geomagnetic storm the different MI coupling methods, i.e., AMIE, empirical ion convection and AMPERE field-aligned current. We illustrate the sensitivity of the Joule heating and low latitude electric field with respect of the spatial distribution of the aurora and ion convection for the different cases. The influence of interhemispheric differences in the MI coupling on the middle and low latitude thermosphere-ionosphere system will be examined.

Revisiting the energy conversion process of Birkeland current generation

*Akimasa Yoshikawa[1]

1. Department of Earth and Planetary Sciences, Kyushu University

As shown by Vasyliunas [1970], the magnetospheric diamagnetic current has a finite divergece when it crosses the region with a finite B gradient and connects to the Field-Aligned Current (FAC). A pressure gradient force, the origin of the diamagnetic current in a force balance to the Ampere force, never twists plasma flow. While for the development of magnetic shear, which corresponds to FAC, combination of Ampere’ s law , Faraday’ s induction law and MHD Ohm’ s law require the gradient of plasma vortex along B-field. In other words, for the existence of a quasi-steady FAC in the MHD scheme, the plasma vorticity along the B-field is inevitably required.

Of course, for the development of plasma vorticity, we need a dynamical process that twists the plasma. What is the dynamical process that twists the plasma as FACs are generated due to the divergence of the diamagnetic current? A conventional answer to this question is a mode conversion between the compressional mode and the Alfven mode when the diamagnetic current is growing (in inductive process). However, in principle, the magnetosphere-ionosphere coupling system forms a dissipative structure in the open solar-terrestrial system. Therefore, even in a macroscopic quasi-steady system, the constant conversion from the thermal energy to the magnetic energy and the internal mode conversion from magnetic compression to the magnetic shear should continuously take place. In this sense, we need to revisit the dynamical process of FAC. In this presentation, we will discuss what is the dynamical process and what is the quasi-steady state of FACs in a dissipative structure of the open magnetosphere-ionosphere system.

Wed. May 29, 2019 9:00 AM - 10:30 AM JST | Wed. May 29, 2019 12:00 AM - 1:30 AM UTC | A04 TOKYO BAY MAKUHARI HALL

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Shinji Saito(ISEE, Nagoya University), Yusuke Ebihara(RISH, Kyoto University)

The inner magnetosphere is characterized by the dominance of intrinsic dipolar Earth's magnetic field. The dipolar magnetic field traps charged particles, resulting in the formation of unique particle environment known as the plasmasphere, the ring current, and the radiation belt. The inner magnetosphere is always changing because of incoming energy from the outer magnetosphere and the ionosphere in the forms of particles and electromagnetic fields. In the inner magnetosphere, the particle energy is transferred to the field energy, and vice versa. The mutual coupling between particles and fields also makes the inner magnetosphere unique. The outgoing energy to these regions is also known to be significant, such as precipitation into the upper atmosphere and sub-auroral disturbances. A number of satellites (e.g., DMSP, NOAA, Geotail, Cluster, THEMIS, Van Allen Probes, MMS, and Arase), ground-based instruments (e.g., SuperDARN and EISCAT radars, magnetometers, and cameras), and numerical simulations (e.g., global particle simulation, PIC simulation, and hybrid simulation) have successfully surveyed the inner magnetosphere, which deepen our knowledge significantly. USAF DSX, UCLA Elfin and NASA CeRES will be launched soon, being expected to provide important information. We solicit papers describing recent results on the inner magnetosphere and/or its coupling with the other regions, including the ionosphere and the outer magnetosphere.

Nonlinear Damping of Oblique Whistler Mode Waves Via Landau Resonance

*Yikai HSIEH[1], Yoshiharu Omura[1]

1. Reserach Institute for Sustainable Humanosphere, Kyoto University

Nonlinear trapping of electrons via Landau resonance is an important mechanism of oblique whistler mode wave-particle interactions. Electrons trapped by Landau resonance gain energies from waves. The Landau resonance velocity becomes very close to the group velocity of nearly parallel whistler mode waves at frequencies around half the electron gyrofrequency, resulting in a long interaction time and possible wave damping. We perform test particle simulations with parameters at L = 5 and a small wave normal angle 10 degrees to study the wave-particle interactions via the Landau resonance. Analyzing the wave electric fields and the resonant currents formed by electrons undergoing Landau and cyclotron resonances, we show that effective wave damping occurs near half the electron gyrofrequency. This nonlinear wave damping is contributed by Landau resonance rather than cyclotron resonance. Furthermore, we confirm that this damping is dominated by perpendicular components of the wave electric field and perpendicular resonant currents. The simulation results indicate that nonlinear damping via Landau resonance is one of the mechanisms dividing chorus emissions into the upper band and the lower band.

National Astronomical Observatory of Japan, 8. Toyama Prefecture University

In the inner magnetosphere, the Arase spacecraft has observed electromagnetic ion cyclotron (EMIC) emissions with both rising and falling frequencies. The instantaneous frequency analyses on the electromagnetic fields of the EMIC rising tone emission have been performed by the Hilbert-Huang transform. The time variation of the instantaneous frequency shows a good agreement with the nonlinear theory for the frequency evolutions. Rapid instantaneous frequency modulation is also found during the rising tone emission. We estimate the peak-to-peak time of the fluctuation in the frequency and find that the fluctuation is caused around a half of the particle trapping time. From the motion of the phase-bunched particle around the resonant velocity, it is expected that the nonlinear resonant current, which induces the falling frequency is formed in half the trapping time.

Rapid Precipitation by EMIC Rising-tone Emissions of Relativistic Electrons Observed by the Van Allen Probes Mission

*Satoko Nakamura[1], Yoshiharu Omura[1], Craig Kletzing[2], Daniel Baker[3]

1. Research Institute for Sustainable Humanosphere, Kyoto University., 2. Department of Physics and Astronomy University of Iowa , 3. The Laboratory for Atmospheric and Space Physics (LASP) at the University of Colorado

On 23 February 2014, Van Allen Probes sensors observed quite strong electromagnetic ion cyclotron waves (EMIC) in the outer dayside magnetosphere. The maximum amplitude was more than 14 nT, comparable to 7 % of the magnitude of the ambient magnetic field. The EMIC waves consisted of a series of coherent rising tone emissions. Rising tones are excited sporadically by energetic protons. At the same time, the probes detected drastic fluctuations in fluxes of MeV electrons. It was found that the electron fluxes decreased by more than 30 % during the one minute following the observation of each EMIC rising tone emissions. Furthermore, it is concluded that the flux reduction is a non-adiabatic (irreversible) process since holes in the particle flux levels appear as drift echoes with energy dispersion. We examine the process of the electron pitch angle scattering by nonlinear wave trapping due to anomalous cyclotron resonance with EMIC rising tone emissions. The energy range of precipitated electrons corresponds to the presumed energy for the threshold amplitude for nonlinear wave trapping. This is the first report of rapid precipitation by this mechanism of relativistic electrons by EMIC rising tone emissions and their drift echoes in time observed by spacecraft.

Plasmaspheric EMIC waves excited through mode conversion from equatorial noise under existence of M/Q=2 ions

*Yoshizumi Miyoshi[1], Shoya Matsuda[2], Satoshi Kurita[1], koji nomura[1], Kunihiro Keika[3], Masafumi Shoji[1], Naritoshi Kitamura[3], Yoshiya Kasahara[4], Ayako Matsuoka[2], Iku Shinohara[2], Kazuo Shiokawa[1], Shinobu Machida[1], Ondrej Santolik[5], Scott Boardsen[6], Richard Horne[7], Wygant John[8]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. JAXA, 3. University of Tokyo, 4. Kanazawa University, 5. CAS, 6. NASA, 7. British Antarctic Survey, 8. University of Minnesota

Equatorial noise (EN, and referred to as magnetosonic mode waves) emissions are observed inside and outside the plasmapause and propagate across the magnetic field. In this study, we found the mode conversion from EN to EMIC waves in the plasmasphere using the plasma wave data from Van Allen Probes and Arase. When EN propagates into the earthward across the field line toward the Earth, EN splits into different waves modes; EN, and EMIC waves with the existence of M/Q=2 ions (deuteron or alpha particles) in the deep plasmasphere and the topside ionosphere. The oblique EMIC waves are excited through this mode conversion process, which are different characteristics of the propagation directions from EMIC waves generated from other processes. This mode conversion contributes to an origin of the plasmaspheric EMIC waves, especially at L<2.

Generation Mechanism of Non-thermal Continuum Radiation

*Yoshiharu Omura[1], Miroslav Horky[1,2]

1. Reserach Institute for Sustainable Humanosphere, Kyoto University, 2. Department of Space Physics, Institute of Atmospheric Physics, Czech Academy of Sciences

We study a possible nonlinear mechanism which could be responsible for generation of the non-thermal continuum radiation. We propose a theoretical model and perform numerical simulations using a 2-D electromagnetic particle code (KEMPO2) [1] to verify the mechanism [2]. In the simulation system, we have density gradient and ring beam electrons in the dense region as a source of electrostatic waves through ring-beam instability. These electrostatic waves cause non-gyrotropy of the ring velocity distribution which is necessary for generation of the harmonic waves. Velocity component V_y together with magnetic field B_z of the generated Z-mode waves creates Lorentz force in the x-direction (along the magnetic field). Hence, oscillating energetic electrons work as an anntenna emiting O-mode waves to the low density region. Electromagnetic O-mode waves are emitted at harmonics of the cyclotron frequency up to the maximal plasma frequency of the high density region, and they are observed as non-thermal continuum radiation in the low density region.

Influence of kappa distributions on the sweep rate of whistler mode chorus waves

*Danny Summers[1]

1. Memorial University of Newfoundland

Kappa particle distributions typically possess a high-energy power-law tail characterized by a spectral index kappa. Here we consider the bi-kappa and kappa-loss-cone distributions. The influence of kappa distributions on the linear growth rate of whistler-mode waves is mediated by the electron anisotropy. The linear growth rate corresponding to kappa distributions (for kappa=2) exceeds that for a bi-Maxwellian distribution for electron anisotropies less than a critical value; for anisotropies greater than the critical value the opposite applies. The influence of kappa distributions on the threshold wave amplitude for nonlinear growth depends on the wave frequency, the electron anisotropy and the temperature of the (hot) energetic electrons that generate the waves. We construct time profiles of the amplitude and frequency of chorus wave elements for various sets of parameters. We examine how the sweep (chirp) rate of the waves depends on the kappa index. Nonlinear growth of whistler mode waves can be enhanced or inhibited by kappa distributions,dependent on the values of the parameters of the background plasma and the properties of the injected energetic electron population that generates the waves.

Substorms are a highly dynamic process that result in the global redistribution of energy within the magnetosphere. The occurrence of a substorm can provide the inner magnetosphere with hot ions and consequently intensify the ring current population. However, substorms are a highly variable phenomenon that can occur as an isolated event or as part of a sequence. In this study we determine the extent to which substorms enhance the ring current energy content and compare how the energy enhancement varies with substorm type.

Using ion observations (H^+, O^+, and He^+) from the RBSPICE and HOPE instruments onboard the Van Allen Probes, we quantify how the total ring current energy content changes during the substorm process. A statistical analysis demonstrates the impact of a typical substorm on the ring current region. We find that ~ 5% of the total energy released at substorm onset is transferred into the ring current population, and energises the ring current by 12% on average. The features of the energy enhancement correlate well with the expected properties of particle injections into the inner magnetosphere, and large enhancements in the O^+ contribution to the energy content suggest important compositional variations.

Analysis also reveals that the ring current response to substorms is strongly dependent upon the type of substorm activity. The results show that substorms followed by a series of successive substorms are associated with significantly different ring current conditions and enhancements compared to isolated substorms. We present clear magnitude and local time differences that illustrate the complexity and variability of the substorm-ring current coupling, along with an interpretation of the details of this relationship.

Dipolarization in the Inner Magnetosphere: Comparison between Geosynchronous Orbit and Further Inside

*Shinichi Ohtani[1], Tetsuo Motoba[1], Matina Gkioulidou[1], Kazue Takahashi[1]

1. The Johns Hopkins University Applied Physics Laboratory

The present study addresses the current system associated with dipolarization in the inner magnetosphere. *Ohtani et al.* [2018] examined dipolarization events observed by the Van Allen Probes (RBSP) satellites within 5.8 R_E from Earth, and by statistically comparing signatures at nearby RBSP or GOES satellites, they found that dipolarization signatures are often highly correlated (c.c. > 0.8) within 1 hr in MLT and 1 R_E in R_{XY}, and the dipolarization region expands earthward as well as azimuthally. In the present study we use, as a reference, the GOES geosynchronous satellites instead, and we examine how the magnetic field at the RBSP position changes responding to sharp dipolarizations at geosynchronous orbit. As expected from the aforementioned result, the two spacecraft occasionally observe similar dipolarization signatures with some time delay. It is, however, also found that in some events the magnetic field changes far less systematically at the RBSP probes, and in other events it barely changes or changes very gradually even if the RBSP probes are located very close to the GOES location in longitude (DMLT = 0.0 ~ 0.5 hr in MLT). By examining such variability with respect to the radial distance and magnetic latitude of the RBSP probes, we address the spatial structure of the associated current system. We also examine the variation of particle fluxes at the RBSP probes for each type of the magnetic response, and discuss the result in terms of the enhancement of local plasma pressure and the formation of a R2-sense field-aligned current system, which we suggest coexists along with the conventional substorm wedge current system.

The injection of electrons during the substorm event, occurring on Apr. 5, 2017, was observed by the ERG (Arase), GOES-15 and GOES-13 spacecraft near/at geosynchronous orbit. The ERG satellite observed the nearly-dispersionless injection and the subsequent drift echoes while the GOES-15 and GOES-13 captured the drift echoes with dispersion. The multipoint observations provide constraints for us to simulate the substorm-associated injection. We improve an existing model in the literature to study the substorm injection event. Since the electron energies of interest are comparable to the rest mass energy, our work further provides the relativistic form of the previous model and employs a semi-empirical model instead of a dipole-based one in the previous study. Our simulations successfully reproduce the key features of the nearly-dispersionless injection and the drift echoes. The periods of drift echoes show a better fit to the spacecraft observations when relativistic effects are taken into account. The substorm-associated injection event can be better simulated by the further-developed model shown in this study.

The Arase (ERG) satellite is possible to observe higher L-value plasma sheet close to the plasma sheet boundary because of its characteristic orbit, and, actually, Arase has observed several lobe entry events just outside of the outer radiation belt. In some of these events, we found that energetic electron bursts up to (sometimes, over) 300 keV appear at the plasma sheet boundary. The purpose of this study is to address where do the energetic electron bursts at higher latitude come from and what is the contribution of magnetotail reconnection and its associated acceleration process to the generation of the energetic electron bursts.

However, the observed energetic electron bursts look quite similar to typical dispersionless substorm injection events. If the observed electron bursts are due to the substorm injection, the observation cannot be explained by the standard understanding of the injection because (1) the injection occurs associated with local magnetic field dipolarizations in downstream of the magnetotail reconnection jets (in deep inside of the plasma sheet) and (2) energetic electrons observed at the plasma sheet boundary are thought to be directly accelerated from magnetotail reconnection sites. Since the pitch angle distribution of 100-200 keV electron shows enhancement both of parallel and perpendicular fluxes, the observed results suggest the coexistence of (1) and (2). In this presentation, we will discuss the physical meanings of the observed electron bursts. The discussion is important to address the relationship between magnetotail reconnection and injections, and the results might contribute to a better understanding of electron acceleration processes and energy input to the inner magnetosphere.

The magneto-hydrodynamic waves propagating in the plasma sheet are recognized to transport substantial energies in the magnetosphere. We investigated magnetic field disturbances of the Alfven waves observed by the Arase spacecraft at about 5 earth-radii distance in the midnight. In the inner plasma sheet Alfven waves were often accompanied by the magnetic dipolarization.
We examined the magnetic disturbances in the plane perpendicular to the ambient magnetic field. In the two events examined in our study, the magnetic field disturbances were linearly polarized and the polarization direction gradually rotated 180 degrees in 200 seconds. It is well interpreted that Arase traversed a magnetic flux tube where torsional Alfven waves propagated. The change of the polarization direction reflected the change of observation location in the flux tube. Torsional-mode is significantly common and natural as the parallel-propagating Alfven wave. It is known that large-scale energy transfer and dissipation of the torsional Alfven waves take place on the solar surface.
Meanwhile, in the boundary plasma sheet adjacent to the lobe, the magnetic field disturbances were linearly polarized again and confined to the dawn-dusk direction. They are interpreted as plane Alfven waves having uniformity in the dawn-dusk direction and propagating obliquely. The kinetic effect of the Alfven waves has been often discussed in previous works in association with the auroral emission at the ionospheric altitude.

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University), Chairperson:Yoshizumi Miyoshi(ISEE, Nagoya University), Yusuke Ebihara(RISH, Kyoto University)

The inner magnetosphere is characterized by the dominance of intrinsic dipolar Earth's magnetic field. The dipolar magnetic field traps charged particles, resulting in the formation of unique particle environment known as the plasmasphere, the ring current, and the radiation belt. The inner magnetosphere is always changing because of incoming energy from the outer magnetosphere and the ionosphere in the forms of particles and electromagnetic fields. In the inner magnetosphere, the particle energy is transferred to the field energy, and vice versa. The mutual coupling between particles and fields also makes the inner magnetosphere unique. The outgoing energy to these regions is also known to be significant, such as precipitation into the upper atmosphere and sub-auroral disturbances. A number of satellites (e.g., DMSP, NOAA, Geotail, Cluster, THEMIS, Van Allen Probes, MMS, and Arase), ground-based instruments (e.g., SuperDARN and EISCAT radars, magnetometers, and cameras), and numerical simulations (e.g., global particle simulation, PIC simulation, and hybrid simulation) have successfully surveyed the inner magnetosphere, which deepen our knowledge significantly. USAF DSX, UCLA Elfin and NASA CeRES will be launched soon, being expected to provide important information. We solicit papers describing recent results on the inner magnetosphere and/or its coupling with the other regions, including the ionosphere and the outer magnetosphere.

Discussion

Statistical Property of Long Lasting Poloidal Pc 4-5 Waves and Relation with Particle Dynamics in the Inner Magnetosphere: Van Allen Probes Observations

*Kazuhiro Yamamoto[1], Masahito Nose[2], Kunihiro Keika[3], Charles W. Smith[4], Robert J. MacDowall[5], Donald G. Mitchell[6], Hyomin Kim[7], John Wygant[8]

1. Graduate School of Science, Kyoto University, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Graduate School of Science, the University of Tokyo, 4. Institute for the Study of Earth, Oceans, and Space, University of New Hampshire, 5. Solar System Exploration Division, Goddard Space Flight Center, 6. The Johns Hopkins University Applied Physics Laboratory, 7. Center for Solar Terrestrial Research, New Jersey Institute of Technology, 8. School of Physics and Astronomy, University of Minnesota

Poloidal ULF waves in the inner magnetosphere have been attracting many attentions because they can interact with plasma particles. A lot of event analysis of the drift-bounce resonance, the bounce resonance, and the drift resonance have been conducted (e.g., *Hughes et al.*, 1978; *Takahashi et al.*, 1990, 2018; *Liu et al.*, 2013; *Dai et al.*, 2013; *Min et al.*, 2017; *Oimatsu et al.*, 2018; *Rubtsov* et al., 2018). However, the statistical relation between the poloidal mode waves and particles is rarely reported, and the phase relation between poloidal oscillations and resonance particles is only studied by *Ren et al.* (2018).

To reveal the importance of a poloidal ULF wave in the dynamics of the inner magnetosphere, we statistically analyzed 91 events of the poloidal waves detected by Van Allen Probes with duration time larger than 2 hr, because significant wave particle interaction is expected for such long lasting waves. We calculated eigen-frequencies of the selected waves using the Tsyganenko 89 model (*Tsyganenko*, 1989), and found that most of them are second harmonic mode waves. The cross phase between the radial magnetic field and the azimuthal electric field also supports this result. Using the ion sounding technique (*Su et al.*, 1977; *Min et al.*, 2017; *Yamamoto et al.*, 2018), we estimated the azimuthal wave number (*m* number) for 47 events from RBSPICE observation. Most of the 47 events have m = -120 to -200 (i.e., westward propagation). These high-m waves can be excited by wave-particle interaction.

Relation between the high-m poloidal waves and the plasmasphere was investigated. When the poloidal waves were observed, cold electron density increased by a factor of ~2. When the electron density decreased to the original state, the poloidal waves disappeared. This implies that the poloidal waves are excited in the structured high electron density region like plasma plume. The scenario of wave excitation through bounce resonance proposed by *Liu et al.* (2013) can explain the density variations during wave appearance.

We will also discuss the variations of proton flux around resonance energy and evaluate the importance of poloidal ULF waves in the dynamics of the inner magnetosphere. During quiet period ($|Dst| < 10$ nT), the proton flux at energy of (0.3-1)W_{res} (W_{res}: resonance energy) was slightly smaller than that on the orbit just before the wave onset. The decrease of resonance particle flux may be caused by wave-particle interaction.

Subauroral Polarization Streams: Indication of Magnetosphere–Ionosphere Coupling

*Fei He[1,2,3], Xiao-Xin Zhang[4], Wenbin Wang[5], Zhonghua Yao[1,2,3], Yong Wei[1,2,3], Zhi-Peng Ren[1,2,3], Xinan Yue[1,2,3], Weixing Wan[1,2,3]

Subauroral polarization streams, or SAPS, are narrow channels of strong westward ion flows in both the subauroral ionosphere and the conjugated inner magnetosphere in the nightside during geomagnetic storms and substorms. The SAPS are closely related with ionospheric conductivity and region–2 field–aligned currents. Many characteristics of SAPS have been determined from space–based measurements of electric fields and ion drifts in the ionosphere and the magnetosphere, and ground–based radar observations, such as the global occurrence based on the statistics of many individual event, long term variabilities, hemispheric asymmetries, electromagnetic wave structures, double peak signatures, and evolution patterns during intense storms and quiet time substorms. Multisatellite observations during a geomagnetic storm indicated that the SAPS were first initiated around the dusk sector and then expanded toward the midnight, moved to low latitudes and formed a wedge-shaped structure during the main phase. More recently, multisatellite observations during a severe storm revealed that strong oscillations occurred in the SAPS channel when IMF By changed from positive to negative. The SAPS oscillations were first observed in the pre–midnight sector and propagated towards the dusk sector. The oscillations may be related to the waves generated by the interaction between the fast–flowing energetic plasma sheet ions and the cold plasmasphere. The new features of SAPS provide new insights in to the coupling dynamics in the magnetosphere.

The purple auroral emission at a wavelength of 427.8nm is often caused by resonant scattering of sunlight by nitrogen molecular ions at the high-latitude part of auroral arcs, and can be a manifestation of ion upflow in the auroral ionosphere. We report the first particle observation for the source region of a purple/green auroral arc in the inner magnetosphere, which was made by the Arase satellite. The auroral arc appeared and expanded equatorward from ~0310 UT (midnight in local time) on September 11, 2018 at Nain, Canada, in association with the expansion phase of a substorm that occurred during the arrival of a corotating interaction region (CIR) in the solar wind. The auroral arc is characterized by purple and green emissions at the top and bottom parts, respectively, suggesting resonant-scattering of sunlight by auroral nitrogen molecular ions. Bi-directional field-aligned electrons with energies of ~keV were observed by the LEP-e onboard the Arase satellite during the arc crossing at L ~ 6.4, while source electrons become isotropic in the diffuse aurora afterwards. Electrons at energies of ~20 keV measured by the MEP-e of Arase also show a bi-directional (nearly) field-aligned distribution, while electron loss cone was identified at the arc crossing. The low-energy protons measured by LEP-i of Arase show time-pitch-angle dispersion from anti-earthward (180 degree) to earthward (0 degree) during the arc crossing. Based on these observations, we discuss physical mechanisms that cause these particle features and the observed purple/green auroral arc.

A recent study employing the Arase and Van Allen Probes A satellites at different MLT revealed an event in which the inner magnetospheric O^+ density enhancement (know as the dense oxygen torus) does not extend over all MLT. Rather, the torus is skewed toward the dawn sector, being described more precisely as a crescent-shaped torus or a pinched torus [Nosé et al., 2018]. In the reported event of 24 April 2017, Arase flying in the morning sector detected an enhancement of the average plasma mass up to ~3.5 amu around *L*=4.9–5.2, while Van Allen Probe A flying in the afternoon sector observed no clear enhancements in the average plasma mass. In the present study, we focus on simultaneous observations of the magnetic field and plasma waves made by the Arase and Van Allen Probes A and B satellites on 12 September 2017. For this event the orbital configuration of the satellites is opposite to that in the study by Nosé et al. [2018]; that is, Arase is in the afternoon and the Van Allen Probes are in the morning. It is found that only Probe B observed a clear enhancement in the average plasma mass up to ~4 amu around *L*=3.5 and MLT=9.0 hr. This result demonstrates that the crescent-shaped O^+ torus is not a unique (single-event) occurrence, and thus may be a general feature of the density enhancement in the inner magnetosphere.

Study of characteristics of storm-time Pc5 ULF waves excited by the drift-bounce resonance with ring current ions based on the global drift-kinetic simulation

*Tomotsugu Yamakawa[1], Kanako Seki[1], Takanobu Amano[1], Yoshizumi Miyoshi[2], Naoko Takahashi[1]

1. Department of Earth and Planetary Science, School of Science, The University of Tokyo, 2. ISEE, Nagoya University

Storm-time Pc5 waves are electromagnetic fluctuations in the inner magnetosphere with the frequency of 1.67-6.67 mHz, and are considered to be generated by ring current ions associated with the injection from the magnetotail during substorms. The excitation mechanism and global distribution of Pc5 waves are keys to understand dynamic variation of the outer radiation belt, since Pc5 waves are considered to contribute to the radial diffusion of radiation belt electrons [e.g. Elkington et al., 2003]. Promising candidates of excitation mechanism of the storm-time Pc5 waves are the drift or drift-bounce resonance [Southwood, 1976]. Although previous spacecraft observations suggest the resonant excitation [e.g., Dai et al., 2013; Yeoman and Wright., 2001], there are other possibilities such as periodic pressure inhomogeneity formed by time-dependent injections. Theoretically, Yamakawa et al. [2019] confirmed the drift resonance excitation of storm-time Pc5 waves in 3D dipole structure based on the drift-kinetic simulation. However, in what kind of situation the drift resonance is switched to the drift-bounce resonance is far from understood.

In order to simulate the excitation of the storm-time Pc5 waves, we perform a kinetic simulation for ring current particles using GEMSIS-RC model [Amano et al., 2011], in which five-dimensional drift-kinetic equation for the phase space density (PSD) of ring current ions and Maxwell equations are solved self-consistently under assumption that the first adiabatic invariant is conserved. In order to simulate consequence of ion injection from the plasma sheet, we set a localized high-pressure region around midnight consisting of H+ ions. We compare two cases of the initial velocity distribution; the Maxwellian velocity distribution with the isotropic temperature of 16 keV (Case a) and the velocity distribution with the phase bunching in the southern hemisphere due to the bounce motion of ions in addition to the background Maxwellian distribution (Case b). For the Case b, we changed the strength of the initial phase bunching to investigate the conditions for drift-bounce resonance to be dominant.In Case a, the simulation results show the drift resonance excitation of both poloidal and toroidal mode waves in Pc5 frequency range in the dayside dusk sector. These waves are fundamental mode waves with azimuthal wave number m ~ - 20 propagating westward. Global distribution of the excited Pc5 waves indicates that they are excited where the local growth rate resultant from the positive PSD gradient in energy is positive. In Case b, excitation of the second harmonic poloidal-mode Pc4 ULF waves due to the drift-bounce resonance was identified in the dayside dusk sector in the strong bunching case. We will also report on characteristics of excited ULF waves and their dependence on the initial bunching strength of injected ions with a focus of the relative contribution of the drift and drift-bounce resonances.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Wed. May 29, 2019 3:30 PM - 5:00 PM JST | Wed. May 29, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University)

The inner magnetosphere is characterized by the dominance of intrinsic dipolar Earth's magnetic field. The dipolar magnetic field traps charged particles, resulting in the formation of unique particle environment known as the plasmasphere, the ring current, and the radiation belt. The inner magnetosphere is always changing because of incoming energy from the outer magnetosphere and the ionosphere in the forms of particles and electromagnetic fields. In the inner magnetosphere, the particle energy is transferred to the field energy, and vice versa. The mutual coupling between particles and fields also makes the inner magnetosphere unique. The outgoing energy to these regions is also known to be significant, such as precipitation into the upper atmosphere and sub-auroral disturbances. A number of satellites (e.g., DMSP, NOAA, Geotail, Cluster, THEMIS, Van Allen Probes, MMS, and Arase), ground-based instruments (e.g., SuperDARN and EISCAT radars, magnetometers, and cameras), and numerical simulations (e.g., global particle simulation, PIC simulation, and hybrid simulation) have successfully surveyed the inner magnetosphere, which deepen our knowledge significantly. USAF DSX, UCLA Elfin and NASA CeRES will be launched soon, being expected to provide important information. We solicit papers describing recent results on the inner magnetosphere and/or its coupling with the other regions, including the ionosphere and the outer magnetosphere.

The Plasma Wave Experiment (PWE) is one of scientific instruments on board the Arase (ERG) satellite to measure electric field from DC to 10 MHz and magnetic field from a few Hz to 100 kHz in the inner magnetosphere. It is well known that chorus wave, one of typical plasma waves in VLF range observed in the inner magnetosphere, is a plausible candidate that accelerates relativistic electrons in the radiation belt. Besides the chorus, the Arase has observed various kinds of plasma waves such as lightning whistlers and hiss waves. It is very important to study the propagation characteristics of these waves.

In the present paper, we developed a direction finding system applicable to whistler mode waves using the data from waveform capture (WFC), which is one of receivers covering the frequency range below 20kHz implemented in the PWE. The absolute directions of the wave normal and Poynting vectors were derived in the coordinate system referring the ambient magnetic field and geomagnetic meridian plane. We also estimated the Poynting vector theoretically using the derived wave normal vector, electron density and ambient magnetic field intensity to confirm the validity of the results from the observation data.

We demonstrated that the results were generally reliable, but further calibration is necessary for electric field to improve the accuracy of Poynting vector because the waveform of electric field is now calibrated under the assumptions of theoretical antenna capacitance in a vacuum and typical plasma impedance. In other words, we expect to be able to correct the calibration table for electric field measurements from the direction finding results.

In the presentation, we introduce some typical results which have been derived from the observation data of upper- and lower-band chorus, and lightning whistlers.

The outer radiation belt consists of high-energy electrons. They are strongly affected by geomagnetic activities in the relation to solar wind conditions. The important science target of the Arase mission is to clarify generation/loss mechanisms of relativistic electrons in the outer radiation belt. Wave-particle interactions are thought to be a plausible mechanism for generation/loss processes of relativistic electrons. S-WPIA (Software-type Wave-Particle Interaction Analyzer) is installed in the Arase satellite. The WPIA is a newly developed observation system that enables us to quantitatively understand the interaction between plasma waves and electrons. The WPIA has the capability to identify a relative phase angle of a plasma wave vector and a velocity vector of each detected particle. Since phase information of observed plasma waves is essential to the WPIA, precise calibrations of plasma wave data are important. While the calibration data for the magnetic field sensors are identical to those we obtained during the ground tests of the instruments, the calibration data for electric field sensors strongly depend on plasma parameters around the satellite. Furthermore, there are still unclear parameters at the inputs of preamplifiers relating to the connection with electric field sensors. The calibration for electric field data needs to be performed carefully consulting observation data after the launch.

The present paper focuses on the calibration of plasma wave data for the S-WPIA’s data processing. We picked up events including whistler-mode chorus emissions and lightning-whistler waves. They all are electromagnetic waves, so-called whistler mode waves. The amplitude ratios of their electric field and magnetic field components can be theoretically calculated referring to the Appleton-Hartlee equations. Poynting vectors of whistler mode waves can be also theoretically obtained. We compared the observation results of the picked up events with the theoretical ones. The results show the precise calibration for the magnetic field data have been made. On the other hand, the calibration for the electric field data should be further modified consulting plasma parameters and other uncertain parameters at the input of preamplifiers. In the present paper, we will discuss the improvement of the calibration for electric field data by correcting the calibration table to aim the precise S-WPIA data processing.

Whistler-mode chorus emissions play significant roles in the acceleration and loss of energetic electrons in the magnetosphere. One of the important factors which control periodic enhancement of chorus emissions is ULF (Ultra Low Frequency) waves. Previous studies reported that the compressional component of Pc4-5 ULF waves modulates the intensity of chorus waves [Li et al., 2011] and that the toroidal and poloidal components of Pc4-5 ULF waves as well [Jaynes et al., 2015]. Previous studies also suggested that enhancement of the temperature anisotropy of energetic electrons in the wave generation region should be required for the chorus generation. In order to understand the reported correspondence, in addition to the wave observation, we should examine simultaneously observed variations of the flux and the pitch angle distribution of energetic electrons.

In the present study, we investigate the relationship between chorus emissions and ULF waves using particle and electromagnetic field observations made by the Arase satellite. First, we analyze data observed by the Onboard Frequency Analyzer (OFA) of the Plasma Wave Experiment (PWE) and the Magnetic Field Experiment (MGF) during the campaign observation period of the Arase satellite with ground stations from March to April in 2017. As a result, we identified the simultaneous enhancement of chorus emissions and Pc4-5 ULF waves, which was dominated by the toroidal component, from 2130 to 2200 UT on March 27, 2017. The Arase satellite was located at the magnetic local time about 04:00, the magnetic latitude about -10 degrees, and the L-value about 6 during the event. We find that there is one-to-one correspondence between chorus emissions and the toroidal component of ULF waves; chorus emissions enhanced at the timings when the toroidal magnetic field component of ULF waves had a peak in the westward direction. The identified phase relationship is different from that reported by Jaynes et al. (2015), which isn't one-to-one correspondence. Next, we evaluate the resonance energy of the observed chorus emissions, using the ratio of the plasma frequency to the electron cyclotron frequency (f_p/f_{ce}) based on the upper-hybrid resonance frequency derived from the spectra observed by the High Frequency Analyzer (HFA) of PWE and the ambient magnetic field intensity observed by MGF. We find that f_p/f_{ce} is 3.3-3.4 during the event and that the resonance energy for whistler-mode waves in the frequency range of 0.1-0.2 f_{ce} is estimated to be about 100-400keV, which is larger than typical energies of resonating electrons observed in the inner magnetosphere. The estimated large resonant energy can be explained by the frequency range of the observed chorus emissions, approximately 0.1 - 0.2 f_{ce}, is relatively lower than that observed in typical cases.
We also analyze variations of the flux and the pitch angle distribution of energetic electrons during the event using data observed by the High-energy electron experiments (HEP) instrument onboard Arase. The result shows that both the flux and the pitch angle distribution of electrons in the kinetic energy range from 100 to 400 keV, which corresponds to the estimated resonance energy, did not fluctuate with the intensity variation of the chorus emissions and the ULF waves. In addition, we analyze the data observed by the Medium-energy particle experiments - electron analyzer (MEP-e) for energetic electrons in the energy range of 10-80 keV, lower than the estimated resonance energy. Then we identify the

©2019. Japan Geoscience Union. All Right Reserved.

corresponding variation of both the flux and the pitch angle distribution in the 40-60 keV energy range. One of the possible reasons why no significant variations were observed in the hundred keV range would be that the Arase satellite was located in the off-equatorial region during the event, and that the satellite was away from the wave generation region.

Electron cyclotron harmonic (ECH) waves are commonly observed in the low latitude region just outside the terrestrial plasmapause. They are purely electrostatic and their frequency spectra show harmonic structures. The harmonic structures are believed to depend on the temperature and density ratio between cold and hot background electrons. The Plasma Wave Experiment (PWE) onboard the Arase satellite has observed ECH waves since the start of its operation. The observed ECH waves are classified into two types. They are the diffuse ECH waves and the enhanced ECH waves. The diffuse ECH waves are weak and they appear as continuous emissions that last for more than a few minutes. The enhanced ECH waves are the sudden enhancements of the diffuse ECH in shorter periods. The present paper focuses on the enhanced ECH waves observed by the Arase satellite.

Kazama et al. (2018) introduced the event that the repeated enhancement of ECH waves is associated with density depletions near the plasmapause. They succeeded in revealing the good correlation of the enhancement of the ECH waves and the sudden decrease of the cold electrons with energies lower than the lowest energy limit of the particle detector. The observed electron features are clear in the relation to the enhancement of ECH waves, but the mechanism of the enhancement is still unclear. We searched for such events of the enhanced ECH waves and examined the correlation of wave intensities, spacecraft potentials and electron velocity distributions observed by the Arase satellite. Some of the events show the features similar to those of Kazama et al. (2018), but there are also many other events with no correlation between the enhancements of the ECH waves and the density depletions. In the present paper, we examine velocity distribution functions of electrons observed by the low-energy particle experiments-electron analyzer (LEPe) onboard Arase. Velocity distribution functions allow us to examine temperature anisotropies of electrons and calculate linear dispersion relations for the ECH waves. Once we get electron temperatures, resonance velocities are calculated. On the other hand, since the wavelength of the ECH waves is very short, the relation of the wavelength and the length of the Arase electric field sensors is also important in evaluating the time variations of the ECH wave intensity. We study the enhanced ECH waves in various viewpoints using wave and electron data observed by the Arase satellite and discuss the generation mechanism in the present paper.

Pulsating auroras (PsAs) are thought to be generated by precipitating electrons scattered by lower-band chorus (LBC) waves near the magnetic equator through cyclotron resonance. Previous studies showed one-to-one correlation between LBC wave intensity observed by satellites near the magnetic equator and PsA intensity obtained by ground-based all-sky imager [e.g., Nishimura et al., Science, 2010, Nishimura et al., JGR, 2011]. In addition, electrostatic electron cyclotron harmonic (ECH) waves can also interact with magnetospheric electrons and scatter their pitch angle theoretically [e.g., Lyons, JGR, 1974]. However, characteristics of aurora caused by ECH are not understood. In our study, we report for the first time in the world that not only LBC but also ECH wave intensity has correlation with the PsA intensity using coordinated Arase and ground-based imager observations. The first campaign observations between the Arase satellite and ground-based optical imager were conducted in March 2017. A typical substorm occurred on 27 March 2017 and the ionospheric footprint of Arase traversed the field of view of all-sky imager at Sodankylä during 00:00–03:15 UT on 29 March 2017. Quasi-periodic LBC and ECH waves were observed by Arase near the magnetic equator and PsA was detected by the all-sky imager during 01:30–02:00 UT. We calculated the cross-correlation coefficients between auroral intensity and LBC or ECH wave intensity from 01:30 UT to 02:00 UT with a time window of every 2 minutes. The highest cross-correlation coefficient between auroral intensity and LBC wave intensity was 0.73 and that between auroral intensity and ECH wave intensity was 0.62 from 01:46 UT to 01:48 UT, and they were statistically significant. The period of auroral intensity which correlated with LBC intensity was shorter than 10 s and that correlated with ECH intensity was 10–20 s. We estimated the precipitating electron energy assuming that the time lag when the cross-correlation coefficient became the highest equals to the travel time of electrons from the modulated source region to the auroral emission height. We shifted the variation of auroral intensity against that of ECH or LBC wave intensity with a time step of 0.01 s using 100 Hz sampling image data taken by the all-sky imager. The estimated energy of precipitating electron interacted with LBC waves was ~20–67 keV and that interacted with ECH waves was ~3–4 keV. On the other hand, we independently estimated the cyclotron resonance energy of LBC and ECH waves from the Arase's observation data and geomagnetic field model by TS04 Model [Tsyganenko and Sitnov, JGR, 2005]. The estimated cyclotron resonance energy of LBC waves was ~30 keV. Although the cyclotron resonance energy of ECH waves could not be estimated because it was difficult to obtain the electron temperature and wave normal angle of ECH waves from Arase data, we suggest the cyclotron resonance energy of ECH waves to be a few keV with probable assumptions. From these results, we suggest that LBC waves interact with high energy electrons which cause auroral emission at lower altitudes, while ECH waves interact with

©2019. Japan Geoscience Union. All Right Reserved.

relatively low energy electrons which cause auroral emission at higher altitudes. These results were published in Fukizawa et al. [GRL, 2018].
To verify whether ECH waves indeed scatter the pitch angle of electrons, we compared ECH wave intensity with electron flux in the loss cone obtained with low-energy particle experiments-electron analyzer onboard Arase. We also give results of other coordinated observation events.

Electron number density is a key parameter for discussions of plasma wave generation/propagation, and wave-particle interaction in the inner magnetosphere. The High Frequency Analyzer (HFA) is a subsystem of Plasma Wave Experiment (PWE) aboard Arase [Kasahara et al. (2018), Kumamoto et al. (2018), Miyoshi et al. (2018)]. The HFA measures electric field spectra in a frequency range from 10 kHz to 10 MHz, which covers a typical frequency range of Upper Hybrid Resonance (UHR) frequency in the inner magnetosphere. Kumamoto et al. (2018) proposed the semiautomatic method for the identification of UHR frequency by computer and a human operator. However, it takes a enormous effort of a human operator.

We propose an automatic determination system of UHR frequency by machine learning. Machine learning is a technique in the field of artificial intelligence to give computers the ability to learn with data. In this study, we defined a task of UHR frequency determination as supervised regression that a computer estimates UHR frequencies using the dataset composed of electric field dynamic spectra with correct UHR frequency labels. We adopted Convolutional Neural Network (CNN) as a machine learning algorithm. In this study, we introduce our machine learning approach and initial results for determining UHR frequency from electric field spectra observed by PWE/HFA.

Amplitude dependence of whistler wave motion on electron scattering process

*Yoshiki Ito[1], Yoshizumi Miyoshi[1], Shinji Saito[1]

1. Nagoya University, ISEE

Whistler mode chorus waves cause scattering and acceleration of energetic electrons in the inner magnetosphere. The interaction processes have been modeled as diffusive process. The pitch angle diffusion coefficients of the pitch angle scattering depend on the power of chorus waves, so that it is expected that the scattering rate also depends on the wave amplitude. On the other hand, several previous studies indicated that the Lorentz force by the wave magnetic field is larger than the mirror force if the wave amplitudes increase and the electron trajectories in the velocity space are different from the diffusive distributions. In this study, we investigate chorus wave amplitude dependence of electron scattering using the GEMSIS-RBW simulation code. The RBW simulation demonstrates generation of periodical rising-tone chorus waves propagating along a magnetic field line to higher latitudes, and calculates local pitch angle and energy change by the imposed waves on the field line. At small wave amplitudes, time variations of pitch angle and energy of electrons are similar to diffusive process. At large wave amplitudes, some electrons increase both pitch angle and energy at interaction with the first rising tone, and then they decrease these parameters at interaction with the second rising tone. The process in the first rising tone seems to be the phase trapping, while the process in the second rising tone seems to be dislocation. Therefore, nonlinear scattering processes, which are phase trapping and dislocations, occur during the interactions with periodical rising-tone chorus waves with large amplitudes, which are quite different from quasi-linear scattering process.

Two-dimensional simulation of whistler mode wave packets interacting with energetic electrons

*Takeshi Nogi[1], Yoshiharu Omura[1]

1. Reserch Institute for Sustainable Humanosphere, Kyoto University

We perform two-dimensional electromagnetic particle simulations to study basic characteristics of whistler-mode wave particle interaction involved in the generation and propagation processes of chorus emissions with wave normal angles oblique to the static magnetic field. We assume a simple periodic (x, y) system with the magnetic field taken in the x-direction. We find the linear phase of the instability is much affected by electrostatic thermal fluctuations. It is necessary to put many super-particles in a grid cell to suppress the thermal fluctuation. We next put an array of antennas perpendicular to the background magnetic field, and oscillate the antenna current to generate obliquely propagating waves. In addition to the nonlinear trapping of energetic electrons through the cyclotron resonance, another nonlinear trapping of electrons takes place through the Landau resonance. Structures of the nonlinear trapping potentials change with the varying frequency, affecting efficiency of energy transfer between the wave and energetic electrons. We study nonlinear evolution of the wave packet, and competing processes of both resonances in accelerating energetic electrons to higher energies.

Relativistic electron acceleration by whistler-mode chorus waves in 1D, 2D, and 3D magnetic field models.

*Keita Takahashi[1], Yoshiharu Omura[1], Yikai HSIEH[1], Danny Summers[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University , 2. Department of Mathematics and Statistics, Memorial University of Newfoundland

We evaluate the acceleration efficiencies of relativistic electrons under a 1D, 2D, and 3D model magnetic fields. We perform test-particle simulations and analyze nonlinear trapping motions of resonant electrons in each model. As a chorus wave model, we assume that a chorus wave packet generated at the magnetic equator propagates along the magnetic field to higher latitudes. When we perform simulations with the whistler mode wave, the cyclotron resonance with energetic electrons occurs at the similar timing in each model. Although we find relativistic turning acceleration (RTA) [1] to take place in each model, acceleration efficiencies of resonant electrons are different in these models. In terms of the numerical Green's function[2], we find a clear difference in time evolution of the distribution function in energy and equatorial pitch angle. The energy gap between resonant electrons and non-resonant electrons in the 1D model is slightly different from those in the 2D and 3D models. The energy gap in the 3D model is the largest among the three magnetic field models. This difference is due to additional oscillations in the velocity phase space, which only occur in the 2D and 3D models. These oscillations occur because the magnitude of the magnetic field changes during one period of relativistic cyclotron motion, affecting the nonlinear trapping conditions of resonant electrons.

Study of global spatio-temporal development of magnetospheric ELF/VLF waves for the 26-30 March 2017 storm based on ground and satellite observations and the RAM simulations

*Yuhei Takeshita[1], Kazuo Shiokawa[1], Yoshizumi Miyoshi[1], Mitsunori Ozaki[2], Yoshiya Kasahara[2], Martine Connors[3], Jyrki Manninen[4], Craig Kletzing[5], Vania Jordanova[6]

1. Nagoya University, Institute for Space-Earth Environmental Resarch, 2. Kanazawa University, 3. Athabasca University, 4. Sodankylä Geophysical Observatory, 5. The University of Iowa, 6. Los Alamos National Laboratory

The magnetospheric ELF/VLF waves are plasma waves generated by energetic electrons from several keV to tens keV with temperature anisotropy at magnetospheric equatorial plane of the inner magnetosphere. These ELF/VLF waves with frequencies lower than local half gyro frequency (lower-band) can propagate to the ground along magnetic field line. It is also known that the ELF/VLF waves interact with electrons drifting longitudinally in the inner magnetosphere, and help accelerating them to relativistic energies. Takeshita et al. [SGEPSS, 2018] statistically investigated the longitudinal extent of the magnetospheric ELF/VLF waves using six ground-based stations for two months, and showed the average extent of the ELF/VLF waves as ~90 degrees in longitude. However, Jordanova et al. [JGR, 2010] investigated the global distribution of linear growth rate of whistler mode chorus waves using global ring current-atmosphere interactions model (RAM), and showed that the region of large linear growth rate can extend ~180 degrees in longitude during the geomagnetic storm of 22 April 2001.

In this study we investigate the spatio-temporal distibution of the source region of magnetospheric ELF/VLF waves based on ground and satellite observations during the geomagnetic storm period from 26-30 March 2017, and compare it with global distribution of non-linear waves proxy of whistler mode chorus waves obtained by the RAM simulation. In this preliminary simulation, the simple dipole field and the Volland-Stern electric field are used as ambient magnetic and electric fields. And we assumed simply the Maxwell distribution as an energy spectrum using the empirical model of Tsyganenko and Mukai [2003]. In order to evaluate the non-linear wave excitation, we have estimated the optimum amplitude and the threshold value indicated by Omura and Nunn [2011]. We investigated the existence of lower band chorus waves using ground based observations at Athabasca (ATH; 54.7N, 246.4E, MLAT: 61.3N), Kapuskasing (KAP; 49.4N, 277.8E, MLAT: 58.7N), Kannuslehto (KAN: 67.7N, 26.3E, MLAT: 64.5N) and satellite-based observations by ERG with an apogee in the pre-dawn sector and RBSP-A and RBSP-B with an apogees in the post-dusk sector. We found the magnetospheric ELF/VLF waves exist from 3 MLT to 12 MLT for most periods from main- to recovery-phases of the magnetic storm. However, the RAM simulation did not predict wave generation during recovery phase of the storm. We compare the simulation and the ground-satellite observation in detail, and calculate the over-estimate rate (the ratio of wave existence period on the simulation to no wave period on the observation) and under-estimate rate (the ratio of no wave period on the simulation to wave existence period on the observation). We found the over-estimate rate become high (0.2~0.9) and under-estimate rate become low (0~0.4) in the main phase of the storm. This indicates that the longitudinal size of chorus source region predicted by simulation is larger than the observed size at the main phase. We also found that the over-estimate rate becomes low (0~0.2) and under-estimate rate becomes high (~1) during the recovery phase of the storm. This indicates that the simulation does not reproduce the wave existence during the recovery phase of the storm. Looking into the MLT distribution, the simulation predicts the wave existence from dusk to the midnight sector, but the

©2019. Japan Geoscience Union. All Right Reserved.

waves were not observed in this local time sector during the main phase. In case of recovery phase, the simulation did not predict wave existence but the observation showed continuous wave existence from dawn to the noon sector.

Flux decrease of outer radiation belt electrons associated with solar wind pressure pulse: A Code coupling simulation of GEMSIS-RB and GEMSIS-GM

*Ito Hiroki[1], Yoshizumi Miyoshi[1], Shinji Saito[2], Yosuke Matsumoto[3], Takanobu Amano[4]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School of Science, Nagoya University, 3. Graduate School of Science, Chiba University, 4. Department of Earth and Planetary Science, University of Tokyo

Relativistic electron flux of the outer radiation belt dynamically changes in response to solar wind variations. There exist several conditions to cause the flux drop-out of the outer belt electrons. The magnetopause shadowing (MPS) is one of the processes to cause the rapid loss of outer belt electrons (e.g.,Kim et al.,2008). In this study, we investigate how radiation belt electrons are lost through the MPS process with a code-coupling simulation using GEMSIS-RB test particle simulation code (Saito et al., 2010) and GEMSIS-GM global MHD magnetosphere simulation code (Matsumoto et al., 2010) by focusing the equatorial pitch angle and local time dependence. We calculate trajectories of electrons in electromagnetic fields calculated from GEMSIS-GM with initial L-shells from 6 to 11, initial energies from 1 MeV to 10 MeV, and initial pitch angles between 50 degrees and 90 degrees, using the relativistic guiding-center equation. The simulation consists of the following three phases associated with variations of the solar wind dynamic pressure; [i] The standoff distance of magnetopause at the subsolar point is 12 Re with the initial dynamic pressure of 1.0 nPa. [ii] The solar wind dynamic pressure becomes 2.5 nPa, and the magnetopause moves to 9 Re. [iii] The solar wind dynamic pressure decreases, so that the inflation of the magnetopause takes place and the standoff distance of the magnetopause is 10 Re. During phase [ii], the high-latitude reconnections occur at dawn-side firstly and many electrons escape from the magnetosphere to the interplanetary magnetic field along the field line in the dawn side. Subsequently, the high-latitude reconnections occur at the high-latitude in the dusk side. In phase [iii], the remained electrons in the magnetosphere escape into the interplanetary in both the dawn and dusk sides. The loss at the dusk-side is outward motion of the trapped electrons caused by the dawn-to-dusk electric fields associated with the inflation of the magnetosphere. The study showed detailed process of the electron escape into the interplanetary magnetic field and the electron escape occur in both enhancement/decrease of the dynamic pressure.

Non-diffusive response of outer belt electrons on interplanetary shock

Takuma Toishi[1], *Yusuke Ebihara[1], Takashi Tanaka[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Kyushu University

Test particle simulation is performed in the electric and magnetic fields given by a global magnetohydrodynamics (MHD) simulation. When an interplanetary shock strikes the magnetosphere, a compressional wave propagates tailward. Pre-existing relativistic electrons that are initially located at fixed radial distances are redistributed by the electric and magnetic fields associated with the compressional wave. When the electrons encounter the nightside, they undergo complicated paths under the complicated distribution of the electric and the magnetic fields. Consequently, a group of isolated electrons forms, suggesting non-diffusive response. We discuss the redistribution processes in terms of the magnetospheric processes.

PARM: Initial result of the auroral camera on the G-CHASER (RockSat-XN) rocket and status of the development of auroral cameras for the LAMP rocket experiment

*Naoshi Yagi[1], Takeshi Sakanoi[1], Fukizawa Mizuki[1], Kazushi Asamura[2], Yoshizumi Miyoshi[3], Keisuke Hosokawa[4], Genki Ishizawa[5]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Department of Communication Engineering and Informatics, University of Electro-Communications, 5. Space & terrestrial plasma pyhsics

We developed an Aurora Imaging Camera (AIC) for NASA’ s G-CHASER (RockSat-XN) sounding rocket launched on 13th January, 2019. In addition, LAMP sounding rocket scheduled to be launched from December 2019 to February 2020 to reveal the spatio-temporal relationship between PsA and relativistic electrons, namely microbursts. In this presentation, we report the development of AIC, the result f the G-CHASER (RockSat-XN) rocket, as well as the current status of LAMP rocket project.

On the G-CHASER rocket experiment, 7 scientific and educational instruments were provided from Japan, U.S., Norway and Puerto Rico. Japanese instrument, called PARM, consists of an intermediate energy (20 - 100 keV) electron detector MED, high energy (several hundred keV - 2 MeV) electron detector HEP, fluxgate magnetometer AFG, and auroral camera AIC. Concerning development of AIC, we carried out sensitivity calibration experiment, electrical function test, fabrications, focus adjustment and environmental (vibration, vacuum and thermal) tests from January to July 2018. AIC consists of detector unit AIC-S and power/data processing electric unit AIC-E. AIC-S consists of a CCD camera (Watec 910 HX), wide-angle lens (F-number: 1.6, focal length: 3.5 mm, field of view: 96.4˚x75˚) and a glass filter (RG665) that transmits light with a wavelength longer than 665 nm.

NASA decided to launch the G-CHASER rocket at 9:00UT on 13rd January 2019 from Andoya Space Center, Norway (69.3˚N, 16.0˚E in the geographic coordinate). At this time, the solar elevation was -4˚, hence twilight had been already started and the region above 15km was sunlit. AIC detected leak light from the rocket skirt until the separation of skirt at an altitude of 82.9km. From time variation of AIC data, rocket spin frequencies were estimated to be ~5Hz at ~20km altitude and ~1Hz at ~80km altitude. This is consistent with the modulation period of magnetic field data observed by AFG. Because AIC was designed to measure weak pulsating aurora with hundreds Rayleigh, the AIC data was saturated above 82.9km after separation of rocket in the sunlit region, and no aurora was observed.

We are also conducting the LAMP sounding rocket project whose PI is Dr. Sarah Jones in NASA/GSFC. This is scheduled to be launched at Poker Flat Research Range in Alaska in 2019 winter. Japanese PARM2 team will provide high energy (several hundred keV - 2 MeV) electron detector HEP, fluxgate magnetometer MIM, and auroral cameras AIC2. We concern AIC2 that consists of two cameras AIC2-S1/AIC2-S2 and power/data processing electric unit AIC2-E. AIC2-S1/S2 and AIC2-E will be installed on a despun platform to derotate rocket spin. AIC2-S1 measures N2 1stPG emission with a narrow FOV lens (F value: 0.95, focal length:17mm, field of view 27x27deg), and AIC-S2 measures OI 844.6nm emission with a wide-angle lens (F value:1.6, focal length:3.5 mm, diagonal field of view:120x120˚). AIC2-S1 will take fine structure of PsA in the region more than 100 x 100 km area around the magnetic footprint with a few kilometer resolution, while AIC2-S2 will obtain an altitude distribution of

©2019. Japan Geoscience Union. All Right Reserved.

PsA in the F-region as well as wide-range distribution of PsA. The characteristic energy of precipitating electron can be estimated from the ration of OI844.6 and N2 1stPG. The cameras are conducted by a single board computer NanoPi M4 via USB3.0 high speed interface. We confirmed to get frame sampling rate with approximately 10Hz with this system. Region-of-interest (ROI) of 3660 x 3660 pixel area is binned with 61x61pixels, and finally image data with 60 x 60 bin (16 bit/bin) is recorded at 10 Hz. The precise imaging and altitude distribution of PsA are obtained with AIC2 at two wavelengths with 10Hz sampling. The imaging data combined with precipitating electron data in the wide energy range enable us to investigate the relativistic electron precipitation in microbursts that is probably caused by chorus waves in the magnetosphere.

Stable Auroral Red (SAR) arc is characterized by a 630.0 nm emission observed at subauroral latitudes. The energy of precipitating electrons that cause the SAR arc emission is several electron volts (eV). Precipitation of low-energy electrons is expected to occur due to spatial overlap between the plasmasphere and the ring current, where high-energy (more than 10 keV) ring current ions heat low-energy (less than 1 eV) electrons in the plasmasphere. Simultaneous observations of SAR arcs using the ionospheric satellite and ground all-sky cameras have been already done [e.g., Foster et al., 1994]. However, there has been no reports on in-situ measurements of plasma and electromagnetic fields in the inner magnetosphere, where the plasmaspheric plasma is heated by the ring current. In this study, we report simultaneous observations of a SAR arc at 22:04 UT on March 28, 2017, by using an all-sky camera at Nyrola (62.34 N, 25.51 E, MLAT 59.4 N) at subauroral latitudes and the Arase satellite. We analyze the all-sky camera data and the satellite data of this event to investigate the generation mechanism of the SAR arc. We find interesting features in the electric field data and the energy flux of electrons observed by the electric field detector of the plasma wave experiment (EFD/PWE) and the low-energy particle experiments–electron analyzer (LEP-e), respectively, onboard the Arase satellite at the crossing of the SAR arc. A negative excursion of the Ez component of the electric field (GSE coordinate system) with an amplitude of ~2.4 mV/m was observed at the crossing time. The Bx component of the magnetic field (GSE coordinate system) was negative. Thus the direction of the E ×B drift is westward, which is consistent with the westward auroral motion observed in the SAR arc by the ground all-sky camera. At the SAR arc crossing, the energy flux of electrons below 100-eV electrons is slightly intensified. We will discuss these observations in relation to the proposed SAR-arc generation mechanisms.

The spatial structure of Pi2 pulsation relative to the plasmasphere has been studied using the magnetic and electric field observed from the equatorial orbiting satellite in the inner magnetosphere by Takahashi et al (2003; 1995). They showed that the nightside Pi2 pulsations in the inner magnetosphere, which have high coherence with those at low-latitude ground station, are dominated by the poloidal component (the radial and compressional components for the magnetic field and azimuthal component for the electric field). The amplitudes of the compressional magnetic field has maximum and azimuthal electric field and the compressional magnetic field have maximum and minimum in the vicinity of the plasmaspause, respectively. The phase of the azimuthal electric field relative to low-latitude Pi2 pulsations on ground is 90 degrees in the plasmasphere. Such radial profile of the amplitude and phase of Pi2 pulsations can be explained by a plasmaspheric cavity mode resonance. However, the latitudinal structure of Pi2 pulsations in the electric field has not been examined. We investigate the latitudinal characteristics of off-equatorial Pi2 pulsations on the nightside and their relation to the plasmapause using the magnetic field measured by the fluxgate magnetometer measured by the Magnetic Field Experiment (MGF), the electric field measured by the Electric field Detector (EFD), and electron density derived from the spectra measured by the High Frequency Analyzer (HFA) from the Arase satellite.

An extreme erosion of the plasmasphere during the 7–10 September 2017 storm

*Yuki Obana[1], Naomi Maruyama[2,3], Atsuki Shinbori[4], Kumiko K. Hashimoto[5], Mariangel Fedrizzi[2,3], Masahito Nose[4], Yuichi Otsuka[4], Nozomu Nishitani[4], Tomoaki Hori[4], Atsushi Kumamoto[6], Fuminori Tsuchiya[6], Shoya Matsuda[7], Ayako Matsuoka[7], Yoshiya Kasahara[8], Akimasa Yoshikawa[9], Yoshizumi Miyoshi[4], Iku Shinohara[7]

We report an extreme erosion of the plasmasphere arising from the September 2017 storm. The cold electron density is identified from the upper limit frequency of UHR waves observed by the HFA of the PWE instrument onboard the Arase spacecraft. The HFA provides the spectrograms of electric fields in a frequency range from 10 kHz to 10 MHz with an 8-sec time resolution (Kasahara et al., 2018; Kumamoto et al., 2018). Such wide frequency coverage allows observation of the UHR frequency even deep inside the plasmasphere.
The electron density profiles reveal that the plasmasphere was severely eroded during the recovery phase of the storm and the plasmapause was located at L~1.7 at 23 UT on 8 Sep 2017. This is the first report of such deep erosion of the plasmasphere (L_{PP}<2) with the in-situ observation of the electron density. The degree of the severity is much more than what is expected from the SYM-H minimum (−146 nT) of the event.
We further study absolute GNSS-TEC, ground-based magnetic field, the doppler velocity obtained from the SuperDARN Hokkaido Radars to investigate the location of the midlatitude ionospheric trough, the penetration of the convection electric field to the equator and middle latitudes, respectively. Our results suggest that the middle latitude electric field was penetrated from the high-latitude storm time convection for several hours. Futhermore, the Ionosphere-Plasmasphere-Electrodynamics (IPE) model (Sun et al., 2015; Maruyama et al., 2016) is used to understand the dynamics of the plasmasphere. The IPE results suggest that the middle latitude electric field penetrates from the high-latitude storm time convection that lasts for several hours can explain the degree of severity during the September 7-11 2017 storm.

Planetary Plasma and Atmospheric Research Center, Tohoku University, 8. Japan Aerospace Exploration Agency

Earth’ s radiation belt is the area where electrons with energies from hundreds of keV to several MeV are trapped. When, where, and how the radiation belt exhibits a dramatic variation during a magnetic storm is of global interest. The dynamic variation of the radiation belt is caused by various wave-particle interactions: (1) the radial diffusion of electrons driven by ultra-low-frequency (ULF) waves in Pc5 frequency ranges (1.6–6.7 mHz) and (2) the local acceleration caused by wave-particle interactions between whistler-mode chorus waves and radiation belt particles. Over the past decade, multi-point observations and numerical simulations have provided evidence to support above physical processes. However, it is debatable how much each wave contributes to the radiation belt variation during a magnetic storm. A few previous studies have quantitatively compared roles of local acceleration and radial transport by calculating diffusion coefficients, whereas the global context between the wave growth and the relativistic electron flux enhancement has not been extensively studied. To address these issues, the comprehensive study using multi-point observations and numerical simulations (not empirical models) makes essential and significant contributions.

We focus on the magnetic storm on 27-30 May 2017. This magnetic storm is triggered by coronal mass ejections and induces a clear interplanetary shock. Fortunately, several satellites are scattered in the inner magnetosphere and detect both ULF and chorus waves during this magnetic storm. Arase and Van Allen Probes also detect variations of relativistic electron fluxes associated with the Dst index variation. We examine L-value dependence of ULF and chorus wave powers and find the difference of wave activity during the recovery phase. The chorus wave activity is large during the early recovery phase, while the ULF wave activity is large during the late recovery phase. The difference of wave activity may contribute to the radial profile in the phase space density of relativistic electrons. To grasp the extent of individual wave contribution, we also perform the comprehensive ring current model (CRCM) coupled with Block-Adaptive-Tree Solar-Wind Roe-Type Upwind Scheme (BATSRUS) simulation. BATSRUS with CRCM well reproduces global characteristics of energetic electron fluxes and wave growth during this magnetic storm. We will further evaluate global distribution of simulated wave power comparing to the observation, and then discuss the temporal and spatial context between each wave growth and the radiation belt variation.

Modulation of the D-region ionosphere by Pc5 waves observed by VLF/LF standard radio waves

*Miyashita Takuya[1], Hiroyo Ohya[1], Fuminori Tsuchiya[2], Hiroyuki Nakata[1], Toshiaki Takano[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3]

1. Chiba University, 2. Tohoku University, 3. Nagoya University

Ionospheric modulation due to ultra low frequency (ULF) Pc5 waves have been observed by GPS-total electron content (TEC), high frequency (HF) Doppler sounders, and SuperDARN HF radars [e.g., Pilipenko et al., 2014; Belakhovsky et al., 2016]. However, there are few reports for the modulation of the lower ionospheric associated with the ULF Pc5 waves using VLF/LF transmitter signals. In this study, we investigate the D-region signatures of the modulation due to the ULF Pc5 waves using a network of very low frequency (VLF)/low frequency (LF) standard radio waves. We show oscillations in intensities of the VLF/LF waves with a period of 4-6 minutes during substorms on 27 April, 2017. The transmitter signals from NAA (USA, 24.0 kHz, L = 2.88), NLK (USA, 24.8 kHz, L = 2.88), NDK (USA, 25.2 kHz, L = 2.98) and WWVB (USA, 60.0 kHz, L = 2.26) were observed by the receivers at ATH (Athabasca, L=4.31) and PKR (Poker Flat, L=5.95). The substorm occurred at 04:30 UT. Based on the wavelet analysis, we found that the intensities for the NDK-ATH and WWVB-ATH paths showed oscillations with a period of 4-6 minutes during the substorm growth phase (05:00-06:00 UT). Magnetic field variations observed by ground magnetometers around the NDK-ATH and WWVB-ATH paths also showed the same periodicity, which means that the variations in the VLF/LF intensities would be caused by Pc5 modulations. The magnetic field oscillations were observed in wide latitude range. The intensity of the oscillation was larger at high latitude magnetometers than those around the location of the NDK-ATH and WWVB-ATH path (mid-latitude). The Pc5 oscillations could be excited by solar wind because solar wind speed had similar period of the 4-6 minutes. In this presentation, we will discuss the cause of these VLF/LF oscillations.

Oxygen-proton differences in ion energies dominating plasma pressure: Dependence on storm phases and solar wind drivers

*Kunihiro Keika[1], Satoshi Kasahara[1], Shoichiro Yokota[2], Masahiro Hoshino[1], Kanako Seki[1], Masahito Nose[3], Yoshizumi Miyoshi[3], Iku Shinohara[4]

1. Graduate School of Science, The University of Tokyo , 2. Graduate School of Science, Osaka University, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The ion pressure in the inner magnetosphere is generally dominated by protons with energies of a few to a few 100s keV. Oxygen ions of ionospheric origin, O+, can make a significant contribution to the ion pressure during geomagnetically active periods. Our previous study (Keika et al., 2018, GRL) examined the radial dependence of contributing energies, which we term an energy range that makes the dominant contribution to the plasma pressure, during the main phase of the six magnetic storms in Year 2017. We found clear oxygen-proton differences in the contributing energies in the outer part (L>5) of the ring current region. The contributing energies were higher for O+ than for H+. The results provided in situ evidence of the contribution from mass-dependent/selective acceleration processes to the energization of the outer part of the ring current.

The present study extends this analysis toward a larger database obtained from a longer period of magnetic storm times including the recovery phase. We also compare mass-dependent/selective energization between different solar wind drivers such as coronal mass ejections and corotational interaction regions. We primarily use data from the MEP-i (Medium-Energy Particle experiments - ion mass analyzer) on board the Arase spacecraft. MEP-i measures ions with energies of 10 to 180 keV/q and distinguishes between different ion species. Arase observed the nightside near-Earth magnetosphere (L<10) during 7 CME-driven and 7 CIR-driven storms with the Dst minimum of smaller than -50 nT in Years 2017 and 2018. The dependence on storm phases and solar wind drivers helps identify magnetospheric conditions favorable for mass-dependent/selective acceleration and in turn provides clues for understanding important physical mechanisms. Utilizing observations made by the MMS spacecraft in the near-Earth plasma sheet, we also compare oxygen-to-proton differences inside earthward bursty bulk flows with the Arase/MEP-i observations. The multi-spacecraft observations help better understand the temporal evolution of the mass-dependent/selective acceleration processes.

Los Alamos National Laboratory

During magnetic storms, the ring current ions move toward the Earth, and the inner edge position of the ring current depends on the convection electric field. We investigate variations of the inner edge of the ring current ions, so-called, penetration depth, during magnetic storms using the ion measurements made by the Low-energy particle experiments-ion mass analyzer (LEP-i)/Medium-energy particle experiments-ion mass analyzer (MEP-i) instruments onboard the Arase satellite. The Arase satellite typically observes the earthward penetration of the ring current protons associated with the enhancement of the dawn-to-dusk electric field in the inner magnetosphere during the storm main phase. The plasmapause moves earthward during the main phase. On the other hand, the convection electric field decreases during the storm recovery phase in which the flux of ring current protons decreases. We identify that the penetration depth of protons depends on the minimum Dst index during the storms as well as the proton energy.

We also investigate the penetration depth of other ions, i.e., helium and oxygen ions. Because the life times of helium and oxygen ions due to charge exchange reaction for are longer than that of protons, it is expected that these ions can penetrate deeper than protons and temporal and spatial evolution can be observed clearly. We will also discuss the relation between the position of ring current inner edge and cross polar cap potential.

Relativistic Acceleration of Energetic Protons by Electromagnetic Ion Cyclotron Waves in the Jovian Magnetosphere

*Tomohiro Sekine[1], Yoshiharu Omura[1], Danny Summers[2], Yikai HSIEH[1], Satoko Nakamura[1]

1. Reserach Institute for Sustainable Humanosphere, Kyoto University, 2. Memorial University of Newfoundland

We perform test particle simulations of nonlinear interaction between energetic protons and EMIC waves. We assume a coherent EMIC waves that have a constant frequency and propagate parallel to the magnetic field. We find that protons can be trapped and accelerated by EMIC waves. We find a very efficient acceleration process of protons in which kinetic energy of protons increases while directions of parallel velocities reverses when we assume parameters in the Jovian magnetosphere. We notice that this phenomenon is very similar to the interaction process between relativistic electrons and whistler-mode waves, which is called Relativistic Turning Acceleration (RTA) [1]. In order to analyze the phenomena, we have developed nonlinear trapping theory of interaction between relativistic protons and EMIC waves. Next, we compare the theory and simulation results. We confirm that the results satisfy the conditions for RTA. Following the trajectories of many resonant protons, we obtain time evolution of the distribution function of relativistic protons as a function of energy and equatorial pitch angle based on the numerical Green’ s function method [2].

Statistical study of IPDP type EMIC wave-related electron precipitation at subauroral latitude

*Asuka Hirai[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Yasumasa Kasaba[1], Yuto Katoh[2], Hiroaki Misawa[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3], Satoshi Kurita[3], Martin G Connors[4]

The outer radiation belt electrons disappear during the main phase of geomagnetic storms. One of the loss mechanisms of electrons from the outer belt is precipitation into the atmosphere due to wave-particle interactions. Electromagnetic ion cyclotron (EMIC) waves are believed to be important plasma waves that contribute to the loss of the outer radiation belt due to pitch angle scattering. They can scatter relativistic and ultra-relativistic electrons. However, there are still questions left about the contribution of EMIC waves to the whole loss of radiation belt electrons and possible conditions favorable to pitch angle scattering.

EMIC waves mainly propagate along magnetic field lines and are observed on the ground as Pc1 geomagnetic pulsations. Intervals of pulsations of diminishing periods (IPDP) are Pc1/EMIC waves that are characterized by frequency rise from 0.1 to 1–2 Hz in a period of ~1 h, and often occur during substorms. Recent studies reported that IPDP are preferentially associated with relativistic electron precipitation. However, the statistical relation between IPDP waves and relativistic electron precipitation, and their physical mechanism, remain open issues.

We investigated differences in characteristics between IPDP and other types of Pc1 by using an induction magnetometer and VLF radio wave data that is a proxy of electron precipitations at subauroral latitude from 1 November 2016 to 30 June 2018. We used the induction magnetometer of PWING (study of dynamical variation of Particles and Waves in the INner magnetosphere using Ground-based network observations) at Athabasca, Canada (54.6˚N, 246.36˚E, L = 4.39). VLF radio waves propagate from transmitters to receivers in subionospheric waveguide. The modulations of VLF signals are detected as occurrence of sub-relativistic and relativistic electron (>100 keV) precipitation due to ionization changes in the lower ionosphere along the radio wave propagation path. VLF radio waves are transmitter from NDK, U.S. (46.367˚N, 261.467˚E, L =3.13) and NLK, U.S. (48.2˚N, 238.083˚E, L =2.84) and received at Athabasca. We selected EMIC wave events on the basis of the following criteria: (1) EMIC wave power is higher than 10^{-5} nT^2/Hz. (2) Duration of EMIC waves is longer than 20 min. (3) Interval between one EMIC wave event and the next one is longer than 30 min. Electron precipitation was identified as a decrease in amplitude of VLF signals from the quiet day curve (QDC). We counted as EMIC wave-driven electron precipitation if we detect temporal correspondence with EMIC waves. In this period, we found 950 EMIC wave events, and 87 of total EMIC wave events were IPDP events (9.2%). Local time dependence of EMIC waves shows that IPDP often occurs in the afternoon and evening sector, while other types of Pc1 occur in all local time range, but with a maximum in 12–16 MLT, which is consistent with previous studies. Simultaneous observation of the magnetometer and VLF radio waves were available for 286 days, and we found 163 EMIC wave events. 19 of 163 EMIC wave events were clearly associated with electron precipitation (12%). Among 19 electron precipitation events, 15 events were caused by IPDP (79%). Also, the electron precipitation events were observed in the evening sector with similar local time dependence to IPDP. This result suggests that IPDP is more likely to cause electron precipitation than other Pc1 wave types. In previous studies, IPDP occurs due to ion cyclotron instability of ring current ions in the evening sector, and favorable region for electron scattering by EMIC waves is high density duskside plasmapause

©2019. Japan Geoscience Union. All Right Reserved.

and plasmaspheric plume because dense plasma lowers minimum resonant energy of electrons. It is assumed that occurrence region of IPDP is coincident with the preferential region for MeV electron scattering by EMIC waves. For this reason, it is expected that IPDP type EMIC waves significantly cause relativistic electron precipitations in the duskside.

Meridional distributions of proton plasma and pressure-driven currents in the nightside inner magnetosphere: Arase observations

*Shun Imajo[1], Masahito Nose[1], Satoshi Kasahara[2], Shoichiro Yokota[3], Ayako Matsuoka[4], Kunihiro Keika[2], Tomoaki Hori[1], Mariko Teramoto[1], Kazuhiro Yamamoto[5], Oimatsu Satoshi[5], Reiko Nomura[6], Akiko Fujimoto[7], Iku Shinohara[4], Yoshizumi Miyoshi[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School of Science, The University of Tokyo, 3. Graduate School of Science, Osaka University, 4. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 5. Graduate School of Science, Kyoto University, 6. National Astronomical Observatory of Japan, 7. Kyushu Institute of Technology

We examine the averaged meridional distributions of proton plasma parameters and pressure-driven currents in the nightside (20–04 h magnetic local time) ring current region during disturbed times (-80 < SYM-H* < -40 nT) using ion measurements covering energy range of 10–180 keV by the Arase satellite. Because the Arase satellite has a large inclination orbit of 31°, it covers the absolute value of magnetic latitude (|MLAT|) range of 0–40° and the radial distance of < 6 Re. We find that the plasma pressure decreases significantly with MLAT. The plasma pressure on the same L^* shell at 30°<|MLAT|<40° is about 10–60% of that at 0°<|MLAT|<10°, and the percentage of decrease is larger on lower L^* shells. The pressure anisotropy which is defined by the perpendicular pressure divided by the parallel pressure decreases with radial distance and shows a weak dependence on |MLAT|. The magnitude of the plasma beta at 30°<|MLAT|<40° is one or two order smaller than that at 0°<|MLAT|<10°. The relative plasma pressure distribution predicted from the magnetic strength and anisotropy is roughly consistent with the observed plasma pressure for L^*=3.5–5.5. The azimuthal pressure-gradient current derived from the plasma pressure distribution spreads over ~-20° |MLAT|, while the curvature current is limited in ~0–10° |MLAT|. We suggest that the latitudinal dependences should be taken into account when considering a temporal evolution of ring current particles from L distributions of successive orbits.

Space Weather Effects on Energetic Proton Flux Response in South Atlantic Anomaly

*Kirolosse Mina GIRGIS[1,2], Tohru Hada[1], Shuichi Matsukiyo[1]

1. Earth System Science and Technology (ESST) Department, Interdisciplinary Graduate School of Engineering Sciences (IGSES), Kyushu University, Japan, 2. Aerospace Engineering Department, Faculty of Engineering, Cairo University, Egypt

In this research, energetic proton flux in the inner radiation belt, is studied inside the South Atlantic Anomaly (SAA) by performing test particle simulations, where the background time-varying magnetic field is provided by Tsyganenko model, according to *Dst* index and altitudes. The objective of this investigation, is to estimate and forecast the additional radiation dose, occurring on spacecraft and human bodies, due to their passage inside the anomaly, and precisely, during intense solar storms. It was found that within minutes, proton flux in the SAA, penetrated deeper downward by about 200 km, when the *Dst* index is decreased (< -210 nT), and a after few more minutes, it was significantly reduced at all the altitudes; the last conclusion was confirmed by satellite observations.

Solar-cycle variations of >30 keV electron flux enhancements under the inner radiation belt

*ALLA SUVOROVA[1]

1. National Central University

Intense fluxes of 30-300 electrons can arise in the equatorial ionosphere outside the South Atlantic Anomaly. It was established that the electrons were injected from the inner radiation belt probably due to a mechanism of fast radial transport in the crossed electric and magnetic fields. Continuous monitoring of energetic particles at low heights of ~850 km with the MEPED instrument onboard the NOAA/POES satellites allowed compiling large statistics of the >30 keV electron enhancements from 1998 to 2018. We studied particle flux variations with geomagnetic activity and solar cycle. We found that geomagnetic activity measured by Dst and AE indices are not key factors of occurrence rate increase for electron injections, but influence on intensity of particles. The occurrence rate is controlled by auroral conductivity on the dayside and significantly enhanced during northern summer. Descending phase of solar cycle plays a major role in the occurrence rate increase.

Energy spectra variations of high energy electrons in the inner magnetosphere observed by HEP/XEP on ARASE and SEDA-e on HIMAWARI

*Takeshi Takashima[1], Takefumi Mitani[1], Nana Higashio[2], Tsutomu Nagatsuma[3]

1. ISAS/JAXA, 2. Research and Development Directorate/JAXA, 3. NiCT

The relativistic electrons in the outer radiation belt were disappeared/increased and their energy spectra were changed dynamically in some storms observed by XEP/HEP onboard the ARASE spacecraft. In the same time, SEDA-e with energy range 200keV-4.5MeV for electron on board the HIMAWARI-8, Japanese weather satellite on GEO, observed increase of relativistic electron in different local time.
When comparing the energy spectra, there are times when the spectrum matches or does not match. It is also observed that the change in the slope of the energy spectrum differs with time. These phenomena are observed even when there are two satellites at the same local time.
We will report on energy spectra variations of high energy electrons including calibrations of differential flux between XEP and HEP and discuss comparisons with energy spectra between ARAE and HIMAWARI that observed each storm in different local time.

Graduate School of Science, The University of Tokyo, 5. Graduate School of Science, Osaka University

An inter-channel comparison of electron fluxes measured by the HEP instrument onboard the Arase satellite is conducted with a focus on the apparent non-uniformity in detection efficiency and relative offset of the background flux level between the channels, which was partly reported previously. We extend the data set to cover the entire two-year period since the start of the regular observations. The flux ratio of different channels is sorted by the electron flux level of much higher energies that was simultaneously measured by the extremely high-energy electron experiment (XEP) instrument onboard Arase. The result shows that the HEP flux of all azimuthal channels is more or less affected by MeV electrons which are most likely to have penetrated into the instrument box and directly hit the detectors. However, it is also revealed that the non-uniform count distribution over the channels still remains even when the penetrating electrons are absent. We conduct a set of Geant-4 simulations to trace electrons with various energies and incident angles to the detector plane in order to give a quantitative interpretation for the resultant count distributions, in terms of the effects of penetrating electrons and obliquely-colliding incident electrons.

Understanding the detailed characteristics of the HEP (High-Energy electron Experiment) instrument onboard the Arase satellite is crucial for data calibration. Due to difficulties of reproducing the severe radiation environment of the inner magnetosphere on the ground, computer simulation is the best method to understand instrument responses to the ambient radiation environment. Through Monte-Carlo simulations using the Geant4 tool, we have reconstructed the geometry of the HEP instrument and modeled the high-energy particle environment. Using the developed model, we have studied the efficiency of the detectors, the angular resolution, and the g-factors, which depend on the particle energy and the sensor channels. While the previous studies were based on a uni-direction simulation with electron pencil beams, this study adopted all the detector channels and energy bends of HEP thus resulting in more advanced simulations. Based on the results, we have made a new calibration table depending on the angle of incident particles. We have also estimated the g-factor which depends on the incident particle energy. The updated calibration table and g-factors are important for calibrating the HEP data as well as inter-calibrations with other particle instruments' data.

The high-energy electron experiments (HEP) instrument installed on the Arase is designed to observe energetic electrons of 70 keV to 2 MeV. The HEP registers high electron counts for the MeV energy range, not only in the outer belt but also in the inner belt, in MeV energy range. On the contrary, Van Allen Probes have hardly detected MeV electrons in the inner radiation belt. A probable interpretation is that the counts of HEP are caused due to contamination of high-energy protons. In order to verify this idea, we have modeled the HEP instrument a Geant4 simulation to determine the energy of penetrating protons. The result clearly shows that high-energy protons, it has become clear that high-energy protons of a few to a few tens of MeV can contribute to the apparent high counts of HEP. No instrument for measuring protons in this energy range is installed on the satellite. We will discuss the possibility of research on the spatial distribution and time variation of high-energy protons in the inner belt based on observation data from the HEP instrument.

The high-energy electron experiments (HEP) onboard the Arase satellite detects 70 keV-2 MeV electrons and generates a three-dimensional velocity distribution for these electrons in every period of the satellite's rotation. Electrons are detected by two instruments, namely, HEP-L and HEP-H, which differ in their geometric factor (G-factor) and range of energies they detect. HEP-L detects 70 keV–1 MeV electrons and its G-factor is 9.3 $\times 10^{-4}$ cm^2 sr at maximum, while HEP-H observes 0.7 MeV–2 MeV electrons and its G-factor is 9.3 $\times 10^{-3}$ cm^2 sr at maximum. The instruments utilize silicon strip detectors and application-specific integrated circuits to readout the incident charge signal from each strip.

In order to deduce the distribution of incident electrons from the direction and energy detections in orbit, we have developed a detector simulator using the Geant4 toolkit. Especially contamination due to high energy particles must be considered quantitatively. We have also been working on electron beam experiments using HEP detector modules which are almost the same as the flight model in order to compare detailed simulations and experimental data.

We will present a comparison between results from the electron beam experiments and those from the detector simulator. And we will discuss its influence on the interpretation of the observational data obtained in orbit.

Wed. May 29, 2019 5:15 PM - 6:30 PM JST | Wed. May 29, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

[P-EM13] Inner magnetosphere: Recent understanding and new insights

convener:Yusuke Ebihara(Research Institute for Sustainable Humanosphere, Kyoto University), Danny Summers(Memorial University of Newfoundland), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Shinji Saito(Graduate School of Science, Nagoya University)

The inner magnetosphere is characterized by the dominance of intrinsic dipolar Earth's magnetic field. The dipolar magnetic field traps charged particles, resulting in the formation of unique particle environment known as the plasmasphere, the ring current, and the radiation belt. The inner magnetosphere is always changing because of incoming energy from the outer magnetosphere and the ionosphere in the forms of particles and electromagnetic fields. In the inner magnetosphere, the particle energy is transferred to the field energy, and vice versa. The mutual coupling between particles and fields also makes the inner magnetosphere unique. The outgoing energy to these regions is also known to be significant, such as precipitation into the upper atmosphere and sub-auroral disturbances. A number of satellites (e.g., DMSP, NOAA, Geotail, Cluster, THEMIS, Van Allen Probes, MMS, and Arase), ground-based instruments (e.g., SuperDARN and EISCAT radars, magnetometers, and cameras), and numerical simulations (e.g., global particle simulation, PIC simulation, and hybrid simulation) have successfully surveyed the inner magnetosphere, which deepen our knowledge significantly. USAF DSX, UCLA Elfin and NASA CeRES will be launched soon, being expected to provide important information. We solicit papers describing recent results on the inner magnetosphere and/or its coupling with the other regions, including the ionosphere and the outer magnetosphere.

The Plasma Wave Experiment (PWE) is one of scientific instruments on board the Arase (ERG) satellite to measure electric field from DC to 10 MHz and magnetic field from a few Hz to 100 kHz in the inner magnetosphere. It is well known that chorus wave, one of typical plasma waves in VLF range observed in the inner magnetosphere, is a plausible candidate that accelerates relativistic electrons in the radiation belt. Besides the chorus, the Arase has observed various kinds of plasma waves such as lightning whistlers and hiss waves. It is very important to study the propagation characteristics of these waves.

In the present paper, we developed a direction finding system applicable to whistler mode waves using the data from waveform capture (WFC), which is one of receivers covering the frequency range below 20kHz implemented in the PWE. The absolute directions of the wave normal and Poynting vectors were derived in the coordinate system referring the ambient magnetic field and geomagnetic meridian plane. We also estimated the Poynting vector theoretically using the derived wave normal vector, electron density and ambient magnetic field intensity to confirm the validity of the results from the observation data.

We demonstrated that the results were generally reliable, but further calibration is necessary for electric field to improve the accuracy of Poynting vector because the waveform of electric field is now calibrated under the assumptions of theoretical antenna capacitance in a vacuum and typical plasma impedance. In other words, we expect to be able to correct the calibration table for electric field measurements from the direction finding results.

In the presentation, we introduce some typical results which have been derived from the observation data of upper- and lower-band chorus, and lightning whistlers.

The outer radiation belt consists of high-energy electrons. They are strongly affected by geomagnetic activities in the relation to solar wind conditions. The important science target of the Arase mission is to clarify generation/loss mechanisms of relativistic electrons in the outer radiation belt. Wave-particle interactions are thought to be a plausible mechanism for generation/loss processes of relativistic electrons. S-WPIA (Software-type Wave-Particle Interaction Analyzer) is installed in the Arase satellite. The WPIA is a newly developed observation system that enables us to quantitatively understand the interaction between plasma waves and electrons. The WPIA has the capability to identify a relative phase angle of a plasma wave vector and a velocity vector of each detected particle. Since phase information of observed plasma waves is essential to the WPIA, precise calibrations of plasma wave data are important. While the calibration data for the magnetic field sensors are identical to those we obtained during the ground tests of the instruments, the calibration data for electric field sensors strongly depend on plasma parameters around the satellite. Furthermore, there are still unclear parameters at the inputs of preamplifiers relating to the connection with electric field sensors. The calibration for electric field data needs to be performed carefully consulting observation data after the launch.

The present paper focuses on the calibration of plasma wave data for the S-WPIA’s data processing. We picked up events including whistler-mode chorus emissions and lightning-whistler waves. They all are electromagnetic waves, so-called whistler mode waves. The amplitude ratios of their electric field and magnetic field components can be theoretically calculated referring to the Appleton-Hartlee equations. Poynting vectors of whistler mode waves can be also theoretically obtained. We compared the observation results of the picked up events with the theoretical ones. The results show the precise calibration for the magnetic field data have been made. On the other hand, the calibration for the electric field data should be further modified consulting plasma parameters and other uncertain parameters at the input of preamplifiers. In the present paper, we will discuss the improvement of the calibration for electric field data by correcting the calibration table to aim the precise S-WPIA data processing.

Enhancement of whistler-mode chorus in association with Pc 4-5 ULF waves and related variation of high energy electrons

*Atsuhiro Ono[1], Yuto Katoh[1], Atsushi Kumamoto[1], Fuminori Tsuchiya[1], Mariko Teramoto[2], Yoshiya Kasahara[3], Shoya Matsuda[4], Ayako Matsuoka[4], Takefumi Mitani[4], Tomoaki Hori[2], Satoshi Kasahara[5], Shoichiro Yokota[6], Kunihiro Keika[5], Yoshizumi Miyoshi[2], Iku Shinohara[4]

Whistler-mode chorus emissions play significant roles in the acceleration and loss of energetic electrons in the magnetosphere. One of the important factors which control periodic enhancement of chorus emissions is ULF (Ultra Low Frequency) waves. Previous studies reported that the compressional component of Pc4-5 ULF waves modulates the intensity of chorus waves [Li et al., 2011] and that the toroidal and poloidal components of Pc4-5 ULF waves as well [Jaynes et al., 2015]. Previous studies also suggested that enhancement of the temperature anisotropy of energetic electrons in the wave generation region should be required for the chorus generation. In order to understand the reported correspondence, in addition to the wave observation, we should examine simultaneously observed variations of the flux and the pitch angle distribution of energetic electrons.

In the present study, we investigate the relationship between chorus emissions and ULF waves using particle and electromagnetic field observations made by the Arase satellite. First, we analyze data observed by the Onboard Frequency Analyzer (OFA) of the Plasma Wave Experiment (PWE) and the Magnetic Field Experiment (MGF) during the campaign observation period of the Arase satellite with ground stations from March to April in 2017. As a result, we identified the simultaneous enhancement of chorus emissions and Pc4-5 ULF waves, which was dominated by the toroidal component, from 2130 to 2200 UT on March 27, 2017. The Arase satellite was located at the magnetic local time about 04:00, the magnetic latitude about -10 degrees, and the L-value about 6 during the event. We find that there is one-to-one correspondence between chorus emissions and the toroidal component of ULF waves; chorus emissions enhanced at the timings when the toroidal magnetic field component of ULF waves had a peak in the westward direction. The identified phase relationship is different from that reported by Jaynes et al. (2015), which isn't one-to-one correspondence. Next, we evaluate the resonance energy of the observed chorus emissions, using the ratio of the plasma frequency to the electron cyclotron frequency (f_p/f_{ce}) based on the upper-hybrid resonance frequency derived from the spectra observed by the High Frequency Analyzer (HFA) of PWE and the ambient magnetic field intensity observed by MGF. We find that f_p/f_{ce} is 3.3-3.4 during the event and that the resonance energy for whistler-mode waves in the frequency range of 0.1-0.2 f_{ce} is estimated to be about 100-400keV, which is larger than typical energies of resonating electrons observed in the inner magnetosphere. The estimated large resonant energy can be explained by the frequency range of the observed chorus emissions, approximately 0.1 - 0.2 f_{ce}, is relatively lower than that observed in typical cases.
We also analyze variations of the flux and the pitch angle distribution of energetic electrons during the event using data observed by the High-energy electron experiments (HEP) instrument onboard Arase. The result shows that both the flux and the pitch angle distribution of electrons in the kinetic energy range from 100 to 400 keV, which corresponds to the estimated resonance energy, did not fluctuate with the intensity variation of the chorus emissions and the ULF waves. In addition, we analyze the data observed by the Medium-energy particle experiments - electron analyzer (MEP-e) for energetic electrons in the energy range of 10-80 keV, lower than the estimated resonance energy. Then we identify the

©2019. Japan Geoscience Union. All Right Reserved.

corresponding variation of both the flux and the pitch angle distribution in the 40-60 keV energy range. One of the possible reasons why no significant variations were observed in the hundred keV range would be that the Arase satellite was located in the off-equatorial region during the event, and that the satellite was away from the wave generation region.

Electron cyclotron harmonic (ECH) waves are commonly observed in the low latitude region just outside the terrestrial plasmapause. They are purely electrostatic and their frequency spectra show harmonic structures. The harmonic structures are believed to depend on the temperature and density ratio between cold and hot background electrons. The Plasma Wave Experiment (PWE) onboard the Arase satellite has observed ECH waves since the start of its operation. The observed ECH waves are classified into two types. They are the diffuse ECH waves and the enhanced ECH waves. The diffuse ECH waves are weak and they appear as continuous emissions that last for more than a few minutes. The enhanced ECH waves are the sudden enhancements of the diffuse ECH in shorter periods. The present paper focuses on the enhanced ECH waves observed by the Arase satellite.

Kazama et al. (2018) introduced the event that the repeated enhancement of ECH waves is associated with density depletions near the plasmapause. They succeeded in revealing the good correlation of the enhancement of the ECH waves and the sudden decrease of the cold electrons with energies lower than the lowest energy limit of the particle detector. The observed electron features are clear in the relation to the enhancement of ECH waves, but the mechanism of the enhancement is still unclear. We searched for such events of the enhanced ECH waves and examined the correlation of wave intensities, spacecraft potentials and electron velocity distributions observed by the Arase satellite. Some of the events show the features similar to those of Kazama et al. (2018), but there are also many other events with no correlation between the enhancements of the ECH waves and the density depletions. In the present paper, we examine velocity distribution functions of electrons observed by the low-energy particle experiments-electron analyzer (LEPe) onboard Arase. Velocity distribution functions allow us to examine temperature anisotropies of electrons and calculate linear dispersion relations for the ECH waves. Once we get electron temperatures, resonance velocities are calculated. On the other hand, since the wavelength of the ECH waves is very short, the relation of the wavelength and the length of the Arase electric field sensors is also important in evaluating the time variations of the ECH wave intensity. We study the enhanced ECH waves in various viewpoints using wave and electron data observed by the Arase satellite and discuss the generation mechanism in the present paper.

Pulsating auroras (PsAs) are thought to be generated by precipitating electrons scattered by lower-band chorus (LBC) waves near the magnetic equator through cyclotron resonance. Previous studies showed one-to-one correlation between LBC wave intensity observed by satellites near the magnetic equator and PsA intensity obtained by ground-based all-sky imager [e.g., Nishimura et al., Science, 2010, Nishimura et al., JGR, 2011]. In addition, electrostatic electron cyclotron harmonic (ECH) waves can also interact with magnetospheric electrons and scatter their pitch angle theoretically [e.g., Lyons, JGR, 1974]. However, characteristics of aurora caused by ECH are not understood. In our study, we report for the first time in the world that not only LBC but also ECH wave intensity has correlation with the PsA intensity using coordinated Arase and ground-based imager observations. The first campaign observations between the Arase satellite and ground-based optical imager were conducted in March 2017. A typical substorm occurred on 27 March 2017 and the ionospheric footprint of Arase traversed the field of view of all-sky imager at Sodankylä during 00:00–03:15 UT on 29 March 2017. Quasi-periodic LBC and ECH waves were observed by Arase near the magnetic equator and PsA was detected by the all-sky imager during 01:30–02:00 UT. We calculated the cross-correlation coefficients between auroral intensity and LBC or ECH wave intensity from 01:30 UT to 02:00 UT with a time window of every 2 minutes. The highest cross-correlation coefficient between auroral intensity and LBC wave intensity was 0.73 and that between auroral intensity and ECH wave intensity was 0.62 from 01:46 UT to 01:48 UT, and they were statistically significant. The period of auroral intensity which correlated with LBC intensity was shorter than 10 s and that correlated with ECH intensity was 10–20 s. We estimated the precipitating electron energy assuming that the time lag when the cross-correlation coefficient became the highest equals to the travel time of electrons from the modulated source region to the auroral emission height. We shifted the variation of auroral intensity against that of ECH or LBC wave intensity with a time step of 0.01 s using 100 Hz sampling image data taken by the all-sky imager. The estimated energy of precipitating electron interacted with LBC waves was ~20–67 keV and that interacted with ECH waves was ~3–4 keV. On the other hand, we independently estimated the cyclotron resonance energy of LBC and ECH waves from the Arase's observation data and geomagnetic field model by TS04 Model [Tsyganenko and Sitnov, JGR, 2005]. The estimated cyclotron resonance energy of LBC waves was ~30 keV. Although the cyclotron resonance energy of ECH waves could not be estimated because it was difficult to obtain the electron temperature and wave normal angle of ECH waves from Arase data, we suggest the cyclotron resonance energy of ECH waves to be a few keV with probable assumptions. From these results, we suggest that LBC waves interact with high energy electrons which cause auroral emission at lower altitudes, while ECH waves interact with

©2019. Japan Geoscience Union. All Right Reserved.

relatively low energy electrons which cause auroral emission at higher altitudes. These results were published in Fukizawa et al. [GRL, 2018].
To verify whether ECH waves indeed scatter the pitch angle of electrons, we compared ECH wave intensity with electron flux in the loss cone obtained with low-energy particle experiments-electron analyzer onboard Arase. We also give results of other coordinated observation events.

Electron number density is a key parameter for discussions of plasma wave generation/propagation, and wave-particle interaction in the inner magnetosphere. The High Frequency Analyzer (HFA) is a subsystem of Plasma Wave Experiment (PWE) aboard Arase [Kasahara et al. (2018), Kumamoto et al. (2018), Miyoshi et al. (2018)]. The HFA measures electric field spectra in a frequency range from 10 kHz to 10 MHz, which covers a typical frequency range of Upper Hybrid Resonance (UHR) frequency in the inner magnetosphere. Kumamoto et al. (2018) proposed the semiautomatic method for the identification of UHR frequency by computer and a human operator. However, it takes a enormous effort of a human operator.

We propose an automatic determination system of UHR frequency by machine learning. Machine learning is a technique in the field of artificial intelligence to give computers the ability to learn with data. In this study, we defined a task of UHR frequency determination as supervised regression that a computer estimates UHR frequencies using the dataset composed of electric field dynamic spectra with correct UHR frequency labels. We adopted Convolutional Neural Network (CNN) as a machine learning algorithm. In this study, we introduce our machine learning approach and initial results for determining UHR frequency from electric field spectra observed by PWE/HFA.

Amplitude dependence of whistler wave motion on electron scattering process

*Yoshiki Ito[1], Yoshizumi Miyoshi[1], Shinji Saito[1]

1. Nagoya University, ISEE

Whistler mode chorus waves cause scattering and acceleration of energetic electrons in the inner magnetosphere. The interaction processes have been modeled as diffusive process. The pitch angle diffusion coefficients of the pitch angle scattering depend on the power of chorus waves, so that it is expected that the scattering rate also depends on the wave amplitude. On the other hand, several previous studies indicated that the Lorentz force by the wave magnetic field is larger than the mirror force if the wave amplitudes increase and the electron trajectories in the velocity space are different from the diffusive distributions. In this study, we investigate chorus wave amplitude dependence of electron scattering using the GEMSIS-RBW simulation code. The RBW simulation demonstrates generation of periodical rising-tone chorus waves propagating along a magnetic field line to higher latitudes, and calculates local pitch angle and energy change by the imposed waves on the field line. At small wave amplitudes, time variations of pitch angle and energy of electrons are similar to diffusive process. At large wave amplitudes, some electrons increase both pitch angle and energy at interaction with the first rising tone, and then they decrease these parameters at interaction with the second rising tone. The process in the first rising tone seems to be the phase trapping, while the process in the second rising tone seems to be dislocation. Therefore, nonlinear scattering processes, which are phase trapping and dislocations, occur during the interactions with periodical rising-tone chorus waves with large amplitudes, which are quite different from quasi-linear scattering process.

Two-dimensional simulation of whistler mode wave packets interacting with energetic electrons

*Takeshi Nogi[1], Yoshiharu Omura[1]

1. Reserch Institute for Sustainable Humanosphere, Kyoto University

We perform two-dimensional electromagnetic particle simulations to study basic characteristics of whistler-mode wave particle interaction involved in the generation and propagation processes of chorus emissions with wave normal angles oblique to the static magnetic field. We assume a simple periodic (x, y) system with the magnetic field taken in the x-direction. We find the linear phase of the instability is much affected by electrostatic thermal fluctuations. It is necessary to put many super-particles in a grid cell to suppress the thermal fluctuation. We next put an array of antennas perpendicular to the background magnetic field, and oscillate the antenna current to generate obliquely propagating waves. In addition to the nonlinear trapping of energetic electrons through the cyclotron resonance, another nonlinear trapping of electrons takes place through the Landau resonance. Structures of the nonlinear trapping potentials change with the varying frequency, affecting efficiency of energy transfer between the wave and energetic electrons. We study nonlinear evolution of the wave packet, and competing processes of both resonances in accelerating energetic electrons to higher energies.

Relativistic electron acceleration by whistler-mode chorus waves in 1D, 2D, and 3D magnetic field models.

*Keita Takahashi[1], Yoshiharu Omura[1], Yikai HSIEH[1], Danny Summers[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University , 2. Department of Mathematics and Statistics, Memorial University of Newfoundland

We evaluate the acceleration efficiencies of relativistic electrons under a 1D, 2D, and 3D model magnetic fields. We perform test-particle simulations and analyze nonlinear trapping motions of resonant electrons in each model. As a chorus wave model, we assume that a chorus wave packet generated at the magnetic equator propagates along the magnetic field to higher latitudes. When we perform simulations with the whistler mode wave, the cyclotron resonance with energetic electrons occurs at the similar timing in each model. Although we find relativistic turning acceleration (RTA) [1] to take place in each model, acceleration efficiencies of resonant electrons are different in these models. In terms of the numerical Green's function[2], we find a clear difference in time evolution of the distribution function in energy and equatorial pitch angle. The energy gap between resonant electrons and non-resonant electrons in the 1D model is slightly different from those in the 2D and 3D models. The energy gap in the 3D model is the largest among the three magnetic field models. This difference is due to additional oscillations in the velocity phase space, which only occur in the 2D and 3D models. These oscillations occur because the magnitude of the magnetic field changes during one period of relativistic cyclotron motion, affecting the nonlinear trapping conditions of resonant electrons.

Study of global spatio-temporal development of magnetospheric ELF/VLF waves for the 26-30 March 2017 storm based on ground and satellite observations and the RAM simulations

*Yuhei Takeshita[1], Kazuo Shiokawa[1], Yoshizumi Miyoshi[1], Mitsunori Ozaki[2], Yoshiya Kasahara[2], Martine Connors[3], Jyrki Manninen[4], Craig Kletzing[5], Vania Jordanova[6]

1. Nagoya University, Institute for Space-Earth Environmental Resarch, 2. Kanazawa University, 3. Athabasca University, 4. Sodankylä Geophysical Observatory, 5. The University of Iowa, 6. Los Alamos National Laboratory

The magnetospheric ELF/VLF waves are plasma waves generated by energetic electrons from several keV to tens keV with temperature anisotropy at magnetospheric equatorial plane of the inner magnetosphere. These ELF/VLF waves with frequencies lower than local half gyro frequency (lower-band) can propagate to the ground along magnetic field line. It is also known that the ELF/VLF waves interact with electrons drifting longitudinally in the inner magnetosphere, and help accelerating them to relativistic energies. Takeshita et al. [SGEPSS, 2018] statistically investigated the longitudinal extent of the magnetospheric ELF/VLF waves using six ground-based stations for two months, and showed the average extent of the ELF/VLF waves as ~90 degrees in longitude. However, Jordanova et al. [JGR, 2010] investigated the global distribution of linear growth rate of whistler mode chorus waves using global ring current-atmosphere interactions model (RAM), and showed that the region of large linear growth rate can extend ~180 degrees in longitude during the geomagnetic storm of 22 April 2001.

In this study we investigate the spatio-temporal distibution of the source region of magnetospheric ELF/VLF waves based on ground and satellite observations during the geomagnetic storm period from 26-30 March 2017, and compare it with global distribution of non-linear waves proxy of whistler mode chorus waves obtained by the RAM simulation. In this preliminary simulation, the simple dipole field and the Volland-Stern electric field are used as ambient magnetic and electric fields. And we assumed simply the Maxwell distribution as an energy spectrum using the empirical model of Tsyganenko and Mukai [2003]. In order to evaluate the non-linear wave excitation, we have estimated the optimum amplitude and the threshold value indicated by Omura and Nunn [2011]. We investigated the existence of lower band chorus waves using ground based observations at Athabasca (ATH; 54.7N, 246.4E, MLAT: 61.3N), Kapuskasing (KAP; 49.4N, 277.8E, MLAT: 58.7N), Kannuslehto (KAN: 67.7N, 26.3E, MLAT: 64.5N) and satellite-based observations by ERG with an apogee in the pre-dawn sector and RBSP-A and RBSP-B with an apogees in the post-dusk sector. We found the magnetospheric ELF/VLF waves exist from 3 MLT to 12 MLT for most periods from main- to recovery-phases of the magnetic storm. However, the RAM simulation did not predict wave generation during recovery phase of the storm. We compare the simulation and the ground-satellite observation in detail, and calculate the over-estimate rate (the ratio of wave existence period on the simulation to no wave period on the observation) and under-estimate rate (the ratio of no wave period on the simulation to wave existence period on the observation). We found the over-estimate rate become high (0.2~0.9) and under-estimate rate become low (0~0.4) in the main phase of the storm. This indicates that the longitudinal size of chorus source region predicted by simulation is larger than the observed size at the main phase. We also found that the over-estimate rate becomes low (0~0.2) and under-estimate rate becomes high (~1) during the recovery phase of the storm. This indicates that the simulation does not reproduce the wave existence during the recovery phase of the storm. Looking into the MLT distribution, the simulation predicts the wave existence from dusk to the midnight sector, but the

©2019. Japan Geoscience Union. All Right Reserved.

waves were not observed in this local time sector during the main phase. In case of recovery phase, the simulation did not predict wave existence but the observation showed continuous wave existence from dawn to the noon sector.

Flux decrease of outer radiation belt electrons associated with solar wind pressure pulse: A Code coupling simulation of GEMSIS-RB and GEMSIS-GM

*Ito Hiroki[1], Yoshizumi Miyoshi[1], Shinji Saito[2], Yosuke Matsumoto[3], Takanobu Amano[4]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School of Science, Nagoya University, 3. Graduate School of Science, Chiba University, 4. Department of Earth and Planetary Science, University of Tokyo

Relativistic electron flux of the outer radiation belt dynamically changes in response to solar wind variations. There exist several conditions to cause the flux drop-out of the outer belt electrons. The magnetopause shadowing (MPS) is one of the processes to cause the rapid loss of outer belt electrons (e.g.,Kim et al.,2008). In this study, we investigate how radiation belt electrons are lost through the MPS process with a code-coupling simulation using GEMSIS-RB test particle simulation code (Saito et al., 2010) and GEMSIS-GM global MHD magnetosphere simulation code (Matsumoto et al., 2010) by focusing the equatorial pitch angle and local time dependence. We calculate trajectories of electrons in electromagnetic fields calculated from GEMSIS-GM with initial L-shells from 6 to 11, initial energies from 1 MeV to 10 MeV, and initial pitch angles between 50 degrees and 90 degrees, using the relativistic guiding-center equation. The simulation consists of the following three phases associated with variations of the solar wind dynamic pressure; [i] The standoff distance of magnetopause at the subsolar point is 12 Re with the initial dynamic pressure of 1.0 nPa. [ii] The solar wind dynamic pressure becomes 2.5 nPa, and the magnetopause moves to 9 Re. [iii] The solar wind dynamic pressure decreases, so that the inflation of the magnetopause takes place and the standoff distance of the magnetopause is 10 Re. During phase [ii], the high-latitude reconnections occur at dawn-side firstly and many electrons escape from the magnetosphere to the interplanetary magnetic field along the field line in the dawn side. Subsequently, the high-latitude reconnections occur at the high-latitude in the dusk side. In phase [iii], the remained electrons in the magnetosphere escape into the interplanetary in both the dawn and dusk sides. The loss at the dusk-side is outward motion of the trapped electrons caused by the dawn-to-dusk electric fields associated with the inflation of the magnetosphere. The study showed detailed process of the electron escape into the interplanetary magnetic field and the electron escape occur in both enhancement/decrease of the dynamic pressure.

Non-diffusive response of outer belt electrons on interplanetary shock

Takuma Toishi[1], *Yusuke Ebihara[1], Takashi Tanaka[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Kyushu University

Test particle simulation is performed in the electric and magnetic fields given by a global magnetohydrodynamics (MHD) simulation. When an interplanetary shock strikes the magnetosphere, a compressional wave propagates tailward. Pre-existing relativistic electrons that are initially located at fixed radial distances are redistributed by the electric and magnetic fields associated with the compressional wave. When the electrons encounter the nightside, they undergo complicated paths under the complicated distribution of the electric and the magnetic fields. Consequently, a group of isolated electrons forms, suggesting non-diffusive response. We discuss the redistribution processes in terms of the magnetospheric processes.

PARM: Initial result of the auroral camera on the G-CHASER (RockSat-XN) rocket and status of the development of auroral cameras for the LAMP rocket experiment

*Naoshi Yagi[1], Takeshi Sakanoi[1], Fukizawa Mizuki[1], Kazushi Asamura[2], Yoshizumi Miyoshi[3], Keisuke Hosokawa[4], Genki Ishizawa[5]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Department of Communication Engineering and Informatics, University of Electro-Communications, 5. Space & terrestrial plasma pyhsics

We developed an Aurora Imaging Camera (AIC) for NASA’ s G-CHASER (RockSat-XN) sounding rocket launched on 13th January, 2019. In addition, LAMP sounding rocket scheduled to be launched from December 2019 to February 2020 to reveal the spatio-temporal relationship between PsA and relativistic electrons, namely microbursts. In this presentation, we report the development of AIC, the result f the G-CHASER (RockSat-XN) rocket, as well as the current status of LAMP rocket project.

On the G-CHASER rocket experiment, 7 scientific and educational instruments were provided from Japan, U.S., Norway and Puerto Rico. Japanese instrument, called PARM, consists of an intermediate energy (20 - 100 keV) electron detector MED, high energy (several hundred keV - 2 MeV) electron detector HEP, fluxgate magnetometer AFG, and auroral camera AIC. Concerning development of AIC, we carried out sensitivity calibration experiment, electrical function test, fabrications, focus adjustment and environmental (vibration, vacuum and thermal) tests from January to July 2018. AIC consists of detector unit AIC-S and power/data processing electric unit AIC-E. AIC-S consists of a CCD camera (Watec 910 HX), wide-angle lens (F-number: 1.6, focal length: 3.5 mm, field of view: 96.4˚x75˚) and a glass filter (RG665) that transmits light with a wavelength longer than 665 nm.

NASA decided to launch the G-CHASER rocket at 9:00UT on 13rd January 2019 from Andoya Space Center, Norway (69.3˚N, 16.0˚E in the geographic coordinate). At this time, the solar elevation was -4˚, hence twilight had been already started and the region above 15km was sunlit. AIC detected leak light from the rocket skirt until the separation of skirt at an altitude of 82.9km. From time variation of AIC data, rocket spin frequencies were estimated to be ~5Hz at ~20km altitude and ~1Hz at ~80km altitude. This is consistent with the modulation period of magnetic field data observed by AFG. Because AIC was designed to measure weak pulsating aurora with hundreds Rayleigh, the AIC data was saturated above 82.9km after separation of rocket in the sunlit region, and no aurora was observed.

We are also conducting the LAMP sounding rocket project whose PI is Dr. Sarah Jones in NASA/GSFC. This is scheduled to be launched at Poker Flat Research Range in Alaska in 2019 winter. Japanese PARM2 team will provide high energy (several hundred keV - 2 MeV) electron detector HEP, fluxgate magnetometer MIM, and auroral cameras AIC2. We concern AIC2 that consists of two cameras AIC2-S1/AIC2-S2 and power/data processing electric unit AIC2-E. AIC2-S1/S2 and AIC2-E will be installed on a despun platform to derotate rocket spin. AIC2-S1 measures N2 1stPG emission with a narrow FOV lens (F value: 0.95, focal length:17mm, field of view 27x27deg), and AIC-S2 measures OI 844.6nm emission with a wide-angle lens (F value:1.6, focal length:3.5 mm, diagonal field of view:120x120˚). AIC2-S1 will take fine structure of PsA in the region more than 100 x 100 km area around the magnetic footprint with a few kilometer resolution, while AIC2-S2 will obtain an altitude distribution of

©2019. Japan Geoscience Union. All Right Reserved.

PsA in the F-region as well as wide-range distribution of PsA. The characteristic energy of precipitating electron can be estimated from the ration of OI844.6 and N2 1stPG. The cameras are conducted by a single board computer NanoPi M4 via USB3.0 high speed interface. We confirmed to get frame sampling rate with approximately 10Hz with this system. Region-of-interest (ROI) of 3660 x 3660 pixel area is binned with 61x61pixels, and finally image data with 60 x 60 bin (16 bit/bin) is recorded at 10 Hz. The precise imaging and altitude distribution of PsA are obtained with AIC2 at two wavelengths with 10Hz sampling. The imaging data combined with precipitating electron data in the wide energy range enable us to investigate the relativistic electron precipitation in microbursts that is probably caused by chorus waves in the magnetosphere.

First simultaneous observation of a SAR arc at subauroral latitudes using a ground all-sky camera and the Arase satellite in the inner magnetosphere

*Yudai Inaba[1], Kazuo Shiokawa[1], Shin-ichiro Oyama[1,8,9], Yuichi Otsuka[1], Atsuki Shinbori[1], Yoichi Kazama[2], Shiang-Yu Wang[2], Sunny W. Y. Tam[2], Shoichiro Yokota[3], Satoshi Kasahara[4], Kunihiro Keika[4], Tomoaki Hori[1], Ayako Matsuoka[5], Yoshiya Kasahara[6], Atsushi Kumamoto[7], Yasumasa Kasaba[7], Yoshizumi Miyoshi[1], Iku Shinohara[5], Arto Oksanen[10]

1. Institute for Space-Earth Environmental Research, 2. Academia Sinica, 3. Osaka Univ, 4. Tokyo Univ, 5. JAXA, 6. Kanazawa University, 7. Tohoku University, 8. University of Oulu, Finland, 9. National Institute of Polar Research, 10. Jyväskylän Sirius ry, Finland

Stable Auroral Red (SAR) arc is characterized by a 630.0 nm emission observed at subauroral latitudes. The energy of precipitating electrons that cause the SAR arc emission is several electron volts (eV). Precipitation of low-energy electrons is expected to occur due to spatial overlap between the plasmasphere and the ring current, where high-energy (more than 10 keV) ring current ions heat low-energy (less than 1 eV) electrons in the plasmasphere. Simultaneous observations of SAR arcs using the ionospheric satellite and ground all-sky cameras have been already done [e.g., Foster et al., 1994]. However, there has been no reports on in-situ measurements of plasma and electromagnetic fields in the inner magnetosphere, where the plasmaspheric plasma is heated by the ring current. In this study, we report simultaneous observations of a SAR arc at 22:04 UT on March 28, 2017, by using an all-sky camera at Nyrola (62.34 N, 25.51 E, MLAT 59.4 N) at subauroral latitudes and the Arase satellite. We analyze the all-sky camera data and the satellite data of this event to investigate the generation mechanism of the SAR arc. We find interesting features in the electric field data and the energy flux of electrons observed by the electric field detector of the plasma wave experiment (EFD/PWE) and the low-energy particle experiments–electron analyzer (LEP-e), respectively, onboard the Arase satellite at the crossing of the SAR arc. A negative excursion of the Ez component of the electric field (GSE coordinate system) with an amplitude of ~2.4 mV/m was observed at the crossing time. The Bx component of the magnetic field (GSE coordinate system) was negative. Thus the direction of the E ×B drift is westward, which is consistent with the westward auroral motion observed in the SAR arc by the ground all-sky camera. At the SAR arc crossing, the energy flux of electrons below 100-eV electrons is slightly intensified. We will discuss these observations in relation to the proposed SAR-arc generation mechanisms.

The spatial structure of Pi2 pulsation relative to the plasmasphere has been studied using the magnetic and electric field observed from the equatorial orbiting satellite in the inner magnetosphere by Takahashi et al (2003; 1995). They showed that the nightside Pi2 pulsations in the inner magnetosphere, which have high coherence with those at low-latitude ground station, are dominated by the poloidal component (the radial and compressional components for the magnetic field and azimuthal component for the electric field). The amplitudes of the compressional magnetic field has maximum and azimuthal electric field and the compressional magnetic field have maximum and minimum in the vicinity of the plasmaspause, respectively. The phase of the azimuthal electric field relative to low-latitude Pi2 pulsations on ground is 90 degrees in the plasmasphere. Such radial profile of the amplitude and phase of Pi2 pulsations can be explained by a plasmaspheric cavity mode resonance. However, the latitudinal structure of Pi2 pulsations in the electric field has not been examined. We investigate the latitudinal characteristics of off-equatorial Pi2 pulsations on the nightside and their relation to the plasmapause using the magnetic field measured by the fluxgate magnetometer measured by the Magnetic Field Experiment (MGF), the electric field measured by the Electric field Detector (EFD), and electron density derived from the spectra measured by the High Frequency Analyzer (HFA) from the Arase satellite.

An extreme erosion of the plasmasphere during the 7–10 September 2017 storm

*Yuki Obana[1], Naomi Maruyama[2,3], Atsuki Shinbori[4], Kumiko K. Hashimoto[5], Mariangel Fedrizzi[2,3], Masahito Nose[4], Yuichi Otsuka[4], Nozomu Nishitani[4], Tomoaki Hori[4], Atsushi Kumamoto[6], Fuminori Tsuchiya[6], Shoya Matsuda[7], Ayako Matsuoka[7], Yoshiya Kasahara[8], Akimasa Yoshikawa[9], Yoshizumi Miyoshi[4], Iku Shinohara[7]

We report an extreme erosion of the plasmasphere arising from the September 2017 storm. The cold electron density is identified from the upper limit frequency of UHR waves observed by the HFA of the PWE instrument onboard the Arase spacecraft. The HFA provides the spectrograms of electric fields in a frequency range from 10 kHz to 10 MHz with an 8-sec time resolution (Kasahara et al., 2018; Kumamoto et al., 2018). Such wide frequency coverage allows observation of the UHR frequency even deep inside the plasmasphere.
The electron density profiles reveal that the plasmasphere was severely eroded during the recovery phase of the storm and the plasmapause was located at L~1.7 at 23 UT on 8 Sep 2017. This is the first report of such deep erosion of the plasmasphere (L_{PP}<2) with the in-situ observation of the electron density. The degree of the severity is much more than what is expected from the SYM-H minimum (−146 nT) of the event.
We further study absolute GNSS-TEC, ground-based magnetic field, the doppler velocity obtained from the SuperDARN Hokkaido Radars to investigate the location of the midlatitude ionospheric trough, the penetration of the convection electric field to the equator and middle latitudes, respectively. Our results suggest that the middle latitude electric field was penetrated from the high-latitude storm time convection for several hours. Futhermore, the Ionosphere-Plasmasphere-Electrodynamics (IPE) model (Sun et al., 2015; Maruyama et al., 2016) is used to understand the dynamics of the plasmasphere. The IPE results suggest that the middle latitude electric field penetrates from the high-latitude storm time convection that lasts for several hours can explain the degree of severity during the September 7-11 2017 storm.

Relative contribution of ULF and chorus waves to the radiation belt variation: Comparison between multi-point observations and BATSRUS + CRCM simulation

*Naoko Takahashi[1], Kanako Seki[1], Mei-Ching Fok[2], Yihua Zheng[2], Yoshizumi Miyoshi[3], David Hartley[4], Ayako Matsuoka[5], Yoshiya Kasahara[6], Yasumasa Kasaba[7], Nana Higashio[8]

Planetary Plasma and Atmospheric Research Center, Tohoku University, 8. Japan Aerospace Exploration Agency

Earth’ s radiation belt is the area where electrons with energies from hundreds of keV to several MeV are trapped. When, where, and how the radiation belt exhibits a dramatic variation during a magnetic storm is of global interest. The dynamic variation of the radiation belt is caused by various wave-particle interactions: (1) the radial diffusion of electrons driven by ultra-low-frequency (ULF) waves in Pc5 frequency ranges (1.6–6.7 mHz) and (2) the local acceleration caused by wave-particle interactions between whistler-mode chorus waves and radiation belt particles. Over the past decade, multi-point observations and numerical simulations have provided evidence to support above physical processes. However, it is debatable how much each wave contributes to the radiation belt variation during a magnetic storm. A few previous studies have quantitatively compared roles of local acceleration and radial transport by calculating diffusion coefficients, whereas the global context between the wave growth and the relativistic electron flux enhancement has not been extensively studied. To address these issues, the comprehensive study using multi-point observations and numerical simulations (not empirical models) makes essential and significant contributions.

We focus on the magnetic storm on 27-30 May 2017. This magnetic storm is triggered by coronal mass ejections and induces a clear interplanetary shock. Fortunately, several satellites are scattered in the inner magnetosphere and detect both ULF and chorus waves during this magnetic storm. Arase and Van Allen Probes also detect variations of relativistic electron fluxes associated with the Dst index variation. We examine L-value dependence of ULF and chorus wave powers and find the difference of wave activity during the recovery phase. The chorus wave activity is large during the early recovery phase, while the ULF wave activity is large during the late recovery phase. The difference of wave activity may contribute to the radial profile in the phase space density of relativistic electrons. To grasp the extent of individual wave contribution, we also perform the comprehensive ring current model (CRCM) coupled with Block-Adaptive-Tree Solar-Wind Roe-Type Upwind Scheme (BATSRUS) simulation. BATSRUS with CRCM well reproduces global characteristics of energetic electron fluxes and wave growth during this magnetic storm. We will further evaluate global distribution of simulated wave power comparing to the observation, and then discuss the temporal and spatial context between each wave growth and the radiation belt variation.

Modulation of the D-region ionosphere by Pc5 waves observed by VLF/LF standard radio waves

*Miyashita Takuya[1], Hiroyo Ohya[1], Fuminori Tsuchiya[2], Hiroyuki Nakata[1], Toshiaki Takano[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3]

1. Chiba University, 2. Tohoku University, 3. Nagoya University

Ionospheric modulation due to ultra low frequency (ULF) Pc5 waves have been observed by GPS-total electron content (TEC), high frequency (HF) Doppler sounders, and SuperDARN HF radars [e.g., Pilipenko et al., 2014; Belakhovsky et al., 2016]. However, there are few reports for the modulation of the lower ionospheric associated with the ULF Pc5 waves using VLF/LF transmitter signals. In this study, we investigate the D-region signatures of the modulation due to the ULF Pc5 waves using a network of very low frequency (VLF)/low frequency (LF) standard radio waves. We show oscillations in intensities of the VLF/LF waves with a period of 4-6 minutes during substorms on 27 April, 2017. The transmitter signals from NAA (USA, 24.0 kHz, L = 2.88), NLK (USA, 24.8 kHz, L = 2.88), NDK (USA, 25.2 kHz, L = 2.98) and WWVB (USA, 60.0 kHz, L = 2.26) were observed by the receivers at ATH (Athabasca, L=4.31) and PKR (Poker Flat, L=5.95). The substorm occurred at 04:30 UT. Based on the wavelet analysis, we found that the intensities for the NDK-ATH and WWVB-ATH paths showed oscillations with a period of 4-6 minutes during the substorm growth phase (05:00-06:00 UT). Magnetic field variations observed by ground magnetometers around the NDK-ATH and WWVB-ATH paths also showed the same periodicity, which means that the variations in the VLF/LF intensities would be caused by Pc5 modulations. The magnetic field oscillations were observed in wide latitude range. The intensity of the oscillation was larger at high latitude magnetometers than those around the location of the NDK-ATH and WWVB-ATH path (mid-latitude). The Pc5 oscillations could be excited by solar wind because solar wind speed had similar period of the 4-6 minutes. In this presentation, we will discuss the cause of these VLF/LF oscillations.

Oxygen-proton differences in ion energies dominating plasma pressure: Dependence on storm phases and solar wind drivers

*Kunihiro Keika[1], Satoshi Kasahara[1], Shoichiro Yokota[2], Masahiro Hoshino[1], Kanako Seki[1], Masahito Nose[3], Yoshizumi Miyoshi[3], Iku Shinohara[4]

1. Graduate School of Science, The University of Tokyo , 2. Graduate School of Science, Osaka University, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The ion pressure in the inner magnetosphere is generally dominated by protons with energies of a few to a few 100s keV. Oxygen ions of ionospheric origin, O+, can make a significant contribution to the ion pressure during geomagnetically active periods. Our previous study (Keika et al., 2018, GRL) examined the radial dependence of contributing energies, which we term an energy range that makes the dominant contribution to the plasma pressure, during the main phase of the six magnetic storms in Year 2017. We found clear oxygen-proton differences in the contributing energies in the outer part (L>5) of the ring current region. The contributing energies were higher for O+ than for H+. The results provided in situ evidence of the contribution from mass-dependent/selective acceleration processes to the energization of the outer part of the ring current.

The present study extends this analysis toward a larger database obtained from a longer period of magnetic storm times including the recovery phase. We also compare mass-dependent/selective energization between different solar wind drivers such as coronal mass ejections and corotational interaction regions. We primarily use data from the MEP-i (Medium-Energy Particle experiments - ion mass analyzer) on board the Arase spacecraft. MEP-i measures ions with energies of 10 to 180 keV/q and distinguishes between different ion species. Arase observed the nightside near-Earth magnetosphere (L<10) during 7 CME-driven and 7 CIR-driven storms with the Dst minimum of smaller than -50 nT in Years 2017 and 2018. The dependence on storm phases and solar wind drivers helps identify magnetospheric conditions favorable for mass-dependent/selective acceleration and in turn provides clues for understanding important physical mechanisms. Utilizing observations made by the MMS spacecraft in the near-Earth plasma sheet, we also compare oxygen-to-proton differences inside earthward bursty bulk flows with the Arase/MEP-i observations. The multi-spacecraft observations help better understand the temporal evolution of the mass-dependent/selective acceleration processes.

Los Alamos National Laboratory

During magnetic storms, the ring current ions move toward the Earth, and the inner edge position of the ring current depends on the convection electric field. We investigate variations of the inner edge of the ring current ions, so-called, penetration depth, during magnetic storms using the ion measurements made by the Low-energy particle experiments-ion mass analyzer (LEP-i)/Medium-energy particle experiments-ion mass analyzer (MEP-i) instruments onboard the Arase satellite. The Arase satellite typically observes the earthward penetration of the ring current protons associated with the enhancement of the dawn-to-dusk electric field in the inner magnetosphere during the storm main phase. The plasmapause moves earthward during the main phase. On the other hand, the convection electric field decreases during the storm recovery phase in which the flux of ring current protons decreases. We identify that the penetration depth of protons depends on the minimum Dst index during the storms as well as the proton energy.

We also investigate the penetration depth of other ions, i.e., helium and oxygen ions. Because the life times of helium and oxygen ions due to charge exchange reaction for are longer than that of protons, it is expected that these ions can penetrate deeper than protons and temporal and spatial evolution can be observed clearly. We will also discuss the relation between the position of ring current inner edge and cross polar cap potential.

Relativistic Acceleration of Energetic Protons by Electromagnetic Ion Cyclotron Waves in the Jovian Magnetosphere

*Tomohiro Sekine[1], Yoshiharu Omura[1], Danny Summers[2], Yikai HSIEH[1], Satoko Nakamura[1]

1. Reserach Institute for Sustainable Humanosphere, Kyoto University, 2. Memorial University of Newfoundland

We perform test particle simulations of nonlinear interaction between energetic protons and EMIC waves. We assume a coherent EMIC waves that have a constant frequency and propagate parallel to the magnetic field. We find that protons can be trapped and accelerated by EMIC waves. We find a very efficient acceleration process of protons in which kinetic energy of protons increases while directions of parallel velocities reverses when we assume parameters in the Jovian magnetosphere. We notice that this phenomenon is very similar to the interaction process between relativistic electrons and whistler-mode waves, which is called Relativistic Turning Acceleration (RTA) [1]. In order to analyze the phenomena, we have developed nonlinear trapping theory of interaction between relativistic protons and EMIC waves. Next, we compare the theory and simulation results. We confirm that the results satisfy the conditions for RTA. Following the trajectories of many resonant protons, we obtain time evolution of the distribution function of relativistic protons as a function of energy and equatorial pitch angle based on the numerical Green’ s function method [2].

Statistical study of IPDP type EMIC wave-related electron precipitation at subauroral latitude

*Asuka Hirai[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Yasumasa Kasaba[1], Yuto Katoh[2], Hiroaki Misawa[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3], Satoshi Kurita[3], Martin G Connors[4]

The outer radiation belt electrons disappear during the main phase of geomagnetic storms. One of the loss mechanisms of electrons from the outer belt is precipitation into the atmosphere due to wave-particle interactions. Electromagnetic ion cyclotron (EMIC) waves are believed to be important plasma waves that contribute to the loss of the outer radiation belt due to pitch angle scattering. They can scatter relativistic and ultra-relativistic electrons. However, there are still questions left about the contribution of EMIC waves to the whole loss of radiation belt electrons and possible conditions favorable to pitch angle scattering.

EMIC waves mainly propagate along magnetic field lines and are observed on the ground as Pc1 geomagnetic pulsations. Intervals of pulsations of diminishing periods (IPDP) are Pc1/EMIC waves that are characterized by frequency rise from 0.1 to 1–2 Hz in a period of ~1 h, and often occur during substorms. Recent studies reported that IPDP are preferentially associated with relativistic electron precipitation. However, the statistical relation between IPDP waves and relativistic electron precipitation, and their physical mechanism, remain open issues.

We investigated differences in characteristics between IPDP and other types of Pc1 by using an induction magnetometer and VLF radio wave data that is a proxy of electron precipitations at subauroral latitude from 1 November 2016 to 30 June 2018. We used the induction magnetometer of PWING (study of dynamical variation of Particles and Waves in the INner magnetosphere using Ground-based network observations) at Athabasca, Canada (54.6˚N, 246.36˚E, L = 4.39). VLF radio waves propagate from transmitters to receivers in subionospheric waveguide. The modulations of VLF signals are detected as occurrence of sub-relativistic and relativistic electron (>100 keV) precipitation due to ionization changes in the lower ionosphere along the radio wave propagation path. VLF radio waves are transmitter from NDK, U.S. (46.367˚N, 261.467˚E, L =3.13) and NLK, U.S. (48.2˚N, 238.083˚E, L =2.84) and received at Athabasca. We selected EMIC wave events on the basis of the following criteria: (1) EMIC wave power is higher than 10^{-5} nT^2/Hz. (2) Duration of EMIC waves is longer than 20 min. (3) Interval between one EMIC wave event and the next one is longer than 30 min. Electron precipitation was identified as a decrease in amplitude of VLF signals from the quiet day curve (QDC). We counted as EMIC wave-driven electron precipitation if we detect temporal correspondence with EMIC waves. In this period, we found 950 EMIC wave events, and 87 of total EMIC wave events were IPDP events (9.2%). Local time dependence of EMIC waves shows that IPDP often occurs in the afternoon and evening sector, while other types of Pc1 occur in all local time range, but with a maximum in 12–16 MLT, which is consistent with previous studies. Simultaneous observation of the magnetometer and VLF radio waves were available for 286 days, and we found 163 EMIC wave events. 19 of 163 EMIC wave events were clearly associated with electron precipitation (12%). Among 19 electron precipitation events, 15 events were caused by IPDP (79%). Also, the electron precipitation events were observed in the evening sector with similar local time dependence to IPDP. This result suggests that IPDP is more likely to cause electron precipitation than other Pc1 wave types. In previous studies, IPDP occurs due to ion cyclotron instability of ring current ions in the evening sector, and favorable region for electron scattering by EMIC waves is high density duskside plasmapause

©2019. Japan Geoscience Union. All Right Reserved.

and plasmaspheric plume because dense plasma lowers minimum resonant energy of electrons. It is assumed that occurrence region of IPDP is coincident with the preferential region for MeV electron scattering by EMIC waves. For this reason, it is expected that IPDP type EMIC waves significantly cause relativistic electron precipitations in the duskside.

Meridional distributions of proton plasma and pressure-driven currents in the nightside inner magnetosphere: Arase observations

*Shun Imajo[1], Masahito Nose[1], Satoshi Kasahara[2], Shoichiro Yokota[3], Ayako Matsuoka[4], Kunihiro Keika[2], Tomoaki Hori[1], Mariko Teramoto[1], Kazuhiro Yamamoto[5], Oimatsu Satoshi[5], Reiko Nomura[6], Akiko Fujimoto[7], Iku Shinohara[4], Yoshizumi Miyoshi[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School of Science, The University of Tokyo, 3. Graduate School of Science, Osaka University, 4. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 5. Graduate School of Science, Kyoto University, 6. National Astronomical Observatory of Japan, 7. Kyushu Institute of Technology

We examine the averaged meridional distributions of proton plasma parameters and pressure-driven currents in the nightside (20–04 h magnetic local time) ring current region during disturbed times (-80 < SYM-H* < -40 nT) using ion measurements covering energy range of 10–180 keV by the Arase satellite. Because the Arase satellite has a large inclination orbit of 31°, it covers the absolute value of magnetic latitude (|MLAT|) range of 0–40° and the radial distance of < 6 Re. We find that the plasma pressure decreases significantly with MLAT. The plasma pressure on the same L^* shell at 30°<|MLAT|<40° is about 10–60% of that at 0°<|MLAT|<10°, and the percentage of decrease is larger on lower L^* shells. The pressure anisotropy which is defined by the perpendicular pressure divided by the parallel pressure decreases with radial distance and shows a weak dependence on |MLAT|. The magnitude of the plasma beta at 30°<|MLAT|<40° is one or two order smaller than that at 0°<|MLAT|<10°. The relative plasma pressure distribution predicted from the magnetic strength and anisotropy is roughly consistent with the observed plasma pressure for L^*=3.5–5.5. The azimuthal pressure-gradient current derived from the plasma pressure distribution spreads over ~-20° |MLAT|, while the curvature current is limited in ~0–10° |MLAT|. We suggest that the latitudinal dependences should be taken into account when considering a temporal evolution of ring current particles from L distributions of successive orbits.

Space Weather Effects on Energetic Proton Flux Response in South Atlantic Anomaly

*Kirolosse Mina GIRGIS[1,2], Tohru Hada[1], Shuichi Matsukiyo[1]

1. Earth System Science and Technology (ESST) Department, Interdisciplinary Graduate School of Engineering Sciences (IGSES), Kyushu University, Japan, 2. Aerospace Engineering Department, Faculty of Engineering, Cairo University, Egypt

In this research, energetic proton flux in the inner radiation belt, is studied inside the South Atlantic Anomaly (SAA) by performing test particle simulations, where the background time-varying magnetic field is provided by Tsyganenko model, according to *Dst* index and altitudes. The objective of this investigation, is to estimate and forecast the additional radiation dose, occurring on spacecraft and human bodies, due to their passage inside the anomaly, and precisely, during intense solar storms. It was found that within minutes, proton flux in the SAA, penetrated deeper downward by about 200 km, when the *Dst* index is decreased (< -210 nT), and a after few more minutes, it was significantly reduced at all the altitudes; the last conclusion was confirmed by satellite observations.

Solar-cycle variations of >30 keV electron flux enhancements under the inner radiation belt

*ALLA SUVOROVA[1]

1. National Central University

Intense fluxes of 30-300 electrons can arise in the equatorial ionosphere outside the South Atlantic Anomaly. It was established that the electrons were injected from the inner radiation belt probably due to a mechanism of fast radial transport in the crossed electric and magnetic fields. Continuous monitoring of energetic particles at low heights of ~850 km with the MEPED instrument onboard the NOAA/POES satellites allowed compiling large statistics of the >30 keV electron enhancements from 1998 to 2018. We studied particle flux variations with geomagnetic activity and solar cycle. We found that geomagnetic activity measured by Dst and AE indices are not key factors of occurrence rate increase for electron injections, but influence on intensity of particles. The occurrence rate is controlled by auroral conductivity on the dayside and significantly enhanced during northern summer. Descending phase of solar cycle plays a major role in the occurrence rate increase.

Energy spectra variations of high energy electrons in the inner magnetosphere observed by HEP/XEP on ARASE and SEDA-e on HIMAWARI

*Takeshi Takashima[1], Takefumi Mitani[1], Nana Higashio[2], Tsutomu Nagatsuma[3]

1. ISAS/JAXA, 2. Research and Development Directorate/JAXA, 3. NiCT

The relativistic electrons in the outer radiation belt were disappeared/increased and their energy spectra were changed dynamically in some storms observed by XEP/HEP onboard the ARASE spacecraft. In the same time, SEDA-e with energy range 200keV-4.5MeV for electron on board the HIMAWARI-8, Japanese weather satellite on GEO, observed increase of relativistic electron in different local time.
When comparing the energy spectra, there are times when the spectrum matches or does not match. It is also observed that the change in the slope of the energy spectrum differs with time. These phenomena are observed even when there are two satellites at the same local time.
We will report on energy spectra variations of high energy electrons including calibrations of differential flux between XEP and HEP and discuss comparisons with energy spectra between ARAE and HIMAWARI that observed each storm in different local time.

Graduate School of Science, The University of Tokyo, 5. Graduate School of Science, Osaka University

An inter-channel comparison of electron fluxes measured by the HEP instrument onboard the Arase satellite is conducted with a focus on the apparent non-uniformity in detection efficiency and relative offset of the background flux level between the channels, which was partly reported previously. We extend the data set to cover the entire two-year period since the start of the regular observations. The flux ratio of different channels is sorted by the electron flux level of much higher energies that was simultaneously measured by the extremely high-energy electron experiment (XEP) instrument onboard Arase. The result shows that the HEP flux of all azimuthal channels is more or less affected by MeV electrons which are most likely to have penetrated into the instrument box and directly hit the detectors. However, it is also revealed that the non-uniform count distribution over the channels still remains even when the penetrating electrons are absent. We conduct a set of Geant-4 simulations to trace electrons with various energies and incident angles to the detector plane in order to give a quantitative interpretation for the resultant count distributions, in terms of the effects of penetrating electrons and obliquely-colliding incident electrons.

Particle simulation for calibrating the HEP data onboard the ARASE satellite

*PARK INCHUN[1], Yoshizumi Miyoshi[1], Takefumi Mitani[2], Tomoaki Hori[1], Satoshi Kurita[1], Mariko Teramoto[1], Takeshi Takashima[2], Nana Higashio[3], Iku Shinohara[2]

1. Nagoya University Institute for Space-Earth Environmental Research, 2. Japan Aerospace Exploration Agency Institute of Space and Astronautical Science , 3. Japan Aerospace Exploration Agency

Understanding the detailed characteristics of the HEP (High-Energy electron Experiment) instrument onboard the Arase satellite is crucial for data calibration. Due to difficulties of reproducing the severe radiation environment of the inner magnetosphere on the ground, computer simulation is the best method to understand instrument responses to the ambient radiation environment. Through Monte-Carlo simulations using the Geant4 tool, we have reconstructed the geometry of the HEP instrument and modeled the high-energy particle environment. Using the developed model, we have studied the efficiency of the detectors, the angular resolution, and the g-factors, which depend on the particle energy and the sensor channels. While the previous studies were based on a uni-direction simulation with electron pencil beams, this study adopted all the detector channels and energy bends of HEP thus resulting in more advanced simulations. Based on the results, we have made a new calibration table depending on the angle of incident particles. We have also estimated the g-factor which depends on the incident particle energy. The updated calibration table and g-factors are important for calibrating the HEP data as well as inter-calibrations with other particle instruments' data.

The high-energy electron experiments (HEP) instrument installed on the Arase is designed to observe energetic electrons of 70 keV to 2 MeV. The HEP registers high electron counts for the MeV energy range, not only in the outer belt but also in the inner belt, in MeV energy range. On the contrary, Van Allen Probes have hardly detected MeV electrons in the inner radiation belt. A probable interpretation is that the counts of HEP are caused due to contamination of high-energy protons. In order to verify this idea, we have modeled the HEP instrument a Geant4 simulation to determine the energy of penetrating protons. The result clearly shows that high-energy protons, it has become clear that high-energy protons of a few to a few tens of MeV can contribute to the apparent high counts of HEP. No instrument for measuring protons in this energy range is installed on the satellite. We will discuss the possibility of research on the spatial distribution and time variation of high-energy protons in the inner belt based on observation data from the HEP instrument.

Validation of High-energy electron detector simulator for the HEP instruments onboard Arase

*Takefumi Mitani[1], PARK INCHUN[2], Tomoaki Hori[2], Taku Namekawa[1,3], Kazushi Asamura[1], Takeshi Takashima[1], Satoshi Kasahara[3], Satoshi Kurita[2], Mariko Teramoto[2], Nana Higashio[1], Yoshizumi Miyoshi[2], Iku Shinohara[1]

1. Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science, 2. Institute for Space-Earth Environmental Research, Nagoya Univ., 3. The university of Tokyo

The high-energy electron experiments (HEP) onboard the Arase satellite detects 70 keV-2 MeV electrons and generates a three-dimensional velocity distribution for these electrons in every period of the satellite's rotation. Electrons are detected by two instruments, namely, HEP-L and HEP-H, which differ in their geometric factor (G-factor) and range of energies they detect. HEP-L detects 70 keV–1 MeV electrons and its G-factor is 9.3 $\times 10^{-4}$ cm^2 sr at maximum, while HEP-H observes 0.7 MeV–2 MeV electrons and its G-factor is 9.3 $\times 10^{-3}$ cm^2 sr at maximum. The instruments utilize silicon strip detectors and application-specific integrated circuits to readout the incident charge signal from each strip.

In order to deduce the distribution of incident electrons from the direction and energy detections in orbit, we have developed a detector simulator using the Geant4 toolkit. Especially contamination due to high energy particles must be considered quantitatively. We have also been working on electron beam experiments using HEP detector modules which are almost the same as the flight model in order to compare detailed simulations and experimental data.

We will present a comparison between results from the electron beam experiments and those from the detector simulator. And we will discuss its influence on the interpretation of the observational data obtained in orbit.

The model study of ionospheric variations during the solar eclipse event by assimulating the GNSS TEC observations

*Chia-Hung Chen[1], Charles Lin[1], Tomoko Matsuo[2]

1. Department of Earth Sciences, National Cheng Kung University, 2. Department of Aerospace Engineering Sciences, University of Colorado at Boulder, CO

Using the physics-based thermosphere-ionosphere model (NCAR-TIEGCM) with an ensemble Kalman filter, this study reports the first data assimilative analysis of the ionosphere responses to the solar eclipse on 21 August 2017. The system, using a 2-minute assimilation cycle of data from ground-based GNSS observations, show dynamic variations of the equatorial ionization anomaly (EIA) due to the electrodynamic effects of the solar eclipse. Two major ionospheric responses are captured: (1) an early appearance of EIA at the westward boundary of moon shadow and (2) an enhanced EIA at lower latitudes and suppressed EIA at the higher latitudes. These eclipse-induced conjugate EIA variations are produced by an eastward electric field perturbation around magnetic equator and a westward electric field perturbation at the higher latitudes.

Characteristics of mesoscale thermospheric-ionospheric dynamics associated with heating in the auroral region

*Tomokazu Oigawa[1], Hiroyuki Shinagawa[2], Satoshi Taguchi[1]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology

The thermosphere and ionosphere in the polar region have been studied for a long time. Recent results of the ground and satellite measurements have suggested that polar thermospheric and ionospheric dynamics are extremely complicated. In particular, in the auroral region, various processes, such as ion-neutral drag, Joule heating, heating and ionization by particle precipitation, chemical processes, diffusion, and atmospheric gravity waves, are strongly coupled. Previous observations have shown some characteristic mesoscale phenomena such as large vertical winds and significant increasing of mass density in the auroral region. It is considered that local heating plays an important role in such phenomena. However, we still have not quantitatively understood how such large vertical winds and significant increasing of mass density occur. In order to study the mesoscale thermospheric and ionospheric dynamics in the auroral region, a high-resolution numerical model including various physical and chemical processes is required. We will report on how the thermospheric and ionospheric dynamics change depending on the magnitude of the heating and the spatial structure of the heating region using a two-dimensional numerical model. In addition, interaction between the thermosphere and the ionosphere will be discussed.

Understanding the flow of energy and mass throughout the magnetosphere-ionosphere-thermosphere coupled system is a fundamental goal of solar-terrestrial physics. Since substantial energy accumulated in the substorm growth phase in the magnetospheric tail flows into the polar ionosphere immediately after the substorm onset, investigating the energy dissipation process at high latitudes around the time of substorm onset can contribute significantly to achieving that objective. The energy dissipation generates acceleration and heating of the ionosphere and thermosphere, but this might occur not only near aurora but also far from it by hundreds kilometers equatorward. We analyzed ionospheric and thermospheric measurements in the northern Scandinavian area (65-80 N) during periods of considerably low geomagnetic activity but with some aurorae above Svalbard (75-80 N). Thermospheric winds measured with a Fabry-Perot interferometer (FPI; 630.0 nm) at Tromsø, Norway (69.6 N) showed westward accelerations coinciding with auroral brightening at the Svalbard area at the dusk sector though the relative distance from Tromsø to the aurora was 200-500 km in some cases. Moving into the dawn sector with the earth’ s rotation, the acceleration direction turned to southeastward through stagnation area or period seen at magnetic local midnight. The acceleration pattern well represents thermospheric responses to the ionospheric convection, but of particular interest is its location, in which the thermospheric wind have been obtained at the sub-auroral region far from the main auroral oval. In this analysis, we cannot infer to horizontal patterns of the wind acceleration because we have only a point measurement from the Tromsø FPI. While this result suggests the importance of two-dimensional measurements of ionosphere and the thermosphere, we need a new configuration of the observation network to infer horizontal winds and accelerations. In this presentation, we will introduce “SDI-3D” project, which aims at developing 3 Scanning Doppler Imagers (SDIs) and deploying them at the same area as for the EISCAT_3D, which may start in operation in 2022.

Analysis of the thermospheric neutral wind vector using observed images of *Trimethylaluminium* (*C6H18Al2*) released from sounding rocket in the upper atmosphere

*Yuki Otsuka[1], Masa-yuki Yamamoto[1], Hiroaki Saito[1]

1. Kochi University of Technology

Altitude profiles such as neutral atmospheric density and ionized atmospheric density in the thermosphere/ionosphere fluctuate by solar activity, season, day and night changes. These fluctuations with affecting on ground, communication with artificial satellites, and make affecting there orbits, but the detailed mechanism of occurrence has not been well understood. We have been conducting collaborative experiments with JAXA, NASA, etc. on inverstigating neutral atmospheric wind in the thermosphere/ionosphere, which is thought to play an important role in this mechanism.
In this research, the main objective is to calculate the neutral wind velocity in the thermosphere from the images of TMA observed in rocket experiment by JAXA conducted in July 2013.
JAXA conducted a rocket experiment in July 2013 to clarify the full picture of electromagnetic interaction and ionized/neutral atmosphere interaction acting on mid-latitude ionosphere. S-310-42 and S-520-27 sounding rocket were launched from Uchinoura Space Center(USC). Trimethylaluminum(TMA)was released in the former and lithium(Li) was released from the latter rocket into the upper atmosphere. Sequential optical observation of changes in these luminescent clouds was operated at each observation point and aircraft. Figure.1 shows the flight path of the aircraft/rockets in the experiment, the observation point, the emission region of TMA and Li, etc.
To calculate the wind speed, we use the images of TMA observed in July 2013 rocket experiment. I analyze the image sequence taken from the aircraft(Figure 2) and those images at USC(Figure 3)as a combination in which the TMA clouds are clearly seen and a long-time optical observations were performed. We use the method of Yokoyama(2011)and Kihara(2015)for caluculating of newtral wind speed.

Method by Yokoyama(2011)[1]
1 From the observed image, the central position of the cloud(TMA gas) is obtained from luminance information. Thereafter, the central axis of the TMA gas is obtained.
2 Choose one of the stars in the observed image as the center star. Also select ten stars around that.
3 Correct the distortion of the lens by using the X,Y coordinates of the stars(right ascension , declination) on the image.
4 Convert the coordinates of the obtained central axis are into celestial spherical coordinates. After that, it converts to earth coordinates using observation point information.
5 From the data of each observation point obtained by the above procedure, wind speed is calculated by using triangulation method.

Method by Kihara(2015)[2]
1 From the observed image, the central position of the cloud(TMA gas) is obtained from luminance information. Thereafter, the central axis of the TMA gas is obtained.
2 Correct distortion of the camera lens. After that, convert the coordinates on the image into the elevation and the azimuth angles.

©2019. Japan Geoscience Union. All Right Reserved.

3 After applying the correction, the difference information is obtained from two images of the same point at different times. Then, the wind speed is calculated from the difference information.

We carried ou extraction of central axis of a TMA cloud, extraction of stars on the images, conversion to elevation and azimuth angles, then derived an approximate wind speed profile. However, it is thought te error at the time of detecting the center axis of the TMA cloud and the conversion error at azimuth/elevation angles are influenced. In the future, it is also necessary to correct lens distortion, tilt of camera, and aircraft velocity and altitude changes.
In this presentation, we would like to introduce more precise caluculation method of neutral wind speed.

Establishment of real-time analysis method in a new HRO interferometer system and operation test of comprehensive meteor observation

*Takumi Sato[1], Seiya Takeda[2], Masa-yuki Yamamoto[1]

1. KOCHI UNIVERSITY OF TECHNOLOGY, 2. Inc.Bascule

Meteors are natural phenomenon that dusts is space with several millimeters to several centimeters in diameter in outer space jump into and collide with upper atmosphere of the earth, vaporizing and getting hot because of adiabatic compression by aerodynamic heating with emitting light at the same time. At the moment, thermal energy by aerodynamic heating make molecules in the atmosphere ionize, with generating a large amount of plasma. This plasma makes a elongated dense-ionized column along the meteoric trajectory. Meteor radio observation is an observation method using scattered radio waves by free electrons in the ionized column. In this research, at Kochi University of Technology (KUT), we conducted Ham-band radio meteor observation (HRO) in forward scattering method using the 53.755 MHz VHF (amateur band) wave that is transmitted stably from Fukui Prefectural University.
The objective of this research is that we apply a new observation method and analyzing algorithm to KUT 5ch meteor radio interferometer and develop meteor research using 5 antennas of the meteor radio interferometer [1]. Because of the limited radio meteor observation in Japan, if we share accurate observation method and observation result with the other observers, we can contribute to the development of study on meteor science.
In this research, we conducted three methods (comprehensive meteor observation [1]) of the new HRO interferometer system (HRO interferometer system), optical observation, and infrasound observation.
In the HRO interferometer system, after the signal received at the antennas was demodulated in their receivers, with making input to an observation PC through an AD board, real-time processing by analysing software on the PC was performed. A group of data set triggered only when exceeding a threshold set in advance on the software are saved as a meteor echo. In the analysis of meteor plasma direction of each meteor with considering intrinsic phase difference, we calculated each phase difference in north-south and east-west directions with baseline length of 0.5 λ and 2.5 λ (λ is observation wavelength), after processing interference calculation among signals of multiple antennas using 5ch meteor radio interferometer [1].
In the optical observation, we used existing high sensitivity B/W CCD camera (WAT-100N) and color 4K camera (Sony, α6300) newly installed with a combination of UFOCaptureV2 and HD2 that are motion capture software. The observation data was analyzed from the information recorded by cameras by analyzing position, velocity, linearity of motion, etc. by using UFOAnalyzerV2 for data stored through UFOCaptureV2 and HD2.
In the infrasound observation, we conducted a unique meteor observation for such as large fireballs by using a group of infrasound sensors that can observe very low frequency sound of less than 20 Hz caused by large scale natural phenomena. It is possible to estimate energy scale of the meteor entry from obtained amplitude and period of the sound wave.
In order to determine the intrinsic phase shift, we searched for the observability of the same phenomenon for the comprehensive meteor observation data.
In this research, we obtained 2 meteor shower data from August 2018 to January 2019. Especially, in 2019 at Quadrantids, three candidates of the intrinsic phase shift was obtained by analysis of comprehensive meteor observation data, but we could not confirm the intrinsic phase shift.

©2019. Japan Geoscience Union. All Right Reserved.

As a result of this research, we obtained the candidate values necessary for accurate calculation of meteor plasma direction by the interferometer data processing. Due to lack of the observation data, we could not confirm the intrinsic phase shift, thus after checking the analyzing process, we will continue to use the system and obtain more data to establish the intrinsic phase shift and ensure the accuracy and reliability of the observation method.
We applied the new trial called real-time analyzing to KUT 5ch radio meteor interferometer with confirming the validity of the new receiver system, and obtained the candidate values of the intrinsic phase shift necessary for our future research. We shared a part of accurately obtained data on the web and a mailing lists, so as to contribute to the development of meteor science.

Solar flare effects of the D-region ionosphere using daytime tweek atmospherics

*Kodai Yamanobe[1], Hiroyo Ohya[2], Hiroyuki Nakata[2], Toshiaki Takano[2], Kazuo Shiokawa[3]

1. Graduate School of Science and Engineering, Chiba University , 2. Graduate School of Science and Engineering, Chiba University, 3. Institute for Space-Earth Environmental Research, Nagoya University

It has been known that intensity and phase of very low frequency (VLF, 3-30 kHz)/low frequency (LF, 30-300 kHz) transmitter signals significantly change due to intense ionization by solar flares [e.g., Mitra, 1974; Thomson et al., 2005]. Santolik and Kolmasova [2017] showed daytime tweek atmospherics (1.5-10.0 kHz) did not become observal for two hours just after a solar flare of M2.2 class, which suggests large absorption due to the solar flare. However, there are little studies for tweeks during solar flares. In this study, we investigate solar flare effects of the D-region ionosphere using tweek atmospherics. We analyzed the daytime tweek atmospherics observed at Kagoshima (31.48N, 130.72E) and Moshiri (44.37N, 142.27E), Japan, during January-July, 2013. The sampling frequency is 20 kHz, and the VLF data were recorded for each two minuteat 20-22 and 50-52 minutes every hour. For two M1.4-class flares, the daytime tweeks were received about 30-40 minutes after the solar flares. For a M5.6-class flare, the daytime tweeks were not observed for about 4 hours after the solar flare. The tweek reflection height had a weak negative correlation (-0.38) with X-ray flux observed by the GOES-13/15 satellites, suggesting that electron density in the D-region ionosphere increased with increasing the X-ray flux.In the presentation, we will discuss the D-region ionization and propagation mechanism of the tweeks during solar flares in more detail.

Toward a detection of sporadic-E episodes by ALOS2 ScaSAR InSAR

*Masato Furuya[1], Jun Maeda[2], Kosuke Heki[1]

1. Department of Earth and Planetary Sciences Hokkaido University, 2. Hokkaido University Library

Maeda et al. (2016) and Furuya et al. (2017) reported their detections of sporadic-E (Es) episodes in Japan, using L-band interferometric synthetic aperture radar (InSAR). The SAR data images are acquired by Advanced Land Observation Satellite (ALOS) 1/2 launched by JAXA in 2006 and 2014, respectively. The high spatial resolution of InSAR data allow us to examine the detailed structure of Es episode, which will complement the high temporal resolution of GNSS TEC data. The previous two studies are based on stripmap-mode SAR images, which have higher spatial resolution but are limitted in terms of the observation swath-width (Maeda et al., 2016; Furuya et al., 2017). Although the stripmap-mode is the most standard SAR imaging mode, ScanSAR mode is also nearly operational nowadays, and can image the Earth with much wider swath-width by as much as 350 km; the standard stripmap-mode of SM1 for ALOS2 covers only 50 km. Although the ScanSAR mode is a bit worse in terms of the spatial resolution along radar range direction than the stripmap mode image, ScanSAR InSAR image can dramatically improve the observation coverage, and thus help detect both small-scale and large-scale structure of Es. We first check the data availability of ScanSAR images in Japan at any specific areas, and then check if any significant anomalies in either TEC or ROTI are observed via the database provided by NICT. We will report our preliminary results of ScanSAR InSAR imaging of Es in Japan.

Vertical fine structure and time evolution of plasma irregularities in the E_s layer, observed by a high resolution Ca^+ lidar

*Mitsumu K. Ejiri[1,2], Takuji Nakamura[1,2], Takuo T. Tsuda[3], Takanori Nishiyama[1,2], Makoto Abo[4], Toru Takahashi[1], Katsuhiko Tsuno[5], Takuya Kawahara[6], Takayo Ogawa[5], Satoshi Wada[5]

1. National Institute of Polar Research, 2. SOKENDAI (Department of Polar Science, The Graduate University for Advanced Studies), 3. The University of Electro-Communications, 4. Tokyo Metropolitan University, 5. RIKEN, RAP, 6. Shinshu University Faculty of Engineering

The vertical fine structures and the time evolution of plasma irregularities in the sporadic E (E_s) layer were observed via calcium ion (Ca^+) density measurements using a resonance scattering lidar with a high time-height resolution (5 s and 15 m) at Tachikawa (35.7˚N, 139.4˚E) on December 24, 2014. The observation successfully provided clearer fine structures of plasma irregularities, such as quasi-sinusoidal variation, localized clumps, “cats-eye” structures, and twist structures, in the sporadic Ca^+ (Ca^+_s) layers at around 100 km altitude. These fine structures suggested that the Kelvin-Helmholtz (K-H) instabilities occurred in the neutral atmosphere whose density changed temporarily or spatially. The maximum Ca^+ density in the Ca^+_s layer was two orders of magnitude smaller than the maximum electron density estimated from the critical frequency (f_oE_s) observed by the ionosonde at Kokubunji (35.7˚N, 139.5˚E) simultaneously. The correlation showed a strong positive correlation with a coefficient of 0.91. These results suggest that Ca^+ contributes forming the E_s layer as well as major metallic ions Fe^+ and Mg^+ in the lower thermosphere. Moreover, the formation of a new Ca^+_s layer at 110 km and the upward motions of the Ca^+_s layers at 100 km and 110 km were observed just after the sunrise time at the conjugation point and before the local sunrise. Although the presence or absence of a causal relationship with the sunrise time was not clear, a possible explanation for the formation and the upward motions of the Ca^+_s layers was the occurrence of strong eastward winds at around 100 km, rather than the enhancement of the eastward electric field.

Study of Effects of Stratospheric Sudden Warming on Medium-Scale Traveling Ionospheric Disturbances Using Total Electron Content Data Obtained from World-Wide GPS Receiver Networks

*Yuichi Otsuka[1], Atsuki Shinbori[1], Prayitno Abadi[2], Takuya Tsugawa[3], Michi Nishioka[3]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. LAPAN, 3. National Institute of Information and Communications Technology

Medium-Scale Traveling Ionospheric Disturbances (MSTIDs) are wavy structures of the ionospheric plasma density with horizontal scale-size of hundreds of kilometers. In order to investigate effects of Stratosphere sudden warming (SSW) on MSTIDs, we have analyzed total electron content (TEC) data obtained from GPS receivers at different four longitudinal sectors (east Asia, Europe, and western and eastern America) before and after SSW that occurred on January 2009 and 2013. To obtain perturbation component of TEC, which could be caused by MSTID, we have subtracted 1-hour running average from the original TEC time series for each pair of satellites and receivers, and converted the slant to vertical TEC. We have defined MSTID activity as dI/I, where dI is the standard deviation of the perturbation component within 1 hour, and I is 1-hour average absolute vertical TEC. In this study, we applied the same method to the GPS-TEC data at mid-latitudes before and after major Stratospheric Sudden Warming (SSW) events that occurred on January 2009 and 2013. We have found that MSTID activity during daytime is high before SSW events and low after SSW events. On the other hand, the nighttime MSTID activity does not show such a difference between before and after SSW events. These results suggest difference of mechanisms generating MSTIDs between daytime and nighttime. The daytime MSTIDs could be caused by gravity waves propagating upward from below into the thermosphere. Recent simulations suggest that these gravity waves are secondary waves generated from dissipation of the primary waves in the MLT region. Miyoshi et al. (JGR, 2015) have reported that the generation of secondary gravity waves is more active when the strato-mesospheric jet is strong, and that the generation of secondary waves is inactive when the strato-mesospheric jet is attenuated or becomes westward. Consequently, low MSTID activity after January 24 could be caused by weaker generation of secondary gravity wave during weaker or westward strato-mesospheric jet. On the other hand, gravity waves propagating from below does not contribute to generation of MSTIDs during nighttime.

Tsunami-generated ionospheric currents inferred from geomagnetic observations at ground level: Case for the 2011 Tohoku Earthquake

*Takuto Minami[1], Masashi Kamogawa[2], Tsutomu Ogawa[1], Makoto Uyeshima[1], Toru Mogi[3], Hiroshi Ichihara[4]

1. Earthquake Research Institute,The University of Tokyo, 2. Department of Physics, Tokyo Gakugei University, 3. Graduate School of Engineering, Hokkaido University, 4. Graduate School of Environmental Studies, Nagoya University

It is known that large earthquakes cause atmospheric gravity/acoustic waves reaching the ionosphere and drive ionospheric dynamo currents at the altitude (e.g. Iyemori et al. 2005). Related phenomena were detected by observations of total electron content (TEC) (e.g. Tsugawa et al. 2011) and reported by numerical simulations (e.g. Kherani et al. 2013). However, the form of electric currents due to the coseismic ionospheric dynamo has never been revealed from the perspective of geomagnetic observations at ground level.

We investigated 1-min sampling magnetic data at nineteen on-land stations on the Japan Arc and at one ocean-bottom magnetometer ~200 km off the Tohoku, to reveal the form of coseismic electric currents in the ionosphere during the 2011 Tohoku earthquake (Mw 9.0). First, we subtracted the effects of non-seismic components of ionospheric and magnetospheric origins from the geomagnetic data, using magnetic transfer functions between the stations of interest along the Japan Arc and a reference site in China, Changchun. Second, we subtracted the oceanic dynamo effects due to the tsunami by a time-domain finite element simulation in the same manner as Minami et al. (2017). By rotating the coordinate system at each station to that consisting of radial and transverse axes in terms of the tsunami centre, we recognized a clear concentric propagation of a trough in the radial magnetic component with a phase velocity of ~ 1 km/sec and a trough amplitude of ~ 7 nT. This propagation happens in all the directions and the propagation velocity is almost the same as that of the slow coseismic ionospheric disturbances (CID) observed by TEC observations (e.g. Kakinami et al., 2013). The radial propagation of a trough in the radial component indicates presence of anti-clockwise electric currents in the ionosphere.

In the presentation, we report our analysis of the geomagnetic data at ground level and the inferred characteristics of the coseismic electric currents in the ionosphere. We also plan to show some results of spectral analyses of the propagation features involved in the geomagnetic data.

Relationship between the magnitude of Sakurajima eruptions and the disturbance of GPS-TEC

*Kiyoto Shoji[1], Hiroyuki Nakata[1], Toshiaki Takano[1], Hiroyo Ohya[1], Takuya Tsugawa[2], Michi Nishioka[2]

1. Graduate School of Science and Engineering, Chiba University, 2. National Institute of Information and Communications Technology

It is reported that ionospheric disturbances are caused by ground and atmospheric perturbations, e.g. earthquakes, typhoons and volcanic eruptions. Even though the volcanic eruptions excite the atmospheric waves, there is little reports of ionospheric disturbances caused by volcanic eruptions. Therefore, in this study, we analyzed the ionospheric disturbances caused by volcanic eruption using Total Electron Content (TEC) determined by GNSS system.
We analyzed TEC data observed in GNSS Earth Observation Network (GEONET) which is maintained by Geospatial Information Authority of Japan. We assumed that the ionospheric pierce points (IPP) are located at the altitude of 300 km. The 30-second TEC data are obtained in about 1200 points of GEONET. The mask angle is 30 degrees. We analyzed four events of Sakurajima eruptions (7:45 UT on Oct.-3-2009, 1:07 UT on Sep.-19-2012, 20:25 UT on Dec.-9-2012 and 20:21 UT on Feb.-12-2014). The magnitudes of the eruptions are estimated by the infrasound meter located at Higawa-Korimoto.
The TEC disturbances are larger in the larger magnitude of the events.
It is expected that the TEC disturbance is inversely correlated with the distance from the crater as the energy of the atmospheric wave spreads according to the distance from the crater. Examining the relationship between TEC disturbances and the distances of IPPs from the crater. There was an inverse correlation with the distance in one events out of four events. However, no correlation was found in the other three events. This may be due to the directions of the magnetic field and the wave normal of the disturbance to the GPS satellite-receiver. In order to correct these effect, we calculated two coupling coefficients of the directions of the atmospheric wave from the calculation results of the acoustic ray tracing the one is related to the direction of the magnetic field, and the other is to the direction between the transmitters (satellites) and GNSS receivers. After this connection, an inverse correlation between TEC disturbances and the distance from the crater was appeared in three events.
However, some data showed higher values than the expected values. In the IPPs where the corrected values are high, the correction coefficients are very small. Therefore, the cause of the high values is too effective correction.

Water vapor estimation using digital terrestriall broadcasting waves - Simultaneous observation with microwave radiometer -

*Hiroshi HANADO[1], Seiji Kawamura[1], Hironori Iwai[1], Shinsuke Satoh[1], Katsuhiro Nakagawa[1], Takuya Tajiri[2], Narihiro Orikasa[2], Yoshinori Shoji[2], Kentaro Araki[2], Hiromu Seko[2]

1. National Institute of Information and Communications Technology, 2. Meteorological Research Institute

1. Introduction

NICT is developing a method that can observe water vapor in a wide area and efficiently. Water vapor is an important quantity along with wind velocity and temperature in the weather prediction. Solid / liquid phase water in the atmosphere can be observed with weather radars, but water vapor, water in gas phase, can not be observed with radars. Water vapor observation methods in a wide area are limited. Currently, GPS / GNSS precipitable water observation which is used as water vapor data in a weather numerical model uses the delay amount of the L-band radio waves from the GPS / GNSS satellites. NICT have demonstrated that similar measurements are possible with the terrestrial digital broadcast wave in UHF [1]. The method is that using delay profile decorded from scattered pilot signals embedded in the terrestrial digital broadcast wave, the reflected wave scattered from the surrounding reflector, building or towers, is separated from the direct wave. By using phase difference between the reflected wave and direct one, the influence of the phase noise of the reference signal at the broadcast station / reception point is canceled, and the propagation delay of the UHF band radio wave is measured with accuracy of picosecond level.

2. Simultaneous observation with microwave radiometer

We installed a microwave radiometer and terrestrial digital broadcasting wave receiver on the roof of the Meteorological Research Institute, Tsukuba, in February 2017, and we are continuing long-term observation. The microwave radiometer is an instrument capable of observing the amount of water vapor accumulated in the vertical direction above the measurement point. On the other hand, water vapor observation by the terrestrial digital broadcast wave means the amount of water vapor along the horizontal direction near surface. These observation volumes are different in size and shape. Therefore, by combining the two sensors, complementary observation of the water vapor amount is expected. In terms of time resolution, the microwave radiometer is not so good as it directs the antenna beams in a plurality of directions and estimates from the received thermal noise powers. In the water vapor estimation by terrestrial digital reception, more than 50 samples are measured per second, and it has a rather high temporal resolution. In this presentation, we will compare the variation of water vapor observed by microwave radiometer and terrestrial digital broadcasting wave for about one and a half years, and introduce the analysis results focusing on the difference in characteristics.

[P-EM18] Heliosphere and Interplanetary Space

convener:Ken Tsubouchi(University of Electro-Communications), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Kazumasa Iwai(Institute for Space?Earth Environmental Research (ISEE), Nagoya University), Chairperson:Yasuhiro Nariyuki, Kazumasa Iwai

This session aims to secure comprehensive insights into physical processes of plasmas and fields in the heliosphere. Presentations of the recent studies from any approaches (integrated observations/theoretical modeling/massive numerical simulation) are welcomed. Topics are not restricted to any specific issues: phenomenological studies on solar flares/CME/solar wind, and related fundamental physics problems such as shocks/waves/turbulence/particle transport and acceleration can be the main target, including heliospheric high-energy phenomena and their impact on the Earth's environment.

The interplanetary magnetic flux ropes (IFRs) are ejected from the Sun to interplanetary space in association with the coronal mass ejections (CMEs). Their magnetic structure is an important research subject which provides information on the mechanism of CMEs. On the other hand, The IFRs often cause strong geomagnetic storms because of intense southward magnetic fields carried from the solar atmosphere. Thus, the IFRs have long been studied since they were discovered more than 30 years ago. It is the first step for such studies to determine the 3-D geometries and internal magnetic field structures of IFRs. We need to assume a physical model of the IFR and compare the model structure with observations. There are 2 representative analysis methods which are currently used along the line. They are: (1) a fitting method to models of force-free magnetic field configurations, and (2) a reconstruction method of magnetic field structures based on the Grad-Shafranov (GS) equation. Recently, Al-Haddad et al. (Solar Phys. 2018) examined the mutual agreement between the results from the two methods for 13 well-determined IFRs carefully selected. They found that the agreement is relatively good in only 6 cases, and thus concluded that the compatibility of different models with specific IFR structures must be taken into account.

The present study is an extension of the work by Al-Haddad et al. In the GS method, 2-D structure (essentially a cylindrical structure) is assumed, and the axis orientation is determined so that the symmetry condition is satisfied between inbound and outbound crossings of the IFR. If the IFR fields satisfy the force-free condition, the internal structures obtained by the 2 methods agree with each other. Actually, however, the GS method includes the effect of plasma pressure while the force-free model neglects the plasma pressure. This can cause the discrepancy between the two. With this idea in mind, we started to examine how the axis orientations deviate from each other. However, we encounter an unexpected problem, that is, it is not easy to point start and end times of an IFR from the observed data. Especially in the GS method, the selection of the IFR interval is strongly affected by the symmetry condition. In this presentation we show results of our trial to determine the axis orientation for many possible IFR intervals.

Validation of estimated interplanetary flux rope axial direction using internal plasma motions: benchmark test

*Nobuhiko Nishimura[1], Munetoshi Tokumaru[1], Katsuhide Marubashi[2]

1. Institute for Space Earth Environmental Research, 2. National Institute of Information and Communications Technology

Interplanetary flux rope (IFR) is a structure with helical magnetic field lines wrapping around a central axis to form a flux rope structure. Accurate estimation of this structure is important for improving the space weather forecasting and understanding the evolution of IFR. Local structures of IFRs have been investigated by many model fittings and reconstruction method. However, the outputs of these model fittings and reconstruction method are often different. The chirality and magnetic flux of corresponding flux rope at the Sun are often compared with those of IFR to check the validity of estimation of IFR properties, but it is questionable whether this consistency check guarantees the validity of IFR axis direction which is one of the important properties of IFR. In this study, we propose a method that validates IFR axial direction based on plasma motion. It is known that the radius of IFRs often expand or sometimes contract during the passage of IFR through a spacecraft and if the expansion or contraction exist, the direction of plasma motion in IFR may be perpendicular to IFR axis in the frame comoving with the IFR. This suggests that plasma velocity in IFR reflects the axial direction of IFR. We test the method for a well-investigated IFR event on May 21-22, 2007. The magnetic field structure of this event has already been investigated by Liu et al. (2008) using multi-spacecraft measurements at STEREO-B, ACE, Wind, and STEREO-A and other researches (e.g. Kilpua et al. 2009) which report similar axial directions to that of Liu et al. (2008). Herein, We consider that the axial direction determined by them is correct since Liu et al. (2008) found that output from reconstruction at STEREO-B agrees fairly well with the observations at ACE and Wind. We fit the cylindrical and toroidal IFR models (Marubashi et al. 2007) to this event and then apply our validation method proposed in this study to the outputs from the fittings. We checked whether the outputs with the correct axial direction are judged to be valid and vice versa. We find that the fitting result with correct axial direction is judged valid. However, our validation method also judged some fitting results with wrong axial direction to be valid. We need to improve our validation method to make it work well.

Effect of line-of-sight integration on locations of coronal mass ejection in the sky projection map of interplanetary scintillation observations

*Munetoshi Tokumaru[1], Ken'ichi Fujiki[1], Kazumasa Iwai[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

The g-value derived from interplanetary scintillation (IPS) observations abruptly enhances when a high density (i.e. shocked) plasma associated with a coronal mass ejection (CME) intersects the line-of-sight (LOS). The plane-of-sky location of the line-of-sight, which shows the g-value enhancement, provide information of the radial distance of the CME-driven shock, and enables determination of the shock transit speed in the solar wind between the Sun and the Earth. It should be noted here that IPS measurements include an effect of the LOS integration, and the plane-of-sky location of g-value enhancements is affected significantly by this effect for some cases. The most significant bias is expected for an Earth-directed event. In this study, we investigated the dependence of the LOS integration effect on the radial distance, the angular width, and the non-uniform expansion for an Earth-directed CME. We made calculations of the sky projection map of g-value using the CME model (Tokumaru et al., 2003). As the result, we found that the plane-of-sky location of g-value enhancements tends to underestimate the actual distance of CME, and that this tendency is distinct in the region near the Sun, being less as the CME moves further from the Sun. This means that apparent acceleration is observed for an Earth directed CME propagating with a constant speed. The degree of this tendency is significant for a case with a small angular extent of CME and also for a case with the non-uniform expansion. Such apparent acceleration of CME near the Sun has seldom reported from IPS measurements for Earth-directed CMEs. This fact may suggest that the CME detected by IPS has a sufficiently large angular width, and hence that the acceleration effect is counterbalanced or overwhelmed by intrinsic deceleration of CME during propagation.

Estimation of spatial structure of whistler mode wave packets in Earth's bow shock by multiple spacecraft analysis

*Chika Umegaki[1], Takanobu Amano[1], Naritoshi Kitamura[1]

1. The university of tokyo

There have been a lot of unresolved issues in the generation mechanism of nonthermal charged particles observed ubiquitously in space plasmas. The Fermi acceleration at a shock wave is one of the leading mechanisms for the nonthermal particle acceleration. In this mechanism, it is necessary to confine charged particles in the vicinity of the shock wave while charged particles are being accelerated, which requires pitch angle scattering due to wave-particle interactions. In the case of electrons, whistler mode waves are considered to play a major role in the pitch angle scattering. Whistler mode waves are electromagnetic waves that are right-hand circularly polarized with respect to the background magnetic field. They are thought to contribute to the scattering of electrons by interacting with counter-streaming electrons. In fact, there have been reports of coherent whistler mode waves propagating parallel to the magnetic field in the vicinity of the shock wave (Hull et al., 2012). Recently, it was found that such whistler mode waves are indeed resonantly interacting with suprathermal electrons (Oka et al., 2017). However, it has been known that the acceleration of electrons at the shock is rare, and the relation between whistler mode waves and electron scattering (or acceleration) efficiency has not yet been clarified. The applicability of the standard quasi-linear theory for the electron scattering efficiency by coherent whistler mode waves seen in the shock transition region is not understood very well. For this purpose, one has to identify the spatio-temporal scale of coherent whistler wave packets.
In this study, we aim to estimate the spatial scale of the coherent whistler mode waves around bow shock. For instance, by estimating the scale size of whistler mode wave packets in the direction perpendicular to the magnetic field, we may impose a limit for the energy of electrons being scattered by the wave. This is because gyroradii of electrons must be sufficiently smaller than the perpendicular size of wave packets otherwise the conventional cyclotron resonance theory should not be applicable. For this purpose, simultaneous observations by multiple spacecraft are necessary. In this study, we performed an analysis for high-frequency (~100 Hz) electromagnetic waves observed during bow shock crossings with enhanced energetic electron flux observed by NASA's MMS (Magnetospheric MultiScale) spacecraft.
In particular, we report results for the following two bow shock crossing events: 11:44 UT on October 7, 2015 (Event 1), and 10:29 UT on December 6, 2016 (Event 2). The spacecraft separation was 20 km and 7 km for the Event 1 and Event 2, and comparison between the two may enable us to estimate the scale size of whistler mode wave packets. We applied a band pass filter with for the frequency range 100-250 Hz (fce > 1 kHz) for Event 1, and 50-150 Hz (fce ~ 300 Hz) for Event 2 where prominent peaks were observed in the magnetic field power spectra. We confirmed that whistler mode waves appeared sporadically as wave packets with a short duration (50 - 100 ms). We used MVA (Minimum Variance Analysis) for determining the wave propagation direction. Note that we eliminated the 180-degree ambiguity by referring the Poynting vector direction. Also, we estimated the wavelength from the wave electric-to-magnetic field amplitude ratio using Faraday's law. The obtained wavelengths of the whistler mode waves were roughly 10 km. This indicates that the spacecraft separations were larger (smaller) than the wavelength for the Event 1 (2). By doing the same analysis for each spacecraft, we found that wave packets observed during Event 1 were almost always uncorrelated. On the other hand, both correlated and uncorrelated wave packets were found for Event 2. This suggests that the whistler mode wave packets have spatial scale of a few km. In this report, we will estimate the spatial scale sizes of wave packets in parallel and perpendicular to the magnetic field direction.

Experimental Test for Stochastic Shock Drift Acceleration Theory

*Takanobu Amano[1], Takuma Katou[1], Naritoshi Kitamura[1], Mitsuo Oka[2], Yosuke Matsumoto[3], Masahiro Hoshino[1]

1. Department of Earth and Planetary Science, University of Tokyo, 2. Space Sciences Laboratory, University of California, Berkeley, 3. Department of Physics, Chiba University

High-energy charged particles are ubiquitous in space. They have energies orders of magnitude higher than the thermal energy and often exhibit a power-law distribution in a wide energy range. The collisionless shock is one of the leading mechanisms that may produce such high-energy non-thermal particles. Indeed, radio, X-ray, and gamma-ray observations strongly suggest that shock waves associated with supernova remnants, pulsar winds, relativistic jets in active galactic nuclei and gamma-ray burst are accelerating relativistic electrons. On the other hand, in-situ observations in the heliosphere (at planetary bow shocks, or interplanetary shocks driven by coronal mass ejections) have shown that the acceleration of electrons is, in general, weak or even absent in many of the shock crossings.

We have recently proposed a theory for electron acceleration at shocks that may resolve the observational controversy. The theory referred to as stochastic shock drift acceleration (SSDA) assumes stochastic pitch-angle scattering during electrons are interacting with a collisionless shock. The energy gain comes from the gradient-B drift (due to the magnetic field compression in the shock transition layer) in the direction anti-parallel to the convection electric field and is not associated with the assumed scattering. The scattering is, however, essential to confine the accelerated electrons in the shock transition layer for a long time, because, otherwise they would quickly escape from the system. In other words, the theory assumes that the electron transport obeys the diffusion-convection equation with an energy gain term determined only by the magnetic field gradient. It successfully explains the formation of a power-law energy spectrum, with a maximum energy cut-off determined by the rate of pitch-angle scattering. We here present the result of an experimental test using NASA's MMS (Magnetospheric MultiScale) spacecraft observation of an Earth's bow shock crossing event on December 9, 2016.

In particular, we have checked the following points that are predicted by the theory: (1) exponential increase in energetic particle intensity toward downstream within the shock transition layer, (2) nearly isotropic pitch-angle distribution. We find that both are reasonably satisfied in a thin layer (~7 sec. or ~350 km assuming a shock propagation speed of ~50 km/s) within the shock transition region. The result is then used to estimate the rate of pitch-angle scattering as a function of energy. We find that the pitch-angle scattering rate increases as increasing the particle energy from just above the thermal energy up to a few keV, beyond which it saturates to a nearly constant value. We find that the observed maximum energy cut-off (~30 keV) in the electron energy spectrum is consistent with that predicted by the theory based on the observed pitch-angle scattering rate. All of these results strongly indicate that the observed non-thermal electrons are accelerated by the SSDA.

Radial structure of heliospheric boundary region

*Shuichi Matsukiyo[1], Gary P. Zank[2], Haruichi Washimi[3], Tohru Hada[1]

1. Faculty of Engineering Sciences, Kyushu University, 2. The Center for Space Plasma and Aeronomic Research, University of Alabama in Huntsville, 3. International Center for Space Weather Science and Education, Kyushu University

The kinetic structure of the heliospheric boundaries is investigated using one-dimensional full PIC (Particle-In-Cell) simulations. Both the termination shock and the heliopause are simultaneously reproduced in the simulation. The spatial scale of the heliopause increases as the angle between the heliopause normal and local magnetic field (referred to as the normal angle, hereafter) becomes increasingly oblique. The VLISM region, out side the heliopause, contains compressible flucturations in both magnetic field and plasma density. The fluctuations are originated from the inner heliosheath, the region between the termination shock and the heliopause, pass the heliopause, and propagate away from it. The total pressure, including the plasma pressure and magnetic pressure, at the heliopause is not constant when the normal angle is oblique in contrast to predictions based on MHD theory. In the oblique case, the solar wind plasma and interstellar plasma are able to inter-penetrate by moving along the local magnetic field. Since their bulk velocities along the magnetic field differ from each other, the distributions overlap in phase space so that the effective local plasma pressure parallel to the magnetic field is enhanced. This results in an increase that resembles a hump in the density and parallel pressure of the local plasma, which is not seen in magnetic field.

[J] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Wed. May 29, 2019 3:30 PM - 5:00 PM JST | Wed. May 29, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

[P-EM18] Heliosphere and Interplanetary Space

convener:Ken Tsubouchi(University of Electro-Communications), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Kazumasa Iwai(Institute for Space?Earth Environmental Research (ISEE), Nagoya University)

This session aims to secure comprehensive insights into physical processes of plasmas and fields in the heliosphere. Presentations of the recent studies from any approaches (integrated observations/theoretical modeling/massive numerical simulation) are welcomed. Topics are not restricted to any specific issues: phenomenological studies on solar flares/CME/solar wind, and related fundamental physics problems such as shocks/waves/turbulence/particle transport and acceleration can be the main target, including heliospheric high-energy phenomena and their impact on the Earth's environment.

Comet is a small celestial object whose size is a few to tens of kilometers, consists mainly of water. Some water molecules sublimated from the cometary surface are ionized by the electron impact ionization and by the photoionization, and spread into space. Understanding the physics related to the motion of cometary ions serves important clues in discussion of the temporal/spatial scale of the molecular supply process from the celestial body to space, the transportation process of materials from the comet to other objects, and the atmospheric outflow process in small bodies.

Rosetta is a spacecraft launched by European Space Agency in 2004 and performed in situ observation around comet 67/P Churyumov-Gerasimenko during 2 years, from August 2014 to September 2016. Previous studies of observation results of Rosetta showed that cometary ions are accelerated radially from the comet nucleus (Behar et al., 2018). The motion of cometary ions has been studied under the influence of the electric field, which is the ambipolar electric field, the motional electric field, and the Hall electric field. Behar et al. (2018) suggested that the ambipolar electric field formed by the pressure gradient of electrons contributes to the acceleration of cometary ions around the comet. Although the diffusion and acceleration due to the electric field around the comet are important in understanding the motion of cometary ions, a quantitative evaluation has not been performed. In the present study, we quantitatively evaluate the contribution of the electric field to the acceleration of cometary ions in order to understand the acceleration process of cometary ions observed by Rosetta. We evaluate the acceleration process of cometary ions under the assumed electric field and compare the simulation results with the observation result of Rosetta.

First, we estimate the distribution of the electric field in the region within 1000 km from the comet nucleus. As a first step, we only consider the ambipolar electric field due to the spatial gradient of the pressure distribution of electrons around the comet nucleus, following the discussion of previous studies. We calculate the pressure distribution of electrons from the release rate of comet gas and the ionization rate, which are determined based on observation results, and assume that the electron temperature is 5eV. Next, we perform a test particle analysis to calculate the time evolution of the speed of an H_2O^+ cometary ion under the assumed electric field. We find that the cometary ion with the initial speed of 0.7 km/s is accelerated to 22.6 km/s at the distance of 1000 km from the nucleus. On the other hand, based on Rosetta's observation results, H_2O^+ ions are accelerated to 40 to 80 km/s in the region from 600 to 1000 km from the comet nucleus. We suggest that the acceleration by the ambipolar electric field alone is insufficient to explain the observation results. In this study, we also consider the motional electric field and discuss the contribution of the electric field to the acceleration of ions around the comet.

Energy conversion process at the lunar wake boundary

*Tomoko Nakagawa[1], Hideo Tsunakawa[2], Yoshifumi Saito[3]

1. Information and Communication Engineering, Tohoku Institute of Technology, 2. Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology , 3. JAXA,ISAS

At the lunar wake boundary, the solar wind ions are accelerated toward the center of the wake due to the pressure gradient, and produce vortex motion whose direction is consistent with the polarization of the magnetic fluctuations. The kinetic energy of the solar wind is converted into the electromagnetic energy and then field-aligned electric current.

Electron acceleration at quasi-perpendicular collisionless shock: One-dimensional PIC simulation

*Fumiko Otsuka[1], Shuichi Matsukiyo[2], Mitsuo Oka[3]

1. NIT, Kurume College, 2. ESST, Kyushu Univ., 3. UC Berkeley

A collisionless shock is thought to be an efficient accelerator of charged particles in space. At the quasi-perpendicular side of the earth's bow shock, non-thermal electrons are observed in-situ measurements. However, the electron acceleration process has not been unclear due to limited accuracies of instruments.Magnetospheric Multiscale (MMS) spacecraft launched on 2015 enables us to reveal the electron acceleration process in detail. The instruments measure the waves and particles with high time (millisecond) resolution and accuracy.

In this presentation, we perform one-dimensional particle-in-cell (PIC) simulation of a quasi-perpendicular collisionless shock and discuss electron acceleration at the shock, considering a direct comparison with MMS spacecraft data in mind. We will report the results of the runs with the Alfven Mach number 7, the shock angle (the angle between the background magnetic field and the shock normal) 70-80 degrees, and plasma beta 0.3-3, respectively. We evaluate electron distributions both in energy and pitch-angle, and upstream wave spectra, and discuss their temporal as well as spatial variations. Further, highly accelerated electrons are traced back to indentify their origin and acceleration process.

Tohoku University, Planetary Plasma and Atmospheric Research Center , 5. Tohoku University, Graduate School of Sciense, 6. The University of Tokyo

The Hisaki (SPRINT-A) satellite has a main scientific topic of the planetary magnetspheic physics and atmospheric evoluiton by long-term observations,
but also carried out an observation of helium atom resonance scattering from interplanetary space.
A material in the interstellar medium (ISM) travels into the heliosphere over the heliopause due to the relative velocity between the heliosphere
and interstellar gases. The helium atoms move into the neighboring from the sun without ionizing because of its high ionization energy.
The helium atoms are bent by sun gravity along the Keplerian orbit and forms a high density region on the down wind side, which is called helium
cone. The distribution of helium atoms in the helium cone can estimate the speed and direction of the interstellar wind, and the density and the
temperature of the helium atom in interstellar gases.
This study was carried out from the 1970s, but the interplanetary helium atoms observation is one of powerful tools to recognize the interstellar medium from inside the heliosphere.
The Hisaki satellite carried out the observaiont of the resonance scattering from inside the helium cone during November and December.
The interstellar parameters derived from The Hisaki's observation results of the helium cone four times in years of 2015 - 2018 are reported.

Structural variations in the pickup ion density associated with magnetic reconnection at the heliopause

*Ken Tsubouchi[1]

1. University of Electro-Communications

Pickup ions (PUIs) can be the probe for the physical processes occurring around the heliopause in the form of energetic neutral atoms (ENAs) after their charge-exchange with interstellar neutral particles. In this study, we focus on the nonstationarity of the heliopause, where the directional change in the magnetic field is approaching. This situation triggers the magnetic reconnection at the heliopause, resulting in the mixing of particles between the heliosphere and interstellar space. We have performed two-dimensional hybrid simulations to follow the PUI kinetics. It is confirmed that PUI in the outer heliosheath are gathered into the reconnection site accompanied with the coalescence of magnetic islands. We calculate the column density integrated across the heliopause, which will be associated with the ENA observations by IBEX. The properties of its spatial and temporal variations are compared with those from the case of Kelvin-Helmholtz instabilities along the heliopause. It will be useful for the identification of the heliopause environment by extracting these properties from the observational data.

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan), Chairperson:Takayuki Muto

The Atacama Large Millimeter/Submillimeter Array (ALMA) starated its science operation in 2011, and long-baseline observations have become available since 2014. With its high sensitivity and resolution, ALMA has provided us with qualitatively new information on star and planet formation and small bodies in our Solar System. For example, in the observations of protoplanetary disks, ring-like structures have been commonly found and the structures with the scale of several-AU are discovered in several systems. In our solar system, 60km pixel-scale non-uniform brightness distribution and the rotation of the asteroid Juno are detected. Spatially-resolved thermal mapping of Europa icy surface enables us to search for thermal anomaly in possible plume source regions. As of Cycle 4, Solar observations are available, enabling us, for example, to determine the physical parameters of plasmoid quantitatively. In this session, we overview the latest results of ALMA observations in the field of planetary sciences. We also accept any theoretical and experimental works that are closely related to the observations and discuss the impact on the planetary science community.

Understanding solar atmosphere by ALMA observations

*Tomoko Kawate[1], Takenori J Okamoto[2], Kazumasa Iwai[3], Satoshi Masuda[3], Masumi Shimojo[2]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. National Astronomical Observatory of Japan, 3. Nagoya University

ALMA started solar observations with Bands 3 and 6 from Cycle 4. Millimeter waves at 100 GHz (band 3) and 240 GHz (band6) are radiated by free-free emission in the chromosphere, and brightness temperatures are directly related with electron temperatures by the Planck function. Before ALMA, observations of the chromosphere are mainly performed by absorption lines from UV to near IR. These lines are formed under non-local thermodynamically equilibrium, and it is difficult to interpret brightness temperatures directly with electron temperatures. Thus, ALMA opens a new window for temperature diagnostics in the solar atmosphere.

Although intensities in millimeter wave in a quiet sun are directly related with electron temperatures, where these emissions come from is not well understood. Numerical and observational comparisons between millimeter waves and UV lines are performed in the past. However, temperature structures in the solar atmosphere are complex and full of varieties. We cannot simply estimate the formation region of millimeter waves from the case studies. In order to understand temperature structures in solar atmosphere by ALMA, it is crucial not only to compare between multiwavelength observations but also to understand radiative processes of millimeter waves and chromospheric lines in multiple regions in the solar atmosphere.

We analyze ALMA data of a plage region observed in Cycle 4. We compare the ALMA data with vector magnetic field in the photosphere by Hinode/SP, transition-region images and spectra by IRIS, and chromospheric and coronal images by SDO/AIA. As a result, velocities of a moving feature in a stripe structure in ALMA data correspond to sound speeds in the chromosphere, and it is reasonable to interpret that millimeter waves are emitted from the mid-chromosphere. However, we do not find the same structures between millimeter waves and chromospheric images. In this presentation, we review the preceding studies on the formation region of millimeter waves in the solar atmosphere, introduce the plage observation, compare with numerical simulation of radiative transfer of millimeter wave and chromospheric lines, and discuss what ALMA is looking in the solar atmosphere.

Multi-thermal structures in a spicule observed with ALMA, IRIS, and AIA/SDO

*Masumi Shimojo[1], Tomoko Kawate[2], Takenori Okamoto[1], Takaaki Yokoyama[3]

1. National Astronomical Observatory of Japan, 2. Institute of Space and Astronautical Science , 3. University of Tokyo

A spicule is a key phenomenon for understanding the solar atmosphere. We succeeded in observing a large spicule with ALMA, IRIS, and AIA/SDO simultaneously, and report the details of the spicule in the paper. While an eruption of a blob-like structure shown in the 100 GHz images started just before appearing a spicule in the He II and Mg II images, a spicule seen in 100 GHz image itself began about one minute after beginning the spicule in the He II and Mg II images. The spicule in the 100 GHz images can be seen as an absorbing structure in the Fe XII images. The maximum height and width of the Mg II/He II spicule are larger than those of the 100 GHz/Fe XII spicule. The 100 GHz/Fe XII spicule is included in the Mg II/He II spicule and is located at the southern edge of the Mg II/He II spicule. The rising velocities of the spicule in the Mg II and He II image, and the erupted blob in the 100 GHz images are ~70 km/s. On the other hand, the rising velocity of the spicule in the 100 GHz and Fe XII images is ~40 km/s. Considering of the differences of the structures shown in the Mg II/He II and 100 GHz/Fe XII images, and the typical formation temperature of each band, the 100 GHz and Fe XII images show a cold and dense component of the spicule. The conclusion is consistent with the recently radiative MHD simulations, and we can explain why the 100 GHz spicule is delayed, shorter, and slower than the Mg II/He II spicule. The solar limb observations with ALMA are very few. Hence, it would be not accidentally that the blob-like eruptions are associated with both two large spicules observed with ALMA. The fact might suggest that large spicules included a cold and dense component is produced by magnetic reconnection that is induced by a plasmoid eruption, like a corona jet.

One of the most striking features in Martian atmosphere is a very large (planet-encircling) storm, "global dust storm". The storm lifts the dust particles from the surface into the air, where the dust particles block sunlight from reaching the surface. This brings a decrease of the surface temperature. In contrast, the thickened dust layer absorbs the radiation, and directly leads to heating the atmosphere. Such a drastic change in the thermal structure in the atmosphere induces significant modulation in the dynamics as well as in the composition.

Starting from the middle of June 2018, a global dust storm has occurred on Mars for the first time in the past 11 years. Taking this unique opportunity, we observed Mars with ALMA on 30 June 2018 and 16 July 2018 that correspond to active periods of the global dust storm.

Observing with submillimeter wavelength has a good advantage compared to other optical and infrared wavelengths, since the dust opacity becomes transparent at the submillimeter wave and the emission from deep inside the global dust storm can be detected. We used Band 5 (183 GHz) and 6 (220 and 230 GHz) on 30 June, and only Band 6 on 16 July. Band 6 measurements allow us to investigate maps of temperature vertical profiles and wind fields from the CO lines. Band 5 measurements enable us to investigate maps of water vapor vertical profiles. The preliminary results from these ALMA observations will be discussed in the presentation.

Atmospheric observation of submillimeter wave and the thermal evolution of ice giants

*Kenji Kurosaki[1], Masahiro Ikoma[2]

1. Department of Physics, Nagoya University , 2. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Our solar system has two ice giants: Uranus and Neptune. Voyager II explored Uranus in 1986 and Neptune in 1989 and observed the effective temperature and the gravitational moments that are important to understand the atmospheric and interior structure. Recently by use of ground telescope submillimeter absorption features are observed. Submillimeter observations showed that Uranus did not have remarkable feature while Neptune had absorption features of HCN and CO. That is, atmospheric structures are different between Uranus and Neptune. Since the amount of CO is related to the atmospheric O/H, the observation is expected to restrict the metal enrichment of ice giants. Moreover, the atmospheric structure affects the thermal evolution of the ice giants. In this talk, we focus on ice giants in our solar system.

Planetary-system formation revealed with ALMA

*Misato Fukagawa[1]

1. National Astronomical Observatory of Japan

I review the current understanding of planetary-system formation that has primarily been obtained from observations of protoplanetary disks, the birthplaces of planets, with the radio astronomical telescope, Atacama Large Millimeter/submillimeter Array (ALMA). High angular resolution is one of the most important observing capabilities to address planetary-system formation, given the spatial scale of the planetary systems including the Solar system (30 au to Neptune), and considering the distance to the nearest star forming regions (>100 pc) where we can observe young planet-forming disks. The resolution of ~5 au at least would be necessary to obtain the spatial distribution of disk material (various gas species, dust grains) which are ingredients of planets. ALMA is the interferometer consisting of multiple antennas, providing us the resolution of about 5 au recently. ALMA has provided at least 43 12-m antennas for recent observations, providing also high sensitivity and good image quality.

The ALMA observations have so far shown that (1) rings are common for protoplanetary disk and (2) the diversity in disk structure is still seen including spiral arms and strong non-axisymmetry. Rings and other disk structures often interpreted as the sign of planet-forming activity and these observations have stimulated theoretical study on how planetesimals (km-sized bodies) form and how planet formation proceeds in an entire region of the disk. The detection of various rare molecules including organic ones is another highlight. The emission from such molecules is quite faint and the detections were owing to the ALMA's high sensitivity. Other ALMA results include finding the possible new tool to probe grain growth using polarization, and detections of tenuous gas that may be produced by collisions of cometary or planetary bodies in more evolved debris disks. Those results also give us an insight on the fruitful future in comparative study with the distribution of various material in the Solar system.

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan), Chairperson:Munetake MOMOSE(Ibaraki University)

The Atacama Large Millimeter/Submillimeter Array (ALMA) starated its science operation in 2011, and long-baseline observations have become available since 2014. With its high sensitivity and resolution, ALMA has provided us with qualitatively new information on star and planet formation and small bodies in our Solar System. For example, in the observations of protoplanetary disks, ring-like structures have been commonly found and the structures with the scale of several-AU are discovered in several systems. In our solar system, 60km pixel-scale non-uniform brightness distribution and the rotation of the asteroid Juno are detected. Spatially-resolved thermal mapping of Europa icy surface enables us to search for thermal anomaly in possible plume source regions. As of Cycle 4, Solar observations are available, enabling us, for example, to determine the physical parameters of plasmoid quantitatively. In this session, we overview the latest results of ALMA observations in the field of planetary sciences. We also accept any theoretical and experimental works that are closely related to the observations and discuss the impact on the planetary science community.

Probing dust aggregate structure in protoplanetary disks by millimeter-wave polarization

*Ryo Tazaki[1], Hidekazu Tanaka[1], Takayuki Muto[2], Akimasa Kataoka[3], Satoshi Okuzumi[4]

1. Tohoku University, 2. Kogakuin University, 3. NAOJ, 4. Tokyo Institute of Technology

Dust coagulation in protoplanetary disks is the first step of planetesimal formation and a pathway from dust aggregates to planetesimals remains unclear. Both laboratory and numerical studies have so far shown that the structure of a dust aggregate plays important roles in planetesimal formation. However, the aggregate structure has been poorly constrained by disk observations. Recently, ALMA opens a new window to observe (sub-)millimeter-wave polarization of disks, which is expected to provide additional constraints on dust aggregate properties. In this study, we perform 3D radiative transfer simulations in order to study how the structure of dust aggregates affects millimeter-wave polarization from disks. As a result, it is found that relatively compact particles are favorable to explain observed millimeter-wave scattering polarization of disks, whereas highly porous and fractal particles fail to explain the observations.

1. Department of Physics, Nagoya University, 2. NAOJ, 3. RIKEN, 4. Osaka University

The faint CO gases in debris disks are easily dissolved into C by UV irradiation so that the ratio of C to CO may show the reformation rate of CO depending on the amount of underlying hydrogen molecules. We conduct radiative transfer calculations with chemical reactions for debris disks. We find the C/CO ratio is proportional to the far UV flux and the hydrogen nucleus number density. Using the deriving formula for the C/CO ratio, we give a constraint on the amount of hydrogen for debris disks around 49 Ceti with age ~ 40 Myr; the hydrogen nucleus density ~ 2x10^{-8} cm^{-3}. That implies that the debris disk contains tenuous gases caused by the depletion of a protoplanetary disk.

Structure of the protoplanetary disk around V1094 Sco obtained from dust continuum emission and SED

*Sanemichi Takahashi[1,2], Takayuki Muto[1], Takashi Tsukagoshi[2], Jun Hashimoto[2]

1. Kogakuin University, 2. NAOJ

Understanding the structure of protoplanetary disks is important for revealing the environment of planet formation. Recent ALMA observations have found that detailed structures are formed in protoplanetary disks. In this work, we investigate the structure of the protoplanetary disk around V1094 Sco. We performed numerical calculations of radiative transfer and compared the results with dust continuum emission obtained from ALMA Band 8 observations and SED. According to the dust continuum emission, we found that the disk consists of two regions, inner optically thick region (< 100 au) and outer optically thin region (> 100 au) . We also found that the results can reproduce the SED observations well when (1) disk inner edge is puffed up and the shadow is formed behind it and (2) the small grain (< 1 um) is depleted in the inner region.

The Synthetic ALMA Multiband Analysis of the Dust Properties of the TW Hya Protoplanetary Disk

*Seongjoong Kim[1], Hideko Nomura[1], Takashi Tsukagoshi[2], Ryohei Kawabe[2,3,4], Takayuki Muto[5]

Department of Astronomy, School of Science, University of Tokyo, 5. Division of Liberal Arts, Kogakuin University

Analyzing multiband observations of dust continuum emission is one of the useful tools to constrain dust properties which help us to understand the physical properties of the disks. We perform the synthetic ALMA multiband analysis to find the best ALMA band set for constraining the dust properties of the TW Hya protoplanetary disk. We find that the Band [10,6,3] set is the best set among the possible combinations of ALMA Band [3,4,5,6,7,8,9,10]. We also find two conditions for the good ALMA band sets providing narrow constraint ranges on dust properties; (1) Band 9 or 10 is included in the band set and (2) Enough frequency intervals between the bands. These are related with the conditions which give good constraints on dust properties: the combination of optically thick and thin bands are required, and large β (β is the power-law index of dust opacity, $\kappa_\nu \propto \nu^\beta$) and low dust temperature are preferable. To examine our synthetic analysis results, we apply the multiband analysis to ALMA archival data of the TW Hya disk at Band 4, 6, 7, and 9. Band [9,6,4] set provides the dust properties close to the model profile, while Band [7,6,4] set gives the dust properties deviating from the model at all radii with too broad constraint range to specify the accurate values of dust temperature, optical depth, and β. Since these features are expected by the synthetic multiband analysis, we confirm that the synthetic multiband analysis is well consistent with the results derived from real data.

Dust evolution in the protoplanetary disk around TW Hya

*Takayuki Matsuura[1], Satoshi Okuzumi[1]

1. Tokyo Institute of Technology

Protoplanetary disks are places of planet formation. Therefore, researching construction and evolution of protoplanetary disks is important when we discuss planet formation. In particular, TW Hya is one of the best interesting stars to understand dust evolution in protoplanetary disks. It is a young star with a protoplanetary disk, and the disk has been observed at various wavelengths due to the good observation condition. Particularly, the latest high resolution imaging observation by ALMA revealed that the disk around TW Hya has gaps at 22 au and 37 au.
Various mechanisms of gap formation have been proposed. One of them is due to gravitational interaction between a planet and a disk. Accordingly, considering existence of planets, simulations on disk evolution are carried out. Those simulations show that dust is depleted and a gap forms at planetary orbit. However, the results of the simulations have different tendencies compared with the observation by ALMA, such as dust inside a gap is less than outside, and much dust accumulates on an outer edge of a gap.
Therefore, in this study, we aim to clarify what kind of physical characteristics the disk around TW Hya has in order to reproduce the dust distribution of TW Hya. For that, we simulate dust evolution in a disk and search for parameter ranges that reproduce the radial distribution of brightness temperature and spectral index obtained by ALMA. We assume that planets exist at 22 au and 37 au. We set the planet masses and the fragmentation velocity of dust to free parameters.
As the result, when the planet masses are 4—10 earth masses and the fragmentation velocity is 0.5 m s^{-1} , the simulation result reproduces observation by ALMA roughly. When we assume faster fragmentation velocity than the value that reproduce observation, dust is depleted inner the gap and more dust accumulates on the outer edge of the gap. When we assume heavier planets, more dust accumulates on the outer edge of the gaps and the contrasts of the gaps grow in excess. Thereby the observation is not reproduced.
The fragmentation velocity obtained in this study is slower than the value that has considered from a conventional growth theory of dust in disk. That suggests a possibility that monomers composing dust are large size of 10 μm or more(Wada et al.,2013), or monomers are covered by CO_2 ice(Musiolik et al.,2016). Additionally, the result suggests a possibility that planetesimals formed with the assumption different form scenario that dust coalesces into planetesimals.

Planets are formed from dust and gas in circumstellar disks around young stars.
Observations of dust and gas in circumstellar disks can provide fundamental information on planet formation processes, and high-resolution (sub-)millimeter imaging is now revealing the dust substructure likely generated by forming planets in disks.
Here we report the detection of an excess in dust continuum emission at 233 GHz (1.3 mm in wavelength) in the circumstellar disk around TW Hya, the closest such system to Earth, revealed through high-sensitivity observations with the Atacama Large Millimeter/submillimeter Array (ALMA).

We have carried out 3 au resolution continuum observations at 233 GHz (Band6) toward the protoplanetary disk (PPD) around TW Hya using ALMA in 2016 and 2017.
The sensitivity has been improved by a factor of 3 than that of our previous cycle 3 observations.
The overall structure is axisymmetric, and there are apparent gaps at 25 and 41 au as previously reported.
The most remarkable new finding is a few au scale excess emission at the south-west part of the PPD.
The excess emission is located at 52 au from the disk center and is 1.5 times brighter than the surrounding PPD.
The extracted emission after subtracting the axisymmetric PPD emission has a size of 4.4x1.0 au and a total flux density of 250 micro-Jy, corresponding to a dust mass of 0.03 earth masses.
Since the excess emission can also be marginally identified in the Band 7 image at almost the same position, the blob is unlikely a background source.
The excess emission can be explained by a massive CPD around a Neptune mass forming-planet or a dust clump accumulated in a small elongated vortex.

Observing isotopic fractionations of atmospheric molecules provides an important quantity to constrain physical and/or chemical processes that occur in the planetary atmosphere. Titan has a thick atmosphere mainly composed of nitrogen (N_2). It also contains many nitrogen-bearing compounds such as hydrogen cyanide (HCN), acetonitrile (CH_3CN), and cyanoacetylen (HC_3N), indicating the presence of a complex atmospheric chemistry among these nitriles. It is known that some of these nitriles have an isotopic fractionation that differs from the terrestrial values; for example, $^{14}N/^{15}N$ of HCN is 60 - 70 in Titan atmosphere whereas it is ~272 in the terrestrial atmosphere. Obtaining the $^{14}N/^{15}N$ values on other nitriles will help us to understand what is happening in Titan atmosphere.

Titan has been used as one of calibrator sources of ALMA observations, and therefore, not a few (> 900) data are stored in the ALMA archive. We surveyed all the Titan data in the ALMA archive, and extracted some data which were taken with sufficiently high spatial and spectral resolutions that can be endurable for scientific analyses. After careful investigation on the extracted data, we found one data set which contain the emission lines of the rotational transitions of $CH_3C^{14}N$ and $CH_3C^{15}N$.

By performing an inversion analysis using a radiative transfer model, we derived the nitrogen isotopic ratio on acetonitrile for the first time. Detail of the analysis will be presented in the meeting.

Investigating the gas-to-dust ratio in the protoplanetary disk of HD 142527

*Soon Kang-Lou[1], Munetake Momose[1], Takayuki Muto[2], Takashi Tsukagoshi[3], Akimasa Kataoka[3], Tomoyuki Hanawa[4], Misato Fukagawa[3], Kazuya Saigo[3], Hiroshi Shibai[5]

1. Ibaraki University, 2. Kogakuin University, 3. National Astronomical Observatory of Japan, 4. Chiba University, 5. Osaka University

We present the ALMA observations of the 98.5 GHz dust continuum and the ^{13}CO J = 1 −0 and C^{18}O J = 1 −0 line emission towards the protoplanetary disk of HD 142527. The 98.5 GHz continuum shows a strong azimuthal-asymmetric distribution similar to the previously reported 336 GHz continuum, and its peak emission at the dust concentrated northern region is optically thin at approximately 8 K. In every position angle, the peak brightness temperature of C^{18}O J = 1 −0 emission (≦ 25 K) is lower than that of the optically thick ^{13}CO J = 3 −2 (≈ 36 K), indicating that the C^{18}O is optically thin. We derive the gas and dust surface densities, Σ_g and Σ_d, of the disk of HD 142527 by using the ALMA Band 3 and Band 7 observations. In the analyses we assume the local thermodynamic equilibrium and the disk temperature to be the same as the peak brightness temperature of ^{13}CO J = 3 −2 with continuum emission. We successfully derived the gas-to-dust ratio G/D, defined as Σ_g/Σ_d, distribution across the disk. The ratio varies azimuthally, where it is ~3 and ~20 in the disk northern and southern regions, respectively. We also found that Σ_g varies approximately as $\propto \Sigma_d^{0.5}$, or equivalently G/D $\propto \Sigma_d^{-0.5}$. In addition, our results show that the peak Σ_d is located ahead of the peak Σ_g; if the latter correspond to a vortex of high gas pressure, the results indicate that the dust are trapped ahead of the vortex, which is predicted by theoretical studies.

Super-resolution Imaging of the Protoplanetary Disk HD 142527 Using Sparse Modeling

*Masayuki Yamaguchi[1,2], Kazunori Akiyama[3,2], Akimasa Kataoka[2,6], Takashi Tsukagoshi[2], Takayuki Muto[4], Shiro Ikeda[5], Misato Fukagawa[2], Mareki Honma[2,6], Ryohei Kawabe[2,1,6]

1. The University of Tokyo, 2. National Astronomical Observatory of Japan, 3. Massachusetts Institute of Technology, Haystack Observatory, 4. Kogakuin University, 5. The Institute of Statistical Mathematics, 6. Graduate University for Advanced Studies

Recent Atacama Large Millimeter/submillimeter Array (ALMA) observations have provided new insights for planet formation process and simultaneously highlighted fundamental importance to pursue higher angular resolutions of observations to address opened questions. With the emphasis on improving the fidelity even at a super-resolution regime, many imaging techniques have been intensively developed in the last several years, which may provide substantial improvements in interferometric observations of protoplanetary disks. The CLEAN technique has been widely used, but recently, a new technique using the sparse modeling approach is suggested. This technique directly solves a set of undetermined equations and has been shown to behave better than the CLEAN technique based on mock observations with VLBI (Very Long Baseline Interferometry). However, it has never been applied to ALMA-like connected interferometers nor real observational data. In this work, for the first time, the sparse modeling technique is applied to observational data sets taken by ALMA. We evaluate the performance of the technique by comparing the resulting images with those derived by the CLEAN technique. We use two sets of ALMA archival data at Band 7 (~350GHz) for the protoplanetary disk around HD 142527. One is taken in the intermediate-baseline array configuration, and the other is in the longer-baseline array configuration. The image resolutions reconstructed from these data sets are different by a factor of ~ 3. With the two data sets independently taken by different array configurations, we show that SpM indeed achieves a higher fidelity than a multi-scale CLEAN technique, and provides consistent images from two data sets even beyond significant differences in angular resolutions by a factor ~ 3-4. Two SpM images consistently resolve radially and azimuthally asymmetric dust-grain emission of the outer disk, including a non-circular ridge shape well characterized by a simple logarithmic spiral. Resolved asymmetric structure of the outer disk provided by two SpM images may suggest complex gas kinematics near the inner-edge of the outer disk. Our results demonstrate that ongoing intensive developments of new imaging techniques will be ubiquitously beneficial to current and next-generation radio interferometers.

Detail Structures of Dust Disk around T-Tauri star RY Tau in ALMA High-Spatial Resolution Imaging

*Mihoko Konishi[1,2], Jun Hashimoto[1,2], Hauyu Liu[3], Ruobing Dong[4], Takayuki Muto[5]

1. Astrobiology Center, National Institute of Natural Science, 2. National Astronomical Observatory of Japan, 3. Institute of Astronomy and Astrophysics, Academia Sinica, 4. University of Victoria, 5. Kogakuin University

RY Tau is categorized as a classical T-Tauri star with a mass of 2 solar mass and an age of 2 Myr (e.g., Calvet et al. 2004). The infrared excess indicates an existence of a protoplanetary disk around RY Tau (Furlan et al. 2009), and also the star is active predicted by jet detections (e.g., St-Onge & Bastien 2008). Previously, the disk imaged by the Combined Array for Research in Millimeter-wave Astronomy (CARMA) showed a cavity structure with a radius of about 0.1 arcsec in millimeter dust continuum (Isella et al. 2010), while no structures at >0.4 arcsec were detected in near infrared by Subaru Telescope (Takami et al. 2013). We investigated the visibilities of Atacama Large Millimeter/submillimeter Array (ALMA) archival data, and predicted other fine structures in RY Tau disk. Therefore, we observed with high spatial resolution.
Our observations (Project: 2017.1.01460.S, PI: J. Hashimoto) were conducted in October 2017 in Band 6 (~230 GHz, ~1.3mm). The total integration time was 5.14 minutes. We obtained three kinds of CO isotope (^{12}CO, ^{13}CO, and C^{18}O) as well as dust continuum. The CLEANed image had a beam size of 0.087×0.036 arcsec (PA: 30.7 degree) after the measurement set was calibrated by the code provided by ALMA. The dust emission from RY Tau disk could be detected (inclination: 65.9 degrees, position angle: 22.4 degrees) and the known cavity structure at 0.1 arcsec was clearly resolved. In addition, we confirmed a spatially-resolved gap structure at 0.35 arcsec and brightness asymmetry in the inner ring that were recently reported by Long et al. 2018. We then constructed a symmetric disk model (1 cavity + 1 gap) by comparing azimuthally-averaged visibilities, to investigate details of the gap structure. The best-fitted properties derived by Markov Chain Monte Carlo method showed that the gap is narrow and deep (width: 1.2 au, depth: 0.41). Although the inclination of RY Tau system is large (about 66 degrees), we could resolve the narrow and deep gap. It indicates that the scale height of RY Tau disk is small (< ~0.27 au). Dust might be settled down by some mechanisms such as low turbulence.
It should be noted that a distance of RY Tau measured by Gaia is largely different between Data Release 1 (170 pc) and 2 (440 pc). We found that it is high possibility of 178 pc based on the velocity distribution of ^{12}CO gas taken in our observation and previous ALMA data. In this abstract, a distance of 178 pc is employed for conversion.

Possible inclined inner protoplanetary disk

*Jun Hashimoto[1], Mihoko Konishi[1], Taichi Uyama[2], Christian Ginski[3], Matthias Samland[4]

1. AstroBiology Center, National Institutes of Natural Sciences, 2. University of Tokyo, 3. University of Amsterdam, 4. Max Planck Institute for Astronomy

A young embedded planet in the protoplanetary disk is expected to interact with a parent disk. When the planet is inclined and massive enough (> 1 Jupiter mass), the disk-planet interaction theory predicts the disk inside the planetary orbit breaks from the outer disk. Such a misaligned inner disk can both warp gas velocity structures observed by ALMA and cast the shadows in the outer disk in the near-infrared image. By analyzing the position of the shadows in the outer disk, one can estimate the inclination of the inner disk relative to the outer disk. Furthermore such systems with shadows should be promising targets for searching young inclined planets in the disks, and would help understanding of planetary orbital evolution.

As a part of our survey in archival data obtained with VLT/SPHERE which is the high contrast instrument in near-infrared, we reduced LkHa 330. LkHa 330 is a T Tauri star with a mass of 2.2 solar mass and known to possess gap and spiral structures. By reducing VLT/SPHERE archival data at H band (1.6 micron), we found shadow structures at PA of 85 and 280 degree in the outer disk at 38 AU in radius. We also found a possible bright blob at PA of 160 degree with a separation of 23 AU from the central star. In the poster, we discuss the inclination of the inner disk by comparing our Monte Carlo radiative transfer calculations for the inclined disks and mention future ALMA proposal plan.

Search for the Inner Disk Structures in "Transitional" Disks

*Takayuki Muto[1], Jun Hashimoto[2], Takashi Tsukagoshi[3], Mihoko Konishi[3], Tomoyuki Kudo[3]

1. Division of Liberal Arts, Kogakuin University, 2. Astrobiology Center, 3. NAOJ

We present the ALMA archival search efforts for the discovery search for the inner disk structures in transitional disks. Transitional disks are the class of protoplanetary disks that have inner cavity. Recent discovery of the inner (a few AU scale) ring structures in the DM Tau disk (Kudo et al. 2018, ApJL, 868, L5) indicates that even if there is no detection of near infrared (NIR) excess in SED, the disk may still harbor an inner disk within a known large cavity structures. Such inner disk structures are important in understanding (extrasolar) planet formation since a few AU corresponds to the scale of the orbits of the planets within our Solar System.

A few AU region from the central star can be only probed by high resolution observations with ALMA. Such region is too cold to account for NIR excess while modest resolution (~0.2asec) radio observations can still not resolve the region at the typical distance (~140 pc) of protoplanetary disks.

We have conducted ALMA archival search for the potential transitional disk targets that may harbor inner disks. We present the methods of our search and possible candidates that deserve follow-up ALMA high resolution observations.

[P-CG24] New Developments of Planetary Sciences with ALMA

convener:Takayuki Muto(Division of Liberal Arts, Kogakuin University), Munetake Momose(The College of Science, Ibaraki University), Hideo Sagawa(Faculty of Science, Kyoto Sangyo University), Masumi Shimojo(National Astronomical Observatory of Japan)

The Atacama Large Millimeter/Submillimeter Array (ALMA) starated its science operation in 2011, and long-baseline observations have become available since 2014. With its high sensitivity and resolution, ALMA has provided us with qualitatively new information on star and planet formation and small bodies in our Solar System. For example, in the observations of protoplanetary disks, ring-like structures have been commonly found and the structures with the scale of several-AU are discovered in several systems. In our solar system, 60km pixel-scale non-uniform brightness distribution and the rotation of the asteroid Juno are detected. Spatially-resolved thermal mapping of Europa icy surface enables us to search for thermal anomaly in possible plume source regions. As of Cycle 4, Solar observations are available, enabling us, for example, to determine the physical parameters of plasmoid quantitatively. In this session, we overview the latest results of ALMA observations in the field of planetary sciences. We also accept any theoretical and experimental works that are closely related to the observations and discuss the impact on the planetary science community.

Nitrogen isotopic fractionation on Titan atmosphere: An analysis of ALMA archive data

*Hideo Sagawa[1], Takahiro Iino[2], Takashi Tsukagoshi[3]

1. Kyoto Sangyo University, 2. Tokyo University of Agriculture and Technology, 3. National Astronomical Observatory of Japan

Observing isotopic fractionations of atmospheric molecules provides an important quantity to constrain physical and/or chemical processes that occur in the planetary atmosphere. Titan has a thick atmosphere mainly composed of nitrogen (N_2). It also contains many nitrogen-bearing compounds such as hydrogen cyanide (HCN), acetonitrile (CH_3CN), and cyanoacetylen (HC_3N), indicating the presence of a complex atmospheric chemistry among these nitriles. It is known that some of these nitriles have an isotopic fractionation that differs from the terrestrial values; for example, $^{14}N/^{15}N$ of HCN is 60 - 70 in Titan atmosphere whereas it is ~272 in the terrestrial atmosphere. Obtaining the $^{14}N/^{15}N$ values on other nitriles will help us to understand what is happening in Titan atmosphere.

Titan has been used as one of calibrator sources of ALMA observations, and therefore, not a few (> 900) data are stored in the ALMA archive. We surveyed all the Titan data in the ALMA archive, and extracted some data which were taken with sufficiently high spatial and spectral resolutions that can be endurable for scientific analyses. After careful investigation on the extracted data, we found one data set which contain the emission lines of the rotational transitions of $CH_3C^{14}N$ and $CH_3C^{15}N$.

By performing an inversion analysis using a radiative transfer model, we derived the nitrogen isotopic ratio on acetonitrile for the first time. Detail of the analysis will be presented in the meeting.

Investigating the gas-to-dust ratio in the protoplanetary disk of HD 142527

*Soon Kang-Lou[1], Munetake Momose[1], Takayuki Muto[2], Takashi Tsukagoshi[3], Akimasa Kataoka[3], Tomoyuki Hanawa[4], Misato Fukagawa[3], Kazuya Saigo[3], Hiroshi Shibai[5]

We present the ALMA observations of the 98.5 GHz dust continuum and the ^{13}CO J = 1 −0 and C^{18}O J = 1 −0 line emission towards the protoplanetary disk of HD 142527. The 98.5 GHz continuum shows a strong azimuthal-asymmetric distribution similar to the previously reported 336 GHz continuum, and its peak emission at the dust concentrated northern region is optically thin at approximately 8 K. In every position angle, the peak brightness temperature of C^{18}O J = 1 −0 emission (≦ 25 K) is lower than that of the optically thick ^{13}CO J = 3 −2 (≈ 36 K), indicating that the C^{18}O is optically thin. We derive the gas and dust surface densities, Σ_g and Σ_d, of the disk of HD 142527 by using the ALMA Band 3 and Band 7 observations. In the analyses we assume the local thermodynamic equilibrium and the disk temperature to be the same as the peak brightness temperature of ^{13}CO J = 3 −2 with continuum emission. We successfully derived the gas-to-dust ratio G/D, defined as Σ_g/Σ_d, distribution across the disk. The ratio varies azimuthally, where it is ~3 and ~20 in the disk northern and southern regions, respectively. We also found that Σ_g varies approximately as $\propto \Sigma_d^{0.5}$, or equivalently G/D $\propto \Sigma_d^{-0.5}$. In addition, our results show that the peak Σ_d is located ahead of the peak Σ_g; if the latter correspond to a vortex of high gas pressure, the results indicate that the dust are trapped ahead of the vortex, which is predicted by theoretical studies.

Super-resolution Imaging of the Protoplanetary Disk HD 142527 Using Sparse Modeling

*Masayuki Yamaguchi[1,2], Kazunori Akiyama[3,2], Akimasa Kataoka[2,6], Takashi Tsukagoshi[2], Takayuki Muto[4], Shiro Ikeda[5], Misato Fukagawa[2], Mareki Honma[2,6], Ryohei Kawabe[2,1,6]

Recent Atacama Large Millimeter/submillimeter Array (ALMA) observations have provided new insights for planet formation process and simultaneously highlighted fundamental importance to pursue higher angular resolutions of observations to address opened questions. With the emphasis on improving the fidelity even at a super-resolution regime, many imaging techniques have been intensively developed in the last several years, which may provide substantial improvements in interferometric observations of protoplanetary disks. The CLEAN technique has been widely used, but recently, a new technique using the sparse modeling approach is suggested. This technique directly solves a set of undetermined equations and has been shown to behave better than the CLEAN technique based on mock observations with VLBI (Very Long Baseline Interferometry). However, it has never been applied to ALMA-like connected interferometers nor real observational data. In this work, for the first time, the sparse modeling technique is applied to observational data sets taken by ALMA. We evaluate the performance of the technique by comparing the resulting images with those derived by the CLEAN technique. We use two sets of ALMA archival data at Band 7 (~350GHz) for the protoplanetary disk around HD 142527. One is taken in the intermediate-baseline array configuration, and the other is in the longer-baseline array configuration. The image resolutions reconstructed from these data sets are different by a factor of ~ 3. With the two data sets independently taken by different array configurations, we show that SpM indeed achieves a higher fidelity than a multi-scale CLEAN technique, and provides consistent images from two data sets even beyond significant differences in angular resolutions by a factor ~ 3-4. Two SpM images consistently resolve radially and azimuthally asymmetric dust-grain emission of the outer disk, including a non-circular ridge shape well characterized by a simple logarithmic spiral. Resolved asymmetric structure of the outer disk provided by two SpM images may suggest complex gas kinematics near the inner-edge of the outer disk. Our results demonstrate that ongoing intensive developments of new imaging techniques will be ubiquitously beneficial to current and next-generation radio interferometers.

[A-AS01] High performance computing for next generation weather, climate, and environmental sc iences

convener:Hiromu Seko(Meteorological Research Institute), Takemasa Miyoshi(RIKEN), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology), Masayuki Takigawa(Japan Agency for Marine-Earth Science and Technology), Chairperson:Hiromu Seko(Meteorological Research Institute), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology)

A lot of advanced simulation studies are being conducted by high performance supercomputers, such as K computer and Earth Simulator, in various fields including meteorology. The high performance supercomputers enable us to conduct numerical simulations and data assimilation of observation big-data (huge high-density and high-frequency data) with an order of magnitude higher resolutions and ensemble numbers than those with the previous supercomputers. In addition, the post-K computer will be available as a successor of K, and studies for the post-K computer are in progress. At this session, we comprehensively pick up the topics in the Atmospheric and Hydrospheric Sciences Sessions of the 2019 Union Meeting that comprise the atmospheric, oceanic and land sciences. This session aims to promote recent studies related to the issues on high performance computing in weather, climate, and environmental studies using the K computer and other supercomputers, and to enhance discussions on future directions of numerical simulations in meteorology.

In the projects of 'Advancement of meteorological and global environmental predictions utilizing observational Big Data' of 'The post K computer development plan of the FLAGSHIP2020 Project' and 'Innovating "Big Data Assimilation" Technology for Revolutionizing Very-short-range Severe Weather Prediction', the data assimilation techniques including the coupling with the ocean model have been developed to improve the prediction accuracy of heavy rainfalls, typhoons and tornadoes, and to obtain the longer leading time (the time from the prediction to the occurrences of severe phenomena). The most of these studies were conducted by using the super computer 'K' and Big Observation Data. In this presentation, the impacts of rapid scan'atmospheric motion vector' and sea surface temperature of Himawari-8 on the Typhoon intensity and track predictions and on the rainfall predictions of heavy rainfalls, the assimilation results of all-sky radiance data in the convection scale prediction, and the reproduction of rainfall system that caused tornadoes by the data of Polarization radar and dense surface observation network will be presented.

High-resolution Numerical Weather Simulation with a Large Domain for Extreme Heavy Rainfall Events

*Tsutao OIZUMI[1,2], Kazuo Saito[4,3], le duc[1], Junshi Ito[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. Meteorological Research Institute, 3. The Atmosphere and Ocean Research Institute, 4. Japan Meteorological Business Support Center

In Japan, heavy rainfall occasionally causes disasters such as debris flows. For example, debris flows induced severe societal damages in Izu Oshima Island on 15-16 October 2013 and in Hiroshima City on 19-20 August 2014, western Japan on July 5th –8th 2018. To mitigate these disasters damage and evacuate residents in a timely fashion, an accurate numerical weather prediction (NWP) system is important.
In this study, we conducted an ultra-high resolution NWP simulations (grid spacing is 5 km to 150 m) with a large and small domain area to above heavy rainfall events. Several important model factors (grid spacing, PBL scheme model domain size) influencing heavy rainfall forecasting in NWP models were investigated. The model was an optimized version of the Japan Meteorological Agency Non-Hydrostatic Model for the supercomputer “K”.
The result showed the 2-km grid spacing models showed better precipitation performance than 5-km resolution models. And the 500-m resolution models showed better precipitation performance than 2-km grid spacing models. The 2-km and 500-m grid spacing models with the large model domain show better performance than those with the small domain. Overall, the results indicated that using a high-resolution model (500-m grid spacing) with the large model domain area provides an advantage for simulating heavy rain events.

A Numerical Case Study on a Tornado that Formed in a Quasi Linear Convective System

*Eigo Tochimoto[1], Hiroshi Niino[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

Tornadoes are mainly classified into three groups based on different types of convective systems: supercells, quasi-linear convective systems (QLCSs), and non-supercells. In the United States, it is estimated that 18% of all tornadoes are spawned by QLCSs. In Japan, although tornadoes associated QLCSs also occur and cause severe damages, the detailed features and formation mechanism of tornadoes have not been well under stood. Thus, we performed a high-resolution numerical simulation to reproduce and examine the formation process of a tornado that formed in a quasi linear convective system at Chiyoda-town, Ibaraki prefecture, Japan on 8 December 1992.

A quadruple-nested simulation using Japanese Meteorological Agency non-hydrostatic model was performed. A simulation with horizontal scale of 2km successfully reproduced the QLCS, which propagated eastward quickly and reached around Chiyoda-town at 0830 JST. A cold pool and its associated downdrafts existed behind the convection region with strong updrafts (>10m/s). A simulation with the finest horizontal scale of 50m successfully reproduced the tornado in the QLCS. The vertical vorticity and horizontal velocity exceeded 0.7 $s^{-1}$and 47m/s, respectively. At around 500m height, a low-level mesocyclone, which was accompanied by strong updrafts (>20m/s), formed and developed around the location of tornadogenesis. Near the surface, at 1 or 2 minutes before the tornadogenesis, strong rear-inflow jet (RIJ) accompanied by relatively cold air developed, and then tornado formed in the north of the RIJ. Thus, it is suggested that the RIJ play some roles in the formation and development of the tornado.

Improving the observation operator for Phased Array Weather Radar in the SCALE-LETKF system

*Arata Amemiya[1], Takumi Honda[1], Takemasa Miyoshi[1]

1. RIKEN Center for Computational Science

The observation operator of Phased Array Weather Radar (PAWR; Ushio et al. 2014; Yoshikawa et al. 2013) in the SCALE-LETKF data assimilation system (Lien et al., 2017) is revisited, and the impact of improving the observation operator on the analysis is examined.
Previous studies (Miyoshi et al., 2016, *IEEE*; Miyoshi et al., 2016, *BAMS*) have shown that the three-dimensional fine-scale structure of radar signals observed by PAWR can be successfully assimilated to produce a high-resolution analysis using a regional model SCALE-RM and the local ensemble transformed Kalman filter (LETKF). Forecasts using a high-resolution regional model from the analysis field has a potential to provide reliable precipitation forecasts for longer period of time than a simple nowcasting technique based on an advection scheme, since the explicit physical processes would allow us to capture the development of new convective cells. However, even with an analysis field incorporating such detailed observational data, accurate forecasting of localized convection systems is generally a challenging issue. In the previous studies mentioned above, there was a known problem that the area of strong radar echo calculated from the forecast field starts to expand unrealistically even within several minutes. Along with systematic model biases and imbalance, the observation operator could be the cause of this misrepresentation. Therefore, the observation operator of PAWR is revisited in this study.
The observation operator calculates equivalent radar reflectivity factor (Z_e [mm6/m3]) from hydrometeor mass density of each particle categories (W [g/m^2]). The cloud microphysics scheme in SCALE-RM (Tomita et al., 2008) is a 1-moment 6-caterogy scheme. They include 3 categories for precipitation particles, namely, rain, snow, and graupel. The relation between Z_e and each of W is obtained by an offline numerical calculation of Mie scattering and approximated in the form of an exponential function.
$Z_e = \alpha_r \exp(\beta_r) + \alpha_s \exp(\beta s) + \alpha_g \exp(\beta_g)$
Previous studies used values from a literature (Xue et al., 2009) for the coefficients. However, the coefficients used for graupel (α_g and β_g) has been originally calculated using assumptions about the particle size distribution different from those in SCALE-RM. In particular, a multiplicative factor of the particle size distribution of graupel in SCALE-RM is much smaller in their calculation ($N_0 = 3 \times 10^4$ m^{-4}) than that in SCALE-RM ($N_0 = 4 \times 10^6$ m^{-4}). This leads to an underestimation in sensitivity of graupel mass to observed radar reflectivity factor.
The new coefficients for graupel are chosen to be consistent with the SCALE-RM cloud microphysics scheme using the Joint-Simulator developed by Japan Aerospace Exploration Agency (JAXA). The results are $\alpha_g = 5.54 \times 10^3$, $\beta_g = 1.70$, where the original values from the literature are $\alpha_g = 8.18 \times 10^4$, $\beta_g = 1.50$.
The case study of PAWR assimilation on the localized short-duration heavy rain event on July 13, 2013 is performed again using the new coefficients and compared to previous results (Miyoshi et al., 2016, *IEEE*; Miyoshi et al., 2016, *BAMS*).
The results are shown in Fig. 1. With the new set of coefficients in PAWR observation operator, the evolution for the 30-minute forecast period is closer to the observation than that with the original coefficients. The rapidly-growing unrealistic spread of a large reflectivity area are significantly suppressed. The difference is also clear in the vertical profiles of area-averaged graupel mass. The rapid increase of graupel in the middle troposphere in the conventional forecast experiment implies the recovery from the imbalance by inconsistency between the observation operator and cloud microphysics scheme. The new coefficients lead to improve hte imbalance and provide physically more consistent analysis fields. To

further improve PAWR assimilation, this modification to the observation operator allows us to focus on other factors such as a model error treatment as the next step.

Data assimilation and forecast experiments for the record-breaking rainfall event in Japan in July 2018 with NICAM-LETKF at 112-km and 28-km resolution

*Koji Terasaki[1], Takemasa Miyoshi[1]

1. RIKEN Center for Computational Science

In July 2018, an active Baiu front caused record-breaking rainfalls and disasters in broad areas in western Japan. This study performs data assimilation and forecast experiments using the NICAM-LETKF system (Terasaki et al. 2015, Terasaki et al. 2017) at 112-km and 28-km resolution with 32 ensemble members. The computational efficiency is essential to run the high-resolution data assimilation cycle. Yashiro et al. (2016) developed a new NICAM-LETKF system to reduce the computational cost of the LETKF part by considering a throughput-aware framework. Data assimilation experiments are performed with conventional observations and advanced microwave sounding unit-A (AMSU-A) satellite radiances for one month starting at 0000 UTC 10 June 2018. Next, forecast experiments are initialized every day at 0000 UTC on 1-5 July 2018. The results show that the 28-km resolution experiment outperforms the 112-km resolution experiment for the location and intensity of the heavy rainfall, although the precipitation amount is significantly underestimated compared with the observation. The locations of the Pacific and Okhotsk highs determine the location of the Baiu front. The 112-km resolution may be too coarse to resolve these phenomena sufficiently.
More than a half of the computational time of the LETKF was occupied by file I/O in the previous NICAM-LETKF system. The new NICAM-LETKF system successfully accelerated by reducing the I/O time to be about 20% of the computational time of the LETKF.

Model Parameter Estimation with Data Assimilation Using NICAM-LETKF

*Shunji Kotsuki[1], Yousuke Sato[2], Koji Terasaki[1], Hasashi Yashiro[1], Hirofumi Tomita[1], Masaki Satoh[3], Takemasa Miyoshi[1]

1. RIKEN Center for Computational Science, 2. Graduate School of Engineering, Nagoya University, 3. Atmosphere and Ocean Research Institute, the University of Tokyo

This study aims to improve forecasts of numerical weather prediction (NWP) models by optimizing model parameters with data assimilation. Kotsuki et al. (2018a, JGR) succeeded in improving global precipitation forecasts at 112-km-resolution NICAM (Nonhydrostatic ICosahedral Atmospheric Model) by estimating a parameter called B1 of Berry (1967)' s large-scale condensation scheme using satellite-observed precipitation data and the Local Ensemble Transform Kalman Filter (LETKF).

Extending the previous study, this study explores to improve the forecasts further using other satellite observations. This study estimates the parameter B1 as a global-constant parameter with cloud liquid water (CLW) data observed by GCOM-W/AMSR2. The parameter estimation successfully reduces excessive bias in CLW although precipitation forecasts are degraded. In addition, this study extends to estimate spatial distributions of the B1 parameter. The spatially-varying B1 parameter shows the best agreement to the spatial pattern of observed LWP. This presentation will include the most recent progress up to the time of the meeting.

3D debris flow simulations by using smoothed particle hydrodynamics (SPH) method

*Shoji Ueta[1], Natsuki Hosono[2], Yosuke Alexandre Yamashiki[1]

1. Kyoto University, 2. JAMSTEC

Yamashiki et al. (2012) and Yamashiki et al. (2013) perform laboratory experiments that represent a debris flow. We use smoothed particle hydrodynamics (SPH), Lagrangian numerical hydrodynamics method, and reproduce the experiments by 2D simulations. We find that water does not erode rock by using same size particles between water and rock, but that water can erode rock by using smaller size water particles than rock particle. We could extend this 2D simulation to 3D one and reproduce more realistic results.
Also, debris flows include not only rock and water but also mud. We developed a 3D SPH code that includes the solid-liquid mutual interaction with fully SPH manner to deal with multiphase flow well. We compare the results of the code with the results of a land slide experiment and some simulations in Igarashi et al. (2012) and find that we can get the results similar to those of experiments. We also try to perform more realistic debris flow simulationsin Hiroshima in 2014’s cases.

Keywords: debris flow, smoothed particle hydrodynamics

Regional atmospheric data assimilation coupled with an ocean mixed layer model: a case of typhoon Soudelor (2015)

*Kohei Takatama[1], Takumi Honda[1], Takemasa Miyoshi[1]

1. RIKEN

This study investigates the effect of atmosphere-ocean coupling in a regional atmospheric data assimilation system for a case of Typhoon Soudelor (2015). A simple ocean mixed layer model, known as the Price-Weller-Pinkel (PWP) model, has been implemented into a regional atmospheric data assimilation system SCALE-LETKF.

The results show that the PWP model produced reasonable sea surface temperature (SST) fields in response to the atmospheric flow, particularly, dropping SST associated with the typhoon’ s mixing the ocean upper layers. However, the analyzed track and intensity of the typhoon were not improved by coupling the PWP model. This can be explained by lower SSTs and by smaller ensemble spread of near surface atmospheric temperature. In the atmosphere-ocean coupling system, the stronger a typhoon, the cooler the SSTs via heat releases from the ocean surface and via vertical mixing of the upper ocean. These processes induce negative feedback for the typhoon development, so that the typhoon growth rates are suppressed (enhanced) in ensemble members with strong (weak) typhoon. This results in more similar typhoon intensities among ensemble members. Therefore, the coupled system reduces the ensemble spreads in the atmospheric fields associated with typhoon. The presentation will include the most up-to-date results at the time of the conference.

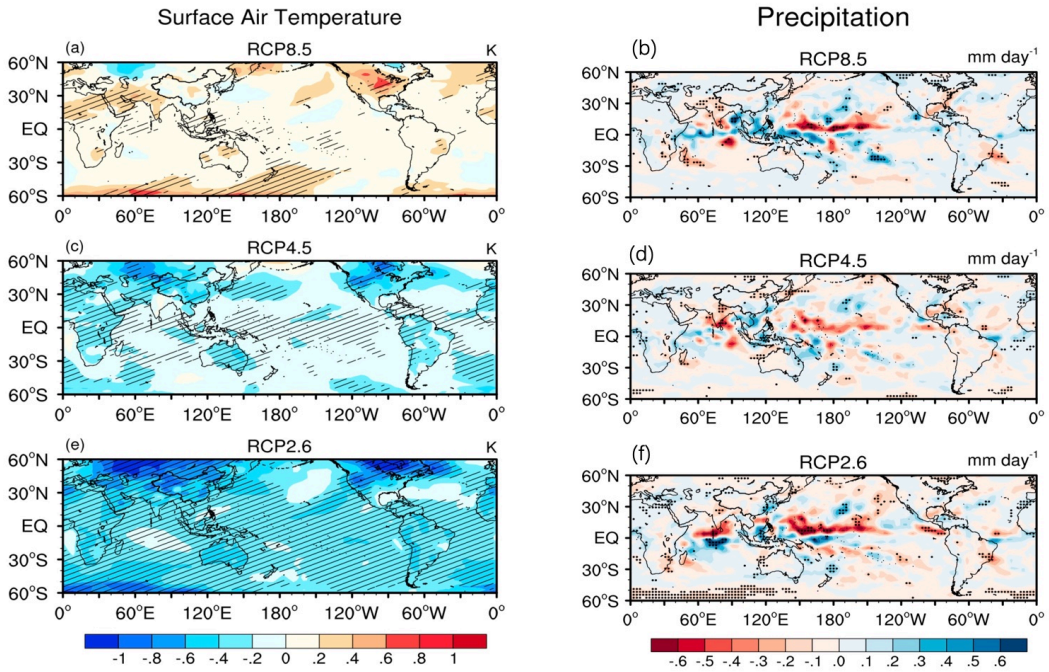
Effective Radiative Forcing and Climate Response to Short-Lived Climate Pollutants Under Different Scenarios

Hua Zhang[1], *Bing Xie[1], Zhili Wang[1]

1. China Meteorological Administration

We used an online aerosol-climate model (BCC_AGCM2.0_CUACE/Aero) to simulate effective radiative forcing and climate response to changes in the concentrations of short-lived climatic pollutants (SLCPs), including methane, tropospheric ozone, and black carbon, for the period 2010–2050 under Representative Concentration Pathway scenarios (RCPs) 8.5, 4.5, and 2.6. Under these three scenarios, the global annual mean effective radiative forcing were 0.1, 0.3, and 0.5 W m^{-2}, respectively. Under RCP 8.5, the change in SLCPs caused significant increases in surface air temperature (SAT) in middle and high latitudes of the Northern Hemisphere and significant decreases in precipitation in the Indian Peninsula and equatorial Pacific. Global mean SAT and precipitation increased by 0.13 K and 0.02 mm d^{-1}, respectively. The reduction in SLCPs from 2010 to 2050 under RCPs 4.5 and 2.6 led to significant decreases in SAT at high latitudes in the Northern Hemisphere. Precipitation increased slightly in most continental regions, and the Intertropical Convergence Zone moved southward under both of these mitigation scenarios. Global mean SAT decreased by 0.20 and 0.44 K, and global averaged precipitation decreased by 0.02 and 0.03 mm d^{-1}under RCPs 4.5 and 2.6, respectively.

Keywords: SLCP/SLCF, ERF, Climate response



The spatial distribution of (left column) surface air temperature and (right column) precipitation resulting from changes of SLCPs, from 2010 to 2050, in (a and b) Representative Concentration Pathway 8.5 (RCP8.5), (c and d) RCP4.5, and (e and f) RCP2.6. The areas with “・” and “/” passed the 95% significance test.

The NICAM–SPRINTARS simulation of the long-range transport of black carbon using the K computer

*Yousuke Yamashita[1], Masayuki Takigawa[1], Daisuke Goto[2], Hisashi Yashiro[3], Masaki Satoh[4,1], Yugo Kanaya[1], Fumikazu Taketani[1], Takuma Miyakawa[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. National Institute for Environmental Studies, 3. RIKEN Advanced Institute for Computational Science (AICS), 4. Atmosphere and Ocean Research Institute, The University of Tokyo

The Nonhydrostatic Icosahedral Atmospheric Model (NICAM)–SPRINTARS is the global aerosol transport model, which has been developed to calculate global aerosol transport and its influences on radiation and precipitation incorporated with the NICAM. The latest model is developed to include the forest fire emission with daily time-scales and has fine horizontal resolution with 56 km, which is capable of simulating fine scales transport processes of aerosols such as the accumulation of black carbon (BC) behind the cold front, and the wetdeposition process around the low-pressure system.
The large and continuous forest fire emission occurred around Lake Baikal of Siberia in September 2016. The observation of BC was performed from August to October by observational cruise of R/V Mirai (MR16-06) possessed by Japan Agency for Marine-Earth Science and Technology (JAMSTEC), and the maximum BC concentration was detected in 25–26 September around Aleutian Islands. These results imply the long-range transport of BC from Lake Baikal to Aleutian Islands, however, possibility of detection of anthropogenic BC emitted in Asia is not ruled out.
To analyze the origin and transport pathway of observed BC by R/V Mirai observation, we performed the experiments of the NICAM–SPRINTARS with anthropogenic and forest fire emission (Ant+Fire simulation) using the K computer. To estimate anthropogenic BC impact, the simulation without fire emission was performed (Ant simulation). Without fire emission, the BC concentration in 25–26 September is much smaller than observation, indicating small impact of anthropogenic BC on this event. In this event the BC is trapped behind the cold front and beyond the warm front to indicate high concentration peak (about 300 ng/m^3) of surface BC with sharp temporal change. This high concentration event is well simulated by the latest 56-km model, however, the low horizontal resolution experiments about 220-km show relatively low concentration peak (about 100–150 ng/m^3) with roughly temporal change.
We also estimate the BC transport to Arctic. The 56-km model simulation with Siberian forest fire emission (Ant+FireSb simulation) indicates a larger increase in Arctic column BC from 22 to 27 September than the Ant simulation, however, the 220-km model simulations indicate no significant difference of the Arctic column BC level to the Ant simulation.
These results indicate that one noticeable impact of latest model development is achieved by replacing the model’s horizontal resolution being 56-km, which is capable of simulating the fine structure of long-range BC transport to impact on the low human activity area such as Arctic and ocean.

High-resolution, ensemble simulations of intense tropical cyclones and their stochasticity during the El Niños of 1997 and 2015

*Yohei Yamada[1], Chihiro Kodama[1], Masaki Satoh[1,2], Masuo Nakano[1], Tomoe Nasuno[1], Masato Sugi[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere and Ocean Research Institute, The university of Tokyo, 3. Meteorological Research Institute, Japan Meteorological Agency

Extreme El Niño events affect the number of intense tropical cyclones (ITCs) over the western North Pacific (e.g., Camargo and Sobel, 2005; Chan 2007). Extreme El Niño events were observed in 1997 and 2015. In the both years, the number of ITC were above normal in the western North Pacific. In order to clarify how, and to what extent, sea surface temperature (SST) anomaly distributions control the ITCs genesis, we conducted 50-member ensemble simulations for boreal summer in 1997 and 2015 using a global nonhydrostatic model called NICAM (Satoh et al. 2014) with a horizontal grid interval of 14 km. Clouds were explicitly calculated using a single-moment bulk microphysics scheme without cumulus convection scheme. The sea surface temperature was nudged toward observed SST data using a slab ocean model.

We found no robust control of ITCs by a prescribed SST distribution. These simulations showed that, even if the same SST was used as the boundary condition for each ensemble simulation, the number of ITCs varied substantially among members. This means that uncertainty remains large for seasonal forecasts of ITC activity. However, the ensemble simulations showed a clear relationship between the number of ITCs and their genesis locations in the western North Pacific. We compared environmental conditions between ensemble members. We found that the simulated numbers of ITCs in the western North Pacific were also closely related to the strength of the monsoon trough, which stochastically varies under given SST conditions. This indicates that reliable seasonal forecasting of ITCs depends on our ability to accurately reproduce the monsoon trough, whose strength is modulated mainly by internal atmospheric variability as well as SST.

NICAM results of the project DYAMOND for global storm-resolving model intercomparison

*Masaki Satoh[1], Ryosuke Shibuya[2], Chihiro Kodama[2]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. JAMSTEC

Project DYAMOND (DYnamics of the Atmospheric general circulation Modeled On Non-hydrostatic Domains; https://www.esiwace.eu/services/dyamond) describes a framework for the intercomparison of an emerging class of atmospheric circulations model that, through their resolution of the major modes of atmospheric heat transport, endeavor to represent the most important scales of the full three-dimensional fluid dynamics of the atmospheric circulation.

Nine models submitted simulations of the forty day intercomparison period. Eight of these employed a tiling of the sphere that was uniformly less than 5km. At these scales vertical accelerations that are non-hydrostatic become important, and convective storms in the tropics can be resolved by the underlying equations of motion. The models and some basic characteristics of their output are described in more detail, as is the availability and planned use of this output for future scientific study.

In this presentation, I will show some results of the DYAMOND simulations with NICAM and current status of DYAMOND with a list of possible participants, together with diagnostics considered.

Categorized correction forecast for accumulative precipitation of heavy rainfall processes based on optimal probability (OPPF) in medium-extended-range forecast time

*Ruoyun Niu[1]

1. National Meteorological Center

By taking the ensemble prediction data from ECMWF and the intensive observations of precipitation in China, the technology of categorized correction forecast for accumulative precipitation of heavy rainfall processes based on optimal probability(OPPF) is developed, and 3 calculation schemes of OPPF are designed according to overall technical route. Then the reforecast test are carried for the accumulative precipitation of 67 heavy rainfall processes from May to September during 1981 to 2015 in China, and the forecast performance of the 3 OPPFs against that of ensemble mean (EMPF) and control number (CTPF) is evaluated and contrasted. The results show that:(1) In the medium-extended-range (096-360h) forecast time, the performance of the 3 OPPFs are better than that of EMPF and CTPF for heavy precipitation forecast and clear-rain forecast. the performance of OPPF1 and OPPF2 is close to that of EMPF for Moderate precipitation and larger precipitation. OPPF3 produces the best performance among the 3 OPPFs. (2) There are obvious regional differences in forecast performances. TS of OPPF3 in southern China are higher than in northern China, and the performance of OPPF3 for heavy precipitation is better than that of EMPF in southern China. During 096-240h forecast time, the performance of OPPF3 for heavy precipitation is also better than that of EMPF in eastern part of Northeast China.

Characteristics of temporal and spatial distribution of regional rainstorm processes to the east of 95ºE in China during 1981-2015

*Ruoyun Niu[1], Couhua Liu[1]

1. National Meteorological Center

The events of the regional rainstorm processes (RRP) to the east of 95ºE in China over 1981-2015 are constructed based on intensive daily observations of precipitation in China and NCEP/NCAR reanalysis data by means of subjective and objective analyses. Temporal and spatial characteristic distribution of RRP in China are further investigated using the methods of wavelet power spectrum, nine-point binomial smoothing and Ward cluster analysis. The main conclusions are as follows. (1) The annual average number of RRP to the east of 95ºE in China is nearly 30. RRP in the Yangtze-Huaihe River valley occur most frequently among the six subareas with an annual average number of about 19, followed by that in South China and the eastern part of Southwest China with the annual average number of RRP 10.5 and 5.8 times respectively. Annual average number of RRP are only about 1-3 times in other subareas. (2) The inter-annual and inter-decadal variations of the annual number of RRP exhibit distinct fluctuation characteristics. The inter-annual and inter-decadal fluctuating variation in the Yangtze-Huaihe River valley is the most consistent with that to the east of 95E in China. Moreover, the fluctuating variations have a significant positive correlation between South China and eastern part of Southwest China, and also between Northeast China and North China. The annual number of RRP over the east of 95E in China and its subareas demonstrates a periodic variation of 2-4a, and also shows a periodic variation of 6-10a in the Yangtze-Huaihe River valley and South China and eastern part of Northwest China, while a 13-17a oscillation can be found in North China.(3) On the whole, the occurrence frequency of RRP to the east of 95E in China is the most in summer (especially in July), the least in winter, and higher in spring than in autumn. The months when RRP occur most frequently are June and July in the Yangtze-Huaihe River valley and eastern part of Southwest China, and May and June in South China. RRP mainly appear in July and August in other subareas.(4) The distribution patterns of RRP to the east of 95E in China are divided into 7 types. The heavy precipitation areas for pattern Ⅰ-Ⅳ migrate northward step by step from South China and southern part of Yangtze River valley to Huanghuai Basin and eastern part of Sichuan Basin.The heavy precipitation areas of pattern Ⅴ-Ⅶ all are located at the Coastal region of Southeast China.

Near-real-time SCALE-LETKF forecasts of the record breaking rainfall in Japan in July 2018

*Takumi Honda[1], Guo-Yuan Lien[2,1], Takemasa Miyoshi[1]

1. RIKEN Center for Computational Science, 2. Central Weather Bureau

In July 2018, a stationary precipitation band associated with the Baiu front induced a record breaking rainfall and caused catastrophic destruction in Japan. This event was successfully captured by the near-real-time (NRT) SCALE-LETKF system (Lien et al. 2017) consisting of the Scalable Computing for Advanced Library and Environment-Regional Model (SCALE-RM, Nishizawa et al. 2015; Sato et al. 2015) and the Local Ensemble Transform Kalman Filter (LETKF, Hunt et al. 2007; Miyoshi and Yamane 2007). This system has been continuously operated since 2015 with an 18-km mesh model domain and the ensemble size of 50. In the NRT SCALE-LETKF system, only conventional observations are assimilated every 6 hours. By conducting a series of 50-member ensemble forecasts from the 6-hourly SCALE-LETKF analyses, this study aims to investigate predictability of this torrential rainfall event and important factors that contributed to the heavy precipitation. In general, the NRT SCALE-LETKF system provides skillful ensemble forecasts of the rainfall a few days in advance. Interestingly, the forecast skill exhibits sudden improvement due to assimilating conventional observations at a single location far southwest from the peak accumulated rainfall location. Forecast differences and ensemble correlations suggest that an extratropical cyclone over the Sea of Japan and a low-level trough near Taiwan play important roles in determining the front location.

An objective Frontal Analysis Techniques and Application in Model Verification

*Couhua Liu[1]

1. National Meteorology Centre of China Meteorological Administration

This paper presents an objective Frontal analysis method based on pressure field for east Asia. Comparing to methods based on thermo-dynamical elements such as temperature, the method developed in this paper can avoid the complex affection from sea-land and landform. The method will be used to identification of fronts in analysis and prediction of ECMWF model all over 2015, and then model error of predicted fronts will be verification. The verification result show that, comparing to analysis field, the moving speed of fronts in prediction field of ECMWF model is slower and strength is weaker.

Assimilating every 30-second phased array weather radar data in a torrential rainfall event on July 6, 2018 around Kobe city

*Yasumitsu Maejima[1], Shigenori Otsuka[1], Takemasa Miyoshi[1,2]

1. RIKEN Center for Computational Science, 2. University of Maryland, College Park

To investigate the impact of every 30-second phased array weather radar (PAWR; Yoshikawa et al. 2013, Ushio et al. 2014) observation on a simulation of a severe rainfall event occurred on July 6, 2018 around Kobe city, we perform 30-second-update 100-m-mesh data assimilation (DA) experiments using the Local Ensemble Transform Kalman Filter with the Scalable Computing for Advanced Library and Environment regional numerical weather prediction model. Two experiments were performed: the test experiment with every 30-second PAWR observation (TEST), and the other without observation (NO-DA).

The TEST analysis shows intense rainfalls with detailed structure of active convection, better matching with the PAWR observation compared to NO-DA analysis. In the forecast experiment, the forecast initialized by the ensemble mean analysis of TEST is skillful for 20 minutes compared with NO-DA, although the skill is decreased rapidly. The results suggest that the PAWR DA have a potential to improve the numerical simulation for this torrential rainfall event.

The impact of range sidelobes from phased array weather radar observations to short-range convective forecasts

*James David Taylor[1], Guo-Yuan Lien[1], Shinsuke Satoh[2], Takemasa Miyoshi[1]

1. RIKEN Research center for computational science, 2. NICT National Institute of Information and Communications Technology

Range sidelobes are an erroneous feature of radar observations that are generated by the pulse compression process used to improve the range resolution of target echoes in high resolution radar systems. Phased array weather radar (PAWR) is an advanced radar system providing very dense observations of reflectivity and Doppler radial velocity at 100m range resolution for over 100 elevation angles every 30 seconds. The use of pulse compression in PAWR to provide very high range resolution data makes it subject to these types of errors, which can result in false echoes observed at other ranges.

In this study we investigate the impact of assimilating range sidelobes from PAWR observations to short-range convective forecasts. This happens frequently in the current QC algorithm, although we plan to improve the QC in the future. We employ the use of the SCALE-LETKF system which couples the Local Ensemble Transform Kalman Filter (LETKF) with the Scalable Computing for Advanced Library and Environment (SCALE)-RM model. We focus on a convective rainfall event in August 2016 that brought heavy, intense rainfall over Osaka. PAWRs located in Suita, Osaka and in Kobe well-captured the convective system over its life cycle but featured prominent range sidelobes as part of their observations. Here, observations from both radars are first used to identify the range sidelobes before performing a series of 30-second update cycling experiments using observations from the Suita PAWR both with and without range sidelobes within a high-resolution 100-m mesh. As well as investigating their impact on short-range forecasts, we aim to show how we can further the usefulness of having two sets of PAWR observations to observe the same convective system by using them to identify and remove range sidelobes and improve short-range forecasts of severe convective events through the assimilation of this data.

Development of Hydro-debris 2D model for larger area

*Yosuke Alexandre Yamashiki[1], Tsutao OIZUMI[2], Bruno Ribeiro[1], Ryusuke Kuroki[1]

1. Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University, 2. Japan Association of Marine-Earth Science and Tecnology

The Hydro-debris 2D model has been developed and applied for both larger and limited zones in the Hiroshima debris-flow disasters that occurred both in 2014 & 2018. The model application for hindcast for wider and limited areas with the same scheme is tested in order to obtain better and precise hindcast as well as a future forecast of rainfall-induced debris flow disasters by improving the geological classification module for the initiation of the debris flow. A universal algorithm for predicting the debris flow disasters solely by the initial geological boundary conditions and forecasted rainfall distribution may contribute to improving early warnings in this field.

Research on the application of an improved terrain-following vertical coordinates on GRAPES model

*chao li[1]

1. NWPC.CMA

Errors caused by topographic feathers of the coordinate planes can be reduced with the Smoothed-level terrain-following coordinate(T-F coordinate for short). On higher layors,coordinate planes of T-F coordinate based on trigonometric function of cos (COS coordinate for short)are horizontal with almost none errors. However,on the lower layers,thickness between planes is too small to keep the model stability.At the same time,it will bring larger calculating errors which result in bad performance of the model.Considering all above,an improved COS coordinate is designed to average the thickness of COS coordinate planes.
Ideal and real case tests are conducted with the GRAPES_Meso model using the improved COS coordinate.The results of the tests indicate that:compared with the COS coordinate, the improved COS coordinate ,on one hand ,keep the planes horizontal on the higher layers ,on the other hand, lead the distribute of the coordinate planes more uniformity , which greatly reduced the errors on the lower layers;The coordinate can reproduce in general the mountain induced gravity waves in comparison to the analytic solution. However, the shapes,vertical structures and intensity of the waves are better simulated by the improved COS coordinate, in the lower levels where the COS coordinate didn’ t behave so better. In the one-month real case tests, the improved COS coordinate gives the better results in terms of smaller forecast bias and root mean square error, and higher anomaly correlation coefficients than the COS coordinate. In conclusion, the improved COS coordinate solves the calculation problems of the COS coordinate ,and improves the prediction ability.

Development of a parallel spherical harmonic transform library: design and performance

*Fuyuki SAITO[1]

1. Japan Agency for Marine-Earth Science and Technology

The spherical harmonic transform (SHT) is a typical method to describe the dynamical core in climate models (e.g. MIROC). SHT is a combination of two transformation: a Fourier transformation in longitude and an associate Legendre transformation in latitude. Therefore, a simple way to introduce SHT in parallel computing is to apply domain decomposition in latitudes only, involving a relocation in latitudes before/after the Legendre transformation. However, the number of maximum processors is limited by the size of latitude dimension, which is an obstacle to more efficient computing. Recently the `physics' routines in a climate model have become more and more complex and expensive, thus the heavy computation significantly suffers from the limitation. A new (yet-another) library, Flageolet, has been developed to help parallel processing of SHT in particular for climate models like MIROC, to support more flexible domain decomposition, following the approach adopted in several 3D FFT libraries and also some climate models. As a continuation of last-year's presentation, which reports the design and performance of FFT part, those of SHT part as well as transposition part between FFT and ALT are reported in this study for various sizes of domain around T213 etc, examined on the Earth simulator.

Global data assimilation of multi-species satellite measurements for atmospheric chemistry analysis

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Koji Ogochi[1], Kengo Sudo[3,1], Masayuki Takigawa[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Jet Propulsion Laboratory/California Institute for Technology, 3. Graduate School of Environmental Studies, Nagoya University

Information on tropospheric ozone and its precursors are important for human health, ecosystem, and climate studies. The combined use of satellite measurements of ozone and its precursors has great potential to provide comprehensive information on the tropospheric chemistry system on various spatial scales. In this study, we present the results of global data assimilation of multi-species measurements (O_3, NO_2, CO, HNO_3, and SO_2) from multi-satellite sensors (OMI, GOME-2, SCIAMACHY, MOPITT, TES, and MLS) using the ensemble Kalman filter approach (Miyazaki et al., 2015). We demonstrated that increasing horizontal resolution from 2.8 to 0.56 degree is necessary for capturing high concentrations of NO_2 in the megacities, whereas 1.1-degree resolution is more suitable for optimizing tropospheric chemistry system on regional and global scales considering the current computational resources (computational cost was larger by a factor of 10 at 0.56-dgree resolution than at 1.1-degree resolution). Using the data assimilation system at 1.1-degree resolution, we constructed an updated version of tropospheric chemistry reanalysis (TCR-2; Miyazaki et al., in prep.) data for 2005—2017, which provide valuable information on decadal changes in air pollutant concentrations and emissions. The estimated NO_x emissions were strongly increased from 2005 to 2011 (+37%/decade) and decreased from 2011 to 2017 (-37%/decade) in China, while the emissions exhibited decreasing trends in Europe (-11%/decade) and the United States (-27%/decade) and an increasing trend in India (+23%/decade) during 2005—2017. A post peta-scale supercomputer such as post-K computer will facilitate the data assimilation calculation to produce tropospheric chemistry reanalysis data at 0.56-degree resolution for air pollutions on a megacity scale globally in a consistent way, which will benefit future study of atmospheric environment on various spatial scales.

The sensitivity to WRF shortwave radiation parameterizations in prediction of global horizontal irradiance for investigating interactions of atmosphere with croplands

*Ankur Srivastava[1], Sarita Kumari[1], Rajkumar Dhakar[2]

1. Indian Institute of Technology Delhi, 2. Indian Agriculture Research Institute

The present study intends to evaluate the Advanced Research Weather Research Forecating (ARW) model performance in representing the observed global horizontal irradiance (GHI) measurements while using different shortwave radiation (SWR) parameterization schemes. Two cases are considered, first case is ‘clear sky condition’ which includes model simulation of a clear/ cloudless day and second case is ‘all sky condition’ which includes model simulations of a cloudy and a rainy day. The above two cases are formulated on the basis that amount of incoming SWR will be different in each case owing to the differences in atmospheric conditions.
For the mentioned instances dates of 23rd February, 9th January and 12th March of 2016, which are clear, cloudy and rainy days respectively, are chosen for WRF model simulation. The shortwave radiation schemes that were evaluated are: Dudhia, Community Atmosphere Model (CAM), the updated Rapid Radiative Transfer Model (RRTMG), the updated Goddard and the
Goddard Fluid Dynamics Laboratory (GFDL) schemes. The model generated predictions are verified against the GHI measurements at weather station of Indian Agriculture Research Institute (IARI), New Delhi.
All schemes perform better under ‘clear sky condition’ i.e. for clear/cloudless day. For both the cases Dudhia scheme performs best with Mean Bias (MB) of 62.84 Wm^{-2} for clear day, 86.44 Wm^{-2} for cloudy day and 89.44 Wm^{-2} for rainy day. All-inclusive, the model derived predictions are over estimated in all the schemes.

The development of an atmospheric aerosol/chemistry–climate model, BCC_AGCM_CUACE2.0, and simulated effective radiative forcing of nitrate aerosols

*QI AN[1,2,4], Hua Zhang[2], Zhili Wang[2], Yi Liu[1,4], Bing Xie[3], Qianxia Liu[3], Zaizhi Wang[3], Sunling Gong[2]

1. LAGEO, IAP, CAS, 2. LaSW, CAMS, 3. NCC,CMA, 4. UCAS

As important components of total anthropogenic aerosols, nitrate aerosols have large impacts on aerosol radiative forcing and climate at regional and seasonal scales, but few current climate models coupled nitrate chemical modules online. This study developed a next-generation atmospheric aerosol/chemistry–climate model, the BCC_AGCM_CUACE2.0. Then, the performance of the model for nitrate was evaluated, and the direct radiative forcing (DRF) and effective radiative forcing (ERF) due to nitrate were simulated for the present day (2010), near future (2030) and middle future (2050) under the Representative Concentration Pathway (RCP) 4.5, 6.0, and 8.5 scenarios relative to the pre-industrial era (1850). The model reproduced the distributions and seasonal changes in nitrate loading well and simulated surface concentrations matched observations in Europe and North America. Current global mean annual loading of nitrates was predicted to increase by 1.12 mg m^{-2} relative to 1850, with the largest increases occurring in East Asia (3.89 mg m^{-2}), Europe (3.6 mg m^{-2}), and South Asia (1.86 mg m^{-2}). The current global mean annual ERF of nitrates was −0.21 W m^{-2} relative to 1850. Due to global reductions in pollutant emissions, the nitrate ERF values were predicted to decrease to −0.17 and −0.20 W m^{-2} in 2030, −0.07 and −0.18 W m^{-2} in 2050 for RCP4.5 and 6.0 relative to 1850, respectively. Under RCP8.5, nitrate ERF values were −0.24 and −0.19 W m^{-2} in 2030 and 2050, respectively. Although global mean nitrate values showed a declining trend, future nitrate loading remained high in East Asia and South Asia.

Impacts of different types and intensities of El Niño events on winter aerosols over China

*Xiaochao Yu[1,2], Zhili Wang[2,1], Hua Zhang[2], Shuyun Zhao[3]

1. Collaborative Innovation Center on Forecast and Evaluation of Meteorological Disasters, Nanjing University of Information Science and Technology, Nanjing, 210044, China, 2. State Key Laboratory of Severe Weather and Key Laboratory of Atmospheric Chemistry of CMA, Chinese Academy of Meteorological Sciences, Beijing, 100081, China., 3. National Climate Center, China Meteorological Administration, Beijing, 100081, China

El Niño is a strong signal of interannual climate variability. The occurrence of an El Niño event may have an important impact on atmospheric pollutant concentrations in China through changes to the regional climate. This study quantitatively examines the differences among the effects of different types and intensities of El Niño events on winter mean aerosol concentration and severe haze days in China. It is found that Central Pacific (CP) El Niño events lead to larger increases in the aerosol burden over southern China relative to the same intensity of Eastern Pacific (EP) events. For El Niño events of the same type but with different intensities, moderate events induce large increases in surface aerosol concentrations over the entire eastern China, while strong and weak events lead to obvious decreases in the surface aerosol concentration over northern China. These differences are mainly attributed to changes in atmospheric circulation, with the resulting changes in aerosol mass transport occurring in response to the different types of El Niño event. Except for moderate CP events, all kinds of El Niño events lead to an increase in severe haze days in winter over northern China. Strong and weak EP El Niño events and weak CP El Niño events lead to an increase in severe haze days in winter over southern China. A change in the south-north transport of aerosols caused by El Niño events also play a dominate role in changing the occurrence of winter haze days in China.

High Cloud Annual Variation and Its Responses to Global Warming in the NICAM AMIP Experiment

*Ying-Wen Chen[1], Masaki Satoh[1,2], Chihiro Kodama[2], Akira Noda[2], Yohei Yamada[2]

1. Atmospheric and Ocean Research Institute, The University of Tokyo , 2. Japan Agency for Marine-Earth Science and Technology

Uncertainties in climate sensitivity mainly come from the ambiguities in simulations of both high- and low-level clouds. The previous studies using NICAM’s short time simulation showed that the both the altitudes and amount of high clouds increase under the global warming condition, while other climate models show high cloud amount contrarily decreases.
Due to the progress in computer performance, long term climate simulation with $x < 20$ km becomes available. A pair of 25-year climate simulation (present and warming climate) with 14-km horizontal resolution (NICAM AMIP-like simulation, Kodama et al. 2015) has been performed by K computer. In this study, we analyze how the annual variation in high clouds is presented in the NICAM AMIP-like simulation. Satellite and in-situ data are used to investigate whether NICAM captures the observed responses of high clouds to the mean sea surface temperature (SST). Regressions between the high cloud amount variation and the SST variation is different with altitudes; positive regressions appear at altitudes above 100 hPa while negative regressions are found in altitudes below 100 hPa. The results are consistent with previous study based on observations (Zelinka and Hartmann 2011). Further analysis showed that the spatial pattern of high clouds is mainly associated with the El Nino response; as SST warmer, the high clouds shift in the eastern Pacific with higher. The increase of high clouds is associated with the increase of ice water content of cloud ice and snow. We argue that the response of high clouds to global warming is also explained by the change in the spatial distribution of the high clouds.

Improvements in Simulating the Relationship between ENSO and East Asian Summer Rainfall in the CMIP5 Models

*Yuanhai FU[1], Riyu Lu[1]

1. IAP, CAS

There is a significant relationship between the preceding winter El Niño–Southern Oscillation (ENSO) and the subsequent East Asian summer rainfall (EASR), and this relationship is helpful for seasonal forecasting in East Asia. This study investigated the relationship between the preceding winter ENSO and EASR in the Coupled Model Intercomparison Project Phase 5 (CMIP5) models and compared the results with those from the CMIP3 models. In general, the CMIP5 models capture the ENSO–EASR relationship more realistically than the CMIP3 models. For instance, approximately two-thirds of the CMIP5 models capture the ENSO–EASR relationship, while less than one-third of the CMIP3 models capture the relationship. Further investigation suggests that the improvement could be attributed to simulating the physical processes of ENSO's impact on the EASR more realistically in the CMIP5 models, particularly the effect of ENSO on tropical Indian Ocean SST and the effect of Indian Ocean SST anomalies on the atmospheric convection over the Philippine Sea. However, there is large diversity in the ENSO–EASR relationship in the CMIP5 models, and most of the models underestimate the relationship. This underestimation comes from the underestimation of the physical processes, particularly from the underestimated impact of the atmospheric convection over the Philippine Sea on the EASR. The CMIP5 models that capture the ENSO–EASR relationship well/bad also show high/low skill in representing the physical processes.

[A-AS01] High performance computing for next generation weather, climate, and environmental sc iences

convener:Hiromu Seko(Meteorological Research Institute), Takemasa Miyoshi(RIKEN), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology), Masayuki Takigawa(Japan Agency for Marine-Earth Science and Technology)

A lot of advanced simulation studies are being conducted by high performance supercomputers, such as K computer and Earth Simulator, in various fields including meteorology. The high performance supercomputers enable us to conduct numerical simulations and data assimilation of observation big-data (huge high-density and high-frequency data) with an order of magnitude higher resolutions and ensemble numbers than those with the previous supercomputers. In addition, the post-K computer will be available as a successor of K, and studies for the post-K computer are in progress. At this session, we comprehensively pick up the topics in the Atmospheric and Hydrospheric Sciences Sessions of the 2019 Union Meeting that comprise the atmospheric, oceanic and land sciences. This session aims to promote recent studies related to the issues on high performance computing in weather, climate, and environmental studies using the K computer and other supercomputers, and to enhance discussions on future directions of numerical simulations in meteorology.

Categorized correction forecast for accumulative precipitation of heavy rainfall processes based on optimal probability (OPPF) in medium-extended-range forecast time

*Ruoyun Niu[1]

1. National Meteorological Center

By taking the ensemble prediction data from ECMWF and the intensive observations of precipitation in China, the technology of categorized correction forecast for accumulative precipitation of heavy rainfall processes based on optimal probability(OPPF) is developed, and 3 calculation schemes of OPPF are designed according to overall technical route. Then the reforecast test are carried for the accumulative precipitation of 67 heavy rainfall processes from May to September during 1981 to 2015 in China, and the forecast performance of the 3 OPPFs against that of ensemble mean (EMPF) and control number (CTPF) is evaluated and contrasted. The results show that:(1) In the medium-extended-range (096-360h) forecast time, the performance of the 3 OPPFs are better than that of EMPF and CTPF for heavy precipitation forecast and clear-rain forecast. the performance of OPPF1 and OPPF2 is close to that of EMPF for Moderate precipitation and larger precipitation. OPPF3 produces the best performance among the 3 OPPFs. (2) There are obvious regional differences in forecast performances. TS of OPPF3 in southern China are higher than in northern China, and the performance of OPPF3 for heavy precipitation is better than that of EMPF in southern China. During 096-240h forecast time, the performance of OPPF3 for heavy precipitation is also better than that of EMPF in eastern part of Northeast China.

Characteristics of temporal and spatial distribution of regional rainstorm processes to the east of 95ºE in China during 1981-2015

*Ruoyun Niu[1], Couhua Liu[1]

1. National Meteorological Center

The events of the regional rainstorm processes (RRP) to the east of 95ºE in China over 1981-2015 are constructed based on intensive daily observations of precipitation in China and NCEP/NCAR reanalysis data by means of subjective and objective analyses. Temporal and spatial characteristic distribution of RRP in China are further investigated using the methods of wavelet power spectrum, nine-point binomial smoothing and Ward cluster analysis. The main conclusions are as follows. (1) The annual average number of RRP to the east of 95ºE in China is nearly 30. RRP in the Yangtze-Huaihe River valley occur most frequently among the six subareas with an annual average number of about 19, followed by that in South China and the eastern part of Southwest China with the annual average number of RRP 10.5 and 5.8 times respectively. Annual average number of RRP are only about 1-3 times in other subareas. (2) The inter-annual and inter-decadal variations of the annual number of RRP exhibit distinct fluctuation characteristics. The inter-annual and inter-decadal fluctuating variation in the Yangtze-Huaihe River valley is the most consistent with that to the east of 95E in China. Moreover, the fluctuating variations have a significant positive correlation between South China and eastern part of Southwest China, and also between Northeast China and North China. The annual number of RRP over the east of 95E in China and its subareas demonstrates a periodic variation of 2-4a, and also shows a periodic variation of 6-10a in the Yangtze-Huaihe River valley and South China and eastern part of Northwest China, while a 13-17a oscillation can be found in North China.(3) On the whole, the occurrence frequency of RRP to the east of 95E in China is the most in summer (especially in July), the least in winter, and higher in spring than in autumn. The months when RRP occur most frequently are June and July in the Yangtze-Huaihe River valley and eastern part of Southwest China, and May and June in South China. RRP mainly appear in July and August in other subareas.(4) The distribution patterns of RRP to the east of 95E in China are divided into 7 types. The heavy precipitation areas for pattern Ⅰ-Ⅳ migrate northward step by step from South China and southern part of Yangtze River valley to Huanghuai Basin and eastern part of Sichuan Basin.The heavy precipitation areas of pattern Ⅴ-Ⅶ all are located at the Coastal region of Southeast China.

Near-real-time SCALE-LETKF forecasts of the record breaking rainfall in Japan in July 2018

*Takumi Honda[1], Guo-Yuan Lien[2,1], Takemasa Miyoshi[1]

1. RIKEN Center for Computational Science, 2. Central Weather Bureau

In July 2018, a stationary precipitation band associated with the Baiu front induced a record breaking rainfall and caused catastrophic destruction in Japan. This event was successfully captured by the near-real-time (NRT) SCALE-LETKF system (Lien et al. 2017) consisting of the Scalable Computing for Advanced Library and Environment-Regional Model (SCALE-RM, Nishizawa et al. 2015; Sato et al. 2015) and the Local Ensemble Transform Kalman Filter (LETKF, Hunt et al. 2007; Miyoshi and Yamane 2007). This system has been continuously operated since 2015 with an 18-km mesh model domain and the ensemble size of 50. In the NRT SCALE-LETKF system, only conventional observations are assimilated every 6 hours. By conducting a series of 50-member ensemble forecasts from the 6-hourly SCALE-LETKF analyses, this study aims to investigate predictability of this torrential rainfall event and important factors that contributed to the heavy precipitation. In general, the NRT SCALE-LETKF system provides skillful ensemble forecasts of the rainfall a few days in advance. Interestingly, the forecast skill exhibits sudden improvement due to assimilating conventional observations at a single location far southwest from the peak accumulated rainfall location. Forecast differences and ensemble correlations suggest that an extratropical cyclone over the Sea of Japan and a low-level trough near Taiwan play important roles in determining the front location.

An objective Frontal Analysis Techniques and Application in Model Verification

*Couhua Liu[1]

1. National Meteorology Centre of China Meteorological Administration

This paper presents an objective Frontal analysis method based on pressure field for east Asia. Comparing to methods based on thermo-dynamical elements such as temperature, the method developed in this paper can avoid the complex affection from sea-land and landform. The method will be used to identification of fronts in analysis and prediction of ECMWF model all over 2015, and then model error of predicted fronts will be verification. The verification result show that, comparing to analysis field, the moving speed of fronts in prediction field of ECMWF model is slower and strength is weaker.

Assimilating every 30-second phased array weather radar data in a torrential rainfall event on July 6, 2018 around Kobe city

*Yasumitsu Maejima[1], Shigenori Otsuka[1], Takemasa Miyoshi[1,2]

1. RIKEN Center for Computational Science, 2. University of Maryland, College Park

To investigate the impact of every 30-second phased array weather radar (PAWR; Yoshikawa et al. 2013, Ushio et al. 2014) observation on a simulation of a severe rainfall event occurred on July 6, 2018 around Kobe city, we perform 30-second-update 100-m-mesh data assimilation (DA) experiments using the Local Ensemble Transform Kalman Filter with the Scalable Computing for Advanced Library and Environment regional numerical weather prediction model. Two experiments were performed: the test experiment with every 30-second PAWR observation (TEST), and the other without observation (NO-DA).

The TEST analysis shows intense rainfalls with detailed structure of active convection, better matching with the PAWR observation compared to NO-DA analysis. In the forecast experiment, the forecast initialized by the ensemble mean analysis of TEST is skillful for 20 minutes compared with NO-DA, although the skill is decreased rapidly. The results suggest that the PAWR DA have a potential to improve the numerical simulation for this torrential rainfall event.

The impact of range sidelobes from phased array weather radar observations to short-range convective forecasts

*James David Taylor[1], Guo-Yuan Lien[1], Shinsuke Satoh[2], Takemasa Miyoshi[1]

1. RIKEN Research center for computational science, 2. NICT National Institute of Information and Communications Technology

Range sidelobes are an erroneous feature of radar observations that are generated by the pulse compression process used to improve the range resolution of target echoes in high resolution radar systems. Phased array weather radar (PAWR) is an advanced radar system providing very dense observations of reflectivity and Doppler radial velocity at 100m range resolution for over 100 elevation angles every 30 seconds. The use of pulse compression in PAWR to provide very high range resolution data makes it subject to these types of errors, which can result in false echoes observed at other ranges.

In this study we investigate the impact of assimilating range sidelobes from PAWR observations to short-range convective forecasts. This happens frequently in the current QC algorithm, although we plan to improve the QC in the future. We employ the use of the SCALE-LETKF system which couples the Local Ensemble Transform Kalman Filter (LETKF) with the Scalable Computing for Advanced Library and Environment (SCALE)-RM model. We focus on a convective rainfall event in August 2016 that brought heavy, intense rainfall over Osaka. PAWRs located in Suita, Osaka and in Kobe well-captured the convective system over its life cycle but featured prominent range sidelobes as part of their observations. Here, observations from both radars are first used to identify the range sidelobes before performing a series of 30-second update cycling experiments using observations from the Suita PAWR both with and without range sidelobes within a high-resolution 100-m mesh. As well as investigating their impact on short-range forecasts, we aim to show how we can further the usefulness of having two sets of PAWR observations to observe the same convective system by using them to identify and remove range sidelobes and improve short-range forecasts of severe convective events through the assimilation of this data.

Development of Hydro-debris 2D model for larger area

*Yosuke Alexandre Yamashiki[1], Tsutao OIZUMI[2], Bruno Ribeiro[1], Ryusuke Kuroki[1]

1. Earth & Planetary Water Resources Assessment Laboratory Graduate School of Advanced Integrated Studies in Human Survivability Kyoto University, 2. Japan Association of Marine-Earth Science and Tecnology

The Hydro-debris 2D model has been developed and applied for both larger and limited zones in the Hiroshima debris-flow disasters that occurred both in 2014 & 2018. The model application for hindcast for wider and limited areas with the same scheme is tested in order to obtain better and precise hindcast as well as a future forecast of rainfall-induced debris flow disasters by improving the geological classification module for the initiation of the debris flow. A universal algorithm for predicting the debris flow disasters solely by the initial geological boundary conditions and forecasted rainfall distribution may contribute to improving early warnings in this field.

Research on the application of an improved terrain-following vertical coordinates on GRAPES model

*chao li[1]

1. NWPC.CMA

Errors caused by topographic feathers of the coordinate planes can be reduced with the Smoothed-level terrain-following coordinate(T-F coordinate for short). On higher layors,coordinate planes of T-F coordinate based on trigonometric function of cos (COS coordinate for short)are horizontal with almost none errors. However,on the lower layers,thickness between planes is too small to keep the model stability.At the same time,it will bring larger calculating errors which result in bad performance of the model.Considering all above,an improved COS coordinate is designed to average the thickness of COS coordinate planes.
Ideal and real case tests are conducted with the GRAPES_Meso model using the improved COS coordinate.The results of the tests indicate that:compared with the COS coordinate, the improved COS coordinate ,on one hand ,keep the planes horizontal on the higher layers ,on the other hand, lead the distribute of the coordinate planes more uniformity , which greatly reduced the errors on the lower layers;The coordinate can reproduce in general the mountain induced gravity waves in comparison to the analytic solution. However, the shapes,vertical structures and intensity of the waves are better simulated by the improved COS coordinate, in the lower levels where the COS coordinate didn’ t behave so better. In the one-month real case tests, the improved COS coordinate gives the better results in terms of smaller forecast bias and root mean square error, and higher anomaly correlation coefficients than the COS coordinate. In conclusion, the improved COS coordinate solves the calculation problems of the COS coordinate ,and improves the prediction ability.

Development of a parallel spherical harmonic transform library: design and performance

*Fuyuki SAITO[1]

1. Japan Agency for Marine-Earth Science and Technology

The spherical harmonic transform (SHT) is a typical method to describe the dynamical core in climate models (e.g. MIROC). SHT is a combination of two transformation: a Fourier transformation in longitude and an associate Legendre transformation in latitude. Therefore, a simple way to introduce SHT in parallel computing is to apply domain decomposition in latitudes only, involving a relocation in latitudes before/after the Legendre transformation. However, the number of maximum processors is limited by the size of latitude dimension, which is an obstacle to more efficient computing. Recently the `physics' routines in a climate model have become more and more complex and expensive, thus the heavy computation significantly suffers from the limitation. A new (yet-another) library, Flageolet, has been developed to help parallel processing of SHT in particular for climate models like MIROC, to support more flexible domain decomposition, following the approach adopted in several 3D FFT libraries and also some climate models. As a continuation of last-year's presentation, which reports the design and performance of FFT part, those of SHT part as well as transposition part between FFT and ALT are reported in this study for various sizes of domain around T213 etc, examined on the Earth simulator.

Global data assimilation of multi-species satellite measurements for atmospheric chemistry analysis

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Koji Ogochi[1], Kengo Sudo[3,1], Masayuki Takigawa[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Jet Propulsion Laboratory/California Institute for Technology, 3. Graduate School of Environmental Studies, Nagoya University

Information on tropospheric ozone and its precursors are important for human health, ecosystem, and climate studies. The combined use of satellite measurements of ozone and its precursors has great potential to provide comprehensive information on the tropospheric chemistry system on various spatial scales. In this study, we present the results of global data assimilation of multi-species measurements (O_3, NO_2, CO, HNO_3, and SO_2) from multi-satellite sensors (OMI, GOME-2, SCIAMACHY, MOPITT, TES, and MLS) using the ensemble Kalman filter approach (Miyazaki et al., 2015). We demonstrated that increasing horizontal resolution from 2.8 to 0.56 degree is necessary for capturing high concentrations of NO_2 in the megacities, whereas 1.1-degree resolution is more suitable for optimizing tropospheric chemistry system on regional and global scales considering the current computational resources (computational cost was larger by a factor of 10 at 0.56-dgree resolution than at 1.1-degree resolution). Using the data assimilation system at 1.1-degree resolution, we constructed an updated version of tropospheric chemistry reanalysis (TCR-2; Miyazaki et al., in prep.) data for 2005—2017, which provide valuable information on decadal changes in air pollutant concentrations and emissions. The estimated NO_x emissions were strongly increased from 2005 to 2011 (+37%/decade) and decreased from 2011 to 2017 (-37%/decade) in China, while the emissions exhibited decreasing trends in Europe (-11%/decade) and the United States (-27%/decade) and an increasing trend in India (+23%/decade) during 2005—2017. A post peta-scale supercomputer such as post-K computer will facilitate the data assimilation calculation to produce tropospheric chemistry reanalysis data at 0.56-degree resolution for air pollutions on a megacity scale globally in a consistent way, which will benefit future study of atmospheric environment on various spatial scales.

The sensitivity to WRF shortwave radiation parameterizations in prediction of global horizontal irradiance for investigating interactions of atmosphere with croplands

*Ankur Srivastava[1], Sarita Kumari[1], Rajkumar Dhakar[2]

1. Indian Institute of Technology Delhi, 2. Indian Agriculture Research Institute

The present study intends to evaluate the Advanced Research Weather Research Forecating (ARW) model performance in representing the observed global horizontal irradiance (GHI) measurements while using different shortwave radiation (SWR) parameterization schemes. Two cases are considered, first case is ‘clear sky condition’ which includes model simulation of a clear/ cloudless day and second case is ‘all sky condition’ which includes model simulations of a cloudy and a rainy day. The above two cases are formulated on the basis that amount of incoming SWR will be different in each case owing to the differences in atmospheric conditions.
For the mentioned instances dates of 23rd February, 9th January and 12th March of 2016, which are clear, cloudy and rainy days respectively, are chosen for WRF model simulation. The shortwave radiation schemes that were evaluated are: Dudhia, Community Atmosphere Model (CAM), the updated Rapid Radiative Transfer Model (RRTMG), the updated Goddard and the
Goddard Fluid Dynamics Laboratory (GFDL) schemes. The model generated predictions are verified against the GHI measurements at weather station of Indian Agriculture Research Institute (IARI), New Delhi.
All schemes perform better under ‘clear sky condition’ i.e. for clear/cloudless day. For both the cases Dudhia scheme performs best with Mean Bias (MB) of 62.84 Wm^{-2} for clear day, 86.44 Wm^{-2} for cloudy day and 89.44 Wm^{-2} for rainy day. All-inclusive, the model derived predictions are over estimated in all the schemes.

The development of an atmospheric aerosol/chemistry–climate model, BCC_AGCM_CUACE2.0, and simulated effective radiative forcing of nitrate aerosols

*QI AN[1,2,4], Hua Zhang[2], Zhili Wang[2], Yi Liu[1,4], Bing Xie[3], Qianxia Liu[3], Zaizhi Wang[3], Sunling Gong[2]

1. LAGEO, IAP, CAS, 2. LaSW, CAMS, 3. NCC,CMA, 4. UCAS

As important components of total anthropogenic aerosols, nitrate aerosols have large impacts on aerosol radiative forcing and climate at regional and seasonal scales, but few current climate models coupled nitrate chemical modules online. This study developed a next-generation atmospheric aerosol/chemistry–climate model, the BCC_AGCM_CUACE2.0. Then, the performance of the model for nitrate was evaluated, and the direct radiative forcing (DRF) and effective radiative forcing (ERF) due to nitrate were simulated for the present day (2010), near future (2030) and middle future (2050) under the Representative Concentration Pathway (RCP) 4.5, 6.0, and 8.5 scenarios relative to the pre-industrial era (1850). The model reproduced the distributions and seasonal changes in nitrate loading well and simulated surface concentrations matched observations in Europe and North America. Current global mean annual loading of nitrates was predicted to increase by 1.12 mg m^{-2} relative to 1850, with the largest increases occurring in East Asia (3.89 mg m^{-2}), Europe (3.6 mg m^{-2}), and South Asia (1.86 mg m^{-2}). The current global mean annual ERF of nitrates was −0.21 W m^{-2} relative to 1850. Due to global reductions in pollutant emissions, the nitrate ERF values were predicted to decrease to −0.17 and −0.20 W m^{-2} in 2030, −0.07 and −0.18 W m^{-2} in 2050 for RCP4.5 and 6.0 relative to 1850, respectively. Under RCP8.5, nitrate ERF values were −0.24 and −0.19 W m^{-2} in 2030 and 2050, respectively. Although global mean nitrate values showed a declining trend, future nitrate loading remained high in East Asia and South Asia.

Impacts of different types and intensities of El Niño events on winter aerosols over China

*Xiaochao Yu[1,2], Zhili Wang[2,1], Hua Zhang[2], Shuyun Zhao[3]

1. Collaborative Innovation Center on Forecast and Evaluation of Meteorological Disasters, Nanjing University of Information Science and Technology, Nanjing, 210044, China, 2. State Key Laboratory of Severe Weather and Key Laboratory of Atmospheric Chemistry of CMA, Chinese Academy of Meteorological Sciences, Beijing, 100081, China., 3. National Climate Center, China Meteorological Administration, Beijing, 100081, China

El Niño is a strong signal of interannual climate variability. The occurrence of an El Niño event may have an important impact on atmospheric pollutant concentrations in China through changes to the regional climate. This study quantitatively examines the differences among the effects of different types and intensities of El Niño events on winter mean aerosol concentration and severe haze days in China. It is found that Central Pacific (CP) El Niño events lead to larger increases in the aerosol burden over southern China relative to the same intensity of Eastern Pacific (EP) events. For El Niño events of the same type but with different intensities, moderate events induce large increases in surface aerosol concentrations over the entire eastern China, while strong and weak events lead to obvious decreases in the surface aerosol concentration over northern China. These differences are mainly attributed to changes in atmospheric circulation, with the resulting changes in aerosol mass transport occurring in response to the different types of El Niño event. Except for moderate CP events, all kinds of El Niño events lead to an increase in severe haze days in winter over northern China. Strong and weak EP El Niño events and weak CP El Niño events lead to an increase in severe haze days in winter over southern China. A change in the south-north transport of aerosols caused by El Niño events also play a dominate role in changing the occurrence of winter haze days in China.

High Cloud Annual Variation and Its Responses to Global Warming in the NICAM AMIP Experiment

*Ying-Wen Chen[1], Masaki Satoh[1,2], Chihiro Kodama[2], Akira Noda[2], Yohei Yamada[2]

1. Atmospheric and Ocean Research Institute, The University of Tokyo , 2. Japan Agency for Marine-Earth Science and Technology

Uncertainties in climate sensitivity mainly come from the ambiguities in simulations of both high- and low-level clouds. The previous studies using NICAM’s short time simulation showed that the both the altitudes and amount of high clouds increase under the global warming condition, while other climate models show high cloud amount contrarily decreases.
Due to the progress in computer performance, long term climate simulation with $x < 20$ km becomes available. A pair of 25-year climate simulation (present and warming climate) with 14-km horizontal resolution (NICAM AMIP-like simulation, Kodama et al. 2015) has been performed by K computer. In this study, we analyze how the annual variation in high clouds is presented in the NICAM AMIP-like simulation. Satellite and in-situ data are used to investigate whether NICAM captures the observed responses of high clouds to the mean sea surface temperature (SST). Regressions between the high cloud amount variation and the SST variation is different with altitudes; positive regressions appear at altitudes above 100 hPa while negative regressions are found in altitudes below 100 hPa. The results are consistent with previous study based on observations (Zelinka and Hartmann 2011). Further analysis showed that the spatial pattern of high clouds is mainly associated with the El Nino response; as SST warmer, the high clouds shift in the eastern Pacific with higher. The increase of high clouds is associated with the increase of ice water content of cloud ice and snow. We argue that the response of high clouds to global warming is also explained by the change in the spatial distribution of the high clouds.

Improvements in Simulating the Relationship between ENSO and East Asian Summer Rainfall in the CMIP5 Models

*Yuanhai FU[1], Riyu Lu[1]

1. IAP, CAS

There is a significant relationship between the preceding winter El Niño–Southern Oscillation (ENSO) and the subsequent East Asian summer rainfall (EASR), and this relationship is helpful for seasonal forecasting in East Asia. This study investigated the relationship between the preceding winter ENSO and EASR in the Coupled Model Intercomparison Project Phase 5 (CMIP5) models and compared the results with those from the CMIP3 models. In general, the CMIP5 models capture the ENSO–EASR relationship more realistically than the CMIP3 models. For instance, approximately two-thirds of the CMIP5 models capture the ENSO–EASR relationship, while less than one-third of the CMIP3 models capture the relationship. Further investigation suggests that the improvement could be attributed to simulating the physical processes of ENSO's impact on the EASR more realistically in the CMIP5 models, particularly the effect of ENSO on tropical Indian Ocean SST and the effect of Indian Ocean SST anomalies on the atmospheric convection over the Philippine Sea. However, there is large diversity in the ENSO–EASR relationship in the CMIP5 models, and most of the models underestimate the relationship. This underestimation comes from the underestimation of the physical processes, particularly from the underestimated impact of the atmospheric convection over the Philippine Sea on the EASR. The CMIP5 models that capture the ENSO–EASR relationship well/bad also show high/low skill in representing the physical processes.

Meteorological Research Institute, 6. Kitami Institute of Technology

Ice cores can reconstruct past atmospheric environment. One of advantages for ice core archive is to reconstruct past gas and aerosols, which are important factors for evaluation of global warming. Antarctica and Greenland ice sheets have some ice domes (summit), where are useful sites for ice core drilling due to high elevation. Highland in the ice sheets can reconstruct wider emission area around the drilling sites.

At first, we will review some famous papers how reconstruct past aerosols from Antarctic dome ice cores. Antarctic dome cores can reconstruct recent 800 kyr BP, and aerosol fluctuation preserves in the cores along eight glacial-interglacial periods. Ice core community turns for obtain old ice archive in inland Antarctica (oldest ice project), so that Antarctic deep ice cores are one of topics for the ice core community.

Then, we will talk about our present project of Greenland SouthEastern Dome shallow ice core project (SE-Dome project). The SE-Dome has a huge accumulation rate (about 1.0 m water equivalent per year), where is about 4 time compared to ordinal Greenlandic dome ice cores, and 30 times to Antarctic ice cores. High accumulation dome has an advantage to reconstruct high-time resolution (e.g. seasonal scale) of recent epoch such as Anthropocene (AD 1750 to present). We obtained a 90 m ice core from the SE-Dome site in 2015, and then reconstructed aerosol fluctuations with seasonal scale from 1960 to 2014. As a result, sulfate flux responds to the decreasing trend of SOx emissions, but the nitrate flux does not follow the decrease in NOx. We have a plan in 2020 for next drilling of about 300 m ice core to reconstruct aerosol fluctuation with seasonal scale over the Anthropocene. We are looking for new joint studies using the ice core with members in the community of atmospheric chemistry.

The 60 years history of atmospheric formation pathways responsible for sulfate based on triple oxygen isotopic composition of sulfate preserved in SE-Dome ice core

*Shohei Hattori[1], Iizuka Yoshinori[2], Koji Fujita[3], Ryu Uemura[4], Sakiko Ishino[1], Naga Oshima[5], Nozomi Suzuki[1], Sumito Matoba[2], Asuka Tsuruta[1], Joel Savarino[6], Naohiro Yoshida[1]

The atmospheric sulfate is important for both climate change and air quality; it influences radiation forcing and cloud’s lifetime, and accounts for major components in fine particulate matter mass in urban regions with affecting visibility and public health. The emitted SO_2 is oxidized by OH radicals in the gas-phase, but modeling studies suggest that the large proportions (~80%) of global sulfate production were occurred in the aqueous-phase. However, the treatment of aqueous-phase in cloud pH set in atmospheric chemistry-transport models had the largest impact for atmospheric sulfate concentrations. Due to the lack of critical understanding for the chemical processes responsible for sulfate production, it is difficult to predict future changes in [SO_4^{2-}] and its effects on climate and air quality.

To help address this, here we use mass-independent oxygen isotopic composition ($\Delta^{17}O$) of sulfate providing insight into past oxidation pathways responsible for sulfate formation. We present $\Delta^{17}O$ of SO_4^{2-} obtained from a 90.45 m depth ice core drilled at a high-elevation dome site in southeast Greenland called SE-Dome, covering the last 60 years. We found that $\Delta^{17}O$ of SO_4^{2-} with low during the 1960s-1970s and high in after the 2000s. This increase in $\Delta^{17}O$ of SO_4^{2-} indicates that sulfate formation pathways responsible for sulfate changed after 1960 to the present along with declining SO_2 emission. In the presentation, we will discuss the enhanced role of a oxidation processes contributing to increase $\Delta^{17}O$ of SO_4^{2-}, and its implication to the changes in atmospheric chemistry though the changes in anthropogenic activities. This provides insight into direct and indirect effects of anthropogenic activities to the air quality by changing sulfate formation pathways. These functions, so called “chemical feedback", should be considered for making efficient mitigation policy for climate change and air quality by controlling emission of anthropogenic pollutants.

Estimation of high sulfate aerosol sources in 2012 spring at Cape Hedo, Okinawa

*Syuichi Itahashi[1], Shiro Hatakeyama[2], Kojiro Shimada[3], Akinori Takami[4]

1. Central Research Institute of Electric Power Industry, 2. Center for Environmental Science in SaitamaCenter for Environmental Science in Saitama, 3. School of Creative Science and Engineering, Waseda University, 4. National Institute for Environmental Studies

Air quality in Asia can cause regional-to-global environmental issues. Intensive observation campaigns approximately 1 week long have been conducted periodically from March 2010 to November 2015 at Cape Hedo, Okinawa, Japan. The period-averaged sulfate aerosol (SO_4^{2-}) concentrations for each campaign ranged from 0.34 to 6.97 $\mu g\ m^{-3}$, and the average concentration of all observations was 3.13 $\mu g\ m^{-3}$. The maximum daily mean concentrations surpassed 15 $\mu g\ m^{-3}$ in springtime 2012. The sources of this high SO_4^{2-} concentrations were estimated by using the air quality model with the tagged tracer method in this study. The main source of the high SO_4^{2-} concentrations in March was volcanoes and that in April was anthropogenic emissions from China. In March, the prevailing northerly wind transported a volcanic SO_2 plume with a low conversion ratio to Cape Hedo. The impacts of 15 volcanoes in Japan were estimated in this study, and a substantial impact of Sakurajima, which accounted for more SO_2 than anthropogenic emissions from Japan, was found. Throughout April, source apportionments from anthropogenic emissions from China were found; hence, the source was further divided into 31 provincial scales. Shandong and Jiangsu provinces, which are the first and seventh largest emission sources in China, were identified as important sources at Cape Hedo. These sources showed day-to-day variation, and the highest contribution from Shandong province was on April 23, whereas that from Jiangsu province was on April 22.

Isotopic constrains on sources and formation pathways of atmospheric nitrate in Mt. Everest

*Kun Wang[1,2,4], Shohei Hattori[2], Shichang Kang[1,3,4], Mang Lin[2], Naohiro Yoshida[2,5]

1. Northwest Institute of Eco-Environment and Resources, Chinese Academy of Sciences , 2. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 3. CAS Center for Excellence in Tibetan Plateau Earth Sciences, 4. University of Chinese Academy of Sciences, 5. Earth-Life Science Institute, Tokyo Institute of Technology

Studies on the sources and formation pathways of nitrate is crucial to better understand nitrogen cycle and atmospheric oxidation capacity. Tibetan Plateau (TP) and surroundings, referred to as the Third Pole and “Asia water tower”, contain the largest number of glaciers outside the polar regions and are largely experiencing shrinkage. A complete understanding on the source and formation mechanisms of atmospheric nitrate in the TP is important to indicate the impact of human activities on the environment and also crucial to investigate nitrogen cycle in glacier-hydrology systems of this region. Besides, it can supply information on interpreting ice core records to understand the past atmosphere chemistry. Here we collected aerosol samples from the Everest through pre-monsoon (April-May) and monsoon season (June-August) in 2018, and measured for the first time the isotopic compositions ($\delta^{15}N$, $\delta^{18}O$ and $\Delta^{17}O$) of nitrate in this region, allowing insights into their sources and potential formation mechanism. The results show that the seasonal variations in both $\delta^{15}N$ and $\Delta^{17}O$ values have a similar trends with maximum during pre-monsoon season and minimum during monsoon season. The relatively high values of $\delta^{15}N$ in pre-monsoon seasons, maybe indicate the enhanced contribution from fossil fuel combustions in South Asia which can be transported to our sampling sites across the Himalayas by the mountain/valley wind system. The $\Delta^{17}O$ (NO_3^-) value, which is dependent on both the $\Delta^{17}O$ (NO_2) value and the oxidation pathways (O_3 and OH) of NO_2 to NO_3^-, show that the O_3 oxidation pathway is dominant during pre-monsoon season, resulting in higher values of both $\delta^{18}O$ and $\Delta^{17}O$. In contrast, during monsoon season, formation involving HO_2/RO_2 radicals becomes important, producing lower values of $\delta^{18}O$ and $\Delta^{17}O$. To better understand the oxidation process of past atmosphere in the Everest region, observations of oxygen-17 excess of nitrate and sulfate in ice cores collected from this region in the future are recommended.

Development of a large volume sampling system for measuring stable isotope analysis of carbonyl sulfide and field observation

*Kazuki Kamezaki[1], Shohei Hattori[1], Naohiro Yoshida[1,2]

1. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 4259 Nagatsuta-cho, Midori-ku, Yokohama, Kanagawa 226-8502, Japan, 2. Earth-Life Science Institute, Tokyo Institute of Technology, 2-12-1-IE-1 Ookayama, Meguro-ku, Tokyo 152-8550, Japan

Carbonyl sulfide (OCS) is the most abundant sulfur-containing gas in the ambient atmosphere, with an average mixing ratio of 500 parts per trillion (ppt) by volume in the troposphere. OCS is suggested as a sulfur source of the stratospheric sulfate aerosols (SSA) which plays an important role for Earth of radiation budget and for ozone depletion. Moreover, since leaves consume OCS whenever they are assimilating CO_2 with same process but plant does not emit OCS to atmosphere by respiration, OCS provides a means to partition net ecosystem exchange into gross primary production (GPP) and respiration on land. Nevertheless, current figures for tropospheric OCS sources and sinks carry large uncertainties.

Isotope analysis is a useful tool to trace sources and transformations of trace gases. Very recently, Angert et al. (2019 Sci. Rep.) reported $d^{34}S$ value at Israel and Canary Island for tropospheric OCS using a gas chromatograph (GC)/multi collector-inductively coupled plasma mass spectrometer (MC-ICP-MS). For the measurement of sulfur isotope ratios of OCS in our laboratory, an online method measuring on a GC/isotope ratio (IR)-MS using S^+ fragmentation ions had been developed (Hattori et al., 2015). This method supports simple analysis of sulfur isotopic compositions of OCS over 8 nmol. However, application this method for atmospheric samples has yet to be done by this GC/IR-MS method, because of the large sample amounts that are necessary (i.e. 500 L of 500 pmol mol^{-1} OCS). Therefore, we developed a large volume air sampling system to apply S^+ IR-MS method for atmospheric samples and we observed $d^{34}S$ value in Suzukakedai campus at Yokohama (Kamezaki et al., 2019 Atmos. Meas. Tech.).

We will discuss the difference between the result of Angert et al. (2019) and our observation. Additionally, we also report the result in field campaign using our developed method.

[A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Takashi Maki(気象研究所)

This session provides a forum for the presentation of the broad spectrum of tropospheric and stratospheric chemistry, including various research topics (e.g., dynamical processes, air quality and climate), approaches (modeling, field measurements, remote sensing, and laboratory studies), and species (gas and aerosol). This session also provides an opportunity for discussing possible future collaboration with other research fields relevant to atmospheric chemistry. We strongly encourage authors to prepare presentation slides and a poster in English.

Observations of aerosol optical properties by sky radiometers at SKYNET Southeast and South Asian sites

*Al Mashroor Fatmi[1], Hitoshi Irie[1], Hossain Mohammed Syedul Hoque[1], Alessandro Damiani[1], Pradeep Khatri[2], Tamio Takamura[1], Thanawat Jurupongsaku[3], Govindan Pandithurai[4]

1. Center for Environmental Remote Sensing Chiba University , 2. Tohoku University, 3. Chulalongkorn University, 4. Indian Institute of Tropical Metereology

Direct and scattered sunlight measurements using sky radiometers were performed at two SKYNET sites –Phimai (15.18˚N, 102.56˚E) in Thailand and New Delhi (28.63˚N, 77.17˚E) in India. Phimai is a rural site and during the dry season (January to April), the site is affected by biomass burning. New Delhi is an urban site and expected to be influenced by vehicular and industrial emissions and agricultural waste burning. Depending on the data availability, aerosol optical properties during the year 2012 and 2016 were analyzed for New Delhi and Phimai, respectively. During the dry season in 2016 at Phimai, enhanced aerosol absorption optical depth (AAOD) was observed corresponding to the influence of biomass burning. The wavelength dependence of AAOD was quantified using the absorption Ångström exponent (AAE). The mean AAE at Phimai during the dry season in 2016 was 1.5±0.2, indicating the presence of organic brown carbon aerosols. This was consistent with coincident multi-axis differential absorption spectroscopy measurements showing higher concentration of organic compounds (formaldehyde and glyoxal) during the dry season, corresponding to biomass burning. At New Delhi, the mean AAE values during winter (December ~ February) and monsoon season (June ~ August) were 1.51±0.23 and 0.88± 0.24, respectively. The higher AAE during winter indicates the significant injection of organic brown carbon, probably due to transportation of carbonaceous materials from agricultural waste burning from Northern India. Thus, deduction of AAE, retrieved through sky radiometers observations, is expected to be useful for better understanding the physical and optical properties of light absorbing organic aerosols.

Analysis of factors causing variations in the absorption Ångström exponent of aerosols in Japan using skyradiometers

*Kodai Yamaguchi[1], Hitoshi Irie[1], Pradeep Khatri[2], Toshihiko Takemura[3], Hirokazu Yamamoto[4]

1. Chiba University, 2. Tohoku University, 3. Kyushu University, 4. National Institute of Advanced Industrial Science and Technology

Aerosols have brought the most significant uncertainty in predicting future climate change. To reduce the uncertainty, it is essential to better understand the optical properties of aerosols. Organic aerosols and mineral dust, which are the main aerosols, have been considered to cause only a weak light absorption, and their radiative forcing has been negative in most climate models. However, recent laboratory experiments and observations indicated that there should be aerosols (such as brown carbon) causing a strong light absorption in particular in the ultraviolet-to-visible wavelength regions. Although the Absorption Ångström exponent (AAE) was used as a useful index for representing the wavelength dependence of such light absorption, its observation has been limited. Under this circumstance, we made long-term observations using skyradiometers of SKYNET at 6 sites in Japan (Chiba, Fukue, Kasuga, Miyakojima, Sendai, and Takayama). Using our newly developed analysis algorithm package (SR-CEReS), we retrieved AAE values for the 6 sites to investigate factors causing their variations. While the theoretical AAE value of black carbon is considered to be unity, our analysis shows that the annual averages of AAE were in the range from 1.15 to 1.51, indicating the presence of aerosols having strong light absorption in the ultraviolet-to-visible wavelength regions at all the 6 sites. Moreover, urban sites tended to show higher AAE values. We additionally analyzed nitrogen dioxide and sulfur dioxide concentration data taken by the Multi-Axis Differential Optical Absorption Spectroscopy (MAX-DOAS) observations, which were conducted simultaneously with the skyradiometer. Then, it was suggested that the AAE could be enhanced by emissions from ships, factories, or steelworks.

Sources of atmospheric black carbon and related carbonaceous components at Rishiri Island, Japan

*Chunmao Zhu[1], Yugo Kanaya[1], Hisayuki Yoshikawa[2], Tomohisa Irino[2], Osamu Seki[2], Yasunori Tohjima[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. Hokkaido University, 3. National Institute for Environmental Studies

A field study was conducted to clarify sourcesof atmospheric black carbon and related carbonaceous components at Rishiri Island, Japan. We quantified equivalent black carbon (eBC) particle mass and the absorption Ångström exponent (AAE), atmospheric CO and CH_4, in addition to levoglucosan in total suspended particles, a typical tracer of biomass burning. Sixteen high eBC events were identified attributable to either anthropogenic sources or biomass burning in Siberia/China. These events were often accompanied by increases of co-emitted gases such as $CH_4$and CO. Specifically, we observed pollution events with elevated eBC, AAE, levoglucosan, and CH_4–CO slope in late July 2014, which were attributed to forest fires in Siberia by reference to the FLEXPART model footprint and fire hotspots. In autumn, drastic increases of eBC, AAE, and levoglucosan were observed, accompanied by an eBC–CO slope of >15 ng m^{-3}/ppb, resulting from long-range transport of emissions from extensive burning of crop residue on the Northeast China Plain. Other than the sources of fossil fuel combustion in China and forest fires in Siberia, we also report that pollution events in northern Japan are caused by crop residue burning in China. This study elucidated valuable information that will improve understanding of the effects of biomass burning in East Asia on atmospheric carbonaceous components.

Black carbon (BC) deposited on snow lowers snow albedo, potentially contributing to the warming in the Arctic. The distributions of inorganic aerosols (ions), which contribute to direct and indirect aerosol effects, are also greatly influenced by deposition. It is critically important to measure the spatial distributions of BC and ions in snowpack in different regions of the Arctic to quantify these effects. Because accurate measurements of BC and ions in snowpack are very limited, we measured the mass concentrations of size-resolved BC (C_{MBC}) and ions in snowpack over Finland, Alaska, Siberia, Greenland, and Spitzbergen in early spring during the period of 2012 –2016 by using a single-particle soot photometer and ion chromatography, respectively. BC deposition amounts (DEP_{MBC}) during snow accumulation periods were derived from C_{MBC} and snow water equivalent (SWE). Detailed analyses have shown that the spatial distributions of the anthropogenic BC flux and topography strongly influenced the latitudinal variations of C_{MBC} and BC size distributions. The average size distributions of BC in snowpack shifted to smaller sizes with the decrease in C_{MBC}, likely due to an increase in the removal efficiency of BC with the increase in BC diameter during transport from major BC sources. The present C_{MBC} were much lower than previous C_{MBC} measured by using an Integrating Sphere/Integrating Sandwich spectrophotometer by a factor of about 13. The present accurate data of C_{MBC}, SWE, and DEP_{MBC} are very useful in constraining climate model to estimate the effect of BC on the climate of the Arctic.

The single-particle extinction and scattering method for online characterization of submicron particles: Principles and applications to aerosol research

*Nobuhiro Moteki[1]

1. The Univerisity of Tokyo

We will introduce the single-particle extinction and scattering (SPES) method as a new fundamental tool for online measurements of submicron particles and its applications to aerosol research. The SPES method accurately determines the amplitude and phase of the forward-scattered wave from a single particle on the basis of the interference patterns between the scattered and the incident fields when the particle traverses a tightly-focused laser beam. The complex refractive index and volume of the detected particle can be estimated from the SPES data using our original data-processing algorithm. In the presentation, we will talk about the measurement principle, the theoretical framework of data analysis including the potential effects of particle shape, the performance tests, and some applications to black carbon and mineral particles.

High spatial resolution vehicular emissions inventory for China using VEIN model

*Sergio Ibarra Espinosa[1], Xuelei Zhang[1], Aijun Xiu[1], Edmilson Dias de Freitas[2]

1. Research Group of Regional Atmospheric Environment, Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, P. R. China, 2. Department of Atmospheric Sciences, University of São Paulo, Brazil.

Vehicular emissions are an important source of pollution in China. These and other anthropocentric emissions, with poor meteorological conditions enhance critic episodes of high concentrations of air pollutants (Wang S. and Hao J., 2012). Environmental policies seeks to improve air quality by diminishing and cutting emissions, making the emissions characterization of crucial importance. Even more, air quality modelers needs emissions inventories as inputs, which usually suffer of limited temporal and spatial representation and over simplification. Under these circumstances, it is not expected good air quality simulations. I other words, garbage-in, garbage-out.

This study aims to improve the temporal and spatial representation of vehicular emissions. This will be achieve using the VEIN model (Ibarra-Espinosa *et al.,* 2017), initially with a top-down approach. The method and data is described as follows: stock vehicles will be obtained for 31 provinces (National Bureau of Statistics (NBS), 2016) considering vehicle survival pattern and average age of use of the fleet (HAO *et al*, 2011; Wang H. *et al*, 2012). NBS data is aggregated without discriminating taxis and motorcycles, therefore, the vehicular composition and activity will be obtained with the percentages of Wang H. *et* al, (2008): Passenger Cars (PC), Taxi, Motorcycle, Moped, Bus, Small Trucks, Medium Trucks and Heavy Trucks by type of fuel. Furthermore, we will divide traffic at peak and off peak hours and by Freeways, Arterial and residential roads, shown on Fig.1, in each province to obtain the representative speed in each case, based on the driving cycles obtained by Wang Q. *et al*, (2008). We will use Copert (Ntziachristos and Samaras, 2016) emissions factors inside VEIN correcting by chemical composition of fuel and deterioration factors. Cold starts and evaporative emissions will be obviously included. To ensure consistency with the emissions and fuel consumed on each province, activity will be calibrated in order that fuel consumption estimation or CO_2 estimations matches with statistics of automotive fuel sales or CO_2 emissions, depending on the availability of data. Top-down emissions will be spatially dis-aggregated by length of type of road from OpenStreetMap in each province as shown by Andrade *et al*, (2015).

[A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Kentaro Ishijima(気象研究所)

This session provides a forum for the presentation of the broad spectrum of tropospheric and stratospheric chemistry, including various research topics (e.g., dynamical processes, air quality and climate), approaches (modeling, field measurements, remote sensing, and laboratory studies), and species (gas and aerosol). This session also provides an opportunity for discussing possible future collaboration with other research fields relevant to atmospheric chemistry. We strongly encourage authors to prepare presentation slides and a poster in English.

Effect of land use change on GHG fluxes of tropical peat forests in Borneo island

*Ryuichi Hirata[1], Habura Borjigin[1], Tomohiro Shiraishi[1], Takashi Hirano[2], Lulie Melling[3]

1. National Institute for Environmental Studies, 2. Hokkaido University, 3. Sarawak Tropical Peat Research Institute

Borneo island, which is located in southeast Asia, has a rich forest and it store a huge carbon in biomass and soil. It is well known that peat, which is large carbon reservoir, widely spreads in the island. While tropical peat forest occupies only 0.25% of surface area on globe, it accounts 3% of soil organic carbon on earth. Tropical peat forest, in which forest grows on peat which depth from 1 to 10 m. Recently, the area of tropical peat forest is rapidly decreasing because of fire or plantation and has resulted in large carbon lost. Therefore, carbon management and control for tropical peat forest is very important with the objective of development, conservation and disaster prevention. In this study, we will introduce the studies to evaluate the effects of land use change on greenhouse gas fluxes of tropical peat lands from site scale to regional scale various methods i.e. flux observation of eddy covariance and chamber methods, remote sensing and numerical simulation under several projects.

Since industrial evolution, global warming has progressed owing to increase of CO_2 emitted by human activities. To deal effectively with this issue by mitigation and adaptation, it is necessary to monitor emission and sequestration of GHGs with their underlying mechanisms including biogeochemical processes. Plant photosynthesis is one of the important factors to drive carbon cycling between atmosphere and biosphere. The terrestrial ecosystems assimilate about 30 % of anthropogenic CO_2 through photosynthesis. Since the photosynthetic process is quite sensitive to climatic conditions such as temperature, radiation and precipitation, there are still uncertainty in the estimation of photosynthetic production of regional to global scale. This uncertainty would be lager under climate change condition in near future. Thus, it is necessary to obtain the temporal dynamics of the photosynthetic production in large area.
Satellite remote sensing has been used to monitor the spatial and temporal dynamics of terrestrial ecosystems that are responsible for such photosynthetic CO_2 absorption. Such observation provides us with geographical information on the potential distribution of carbon sequestration by the aid of ecosystem models. In these years, advent of the spectroradiometer, which has high wavelength resolution, such as TANSO FTS on Greenhouse Gases Observing Satellite (GOSAT) enable us to observe solar-induced chlorophyll fluorescence (SIF) emitted from the terrestrial ecosystems. Since the chlorophyll fluorescence is emitted from photosynthetic process itself, SIF remote sensing is drawn considerable attention as a new technique to observe the photosynthetic activity of the vegetation. SIF has been measured by gas-measurement satellites, such as GOSAT, GOSAT-2, OCO-2 and GOME2 on MetOp A and B.
In this talk, we will introduce our previous and on-going studies about estimation of photosynthetic production of the terrestrial ecosystem. We also discuss about future perspective about SIF studies in GOSAT and GOSAT-2 projects.

Analysis of the carbon dioxide in the upper troposphere and lower stratosphere by the data from GOSAT TANSO-FTS TIR

*Nawo Eguchi[1], Akihiro Honda[1], Naoko Saitoh[2], Yosuke Niwa[3]

1. Kyushu University, 2. Chiba University, 3. National Institute for Environmental Studies

Stratospheric cooling was reported, it could be caused by increasing the carbon dioxide (CO_2), which is a major greenhouse gas. While, the concentration of CO_2 in the stratosphere is not well understood, nor are the exchange processes between the upper troposphere and lower stratosphere (UT/LS ; 250-100hPa). The present study investigated the intra-seasonal, seasonal and inter-annual variations of CO_2 to understand the CO_2 concentration at UT/LS and the Stratosphere and Troposphere exchange process.

We used the vertical profile data (Level 2) of CO_2 derived from thermal infrared (TIR) region (Band 4: 5.5 - 14.3 μm) of the Thermal And Near-infrared Sensor for carbon Observation (TANSO) - Fourier Transform spectrometer (FTS) on board Greenhouse gas Observing SATellite (GOSAT). The analysis period is four years from January 2010 to December 2013. We adapted the bias correction values derived from Saitoh et al. [AMT, 2016] which validated the TIR CO_2 profiles at UT/LS region with the Comprehensive Observation Network for TRace gases by AIrLiner (CONTRAIL). For reference, the atmospheric transport model, NIES-TM (ver.5) and the Nonhydrostatic Icosahedral Atmospheric Model (NICAM)–based Transport Model (TM) were used [Niwa et al., 2011; 2017].

The growth rate of CO_2 concentration at UT/LS were approximately 2 ppmv/year, which one at southern hemisphere were relatively larger than one at northern hemisphere. The seasonal variation of CO_2 concentration, showed that the maximum peak existed after a few month with respect to the peak at the middle or lower troposphere. The inter-annual variations were affected by the ENSO cycle; the higher (lower) CO_2 concentration at UT were seen during La Nina (Normal / El Nino) period. Finally, the intra-seasonal variation CO_2 concentration at UT/LS were associated with both the vertical and horizontal transportation due to the deep convection and the Asian monsoon anticyclonic circulation, respectively. To clarify the dynamics of CO_2 concentration on the time scale within the area and season within which we could not observe by aircraft observation or balloon observation, the results are used for verification of physicochemical process of global model and also for their development can do.

Seasonal and interannual variations of the Atmospheric Potential Oxygen over the Western North Pacific observed by using a cargo aircraft C-130H

*Shigeyuki Ishidoya[1], Kazuhiro Tsuboi[2], Yosuke Niwa[3], Shohei Murayama[1], Hidekazu Matsueda[2], Yousuke Sawa[2], Nobuyuki Aoki[1], Kentaro Ishijima[2], Kentaro Kozumi[4], Genta Umezawa[4], Kazuya Yukita[4], Shigeharu Nishida[4], Megumi Yamamoto[4]

1. National Institute of Advanced Industrial Science and Technology (AIST), 2. Meteorological Research Institute, 3. National Institute for Environmental Studies, 4. Japan Meteorological Agency

The cargo aircraft C-130H flies once per month from Atsugi Base (35.45˚N, 139.45˚E), Kanagawa, Japan, to Minamitorishima (MNM; 24.28˚N, 153.98˚E), and air samples are collected during the level flight (~6 km) and the descent portion at MNM. The air samples have been analyzed for $O_2/N_2$and Ar/N_2ratios and stable isotopic ratios of N_2, $O_2$and Ar since May 2012. The analysis indicated a significant artificial fractionation due to thermal diffusion during the air sample collection. Nevertheless we succeeded to correct the effects of the fractionation on the observed O_2/N_2ratio precisely by using the observed Ar/N_2 ratio (Ishidoya et al., 2014). The corrected O_2/N_2ratio showed a secular decrease accompanied by a prominent seasonal cycle. The average secular change rate of the mid-tropospheric corrected O_2/N_2ratio was found to be -25.2±0.5 per meg $yr^{-1}$for the period 2012 –2018, which agreed well with that observed at La Jolla, USA by Scripps O_2program (Keeling and Manning, 2014). As the uncertainty of the change rate, we considered the spatial difference of the rates and the stability of the O_2/N_2ratio of standard air.

The Atmospheric Potential Oxygen ($APO=O_2+1.1xCO_2$), calculated by using the corrected O_2/N_2ratio, also showed prominent seasonal cycles, and the amplitude of the mid-tropospheric seasonal APO cycle observed at 25.5˚N was found to be 55 and 31 % of those observed at 33.5˚N and the surface MNM (Ishidoya et al., 2017), respectively. On the other hand, the corresponding seasonal amplitude of CO_2at 25.5˚N was found to be 72 and 93 % of those at 33.5˚N and the surface MNM, respectively. An atmospheric transport model (Niwa et al., 2017) reproduced general features of the observed seasonal APO and CO_2cycles, and its tagged simulation suggested that the mid-tropospheric seasonal APO cycle in the northern low latitudes was reduced significantly by the anti-phase seasonal APO cycle from the southern hemisphere. The observed APO showed interannual variations superimposed on secular downward trends, and the temporal change rates take maxima from the end of 2014 to the beginning of the 2015 at the surface MNM and in the mid-troposphere at 29 –34 ˚N. A comparison between the observed and simulated interannual variations of APO suggested that an interannual variation of the atmospheric transport contributed about 30 % of the observed variation.

Acknowledgments

We thank the staff of Japan Meteorological Agency for their work to collect the air samples onboard a cargo aircraft C-130H. This study was partly supported by the JSPS KAKENHI Grant Number 15H02814, and the Global Environment Research Coordination System from the Ministry of the Environment, Japan.

Discussion

Turbulent kinetic energy dissipation rates depending on the polar vortex and on synoptic-scale disturbances in the UTLS region in the Antarctic

*Masashi Kohma[1], Kaoru Sato[1], Koji Nishimura[2], Masaki Tsutsumi[2]

1. Department of Earth and Planet Science, Graduate School of Science, The University of Tokyo, 2. National Institute of Polar Research and The Graduate University for Advanced Studies (SOKENDAI)

The turbulence kinetic energy dissipation rate (TKEDR) is a fundamental parameter describing atmospheric turbulence. Our previous study reported the first estimation of the TKEDR in the free atmosphere in the Antarctic from atmospheric radar measurements at Syowa Station, and showed that the TKEDR in the 10–15 km height range became large in May through October. This fact suggests that the seasonal evolution of polar vortex has impact on the TKEDR in the upper troposphere and lower stratosphere (UTLS). The present study investigates the dependence of the TKEDR on the relative location to the polar vortex and on each phase of synoptic scale disturbances during austral winter in the UTLS region using the radar measurements at Syowa Station. First, the TKEDR is obtained as a function of the relative distance from the edge of the polar vortex. The edge of the polar vortex was determined from Ertel’ s potential vorticity on 475-K isentropic surface (Nash et al., 1996). The result showed that the TKEDR is significantly large near the polar vortex edge compared to that outside and deep inside the polar vortex. Furthermore, it is clarified that the TKEDR largely depends on synoptic-scale PV perturbation around the tropopause (300-K isentropic surface).

Momentum budget of semiannual oscillation around the tropical stratopause

*Yoshihiro Tomikawa[1,2], V. Lynn Harvey[3], John A. Knox[4], Masatomo Fujiwara[5]

1. National Institute of Polar Research, 2. SOKENDAI, 3. University of Colorado Boulder, 4. University of Georgia, 5. Hokkaido University

Meteorological reanalysis data have been updated and improved in the past decade, which are pretty useful for climate and meteorological studies. Their comprehensive evaluation is going underway as the SPARC Reanalysis Intercomparison Project (S-RIP). This study reports the momentum budget of semiannual oscillation around the tropical stratopause for four kinds of the latest reanalysis data (i.e., MERRA, MERRA2, ERA-Interim, and JRA55) as a part of S-RIP. They showed that, while the westerly acceleration is primarily due to unresolved wave drag (i.e. gravity wave drag), the easterly acceleration is induced by momentum transport due to meridional circulation and resolved wave drag. This feature is consistent with previous studies based on simulation and observation. However, the contribution of unresolved wave drag is maximized in MERRA/MERRA2 later than in ERA-Interim/JRA55. We discuss the difference between the latest reanalyses and its impact on the tropical dynamics.

A study on sources of gravity waves that reach the summer stratosphere and mesosphere based on high-resolution radiosonde data

*Haruka Okui[1], Masashi Kohma[1], Kaoru Sato[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Gravity waves (GWs) are mainly generated in the troposphere and play a crucial role in the momentum transport in the stratosphere and mesosphere. Several possible main sources of GWs are suggested by theoretical, numerical and observational studies; topography and jet-front systems in winter, and strong convection in summer (e.g. Sato *et al.*, 2009). In addition, theoretical work by Bühler *et al.* (1999) indicated that the Kelvin-Helmholtz (KH) shear instability can cause significant emission of GWs in summer. Having critical layers in the lower stratosphere, orographic waves hardly propagate into the summer stratosphere and mesosphere. On the other hand, most GWs emitted from the KH instability above the tropopausal jet do not encounter their critical layer and can reach the stratosphere and mesosphere. However, observational studies from this view point are insufficient. In this study, using high-resolution radiosonde data from 9 stations in Japan, the generation and propagation of GWs with short vertical wave length ($\leq$ 4 km) in the troposphere and lower stratosphere are investigated. The parameters describing the wave structure are estimated by a hodograph analysis. Drawing a comparison with GWs observed in winter, source and propagation characteristics of GWs in summer are highlighted. The latitude-height distribution of wave amplitudes and phase velocity characteristics suggests that orographic waves are not dominant in summer in contrast with those in winter. The vertical direction of wave energy propagation shows that summer GWs propagate upward and downward from the 10-15 km height region, where the occurrence frequency of the events with Richardson number (Ri) less than 0.25 (which is a necessary condition for the KH instability) is high. In addition, wave amplitudes in the lower stratosphere are relatively large above the peak of the occurrence frequency of $Ri < 0.25$, which is located around the latitude and height region of 30°N-35°N, 12-15 km. These results suggest that the KH instability is one of major sources of GWs in the summer stratosphere. The KH instability tends to occur when the vertical wind shear is large and the static stability is low. In summer, the vertical shear associated with the jet is stronger at higher latitudes and the static stability is lower at lower latitudes. The peak of occurrence frequency of $Ri < 0.25$ as mentioned above is situated at the middle latitudes inbetween. Therefore, it can be inferred that this region is climatologically important for shear-generated GWs which can reach the summer stratosphere.

Stratospheric initial conditions provide seasonal predictability of the North Atlantic and Arctic Oscillations

*Yu Nie[1], Adam Scaife[2,3], Hong-Li Ren[1,4], Ruth Comer[2], Martin Andrews[2]

1. Laboratory for Climate Studies, National Climate Center, China Meteorological Administration, Beijing, China, 2. Met Office Hadley Centre, Exeter, UK, 3. College of Engineering, Mathematics and Physical Sciences, University of Exeter, Exeter, UK, 4. Department of Atmospheric Science, School of Environmental Studies, China University of Geoscience, Wuhan, China

The North Atlantic Oscillation (NAO), the regional manifestation of the Arctic Oscillation (AO), dominates winter climate variability in Europe and North America. Skilful seasonal forecasting of the winter NAO/AO has been demonstrated recently by dynamical prediction systems. However, the role of initial conditions in this predictability remains unknown. Using a latest generation seasonal forecasting system and reanalysis data, we show that the initial upper stratospheric zonal wind anomaly contributes to winter NAO/AO predictability through downward propagation of initial conditions. An initial polar westerly/easterly anomaly in the upper stratosphere propagates down to the troposphere in early winter, favoring a poleward/equatorward shift of the tropospheric mid-latitude jet. This tropospheric anomaly persists well into the late winter and induces the positive/negative phase of NAO/AO in the troposphere. Our results imply that good representation of stratospheric initial condition and stratosphere-troposphere coupling in models is important for winter climate prediction.

To investigate the seasonal characteristics of chemical tracer distributions in the extratropical upper troposphere and lower stratosphere (ExUTLS) as well as stratosphere–troposphere exchange processes, origin fractions of air masses originating in the stratosphere, tropical troposphere, mid-latitude lower troposphere (LT), and high-latitude LT in the ExUTLS are estimated using 10-year backward trajectories calculated with European Centre For Medium-Range Weather Forecasts (ECMWF) ERA-Interim data as the meteorological input. Time-series of chemical tracers obtained from ground-based and airborne observations are incorporated into the trajectories, thus reconstructing spatiotemporal distributions of chemical tracers in the ExUTLS. The reconstructed tracer distributions are analysed with the origin fractions and the stratospheric age of air (AoA) estimated using the same backward trajectory. The reconstructed distributions of CO and CO_2 in the ExUTLS are affected primarily by tropospheric air masses because of the short chemical lifetime of the former and large seasonal variations in the troposphere of the latter. Distributions of CH_4, N_2O, and SF_6 are controlled primarily by seasonally varying air masses transported from the stratosphere. For CH_4 and N_2O distributions, their seasonally varying photochemical decay along the average pathway from the source region are particularly important. This study developed and demonstrated a unique and effective method to exploit the advantages of observational data in combination with trajectory analysis. This method provides a means to understand both air mass transport and chemical decay for photochemical active substances from a new perspective.

Possible impacts of stratospheric ozone on circulation changes in the tropical troppposphere following a stratospheric sudden warming event

*Makoto Deushi[1]

1. Department of Atmospheric Environment and Applied Meteorology, Meteorological Research Institute

Many studies have shown that there are significant impacts of the stratospheric ozone on dynamical coupling between the stratosphere and troposphere (S-T) at middle and high latitudes, especially in the Southern hemisphere (e.g. Marshall *et al.*, JC, 2006; Thompson *et al.*, Nature Geo, 2011). In contrast, little attention has been given to role of the stratospheric ozone in modulating S-T dynamical coupling in the tropics (and sub-tropics) so far. Recently, there has been an increasing interest in the S-T dynamical coupling in the tropics because it has been recognized that this coupling has significant influences on moist convection and organized convective systems in the tropics (e.g. Son *et al.*, JC, 2017; Nishimoto and Yoden, JAS, 2017).
In this study, possible impacts of the stratospheric ozone on tropospheric circulation and precipitation in the tropical and sub-tropical regions were examined, focusing on a period of several months following a major stratospheric sudden warming (SSW) event. As a case study, the major SSW occurred in the winter of 2003/2004 was investigated. A set of ensemble re-forecasts was performed by using a chemistry-climate model (CCM) and an atmospheric general circulation model (AGCM) to elucidate radiative effects of the stratospheric ozone anomalies induced by the major SSW on the troposphere at low latitudes. The ensemble re-forecasts were conducted using the Lagged Averaged Forecasting (LAF) method with 60 ensemble members, where the initial-times were set just before the occurrence of the major SSW. The CCM resolves well full stratospheric and tropospheric chemistry processes, and considers online radiative feedbacks from the simulated atmospheric ozone. The CCM ensemble re-forecast was compared to the AGCM ensemble re-forecast in which climatological monthly mean ozone was forced. The CCM ensemble re-forecast reproduced well significant ozone decrease in the lower tropical stratosphere due to rapidly enhanced upward Brewer-Dobson circulation there after the major SSW. About two weeks after the occurrence of the major SSW, systematic differences with statistical significance between the two ensemble re-forecasts were simulated in the tropospheric circulation and precipitation especially in the northern tropics and sub-tropics. The northern cell of the Hadley circulation became stronger in the CCM ensemble re-forecast than in the AGCM one, with the larger amount of precipitation over the Intertropical Convergence Zone (ITCZ). To confirm these impacts of the stratospheric ozone on the (sub-) tropical troposphere, other major SSW events are also investigated.

Stratosphere-troposphere exchange of ozone and carbon monoxide over the northern Pacific Ocean in northern winter using two chemical reanalysis data sets

*Haosen Xi[1], Masatomo Fujiwara[1], Kazuyuki Miyazaki[2]

1. Graduate School of Environmental Science, Hokkaido University, 2. NASA Jet Propulsion Laboratory, California Institute of Technology, USA

Stratosphere-troposphere exchange (STE) is one of the important factors that determine the distribution of constituents in the troposphere and stratosphere. Two-way airmass exchange between the lower stratosphere and the troposphere occurs in association with mid-latitude weather disturbances, with the net transport from the stratosphere to troposphere. In this study, we analyze the STE over the northern hemisphere Pacific Ocean in northern winter, focusing on transport of ozone and carbon monoxide (CO) using two chemical reanalysis data sets, the Tropospheric Chemical Reanalysis version 1 (TCR-1; Miyazaki et al., 2015) and the Monitoring Atmospheric Composition and Climate (MACC; Inness et al., 2013). The TCR-1 is a 10-year chemical reanalysis data set for the period from 2005 to 2014, while the MACC is for 2003 to 2012. Both reanalyses assimilate major satellite chemistry data during the respective periods. We calculate the amount of CO transported from the troposphere to stratosphere (TST) and ozone transported from the stratosphere to troposphere (STT) on the 350-K isentropic surface, by using 4 PVU potential vorticity to evaluate irreversible transport across the tropopause (e.g., Homeyer and Bowman, 2013). Results from the analysis of TCR-1 data are as follows. The amount of ozone transport per case maximizes in November and minimizes in February, and that in years 2005-2008 is significantly smaller than that in years 2009-2014 with the maximum in the 2010 winter (i.e., from November 2010 to March 2011). The amount of CO transport per case maximizes in March and minimizes in November, and that in years 2005-2009 is significantly larger than that in years 2010-2014 with the maximum in the 2009 winter. Results from MACC data are qualitatively similar. In the presentation we will also show the results with additional criteria for irreversibility by using trajectory calculations.

Inter-comparison of Upper Air Temperature in China between Satellite MSU and Radiosonde Datasts

*Yanjun GUO[1], Cheng-zhi Zou[2], Panmao Zhai[3], Guofu Wang[1]

1. National Climate Center(NCC), China Meteorological Administration(CMA) , 2. Center for Satellite Applications and Research, NOAA/NESDIS, 3. Chinese Academy of Meteorolgical Sciences (CAMS), China Meteorological Administration (CMA)

Reconciling upper-air temperature trends derived from radiosonde and satellite observations is a necessary step to confidently determine the global warming rate. This study examines the raw and homogenized radiosonde observations over China and compares them with layer-mean atmospheric temperatures derived from satellite microwave observations for the lower-troposphere (TLT), mid-troposphere (TMT), upper troposphere (TUT), and lower stratosphere (TLS) by three research groups. The comparisons are for averages over China, excluding Tibetan Plateau, and at individual stations where metadata contain information on radiosonde instrument changes. It is found that major differences between the satellite and radiosonde observations are related to artificial systematic changes. The radiosonde system updates in early 2000s over China caused significant discontinuities and led the radiosonde temperature trends to exhibit less warming in the middle and upper troposphere and more cooling in the lower stratosphere than the satellite temperatures. Homogenized radiosonde data have been further adjusted using shift-point adjustment approaches to match with satellite products for China average. The obtained trends during 1979-2015 from the re-adjusted radiosonde observation are respectively 0.203±0.066, 0.128±0.044, 0.034±0.039, and -0.329±0.135 K Decade^{-1} for TLT, TMT, TUT, and TLS equivalents. Compared to satellite trends, the re-adjusted radiosonde trends are within 0.01 K Decade^{-1} for TMT and TUT, and 0.054 K Decade^{-1} warmer for TLT and 0.051 K Decade^{-1} cooler for TLS. The results suggest that the use of satellite data as a reference are helpful in identifying and removing inhomogeneities of radiosonde temperatures over China and reconciling their trends to satellite microwave observations. Future efforts are to homogenize radiosonde temperatures at individual stations over China using similar approaches.

Environmental Characterization of the Atmosphere Using WACCM-X

*Rose Tseng[1], Michelle Kanipe[1], Brian Urbancic[1], Robert Tournay[1], Omar Nava[1], Daniel Emmons[1], Robert Loper[1], Charlton Lewis[1]

1. Air Force Institute of Technology

Researching the characteristics of the whole atmosphere can yield a variety of weather and climate understanding for the terrestrial and space environments. Of particular interest are the neutral species, wind, and temperature distributions from the surface to the middle atmosphere and across multiple latitudes. This is accomplished using data from the Whole Atmosphere Community Climate Model-Extended (WACCM-X) with the ionosphere, a model developed by inter-divisional collaboration at the University Corporation for Atmospheric Research. Presented here are the vertical profiles of neutral species, wind speed, and temperature of the troposphere and middle atmosphere up to 80 km. Preliminary results from a 10-year period show all three parameters vary temporally and spatially, particularly across latitudes and seasons. Ongoing work includes rigorous analysis, utilizing all years of WACCM-X data available.

Observational features of atmospheric fields during a zonal wavenumber two (WN2) type major sudden stratospheric warming (MSSW) event that occurred in February 2018 (MSSW18) are analyzed using the Japanese 55-year Reanalysis, satellite measurements by a microwave limb sounder, and a new three-dimensional wave activity flux. MSSW18 was characterized by a clear polar vortex split, continuance of easterlies with remarkable double peaks, clear planetary-wave propagation in the easterly region of the upper stratosphere and extraordinary upward propagation of WN2 planetary waves from the upper troposphere whose peak was comparable to that during an MSSW event that occurred in January 2009 (MSSW09), although MSSW18 showed relatively modest warming, unclear disappearance of the stratopause and weak stratopause elevation compared to those during MSSW09. Further analyses revealed that wave packets propagated upward simultaneously in both the Eastern and Western Hemispheres. Those observed in the Eastern Hemisphere converged strongly at the western edge of the Aleutian High and most of them did not propagate into the upper stratosphere. The wave packets observed in the Western Hemisphere locally propagated into the upper stratosphere over North America despite the fact that easterlies were predominant there in the mature stage of MSSW18. Furthermore, our results revealed that the regions and levels of wave-packet attenuation corresponded well to the area of weak eastward phase tilt or the quasi-barotropic condition of smaller-scale waves during MSSW18, whereas during MSSW09 the westward phase tilts of smaller-scale waves were clearly visible in the upper stratosphere.

Response of the Southern Hemisphere atmosphere to the QBO from winter to early summer

*Yousuke Yamashita[1], Hiroaki Naoe[2], Makoto Inoue[3], Masaaki Takahashi[4]

1. Japan Agency for Marine-Earth Science and Technology, 2. Meteorological Research Institute, 3. Akita Prefectural University, 4. National Institute for Environmental Studies

The equatorial quasi-biennial oscillation (QBO) is dominant variability in the tropical stratosphere and is characterized by the oscillation of downward propagating easterly and westerly wind regimes. Several studies have examined possible linkages between the QBO and atmospheric circulations, such as the meridional circulation around tropics and the polar vortex intensity in the Northern Hemisphere (NH), which are related to the changes of waves and circulations in the stratosphere (e.g., Plumb and Bell 1982, Holton and Tan 1980). On the other hand, the mechanism by which the QBO modulates extratropical circulation over the Southern Hemisphere (SH) is poorly understood, as the various studies employed different height levels and metrics to define the phase of the QBO (e.g., Garcia and Solomon 1987; Baldwin and Dunkerton 1998; Naito 2002; Hitchman and Huesmann 2009). Previous studies employed composite analysis that possibly includes signals other than the response to the stratospheric QBO, such as the responses to solar cycle and El Niño-Southern Oscillation (ENSO). In this study, we examined the response of atmospheric circulation over the SH to the stratospheric QBO, using multiple linear regression analysis for the long-term Japanese 55-year Reanalysis (JRA-55) dataset to separate the influences of the QBO and other factors on the SH polar vortex. In addition to the terms of middle- and lower-stratospheric QBO, the multiple linear regression includes equivalent effective stratospheric chlorine (EESC), solar cycle, ENSO, and volcanic aerosol terms as explanatory variables. Analyses of the regression coefficients associated with both middle- and lower-stratospheric QBO suggest an influence on the SH polar vortex from SH winter through early summer in the seasonal evolution. One possible pathway is that the middle-stratospheric QBO results in the SH low latitudes stratospheric response through the QBO-induced mean meridional circulation, leading to a high-latitude response. This favors delayed downward evolution of the axis of SH polar vortex at high latitudes (around 60˚S) from August to November during the westerly phase of the QBO. Although this pathway is inconsistent with weakening of the SH polar vortex in August, the other possible pathway is unveiled from the detailed analysis. The other possible pathway involves the response to lower stratospheric QBO that induces the increase in upward propagation of planetary waves from the SH extratropical troposphere to stratosphere in August. This pathway is consistent with weakening of the SH polar vortex in August.

Influence of QBO-like Oscillation on Tropical Convective Systems in a Three-Dimensional Minimal Model Framework of the Stratosphere-Troposphere Coupled System

*Shigeo Yoden[1], Hai Bui[2], Takahiro Banno[1]

1. Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2. Geophysical Institute, University of Bergen

We report on the three-dimensional minimal model of the stratosphere-troposphere coupled system that produces a self-sustained oscillation reminiscent of the quasi-biennial oscillation (QBO) in a radiative-moist convective quasi-equilibrium state. The computational domain is rectangular (640 km x 160 km, 5 km grid size; Bui et al., 2019), or square (100 km x 100 km, 1 km grid size), without Coriolis effects under doubly periodic boundary conditions. After initial transient time, a QBO-like oscillation with a period of about 300 days emerges in the stratosphere, both in the domain-averaged zonal wind and meridional wind (Figure-left). Synchronization of the zonal and meridional winds is characterized as an anti-clockwise rotation of a skewed spiral feature with height in the horizontal wind hodograph (Figure-right).

The QBO-like wind oscillation penetrates into the troposphere with large reduction of oscillation amplitude, and influences tropospheric temperature anomalies and precipitation with an irregular period of about 100 days. Heavy precipitation is associated with positive temperature anomalies. The simulation reveals three types of precipitation patterns; isolated quasi-stationary type clusters, fast-moving back-building type and squall-line type patterns. The quasi-stationary type is newly identified in the present three-dimensional model, and the zonal-height cross sections of the meridionally averaged clouds and relative humidity for this pattern show clear-sky areas without shallow clouds and with low humidity, whereas shallow clouds exist over the entire domain including non-precipitating areas with high humidity for the fast-moving back-building type or squall-line type patterns. Intermittent self-organization of convective systems into quasi-stationary type and transition back to the fast-moving back-building type or squall-line type are fundamental characteristics of self-aggregation in the three-dimensional minimal model framework.

Downward Propagation of Planetary Wave Packets from the Stratosphere to the Troposphere During Northern Hemisphere Winter

*Matsuyama Yuya[1], Toshihiko Hirooka[2]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University

Downward propagation of planetary wave packets from the stratosphere to the troposphere is often observed during Northern Hemisphere winter and their influence on the tropospheric circulation has been also reported by various authors. Recent observational studies show that the downward propagation into the troposphere frequently occurs over the North America centered around 90W. Hence, we investigate the frequency distribution of downward propagation events of planetary wave packets and its relationship to the background field using the Japanese 55-year Reanalysis (JRA-55) data. We calculate Plumb’ s (1985) wave activity flux (WAF) and extract the downward propagation events over the analysis period (1958-2016) based on a specified criterion value for the vertical component of WAF at 30 hPa. Next, we investigate the longitudinal location of each downward propagation event and classify it into eight sectors of 45 degrees along the longitudinal circle to make a composite analysis of the classified events. Resultantly, around 500 events are extracted during the analysis period and it is found that about more than 80% of the events occurred in three sectors between 135W to 0E; these events are shown to be intimately related to the development of the Aleutian High in the stratosphere, which is located in the west of the downward propagation region. As for the other events, a developed anticyclone was also observed in the west of each downward propagation region.

An advanced impact of Arctic stratospheric ozone changes on spring precipitation in China

*Fei Xie[1]

1. Beijing Normal University

The effect of spring Arctic Stratospheric Ozone (ASO) changes on spring precipitation in China is analyzed using observations, reanalysis data, and the Whole Atmosphere Community Climate Model version 4 (WACCM4). We find that February–March mean ASO changes have a significant impact on April–May mean precipitation over the Loess Plateau and the middle–lower reaches of the Yangtze River—two important grain-producing regions with large populations. Changes in the polar vortex link the ASO to precipitation in China. Stratospheric circulation anomalies caused by ASO changes can propagate to the North Pacific. An increase in ASO leads to enhanced westerlies in the high and low latitudes of the North Pacific but weakened westerlies in the mid-latitudes of the North Pacific. The circulation anomalies over the North Pacific, forced by the increase of ASO, can extend westwards to East Asia, leading to an abnormal anticyclone in the East Asian upper and middle troposphere, and an abnormal cyclone in the lower troposphere. This enhances the warm and humid airstream from the Western Pacific to the Chinese mainland and strengthens upwelling over the Loess Plateau and the middle–lower reaches of the Yangtze River. These conditions enhance precipitation in central China during positive ASO anomaly events and reduce precipitation during negative events. The WACCM4 simulations support the results from our statistical analysis of observations and reanalysis data. Our results suggest that ASO variation can serve as a predictor of spring precipitation variation over the Loess Plateau and the middle–lower reaches of the Yangtze River.

Global Cooling System installed on the beach by means of Artificial Convection and Artificial Rain

*Murakami Hideyo[1]

1. Ii Ecology Development

In recent years the Earth is warming. The sun radiates sunlight energy and warms the Earth. The Earth reflects a part of sunlight energy to space and radiates infrared ray including latent heat energy to space. An amount of sunlight energy received by the earth is almost the same as an amount of energy sent out by the earth. The amount of sunlight energy is almost constant. On the other hand Greenhouse gas such as CO_2 decreases a ratio of a heat enrgy which air sent out to space to a heat enrgy which air radiates. Then global mean temperature is increasing and many severe climate events due to mean temperature increase happen. In the world many people study to decrease CO_2 accumulation in air and not to increase global mean temperature. However a useful system for decreasing CO_2 accumulation cannot be developed.

This paper studies Global Cooling System. Global Cooling System is composed of Artificial Convection Equipment (type II) and a control center. Global Cooling System can cancel mean temperature increase and cools the Earth, even if air has a lot of greenhouse gas and mean temperature increase is 2℃.

Artificial Convection Equipment looks like a large greenhouse, which is composed of 1 roof, 1 wall, 1 air inlet, 1 air outlet and 1 heater. Artificial Convection Equipment is installed on a tropical beach where it is hot and humidity (35℃, 26.2g kg^{-1}), and a sea breeze during daytime. The roof and the wall are made of transparent plastic sheet and there are the heater (black sheet) under the roof. The heater receives sunlight energy under the roof and changes sunlight energy to heat energy, and warms air inputted from the inlet and sends out heated air from the outlet. Heated air is lighter than circumstance air and is lifted up to the troposphere. The lifted air, which includes a lot of vapor, is cooled in the troposphere. Then vapor is cooled and is changed to artificial rain or snow in the troposphere. The artificial rain or snow falls down to the land. As a result Artificial Convection Equipment artificially makes convection between the beach surface and the troposphere, by transporting warmed air from the beach surface to the troposphere upward and bringing down artificial rain or snow with high altitude air downward. The lifted air sends out latent heat and sensing heat energy of circumstance air including vapor on the beach surface to space, and the artificial rain or snow with the high altitude air absorbs sensing heat and dissolution heat from circumstance air on the land, and cools the land surface too. Furthermore in a region where it is hot and small rain, a half amount of artificial rain is absorbed by plants. Plants vaporize it and absorbs latent heat from circumstance air. Then the earth is cooled by plants too.

This paper analyses Global Cooling System by means of Artificial Convection and Artificial Rain, and shows that mean temperature increase can be stop by Global Cooling System. A large scale of experiment is required to reconfirm a characteristics of Global Cooling System.

Keywords: global cooling, artificial convection, latent heat, artificial rain

Stratospheric front-like temperature structure and gravity wave activity during a stratospheric sudden warming event in 2016

*Yukari Sumi[1], Kaoru Sato[1]

1. University of Tokyo

A large-scale front-like temperature structure is observed in the Arctic stratosphere during a stratospheric sudden warming (SSW) event in 2016. As reported by previous studies, it is shown that a stratospheric front with a vertical scale of about 15 km is formed near the polar vortex edge and vertically tilts toward a colder region. Moreover, we found that the front is the strongest a few days prior to the major warming and that a local maximum of temperature appears in the exit region of a jet streak. These characteristics of the front are roughly common among other SSW events. However, it is not clear as to why the front-like structure is strengthened during the SSW event, which still needs more observational analysis. In the present study, the semi-geostrophic system is considered to better understand the frontogenesis in the stratosphere. Q-vector and frontogenesis function are computed by using MERRA-2 reanalysis data. Near the front region, the geostrophic and ageostrophic parts of the frontogenesis function have large negative and small positive values, respectively. Therefore, it is suggested that the weakening of the front due to geostrophic flow is dominant over the strengthening of the front due to ageostrophic flow. The ageostrophic part is further separated into horizontal and vertical components. The vertical component is positive and significantly larger than the horizontal component. This result implies that the frontogenetic effect of the ageostrophic motion mainly comes from the vertical motion, which seems to be different from the tropospheric front: convergence of the horizontal ageostrophic wind is dominant for the tropospheric front because the vertical motion is suppressed near the ground surface. In addition, gravity wave (GW) activity near the front is examined by using dry temperature data from FORMOSAT-3/COSMIC satellite. The vertical wavelength of the GW is estimated from 1D-Stockwell transform (S-transform) for the temperature data. The S-transform spectra have a peak around 4–7 km in the vertical range between 25 and 35 km where the stratospheric front is the strongest.

The effects of a well-resolved stratosphere on the simulated boreal winter circulation in a climate model

*Yoshio Kawatani[1], Kevin Hamilton[2], Lesley J. Gray[3], Scott M. Osprey[3], Shingo Watanabe[1], Yousuke Yamashita[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. International Pacific Research Center, University of Hawaii, 3. Atmospheric, Oceanic and Planetary Physics, Department of Physics, University of Oxford

The impact of stratospheric representation is investigated using the Model for Interdisciplinary Research On Climate Atmospheric General Circulation Model (MIROC-AGCM) run with different model-lid heights and stratospheric vertical resolutions, but unchanged horizontal resolutions (~1.125°) and subgrid parameterizations. One hundred year integrations of the model were conducted using configurations with 34, 42, 72 and 168 vertical layers and model-lid heights of ~27 km (L34), 47 km (L42), 47 km (L72) and 100 km (L168). Analysis of the results focused on the Northern Hemisphere in winter. Compared with the L42 model, the L34 model produces a poorer simulation of the stratospheric Brewer-Dobson circulation (BDC) in the lower stratosphere, with weaker polar downwelling and accompanying cold pole and westerly jet biases. The westerly bias extends into the troposphere and even to the surface. The tropospheric westerlies and zone of baroclinic wave activity shift northward; surface pressure has negative (positive) biases in the high (mid) latitudes, with concomitant precipitation shifts. The L72/L168 models generate a Quasi-Biennial Oscillation (QBO) while the L34/42 models do not. The L168 model includes the mesosphere, and thus resolves the upper branch of the BDC. The L72 model simulates stronger polar downwelling associated with the BDC than does the L42 model. However, experiments with prescribed nudging of the tropical stratospheric winds suggest differences in the QBO representation cannot account for L72-L42 differences in the climatological polar night jet structure. The results show that the stratospheric vertical resolution and inclusion of the full middle atmosphere significantly affect tropospheric circulations.

On the relation between three-dimensional wave activity flux and pseudo momentum without using intrinsic phase velocities

*Takenari Kinoshita[1]

1. Japan Agency for Marine-Earth Science and Technology

The middle-atmosphere general circulation is driven by various wave activities. The transformed Eulerian-Mean (TEM) are the useful tools to diagnose interaction between waves and mean state. The three-dimensional (3D) extension of TEM equations has been conducted since 1980s and the recent study uses the 3D wave activity flux for the analysis of special structure of Rossby wave activities during Stratospheric Sudden Warming. It was proved that divergence of wave activity flux corresponds to the time variation of pseudo momentum in the TEM equations (Eliassen-Palm relation). Also, this relation is proved in the 3D-TEM equations. However, the pseudo momentum used in the relation is defined as the wave energy divided by intrinsic phase velocities and is difficult to use in the data analysis. In this study, referring Double Impulse pseudo momentum of Aiki et al. (2015), the pseudo momentum without using intrinsic phase velocities are introduced and the relation between 3D wave activity flux divergence and time variation of pseudo momentum in the middle atmosphere is reported.

Keywords: wave activity flux, pseudo momentum

Hindcasts of the 2016 Disruption of the Stratospheric Quasi-biennial Oscillation

*Shingo Watanabe[1], Kevin Hamilton[2], Scott Osprey[3], Yoshio Kawatani[1], Eriko Nishimoto

1. Japan Agency for Marine-Earth Science and Technology, 2. International Pacific Research Center, University of Hawaii at Manoa, 3. NCAS-Climate, University of Oxford

In early 2016 the quasi-biennial oscillation in tropical stratospheric winds was disrupted by an anomalous easterly jet centered at ~40 hPa, a development that was completely missed by all operational extended range weather forecast systems. This event and its predictability are investigated through ensemble hindcasts using a global model notable for its sophisticated representation of the upper atmosphere. Key to prediction of this event is simulating the slowly evolving mean winds in the winter subtropics that provide a waveguide for Rossby waves propagating from the winter hemisphere. Its association to the strong El Nino condition in 2015 is also investigated by changing sea surface temperatures.

Selection bias of quasi-fixed-point observations in the ExUTLS and its impact on the seasonal record

*Yoichi Inai[1], Toshinobu Machida[2], Hidekazu Matsueda[3], Yousuke Sawa[3], Kazuhiro Tsuboi[3], Keiichi Katsumata[2,4], Shinji Morimoto[1], Shuji Aoki[1], Takakiyo Nakazawa[1], Ryo Fujita[5,1]

1. Tohoku Univ., 2. NIES, 3. MRI, 4. Takachiho Chem. Industrial, 5. Imperial College London

Fixed-point observations are essential for long-term monitoring of the atmospheric environment. However, some attention might be paid to the interpretation of seasonal variations appearing in the observational record, particularly for regions with large seasonal variations. In the extra-tropical upper troposphere/lower stratosphere (ExUTLS), the climatological tropopause height changes with season. This leads to a seasonal dependence of whether individual fixed-point observations are included in the stratosphere or the troposphere. In this study, using the reanalysis fields, quasi-fixed-point observations in the ExUTLS are simulated and categorized as being in the troposphere or stratosphere based on their position relative to the dynamic tropopause, to investigate seasonal tendencies of the categorization. The influence of these tendencies on seasonal variations of atmospheric composition in the categorized data is estimated. The seasonal cycles of CH_4, N_2O and SF_6 mixing ratios are found to change with the categorization method. In particular, the minimum values for these tropospheric tracers in observations categorized as stratospheric occur 1–2 months later than in uncategorized observations. This delay in stratospheric record is interpreted as the selection bias, that is, the air mass categorized as the stratospheric atmosphere biased to some specific meteorological situation due to the seasonal variation of ExUTLS meteorological field.

Varying Rossby Wave Trains from the Developing to Decaying Period of the Upper Atmospheric Heat Source over the Tibetan Plateau in Boreal Summer

*Chuandong Zhu[1,2], Rongcai Ren[1]

1. Institute of Atmospheric Physics, Chinese Academy of Sciences, 2. University of Chinese Academy of Sciences

This study demonstrates the two different Rossby wave train (RWT) patterns related to the developing/decaying upper atmospheric heat source over the Tibetan Plateau (TPUHS) in boreal summer. The results show that the summer TPUHS is dominated by quasi-biweekly variability, particularly from late July to mid-August when the subtropical jet steadily stays to the north of the TP. During the developing period of TPUHS events, the intensifying TPUHS corresponds to an anomalous upper-tropospheric high over the TP, which acts as the main source of a RWT that extends northeastward, via North China, the central Pacific and Alaska, to the northeastern Pacific region. This RWT breaks up while the anomalous high is temporarily replaced by an anomalous low due to the further deepened convective heating around the TPUHS peak. However, this anomalous low, though existing for only three to four days due to the counteracting dynamical effects of the persisting upper/lower divergence/convergence over the TP, acts as a new wave source to connect to an anomalous dynamical high over the Baikal region. Whilst the anomalous low is diminishing rapidly, this Baikal high becomes the main source of a new RWT, which develops eastward over the North Pacific region till around eight days after the TPUHS peak. Nevertheless, the anomaly centers along this decaying-TPUHS-related RWT mostly appear much weaker than those along the previous RWT. Therefore, their impacts on circulation and weather differ considerably from the developing to the decaying period of TPUHS events.

Equilibrium Climate Responses of the East Asian Summer Monsoon to Various Anthropogenic Aerosol Species

*Qiuyan Wang[2,1], Zhili Wang[1,2], Hua Zhang[3,2]

1. State Key Laboratory of Severe Weather & Key Laboratory of Atmospheric Chemistry of CMA, Chinese Academy of Meteorological Sciences, Beijing, 2. Collaborative Innovation Center on Forecast and Evaluation of Meteorological Disasters, Nanjing University of Information Science and Technology, Nanjing, 3. Laboratory for Climate Studies, National Climate Center, China Meteorological Administration, Beijing

The equilibrium climate responses of the East Asian summer monsoon (EASM) to increases in various types of anthropogenic aerosol emissions, including sulfate, organic carbon (OC), and black carbon (BC), from 1850 to 2000 are studied using an aerosol-climate online model. The results show that various aerosol species have substantially different impacts on the EASM by changing the local sea-land surface thermal difference and atmospheric circulation. The increased sulfate leads to decrease in the surface thermal difference between the land and ocean, the southward shift of the East Asian subtropical jet (EASJ), and significant northerly wind anomalies at 850 hPa over eastern China and the ambient oceans, thus dampening the EASM markedly. Pronounced surface cooling appears and an anomalous anticyclone is formed over the oceans north of 30˚N due to the increase of OC. These cause slight increase in sea-land surface thermal difference and southerly flow anomalies to the west of the anticyclonic center, thereby strengthening the northern East Asian summer monsoon (NEASM). However, the increased OC decreases the sea-land surface thermal contrast over southern China, which weakens the southern East Asian summer monsoon (SEASM). The responses of summer 850 hPa winds and rainfall over the East Asian monsoon region (EAMR) to increase in BC are generally consistent with those to increase in OC. The increased BC leads to the strengthening of the NEASM north of 35˚N and slight weakening of the SEASM south of 35˚N. Also, the simulated responses of the EASM to increase in BC are not changed when BC emission is scaled up by five times its 2000 levels, but the intensities of responses are enhanced. Overall, the increase in sulfate primarily weakens the EASM, while the increases in BC and OC mitigate the weakening of the NEASM to some extent.

Analysis of specific energy in zonal currents focusing on the analogy between jet stream and open channel flow

*Yoshikazu Kitano[1], Tomohito J. Yamada[2]

1. Central Research Institute of Electric Power Industry, 2. Faculty of Engineering, Hokkaido University

Atmospheric blocking is one of the important causes of meteorological extremes in mid-latitude, such as cold spells, heat waves and long-term heavy rainfalls. Rossby (1950) focused on dynamical analogies between the hydraulic jump in open channel flow and the atmospheric blocking in jet stream, and proposed a theoretical formula to explain the two dynamically possible states in zonal currents which are compatible with supercritical and subcritical flow in an open channel flow. Armi (1989) focused on the specific energy flux in zonal currents and showed that a dimensionless parameter, which is called Froude/Rossby number, is analogous to the Froude number of open channel flow. Kitano and Yamada (2017) extended these theories to realistic conditions in atmosphere and showed a relationship between typical blocking flow and specific energy flux in jet stream. In this study, we analyzed several blocking episodes using specific energy flux and found energetic signals over Japan and its surroundings before Pacific blocking occasions. These signals may contribute to prediction on blocking.

Analysis of the ozone reduction event over the southern tip of South America in November 2009

*Hideharu Akiyoshi[1], Masanao Kadowaki[2], Haruna Nakamura[3], Takafumi Sugita[1], Toshihiko Hirooka[4], Yayoi Harada[5], Akira Mizuno[6]

1. National Institute for Environmental Studies, 2. Japan Atomic Energy Agency, 3. Fujitsu FIP Corporation, 4. Department of Earth and Planetary Sciences, Kyushu University, 5. Meteorological Research Institute, 6. Institute for Space-Earth Environmental Research, Nagoya University

A reduction of the total ozone over the southern tip of South America lasting 3 weeks occurred in November 2009. Analyses of the ERA-Interim reanalysis data and the total ozone observed by the OMI indicate that the total ozone reduction event was caused by a migration of the polar vortex toward the South American continent at the time of the vortex breakup. The vortex migration is associated with an enhanced wave flux from the troposphere at 120–150˚W and 50–60˚S to the west of the South American continent to the stratosphere over the southern part of the continent, which led to a large negative geopotential height anomaly in the lower stratosphere. In November, a blocking pattern was diagnosed from the 500 hPa geopotential height over the west of the South American continent. These results suggest a relation between the long-lasting reduction of the total ozone over the southern tip of South America and the blocking phenomenon in the troposphere of the Southern Hemisphere through wave propagation from the blocking region in 2009.

The total ozone, the geopotential height at 50 hPa and 500 hPa, the wave activity flux, the polar vortex migration and elongation, and the blocking pattern in the Southern Hemisphere November for 1979–2015 as well as 2009 were investigated. The results show that the relation between the blocking pattern in the troposphere and the large polar vortex migration and elongation in the stratosphere is also evident in November 1987, 1994, 1997, 2001, and 2011. Especially, in November 1994, 1997, and 2011, the blocking pattern and the polar vortex migration occurred near the South American continent.

These results indicate that the migration of the Antarctic polar vortex to the southern tip of South America in November occurred occasionally in the past. They also suggest that diagnosis of blocking pattern in the Southern Hemisphere troposphere may be useful for prediction of the direction of polar vortex migration in the stratosphere, and hence, prediction of high UV radiation risk over the southern tip of South America in early summer.

This research was supported by JST/JICA, SATREPS, the Environment Research and Technology Development Fund.

Analysis of relatively low ozone in Arctic spring during the QBO-westerly and solar-minimum years

*Yousuke Yamashita[1,2], Hideharu Akiyoshi[2], Masaaki Takahashi[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. National Institute for Environmental Studies

The equatorial quasi-biennial oscillation (QBO) and the 11-year solar cycle are known to cause year-to-year variability of the Northern Hemisphere (NH) polar vortex (e.g. Holton and Tan, 1980; Labitzke, 1987). Labitzke (1987) and several studies following her work have been used the four categories of the QBO and 11-year solar cycle, according to the westerly/easterly phase of the QBO (QBO-W/QBO-E) and the maximum/minimum phase of the 11-year solar cycle (S_{max}/ S_{min}). Camp and Tung (2007) suggested that the NH polar vortex is the most stable and the least perturbed state in late winter during the QBO-W/S_{min} years relative to the other three groups (QBO-W/S_{max}, QBO-E/S_{max}, and QBO-E/S_{min}), in agreement with the work of Labitzke and van Loon (1988). Their findings are in agreement with the smallest magnitude of the Arctic total ozone in QBO-W/S_{min} years among the four categories (Li and Tung 2014), because the ozone depletion is enhanced in the stable and cold polar vortex associated with an increase in chemical destruction through heterogeneous reactions on the Polar Stratospheric Clouds (PSCs). Since the Arctic ozone amount is related to the ozone transport as well as the chemical ozone destruction, the estimation of their influences is still challenging issue for understanding the small amount of the Arctic total ozone in March.

In this study, we analyze the Arctic ozone amount using TOMS/OMI observations, ERA-interim reanalysis data, and the outputs of a chemistry climate model (CCM) with REF-C1SD hindcast simulation, in which the model’s zonal/meridional wind and temperature are nudged toward those of the ERA-interim reanalysis data with a 6-hour interval. The anomaly from the average for all the years of 1979–2011 in the Arctic total ozone amount is calculated for QBO-W/S_{min} group in late winter. We estimate the amounts of ozone transport and chemical ozone destruction and their effects on the derived Arctic ozone anomaly for the QBO-W/S_{min} group with CCM outputs.

Result of the composite mean for QBO-W/S_{min} years shows negative anomaly (relatively small amount) of total ozone in February–March compared to the 1979–2011 average from the CCM output, in agreement with the satellite observation, reanalysis data. To distinguish the effect of chemical ozone destruction from that of ozone transport for the total ozone anomaly in February–March, we analyze the total ozone anomaly of the passive ozone tracer without any chemical change in the CCM. The negative anomalies of the passive ozone tracer have a similar distribution to that of chemically reactive ozone with similar magnitude, suggesting that the negative anomalies of total ozone are mainly caused by ozone transport.

The outputs of CCM are also analyzed for vertical profile of ozone concentration, which indicates negative anomaly of the Arctic ozone in the upper troposphere and the lower stratosphere for the QBO-W/S_{min} condition, the maximum anomaly of ozone partial column is located around 50–70 hPa. The partial column of the passive ozone tracer at these levels also shows negative anomalies, whilst their magnitudes are small, especially at 50 hPa in March. These results suggest the significant influence of ozone transport on the negative ozone anomaly in February–March, whilst the influence of chemistry is partially large at 50 hPa in March.

Evaluation of ozone in the upper troposphere and lower stratosphere derived from multi-species satellite data assimilation

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Koji Ogochi[1], Kengo Sudo[3,1], Masayuki Takigawa[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Jet Propulsion Laboratory/California Institute for Technology, 3. Graduate School of Environmental Studies, Nagoya University

Ozone (O_3) in the upper troposphere and lower stratosphere (UTLS) has a stronger greenhouse effect than in the lower troposphere. However, information on O_3 in the UTLS from observations with the global coverage is still limited. Multi-species satellite data assimilation of stratospheric O_3, and tropospheric O_3 and its precursors is expected to provide better constraints on O_3 in the UTLS, because O_3 in the UTLS is controlled by stratospheric O_3 intrusions, O_3 transport from middle and lower troposphere, and in-situ O_3 chemical production. In this study, we evaluate O_3 in the UTLS derived from the multi-species data assimilation with horizontal resolutions of 2.8, 1.1, and 0.56 degree using ozonesonde observations (not used for data assimilation) in April 2008. Assimilated data were obtained from the OMI, GOME-2, and SCIAMACHY for tropospheric NO_2 column, the TES for O_3 profile, the MOPITT for total CO column, the MLS for O_3 and HNO_3 profiles, and the OMI for total SO_2 column. At 200 hPa, 300 hPa, and 500 hPa, the data assimilation at 0.56-degree resolution reduced root mean square errors (RMSEs) against ozonesonde observations in the northern midlatitudes by 32%, 31%, and 13%, respectively, compared to the model simulation without data assimilation. The overall data assimilation performance for O_3 concentrations is not sensitive to horizontal resolution in the altitudes between 200 hPa and 500 hPa (i.e., the RMSEs were within 7% at all resolutions). Meanwhile, the data assimilation at 0.56-degree resolution improved agreements with ozonesonde observations at 300 hPa by up to 55% compared to 1.1- and 2.8-degree resolutions during a deep stratospheric intrusion episode at Trinidad Head (124˚W, 41˚N) through resolving small-scale transport processes. These results confirm that O_3 analyses derived from multi-species data assimilation are suitable for understanding spatial and temporal variations in O_3 in the UTLS and their controlling processes.

Characteristics of Initial Perturbation of JMA GEPS during Sudden Stratospheric Warmings

*Shunsuke Noguchi[1,2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Meteorological Research institute, Japan Meteorological Agency

In order to sophisticate the ensemble forecasting and data assimilation system of the whole atmosphere, it is necessary to accumulate the knowledge about the uncertainty of the analysis in the stratosphere and mesosphere, which is poor in comparison with that in the troposphere. Therefore, this study investigates characteristics of initial perturbation of the Japan Meteorological Agency (JMA) Global Ensemble Prediction System (GEPS), which has been replaced in March 2017.

By focusing on two Sudden Stratospheric Warming (SSW) events occurred in 2017-2018 and 2018-2019 winters, several aspects of the new JMA GEPS are revealed as follows: (1) There is large uncertainty above the upper stratosphere (which has not been reflected in the previous system). (2) The analysis ensemble spread increases and penetrates downward from the upper stratosphere during the onset period of both SSW events, though its precursory nature is not so evident as pointed by previous studies (e.g. Enomoto et al. 2010). (3) After SSW events, the analysis ensemble spread in the middle and upper stratosphere shrinks in association with the change of dominant physical processes. However, relatively large spreads, which may have implications for the stratosphere-troposphere coupling, are sometimes found in the lower stratosphere.

The quality of forecasts and analyses above the upper stratosphere would be inevitable from the artificial effect of sponge layers near the model top. Therefore, it is worth comparing or communicating with results of some high-top system to validate the appropriateness of above-mentioned aspects (e.g. (1)) and recognize limitations of current operational settings.

An advanced impact of Arctic stratospheric ozone changes on spring precipitation in China

*Fei Xie[1]

1. Beijing Normal University

The effect of spring Arctic Stratospheric Ozone (ASO) changes on spring precipitation in China is analyzed using observations, reanalysis data, and the Whole Atmosphere Community Climate Model version 4 (WACCM4). We find that February–March mean ASO changes have a significant impact on April–May mean precipitation over the Loess Plateau and the middle–lower reaches of the Yangtze River—two important grain-producing regions with large populations. Changes in the polar vortex link the ASO to precipitation in China. Stratospheric circulation anomalies caused by ASO changes can propagate to the North Pacific. An increase in ASO leads to enhanced westerlies in the high and low latitudes of the North Pacific but weakened westerlies in the mid-latitudes of the North Pacific. The circulation anomalies over the North Pacific, forced by the increase of ASO, can extend westwards to East Asia, leading to an abnormal anticyclone in the East Asian upper and middle troposphere, and an abnormal cyclone in the lower troposphere. This enhances the warm and humid airstream from the Western Pacific to the Chinese mainland and strengthens upwelling over the Loess Plateau and the middle–lower reaches of the Yangtze River. These conditions enhance precipitation in central China during positive ASO anomaly events and reduce precipitation during negative events. The WACCM4 simulations support the results from our statistical analysis of observations and reanalysis data. Our results suggest that ASO variation can serve as a predictor of spring precipitation variation over the Loess Plateau and the middle–lower reaches of the Yangtze River.

Global Cooling System installed on the beach by means of Artificial Convection and Artificial Rain

*Murakami Hideyo[1]

1. Ii Ecology Development

In recent years the Earth is warming. The sun radiates sunlight energy and warms the Earth. The Earth reflects a part of sunlight energy to space and radiates infrared ray including latent heat energy to space. An amount of sunlight energy received by the earth is almost the same as an amount of energy sent out by the earth. The amount of sunlight energy is almost constant. On the other hand Greenhouse gas such as CO_2 decreases a ratio of a heat enrgy which air sent out to space to a heat enrgy which air radiates. Then global mean temperature is increasing and many severe climate events due to mean temperature increase happen. In the world many people study to decrease CO_2 accumulation in air and not to increase global mean temperature. However a useful system for decreasing CO_2 accumulation cannot be developed.

This paper studies Global Cooling System. Global Cooling System is composed of Artificial Convection Equipment (type II) and a control center. Global Cooling System can cancel mean temperature increase and cools the Earth, even if air has a lot of greenhouse gas and mean temperature increase is 2℃.

Artificial Convection Equipment looks like a large greenhouse, which is composed of 1 roof, 1 wall, 1 air inlet, 1 air outlet and 1 heater. Artificial Convection Equipment is installed on a tropical beach where it is hot and humidity (35℃, 26.2g kg^{-1}), and a sea breeze during daytime. The roof and the wall are made of transparent plastic sheet and there are the heater (black sheet) under the roof. The heater receives sunlight energy under the roof and changes sunlight energy to heat energy, and warms air inputted from the inlet and sends out heated air from the outlet. Heated air is lighter than circumstance air and is lifted up to the troposphere. The lifted air, which includes a lot of vapor, is cooled in the troposphere. Then vapor is cooled and is changed to artificial rain or snow in the troposphere. The artificial rain or snow falls down to the land. As a result Artificial Convection Equipment artificially makes convection between the beach surface and the troposphere, by transporting warmed air from the beach surface to the troposphere upward and bringing down artificial rain or snow with high altitude air downward. The lifted air sends out latent heat and sensing heat energy of circumstance air including vapor on the beach surface to space, and the artificial rain or snow with the high altitude air absorbs sensing heat and dissolution heat from circumstance air on the land, and cools the land surface too. Furthermore in a region where it is hot and small rain, a half amount of artificial rain is absorbed by plants. Plants vaporize it and absorbs latent heat from circumstance air. Then the earth is cooled by plants too.

This paper analyses Global Cooling System by means of Artificial Convection and Artificial Rain, and shows that mean temperature increase can be stop by Global Cooling System. A large scale of experiment is required to reconfirm a characteristics of Global Cooling System.

Stratospheric front-like temperature structure and gravity wave activity during a stratospheric sudden warming event in 2016

*Yukari Sumi[1], Kaoru Sato[1]

1. University of Tokyo

A large-scale front-like temperature structure is observed in the Arctic stratosphere during a stratospheric sudden warming (SSW) event in 2016. As reported by previous studies, it is shown that a stratospheric front with a vertical scale of about 15 km is formed near the polar vortex edge and vertically tilts toward a colder region. Moreover, we found that the front is the strongest a few days prior to the major warming and that a local maximum of temperature appears in the exit region of a jet streak. These characteristics of the front are roughly common among other SSW events. However, it is not clear as to why the front-like structure is strengthened during the SSW event, which still needs more observational analysis. In the present study, the semi-geostrophic system is considered to better understand the frontogenesis in the stratosphere. Q-vector and frontogenesis function are computed by using MERRA-2 reanalysis data. Near the front region, the geostrophic and ageostrophic parts of the frontogenesis function have large negative and small positive values, respectively. Therefore, it is suggested that the weakening of the front due to geostrophic flow is dominant over the strengthening of the front due to ageostrophic flow. The ageostrophic part is further separated into horizontal and vertical components. The vertical component is positive and significantly larger than the horizontal component. This result implies that the frontogenetic effect of the ageostrophic motion mainly comes from the vertical motion, which seems to be different from the tropospheric front: convergence of the horizontal ageostrophic wind is dominant for the tropospheric front because the vertical motion is suppressed near the ground surface. In addition, gravity wave (GW) activity near the front is examined by using dry temperature data from FORMOSAT-3/COSMIC satellite. The vertical wavelength of the GW is estimated from 1D-Stockwell transform (S-transform) for the temperature data. The S-transform spectra have a peak around 4–7 km in the vertical range between 25 and 35 km where the stratospheric front is the strongest.

The effects of a well-resolved stratosphere on the simulated boreal winter circulation in a climate model

*Yoshio Kawatani[1], Kevin Hamilton[2], Lesley J. Gray[3], Scott M. Osprey[3], Shingo Watanabe[1], Yousuke Yamashita[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. International Pacific Research Center, University of Hawaii, 3. Atmospheric, Oceanic and Planetary Physics, Department of Physics, University of Oxford

The impact of stratospheric representation is investigated using the Model for Interdisciplinary Research On Climate Atmospheric General Circulation Model (MIROC-AGCM) run with different model-lid heights and stratospheric vertical resolutions, but unchanged horizontal resolutions (~1.125°) and subgrid parameterizations. One hundred year integrations of the model were conducted using configurations with 34, 42, 72 and 168 vertical layers and model-lid heights of ~27 km (L34), 47 km (L42), 47 km (L72) and 100 km (L168). Analysis of the results focused on the Northern Hemisphere in winter. Compared with the L42 model, the L34 model produces a poorer simulation of the stratospheric Brewer-Dobson circulation (BDC) in the lower stratosphere, with weaker polar downwelling and accompanying cold pole and westerly jet biases. The westerly bias extends into the troposphere and even to the surface. The tropospheric westerlies and zone of baroclinic wave activity shift northward; surface pressure has negative (positive) biases in the high (mid) latitudes, with concomitant precipitation shifts. The L72/L168 models generate a Quasi-Biennial Oscillation (QBO) while the L34/42 models do not. The L168 model includes the mesosphere, and thus resolves the upper branch of the BDC. The L72 model simulates stronger polar downwelling associated with the BDC than does the L42 model. However, experiments with prescribed nudging of the tropical stratospheric winds suggest differences in the QBO representation cannot account for L72-L42 differences in the climatological polar night jet structure. The results show that the stratospheric vertical resolution and inclusion of the full middle atmosphere significantly affect tropospheric circulations.

On the relation between three-dimensional wave activity flux and pseudo momentum without using intrinsic phase velocities

*Takenari Kinoshita[1]

1. Japan Agency for Marine-Earth Science and Technology

The middle-atmosphere general circulation is driven by various wave activities. The transformed Eulerian-Mean (TEM) are the useful tools to diagnose interaction between waves and mean state. The three-dimensional (3D) extension of TEM equations has been conducted since 1980s and the recent study uses the 3D wave activity flux for the analysis of special structure of Rossby wave activities during Stratospheric Sudden Warming. It was proved that divergence of wave activity flux corresponds to the time variation of pseudo momentum in the TEM equations (Eliassen-Palm relation). Also, this relation is proved in the 3D-TEM equations. However, the pseudo momentum used in the relation is defined as the wave energy divided by intrinsic phase velocities and is difficult to use in the data analysis. In this study, referring Double Impulse pseudo momentum of Aiki et al. (2015), the pseudo momentum without using intrinsic phase velocities are introduced and the relation between 3D wave activity flux divergence and time variation of pseudo momentum in the middle atmosphere is reported.

Hindcasts of the 2016 Disruption of the Stratospheric Quasi-biennial Oscillation

*Shingo Watanabe[1], Kevin Hamilton[2], Scott Osprey[3], Yoshio Kawatani[1], Eriko Nishimoto

1. Japan Agency for Marine-Earth Science and Technology, 2. International Pacific Research Center, University of Hawaii at Manoa, 3. NCAS-Climate, University of Oxford

In early 2016 the quasi-biennial oscillation in tropical stratospheric winds was disrupted by an anomalous easterly jet centered at ~40 hPa, a development that was completely missed by all operational extended range weather forecast systems. This event and its predictability are investigated through ensemble hindcasts using a global model notable for its sophisticated representation of the upper atmosphere. Key to prediction of this event is simulating the slowly evolving mean winds in the winter subtropics that provide a waveguide for Rossby waves propagating from the winter hemisphere. Its association to the strong El Nino condition in 2015 is also investigated by changing sea surface temperatures.

Selection bias of quasi-fixed-point observations in the ExUTLS and its impact on the seasonal record

*Yoichi Inai[1], Toshinobu Machida[2], Hidekazu Matsueda[3], Yousuke Sawa[3], Kazuhiro Tsuboi[3], Keiichi Katsumata[2,4], Shinji Morimoto[1], Shuji Aoki[1], Takakiyo Nakazawa[1], Ryo Fujita[5,1]

1. Tohoku Univ., 2. NIES, 3. MRI, 4. Takachiho Chem. Industrial, 5. Imperial College London

Fixed-point observations are essential for long-term monitoring of the atmospheric environment. However, some attention might be paid to the interpretation of seasonal variations appearing in the observational record, particularly for regions with large seasonal variations. In the extra-tropical upper troposphere/lower stratosphere (ExUTLS), the climatological tropopause height changes with season. This leads to a seasonal dependence of whether individual fixed-point observations are included in the stratosphere or the troposphere. In this study, using the reanalysis fields, quasi-fixed-point observations in the ExUTLS are simulated and categorized as being in the troposphere or stratosphere based on their position relative to the dynamic tropopause, to investigate seasonal tendencies of the categorization. The influence of these tendencies on seasonal variations of atmospheric composition in the categorized data is estimated. The seasonal cycles of CH_4, N_2O and SF_6 mixing ratios are found to change with the categorization method. In particular, the minimum values for these tropospheric tracers in observations categorized as stratospheric occur 1–2 months later than in uncategorized observations. This delay in stratospheric record is interpreted as the selection bias, that is, the air mass categorized as the stratospheric atmosphere biased to some specific meteorological situation due to the seasonal variation of ExUTLS meteorological field.

Varying Rossby Wave Trains from the Developing to Decaying Period of the Upper Atmospheric Heat Source over the Tibetan Plateau in Boreal Summer

*Chuandong Zhu[1,2], Rongcai Ren[1]

1. Institute of Atmospheric Physics, Chinese Academy of Sciences, 2. University of Chinese Academy of Sciences

This study demonstrates the two different Rossby wave train (RWT) patterns related to the developing/decaying upper atmospheric heat source over the Tibetan Plateau (TPUHS) in boreal summer. The results show that the summer TPUHS is dominated by quasi-biweekly variability, particularly from late July to mid-August when the subtropical jet steadily stays to the north of the TP. During the developing period of TPUHS events, the intensifying TPUHS corresponds to an anomalous upper-tropospheric high over the TP, which acts as the main source of a RWT that extends northeastward, via North China, the central Pacific and Alaska, to the northeastern Pacific region. This RWT breaks up while the anomalous high is temporarily replaced by an anomalous low due to the further deepened convective heating around the TPUHS peak. However, this anomalous low, though existing for only three to four days due to the counteracting dynamical effects of the persisting upper/lower divergence/convergence over the TP, acts as a new wave source to connect to an anomalous dynamical high over the Baikal region. Whilst the anomalous low is diminishing rapidly, this Baikal high becomes the main source of a new RWT, which develops eastward over the North Pacific region till around eight days after the TPUHS peak. Nevertheless, the anomaly centers along this decaying-TPUHS-related RWT mostly appear much weaker than those along the previous RWT. Therefore, their impacts on circulation and weather differ considerably from the developing to the decaying period of TPUHS events.

Equilibrium Climate Responses of the East Asian Summer Monsoon to Various Anthropogenic Aerosol Species

*Qiuyan Wang[2,1], Zhili Wang[1,2], Hua Zhang[3,2]

1. State Key Laboratory of Severe Weather & Key Laboratory of Atmospheric Chemistry of CMA, Chinese Academy of Meteorological Sciences, Beijing, 2. Collaborative Innovation Center on Forecast and Evaluation of Meteorological Disasters, Nanjing University of Information Science and Technology, Nanjing, 3. Laboratory for Climate Studies, National Climate Center, China Meteorological Administration, Beijing

The equilibrium climate responses of the East Asian summer monsoon (EASM) to increases in various types of anthropogenic aerosol emissions, including sulfate, organic carbon (OC), and black carbon (BC), from 1850 to 2000 are studied using an aerosol-climate online model. The results show that various aerosol species have substantially different impacts on the EASM by changing the local sea-land surface thermal difference and atmospheric circulation. The increased sulfate leads to decrease in the surface thermal difference between the land and ocean, the southward shift of the East Asian subtropical jet (EASJ), and significant northerly wind anomalies at 850 hPa over eastern China and the ambient oceans, thus dampening the EASM markedly. Pronounced surface cooling appears and an anomalous anticyclone is formed over the oceans north of 30˚N due to the increase of OC. These cause slight increase in sea-land surface thermal difference and southerly flow anomalies to the west of the anticyclonic center, thereby strengthening the northern East Asian summer monsoon (NEASM). However, the increased OC decreases the sea-land surface thermal contrast over southern China, which weakens the southern East Asian summer monsoon (SEASM). The responses of summer 850 hPa winds and rainfall over the East Asian monsoon region (EAMR) to increase in BC are generally consistent with those to increase in OC. The increased BC leads to the strengthening of the NEASM north of 35˚N and slight weakening of the SEASM south of 35˚N. Also, the simulated responses of the EASM to increase in BC are not changed when BC emission is scaled up by five times its 2000 levels, but the intensities of responses are enhanced. Overall, the increase in sulfate primarily weakens the EASM, while the increases in BC and OC mitigate the weakening of the NEASM to some extent.

Analysis of specific energy in zonal currents focusing on the analogy between jet stream and open channel flow

*Yoshikazu Kitano[1], Tomohito J. Yamada[2]

1. Central Research Institute of Electric Power Industry, 2. Faculty of Engineering, Hokkaido University

Atmospheric blocking is one of the important causes of meteorological extremes in mid-latitude, such as cold spells, heat waves and long-term heavy rainfalls. Rossby (1950) focused on dynamical analogies between the hydraulic jump in open channel flow and the atmospheric blocking in jet stream, and proposed a theoretical formula to explain the two dynamically possible states in zonal currents which are compatible with supercritical and subcritical flow in an open channel flow. Armi (1989) focused on the specific energy flux in zonal currents and showed that a dimensionless parameter, which is called Froude/Rossby number, is analogous to the Froude number of open channel flow. Kitano and Yamada (2017) extended these theories to realistic conditions in atmosphere and showed a relationship between typical blocking flow and specific energy flux in jet stream. In this study, we analyzed several blocking episodes using specific energy flux and found energetic signals over Japan and its surroundings before Pacific blocking occasions. These signals may contribute to prediction on blocking.

Analysis of the ozone reduction event over the southern tip of South America in November 2009

*Hideharu Akiyoshi[1], Masanao Kadowaki[2], Haruna Nakamura[3], Takafumi Sugita[1], Toshihiko Hirooka[4], Yayoi Harada[5], Akira Mizuno[6]

1. National Institute for Environmental Studies, 2. Japan Atomic Energy Agency, 3. Fujitsu FIP Corporation, 4. Department of Earth and Planetary Sciences, Kyushu University, 5. Meteorological Research Institute, 6. Institute for Space-Earth Environmental Research, Nagoya University

A reduction of the total ozone over the southern tip of South America lasting 3 weeks occurred in November 2009. Analyses of the ERA-Interim reanalysis data and the total ozone observed by the OMI indicate that the total ozone reduction event was caused by a migration of the polar vortex toward the South American continent at the time of the vortex breakup. The vortex migration is associated with an enhanced wave flux from the troposphere at 120–150˚W and 50–60˚S to the west of the South American continent to the stratosphere over the southern part of the continent, which led to a large negative geopotential height anomaly in the lower stratosphere. In November, a blocking pattern was diagnosed from the 500 hPa geopotential height over the west of the South American continent. These results suggest a relation between the long-lasting reduction of the total ozone over the southern tip of South America and the blocking phenomenon in the troposphere of the Southern Hemisphere through wave propagation from the blocking region in 2009.

The total ozone, the geopotential height at 50 hPa and 500 hPa, the wave activity flux, the polar vortex migration and elongation, and the blocking pattern in the Southern Hemisphere November for 1979–2015 as well as 2009 were investigated. The results show that the relation between the blocking pattern in the troposphere and the large polar vortex migration and elongation in the stratosphere is also evident in November 1987, 1994, 1997, 2001, and 2011. Especially, in November 1994, 1997, and 2011, the blocking pattern and the polar vortex migration occurred near the South American continent.

These results indicate that the migration of the Antarctic polar vortex to the southern tip of South America in November occurred occasionally in the past. They also suggest that diagnosis of blocking pattern in the Southern Hemisphere troposphere may be useful for prediction of the direction of polar vortex migration in the stratosphere, and hence, prediction of high UV radiation risk over the southern tip of South America in early summer.

This research was supported by JST/JICA, SATREPS, the Environment Research and Technology Development Fund.

Analysis of relatively low ozone in Arctic spring during the QBO-westerly and solar-minimum years

*Yousuke Yamashita[1,2], Hideharu Akiyoshi[2], Masaaki Takahashi[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. National Institute for Environmental Studies

The equatorial quasi-biennial oscillation (QBO) and the 11-year solar cycle are known to cause year-to-year variability of the Northern Hemisphere (NH) polar vortex (e.g. Holton and Tan, 1980; Labitzke, 1987). Labitzke (1987) and several studies following her work have been used the four categories of the QBO and 11-year solar cycle, according to the westerly/easterly phase of the QBO (QBO-W/QBO-E) and the maximum/minimum phase of the 11-year solar cycle (S_{max}/ S_{min}). Camp and Tung (2007) suggested that the NH polar vortex is the most stable and the least perturbed state in late winter during the QBO-W/S_{min} years relative to the other three groups (QBO-W/S_{max}, QBO-E/S_{max}, and QBO-E/S_{min}), in agreement with the work of Labitzke and van Loon (1988). Their findings are in agreement with the smallest magnitude of the Arctic total ozone in QBO-W/S_{min} years among the four categories (Li and Tung 2014), because the ozone depletion is enhanced in the stable and cold polar vortex associated with an increase in chemical destruction through heterogeneous reactions on the Polar Stratospheric Clouds (PSCs). Since the Arctic ozone amount is related to the ozone transport as well as the chemical ozone destruction, the estimation of their influences is still challenging issue for understanding the small amount of the Arctic total ozone in March.

In this study, we analyze the Arctic ozone amount using TOMS/OMI observations, ERA-interim reanalysis data, and the outputs of a chemistry climate model (CCM) with REF-C1SD hindcast simulation, in which the model’s zonal/meridional wind and temperature are nudged toward those of the ERA-interim reanalysis data with a 6-hour interval. The anomaly from the average for all the years of 1979–2011 in the Arctic total ozone amount is calculated for QBO-W/S_{min} group in late winter. We estimate the amounts of ozone transport and chemical ozone destruction and their effects on the derived Arctic ozone anomaly for the QBO-W/S_{min} group with CCM outputs.

Result of the composite mean for QBO-W/S_{min} years shows negative anomaly (relatively small amount) of total ozone in February–March compared to the 1979–2011 average from the CCM output, in agreement with the satellite observation, reanalysis data. To distinguish the effect of chemical ozone destruction from that of ozone transport for the total ozone anomaly in February–March, we analyze the total ozone anomaly of the passive ozone tracer without any chemical change in the CCM. The negative anomalies of the passive ozone tracer have a similar distribution to that of chemically reactive ozone with similar magnitude, suggesting that the negative anomalies of total ozone are mainly caused by ozone transport.

The outputs of CCM are also analyzed for vertical profile of ozone concentration, which indicates negative anomaly of the Arctic ozone in the upper troposphere and the lower stratosphere for the QBO-W/S_{min} condition, the maximum anomaly of ozone partial column is located around 50–70 hPa. The partial column of the passive ozone tracer at these levels also shows negative anomalies, whilst their magnitudes are small, especially at 50 hPa in March. These results suggest the significant influence of ozone transport on the negative ozone anomaly in February–March, whilst the influence of chemistry is partially large at 50 hPa in March.

Evaluation of ozone in the upper troposphere and lower stratosphere derived from multi-species satellite data assimilation

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Koji Ogochi[1], Kengo Sudo[3,1], Masayuki Takigawa[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Jet Propulsion Laboratory/California Institute for Technology, 3. Graduate School of Environmental Studies, Nagoya University

Ozone (O_3) in the upper troposphere and lower stratosphere (UTLS) has a stronger greenhouse effect than in the lower troposphere. However, information on O_3 in the UTLS from observations with the global coverage is still limited. Multi-species satellite data assimilation of stratospheric O_3, and tropospheric O_3 and its precursors is expected to provide better constraints on O_3 in the UTLS, because O_3 in the UTLS is controlled by stratospheric O_3 intrusions, O_3 transport from middle and lower troposphere, and in-situ O_3 chemical production. In this study, we evaluate O_3 in the UTLS derived from the multi-species data assimilation with horizontal resolutions of 2.8, 1.1, and 0.56 degree using ozonesonde observations (not used for data assimilation) in April 2008. Assimilated data were obtained from the OMI, GOME-2, and SCIAMACHY for tropospheric NO_2 column, the TES for O_3 profile, the MOPITT for total CO column, the MLS for O_3 and HNO_3 profiles, and the OMI for total SO_2 column. At 200 hPa, 300 hPa, and 500 hPa, the data assimilation at 0.56-degree resolution reduced root mean square errors (RMSEs) against ozonesonde observations in the northern midlatitudes by 32%, 31%, and 13%, respectively, compared to the model simulation without data assimilation. The overall data assimilation performance for O_3 concentrations is not sensitive to horizontal resolution in the altitudes between 200 hPa and 500 hPa (i.e., the RMSEs were within 7% at all resolutions). Meanwhile, the data assimilation at 0.56-degree resolution improved agreements with ozonesonde observations at 300 hPa by up to 55% compared to 1.1- and 2.8-degree resolutions during a deep stratospheric intrusion episode at Trinidad Head (124˚W, 41˚N) through resolving small-scale transport processes. These results confirm that O_3 analyses derived from multi-species data assimilation are suitable for understanding spatial and temporal variations in O_3 in the UTLS and their controlling processes.

Characteristics of Initial Perturbation of JMA GEPS during Sudden Stratospheric Warmings

*Shunsuke Noguchi[1,2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Meteorological Research institute, Japan Meteorological Agency

In order to sophisticate the ensemble forecasting and data assimilation system of the whole atmosphere, it is necessary to accumulate the knowledge about the uncertainty of the analysis in the stratosphere and mesosphere, which is poor in comparison with that in the troposphere. Therefore, this study investigates characteristics of initial perturbation of the Japan Meteorological Agency (JMA) Global Ensemble Prediction System (GEPS), which has been replaced in March 2017.

By focusing on two Sudden Stratospheric Warming (SSW) events occurred in 2017-2018 and 2018-2019 winters, several aspects of the new JMA GEPS are revealed as follows: (1) There is large uncertainty above the upper stratosphere (which has not been reflected in the previous system). (2) The analysis ensemble spread increases and penetrates downward from the upper stratosphere during the onset period of both SSW events, though its precursory nature is not so evident as pointed by previous studies (e.g. Enomoto et al. 2010). (3) After SSW events, the analysis ensemble spread in the middle and upper stratosphere shrinks in association with the change of dominant physical processes. However, relatively large spreads, which may have implications for the stratosphere-troposphere coupling, are sometimes found in the lower stratosphere.

The quality of forecasts and analyses above the upper stratosphere would be inevitable from the artificial effect of sponge layers near the model top. Therefore, it is worth comparing or communicating with results of some high-top system to validate the appropriateness of above-mentioned aspects (e.g. (1)) and recognize limitations of current operational settings.

[A-OS08] ECS-Kuroshio and Ryukyu Current System -Observation, modeling and theory-

convener:Hirohiko Nakamura(Kagoshima University, Faculy of Fisheries), Xiao-Hua Zhu(Second Institute of Oceanography)

The East China Sea (ECS) is separated from the North Pacific basin by the Ryukyu Islands. On each side of the Ryukyu Islands, there lies two western boundary currents -the Kuroshio on the northwest and the Ryukyu Current on the southeast. These two currents play an important role in the global substance cycle and have a remarkable impact on the climate and adjacent marginal seas. Our knowledge of the Kuroshio and the Ryukyu Current's dynamics, variability, and impact has advanced significantly over the last decade, because of recent international collaborative field programs, improvement in satellite measurements, and advancement in high-resolution numerical models. This session seeks contributions from ECS-Kuroshio and Ryukyu Current studies and will cover a wide range of topics of observation, modeling and theory. The dynamics of the Kuroshio and the Ryukyu Current's variability at all spatio-temporal scales, the influence of the Kuroshio on typhoons and climate, the interactions among the Kuroshio, Ryukyu Current and eddies, internal waves including near-internal waves and their interactions with background currents, and the water mass exchanges through the gaps between the Ryukyu Islands are welcome to be discussed in this session.

Impact of the mesosacle eddies on the western boundary current over the entire western North Pacific

*Kako Shinichiro[1], Hirohiko Nakamura[2]

1. Graduate School of Science and Engineering, Kagoshima University, 2. Faculty of Fisheries, Kagoshima University

Although many previous studies have suggested that the mesoscale eddies affect the variations of the Kuroshio and Ryukyu current systems, the generated regions and paths to the western boundary have not been well explained yet. We constructed a mesosacle eddy tracking dataset using FORA-WNP30 in conjunction with Okubo-Weiss parameters to investigate the effects of eddies on the western boundary current over the entire North Pacific. We observed that cyclonic eddies with relatively long durations (>120 days) were mainly generated around the southern Kuroshio Extension region, while anti-cyclonic eddies were generated around the subtropical counter current. In addition, we found that the cyclonic eddies propagate westward along the Kuroshio region and reach the western boundary, while the anti-cyclonic eddies propagate westward from their regions of origin and thereafter reach the Kuroshio recirculation region and Ryukyu current. The comparison of the Ryukyu-current at a depth of 600 m and the number of times the meso-scale eddies passed over the Ryukyu current demonstrated that the weakening (strengthening) of the northward current in the northern part of the Ryukyu region was consistent with the number of times the cyclonic (anti-cyclonic) eddies passed over the northern part of the Ryukyu current.

Glider observations of interleaving layers in the Kuroshio

*Sen Jan[1], Shih-Hong Wang[1], Kai-Chieh Yang[1], Yiing Jang Yang[1], Ming-Huei Chang[1]

1. Institute of Oceanography, National Taiwan Univ.

Interleaving layers (or thermohaline intrusions) were sometimes observed by repeated ship-based hydrographic surveys with coarse spacing between adjacent stations in the Kuroshio off Taiwan, but have never been examined in a dynamic context. A Seaglider was navigated along a triangle track east of Taiwan to complete two repeated high-resolution hydrographic observations from December 2016 to March 2017. Prominent interleaving layers were observed between dissimilar intermediate water masses across the Kuroshio. During the observations, a diple eddy pair and a relatively large anticyclonic eddy impinged on the offshore flank of the Kuroshio, respectively, which brought certain impacts on the formation and growth of the interleaving. Aside from the complicated physical processes in the upper 200 m, salinity profiles indicate that interleaving layers appeared within 500 and 800 m with vertical and horizontal length scales of O(50 m) and O(10-100 km), respectively. The time scale for the interleaving layers should be much less than 30 days, inferred from the discrepancy in the interleaving features between the two surveys. The instability analysis together with values of the Turner angle calculated from the hydrographic data suggests that the double-diffusive instability is the primary driving mechanism for the observed interleaving layers.

A two-year ocean bottom pressure record acquired between June 2015 and June 2017 observed by two pressure-recording inverted echo sounders (PIESs) and five current and pressure-recording inverted echo sounders (CPIESs) deployed along a section southwest of the Kerama Gap showed a significant 21-day variability. This 21-day bottom pressure variability (P_{bot21}) was particularly strong from July 2016 to January 2017, and it showed a squared coherence of 0.72 with wind stress curl around the Yangtze estuary in the East China Sea (ECS) during this period with a nearly 3-day time lag. A barotropic ocean model demonstrated the generation, spread, and dissipation of P_{bot21}. The modeling results showed that the P_{bot21} was driven by wind stress curl on the continental shelf of the ECS, where depths are shallower than 100 m, and spread southeastward to the Ryukyu Island Chain (RIC). The P_{bot21} was generated and remained on the shallow continental shelf, and only little power spread toward the RIC; thus, whether the signal could be observed by the mooring array was related to where it was generated. Significant P_{bot21} was generated southeast of the Yangtze estuary and measured by the mooring array from July 2016 to January 2017. However, P_{bot21} generated northeast of the Yangtze estuary, far from the mooring section, from January 2016 to April 2016 was exhausted before reaching the mooring array due to the long distance. It is suggested that the spatial pattern of 21-day wind stress curl over the ECS strongly influences P_{bot21} near the RIC.

A numerical study on the dynamics of seasonal velocity variation in the East China Sea

*ZHENLONG ZHANG[1], Nakamura Hirohiko[1], Xiao-Hua Zhu[2]

1. Kagoshima University, 2. Ministry of Natural Resources, CHINA.

In our previous study, we investigated the seasonal velocity variations at different depths over the entire Kuroshio path. It showed that the upper layer (< ~500 m depth) velocity variation over the entire Kuroshio path has a coherent seasonal feature, which reaches a maximum in July and a minimum in autumn or winter, over most of the regions along the Kuroshio path. However, the lower layer velocity (> ~500 m depth, in the continental slope area from the east of Luzon Island to the east of the Ryukyu Island chain) shows a reversed seasonal variation with a maximum in winter. Several numerical experiments were carried out to clarify the essential mechanisms. Although it was shown that the local wind stress upon the current region is a key factor for the seasonal velocity variation in the upper layer, the detailed driving mechanism has been still unknown. Thus, we perform further numerical experiments to clarify the concreate mechanism in this study. Using a rectilinear regional model with idealized continental slope, we have successfully reproduced the seasonal velocity variation of the jet (the Kuroshio) by the seasonal wind stress variation over the jet. It turns out that the velocity of the jet increases (decreases) when the wind stress is directed to downstream (upstream) direction of the jet. We will report the concrete process underlying acceleration and deceleration processes of the upper layer velocity related to the local wind stress.

Temporal and spatial velocity variations over the Kuroshio Extension, Kuroshio and Ryukyu Current System in 1982-2014

*YUXIANG QIAO[1], Hirohiko Nakamura[2], AYAKO NISHINA[2]

1. Kagoshima University, Graduate School of Fisheries, 2. Kagoshima University, Faculty of Fishries

Four dimensional variational Ocean ReAnalysis for the Western North Pacific (FORA-WNP30) from 1982 to 2014 is used to investigate temporal and spatial velocity variations over the regions consisting of Kuroshio Extension (KE), Kuroshio and Ryukyu Current System (RCS). In order to identify such temporal and spatial features, we made Hovmöller diagrams at several depths, which display temporal variations of along-stream velocity along the current path from Luzon Island to KE region. In this study, we particularly examine long-term (> 1 year) variations for their regional characteristics (Luzon Island to KE region) and their vertical features (sea surface to 1000 m depth). The results revealed that 1) the KE is dominated by decadal signals while the upstream regions include clearer interannual signals in addition to decadal ones, 2) decadal variations in the KE tends to be almost out of phase to those variations in the upstream regions from Luzon Island to Izu-Ridge, and 3) the velocity variations at the sea surface tend to be similar to those variations at 1000 m depth.

The Okinawa Trough is a basin within the East China Sea, where maximum depth reaches 2300 m. There are two characteristic water masses in the Okinawa Trough. One is the high salinity water in the sub-surface layer shallower than 300 m and the other is the low salinity water in the intermediate layer from 400 m to 700 m. According to the previous studies, the former water is occupied by the South China Sea Tropical Water (SCSTW) and the Kuroshio Tropical Water (KTW), and the latter is dominated by modified water masses of the North Pacific Intermediate Water (NPIW) and the South China Sea Intermediate Water (SCSIW). However, in the previous studies, the southern part of the Okinawa Trough remains to be observed, and it should be confirmed whether the previous results can apply to the southern part.
In this study, water mass properties in the southern part of the Okinawa Trough are investigated in detail. We mainly used CTD data from T/V Kagoshima-maru cruises in Junes from 2013 to 2018. The high salinity waters in the sub-surface layer were classified into three groups: SCSTW, KTW and the tropical waters in the east of Ryukyu Islands chain. The low salinity water in the intermediate layer had a complicated distribution in which the low salinity water from the east of Taiwan and that from the Kerama Gap.

[A-OS08] ECS-Kuroshio and Ryukyu Current System -Observation, modeling and theory-

convener:Hirohiko Nakamura(Kagoshima University, Faculy of Fisheries), Xiao-Hua Zhu(Second Institute of Oceanography)

The East China Sea (ECS) is separated from the North Pacific basin by the Ryukyu Islands. On each side of the Ryukyu Islands, there lies two western boundary currents -the Kuroshio on the northwest and the Ryukyu Current on the southeast. These two currents play an important role in the global substance cycle and have a remarkable impact on the climate and adjacent marginal seas. Our knowledge of the Kuroshio and the Ryukyu Current's dynamics, variability, and impact has advanced significantly over the last decade, because of recent international collaborative field programs, improvement in satellite measurements, and advancement in high-resolution numerical models. This session seeks contributions from ECS-Kuroshio and Ryukyu Current studies and will cover a wide range of topics of observation, modeling and theory. The dynamics of the Kuroshio and the Ryukyu Current's variability at all spatio-temporal scales, the influence of the Kuroshio on typhoons and climate, the interactions among the Kuroshio, Ryukyu Current and eddies, internal waves including near-internal waves and their interactions with background currents, and the water mass exchanges through the gaps between the Ryukyu Islands are welcome to be discussed in this session.

Impact of the mesosacle eddies on the western boundary current over the entire western North Pacific

*Kako Shinichiro[1], Hirohiko Nakamura[2]

1. Graduate School of Science and Engineering, Kagoshima University, 2. Faculty of Fisheries, Kagoshima University

Although many previous studies have suggested that the mesoscale eddies affect the variations of the Kuroshio and Ryukyu current systems, the generated regions and paths to the western boundary have not been well explained yet. We constructed a mesosacle eddy tracking dataset using FORA-WNP30 in conjunction with Okubo-Weiss parameters to investigate the effects of eddies on the western boundary current over the entire North Pacific. We observed that cyclonic eddies with relatively long durations (>120 days) were mainly generated around the southern Kuroshio Extension region, while anti-cyclonic eddies were generated around the subtropical counter current. In addition, we found that the cyclonic eddies propagate westward along the Kuroshio region and reach the western boundary, while the anti-cyclonic eddies propagate westward from their regions of origin and thereafter reach the Kuroshio recirculation region and Ryukyu current. The comparison of the Ryukyu-current at a depth of 600 m and the number of times the meso-scale eddies passed over the Ryukyu current demonstrated that the weakening (strengthening) of the northward current in the northern part of the Ryukyu region was consistent with the number of times the cyclonic (anti-cyclonic) eddies passed over the northern part of the Ryukyu current.

Glider observations of interleaving layers in the Kuroshio

*Sen Jan[1], Shih-Hong Wang[1], Kai-Chieh Yang[1], Yiing Jang Yang[1], Ming-Huei Chang[1]

1. Institute of Oceanography, National Taiwan Univ.

Interleaving layers (or thermohaline intrusions) were sometimes observed by repeated ship-based hydrographic surveys with coarse spacing between adjacent stations in the Kuroshio off Taiwan, but have never been examined in a dynamic context. A Seaglider was navigated along a triangle track east of Taiwan to complete two repeated high-resolution hydrographic observations from December 2016 to March 2017. Prominent interleaving layers were observed between dissimilar intermediate water masses across the Kuroshio. During the observations, a diple eddy pair and a relatively large anticyclonic eddy impinged on the offshore flank of the Kuroshio, respectively, which brought certain impacts on the formation and growth of the interleaving. Aside from the complicated physical processes in the upper 200 m, salinity profiles indicate that interleaving layers appeared within 500 and 800 m with vertical and horizontal length scales of O(50 m) and O(10-100 km), respectively. The time scale for the interleaving layers should be much less than 30 days, inferred from the discrepancy in the interleaving features between the two surveys. The instability analysis together with values of the Turner angle calculated from the hydrographic data suggests that the double-diffusive instability is the primary driving mechanism for the observed interleaving layers.
