# Thu. May 30, 2019

[J] Oral | U (Union )：Union

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | IC 2F

## [U-06] Japan's contribution to IUGG celebrating 100th anniversary

convener:Setsuya Nakada(National Research Institute for Earth Science and Disaster Resilience), Kenji Satake(Earthquake Research Institute, University of Tokyo), Kumiko Goto-Azuma(National Institute of Polar Research), Chairperson:Kumiko Goto-Azuma(National Institute of Polar Research), Setsuya Nakada(NIED)

9:00 AM - 9:20 AM JST | 12:00 AM - 12:20 AM UTC

[U06-01] **Centennial of the International Cooperation in Earth and Space Sciences**

★Invited Papers

*Alik Ismail-Zadeh[1,2,3] (1.Karlsruhe Institute of Technology, 2.International Union of Geodesy and Geophysics, 3.International Science Council)

---

9:20 AM - 9:40 AM JST | 12:20 AM - 12:40 AM UTC

[U06-02] IUGG and Japan: the past, the present, and the way to go from now

★Invited Papers

*Masaru Kono[1] (1.Tokyo Institute of Technology)

---

9:40 AM - 9:55 AM JST | 12:40 AM - 12:55 AM UTC

[U06-03] **Contributions from the Science Council of Japan to international cooperation in the field of Earth and planetary science**

*Hisashi Nakamura[1] (1.Research Center for Advanced Science and Technology, University of Tokyo)

---

9:55 AM - 10:15 AM JST | 12:55 AM - 1:15 AM UTC

[U06-04] History and Japanese contribution to the International Association of Cryospheric Sciences IACS

★Invited Papers

*Ralf Greve[1] (1.Institute of Low Temperature Science, Hokkaido University)

---

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[U06-05] **Japan's Contributions to IAG**

*Yoichi Fukuda[1] (1.Department of Geophysics, Graduate School of Science, Kyoto University)

[J] Oral | U (Union )：Union

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | IC 2F

## [U-06] Japan's contribution to IUGG celebrating 100th anniversary

convener:Setsuya Nakada(National Research Institute for Earth Science and Disaster Resilience), Kenji Satake(Earthquake Research Institute, University of Tokyo), Kumiko Goto-Azuma(National Institute of Polar Research), Chairperson:Kumiko Goto-Azuma(National Institute of Polar Research), Kenji Satake(Earthquake Research Institute, the University of Tokyo)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[U06-06] IAGA activities in the era of too many international conferences

*Toshihiko Iyemori[1] (1.Kyoto University)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[U06-07] The role of IAHS in education, research, social issues concerning water and future perspective

*Maki Tsujimura[1] (1.Faculty of Life and Environmental Sciences, University of Tsukuba)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[U06-08] Centenary of the atmospheric sciences: Its progress and future issues

*Teruyuki Nakajima[1] (1.Japan Aerospace Exploration Agency)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[U06-09] Contributuins of Japan to IAPSO

*Yukio Masumoto[1] (1.Graduate School of Science, The University of Tokyo)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[U06-10] IASPEI- activities, history and Japan’s contribution

*Kenji Satake[1], Thorne Lay[2], Johannes Schweitzer[3] (1.Earthquake Research Institute, University of Tokyo, 2.IASPEI President , 3.IASPEI Secretary General)

---

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[U06-11] Recent history of IAVCEI in Japan and young researchers’ response to IUGG and IAVCEI

*Setsuya Nakada[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[J] Oral | U (Union )：Union

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 101 1F

## [U-08] Opinions and recommendations from meeting participants to the future of the Japan Geoscience Union

convener:Yozo Hamano(KOBE Ocean-Bottom Exploration Center, Kobe University), Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita(Geosciences and Civil Engineering, Institute of Science and Engineering, Kanazawa University), Chairperson:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita

1:51 PM - 2:03 PM JST | 4:51 AM - 5:03 AM UTC

[U08-01] Request and proposal from the Committee on Earth and Planetary Sciences of the Science Council of Japan to JpGU

*Ryoichi Fujii[1] (1.Research Organization of Information and Systems)

2:03 PM - 2:15 PM JST | 5:03 AM - 5:15 AM UTC

[U08-02] Geography in JpGU: current status and future perspectives

*Takashi Oguchi[1], Ikuho Yamada[2], Yuichi S. Hayakawa[3], Daichi Kohmoto[4], Hitoshi Saito[5] (1.Center for Spatial Information Science, The University of Tokyo, 2.Faculty of Science and Engineering, Chuo University, 3.Graduate School of Env.Science, Hokkaido University , 4.Nara University of Education, 5.College of Economics, Kanto Gakuin University)

2:15 PM - 2:27 PM JST | 5:15 AM - 5:27 AM UTC

[U08-03] Biogeoscineces will connect everthing together

*Takeshi Kakegawa[1] (1.Graduate School of Science, Tohoku University)

2:27 PM - 2:39 PM JST | 5:27 AM - 5:39 AM UTC

[U08-04] Coverage of JpGU

*Yukihiro Takahashi[1] (1.Department of Cosmosciences, Graduate School of Science, Hokkaido University)

2:39 PM - 2:51 PM JST | 5:39 AM - 5:51 AM UTC

[U08-05] Is he a bit overkill for English?

*Yoshi-Yuki Hayashi[1] (1.Department of Planetology/CPS, Graduate School of Science, Kobe University)

2:51 PM - 3:03 PM JST | 5:51 AM - 6:03 AM UTC

[U08-06] Globalization of Japan Geoscience Union

*Hirokuni Oda[1] (1.Institute of Geology and Geoinformation, Geological Survey of Japan, AIST)

3:03 PM - 3:15 PM JST | 6:03 AM - 6:15 AM UTC

[U08-07] A proposal for JpGU based on the questionaires to SSJ members

*Koshun Yamaoka[1] (1.Earthquake and Volcano Research Center, Graduate School of Environmental Studies, Nagoya University)

[J] Oral | U (Union )：Union

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 101 1F

## [U-08] Opinions and recommendations from meeting participants to the future of the Japan Geoscience Union

convener:Yozo Hamano(KOBE Ocean-Bottom Exploration Center, Kobe University), Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita(Geosciences and Civil Engineering, Institute of Science and Engineering, Kanazawa University), Chairperson:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita

3:30 PM - 3:42 PM JST | 6:30 AM - 6:42 AM UTC

[U08-08] Opinions and recommendations to the Japan Geoscience Union from Society of Geomagnetism and Earth, Planetary and Space Sciences

Yoshiharu Omura[2], Shigeto Watanabe[3], *Yuto Katoh[1], Takuya Tsugawa[4], Yuichi Otsuka[5], SGEPSS steering committee (1.Graduate School of Science, Tohoku University, 2.Research Institute for Sustainable Humanosphere, Kyoto University, 3.Hokkaido Information University, 4.National Institute of Information and Communications Technology, 5.Institute for Space–Earth Environmental Research, Nagoya University)

3:42 PM - 3:54 PM JST | 6:42 AM - 6:54 AM UTC

[U08-09] Collaboration between Earth & Planetary Science and Information Science ~A trial of mutual benefit in the interdisciplinary field~

*Hirohide Demura[1] (1.The University of Aizu)

3:54 PM - 4:06 PM JST | 6:54 AM - 7:06 AM UTC

[U08-10] Comments from young planetary scientists

*Shunichi Kamata[1], Keiko Hamano[2], Go Murakami[3], Ryuki Hyodo[2], Yusuke Nakauchi[3] (1.Hokkaido University, 2.Tokyo Institute of Technology, 3.JAXA/ISAS)

4:06 PM - 4:18 PM JST | 7:06 AM - 7:18 AM UTC

[U08-11] Japan Geoscience Union should operate based on the perspective of individual academic society and fulfill accountability

*Naoji Koizumi[1] (1.School of Environmental Science,the University of Shiga Prefecture)

4:18 PM - 4:30 PM JST | 7:18 AM - 7:30 AM UTC

[U08-12] A proposal from a representative of General Geoscience Sector on a possible direction to future JpGU: actions for domestic activities could be weighted

*Hidenori Kumagai[1] (1.Japan Agency for Marine-Earth Science and Technology)

4:30 PM - 4:42 PM JST | 7:30 AM - 7:42 AM UTC

[U08-13] Fifteen years of Japan Geoscience Letters and its future

*Shogo Tachibana[1], Eiichi Tajika[2] (1.UTokyo Organization for Planetary and Space Science, University of Tokyo , 2.Dept. Earth and Planetary Science, University of Tokyo)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 103 1F

## [P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University), Chairperson:Satoshi Tanaka, Masaki Nishino(名古屋大学宇宙地球環境研究所)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PPS08-01] Observing simulations of impact-induced moonquakes combined with the lunar impact flash observation data for future lunar seismic explorations

*Keisuke Onodera[1,2], Taichi Kawamura[3], Satoshi Tanaka[2], Yoshiaki Ishihara[4], Takuto Maeda[5], Masahisa Yanagisawa[6], Yuki Uchida[6], Shinsuke Abe[7], Ryuhei Yamada[8], Takaya Okamoto[2] (1.SOKENDAI (The Graduate University for Advanced Studies), 2.Institute of Space and Astronautical Science / Japan Aerospace Exploration Agency, 3.Insitut de Physique du Globe de Paris, 4.National Institute for Environmental Studies, 5.Hirosaki University, 6.The University of Electro-Communications, 7.Nihon University, 8.University of Aizu)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PPS08-02] New Results from Restored Apollo Magnetic Field Records

*Peter J Chi[1] (1.University of California Los Angeles)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PPS08-03] Analysis of the High Latitude Region of the Moon with Spectral Profiler Data: Possible Presence of Water Ice

Haramitsu Kyoda[3], *Satoshi Tanaka[1], Makiko Ohtake[1], Hiroshi Nagaoka[2], Yusuke Nakauchi[2], Keisuke Onodera[4] (1.Department of Solid Planetary Sciences Institute of Space and Astronautical Science, 2.Japan Aerospace Exploration Agency, 3.Department of Complexity Science and Enginnering, the University of Tokyo, 4.Department of Space and Astronautical Science, SOKENDAI)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PPS08-04] **Detection of Dark Regions on the Lunar Surface with Shadow Masked Multiband Imager Data**

*Riho Ito[1], Hiroka Inoue[2], Makiko Ohtake[2], Hisashi Otake[2], Ryosuke Nakamura[1] (1.National Institute of Advanced Industrial Science and Technology, 2.Japan Aerospace Exploration Agency)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PPS08-05] Estimation of Moho depth under lunar basins by using only the GRAIL gravity data

*Gaku Nishiyama[1], Noriyuki Namiki[2] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.RISE Project, National Astronomical Observatory of Japan)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PPS08-06] Ejecta Thickness Distribution of Lunar Schrödinger Basin

*Luyuan Xu[1], Minggang Xie[1] (1.State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 103 1F

## [P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University), Chairperson:Ko Hashizume, Hiroshi Nagaoka

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PPS08-07] Possible evolution paths of the lunar orbit based on tidal response in the global ocean model of the early Earth

*Mai Motoyama[1], Hideo Tsunakawa[1], Futoshi Takahashi[2] (1.Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology, 2.Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PPS08-08] Geochemical and Petrological Investigations of Lunar Feldspathic Crust by Lunar Sample Studies and Remote Sensing Data

*Hiroshi Nagaoka[1], Yuzuru Karouji[1], Makiko Ohtake[1] (1.Japan Aerospace Exploration Agency)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PPS08-09] Development of frosting system for lunar simulant and the detectability of ice growing on the simulant by NIR measurement

*Aoi Ogishima[1], Kazuto Saiki[1] (1.Department of Earth and Space Science, Graduate School of Science, Osaka University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PPS08-10] Volatile studies on Moon - A review toward future exploration programs

*Ko Hashizume[1] (1.Faculty of Science, Ibaraki University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PPS08-11] Scientific approach for the promotion of lunar polar exploration mission

*Masahiro KAYAMA[1], Ko Hashizume[2], Hiroshi Nagaoka[3], Kazuto Saiki[4], Chihiro Yamanaka[4], Makoto Hareyama[5], Makiko Ohtake[3] (1.Tohoku University, 2.Ibaraki University, 3.Japan Aerospace Exploration Agency, 4.Osaka University, 5.St. Marianna University School of Medicine)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PPS08-12] Feasibility study of detection of the lunar subsurface ice with UHF-band GPR based on FDTD electromagnetic simulation

*Atsushi Kumamoto[1], Hideaki Miyamoto[2], Toshifumi Nishibori[3], Takafumi Niihara[2], Fuminori Tsuchiya[1], Ken Ishiyama[3] (1.Tohoku University, 2.University of Tokyo, 3.JAXA)

[J] Oral | P (Space and Planetary Sciences)：P-PS Planetary Sciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 103 1F

## [P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University), Chairperson:Masahiro Kayama(東北大学), Yusuke Nakauchi(JAXA/ISAS)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PPS08-13] **Geology of the SLIM landing site on the Moon**

★Invited Papers

*Makiko Ohtake[1], Kazuto Saiki[2], Yusuke Nakauchi[1], Hiroaki Shiraishi[1], Yoshiaki Ishihara[3], Hiroyuki Sato[1], Chikatoshi Honda[4] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Osaka University, 3.National Institute for Environmental Studies, 4.University of Aizu)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PPS08-14] Observing scenario for the Multi-Band Camera onboard SLIM

*Kazuto Saiki[1], Yuya Igarashi[1], Yusuke Nakauchi[2], Chikatoshi Honda[3], Makiko Ohtake[2], Hiroaki Shiraishi[2], Hiroyuki Satoh[2], Yoshiaki Ishihara[4], Takao Maeda[5], Chihiro Yamanaka[1] (1.Osaka Univ., 2.JAXA, 3.Univ. Aizu, 4.National Institute for Environmental Studies, 5.Chuo Univ.)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PPS08-15] **Current status of a Japanese lunar polar exploration mission**

*Takeshi Hoshino[1], Makiko Ohtake[1], Yuzuru Karouji[1], Hiroaki Shiraishi[1] (1.Japan Aerospace Exploration Agency)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PPS08-16] HERACLES mission: Returning to the Moon by an ESA-JAXA-CSA Joint Study

*Yuzuru Karouji[1], Hiroshi Nagaoka[1], Yoshiaki Ishihara[2], Masahiro KAYAMA[3], Satoru Yamamoto[4], Nobuyuki Hasebe[5], Ko Hashizume[6], Yoshiko Ogawa[7], Toru Yada[1], Junichi Haruyama[1], Masanao Abe[1], Makiko Ohtake[1], HERACLES Science Working Group, HERACLES International Science Definition Team (1.Japan Aerospace Exploration Agency, 2.National Institute for Environmental Studies, 3.Faculty of Science, Tohoku University, 4.J-spacesystems, 5.Advanced Research Institute for Science and Engineering, Waseda University, 6.Faculty of Science, Ibaraki University, 7.The University of Aizu)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PPS08-17] **Lunar Science for Landed Missions – High-Priority Landing Sites Visualized with NASA's Moon Trek**

*Brian Hamilton Day[1], Emily Law[2] (1.NASA Solar System Exploration Research Virtual Institute, NASA Ames Research Center, 2.NASA Jet Propulsion Laboratory, California Institute of Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PPS08-18] NASA SSERVI: Merging Science and Human Exploration

*Brad Eugene Bailey[1], Kristina Gibbs[1], Gregory Schmidt[1] (1.NASA)

[J] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

## [P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University)

[PPS08-P01] Estimation of lava tube cave height below the vertical hole from the surface topography of the Moon

*Tsutomu Honda[1] (1.Vulcano-speleological Society)

[PPS08-P02] Detecting mare basalts intruded into the crust on the early Moon

*Ayame Ikeda[1], Tomokatsu Morota[2], Hiroshi Nagaoka[3] (1.Department of Science, Nagoya University, 2.Graduate School of Enviromental Studies, Nagoya University, 3.Japan Aerospace Exploration Agency)

[PPS08-P03] Distribution of major minerals around the Crisium and Moscoviense basins of the Moon revealed by SELENE Multiband Imager

Yuji Agatsuma[1], *Naru Hirata[1], Satoru Yamamoto[2], Makiko Ohtake[3] (1.Dep. of Computer Science and Engineering, Univ. of Aizu, 2.J-spacesystems, 3.Department of Planetary Science, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PPS08-P04] Searching for lunar swirls with deep learning

*Yurika Iwabuchi[1], Yoshiko Ogawa[1] (1.The University of Aizu)

[PPS08-P05] Lunar surface feature reconstruction by deep learning using synthetic data

*Koichi Tsuru[1], Toru Kouyama[1], Ryosuke Nakamura[1] (1.National Institute of Advanced Industrial Science and Technology)

[PPS08-P06] Evaluation of the influence of alkali elements on hydrogen solubility of clinopyroxene for estimating water content of lunar mantle

*Miki Muranushi[1], Akio Suzuki[1], Masahiro KAYAMA[1], Tsuyoshi MIYAMOTO[2] (1.Graduate school of Science, Tohoku university , 2.Center for Northeast Asian Studies, Tohoku university)

[PPS08-P07] Preliminary examination of mineral structure effect on relative permittivity

*Makito Kobayashi[1], Takafumi Niihara[2], Hideaki Miyamoto[2,1] (1.Department of Earth and Planetary Science, School of Science, University of Tokyo, 2.Department of Systems Innovation, School of Engineering, University of Tokyo)

[PPS08-P08] Lunar surface magnetic field intensity in the solar wind inferred from electron reflectometry

*Tomoki Kawaguchi[1], Yuki Harada[1], Yoshifumi Saito[2], Shoichiro Yokota[3], Masaki N Nishino[4], Hideyuki Usui[5], Yohei Miyake[6], Hideo Tsunakawa[7], Daiba Kato[8] (1.Dept. Geophysics, Kyoto Univ., 2.Solar System Science Division, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Graduate School of Science, Osaka University, 4.Institute for Space-Earth Environmental Research, Nagoya University, 5.Graduate school of system informatics Kobe University, 6.Education Center on Computational Science and Engineering, Kobe University, 7.Deparment of Earth and Planetary Sciences, Tokyo Institute of Technology, 8.The University of Tokyo)

[PPS08-P09] Objective and Current Development Status of Multi-Band Camera on SLIM

*Yusuke Nakauchi[1], Kazuto Saiki[2], Makiko Ohtake[1], Hiroaki Shiraishi[1], Chikatoshi Honda[3], Hiroyuki Sato[1], Yoshiaki Ishihara[4], Takao Maeda[5], Masatsugu Otsuki[1], Sin-ichiro Sakai[1], Shujiro Sawai[1], SLIM Project Team (1.Japan Aerospace Exploration Agency, 2.Osaka University, 3.Aizu University, 4.National Institute for Environmental Studie, 5.Chuo University)

[PPS08-P10] Monte Carlo simulation of neutron production and transport in the Moon: Effect of lunar subsurface water

*Hiroki Kusano[1], Yuzuru Karouji[1], Hiroshi Nagaoka[1], Naoyuki Yamashita[2], Makoto Hareyama[3] (1.Japan Aerospace Exploration Agency, 2.Planetary Science Institute, 3.St. Marianna University School of Medicine)

[PPS08-P11] **Exploration of ice deposits on the Moon using continuous seismic source system**

*Yuichiro Nagata[1], Takeshi Tsuji[1,2], Hideaki Miyamoto[9], Taichi Kawamura[3], Akito Araya[4], Yoshiaki Ishihara[5], Kazunori Ogawa[6], Taizo Kobayashi[7], Yuzuru Karouji[8], Satoshi Tanaka[10] (1.Department of Earth Resources Engineering,

Kyushu University, 2.International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, 3.Institut de Physique du Globe de Paris, 4.Earthquake Research Institute, University of Tokyo, 5.National Institute for Environmental Studies, 6.Kobe University, 7.Ritsumeikan University, 8.Japan Aerospace Exploration Agency, 9.University of Tokyo, 10.Department of Solid Planetary Sciences Institute of Space and Astronautical Science)

[PPS08-P12] Orbit determination of the Chang'E-5 Test 1 and a new gravity field model

*shanhong liu[1], Jianguo Yan[1] (1.Wuhan University)

[J] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

## [P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University)

[PPS08-P01] Estimation of lava tube cave height below the vertical hole from the surface topography of the Moon

*Tsutomu Honda[1] (1.Vulcano-speleological Society)

[PPS08-P02] Detecting mare basalts intruded into the crust on the early Moon

*Ayame Ikeda[1], Tomokatsu Morota[2], Hiroshi Nagaoka[3] (1.Department of Science, Nagoya University, 2.Graduate School of Enviromental Studies, Nagoya University, 3.Japan Aerospace Exploration Agency)

[PPS08-P03] Distribution of major minerals around the Crisium and Moscoviense basins of the Moon revealed by SELENE Multiband Imager

Yuji Agatsuma[1], *Naru Hirata[1], Satoru Yamamoto[2], Makiko Ohtake[3] (1.Dep. of Computer Science and Engineering, Univ. of Aizu, 2.J-spacesystems, 3.Department of Planetary Science, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PPS08-P04] Searching for lunar swirls with deep learning

*Yurika Iwabuchi[1], Yoshiko Ogawa[1] (1.The University of Aizu)

[PPS08-P05] Lunar surface feature reconstruction by deep learning using synthetic data

*Koichi Tsuru[1], Toru Kouyama[1], Ryosuke Nakamura[1] (1.National Institute of Advanced Industrial Science and Technology)

[PPS08-P06] Evaluation of the influence of alkali elements on hydrogen solubility of clinopyroxene for estimating water content of lunar mantle

*Miki Muranushi[1], Akio Suzuki[1], Masahiro KAYAMA[1], Tsuyoshi MIYAMOTO[2] (1.Graduate school of Science, Tohoku university , 2.Center for Northeast Asian Studies, Tohoku university)

[PPS08-P07] Preliminary examination of mineral structure effect on relative permittivity

*Makito Kobayashi[1], Takafumi Niihara[2], Hideaki Miyamoto[2,1] (1.Department of Earth and Planetary Science, School of Science, University of Tokyo, 2.Department of Systems Innovation, School of Engineering, University of Tokyo)

[PPS08-P08] Lunar surface magnetic field intensity in the solar wind inferred from electron reflectometry

*Tomoki Kawaguchi[1], Yuki Harada[1], Yoshifumi Saito[2], Shoichiro Yokota[3], Masaki N Nishino[4], Hideyuki Usui[5], Yohei Miyake[6], Hideo Tsunakawa[7], Daiba Kato[8] (1.Dept. Geophysics, Kyoto Univ., 2.Solar System Science Division, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Graduate School of Science, Osaka University, 4.Institute for Space-Earth Environmental Research, Nagoya University, 5.Graduate school of system informatics Kobe University, 6.Education Center on Computational Science and Engineering, Kobe University, 7.Deparment of Earth and Planetary Sciences, Tokyo Institute of Technology, 8.The University of Tokyo)

[PPS08-P09] Objective and Current Development Status of Multi-Band Camera on SLIM

*Yusuke Nakauchi[1], Kazuto Saiki[2], Makiko Ohtake[1], Hiroaki Shiraishi[1], Chikatoshi Honda[3], Hiroyuki Sato[1], Yoshiaki Ishihara[4], Takao Maeda[5], Masatsugu Otsuki[1], Sin-ichiro Sakai[1], Shujiro Sawai[1], SLIM Project Team (1.Japan Aerospace Exploration Agency, 2.Osaka University, 3.Aizu University, 4.National Institute for Environmental Studie, 5.Chuo University)

[PPS08-P10] Monte Carlo simulation of neutron production and transport in the Moon: Effect of lunar subsurface water

*Hiroki Kusano[1], Yuzuru Karouji[1], Hiroshi Nagaoka[1], Naoyuki Yamashita[2], Makoto Hareyama[3] (1.Japan Aerospace Exploration Agency, 2.Planetary Science Institute, 3.St. Marianna University School of Medicine)

[PPS08-P11] **Exploration of ice deposits on the Moon using continuous seismic source system**

*Yuichiro Nagata[1], Takeshi Tsuji[1,2], Hideaki Miyamoto[9], Taichi Kawamura[3], Akito Araya[4], Yoshiaki Ishihara[5], Kazunori Ogawa[6], Taizo Kobayashi[7], Yuzuru Karouji[8], Satoshi Tanaka[10] (1.Department of Earth Resources Engineering,

Kyushu University, 2.International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, 3.Institut de Physique du Globe de Paris, 4.Earthquake Research Institute, University of Tokyo, 5.National Institute for Environmental Studies, 6.Kobe University, 7.Ritsumeikan University, 8.Japan Aerospace Exploration Agency, 9.University of Tokyo, 10.Department of Solid Planetary Sciences Institute of Space and Astronautical Science)

[PPS08-P12] Orbit determination of the Chang'E-5 Test 1 and a new gravity field model

*shanhong liu[1], Jianguo Yan[1] (1.Wuhan University)

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A03 TOKYO BAY MAKUHARI HALL

## [P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Huixin Liu(Kyushu University, Japan), Stan Solomon(National Center for Atmospheric Research, US)

9:00 AM - 9:20 AM JST | 12:00 AM - 12:20 AM UTC

[PEM09-11] Assimilation products of thermospheric and ionospheric measurements by the NASA Ionopsheric Connection Explorer

★Invited Papers

*Thomas J Immel[1], Chihoko Cullens[1], Yen-Jung Wu[1], Gary Bust[2], Jeffrey Forbes[3], Scott L England[4] (1.University of California, Berkeley, 2.Johns Hopkins University, 3.University of Colorado, 4.Virginia Tech)

9:20 AM - 9:35 AM JST | 12:20 AM - 12:35 AM UTC

[PEM09-12] petitSat - A 6U CubeSat to examine the link between MSTIDS and ionospheric plasma density enhancements

*Jeffrey Klenzing[1], Ryan L Davidson[2], Gregory D Earle[3], Alexa J Halford[4], Sarah L Jones[1], Carlos Martinis[5], Nikolaos Paschalidis[1], Robert F Pfaff[1], Jonathon M Smith[1,6] (1.NASA Goddard Space Flight Center, Greenbelt, MD, USA, 2.Utah State University, Logan, UT, USA, 3.Virginia Tech, Blacksburg, VA, USA, 4.The Aerospace Corporation, Chantilly, VA, USA, 5.Boston University, Boston, MA, USA, 6.Catholic Universtiy of America, Washington, DC, USA)

9:35 AM - 9:55 AM JST | 12:35 AM - 12:55 AM UTC

[PEM09-13] A three-dimensional ionospheric electrodynamics model

★Invited Papers

*Astrid I Maute[1], Arthur D Richmond[1] (1.High Altitude Observatory, National Center for Atmospheric Research, Boulder CO, USA.)

9:55 AM - 10:10 AM JST | 12:55 AM - 1:10 AM UTC

[PEM09-14] **Spatial Fluctuation of TEC Index: A new index of ionospheric irregularities**

*Guanyi Ma[1], Takashi Maruyama[2] (1.National Astronomical Observatories, Chinese Academy of Sciences, 2.National Institute of Information and Communications Technology)

10:10 AM - 10:25 AM JST | 1:10 AM - 1:25 AM UTC

[PEM09-15] Coupling of lower thermosphere planetary wave energy into the ionosphere

*Patrick J Espy[1,2], Nora Stray[1,2,3], Robert Hibbins[1,2] (1.Norwegian University of Science and Technology, Trondheim, Norway, 2.Birkeland Centre for Space Science, Bergen, Norway, 3.Teknova AS, Tordenskjolds Gate 9, 4612 Kristiansand, Norway)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A03 TOKYO BAY MAKUHARI HALL

## [P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Jann-Yenq Liu(National Central University, Taiwan), Loren Chang(National Central University, Taiwan)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PEM09-16] Modulation of Lightning Occurrence by the Solar Wind

*Omar Angelo Nava[1], Daniel Emmons[1], Robert Loper[1] (1.Air Force Institute of Technology)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PEM09-17] Long Term Mesopause Temperature Variations resolved by SD-WACCM, MSISE-00,TIMED SABER and Local Observations in Irkutsk (52.29o, 104.29o), Russia

*Yi Chung Chiu[1], Loren Chang[1], Yi Duann[1], ALEXEI DMITRIEV[1], Irina Medvedeva[2], Konstantin Ratovsky[2], Jia Yue[3] (1.Institute of Space Science, National Central University, 2.Russian Academy of Sciences, Russian Federation, 3.Hampton University, USA)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PEM09-18] ISS-IMAP observation of the mesospheric disturbances generated by tropical cyclones

*Akinori Saito[1], Takeshi Sakanoi[2], Septi Perwitasari[4], Yuta Hozumi[3], Ryota Okada[1], Ryo Murakami[1] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 3.University of Electro-Communications, 4.Space and Upper Atmospheric Sciences Group, National Institute of Polar Research)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PEM09-19] A fast acoustic wave detected in GNSS total electron content after the foreshock of the 2011 Tohoku Earthquake

*Yoshihiro Kakinami[1], Hiroaki Saito[2], Tetsuo Yamamoto[3], Chia-Hung Chen[4], Masa-yuki Yamamoto[2], Kensuke Nakajima[5], JANN-YENQ Liu[6] (1.Hokkaido Information University, 2.Kochi University of Technology, 3.Hokkaido University, 4.National Cheng Kung University, 5.Kyushu University, 6.National Central University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PEM09-20] **Study of quiet-time high-latitude thermospheric winds using a Fabry-Perot interferometer at Tromsoe: Averages and exceptional events**

*Heqiucen XU[1], Kazuo Shiokawa[1], Shin-ichiro Oyama[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PEM09-21] **The longitudinal differences of lunar tidal characteristics between East Asian and American sectors during stratospheric sudden warming events: 2009-2018.**

*Jing Liu[1], Donghe Zhang[1] (1.Peking University)

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A04 TOKYO BAY MAKUHARI HALL

## [P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Shin'ya Nakano(情報・システム研究機構 統計数理研究所), Motoharu Nowada(Shandong University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[PEM11-07] **Nightside Distorted Transpolar Arcs and Their Possible Formation Process Model**

*Nowada Motoharu[1], Jun Yang[1], Benoit Hubert[2], Qiu-Gang Zong[3], Quan-Qi Shi[1], Yong-Fu Wang[3], Xu-Zhi Zhou[3], Zhao Hua-Yu[3] (1.Shandong University at Weihai, 2.Université de Liège, 3.Peking University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[PEM11-08] Ionospheric Conductivity Dependence of the Subauroral Polarization Streams Observed by the SuperDARN HF Radars

Yuting Zhang[1], *Nozomu Nishitani[1], Tomoaki Hori[1], Simon G. Shepherd[2], William A. Bristow[3] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Thayer School of Engineering, Dartmouth College, 3.University of Alaska Fairbanks)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[PEM11-09] Ionospheric convection modeling based on convolution with a localized vector-valued basis function

*Shin ya Nakano[1], Tomoaki Hori[2], Kanako Seki[3], Nozomu Nishitani[2] (1.The Institute of Statistical Mathematics, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Graduate School of Science, University of Tokyo)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[PEM11-10] **Occurrence Statistics and Driving Mechanisms of Ionospheric ULF Waves Observed by SuperDARN Radars**

★Invited Papers

*Xueling Shi[1], Joseph B. H. Baker[1], John Michael Ruohoniemi[1], Dong Lin[1], Michael Hartinger[1,2] (1.Virginia Tech, 2.Space Science Institute)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[PEM11-11] Magnetic Field Oscillations Observed by Swarm Satellites in the Nightside Upper Ionosphere During Low-latitude Pi2 Pulsations

*Khan-Hyuk Kim[1], Jae-Hee Park[1] (1.School of Space Research, Kyung Hee Univ.)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[PEM11-12] Magnetospheric Multiscale observations of ULF waves and correlated low-energy ion monoenergetic acceleration

*Bin Li[1], De-sheng Han[2], Ze-jun Hu[1], Jian-jun Liu[1], Lei Dai[3] (1.Polar Research Institute of China, 2.Tongji University, 3.National Space Science Center, Chinese Academy of Sciences)

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

## [P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Kunuhiro Keika(東京大学大学院理学系研究科), Shin'ya Nakano(情報・システム研究機構 統計数理研究所), Motoharu Nowada(Shandong University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[PEM11-13] Statistical study on warm plasma in the magnetotail based on two-component fits of distribution functions

*Kunihiro Keika[1], Ryuta Asami[1], Masahiro Hoshino[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[PEM11-14] Analysis on anisotropy variations for pitch angle distributions of electrons with various parameters at dipolarization sites in the inner plasma sheet

*Kaiti Wang[1], Zhuo-Ren Lang[2], Ching-Huei Lin[3], Tohru Hada[4], Toshi Nishimura[5] (1.Tamkang Univ., 2.National Cheng Kung Univ., 3.Chien-Hsin Univ. of Sci. & Tech., 4.Kyushu Univ., 5.Boston Univ.)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PEM11-15] Study of slow-mode shock formation in the symmetric magnetic reconnection based on hybrid simulations

*Nehpreet Kaur Walia[1], Kanako Seki[1], Takanobu Amano[1] (1. Department of Earth & Planetary Science, Graduate School of Science, University of Tokyo)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PEM11-16] Reconstruction of the electron diffusion region of magnetotail reconnection seen by the Magnetospheric Multiscale spacecraft

*Hiroshi Hasegawa[1], Richard E. Denton[2], Rumi Nakamura[3], Kevin J. Genestreti[4], Takuma Nakamura[3], Kyoung Joo Hwang[5], Tai D. Phan[6], Roy B. Torbert[4], Jim L. Burch[5], Barbara L. Giles[7], Dan J. Gershman[7], Chris T. Russell[8], Bob J. Strangeway[8], Per Arne Lindqvist[9], Yuri V. Khotyaintsev[10], Robert E. Ergun[11], Naritoshi Kitamura[12], Yoshifumi Saito[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Dartmouth College, 3.Space Research Institute, Austrian Academy of Science, 4.University of New Hampshire, 5.Southwest Research Institute, 6.University of California Berkeley, 7.NASA Goddard Space Flight Center, 8.University of California Los Angeles, 9.Royal Institute of Technology, 10.Swedish Institute of Space Physics, 11.University of Colorado, 12.University of Tokyo)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PEM11-17] **MMS observations of the dense high speed flow in the magnetotail**

*Mingyu Wu[1], Tielong Zhang[1] (1.Harbin Insitute of Technology, Shenzhen)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PEM11-18] The spatio-temporal development of lightning-induced electron precipitation events

★Invited Papers

*Robert C Moore[1], Dooyoung Kim[1] (1.University of Florida)

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A04 TOKYO BAY MAKUHARI HALL

## [P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Naritoshi Kitamura(東京大学大学院理学系研究科), Yuka Sato(日本工業大学)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PEM11-19] Energy flow, dynamo and field-aligned current during a substorm

*Yusuke Ebihara[1], Takashi Tanaka[2] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.Kyushu University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PEM11-20] **Electron flux and field-aligned current associated with Pc5 auroral arc pulsations observed onboard THEMIS and DMSP satellites**

*Natsuo Sato[1], Akira S Yukimatu[1,2], Yoshimasa Tanaka[1,2], Tomoaki Hori[3], Akira Kadokura[1,2], Tohru Sakurai[4], Desheng Han[5], Yuzhang Ma[6], Qinghe Zhang[6] (1.National Institute of Polar Research, 2.SOKENDAI, 3.Nagoya University, 4.Tokai University, 5.Tongji University, 6.Shandong University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PEM11-21] Multiple spots of enhanced electron precipitation near the equatorward boundary of the cusp

*Satoshi Taguchi[1], Satoshi Kose[1], Kohei Takasu[1], Morio Tanaka[1], Keisuke Hosokawa[2], Yasunobu Ogawa[3] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Department of Communication Engineering and Informatics, University of Electro-Communications, 3.National Institute of Polar Research)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PEM11-22] Statistical study of auroral/resonant-scattering 427.8-nm emission observed at subauroral latitudes over 14 years

*Kazuo Shiokawa[1], Yuichi Otsuka[1], Martin Connors[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Athabasca University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PEM11-23] Antarctic large area network observation of auroral phenomena using unmanned system: Conjugate auroral event studies (2)

*Akira Kadokura[1], Hisao Yamagishi[1], Masaki Okada[1], Yasunobu Ogawa[1], Yoshimasa Tanaka[1], Ryuho Kataoka[1], Herbert Akihito Uchida[1], Yuichi Otsuka[2] (1.National Institute of Polar Research, 2.Nagoya University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PEM11-24] **Dawn-Dusk Asymmetry in Dayside and Nightside auroral Ovals: Surveys of auroral emissions based on the all-sky imagers in Arctic and Antarctic**

★Invited Papers

*Zejun Hu[1] (1.Polar Research Institute of China)

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A04 TOKYO BAY MAKUHARI HALL

## [P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Naritoshi Kitamura(東京大学大学院理学系研究科), Yuka Sato(日本工業大学), Masaki Nishino(名古屋大学宇宙地球環境研究所)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PEM11-25] Enhancement of 10MeV protons associated with a change of magnetic field configuration at geosynchronous orbit

*Takahiro Obara[1] (1.Planetary Plasma and Atmospheric Research Center,Tohoku University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PEM11-26] Solar-cycle variations of >30 keV proton flux enhancements under the inner radiation belt

*ALLA SUVOROVA[1] (1.National Central University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PEM11-27] Auroral Imaging with Commercial DSLR Cameras near Athabasca, Canada

*Martin G Connors[1,2], Ian Schofield[1], Mike Noble[2], Alister Ling[2], Ryuho Kataoka[3], Ken Murata[4], Kazunori Yamamoto[4] (1.Athabasca University, 2.Edmonton Centre, Royal Astronomical Society of Canada, 3.National Institute for Polar Research, 4.National Institute for Communications Technology)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PEM11-28] PARM: Investigation of precipitating high-energy electrons into the auroral ionosphere with sounding rockets

*Kazushi Asamura[1], Yoshizumi Miyoshi[2], Keisuke Hosokawa[3], Takefumi Mitani[1], Taku Namekawa[1,5], Takeshi Sakanoi[4], Naoshi Yagi[4], Mizuki Fukizawa[4], Genki Ishizawa[4], Satoshi Kasahara[5], Shin Sugo[5], Oya Kawashima[5], Reiko Nomura[6], Masahito Nose[2], Mariko Teramoto[2], Yasunobu Ogawa[7], Shinji Saito[2], Ryoichi Fujii[8] (1.ISAS / JAXA, 2.ISEE, Nagoya University, 3.The University of Electro-Communications, 4.Tohoku University, 5.The University of Tokyo, 6.NAOJ / NINS, 7.NiPR / ROIS, 8.ROIS)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PEM11-30] Development of a miniaturized X-ray imager for GEOspace X-ray imager (GEO-X)

*Kumi Ishikawa[1], Yuichiro Ezoe[2], Masaki Numazawa[2], Daiki Ishi[2], Maiko Fujitani[2], Ryota Otsubo[2], Aoto Fukushima[2], Hikari Suzuki[2], Tatsuya Yuasa[2], Hiroshi Nakajima[3], Junko Hiraga[4], Yoshizumi Miyoshi[5], Satoshi Kasahara[6], Kazuhisa Mitsuda[1] (1.Japan Aerospace Exploration Agency/Institute of Space and Astronautical Science , 2.Tokyo Metropolitan University, 3.Kanto Gakuin University, 4.Kwansei Gakuin University, 5.Nagoya University, 6.The university of Tokyo)

[E] Oral | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A01 TOKYO BAY MAKUHARI HALL

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University), Chairperson:Mamoru Yamamoto

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

### [PEM15-01] Status of Equatorial MU Radar project in 2019

*Mamoru Yamamoto[1], Hiroyuki Hashiguchi[1], Tatsuhiro Yokoyama[1], Toshitaka Tsuda[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

### [PEM15-02] Recent Progress and Current Status of EISCAT_3D in 2018-2019

*Hiroshi Miyaoka[1], Yasunobu Ogawa[1], Satonori Nozawa[2], Koji Nishimura[1], Shin-ichiro Oyama[2], Takuji Nakamura[1], Ryoichi Fujii[2], Craig James Heinselman[3] (1.National Institute of Polar Research, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.European Incoherent Scatter Scientific Association)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

### [PEM15-03] Current status of the ground-based multi-point network observation of the upper atmosphere, ionosphere, and magnetosphere by the PWING Project and the Optical Mesosphere Thermosphere Imagers (OMTIs)

*Kazuo Shiokawa[1], Yuichi Otsuka[1], PWING Team (1.Institute for Space-Earth Environmental Research, Nagoya University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

### [PEM15-04] Development of MAGDAS project: Search for global electromagnetic coupling from polar to equatorial ionosphere

*Akimasa Yoshikawa[1], Taisei Kabasawa[2], Teiji Uozumi[3], Akiko Fujimoto[4], Shuji Abe[3] (1.Department of Earth and Planetary Sciences, Kyushu University, 2.Graduate school of Sciences, Kyushu Univerity, 3.International center for Space weather science and education, Kyushu University, 4.Kyushu Institute of Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

### [PEM15-05] IUGONET data analysis system for a study of coupling processes in the solar-terrestrial system

*Atsuki Shinbori[1], Yoshimasa Tanaka[2], Norio Umemura[1], Shuji Abe[3], Masahito Nose[1], Satoru UeNo[4] (1.Institute for Space-Earth Environment Research (ISEE), Nagoya University, 2.National institute of Polar Research, 3.International Center for Space Weather Science and Education Kyushu University, 4.Observatory, Kyoto University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

### [PEM15-06] Discussion on large-scale research project "Study of coupling processes in solar-terrestrial system" (1)

*Mamoru Yamamoto[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University), Chairperson:Satonori Nozawa

10:45 AM - 11:15 AM JST | 1:45 AM - 2:15 AM UTC

[PEM15-07] Numerical Experiments on Stratosphere-Troposphere Two-Way Dynamical Coupling in the Tropics through Organizations of Moist Convective Systems

★Invited Papers

*Shigeo Yoden[1], Hai Bui[2], Takahiro Banno[1] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2.Geophysical Institute, University of Bergen)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[PEM15-08] Future development of numerical simualtion of equatorial plasma bubbles

*Tatsuhiro Yokoyama[1] (1.Kyoto University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[PEM15-09] Characteristics of CME- and CIR-driven ion upflows in the polar ionosphere

*Yasunobu Ogawa[1], Kanako Seki[2], Kunihiro Keika[2], Yusuke Ebihara[3] (1.National Institute of Polar Research, 2.School of Science, the University of Tokyo, 3.Research Institute for Sustainable Humanosphere, Kyoto University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[PEM15-10] SuperDARN Hokkaido Pair of (HOP) radars and mid-latitude SuperDARN: today and future

*Nozomu Nishitani[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[PEM15-11] Simultaneous observation of Ionospheric Incoherent Scatter and Field Aligned Irregularities using adaptive signal processing techniques by the PANSY radar at Antarctic Syowa Station (39.6°E, 69.0°S)

*Taishi Hashimoto[1], Akinori Saito[2], Koji Nishimura[3], Masaki Tsutsumi[3], Kaoru Sato[4], Toru Sato[1] (1.Graduate School of Informatics, Kyoto University, 2.Graduate School of Science, Kyoto University, 3.National Institute of Polar Research, 4.Graduate School of Science, The University of Tokyo)

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University), Chairperson:Yasunobu Ogawa

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PEM15-12] Mini/Micro Satellite Constelaltion for the study of LAI coupling

*Koichiro Oyama[1,2,3] (1.Institute of Plasma and Space Sciences,National Cheng Kung Univ., Taiwan, 2.International Ceneter for Space Weather Sudy and Education, Kyushu Univ.,, 3.CoLtd. Asia Space Environment Research Consortium, Japan)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PEM15-13] Statistical study of daily and seasonal variation of the equatorial anomaly in Asia based on satellite-ground beacon experiment

*Yuki Sakamoto[1], Mamoru Yamamoto[1], Kornyanat Hozumi[2] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.National Institute of Information and Communications Technology)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PEM15-14] Latest installation of FM-CW radar in Peru

*Akiko Fujimoto[1], Akihiro Ikeda[2], Akimasa Yoshikawa[3] (1.Kyushu Institute of Technology, 2.National Institute of Technology,Kagoshima College, 3.Kyushu University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PEM15-15] **Understanding the OH Meinel Band Emissions on the Terrestrial Planets**

*Konstantinos S. Kalogerakis[1] (1.Center for Geospace Studies, SRI International, Menlo Park, California, U.S.A.)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PEM15-16] Statistical study of Sporadic Sodium Layer (SSL) observed at Tromsø

*Satonori Nozawa[1], Takuo T. Tsuda[2], Norihito Saito[3], Toru Takahashi[4], Takuya Kawahara[5], Yasunobu Ogawa[4], Hitoshi Fujiwara[6], Satoshi Wada[3], Youhei Ogawa[1], Chris Hall[7], Asgeir Brekke[7] (1.Institute for Space-Earth Environment Research, 2.The University of Electro-Communications, 3.RIKEN Center for Advanced Photonics, 4.National Institute of Polar Research, 5.Faculty of Engineering, Shinshu University, 6.Faculty of Science and Technology, Seikei University, 7.UiT The Arctic University of Norway)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PEM15-17] Discussion on large-scale research project "Study of coupling processes in solar-terrestrial system" (2)

*Mamoru Yamamoto[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

[E] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University)

### [PEM15-P01] Study on adaptive clutter rejection system using external receiving antennas for the MU radar

*Hiroyuki Hashiguchi[1], Issei Terada[1], Mamoru Yamamoto[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

### [PEM15-P02] Detached cusp aurora for southward IMF

*Kohei Takasu[1], Satoshi Taguchi[1], Keisuke Hosokawa[2] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Department of Communication Engineering and Informatics, University of Electro-Communications)

### [PEM15-P03] Motion of the inverted-V structure during an isolated substorm

*Morio Tanaka[1], Satoshi Taguchi[1], Kohei Takasu[1], Tomokazu Oigawa[1], Keisuke Hosokawa[2] (1.Department of Geophysics, Graduate school of science, Kyoto University, 2.Department of Communication Engineering and Informatics, University of Electro-Communications)

### [PEM15-P04] Observation and modeling of Na layer response to energetic particle precipitation

*Takuo T. Tsuda[1], Kyogo Takizawa[1], Ryo Tozu[1], Takuya Kawahara[2], Yoshimasa Tanaka[3], Mitsumu K. Ejiri[3], Takanori Nishiyama[3], Takuji Nakamura[3] (1.The University of Electro-Communications, 2.Shinshu University, 3.National Institute of Polar Research)

### [PEM15-P05] Lidar data analysis of the sodium atoms in the thermosphere observed at Tromsoe, Norway

*Takuya Kawahara[1], Satonori Nozawa[2], Norihito Saito[3], Takuo T. Tsuda[4], Toru Takahashi[5], Testuya Kawabata[2], Miki Nishimura[1], Yoshitaka Kobayashi[1] (1.Faculty of Engineering, Shinshu University, 2.ISEE, Nagoya University, 3.RIKEN, Center for Advanced Photonics, 4.The University of Electro-Communications, 5.National Institute of Polar Research)

### [PEM15-P06] Spatial-temporal distribution of anomalous enhancement of ambipolar diffusion coefficient observed by meteor radars installed in the polar region

*Toru Takahashi[1], Masaki Tsutsumi[1,2], Yasunobu Ogawa[1,2,3], Satonori Nozawa[3], Chris Hall[4], Hiroshi Miyaoka[1,2] (1.National Institute of Polar Research, 2.SOKENDAI, 3.Institute for Space-Earth Environmental Research, 4.TGO, The Arctic University of Norway)

### [PEM15-P07] Progress of ICSWSE and MAGDAS project in recent years

*Shuji Abe[1], Akimasa Yoshikawa[2,1], Teiji Uozumi[1], Akiko Fujimoto[3] (1.International Center for Space Weather Science and Education, Japan, 2.Department of Earth and Planetary Sciences, Kyushu University, 3.Kyushu Institute of Technology)

### [PEM15-P08] Status of GNU Radio Beacon Receiver 2 (GRBR2) development

*Mamoru Yamamoto[1], Mayumi Matsunaga[2], Roland Tsunoda[3] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.Tokyo University of Technology, 3.SRI International)

### [PEM15-P09] Statistical comparison between plasma bubble day-to-day variability and neutral atmosphere by using GPS scintillation and GAIA model

*Mamoru Yamamoto[1], Keigo Kono[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

### [PEM15-P10] Redevelopment of the MU radar transceiver-module control system

*Mamoru Yamamoto[1], Koki Kurokawa[1], Hiroyuki Hashiguchi[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

[E] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University)

### [PEM15-P01] Study on adaptive clutter rejection system using external receiving antennas for the MU radar

*Hiroyuki Hashiguchi[1], Issei Terada[1], Mamoru Yamamoto[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

### [PEM15-P02] Detached cusp aurora for southward IMF

*Kohei Takasu[1], Satoshi Taguchi[1], Keisuke Hosokawa[2] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Department of Communication Engineering and Informatics, University of Electro-Communications)

### [PEM15-P03] Motion of the inverted-V structure during an isolated substorm

*Morio Tanaka[1], Satoshi Taguchi[1], Kohei Takasu[1], Tomokazu Oigawa[1], Keisuke Hosokawa[2] (1.Department of Geophysics, Graduate school of science, Kyoto University, 2.Department of Communication Engineering and Informatics, University of Electro-Communications)

### [PEM15-P04] Observation and modeling of Na layer response to energetic particle precipitation

*Takuo T. Tsuda[1], Kyogo Takizawa[1], Ryo Tozu[1], Takuya Kawahara[2], Yoshimasa Tanaka[3], Mitsumu K. Ejiri[3], Takanori Nishiyama[3], Takuji Nakamura[3] (1.The University of Electro-Communications, 2.Shinshu University, 3.National Institute of Polar Research)

### [PEM15-P05] Lidar data analysis of the sodium atoms in the thermosphere observed at Tromsoe, Norway

*Takuya Kawahara[1], Satonori Nozawa[2], Norihito Saito[3], Takuo T. Tsuda[4], Toru Takahashi[5], Testuya Kawabata[2], Miki Nishimura[1], Yoshitaka Kobayashi[1] (1.Faculty of Engineering, Shinshu University, 2.ISEE, Nagoya University, 3.RIKEN, Center for Advanced Photonics, 4.The University of Electro-Communications, 5.National Institute of Polar Research)

### [PEM15-P06] Spatial-temporal distribution of anomalous enhancement of ambipolar diffusion coefficient observed by meteor radars installed in the polar region

*Toru Takahashi[1], Masaki Tsutsumi[1,2], Yasunobu Ogawa[1,2,3], Satonori Nozawa[3], Chris Hall[4], Hiroshi Miyaoka[1,2] (1.National Institute of Polar Research, 2.SOKENDAI, 3.Institute for Space-Earth Environmental Research, 4.TGO, The Arctic University of Norway)

### [PEM15-P07] Progress of ICSWSE and MAGDAS project in recent years

*Shuji Abe[1], Akimasa Yoshikawa[2,1], Teiji Uozumi[1], Akiko Fujimoto[3] (1.International Center for Space Weather Science and Education, Japan, 2.Department of Earth and Planetary Sciences, Kyushu University, 3.Kyushu Institute of Technology)

### [PEM15-P08] Status of GNU Radio Beacon Receiver 2 (GRBR2) development

*Mamoru Yamamoto[1], Mayumi Matsunaga[2], Roland Tsunoda[3] (1.Research Institute for Sustainable Humanosphere, Kyoto University, 2.Tokyo University of Technology, 3.SRI International)

### [PEM15-P09] Statistical comparison between plasma bubble day-to-day variability and neutral atmosphere by using GPS scintillation and GAIA model

*Mamoru Yamamoto[1], Keigo Kono[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

### [PEM15-P10] Redevelopment of the MU radar transceiver-module control system

*Mamoru Yamamoto[1], Koki Kurokawa[1], Hiroyuki Hashiguchi[1] (1.Research Institute for Sustainable Humanosphere, Kyoto University)

[J] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

## [P-EM16] Physics and Chemistry in the Atmosphere and Ionosphere

convener:Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Takuya Tsugawa(National Institute of Information and Communications Technology), Seiji Kawamura(National Institute of Information and Communications Technology)

### [PEM16-P01] Temporal and spatial variation of GPS phase scintillation during substorms and auroral breakups

*Paul Prikryl[1,2], James M. Weygand[3], Reza Ghoddousi-Fard[4], P. Thayyil Jayachandran[1], David R. Themens[1], Anthony M. McCaffrey[1], Bharat S. R. Kunduri[5], Emma Spanswick[6], Yongliang Zhang[7], Akira Sessai Yukimatu[8] (1.Physics Department, University of New Brunswick, Fredericton, NB, Canada, 2.Geomagnetic Laboratory, Natural Resources Canada, Ottawa, ON, Canada, 3.Earth Planetary and Space Sciences, University of California, Los Angeles, CA, USA, 4.Canadian Geodetic Survey, Natural Resources Canada, Ottawa, ON, Canada, 5.Bradley Dept. of Electrical and Computer Engineering, Virginia Tech, USA, 6.Dept. of Physics and Astronomy, University of Calgary, AB, Canada, 7.Johns Hopkins University Applied Physics Laboratory, Laurel, MD, USA, 8.National Institute of Polar Research, Tokyo, Japan)

### [PEM16-P02] Statistical study of SAPS occurrence characteristics using the SuperDARN Hokkaido HF radar

*Kento Oya[1], Nozomu Nishitani[1], Tomoaki Hori[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

### [PEM16-P03] Spectral investigations of near infrared aurora and airglow at 1.0-1.6 microns: 1-year ground-based imaging spectroscopic observation at Syowa station (69.0°S, 39.6°E)

*Takanori Nishiyama[1], Takeshi Sakanoi[2], Makoto Taguchi[3], Hidehiko Suzuki[4] (1.National Institute of Polar Research, 2.Planetary Plasma and Atmospheric Research Center, Tohoku University, 3.Rikkyo University, 4.Department of Physics, Meiji University)

### [PEM16-P04] The study of the lower ionosphere in the South Atlantic Anomaly (SAA) Region

*Chih-Yu Chiang[1], Tzu-Fang Chang[2,1], Sunny W. Y. Tam[1] (1.Institute of Space and Plasma Sciences, National Cheng Kung University, Tainan, Taiwan, 2.Institute for Space-Earth Environmental Research, Nagoya University, Japan)

### [PEM16-P05] Multi-GNSS observation of LSTID in Japan and its link with auroral activities

*Mayumi Hashimoto[1], Kosuke Heki[1] (1.Hokkaido University)

### [PEM16-P06] Basic development of accurate analytical method in order to determine coordinates of artificial illuminating clouds of Barium and Strontium for chemical-release rocket experiments

*Taro Watanabe[1], Masa-yuki Yamamoto[1], Yoshihiro Kakinami[2] (1.Kochi University of Technology, 2.Hokkaido Information University)

### [PEM16-P07] Neutral and plasma density perturbations in the top-/bottom-side ionosphere associated with MSTIDs

*Shin Suzuki[1], Jaeheung Park[2], Yuichi Otsuka[3], Kazuo Shiokawa[3], Huixin Liu[4], Hermann Luehr[5] (1.Faculty of Regional Policy, Aichi University, 2.Korea Astronomy and Space Science Institute, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Earth and Planetary Science Division, Kyushu University SERC, Kyushu University, 5.Helmholtz Centre Potsdam, GFZ, German Research Centre for Geosciences)

### [PEM16-P08] Analysis of ionospheric TEC fluctuation by rocket

*Tsuyoshi Takegawa[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Takuya Tsugawa[2], Michi Nishioka[2] (1.Graduate School of Integrated Science and Technology, Chiba University, 2.National Institute of Information and Communications Technology)

### [PEM16-P09] Examinations of the ionospheric perturbation associated with H-IIA rockets launching

*Junpei Yamazaki[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Keisuke Hosokawa[2], Ichiro Tomizawa[2] (1.Graduate School of Engineering, Chiba University, 2.Department of Communication Engineering and Informatics, University of Electro-Communications)

[PEM16-P10] Explosion energy derived from the 2015 Kuchinoerabujima eruption: Estimation from infrasound less than 0.01 Hz detected by barometers, seismometers, and TEC

*Yuki Nakashima[1], Kiwamu Nishida[1], Yosuke Aoki[1], Kosuke Heki[2] (1.Earthquake Research Institute, 2.Natural History Sciences, Hokkaido University)

---

[PEM16-P11] Detection of spread-F echoes in ionograms using machine learning

*Hiroyuki Nakata[1], Yuta Goto[2], Hiroyo Ohya[1], Toshiaki Takano[1] (1.Graduate School of Engineering, Chiba University, 2.Department of Electrical and Electronics Engineering)

---

[PEM16-P12] Evaluation of GNSS-TEC receiver performance for sounding rocket installation

*Makoto Okumura[1], Yuki Ashihara[1] (1.National Institute of Technology, Nara College)

---

[PEM16-P13] Relationship between mesosperical airglow disturbance and occurrence of equatorial plasma bubbles

*Ryota Okada[1], Akinori Saito[1], Takafumi Ikeda[1], Hiroyuki Shinagawa[2], Takuya Tsugawa[2], Takeshi Sakanoi[3] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.National Institute of Information and Communications Technology, 3.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University)

---

[PEM16-P14] Analysis of parameters controlling the occurrence and growth of equatorial plasma bubbles using GAIA

*Hiroyuki Shinagawa[1], Hidekatsu Jin[1], Yasunobu Miyoshi[2], Hitoshi Fujiwara[3], Tatsuhiro Yokoyama[4], Yuichi Otsuka[5] (1.National Institute of Information and Communications Technology, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 3.Faculty of Science and Technology, Seikei University, 4.Kyoto University, 5.Institute for Space-Earth Environmental Research, Nagoya University)

---

[PEM16-P15] A three-dimensional numerical model to study the modulation of midlatitude $E_s$-layers

*Satoshi Andoh[1], Akinori Saito[1], Hiroyuki Shinagawa[2], Shin'ichi Miyazaki[1] (1.Graduate School of Science, Kyoto University, 2.National Institute of Information and Communications Technology)

---

[PEM16-P16] Statistical analysis of the horizontal phase velocity distribution of mesospheric and ionospheric waves observed in airglow images in Hawaii

*Hideto Naito[1], Kazuo Shiokawa[1], Yuichi Otsuka[1], Takeshi Sakanoi[2], Akinori Saito[3], Takuji Nakamura[4] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 3.Department of Geophysics, Graduate school of science, Kyoto University, 4.National Institute of Polar Research)

---

[PEM16-P17] Estimation of mesospheric OH temperature by observation data by ISS-IMAP VISI

*Ryo Murakami[1], Akinori Saito[1], Takeshi Sakanoi[2], Yuta Hozumi[3] (1.Kyoto University, 2.Tohoku University, 3.University of Electro-Communications)

---

[PEM16-P18] Implementation of photochemical process of NOx and HOx into a whole atmosphere GCM

*Yasunobu Miyoshi[1], Hitoshi Fujiwara[2] (1.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 2.Seikei University)

---

[PEM16-P19] Development of a Lagrangian chemical transport model to understand the mechanism of composition change due to change in atmospheric environment

*Shingo Nakanishi[1], Tomoo Nagahama[1], Akira Mizuno[1], Tac Nakajima[1], Riku Ishijima[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

[J] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

## [P-EM16] Physics and Chemistry in the Atmosphere and Ionosphere

## [P-EM17] Space Plasma Physics: Theory and Simulation

convener:Takayuki Umeda(Institute for Space-Earth Environmental Research, Nagoya University), Takanobu Amano(Department of Earth and Planetary Science, University of Tokyo), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Tadas Nakamura(Fukui Prefectural University), Chairperson:Takayuki Umeda(Institute for Space-Earth Environmental Research, Nagoya University), Takanobu Amano(Department of Earth and Planetary Science, University of Tokyo)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[PEM17-01] Prediction of the high-resolution numerical flux by using a deep neural network

*Yosuke Matsumoto[1] (1.Graduate School of Science, Chiba University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[PEM17-02] Multiple Boris integrators for particle-in-cell simulation

*Seiji Zenitani[1], Tsunehiko N Kato[2] (1.Kyoto University, 2.National Astronomical Observatory of Japan)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[PEM17-03] Contour Dynamics for Vlasov–Poisson Plasma with the Periodic Boundary

*Hiroki Sato[1], Tomo-Hiko Watanabe[1], Shinya Maeyama[1] (1.Nagoya University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[PEM17-04] Simulation methods and visualization tools for MHD simulations in a sphere

*Akira Kageyama[1], Kumiko Hori[1], Naohisa Sakamoto[1] (1.Graduate School of System Informatics, Kobe University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[PEM17-05] Kármán Vortex Street, Strouhal Number, Hairpin Vortex in 3D global Magnetohydrodynamic MHD simulations in Northward IMF

*DongSheng CAI[1] (1.University of Tsukuba)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[PEM17-06] Correlations between plasma density and magnetic field strength in MHD turbulence in space

*Tohru Hada[1], Yasuhito Narita[2], Yasuhiro Nariyuki[3] (1.Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2.Space Research Institute, Austrian Academy of Sciences, 3.Faculty of Human Development, University of Toyama)

[J] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A03 TOKYO BAY MAKUHARI HALL

## [P-EM17] Space Plasma Physics: Theory and Simulation

convener:Takayuki Umeda(Institute for Space-Earth Environmental Research, Nagoya University), Takanobu Amano(Department of Earth and Planetary Science, University of Tokyo), Yasuhiro Nariyuki(Faculty of Human Development, University of Toyama), Tadas Nakamura(Fukui Prefectural University), Chairperson:Tadas Nakamura(Fukui Prefectural University), Yasuhiro Nariyuki

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[PEM17-07] Stochastic models of phase space diffusion via wave-particle interaction with parallel propagating electromagnetic waves

*Yasuhiro Nariyuki[1] (1.Faculty of Human Development, University of Toyama)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[PEM17-08] Electron beam instability in collisionless magnetic reconnection with a strong guide field

*Kazuya Shimomura[1], Tomo-Hiko Watanabe[1], Shinya Maeyama[1], Akihiro Ishizawa[2] (1.Nagoya Univertsity, 2.Kyoto University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[PEM17-09] Particle acceleration with precursor wave driven wakefield in relativistic shocks

*Masanori Iwamoto[1], Takanobu Amano[1], Masahiro Hoshino[1], Yosuke Matsumoto[2] (1.Graduate School of Science,The University of Tokyo, 2.Graduate School of Science, Chiba University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[PEM17-10] Stochastic Shock Drift Acceleration in the Shock Transition Region with Finite Pitch-Angle Anisotropy

*Takuma Katou[1], Takanobu Amano[1] (1.The University of Tokyo)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[PEM17-11] Near-fields and its Applications in Space Plasmas

*Tadas Nakamura[1] (1.Fukui Prefectural University)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[PEM17-12] Problems of Gravitational Waves and Origin of Gravitational Fields Raised by Studies on Binary Black Hole

*Hiroshi Oya[1] (1.Department of Geophysics Graduate School for Science Tohoku University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 104 1F

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University), Chairperson:Sachie Kanada(Nagoya University), Akiyoshi Wada(Meteorological Research Institute)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AAS02-01] A GRAPES-based mesoscale EPS for TC forecasting: configuration and performance

*Xubin Zhang[1] (1.Institute of Tropical and Marine Meteorology, CMA)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AAS02-02] **Evaluation of operational Ensemble based Global Forecast System prediction for Tropical Cyclones over the North Indian Ocean**

*Medha Deshpande[1], Radhika Kanase[1], R P M Krishna[1], Emmanuel Rongmie[1], P Mukhopadhyay[1] (1.IITM, Pune, INDIA)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AAS02-03] Structural Changes Preceding Rapid Intensification in Tropical Cyclones as shown in a Large Ensemble of Idealized Simulations

*Yoshiaki Miyamoto[1], David S Nolan[2] (1.Faculty of Environment and Information Studies, Keio University, 2.Rosenstiel School of Marine and Atmospheric Science, University of Miami)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AAS02-04] Potential impacts of tropical cyclone inner-core convective activity on the predictability of rapid intensification

*Masashi Minamide[1], Derek J. Posselt[1] (1.Jet Propulsion Laboratory, california institute of technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AAS02-05] A link between high-speed solar wind streams and rapid intensification of tropical cyclones

*Paul Prikryl[1,2], Lidia Nikitina[2], Vojto Rušin[3] (1.Physics Department, University of New Brunswick, Fredericton, NB, Canada, 2.Geomagnetic Laboratory, Natural Resources Canada, Ottawa, ON, Canada, 3.Astronomical Institute, Slovak Academy of Sciences, Tatranská Lomnica, Slovak Republic)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AAS02-06] Influence of Tropical Lower Stratospheric Cooling on Extreme Deep Convective Activity and Tropical Cyclones

*Kunihiko Kodera[1], Nawo Eguchi[2], Rei Ueyama[3], Beatriz M Funatsu[4], Chantal Claud[5] (1.Meteorological Research Institute, 2.Kyushu University, 3.NASA Ames Research Center, 4.Université de Nantes, 5.Ecole Polytechnique)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 104 1F

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University), Chairperson:Yoshiaki Miyamoto, Kosuke Ito(University of Ryukyus)

10:45 AM - 11:15 AM JST | 1:45 AM - 2:15 AM UTC

[AAS02-07] A change in the inner-core structure of Typhoon Trami (2018) as observed through upper-tropospheric aircraft reconnaissance of T-PARCII

★Invited Papers

*Hiroyuki Yamada[1], Kazuhisa Tsuboki[2], Taro Shinoda[2], Hisayuki Kubota[3], Yukihiro Takahashi[3], Norio Nagahama[4], Kensaku Shimizu[4], Tadayasu Ohigashi[5], Kosuke Ito[1], Munehiko Yamaguchi[6], Tetsuo Nakazawa[6] (1.University of the Ryukyus, 2.Nagoya University, 3.Hokkaido University, 4.Meisei Electric, 5.National Research Institute for Earth Science and Disaster Resilience, 6.Meteorological Research Institute, Japan Meteorological Agency)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AAS02-08] **Dramatic changes in the inner-core structure of Typhoon Jebi (2018) at landfall and relationship between a mesovortex and strong wind gusts**

*Udai Shimada[1], Ryo OYAMA[1], shingo shimizu[2] (1.Meteorological Research Institute, 2.National Research Institute for Earth Science and Disaster Prevention)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AAS02-09] **Revisiting Asymmetric CAPE in Sheared Tropical Cyclones**

*Qingqing Li[1] (1.NUIST Nanjing University of Information Science and Technology)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AAS02-10] **Observed rainfall asymmetry of tropical cyclone in the process of making landfall in Guangdong, South China**

*Guanhuan Wen[1] (1.Guangzhou Institute of Tropical and Marine Meteorology, China Meteorological Administation)

---

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AAS02-11] Volumetric Detection of Tornadic Vortices Associated with Typhoon Nanmadol (2017) Using PAWR and Deep Learning

*Toru Adachi[1], Naoki Ishitsu[2], Kenichi Kusunoki[1], Hanako Inoue[1], Ken-ichiro Arai[2], Chusei Fujiwara[3], Hiroto Suzuki[3] (1.Meteorological Research Institute, 2.Alpha Denshi/Meteorological Research Institute, 3.East Japan Railway Company)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University)

[AAS02-P01] Numerical study on lightning frequency in a tropical cyclone

*Yousuke Sato[1,3], Yoshiaki Miyamoto[2,3], Tomita Hirofumi[3] (1.Department of Applied Energy, Nagoya University, 2.Faculty of Environment and Information Studies, Keio University, 3.RIKEN Center for Computational Science)

[AAS02-P02] **Sensitivity of Numerical Simulation of Typhoon Nepartak (2016) to Cloud Condensation Nuclei Concentration**

*Yu-De Wu[1], Jian-Liang Wang[1] (1.Dept. of Environmental Informational and Engineering, Chung Cheng Institute of Technology, National Defense University, Taiwan)

[AAS02-P03] Moisture Budget Analysis for Hurricane Precipitation on Texas

*Satoshi Iizuka[1], Naoki Sakai[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[AAS02-P04] Remote response of a developing tropical cyclone over the western North Pacific to large-scale vapor transport from the Kuroshio in boreal fall

*Keita Fujiwara[1], Ryuichi Kawamura[2], Tetsuya Kawano[2] (1.Graduate School of Science, Kyushu University, 2.Faculty of Science, Kyushu University)

[AAS02-P05] Asymmetrically Intensifying Processes of a Category 4 Super Typhoon Lan (2017) during High Vertical Wind Shear

*Sachie Kanada[1], Akiyoshi Wada[2], Kazuhisa Tsuboki[1] (1.Nagoya University, 2.Meteorological Research Institute)

[AAS02-P06] Roles of preexisting oceanic condition and ocean coupling processes in the intensity prediction during the mature phase of Typhoon Trami (2018)

*Akiyoshi Wada[1] (1.Typhoon Research Department Meteorological Research Institute)

[AAS02-P07] Development and assessment of the probabilistic storm surge forecast system in Taiwan: Case Study of Typhoon Maria in 2018

*Chun-Wei Lin[1], Tso-Ren Wu[1], Yu-Lin Tsai[1], Shu-Chun Chuang[1], Chi-Hao Chu[2], Chuen-Teyr Terng[2] (1.Graduate Institute of Hydrological and Oceanic Sciences, National Central University, Chungli, Taiwan, 2.Marine Meteorology Center, Central Weather Bureau, Taipei, Taiwan)

[AAS02-P08] Basic Data Construction for a Typhoon Disaster Prevention Model : Analysis and Changes by El Nino and La Nina year

*HANA NA[1], Woo-Sik Jung[1] (1.Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea)

[AAS02-P09] Basic Data Construction for a Typhoon Disaster Prevention Model : Analysis According to the Typhoon Path Type

*HANA NA[1], Woo-Sik JUNG[1] (1.Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea)

[AAS02-P10] Basic Data Construction for a Typhoon Disaster Prevention Model : Monthly Characteristics of Typhoon Rusa, Maemi, Kompasu, and Bolaven

*HANA NA[1], Woo-Sik Jung[1] (1.Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea)

[AAS02-P11] The mechanism of typhoon generated in the earth that rotates in the space where the solar wind blows

*Shinji Karasawa[1] (1.Miyagi National College of Technology Professor emeritus)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University)

[AAS02-P01] Numerical study on lightning frequency in a tropical cyclone

*Yousuke Sato[1,3], Yoshiaki Miyamoto[2,3], Tomita Hirofumi[3] (1.Department of Applied Energy, Nagoya University, 2.Faculty of Environment and Information Studies, Keio University, 3.RIKEN Center for Computational Science)

[AAS02-P02] **Sensitivity of Numerical Simulation of Typhoon Nepartak (2016) to Cloud Condensation Nuclei Concentration**

*Yu-De Wu[1], Jian-Liang Wang[1] (1.Dept. of Environmental Informational and Engineering, Chung Cheng Institute of Technology, National Defense University, Taiwan)

[AAS02-P11] The mechanism of typhoon generated in the earth that rotates in the space where the solar wind blows

*Shinji Karasawa[1] (1.Miyagi National College of Technology Professor emeritus)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 104 1F

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University), Chairperson:Sachie Kanada(Nagoya University), Yoshiaki Miyamoto

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[AAS02-12] Evaluation of the monthly Potential of the 2018 typhoon activity and the effect of the positive PMM and SST of the eastern northwestern Pacific

*Takahiro Ishiyama[1], Masaki Satoh[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AAS02-13] **Contributions of different time scale variations to tropical cyclogenesis over the western North Pacific**

*Xi Cao[1] (1. Institute of Atmospheric Physics, Chinese Academy of Sciences)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AAS02-14] Binary interaction between TC Chanthu (2016) and a nearby cold low

*Kosuke Ito[1], Miyabi Higa[1], Johnny Chan[2] (1.University of the Ryukyus, 2.City University of Hong Kong)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AAS02-15] **Response of landfalling North Indian Ocean cyclonic disturbances to warming climate and associated environmental parameters**

*JAGABANDHU PANDA[1], KASTURI SINGH[1] (1.Department of Earth and Atmospheric Sciences, National Institute of Technology Rourkela, India)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AAS02-16] **Rainfall contribution of North Indian Ocean cyclonic disturbances over India in a warming climate**

*KASTURI SINGH[1], JAGABANDHU PANDA[1] (1.Department of Earth and Atmospheric Sciences, National Institute of Technology Rourkela, India)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AAS02-17] Analysis of typhoon tracks and associated precipitation amount over western Japan: A case study with Typhoon Nancy and Typhoon Jebi

*Sridhara Nayak[1], Tetsuya Takemi[1] (1.Disaster Prevention Research Institute, Kyoto University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 102 1F

## [A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Hisahiro Takashima(福岡大学)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AAS04-16] Toward the Reduction of Radiative Forcing of Methane and Tropospheric Ozone: Aiming at the Emission Control of $CH_4$, $NO_x$and NMVOC in Asia

*Hajime Akimoto[1], Tatsuya NNagashima[1], Hiroshi Tanimoto[1], Zig Klimont[2], Markus Amann[2] (1.National Institute for Environmental Studies, 2.International Institute for Applied Systems Analysis)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AAS04-17] **Determination of atmospheric $NO_2$ column densities using a Pandora instrument measuring direct-sun spectra at Yokosuka, Japan: Improved validation of TROPOMI satellite observations**

*Yugo Kanaya[1], Hisahiro Takashima[2,1], Masato I. Nodzu[3], Takashi Sekiya[7], Kazuyuki Miyazaki[1], Henk Eskes[4], Gaia Pinardi[5], Daniel Santana Diaz[6], Moritz Müller[6], Alexander Cede[6] (1.Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.Fukuoka University, 3.Tokyo Metropolitan University, 4.KNMI, 5.BIRA-IASB, 6.LuftBlick, 7.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AAS04-18] A high-resolution global data assimilation for air pollution analysis on megacity scale using multi-sensor satellite measurements including TROPOMI $NO_2$ data

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Henk Eskes[3], Folkert Boersma[3], Koji Ogochi[1], Kengo Sudo[4,1], Masayuki Takigawa[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Jet Propulsion Laboratory/California Institute for Technology, 3.Royal Netherlands Meteorological Institute (KNMI), 4.Graduate School of Environmental Studies, Nagoya University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AAS04-19] Recent trends of $NO_2$, VOC, and tropospheric ozone concentrations observed around Chiba, Japan in 2013-2018

*Daichi Yonekawa[1], Hitoshi Irie[2] (1.Chiba university Graduate school, 2.Chiba university)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AAS04-20] Long-term seasonal changes in tropospheric ozone over Japan

*Natsumi Kawano[1], Tatsuya Nagashima[1], Seiji Sugata[1] (1.National Institute for Environmental Studies)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AAS04-21] **Characteristics of Atmospheric Photochemical Pollution at a Comprehensive Site in Guangzhou, China**

*Yu Zou[1] (1.Institute of Tropical and Marine Meteorology, CMA,Guangzhou,China)

[J] Oral | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 102 1F

## [A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Fumikazu Taketani(海洋研究開発機構), Michihiro Mochida(名古屋大学)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AAS04-22] LC/MS analysis of molecular markers present in biogenic secondary organic aerosols collected during year-round observations at a cool-temperature forest

*Kei Sato[1], Sathiyamurthi Ramasamy[1], Satoshi Inomata[1], Yuzo Miyazaki[2] (1.National Institute for Environmental Studies, 2.Hokkaido University)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AAS04-23] Surfactant Effects on Acid-Catalyzed Reactions at Aqueous Aerosol Surfaces

*Shinnosuke Ishizuka[1], Tetsuya Hama[2], Shinichi Enami[1] (1.National Institute for Environmental Studies, 2.Institute for Low Temperature Science, Hokkaido University)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AAS04-24] Roles of heterogeneous reactions in the tropospheric chemistry: a global modeling study

*Phuc Thi Minh Ha[1], Fumikazu Taketani[2], Yugo Kanaya[2], Kengo Sudo[1,2] (1.Graduate School of Environmental Studies, Nagoya University, 2.Research and Development Center for Global Change, JAMSTEC)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AAS04-25] Sensitivity of regional deposition of inhaled atmospheric aerosols in human respiratory tract to their size distribution and hygroscopicity: A case study

*Minrui Wang[1], Toshiyuki Mihara[2,4], Mizuo Kajino[5], Kaori Kawana[2,6], Michihiro Mochida[1,2,3] (1.Institute for Space Earth Environmental Research, 2.Graduate School of Environmental Studies, Nagoya University, 3.Institute for Advanced Research, Nagoya University, 4.Now at Gifu Prefectural Industrial Research Institute, 5.Meteorological Research Institute, Japan Meteorological Agency, 6.Now at Research and Development Center for Global Change, JAMASTEC)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AAS04-26] Biogeochemical cycle between atmosphere and ocean via particulate matters
-Award lecture for JpSAC Young Scientist Award-

★Invited Papers

*Yoko Iwamoto[1] (1.Graduate School of Biosphere Science, Hiroshima University)

---

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AAS04-27] Kinetic Studies for Quantitative Elucidation of Heterogeneous Halogen Chemistry in the Troposphere
-JpSAC Early Career Scientist Award Lecure-

★Invited Papers

*Yosuke Sakamoto[1,2] (1.Graduate School of Global Environmental Studies, Kyoto University , 2.Graduate School of Human and Environmental Studies, Kyoto University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

## [A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University)

[AAS04-P01] Validation of GOSAT cloud judgement by using Himawari-8 data

*Kitamura Katsuki[1], Naoko Saitoh[2] (1.Chiba University Graduate School of Science and Engineering Division of Earth Environmental Science , 2.Center for Environmental Remote Sensing Chiba University)

[AAS04-P02] Measurement of temperature that fungal spores form ice nuclei

*Kazuyuki Kita[1], Kansei Sasaki[1], Koutaro Minami[1], Takeshi Kinase[2], Kouji Adachi[2], Yuji Zaizen[2], Kentaro Hosaka[3], Teruya Maki[4], Yasuhito Igarashi[1,5] (1.Ibaraki University, 2.Meteorological Research Laboratory, 3.National Musium of Nature and Science, 4.Kanazawa University, 5.Kyoto University)

[AAS04-P03] **Investigation of Atmospheric Aerosol Particles and gases by R/V Mirai cruise over the Arctic Ocean on 2017**

*Fumikazu Taketani[1], Saki Kato[1,2], Takuma Miyakawa[1], Masayuki Takigawa[1], Masahiro Yamaguchi[1], Hisahiro Takashima[1,2], Petr Mordovskoi[1], Yugo Kanaya[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Fukuoka University)

[AAS04-P04] Characterization of carbonaceous aerosols in East Asia in the spring of 2015: Importance of non-fossil fuel sources

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

## [A-OS07] Climate variability and predictability on subseasonal to decadal timescales

convener:Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL), Doug Smith(Met Office), Yushi Morioka(Japan Agency for Marine-Earth Science and Technology)

[AOS07-P01] Changes in North American and European Heatwave Characteristics

*Szandra A. Peter[1], Ben Kirtman[1] (1.Rosenstiel School of Marine and Atmospheric Science)

[AOS07-P02] **The effects of the "New Climate" Warming on Western Mediterranean: Situation of the Recent Extreme Events**

*Mohammed-Said KARROUK[1] (1.Hassan II University of Casablanca)

[AOS07-P03] **Month-to-month Difference of the Western Pacific Subtropical High Simulated by CMIP5 Models**

*Xiao Dong[1], Renping Lin[1] (1.Institute of Atmospheric Physics)

[AOS07-P04] Potential regulation on the climatic effect of Tibetan Plateau heating by tropical air–sea coupling

*Ziqian Wang[1], Anmin Duan[2], Song Yang[1] (1.School of Atmospheric Sciences, Sun Yat-sen University, 2.Institute of Atmospheric Physics, Chinese Academy of Sciences)

[AOS07-P05] Intraseasonal variation of the South Asian high and its role in connecting the Indian and East Asian summer monsoons

*Wei Wei[1] (1.Sun Yat-sen University)

[AOS07-P06] Mean Surface Air Temperatures in Japan - Regional Classification and Interranual Variability

*Pascal Oettli[1], Masami Nonaka[1], Swadhin Behera[1] (1.Japan Agency for Marine-Earth Science and Technology)

[AOS07-P07] Inter-Annual Variability of the Indonesian Rainfall and Air-Sea Interaction over the Indian-Pacific Ocean Associated with Regime Shift

*Murni Ngestu Nurutami[1], Tadahiro Hayasaka[1] (1.Center for Atmospheric and Oceanic Studies, Graduate School of Science, Tohoku University)

[AOS07-P08] Exploring synoptic-scale drivers of interannual rainfall variability over Africa

*Piotr Wolski[1], Chris Jack[1], Waarith Abrahams[1], Stefaan Conradie[1] (1.University of Cape Town)

[AOS07-P09] **Effect of El Niño on the response ratio of Hadley circulation to different SST meridional structures**

*Juan Feng[1] (1.Beijing Normal University)

[AOS07-P10] **Novel data-driven approach for ENSO prediction**

*Dmitri Kondrashov[1], Evgeniy Loskutov[2], Andrei Gavrilov[2], Dmitry Mukhin[2], Alexander Feigin[2] (1.University of California, Los Angeles, United States, 2.Institute of Applied Physics of the Russian Academy of Sciences, Nizhny Novgorod, Russian Federation)

[AOS07-P11] Experimental seasonal climate prediction using CFES: Comparison with the SINTEX-F systems

*Nobumasa Komori[1], Bunmei Taguchi[2], Akira Kuwano-Yoshida[3,1], Takeshi Doi[1], Masami Nonaka[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Research Center for Advanced Science and Technology, The University of Tokyo, 3.Disaster Prevention Research Institute, Kyoto University)

[AOS07-P12] Exploring the SST error growth during ENSO developing phase by using BCC_CSM1.1(m)

*Ben Tian[1], Hongli Ren[1] (1.National Climate Center, China Meteorological Administration)

[AOS07-P13] Role of sea-ice initialization in climate predictability over the Weddell Sea

*Yushi Morioka[1], Takeshi Doi[1], Doroteaciro Iovino[2], Simona Masina[2], Swadhin Behera[1] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.Centro Euro-Mediterraneo sui Cambiamenti Climatici (CMCC))

[AOS07-P14] Observed and hindcasted subdecadal variability of the tropical Pacific climate

*Takashi Mochizuki[1], Masahiro Watanabe[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere-Ocean Research Institute, The University of Tokyo)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

*Takashi Mochizuki[1], Masahiro Watanabe[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere-Ocean Research Institute, The University of Tokyo)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-OS Ocean Sciences & Ocean Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 105 1F

## [A-OS07] Climate variability and predictability on subseasonal to decadal timescales

convener:Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL), Doug Smith(Met Office), Yushi Morioka(Japan Agency for Marine-Earth Science and Technology), Chairperson:V Ramaswamy(NOAA GFDL), Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[AOS07-01] Seasonal Predictions of Tropical Cyclones in 2018 using GFDL and NICAM High-Resolution Global Models

★Invited Papers

*Hiroyuki Murakami[1,2], Masuo Nakano[3], V Ramaswamy[1], Thomas Delworth[1], Sarah Kapnick[1], Rich Gudgel[1], Takashi Mochizuki[3], Takeshi Doi[3], Yushi Morioka[3] (1.Geophysical Fluid Dynamics Laboratory, 2.University Corporation for Atmospheric Research, 3.JAMSTEC)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[AOS07-02] **Future change of tropical cyclone-induced waves in the Indian Ocean; An analysis based on super-high-resolution MRI-AGCM3.2 climate model**

*Bahareh Kamranzad[1,2], Nobuhito Mori[1] (1.Disaster Prevention Research Institute, Kyoto University, 2.Hakubi Center for Advanced Research, Kyoto University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[AOS07-03] The ocean-coupled global cloud-resolving modeling era

★Invited Papers

*Tomoki Miyakawa[1] (1.Atmosphere and Ocean Research Institute University of Tokyo)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[AOS07-04] Westerly Wind Burst (WWB)/Easterly Wind Surge (EWS)-like stochastic forcing and the effects on ENSO prediction by the SINTEX-F system

*Takeshi Doi[1], Swadhin Behera[1], Toshio Yamagata[1] (1.JAMSTEC)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[AOS07-05] **The life-cycle of annual waves in the Pacific Ocean as identified by a seamless diagnosis for the energy flux**

*Hidenori AIKI[1], Takahiro Shimura[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Graduate School for Environmental Studies, Nagoya University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[AOS07-06] Development of weakly coupled atmosphere-ocean data assimilation system and the evaluation of the coupled reanalysis in JMA/MRI

★Invited Papers

*Yosuke Fujii[1], Chiaki Kobayashi[1], Toshiyuki Ishibashi[1], Yuhei Takaya[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 105 1F

## [A-OS07] Climate variability and predictability on subseasonal to decadal timescales

convener:Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL), Doug Smith(Met Office), Yushi Morioka(Japan Agency for Marine-Earth Science and Technology), Chairperson:Yushi Morioka(Japan Agency for Marine-Earth Science and Technology), Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[AOS07-07] Decadal variability and predictability of the North Atlantic Oscillation

★Invited Papers

*Rosemary Eade[1,2], David Stephenson[2], Doug Smith[1], Adam Scaife[1,2], Leon Hermanson[1], Nick Dunstone[1] (1.Met Office Hadley Centre, 2.University of Exeter)

---

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[AOS07-08] Seasonal to multi-year climate predictability in a climate model MIROC6

*Takahito Kataoka[1], Hiroaki Tatebe[1], Hiroshi Koyama[1], Takashi Mochizuki[1] (1.JAMSTEC Japan Agency for Marine-Earth Science and Technology)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[AOS07-09] Identifying the early 2000s hiatus associated with internal climate variability

*Xin-Gang Dai[1], Ping Wang[2] (1.Institute of Atmospheric Physics, Chinese Academy of Sciences, 2.Chinese Academy of Meteorological Sciences)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[AOS07-10] Decadal Evolution of the Surface Energy Budget during the Fast Warming and Global Warming Hiatus Periods in the ERA-Interim

*XIAOMING HU[1] (1.Sun Yat-sen University)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[AOS07-11] **The role of ocean variability for multi-year droughts in Australia**

*Andrea Taschetto[1,2], Alex Sen Gupta[1,2], Caroline C Ummenhofer[3], Matthew H England[1,2] (1.Climate Change Research Centre, University of New South Wales, Sydney, Australia, 2.ARC Centre of Excellence for Climate Extremes, University of New South Wales, Sydney, Australia, 3.Department of Physical Oceanography, Woods Hole Oceanographic Institution, Woods Hole, MA, USA)

---

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[AOS07-12] Decadal variability and predictability in the Southern Ocean - implications for interpreting recent observed trends

★Invited Papers

*Liping Zhang[1,2], Thomas L Delworth[2], William Cooke[2,3], Xiaosong Yang[2,3] (1.Princeton University, 2.Geophysical Fluid Dynamics Laboratory, 3.UCAR)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-OS Ocean Sciences & Ocean Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 105 1F

## [A-OS10] Atlantic climate variability, and its global impacts and predictability

convener:Ingo Richter(JAMSTEC Japan Agency for Marine-Earth Science and Technology), Hiroki Tokinaga(Research Institute for Applied Mechanics, Kyushu University), Noel S Keenlyside(Geophysical Institute Bergen), Carlos R Mechoso(University of California Los Angeles), Chairperson:Hiroki Tokinaga(京都大学白眉センター), Ingo Richter

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[AOS10-01] Atlantic impacts on the tropical Pacific climate in the 2000s

*Takashi Mochizuki[1], Masahiro Watanabe[2], Masahide Kimoto[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere-Ocean Research Institute, The University of Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[AOS10-02] Recent acceleration of Arabian Sea warming induced by the Atlantic-western Pacific trans-basin multidecadal variability

*Cheng Sun[1] (1.Beijing Normal University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[AOS10-03] **Westward Wind Changes over the Tropical and Mid-latitude Pacific in the Past Three Decades Driven by the Inter-basin Teleconnections**

★Invited Papers

*Xichen Li[1] (1.Institute of Atmospheric Physics)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[AOS10-04] On the Usefulness of the Atlantic Multidecadal Oscillation Index for Identifying Origins of North Atlantic Sea Surface Temperature Variability

*Jing Sun[1,2], Mojib Latif[1,3], Wonsun Park[1], Taewook Park[1,4] (1.GEOMAR Helmholtz Centre for Ocean Research Kiel, 2.Ocean University of China, 3.University of Kiel, 4.Korea Polar Research Institute)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[AOS10-05] Atlantic Multidecadal SST Signal Modulated by the Low-Frequency Mixed Layer Depth Variability

*Ayako Yamamoto[1], Hiroaki Tatebe[1], Masami Nonaka[1] (1.Japan Agency for Marine-Earth Science and Technology)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[AOS10-06] A High-Resolution Future Wave Climate Projection for the Northwestern Atlantic

*Adrean Webb[1], Tomoya Shimura[1], Nobuhito Mori[1] (1.Kyoto University, Disaster Prevention Research Institute)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-OS Ocean Sciences & Ocean Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 105 1F

## [A-OS10] Atlantic climate variability, and its global impacts and predictability

convener:Ingo Richter(JAMSTEC Japan Agency for Marine-Earth Science and Technology), Hiroki Tokinaga(Research Institute for Applied Mechanics, Kyushu University), Noel S Keenlyside(Geophysical Institute Bergen), Carlos R Mechoso(University of California Los Angeles), Chairperson:Ingo Richter, Hiroki Tokinaga(京都大学白眉センター)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AOS10-07] Tropical Atlantic Impact on ENSO predictability

★Invited Papers

*Belen Rodriguez-Fonseca[1,2], Irene - Polo[1], Elsa - Mohino[1], Teresa - Losada[1], Marta - Martin-Rey[5], Roberto - Mechoso[3], Noel - Keenlyside[4] (1.Department of Physics of the Earth and Astrophysics, UCM, Madrid, Spain, 2.Institute of Geosciences, IGEO, UCM-CSIC, Madrid, Spain, 3.Department of Atmospheric and Oceanic Sciences, UCLA, Los Angeles, USA, 4.Geophysical Institute, University of Bergen, Norway, 5.Instituto de Ciencias del Mar, Barcelona, Spain)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AOS10-08] **Interannual variability of Antarctic Intermediate Water in the tropical North Atlantic**

*Yao Fu[1], Chunzai Wang[1], Peter Brandt[2,3], Richard J. Greatbatch[2,3] (1.State Key Laboratory of Tropical Oceanography, South China Sea Institute of Oceanology, Chinese Academy of Sciences, Guangzhou, China, 2.GEOMAR Helmholtz Centre for Ocean Research Kiel, Kiel, Germany , 3.Christian-Albrechts-Universität zu Kiel, Kiel, Germany)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AOS10-09] **Understanding the mechanisms of the Atlantic meridional climate variability**

*Hyacinth C Nnamchi[1], Riccardo Farneti[2], Noel S Keenlyside[3], Fred Fred Kucharski[2], Mojib Latif[1] (1.GEOMAR Helmholtz Centre for Ocean Research Kiel, Kiel, Germany, 2.Abdus Salam International Centre for Theoretical Physics, Trieste, Italy, 3.Geophysical Institute, University of Bergen, and Bjerknes Centre for Climate Research, Bergen, Norway)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AOS10-10] The corss-equatorical gradient variability: The role of heat, momentum, and freshwater flux

*Takahito Kataoka[1] (1.JAMSTEC Japan Agency for Marine-Earth Science and Technology)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AOS10-11] Generation mechanisms of the Benguela Nino with a focus on local amplification

*Tomoki Tozuka[1], Ryo Kobayashi[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AOS10-12] **Seasonal energy analysis for baroclinic waves in equatorial Atlantic through a diagnostic scheme for energy flux**

*Qingyang Song[1], Hidenori AIKI[1] (1.Institute of space-earth environmental research, Nagoya University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-OS Ocean Sciences & Ocean Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

## [A-OS10] Atlantic climate variability, and its global impacts and predictability

convener:Ingo Richter(JAMSTEC Japan Agency for Marine-Earth Science and Technology), Hiroki Tokinaga(Research Institute for Applied Mechanics, Kyushu University), Noel S Keenlyside(Geophysical Institute Bergen), Carlos R Mechoso(University of California Los Angeles)

[AOS10-P01] The strengthening of Amazonian precipitation during the wet season driven by tropical sea surface temperature forcing

*Xinyue Wang[1], Xichen Li[1], Jiang Zhu[1], Clemente A S Tanajura[2] (1.Institute of Atmospheric Physics, Chinese Academy of Sciences, 2.Institute of Physics, Federal University of Bahia, Salvador, Brazil)

[AOS10-P02] **Linear inverse modeling of the tropical Atlantic**

*Ingo Richter[1], Ping Chang[2] (1.JAMSTEC Japan Agency for Marine-Earth Science and Technology, 2.Texas A&M University)

[AOS10-P03] Relationships Among Inter-model Spread and Biases in Tropical Atlantic Sea Surface Temperatures

Elsa - Mohino Harris[1], *Belen Rodriguez-Fonseca[1,2], Teresa - Losada[1], Irene - Polo[1], Roberto - Mechoso[3] (1.Department of Physics of the Earth and Astrophysics, Universidad Complutense de Madrid, 28040, Madrid, Spain. , 2.Institute of Geosciences IGEO,UCM-CSIC, 28040, Madrid, Spain., 3.Department of Atmospheric and Oceanic Sciences, UCLA, Los Angeles, USA)

[AOS10-P04] **Revisiting the CMIP5 Thermocline in the Equatorial Pacific and Atlantic Oceans**

Antonio - Castaño[1,2], Elsa - Mohino[1], *Belen Rodriguez-Fonseca[1,2], Teresa - Losada[1] (1.Department of Physics of the Earth and Astrophysics, Universidad Complutense de Madrid, 28040, Madrid, Spain., 2.Institute of Geosciences, IGEO, UCM-CSIC 28040, Madrid, Spain.)

[AOS10-P05] Lagged Effects of North Atlantic SST Anomalies on Weather in Remote Areas

*Natalia Gnatiuk[1], Timo Vihma[2], Leonid Bobylev[1] (1.Nansen International Environmental and Remote Sensing Centre, 2.Finnish Meteorological Institute)

[AOS10-P06] **SST anomalies in the northern tropical Atlantic as a negative feedback to ENSO development**

*Ingo Richter[1], Hiroki Tokinaga[2], Yu Kosaka[3], Takeshi Doi[1] (1.JAMSTEC Japan Agency for Marine-Earth Science and Technology, 2.Kyoto University, 3.University of Tokyo)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-OS Ocean Sciences & Ocean Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

## [A-OS10] Atlantic climate variability, and its global impacts and predictability

convener:Ingo Richter(JAMSTEC Japan Agency for Marine-Earth Science and Technology), Hiroki Tokinaga(Research Institute for Applied Mechanics, Kyushu University), Noel S Keenlyside(Geophysical Institute Bergen), Carlos R Mechoso(University of California Los Angeles)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 201B 2F

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz), Chairperson:Adina Paytan(University of California, Santa Cruz)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

### [AHW22-06] Biodiversity increases integrated trophic position of macroinvertebrate communities in coastal food webs: testing the vertical diversity hypothesis

*Noboru Okuda[1], Jin'ichi Karube[2], Yoichiro Sakai[3], Tomohiro Takeyama[4], Ichiro Tayasu[1], Chikage Yoshimizu[1], Toshi Nagata[5] (1.Research Institute for Humanity and Nature, 2.Kindai University, 3.Lake Biwa Environmental Research Institute, 4.Okayama University of Science, 5.University of Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

### [AHW22-07] The analysis of the community composition of riverine bacteria and microalgae in relation to nutrient status and diversity: the case in irrigation season in the Yasu River, Japan

*Tohru Ikeya[1], Takuya Ishida[1], Yoshitoshi Uehara[1], Satoshi Asano[2], Ichiro Tayasu[1], Noboru Okuda[1], Masayuki Ushio[3,4,5], Shohei Fujinaga[4], Chia-Ying Ko[6], Elfritzson Martin Peralta[7], Naoto F. Ishikawa[8], Tomoya Iwata[9] (1.Research Institute for Humanity and Nature, 2.Lake Biwa Environmental Research Institute, 3.Hakubi Center, Kyoto University, 4.Center for Ecological Research, Kyoto University, 5.PRESTO, Japan Science and Technology Agency, 6.National Taiwan University, 7.University of Santo Tomas, 8.Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology, 9.Faculty of Life and Environmental Sciences, Yamanashi University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

### [AHW22-08] Multiple stressors and protection efforts in highly urbanized watersheds in the Philippines

*Elfritzson M. Peralta[1,3], Leocris S. Batucan Jr.[4,6], Alexis E. Belen[2,3], Irisse Bianca B. De Jesus[1,3], Takuya Ishida[5], Chia-Ying Ko[7], Yuki Kobayashi[5], Tohru Ikeya[5], Yoshitoshi Uehara[5], Tomoya Iwata[8], Adelina S. Borja[9], Jonathan Carlo A. Briones[1,2,3], Francis S. Magbanua[4], Rey Donne S. Papa[1,2,3], Noboru Okuda[5] (1.Research Center for the Natural and Applied Sciences, University of Santo Tomas, PH, 2.Department of Biological Sciences, University of Santo Tomas, PH, 3.The Graduate School, University of Santo Tomas, PH, 4.Institute of Biology, University of the Philippines Diliman, PH, 5.Research Institute for Humanity and Nature, JP, 6.Academia Sinica and Department of Life Science, National Taiwan Normal University, TW, 7.Institute of Fisheries Science and Department of Life Science, National Taiwan University, TW, 8.Faculty of Life and Environmental Sciences, University of Yamanashi, JP, 9.Resource Management and Development Department, Laguna Lake Development Authority, PH)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

### [AHW22-09] Ammonium contamination of shallow groundwater beneath vegetable fields in Central Vietnam

★Invited Papers

*Maeda Morihiro[1], Takuya Fujimura[1], Van Ngoc Tuong Hoang[2], Daisuke Inoue[3], Hidetaka Chikamori[1], Fujio Hyodo[1] (1.Okayama University, 2.Hue University, 3.Osaka University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

### [AHW22-10] Modelling nutrient and organic waste behaviour in a tropical wetland in Singapore under projected anthropogenic scenarios

*Swee Yang Edmund Low[1], Dong Eon Kim[1], Canh Tien Trinh Nguyen[1], Yixiong Cai, Shie-Yui Liong[1] (1.National University of Singapore)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

### [AHW22-11] Benthic macroinvertebrate assemblages and water quality reflect the impacts of land use and land cover in Marikina Watershed, Philippines

*Julie - An N. Gregorio[1,2], Elfritzson M. Peralta[3,5], Irisse Bianca B. de Jesus[3,5], Tohru Ikeya[6], Jonathan Carlo A. Briones[3,4,5], Rey Donne S. Papa[3,4,5], Francis S. Magbanua[1], Noboru Okuda[6] (1.Institute of Biology, University of the Philippines, Diliman, Quezon City, 1101 Philippines, 2.Institute of Environmental Science and Meteorology, University of the Philippines, Diliman, Quezon City 1101 Philippines, 3.Research Center for the Natural and Applied Sciences, University of Santo Tomas, España Boulevard, Manila, 1015, Philippines, 4.Department of Biological Sciences,

University of Santo Tomas, España Boulevard, Manila, 1015, Philippines, 5.The Graduate School, University of Santo Tomas, España Boulevard, Manila, 1015, Philippines, 6.Research Institute for Humanity and Nature, 457-4 Motoyama, Kamigamo, Kyoto, 603-8047, Japan)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-HW Hydrology & Water Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 201B 2F

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz), Chairperson:Yasumoto Jun(University of the Ryukyus, Faculty of Agriculuture Department of Regional Agricultural Engineering)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[AHW22-12] **Characterization, distribution and degradation of environmental plastics in inland river system of Mongolia**

*Batdulam Battulga[1], Masayuki Kawahigashi[1], Bolormaa Oyuntsetseg[2] (1.Department of Geography, Tokyo Metropolitan University, Tokyo, 192-0397, Japan , 2.Department of Chemistry, National University of Mongolia, Ulaanbaatar, 210646, Mongolia)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[AHW22-13] Multi-site and multi-approach sediment transport modeling in tropical watersheds

★Invited Papers

*Assefa M Melesse[1], Alemu Osore Aga[2], Hagos Gebreselassie[2] (1.Florida International University, 2.Addis Ababa University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[AHW22-14] Calculation of SS concentration coefficients of river water for each land use by a simple watershed model.

*Seiko Yoshikawa[1], Donglai Ma[1,2], Tadamasa Saito[1,3], Kenji Matsumori[4], Yuko Itoh[5], Masahiro Kobayashi[5] (1.Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization, 2.Graduate Scool, Tsukuba University , 3.Faculty of Agriculture, Ibaraki University , 4.Western Region Agricultural Research Center, National Agriculture and Food Research Organization, 5.Forestry and Forest Products Research Institute)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[AHW22-15] Evaluation of long term variation in water balance and discharge of sediment and nitrogen in the urbanized catchment of Yamato River, using SWAT model

*Kunyang Wang[1,2], Yuta Shimizu[3], Shin-ichi Onodera[1], Mitsuyo Saito[4], Yusuke Tomozawa[1] (1.Graduate School of Integrated Arts and Science, Hiroshima University, 2.Capital Normal University, 3.National Agriculture and Food Research Organization, 4.Okayama University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[AHW22-16] Causal correlation between water-use of the Tedori River and coastal erosion of Chirihama Nagisa Driveway, Ishikawa, Japan

*Toshihiko Momose[1] (1.Ishikawa Prefectural University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[AHW22-17] Role of suspended solids on elemental dynamics in the Selenga River system

★Invited Papers

*Masayuki Kawahigashi[1], Orgilbold Myangan[2], Bolormaa Oyuntsetseg[2] (1.Tokyo Metropolitan University, 2.National University of Mongolia)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-HW Hydrology & Water Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 201B 2F

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz), Chairperson:Yoshikawa Seiko(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[AHW22-18] Relationship between topographical characteristics in catchment area and dissolved iron concentration of river in permafrost area

*Yuto Tashiro[1], Muneoki Yoh[1], Takayuki Shiraiwa[2], Takeo Onishi[3] (1.Tokyo University of Agriculture and Technology, 2.Hokkaido University, 3.Gifu University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[AHW22-19] Water Source Zones and Hydrochemical Properties of Fluoride Water in Mt. Meru Watershed, Tanzania

*Shinji Nakaya[1], Ryogo Takada[1], Jun Yasumoto[2], Junichi Yoshitani[1], Innocent Lugodisha[3], Zuberi Dominicus Lwimbo[3], Hans Komakech[4], Thomas Reuben Mollel[5] (1.Department of Water Environment and Civil Engineering, Faculty of Engineering, Shinshu University, Japan, 2.Department of Regional Agriculture Engineering, University of the Rykuyus, Japan, 3.School of Materials, Energy, Water and Environmental Sciences, NM-AIST, Tanzania, 4.WISE-Future, NM-AIST, Tanzania, 5.SGSS and Institute of resources assessment-UDSM, Tanzania)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[AHW22-20] Development and Application of a System for Measurement of Total Load of Water Quality

★Invited Papers

*Keiji Takase[1], Yuko Itoh[2] (1.Ishikawa Prefectual University, 2.Forestry and Forest Products research Institute, Japan)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[AHW22-21] Water infiltration and uptake around a Japanese cypress growing on a flat upland

*Masahiro Kobayashi[1], Shin-ichi Onodera[2], Yuko Itoh[1], Tadashi Sakata[1] (1.Forestry and Forest Products Research Institute, 2.Graduate School of Integrated and Arts Sciences, Hiroshima University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[AHW22-22] Innovative Rainfall Simulator Design for Moving Storm Scenarios with Different Storm Patterns

*RAVI KUMAR MEENA[1], SUMIT SEN[2] (1.M.Tech Student, Department of Hydrology, Indian Institute of Technology Roorkee, Roorkee, Uttarakhand, India, 2. Associate Professor, Department of Hydrology, Indian Institute of Technology Roorkee, Roorkee, Uttarakhand, India)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-HW Hydrology & Water Environment

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz)

[AHW22-P01] Phosphate Enrichment Hampers Development of Juvenile Acropora digitifera Coral by Inhibiting Skeleton Formation

Mariko Iijima[1], *Yasumoto Ko[1], Jun Yasumoto[2], Mina Hirose[3], Mitsuru Jimbo[1], Shugo Watabe[1] (1.Kitasato University School of Marine Biosciences, 2.Faculty of Agriculture, University of the Ryukyus, 3.Tropical Technology Plus)

[AHW22-P02] Modeling chlorophyll-a concentration using remote sensing in shallow water systems: Comparison of sensors

*Assefa M Melesse[1], Tara Blakey[1], Mohammad Haji Gholizadeh[1], Mohd Manzar Abbas[1] (1.Florida International University)

[AHW22-P03] Dynamics in groundwater flow system with seasonal water table variation in a coastal and island

*Yusuke Tomozawa[1], Shin-ichi Onodera[1], Mitsuyo Saito[2] (1.Graduate School of Integrated Arts and Sciences Hiroshima University, 2.Graduate School of Environmental and Life Science, Okayama University)

[AHW22-P04] **The Tracing of Groundwater Contamination Sources in Indonesian Coastal Alluvial Groundwater using $\delta^{34}S$ and $\delta^{15}N$ Isotopes**

*Anna Fadliah Rusydi[1,4], Mitsuyo Saito[2], Seiichiro Ioka[3], Shin-ichi Onodera[1] (1.Graduate School of Integrated Arts and Sciences, Hiroshima University, Japan, 2.Graduate School of Environmental and Life Sciences, Okayama University, Japan, 3.Research Institute for Sustainable Energy, Hirosaki University, Japan, 4.Research Center for Geotechnology, Indonesian Institute of Sciences, Indonesia)

[AHW22-P05] Spatio-temporal dynamics of orthophosphate with implications for limitation of phytoplankton growth in north basin of Lake Biwa, Japan

*Xin Liu[1], Rong Yi[1], Masahiro Maruo[1], Syuhei Ban[1] (1.The University of Shiga Prefecture)

[AHW22-P06] Microbial phase analysis in aquifer of Ryukyu Limestone Zone using next generation sequencer

*Umi Murao[1], Jun Yasumoto[1], Yasumoto Ko[3], Mina Hirose[2], Nanami Mizusawa[3], Ryo Iguchi[4], Bam H.N. Razafindrabe[5], Syugo Watabe[3] (1.University of the Ryukyus, Faculty of Agriculuture Department of Regional Agricultural Engineering, 2.Tropical Tecnology Plus, 3.Kitasato University School of Marine Biosciences, 4.National Institute of Advanced Industrial Science and Technology, 5.University of the Ryukyus, Faculty of Agriculuture Department of Subtropical Agro-Environmental Sciences)

[AHW22-P07] Evaluation for temporal variation in groundwater inflow to the lagoons connected to Lake Biwa by radon ($^{222}Rn$) tracer analysis

*Mitsuyo Saito[1], Shin-ichi Onodera[2], Yusuke Tomozawa[2], Kunyang Wang[2], Syuhei Ban[3], Noboru Okuda[4] (1.Graduate School of Environmental and Life Science, Okayama University, 2.Graduate School of Integrated Arts and Sciences, Hiroshima University, 3.School of Environmental Sciences, The University of Shiga Prefecture, 4.Research Institute for Humanity and Nature)

[AHW22-P08] Br/Cl ratio characteristics of groundwater in coastal areas in Indonesia

*Seiichiro Ioka[1], Shin-ichi Onodera[2], Mitsuyo Saito[3], Anna Fadliah Rusydi[2,4] (1.Institute of Regional Innovation, Hirosaki University, Japan, 2.Graduate School of Integrated Arts and Sciences, Hiroshima University, Japan, 3.Graduate School of Environmental and Life Sciences, Okayama University, Japan, 4.Research Center for Geotechnology, Indonesian Institute of Sciences, Indonesia)

[AHW22-P09] Estimation of groundwater recharge and phosphorus transport under different precipitation conditions in a suburban catchment, using SWAT model

*Kunyang Wang[1,2], Shin-ichi Onodera[1], Mitsuyo Saito[3], Noboru Okuda[4], Takuya Okubo[5] (1.Graduate School of Integrated Arts and Science, Hiroshima University, 2.Capital Normal University, 3.Okayama University, 4.Research

Institute for Humanity and Nature, 5.University of the Shiga Prefecture)

[AHW22-P10] Losses of phosphorus with soil erosion and nitrate with groundwater recharge in an agricultural catchment, subtropical small island

*Shin-ichi Onodera[1], Mitsuyo Saito[2], Yang Cao[1], Anna Fadliah Rusydi[1], Hide Omae[3], Yoshiko Iizumi[4], Yusuke Tomozawa[1] (1.Graduate School of Integrated and Arts Sciences, Hiroshima University, 2.Graduate School of Environmental and Life Science, Okayama University, 3.JIRCAS TARF, 4.JIRCAS HQ)

[AHW22-P11] Phosphate solubilizing bacteria as an indicator of sediment phosphorus in freshwater lakes

*Sreekumari Kurissery[1], Katelynn Crawford[1], Nandakumar Kanavillil[1] (1.Lakehead University, Canada)

[AHW22-P12] A Study on the dynamics of various phosphate forms in soil and groundwater in Ryukyu limestone regions

*Masashi Nozaki[1], Jun Yasumoto[2], Yasumoto Ko[3], Hirose Mina[4], Iijima Mariko[3], Ryuichi Shinjo[5], Bam H.N. Razafindrabe[6] (1.University of The Ryukyus, Graduate School of Agriculture,, 2.University of the Ryukyus, Faculty of Agriculture, Department of Regional Agricultural Engineering, 3.Kitasato University School of Marine Biosciences, 4.Tropical Technology Plus, 5.Department of Physics and Earth Sciences, University of the Ryukyus, 6.University of the Ryukyus, Faculty of Agriculture, Department of Subtropical Agro-Environmental Sciences)

[AHW22-P13] Impacts of highly concentrated turbid water on the groundwater in the Tedori River alluvial fan, Japan

*Yoichi Fujihara[1], Shunsuke Chono[1], Keiji Takase[1], Eiji Ichion[1] (1.Department of Environmental Science, Ishikawa Prefectural University)

[AHW22-P14] Altitude effect of water stable isotopic ratio of ravine water and its contribution to groundwater in alluvial plains - Comparison in east and west side catchments of Lake Biwa –

*Yusuke Tomozawa[1], Kunyang Wang[1], Mitsuyo Saito[2], Syuhei Ban[3], Noboru Okuda[4], Shin-ichi Onodera[1] (1.Graduate School of Integrated Arts and Sciences Hiroshima University, 2.Graduate School of Environmental and Life Science, Okayama University, 3.School of Environmental Science, The University of Shiga Prefecture, 4.Research Institute for Humanity and Nature)

[AHW22-P15] Calculation of TN and TP concentration coefficients of river water for each land use by a simple watershed model.

*Seiko Yoshikawa[1], Donglai Ma[1,4], Tadamasa Saito[1,5], Kenji Matsumori[2], Yuko Itoh[3], Masahiro Kobayashi[3] (1.Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization, 2.Western Region Agricultural Research Center, National Agriculture and Food Research Organization, 3.Forestry and Forest Products Research Institute, 4.Graduate school,Tsukuba University, 5.Faculty of Agriculture, Ibaraki University)

[AHW22-P16] **Possibility of nutrients transportation from littoral slope for enhancement of phytoplankton growth in north basin of Lake Biwa**

*Syuhei Ban[1], Rong YI[1], Xin Liu[1], Masahiro Maruo[1], Miki Sudo[1], Naoshige Goto[1], Jun Murase[2] (1.The University of Shiga Prefecture, 2.Nagoya University)

[AHW22-P17] SWAT model analysis for confirming the effects of crop growth on the suspended sediment concentration from a settling basin catchment on Ishigaki island

*Yang Cao[1], Shin-ichi Onodera[1], Mitsuyo Saito[2], Hide Omae[3], Yoshiko Iizumi[3] (1.Graduate School of Integrate Arts and Sciences, Hiroshima University, 2.Graduate School of Environmental and life Science, Okayama University, 3.Tropical Agriculture Research Front (TARF), Japan International Research Center for Agricultural Sciences (JIRCAS))

[AHW22-P18] Estimating the runoff of water, sediment, and nutrient using SWAT model in Kikuchi-river watershed, Kumamoto, and the influence of the forest

*Soichiro Fujii[1], Masahiko Kanamori[1], Yuko Nagano[1], Maki Kinoshita[2], Yuta Shimizu[3], Shin-ichi Onodera[4] (1.Japan Forest Technology Association, 2.PASCO Corporation, 3.Western Region Agricultural Research Center, National Agriculture and Food Research Organization, 4.Graduate School of Integrated and Arts Sciences, Hiroshima University)

[AHW22-P19] Atmospheric depositions on forest ecosystems in areas along the Sea of Japan

*Yuko Itoh[1], Keiji Takase[2], Yoichi Fujihara[2], Toru Okamoto[1] (1.Forestry and Forest Products Research Institute, Japan, 2.Ishikawa Prefectural University)

[AHW22-P20] Continuous and simultaneous flux measurement of $N_2O$ and $CO_2$ from agricultural soil using a portable multi-turn time-of-flight mass spectrometer

*Noriko Nakayama[1], Yusuke Iwai[1], Yo Toma[2], Hiroshi Furutani[1], Ryusuke Hatano[3], Michisato Toyoda[1] (1.Osaka University, 2.Ehime University, 3.Hokkaido University)

---

[AHW22-P21] Effects of introduction of cyclic irrigation system on mass balances of SS and T-P in Lake Inbanuma, Chiba, Japan

*Tomijiro Kubota[1] (1.National Agriculture and Food Research Organization, Institute for Rural Engineering)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-HW Hydrology & Water Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz)

[AHW22-P01] Phosphate Enrichment Hampers Development of Juvenile Acropora digitifera Coral by Inhibiting Skeleton Formation

Mariko Iijima[1], *Yasumoto Ko[1], Jun Yasumoto[2], Mina Hirose[3], Mitsuru Jimbo[1], Shugo Watabe[1] (1.Kitasato University School of Marine Biosciences, 2.Faculty of Agriculture, University of the Ryukyus, 3.Tropical Technology Plus)

[AHW22-P02] Modeling chlorophyll-a concentration using remote sensing in shallow water systems: Comparison of sensors

*Assefa M Melesse[1], Tara Blakey[1], Mohammad Haji Gholizadeh[1], Mohd Manzar Abbas[1] (1.Florida International University)

[AHW22-P03] Dynamics in groundwater flow system with seasonal water table variation in a coastal and island

*Yusuke Tomozawa[1], Shin-ichi Onodera[1], Mitsuyo Saito[2] (1.Graduate School of Integrated Arts and Sciences Hiroshima University, 2.Graduate School of Environmental and Life Science, Okayama University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 301A 3F

## [A-GE28] Subsurface Mass Transport, Material Cycle, and Environmental Assessment

convener:Yuki Kojima(Department of Civil Engineering, Gifu University), Shoichiro Hamamoto(Department of Biological and Environmental Engineering, The University of Tokyo), Hirotaka Saito(Department of Ecoregion Science, Tokyo University of Agriculture and Technology), Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University), Chairperson:Yuki Kojima(Gifu University), Shoichiro Hamamoto(The University of Tokyo), Yasushi Mori(Okayama University), Hirotaka Saito(Tokyo University of Agriculture and Technology)

9:00 AM - 9:25 AM JST | 12:00 AM - 12:25 AM UTC

[AGE28-01] **Humic substances in deep sedimentary groundwater**

★Invited Papers

*Takumi Saito[1] (1.School of Engineering, The University of Tokyo)

---

9:25 AM - 9:40 AM JST | 12:25 AM - 12:40 AM UTC

[AGE28-02] Nano-Bubble Retention in Saturated Porous Media under Different Solution Chemistry

*Shoichiro Hamamoto[1], Takuya Sugimoto[1], Takato Takemura[2], Taku Nishimura[1], Scott A Bradford[3] (1.Department of Biological and Environmental Engineering, The University of Tokyo, 2.College of Humanities and Sciences, Nihon University, 3.U. S. Salinity Laboratory)

---

9:40 AM - 9:55 AM JST | 12:40 AM - 12:55 AM UTC

[AGE28-03] **Geochemical Investigation of Metals and Trace Elements around the Abandoned Cu – Ni Mine Site in Selibe Phikwe, Botswana**

*Fiona Segolame Motswaiso[1], Kengo - Nakamura[1], Noriaki - Watanabe[1], Takeshi - Komai[1] (1.Tohoku Univeristy Graduate School of Environmental Studies)

---

9:55 AM - 10:10 AM JST | 12:55 AM - 1:10 AM UTC

[AGE28-04] Removal of Arsenic (III) From Aqueous Solution Using Pumice and Zeolite Supported Zero-Valent Iron Nanoparticle

*Shashi Ranjan[1], Brijesh kumar yadav[1], Himanshu Joshi[1] (1.Indian Institute of Technology Roorkee)

---

10:10 AM - 10:25 AM JST | 1:10 AM - 1:25 AM UTC

[AGE28-05] **Unsaturated Hydraulic Conductivity Estimation from Multi-step Centrifuge Outflow**

*Thanh Long Bui[1], Yasushi Mori[1] (1.Graduate School of Environmental and Life Science, Okayama University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-GE Geological & Soil Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

## [A-GE28] Subsurface Mass Transport, Material Cycle, and Environmental Assessment

convener:Yuki Kojima(Department of Civil Engineering, Gifu University), Shoichiro Hamamoto(Department of Biological and Environmental Engineering, The University of Tokyo), Hirotaka Saito(Department of Ecoregion Science, Tokyo University of Agriculture and Technology), Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University)

### [AGE28-P01] Vegetation pellets development and feasibility evaluation for unmanned-aerial-vehicle seeding on post-landslide sites

*Kai-Chi Hsu[1], Guo-Zhang M. Song[1], Shin-Hwei Lin[1], Chi-Hao Chang[2] (1.Department of Soil and Water Conservation, National Chung Hsing University, 2.Department of Landscape Architecture, Tunghai University)

### [AGE28-P02] Characterizing Soil Environment in The Rice Terraces of the Philippine Cordilleras

*Tomoyo Kurozumi[1], Yasushi Mori[2], Hiroaki Somura[2], Milagros Ong How[3] (1.Faculty of Environmental Science and Technology, Okayama University, 2.Graduate School of Environmental and Life Science, Okayama University , 3.Universal Harvested Incorporated)

### [AGE28-P03] Web-based interactive platform for analysis of regional-scale groundwater resources

*Chuen-Fa Ni[1], I-Hsien Lee[1], Chi-Ping Lin[1], Wi-Ci Li[1] (1.National Central University)

### [AGE28-P04] Development of simultaneous measurement system of viscosity and permeability for highly accurate evaluation of flow characteristic of Geofluid

*Tomoya Muramoto[1], Yoshitaka Fujita[1], Hiroaki Kajikawa[1], Hideaki Iizumi[1], Kazunori Ide[1] (1.National Institute of Advanced Industrial Science and Technology, National Metrology Institute of Japan)

### [AGE28-P05] Soil hydraulic parameter estimation by evaporation method

Shintaro Kubota[1], *Hirotaka Saito[1] (1.Graduate School of Agriculture, Tokyo University of Agriculture and Technology)

### [AGE28-P06] Measurement of apparent gas diffusion coefficient in poorly tilled seedbed under windy condition.

*Yoshihiro Matsumoto[1], Shuichiro Yoshida[1], Hiroyuki Sekiya[2], Kazuhiro Nishida[1] (1.Graduate School of Agricultural and Life Sciences, The University of Tokyo, 2.National Agricultural Research Center NARO)

### [AGE28-P07] Evaluating improvement techniques for phytosuction separation method to remove heavy metals from contaminated soils

*Yuki Kojima[1], Hayata Terada[1], Masahiko Katoh[2], Kohji Kamiya[1] (1.Department of Civil Engineering, Gifu University, 2.School of Agriculture, Meiji University)

### [AGE28-P08] Transport of Colloidal Particles in Saturated Toyoura Sand: Effects of Flow Rate on Importance of Electrostatic Repulsion

*Takuya Sugimoto[1], Shoichiro Hamamoto[1], Taku Nishimura[1], Yasuhisa Adachi[2], Motoyoshi Kobayashi[2] (1.Graduate School of Agricultural and Life Sciences, The University of Tokyo, 2.Faculty of Life and Environmental Sciences, University of Tsukuba)

### [AGE28-P09] Leaching behavior of As, Pb, Cd and Se in subsurface marine and nonmarine sedimentary environment in central Kanto plain, Japan

*SUSHMITA HOSSAIN[1], Takashi Ishiyama[2], Shoichi Hachinohe[2], Chiaki T. Oguchi[1] (1.Graduate school of Science and Engineering, Saitama University, 2.Center for Environmental Science in Saitama)

### [AGE28-P10] Colloid transport in a quasi-saturated porous media

*Yushi Ooko[1], Takuya Sugimoto[2], Shoichiro Hamamoto[2], Taku Nishimura[2] (1.The University of Tokyo, 2.Graduate School of Agricultural and Life Sciences, The University of Tokyo)

[E] Oral | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 301A 3F

## [A-GE29] Energy-Environment-Water Nexus and Sustainable Development

convener:Ming Zhang(Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST), Ken Kawamoto(Graduate School of Science and Engineering, Saitama University), Jet-Chau Wen(National Yunlin University of Science and Technology), Yonghong Hao(Tianjin Normal University), Chairperson:Ming Zhang(AIST), Hirotaka Saito(Tokyo University of Agriculture and Technology), Yonghong Hao(Tianjin Normal University)

10:50 AM - 11:05 AM JST | 1:50 AM - 2:05 AM UTC

[AGE29-01] Input-Output Analysis of Taiwan's Food-Energy-Water Risk

*CHU-CHUN YAO[1], Gene Jiing-yun You[1] (1.National Taiwan University)

---

11:05 AM - 11:20 AM JST | 2:05 AM - 2:20 AM UTC

[AGE29-02] **Groundwater potential analysis using the multiple spatiotemporal remote sensing approach in fractured rock of mountainous region**

*Jung-Jun Lin[1,2], Yuei-An Liou[1], Chien-Chung Ke[2], Su-Yun Chi[2], Jia-Hung Liang[3] (1.National Central Univ., 2.Sinotech Engineering Consultants, Inc., 3.Ministry of Economic Affairs)

---

11:20 AM - 11:35 AM JST | 2:20 AM - 2:35 AM UTC

[AGE29-03] Estimating Soil Water Content with Color Calibration Method in the Image of Remote Sensing by Unmanned Aerial Vehicle

*Hong-Yi Li[1], Hong-Ru Lin[1], Jyun-Lin Chen[1], Shao-Yang Huang[1], Jet-Chau Wen[1] (1.National Yunlin University of Science and Technology)

---

11:35 AM - 11:50 AM JST | 2:35 AM - 2:50 AM UTC

[AGE29-04] **Characterizing Geotechnical Properties of Drinking Water Sludge Blended with Graded Crushed Clay Brick for Road Subgrade: Effects of Gradation and Mixing Proportion of Crushed Clay Brick on CBR and Water Permeability**

*Muhammad Rashid Iqbal[1], Akihiro Matsuno[1], Ken Kawamoto[1] (1.Graduate School of Science and Engineering, Saitama University)

---

11:50 AM - 12:05 PM JST | 2:50 AM - 3:05 AM UTC

[AGE29-05] Investigation and Evaluation of the Multiple-liquefaction Site at the Southern Taiwan

*Chih-Sheng KU[1] (1.I-Shou University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-GE Geological & Soil Environment

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 301A 3F

## [A-GE29] Energy-Environment-Water Nexus and Sustainable Development

convener:Ming Zhang(Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST), Ken Kawamoto(Graduate School of Science and Engineering, Saitama University), Jet-Chau Wen(National Yunlin University of Science and Technology), Yonghong Hao(Tianjin Normal University), Chairperson:Ken Kawamoto(Saitama University), Jet- Chau Wen(National Yunlin University of Science and Technology, Taiwan)

1:50 PM - 2:05 PM JST | 4:50 AM - 5:05 AM UTC

[AGE29-06] Investigating the Reproducibility of Hydraulic Tomography Estimates with Time-Variable Boundary Conditions

*Jian-Dao Li[1], Jyun-Lin Chen[1], Hong-Ru Lin[1], Shao-Yang Huang [1], Tian-Chyi Jim Yeh[2], Jet-Chau Wen[1] (1.National Yunlin University of Science and Technology, 2.The University of Arizona)

---

2:05 PM - 2:20 PM JST | 5:05 AM - 5:20 AM UTC

[AGE29-07] **Applying river pollution index and QUAL2K model for water quality assessment and management in Ke-Ya river, Taiwan**

*Hong-Syuan Li[1], Yu-Chih Lin[1] (1.Department of Environmental Engineering & Health, Yuanpei University of Medical Technology)

---

2:20 PM - 2:35 PM JST | 5:20 AM - 5:35 AM UTC

[AGE29-08] Environmental assessment at CDW disposal sites in Vietnam: Case study in Thanh Tri landfill, Hanoi

*Thanh Ha Ngo[1], Akihiro Matsuno[1], Ken Kawamoto[1] (1.Graduate School of Science and Engineering, Saitama University)

---

2:35 PM - 2:50 PM JST | 5:35 AM - 5:50 AM UTC

[AGE29-09] **Modeling Study on the Impacts of Groundwater Pumping to Regional Hydroclimatology in 37 World Major Aquifers**

*Pat J.-F. Yeh[1] (1.Monash University Malaysia)

---

2:50 PM - 3:05 PM JST | 5:50 AM - 6:05 AM UTC

[AGE29-10] CHRATERIZING BURIED WASTE COMPOSITION AT CONSTRUCTION AND DEMOLITION WASTE (CDW) DISPOSAL SITE IN VIETNAM: A CASE STUDY IN THANH TRI LANDFILL IN HANOI

*Tselmeg Aldarjav[1], Akira Kato[1], Akihiro Matsuno[1], Ken Kawamoto[1,2] (1.Graduate School of Science and Engineering, Saitama University, Japan , 2.International Institute for Resilient Society, Saitama University, Japan)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-GE Geological & Soil Environment

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_11

## [A-GE29] Energy-Environment-Water Nexus and Sustainable Development

convener:Ming Zhang(Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST), Ken Kawamoto(Graduate School of Science and Engineering, Saitama University), Jet-Chau Wen(National Yunlin University of Science and Technology), Yonghong Hao(Tianjin Normal University)

[AGE29-P01] **The role of anthropogenic activities in spring discharge cessation: Jinci Springs China**

Yaru Guo[1], *Yonghong Hao[1], Chun Zhao[1], Huan Lian[1] (1.Tianjin Normal University)

[AGE29-P02] **Groundwater response to tidal fluctuations in a leaky confined coastal aquifer with finite length**

*Zhi-Xue Zhao[1], Tongke Wang[1], Jun Li[1] (1.Tianjin Normal University, Tianjin, China)

[AGE29-P03] Relationship between "source and sink"landscape patterns and river nutrient discharge in a peri-urban watershed

*Chongwei Li[1] (1.Tianjin Normal University)

[AGE29-P04] Assessing the Urban Storm-Flood Disaster of Zhengzhou city Based on Fuzzy Methods

*Caihong Hu[1], Xian Du[1], Ying Zhang[1], SHAN E HYDER ALIAS TAHIR[1], Shengqi Jian[1] (1.School of water conservancy and environment, Zhengzhou University, Zhengzhou City, Henan Province, P.R. China, 450001)

[AGE29-P05] Application of RAMMS Software to Predict the submerged area of Debris Flow: A Case Study of Feng-Chiou torrent in Taiwan

*Hsin-Ying Hsieh[1], Chun-Yi Wu[1] (1.Department of Soil and Water Conservation, National Chung Hsing University)

[AGE29-P06] Applications of the Cholesteric Liquid Crystal (CLC) Sensor to Rapidly Measure the Volatile Organic Compounds in the Atmosphere Environment

Ruey-Fang YU[1], *GUAN-BO CHAO[1], Jian-cheng XU[1], KUANG-PENG HSIEH[1] (1.Department of Safety, Health and Environmental Engineering, National United University, Taiwan, R. O. C.)

[AGE29-P07] Solar Ag/P3HT@$TiO_2$ Photocatalysis of Phenol Wastewater by a Pilot-Scale Fresnel Lens Assisted IPCC Reactor

*An-Chi Chen[1], Ting-Yu Zeng [1], Wen-Shiuh Kuo[1] (1.National United University,Department of Safety, Health and Environmental Engineering)

[AGE29-P08] Using fluorescence quenching effect to investigate the electrical neutralization ability for different aromatic organic compounds

*Yu-Ting Chen[1], Wen-Po Cheng[1] (1.National United University,Department of Safety, Health and Environmental Engineering)

[AGE29-P09] **Sustainable recovery of sugarcane biowastes to prepare biochar-derived electrodes for recycling of brackish water**

*Shou-Heng Liu[1] (1.National Cheng Kung University)

[AGE29-P10] The National Survey of POPs in Soil: A study of polybrominated diethyl ethers (PBDEs) in Soil in Taiwan

*Shyh-Wei Chen[1], Ming-Yang Syue[2], I HSIN LEE[3], Chia Hsin Li[3], Yihsin Lai[3], Bo-Wei Power Liang[3] (1.Chung Yuan Christian Univ. Taiwan, 2.Soil and Groundwater Pollution Remediation Fund Management Board, EPA, Taiwan, 3.Sinotech Engineering Service LTD., Taiwan)

[AGE29-P11] **Remediation of Total Peteoleum Hydrocarbons in Soils by Combining Cyclodextrin and Microbubble Ozonation**

*Kuan-Yi Kuo[1], Meng-hau Sung[1], Fu-yin Xie[1] (1.Department of Environmental Science and Engineering,Tunghai University,Taiwan)

[AGE29-P12] **Treatment of organic pollutants in wastewater by ozone microbubbles and cyclodextrins**

*Fu-Yin XIE[1], Meng-hau Sung[1] (1.Department of Environmental Science and Engineering,Tunghai University,Taichung City,Taiwan)

[AGE29-P13] High Addition Valued Recycling Technology of Lithium-ion Battery

*YI-CHEN TSENG[1], TIEN-CHIN CHANG[1], YI-HSIANG HONG[1] (1.Institute of Environmental Engineering and Management, National Taipei University of Technology, No. 1, Sec. 3, Zhongxiao E. Rd., Da'an Dist., Taipei City 106, Taiwan (R.O.C.))

[AGE29-P14] Applying GIS Site Suitability Analysis to Optimize Landfill Selection in Mozambique

*Chelsea Adelina Langa[1] (1.Tohoku University, Graduate School of Environmental Studies)

[AGE29-P15] Effectiveness of Solidification/Stabilization of a Heavy Metal-Contaminated Soil Using a Sustainable Binder

*Yasong Feng[1,2,3], Weiyi Xia[1], Shiji Zhou[1], Ming Zhang[2], Yanjun Du[1] (1.Southeast Univ., 2.AIST, 3.Tohoku Univ.)

[AGE29-P16] **Determining diffusive parameters using out-diffusion experiment with consideration of sampling effect**

*Ranran Song[1], Chihiro Inoue[1], Ming Zhang[2] (1. Tohoku University, 2.Geological Survey of Japan, AIST)

[AGE29-P17] **Exploring the removal characteristics of heavy metals employing Nanofiltration (NF) technique**

*Jagdeesh Kumar[1], Himanshu Joshi[1] (1.INDIAN INSTITUTE OF TECHNOLOGY ROORKEE)

[AGE29-P18] **Potential of Potash Recovery Employing Electrodialysis(ED) Technique from Distillery Effluent**

*SUNIL YADAV[1], HIMANSHU JOSHI[1] (1.INDIAN INSTITUTE OF TECHNOLOGY ROORKEE)

[AGE29-P19] CHARACTERIZATION OF WATER RETENTION AND MASS TRANSPORT PROPERTIES FOR RECYCLED ROADBED MATERIALS BLENDED WITH AAC FINES

*Ryohei ITO[1], Akira KATO[1], Akihiro MATSUNO[1], Ken KAWAMOTO[1,2] (1.Graduate School of Science and Engineering, Saitama University, 2.National University of Civil Engineering, Vietnam)

[AGE29-P20] **Characterizing Geotechnical Properties of Drinking Water Sludge Blended with Graded Crushed Clay Brick for Road Subgrade: Effects of Gradation and Mixing Proportion of Crushed Clay Brick on Compaction Property**

*Tserenlkham lkhagvasuren[1], Muhammad Rashid Iqbal[1], Ken Kawamoto[1] (1.Graduate school of science and engineering Saitama University, Japan)

[AGE29-P21] CHARACTERIZING PHYSICAL AND CHEMICAL PROPERTIES OF RESIDUES GENERATED FROM CONSTRUCTION AND DEMOLITION WASTE

*NINGNING HAO[1], Ken Kawamoto[1], Akihiro Matsuno[1] (1.Saitama University)

[AGE29-P22] CHARACTERIZATION OF PORE-STRUCTURE PARAMETERS FOR UNDISTURBED AND REPACKED SAMPLES AT FIELD WATER CONTENTS

*Arjun Baniya[1], Akihiro Matsuno[1], Ken Kawamoto[1] (1.Saitama University , Graduate school of Science and Engineering)

[AGE29-P23] **CHECK SHEET SURVEY FOR ESTIMATING CDW GENERATION AND CASH FLOW AT BUILDING DEMOLISHING SITES IN HANOI, VIETNAM**

*Cuong Viet Tran[1], Kawamoto Ken[1] (1.Graduate School of Science and Engineering, Saitama University)

[AGE29-P24] APPLICATION OF CRUSHED GRAINS OF LATERITE AND AUTOCLAVED AERATED CONCRETE FOR HEAVY METAL REMOVAL FROM WASTEWATER

*Buddhika Priyadarshani Bandara Arachchillage[1], Yuki Yoshida[1], Pradeep Kumara Gajanayake Mudalige[1], Akihiro Matsuno[1], Ken Kawamoto[1] (1.Graduate School of Science and Engineering, Saitama University)

[AGE29-P25] Effects of Silicic Acid on Environmental Stability of Spent Calcium-based Arsenic Adsorbents

*Hajime Sugita[1], Terumi Oguma[1], Ming Zhang[1], Junko Hara[1], Yoshishige Kawabe[1] (1.National Institute of Advanced Industrial Science and Technology)

[AGE29-P26] The Fate of Chloroethene in Geo-environment

*Ming Zhang[1], Miho Yoshikawa[1] (1.Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 302 3F

## [A-CG34] Satellite Earth Environment Observation

convener:Riko Oki(Japan Aerospace Exploration Agency), Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Tsuneo Matsunaga(Center for Global Environmental Research and Satellite Observation Center, National Institute for Environmental Studies), Chairperson:Kentaroh Suzuki

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

### [ACG34-07] GCOM-C “Shikisai” FIRST YEAR OBSERVATIONS

★Invited Papers

*Hiroshi Murakami[1], Masahiro Hori[1], Risa Miyazaki[1], Toshiyuki Kobayashi[1], Takashi M. Nagao[1], Kazunori Ogata[1], Rigen Shimada[1], Junichi Takaku[2] (1.Earth Observation Research Center, Japan Aerospace Exploration Agency, 2.Remote Sensing Technology Center of Japan)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

### [ACG34-08] Algorithm improvement for GCOM-C/SGLI Above Ground Biomass Standard product.

*KAJIWARA Koji[1], Yoshiaki HONDA[1] (1.Chiba University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

### [ACG34-09] Common retrieval of Atmospheric Aerosol Properties for geostationary and polar-orbital Satellite Imaging Sensors: Himawari8/AHI and GCOM-C/SGLI results

*Yoshida Mayumi[1], Maki Kikuchi[1], Takashi M. Nagao[1], Hiroshi Murakami[1], Keiya Yumimoto[2] (1.Japan Aerospace Exploration Agency, 2.Kyusyu University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

### [ACG34-10] Cloud optical properties from various ground and satellite instruments evaluated during an intensive campaign

*Alessandro Damiani[1], Hitoshi Irie[1], Takashi Horio[1], Tamio Takamura[1], Rei Kudo[2], Pradeep Khatri[3], Hironobu Iwabuchi[3], Ryosuke Masuda[3], Takashi M. Nagao[4] (1.CEReS, Chiba University, 2.Meteorological Research Institute, Japan Meteorological Agency, 3.Graduate School of Science, Tohoku University, 4.Earth Observation Research Center, JAXA)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

### [ACG34-11] Issues in aerosol-cloud-climate interaction: Needs for future satellite mission

★Invited Papers

*Kentaroh Suzuki[1] (1.Atmosphere and Ocean Research Institute, University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

### [ACG34-12] Impact of aerosol vertical profile and optical parameters on the accuracy of satellite AOD retrieval

*Jing Li[1], Chong Li[1] (1.Peking University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 302 3F

## [A-CG34] Satellite Earth Environment Observation

convener:Riko Oki(Japan Aerospace Exploration Agency), Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Tsuneo Matsunaga(Center for Global Environmental Research and Satellite Observation Center, National Institute for Environmental Studies), Chairperson:Nobuhiro Takahashi(Institute for Space-Earth Environmental Research, Nagoya University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACG34-13] Statistical validation of drop size distribution estimated by GPM/DPR

*Nobuhiro Takahashi[1] (1.Institute for Space-Earth Environmental Research, Nagoya University)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACG34-14] Impact study of DPR SLH nudging method for data assimilation in the JMA Local NWP system

★Invited Papers

*Yasutaka Ikuta[1] (1.Japan Meteorological Agency)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACG34-15] Precipitation Extremes Monitoring using Global Satellite Mapping of Precipitation (GSMaP) Product

*Takuji Kubota[1], Tashima Tomoko[1], Riko Oki[1], Tomoaki Mega[2], Tomoo Ushio[2] (1.Earth Observation Research Center,Japan Aerospace Exploration Agency, 2.Department of Aerospace Engineering, Tokyo Metropolitan University)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACG34-16] Estimation of cloud water content over land using satellite-based passive microwave observations with a coupled land and atmosphere assimilation method

*Rie Seto[1], Shinjiro Kanae[1] (1.Tokyo Institute of Technology)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[ACG34-17] Ensemble-Based Data Assimilation of GPM/DPR Reflectivity into the Nonhydrostatic Icosahedral Atmospheric Model NICAM

*Shunji Kotsuki[1], Koji Terasaki[1], Takemasa Miyoshi[1] (1.RIKEN Center for Computational Science)

---

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[ACG34-18] **An ecohydrological land reanalysis by integrating simulation and satellite observations**

*Yohei Sawada[1], Tosiyuki Nakaegawa[1], Kozo Okamoto[1], Takeshi Iriguchi[1], Hideyuki Fujii[2] (1.Meteorological Research Institute, 2.Japan Aerospace Exploration Agency)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

## [A-CG34] Satellite Earth Environment Observation

convener:Riko Oki(Japan Aerospace Exploration Agency), Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Tsuneo Matsunaga(Center for Global Environmental Research and Satellite Observation Center, National Institute for Environmental Studies)

[ACG34-P01] **Impact of usage of multiple-satellite sensors on accuracy of daily-mean sea surface wind data**

*Ayumi Koizumi[1], Masahisa Kubota[2], Kunio Kutsuwada[3], Hiroyuki Tomita[4], Tsutomu Hihara[5] (1.Tokai University, 2.Tokai University, Institute of Ocean Research and Development, 3.School of Marine Science and Technology, Tokai University, 4.Institute for Space-Earth Environmental, Nagoya University, 5.Japan Agency for Marine-Erth Science and Technology)

[ACG34-P02] Temperature and Size Variability of Warm Pools in the Global Oceans

*ChunYi Lin[1] (1.National Museum of Marine Science & Technology)

[ACG34-P03] Sea surface temperature from SGLI aboard the GCOM-C satellite of JAXA

*Yukio Kurihara[1], Kazunori Ogata[2], Hiroshi Murakami[2], Misako Kachi[2] (1.Tripli-I Co., Ltd., 2.JAXA EORC)

[ACG34-P04] Concept of small satellite UV/visible imaging spectrometer optimized for tropospheric $NO_2$ measurements in air quality monitoring

*Tamaki Fujinawa[1,5], Katsuyuki Noguchi[2], Akihiko Kuze[3], Andreas Richter[4], John P. Burrows[4], Andreas C. Meier[4], Tomohiro Sato[1], Takeshi Kuroda[1], Naohiro Yoshida[5], YASUKO KASAI[1,5] (1.National Institute of Information and Communications Technology, 2.Nara Women's University, 3.Japan Aerospace Exploration Agency, 4.University of Bremen, 5.Tokyo Institute of Technology)

[ACG34-P05] EarthCARE L2 algorithms for cloud and precipitation

*Kaori Sato[1], Hajime Okamoto[1], Hiroshi Ishimoto[2] (1.Research Institute for Applied Mechanics, Kyushu University, 2.Meteorological Research Institute)

[ACG34-P06] Analysis of the Surface Echo Characteristics Derived from GPM/DPR Wide Swath Observation Experiment

*Kosuke Yamamoto[1], Kinji Furukawa[1], Nobuhiro Takahashi[2], Takuji Kubota[1] (1.Japan Aerospace Exploration Agency, 2.Nagoya University)

[ACG34-P07] The Recent Results from the Global Precipitation Measurement (GPM) mission in Japan

*Riko Oki[1], Takuji Kubota[1], Kinji Furukawa[1], Yuki Kaneko[1], Moeka Yamaji[1], Kosuke Yamamoto[1], Toshio Iguchi[2], Yukari Takayabu[3] (1.Japan Aerospace Exploration Agency, 2.NICT, 3.the University of Tokyo)

[ACG34-P08] **Verification of Global Satellite Mapping of precipitation (GSMaP) for providing its error information**

*Moeka Yamaji[1], Takuji Kubota[1] (1.Earth Observation Research Center, Japan Aerospace Exploration Agency)

[ACG34-P09] Detection of the mixed phase top using the measured dual-frequency ratio of reflectivity with GPM/DPR

*Yuki Kaneko[1], Toshio Iguchi[2] (1.Japan Aerospace Exploration Agency, 2.National Institute of Information and Communications Technology)

[ACG34-P10] **Comparison between high frequency satellite rainfall estimation and APHRODITE-2 ground rain gauge observation**

*Hitoshi Hirose[1], Koichi Toyoshima[1], Atsushi Higuchi[1], Akiyo Yatagai[2], Natsuko Yasutomi[3] (1.Center for Environmental Remote Sensing, Chiba University, 2.Hirosaki University, 3.Disaster Prevention Research Institute, Kyoto University)

[ACG34-P11] Development of the high resolution GSMaP by the Himawari-8

*Tomoaki Mega[1], Tomoo Ushio[1] (1.Tokyo Metropolitan University)

[ACG34-P12] Preliminary results of on-orbit estimation for polarization sensitivity of GCOM-C/SGLI

*Risa Miyazaki[1], Hiroshi Murakami[1], Masahiro Hori[1] (1.Japan Aerospace Exploration Agency)

[ACG34-P13] Analysis of SGLI validation datas based on the effects of the growth and ground types for the AGB development

*Ryota Ishibashi[1], Koji KAJIWARA[1], Yoshiaki HONDA[1] (1.Center for environmental remote sensing, Chiba University)

[ACG34-P14] Remote sensing of aerosol optical properties and water-leaving radiance based on the optimal estimation approach

*Chong Shi[1], Teruyuki Nakajima[1], Makiko Hashimoto[1], Hideaki Takenaka[1] (1.Japan Aerospace Exploration Agency)

[ACG34-P15] Aerosol retrieval and PM2.5 from space using GOSAT/TANSO-CAI

*Makiko Hashimoto[1], Hideaki Takenaka[1], Teruyuki Nakajima[1], Akiko Higurashi[2] (1.Japan Aerospace Explortion Agency, 2.NIES)

[ACG34-P16] **Establishing a high resolution road fugitive dust emission inventory in Kaifeng City, China**

*Yiming Xu[1], Shili Liu[1], Xinyue Cao[1], Xianbao Shen[1], Zhiliang Yao[1] (1.Department of Environmental Science and Engineering, Beijing Technology and Business University)

[ACG34-P17] A Relationship between Diurnal Change Patterns of Land Surface Temperature and Spatial Configuration of the Osaka Metropolitan Area Captured by Himawari-8

*Yuhei Yamamoto[1], Hirohiko Ishikawa[1] (1.Disaster Prevention Research Institute, Kyoto University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

[ACG34-P04] Concept of small satellite UV/visible imaging spectrometer optimized for tropospheric $NO_2$ measurements in air quality monitoring

*Tamaki Fujinawa[1,5], Katsuyuki Noguchi[2], Akihiko Kuze[3], Andreas Richter[4], John P. Burrows[4], Andreas C. Meier[4], Tomohiro Sato[1], Takeshi Kuroda[1], Naohiro Yoshida[5], YASUKO KASAI[1,5] (1.National Institute of Information and Communications Technology, 2.Nara Women's University, 3.Japan Aerospace Exploration Agency, 4.University of Bremen, 5.Tokyo Institute of Technology)

[ACG34-P05] EarthCARE L2 algorithms for cloud and precipitation

*Kaori Sato[1], Hajime Okamoto[1], Hiroshi Ishimoto[2] (1.Research Institute for Applied Mechanics, Kyushu University, 2.Meteorological Research Institute)

[ACG34-P06] Analysis of the Surface Echo Characteristics Derived from GPM/DPR Wide Swath Observation Experiment

*Kosuke Yamamoto[1], Kinji Furukawa[1], Nobuhiro Takahashi[2], Takuji Kubota[1] (1.Japan Aerospace Exploration Agency, 2.Nagoya University)

[ACG34-P07] The Recent Results from the Global Precipitation Measurement (GPM) mission in Japan

*Riko Oki[1], Takuji Kubota[1], Kinji Furukawa[1], Yuki Kaneko[1], Moeka Yamaji[1], Kosuke Yamamoto[1], Toshio Iguchi[2], Yukari Takayabu[3] (1.Japan Aerospace Exploration Agency, 2.NICT, 3.the University of Tokyo)

[ACG34-P08] **Verification of Global Satellite Mapping of precipitation (GSMaP) for providing its error information**

*Moeka Yamaji[1], Takuji Kubota[1] (1.Earth Observation Research Center, Japan Aerospace Exploration Agency)

[ACG34-P09] Detection of the mixed phase top using the measured dual-frequency ratio of reflectivity with GPM/DPR

*Yuki Kaneko[1], Toshio Iguchi[2] (1.Japan Aerospace Exploration Agency, 2.National Institute of Information and Communications Technology)

[ACG34-P10] **Comparison between high frequency satellite rainfall estimation and APHRODITE-2 ground rain gauge observation**

*Hitoshi Hirose[1], Koichi Toyoshima[1], Atsushi Higuchi[1], Akiyo Yatagai[2], Natsuko Yasutomi[3] (1.Center for Environmental Remote Sensing, Chiba University, 2.Hirosaki University, 3.Disaster Prevention Research Institute, Kyoto University)

[ACG34-P11] Development of the high resolution GSMaP by the Himawari-8

*Tomoaki Mega[1], Tomoo Ushio[1] (1.Tokyo Metropolitan University)

[ACG34-P12] Preliminary results of on-orbit estimation for polarization sensitivity of GCOM-C/SGLI

*Risa Miyazaki[1], Hiroshi Murakami[1], Masahiro Hori[1] (1.Japan Aerospace Exploration Agency)

[ACG34-P13] Analysis of SGLI validation datas based on the effects of the growth and ground types for the AGB development

*Ryota Ishibashi[1], Koji KAJIWARA[1], Yoshiaki HONDA[1] (1.Center for environmental remote sensing, Chiba University)

[ACG34-P14] Remote sensing of aerosol optical properties and water-leaving radiance based on the optimal estimation approach

*Chong Shi[1], Teruyuki Nakajima[1], Makiko Hashimoto[1], Hideaki Takenaka[1] (1.Japan Aerospace Exploration Agency)

[ACG34-P15] Aerosol retrieval and PM2.5 from space using GOSAT/TANSO-CAI

*Makiko Hashimoto[1], Hideaki Takenaka[1], Teruyuki Nakajima[1], Akiko Higurashi[2] (1.Japan Aerospace Explortion Agency, 2.NIES)

[ACG34-P16] **Establishing a high resolution road fugitive dust emission inventory in Kaifeng City, China**

*Yiming Xu[1], Shili Liu[1], Xinyue Cao[1], Xianbao Shen[1], Zhiliang Yao[1] (1.Department of Environmental Science and Engineering, Beijing Technology and Business University)

[ACG34-P17] A Relationship between Diurnal Change Patterns of Land Surface Temperature and Spatial Configuration of the Osaka Metropolitan Area Captured by Himawari-8

*Yuhei Yamamoto[1], Hirohiko Ishikawa[1] (1.Disaster Prevention Research Institute, Kyoto University)

[E] Oral | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 302 3F

## [A-CG34] Satellite Earth Environment Observation

convener:Riko Oki(Japan Aerospace Exploration Agency), Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Tsuneo Matsunaga(Center for Global Environmental Research and Satellite Observation Center, National Institute for Environmental Studies), Chairperson:Tsuneo Matsunaga

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[ACG34-19] How GOSAT has survived in-orbit anomalies and calibrated radiance spectra for 10 years.

★Invited Papers

*Akihiko Kuze[1], hiroshi Suto[1], Kei Shiomi[1], Nobuhiro Kikuchi[1], Makiko Hashimoto[1], Fumie Kataoka[2] (1.Japan Aerospace Exploration Agency, 2.RESTEC)

---

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[ACG34-20] Estimating regional anthropogenic methane emissions with GOSAT satellite retrievals and ground-based observations

*Shamil Maksyutov[1], Aki Tsuruta[2], Rajesh Janardanan[1], Fenjuan Wang[1], Akihiko Ito[1], Motoki Sasakawa[1], Toshinobu Machida[1], Isamu Morino[1], Yukio Yoshida[1], Johannes Kaiser[3], Greet Janssens-Maenhout[4], Ed Dlugokencky[5], Tsuneo Matsunaga[1] (1.National Institute for Environmental Studies, 2.Finnish Meteorological Institute, 3.Deutscher Wetterdienst, 4.European Commission, Joint Research Centre , 5.National Oceanic and Atmospheric Administration, Global Monitoring Division)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[ACG34-21] The Status and the Future Plan of GOSAT-2 Level 2 and 4 Products

★Invited Papers

*Tsuneo Matsunaga[1], Isamu Morino[1], Yukio Yoshida[1], Makoto Saito[1], Hibiki M Noda[1], Hirofumi Ohyama[1], Akihide Kamei[1], Fumie Kawazoe[1], Ryoichi Imasu[2], Teruyuki Nakajima[4], Takashi Nakajima[5], Naoko Saitoh[3], Makiko Hashimoto[4] (1.Center for Global Environmental Research and Satellite Observation Center, National Institute for Environmental Studies, 2.The University of Tokyo, 3.Chiba University, 4.Japan Aerospace Exploration Agency, 5.Tokai University)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[ACG34-22] A preliminary initial check of the cloud discrimination products by CAI-2 onboard GOSAT-2

*Yoshiaki Ishihara[1], Yu Oishi[2], Haruma Ishida[3], Takashi Nakajima[4] (1.NIES, 2.NARO, 3.JMA, 4.Tokai Univ.)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[ACG34-23] **Drought monitoring and evaluation performance of temperature vegetation drought index (TVDI) over Eurasia**

*Fengmei Yao[1], Siqi Shi[1], Jiahua Zhang[2] (1.UCAS University of Chinese Academy of Sciences, 2.Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences)

---

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[ACG34-24] **IMPACT OF CHANGE IN LAND USE AND LAND COVER PATTERN ON LAND SURFACE TEMPERATURE AND THERMAL COMFORT USING MICRO-SCALE AREA MODEL: CASE STUDY OF AN EDUCATIONAL CAMPUS.**

*DILJIT KUMAR NAYAK[1], MANJU MOHAN[1] (1.IIT DELHI)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 106 1F

## [A-CG36] Earth & Environmental Sciences and Artificial Intelligence

convener:Tomohiko Tomita(Faculty of Advanced Science and Technology, Kumamoto University), Ken-ichi Fukui(Osaka University), Daisuke Matsuoka(Japan Agency for Marine-Earth Science and Technology), Satoshi Ono(Kagoshima University), Chairperson:Tomohiko Tomita(Kumamoto University, Faculty of Advanced Science and Technology)

10:50 AM - 11:20 AM JST | 1:50 AM - 2:20 AM UTC

[ACG36-01] Recent Progress in Deep Neural Network Architectures and their Applications

★Invited Papers

*Shinichi Shirakawa[1] (1.Yokohama National University)

---

11:20 AM - 11:35 AM JST | 2:20 AM - 2:35 AM UTC

[ACG36-02] Improving performance of oxidant prediction using machine learning by optimizing input data based on atmospheric science knowledge

*Tomohiro Sato[1], Peijiang Zhao[1], Koji Zettsu[1] (1.National Institute of Information and Communications Technology)

---

11:35 AM - 11:50 AM JST | 2:35 AM - 2:50 AM UTC

[ACG36-03] Spatiotemporal Climate Forecasting with ConvLSTM

*Ekasit Phermphoonphiphat[1], Tomohiko Tomita[3], Masayuki Numao[2], Ken-ichi Fukui[2] (1.Graduate School of Information Science and Technology, Osaka University, 2.The Institute of Scientific and Industrial Research, Osaka University, 3.Faculty of Advanced Science and Technology, Kumamoto University)

---

11:50 AM - 12:05 PM JST | 2:50 AM - 3:05 AM UTC

[ACG36-04] Deep-Learning Based Short-Term Prediction Method for Sea Ice Concentration Using Explanatory Variables

*Issei Kawashima[1], Toru Kouyama[1], Ryu Sugimoto[1], Ryosuke Nakamura[1] (1.National Institute of Advanced Industrial Science and Technology)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 104 1F

## [A-CG36] Earth & Environmental Sciences and Artificial Intelligence

convener:Tomohiko Tomita(Faculty of Advanced Science and Technology, Kumamoto University), Ken-ichi Fukui(Osaka University), Daisuke Matsuoka(Japan Agency for Marine-Earth Science and Technology), Satoshi Ono(Kagoshima University), Chairperson:Tomohiko Tomita(Kumamoto University, Faculty of Advanced Science and Technology)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[ACG36-05] **Remote sensing of cloud using the deep learning based on three-dimensional radiative transfer**

*Hironobu Iwabuchi[1], Ryosuke Masuda[1], K. Sebastian Schmidt[2,3], Alessandro Damiani[4], Rei Kudo[5] (1.Graduate School of Science, Tohoku University, 2.Department of Atmospheric and Oceanic Sciences, University of Colorado, 3.Laboratory for Atmospheric and Space Physics, University of Colorado, 4.Center for Environmental Remote Sensing, Chiba University, 5.Meteorological Research Institute, Japan Meteorological Agency)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[ACG36-06] Time series of cloud cover during the night derived from an omnidirectional camera

*Karin miyabe[1], Kazunori Ogohara[1] (1.University of Shiga Prefecture)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[ACG36-07] Time series prediction of cloud cover using whole-sky images and meteorological elements

*Kazunori Ogohara[1], Teppei Sonoda[2] (1.School of Engineering, University of Shiga Prefecture, 2.Graduate School of Engineering, University of Shiga Prefecture)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[ACG36-08] Fundamental investigation about the inductive prediction of precipitation based on the time series data

*Naoki Matsumoto[1], Tomohiko Tomita[1], Kenichi Fukui[2] (1.Kumamoto Univ., 2.Osaka Univ.)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[ACG36-09] Identification of ships image on SAR data using machine learning

*Takashi Sonoke[1], Hirohide Demura[1] (1.University of Aizu)

[J] Poster | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

## [A-CG36] Earth & Environmental Sciences and Artificial Intelligence

convener:Tomohiko Tomita(Faculty of Advanced Science and Technology, Kumamoto University), Ken-ichi Fukui(Osaka University), Daisuke Matsuoka(Japan Agency for Marine-Earth Science and Technology), Satoshi Ono(Kagoshima University)

[ACG36-P01] **Automatic Detection of Illegal Waste Sites in UAS Orthoimages**

Wei-De Chen[1], *Yu-Ching Lin[1], Hsien-Min Wu[1] (1.Chung Cheng Institute of Technology, Taiwan)

[ACG36-P02] Using machine learning models to predict the benefits of solar power generation in northern Taiwan

*SHIH-CHIAO TSAI[1], KUO-CHIH HUANG[1], DUN-REN GUO[1] (1.National Defense Univ.)

[ACG36-P03] Change Point Detection and Visualization of Region of Interests on Weather Time Series Data Using Three-dimensional Convolutional Neural Network

*Satoshi Ono[1], Sotaro Maehara[1], Takahiro Kinoshita[1], Ken-ichi Fukui[2], Tomohiko Tomita[3] (1.Kagoshima University, 2.Osaka University, 3.Kumamoto University)

[ACG36-P04] Estimation of sediment disaster risk around the Fuji River Basin using a machine learning method that considers trigger and inherent factors

*Kazuyoshi Souma[1], Sei Kuroda[2], Takeru Kurakami[2], Takashi Miyamoto[1] (1.Interdisciplinary Graduate School, University of Yamanashi, 2.Integrated Graduate School of Medicine, Engineering, and Agricultural Sciences)

[ACG36-P05] Application of deep learning techniques to precipitation guidance in short-term weather predictions

*TAKERU KURAKAMI[1], Kazuyoshi Souma[1], Takashi Miyamoto[1], Takahiko Huruya[1], Jun Magome[1], Hiroshi Ishidaira[1] (1.University of Yamanashi)

[ACG36-P06] Characteristics of precipitation in Japan evaluated from the ratio of precipitation events

*Kenta Ogino[1], Tomohiko Tomita[1], Naoki Matsumoto[1] (1.Kumamoto University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_13

## [A-CG37] Science in the Arctic Region

convener:NAOYA KANNA(Arctic Research Center, Hokkaido University), Masashi Niwano(Meteorological Research Institute), Tetsu Nakamura(Faculty of Environmental Earth Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University), Chairperson:Tetsu Nakamura(Faculty of Earth Environmental Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[ACG37-01] **Arctic midlatitude linkage modulated by the QBO**

*Jinro Ukita[1], Kazuhiro Hoshi[1], Meiji Honda[1], Tetsu Nakamura[2], Koji Yamazaki[2] (1.Niigata University, 2.Hokkaido University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[ACG37-02] **Interhemispheric synchronization between the AO and the AAO**

*Yoshihiro Tachibana[1], Yusuke Inoue[1], Kensuke K komatsu[1], Tetsu Nakamura[2], Meiji Honda[3], Koto Ogata[1,4], Koji Yamazaki[2] (1.Mie University, 2.Hokkaido University, 3.Niigata University, 4.Japan Meteorological Agency)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[ACG37-03] Marginal ice zone sea ice observations in the refreezing Chukchi Sea

*Takehiko Nose[1], Tsubasa Kodaira[1], Takuji Waseda[1], Jun Inoue[2] (1.The university of Tokyo, 2.National Institute of Polar Research)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[ACG37-04] **Prediction of wildfire and air pollution with machine learning over the five domains of Eastern Eurasia**

*Teppei J Yasunari[1,2], Ichigaku Takigawa[3], Kyu-Myong Kim[4], Arlindo M da Silva[4] (1.Faculty of Engineering, Hokkaido University, 2.Arctic Research Center, Hokkaido University, 3.Graduate School of Information Science and Technology, Hokkaido University, 4.NASA Goddard Space Flight Center)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[ACG37-05] Hydrological Changes in the Four Largest Siberian Arctic River Basins

*Kazuyoshi Suzuki[1], Tetsuya Hiyama[2], Kazuhito Ichii[3], Yoshihiro Iijima[4], Koji Matsuo[5], Dai Yamazaki[6,1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Chiba University, 4.Graduate School of Bioresources, Mie University, 5.Geospatial Information Authority of Japan, 6.Institute of Industrial Sciences, The University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[ACG37-06] Mapping thermokarst subsidence in Central Yakutia using L-band SAR interferometry

*Takahiro Abe[1], Go Iwahana[2,3], Takeo Tadono[1] (1.Earth Observation Research Center, Japan Aerospace Exploration Agency, 2.International Arctic Research Center, University of Alaska, Fairbanks, 3.Arctic Research Center, Hokkaido University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 303 3F

## [A-CG37] Science in the Arctic Region

convener:NAOYA KANNA(Arctic Research Center, Hokkaido University), Masashi Niwano(Meteorological Research Institute), Tetsu Nakamura(Faculty of Environmental Earth Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University), Chairperson:Shunsuke Tei(Arctic Research Center, Hokkaido University), Masashi Niwano(Meteorological Research Institute)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[ACG37-07] Spatiotemporal variation of thaw subsidence and frost heave of permafrost caused by wildfire around Batagay, East Siberia

*Kazuki Yanagiya[1], Masato Furuya[2] (1.Graduate School of Science, Hokkiado University, 2.Faculty of Science, Hokkaido University)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[ACG37-08] Influence of recent climate change on permafrost coast dynamics in the Kara Sea, Russian Arctic Ocean

*A. Kioka[1,2], V. S. Isaev[2], A. V. Koshurnikov[2], A. Pogorelov[2], R. M. Amangurov[2], O. Podchasov[2], D. O. Sergeev[3], S. N. Buldovich[2], D. M. Aleksyutina[4], E. A. Grishakina[5] (1.Institut für Geologie, Leopold-Franzens-Universität Innsbruck, Austria, 2.Department of Geocryology, Lomonosov Moscow State University, Russia, 3.Sergeev Institute of Environmental Geoscience, Russian Academy of Science, Russia, 4.Research Laboratory of Geoecology of the Northern Territories, Lomonosov Moscow State University, Russia, 5.Vernadsky Institute of Geochemistry and Analytical Chemistry, Russian Academy of Science, Russia)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[ACG37-09] Ice front variations of Heilprin Glacier in northwestern Greenland controlled by the ocean and glacier bed geometries

*Izumi Asaji[1,2], Daiki Sakakibara[3], Takuto Ando[3], Shin Sugiyama[1] (1.Institute of Low Temperature Science, Hokkaido University, 2.Graduate School of Environmental Science, Hokkaido University, 3.Arctic Research Center, Hokkaido University)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[ACG37-10] Meltwater discharge and flooding of the outlet stream of Qaanaaq Glacier, northwestern Greenland

*Ken Kondo[1,2], Daiki Sakakibara[3,2], Shungo Fukumoto[1,2], Shin Sugiyama[2] (1.Graduate School of Environmental Science, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Arctic Research Center, Hokkaido University)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[ACG37-11] Occurrence frequency of lee-side downslope winds near Siorapaluk in northwest Greenland

*Akihiro Hashimoto[1], Tetsuhide Yamasaki[2], Teruo Aoki[3,1], Masashi Niwano[1], Satoru Yamaguchi[4] (1.Meteorological Research Institute, 2.Avangnaq, 3.The Graduate School of Natural Science and Technology, Okayama University, 4.Snow and Ice Research Center, National Research Institute for Earth Science and Disaster Resilience)

---

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[ACG37-12] **Impacts of clouds on the Greenland ice sheet surface melt and mass balance**

*Masashi Niwano[1], Akihiro Hashimoto[1], Teruo Aoki[2] (1.Meteorological Research Institute, 2.Graduate School of Natural Science and Technology, Okayama University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

## [A-CG37] Science in the Arctic Region

convener:NAOYA KANNA(Arctic Research Center, Hokkaido University), Masashi Niwano(Meteorological Research Institute), Tetsu Nakamura(Faculty of Environmental Earth Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University)

### [ACG37-P01] Increasing trend of downward long-wave radiation at the surface in the winter Arctic

*Yuta Miwa[1], Toru Nozawa[2] (1.Faculty of Science, Okayama University , 2.Graduate School of Natural Science and Technology, Okayama University)

### [ACG37-P02] Climate memory of the Eurasian land process for the Arctic amplification

*Tetsu Nakamura[1], Koji Yamazaki[1], Tomonori Sato[1], Jinro Ukita[2] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Faculty of Science , Niigata University)

### [ACG37-P03] Interannual variation of summer precipitation and atmospheric water circulation over and around Alaska

*Shohei Morino[1], Tetsuya Hiyama[2], Hatsuki Fujinami[2], Hironari Kanamori[2], Masahito Ueyama[3] (1. Graduate School of Environmental Studies, Nagoya University, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Graduate School of Life and Environmental Sciences, Osaka Prefecture University)

### [ACG37-P04] Detection of a climatological short break in the polar night jet in early winter and its relation to cooling over Siberia

*Yuta Ando[1], Koji Yamazaki[2], Yoshihiro Tachibana[1], Masayo Ogi[3], Jinro Ukita[4] (1.Graduate School of Bioresources, Mie University, 2.Hokkaido University, 3.Centre for Earth Observation Science, University of Manitoba, 4.Faculty of Science, Niigata University)

### [ACG37-P05] Recent breakdown of the seasonal linkage between the winter North Atlantic Oscillation/Northern Annular Mode and summer Northern Annular Mode

*Koji Yamazaki[1], Yoshihiro Tachibana[2], Masayo Ogi[1], Tetsu Nakamura[1], Kazuhiro Oshima[3] (1.Hokkaido University, 2.Mie University, 3.Institute of Environmental Sciences)

### [ACG37-P06] Did an Arctic sea-ice hole cause hemispheric extreme cold winter in 2017/18?

*Keisuke Ota[1], Yoshihiro Tachibana[1], Kensuke K. Komatsu[1], Alexeev A. Vladimir[2], Cai Lei[2], Yuta Ando[1] (1.Graduate School of Bioresources, Mie University, 2.International Arctic Research Center, University of Alaska Fairbanks)

### [ACG37-P07] Flood affects vegetation at plant species level to regional level: *Arctagrostis latifolia* increased one year after flooding in Indigirka lowland, northeastern Siberia

*Tomoki Morozumi[1,2], Shihong Zhong[1], Ryo Shingubara[5,1], Shunsuke Tei[2], Shinya Takano[1], Rong Fan[1,2], Yumiko Miyamoto[2], Ruslan Shakhmatov[1], Shin Nagai[3], Hideki Kobayashi[3], Rikie Suzuki[3], Trofim C Maximov[4,6], Atsuko Sugimoto[2,7] (1.Graduate School of Environmental Science, Hokkaido University, 2.Arctic Research Center, Hokkaido University, 3.Japan Agency for Marine-Earth Science and Technology, 4.Institute for Biological Problems of Cryolithozone SB RAS, 5.Graduate School of Environmental Studies, Nagoya University, 6.North Eastern Federal University, 7.Station for Arctic Research, Global Institution for Collaborative Research and Education, Hokkaido University)

### [ACG37-P08] Extent and cause of an extreme flooding occurred in spring - summer 2017 over the Indigirka River lowland in Northeastern Siberia

*Shunsuke Tei[1], Tomoki Morozumi[2], Shin Nagai[3], Shinya Takano[2], Atsuko Sugimoto[1], Ryo Shingubara[4], RONG FAN[2], Alexander Fedorov[5], Trofim Maximov[6] (1.Arctic Research Center, Hokkaido University, 2.Graduate School of Environmental Science, Hokkaido University, 3.Japan Agency for Marine Earth Science and Technology, 4.Graduate School of Environmental studies, Nagoya University, 5.Melnikov Permafrost Institute, 6.North-Eastern Federal University)

### [ACG37-P09] Monitoring of the light absorbing aerosols and the impact on radiation budget of atmosphere and snow

*Masahiro Hosaka[1], Hiroshi Ishimoto[1], Tomonori Tanikawa[1], Masashi Niwano[1], Kouji Adachi[1], Naga Oshima[1], Mizuo Kajino[1], Taichu Y Tanaka[1], Sumito Matoba[2] (1.Meteorological Research Institute, 2.Hokkaido University)

[ACG37-P10] Mass concertation and particle number of black carbon on glaciers in the eastern Alaskan Range, Alaska USA

*Keiko Konya[1], Takuma Miyakawa[1], Masayuki Takigawa[1], Masahiro Yamaguchi[1], Shad O'neel[2], Martin Truffer[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.USGS, 3.University of Alaska, Fairbanks)

[ACG37-P11] Remote estimation of phenological shifts in phytoplankton community in the Pacific Arctic Region

*Hisatomo Waga[1], Toru Hirawake[1] (1.Hokkaido University)

[ACG37-P12] Seasonality of diatom and silicoflagellate assemblages observed in settling particles of the western Arctic Ocean

*Jonaotaro Onodera[1,2], EIJI WATANABE[2], Naomi Harada[1,2] (1.Research and Development Center for Global Change, JAMSTEC, 2.Institute of Arctic Climate and Environment Change Research, JAMSTEC)

[ACG37-P13] Iron and macronutrient distributions near the fronts of marine-terminating glaciers in Inglefield Gulf, northwestern Greenland

*NAOYA KANNA[1], Shin Sugiyama[2], Takuto Ando[1], Izumi Asaji[3,2], Yoshiki Fujishi[3,2], Jun Nishioka[2] (1.Arctic Research Center, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Graduate School of Environmental Science, Hokkaido University)

[ACG37-P14] Paleoenvironmental reconstruction from sediments of Bowdoin fjord, northwestern Greenland

*Takuto Ando[1], NAOYA KANNA[1], Izumi Asaji[2,3], Yoshiki Fujishi[2,3], Shin Sugiyama[1,2,3] (1.Arctic Research Center, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Graduate School of Environmental Science, Hokkaido University)

[ACG37-P15] A large-eddy simulation of upwelling meltwater plume at marine-terminating glacier fronts

*Yoshimasa Matsumura[1], Naoya Kanna[2], Shin Sugiyama[3,2] (1.Atmosphere and Ocean Research Institute, University of Tokyo, 2.Arctic Research Center, Hokkaido University, 3.Institute of Low Temperature Science, Hokkaido University)

[ACG37-P16] Impact of observation-based snow/ice albedo with starting temperature of −2°C for surface melting effect on a global ocean simulation

*Takahiro Toyoda[1], Teruo Aoki[1,2], Masashi Niwano[1], Tomonori Tanikawa[1], Shogo Urakawa[1], Hiroyuki Tsujino[1], Hideyuki Nakano[1], Kei Sakamoto[1], Nariaki Hirose[1], Goro Yamanaka[1] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Graduate School of Natural Science and Technology, Okayama University)

[J] Poster | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_14

## [A-CG37] Science in the Arctic Region

convener:NAOYA KANNA(Arctic Research Center, Hokkaido University), Masashi Niwano(Meteorological Research Institute), Tetsu Nakamura(Faculty of Environmental Earth Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University)

### [ACG37-P01] Increasing trend of downward long-wave radiation at the surface in the winter Arctic

*Yuta Miwa[1], Toru Nozawa[2] (1.Faculty of Science, Okayama University , 2.Graduate School of Natural Science and Technology, Okayama University)

### [ACG37-P02] Climate memory of the Eurasian land process for the Arctic amplification

*Tetsu Nakamura[1], Koji Yamazaki[1], Tomonori Sato[1], Jinro Ukita[2] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Faculty of Science , Niigata University)

### [ACG37-P03] Interannual variation of summer precipitation and atmospheric water circulation over and around Alaska

*Shohei Morino[1], Tetsuya Hiyama[2], Hatsuki Fujinami[2], Hironari Kanamori[2], Masahito Ueyama[3] (1. Graduate School of Environmental Studies, Nagoya University, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.Graduate School of Life and Environmental Sciences, Osaka Prefecture University)

### [ACG37-P04] Detection of a climatological short break in the polar night jet in early winter and its relation to cooling over Siberia

*Yuta Ando[1], Koji Yamazaki[2], Yoshihiro Tachibana[1], Masayo Ogi[3], Jinro Ukita[4] (1.Graduate School of Bioresources, Mie University, 2.Hokkaido University, 3.Centre for Earth Observation Science, University of Manitoba, 4.Faculty of Science, Niigata University)

### [ACG37-P05] Recent breakdown of the seasonal linkage between the winter North Atlantic Oscillation/Northern Annular Mode and summer Northern Annular Mode

*Koji Yamazaki[1], Yoshihiro Tachibana[2], Masayo Ogi[1], Tetsu Nakamura[1], Kazuhiro Oshima[3] (1.Hokkaido University, 2.Mie University, 3.Institute of Environmental Sciences)

### [ACG37-P06] Did an Arctic sea-ice hole cause hemispheric extreme cold winter in 2017/18?

*Keisuke Ota[1], Yoshihiro Tachibana[1], Kensuke K. Komatsu[1], Alexeev A. Vladimir[2], Cai Lei[2], Yuta Ando[1] (1.Graduate School of Bioresources, Mie University, 2.International Arctic Research Center, University of Alaska Fairbanks)

### [ACG37-P07] Flood affects vegetation at plant species level to regional level: *Arctagrostis latifolia* increased one year after flooding in Indigirka lowland, northeastern Siberia

*Tomoki Morozumi[1,2], Shihong Zhong[1], Ryo Shingubara[5,1], Shunsuke Tei[2], Shinya Takano[1], Rong Fan[1,2], Yumiko Miyamoto[2], Ruslan Shakhmatov[1], Shin Nagai[3], Hideki Kobayashi[3], Rikie Suzuki[3], Trofim C Maximov[4,6], Atsuko Sugimoto[2,7] (1.Graduate School of Environmental Science, Hokkaido University, 2.Arctic Research Center, Hokkaido University, 3.Japan Agency for Marine-Earth Science and Technology, 4.Institute for Biological Problems of Cryolithozone SB RAS, 5.Graduate School of Environmental Studies, Nagoya University, 6.North Eastern Federal University, 7.Station for Arctic Research, Global Institution for Collaborative Research and Education, Hokkaido University)

### [ACG37-P08] Extent and cause of an extreme flooding occurred in spring - summer 2017 over the Indigirka River lowland in Northeastern Siberia

*Shunsuke Tei[1], Tomoki Morozumi[2], Shin Nagai[3], Shinya Takano[2], Atsuko Sugimoto[1], Ryo Shingubara[4], RONG FAN[2], Alexander Fedorov[5], Trofim Maximov[6] (1.Arctic Research Center, Hokkaido University, 2.Graduate School of Environmental Science, Hokkaido University, 3.Japan Agency for Marine Earth Science and Technology, 4.Graduate School of Environmental studies, Nagoya University, 5.Melnikov Permafrost Institute, 6.North-Eastern Federal University)

### [ACG37-P09] Monitoring of the light absorbing aerosols and the impact on radiation budget of atmosphere and snow

*Masahiro Hosaka[1], Hiroshi Ishimoto[1], Tomonori Tanikawa[1], Masashi Niwano[1], Kouji Adachi[1], Naga Oshima[1], Mizuo Kajino[1], Taichu Y Tanaka[1], Sumito Matoba[2] (1.Meteorological Research Institute, 2.Hokkaido University)

[ACG37-P10] Mass concertation and particle number of black carbon on glaciers in the eastern Alaskan Range, Alaska USA

*Keiko Konya[1], Takuma Miyakawa[1], Masayuki Takigawa[1], Masahiro Yamaguchi[1], Shad O'neel[2], Martin Truffer[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.USGS, 3.University of Alaska, Fairbanks)

[ACG37-P11] Remote estimation of phenological shifts in phytoplankton community in the Pacific Arctic Region

*Hisatomo Waga[1], Toru Hirawake[1] (1.Hokkaido University)

[ACG37-P12] Seasonality of diatom and silicoflagellate assemblages observed in settling particles of the western Arctic Ocean

*Jonaotaro Onodera[1,2], EIJI WATANABE[2], Naomi Harada[1,2] (1.Research and Development Center for Global Change, JAMSTEC, 2.Institute of Arctic Climate and Environment Change Research, JAMSTEC)

[ACG37-P13] Iron and macronutrient distributions near the fronts of marine-terminating glaciers in Inglefield Gulf, northwestern Greenland

*NAOYA KANNA[1], Shin Sugiyama[2], Takuto Ando[1], Izumi Asaji[3,2], Yoshiki Fujishi[3,2], Jun Nishioka[2] (1.Arctic Research Center, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Graduate School of Environmental Science, Hokkaido University)

[ACG37-P14] Paleoenvironmental reconstruction from sediments of Bowdoin fjord, northwestern Greenland

*Takuto Ando[1], NAOYA KANNA[1], Izumi Asaji[2,3], Yoshiki Fujishi[2,3], Shin Sugiyama[1,2,3] (1.Arctic Research Center, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Graduate School of Environmental Science, Hokkaido University)

[ACG37-P15] A large-eddy simulation of upwelling meltwater plume at marine-terminating glacier fronts

*Yoshimasa Matsumura[1], Naoya Kanna[2], Shin Sugiyama[3,2] (1.Atmosphere and Ocean Research Institute, University of Tokyo, 2.Arctic Research Center, Hokkaido University, 3.Institute of Low Temperature Science, Hokkaido University)

[ACG37-P16] Impact of observation-based snow/ice albedo with starting temperature of −2°C for surface melting effect on a global ocean simulation

*Takahiro Toyoda[1], Teruo Aoki[1,2], Masashi Niwano[1], Tomonori Tanikawa[1], Shogo Urakawa[1], Hiroyuki Tsujino[1], Hideyuki Nakano[1], Kei Sakamoto[1], Nariaki Hirose[1], Goro Yamanaka[1] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Graduate School of Natural Science and Technology, Okayama University)

[J] Oral | A (Atmospheric and Hydrospheric Sciences )：A-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 303 3F

## [A-CG37] Science in the Arctic Region

convener:NAOYA KANNA(Arctic Research Center, Hokkaido University), Masashi Niwano(Meteorological Research Institute), Tetsu Nakamura(Faculty of Environmental Earth Science, Hokkaido University), Shunsuke Tei(Arctic Research Center, Hokkaido University), Chairperson:Naoya Kanna(Arctic Research Center, Hokkaido University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[ACG37-13] Introduction of the IASC project "T-MOSAiC"

Masaki Uchida[1], *Tetsuo Sueyoshi[1] (1.National Institute of Polar Research)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[ACG37-14] Estimation of ice thickness and volume in the Sea of Okhotsk using ICESat and CryoSat-2 data

*Sohey Nihashi[1], Nathan T. Kurtz[2], Takenobu Toyota[3] (1.National Institute of Technology, Tomakomai College, 2.NASA GSFC, 3.Institute of Low Temperature Science, Hokkaido University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[ACG37-15] Arctic Sea Ice Changes in the DAMIP experiments using the MRI Earth System Model

*Takuro Aizawa[1], Masayoshi Ishii[2], Naga Oshima[2], Seiji Yukimoto[2], Hiroyasu Hasumi[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Meteorological Reseaerch Institute)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[ACG37-16] **Oceanographic Observation in the Refreezing Warm Chukchi Sea during 2018 Mirai Cruise**

*Tsubasa Kodaira[1], Takehiko Nose[1], Takuji Waseda[1], Jun Inoue[2] (1.The University of Tokyo, 2.National Institute of Polar Research)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[ACG37-17] **Observed Waves in the refreezing eastern Chukchi Sea during 2018 Mirai Cruise**

*Takuji Waseda[1], Takehiko Nose[1], Tsubasa Kodaira[1], Alison Kohout[2], Johannes Gemmrich[3], Hui Shen[4], Jun Inoue[5] (1.The University of Tokyo, 2.National Institute of Water and Atmospheric Research, 3.University of Victoria, 4.Bedford Institute of Oceanography, 5.National Institute for Polar Research)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[ACG37-18] Mooring measurement near a marine-terminating glacier in Bowdoin Fjord in northwestern Greenland

*Yoshiki Fujishi[1,2], Yasushi Fukamachi[1,3], NAOYA KANNA[3], Shin Sugiyama[1,3] (1.Institute of Low Temperature Science, Hokkaido University, 2.Graduate School of Environmental Science, Hokkaido University , 3.Arctic Research Center, Hokkaido University)

[J] Oral | H (Human Geosciences )：H-DS Disaster geosciences

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 106 1F

## [H-DS15] Human environment and disaster risk

convener:Tatsuto Aoki(School of Regional Development Studies, Kanazawa University), Hisao Kondo(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Tatsuto Aoki(金沢大学地域創造学類)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[HDS15-01] Influence of inhomogeneous structure in surficial reclaimed body traced by aerial photos and delineated by near surface geophysical survey at Makuhari-Kaihin Park liquefied by the 2011 off the Pacific coast of Tohoku earthquake.

*Tomio INAZAKI[1], Takanori Ogahara[1] (1.Public Works Research Institute, Tsukuba Central Institute)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[HDS15-02] Distribution morphology of deformed reclaimed valley associated with the 2018 Hokkaido Eastern Iburi Earthquake

*Takayuki Nakano[1], Satoshi Fujiwara[1], Hiroshi Une[1] (1.GSI of Japan)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[HDS15-03] Liquefaction risk evaluation using relative height data of natural levee

*Mamoru Koarai[1], Kouta Uchiyama[1], Takayuki Nakano[2] (1.Earth Science course, College of Science, Ibaraki University, 2.Geospatial Information Authority of Japan)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[HDS15-04] **Spatial Analysis of Social Vulnerability to large-scale flood: a case study on the Katsushika Ward, Tokyo**

*LIAN XIAO[1] (1.University of Tsukuba)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[HDS15-05] Importance and method of visualization of future occurrence possibilities of giant earthquakes along the Nankai trough

*Yo Fukushima[1] (1.International Research Institute of Disaster Science, Tohoku University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[HDS15-06] Investigation of efficient tsunami evacuation using real-time disaster information

*Yusuke Oishi[1,2,3], Takashi Furumura[2], Fumihiko Imamura[3], Yoshiteru Mihara[4], Fumiyasu Makinoshima[3], Yamashita Kei[3], Takao Higashiyama[5], Tomonori Goto[5], Makoto Oomura[4], Mitsuyuki Nagayama[4] (1.Fujitsu Laboratories Ltd., 2.Earthquake Research Institute, the University of Tokyo, 3.IRIDeS, Tohoku University, 4.Kawasaki City, 5.Fujitsu Ltd.)

[J] Poster | H (Human Geosciences )：H-DS Disaster geosciences

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

## [H-DS15] Human environment and disaster risk

convener:Tatsuto Aoki(School of Regional Development Studies, Kanazawa University), Hisao Kondo(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[HDS15-P01] Validity Verification in Typhoon Disaster Prevention Model for Typhoon Damage Reduction– GUST Wind Speed, Maximum Wind Speed -

*Woo-Sik JUNG[1], Hana Na[1] (1.Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea)

[HDS15-P02] A Study on the Assimilation of Meteorological Data and Sea Surface Temperature Data for Improving the Accuracy of WRF Prediction during Typhoon periods on the Korean Peninsula

*Woo-Sik JUNG[1], Hana Na[1] (1.Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea)

[HDS15-P03] Validation and application of a finite element approach on field mechanically stabilized earth walls with secondary reinforcement

*BING-RU WU[1], CHIH-HSUAN LIU[1], CHING HUNG[1] (1.National Cheng Kung University)

[HDS15-P04] **EXPERIMENTAL STUDY ON POLYUREA-COATED RC SLAB SUBJECTED TO CONTACT EXPLOSIONS**

*Minghsien Wu[1], Yingkuan Tsai[1], Chien-Hsien Liu[1], Pang-Ting Pai[1], Feng-Cheng Yang[1], Chun-Chia Huang[1] (1.Chung Cheng Institute of Technology National Defense University)

[HDS15-P05] Simulation and field investigation of scour and sediment transport after Dam removal in the mountainous creek in Central Taiwan

*Chunhung WU[1] (1.Feng Chia University)

[HDS15-P06] Examination and systematization of predispositions to floods in the Heavy Rain in July 2018

*Kanako Kimura[1], Toshihiko Sugai[2] (1.The University of Tokyo, 2.Graduate School of Frontier Sciences, the University of Tokyo)

[HDS15-P07] Expand various disaster risk information and sophisticate methods to disseminate on the Hazard Map Portal Site

*Takuya Ueshiba[1], Yumeka Fujii[1], Naoki Yoshimatsu[1], Noriyuki Takakuwa[1], Wataru Yamasaki[1], Jun Suwabe[1] (1.GSI of Japan)

[HDS15-P08] A study on evaluation formulae of the principal fault in PFDHA- In consideration of a relevance to known active faults-

*Tsuyoshi Kanda[1], Makoto Takao[1], Toshimichi Kaneto[1], Takehisa Arakawa[1] (1.Tokyo Electoric Power Company Holdings, Inc)

[HDS15-P09] Characteristics of sediment deposition distribution in debris flow disasters in caused by heavy rain in August 2014 Hiroshima, Japan

*Shoichiro Uchiyama[1], Toshihiko Sugai[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.The University of Tokyo)

[HDS15-P10] Land use change after tsunami and its problems in Kii peninsula

*Kenta Okidate[1], Tatsuto Aoki[2] (1.School of Humanities, Kanazawa University, 2.School of Regional Development Studies, Kanazawa University)

[HDS15-P11] Reconstruction of the building damages caused by the Typhoon Kathleen and analyses of their land conditions at the southern foot of the Akagi Volcano using U.S. military aerial photographs

*Masafumi Aoyama[1], Yoshiki Saito[2] (1.Faculty of Education, Gunma University, 2.Graduate Student, Gunma University)

[J] Poster | H (Human Geosciences )：H-DS Disaster geosciences

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_15

## [H-DS15] Human environment and disaster risk

convener:Tatsuto Aoki(School of Regional Development Studies, Kanazawa University), Hisao Kondo(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

## [H-TT19] Geographic Information Systems and Cartography

convener:Takashi Oguchi(Center for Spatial Information Science, The University of Tokyo), Yuji Murayama(Graduate School of Life and Environmental Sciences), Yoshiki Wakabayashi(Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University)

[HTT19-P01] **Monitoring and Simulating Land Use/Cover Changes and its Impact on Land Surface Temperature in Sapporo City, Japan**

*RUCI WANG[1], YUJI MURAYAMA[1] (1.University of Tsukuba)

---

[HTT19-P02] **Spatiotemporal Variations of Land Cover/Use and Sustainable Urban Heat Island (UHI) Mitigation Strategies: A Case Study of Chinese Bay Megacities**

★Invited Papers

*Fei LIU[1], Yuji MURAYAMA[1] (1. University of Tsukuba)

---

[HTT19-P03] A LST Study of the Seoul Metropolitan City, South Korea, Based on Landsat Data (1996 – 2017)

*Prabath Priyankara[1,3], Manjula Ranagalage[1,4], DMSLB Dissanayake[1,4], Takehiro Morimoto[1,2], Yuji Murayama[1,2] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba, Japan, 2.Faculty of Life and Environmental Sciences, University of Tsukuba, Japan, 3.Faculty of Agriculture, University of Ruhuna, Sri Lanka, 4.Faculty of Social Sciences and Humanities, Rajarata University of Sri Lanka, Sri Lanka)

---

[HTT19-P04] Improvement of GIS exercise classes using the GIS open educational resources based on questionnaire surveys

★Invited Papers

*Hiroyuki Yamauchi[1], Takashi Oguchi[1], Yuichi S. Hayakawa[2,1], Kotaro Iizuka[1] (1.Center for Spatial Information Science, The University of Tokyo, 2.Environmental Geography, Faculty of Environmental Earth Science, Hokkaido University)

---

[HTT19-P05] **The Development of COP for Tzu Chi Disaster Prevention System by Using QGIS-Taking 2018 Hualien Earthquake as an Example**

*kuan-wen tseng[1], Ming-Ta Tsai[1], Yun-Ching Wang[1], Ming-Chih Wang[1], Chien-Hsien Liu[1] (1.03-3809093)

---

[HTT19-P06] Comparative study on shape and distribution of landslides caused by the 2012 Northern Kyushu heavy rainfall and the 2016 Kumamoto earthquake in the Aso region, Kumamoto, Japan

*Yasutaka Haneda[1], Takashi Oguchi[2], Kotaro Iizuka[2], Hitoshi SAITO[3,2], Yuichi S. Hayakawa[4,2], Shoichiro Uchiyama[5] (1.Graduate School of Frontier Science, The University of Tokyo, 2.Center for Spatial Information Science, The University of Tokyo, 3.College of Economics, Kanto Gakuin University, 4.Faculty of Environmental Earth Science, Hokkaido University, 5.National Research Institute for Earth Science and Disaster Resilience)

---

[HTT19-P07] Using GIS and remote sensing to assess relationships between landslides and land cover changes in the Sanbagawa and Mikabu Belts, Shikoku, Japan

*Roxanne Lai[1], Takashi Oguchi[1] (1.University of Tokyo)

---

[HTT19-P08] **Analysis of Morphometric Parameters for Mountains Ranges and Landslides due to the July 2018 Heavy Rain in Western Japan Using GIS Data**

*Toshikazu Fukuba[1], Takashi Oguchi[2] (1.Department of Earth and Planetary Environmental Science, The University of Tokyo, 2.Center for Spatial Information Science, The University of Tokyo)

---

[HTT19-P09] Analyzing short-term topographic change in coastal sand dunes using UAS-SfM photogrammetry: A case study in Northern Kujukuri, Japan

*Ruiqi Zhang[1], Takashi Oguchi[2] (1. Department of Natural Environmental Studies, Graduate School of Frontier Sciences, The University of Tokyo, 2.Center for Spatial Information Science, The University of Tokyo)

[E] Oral | H (Human Geosciences)：H-TT Technology & Techniques

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 301B 3F

## [H-TT19] Geographic Information Systems and Cartography

convener:Takashi Oguchi(Center for Spatial Information Science, The University of Tokyo), Yuji Murayama(Graduate School of Life and Environmental Sciences), Yoshiki Wakabayashi(Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University), Chairperson:Yuji Murayama, Yoshiki Wakabayashi

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[HTT19-01] **A study on geographical changes in main roads and coastlines in the 200 years in Japan**

*Yuki IWAI[1], Yuji Murayama[1] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[HTT19-02] Comparative analysis of foreign tourists' spatial behavior in Tokyo using locational data from the photo-sharing service of Flickr

*Bochra Bettaieb[1], Yoshiki Wakabayashi[1] (1.Tokyo Metropolitan University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[HTT19-03] Neighborhood Walkability and its Potential Associations with Residents' Walking Habits

★Invited Papers

*Ikuho Yamada[1], Keiichiro Sanada[2] (1.Faculty of Science and Engineering, Chuo University, 2.Graduate School of Science and Engineering, Chuo University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[HTT19-04] **THE STUDY OF USING PARTICLE FILTER METHOD COMBINED INDOOR MAGNETIC MAP AND PEDESTRIAN DEAD RECKONING FOR INDOOR POSITIONING.**

*Yu-Chun Chen[1] (1.Department of Land Economics, National Chengchi University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[HTT19-05] Assessing the Agriculture Sustainability based on Geospatial Technique in a Tropical Mountain Area : A Case Study in Kotmale Catchment in Sri Lanka.

*DM Sanjeewa Lasantha Bandara[1], Takehiro Morimoto [2] (1.Division of Spatial Information Science, Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Faculty of Life and Environmental Sciences, University of Tsukuba)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[HTT19-06] **Spatial Evaluation of Potential Tsunami Vertical Evacuation: A Case Study of the Western Coastal Belt in Sri Lanka**

*Ranagalage Mahinda Manjula[1], Yuji Murayama[1] (1.Division of Spatial Science, Graduate School of Life and Environmental Sciences, University of Tsukuba, Japan)

[E] Oral | H (Human Geosciences)：H-TT Technology & Techniques

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 301B 3F

## [H-TT19] Geographic Information Systems and Cartography

convener:Takashi Oguchi(Center for Spatial Information Science, The University of Tokyo), Yuji Murayama(Graduate School of Life and Environmental Sciences), Yoshiki Wakabayashi(Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University), Chairperson:Takashi Oguchi, Ikuho Yamada(Chuo University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[HTT19-07] A Framework for Assessing the Spatial Distribution of Vulnerability of Communities to Landslides in Tropical Mountainous Region: A Case study from Kegalle District – Sri Lanka.

★Invited Papers

*Nimala Chinthake Perera[1] (1.SANASA CAMPUS - SRI LANKA, IHRA - UNIVERSITY OF COLOMBO - SRI LANKA)

---

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[HTT19-08] Applications of WebGIS to Educating Disaster Risk Reduction for Chinese and Japanese Students

*Jiali SONG[1], Takashi Oguchi[2], Hiroyuki Yamauchi[2], Takuro Ogura[1] (1.Graduate School of Frontier Sciences, The University of Tokyo, 2.Center for Spatial Information Science, The University of Tokyo)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[HTT19-09] Solar System Treks - GIS that provides interactive visualization and analysis for planetary science and exploration

★Invited Papers

*Emily Law[1], Brian Hamilton Day[2] (1.NASA Jet Propulsion Laboratory, 2.NASA Ames Research Center)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[HTT19-10] **Landslide Recognition using Remote Sensing Images and PCANet**

*Yimei Wei[1], Takashi Oguchi[1] (1.Graduate School of Frontier Science, the University of Tokyo)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[HTT19-11] Estimating the fractional vegetation cover using fixed-wing drone and multiple vegetation indices

★Invited Papers

*Kotaro Iizuka[1] (1.Center for Spatial Information Science, The University of Tokyo)

---

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[HTT19-12] Topographic surveys in Ny-Alesund, Svalbard, and improvement of mapping methods

*Jaeyong Lee[1], Takashi Oguchi[2] (1.Department of Environmental Studies, Graduate School of Frontier Sciences, The University of Tokyo, 2.Center for Spatial Information Science, The University of Tokyo)

[J] Oral | H (Human Geosciences )：H-TT Technology & Techniques

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 301B 3F

## [H-TT23] Geographic Information System and Cartography

convener:Mamoru Koarai(Earth Science course, College of Science, Ibaraki University), Kazunari Tanka(Department of Civil Engineering and Urban Design, Faculty of Engineering, Osaka Institute of Technology), Kazuhiko Nakamura(The University of Tokyo), Chairperson:Mamoru KOARAI(Ibaraki University), Kazunari Tanaka(大阪工業大学)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[HTT23-01] **An analysis of the year-round distribution of $PM_{2.5}$ and Oxidant by (Web)GIS and R**

★Invited Papers

*Junji Yamakawa[1] (1.Graduate School of Natural Science and Technology, Okayama University)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[HTT23-02] Development Process and Spatial Structure of Urban Villages in Shenzhen City China

*YARONG LUAN

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HTT23-03] An analysis on the location characteristic of alley spaces in Tokyo

*Ryo Taniguchi[1], Go Ishikawa[1], Mayumi Oka[2] (1.Tokyo Map Research Inc., 2.Research Organization of Information and Systems The Institute of Statistical Mathematics)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HTT23-04] Image analysis of night scape using lyrics

*Hiroki Komai[1], Kazunari Tanaka[1] (1.Osaka Institute of Technology)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HTT23-05] On the Method to Evaluate Signboards based on the Relationship with the Surrounding Space

*Akihiro Kishikawa[1], Kazunari Tanaka[1] (1.Osaka Institute of Technology)

---

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[HTT23-06] ON THE LANDSCAPES ELEMENTS FROM A BIRD'S-EYE VIEW SCAPE

*Nobuaki Tanaka[1], kazunari Tanaka[1] (1.Osaka Institute of Technology)

[J] Poster | H (Human Geosciences )：H-TT Technology & Techniques

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

## [H-TT23] Geographic Information System and Cartography

convener:Mamoru Koarai(Earth Science course, College of Science, Ibaraki University), Kazunari Tanka(Department of Civil Engineering and Urban Design, Faculty of Engineering, Osaka Institute of Technology), Kazuhiko Nakamura(The University of Tokyo)

### [HTT23-P01] Development of 3D Web map making service, MyMap3D

★Invited Papers

*Yoshiharu Nishioka[1], Kaoru Kitao[2] (1.National Insititute of Advanced Industrial Science and Technology, 2.CubeWorks Inc.)

### [HTT23-P02] Experimental hazard map for accurate communication

*Ryo Endo[1], Takayuki Nakano[1] (1.GSI of Japan)

### [HTT23-P03] Effectiveness of color hillshade with multiple light sources for geopark guide maps : A case of the North Ibaraki Geopark Project

*Keiko SUZUKI[1], Go ISHIKAWA[1], Mamoru KOARAI[2], Rika IMAIZUMI[3], Naoki TAKEDA[4] (1.Tokyo Map Research Inc., 2.Ibaraki University, 3.Aero Asahi Co., Ltd., 4.Association for Promotion of North Ibaraki Geopark Project)

### [HTT23-P04] Estimation of three-dimensional structure of forest using LiDAR data in Abukuma mountainous region

Akane Narikiyo[1], *Mamoru Koarai[1], Wataru Murakami[2], Yasuhiro Ogawa[2] (1.Earth Science course, College of Science, Ibaraki University, 2.Forest Research Institute)

### [HTT23-P05] Disaster information sharing of welfare service workers based on knowledge from experience in a tsunami disaster area

*ARISA INOUE[1], Yoshiki Wakabayashi[1] (1.Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University)

### [HTT23-P06] Spatial analysis of children's commuting space - a case study of Toyama city elementary school -

*Koji Ohnishi[1] (1.Department of Humanities, University of Toyama)

[J] Poster | H (Human Geosciences )：H-TT Technology & Techniques

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_17

## [H-TT23] Geographic Information System and Cartography

convener:Mamoru Koarai(Earth Science course, College of Science, Ibaraki University), Kazunari Tanka(Department of Civil Engineering and Urban Design, Faculty of Engineering, Osaka Institute of Technology), Kazuhiko Nakamura(The University of Tokyo)

### [HTT23-P01] Development of 3D Web map making service, MyMap3D

★Invited Papers

*Yoshiharu Nishioka[1], Kaoru Kitao[2] (1.National Insititute of Advanced Industrial Science and Technology, 2.CubeWorks Inc.)

### [HTT23-P02] Experimental hazard map for accurate communication

*Ryo Endo[1], Takayuki Nakano[1] (1.GSI of Japan)

### [HTT23-P03] Effectiveness of color hillshade with multiple light sources for geopark guide maps : A case of the North Ibaraki Geopark Project

*Keiko SUZUKI[1], Go ISHIKAWA[1], Mamoru KOARAI[2], Rika IMAIZUMI[3], Naoki TAKEDA[4] (1.Tokyo Map Research Inc., 2.Ibaraki University, 3.Aero Asahi Co., Ltd., 4.Association for Promotion of North Ibaraki Geopark Project)

### [HTT23-P04] Estimation of three-dimensional structure of forest using LiDAR data in Abukuma mountainous region

Akane Narikiyo[1], *Mamoru Koarai[1], Wataru Murakami[2], Yasuhiro Ogawa[2] (1.Earth Science course, College of Science, Ibaraki University, 2.Forest Research Institute)

*ARISA INOUE[1], Yoshiki Wakabayashi[1] (1.Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University)

### [HTT23-P06] Spatial analysis of children's commuting space - a case study of Toyama city elementary school -

*Koji Ohnishi[1] (1.Department of Humanities, University of Toyama)

[J] Oral | H (Human Geosciences)：H-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 101 1F

## [H-CG31] Nuclear Energy and Geoscience

convener:Eiji Sasao(Tono Geoscience Center, Japan Atomic Energy Agency), Ryuta Hataya(Central Research Institute of Electric Power Industry), Shinji Takeuchi(Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University), Chairperson:Tadafumi Niizato

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[HCG31-01] **Uplift estimation in coastal sea area by extrapolation of the land area model and its uncertainty**

*Ryuta Hataya[1], Takaomi Hamada[1], Yohei Shimizu[1] (1.Central Research Institute of Electric Power Industry)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[HCG31-02] Deep groundwater mobility at costal area estimated by groundwater dating

*Takuma HASEGAWA[1], Kotaro NAKATA[1], Yuichi Tomioka[1], Tomoko Ota[1], Atsunao Marui[2], Isao Machida[2], Reo Ikawa[2], Masahiko Ono[2], Shinji Matsumoto[2] (1.Central Research Institute of Electric Power Industry, 2.The National Institute of Advanced Industrial Science and Technology)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[HCG31-03] Attempt to Estimate permeability of rock mass based on elasticity and resistivity measurement in underground tunnel

*Sota Kawaguchi[1], Tada-nori Goto[1], Koki Kashiwaya[1] (1.Graduate School of Engineering, Kyoto University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[HCG31-04] Study on relationship between pathway of groundwater and mass transport, and cooling process of granitic rock

*Eiji Sasao[1], Takashi Yuguchi[2], Masayuki Ishibashi[1] (1.Tono Geoscience Center, Japan Atomic Energy Agency, 2.Faculty of Science, Yamagata University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[HCG31-05] Fracture characterization in the accretionary complex from the view point of mass transfer

*Shinji Takeuchi[1], Chikara Kurata[1], Masakazu Niwa[2], Tadamasa Ueki[2] (1.Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University, 2.Japan Atomic Energy Agency)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[HCG31-06] Retardation of Cs and Sr leachings by geopolymer matrices with zeolte and titanate adsorbent

*Kazuma Kuroda[1], Soonthornwiphat Natatsawas[1], Chaerun Raudhatul Islam[1], Hnin Wint Wint Two[1], Kanako Toda[1], Yutaro Kobayashi[1], Tsutomu Sato[2], Tsubasa Otake[2] (1.Graduate school of Engineering, Hokkaido University, 2.Faculty of Engineering, Hokkaido University)

[J] Oral | H (Human Geosciences )：H-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 101 1F

## [H-CG31] Nuclear Energy and Geoscience

convener:Eiji Sasao(Tono Geoscience Center, Japan Atomic Energy Agency), Ryuta Hataya(Central Research Institute of Electric Power Industry), Shinji Takeuchi(Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University), Chairperson:Shinji Takeuchi

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[HCG31-07] Focus points of post-closure monitoring in geological disposal

*Hiroaki Murakami[1], Yusuke Watanabe[1], Kenji Fukuda[1], Teruki Iwatsuki[1] (1.Japan Atomic Energy Agency)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[HCG31-08] 5 years monitoring results for the environmental dynamics of radiocesium in mountainous forest of the Abukuma Mountains, Fukushima

*Tadafumi Niizato[1], Takayoshi Watanabe[1], Yoshito Sasaki[1], Katsuaki Mitachi[2], Satomi Ito[1], Hironobu Abe[1] (1.Japan Atomic Energy Agency, 2.ATOM TRANSPORT SERVICE CO., LTD)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[HCG31-09] Problems of geological disposal based on the contaminated water issues at Fukushima Daiichi NPS

*Naoaki Shibasaki[1] (1.Fukushima University)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[HCG31-10] Examination of "Nationalwide Map of Scientific Features" for HLRW geological disposal in case of Niigata Prefecture and fundamental problems in the fair discussion on this task

*Junji Akai[1], Ryuichiro Ohno (1.Emeritus Professor of Niigata University)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[HCG31-11] Problems of the "Nationwide Map of Scientific Features for Geological Disposal" in Saitama prefecture and storage method of High-level Radioactive Waste (HLW)

*Kazuaki SEKINE[1], Kazuyuki SUENAGA[2], Tadao KOBAYASHI (1.Saitama Prefectural Chichibu High School, 2.SUENAGA Environmental Geology)

[J] Poster | H (Human Geosciences )：H-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

## [H-CG31] Nuclear Energy and Geoscience

convener:Eiji Sasao(Tono Geoscience Center, Japan Atomic Energy Agency), Ryuta Hataya(Central Research Institute of Electric Power Industry), Shinji Takeuchi(Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University)

[HCG31-P01] Better identification of submerged terraces based on digital terrain analysis

*Hiura Yuki[1], Tetsuya Komatsu[1], Toshihiko Sugai[2] (1.Japan Atomic Energy Agency, 2.Graduate School of Frontier Sciences, The University of Tokyo)

[HCG31-P02] Advanced examination technique for river erosion in inland area – a case study of the Kii Peninsula, Japan –

*Nakanishi Toshimichi[1], Tetsuya Komatsu[1], Manabu Ogata[1], Takashi Hosoya[2], Takumi Kaga[2] (1.Japan Atomic Energy Agency, 2.Chuo Kaihatsu Corporation)

[HCG31-P03] Hydrothermal experiment on quartz hydration: Toward a development of new dating method for natural phenomena

*Masakazu Niwa[1], Koji Shimada[1] (1.Japan Atomic Energy Agency)

[HCG31-P04] **Diffusion Coefficient and Porosity of Granite for Evaluation of Mobility Parameter**

*Kenji Fukuda[1], Hiroaki Murakami[1], Kaori Itai[2], Masayuki Ishibashi[1], Eiji Sasao[1] (1.Japan Atomic Energy Agency, 2.C・TECH corporation)

[HCG31-P05] Hydrogeological structure of hydraulic conductive fractures in gallery scale and their rock matrix

*Ai Hamada[1] (1.Central Research Institute of Electric Power Industry)

[J] Poster | H (Human Geosciences )：H-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_18

## [H-CG31] Nuclear Energy and Geoscience

convener:Eiji Sasao(Tono Geoscience Center, Japan Atomic Energy Agency), Ryuta Hataya(Central Research Institute of Electric Power Industry), Shinji Takeuchi(Department of Earth and Environmental Sciences, College of Humanities & Sciences, Nihon University)

[HCG31-P01] Better identification of submerged terraces based on digital terrain analysis

*Hiura Yuki[1], Tetsuya Komatsu[1], Toshihiko Sugai[2] (1.Japan Atomic Energy Agency, 2.Graduate School of Frontier Sciences, The University of Tokyo)

[HCG31-P02] Advanced examination technique for river erosion in inland area – a case study of the Kii Peninsula, Japan –

*Nakanishi Toshimichi[1], Tetsuya Komatsu[1], Manabu Ogata[1], Takashi Hosoya[2], Takumi Kaga[2] (1.Japan Atomic Energy Agency, 2.Chuo Kaihatsu Corporation)

[HCG31-P03] Hydrothermal experiment on quartz hydration: Toward a development of new dating method for natural phenomena

*Masakazu Niwa[1], Koji Shimada[1] (1.Japan Atomic Energy Agency)

[HCG31-P04] **Diffusion Coefficient and Porosity of Granite for Evaluation of Mobility Parameter**

*Kenji Fukuda[1], Hiroaki Murakami[1], Kaori Itai[2], Masayuki Ishibashi[1], Eiji Sasao[1] (1.Japan Atomic Energy Agency, 2.C・TECH corporation)

[HCG31-P05] Hydrogeological structure of hydraulic conductive fractures in gallery scale and their rock matrix

*Ai Hamada[1] (1.Central Research Institute of Electric Power Industry)

[J] Poster | H (Human Geosciences )：H-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

## [H-CG34] Education and research for rehabilitation of agriculture against harmful rumors in nuclear disaster areas

convener:Masaru Mizoguchi(Graduate school of Agricultural and Life Sciences, The University of Tokyo)

[HCG34-P01] Calculation of water and sediment discharge from a small forested catchment for evaluating load of the particulate radioactive cesium

*Takuhei Yamasaki[1], Shoichiro Hamamoto[1], Taku Nishimura[1] (1.University of Tokyo)

[HCG34-P02] Radiocesium Inter-Annual Variations and Spatial Dynamics in Watershed in Iitate, Fukushima, Japan

*Saito Mari[1], Kazutoshi Osawa[1], Naoto Nihei[2] (1.Utsunomiya University, 2.Tokyuo University)

[HCG34-P03] Efforts in university to keep consciousness of disaster caused by The Great East Japan Earthquake for resurrection of agriculture at Iitate village

*Junko NISHIWAKI[1], Masaru Mizoguchi[2] (1.College of Agriculture, Ibaraki University, 2.Graduate School of Agricultural and Life Sciences, The University of Tokyo)

[HCG34-P04] Effects of remaining radiocesium in bunds and slopes of paddy fields on ambient dose and downstream environment.

*Yoshida Shuichiro[1], Kazuhiro Nishida[1], Taku Fukui[1] (1.The University of Tokyo)

[J] Poster | H (Human Geosciences )：H-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_19

## [H-CG34] Education and research for rehabilitation of agriculture against harmful rumors in nuclear disaster areas

convener:Masaru Mizoguchi(Graduate school of Agricultural and Life Sciences, The University of Tokyo)

[HCG34-P01] Calculation of water and sediment discharge from a small forested catchment for evaluating load of the particulate radioactive cesium

*Takuhei Yamasaki[1], Shoichiro Hamamoto[1], Taku Nishimura[1] (1.University of Tokyo)

[HCG34-P02] Radiocesium Inter-Annual Variations and Spatial Dynamics in Watershed in Iitate, Fukushima, Japan

*Saito Mari[1], Kazutoshi Osawa[1], Naoto Nihei[2] (1.Utsunomiya University, 2.Tokyuo University)

[HCG34-P03] Efforts in university to keep consciousness of disaster caused by The Great East Japan Earthquake for resurrection of agriculture at Iitate village

*Junko NISHIWAKI[1], Masaru Mizoguchi[2] (1.College of Agriculture, Ibaraki University, 2.Graduate School of Agricultural and Life Sciences, The University of Tokyo)

[HCG34-P04] Effects of remaining radiocesium in bunds and slopes of paddy fields on ambient dose and downstream environment.

*Yoshida Shuichiro[1], Kazuhiro Nishida[1], Taku Fukui[1] (1.The University of Tokyo)

[J] Oral | H (Human Geosciences)：H-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 202 2F

## [H-CG34] Education and research for rehabilitation of agriculture against harmful rumors in nuclear disaster areas

convener:Masaru Mizoguchi(Graduate school of Agricultural and Life Sciences, The University of Tokyo), Chairperson:Masaru Mizoguchi(The University of Tokyo), Kousuke Noborio(School of Agricultural Science, Meiji University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[HCG34-01] Education and research for rehabilitation of agriculture against harmful rumors in nuclear disaster areas

*Masaru Mizoguchi[1] (1.Graduate school of Agricultural and Life Sciences, The University of Tokyo)

---

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[HCG34-02] Towards the reborn of Iitate village 'Agriculture'

★Invited Papers

Makoto Sugisoka[2], *Masaru Mizoguchi[1] (1.Graduate school of Agricultural and Life Sciences, The University of Tokyo, 2.Division of Reconstruction Measures, Iitate Village)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[HCG34-03] Difference among crop species by radiocesium absorption from different soil fractions

*Nihei Naoto[1], Yoshimi Ohmae[1], Makoto Furukawa[1], Syuichiro Yoshida[1] (1.The University of Tokyo, Graduate School of Agricultural and Life Sciences)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[HCG34-04] Wild vegetables and mushrooms retrieving agriculter in Iitate Village, Fukushima Prefecture

*Kosuke Noborio[1], Yudai Fukuyama[2], Satoko Fujita[1], Hiroaki Sugino[2], Masaru Mizoguchi[2] (1.Meiji University, 2.the Univewrsity of Tokyo)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[HCG34-05] Effect of Study Tour toward Participants' Attachment on the Study Site - Case Study of University Student Tour to
Iitate Village, Fukushiima Prefecture -

*Natsumi Ebitani[1], Masaru Mizoguchi[1], Hiroaki Sugino[1] (1.Graduate school of Agricultural and Life Sciences, The University of Tokyo)

[J] Poster | S (Solid Earth Sciences )：S-SS Seismology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_4

## [S-SS12] Crustal Structure

convener:Kazuo Nakahigashi(Tokyo University of Marine Science and Technology)

[SSS12-P01] Regional difference in long period surface wave phase velocity by an explosive phenomenon generated in North Korea on September 3, 2017

*Koji Yamada[1] (1.Hanshin Consultants co., ltd.)

---

[SSS12-P02] Phase velocity estimation based on spatial gradient of surface wave arrival time of teleseismic earthquakes observed by S-net

*Akira Ishigami[1], Ryota Takagi[1] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science)

---

[SSS12-P03] Crustal seismic velocity structure in the Japanese Islands from receiver function analysis using similar earthquakes

*Toshihiro Igarashi[1] (1.Earthquake Research Institute, University of Tokyo)

---

[SSS12-P04] **Estimation of the Crustal Structure beneath the Broadband Seismic Network in the Eskisehir Region, Turkey, by Using Receiver Function Method**

*Pinar Duran[1], Asim Oguz Ozel[1], Hiroaki Yamanaka[2] (1.ISTANBUL UNIVERSITY-CERRAHPASA, 2.TOKYO INSTITUTE OF TECHNOLOGY)

---

[SSS12-P05] Three-dimensional S-wave attenuation structure in and around Hokkaido, Japan

*Ryoichi Nakamura[1], Takahiro Shiina[1] (1.Earthquake Research Institute, The University of Tokyo)

---

[SSS12-P06] Reexamination for the subsurface structure beneath the southern part of the Hidaka Collision Zone, Hokkaido, Japan by using a numerical test of wave propagation

*Masahiro Shimazaki[1], Noriko Tsumura[2] (1.Graduate School of Science and Engineering, Chiba University, 2.Graduate School of Science, Chiba University)

---

[SSS12-P07] High resolution seismic surveys in the Kuril trench off Hokkaido

*Yasuyuki Nakamura[1], Shuichi Kodaira[1], Mikiya Yamashita[1], Seiichi Miura[1], Gou Fujie[1] (1.Japan Agency for Marine Earth Science and Technology)

---

[SSS12-P08] Subsurface Structure at the North of the Yokosuka Fault by Seismic Reflection Survey

*Shinobu Ito[1] (1.Geological Survey of Japan, AIST)

---

[SSS12-P09] **Crust and Uppermost mantle P-wave velocity structure of the Ordos block and its neighbors based on travel time tomography**

*Yaning Liu[1], Jianping Wu[1], Shuxian Bao[1], Xiaohong Meng[2] (1.Institute of Geophysics, China Earthquake Administration, 2.China University of Geosciences (Beijing))

---

[SSS12-P10] Seismic imaging of the 2016 Kumamoto earthquake area using P and PmP data

*Dapeng Zhao[1], Haibo Wang[2], Zhouchuan Huang[2], Mingjie Xu[2], Liangshu Wang[2] (1.Department of Geophysics, Tohoku University, 2.School of Earth Sciences and Engineering, Nanjing University)

---

[SSS12-P11] Estimation of 3D velocity structure in Kyushu region by the seismic tomography

*Toya Mitsuhiro[1], Koji Yamada[1] (1.Hanshin Consultants Co., Ltd.)

---

[SSS12-P12] Estimation of the structure of the Philippine Sea slab under south Kyushu using receiver function analysis

*Masaki Uchida[1], Takahiro Ohkura[1], Takuo Shibutani[1], Yuki Abe[2], Shintaro Komatsu[1], Ken'ichi Yamazaki[1], Yusuke Yamashita[1], Shin Yoshikawa[1], Masato Iguchi[1], Takeshi Tameguri[1], Tadaomi Sonoda[1] (1.Kyoto Univ., 2.Hot Springs Research Institute)

---

[SSS12-P13] Imaging subduction structure beneath the eastern part of Kii Peninsula, SW Japan, using an earthquake reflection method

*Eiji Kurashimo[1], Takashi Iidaka[1], Noriko Tsumura[2], Takaya Iwasaki[1] (1.Earthquake Research Institute, the University of Tokyo, 2.Chiba University)

[SSS12-P14] **Tomography of Mejillones Peninsula using cross-correlation of ambient seismic noise**

*Kellen Azua Quezada[1], Sergio Ruiz[1], Francisco Pasten-Araya[2,3], José Salomón[4], Pablo Salazar[2,3], Miguel Saez[1], César Pastén[4], Felipe Leyton[5], Wasja Bloch[6] (1.DGF, UChile, 2.DG, UCN, 3.CIGIDEN, 4.DIC, UChile, 5.CSN, Chile, 6.GFZ)

[SSS12-P15] **Crustal thickness beneath Central Indonesia by the cross-correlation analysis of seismic ambient noise (2)**

*Masyitha Retno Budiati[1], Genti Toyokuni[1], Tomomi Okada[1], Toru Matsuzawa[1] (1.Graduate School of Science, Geophysics Department, Tohoku University)

[SSS12-P16] Subsurface structure below the southernmost area of South Japanese Alps estimated by seismic interferometry imaging

*Toshiki Watanabe[1], Hasegawa Daima[1], Tanio Ito[2], Ken'ichi Kano[3], Susumu Abe[4], Akira Fujiwara[5], Yoshinori Kouchi[6] (1.Graduate School of Environmental Studies, Nagoya University, 2.Association for the Development of Earthquake Prediction, 3.Shizuoka Univertity, 4.JAPEX, Co. Ltd., 5.JOGMEC, 6.Geosys, Inc.)

[SSS12-P17] Strong variations of near-surface seismic anisotropy of Taiwan revealed by coda interferometry

*Hsin-Yu Lee[1], Yuancheng Gung[1], Li-Wei Chen[2], Ling-Yun Chiao[3] (1.Department of Geosciences, National Taiwan University, Taiwan, 2.Department of Earth and Planetary Science, University of California at Berkeley, CA, USA, 3.Institute of Oceanography, National Taiwan University, Taiwan)

[SSS12-P18] Investigating anomalous crustal structures along the convergent zone in eastern Taiwan with the new airborne magnetic survey and updated seismic tomographic models

*Chi-Hsuan Chen[1], Hsin-Hua Huang[2], Lun-Tao Tong[3], Wayne Lin[3], Po-Tsun Lee[1], Shou-Fang Chang[1], Jin-Fa Lee[1] (1.Cntrl. Geo. Surv., MOEA, Taiwan, 2.Inst. Earth. Sc., Acad. Sinica, Taiwan , 3.Industr. Technol. Res. Inst., Taiwan)

[J] Poster | S (Solid Earth Sciences )：S-SS Seismology

## [S-SS12] Crustal Structure

convener:Kazuo Nakahigashi(Tokyo University of Marine Science and Technology), Chairperson:Yoshio Murai(Hokkaido University), Genti Toyokuni(東北大学)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SSS12-01] Shrinking and draining continental lower crust: its binary effects of stress and fluid on crustal activities

*Takehito Koyama[1] (1.Institute of Industrial Science, the University of Tokyo)

---

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SSS12-02] Seismic velocity structure in southern Hokkaido deduced from ocean-bottom seismographic and land observations

*Yoshio Murai[1], Kei Katsumata[1], Tetsuo Takanami[2], Tomoki Watanabe[3], Tadashi Yamashina[4], Ikuo Cho[5], Masayuki Tanaka[6], Ryosuke Azuma[7] (1.Institute of Seismology and Volcanology, Faculty of Science, Hokkaido University, 2.Department of Terrestrial Magnetism, Carnegie Institution of Washington, 3.Marine Works Japan LTD, 4.Kochi University, 5.National Institute of Advanced Industrial Science and Technology, 6.Meteorological Research Institute, 7.Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University)

---

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SSS12-03] Structural Complexity Associated with Arc-Arc Collision in Hokkaido Island, Japan - Review on Controlled-Source Seismic Researches in Western and Central Hokkaido -

★Invited Papers

*Takaya Iwasaki[1], Noriko Tsumura[2], Tanio Ito[3], Kazunori Arita[4], Hiroshi Sato[1] (1.Eathquake Research Institute, the University of Tokyo, 2.Graduate School of Science, Chiba University, 3.Association for the Development of Earthquake Prediction, 4.Hokkaido Research Center of Geology)

---

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SSS12-04] **Seismic imaging of the eastern Japan forearc region using S-net data**

*Genti Toyokuni[1], Dapeng Zhao[1], Naoki Uchida[1], Takashi NAKAYAMA[1] (1.RCPEVE, Tohoku Univ.)

---

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SSS12-05] The relationship between the location of the mid crustal reflector and seismicity in Iwaki area, northeastern Japan

*Takashi Iidaka[1], Shin'ichi Sakai[1], Toshihiro Igarashi[1], Kazushige Obara[1], Aitaro Kato[1], Tetsuya Takeda[2], Shigeki Nakagawa[1] (1.Earthquake Research Institute, University of Tokyo, 2.National Research Institute for Earth Science and Disaster Resilience)

---

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SSS12-06] Abnormal Seismic Anisotropy beneath the Tokyo Metropolitan Area (1) Mantle of the Philippine Sea Slab

*Motoko Ishise[1], Shin'ichi Sakai[1], Aitaro Kato[1], Shin Aoi[2], Makoto MATSUBARA[2] (1.Earthquake Reseach Institute, University of Tokyo, 2.National Research Institute for EarthScience and Disaster Resillience)

[J] Oral | S (Solid Earth Sciences )：S-SS Seismology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A05 TOKYO BAY MAKUHARI HALL

## [S-SS12] Crustal Structure

convener:Kazuo Nakahigashi(Tokyo University of Marine Science and Technology), Chairperson:Tsuruga Kayoko(Tokyo University of Marine Science and Technology), Yojiro Yamamoto(Japan Agency for Marine-Earth Science and Technology)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

### [SSS12-07] Deep seismic reflection profiling across the Suruga trough, Shizuoka, Japan

*Hiroshi Sato[1], Kayoko Tsuruga[2], Hisatoshi Baba[3], Tatsuya Ishiyama[1], Shinji Kawasaki[4], Yasuhisa Tanaka[4], Toshifumi Hayashi[2], Yoshihiro Sekino[2], Masanao Shinohara[1], Takaya Iwasaki[1], Makoto MATSUBARA[5], Naoshi Hirata[1,5] (1.Earthquake Research Institute, The University of Tokyo, 2.Tokyo University of Marine Science and Technology, 3.Tokai Univerisity, 4.JGI Inc., 5.National Research Institute for Earth Science and Disaster Resilience)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

### [SSS12-08] Multi-channel seismic profiling in the northern part of Suruga bay using the Shiyomaru-vessel of Tokyo University of Marine Science and Technology (Preliminary report)

*Kayoko Tsuruga[1], Hiroshi Sato[2], Hisatoshi Baba[3], Yoshihiro Sekino[1], Toshifumi Hayashi[1], Hayato Kondotec[1], Chiharu Aoyama[1], Tetsutaro Aikawa[1], Tatsuya Ishiyama[2], Masanao Shinohara[2], Shinji Kawasaki[4], Yasuhisa Tanaka[4] (1.Tokyo University of Marine Science and Technology, 2.University of Tokyo, 3.Tokai University, 4.JGI, Inc.)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

### [SSS12-09] Crustal structure refraction survey using Airgun-OBS in the northern part of Suruga Bay -Fujikawa fault zone- (Preliminary Report)

*Hisatoshi Baba[1], Kayoko Tsuruga[2], Hiroshi Sato[3], Tatsuya Ishiyama[3], Masanao Shinohara[3], Takahito Nishimiya[4], Shintaro Abe[5] (1.Department of Marine and Earth Science, Tokai University, 2.Tokyo University of Marine Science and Technology, 3.Earthquake Research Institute, University of Tokyo, 4.Meteorological Research Institute, Japan Meteorological Agency, 5.Association for the Development of Earthquake Prediction)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

### [SSS12-10] 3D seismic attenuation profiling for imaging an active fault in Uchiura wan

*Tetsuro Tsuru[1], Shio Shimizu[1], Mayu Ogawa[1], Jin-Oh Park[2], Seishiro Furuyama[1], Kosaku Arai[3], Takahiko Inoue[3], Chen Guo[2] (1.Tokyo University of Marine Science and Technology, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.National Institute of Advanced Industrial Science and Technology)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

### [SSS12-11] Gravity survey at the extension of the Takahama fault and the Yokosuka fault in Nishio City, Aichi Prefecture

*Tokunosuke Tatsuzawa[1,2], Tatsuya Sumita[2], Shinobu Ito[2], Tomoya Abe[2] (1.Department of Earth Sciences, Resources and Environmental Engineering, Creative Science and Engineering, Faculty of Science and Engineering, Waseda University, 2.National Institute of Advanced Industrial Science and Technology)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

### [SSS12-12] Subduction geometry and seismicity around northern Ryukyu subduction zone

*Yojiro Yamamoto[1], Tsutomu Takahashi[1], Yasushi Ishihara[1], Koichiro Obana[1], Seiichi Miura[1], Shuichi Kodaira[1], Yoshiyuki Kaneda[2] (1.Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.Kagawa University)

[E] Oral | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A09 TOKYO BAY MAKUHARI HALL

## [S-IT25] Planetary cores: Structure, formation, and evolution

convener:Hidenori Terasaki(Graduate School of Science, Osaka University), Eiji Ohtani(Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University), William F McDonough(University of Maryland College Park), George Helffrich(Earth-Life Science Institute, Tokyo Institute of Technology), Chairperson:George Helffrich(ELSI, Tokyo Institute of Technology), Hidenori Terasaki

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SIT25-01] **High-pressure Equation of State of Schreibersite $Fe_{2.15}Ni_{0.85}P$: Implications for the Martian Core**

*Xuejing He[1], Jiazeng Guo[2], Xiang Wu[3], Shengxuan Huang[1], Fei Qin[1], Xiangping Gu[4], Shan Qin[1] (1.Peking Univ., 2.Nanyang Normal Univ., 3.China Univ. of Geosciences, 4.Central South Univ.)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SIT25-02] Bottom-up solidification versus top-down solidification of the liquid core of the relatively small planetary bodies

*Satoru Urakawa[1], Hidenori Terasaki[2] (1.Department of Earth Sciences, Okayama University, 2.Department of Earth and Space Science, Osaka University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SIT25-03] P-wave velocity of $Fe_3S$ under high pressure and temperature

*Seiji Kamada[1,2], Hidenori Terasaki[3], Hiroshi Fukui[4,5], Tatsuya Sakamaki[2], Hiroshi Uchiyama[6], Satoshi Tsutsui[6], Eiji Ohtani[2], Alfred Q.R. Baron[5] (1.Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, 2.Department of Earth Science, Graduate School of Science, Tohoku University, 3.Department of Earth and Space Science, Graduate School of Science, Osaka University, 4.Graduate School of Material Science, University of Hyogo, 5.RIKEN, 6.JASRI)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SIT25-04] The sound velocity of liquid Fe-Ni-S-Si alloys under Mercury's core condition

*Iori Yamada[1], Hidenori Terasaki[1], Asaka Kamiya[1], Ryo Tsuruoka[1], Yuji Higo[2], Akihiko Machida[3] (1.Graduate School of Science, Osaka University, 2.Japan Synchrotron Radiation Research Institute, 3.National Institute for Quantum and Radiological Science and Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SIT25-05] In situ observation of Rayleigh–Taylor instability growth of liquid Fe-Si using laser shock

*Hidenori Terasaki[1], Tatsuhiro Sakaiya[1], Keisuke Shigemori[2], Hiroki Kato[2], Yoichiro Hironaka[2], Tadashi Kondo[1] (1.Graduate School of Science, Osaka University, 2.Institute of Laser Engineering, Osaka University)

[E] Oral | S (Solid Earth Sciences )：S-IT Science of the Earth's Interior & Techtonophysics

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A09 TOKYO BAY MAKUHARI HALL

## [S-IT25] Planetary cores: Structure, formation, and evolution

convener:Hidenori Terasaki(Graduate School of Science, Osaka University), Eiji Ohtani(Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University), William F McDonough(University of Maryland College Park), George Helffrich(Earth-Life Science Institute, Tokyo Institute of Technology), Chairperson:William McDonough(University of Maryland / Tohoku University), Eiji Ohtani(Tohoku University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SIT25-06] *P-V-T* equation-of-state of liquid Fe from *ab-initio* simulations to the TPa regime

*Gerd Steinle-Neumann[1], Fabian Wagle[1] (1.Bayerisches Geoinstitut, University of Bayreuth, Germany)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SIT25-07] ***Ab initio* study of Iron-Nickel alloys in Super-Earths cores**

*Francois Soubiran[1], Razvan Caracas[1] (1.Ecole normale superieure de Lyon, Laboratoire de Géologie de Lyon, Université Lyon 1, CNRS UMR 5276, Lyon, France)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SIT25-08] **Impurity effect on the iron's transport properties at Earth's core conditions: A key constraint for the evolution of the Earth's core**

*Youjun Zhang[1], Mingqiang Hou[2], Nilesh Salke[2], Jung-Fu Lin[3] (1.Sichuan University, 2.HPSTAR, 3.University of Texas at Austin)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SIT25-09] Melting in the Fe-FeO system to 214 GPa

*Kenta Oka[1], Yuto Kidokoro, Kei Hirose[1], Yoichi Nakajima[2], Guillaume Morard[3], Guillaume Fiquet[3], Nicolas Coudurier[3] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Priority Organization for Innobation and Excellence, 3.Sorbonne Université)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SIT25-10] B2 phase in the inner core: constraints from high pressure experiments

*Eiji Ohtani[1], Daijo Ikuta[1], Seiji Kamada[2], Tatsuya Sakamaki[1], Naohisa Hirao[3] (1.Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University, 2.Frontier Institute for Interdisciplinary Research, Tohoku University, 3.SRring-8, Japan Synchrotron Research Institute)

[E] Poster | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

## [S-IT25] Planetary cores: Structure, formation, and evolution

convener:Hidenori Terasaki(Graduate School of Science, Osaka University), Eiji Ohtani(Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University), William F McDonough(University of Maryland College Park), George Helffrich(Earth-Life Science Institute, Tokyo Institute of Technology)

[SIT25-P01] Stratification of the Earth's core by $SiO_2$ crystallisation

*George Helffrich[1], Satoshi Kaneshima[2], Kei Hirose[1,3] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.Earth and Planetary Sciences, Kyushu University, 3.Earth and Planetary Sciences Department, University of Tokyo)

[SIT25-P02] Relation between sound velocity and density for liquid iron alloys under Earth's core pressures by laser-shock compression

*Tatsuhiro Sakaiya[1], Tadashi Kondo[1], Hidenori Terasaki[1], Keisuke Shigemori[2], Yoichiro Hironaka[2] (1.Graduate School of Science, Osaka University, 2.Institute of Laser Engineering, Osaka University)

[SIT25-P03] **Geochemical estimates of Earth's core heat content at the end of accretion**

*Vincent Clesi[1], Renaud Deguen[1] (1.Laboratoire de Geologie de Lyon - Terre, Planètes, Environnement, Université Claude Bernard Lyon 1, CNRS, ENS-Lyon, 69622 Villeurbanne, France.)

[SIT25-P04] The effect of temperature on density of solid metals

*Asaka Kamiya[1], Hidenori Terasaki[1], Tadashi Kondo[1] (1.Osaka University)

[SIT25-P05] Phase relations in the Fe-Ni-Si system at high pressures and high temperatures

*Daijo Ikuta[1], Eiji Ohtani[1], Saori Kawaguchi[2], Naohisa Hirao[2], Yasuo Ohishi[2] (1.Department of Earth Science, Tohoku University, 2.JASRI)

[E] Poster | S (Solid Earth Sciences)：S-IT Science of the Earth's Interior & Techtonophysics

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A10 TOKYO BAY MAKUHARI HALL

## [S-GL27] Geochronology and Isotope Geology

convener:Takahiro Tagami(Graduate School of Science, Kyoto University), Yuji Sano(Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo), Chairperson:Takahiro Tagami, Yuji Sano

9:00 AM - 9:30 AM JST | 12:00 AM - 12:30 AM UTC

### [SGL27-01] Terrestrial cosmogenic nuclides as a dating tool of landforms and near-surface materials: applicability and limitations

★Invited Papers

*Yuki Matsushi[1] (1.Disaster Prevention Research Institute, Kyoto University)

---

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

### [SGL27-02] Dating of marine erosional terraces using cosmogenic nuclides: A case study of the Hyuga City, Miyazaki Prefecture, southwest Japan (preliminary results)

*Shigeru Sueoka[1], Tetsuya Komatsu[1], Yuki Matsushi[2], Yusuke Yonaga[1], Naomi Sano[1], Noriaki Hirao[1], Tadamasa Ueki[1], Natsuko Fujita[1], Yoko Kokubu[1], Masakazu Niwa[1] (1.Japan Atomic Energy Agency, 2.Disaster Prevention Research Institute, Kyoto University)

---

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

### [SGL27-03] Estimation of thermal history of Toki granite over 0.1Myr timescale by Multi-OSL-thermochronometry

*Manabu Ogata[1], Georgina E King[2], Frédéric Herman[2], Shigeru Sueoka[1] (1.Tono Geoscience Center, Japan Atomic Energy Agency, 2.University of Lausanne)

---

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

### [SGL27-04] Depth condition under which OSL signal of quartz gouge experiences coseismic zeroing

*Yuki Minomo[1], Kiyokazu Oohashi[1], Noriko Hasebe[2], Kazumasa Miura[3] (1.Graduate School of science and Technology for Innovation, Yamaguchi University , 2.Institute of Nature and Environmental Technology, Kanazawa University, 3.Kanazawa University)

---

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

### [SGL27-05] Result of age determination of samples from Hokuriku Group

*Noriko Hasebe[1], Ryo Kamiguchi[2] (1.Institute of Nature and Environmental Technology, Kanazawa University, 2.Department of Earth Sciences, Kanazawa University)

[J] Oral | S (Solid Earth Sciences)：S-GL Geology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A10 TOKYO BAY MAKUHARI HALL

## [S-GL27] Geochronology and Isotope Geology

convener:Takahiro Tagami(Graduate School of Science, Kyoto University), Yuji Sano(Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo), Chairperson:Yuji Sano, Takahiro Tagami

10:45 AM - 11:15 AM JST | 1:45 AM - 2:15 AM UTC

[SGL27-06] **Geochemical origin/cycle analysis with isotopologues and isotopomers**

★Invited Papers

*Naohiro Yoshida[1] (1.Department of Chemical Science and Engineering, Earth-Life Science Institute, Tokyo Institute of Technology)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SGL27-07] Estimation of Paleoenvironment by sedimentary rocks in Labrador, Cacada

*katsutaka sudo[1], Yuji Sano[1], Tsuyoshi Komiya[1], Bakert David[2], Michael Broadley[2], Bernard Marty[2] (1.University of Tokyo, 2.CRPG-CNRS, Université de Lorraine)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SGL27-08] Hf-W dating of zircons from mesosiderites with high-pressure sintered sample

*Yuta Koyama[1], Naoto Takahata[1], Yuji Sano[1], Naoji Sugiura[1], Mizuho Koike[2], Makiko K. Haba[3], Sakata Shuhei[4], Hideharu Kuwahara[5], Tetsuo Irifune[5] (1.the University of Tokyo, 2.Japan Aerospace Exploration Agency, 3.Tokyo Institute of Technology, 4.Gakushuin University, 5.Geodynamics Research Center, Ehime University)

---

11:45 AM - 12:15 PM JST | 2:45 AM - 3:15 AM UTC

[SGL27-09] Radiometric ages *vs.* astrophysical ages -with regard to the numerical age in the International Stratigraphic Chart

★Invited Papers

*Ichiro Kaneoka[1] (1.Earthquake Research Institute, University of Tokyo)

[J] Poster | S (Solid Earth Sciences )：S-GL Geology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_11

## [S-GL27] Geochronology and Isotope Geology

convener:Takahiro Tagami(Graduate School of Science, Kyoto University), Yuji Sano(Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo)

[SGL27-P01] Research report on long-term stability of geological environments and LA-ICP-MS-based age dating

★Invited Papers

*Tatsunori Yokoyama[1], Takehiro Mitsucuchi[1], Shigeru Sueoka[1] (1.Japan Atomic Energy Agency)

---

[SGL27-P02] **U-Pb detrital zircon age dating from the Aileu Formation of Timor-Leste; Estimate depositional age and provenance of the sediment**

*Jovita Elisa Fatima da Costa[1], Shoichi Kiyokawa[1], Yukiyasu Tsutsumi[2] (1.Kyushu University, 2.National Museum of Nature and Science)

---

[SGL27-P03] Petrological, geochemical, and geochronological characteristics of the Oritate travertine from Unazuki area, Toyama, Japan: possibility of U-Pb geochronology of carbonates with high common Pb.

*Mayuko Fukuyama[1], Masatsugu Ogasawara[2] (1.Graduate School of Engineering Science, Akita University, 2.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

---

[SGL27-P04] Zircon U-Pb age and tectonics of shirakamidake granitic complex

*Hiroki Sato[1], Koji Umeda[1] (1.Hirosaki University)

---

[SGL27-P05] Zircon U-Pb dating of plutonic rocks from Yamizo Area, northeast Japan

*Terumi Ejima[1,2], Yoshiaki Kon[2], Daisuke Araoka[2], Shigenori Kawano[3], Yutaka Takahashi[2] (1.Shinshu University, 2.Geological Survey of Japan, 3.Tochigi Prefectural Museum)

---

[SGL27-P06] Denudation history of the Higher Himalayan Crystallines in West-Central Nepal: insights from zircon fission-track dating and thermokinematic modeling

*Nakajima Toru[1], Harutaka Sakai[1], Hideki Iwano[2], Tohru Danhara[2], Takafumi Hirata[3] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2.Kyoto Fission-Track Co., Ltd., 3. Geochemical Research Center, The University of Tokyo)

---

[SGL27-P07] Thermochronology on the fore-arc side of Northeast Japan Arc

*Yuya Kajita[1], Shigeru Sueoka[2], Shoma Fukuda[1], Noriko Hasebe[3], Akihiro Tomoaki[4], Tomoaki Morishita[4], Barry P. Kohn[5], Tatsunori Yokoyama[2], Takahiro Tagami[1] (1.Graduate School of Science, Kyoto University , 2.Japan Atomic Energy Agency, 3.Institute of Nature and Environmental Technology, Kanazawa University, 4.Department of Sciences, Kanazawa University, 5.School of Earth Sciences, University of Melbourne)

---

[SGL27-P08] Argon diffusion in rocks - classical approach in view of heating and relaxation

Horst Zwingmann[1], *Hironobu Hyodo[2] (1.KUEPS, Kyoto University, 2.Research Institute of Natural Sciences, Okayama University of Science)

---

[SGL27-P09] $^{4}$He/U-Th dating of pore waters from Quaternary sediments in Switzerland: potential and challenges

*Yama Tomonaga[1], Edith Horstmann[1], Gaudenz Deplazes[2], Rolf Kipfer[1] (1.Swiss Federal Institute of Aquatic Science and Technology (Eawag), 2.National Cooperative for the Disposal of Radioactive Waste (Nagra))

---

[SGL27-P10] Compound-specific radiocarbon analysis of lipid biomarkers in surface sediment from Lake Kawaguchi, central Japan

*Shinya Yamamoto[1], Yosuke Miyairi[2], Yusuke Yokoyama[2], Hisami Suga[3], Nanako O. Ogawa[3], Naohiko Ohkouchi[3] (1.Mount Fuji Research Institute, Yamanashi Prefectural Government, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.Japan Agency for Marine-Earth Science and Technology)

---

[SGL27-P11] Reestablishment of the Mesozoic and Cenozoic Stratigraphic Events of the Fergana Basin, Uzbekistan

*OTABEK ULUGBEK OGLI ANVAROV[1], Ken-ichiro Hisada[1], Teruyuki Maruoka[1], Junichiro Kuroda[2], Sherzod Makhmudov[3] (1.UNIVERSITY OF TSUKUBA, 2.Atmosphere and Ocean Research Institute, the University of Tokyo , 3.State Comittee of Geology and Mineral Resources of Uzbekistan)

[J] Poster | S (Solid Earth Sciences )：S-GL Geology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_22

## [S-GL27] Geochronology and Isotope Geology

convener:Takahiro Tagami(Graduate School of Science, Kyoto University), Yuji Sano(Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo)

### [SGL27-P01] Research report on long-term stability of geological environments and LA-ICP-MS-based age dating

★Invited Papers

*Tatsunori Yokoyama[1], Takehiro Mitsucuchi[1], Shigeru Sueoka[1] (1.Japan Atomic Energy Agency)

### [SGL27-P02] U-Pb detrital zircon age dating from the Aileu Formation of Timor-Leste; Estimate depositional age and provenance of the sediment

*Jovita Elisa Fatima da Costa[1], Shoichi Kiyokawa[1], Yukiyasu Tsutsumi[2] (1.Kyushu University, 2.National Museum of Nature and Science)

### [SGL27-P03] Petrological, geochemical, and geochronological characteristics of the Oritate travertine from Unazuki area, Toyama, Japan: possibility of U-Pb geochronology of carbonates with high common Pb.

*Mayuko Fukuyama[1], Masatsugu Ogasawara[2] (1.Graduate School of Engineering Science, Akita University, 2.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

### [SGL27-P04] Zircon U-Pb age and tectonics of shirakamidake granitic complex

*Hiroki Sato[1], Koji Umeda[1] (1.Hirosaki University)

### [SGL27-P05] Zircon U-Pb dating of plutonic rocks from Yamizo Area, northeast Japan

*Terumi Ejima[1,2], Yoshiaki Kon[2], Daisuke Araoka[2], Shigenori Kawano[3], Yutaka Takahashi[2] (1.Shinshu University, 2.Geological Survey of Japan, 3.Tochigi Prefectural Museum)

### [SGL27-P06] Denudation history of the Higher Himalayan Crystallines in West-Central Nepal: insights from zircon fission-track dating and thermokinematic modeling

*Nakajima Toru[1], Harutaka Sakai[1], Hideki Iwano[2], Tohru Danhara[2], Takafumi Hirata[3] (1.Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2.Kyoto Fission-Track Co., Ltd., 3. Geochemical Research Center, The University of Tokyo)

### [SGL27-P07] Thermochronology on the fore-arc side of Northeast Japan Arc

*Yuya Kajita[1], Shigeru Sueoka[2], Shoma Fukuda[1], Noriko Hasebe[3], Akihiro Tomoaki[4], Tomoaki Morishita[4], Barry P. Kohn[5], Tatsunori Yokoyama[2], Takahiro Tagami[1] (1.Graduate School of Science, Kyoto University , 2.Japan Atomic Energy Agency, 3.Institute of Nature and Environmental Technology, Kanazawa University, 4.Department of Sciences, Kanazawa University, 5.School of Earth Sciences, University of Melbourne)

### [SGL27-P08] Argon diffusion in rocks - classical approach in view of heating and relaxation

Horst Zwingmann[1], *Hironobu Hyodo[2] (1.KUEPS, Kyoto University, 2.Research Institute of Natural Sciences, Okayama University of Science)

### [SGL27-P09] $^{4}$He/U-Th dating of pore waters from Quaternary sediments in Switzerland: potential and challenges

*Yama Tomonaga[1], Edith Horstmann[1], Gaudenz Deplazes[2], Rolf Kipfer[1] (1.Swiss Federal Institute of Aquatic Science and Technology (Eawag), 2.National Cooperative for the Disposal of Radioactive Waste (Nagra))

### [SGL27-P10] Compound-specific radiocarbon analysis of lipid biomarkers in surface sediment from Lake Kawaguchi, central Japan

*Shinya Yamamoto[1], Yosuke Miyairi[2], Yusuke Yokoyama[2], Hisami Suga[3], Nanako O. Ogawa[3], Naohiko Ohkouchi[3] (1.Mount Fuji Research Institute, Yamanashi Prefectural Government, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.Japan Agency for Marine-Earth Science and Technology)

[J] Oral | S (Solid Earth Sciences )：S-MP Mineralogy & Petrology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 301B 3F

## [S-MP32] Deformed rocks, Metamorphic rocks and Tectonics

convener:Yumiko Harigane(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Yoshihiro Nakamura(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Yoshihiro Nakamura(産総研), Yumiko Harigane(産総研)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SMP32-19] Thermal interaction of the lithosphere and asthenosphere revealed from internal variations of pressure-temperature history in orogenic peridotite complexes

*Kazuhito Ozawa[1], Carlos J. Garrido[2], Karoly Hidas[2], Jean-Louis Bodinier[3] (1.Department of Earth and Planetary Science, Graduate School of Science, University of Tokyo, 2.Instituto Andaluz de Ciencias de la Tierra (IACT), CSIC – UGR, Armilla, Granada, Spain, 3.Geosciences Montpellier, Montpellier, France)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SMP32-20] **Hydration and Ca-metasomatism in Mantle Wedge: An evidence from the Alag Khadny Accretionary Wedge, Western Mongolia**

*OTGONBAYAR DANDAR[1], Atsushi Okamoto[1], Masaoki Uno[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SMP32-21] **Attenuated Total Reflection Infrared (ATR-IR) Spectroscopy of Antigorite, Chrysotile and Lizardite**

*Ilona Talvikki Sakaguchi[1] (1.Nagoya University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SMP32-22] Fabric and petrological characteristics of sheared peridotites in Marion transform fault, Southwest Indian Ridge

*Kakihata Yuki[1], Katsuyoshi Michibayashi[2], Henry Dick[3] (1.Shizuoka University Graduate School of Science, 2.Nagoya University Graduate School of Environmental Studies, 3.Woods Hole Oceanographic Institution)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SMP32-23] Structure and formation mechanism of lithosphere-asthenosphere boundary decoded from Ichinomegata peridotite xenoliths

*Yuto Sato[1], Kazuhito Ozawa[1] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SMP32-24] Metasomatic banding and deformation instability in the metamorphic rocks

*mitsuhiro toriumi[1] (1.Japan agency of marine science and technology)

[E] Oral | S (Solid Earth Sciences)：S-VC Volcanology

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A07 TOKYO BAY MAKUHARI HALL

## [S-VC34] Connecting magma dynamics in vent-conduit system with surface expression of volcanic eruption

convener:Takahiro Miwa(National research institute for earth science and disaster prevention), Nobuo Geshi(Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology), Chairperson:Takahiro Miwa, Jacopo Taddeucci

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SVC34-01] An experimental basis for estimating particle properties following volcanic ash emissions

★Invited Papers

*Adrian Hornby[1], Ulrich Kueppers[1], Hanna Horsch[2], Paul Ayris[1], Nick Varley[3], Daniele Andronico[4], Boris Behncke[4], Yan Lavallée[5], Jackie E Kendrick[5], James Utley[5], Amy Hughes[5], David Damby[6], Benedikt Maurer[1], Marlin Juchem[1], Donald B Dingwell[1] (1.Ludwig-Maximilians-Universität München, DE, 2.Hazen Research, Golden, USA, 3.University of Colima, MX, 4.INGV Catania, IT, 5.University of Liverpool, UK, 6.USGS Cascades Volcano Observatory, USA)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[SVC34-02] **Vapor transport in shallow intruded magmas: insights from diktytaxitic texture**

*Ryosuke Sakurai[1], Michihiko Nakamura[2], Satoshi Okumura[2], Mayumi Mujin[2], Takayuki Nakatani[2] (1.Division of Earth and Planetary Materials Science, Faculty of Science, Tohoku University, 2.Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[SVC34-03] First observation of nanolites and ultrananolites in alkaline volcanic glasses (Eifel, Germany)

*Marija Putak Juricek[1], Michihiko Nakamura[2], Mayumi Mujin[2], Hans-Ulrich Schmincke[3], Mari Sumita[3], Nobuyoshi Miyajima[1] (1.BGI, 2.Tohoku Univ., 3.GEOMAR)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SVC34-04] Textural Study of Pumice Clasts from The Youngest Toba Tuff Eruption

*Gabriela Nogo Retnaningtyas Bunga Naen[1], Atsushi Toramaru[1], Tomoharu Miyamoto[1], Haryo Edi Wibowo[2] (1.Department Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, Nishiku, 744, Motooka, Fukuoka, 819-0395, Japan, 2.Geological Engineering Department, Universitas Gadjah Mada, 55284, Yogyakarta, Indonesia)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SVC34-05] **Oomurodashi volcano: Past effusive and phreatomagmatic activity revealed by submarine and subaerial deposits**

*Iona McIntosh[1], Kenichiro Tani[2], Alexander Nichols[3], Qing Chang[1], Jun-Ichi Kimura[1] (1.Japan Agency for Marine-Earth Science and Technology, Yokosuka, 2.National Museum of Nature and Science, Tsukuba, 3.University of Canterbury, Christchurch, New Zealand)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SVC34-06] Mechanism of volatile transport from mafic to silicic magma upon mixing

*Shumpei Yoshimura[1], Akiko Matsumoto[1], Mitsuhiro Nakagawa[1] (1.Department of Earth and Planetary Sciences, Hokkaido University)

[E] Oral | S (Solid Earth Sciences)：S-VC Volcanology

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

## [S-VC34] Connecting magma dynamics in vent-conduit system with surface expression of volcanic eruption

convener:Takahiro Miwa(National research institute for earth science and disaster prevention), Nobuo Geshi(Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology), Chairperson:Nobuo Geshi(GSJ/AIST), Adrian Hornby(Ludwig-Maximilians-University Munich)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SVC34-07] The in-flight grain size distribution of lapilli and bombs from Strombolian explosions

*Jacopo Taddeucci[1], Piergiorgio Scarlato[1], Elisabetta Del Bello[1], Tullio Ricci[1], Ulrich Kueppers[2], Bruce Houghton[3] (1.Istituto Nazionale di Geofisica e Vulcanologia, Rome, Italy, 2.Department of Earth and Environmental Sciences. Ludwig-Maximilians-Universität (LMU). Munich, Germany, 3.Department of Earth Sciences, University of Hawai‘i at Mānoa, Honolulu, USA)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SVC34-08] **Pyrrotite oxidation as a proxy for air entrainment in eruption columns**

*Keiko Matsumoto[1], Michihiko Nakamura[2] (1.Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology, 2.Faculty of Science, Tohoku University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SVC34-09] **Thermal signals in volcano monitoring: combining MODIS-MIROVA data with ground-based measurements at Aso Volcano, Japan**

*Corrado CIGOLINI[1], Akihiko Yokoo[2], Diego Coppola[1], Marco Laiolo[1] (1.Department of Earth Sciences, University of Torino, Italy, 2.Aso Volcanological Laboratory, Institute for Geothermal Sciences, Kyoto University, Japan)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SVC34-10] Magma transfer processes in the NE Japan arc: insights from crustal ambient noise tomography combined with volcanic eruption records

*Georg F Zellmer[1], Kai-Xun Chen[2], Yuancheng Gung[2], Ban-Yuan Kuo[3], Takeyoshi Yoshida[4] (1.Massey University, Palmerston North, New Zealand, 2.National Taiwan University, Taipei, Taiwan, 3.Academia Sinica, Taipei, Taiwan, 4.Tohoku University, Sendai, Japan)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SVC34-11] **STRATIGRAPHY RENEWAL, MAGMA CHAMBER STRATIFICATION, AND CONDUIT PROCESS OF THE 1815 TAMBORA CALDERA FORMING ERUPTION**

*Indranova Suhendro[1], Atsushi Toramaru[1], Yasuo Miyabuchi[2], Tomoharu Miyamoto[1] (1.Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, Japan, 2.Faculty of Advanced Science and Technology, Kumamoto University, Kurokami 2-40-1, Chuo-ku, Kumamoto 860-8555, Japan)

[E] Poster | S (Solid Earth Sciences)：S-VC Volcanology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_12

## [S-VC34] Connecting magma dynamics in vent-conduit system with surface expression of volcanic eruption

convener:Takahiro Miwa(National research institute for earth science and disaster prevention), Nobuo Geshi(Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology)

[SVC34-P01] A new formulation of viscosity-included bubble nucleation rate in ascending magmas and re-estimation of bubble number density (2)

*Mizuki Nishiwaki[1], Atsushi Toramaru[2] (1.Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University)

[SVC34-P02] Kinetic delay of crystal growth controls plagioclase-basaltic melt apparent disequilibrium

*Ryoya Oida[1], Hidemi Ishibashi[1], ATSUSHI YASUDA[2], Natsumi Hokanishi[2] (1.Faculty of Science, Shizuoka University, 2.Earthquake Research Institute, University of Tokyo)

[SVC34-P03] **Eruptive trends and dynamics of remote volcanoes detected form space-based thermal data and $SO_2$ emissions: a comparative analysis of Stromboli, Batu Tara and Tinakula volcanoes**

*Corrado CIGOLINI[1], Marco Laiolo[1], Francesco Massimetti[1,2], Maurizio Ripepe[2], Diego Coppola[1] (1.Department of Earth Sciences, University of Torino, Italy, 2.Department of Earth Sciences, University of Firenze, Italy)

[SVC34-P04] The source depth of Strombolian explosions: a multiparametric approach and comparison

*Jacopo Taddeucci[1], Miguel Angel Alatorre-Ibarguengoitia[2], Valeria Cigala[3], Elisabetta Del Bello[1], Damien Gaudin[4], Ulrich Kueppers[4], Tullio Ricci[1], Valentino Salvatore[5], Piergiorgio Scarlato[1] (1.Istituto Nazionale di Geofisica e Vulcanologia, Rome, Italy, 2.Centro de Investigación en Gestión de Riesgo y Cambio Climático, Universidad de Ciencias y Artes de Chiapas, Tuxtla Gutiérrez, Mexico, 3.Department of Geosciences, Università degli Studi di Padova, Padua, Italy, 4.Department of Earth and Environmental Sciences. Ludwig-Maximilians-Universität (LMU). Munich, Germany, 5.Dipartimento di Scienze della Terra, Sapienza Università di Roma, Rome, Italy)

[SVC34-P05] Magmatic aggregate of basaltic ash particles

*Takahiro Miwa[1], Nobuo Geshi[2] (1.National research institute for earth science and disaster prevention, 2.National Institute of Advanced Industrial Science and Technology)

[SVC34-P06] Melt inclusion study on the eruption process of Izu-Omuroyama monogenetic volcano, Japan

Risako Hatada[1], *Hidemi Ishibashi[1], Yusuke Suzuki[2], ATSUSHI YASUDA[3], Natsumi Hokanishi[3] (1.Faculty of Science, Shizuoka University, 2.Izu Peninsula Geopark, 3.Earthquake Research Institute, University of Tokyo)

[SVC34-P07] Time-series variation in the textures of ejecta of the An'ei eruption, Izu-Oshima

*Yuya Ikenaga[1], Fukashi Maeno[1], ATSUSHI YASUDA[1] (1.Earthquake Research Institute, The University of Tokyo)

[SVC34-P08] The textural analysis of pumice from the Plinian eruption of Taupo volcano: implications for tube pumice

*Masatoshi Ohashi[1], Mie Ichihara[2], Fukashi Maeno[2], Ben Kennedy[3], Darren Gravley[3] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Earthquake Research Institute, The University of Tokyo, 3.Department of Geological Sciences, The University of Canterbury)

[E] Poster | S (Solid Earth Sciences)：S-VC Volcanology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_23

## [S-VC34] Connecting magma dynamics in vent-conduit system with surface expression of volcanic eruption

convener:Takahiro Miwa(National research institute for earth science and disaster prevention), Nobuo Geshi(Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology)

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

## [S-VC37] Dynamics of volcanic eruptions and their physical and chemical processes

convener:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo)

[SVC37-P01] **Geochemical interpretation of Ulleung Island volcanic rocks: Implication for the new magmatic model for plume-slab interaction in East Asia**

*Chungwan LIM[1], Dohyun Kim[1] (1.Kongju National University)

[SVC37-P02] 1D particle model for vertiacal non-uniform bubble coalescence

*Maruishi Takafumi[1] (1.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University)

[SVC37-P03] The formation process of a 100m thick basaltic lava flow in the Kitamatsuura basalts, northwestern Kyushu

*Ryotaro Araki[1], Tetsuya Sakuyama[1] (1.Osaka City University)

[SVC37-P04] An introduction to the observation method of imaging volcanoes by using cosmic-ray muons

*Seigo Miyamoto[1] (1.Earth Reasearch Institute, University of Tokyo)

[SVC37-P05] Simulation and test observation for omni-directional muography at Omuro-yama

*Shogo Nagahara[1], Seigo Miyamoto[1], Kunihiro Morishima[2], Toshiyuki Nakano[2], Masato Koyama[3], Yusuke Suzuki[4] (1.Earthquake Research Institute,the University of Tokyo, 2.Nagoya University, 3.Shizuoka University, 4.Izu Peninsula Geopark Promotion Council)

[SVC37-P06] Estimation of pressure source occurring volcanic crustal deformation with FEM considering topography

*Shinya Yamada[1], Tomokazu Kobayashi[1] (1.GSI of Japan)

[J] Poster | S (Solid Earth Sciences )：S-VC Volcanology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_24

## [S-VC37] Dynamics of volcanic eruptions and their physical and chemical processes

convener:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo)

[SVC37-P01] **Geochemical interpretation of Ulleung Island volcanic rocks: Implication for the new magmatic model for plume-slab interaction in East Asia**

*Chungwan LIM[1], Dohyun Kim[1] (1.Kongju National University)

[SVC37-P02] 1D particle model for vertiacal non-uniform bubble coalescence

*Maruishi Takafumi[1] (1.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University)

[SVC37-P03] The formation process of a 100m thick basaltic lava flow in the Kitamatsuura basalts, northwestern Kyushu

*Ryotaro Araki[1], Tetsuya Sakuyama[1] (1.Osaka City University)

[SVC37-P04] An introduction to the observation method of imaging volcanoes by using cosmic-ray muons

*Seigo Miyamoto[1] (1.Earth Reasearch Institute, University of Tokyo)

[SVC37-P05] Simulation and test observation for omni-directional muography at Omuro-yama

*Shogo Nagahara[1], Seigo Miyamoto[1], Kunihiro Morishima[2], Toshiyuki Nakano[2], Masato Koyama[3], Yusuke Suzuki[4] (1.Earthquake Research Institute,the University of Tokyo, 2.Nagoya University, 3.Shizuoka University, 4.Izu Peninsula Geopark Promotion Council)

[SVC37-P06] Estimation of pressure source occurring volcanic crustal deformation with FEM considering topography

*Shinya Yamada[1], Tomokazu Kobayashi[1] (1.GSI of Japan)

[J] Oral | S (Solid Earth Sciences )：S-VC Volcanology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A07 TOKYO BAY MAKUHARI HALL

## [S-VC37] Dynamics of volcanic eruptions and their physical and chemical processes

convener:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo), Chairperson:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo), Hiroyuki Shimizu(Earthquake Research Institute, The University of Tokyo)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SVC37-01] Volcanic activities triggered or inhibited by resonance of volcanic edifices to large earthquakes

*Atsuko Namiki[1], Eleonora Rivalta[2], Heiko Woith[2], Timothy Willey[2], Stefano Parolai[3], Thomas R Walter[2] (1.Graduate School of Integrated Arts and Sciences, Hiroshima University, 2.GFZ, 3.OGS)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SVC37-02] **Groundmass crystallization experiments of an andesitic pumice under low vapor pressure.**

*Yasukawa Hiroki[1], Mayumi Mujin[1], Michihiko Nakamura[1], Shizuka Otsuki[2] (1.Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University., 2.National Institute of Advanced Industrial Science and Technology)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SVC37-03] Decoding pre-eruptive magma evolution and water behavior from plagioclase phenocrysts: Application to the Hoei eruption of Mt. Fuji

*Tsuyoshi Iizuka[1], Chiyo Harada[1], Kenji Shimizu[2], Takayuki Ushikubo[2], Morihisa Hamada[2], Mitsuhiro Yoshimoto[3] (1.University of Tokyo, 2.JAMSTEC, 3.Mount Fuji Research Institute)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SVC37-04] Probing magmatic processes just prior to historic eruptions at Sakurajima volcano: Toward understanding “magma pre-charge”

*Naoki Araya[1], Michihiko Nakamura[1], Satoshi Okumura[1] (1.Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku UniversityUniversity)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SVC37-05] Magmatic processes prior to the Vulcanian eruptions of Sakurajima volcano: A combined petrologic and geophysical approach

*Sakauchi Nono[2], Michihiko Nakamura[2], ATSUSHI YASUDA[1], Satoshi Okumura[2], Naoki Araya[2], Masato Iguchi[3], Daisuke Miki[3], Nobuo Geshi[4] (1.Earthquake Research Institute, University of Tokyo, 2.Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University, 3.Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University, 4.Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SVC37-06] Cyclic degassing behavior accompanying dome-forming lava effusion at Shinmoedake volcano in the 2018 eruption

★Invited Papers

*Taishi Yamada[1], Hideki Ueda[1], Toshiya Mori[2], Toshikazu Tanada[1] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Geochemical Research Center, Graduate School of Science, The University of Tokyo)

[J] Oral | S (Solid Earth Sciences )：S-VC Volcanology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A07 TOKYO BAY MAKUHARI HALL

## [S-VC37] Dynamics of volcanic eruptions and their physical and chemical processes

convener:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo), Chairperson:Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo), Taishi Yamada

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SVC37-07] Estimation of the amplitude of infrasoundsignal based on sound diffraction

*Kyoka Ishii[1], Akihiko Yokoo[1] (1.Graduate School of Science, Kyoto University)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SVC37-08] Mechanism and frequency change of pressure oscillation in the laboratory geyser system

*Noriko Teshima[1], Atsushi Toramaru[2] (1.Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SVC37-09] Effects of temperature on the run-out distance of large-scale pyroclastic density currents: Numerical simulation of a two-layer depth-averaged model

*Hiroyuki A. Shimizu[1], Takehiro Koyaguchi[1], Yujiro J. Suzuki[1] (1.Earthquake Research Institute, The University of Tokyo)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SVC37-10] **Total grain-size distribution of pumice fallout deposits (Kj-P1) from 54 ka plinian eruption at Kuju Volcano**

*Tomohiro Tsuji[1], Kishimoto Hiroshi[2], Fujita Kouji[2], Chisato Nakamura[3], Nagata Tomohiro[3], Kimura Kazunari[3], Michiharu Ikeda[1], Naoki Nishizaka[4], Kozo Onishi[4] (1.Shikoku Research Institute Inc., 2.Asia Air Survey Co. Ltd., 3.Naiba, 4.Shikoku Electric Power Co. Inc.)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SVC37-11] Estimating ashfall volumes for the 2018 Shinmoedake eruptions using the Ellipse Approximated Isopach (EAI) method - How to quantify ashfall volumes from limited ashfall observation locations

*Yasuhisa Tajima[1], Setsuya Nakada[2], Masashi NAGAI[2], Fukashi Maeno[3], Jun Oikawa[3], Teruki Oikawa[4], Yasuo Miyabuchi[5], Toshiaki Hasenaka[5], Masataka Kawaguchi[5] (1.NIPPON KOEI CO.,LTD., 2.NIED, 3.ERI, the Univ. Tokyo, 4.Geological Survey of Japan, AIST, 5.Kumamoto Univ.)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SVC37-12] Optical disdrometer measurement of tephra fall: Constraints on radar parameters for eruption cloud observations

★Invited Papers

*Tomofumi Kozono[1], Masato Iguchi[2], Takahiro Miwa[3], Masayuki Maki[4], Takeshi Maesaka[3], Daisuke Miki[2], Takeshi Nishimura[1] (1.Department of Geophysics, Graduate School of Science, Tohoku University, 2.Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Research and Education Center for Natural Hazards, Kagoshima University)

[J] Oral | S (Solid Earth Sciences )：S-TT Technology & Techniques

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A11 TOKYO BAY MAKUHARI HALL

## [S-TT43] seismic monitoring and processing system

convener:Takahiro Maeda(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Masanao Shinohara(Earthquake Research Institute, The University of Tokyo)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[STT43-01] Summary and Considerations about Characteristics of Borehole Stress Meter for Continuous Observation

*Hiroshi Ishii[1], Yasuhiro Asai[1] (1.Tono Research Institute of Earthquake Science, Association for the Development of Earthquake Prediction)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[STT43-02] Seismic monitoring by an autonomous robotic float equipped with a hydrophone: MERMAID

*Masayuki Obayashi[1], Hiroko Sugioka[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Department of Planetology, Kobe University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[STT43-03] Earthquake observation in a borehole over 250 °C using high temperature optical fiber and DAS technology

*Tsunehisa KIMURA[1] (1.Schlumberger)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[STT43-04] Distributed Acoustic Sensing measurement by using seafloor optical fiber cable system off Sanriku for dense seismic observation

*Masanao Shinohara[1], Tomoaki Yamada[1], Takeshi Akuhara[1], Kimihiro Mochizuki[1], Takeo Kasajima[2], Takahiro Arioka[2], Masayuki Hamakawa[3], Shunsuke Kubota[4] (1.Earthquake Research Institute, University of Tokyo, 2.Fujitsu Laboratories Ltd., 3.Fujitsu Limited, 4.YK Giken Co., Ltd.)

[J] Poster | S (Solid Earth Sciences )：S-TT Technology & Techniques

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_13

## [S-TT43] seismic monitoring and processing system

convener:Takahiro Maeda(National Research Institute for Earth Science and Disaster Resilience)

[STT43-P01] Proposal of the low cost seismometer network system

*Takamori Ito[1], Takashi Akazawa[2], Koichi Kusunoki[3], Masato Yazawa[4] (1.aLab Inc., 2.Geo-Research Institute, 3.ERI, The University of Tokyo, 4.MAD Lab.)

[STT43-P02] Experimental observation toward the realization of low-cost and high-density strong-motion observation network

*Takashi Akazawa[1], Takamori Ito[2] (1.Geo-Research Institute, 2.aLab Inc.)

[STT43-P03] Comparison of noise levels of the JMA and F-net broadband seismographs / strong motion velocity-type seismographs in long-period range for the purpose of magnitude estimation of tsunami earthquakes

*Masayuki Tanaka[1], Akio Katsumata[1] (1.Meteorological Research Institute)

[STT43-P04] Estimation of seismic wave velocity of seafloor surface and installation orientation at S-net station based on observed waveform of air gun: Toward sound source localization of large baleen whale

*Ryoichi Iwase[1] (1.National Research and Development Agency, Japan Agency for Marine-Earth Science and Technology)

[STT43-P05] **Parametric time series – video sincronization tool**

*Gerardo Manuel Mendo Pérez[1], Alejandra Arciniega Ceballos[1,2], Alejandro Rosado Fuentes[1] (1.Earth Science Graduate Program, National Autonomous University of Mexico, 2.Department of Volcanology, Institute of Geophysics, National Autonomus University of Mexico)

[J] Poster | S (Solid Earth Sciences )：S-TT Technology & Techniques

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_25

## [S-TT43] seismic monitoring and processing system

convener:Takahiro Maeda(National Research Institute for Earth Science and Disaster Resilience)

[STT43-P01] Proposal of the low cost seismometer network system

*Takamori Ito[1], Takashi Akazawa[2], Koichi Kusunoki[3], Masato Yazawa[4] (1.aLab Inc., 2.Geo-Research Institute, 3.ERI, The University of Tokyo, 4.MAD Lab.)

[STT43-P02] Experimental observation toward the realization of low-cost and high-density strong-motion observation network

*Takashi Akazawa[1], Takamori Ito[2] (1.Geo-Research Institute, 2.aLab Inc.)

[STT43-P03] Comparison of noise levels of the JMA and F-net broadband seismographs / strong motion velocity-type seismographs in long-period range for the purpose of magnitude estimation of tsunami earthquakes

*Masayuki Tanaka[1], Akio Katsumata[1] (1.Meteorological Research Institute)

[STT43-P04] Estimation of seismic wave velocity of seafloor surface and installation orientation at S-net station based on observed waveform of air gun: Toward sound source localization of large baleen whale

*Ryoichi Iwase[1] (1.National Research and Development Agency, Japan Agency for Marine-Earth Science and Technology)

*Gerardo Manuel Mendo Pérez[1], Alejandra Arciniega Ceballos[1,2], Alejandro Rosado Fuentes[1] (1.Earth Science Graduate Program, National Autonomous University of Mexico, 2.Department of Volcanology, Institute of Geophysics, National Autonomus University of Mexico)

[E] Oral | S (Solid Earth Sciences )：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | Convention Hall A 2F

## [S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo), Chairperson:Kimihiro Mochizuki(Earthquake Research Institute, University of Tokyo), Ryuta Arai

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[SCG48-17] Three-dimensional seismic structure of the shallow plate boundary in the northern Hikurangi margin from NZ3D OBS data

*Ryuta Arai[1], Shuichi Kodaira[1], Richard Kellett[2], Valerie Stucker[2], Dan Bassett[2], Stuart Henrys[2], Koichiro Obana[1], Nathan Bangs[3], Dan Barker[2], Rebecca Bell[4], Kimihiro Mochizuki[5], Gou Fujie[1], Seiichi Miura[1], Bill Fry[2], team NZ3D (1.Japan Agency for Marine-Earth Science and Technology, 2.GNS Science, 3.University of Texas Institute for Geophysics, 4.Imperial College London, 5.Earthquake Research Institute, University of Tokyo)

9:15 AM - 9:45 AM JST | 12:15 AM - 12:45 AM UTC

[SCG48-18] **Using earthquake focal mechanisms to investigate slow slip driving forces in the northern Hikurangi**

★Invited Papers

*Emily Warren-Smith[1], Bill Fry[1], Laura Wallace[1] (1.GNS Science)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[SCG48-19] Seismological structural changes around source regions of slow earthquakes in Nankai subduction zone inferred from broadband receiver functions

*Yasunori Sawaki[1], Yoshihiro Ito[2], Kazuaki Ohta[2], Takuo Shibutani[2], Tomotaka Iwata[2] (1.Graduate School of Science, Kyoto University , 2.Disaster Prevention Research Institute, Kyoto University)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[SCG48-20] Slip tendency maps for compressional and extensional stress states on a shallow decollement in Nankai Trough

*Yoshitaka Hashimoto[1], Shigeyuki Sato[1], Gregory F Moore[2], Masataka Kinoshita[3], Gaku Kimura[4], Ayumu Miyakawa[5], Kazuya Shiraishi[6], Yasuhiro Yamada[6] (1.Kochi University, 2.University of Hawaii, 3.University of Tokyo, 4.Tokyo University of Marine Science and Technology, 5.AIST, 6.JAMSTEC)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[SCG48-21] Permeability and its anisotropy on creeping Chihshang Fault, Taiwan

*Tyas Dwi Aprilniadi[1], Wen-Jie Wu[1], Li-Wei Kuo[1], Jian-Cheng Lee[2], Jia-Jyun Dong[3] (1.Department of Earth Sciences, National Central University, 2.Institute of Earth Sciences, Academia Sinica, 3.Graduate Institute of Applied Geology, National Central University)

[E] Oral | S (Solid Earth Sciences )：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Convention Hall A 2F

## [S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo), Chairperson:Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Simon Wallis(Nagoya University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SCG48-22] Short fluid infiltration events in the low permeable metamorphic rocks triggered by crustal fracturing at amphibolite–granulite facies conditions

*Diana Mindaleva[1], Masaoki Uno[1], Fumiko Higashino[1], Atsushi Okamoto[1], Noriyoshi Tsuchiya[1] (1.Graduate school of environmental studies, Tohoku University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SCG48-23] Generation of high fluid pressure at the base of the shallow mantle wedge—evidence from serpentinite of the Sanbagawa belt, SW Japan

*Simon Richard Wallis[1], Yui Kouketsu[2], Mari Yokota[1,2] (1.University of Tokyo, 2.Nagoya University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SCG48-24] **Overpressured subduction plate boundary caused by infiltration of mantle-derived fluids: Evidence from helium isotope analysis on veins in subduction mélange**

*Naoki Nishiyama[1], Kohtaro Ujiie[1], Hirochika Sumino[2] (1.University of Tsukuba, 2.The University of Tokyo)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SCG48-25] **Geological and rheological conditions of subduction plate boundary between the seismogenic zone and the ETS zone in warm-slab environments**

*Kohtaro Ujiie[1], Kazuya Noro[1], Norio Shigematsu[2], Ake Fagereng[3], Naoki Nishiyama[1], Christopher Tulley[3], Haruna MASUYAMA[1], Yasushi Mori[4] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Research Institute of Earthquake and Volcano Geology, National Institute of Advanced Industrial Science and Technology, Japan, 3.Cardiff University, 4.Kitakyushu Museum of Natural History and Human History)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SCG48-26] Temperature variation in tectonic mélanges of the Shimanto Belt, SW Japan

*Tsai-Wei Chen[1], Donald M Fisher[1], Andrew J Smye[1], Yoshitaka Hashimoto[2] (1.Penn State Univ., 2.Kochi Univ.)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SCG48-27] Frictional properties of opal gouge at low-temperature hydrothermal conditions and their implications for seismogenic faulting along subduction-zone megathrusts

*Kyuichi Kanagawa[1], Tomoya Nakanishi[2], Morito Kuwana[3], Michiyo Sawai[1], Takehiro Hirose[4] (1.School of Science, Chiba University, 2.Graduate School of Science and Engineering, Chiba University, 3.Faculty of Science, Chiba University, 4.Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology)

[E] Oral | S (Solid Earth Sciences)：S-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | Convention Hall A 2F

## [S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo), Chairperson:Takahiro Hatano, Takehito Suzuki

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SCG48-28] **Rate and State Dependent Friction Law and Static Friction Force**

*Hiroshi Matsukawa [1] (1.Aoyama Gakuin University)

---

2:00 PM - 2:30 PM JST | 5:00 AM - 5:30 AM UTC

[SCG48-29] **Stable sliding, slow and silent slip events and laboratory earthquakes across the brittle ductile transition**

★Invited Papers

*Alexandre Schubnel[1], Aubry Jérôme[1], François Passelègue[2] (1.Laboratoire de Géologie, ENS, PARIS, France, 2.EPFL, Switzerland)

---

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SCG48-30] Dramatic velocity weakening of dry quartz friction at relatively slow slip velocities

*Akito Tsutsumi[1], Hirotaka Iida[2], Yuko Onoe[1] (1.Graduate School of Science, Kyoto University, 2.Geothermal Engineering. Co. Ltd.)

---

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SCG48-31] Rupture nucleation processes accompanying tremor and slow slip in gel friction experiments

*Tetsuo Yamaguchi[1] (1.Graduate school of Engineering, Kyushu University)

---

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SCG48-32] Solution Orbit for k and epsilon Model for Turbulent Flow in Porous Media

*Takehito Suzuki[1] (1.Department of Physics and Mathematics, Aoyama Gakuin University)

[E] Oral | S (Solid Earth Sciences )：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Convention Hall A 2F

## [S-CG48] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Earthquake Research Institute, University of Tokyo), Chairperson:Naofumi Aso, Takahiro Hatano

3:30 PM - 4:00 PM JST | 6:30 AM - 7:00 AM UTC

[SCG48-33] **Modelling precursory seismicity in the laboratory using a roughness derived rate and state friction model**

★Invited Papers

*Paul A Selvadurai[1], Percy Galvez[2], Stefan Wiemer[1], P. Martin Mai[2] (1.Swiss Seismological service, ETH Zurich, Switzerland, 2.King Abdullah University of Science and Technology, Thuwal, Saudi Arabia)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SCG48-34] Exponential dependence on perturbation stress of earthquake nucleation

*Saito Takuya[1], Takahiro Hatano[1] (1.The University of Tokyo)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SCG48-35] Stochastic modeling of slow earthquakes comparable to observations

*Naofumi Aso[1], Ryosuke Ando[2], Satoshi Ide[2] (1.Tokyo Institute of Technology, 2.University of Tokyo)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SCG48-36] Migration of aqueous fluid near the subducting plate interface

*Manabu Morishige[1] (1.Japan Agency for Marine-Earth Science and Technology)

---

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SCG48-37] EnKF estimation of frictional properties and slip evolution on a LSSE fault and the changing slip deficit rate on a megathrust fault

*Kazuro Hirahara[1,2] (1.Institute of Education, Research and Regional Cooperation for crisis Management Shikoku, Kagawa University , 2.Riken, AIP center)

[E] Oral | S (Solid Earth Sciences )：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A02 TOKYO BAY MAKUHARI HALL

## [S-CG50] Intraslab and intraplate earthquakes

convener:Saeko Kita(International Institute of Seismology and Earthquake Engineering, BRI), Tomohiro Ohuchi(Geodynamics Research Center, Ehime University), Marcel Thielmann(Bavarian Geoinstitute, University of Bayreuth), Ryo Okuwaki(Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Saeko Kita(Building Research Insitute), Tomohiro Ohuchi(Geodynamics Research Center, Ehime University), Marcel Thielmann(University of Bayreuth), Ryo Okuwaki(筑波大学), Thomas Ferrand(UC San Diego)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

### [SCG50-01] On a reversely-dipping low-velocity layer in the Tohoku-slab beneath the forearc: unbending induced fluid pathway?

★Invited Papers
# Cancelled

*Hitoshi Kawakatsu[1], HyeJeong Kim[1] (1.Earthquake Research Institute, University of Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

### [SCG50-02] Evidence for transient fluid pathways in the mantle of the subducting Nazca slab from seismological observations and modeling of the Poisson's ratio

★Invited Papers

*Wasja Bloch[1,2], Timm John[2], Jörn Kummerow[2], Bernd Schurr[1], Pablo Salazar[3,4], Serge A. Shapiro[2] (1.GeoForschungszentrum GFZ, Potsdam, Germany, 2.Freie Universität Berlin, Germany, 3.Universidád Católica del Norte, Antofagasta, Chile, 4.National Research Center for Integrated Natural Disasters Management (CIGIDEN), Santiago, Chile)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

### [SCG50-03] Numerical simulation of water transportation along subducting slabs and implications for intraslab earthquakes

★Invited Papers

*Atsushi Nakao[1], Hikaru Iwamori[1,2,3], Tomoeki Nakakuki[4], Yujiro Suzuki[1], Takashi Nakagawa[5], Hitomi Nakamura[2,3,6,7] (1.Earthquake Research Institute, University of Tokyo, 2.Department of Solid Earth Geochemistry, Japan Agency for Marine-Earth Science and Technology, 3.Department of Earth and Planetary Sciences, Tokyo Institute of Technology, 4.Department of Earth and Planetary Systems Science, Hiroshima University, 5.Department of Earth Sciences, The University of Hong Kong, 6.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 7.Ocean Resource Research Center for Next Generation, Chiba Institute of Technology)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

### [SCG50-04] Subduction of serpentinized fracture zone and intraslab earthquakes in southern Mexico

★Invited Papers

*Marina Manea[1,2] (1.Computational Geodynamics Laboratory, Geosciences Center, National Autonomous University of Mexico, 2.Institute of Astronomy, Romanian Academy)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

### [SCG50-05] Reaction-induced embrittlement of the lower continental crust

*Alexandre Schubnel[1], Sarah Incel[2], Julien Gasc[1], Nadège Hilairet[5], Yanbin Wang[3], Feng Shi[3], Loic Labrousse[4] (1.Laboratoire de Géologie, ENS, 2.University of Oslo, 3.GCECARS, University of Chicago, 4.ISTEP, Sorbonne Université, 5.UMET, Université de Lille)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

### [SCG50-06] Transformation-induced, melt-enhanced faulting in orthoenstatite: implications for global intermediate-depth earthquakes

Feng Shi[1], Jianguo Wen[2], Tony Yu[1], Lupei Zhu[3], *Yanbin Wang[1] (1.Center for Advanced Radiation Sources, University of Chicago, Chicago, IL, USA, 2.Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL, USA, 3.Department of Earth & Atmospheric Sciences, Saint Louis University, St. Louis, MO, USA)

[E] Oral | S (Solid Earth Sciences )：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A02 TOKYO BAY MAKUHARI HALL

## [S-CG50] Intraslab and intraplate earthquakes

convener:Saeko Kita(International Institute of Seismology and Earthquake Engineering, BRI), Tomohiro Ohuchi(Geodynamics Research Center, Ehime University), Marcel Thielmann(Bavarian Geoinstitute, University of Bayreuth), Ryo Okuwaki(Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Chairperson:Saeko Kita(Building Research Insitute), Tomohiro Ohuchi(Geodynamics Research Center, Ehime University), Marcel Thielmann(University of Bayreuth), Ryo Okuwaki(筑波大学), Thomas Ferrand(UC San Diego)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SCG50-07] The Isolated M7.9 Deep Earthquake of 30 May 2015 Under the Present Bonin Wadati-Benioff Zone: Evidence from the New ISC-EHB Earthquake Catalogue (1930-2015) and CMT Focal Mechanisms

*Stephen Kirby[1], E. Robert Engdahl[2], Emile Andre Okal[3] (1.United States Geological Survey, Menlo Park, 2.University of Colorado, 3.Northwestern University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SCG50-08] What Can $M_W$ –4 Lab-Quakes Teach Us About Deep-Focus Earthquakes?

★Invited Papers

*Julien Gasc[1], Julien Fauconnier[1], Clémence Daigre[1], Arefeh Moarefvand[1], Damien Deldicque[1], Blandine Gardonio[1], Alexandre Schubnel[1], Pamela Burnley[2] (1.Laboratoire de Géologie, ENS-CNRS, Paris, FRANCE, 2.University of Nevada Las Vegas, Las Vegas, USA)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SCG50-09] Deep intraslab earthquake rupture due to grain size assisted thermal runaway

*Marcel Thielmann[1], Thibault Duretz[2] (1.Bavarian Geoinstitute, University of Bayreuth, Germany, 2.Université de Rennes, Rennes, France)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SCG50-10] Fault model of the 2012 off-Miyagi intraslab earthquake doublet and its implication for rheological signature of incoming Pacific plate

*Tatsuya Kubota[1], Ryota Hino[2], Syuichi Suzuki[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Graduate School of Science, Tohoku University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SCG50-11] Source-rupture process of the intraplate earthquake; its diversity related to the fault geometry and damaged fault zone

*Ryo Okuwaki[1], Yuji Yagi[1] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SCG50-12] **Aftershocks of the NEXT Cascadia Intraslab Earthquake**

*Paul Bodin[1,2] (1.University of Washington Seattle, 2.Pacific Northwest Seismic Network)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_14

## [S-CG50] Intraslab and intraplate earthquakes

convener:Saeko Kita(International Institute of Seismology and Earthquake Engineering, BRI), Tomohiro Ohuchi(Geodynamics Research Center, Ehime University), Marcel Thielmann(Bavarian Geoinstitute, University of Bayreuth), Ryo Okuwaki(Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SCG50-P01] Changes in seismicity rate, stress orientations, and b-values before and after ETS events in the Philippine sea plate under Kii Peninsula

*Saeko Kita[1], Heidi Houston[2], Sachiko Tanaka[3], Youichi Asano[3], Takuo Shibutani[4], Naoki Suda[5] (1.Building Research Institute, 2.USC, 3.NIED, 4.DPRI, Kyoto University, 5.Hiroshima University)

[SCG50-P02] **Inhomogeneous conduit across slab controlled by intraslab stress heterogeneity in the Nankai subduction zone**

*Makoto Otsubo[1], Ayumu Miyakawa[2], Ikuo Katayama[3], Keishi Okazaki[4] (1.Geological Survey of Japan, Research Institute of Earthquake and Volcano Geology, 2.Geological Survey of Japan, Research Institute of Geology and Geoinformation, 3.Hiroshima University, 4.JAMSTEC)

[SCG50-P03] New insights into the mechanism of deep-focus earthquakes

*Ayako Tsuchiyama[1], Junichi Nakajima[1] (1.Tokyo Institute of Technology)

[SCG50-P04] Faulting in deforming harzburgite under wet conditions

*Tomohiro Ohuchi[1], Xinglin Lei[2], Yuji Higo[3], Yoshinori Tange[3], Takeshi Sakai[1] (1.Geodynamics Research Center, Ehime University, 2.National Institute of Advanced Industrial Science and Technology, 3.Japan Synchrotron Radiation Research Institute)

[SCG50-P05] Semi-brittle behavior of olivine single crystals under the conditions of Earth's mantle transition zone

Yoshihisa Naruse[1], *Tomohiro Ohuchi[1] (1.Geodynamics Research Center, Ehime University)

[SCG50-P06] High-pressure deformation experiments on peridotite gouges under hydrothermal conditions, using a deformation-DIA apparatus

*Maki Semba[1], Ken-ichi Hirauchi[1], Tomohiro Ohuchi[2], Katsuyoshi Michibayashi[3] (1.Department of Geosciences, Faculty of Science, Shizuoka University, 2.Geodynamics Research Center, Ehime University, 3.Department of Earth and Planetary Sciences, Nagoya university)

[SCG50-P07] Stable fault slip in antigorite-olivine aggregates at high pressures

Mai Ikehara[1], *Tomoaki Kubo[1], Takuya Iwasato[2], Yuji Higo[3], Masahiro Imamura[1], Yoshinori Tange[3] (1.Kyushu University, 2.Shin-Nippon Nondestructive Inspection Co., Ltd., 3.JASRI)

[SCG50-P08] Rheology and frictional instability of lawsonite in high pressure deformation experiments

*Rei Shiraishi[1], Jun Muto[1], Akihiro Tsunoda[2], Sando Sawa[1], Akio Suzuki[1] (1.Department of Earth Science, Graduate School of Science, Tohoku University, 2.Earthquake Research Institute, University of Tokyo)

[SCG50-P09] Grain Size Dependency of Olivine-Spinel Phase Transformational Mechanism Responsible for Deep-focus Earthquakes

*Sando Sawa[1], Jun Muto[1], Nobuyoshi Miyajima[2], Hiroyuki Nagahama[1] (1.Department of Earth Science, Tohoku University, 2.Bayerisches Geoinstitut, University of Bayreuth)

[SCG50-P10] **Seismicity and mineral destabilizations in the subducting mantle up to 6 GPa, 200 km depth**

*Thomas P. Ferrand[1] (1.Earthquake Research Institute)

[SCG50-P11] Receiver function imaging of subducting Pacific plate and mantle wedge under Japanese islands using denser network of stations

*HyeJeong Kim[1], Hitoshi Kawakatsu[1], Takeshi Akuhara[1], Masanao Shinohara[1] (1.Earthquake Research Institute, The University of Tokyo)

[SCG50-P12] Strong S-wave attenuation in the mantle wedge beneath the NE Japan and interpretations of high-frequency wave propagation path of intraslab earthquakes

*Takahiro Shiina[1,2], Kei Katsumata[2], Kiyoshi Yomogida[3], Aitaro Kato[1] (1.Earthquake Research Institute, The University of Tokyo, 2.Institute of Seismology and Volcanology, Graduate School of Science, Hokkaido University, 3.Graduate School of Science, Hokkaido University)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_26

## [S-CG51] Role of volatiles on Earth and planetary dynamics

convener:Takayuki Ishii(Bavarian Research Institute, University of Bayreuth), Eiji Ohtani(Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University), Michihiko Nakamura(Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University), Bjorn Mysen(Geophysical Laboratory, Carnegie Inst. Washington)

[SCG51-P01] Permeability prediction of porous media with the finite difference Stokes solver LaMEM

*Philipp Eichheimer[1], Wakana Fujita[2], Marcel Thielmann[1], Anton Popov[3], Gregor Golabek[1], Boris Kaus[3], Maximilian Kottwitz[3] (1.Bayerisches Geoinstitut, University of Bayreuth, 2.Department of Earth Science, Tohoku University, Sendai, 3.Institute of Geosciences, Johannes Gutenberg University Mainz)

[SCG51-P02] Grain growth-induced fluid localization and permeability reduction

*Wakana Fujita[1], Michihiko Nakamura[1], Kentaro Uesugi[2] (1.Graduate School of Science, Tohoku University, 2.JASRI/SPring-8)

[SCG51-P03] Pargasite stability in the upper mantle at $H_2O$-undersaturated conditions

*Marija Putak Juricek[1], Hans Keppler[1] (1.BGI)

[SCG51-P04] **Constraining the water content at the top of the mantle transition zone with the elasticity of wadsleyite and olivine**

*Zhongqing Wu[1] (1.University of Science and Technology of China)

[SCG51-P05] ***Single crystal elasticity of Fe-bearing phase E by Brillouin spectroscopy***

*Niccolo Satta[1], Hauke Marquardt [2], Alexander Kurnosov[1], Tiziana Boffa Ballaran [1], Johannes Buchen[3], Catherine McCammon[1], Takaaki Kawazoe[4] (1.Bayerisches Geoinstitut, University of Bayreuth, 95440 Bayreuth, Germany, 2.Department of Earth Sciences, University of Oxford, South Parks Road, Oxford, UK., 3.Seismological Laboratory, California Institute of Technology, Pasadena, CA 91125, USA., 4.Department of Earth and Planetary Systems Science, Hiroshima University, Hiroshima 739-8526, Japan.)

[SCG51-P06] Discovery of two hexagonal phases in (Fe,Al)OOH under the P-T conditions of the deep lower mantle

*Lu Liu[1,2], Li Zhang[1], Hongsheng Yuan[1] (1.Center for High Pressure Science and Technology Advanced Research, 2.University of Science and Technology of China)

[SCG51-P07] **Effect of grid resolution on tectonic regimes in global-scale convection models**

*Enrico Marzotto[1], Marcel Thielmann[1], Gregor Golabek[1] (1.Bayerisches Geoinstitut)

[SCG51-P08] A 3-D crust and uppermost mantle electrical conductivity model of subduction zone beneath NE Japan

*Masahiro Ichiki[1,2], Toshiki Kaida[1], Yasuo Ogawa[3] (1.Graduate School of Science, Tohoku University, 2.International Research Institute of Disaster Science, 3.School of Science, Tokyo Institute of Technology)

[SCG51-P09] *The conditions of sublithospheric diamond formation constrained from ferric iron-rich exsolution from ferropericlase inclusions.*

*Caterina Melai[1], Daniel Frost[1], Tiziana Boffa Ballaran[1], Catherine McCammon[1] (1.Bayerisches Geoinstitute)

[SCG51-P10] **Probing the variation of the oxygen fugacity in diamond anvil cells using the Fe-Ir alloy as redox sensor**

*Serena Dominijanni[1], Catherine McCammon[1], Leonid Dubrovinsky[1], Dan Frost[1], Nobuyoshi Miyajima[1] (1.Bayerisches Geoinstitut)

[SCG51-P11] Goethite behavior at Earth's lower mantle conditions

*Egor Gennadievich Koemets[1], Maxim Bykov[1], George Aprilis[2], Timofey Fedotenko[2], Stella Chariton[1], Saiana Khandarkhaeva[1], Iuliia Koemets[1], Marcel Thielmann[1], Natalia Dubrovinsaia[2], Leonid Dubrovinsky[1] (1.BGI (Bayerisches Geoinstitut), Universität Bayreuth, Germany, 2.Material Physics and Technology at Extreme Conditions, Laboratory of Crystallography, Universität Bayreuth, Germany)

[SCG51-P12] The oxygen content of sulphides in the mantle and a geothermometer for diamond formation

*Sumith Abeykoon[1], Dan Frost[1], Vera Laurenz[1] (1.Bayerisches Geoinstitut, University of Bayreuth)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_27

## [S-CG51] Role of volatiles on Earth and planetary dynamics

convener:Takayuki Ishii(Bavarian Research Institute, University of Bayreuth), Eiji Ohtani(Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University), Michihiko Nakamura(Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University), Bjorn Mysen(Geophysical Laboratory, Carnegie Inst. Washington), Chairperson:Michihiko Nakamura, Eiji Ohtani(Tohoku University)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SCG51-01] Constraining the degassing rate of the mantle since 3 Ga using the deficit of xenon-129 in the ancient atmosphere

★Invited Papers

*Bernard Marty[1], David Bekaert[1], Michael Broadley[1] (1.Centre de Recherches Pétrographiques et Géochimiques/ CNRS - Universite de Lorraine France)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SCG51-02] **Investigating volatile cycles in the terrestrial mantle by incorporating He and Ar isotopes into geodynamical models of mantle convection**

★Invited Papers

*Rosie Ellen Jones[1], Peter van Keken[2], Jonathan M Tucker[2], Chris J Ballentine[1] (1.Department of Earth Sciences, University of Oxford, Oxford, UK, 2.Department of Terrestrial Magnetism, Carnegie Institution of Washington, Washington, USA)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SCG51-03] Fluid circulation in the forearc mantle wedge inferred from the dihedral angle in an olivine-$H_2O$-NaCl system

*Yongsheng HUANG[1], Takayuki Nakatani[1], Michihiko Nakamura[1], Catherine McCammon[2] (1.Graduate School of Science, Tohoku University, 2.Byerisches Geoinstitut, University of Bayreuth)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SCG51-04] The oxygen fugacity of serpentinites: implications for subduction zone redox evolution

*Lisa Eberhard[1], Dan Frost[1], Catherine McCammon[1] (1.BGI)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SCG51-05] Experimental study of the effect of composition on water solubility in natural silicate melts

*Shigeru Yamashita[1] (1.Institute for Planetary Materials, Okayama University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SCG51-06] Deep mantle volatile cycle and plate tectonics: Impact to the climate evolution

*Takashi Nakagawa[1], Shintaro Kadoya[2], Eiichi Tajika[3] (1.Department of Earth Sciences, The University of Hong Kong, 2.Department of Earth and Space Sciences, University of Washington, 3.Department of Earth and Planetary Sciences, The University of Tokyo)

[E] Oral | S (Solid Earth Sciences )：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A11 TOKYO BAY MAKUHARI HALL

## [S-CG51] Role of volatiles on Earth and planetary dynamics

convener:Takayuki Ishii(Bavarian Research Institute, University of Bayreuth), Eiji Ohtani(Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University), Michihiko Nakamura(Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University), Bjorn Mysen(Geophysical Laboratory, Carnegie Inst. Washington), Chairperson:Takayuki Ishii(Bavarian Research Institute, University of Bayreuth), Bjorn Mysen(Carnegie Institution of Washington)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SCG51-07] The nature of water induced small degree melts in the deep mantle

★Invited Papers

*Daniel James Frost[1], Pierre Condamine[3], Davide Novella[2], Rong Huang[1] (1.University of Bayreuth, 2.University of Cambridge, 3.Université de Lorraine)

---

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SCG51-08] **Phase separation of hydrous Vesuvius melt: vesicle nucleation or spinodal decomposition?**

★Invited Papers

*Anja Allabar[1], Marcus Nowak[1] (1.University of Tuebingen)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SCG51-09] Role of water on dynamics in the lower mantle and core-mantle boundary regions

*Eiji Ohtani[1], Takayuki Ishii[2], Liang Yuan[1], Daijo Ikuta[1], Tomoo Katsura[2], Dan Frost[2] (1.Department of Earth and Planetary Materials Science, Graduate School of Science, Tohoku University, 2.Bavarian Research Institute, University of Bayreuth)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SCG51-10] Stability of Fe-bearing hydrous phases and element partitioning in the system MgO-$Al_2O_3$-$Fe_2O_3$-$SiO_2$-$H_2O$ in Earth's lowermost mantle

*Hongsheng Yuan[1], Li Zhang[1], Eiji Ohtani[2], Yue Meng[3], Eran Greenberg[4], Vitali B. Prakapenka [4] (1.Center for High Pressure Science and Technology Advanced Research, 2.Department of Earth Science, Graduate School of Science, Tohoku University, 3.HPCAT, X-Ray Science Division, Argonne National Laboratory, 4.Center for Advanced Radiation Sources, University of Chicago)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SCG51-11] **Laboratory Micro-Seismicity during Serpentinite Deformation as a Potential Analogue for Lower Wadati-Benioff Plane Seismicity**

*Julien Gasc[1,3], Nadège Hilairet[2], Tony Yu[3], Yanbin Wang[3], Thomas P. Ferrand[1], Alexandre Schubnel[1] (1.Laboratoire de Géologie, CNRS - ENS, Paris, FRANCE, 2.Unité Matériaux et Transformations, CNRS - Lille University, Villeneuve d'Ascq, FRANCE, 3.GeoSoilEnviro-CARS, University of Chicago, Argonne IL, USA)

---

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SCG51-12] Water transport and mixing in the whole-mantle scale convection

*Takeo Kaneko[1], Tomoeki Nakakuki[1], Masanori Kameyama[2], Hikaru Iwamori[3] (1.Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2.Geodynamics Research Center, Ehime University, 3.Earthquake Research Institute, University of Tokyo)

[J] Oral | S (Solid Earth Sciences )：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A08 TOKYO BAY MAKUHARI HALL

## [S-CG52] Petrology, Mineralogy & Resource Geology

convener:Tatsuo Nozaki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Satoshi SAITO(Graduate School of Science and Engineering, Ehime University), Koichi Momma(National Museum of Nature and Science), Nobutaka Tsuchiya(Department of Geology, Faculty of Education, Iwate University), Chairperson:Tatsuo Nozaki(JAMSTEC), Satoshi Saito

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

### [SCG52-01] Coordinated sample preparation with cryo-FIB-SEM and X-ray CT: Applications to chemical analysis for fluid inclusions in minerals

*Yu Kodama[1], Naotaka Tomioka[2], Tatsuhiko Kawamoto[3], Junichiro Kuroda[4], Masafumi MURAYAMA[5], Motoo Ito[2] (1.Marine Works Japan Ltd., 2.Kochi Institute for Core Sample Research, JAMSTEC, 3.Department of Geoscience, Faculty of Science, Shizuoka University, 4.Atmosphere and Ocean Research Institute, the University of Tokyo, 5.Faculty of Agriculture and Marine Science, Kochi University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

### [SCG52-02] Feasibility Study for Precise Particle Characterization of Fine Clay Particle Using An Automated Particle Image Analysis and Nanotrakcking Analysis.

*Daisuke Sasakura[1], Aiko Hayauchi[1], Sho Kimura[2] (1.MalvernPanalytical Japan ,Div of Spectris Co.Ltd,., 2.Faculty of Agriculture, University of the Ryukyu)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

### [SCG52-03] Crystal structure and local structures of natural perovskite-type (Na,REE,Ca)(Ti, Nb)$O_3$ loparite by single crystal diffraction and XAFS analyses

*Ginga Kitahara[1], Akira Yoshiasa[1], Makoto Tokuda[1], Kazumasa Sugiyama[2] (1.Kumamoto University, 2.Tohoku University)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

### [SCG52-04] Crystal Size Distributions based on crystal habit of groundmass pyroxene crystals in the ejecta of the Shinmoedake 2011 eruption

*Shota Okumura[1], Mayumi Mujin[2], Akira Tsuchiyama[1], Norimasa Shimobayashi[1], Akira Miyake[1] (1.Department of Geology and Mineralogy, Graduate School of Science, Kyoto University, 2.Division of Earth and Planetary Materials Science, Department of Earth Science, Tohoku University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

### [SCG52-05] Petrochemistry and zircon U-Pb age of ``lateritic'' metamorphic rocks from the Kitakami Mountains

*Nobutaka Tsuchiya[1], Yamato Kumagai[1], Tatsuro Adachi[2], Nobuhiko Nakano[2], Yasuhito Osanai[2] (1.Department of Geology, Faculty of Education, Iwate University, 2.Department of Earth Sciences, Faculty of Social and Cultural Studies, Kyushu University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

### [SCG52-06] How to make 'syn-plutonic dike' - - - Another story from the Ryoke granitic province, Southwest Japan

*Takashi Nakajima[1], Hiroyuki Kamiyama[2], Ian S. Williams[3] (1.Geological Survey of Japan, 2.Ueyama-Shisui, Co. Ltd., 3.Australian National University)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_15

## [S-CG52] Petrology, Mineralogy & Resource Geology

convener:Tatsuo Nozaki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Satoshi SAITO(Graduate School of Science and Engineering, Ehime University), Koichi Momma(National Museum of Nature and Science), Nobutaka Tsuchiya(Department of Geology, Faculty of Education, Iwate University)

[SCG52-P01] Combined microspectroscopic characterization of a red-colored granite rock sample

*Katsuya Okada[1], Satoru Nakashima[1] (1.Department of Earth and Space Science, Graduate School of Science, Osaka University)

[SCG52-P02] Crystal chemistry of synthetic mukhinite, V-analogue of clinozoisite, on the join $Ca_2Al_3Si_3O_{12}(OH)$-$Ca_2Al_2VSi_3O_{12}(OH)$

*Mariko Nagashima[1], Daisuke Nishio-Hamane[2], Nobuhiko Nakano[3], Toshisuke Kawasaki[4] (1.Graduate school of Sciences and Technology for Innovation, Yamaguchi University, 2.The institute for Solid State Physics, the University of Tokyo, 3.Department of Environmental Changes, Faculty of Social and Cultural Studies, Kyushu University, 4.Faculty of Science, Ehime University)

[SCG52-P03] High temperature In-situ TEM observation of crystallization in Sakurajima volcanic glass

*Akira Miyake[1], Shota Okumura[1] (1.Department of Geology and Mineralogy, Graduate School of Science, Kyoto University)

[SCG52-P04] Timing of intrusion and Sr isotopic composition of granodiorite porphyrites in the Noko Island, western part of northern Kyushu

*Masaki Yuhara[1], Yoshinobu Kawano[2], Osamu Okano[3] (1.Department of Earth System Science, Faculty of Science, Fukuoka University, 2.Department of Environment Systems, Faculty of Geo-environmental Science, Rissho University, 3.Department of Earth Sciences, Faculty of Science, Okayama University)

[SCG52-P05] Petrological study of crystallization process of a composite dike in the Ryoke belt (Mie Prefecture, SW Japan)

*Ayu Yamazaki[1], Tetsuo Kawakami[1], Fumiko Higashino[2] (1.Department of Geology and Mineralogy, Graduate school of Science, Kyoto University , 2.Graduate school of Environmental Studies, Tohoku University)

[SCG52-P06] Petrography and Zircon U-Pb ages of the Ryoke Granitoids distributed in the Takanawa Peninsula, Ehime Prefecture.

*Kazuya Shimooka[1], Satoshi SAITO[1], Kenichiro Tani[2] (1.Graduate School of Science and Engineering, Ehime University, 2.Department of Geology and Paleontology, National Museum of Nature and Science)

[SCG52-P07] Neoproterozoic arc magmatism and high-grade metamorphism of the basement rocks in southern Malawi

*Toshiaki Tsunogae[1], Sam Uthup[1], Mzee Wandembo Nyirongo[2], Md. Sazzadur Rahman[1], Yusuke Takamura[1], Kazuki Takahashi[1] (1.University of Tsukuba, 2.Malawi University of Science and Technology)

[SCG52-P08] Geochemical features of Quaternary rhyolitic magma and xenolith from Hime-shima volcanic group

*Takehiro Hirayama[1], Tomoyuki Shibata[1], Masako Yoshikawa[1], Yasutaka Hayasaka[1], Keiji Takemura[2] (1.Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2.Kyoto university)

[SCG52-P09] Petrological study on the intrusive contact of a Setouchi volcanic rock dike in the Nakajima Island, Ehime Prefecture

*Taiki Omori[1], Satoshi SAITO[2] (1.Department of Earth Science, Faculty of Science, Ehime University , 2.Department of Earth Science, Graduate Schoole of Science, Ehime University)

[SCG52-P10] **Fundamental evaluation for making simulated sea bed floc**

*AIKO HAYAUCHI[1], Daisuke Sasakura[1], Hisato Yasuda[2], Shinya Nakamura[3], Sho Kimura[3], Shohei Noda[4] (1.Malvern Panalytical division of Spectris Co., Ltd, 2.Kochi University, 3.UNIVERSITY OF THE RYUKYU, 4.TOKYO UNIVESITY OF SCIENCE)

[SCG52-P11] Petrology of the Morobe Granodiorite in the Kuper Range, Morobe Province, Papua New Guinea

Angela Lynett Bokuik[1], *Takashi Hoshide[1] (1.Faculty of International Resource Sciences, Akita University)

---

[SCG52-P12] Sr–Nd isotopic compositions of the San-yo Belt, Southwest Japan: Implications for the Cretaceous enriched mantle

*Shogo Kodama[1], Masaaki Owada[1], Teruyoshi Imaoka[1], Atsushi Kamei[2] (1.Yamaguchi University, 2.Shimane University)

---

[SCG52-P13] Lithological variation of massive serpentinites in marginal zone of serpentinite body in Kamuikotan belt, Hokkaido, Japan: Analysis of advanced-boring cores for tunnel construction

*Shusaku Yamazaki[1], Kenji Okazaki[1], Toshiyuki Kurahashi[1] (1.Civil Engineering Research Institute for Cold Region, Public Works Research Institute, National Research and Development Agancy)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_28

## [S-CG52] Petrology, Mineralogy & Resource Geology

convener:Tatsuo Nozaki(Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology), Satoshi SAITO(Graduate School of Science and Engineering, Ehime University), Koichi Momma(National Museum of Nature and Science), Nobutaka Tsuchiya(Department of Geology, Faculty of Education, Iwate University)

[SCG52-P01] Combined microspectroscopic characterization of a red-colored granite rock sample

*Katsuya Okada[1], Satoru Nakashima[1] (1.Department of Earth and Space Science, Graduate School of Science, Osaka University)

[SCG52-P02] Crystal chemistry of synthetic mukhinite, V-analogue of clinozoisite, on the join $Ca_2Al_3Si_3O_{12}(OH)$-$Ca_2Al_2VSi_3O_{12}(OH)$

*Mariko Nagashima[1], Daisuke Nishio-Hamane[2], Nobuhiko Nakano[3], Toshisuke Kawasaki[4] (1.Graduate school of Sciences and Technology for Innovation, Yamaguchi University, 2.The institute for Solid State Physics, the University of Tokyo, 3.Department of Environmental Changes, Faculty of Social and Cultural Studies, Kyushu University, 4.Faculty of Science, Ehime University)

[SCG52-P03] High temperature In-situ TEM observation of crystallization in Sakurajima volcanic glass

*Akira Miyake[1], Shota Okumura[1] (1.Department of Geology and Mineralogy, Graduate School of Science, Kyoto University)

[SCG52-P04] Timing of intrusion and Sr isotopic composition of granodiorite porphyrites in the Noko Island, western part of northern Kyushu

*Masaki Yuhara[1], Yoshinobu Kawano[2], Osamu Okano[3] (1.Department of Earth System Science, Faculty of Science, Fukuoka University, 2.Department of Environment Systems, Faculty of Geo-environmental Science, Rissho University, 3.Department of Earth Sciences, Faculty of Science, Okayama University)

[SCG52-P05] Petrological study of crystallization process of a composite dike in the Ryoke belt (Mie Prefecture, SW Japan)

*Ayu Yamazaki[1], Tetsuo Kawakami[1], Fumiko Higashino[2] (1.Department of Geology and Mineralogy, Graduate school of Science, Kyoto University , 2.Graduate school of Environmental Studies, Tohoku University)

[SCG52-P06] Petrography and Zircon U-Pb ages of the Ryoke Granitoids distributed in the Takanawa Peninsula, Ehime Prefecture.

*Kazuya Shimooka[1], Satoshi SAITO[1], Kenichiro Tani[2] (1.Graduate School of Science and Engineering, Ehime University, 2.Department of Geology and Paleontology, National Museum of Nature and Science)

[SCG52-P07] Neoproterozoic arc magmatism and high-grade metamorphism of the basement rocks in southern Malawi

*Toshiaki Tsunogae[1], Sam Uthup[1], Mzee Wandembo Nyirongo[2], Md. Sazzadur Rahman[1], Yusuke Takamura[1], Kazuki Takahashi[1] (1.University of Tsukuba, 2.Malawi University of Science and Technology)

[SCG52-P08] Geochemical features of Quaternary rhyolitic magma and xenolith from Hime-shima volcanic group

*Takehiro Hirayama[1], Tomoyuki Shibata[1], Masako Yoshikawa[1], Yasutaka Hayasaka[1], Keiji Takemura[2] (1.Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2.Kyoto university)

[SCG52-P09] Petrological study on the intrusive contact of a Setouchi volcanic rock dike in the Nakajima Island, Ehime Prefecture

*Taiki Omori[1], Satoshi SAITO[2] (1.Department of Earth Science, Faculty of Science, Ehime University , 2.Department of Earth Science, Graduate Schoole of Science, Ehime University)

[SCG52-P10] **Fundamental evaluation for making simulated sea bed floc**

*AIKO HAYAUCHI[1], Daisuke Sasakura[1], Hisato Yasuda[2], Shinya Nakamura[3], Sho Kimura[3], Shohei Noda[4] (1.Malvern Panalytical division of Spectris Co., Ltd, 2.Kochi University, 3.UNIVERSITY OF THE RYUKYU, 4.TOKYO UNIVESITY OF SCIENCE)

[SCG52-P11] Petrology of the Morobe Granodiorite in the Kuper Range, Morobe Province, Papua New Guinea

Angela Lynett Bokuik[1], *Takashi Hoshide[1] (1.Faculty of International Resource Sciences, Akita University)

[SCG52-P12] Sr–Nd isotopic compositions of the San-yo Belt, Southwest Japan: Implications for the Cretaceous enriched mantle

*Shogo Kodama[1], Masaaki Owada[1], Teruyoshi Imaoka[1], Atsushi Kamei[2] (1.Yamaguchi University, 2.Shimane University)

[SCG52-P13] Lithological variation of massive serpentinites in marginal zone of serpentinite body in Kamuikotan belt, Hokkaido, Japan: Analysis of advanced-boring cores for tunnel construction

*Shusaku Yamazaki[1], Kenji Okazaki[1], Toshiyuki Kurahashi[1] (1.Civil Engineering Research Institute for Cold Region, Public Works Research Institute, National Research and Development Agancy)

[J] Oral | S (Solid Earth Sciences )：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | A05 TOKYO BAY MAKUHARI HALL

## [S-CG53] Environment formed and maintained by active faults

convener:Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Makoto Yamano(Earthquake Research Institute, the University of Tokyo), Takafumi Kasaya(Japan Agency for Marine-Earth Science and Technology), Hideki Hamamoto(Center for Environmental Science in Saitama), Chairperson:NAOJI KOIZUMI, TADANORI GOTO(Graduate School of Engineering, Kyoto University)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[SCG53-01] **Effect of the Hanaore fault and Biwako-seigan fault on the water quality of the Ado river in Shiga Prefecture**

*Naoji Koizumi[1], Masahiro Ueda[1], Shinsuke Minote[1], Tatsuya Tanaka[1], Masahiro Maruo[1], Kanto Mitani[2] (1.School of Environmental Science,the University of Shiga Prefecture, 2.Daikokuten Bussan Co., Ltd.)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[SCG53-02] **Hydrothermal vents in the deep basin of Lake Biwa**

★Invited Papers

*Michio Kumagai[1] (1.Ritsumeikan University)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[SCG53-03] Heat flow anomalies observed on the seafloor in the vicinity of faults: indication of fluid flow

*Makoto Yamano[1], Shusaku Goto[2], Yoshifumi Kawada[3], Hideki Hamamoto[4] (1.Earthq. Res. Inst., Univ. Tokyo, 2.Geol. Surv. Japan, AIST, 3.IRIDeS, Tohoku Univ., 4.Center Environ. Sci. Saitama)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[SCG53-04] How can we quantify the hydraulic permeability of fault based on geophysical survey?

*Tada-nori Goto[1], Sota Kawaguchi[1] (1.Graduate School of Engineering, Kyoto University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[SCG53-05] Healing process of the Nojima Fault zone after 1995 Hyogo-ken Nanbu earthquake

*Hideki Murakami[1], Naoto Oshiman[2], Ryokei Yoshimura[2], Tsutomu Miura[2], Masato Kamo[2] (1.Research and Education Faculty,Kochi University, 2.Disaster Prevention Research Institute,Kyoto University)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[SCG53-06] Discussion on the environment formed and maintained by active faults

*Naoji Koizumi[1] (1.School of Environmental Science,the University of Shiga Prefecture)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_16

## [S-CG53] Environment formed and maintained by active faults

convener:Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Makoto Yamano(Earthquake Research Institute, the University of Tokyo), Takafumi Kasaya(Japan Agency for Marine-Earth Science and Technology), Hideki Hamamoto(Center for Environmental Science in Saitama)

### [SCG53-P01] Heat flow measurement in Lake Biwa

*Hideki Hamamoto[1], Makoto Yamano[2] (1.Center for Environmental Science in Saitama, 2.Earthquake Research Institute, University of Tokyo)

### [SCG53-P02] Shallow Resistivity Structure across the Futagawa-Fault Nishihara Area and the Reliability

*Tada-nori Goto[1], Hisatoshi Koji[1], Sota Kawaguchi[1], Satoru Yamaguchi[2], Yuto Yamalaka[2], Daigo Furukawa[2], Koki Aizawa[3] (1.Graduate School of Engineering, Kyoto University, 2.Graduate School of Science, Osaka City University, 3.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University)

### [SCG53-P03] Detailed topography and sub-surface structure around the 2016 Fukushima Earthquake

*Takafumi Kasaya[1], Toshiya Fujiwara[1], Toshiya Kanamatsu[1], Katsunori FUJIKURA[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_29

## [S-CG53] Environment formed and maintained by active faults

convener:Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Makoto Yamano(Earthquake Research Institute, the University of Tokyo), Takafumi Kasaya(Japan Agency for Marine-Earth Science and Technology), Hideki Hamamoto(Center for Environmental Science in Saitama)

### [SCG53-P01] Heat flow measurement in Lake Biwa

*Hideki Hamamoto[1], Makoto Yamano[2] (1.Center for Environmental Science in Saitama, 2.Earthquake Research Institute, University of Tokyo)

### [SCG53-P02] Shallow Resistivity Structure across the Futagawa-Fault Nishihara Area and the Reliability

*Tada-nori Goto[1], Hisatoshi Koji[1], Sota Kawaguchi[1], Satoru Yamaguchi[2], Yuto Yamalaka[2], Daigo Furukawa[2], Koki Aizawa[3] (1.Graduate School of Engineering, Kyoto University, 2.Graduate School of Science, Osaka City University, 3.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University)

### [SCG53-P03] Detailed topography and sub-surface structure around the 2016 Fukushima Earthquake

*Takafumi Kasaya[1], Toshiya Fujiwara[1], Toshiya Kanamatsu[1], Katsunori FUJIKURA[1] (1.Japan Agency for Marine-Earth Science and Technology)

[J] Oral | S (Solid Earth Sciences )：S-CG Complex & General

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A11 TOKYO BAY MAKUHARI HALL

## [S-CG55] Crustal fluids and deformation

convener:Yuichi Kitagawa(Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Koji Umeda(Hirosaki University), Fumiaki Tsunomori(Geochemical Research Center, Graduate School of Science, University of Tokyo), Chairperson:Yuichi Kitagawa(産業技術総合研究所地質調査総合センター地震地下水研究グループ), Fumiaki Tsunomori(東京大学大学院理学系研究科地殻化学実験施設)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

### [SCG55-01] Estimation of fault models of the short-term SSE using groundwater pressures at the Hokusei observation site

*Yuichi Kitagawa[1], Norio Matsumoto[1] (1.Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

---

9:15 AM - 9:35 AM JST | 12:15 AM - 12:35 AM UTC

### [SCG55-02] Groundwater level changes during the 2018 Hokkaido Eastern Iburi earthquake

★Invited Papers

*Tomo Shibata[1], Ryo Takahashi[2], Hiroaki Takahashi[3], Takanori Kagoshima[4], Yuji Sano[4], Daniele Pinti[5] (1.Graduate School of Science, Kyoto University, 2.Geological Survey of Hokkaido, Hokkaido Research Organization, 3.Graduate School of Science, Hokkaido University, 4.Atmosphere and Ocean Research Institute, The University of Tokyo, 5.GEOTOP, Université du Québec)

---

9:35 AM - 9:50 AM JST | 12:35 AM - 12:50 AM UTC

### [SCG55-03] Postseismic streamflow changes after the 2016 Kumamoto earthquake

*Naoji Koizumi[1], Shinsuke Minote[1], Tatusya Tanaka[1] (1.School of Environmental Science,the University of Shiga Prefecture)

---

9:50 AM - 10:05 AM JST | 12:50 AM - 1:05 AM UTC

### [SCG55-04] Development of Radium Concentration Monitoring System based on Gamma-Ray Spectroscopy

*Fumiaki Tsunomori[1], Shigekazu Nagai[2], Junji Yoshii[3], Yoshihide Kimura[4], Yoriyuki Kamakura[5], Yuki Inoue[5], Norihito Sato[6], Shiro Sakuragi[7], Ryuichi Shimizu[8], V N Gluchschenko[9] (1.Geochemical Research Center, Graduate School of Science, University of Tokyo, 2.Graduate School of Engineering, Mie University, 3.Advanced Clinical Research Center, Fukushima Medical University, 4.Graduate School of Engineering, Osaka University, 5.Faculty of Information Science and Technology, Osaka Institute of Technology, 6.Chiyoda Technol corp., 7.Union Material Inc., 8.Office for University-Industry Collaboration, Osaka University, 9.Institute of Nuclear Physics, Almaty, Republic of Kazakhstan)

---

10:05 AM - 10:25 AM JST | 1:05 AM - 1:25 AM UTC

### [SCG55-05] $^{222}$Rn concentration distribution in Yatsushiro Sea

★Invited Papers

*Kuniyo Kawabata[1], Fumiaki Tsunomori[2], Yujin Kitamura[1], Hakuho-Maru K18-3 scientists (1.Graduate School of Science and Engineering, KAGOSHIMA UNIVERSITY, 2.Geochemical Research Center, Graduate School of Science, University of Tokyo)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_17

## [S-CG55] Crustal fluids and deformation

convener:Yuichi Kitagawa(Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Koji Umeda(Hirosaki University), Fumiaki Tsunomori(Geochemical Research Center, Graduate School of Science, University of Tokyo)

[SCG55-P01] Application of slug test model to earthquake-related groundwater-level change in the Oi well Kanagawa Prefecture, Center Japan

*Yang Li[1], Motoo Ukawa[1], Kazuhiro Itadera[2], Masatake Harada[2] (1.Nihon University, 2.Hot Spring Research Institute of Kanagawa Prefecture)

[SCG55-P02] Changes in groundwater level and borehole strain data associated with the 2018 Osaka Hokubu earthquake (M6.1) at the Takarazuka observatory

*Norio Matsumoto[1], Tsutomu Kiguchi[1] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST))

[SCG55-P03] Changes in groundwater level at the Kusanagi observatory

*Norio Matsumoto[1] (1.Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST))

[SCG55-P04] Spatial and temporal changes of $^{3}He/^{4}He$ ratios around a source region before and after an inland earthquake

*Koji Umeda[1] (1.Hirosaki University)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_30

## [S-CG55] Crustal fluids and deformation

convener:Yuichi Kitagawa(Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Naoji Koizumi(School of Environmental Science,the University of Shiga Prefecture), Koji Umeda(Hirosaki University), Fumiaki Tsunomori(Geochemical Research Center, Graduate School of Science, University of Tokyo)

[SCG55-P01] Application of slug test model to earthquake-related groundwater-level change in the Oi well Kanagawa Prefecture, Center Japan

*Yang Li[1], Motoo Ukawa[1], Kazuhiro Itadera[2], Masatake Harada[2] (1.Nihon University, 2.Hot Spring Research Institute of Kanagawa Prefecture)

[SCG55-P02] Changes in groundwater level and borehole strain data associated with the 2018 Osaka Hokubu earthquake (M6.1) at the Takarazuka observatory

*Norio Matsumoto[1], Tsutomu Kiguchi[1] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST))

[SCG55-P03] Changes in groundwater level at the Kusanagi observatory

*Norio Matsumoto[1] (1.Tectono-Hydrology Research Group, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST))

[SCG55-P04] Spatial and temporal changes of $^{3}He/^{4}He$ ratios around a source region before and after an inland earthquake

*Koji Umeda[1] (1.Hirosaki University)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

## [S-CG58] Brittle-Ductile Transition and Supercritical Geofluids for Crustal Energy in Island Arc

convener:Noriyoshi Tsuchiya(Graduate School of Environmental Studies, Tohoku University), Hiroshi Asanuma(AIST), Yasuo Ogawa(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Shigemi Naganawa(Akita University)

[SCG58-P01] Mechanical and hydrological properties of granite under supercritical fluid conditions

*Manami Kitamura[1], Miki Takahashi[1] (1.National Institute of Advanced Industrial Science and Technology)

[SCG58-P02] Three-dimensional electrical resistivity structure of kuju Volcano, Central Kyushu, Japan revealed by Magnetotelluric survey data

*Sabry Abdallah[1], Mitsuru Utsugi [1], Koki Aizawa[2], Makoto Uyeshima[3], Wataru Kanda[4], Takao Koyama[3] (1.Institute of geothermal science, Faculty of Science, Kyoto University, 2.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University, 3.Earthquake Research Institute, The University of Tokyo, 4.Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology)

[SCG58-P03] Preliminary Report on Themoluminescence Geothermal Exploration in Northern Area of Mt. Kurikoma (Akayumata-River), NE Japan.

*Hiroki Okano[1], Nobuo Hirano[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies Tohoku University)

[SCG58-P04] Experimental Study of Critical Point Determination for Multicomponent Fluids using light-scattering Spectroscopic Method

*Nobuo Hirano[1], Yuta Oshima[1], Atsushi Okamoto[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental studies, Tohoku University)

[SCG58-P05] Transport and Reaction Behavior of Supercritical Geofluid Revealed by Porphyry Copper Deposit

*Geri Agroli[1], Noriyoshi Tsuchiya[1] (1.Tohoku University)

[SCG58-P06] Characteristics of precipitation of amorphous silica and its influences on permeability of fractured granite in superhot geothermal environments

*Hikaru Abe[1], Noriaki Watanabe[1], Kengo Nakamura[1], Atsushi Okamoto[1], Takeshi Komai[1] (1.Graduate School of Environmental Studies, Tohoku University)

[SCG58-P07] **Evolution and The Total Budget of Fluid in Granitic Magma through Magmatism and Volcanism in The Subduction Zone, NE Japan**

*Fajar Febiani Amanda[1], Ryoichi Yamada[2], Satoshi Okumura[2], Masaoki Uno[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University, 2.Graduate School of Science, Tohoku University)

[SCG58-P08] **Porosity generation during feldspar replacement as the mark of potassium-rich supercritical fluids on the top of granitic intrusion**

*Astin Nurdiana[1], Atsushi Okamoto[1], Masaoki Uno[1], Kenta Yoshida[2], Noriyoshi Tsuchiya[1] (1.Tohoku University, 2.Japan Agency for Marine-earth Science and Technology)

[SCG58-P09] Quantitative evaluation of fracture distribution in granite and the relationship between fracture distribution and physical properties

*Manami Kadono[1], Shin-ichi Uehara[2], Miki Takahashi[3], Manami Kitamura[3] (1.Department of Environment Systems, Graduate School of frontier Science, The University of Tokyo, 2.Department of Enviroment Science, Faculty of Science, Toho University, 3.National Institute of Advanced Industrial Science and Technology)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_31

## [S-CG58] Brittle-Ductile Transition and Supercritical Geofluids for Crustal Energy in Island Arc

convener:Noriyoshi Tsuchiya(Graduate School of Environmental Studies, Tohoku University), Hiroshi Asanuma(AIST), Yasuo Ogawa(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Shigemi Naganawa(Akita University)

[SCG58-P01] Mechanical and hydrological properties of granite under supercritical fluid conditions

*Manami Kitamura[1], Miki Takahashi[1] (1.National Institute of Advanced Industrial Science and Technology)

---

[SCG58-P02] Three-dimensional electrical resistivity structure of kuju Volcano, Central Kyushu, Japan revealed by Magnetotelluric survey data

*Sabry Abdallah[1], Mitsuru Utsugi [1], Koki Aizawa[2], Makoto Uyeshima[3], Wataru Kanda[4], Takao Koyama[3] (1.Institute of geothermal science, Faculty of Science, Kyoto University, 2.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University, 3.Earthquake Research Institute, The University of Tokyo, 4.Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology)

---

[SCG58-P03] Preliminary Report on Themoluminescence Geothermal Exploration in Northern Area of Mt. Kurikoma (Akayumata-River), NE Japan.

*Hiroki Okano[1], Nobuo Hirano[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies Tohoku University)

---

[SCG58-P04] Experimental Study of Critical Point Determination for Multicomponent Fluids using light-scattering Spectroscopic Method

*Nobuo Hirano[1], Yuta Oshima[1], Atsushi Okamoto[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental studies, Tohoku University)

---

[SCG58-P05] Transport and Reaction Behavior of Supercritical Geofluid Revealed by Porphyry Copper Deposit

*Geri Agroli[1], Noriyoshi Tsuchiya[1] (1.Tohoku University)

---

[SCG58-P06] Characteristics of precipitation of amorphous silica and its influences on permeability of fractured granite in superhot geothermal environments

*Hikaru Abe[1], Noriaki Watanabe[1], Kengo Nakamura[1], Atsushi Okamoto[1], Takeshi Komai[1] (1.Graduate School of Environmental Studies, Tohoku University)

---

[SCG58-P07] **Evolution and The Total Budget of Fluid in Granitic Magma through Magmatism and Volcanism in The Subduction Zone, NE Japan**

*Fajar Febiani Amanda[1], Ryoichi Yamada[2], Satoshi Okumura[2], Masaoki Uno[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University, 2.Graduate School of Science, Tohoku University)

---

[SCG58-P08] **Porosity generation during feldspar replacement as the mark of potassium-rich supercritical fluids on the top of granitic intrusion**

*Astin Nurdiana[1], Atsushi Okamoto[1], Masaoki Uno[1], Kenta Yoshida[2], Noriyoshi Tsuchiya[1] (1.Tohoku University, 2.Japan Agency for Marine-earth Science and Technology)

---

[SCG58-P09] Quantitative evaluation of fracture distribution in granite and the relationship between fracture distribution and physical properties

*Manami Kadono[1], Shin-ichi Uehara[2], Miki Takahashi[3], Manami Kitamura[3] (1.Department of Environment Systems, Graduate School of frontier Science, The University of Tokyo, 2.Department of Enviroment Science, Faculty of Science, Toho University, 3.National Institute of Advanced Industrial Science and Technology)

[J] Oral | S (Solid Earth Sciences )：S-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A09 TOKYO BAY MAKUHARI HALL

## [S-CG58] Brittle-Ductile Transition and Supercritical Geofluids for Crustal Energy in Island Arc

convener:Noriyoshi Tsuchiya(Graduate School of Environmental Studies, Tohoku University), Hiroshi Asanuma(AIST), Yasuo Ogawa(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Shigemi Naganawa(Akita University), Chairperson:Noriyoshi Tsuchiya, Atsushi Okamoto

1:45 PM - 1:55 PM JST | 4:45 AM - 4:55 AM UTC

[SCG58-01] Supercritical Geothermal Resources as a Function of Mass and Energy Transport in Subduction Zone

*Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University)

1:55 PM - 2:05 PM JST | 4:55 AM - 5:05 AM UTC

[SCG58-02] Outline of NEDO Supercritical Geothermal Project

*Hiroshi Asanuma[1] (1.AIST)

2:05 PM - 2:30 PM JST | 5:05 AM - 5:30 AM UTC

[SCG58-03] Mineral precipitation/dissolution from water and brine with decreasing temperatures along hydrostatic pressures

★Invited Papers

*Kenichi Hoshino[1] (1.Department of Earth and Planetary Systems Science, Hiroshima University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SCG58-04] Thermodynamic data of aqueous species for supercritical water–rock interaction: dissolution experiments and density-based extrapolation

*Atsushi Okamoto[1], Hajime Ishii[1], Ryosuke Oyanagi[2], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, 2.JAMSTEC)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SCG58-05] Nitrogen isotope ratios of ammonium in hypersaline hot spring waters distributed along Arima-Takatsuki fault zone.

*Kazuhiro Amita[1], Takashi Nakamura[2], Shinji Ohsawa[3] (1.Faculty of Engineering Science, Akita University, 2.International Research Center for River Basin Environment, University of YAMANASHI, 3.Institute for Geothermal Sciences, Graduate School of Science, Kyoto University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SCG58-06] **Crustal fluid pressure gradients and permeability estimated from fluid-rock reaction zones**

*Masaoki Uno[1], Diana Mindaleva[1], Noriyoshi Tsuchiya[1] (1.Graduate School of Environmental Studies, Tohoku University)

[J] Oral | S (Solid Earth Sciences )：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A09 TOKYO BAY MAKUHARI HALL

## [S-CG58] Brittle-Ductile Transition and Supercritical Geofluids for Crustal Energy in Island Arc

convener:Noriyoshi Tsuchiya(Graduate School of Environmental Studies, Tohoku University), Hiroshi Asanuma(AIST), Yasuo Ogawa(Volcanic Fluid Research Center, School of Science, Tokyo Institute of Technology), Shigemi Naganawa(Akita University), Chairperson:Noriyoshi Tsuchiya

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SCG58-07] 3D S-wave velocity structure in volcanic region using surface-wave tomography

*Hiro Nimiya[1], Tatsunori Ikeda[1], Takeshi Tsuji[1] (1.Kyushu University)

---

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SCG58-08] Resistivity-Based Temperature and Permeability Estimation of the Kakkonda Geothermal Field, Japan, Using a Neural Network

*Ugou Tsubasa[1], Kazuya Ishitsuka[2], Toru Mogi[3] (1.Department of Socio-Environmental Engineering Scool of Engineering Hokkaido University, 2.Division of Urban Management, Grduate School of Engineering, Kyoto University, 3.Division of Sustinable Resources Enginieering, Faculty of Engineering, Hokkaido University)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SCG58-09] Preliminary report on geothermal structure revealed by geological and MT surveys around Akayumatasawa river in Sanzugawa caldera, NE Japan

*Keishi Nunohara[1], Kuo Hsuan Tseng[2], Hiroki Okano[1], Yasuo Ogawa[2], Noriyoshi Tsuchiya[1] (1.Graduate school of Environmental Studies Tohoku University , 2.Graduate school of Science , Tokyo Institute of Technology)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SCG58-10] Characterization of hydraulic fracturing phenomena in supercritical geothermal environments revealed by elastic wave measurements

*Miura Takahiro[1], Noriaki Watanabe[1], Kiyotoshi Sakaguchi[1], Ryota Goto, Kota Yamane, Takeshi Komai[1], Youqing CHEN[2], Takuya ISHIBASHI[3], Noriyoshi Tsuchiya[1] (1. Graduate School of Environmental Studies, Tohoku University, 2.Graduate School of Energy Science, Kyoto University, 3.AIST, FREA)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SCG58-11] Experimental measurements of transport pore radius of thermally cracked granite and the relationship of pore structure to permeability

*Sueyoshi Kazumasa[1], Tadashi Yokoyama[2], Ikuo Katayama[1] (1.Department of Earth and Planetary Systems Science, Hiroshima University, 2.Graduate School of Integrated Arts and Sciences, Hiroshima University)

---

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SCG58-12] Geothermal reservoir evaluation by using TL of Quartz and Fluid Flow Simulation Model of the Kakkonda system in Japan

*Alvaro Josue Amaya[1], Nobuo Hirano[1], Noriyoshi Tsuchiya[1] (1.Tohoku University. Graduate School of Environmental Studies)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_8

## [S-CG59] Reducing risks from earthquakes, tsunamis & volcanoes: new applications of realtime geophysical data

convener:Masashi Ogiso(Meteorological Research Institute, Japan Meteorological Agency), Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Satoshi Kawamoto(Geospatial Information Authority of Japan), Mitsuyuki Hoshiba(Meteorological Research Institute)

[SCG59-P01] Numerical Shake Prediction for earthquake early warning: prediction of distant future using Green function method

*Mitsuyuki Hoshiba[1] (1.Meteorological Research Institute)

[SCG59-P02] Introduction of forward scattering model into the Numerical Shake Prediction scheme

*Masashi Ogiso[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

[SCG59-P03] Magnitude estimation by using ocean-bottom pressure gauge data

*Takeshi Nakamura[1], Eiichiro Araki[2], Narumi Takahashi[1], Kensuke Suzuki[2], Shunroku Yamamoto[3], Masahiro Korenaga[3], Shunta Noda[3] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Japan Agency for Marine-Earth Science and Technology, 3.Railway Technical Research Institute)

[SCG59-P04] Calculation of tsunami propagation by applying ray tracing based on the shortest path method to tsunamis

*Shoji Sekiguchi[1] (1.National Research Institute for Earth Science and Disaster Prevention)

[SCG59-P05] Derivation of the series expansion of Kajiura filter, Green's function of a tsunami

*Nobuki Kame[1], Tetsuya Kusakabe[1], Shingo Watada[1] (1.Earthquake Research Institute, the University of Tokyo)

[J] Poster | S (Solid Earth Sciences )：S-CG Complex & General

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_32

## [S-CG59] Reducing risks from earthquakes, tsunamis & volcanoes: new applications of realtime geophysical data

convener:Masashi Ogiso(Meteorological Research Institute, Japan Meteorological Agency), Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Satoshi Kawamoto(Geospatial Information Authority of Japan), Mitsuyuki Hoshiba(Meteorological Research Institute)

[SCG59-P01] Numerical Shake Prediction for earthquake early warning: prediction of distant future using Green function method

*Mitsuyuki Hoshiba[1] (1.Meteorological Research Institute)

[SCG59-P02] Introduction of forward scattering model into the Numerical Shake Prediction scheme

*Masashi Ogiso[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

[SCG59-P03] Magnitude estimation by using ocean-bottom pressure gauge data

*Takeshi Nakamura[1], Eiichiro Araki[2], Narumi Takahashi[1], Kensuke Suzuki[2], Shunroku Yamamoto[3], Masahiro Korenaga[3], Shunta Noda[3] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Japan Agency for Marine-Earth Science and Technology, 3.Railway Technical Research Institute)

[SCG59-P04] Calculation of tsunami propagation by applying ray tracing based on the shortest path method to tsunamis

*Shoji Sekiguchi[1] (1.National Research Institute for Earth Science and Disaster Prevention)

[SCG59-P05] Derivation of the series expansion of Kajiura filter, Green's function of a tsunami

*Nobuki Kame[1], Tetsuya Kusakabe[1], Shingo Watada[1] (1.Earthquake Research Institute, the University of Tokyo)

[J] Oral | S (Solid Earth Sciences )：S-CG Complex & General

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A08 TOKYO BAY MAKUHARI HALL

## [S-CG59] Reducing risks from earthquakes, tsunamis & volcanoes: new applications of realtime geophysical data

convener:Masashi Ogiso(Meteorological Research Institute, Japan Meteorological Agency), Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Satoshi Kawamoto(Geospatial Information Authority of Japan), Mitsuyuki Hoshiba(Meteorological Research Institute), Chairperson:Mitsuyuki Hoshiba(Meteorological Res. Inst., JMA, Japan), Satoshi Kawamoto(Geospatial Information Authority of Japan )

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[SCG59-01] Earthquake early warning in the United States and beyond

★Invited Papers

*Richard M Allen[1] (1.University of California Berkeley)

---

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[SCG59-02] Study on the relationship between seismometer site environment and earthquake early warning seismic parameter estimation accuracy

*Katsutomo Niwa[1], Naoyasu Iwata[1], Shunroku Yamamoto[1] (1.Railway Technical Research Institute)

---

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[SCG59-03] **Prediction of surface ground motion using underground seismic records based on data assimilation (2)**

*Masaya Ishihara[1], Hisashi Nakahara[1] (1.Solid Earth Physics Laboratory, Department of Geophysics, Graduate School of Science, Tohoku University)

---

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[SCG59-04] Development of Realtlime Long-Period Ground-Motion Prediction System and Demonstration Experiment

★Invited Papers

*Shin Aoi[1], Takeshi Kimura[1], Takashi Kunugi[1], Wataru Suzuki[1], Yadab Prasad Dhakal[1], Naoto Kojya[2] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Japan Meteorological Agency)

---

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[SCG59-05] Real-time forecasting of long-period ground motions for the Nankai Trough earthquake: The effectivity of the Green function-based data assimilation method

*Atsuki Oba[1], Takashi Furumura[1], Takuto Maeda[2] (1.Earthquake Research Institute, University of Tokyo, 2.Graduate School of Science and Technology, Hirosaki University)

---

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[SCG59-06] Development of EEW system exchanging real-time seismic intensity and seismic waveform

*Shigeki Horiuchi[1], Yuko Sato[1], Taku Urabe[2], Yamaimaiti Nizhamudong[3], Kazuo Sasaki[3] (1.Home Seismometer Corporation, 2.telemetra , 3.Challenge)

[J] Oral | S (Solid Earth Sciences )：S-CG Complex & General

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A08 TOKYO BAY MAKUHARI HALL

## [S-CG59] Reducing risks from earthquakes, tsunamis & volcanoes: new applications of realtime geophysical data

convener:Masashi Ogiso(Meteorological Research Institute, Japan Meteorological Agency), Naotaka YAMAMOTO CHIKASADA(National Research Institute for Earth Science and Disaster Resilience), Satoshi Kawamoto(Geospatial Information Authority of Japan), Mitsuyuki Hoshiba(Meteorological Research Institute), Chairperson:Naotaka Chikasada(National Res. Inst. for Earth Science and Disaster Resilience), Masashi Ogiso(Meteorological Research Institute, JMA)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[SCG59-07] Enhancements of real time seismic intensity estimation using seismic intensity meters maintained by a local government – Case study on Tottori prefecture -

*Takao Kagawa[1] (1.Tottori University Graduate School of Engineering)

---

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[SCG59-08] **Drawig of the realtime seismic intesity on live screen and maximum distribution map for the Earthquak disaster prevension.**
**-Planar indication of seismic intensity using surface ground amplification factor-**

*Kenji Kanjo[1], Isao Takahashi[1], Yoshinori Shinohara[1], Rami Ibrahim[2] (1.Takamisawa cybernetics Co. Ltd, 2.Earthquake Research Institute, University of Tokyo)

---

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[SCG59-09] Improvements of the GEONET real-time analysis system (REGARD) for more reliable operation

*Kazuyuki Ohashi[1], Satoshi Abe[1], Yasuaki Kakiage[1], Satoshi Kawamoto[1], Hiroshi Munekane[1] (1.GSI of Japan)

---

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[SCG59-10] Development of “real-time” uncertainty evaluation algorithm for the estimated coseismic fault model using MCMC approach

*Keitaro Ohno[1], Yusaku Ohta[1] (1.Recerch Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University)

---

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[SCG59-11] Drifting float measurement of pressure change by tsunami

*Masayuki Obayashi[1], Shingo Watada[2], Hiroko Sugioka[3] (1.Japan Agency for Marine-Earth Science and Technology, 2.Earthquake Research Institute, University of Tokyo, 3.Department of Planetology, Kobe University)

---

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[SCG59-12] Development of the Real-time Forecasting for Meteorite Impact Tsunami

*Naotaka YAMAMOTO CHIKASADA[1], Toshitaka Baba[2], Tetsuharu Fuse[3] (1.NIED, 2.Tokushima University, 3.NICT)

[J] Oral | B (Biogeosciences) : B-PT Paleontology

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 201A 2F

## [B-PT05] Biotic History

convener:Isao Motoyama(Department of Earth and Environmental Sciences, Yamagata University), Takao Ubukata(Division of Geology & Mineralogy, Department of Earth & Planetary Sciences, Kyoto University), Kazuyoshi Moriya(Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University), Chairperson:Isao Motoyama, Takao Ubukata, Kazuyoshi Moriya

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

### [BPT05-01] Cause of accelerated evolution of Earth's life; four-layered underground robust bio-communities played a critical role for the accelerated genome evolution as a response of mass extinction

*Shigenori Maruyama[1], Akio Kanai[2], Issay Narumi[3] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.keio University, 3.Toyo University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

### [BPT05-02] Amino acid composition in molluscan shells and its relation to taxa and shell microstructure ~ Toward reconstruction of ancient trophic level using compound specific isotope analysis of amino acids ~

*Naoki Yugami[1], Akiko Goto[2], Robert Jenkins[2] (1.Graduate School of Natural Science & Technology. Kanazawa Univercity, 2.Institute of Science & Engineering . Kanazawa Univercity)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

### [BPT05-03] Relation of shell form to rocking motion in planispiral cephalopods

*Takao Ubukata[1] (1.Division of Geology & Mineralogy, Department of Earth & Planetary Sciences, Kyoto University)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

### [BPT05-04] Paleoenvironment aross the Meddle Eocene Climatic Optimum

Hiroki Masui[1], *Kazuyoshi Moriya[1] (1.Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

### [BPT05-05] Reconstruction of the North Pacific subtropical gyre from the Middle to Late Miocene as inferred from radiolarian assemblages

*Shin-ichi Kamikuri[1], Isao Motoyama[2], Taiki Sawada[3] (1.Faculty of Education, Ibaraki University, 2.Faculty of Science, Yamagata University, 3.Japan Petroleum Exploration Co.,Ltd.)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

### [BPT05-06] Fossilization processes of Pliocene tree fossils from the Yasu River, Shiga Prefecture, Japan: Organic geochemical approach

*Jinya Nakamura[1], Ken Sawada[2], Masashi A Ikeda[1], Hideto Nakamura[3], Minoru Tsukagoshi[4] (1.Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 3.Faculty of Science, Osaka City Univerisity, 4.Osaka Museum of Natural History)

[J] Poster | B (Biogeosciences )：B-PT Paleontology

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_18

## [B-PT05] Biotic History

convener:Isao Motoyama(Department of Earth and Environmental Sciences, Yamagata University), Takao Ubukata(Division of Geology & Mineralogy, Department of Earth & Planetary Sciences, Kyoto University), Kazuyoshi Moriya(Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University)

[BPT05-P01] Simultaneous observations of both hard and soft tissues of *Oulastrea crispata* (Cnidaria: Scleractinia)

*Rie Tajiri[1], Yuki Tokuda[2], Yoichi Ezaki[1] (1.Osaka City University, 2.Tottori University of Environment Studies)

---

[BPT05-P02] Coral-based paleoenvironmental interpretation and depositional history of the late middle Pleistocene Minatogawa Formation, southern Okinawa-jima, Japan

*Riho Tomatsu[1], Marc Humblet[1], Kazuhiko Fujita[2] (1.Graduate School of Environmental Studies, Nagoya University, 2.Department of Physics and Earth Sciences, University of the Ryukyus)

---

[BPT05-P03] Calcareous nannofossil biostratigraphy and oxygen isotope stratigraphy of the lower part of the Pleistocene formation distributed in the central part of the Pacific side of Japan

*Daisuke Kuwano[1], Yoshimi Kubota[2], Kanako Mantoku[2], Koji Kameo[3] (1.Division of Earth and Environmental Sciences, Graduate School of Science and Engineering, Chiba University, 2.National Museum of Nature and Science, 3.Department of Earth Sciences, faculty of Science, Chiba University)

---

[BPT05-P04] Cretaceous and Miocene geology and paleontology of the Tounai River region, Biratori, Hokkaido

*Isao Motoyama[1], Kotaro Uchimura[2], Tomohiro Nishimura[3], Yojiro Taketani (1.Department of Earth and Environmental Sciences, Yamagata University, 2.JCE Co.,LTD, 3.Hobetsu Museum)

---

[BPT05-P05] Response of benthic organisms to oceanic anoxic event in the Early Jurasic (T-OAE): Insights from quantitative analysis of the trace fossil Phycosiphon from the Nishinakayama Formation, Toyora Group

*Kyosuke Kitabatake[1,2], Kentaro Izumi[3], Kenji Okoshi[1] (1.Department of Environmental Science, Faculty of Science, Toho University, 2.Department of Earth Sciences, College of Science, Ibaraki University, 3.Faculty & Graduate School of Education, Chiba University)

[J] Poster | B (Biogeosciences )：B-PT Paleontology

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_33

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

## [M-IS03] Evolution and variability of the Asian monsoon in Cenozoic global climate changes

convener:Masanobu Yamamoto(Faculty of Environmental Earth Science, Hokkaido University), Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo)

[MIS03-P01] Asian dust source variability since 10 Ma based on grain size specific mineral composition at IODP Site U1425 in the Japan Sea

*Mui Fa Alison Lee[1], Tomohisa Irino[1] (1.Faculty of Environmental Earth Science, Hokkaido University)

[MIS03-P02] Sources and formation environment of biomass burning products in Pliocene and Pleistocene marine sediments in the Japan Sea

*Song Lu[1], Youhei Yamashita[2], Tomohisa Irino[2] (1.Graduate School of Environmental Science, Hokkaido University , 2.Faculty of Environmental Earth Science, Hokkaido University)

[MIS03-P03] Variation of mineral dust flux in peat at a high moor on the Mt. Daisetsu during Holocene

*Tomohisa Irino[1], Keisuke Hirai[1], Osamu Seki[1], James Hooper[2], Samuel Marx[2] (1.Hokkaido University, 2.University of Wollongong)

[MIS03-P04] Variations in sea surface environments recorded by algal biomarkers in the Japan Sea off the western coast of Hokkaido (IODP Site U1422) over the last 250 ka

*Asako Suzuki[1], Ken Sawada[2], Satoshi Furota[3], Yaeko Igarashi[4], Tomohisa Irino[5] (1.Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 3.Japan Agency for Marine-Earth Science and Technology, 4.Institute for Paleoenvironment of Northern Regions, 5.Faculty of Environmental Earth Science, Hokkaido University)

[MIS03-P05] **Decadal oscillation in hydrogen stable isotope ratio of long chain fatty acids in Lake Suigetsu sediment core**

*Masaya Inagaki[1], Masanobu Yamamoto[1,2], Takeshi Nakagawa[3] (1.Graduate School of Environmental Science, Hokkaido University, 2.Faculty of Environmental Earth Science, Hokkaido University, 3.Research Center for Palaeoclimatology, Ritsumeikan University)

[MIS03-P06] **Amplitude modulation of sea surface temperature variability in the Bay of Bengal by 400-kyr eccentricity cycle**

*Masanobu Yamamoto[1], Yuko Tsuchiya[1], Steven Clemens[2] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Department of Earth, Planetary and Environmental Sciences, Brown University)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_34

## [M-IS03] Evolution and variability of the Asian monsoon in Cenozoic global climate changes

convener:Masanobu Yamamoto(Faculty of Environmental Earth Science, Hokkaido University), Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo)

[MIS03-P01] Asian dust source variability since 10 Ma based on grain size specific mineral composition at IODP Site U1425 in the Japan Sea

*Mui Fa Alison Lee[1], Tomohisa Irino[1] (1.Faculty of Environmental Earth Science, Hokkaido University)

[MIS03-P02] Sources and formation environment of biomass burning products in Pliocene and Pleistocene marine sediments in the Japan Sea

*Song Lu[1], Youhei Yamashita[2], Tomohisa Irino[2] (1.Graduate School of Environmental Science, Hokkaido University , 2.Faculty of Environmental Earth Science, Hokkaido University)

[MIS03-P03] Variation of mineral dust flux in peat at a high moor on the Mt. Daisetsu during Holocene

*Tomohisa Irino[1], Keisuke Hirai[1], Osamu Seki[1], James Hooper[2], Samuel Marx[2] (1.Hokkaido University, 2.University of Wollongong)

[MIS03-P04] Variations in sea surface environments recorded by algal biomarkers in the Japan Sea off the western coast of Hokkaido (IODP Site U1422) over the last 250 ka

*Asako Suzuki[1], Ken Sawada[2], Satoshi Furota[3], Yaeko Igarashi[4], Tomohisa Irino[5] (1.Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 3.Japan Agency for Marine-Earth Science and Technology, 4.Institute for Paleoenvironment of Northern Regions, 5.Faculty of Environmental Earth Science, Hokkaido University)

[MIS03-P05] **Decadal oscillation in hydrogen stable isotope ratio of long chain fatty acids in Lake Suigetsu sediment core**

*Masaya Inagaki[1], Masanobu Yamamoto[1,2], Takeshi Nakagawa[3] (1.Graduate School of Environmental Science, Hokkaido University, 2.Faculty of Environmental Earth Science, Hokkaido University, 3.Research Center for Palaeoclimatology, Ritsumeikan University)

[MIS03-P06] **Amplitude modulation of sea surface temperature variability in the Bay of Bengal by 400-kyr eccentricity cycle**

*Masanobu Yamamoto[1], Yuko Tsuchiya[1], Steven Clemens[2] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Department of Earth, Planetary and Environmental Sciences, Brown University)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 304 3F

## [M-IS03] Evolution and variability of the Asian monsoon in Cenozoic global climate changes

convener:Masanobu Yamamoto(Faculty of Environmental Earth Science, Hokkaido University), Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo), Chairperson:Masanobu Yamamoto(Hokkaido University), Tomohisa Irino, Yoshimi Kubota(National Science Museum), Ryuji Tada(The University of Tokyo)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS03-01] **Reconstruction of Indian summer monsoon variability during the last 1,460,000 years**

*Masanobu Yamamoto[1], Steven Clemens[2] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Department of Earth, Environmental and Planetary Sciences, Brown University)

---

2:00 PM - 2:20 PM JST | 5:00 AM - 5:20 AM UTC

[MIS03-02] Pleistocene Seawater $\delta^{18}O$ reconstructions from the Indian and East Asian Monsoon Regions

★Invited Papers

*Steven C Clemens[1], Masanobu Yamamoto[2] (1.Brown University, 2.Hokkaido University)

---

2:20 PM - 2:40 PM JST | 5:20 AM - 5:40 AM UTC

[MIS03-03] The Monsoon Erosion Pump

★Invited Papers
# Cancelled

*Liviu Giosan[1] (1.Woods Hole Oceanographic Institution)

---

2:40 PM - 3:00 PM JST | 5:40 AM - 6:00 AM UTC

[MIS03-04] East Asian winter monsoon intensity in the Pleistocene based on seasonal land snail shell stable isotope ratios

★Invited Papers

*David L Dettman[1,3], Xin Wang[2], Mi Wang[2], Junhui Zhang[2] (1.University of Arizona, Geosciences Dept., Environmental Isotope Lab., 2.Lanzhou University, Key Laboratory of Western China's Environmental Systems, College of Earth and Environmental Sciences, 3.Shimane University, Estuary Research Center)

---

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS03-05] Reconstruction of ventilation history of the Japan Sea based on physical properties data collected during IODP Exp. 346

*Tomohisa Irino[1], Liviu Giosan[2], Ryuji Tada[3], Ken Ikehara[4] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Woods Hole Oceanographic Institution, 3.Graduate School of Science, University of Tokyo, 4.Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 304 3F

## [M-IS03] Evolution and variability of the Asian monsoon in Cenozoic global climate changes

convener:Masanobu Yamamoto(Faculty of Environmental Earth Science, Hokkaido University), Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo), Chairperson:Ryuji Tada(The University of Tokyo), Yoshimi Kubota(National Science Museum), Masanobu Yamamoto(Hokkaido University)

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MIS03-06] The spatial-temporal patterns of Indian monsoonal variations during the past 80 kyr recorded in NGHP-02 Hole 19B, western Bay of Bengal: Implications from chemical and mineral properties

*Yuki Ota[1,2,3,4], Hodaka Kawahata[4], Junichiro Kuroda[4,3], Atsushi Suzuki[2], Daisuke Araoka[2], Asuka Yamaguchi[4], Ayako Abe-Ouchi[4] (1.Department of Earth and Planetary Science, The University of Tokyo, 2.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 3.Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology, 4.Atmosphere and Ocean Research Institute, The University of Tokyo)

3:45 PM - 4:05 PM JST | 6:45 AM - 7:05 AM UTC

[MIS03-07] **400,000 years millennial scale temperature and rainfall in East Asia deduced from paired Mg/Ca and oxygen isotope of planktic foraminifera from the East China Sea**

★Invited Papers

*Yoshimi Kubota[1], Steven Clemens[2], Kyung-Eun Lee[3], Ann Holbourn[4], Etsuko Wakisaka[5], Keiji Horikawa[5], Ryuji Tada[6], Katsunori Kimoto[7] (1.National Museum of Nature and Science, 2.Brown University, 3.Korea Maritime and Ocean University, 4.Christian-Albrechts-University, 5.University of Toyama, 6.The University of Tokyo, 7.Japan Agency for Marine-Earth Science and Technology)

4:05 PM - 4:20 PM JST | 7:05 AM - 7:20 AM UTC

[MIS03-08] Onset and evolution of millennial-scale variability of East Asian Monsoon recorded in the Japan Sea sediments: New data with new interpretation

*Ryuji Tada[1], Tomohisa Irino[2], Arisa Seki[3], Masafumi Murayama[4], Kaz Mitake[1], Masayuki Ikeda[5] (1.Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo, 2.Faculty of Environmental Earth Science, Hokkaido University, 3.Faculty of Science, Shinshu University, 4.Faculty of Agriculture and Marine Science, 5.Shizuoka University)

4:20 PM - 4:40 PM JST | 7:20 AM - 7:40 AM UTC

[MIS03-09] Interhemispheric linkages of Australian and Asian monsoons on a warmer-than-modern Earth

★Invited Papers

*Ann E Holbourn[1], Wolfgang Kuhnt[1], Janika Joehnck[1], Sebastian Beil[1], Julia Luebbers[1], Kenji Marc Raymond Matsuzaki[2], Yair Rosenthal[3], Denise Kulhanek[4], IODP Expedition 363 Scientists (1.University of Kiel, 2.University of Tokyo, 3.Rutgers University, 4.Texas A&M University)

4:40 PM - 5:00 PM JST | 7:40 AM - 8:00 AM UTC

[MIS03-10] **Miocene evolution of the Asian Monsoon from climate and productivity proxies in the Bay of Bengal and South China Sea**

★Invited Papers

*Wolfgang Kuhnt[1], Julia Luebbers[1], Ann Holbourn[1], Karlos GD Kochhann[2], Steven C Clemens[3], Clara T Bolton[4], Yoichi Usui[5] (1.University of Kiel, 2.UNISINOS University, 3.Brown University, 4.Aix-Marseille Université, 5.Japan Agency for Marine-Earth Science and Technology)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

## [M-IS04] Interdisciplinary studies on pre-earthquake processes

convener:Katsumi Hattori(Department of Earth Sciences, Graduate School of Science, Chiba University), JANN-YENQ Liu(Institute of Space Science, National Central University, Taiwan), Dimitar Ouzounov(Center of Excellence in Earth Systems Modeling & Observations (CEESMO) , Schmid College of Science & Technology Chapman University, Orange, California, USA), Qinghua Huang(Peking University)

### [MIS04-P01] Statistical analysis and Evaluation of ULF seismo-magnetic phenomena at Kakioka, Japan, during 1983-2017

*Kei Takahashi[1], Katsumi Hattori[2], Peng Han[3] (1.Faculty of Science, Chiba University, 2.Graduate School of Science, Chiba University, 3.Southern University of Science and Technology, China)

### [MIS04-P02] Pre-seismic anomalies on Earth's magnetic field and ionosphere electron density using Swarm data

*Amune Yamazaki[1], Katsumi Hattori[1], Rui Song[1] (1.Chiba University)

### [MIS04-P03] Measurement of radon density in the atmosphere at Okayama, Kochi, Choshi and Kiyosumi, II

*Tohru Okabayashi[1], Kiyotaka Ninagawa[2], Isao Yamamoto[3], Katsumi Hattori[4], Chie Yoshino[4], Haruna Kojima[4], Nobuhiro Maeda (1.Department of Merical Risk and Crisis Management, Faculty of Risk and Crisis Management, Chiba Institute of Science, 2.Faculty of Science, Okayama University of Science, 3.Falcuty of Engineering, Okayama University of Science, 4.Graduate school of Science, Chiba University)

### [MIS04-P04] Possible anomalous changes in solar quiet-daily geomagnetic variation *Sq* related to the 2011 off the Pacific coast of Tohoku earthquake (Mw 9.0)

*Xiaocan Liu[1], Katsumi Hattori[2,3], Peng Han[4], Huaran Chen[1] (1.Institute of geophysics China Earthquake Administrition, 2.Graduate School of Science, Chiba University, Chiba, Japan, 3. Center for Environmental Remote Sensing, Chiba University, Chiba, Japan, 4.Department of Earth and Space Sciences, Southern University of Science and Technology, ShenZhen, China)

### [MIS04-P05] Co-seismic geomagnetic fluctuations and atmospheric disturbances during the 2018 M6.2 Hualien Earthquake

*Chun-Rong Chen[1], JANN-YENQ Liu[1] (1.Graduate Institute of Space Science, National Central University)

### [MIS04-P06] Multi-sensor monitoring network for earthquake precursor study near subduction zone at Boso, Japan

*Katsumi Hattori[1], Chie Yoshino[1], WEIYUN XIE[2], Sanaka Saito[2], Haruna Kojima[2], Rui Song[2], Peng Han[3], Toru Mogi[4], Tada-nori Goto[5], Ichi Takumi[6], Hiroshi Yasukawa[7], Motoaki Mouri[8], Jun Izutsu[9], Tadashi Takano[10], Chihiro Yamanaka[11], Masashi Kamogawa[12], Yoshiaki Ando[13], JANN-YENQ Liu[14], Dimitar Ouzounov[15], Valery Tramutoli[16] (1.Department of Earth Sciences, Graduate School of Science, Chiba University, 2.Graduate School of Science and Engineering, Chiba University, 3.Southern University of Science and Technology, China, 4.Hokkaido University, 5.Kyoto University, 6.Nagoya Institute of Technology, 7.Aichi Prefectural University, 8.Aichi University, 9.Chubu University, 10.Nihon University, 11.Osaka University, 12.Tokyo Gakugei University, 13.The University of Electro-Communications, 14.National Central University, Taiwan, 15.Chapman University, US, 16.University of Basilicagta, Italy)

### [MIS04-P07] Transient Effects in Atmosphere and Ionosphere Associated with 2018 Mw 7.5 Sulawesi Indonesia Earthquake and Triggered Tsunami and Volcano Activities

★Invited Papers

*Dimitar Ouzounov[1], Sergey Pulinets[2], Dmitry Davidenko[2], Alexander Rozhnoi[3], Maria Solovieva[3], Tiger Liu[4] (1.Center of Excellence in Earth Systems Modeling & Observations (CEESMO) , Schmid College of Science & Technology Chapman University, Orange, California, USA, 2.Space Research Institute, RAS, Moscow, Russia, 3.The Schmidt Institute of Physics of the Earth, RAS, Moscow, Russia, 4.Center for Astronautical Physics and Engineering, National Central University, Taoyuan City, Taiwan)

### [MIS04-P08] Seismicity change and b value variation prior to the Wenchuan earthquake (*Ms 8.0*)

*Peng Han[1], Rui Wang[1], Ying Chang[1], Miao Miao[1], Haixia Shi[2], Lingyuan Meng[2], Xuemei Zhang[2], Weiyun Xie[3], Katsumi Hattori[3] (1.Southern University of Science and Technology, Shenzhen, China, 2.China Earthquake Networks

Center, Beijing 100045, China, 3.Chiba University, Chiba, Japan)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_35

## [M-IS04] Interdisciplinary studies on pre-earthquake processes

convener:Katsumi Hattori(Department of Earth Sciences, Graduate School of Science, Chiba University), JANN-YENQ Liu(Institute of Space Science, National Central University, Taiwan), Dimitar Ouzounov(Center of Excellence in Earth Systems Modeling & Observations (CEESMO) , Schmid College of Science & Technology Chapman University, Orange, California, USA), Qinghua Huang(Peking University)

### [MIS04-P01] Statistical analysis and Evaluation of ULF seismo-magnetic phenomena at Kakioka, Japan, during 1983-2017

*Kei Takahashi[1], Katsumi Hattori[2], Peng Han[3] (1.Faculty of Science, Chiba University, 2.Graduate School of Science, Chiba University, 3.Southern University of Science and Technology, China)

[E] Oral | M (Multidisciplinary and Interdisciplinary) : M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | A02 TOKYO BAY MAKUHARI HALL

## [M-IS04] Interdisciplinary studies on pre-earthquake processes

convener:Katsumi Hattori(Department of Earth Sciences, Graduate School of Science, Chiba University), JANN-YENQ Liu(Institute of Space Science, National Central University, Taiwan), Dimitar Ouzounov(Center of Excellence in Earth Systems Modeling & Observations (CEESMO) , Schmid College of Science & Technology Chapman University, Orange, California, USA), Qinghua Huang(Peking University), Chairperson:Jann-Yenq Liu(National Central University, Taiwan), Toshiyasu Nagao

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS04-01] Application of blind source separation method in seismo-magnetic data analysis

★Invited Papers

*Peng Han[1], Yi Zhong[1], Yuanyuan Zhou[1], Yonghui Ma[2], Chengliang Xie[3], Katsumi Hattori[4], Chie Yoshino[4] (1.Southern University of Science and Technology, Shenzhen, China, 2.Harbin Institute of Technology (Shenzhen), Shenzhen 518055, China, 3.China University of Geosciences (Beijing), Beijing, 100083, China, 4.Chiba University, Chiba, Japan)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS04-02] Rn flux anomaly and local seiemicity around Asahi station,Boso,Japan

*Haruna Kojima[1], Katsumi Hattori[2], Chie Yoshino[2], Michikuni Shimo[3], Toshiharu Konishi[4], Ryuichi Furuya[5] (1.Graduate School of Science and Engineering,Chiba University, 2.Department of Earth Sciences,Graduate School of Science,Chiba University, 3.Fujita Hearth University, 4.OHYO KOKEN KOGYO Co.,Ltd, 5.COM SYSTEM ,INC.)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS04-03] Geochemical evidence for the occurrence of 2018 Hualien earthquake triggered by earlier earthquake swarm

*Ching-Chou Fu[1], Lou-Chuang Lee[1], Cheng-Horng Lin[1], Vivek Walia[2], Dimitar Ouzounov[3] (1.Institute of Earth Sciences, Academia Sinica, 2.National Center for Research on Earthquake Engineering, NARL, Taiwan, 3.Chapman University, One University Drive, Orange, CA, USA)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS04-04] Temporal Variation and Statistical Assessment of b value

*weiyun xie[1], Katsumi Hattori[1], Peng Han[2] (1.chiba university, 2. Southern University of Science and Technology)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS04-05] The S-K characteristics of the borehole areal strains associated with the Ms 8.0 Wenchuan and Ms 7.0 Lushan earthquakes

★Invited Papers

*Kaiguang Zhu[1], Zining Yu[1], Chenquan Chi[1], Mengxuan Fan[1], Kaiyan Lii[1] (1.Jilin University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS04-06] The Relationship between Earthquakes and Lightning Events of the globe during 2009-2017

*Ching-Chung Cheng[1], JANN-YENQ Liu[1,2,3] (1.Graduate Institute of Space Science, National Central University, TAIWAN, 2.Center for Astronautical Physics and Engineering, National Central University, TAIWAN, 3.Center for Space and Remote Sensing Research, National Central University, TAIWAN)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | A02 TOKYO BAY MAKUHARI HALL

## [M-IS04] Interdisciplinary studies on pre-earthquake processes

convener:Katsumi Hattori(Department of Earth Sciences, Graduate School of Science, Chiba University), JANN-YENQ Liu(Institute of Space Science, National Central University, Taiwan), Dimitar Ouzounov(Center of Excellence in Earth Systems Modeling & Observations (CEESMO) , Schmid College of Science & Technology Chapman University, Orange, California, USA), Qinghua Huang(Peking University), Chairperson:Peng Han, Katsumi Hattori

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MIS04-07] 3D-Tomography of the Ionospheric Anomalies Preceding the 2011 Tohoku-Oki ($M_w$9.0) Earthquake

*Ihsan Naufal Muafiry[1,2], Kosuke Heki[1] (1.Hokkaido University, Japan, 2.Universitas Esa Unggul, Indonesia)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MIS04-08] Statistical Analysis of Pre-seismic Ionospheric Electron Density Anomalies and Investigation of Precursor

*Sanaka Saito[1], Chie Yoshino[1], Katsumi Hattori[1] (1.Chiba University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MIS04-09] Spatial clustering of pre-earthquake anomalies as an indicator of the preparation/activation zone

*Dimitar Ouzounov[1], Sergey Pulinets[2], Tiger Liu[3], Katsumi Hattori[4] (1.Center of Excellence in Earth Systems Modeling & Observations (CEESMO) , Schmid College of Science & Technology Chapman University, Orange, California, USA, 2.Space Research Institute, RAS, Moscow, Russia, 3.National Central University, Taoyuan City, Taiwan, 4. Chiba University, Chiba, Japan)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MIS04-10] **Application of the ionospheric parameters on the seismic research**- -Seismic-ionospheric effect detected from China Seismo-Electromagnetic Satellite

★Invited Papers

*Rui Song[1], Hattori Katsumi[2], Xuemin Zhang[3] (1.Graduate School of Science and Engeering, Chiba University, 2.Graduate School of Science, Chiba University, 3.Institute of Earthquake Science, China Earthquake Administration)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MIS04-11] ROC curve analyses on the ionospheric TEC of M>=6.0 earthquakes in Japan during 1998-2015

★Invited Papers

*JANN-YENQ Liu[1], Yuh-Ing Chen[2], Pei-Jung Lee[1] (1.Center for Astronautical Physics and Engineering; Graduate Institute of Space Science, National Central University, Taiwan, 2.Graduate Institute of Statistics, National Central University, Taiwan)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MIS04-12] FORMOSAT-5/AIP observes seismo-ionospheric precursors

*JANN-YENQ Liu[1], Chi-Kuang Chao[1] (1.Center for Astronautical Physics and Engineering; and Graduate Institute of Space Science, National Central University, TAIWAN)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 202 2F

## [M-IS06] Conservation of geoparks, natural geosites and cultural heritage: weathering process and damage assessment

convener:Chiaki T. Oguchi(Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University), Tetsuya Waragai(Graduate School of Science and Engineering, Nihon University), Kuniyasu Mokudai(Tohoku Gakuin University), Magdalini Theodoridou(School of Engineering, Cardiff University), Chairperson:Tetsuya Waragai(日本大学大学院　理工学研究科), Kuniyasu Mokudai(Japan Geoservicee)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS06-01] Geopark's response to conservation of geosites from natural hazards

*Kuniyasu Mokudai[1], Shuichi Hasegawa[2] (1.Japan Geoservice Incorporated, 2.Kagawa Univ.)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS06-02] Physical and mechanical properties for damage assesment of Taya Cave rocks, central Japan

*Chiaki T. Oguchi[1], Yurina Akimoto[2], Yasuhiko TAMURA[3], Kaisei Sakane[1] (1.Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University, 2.Faculty of Engineering, Saitama University, 3.The Exective Committee for the Preservation of TAYA CAVERN)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS06-03] Interdisciplinary approaches on conservation of underground geoheritage for community development of Taya Cave and its adjacent area

★Invited Papers

*Yasuhiko TAMURA[1,2], Chiaki T. Oguchi[4], Yuichi S. Hayakawa[5,2], Takuro Ogura[2], OGATA KEISUKE[6], Masashi MORITA[3] (1.The Executive Committee for the Preservation of TAYA CAVERN , 2.The University of Tokyo, Center for Spatial Information Science, 3.Yokohama National University, Institute of Urban Innovation, 4.Saitama University, Graduate School of Science and Engineering, 5.Hokkaido University, Faculty of Environmental Earth Science, 6.Tsurumi University, The Department of Cultural Properties)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS06-04] Italian underground cultural heritage: from monitoring to enhancement

★Invited Papers

*Mario Parise[1], Tiziana Vitolo[2], Roberta Varriale[2] (1.Univ. Aldo Moro, Dept. Earth and Environmental Sciences, Bari, Italy, 2.CNR-ISSM, Italy)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS06-05] Possibility of insolation weathering of sandstone blocks composing Angkor temples, Cambodia

*Tetsuya Waragai[1] (1.Graduate School of Science and Engineering, Nihon University)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS06-06] Durability evaluation of pyroclastic rocks used in the historical built environment of Hungary

*Luigi Germinario[1,2], Ákos Török[1] (1.Budapest University of Technology and Economics, Hungary, 2.Saitama University, Japan)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_19

## [M-IS06] Conservation of geoparks, natural geosites and cultural heritage: weathering process and damage assessment

convener:Chiaki T. Oguchi(Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University), Tetsuya Waragai(Graduate School of Science and Engineering, Nihon University), Kuniyasu Mokudai(Tohoku Gakuin University), Magdalini Theodoridou(School of Engineering, Cardiff University)

[MIS06-P01] The artistic qualities of religion reliefs in Taya-cave.Japan

*OGATA KEISUKE[1] (1.TSURUMI UNIVERSITY)

---

[MIS06-P02] Effect of stress concentration on the Weathering Mechanism of Sandstone Pillars of Angkor Wat, Cambodia by means of numerical simulation

*Takato Takemura[1], Tetsuya Waragai[2] (1.Nihon Univ., 2.Nihon University)

---

[MIS06-P03] Meaning to preserve evidence of large scale landslide

*Kuniyasu Mokudai[1], Hidekazu Sato[2] (1.Japan Geoservice Incorporated, 2.Mt. Kurikoma Area Geopark)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_36

## [M-IS06] Conservation of geoparks, natural geosites and cultural heritage: weathering process and damage assessment

convener:Chiaki T. Oguchi(Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University), Tetsuya Waragai(Graduate School of Science and Engineering, Nihon University), Kuniyasu Mokudai(Tohoku Gakuin University), Magdalini Theodoridou(School of Engineering, Cardiff University)

[MIS06-P01] The artistic qualities of religion reliefs in Taya-cave.Japan

*OGATA KEISUKE[1] (1.TSURUMI UNIVERSITY)

---

[MIS06-P02] Effect of stress concentration on the Weathering Mechanism of Sandstone Pillars of Angkor Wat, Cambodia by means of numerical simulation

*Takato Takemura[1], Tetsuya Waragai[2] (1.Nihon Univ., 2.Nihon University)

---

[MIS06-P03] Meaning to preserve evidence of large scale landslide

*Kuniyasu Mokudai[1], Hidekazu Sato[2] (1.Japan Geoservice Incorporated, 2.Mt. Kurikoma Area Geopark)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | 201A 2F

## [M-IS07] Astrobiology

convener:Hikaru Yabuta(Hiroshima University, Department of Earth and Planetary Systems Science), Seiji Sugita(Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo), Misato Fukagawa(National Astronomical Observatory of Japan), Fujishima Kosuke(Tokyo Institute of Technology, Earth-Life Science Institute), Chairperson:Hikaru Yabuta(Hiroshima University), Seiji Sugita(東京大学大学院 理学系研究科), Misato Fukagawa(名古屋大学大学院 理学研究科), Kosuke Fujishima(ELSI 地球生命研究所)

9:00 AM - 9:20 AM JST | 12:00 AM - 12:20 AM UTC

[MIS07-06] How to find and characterize nearby habitable exoplanets

★Invited Papers

*Norio Narita[1] (1.Astrobiology Center)

---

9:20 AM - 9:40 AM JST | 12:20 AM - 12:40 AM UTC

[MIS07-07] **Organic Matter Preserved in Mudstones of a 3-Billion-Year-Old Lake Deposit in Gale Crater, Mars**

★Invited Papers

*Jennifer L Eigenbrode[1], Roger E Summons[2], Andrew Steele[3], Caroline Freissinet[4], Maëva Millan[5], Rafael Navarro-González[6], Paul Mahaffy[1] (1.NASA Goddard Space Flight Center, 2.Massachusetts Institute of Technology, 3.Carnegie Institution of Washington, 4.Institut Pierre Simon Laplace, CNRS, 5.Georgetown University, 6.Universidad Nacional Autónoma de México)

---

9:40 AM - 9:55 AM JST | 12:40 AM - 12:55 AM UTC

[MIS07-08] **The third year sample return of Tanpopo: Capture and Exposure Experiment of Micrometeorite and Microbes on Exposure Facility of International Space Station**

*Akihiko Yamagishi[1], Hirofumi Hashimoto[2], Hajime Yano[2], Shin-ichi Yokobori[3], Kensei Kobayashi[4], Hajime Mita[5], Hikaru Yabuta[6], Masumi Higashide[7], Makoto Tabata[8], Hideyuki Kawai[8], Eiichi Imai[9] (1.Tokyo University of Pharmacy and Life Science, Department of Molecular Biology, 2.ISAS/JAXA, Sagamihara, Japan, 3.Tokyo University of Pharmacy and Life Science, Tokyo, Japan, 4.Yokohama National University, Yokohama, Japan, 5.Fukuoka Institute of Technology, Fukuoka, Japan, 6.Hiroshima University, Hirosima, Japan, 7.Japan Aerospace Exploration Agency (JAXA), Tokyo, Japan, 8.Chiba University, Chiba, Japan, 9.Nagaoka University of Technology, Nagaoka, Japan)

---

9:55 AM - 10:10 AM JST | 12:55 AM - 1:10 AM UTC

[MIS07-09] Theoretical search for photosynthetic pigments applicable around low temperature stars: Modulation of physical-chemical properties by central metals

*Yu Komatsu[1,2], Kenji Takizawa[1,3] (1.Astrobiology Center, 2.National Astronomical Observatory of Japan, 3.National Institute for Basic Biology)

---

10:10 AM - 10:25 AM JST | 1:10 AM - 1:25 AM UTC

[MIS07-10] Effects of the formation of hydrocarbon aerosols on the climate stability of Earth-like planets and their habitability

*Yasuto Watanabe[1], Eiichi Tajika[1], Kazumi Ozaki[2], Peng Hong[3] (1.The University of Tokyo, 2.Toho University, 3.Chiba Institute of Technology)

[E] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 201A 2F

## [M-IS07] Astrobiology

convener:Hikaru Yabuta(Hiroshima University, Department of Earth and Planetary Systems Science), Seiji Sugita(Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo), Misato Fukagawa(National Astronomical Observatory of Japan), Fujishima Kosuke(Tokyo Institute of Technology, Earth-Life Science Institute), Chairperson:Kosuke Fujishima(ELSI 地球生命研究所), Misato Fukagawa(名古屋大学大学院 理学研究科), Seiji Sugita(東京大学大学院 理学系研究科), Hikaru Yabuta(Hiroshima University)

10:45 AM - 11:05 AM JST | 1:45 AM - 2:05 AM UTC

[MIS07-11] the emergence of iron-sulfur protometabolism

★Invited Papers

*Sheref Mansy[1] (1.University of Trento)

---

11:05 AM - 11:25 AM JST | 2:05 AM - 2:25 AM UTC

[MIS07-12] Life-water-mineral interactions and their products

★Invited Papers

*Fumito Shiraishi[1] (1.Hiroshima University)

---

11:25 AM - 11:40 AM JST | 2:25 AM - 2:40 AM UTC

[MIS07-13] How much can we learn about ancient cells from sequence analysis? New metrics on an old problem.

*Shawn E McGlynn[1], Sarah J Berkemer[2,3] (1.Earth-Life Science Institute, Tokyo Institute of Technology, 2.Bioinformatics Group, Department of Computer Science, Interdisciplinary Center for Bioinformatics, University of Leipzig, 3.Max Planck Institute for Mathematics in the Sciences, Leipzig, Germany)

---

11:40 AM - 11:55 AM JST | 2:40 AM - 2:55 AM UTC

[MIS07-14] Scientific significance of searching living cells on Mars surface by Life Detection Microscope (LDM )

*Yoshitaka Yoshimura[1], Akihiko Yamagishi[2], Takehiko Satoh[3], Atsuo Miyakawa[2], Eiichi Imai[4], Satoshi Sasaki[5], Kensei Kobayashi[6], Yoko Kebukawa[6], Tomoka Okada[6], Keigo Enya[3], Hikaru Yabuta[7], Takeshi Naganuma[7], Hajime Mita[8], Kazuhisa Fujita[3], Tomohiro Usui[3] (1.College of Agriculture, Tamagawa University, 2.Tokyo University of Pharmacy and Life Science, 3.Japan Aerospace Exploration Agency, 4.Nagaoka University of Technology, 5.Tokyo University of Technology, 6.Yokohama National University, 7.Hiroshima University, 8.Fukuoka Institute of Technology)

---

11:55 AM - 12:10 PM JST | 2:55 AM - 3:10 AM UTC

[MIS07-15] Civilization-bearing planets in the Milky-Way Galaxy; 50 necessary conditions must be satisfied in order

*Shigenori Maruyama[1] (1.Earth-Life Science Institute, Tokyo Institute of Technology)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_20

## [M-IS07] Astrobiology

convener:Hikaru Yabuta(Hiroshima University, Department of Earth and Planetary Systems Science), Seiji Sugita(Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo), Misato Fukagawa(National Astronomical Observatory of Japan), Fujishima Kosuke(Tokyo Institute of Technology, Earth-Life Science Institute)

### [MIS07-P01] Exoplanets Revealed by High-Precision Infrared Doppler Technique Using IRD: Large Exploration for Planets around Cool M-type Stars Begins

*Masayuki Kuzuhara[1,3], Bunei Sato[4], Motohide Tamura[2,1,3], Takayuki Kotani[1,3,5], Nagayoshi Ohashi[3,6], Masashi Omiya[1,3], Teruyuki Hirano[4], Hiroki Harakawa[6,3,1], Wako Aoki[3,5], Norio Narita[2,1], Yasunori Hori[1,3], Akitoshi Ueda[3,5], Akihiko Fukui[2], Hiroyuki Tako Ishikawa[5,3], Ishizuka Masato[2], Takashi Kurokawa[1,7], Nobuhiko Kusakabe[1,3], Tomoyuki Kudo[6,3,1], Eiichiro Kokubo[3], Mihoko Konishi[1,3], Tadashi Nakajima[1,3,5], Jun Nishikawa[3,5,1], Masahiro Ogihara[3], Takuma Serizawa[7] (1.Astrobiology Center of NINS, 2.The University of Tokyo, Graduate School of Science, 3.National Astronomical Observatory of Japan, 4.Tokyo Institute of Technology, 5.SOKENDAI, 6.Subaru Telescope, 7.Tokyo University of Agriculture and Technology)

### [MIS07-P02] Discrimination of organic compounds and mineral particles by fluorescent microscopy for the detection of Martian life.

*Tomoka Okada[1], Yoshitaka Yoshimura[2], Atsuo Miyakawa[3], Yuka Murano[3], Shin-ichi Yokobori[3], Akihiko Yamagishi[3], Kensei Kobayashi[1], Yoko Kebukawa[1] (1.YOKOHAMA National university, 2.Tamagawa University, 3.Tokyo University of Pharmacy and Life Sciences)

### [MIS07-P03] Morphological and spectroscopic characteristics of organic matter in Banded Iron Formation, Barberton Greenstone Belt, South Africa

*Hiroki Amemiya[1], Ryo Nakajima[1], Yoko Ohtomo[1], Tsubasa Otake[1], Tsutomu Sato[1] (1.Division of sustainable Resources Engineering, Faculty of Engineering, Hokkaido University)

### [MIS07-P04] Understanding peptide sequence selectivity on iron sulfide (FeS) nanoparticle surfaces

*Fujishima Kosuke[1], Norio Kitadai[1], Kenji Kasama[1] (1.Earth-Life Science Institute, Tokyo Institute of Technology)

### [MIS07-P05] A process model of L-homochiral peptides formation initiated with L-alanine

*Toratane Munegumi[1], Taisuke Yamaga[1] (1.Department of Science Education, Naruto University of Education)

### [MIS07-P06] Possible Formation of Amino Acids and Carboxylic Acids in Slightly-Reducing Primitive Earth Atmospheres

*Miei Kinoshita[1], Shintaro Ikeda[1], Kimitaka Kawamura[2], Bhagawati Kunwar[2], Hitoshi Fukuda[3], Yoshiyuki Oguri[3], Hiromi Shibata[4], Junichi Takahashi[1], Vladimir Airapetian[5], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.Yokohama National University, 2.Chubu University, 3.Tokyo Institute of Technology, 4.Osaka University, 5.NASA Goddard SFC)

### [MIS07-P07] Application of Machine learning and software development for initial analysis in the TANPOPO mission

*Kyoko Okudaira[1], Yuto Toda[1], Takashi Sonoke[1], Yuichi Yaguchi[1], Masashi Yoshida[1], Junya Imani[2], Satoshi Sasaki[3], Hajime Yano[4], Hirohide Demura[1], Makoto Tabata[5], Akihiko Yamagishi[6] (1.The University of Aizu, 2.YUKI Precision, 3.Tokyo University of Technology, 4.JAXA, 5.Chiba University, 6.Tokyo University of Pharmacy and Life Science)

### [MIS07-P08] Structure analysis of the hyper velocity impact tracks of the particles captured by silica aerogel on the International Space Station

*Mizuho Nishi[1], Akira Tsuchiyama[1], Hajime Yano[2], Hikaru Yabuta[3], Kyoko Okudaira[4], Junya Matsuno[1], Masayuki Uesugi[5], Uesugi Kentaro[5], Nakano Tukasa[6], Takaaki Noguchi[7], MITA Hajime[8], Akihiko Yamagishi[9] (1.Kyoto University, 2.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 3.Hiroshima University, 4.The University of Aizu, 5.JASRI/SPring-8, 6.National Institute of Advanced Industrial Science and Technology, 7.Kyusyu University, 8.Fukuoka Institute of Technology, 9.Tokyo University of Pharmacy and Life Science)

### [MIS07-P09] High-Angular-Resolution Observations of Protoplanetary Disks

*Misato Fukagawa[1] (1.National Astronomical Observatory of Japan)

[MIS07-P10] Characterization of high molecular weight amino acid precursors formed in interstellar ice analog

*Soushi Kuramoto[1], Tomohito Sato[1], Hitoshi Fukuda[2], Yoshiyuki Oguri[2], Kotaro Kondo[2], Hiromi Shibata[3], Yoko Kebukawa[1], Kensei Kobayashi[1], Satoshi Yoshida[4] (1.Yokohama National University, 2.Tokyo Institute of Technology, 3.University of Osaka, 4.National Institutes for Quantum Radiological Science and Technology)

---

[MIS07-P11] Theoretical elucidation of prebiotic formation processes into nucleobases

*Yu Komatsu[1,2], Taiki Suzuki[1,2] (1.Astrobiology Center, 2.National Astronomical Observatory of Japan)

---

[MIS07-P12] Formation Process of A Glycine's Precursor Candidate, CH3NH2

*Taiki Suzuki[1,2], Liton Majumdar[3], Masatoshi Ohishi[2] (1.National Institutes of Natural Sciences Astrobiology Center, 2.National Astronomical Observatory of Japan, 3.NASA Jet Propulsion Laboratory (JPL))

---

[MIS07-P13] Numerical study on the stellar atmosphere & wind of Cool Stars

*Takahito Sakaue[1], Kazunari Shibata[1] (1.Kyoto University)

---

[MIS07-P14] Design of space exposure experiments of organic matter in Tanpopo 2

*Takuya Yokoo[1], tomohito sato[1], Itsuki Sakon[2], Kazumichi Nakagawa[3], Hajime Yano[4], Miki Nakayama[5], Hajime Mita[5], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.Yokohama National University, 2.University of Tokyo, 3.Kobe University, 4.JAXA, 5.Fukuoka Institute of Technology)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_37

## [M-IS07] Astrobiology

convener:Hikaru Yabuta(Hiroshima University, Department of Earth and Planetary Systems Science), Seiji Sugita(Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo), Misato Fukagawa(National Astronomical Observatory of Japan), Fujishima Kosuke(Tokyo Institute of Technology, Earth-Life Science Institute)

[MIS07-P14] Design of space exposure experiments of organic matter in Tanpopo 2

*Takuya Yokoo[1], tomohito sato[1], Itsuki Sakon[2], Kazumichi Nakagawa[3], Hajime Yano[4], Miki Nakayama[5], Hajime Mita[5], Yoko Kebukawa[1], Kensei Kobayashi[1] (1.Yokohama National University, 2.University of Tokyo, 3.Kobe University, 4.JAXA, 5.Fukuoka Institute of Technology)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 102 1F

## [M-IS09] dust

convener:Ishizuka Masahide(Kagawa University), Yasunori Kurosaki(Arid Land Research Center, Tottori University), Thomas Sekiyama(Meteorological Research Institute), Kana Nagashima(Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change), Chairperson:Tsuyoshi Sekiyama

1:55 PM - 2:15 PM JST | 4:55 AM - 5:15 AM UTC

### [MIS09-01] Global modeling study of atmospheric supply of lithogenic and pyrogenic Fe-containing aerosols to the ocean

★Invited Papers

*Akinori Ito[1], Akitomo Yamamoto[1], Michio Watanabe[1], Maki Noguchi Aita[1], Ying Ye[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Alfred Wegener Institute for Polar and Marine Research)

---

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

### [MIS09-02] Regional variations in the elemental and mineral compositions of solid particles in rainwater in Iran

*Yoriko Yokoo[1], Chihiro Sakamoto[1], Atsushi Kitamura[1], Ryo Anma[2], Shiva Mehrabani[3] (1.Faculty of Science and Engineering, Doshisha University, 2.Tokushima University, 3.Kurdistan University)

---

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

### [MIS09-03] Comparison of airborne microbial variations in air samples from Asian-dust source and arrival regions

*Teruya Maki[1], Tatsuyuki Fujita[1], Yuuma Mastuba[1], Yasunori Kurosaki[2], Masahide Ishizuka[3], Kei Kawai[4], Yasunobu Iwasaka[5] (1.College of Science and Engineering, Kanazawa University, 2.Arid Land Research Center, Tottori University, Tottori University, 3.Faculty of Engineering, Kagawa University, 4.Graduate School of Environmental Studies, Nagoya Universit, 5.Center for Environmental Creative Studies)

---

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

### [MIS09-04] Prediction of health effects of cross-border atmospheric pollutants using the Model of Aerosol Species in the Global Atmosphere (MASINGAR)

*Kazunari Onishi[1], Thomas Sekiyama[2], Yasunori Kurosaki[3], Masato Shinoda[4] (1.Graduate School of Public Health, Support Unit for Conducting Clinically Essential Studies, St.Luke's International University, 2.Meteorological Research Institute, 3.Arid Land Research Center, Tottori University, 4.Graduate School of Environmental Studies Nagoya University)

---

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

### [MIS09-05] Dust layer captured by an inversion layer over the Gobi Desert on 29–30 April 2015

*Kei Kawai[1], Yuta Nishio[2], Kenji Kai[1,3], Jun Noda[4], Erdenebadrakh Munkhjargal[1,5], Masato Shinoda[1], Nobuo Sugimoto[6], Atsushi Shimizu[6], Enkhbaatar Davaanyam[5,7], Dashdondog Batdorj[8] (1.Nagoya University, 2.Japan Meteorological Agency, 3.Ibaraki University, 4.Rakuno Gakuen University, 5.Information and Research Institute of Meteorology, Hydrology and Environment, Mongolia, 6.National Institute for Environmental Studies, 7.University of Tsukuba, 8.National Agency for Meteorology and Environmental Monitoring, Mongolia)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | 102 1F

## [M-IS09] dust

convener:Ishizuka Masahide(Kagawa University), Yasunori Kurosaki(Arid Land Research Center, Tottori University), Thomas Sekiyama(Meteorological Research Institute), Kana Nagashima(Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change), Chairperson:Kana Nagashima

3:30 PM - 3:45 PM JST | 6:30 AM - 6:45 AM UTC

[MIS09-06] Favorable regions for dust haze transport revealed by ensemble simulations

*Kazunori Ogohara[1], Shogo Isoda[1] (1.School of Engineering, University of Shiga Prefecture)

3:45 PM - 4:00 PM JST | 6:45 AM - 7:00 AM UTC

[MIS09-07] Measurement of adhesion force of individual aerosol particles by atomic force microscopy

*Kohei Ono[1], Yuki Mizushima[4], Ayumi Iwata[3], Furuya Masaki[1], Nozomu Tsuchiya[1], Atsushi Matsuki[2] (1.Graduate School of Natural Science and Technology, Kanazawa University, 2.Institute of Nature and Environmental Technology, Kanazawa University, 3.Faculty of Science and Technology, Keio University, 4.College of Science and Technology, Kanazawa University)

4:00 PM - 4:15 PM JST | 7:00 AM - 7:15 AM UTC

[MIS09-08] Occurrence of micro-meso scale dust storms and its relationship to the vegetation and topography in Mongolian grassland and Gobi Desert

*Kenji Kai[1], Kei Kawai[2], Teruya Maki[3], Jun Noda[4] (1.College of Education, Ibaraki University , 2.Nagoya University, 3.Kanazawa University, 4.Rakuno-Gakuen University)

4:15 PM - 4:30 PM JST | 7:15 AM - 7:30 AM UTC

[MIS09-09] A trial of elucidation for dust emission conditions in East Asia by synoptic data analyses and a field observation

*Yasunori Kurosaki[1], Jing Wu[1], Batjargal Buyantogtokh[1], Ishizuka Masahide[2], Batdelger Gantsetseg[3] (1.Tottori University, 2.Kagawa University, 3.IRIMHE, Mongolia)

4:30 PM - 4:45 PM JST | 7:30 AM - 7:45 AM UTC

[MIS09-10] Monitoring and assessing aeolian desertification processes based on a dust erodibility index – A case study in the Xilingol grassland, China

*Jing Wu[1], Yasunori Kurosaki[1], Chunling Du[2], Tao Wang[3] (1. Arid Land Research Center, Tottori University, 2.School of Economics and Management, Inner Mongolia Agricultural University, 3.Northwest Institute of Eco-Environment and Resources, Chinese Academy of Sciences)

4:45 PM - 5:00 PM JST | 7:45 AM - 8:00 AM UTC

[MIS09-11] Influences of land surface conditions and human activities on dust events in Inner Mongolian grasslands, China

*Mei Yong[1], Masato Shinoda[2], Nandintsetseg Banzragch[2] (1.Inner Mongolia normal university, 2.Nagoya university)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_38

## [M-IS09] dust

convener:Ishizuka Masahide(Kagawa University), Yasunori Kurosaki(Arid Land Research Center, Tottori University), Thomas Sekiyama(Meteorological Research Institute), Kana Nagashima(Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change)

[MIS09-P01] Study on decadal influencing of the teleconnection pattern EA and SCAND on major atmospheric circulation systems of the northern China dust storms during the past 65 years (1954-2018)

*Gao Tao[1], Mei Yong[2] (1.Inner Mongolia Meteorological Institute, 2.Inner Mongolia Normal University)

[MIS09-P02] **Effects of freeze-thaw and land-surface processes on dust occurrence in the Mongolian desert steppe**

*Kaman kong[1], Masato Shinoda[1], Banzragch Nandintsetseg[1,2,3], Yasunori Kurosaki[4] (1.Nagoya Unviserity, 2.Information and Research Institute of Meteorology, Hydrology, and Environment, 3.National University of Mongolia, 4.Tottori University)

[MIS09-P03] Mineral particles suspending in the surface waters of the North Pacific and its marginal seas – atmospheric dust deposition as investigated from seawater analysis

*Yoko Iwamoto[1], Mitsuo Uematsu[2] (1.Graduate School of Biosphere Science, Hiroshima University, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

[MIS09-P04] Seasonal change of the Asian dust provenance within the Canadian ice core estimated from cathodoluminescence spectra of single quartz grains

*Kana Nagashima[1], Kumiko Goto-Azuma[2] (1.Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change, 2.National Institute of Polar Research)

[MIS09-P05] Wind tunnel experiments for saltation and dust emission under weak crusted Mongolian soil

*Ishizuka Masahide[1], Yusuke Nakahara[5], Hitomi Masaoka[6], Genki Nakao[6], Tomoyuki Ishii[6], Yasunori Kurosaki[2], Hagino Hiroaki[3], Kouichi Nakamura[7], Batdelger Gantsetseg[4], Kazuki Nanko[9], Eiji Nishihara[8], Satoru Suzuki[9] (1.Kagawa University, Faculty of Engineering and Design, 2.Tottori University, Arid land research center, 3.Forestry and Forest Products Research Institute, Tohoku Research Center, 4.Information and Research Institute of Meteorology Hydrology and Environment, 5.Kagawa University, Graduate school of Engineering, 6.Kagawa University, Faculty of Engineering, 7.Tottori University, Faculty of Engineering, 8.Tottori University, Faculty of Agriculture, 9.Forestry and Forest Products Research Institute, Meteorology and Hydrology)

[MIS09-P06] **Effect of stone on sand saltation in Tsogt-Ovoo, Mongolia: Observation and Model simulation**

*Batjargal Buyantogtokh[1], Yasunori Kurosaki[1], Masahide Ishizuka[2], Tsuyoshi Sekiyama[3] (1.Arid Land Research Center, Tottori University, 2.Faculty of Engineering and Design, Kagawa University, 3.Japan Meteorological Agency, Meteorological Research Institute)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | Convention Hall B 2F

## [M-IS12] tsunami deposit

convener:Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics (CRiED), University of Tsukuba), Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University), Chairperson:Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

### [MIS12-01] Geological Record of Tsunamis and Storms Influenced by Relative Sea-Level Change, Southern Hidaka Coast, Hokkaido, Japan.

*RYO NAKANISHI[1], Satoshi Okamura[1,2], Tsumoru Sagayama[3], Yusuke Yokoyama[4], Yosuke Miyairi[4] (1.Hokkaido Edu. Univ., 2.Hokkaido Soil Res. Co-op., 3.HRCG, 4.Univ. Tokyo)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

### [MIS12-02] Before and after relationship between the seismic uplift and the large tsunami due to the seventeenth-century giant earthquake observed in the seismic barrier systems around the Kuril subduction zone

*Futoshi Nanayama[1,5], Kazuaki Watanabe[1], Keita Fukatsu[2], Takeshi Hasegawa[4], Kiyoyuki Shigeno[3], Masayuki Ishii[6], Kazuhito Ishiwata[7], Shigeto Inokuma[8] (1.Geological Survey of Japan, AIST, 2.Notsuke Peninsula Nature Center, 3.Meiji consultant Co., Ltd., 4.Ibaraki University, 5.CWMD, Kumamoto Univ., 6.Ishii Professional Engineer Office, 7.Betsukai municipal museum, 8.Nemuro City museum history and nature)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

### [MIS12-03] Coastal landform changes and Washover deposits due to high waves generated by anatmospheric low-pressure system in June 2016 at Horokayanto, Hokkaido, Japan

*Takashi Chiba[1], Yuichi Nishimura[2] (1.Faculty of Bioresource Sciences, Akita Prefectural University, 2.Graduate School of Science, Hokkaido University)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

### [MIS12-04] Survey of tsunami deposits in Kunashiri Island: Results obtained in the 2015-2018 projects

*Yuichi Nishimura[1], Yasuhiro Takashimizu[2], Daisuke Sugawara[3], Takafumi Enya[4], Takashi Chiba[5], Ryo Nakanishi[6], Alexander Shishkin[7], Alexey Gorbunov[8], Victor Kaistrenko[8], Asuka Takahashi[9], Hiroki Muramatsu[10], Yasuyuki Kawazoe[11], Naofumi Takamatsu[11] (1.Graduate School of Science, Hokkaido University, 2.Institute of Humanities, Social Sciences and Education, Niigata University, 3.Museum of Natural and Environmental History, Shizuoka, 4.Hokkaido Museum, 5.Faculty of Bioresource Sciences, Akita Prefectural University, 6.Hokkaido Education University, 7.Shikotan Geophysical Observatory, 8.Institute of Marine Geology and Geophysics, Russian Academy of Sciences, 9.Japan Meteorological Agency, 10.Geospatial Information Authority of Japan, 11.Ministry of Education, Culture, Sports, Science and Technology)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

### [MIS12-05] Deposit-based assessment of tsunami size: example from Nankai-Trough earthquakes

*Daisuke Sugawara[1], Kentaro Imai[2], Shinsuke Okada[3], Takuto Maeda[4] (1.Museum of Natural and Environmental History, Shizuoka, 2.JAMSTEC, 3.Tohoku University, 4.Hirosaki University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

### [MIS12-06] Flume experiments for understanding variety of tsunami deposit

★Invited Papers

*Naofumi Yamaguchi[1] (1.Center for Water Environment Studies, Ibaraki University)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | Convention Hall B 2F

## [M-IS12] tsunami deposit

convener:Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics (CRiED), University of Tsukuba), Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University), Chairperson:Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics, University of Tsukuba)

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS12-07] **Inverse modeling of Tsunami deposit using Deep Learning Neural Network**

*Rimali Mitra[1], Hajime Naruse[1] (1.Kyoto University, Graduate School of Science)

---

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS12-08] Numerical estimation of tsunami size using boulders deposited by the 2011 Tohoku-oki tsunami at Settai, Miyako city, Japan

*Tatsuya Takei[1,4], Kazuhisa Goto[2], Masaki Yamada[3] (1.Department of Earth Sciences, Graduate School of Science, Tohoku University, 2.International Research Institute of Disaster Science (IRIDeS), Tohoku University, 3.Earthquake Research Institute, University of Tokyo, 4.Department of Complexity Science and Engineering, Graduate School of Frontier Sciences, Tokyo University)

---

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS12-09] Constraint of the ages of historical tsunami deposits on the Ishinomaki Plain

*Hiroshi Tetsuka[1], Kazuhisa Goto[2], Takashi Ishizawa[1], Daisuke Sugawara[3], Yusuke Yokoyama[4], Yosuke Miyairi[4] (1.Department of Earth Science, Tohoku University, 2.International Research Institute of Disaster Science, Tohoku University, 3.Museum of Natural and Environmental History, Shizuoka, 4.Atmosphere and Ocean Research Institute, University of Tokyo)

---

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS12-10] Non-destructive analyzes of sediments to discern tsunami-related mud cap and overlying muds to improve age determination of tsunami deposits

*Takashi Ishizawa[1], Kazuhisa Goto[2], Yusuke Yokoyama[3], Yosuke Miyairi[3] (1.Department of Earth Science, Tohoku University, 2.International Research Institute of Disaster Science, Tohoku University, 3.Atmosphere and Ocean Research Institute, The University of Tokyo)

---

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS12-11] Sedimentological and paleontological studies of storm surge deposits in intertidal mud floor -case study of Ena Bay on Miura Peninsula, Central Japan.

*Akihisa Kitamura[1], yamamoto yuka[1], Takashi Toyofuku[2] (1.Institute of Geosciences, Faculty of Science, Shizuoka University, 2.Japan Agency for Marine-Earth Science and Technology (JAMSTEC))

---

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[MIS12-12] Shallow marine tsunami deposits and bioturbation

★Invited Papers

*Koji Seike[1] (1.Geological Survey of Japan, AIST)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_21

## [M-IS12] tsunami deposit

convener:Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics (CRiED), University of Tsukuba), Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University)

[MIS12-P01] Discussion of tsunami age estimation using coralline tsunami deposits

*Ryosuke Fujita[1], Kazuhisa Goto[1], Yasufumi Iryu[1], Takashi Ishizawa[1], Yusuke Yokoyama[2], Yosuke Miyairi[2] (1.TOHOKU University, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

[MIS12-P02] Identification method of event deposits caused by natural hazards

*Takumi Yoshii[1], Shiro Tanaka[1], Yuki Ito[1], Takaomi Hamada[1], Masafumi Matsuyama[1] (1.Central Research Institute of Electric Power Industry)

[MIS12-P03] Investigation of event deposits for construction of tsunami deposit discriminating method

*Shiro Tanaka[1], Takumi Yoshii[1], Yasuto Hirata[1], Takaomi Hamada[1], Masafumi Matsuyama[1], Yuki Ito[1] (1.Central Research Institute of Electric Power Industry)

[MIS12-P04] Lateral variation of mud clasts in onshore tsunami deposits

*Yasuhiro Takashimizu[1], Daichi Ito (1.Niigata University)

[MIS12-P05] Examination of model validity and sensitivity of tsunami sediment transport modeling using the 2011 Tohoku tsunami deposits in Iwate, Miyagi, and Fukushima Prefectures

*Satoshi Kusumoto[1], Aditya Gusman[2], Kenji Satake[1] (1.Earthquake Research Institute, the Univ. of Tokyo, 2.GNS Science)

[MIS12-P06] Paleotsunami History in Hachinohe, Aomori Prefecture, northern Japan

*Erick Velasco R.[1], Kazuhisa Goto[2], Takahiro Shinohara[1], Daisuke Sugawara[3], Yuichi Nishimura[4], Takashi Chiba[5] (1.Earth Science Department, Graduate Faculty of Science, Tohoku Univ., 2.International Research Institute of Disaster Science (IRIDeS), Tohoku Univ., 3.Museum of Natural and Environmental History, Shizuoka, 4.Graduate School of Science, Hokkaido Univ., 5.Faculty of Bioresource Sciences, Akita Prefectural Univ.)

[MIS12-P07] Characteristics of event deposits and their source in Sekine-hama, Mutsu city, Aomori prefecture

# Cancelled

*Daisuke Ishimura[1], Kaori Aoki[2] (1.Department of Geography, Tokyo Metropolitan University, 2.Research Center for Volcanic Hazards and Their Mitigation, Tokyo Metropolitan University)

[MIS12-P08] **Sedimentary structure and composition of sand blows and sand dikes formed by the 2018 Iburi-Tobu Earthquake, Hokkaido, Japan**

*Yuichi Nishimura[1], Takashi Chiba[2] (1.Graduate School of Science, Hokkaido University, 2.Faculty of Bioresource Sciences, Akita Prefectural University)

[MIS12-P09] Tsunami deposits and tsunami wave source of the southern part of Okushiri Island, Hokkaido

*Atsushi Urabe[1], Yoshihiro Kase[2], Gentaro Kawakami[2], Kenji Nishina[2], Hiromichi Koyasu[2] (1.Research Institute for Natural Hazards and Disaster Recovery, Niigata University, 2.Geological Survey of Hokkaido, Hokkaido Research Organization)

[MIS12-P10] Inter-seismic and post-seismic tectonic movements detected during the 17th century earthquake and inferred from diatom analysis in Tokachi area, Hokkaido, Japan

*Takashi Chiba[1], Yuichi Nishimura[2] (1.Faculty of Bioresource Sciences, Akita Prefectural University, 2.Graduate School of Science, Hokkaido University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_39

## [M-IS12] tsunami deposit

convener:Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Tetsuya Shinozaki(Center for Research in Isotopes and Environmental Dynamics (CRiED), University of Tsukuba), Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University)

[MIS12-P01] Discussion of tsunami age estimation using coralline tsunami deposits

*Ryosuke Fujita[1], Kazuhisa Goto[1], Yasufumi Iryu[1], Takashi Ishizawa[1], Yusuke Yokoyama[2], Yosuke Miyairi[2] (1.TOHOKU University, 2.Atmosphere and Ocean Research Institute, the University of Tokyo)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

9:00 AM - 10:30 AM JST | 12:00 AM - 1:30 AM UTC | A05 TOKYO BAY MAKUHARI HALL

## [M-IS16] Dynamics of eruption cloud and cumulonimbus; modelling and observation

convener:Eiichi Sato(Meteorological Research Institute), Fukashi Maeno(Earthquake Research Institute, University of Tokyo), Takeshi Maesaka(National Research Institute for Earth Science and Disaster Resilience), Chairperson:Eiichi Sato(Meteorological Research Institute)

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

[MIS16-01] **Observations of Volcanic Eruption Columns with Different Types of Weather Radars**

★Invited Papers

*Masayuki Maki[1], Takehiko KOBORI[1], Yura Kim[1], Yasushi Fujiyoshi[2], Eiichi Sato[3], Hidehiko Tokushima[4], Masato Iguchi[5] (1.Kagoshima University, 2.Hokkaido University, 3.Meteorological Research Institute, 4.Field Researchers Corporation, 5.Kyoto University)

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

[MIS16-02] Observation of Eruption Plumes by X-Band MP radar and Lidar at Sakurajima and Kuchinoerabujima

*Haruhisa Nakamichi[1], Atsushi Shimizu[2], Makoto Shimomura[1], Magfira Syarifuddin[1], Masato Iguchi[1] (1.Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University, 2.National Institute for Environmental Studies)

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

[MIS16-03] 2018-2019 Kuchinoerabu-jima eruption plume/cloud echoes observed by JMA weather radar network

*Eiichi Sato[1], Keiichi Fukui[2], Toshiki Shimbori[1] (1.Meteorological Research Institute, 2.Japan Meteorological Agency)

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

[MIS16-04] Numerical Study on the Ejection Conditions of Ash Clouds during Recent Eruptions of Kuchinoerabujima Volcano

*Yasuhiro Ishimine[1], Teruki Oikawa[2], Nobuo Geshi[2] (1.Research and Education Center for Natural Hazards, Kagoshima University, 2.Geological Survey of Japan, AIST)

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

[MIS16-05] Image analysis of volcanic clouds during the 2011 Kirishima Shinmoedake eruption

*Takehiko KOBORI[1], Kisei KINOSHITA[1], Naoko IINO[2], Masayuki MAKI[1], Seiji FUKUSHIMA[1] (1.Kagoshima University, 2.Kumamoto University)

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

[MIS16-06] Cloud Radar Network for Early Detection of Cumulonimbus Generation

*Takeshi Maesaka[1], Tadayasu Ohigashi[1], Koyuru Iwanami[1], Shin-Ichi Suzuki[1], Yukari Shusse[1], Namiko Sakurai[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_22

## [M-IS16] Dynamics of eruption cloud and cumulonimbus; modelling and observation

convener:Eiichi Sato(Meteorological Research Institute), Fukashi Maeno(Earthquake Research Institute, University of Tokyo), Takeshi Maesaka(National Research Institute for Earth Science and Disaster Resilience)

[MIS16-P01] Redesign of the Japan Meteorological Agency Atmospheric Transport Model

*Toshiki Shimbori[1], Kensuke Ishii[1] (1.Volcanology Research Department, Meteorological Research Institute)

[MIS16-P02] Mathematical mechanism of an inverse problem for tephra transport and dispersal model

*Kensuke Ishii[1], Takehiro Koyaguchi[2] (1.Meteorological Research Institute, 2.Earthquake Research Institute, the University of Tokyo)

[MIS16-P03] Development of the plume source model for inversion of tephra fallout

*Akira Nishijo[1], Takehiro Koyaguchi[1], Yujiro Suzuki[1] (1.The University of Tokyo Earthquake Research Institute)

[MIS16-P04] Segregation height and size distribution of volcanic ash of Sakurajima eruptions inferred by observed settling velocity

*Kosei Takishita[1], Masato Iguchi[2], Tadaomi Sonoda[2] (1.Graduate School of Science, Kyoto Univ., 2.DPRI, Kyoto Univ.)

[MIS16-P05] Distant tracking of maximum pumice diameter in pumice-fall of the Tenmei eruption of Asama volcano: An attempt to draw isopleth lines of mm scale-maximum pumice diameter in the Kanto Plain

*Shingo Takeuchi[1], Shimpei Uesawa[1] (1.Central Research Institute of Electric Power Industry, Civil Engineering Research Laboratory, Geosphere Sciences)

[MIS16-P06] Degassing activity of Aso volcano, Japan, before the 8 October 2016 eruption measured by satellite and ground-based remote sensing techniques

*Masaaki Morita[1] (1.Geological Survey of Japan, AIST)

[MIS16-P07] Characteristics of polarimetric radar parameters of dry volcanic ash clouds

*Yura Kim[1], Masayuki Maki[1], Masato Iguchi[2], Dong-In Lee[3] (1.Research and Education Center for Natural Hazards, Kagoshima University, Korimoto, Kagoshima, Japan, 2.Sakurajima Volcano Research Center/DPRI, Kyoto University, Sakurajima, Kagoshima, Japan, 3.Department of Atmospheric Sciences, Pukyong National University, Namgu, Busan, Republic of Korea)

[MIS16-P08] Development of easy tools for volcanic eruption plume/cloud analysis using weather radars

*Eiichi Sato[1], Ryutaro Senba[2] (1.Meteorological Research Institute, 2.Fukuoka Regional Headquarter, Japan Meteorological Agency)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_40

## [M-IS16] Dynamics of eruption cloud and cumulonimbus; modelling and observation

convener:Eiichi Sato(Meteorological Research Institute), Fukashi Maeno(Earthquake Research Institute, University of Tokyo), Takeshi Maesaka(National Research Institute for Earth Science and Disaster Resilience)

[MIS16-P01] Redesign of the Japan Meteorological Agency Atmospheric Transport Model

## [M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Hitoshi Hasegawa

9:00 AM - 9:15 AM JST | 12:00 AM - 12:15 AM UTC

### [MIS19-17] Paleotemperature and precipitation history (18.1–4.5 ka) in stalagmite bulk and clumped isotopes from Hiroshima, Japan

*Hirokazu Kato[1], Shota Amekawa[1], Akihiro Kano[1] (1.Department of Earth and Planetary Science, The University of Tokyo)

---

9:15 AM - 9:30 AM JST | 12:15 AM - 12:30 AM UTC

### [MIS19-18] Terrestrial paleoclimate since 80 ka recorded in stable and clumped isotopes of two stalagmites obtained from the Pacific side of the Japanese islands

*Shota Amekawa[1], Hirokazu Kato[1], Akihiro Kano[1], Kenji Kashiwagi[2], Taiki Mori[3], Ryoko Senda[3], Chuan–Chou Shen[4] (1.Graduate School of Science, The University of Tokyo, 2.Graduate School of Science and Engineering for Research, University of Toyama, 3.Graduate School of Integrated Sciences for Global Society, Kyushu University, 4.Department of Geosciences, National Taiwan University)

---

9:30 AM - 9:45 AM JST | 12:30 AM - 12:45 AM UTC

### [MIS19-19] Seasonal changes in Li/Ca ratio and inferred phytoplankton abundance as analyzed by daily growth increments of *Pecten albicans* (Bivalvia)

*Kondo Yasuo[1], Hondo Shutaro, Hasegawa Hitoshi[1], Nshio Yoshiro[1], Hirota Takayoshi (1.National University Corporation Kochi University)

---

9:45 AM - 10:00 AM JST | 12:45 AM - 1:00 AM UTC

### [MIS19-20] Geological reconstruction of Antarctic Ice Sheet deglaciation on Soya Coast, East Antarctica since the Last Glacial Maximum

*Moto Kawamata[1], Yusuke Suganuma[2,1], Koichiro Doi[2,1], Takanobu Sawagaki[3], Akihisa Hattori[1] (1.Department of Polar Science, School of Multidisciplinary Science, SOKENDAI (The Graduate Unversity for Advanced Studies), 2.National Institute of Polar Research, 3.Hosei University)

---

10:00 AM - 10:15 AM JST | 1:00 AM - 1:15 AM UTC

### [MIS19-21] Os isotope record of the Quaternary seawater derived from pelagic sediment in the Lau Basin, western South Pacific Ocean, and its implications for global climate changes

*Yusuke Kuwahara[1], Kazutaka Yasukawa[1,2], Koichiro Fujinaga[2,3], Tatsuo Nozaki[4,3,5,2], Junichiro Ohta[2,6,3], Honami Sato[2,4], Jun-Ichi Kimura[6], Kentaro Nakamura[1], Yasuhiro Kato[3,1,2] (1.Department of Systems Innovation, School of Engineering, The University of Tokyo, 2.Ocean Resources Research Center for Next Generation, Chiba Institute of Technology, 3.Frontier Research Center for Energy and Resources, School of Engineering, The University of Tokyo, 4.Research and Development Center for Submarine Resources, Japan Agency for Marine-Earth Science and Technology , 5.Department of Planetology, Graduate School of Science, Kobe University, 6.Department of Solid Earth Geochemistry, Japan Agency for Marine-Earth Science and Technology)

---

10:15 AM - 10:30 AM JST | 1:15 AM - 1:30 AM UTC

### [MIS19-22] Rapid glaciation and sea level changes during the Last Glacial Maximum and the deglaciation

*Yusuke Yokoyama[1], Tezer M Esat[9], William G Thompson[10], Alexandar L Thomas[11], Jody W Webster[2], Yosuke Miyairi[1], Chikako Sawada[1], Takahiro AZE[1], Hiroyuki Matsuzaki[1], Jun'ichi Okuno[3], Stewart Fallon[9], Juan-Carlos Braga[12], Marc Humblet[4], Yasufumi Iryu[5], Donald C Potts[13], Kazuhiko Fujita[6], Atsushi Suzuki[7], Hironobu Kan[8] (1.Atmosphere and Ocean Research Institute, University of Tokyo, 2.University of Sydney, Australia, 3.National Institute of Polar Research, 4.Nagoya University, 5.Tohoku University, 6.University of the Ryukyus, 7.The Geological Survey of Japan, AIST, 8.Kyushu University, 9.Research School of Earth Sciences, The Australian National University, Australia, 10.Woods Hole Oceanographic Institute, USA, 11.University of Edinburgh, UK, 12.Universidad de Granada, Spain, 13.University of California Santa Cruise, USA)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

10:45 AM - 12:15 PM JST | 1:45 AM - 3:15 AM UTC | 304 3F

## [M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University), Chairperson:Yusuke Okazaki

10:45 AM - 11:00 AM JST | 1:45 AM - 2:00 AM UTC

[MIS19-23] Long-chain alkenediones found from marine sediments and their unsaturation ratios: key compounds to study the evolution of alkenone biosynthetic pathway?

*Satoshi Furota[1], Hideto Nakamura[2], Ken Sawada[3] (1.Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2.Faculty of Science, Osaka City University, 3.Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University)

11:00 AM - 11:15 AM JST | 2:00 AM - 2:15 AM UTC

[MIS19-24] **Geomorphic and pedogenic forcing on the distribution of organic matter from vegetation to soil- a concern for paleoenvironment studies**

*Biswajit Roy[1], Kanva Goyal[1], Prasanta Sanyal[1] (1.Indian Institute of Science Education Research Kolkata)

11:15 AM - 11:30 AM JST | 2:15 AM - 2:30 AM UTC

[MIS19-25] Sea surface salinity of the Kuroshio Current along the Nansei Islands in the mid-Holocene inferred from fossil corals

*Kohki Sowa[1], Chuki Hongo[2], Kentaro Tanaka[3], Takuma Fujii[4], Saburo Sakai[1], Kosei E. Yamaguchi[6,5] (1.Japan Agency for Marine-Earth Science and Technology, 2.Ryukyu University, 3.The University of Tokyo , 4.Kagoshima University, 5.Toho University, 6.NASA Astrobiology Institute)

11:30 AM - 11:45 AM JST | 2:30 AM - 2:45 AM UTC

[MIS19-26] An ocean-dynamic model for the periodic inflow of Tsushima Current in the early Holocene

*Atsuhiko Isobe[1] (1.Research Institute for Applied Mechanics, Kyushu University)

11:45 AM - 12:00 PM JST | 2:45 AM - 3:00 AM UTC

[MIS19-27] Centennial to millennial scale variability of the Aleutian Low and Westerly Jet during the Holocene

*Kana Nagashima[1], Naomi Harada[1] (1.Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change)

12:00 PM - 12:15 PM JST | 3:00 AM - 3:15 AM UTC

[MIS19-28] **Monsoon-related errors in paleotemperature estimation based on leaf margin analysis in central Japan**

*Yuqing Wang[1], Arata Momohara[1], Yongjiang Huang[2] (1.Graduate School of Horticulture, Chiba University, 2.Key Laboratory for Plant Diversity and Biogeography of East Asia, Kunming Institute of Botany, CAS)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

3:30 PM - 5:00 PM JST | 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_23

## [M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University)

### [MIS19-P01] Orbital-scale changes in redox condition and biogenic silica/detrital fluxes of the Jurassic Radiolarite: Possible link with glaciation?

*Masayuki Ikeda[1] (1.Shizuoka University)

### [MIS19-P02] Evaluation of hinterland weathering and paleoclimate of the Cretaceous strata in the Sichuan basin, central China

*Tenichi Cho[1], Hideaki Mantani[1], Tohru Ohta[1], Gang Li[2] (1.Waseda University, 2.Nanjing Institute of Geology and Paleontology)

### [MIS19-P03] Productivity-induced lacustrine bedded chert formation in the Eocene Green River Formation

*Ryusei Kuma[1], Hitoshi Hasegawa[2], Koshi Yamamoto[1], Hidekazu Yoshida[1], Masayuki Ikeda[3], Nagayoshi Katsuta[4], J. Whiteside[5] (1.Nagoya University, 2.Kochi University, 3.Shizuoka University, 4.Gifu University, 5.Southampton University)

### [MIS19-P04] Extraction of the sedimentary cycles and application of cyclostratigraphy to the Middle Miocene Onnagawa Formation in Yashima District, Akita Prefecture, Japan

*Jumpei Yoshioka[1], Ryuji Tada[1,3], Kenji Marc Raymond Matsuzaki[2], Toshihiro Tada[1], Aki Sakuma[1], Yusuke Umemiya[1], Shunsuke Kurokawa (1.Department of Earth and Planetary Science, the University of Tokyo, 2.Atmosphere and Ocean Research Institute, the University of Tokyo, 3.Yunnan University)

### [MIS19-P05] Pliocene magneto–oxygen isotope stratigraphy from the Anno Formation, Awa Group, central Japan

*Yuki Haneda[1], Makoto Okada[1] (1.College of Science, Ibaraki University)

### [MIS19-P06] Planktonic foraminiferal assemblage and paleoceanography of the Plio-Pleistocene sequence at IODP Site U1499 in the northern South China Sea

*Mizuki Kitamura[1], Akira Furusawa[1], Hiroki Hayashi[1] (1.SHIMANE University)

### [MIS19-P07] Reconstruction of the surface water mass fluctuation during the late Pliocene to early Pleistocene based on planktonic foraminiferal fossils from the Mera Formation, Chikura Group, in the southernmost part of the Boso Peninsula

*Makoto Okada[1], Daisuke Hasegawa[2] (1.Department of Earth Sciences, Faculty of Science, Ibaraki University, 2.Graduate School of Scinece and Engineering, Ibaraki University)

### [MIS19-P08] Centennial-scale bioproductivity changes during the earliest Middle-Pleistocene

*Waka Fujii[1], Masayuki Hyodo[1], Shigehiro Katoh[2], Yosuke Miyairi[3], Haruka Yamaguchi[1], Yusuke Yokoyama[3] (1.Kobe University, 2.Hyogo Museum of Nature and Human Activities, 3.University of Tokyo)

### [MIS19-P09] Development of new-paleoceanographic proxies based on oxygen isotope analysis of sponge spicule

*Hitomi Uchimura Wakaki[1], Akira Ijiri[2], Minoru Ikehara[1], Sangmin Hyun[3] (1.Center for Advanced Marine Core Research, Kochi University, 2.Japan Agency for Marine-Earth Science and Technology, 3.Korea Institute of Ocean Science & Technology)

### [MIS19-P10] A system for automatic collection of specific microfossil species using a deep learning classification

*Takuya Itaki[1], Yosuke Taira[2], Naoki Kuwamori[2], Toshinori Maebayashi[3], Satoshi Takeshima[4], Kenji Toya[4] (1.Geological Survey of Japan, AIST, 2.NEC Corporation, 3.Microsupport Co.Ltd, 4.Mitani-Corporation)

[MIS19-P11] Towards reconstructing environmental conditions related to Australian Great Barrier Reef initiation

*Stephen Obrochta[1], Wataru Miwa[1], Kotaro Shirai[2], Yusuke Yokoyama[2], Yosuke Miyairi[2], Jody Webster[2,3], Albert Hine[4] (1.Akita University, 2.University of Tokyo Atmosphere and Ocean Research Institute, 3.University of Sydney, 4.University of South Florida College of Marine Science)

[MIS19-P12] An 8,000-year climate record from Lake Motosu, Japan: Implications for the East Asian Monsoon

Sarah McDonlad[3], Jonathan Tyler[3], *Stephen Obrochta[1], Yusuke Yokoyama[2], Yosuke Miyairi[2], Kosuke Ota[2] (1.Akita University, 2.University of Tokyo Atmosphere and Ocean Research Institute, 3.Department of Earth Sciences, The University of Adelaide)

[MIS19-P13] Environmental changes in northern Mongolia in During the Late Pleistocene: chemical analyses of lacustrine sedimentary sequences in Darhad basin

Yumiko Ohno[1], Sayuri Naito[1], *Nagayoshi Katsuta[1], Takuma Murakami[3], Shinya Ochiai[2], Noriko Hasebe[2], Shin-ichi kawaka[4] (1.Faculty of Education, Gifu University, 2.Institute of Natural and Environmental Technology, Kanazawa University, 3.Horonobe Research Inst. for the Subsurface Environment, 4.Faculty of Education, Gifu Shotoku Gakuen University)

[MIS19-P14] Paleoenvironmental changes recorded in Orog Lake, southwestern Mongolia during MIS 3 and its relationship with *Homo sapiens*'s migration into northern Asia

*Hitoshi Hasegawa[1], Nanase Noma[1], Nagayoshi Katsuta[2], Masafumi MURAYAMA[3], Toru Tamura[4], Masami Izuho[5], Niiden Ichinnorov[6], Davaasuren Davaadorj[7], Noriko Hasebe[8], Miho Sasaoka[9], Masao Iwai[9] (1.Faculty of Science and Technology, Kochi Univ., 2.Faculty of Education, Gifu Univ., 3.Faculty of Agriculture and Marine Science, Kochi Univ., 4.Geological Survey of Japan, AIST, 5.Faculty of Social Sciences and Humanities, Tokyo Metropolitan Univ., 6.Mongolian Academy of Sciences, 7.National University of Mongolia, 8.Institute of Nature and Environmental Technology, Kanazawa Univ., 9.Center for Advanced Marine Core Research, Kochi Univ.)

[MIS19-P15] Reconstruction for water-mass structure of the Okhotsk Sea for the past 1.5 million years based on radiolarian assemblages

*Tatuya Sakamoto[1], Yusuke Okazaki[1] (1.Department of Earth and Planetary Sciences, School of Science, Kyushu University)

[MIS19-P16] Silicoflagellate assemblages in the Okhotsk Sea during the interglacial periods

*Kazuki Egashira[1], Yusuke Okazaki[2], Tatsuhiko Sakamoto[3] (1.Department of Earth and Planetary Sciences, Kyushu University, 2.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University , 3.Mie University)

[MIS19-P17] Role of wind stress and sea surface thermal forcing in the formation of the Atlantic meridional overturning circulation at the Last Glacial Maximum

*Akira Oka[1], Kazuki Togawa[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[MIS19-P18] Comparison of the Kuroshio during LGM simulated by an ocean general circulation model driven by multiple paleoclimate models

*Kensho Ichikawa[1], Haiyan Yang[2], Xinyu Guo[2], Yasumasa Miyazawa[3] (1.Graduate School of Science and Engineering,Ehime University, 2.Center for Marine Environmental Studies,Ehime University, 3.Japan Agency for Marine-Earth Science and Technology)

[MIS19-P19] The changes of the Kuroshio path in the Northwest Pacific since 35ka

*Haiyan Yang[1], Xinyu Guo[1], Ayako Abe-Ouchi[2], Yasumasa Miyazawa[3], Sergey Varlamov[4], Wing-Le Chan[2] (1.Center for Marine Environmental Studies, Ehime University, 2.Atmosphere and Ocean Research Institute, University of Tokyo, 3.Research Institute for Global Change, Japan Agency for Marine-Earth Science and Technology, 4.Application Laboratory, Japan Agency for Marine-Earth Science and Technology)

[MIS19-P20] Temperature reconstruction in the late Pleistocene using fossil terrestrial snails and a stalagmite from an archaeological cave in Okinawa

*Ryuji Asami[1], Rikuto Hondoh[2], Ryu Uemura[3], Ryuichi Shinjo[3], Akihiro Kano[4], Masaki Fujita[5], Shinji Yamasaki[6], Hideko Takayanagi[1], Yasufumi Iryu[1] (1.Graduate School of Science, Tohoku University, 2.Faculty of Science, Tohoku University, 3.Faculty of Science, University of the Ryukyus, 4.School of Science, the University of Tokyo, 5.National Museum of Nature and Science, 6.Okinawa Prefectural Museum and Art Museum)

[MIS19-P21] Silicoflagellate and *Actiniscus* response to meltwater during the last deglaciation in the Alaska margin

*Asuka Tomokawa[1], Yusuke Okazaki[1], Jonaotaro Onodera[2], Keiji Horikawa[3] (1.Department of Earth and Planetary Sciences, Kyushu University, 2.Research and Development Center for Global Change, JAMSTEC, 3.Graduate School of Engineer and Science, University of Toyama)

---

[MIS19-P22] Application of the ramped pyrolysis $^{14}C$ dating to postglacial sediments from the Alaskan margin, Arctic Ocean

*Kenta Suzuki[1], Masanobu Yamamoto[1,2], Brad Rosenheim[3], Takayuki Omori[4], Leonid Polyak[5] (1.Graduate School of Environmental Science, Hokkaido University, 2.Faculty of Environmental Earth Science, Hokkaido University, 3.College of Marine Science, University of South Florida, 4.The University Museum, The University of Tokyo, 5.Bard Polar and Climate Research Center, Ohio State University)

---

[MIS19-P23] Utility of sedimentary environmental DNA for indices of past pelagic fish species populations

*Hiromichi Tamai[1], Michinobu Kuwae[2], Hideyuki Doi[3], Toshihumi Minamoto[4] (1.Graduate School of Science and Engineering, Ehime university, 2.Center for Marine Environmental Studies, Ehime university, 3.Graduate School of Simulation Studies, University of Hyogo, 4.Graduate School of Human Development and Environment, Kobe University)

---

[MIS19-P24] Improvements of extraction methods of sedimentary fish-origin DNA for reconstruction of marine fish communities

*Jun Kurata[1], Hiromichi Tamai[2], Hideyuki Doi[3], Toshihumi Minamoto[4], Michinobu Kuwae[5] (1. department of earth science, Ehime university, 2.Graduate School of Science and Engineering, Ehime university, 3.Graduate School of Simulation Studies, University of Hyogo, 4.Graduate School of Human Development and Environment, Kobe University, 5.Center for Marine Environmental Studies, Ehime university)

---

[MIS19-P25] The paleotemperature reconstruction during the late-Holocene using the sediment core recovered from the Tokyo Bay, Japan

*Hiroto Kajita[1,2,3,4], Naomi Harada[5], Miyako Sato[5], Nanako Ogawa[1], Yusuke Yokoyama[1,2,4], Chikako Sawada[1], Yosuke Miyairi[1], Masayuki Utsunomiya[3], Atsushi Suzuki[3], Hodaka Kawahata[1,2,3] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, Japan, 2.Department of Earth and Planetary Science, Graduate school of Science, The University of Tokyo, Japan, 3. Research Institute of Geology and Geoinformation, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST), Japan, 4.Department of Biochemistry, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Japan, 5.Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Japan)

---

[MIS19-P26] Summer monsoon variability over the past 400 years in Tateyama, Japan, as reconstructed from tree-ring oxygen isotope data

*Masaki Sano[1], Kota Mori[1], Akane Tsushima[2], Zhen Li[3], Koh Yasue[4], Takeshi Nakatsuka[2,3] (1.Faculty of Human Sciences, Waseda University, 2.Nagoya University, 3.Research Institute for Humanity and Nature, 4.Shinshu University)

---

[MIS19-P27] Eventural Layers of anciant disasters during these 4500 years at Lake Ikeda (Lake Daijya), western coast of Kyushu Island presumed by diatom assemblages in lake deposits

*Kaoru Kashima[1], Tomokazu Mita[1], Yu Fukumoto[3], Tsuyoshi Haraguchi[2], Kazuyoshi Yamada[4] (1.Department of Earth and Planetary Sciences, Kyushu University, 2.Department of Geosicneces, Graduate School of Science, Osaka City University, 3.Ritsumeikan University, 4.Museum of Natural and Environmental History, Shizuoka)

---

[MIS19-P28] Variability of hemipelagic and event depositions in the Beppu Bay during Holocene

*Tomohisa Irino[1], Airi Maruyama[1], Ken Ikehara[2], Masanobu Yamamoto[1], Michinobu Kuwae[3] (1.Graduate School of Environmental Science, Hokkaido University, 2.Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology, 3. Center for Marine Environmental Studies, Ehime University)

---

[MIS19-P29] The composition of laminae in the sediment of Beppu-Bay and potential as annual laminations

*Yoshiaki Suzuki[1], Michinobu Kuwae[2], Kazuno Arai[3], Ken Ikehara[4], Masafumi MURAYAMA[3] (1.Waseda University, 2.Ehime University, 3.Kochi University, 4.AIST)

---

[MIS19-P30] Simulation of global distribution of Pa/Th using an ocean general circulation model

*Yusuke Sasaki[1], Akira Oka[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[MIS19-P31] Construction of modern silicoflagellate assemblage dataset in the North Pacific for paleo sea-surface temperature and its application for sediment cores

*Yusuke Okazaki[1], fumiaki nishizono[1], Tanizaki Kyohei[1] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University)

[MIS19-P32] Microplastics in surface sediments of the Ariake Bay

Hiroki Sonoda[1], *Yusuke Okazaki[1], Atsuhiko Isobe[2] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Research Institute for Applied Mechanics, Kyushu University)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

5:15 PM - 6:30 PM JST | 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_41

## [M-IS19] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Michinobu Kuwae(Center for Marine Environmental Studies), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University)

### [MIS19-P01] Orbital-scale changes in redox condition and biogenic silica/detrital fluxes of the Jurassic Radiolarite: Possible link with glaciation?

*Masayuki Ikeda[1] (1.Shizuoka University)

### [MIS19-P02] Evaluation of hinterland weathering and paleoclimate of the Cretaceous strata in the Sichuan basin, central China

*Jun Kurata[1], Hiromichi Tamai[2], Hideyuki Doi[3], Toshihumi Minamoto[4], Michinobu Kuwae[5] (1. department of earth science, Ehime university, 2.Graduate School of Science and Engineering, Ehime university, 3.Graduate School of Simulation Studies, University of Hyogo, 4.Graduate School of Human Development and Environment, Kobe University, 5.Center for Marine Environmental Studies, Ehime university)

[MIS19-P25] The paleotemperature reconstruction during the late-Holocene using the sediment core recovered from the Tokyo Bay, Japan

*Hiroto Kajita[1,2,3,4], Naomi Harada[5], Miyako Sato[5], Nanako Ogawa[1], Yusuke Yokoyama[1,2,4], Chikako Sawada[1], Yosuke Miyairi[1], Masayuki Utsunomiya[3], Atsushi Suzuki[3], Hodaka Kawahata[1,2,3] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, Japan, 2.Department of Earth and Planetary Science, Graduate school of Science, The University of Tokyo, Japan, 3. Research Institute of Geology and Geoinformation, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST), Japan, 4.Department of Biochemistry, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Japan, 5.Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Japan)

[MIS19-P26] Summer monsoon variability over the past 400 years in Tateyama, Japan, as reconstructed from tree-ring oxygen isotope data

*Masaki Sano[1], Kota Mori[1], Akane Tsushima[2], Zhen Li[3], Koh Yasue[4], Takeshi Nakatsuka[2,3] (1.Faculty of Human Sciences, Waseda University, 2.Nagoya University, 3.Research Institute for Humanity and Nature, 4.Shinshu University)

[MIS19-P27] Eventural Layers of anciant disasters during these 4500 years at Lake Ikeda (Lake Daijya), western coast of Kyushu Island presumed by diatom assemblages in lake deposits

*Kaoru Kashima[1], Tomokazu Mita[1], Yu Fukumoto[3], Tsuyoshi Haraguchi[2], Kazuyoshi Yamada[4] (1.Department of Earth and Planetary Sciences, Kyushu University, 2.Department of Geosicneces, Graduate School of Science, Osaka City University, 3.Ritsumeikan University, 4.Museum of Natural and Environmental History, Shizuoka)

[MIS19-P28] Variability of hemipelagic and event depositions in the Beppu Bay during Holocene

*Tomohisa Irino[1], Airi Maruyama[1], Ken Ikehara[2], Masanobu Yamamoto[1], Michinobu Kuwae[3] (1.Graduate School of Environmental Science, Hokkaido University, 2.Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology, 3. Center for Marine Environmental Studies, Ehime University)

[MIS19-P29] The composition of laminae in the sediment of Beppu-Bay and potential as annual laminations

*Yoshiaki Suzuki[1], Michinobu Kuwae[2], Kazuno Arai[3], Ken Ikehara[4], Masafumi MURAYAMA[3] (1.Waseda University, 2.Ehime University, 3.Kochi University, 4.AIST)

[MIS19-P30] Simulation of global distribution of Pa/Th using an ocean general circulation model

*Yusuke Sasaki[1], Akira Oka[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo)

[MIS19-P31] Construction of modern silicoflagellate assemblage dataset in the North Pacific for paleo sea-surface temperature and its application for sediment cores

*Yusuke Okazaki[1], fumiaki nishizono[1], Tanizaki Kyohei[1] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University)

[MIS19-P32] Microplastics in surface sediments of the Ariake Bay

Hiroki Sonoda[1], *Yusuke Okazaki[1], Atsuhiko Isobe[2] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Research Institute for Applied Mechanics, Kyushu University)

[J] Oral | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

1:45 PM - 3:15 PM JST | 4:45 AM - 6:15 AM UTC | 303 3F

## [M-IS26] Arctic and Antarctic Science and Future Plan

convener:Yoshifumi Nogi(National Institute of Polar Research), Takuji Nakamura(National Institute of Polar Research), Atsuko Sugimoto(Arctic Research Center, Hokkaido University), Shin Sugiyama(Institute of Low Temperature Science, Hokkaido University), Chairperson:Tetsuo Sueyoshi(National Institute of Polar Research), Yoshifumi Nogi(National Institute of Polar Research)

1:45 PM - 2:00 PM JST | 4:45 AM - 5:00 AM UTC

[MIS26-01] Antarctic Circumpolar Interdisciplinary Survey - ACIS

★Invited Papers

*Robin Elizabeth Bell[1], Kirsteen Tinto[1], Xiaojun Yuan[1] (1.Lamont Doherty Earth Observatory of Columbia University)

2:00 PM - 2:15 PM JST | 5:00 AM - 5:15 AM UTC

[MIS26-02] Proposal of Polar Science to Master Plan 2020

*Takuji Nakamura[1], Atsuko Sugimoto[2], Shin Sugiyama[2], Yoshifumi Nogi[1], Tetsuo Sueyoshi[1] (1.National Institute of Polar Research, 2.Hokkaido University)

2:15 PM - 2:30 PM JST | 5:15 AM - 5:30 AM UTC

[MIS26-03] Towards the understanding of mass balance variation of Arctic and Antarctic ice sheets

Teruo Aoki[1,2,4], Masashi Niwano[4], *Tetsuo Sueyoshi[2,3] (1.Okayama Univ., 2.National Institute of Polar Research, 3.Japan Agency for Marine-Earth Science and Technology, 4.Meteorological Research Institute)

2:30 PM - 2:45 PM JST | 5:30 AM - 5:45 AM UTC

[MIS26-04] **Modelling Perspective for the Past and Future tipping points of ice-sheets and climate**

*Ayako Abe-Ouchi[1,2,3], Fuyuki SAITO[2], Takashi Obase[1], Ralf Greve[4], Sam Sherriff-Tadano[1] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.JAMSTEC, 3.NIPR, 4.Hokkaido University)

2:45 PM - 3:00 PM JST | 5:45 AM - 6:00 AM UTC

[MIS26-05] Prediction of sea level rise caused by ice sheet melt

*Takeshi Tamura[1], Junichi Okuno[1], Yusuke Suganuma[1], Tetsuo Sueyoshi[1], Yoshifumi Nogi[1], Takuji Nakamura[1] (1.NIPR National Institute of Polar Research)

3:00 PM - 3:15 PM JST | 6:00 AM - 6:15 AM UTC

[MIS26-06] Future Research Plan in the Polar region

*Yoshifumi Nogi[1], Tetsuo Sueyoshi[1], Takuji Nakamura[1] (1.National Institute of Polar Research)

[J] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

## [U-06] Japan's contribution to IUGG celebrating 100th anniversary

convener:Setsuya Nakada(National Research Institute for Earth Science and Disaster Resilience), Kenji Satake(Earthquake Research Institute, University of Tokyo), Kumiko Goto-Azuma(National Institute of Polar Research), Chairperson:Kumiko Goto-Azuma(National Institute of Polar Research), Setsuya Nakada(NIED)

International Union of Geodesy and Geophysics (IUGG) is one of the 40 unions in the International Science Council (ISC), celebrating its 100th anniversary in 2019. IUGG promotes and coordinates research on the interior and the periphery of the Earth. The IUGG has associations of eight research fields (IACS, IAG, IAGA, IAHS, IAMAS, IAPSO, IASPEI, and IAVCEI), which carry out semi-autonomously activities in cooperation with each other. In addition, IUGG encourages research to respond to social needs such as reduction of natural disasters and environmental conservation. The IUGG Subcommittee at the Japan Science Council's Earth and Planetary Science Committee and the eight association-committees under the former serve as representatives of Japan for the IUGG and 8 Associations.<br/> In this session, as IUGG celebrates its 100th anniversary, researchers related to each association exchange the ideas on the role of IUGG in earth science and the contribution that Japanese researchers should make to IUGG.

# Centennial of the International Cooperation in Earth and Space Sciences

*Alik Ismail-Zadeh[1,2,3]

1. Karlsruhe Institute of Technology, 2. International Union of Geodesy and Geophysics, 3. International Science Council

The International Union of Geodesy and Geophysics (IUGG) was established in 1919 under the umbrella of the International Research Council (later ICSU, and now the International Science Council) as one of the unions to promote activities of existing associations dealing with geodesy, terrestrial magnetism and electricity, hydrology, meteorology, physical oceanography, seismology, volcanology. This presentation describes the origin and the development of the Union for the last century and until today. During the initial period (1919-1939), the number of member countries increased from nine founding Member countries to 35 Member countries; general assemblies were held every three years, each in a different international venue, and the number of delegates attending the assemblies increased from a few dozen to several hundred scientists. The World War II (WWII) interrupted the cooperation, and international scientific activities were resumed in 1946. The Union continued cooperation with many international scientific organizations of ICSU, and began cooperation with new intergovernmental organizations such as UNESCO and the World Meteorological Organization, and their programs. The technologies developed during the WWII were brought to bear in the extraordinary global scientific effort that was the International Geophysical Year (1957-1958). Changes in the geopolitical landscape brought about changes in the IUGG's structure. International campaigns encompassing multiple disciplines became commonplace, and international scientific bodies were organized. At the beginning of the 21st century IUGG added an eighth association on cryospheric sciences, developed new grants, science education, and recognition programs, and added new commissions on geophysical risk & sustainability, climatic & environmental change, data & information, and planetary sciences to existing commissions on mathematical geophysics and study of the Earth's deep interior. IUGG has been initiating, developing, and implementing international cooperative programs, setting scientific standards, developing research tools, educating and building capacity, and contributing to science for policy. Today, IUGG is a vibrant modern scientific union of 72 nations and scientists from all over the world promoting research, linking scientific knowledge to societal needs, and working toward a sustainable Earth.

# IUGG and Japan: the past, the present, and the way to go from now

*Masaru Kono[1]

1. Tokyo Institute of Technology

International Union of Geodesy and Geophysics (IUGG) was formed in 1919 and held its first General Assembly in 1922. A hundred years has passed since then. Japan was one of the seven member countries which joined IUGG at the inauguration. Prof. A. Tanakadate of Tokyo University represented Japan at that time, and he was elected as one of three Vice-Presidents for 1919-1922. Since then, except the period that Japan was vetoed to take part in the Assemblies after Japan was defeated in 1945, Japan has consistently been a strong supporter of the IUGG activities.

Because of the "cold war" after the end of the world war, there were very few chances that east and west scientists meet at the same place, IUGG and other international scientific organizations were playing an important role in providing such opportunities. In particular the International Geophysical Year (IGY) of 1957-1958 was a splendid opportunity for cooperation between east and west countries. Japan took part in this project in many subject including the rocket observation, but among them, the start of the antarctic research which was carried out with the concent of the international community, was a highlight of this project.

Several decades have passed since then. In these years, the status of IUGG became quite low. IUGG holds it General Assembly every four years, collecting 3000 to 4000 scientists, but AGU Fall meeting is held every year, and nowadays they receive about 30,000 participants while keeping the scientific standards quite high. Nowadays, there are EGU, JpGU, and others which collect more than 10,000 participants. These societies also have well-cited jounals to output scientific results in printed form. It looks that there is little possibility that IUGG can compete with these societies in the scientific merit.

With these situations in mind, which way should IUGG go in the future? One possibility is to work in problems which concerns the whole Earth, and thus it is impossible to find the solution in a single country. A clear example of such a problem is the Global Warming. The international scientific organization which deals with this is IPCC, but the scientists working in IPCC have strong ties with some of the Associations in IUGG (eg., IAMAS, IAPSO, IAHS). Another possibility is to look for a scientifically important probem, which usually has small number of scientists engaged in the problem. A good example in IUGG is SEDI which works in the deep interior of the Earth. It is also an interdisciplinary science including seismology, geomagnetism and others. SEDI seems to prosper by providing an interdisciplinary platform for these hundred or so very high-level scientists.

# Contributions from the Science Council of Japan to international cooperation in the field of Earth and planetary science

*Hisashi Nakamura[1]

1. Research Center for Advanced Science and Technology, University of Tokyo

Since its establishment in 1949, the Science Council of Japan (SCJ) has made a variety of contributions to international academic cooperation in every field of natural and social sciences as an official member of the International Science Council (ICSU: currently InterAcademy Council). The budget for international commitment has been stable in spite of continuous decline of the entire budget of SCJ. Recognizing that international cooperation is essential for research activities in the field of Earth and planetary science, ICSU has promoted the International Geophysical Year (IGY: 1957-58) and the 4th International Polar Year (IPY: 2007-08), while offering its membership to 12 international unions/associations in our field, including the International Union of Geodesy and Geophysics (IUGG). Under this international framework, the Japanese government has been offering financial support to those unions/associations through SCJ, in which 12 branch committees are organized under the Earth and Planetary Science Committee to appoint some members as delegates to executive meetings of those unions/associations and promote related domestic activities. In addition, SCJ co-hosts a general assembly of an international union/association held in Japan under the approval of the SCJ International Affairs Committee, as exemplified by the 2017 IAG-IASPEI Joint Scientific Assembly in Kobe. This presentation offers an overview of specific contributions from SCJ to international cooperation in the field of Earth and planetary science.

# History and Japanese contribution to the International Association of Cryospheric Sciences IACS

*Ralf Greve[1]

1. Institute of Low Temperature Science, Hokkaido University

The International Association of Cryospheric Sciences, or IACS, is the eighth association of the International Union of Geodesy and Geophysics (IUGG), launched by the IUGG Council on 2007-07-04. Despite being the latest of the IUGG associations, IACS looks back on a history of 125 years, starting with the International Commission on Glaciers (Commission Internationale des Glaciers) founded in 1894. It then evolved via the International Commission of Snow and Ice (ICSI) of the International Association of Hydrological Sciences (IAHS) and the transitional Union Commission for the Cryospheric Sciences (UCCS) into its current constitution as an independent IUGG association, recognizing the increased importance of cryospheric sciences within the context of Global Change. In this presentation, we will outline the history of IACS and its precursor organizations, describe the current activities of IACS and highlight the Japanese links with IACS in the form of contributions to its governance, divisions and research activities.

# IAGA activities in the era of too many international conferences

*Toshihiko Iyemori[1]

1. Kyoto University

During the last 20 years, the size of international meeting such as AGU, EGU and AOGS has been getting larger and larger, and they are now the major place for the researchers in geoscience and space science to show their results and collect new information. This tendency is the same also for the scientists in our country, and the role of IAGA need to change its role. In this presentation, IAGA activities and our contribution in the last 20 years will be presented.

# The role of IAHS in education, research, social issues concerning water and future perspective

*Maki Tsujimura[1]

1. Faculty of Life and Environmental Sciences, University of Tsukuba

IAHS (International Association of Hydrological Sciences) was launched in 1922, and now have approximately 5500 individuals, 10 commissions and 3 working groups. The Scientific Assembly is held every 4 years and held in Yokohama, Japan 1993. Professor in Emeritus Dr. Kuniyoshi Takeuchi, Yamanashi University has served as a president of IAHS from 2001 through 2005, thus Japan has taken an important role in IAHS.

The commission consists of Continental Erosion, Coupled Land-Atmosphere Systems, Groundwater, Remote Sensing, Statistical Hydrology, Snow and Ice Hydrology, Surface Water, Tracers, Water Quality, Water Resources Systems, and it covers a variety of field in hydrology. Also, a working group “PANTA RHEI –Change in Hydrology and Society” has been launched in 2013 focusing on changing hydrological cycle system with changing human system.

The Japan National Committee of IAHS in cooperation with Japan National Committee of IHP (International Hydrology Programme) hold a symposium “Japan Water 2012: International Contribution from Japan in education/ research of water science and technology”. Also, Japan Association of Hydrology and Water Resources, Japanese Association of Hydrological Sciences, Japanese Association of Groundwater Hydrology and Japan Society of Physical Hydrology collaborated to publish Hydrological Research Letters (HRL) since 2017. Additionally, IAEA (International Atomic Energy Agency) Regional Training Course on Isotopic Data Processing and Interpretation –Hands on Exercises is held in March 2019, Tsukuba, Japan supported by Japan National Committee of IAHS and Japan National Committee of IHP.
On the other hand, the changing environment in hydrology and water resources in Japan and the world requires the change of the role in IAHS. We need to promote a collaboration between IAHS and IHP, early career support and career paths developments in future.

# Centenary of the atmospheric sciences: Its progress and future issues

*Teruyuki Nakajima[1]

1. Japan Aerospace Exploration Agency

IAMAS (International Association of Meteorology and Atmospheric Sciences), one of associations of IUGG (International Union of Geodesy and Geophysics), celebrates in 2019 its centenary after establishment with IUGG. Held are commemorative projects and memorial events at the IUGG general meeting in Montreal in this July. Atmospheric science has long been developed as a science related to various weather phenomena related to the lives of mankind. As a result, there are many important issues related to society. Especially over the past 100 years, there are major developments such as establishment of weather prediction infrastructure, researches to global warming problem and environmental problems such as ozone hole etc. An overview of these progresses will be important for us to think about what we should do next. In particular, in this era, as climate and environment changes have become apparent and disasters increase, observation and understanding of the phenomena is increasingly necessary through collaborations with other areas such as the social science etc. I like to discuss that point.

# Contributuins of Japan to IAPSO

*Yukio Masumoto[1]

1. Graduate School of Science, The University of Tokyo

The International Association for the Physical Sciences of the Oceans (IAPSO) is one of eight associations of the International Union of Geodesy and Geophysics (IUGG). IAPSO is promoting the study of scientific problems relating to the oceans and the interactions taking places at the sea floor, coastal, and atmospheric boundaries insofar as such research is conducted by the use of mathematics, physics, and chemistry. IAPSO has addressed this goal through four fundamental objectives: (1) Organize, sponsor, and co-sponsor formal and informal international forums permitting ready means of communication amongst ocean scientists throughout the world; (2) Establish commissions, sub-committees, and organize commensurate workshops to encourage, stimulate, and coordinate new and advanced international research activities; (3) Provide basic services significant to the conduct of physical oceanography, and (4) Publish proceedings of symposia, meetings, and workshops, and fundamental references on the current state-of-the art and knowledge of physical oceanography.
The Japanese ocean research communities have been contributing to IAPSO mainly through their research activities at the IAPSO assemblies and through administrative works by taking a position of the exective committee member for about 20 years, with the president position by Prof. Imawaki for four years from 2003. This presentation summarizes the Japanese contributions to IAPSO and discuss on future relation between the Japanese research communities and IAPSO.

# IASPEI- activities, history and Japan’s contribution

*Kenji Satake[1], Thorne Lay[2], Johannes Schweitzer[3]

1. Earthquake Research Institute, University of Tokyo, 2. IASPEI President , 3. IASPEI Secretary General

IASPEI (International Association of Seismology and Physics of the Earth’s Interior) is one of the eight associations of IUGG, and promotes the study of earthquakes and other seismic sources, the propagation of seismic waves, and the Earth's internal structure, properties, and processes. IASPEI has seven commissions on seismological observation and interpretation, on tectonophysics and crustal structure, on earthquake generation process - physics, modelling, and monitoring for forecast, on earth structure and geodynamics, on earthquake hazard, risk and strong ground motion, on earthquake source mechanics, and on education and outreach. Besides these topical commissions, IASPEI has their regional commissions in Europe (since 1951), Asia (since 1996), Africa (since 2011) and Latin America (since 2013). These regional commissions meet bi-annually, typically with training courses, to promote seismology in each region.

Seismology started as national scale for describing the earthquake phenomena and their effects. First seismological societies were established in Switzerland (1878), in Italy (1879) and in Japan (1880). After the first teleseismic recording in Germany from an earthquake in Japan (1889), seismology became an international science, and Frist International Seismological Conference was held in Strasbourg in 1901, representing 8 countries including Japan. In 1904, International Seismological Society was established. In 1922, it became a part of IUGG (established in 1919), with changing name to IAS in 1930 and IASPEI in 1951.

IASPEI plays important roles in unifying seismological observations, such as naming seismic phases, defining measurement procedures, or improving the network of seismic stations, and published Manuals of Seismological Observatory Practice (the latest version in 2012). IASPEI has a close relation with International Seismological Centre, which has produced seismological bulletins based on the IASPEI standard. IASPEI also provided standard seismic velocity structure models of the earth, such as iasp91 or ak135. Global distribution of earthquakes in the earth and the reference earth models have been important basic data for developing the science such as plate tectonics, or structure and dynamics of the earth’s interior. IASPEI also conducted peer reviews and evaluated the published precursory phenomena for earthquakes. IASPEI developed and distributed seismological software, and International Handbook of Earthquake and Engineering Seismology.

IASPEI supports FDSN (International Federation of Digital Seismograph Networks) which is composed of groups responsible for installation and maintenance of seismological networks, and activities of CTBTO (Comprehensive Test-Ban Treaty Organization) which uses seismic data to detect nuclear explosions. IASPEI also supports joint commissions with other associations of IUGG, such as ILP (International Lithosphere Project), on tsunamis, volcanology or on space geodesy.

The IASPEI commission of Seismological Society of Japan practically acts as the national committee of IASPEI, and disseminates IASPEI information to Japanese seismological community, nominates officers and award candidates. SSJ has made financial supports to ASC (Asian Seismological Commission) and IASPEI, for travel support of participants and for management of the ASC meetings. Several members of executive committees and chairs of commission are elected from Japan. The last scientific assembly of

©2019. Japan Geoscience Union. All Right Reserved. 

IASPEI, joint with IAG, was held in Kobe, Japan, in 2017 with great success.

# Recent history of IAVCEI in Japan and young researchers' response to IUGG and IAVCEI

*Setsuya Nakada[1]

1. National Research Institute for Earth Science and Disaster Resilience

Japanese volcano researchers, especially young scientists, do not recognize well the relationship of IAVCEI with IUGG. IUGG is less visible than IAVCEI to them. The latter used to be introduced first as the international conference that they can challenge. IAVCEI is visible also in the Volcanological Society of Japan (VSJ) of which they are members. Japanese researchers served as the executive board members of IAVCEI, such as its presidents by Hisashi Kuno, Shigeo Aramaki, and Setsuya Nakada for these 100 years. Scientific Assemblies of IAVCEI were held in Japan in 1962, 1981, and 2013. The Cities on Volcanoes (COV) is the second largest international conference of IAVCEI, held every two years between the years of IAVCEI Scientific Assembly and IUGG General Assembly since 1998. COV conference originates from the International Volcano Conference, which was held in the Kagoshima City in 1988, as a forum between scientists and non-scientists for mitigating volcanic disasters. The fifth COV conference was held in the Shimabara City in 2007.

In spite of the fact that IUGG General Assembly was held in Sapporo in 2003, it seems that IUGG has not become well known among young, possibly middle-aged volcano researchers. For example, recent IAVCEI Science Assembly gathers over 1000 participants, while there are only about 300 participants at General Assemble of IAVCEI when IUGG. The latter number is much smaller than around 1000 participants of recent COV. Though one of the reasons may be few excursions for volcanologists, organized in IUGG conferences, it is likely that a simple reason is the size of fields covered by the conferences. Each association itself is wide in fields enough and the assemble of 8 associations will be too wide for young researchers to attend. They may feel not comfortable like business even in AGU and EGU, contrasting to comfort in own associational conference.

This may be similar to the relationship between JpGU and individual national societies. We have to confirm and share the merit of assemblage of large international associations having fields related to but different from each other. In addition, roles of government-contributing organization like IUGG and International Science Council (ISC) should be confirmed among us. In this case, increasing the number of participants to the conference is not the first priority. Global climate change and regional geological hazards such as large earthquakes and volcanic eruptions have become worldwide high priority issues to reduce the risks. Under this situation, the United Nation clarified the sustainable development goals (SDGs) until 2030, therefore, the missions by IUGG and ISC, which are guaranteed by governments, have expanded to solve these issues.

## [U-08] Opinions and recommendations from meeting participants to the future of the Japan Geoscience Union

convener:Yozo Hamano(KOBE Ocean-Bottom Exploration Center, Kobe University), Eiichi Tajika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita(Geosciences and Civil Engineering, Institute of Science and Engineering, Kanazawa University), Chairperson:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Ikuro Sumita

The JpGU meeting 2019 will be the 30th since the start of the Joint Meeting of the Earth and Planetary Science societies, and 15th after the foundation of the Japan Geoscience Union (JpGU).Today, JpGU is becoming indispensable for the Earth and Planetary Science community due to the significant increase in the number of participants and the progress towards one of the International Organization of Geosciences. However, since the voluntary group that originally started aggregating the individual's intentions of the community, grew to a huge organization of about 10,000 members, it becomes rather difficult to reflect requests and opinions as individuals. In addition, by becoming a public interest corporation, it is rather difficult to operate as an academic organization under the constraints of the public interest corporation law. In aiming for further development of JpGU in the future, we would like to invite all the participants of the meeting to express their strict opinion and constructive proposal for the future of JpGU. The opinions of participants will be valuable materials for considering the direction of JpGU after 2020. We would like to invite many participants to present opinions and recommendations from various viewpoints, returning to the bottom-up spirit which is the basic philosophy of the science community.

# Request and proposal from the Committee on Earth and Planetary Sciences of the Science Council of Japan to JpGU

*Ryoichi Fujii[1]

1. Research Organization of Information and Systems

Japan Geoscience Union (JpGU) and the Committee on Earth and Planetary Sciences (EPS) of the Science Council of Japan (SCJ) has long been collaborating closely for the wide developments of earth and planetary sciences. Recent collaborations are being done, e.g., for the revision of the dream roadmap and the proposal of the large-scale research programs.
In this presentation we would like to present our request and proposal to JpGU and to discuss in depth the future, closer collaborations between the two organizations.

Keywords: JpGU, Dream roadmap, Science Council of Japan

# Geography in JpGU: current status and future perspectives

*Takashi Oguchi[1], Ikuho Yamada[2], Yuichi S. Hayakawa[3], Daichi Kohmoto[4], Hitoshi Saito[5]

1. Center for Spatial Information Science, The University of Tokyo, 2. Faculty of Science and Engineering, Chuo University, 3. Graduate School of Env.Science, Hokkaido University , 4. Nara University of Education, 5. College of Economics, Kanto Gakuin University

Although some geographers and geographical societies have been members of JpGU, the majority of geographers in Japan seldom contribute to JpGU activities. One reason for this is that more than half of Japanese geographers are specialized in human geography, whereas JpGU focuses on physical sciences. However, interdisciplinary studies integrating arts and sciences are becoming all the more important, and modern geography linked to natural hazards and global environmental issues requires knowledge of earth sciences. Therefore, geography in JpGU should play an increasing role. This presentation aims to discuss how to strengthen collaborative relationships between JpGU and geographers.

# Biogeoscineces will connect everthing together

*Takeshi Kakegawa[1]

1. Graduate School of Science, Tohoku University

Biogeosciences Section is unique compared to other sections at JPGU. Other sections have strong affiliation with big national projects, such as wide-sale observation of earthquake, space mission, climate change observation, etc. As a result, Biogeosciences Section has difficulty to establish main or leading subjects in JPGU. Scientific subjects and themes are often overlapped between Biogeosciences Section and other sections. This makes presence of Biogeosciences Section unclear at JPGU. In order to promote Biogeosciences Sections, I am going to suggest some points. It will be important to establish strategic collaborations with other sections of JPGU and other communities, such as microbiology, ecology, agriculture, and /or bio-engineering fields. I think that organizing temporal sections with other communities or having invite speaker from other community will be effective. Biogeosciences Sections should have more functions as an interface with others.

# Coverage of JpGU

*Yukihiro Takahashi[1]

1. Department of Cosmosciences, Graduate School of Science, Hokkaido University

Geoscience unions originally started from classical several categories, namely, solid earth, atmosphere, land and ocean water, upper atmosphere and space, and plant. However, in AGU or EGU, adding to those conventional fields, many new science targets or methodologies are becoming important player in the union. Especially, biology including agriculture and natural hazard became one of the largest communities. On the other hand, such movement in JpGU is going at very slow speed. Here we discuss the strategy about this matter.

Keywords: Coverage , Union

# Is he a bit overkill for English?

*Yoshi-Yuki Hayashi[1]

1. Department of Planetology/CPS, Graduate School of Science, Kobe University

English is taught in English or a special subject is also taught in English, indeed, English has been introduced to elementary school, and English examination of college entrance examination has become to be said to be four skill test today, lead this The importance of "international" importance of the leadership including not only the Keidanren that causes it but also the academic community, the direction of individuals' shooting spirit towards these, ... ... that socioeconomic and cultural academic background I do not know that the various aspects of JpGU are no exception.

However, has not underestimated the influence of stopping recharging of the Japanese space which I have been working diligently since the Meiji era so that education and practice up to the research level can be conducted in my mother tongue almost exclusively in European languages? Do you think that a Japanese language space and its operation ability are natural there and there is nothing to think that it is acquired naturally? As a mother tongue is being trained, we have a wide width and deep depth Although I am able to acquire imagination comprehension ability with, but because it is too "nature" its cost and power can not be forecasted easily, but I am worried that the power is rapidly declining.The language is recharged It goes without saying that training is necessary in order to master this.

I can not predict how far the convergence of language (Englishization) will proceed.The leap in China may brake somebody, but if it keeps it as it is, it will be several generations and Japanese will become a daily word It is a momentum to degenerate into a language that can only be used for the languages of European languages Unlike the multilingualization of the European languages group, it is not easy for the language system to respond at a high level to multilingualization between different languages If you try to secure the breadth and depth of thinking you will have to concentrate on a specific language system and you may be made to choose to switch at the language selection stage. I do not like being there, so I wonder if there can be an avalanche decline.
Advanced knowledge is accumulated in the English space Today, it is desirable to improve the management system to ensure that it contributes to the participation in the Japanese-English system, and it is also wonderful to build an operational system that can accept English sessions. I would like to have English, I would like to forcibrate that the material must be in English, eliminate Japanese sessions that emphasize Japanese language spaces and emphasize provision of knowledge to those with their native language. I would like to be able to accept it rather than it.

By the way I put a raw google translation in English abstract AI seems to need a little time to engage in this issue.

Keywords: Englishization problem

# Globalization of Japan Geoscience Union

*Hirokuni Oda[1]

1. Institute of Geology and Geoinformation, Geological Survey of Japan, AIST

In the presentation, globalization of Japan Geoscience Union (JpGU) is going to be discussed as a member. Although activities of JpGU is broad, JpGU annual meeting and academic publishing are considered as the key pillars. Also, the necessity of globalization on these two have been emphasized. On academic publishing, journal PEPS has been started on 2014 supported by Grant-in-Aid for Publication of Scientific Research Results "Enchancement of International Dissemination of Information" of JSPS. In addition, Impact Factor 2017 has been given to the journal and its future is promising. JpGU meeting was jointly organized successfully with AGU in 2017 and the next JpGU-AGU meeting will be held in 2020. Although globalization of JpGU meeting has been promoted, Japanese language is also considered as important. The burden on the participants and organizers of the meeting by the requirements both in English and Japanese cannot be ignored. Also, there seems to be a barrier in inviting researchers to JpGU meeting from abroad, where number of international sessions and attendees are limited. Number of international meetings on geosciences has been increasing and relative importance of JpGU meeting in the world is decreasing. Thus, the meaning of globalization for JpGU and significant increase of the number of English sessions (or significant decrease of the number of Japanese sessions) of JpGU meeting will be discussed.

Keywords: globalization, academic publishing, JpGU meeting, attendees from abroad, Joint meeting with AGU

# A proposal for JpGU based on the questionaires to SSJ members

*Koshun Yamaoka[1]

1. Earthquake and Volcano Research Center, Graduate School of Environmental Studies, Nagoya University

The Seismological Society of Japan (hereafter, SSJ) is one of the original members of the group which is ancestral of present JpGU. The group consists of several societies including SSJ organized a joint meeting instead of independent meetings which were usually held in early April every year. In this historical circumstances SSJ expects JpGU meeting as one of the regular meetings of SSJ in addition to the SSJ fall meeting. In this regard, sessions that are equivalent to those in the SSJ fall meeting are proposed for JpGU meeting every year.
Academic society exists because members expect benefits in participating the society. Similarly member societies such as SSJ also expect benefits in participating JpGU. JpGU is expected to represent academic community of earth and planetary science, which is sometimes called geoscience, of Japan to raise visibility and recognition in Japan’ s society. Visibility of geoscience, especially in high school education, is still low in spite of Japan’ s geological unstableness. This is one reason that Japan has underestimated the risk of geohazards. Academic characteristics of geoscience which inevitably need tackle the complexity, irreversibility and unrepeatability of earth’ s process is sometimes unreasonably degraded relative to other fields. JpGU also works for encouraging collaboratory researches beyond conventional discipline and national boundaries.
The results of such function of JpGU are sometimes opposed to by members. One member of SSJ make an opposition of the management of JpGU meeting, saying that JpGU meeting is too long, too expensive and too much obsequious to English language. The first issue come from the recent condition of universities, in which academic schedule is getting more and more tight. SSJ send questionnaires asking for such an opinion is common or not. Half of the answers favor the opinion although 2/3 of the answers express the satisfaction in participating JpGU meeting. More effort should be made on the session scheduling by considering the participants’ needs. 90% of the answer favors variety of JpGU sessions which cannot be enjoyed in the independent society meeting. I am personally happy to be able to have sessions in English in regular scientific meetings in Japan because English is de facto common language in science community, and because it is what I dreamed when joint meeting started when I was young.
Another function to be expected to JpGU is providing inter-society communication opportunity. Recently many societies suffer gradual decline of members, especially of young generation. Sharing administration may be one of the measures against financial decline. Merging of societies can also be a solution. We need to look for a relation between JpGU and each societies for the development of science.

Discussion

# Opinions and recommendations to the Japan Geoscience Union from Society of Geomagnetism and Earth, Planetary and Space Sciences

Yoshiharu Omura[2], Shigeto Watanabe[3], *Yuto Katoh[1], Takuya Tsugawa[4], Yuichi Otsuka[5], SGEPSS steering committee

1. Graduate School of Science, Tohoku University, 2. Research Institute for Sustainable Humanosphere, Kyoto University, 3. Hokkaido Information University, 4. National Institute of Information and Communications Technology, 5. Institute for Space–Earth Environmental Research, Nagoya University

We present opinions and recommendations to the future of the Japan Geoscience Union (JpGU) from members of Society of Geomagnetism and Earth, Planetary and Space Sciences (SGEPSS). The opinions and recommendations are categorized into (1) opinions for the future perspective of JpGU and (2) comments and requests to the organization of the JpGU meeting.

- Future perspective of JpGU as an international meeting and the relation with AOGS

- Increase the number of sessions jointly organized by multiple societies

- Official channel of opinions/suggestions from participants/conveners to JpGU

In this presentation, we summarize the opinions and recommendations from the members of SGEPSS.

As one of the representative of General Geoscience Sector, here I pointed following items as to be discussed in order to strengthen foundations of JpGU through activation and diversification of domestic earth science community: 1) too much internationalization is to be suppressed, 2) accessibility for the members outside the metropolitan area or the member societies, 3) support for member societies and 4) enhance the function as the "Union." Details described in Japanese (see abstract written in Japanese).

# Fifteen years of Japan Geoscience Letters and its future

*Shogo Tachibana[1], Eiichi Tajika[2]

1. UTokyo Organization for Planetary and Space Science, University of Tokyo , 2. Dept. Earth and Planetary Science, University of Tokyo

It has been 15 years since the first issue of Japan Geoscience Letters (JGL), which is a newsletter of JpGU. Fifty-five issues have been published with 157 articles on hot topics in the Earth and planetary science field. The JGL has been a window into various disciplines in Earth and planetary science and is potentially be a good outreach tool to the society. There are many things to do to make the JGL better as the newsletter of JpGU that has been expanding as the largest geoscience community in Japan. However, it is not possible to make them a reality because of limited human resources. In this talk, we will discuss the 15-year publication activity of JGL and its future.

Over the past 50 years, the lunar interior has been investigated by analyzing the Apollo lunar seismic data (e.g. [1]-[3]). However, currently proposed models of the internal structure are not in accordance with each other although each model can explain the Apollo seismic data. This means there still exists a large uncertainty in the lunar internal structure because the Apollo data does not have enough quality to determine the inner structure precisely. Since the internal structure is a significant factor to elucidate the origin of the Moon, it is essential to obtain new seismic data in order to improve our knowledge of the lunar internal structure.

In particular, the lunar crustal structure (e.g. elastic velocity, density, layer-thickness) is significant when discussing the thermal environment at the initial stage of the lunar formation. From the observation results of KAGUYA (SELENE), it is suggested that the lunar crust consists of very pure anorthosite, which means the refractory element Al concentrates within the crust (e.g. [4][5]). Since the bulk amount of refractory elements gives a strong constraint on the thermal condition of the lunar formation, revealing the lunar crustal structure will lead to better understanding of the history of the Moon.

When determining the lunar crustal structure, impact-induced seismic waves are usually used [6]. Generally, at least 3 seismic stations are required to determine seismic source locations. In the case of the Apollo, although 4 seismic stations were placed and made a network on the nearside of the Moon, it was difficult to determine the impact locations (seismic source locations) precisely due to uncertain arrival time readings and unknown origin times. In future seismic explorations, it is required to carry out seismic observations even at a single point since it is difficult to deploy multi-seismic stations at once. In this situation, the precise determination of origin times and impact locations will play an important role in order to improve the crustal structure. However, as described above, it is considered that a single seismic station is not adequate for the precise determination of origin times and impact locations. This is one of the serious problems when performing a future seismic exploration.

In order to overcome this problem, it has been proposed to apply ground observation data of lunar impact flashes to seismic observations on the Moon [7][8]. Since the basic recording system of the impact flash observation allows us to determine impact times and locations more precisely compared to seismological approaches, it will enable to realize seismic observation at single point. However, these fields of study (lunar impact flash and lunar seismology) have been carried out independently in the past. In this study, we bring these two field together by performing observing simulations of impact-induced seismic waves by combining a seismological simulation with the lunar impact flash observation data as a first step for the consideration of a future seismic exploration.

# New Results from Restored Apollo Magnetic Field Records

*Peter J Chi[1]

1. University of California Los Angeles

Three Apollo missions collected digital magnetic field measurements by the Lunar Surface Magnetometers on the surface (Apollo 12, 15, and 16) and by Subsatellite Biaxial Magnetometers in orbit surrounding the Moon (Apollo 15 and 16). After approximately a half century, the Apollo 15 and 16 missions are still the only lunar missions conducting simultaneous surface and orbital magnetic field experiments. The Apollo magnetic field experiments enabled many first discoveries, such as the lunar magnetic anomalies and the electrical conductivity of the Moon.

A recent effort has restored all the Apollo magnetic field records from the archaic data format originally archived. The restored LSM data have revealed many narrowband ion cyclotron waves in the Earth’s magnetotail that were not investigated during Apollo years. The restored data also allow re-analyses for the Moon-solar wind interaction and magnetic sounding of the lunar interior. We find that the observed transfer function responses in both tangential and radial components on the lunar surface are consistent with theoretical expectations at least for frequencies greater than $10^{-4}$ Hz. The comparison between SBM and LSM data indicates that, when the Moon is in the solar wind, the surface magnetic field is slightly enhanced on the sunward side. This paper summarizes the recent findings from the restored Apollo magnetic field data and discusses the unexplored topics for future magnetic field measurements on the lunar surface.

# Analysis of the High Latitude Region of the Moon with Spectral Profiler Data: Possible Presence of Water Ice

Haramitsu Kyoda[3], *Satoshi Tanaka[1], Makiko Ohtake[1], Hiroshi Nagaoka[2], Yusuke Nakauchi[2], Keisuke Onodera[4]

1. Department of Solid Planetary Sciences Institute of Space and Astronautical Science, 2. Japan Aerospace Exploration Agency, 3. Department of Complexity Science and Enginnering, the University of Tokyo, 4. Department of Space and Astronautical Science, SOKENDAI

Recently, space agencies such as NASA and JAXA are actively planning to explore the polar region of the Moon since its usability as lunar base and possible existence of volatile elements([1],[2]). Landing site selection should be taken into consideration of the sunshine rate, existence of volatile materials in the vicinity [3], and so on. Therefore, geological and geomorphological studies in the polar region of the Moon have become more important. In this paper, we focused on detecting of water ice in the polar region using Spectral Proler(SP) data obtained by KAGUYA. Li et al.,(2018)[4] reported exposed water in the permanently shaded area by $M^3$ data. It is possible to detect more distinct feature of water absorption by the SP data with high S/N ratio. Data analysis by the SP data in the polar region is still difficult due to the large solar incidence angle, however, we reported that the data could be handled with high-accuracy by estimation of insolation area for each spectrum using deep learning method [5]. Based on the SP data in the fully shaded area classied by the method above, we investigated the spectrum having absorption at 1260 nm and 1500 nm both of which are featured by ice and frost of water. As a result, we found about 300 spectrum data having distinct water absorption. One of the data with this absorption obtained in the middle of April, 2009 was located at around (lat. , lon.)=(-85, 50) at where Li et al., (2018) indicated the presence of water ice, but most of the data locations are not overlapped. Moreover, the solar incident angles of all selected data are too high to detect the direct nor the secondary reflected light from the surface of the target area. It is possible that the floating dust at a distance of several tens of kilometers the Moon originated from the impacts or levitation may have been detected[6].

# Detection of Dark Regions on the Lunar Surface with Shadow Masked Multiband Imager Data

*Riho Ito[1], Hiroka Inoue[2], Makiko Ohtake[2], Hisashi Otake[2], Ryosuke Nakamura[1]

1. National Institute of Advanced Industrial Science and Technology, 2. Japan Aerospace Exploration Agency

The lunar low-reflectance regions, such as Dark Mantle Deposits (DMDs), iron or titanium rich regions, or weathered older mare, have important information for clarifying the process of lunar evolution. To locate the global distribution of the low-reflectance (dark) region is one of important studies for lunar geological science. Since even small dark regions can be detected based on high-resolution lunar images such as Kaguya's Multiband Imager (MI) images, a goal of this research is to identify candidates of the darkest region with various spatial scale on the global lunar surface. However, a simple automatic identification of small dark regions from Kaguya's MI images, such as using a threshold value, may be hindered by shadows. Therefore, in this research, dark regions other than shadows were identified after removing the shadow regions from the MI images.

The areas that have relatively lower reflectance than the surrounding area due to the difference in the local solar incidence angle are treated as same as actual shadows cast by being hidden from sunshine because the areas often show abnormal spectrum patterns. In the first step, to detect shadow regions, we employed conditional generative adversarial networks (cGAN) which is deep learning method. The cGAN is composed of the generator neatwork and the discriminator network. The Generator is trained to generate realistic fake images that cannot be distinguished from real images by the Discriminator, whereas the Discriminator is trained to detect the fake images generated by the Generator. We prepared supervised data which are pair of MI images and correct shadow masks for training the cGAN networks. In this step, Generator was trained for generating a realistic shadow mask as much as possible according to an input MI image. After the training, our Generator successfully provide a shadow mask in which we can detect high contrast shadows and shadows by craters or other land features. On the other hand, we found that our network had low accuracy for smaller shadows and surround regions of invalid values, and these detected shadow masks included many noises.

In the next step, we employed simple thresholding to detect candidates of DMD from the MI images with shadow masks generated by the trained Generator. Since the results of shadow detection are not stable when an image has many invalid values., regions higher than ±60 ˚including relatively many invalid values were excluded from target regions. The threshold value was determined from a histogram of the reflectance which calculated from the band 2 (750 nm) of the MI image after the shadow removal, and regions where the reflectance was lower than the threshold were detected as candidate of the dark region. In this study, because dark regions with a small size in the detected candidates may be mis-detection of the small shadow regions that could not be distinguished and removed by the trained network, dark regions which area are smaller than 900 pixels (0.36 $km^2$) were excluded from candidates. Though this process may exclude candidates for actual small dark regions that are not shadows, we decided to focus on locating candidates that can be more reliably determined as dark regions. As threshold processing and noise removal method are important factors greatly affecting the detection of the final candidate points, we will consider the improvements for detecting smaller dark regions in the future work.

In the result of applying this method, although some noise remained, some known DMDs, in the Sinus Aestuum, Taurus-Littrow, Sulpicius-Gallus and Mare Vaporum, were detected as candidates of dark regions. Most of the other detected points were also located in the region of high titanium. In this work, analysis results of detected dark regions and utility of the detection methods will be reported and

# Estimation of Moho depth under lunar basins by using only the GRAIL gravity data

*Gaku Nishiyama[1], Noriyuki Namiki[2]

1. Department of Earth and Planetary Science, The University of Tokyo, 2. RISE Project, National Astronomical Observatory of Japan

In order to unravel the formation of solar-system, the subsurface structure of planets and moons will be a key to constrain early differentiation and subsequent thermal evolution. In particular, lunar crustal thickness is of importance for understanding the volume of the ancient magma ocean. Conventionally planetary crustal thickness is estimated by analyzing gravity anomaly data derived from tracking data of spacecrafts using downward continuation filter. In this method, the relief of crust-mantle interface (Moho) are calculated as a variation of surface density anomalies under the condition that a mean crustal thickness or crustal thickness at a specific location has been already known from seismic observation. In this study, however, we demonstrate that the calculation is theoretically incorrect in the point that the Moho relief is imposed on the surface density at certain depth. Downward continuation filter is mathematical trick to stabilize the previous calculation, but it indeed violating gravity theory.

In this study, we show a new method which doesn't require ad hoc assumptions of crustal thickness nor downward continuation filter, but assumes the simple shape of Moho uplift. Under the assumption that the Moho is uplifted like an axisymmetric cylinder beneath Crisium basins , the observed Bouguer gravity anomalies can be expanded in the Bessel-Fourier coefficients . Then we find the best fit parameters such as radius, height and depth of cylinder. Thus, the depth of surrounding crust is estimated to be 37.9±7.7 km. Our estimate is consistent with that of the analysis result of moonquake data measured at Apollo 12 & 14 landing sites. This result indicates that the new method can estimate crustal thicknessby gravity data alone and independently from seismic data. Here we assumed a simple morphology of mass anomalies beneath Crisium basin, however, the top surface of the cylinder as well as surrounding Moho boundary shall be laterally variable. In further research we evaluate an influence of the shape, crustal flexure, and other effects.

# Ejecta Thickness Distribution of Lunar Schrödinger Basin

*Luyuan Xu[1], Minggang Xie[1]

1. State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology

A hypervelocity impact on a target with solid surface forms an impact crater, and a fraction of debris is ejected and emplaced ballistically from the crater. The thickness distribution of primary ejecta gives insight into the processes of impact cratering, the stratigraphy of planetary crust, the evolution of planetary surface, and the source of lunar samples. However, the widely used empirical ejecta thickness distribution model of McGetchin et al. (1973) is inconsistent with recent observations of complex craters and the Orientale basin.

As a typical case to address this problem, here we conducted detailed measurements of ejecta thickness distribution for Schrödinger Basin, which is a large impact basin located near the lunar south pole, the best-preserved peak-ring basin, and the second youngest one on the Moon.

Based on LROC WAC, Kaguya TC, and LOLA DTM data, the thickness of primary ejecta is estimated indirectly from the measurements of partially filled pre-basin craters using crater morphometry and the effect of crater degradation is taken into considerations. The results show that the ejecta thickness distribution of Schrödinger Basin is more consistent with Pike (1974)’s model rather than McGetchin et al. (1973)’s, the excavation of Schrödinger basin-forming impact does not penetrate through lunar crust, and the rim relief of Schrödinger Basin consists mostly of rim uplift rather than the primary ejecta.

# Possible evolution paths of the lunar orbit based on tidal response in the global ocean model of the early Earth

*Mai Motoyama[1], Hideo Tsunakawa[1], Futoshi Takahashi[2]

1. Department of Earth and Planetary Sciences, School of Science, Tokyo Institute of Technology, 2. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University

The Moon's orbital evolution has been affected by the Earth's ocean tide as well as the solid Earth's tide (e.g. MacDonald, 1964, Kaula, 1964). Many previous studies pointed out that the continental crusts would be few amounts in the early Earth (e.g. Stein & Ben-Avraham, 2007, Rino et. al., 2004), possibly with larger seawater volume than the present day (e.g. Kurokawa et al., 2018, Korenaga et. al., 2017). Thus the early Earth is considered to have been covered by the global ocean for a long time, strongly implying the importance of the ocean tide for the early evolution of the Earth-Moon system. Most of previous studies of the evolution of the Earth-Moon system calculated back to the past with the initial condition of the present state (e.g. Abe et. al., 1997, Rubincam, 2015). The backward calculation is inappropriate to estimate the effects of various parameters concerning the early Earth’s ocean, since there are many uncertain factors such as continental drift. Thus we carried out forward calculation of the lunar orbit from the past for the first 2 billion years to understand characteristic effects of the ocean state in the global ocean model.
Energy dissipation mechanism of the ocean is one of the critical factors in the Moon’s orbital evolution (e.g. Webb, 1982, Lambeck, 1977). Recent studies have revealed that the internal gravity wave, so-called internal tide, is a main mechanism of tidal energy dissipation in the deep ocean (e.g. Taguchi et. al., 2014, Egbert & Ray, 2000). In this study, we considered its effect on the early evolution, assuming the early ocean is as deep as the present abyssal depth.
Our results show that the eigenmode resonance occurs once or more for the first 2 billion years. The Earth-Moon distance rapidly increases with a step-like change at the eigenmode resonance. In the case of the ocean depth decreasing linearly to the time, it is found that the torque due to the oceanic tidal bulge causes continuous increase in the Earth-Moon distance with an especial response of eigenmode oscillation. These acceleration effects could work in the coevolution of the early Earth-Moon system.

# Geochemical and Petrological Investigations of Lunar Feldspathic Crust by Lunar Sample Studies and Remote Sensing Data

*Hiroshi Nagaoka[1], Yuzuru Karouji[1], Makiko Ohtake[1]

1. Japan Aerospace Exploration Agency

Feldspathic highland crust deriving from ferroan anorthosite (FAN) have been assumed to be formed by the lunar magma ocean (LMO) model, whose the early crust was accumulated by the crystallization and flotation of plagioclase (Warren, 1985). However, the studies of lunar meteorites which originated from the highlands not covered by the Apollo missions, found more magnesian anorthosites than FAN (e.g., Takeda et al., 2006). Furthermore, Kaguya observation revealed feldspathic crust with higher Mg# (= molar 100 ×Mg/(Mg + Fe)) than FAN (Ohtake et al., 2012).
Furthermore, purest anorthosite (PAN) (>98% plagioclase) lithology was found in central peak of several large craters by Kaguya observation. On the basis of Kaguya results, the massive PAN layer are assumed to be distributed under mafic-rich mixing layer in highlands (Ohtake et al., 2009; Yamamoto et al., 2012).
Like this, lunar meteorite studies and global remote sensing data have provided new global information on geological features of lunar crust.

Feldspathic meteorites from lunar highlands are brecciated by impacts on the lunar surface.
The 10-30% mafic minerals (pyroxene and olivine) are included in the meteorites.
These feldspathic meteorites is similar with the surface composition of mafic-rich mixing layer of feldspathic crust in elemental composition (e.g., FeO, Th).
On the other hand, several highly pure anorthosite (PAN) clasts were found among some of feldspathic lunar meteorites (Nagaoka et al., 2014). They are correspond with PAN lithology observed by Kaguya.

In this work, we have measured and summarized the elemental and mineral composition of feldspahtic lunar meteorites, by bulk chemical analyses, electron micro-probe analyses, and UV-VIS-NIR reflectance spectroscopy. In this presentation, we report and discuss geochemical and petrological features of lunar crust on the basis of recent geochemical and petrological studies combined the above lunar samples analyses data and the recent remote sensing data.

# Development of frosting system for lunar simulant and the detectability of ice growing on the simulant by NIR measurement

*Aoi Ogishima[1], Kazuto Saiki[1]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University

In recent years, many remote sensing studies have suggested the existence of lunar water, but it is still an open issue how or how much water is on the Moon. Lunar prospector launched in 1998 found the concentration of proton around lunar poles. In 2009 Lunar Crater Observation and Sensing Satellite (LCROSS) project observed ejecting debris from Cabeus crater and estimated that concentration of water ice is 5.6±2.9 wt%. Chandrayaan-1 data suggested the abundance of water could be as high as 0.077wt%. After these results, Japan’ s space agency JAXA and India’ s space agency ISRO have signed an Implementation Arrangement (IA) for a Joint Lunar Polar Expedition in December 2017. In preparation for this mission, assuming that the grains of lunar regolith are covered by water frost on the lunar permanently shadowed regions, we made minute ice on lunar simulants and measured their Near-Infrared reflectance spectra. As lunar simulant we use olivine (from San Carlos, 125-250um, Fo90) and lunar simulant FJS-1 (Shimizu Corporation). We developed a frosting system. It’ s a kind of cooling stage in which simulant grains cooled with liquid N2 can be mixed with highly humid air and vibrated. In the stage, water frosts condensed and cover the surface of grains. The top of the stage is covered with silica glass plate, so we can observe the spectra without taking out samples from the stage. We observed the reflectance spectra of the frosted simulants with a Near-Infrared imaging spectrometer developed by Saiki at 950-1600 nm, angle of incidence = 30˚, angle of viewing = 0˚. After the measurement, we weighed the mass of frosts. In order to prevent additional frost during weighing, we made a vinyl house and weighed frosted samples in the house purged with dry N2 gas. Then, the samples were heated and the frosts on them evaporated. After heating we weighed the samples again, regarded the decreased mass as the mass of frosts, and calculated mass fraction of frosts. We succeeded in making the minute ice less than 1wt% on the simulant, but it is difficult to make ice homogeneously and to control the amount. In order to address these problems, we developed a new fall-type frosting system. In this system cooled simulant fall down in humid air and covered by minute ice homogeneously.We continue trial and error on falling distance and humid air volume aiming to control the amount of frost on the order of 0.1 wt%. Latest results will be reported.

Remote sensing spacecraft missions (e.g., LCROSS and Deep Impact), lunar sample studies, and theoretical simulations suggest the existence of various water species (e.g., $H_2O$ ice, hydroxyl and molecular water, and aqueous phase) on the lunar surface and in the subsurface. Lunar water is thought to originate from solar wind, meteorite/asteroid/comet collisions, and/or volcanic eruptions and concentrated locally on the lunar surface to subsurface, especially permanently shadowed regions near the lunar poles. These findings indicate the possibility of the presence of available water resources for future human activity on the Moon. Moreover, lunar water is significant because it is closely related to a formation process of the lunar magma ocean and its differentiation to the mantle. Therefore, Lunar Polar Exploration Mission is planned to be launched in the 2020’s to survey lunar water. From the viewpoint of resources, science and engineering, this mission provides new insights into lunar evolutionary history and lunar base construction. Here, we will discuss analytical techniques for in-situ water analyses on the lunar poles and experiments simulating low-temperature and high-vacuum lunar environment.

# Feasibility study of detection of the lunar subsurface ice with UHF-band GPR based on FDTD electromagnetic simulation

*Atsushi Kumamoto[1], Hideaki Miyamoto[2], Toshifumi Nishibori[3], Takafumi Niihara[2], Fuminori Tsuchiya[1], Ken Ishiyama[3]

1. Tohoku University, 2. University of Tokyo, 3. JAXA

Detectability of the subsurface ice by UHF-band (0.5-3 GHz) ground penetrating radar (GPR) onboard the rover in the lunar polar region was investigated based on electromagnetic simulation using finite-difference time-domain (FDTD) method. The water brought on the lunar surface is lost within 1 day due to photodissociation. However, if a part of water molecules jump to polar region within 1 day, they can be kept in the polar shadowed region [Arnord, 1979]. Some observations such as impact experiment in LCROSS mission [Colaprete et al., 2010] and SAR polarization measurements in Chandrayaan mission [Spudis et al., 2010] suggests the existence of the water in the lunar polar region.

In this study, we used Meep code [Oskooi et al., 2010] for FDTD simulation. The simulation space with a size of 0.25 m x 1.25 m is divided into meshes with a size of 0.3 mm x 0.3 mm. The uppermost part with a height of 0.5 m is filled with vacuum (permittivity: 1). The second part with a thickness of 0.5 m is filled with dry regolith, basalt (permittivity: 7) including voids (vacuum). The lowermost part with a thickness of 0.25 m is filled with several kind of media such as (i) cavity (vacuum), (ii) rocks (basalt without pores), (iii) pure ice (permittivity: 3), and (iv) icy regolith, regolith whose voids are filled ice. The porosity of the dry and icy regolith layers was determined based on the report from Apollo missions on the vertical profile of the bulk density of the lunar subsurface soils up to depth of 3 m [Carrier et al., 1991]. Chirp pulse in a frequency range from 0.5 to 3 GHz was transmitted for 167 ns from 0.4 m above the dry regolith surface. The electromagnetic fields in simulation space were evolved with time step of 0.52 ps. At the transmission point, the waveform of electric field component of the echoes was recorded at an interval of 33 ps.

Calculation results suggests that subsurface echoes from (i) cavity, (iii) rocks, and (iv) icy regolith at a depth of 0.5 m can be detected with enough echo powers while the echo power from (iii) pure ice were as large as volume scatters due to inhomogeneity in the regolith. They are a little different from the results of our previous calculation performed in a frequency range 1-15 GHz with subsurface materials at a depth of 0.1 m: The echo powers from ice and icy regolith were as large as volume scatters. We can consider that the difference is from (a) the decrease of the volume scatters power by changing the operation frequency range, and (b) the depth dependence of permittivity contrast in inhomogeneous regolith.

**Introduction:** Smart Lander for Investigating Moon (SLIM) is a Japanese technology demonstration mission to pinpoint landing within a hundred meters in radius, which will be launched in fiscal year 2021. The lander carries one small instrument (high-resolution Multiband Camera; see Saiki et al. in this conference) to derive the detailed mineralogy of the olivine-rich exposure to investigate a olivine bearing lithology for understanding their origin and investigating the composition of the lunar unsampled mantle or deep crustal material. To directly explore this unexplored lithology, one of the small fresh craters just outside of the Theophilus crater is selected as a landing site for the SLIM mission. In this study, we analyzed geology of Theophilus crater and the selected landing site.

Crater Theophilus (11.4˚S, 26.4˚E) is located in the immediate vicinity (northwest) of the Mare Nectaris on the Moon. It is on the ring of the Nectaris basin. Its diameter is 110 km, and it has a clear central peak at the center of the crater. Previous study revealed the central peak’ s compositional diversity [1][2]. However, the origin of other lithologies and the relation of these rare geologic lithologies in this unique central peak are still not clear. In addition to their geological (mineralogical) diversity.

**Data and Results:**We used remote sensing reflectance spectra and spectral images obtained by the SELENE (Kaguya) Spectral Profiler (SP) and Multiband Imager (MI). Olivine-dominant lithology at the central peak have clear diagnostic absorption of olivine. Percentage of olivine among olivine and pyroxene of the olivine dominant lithology is estimated to be more than 70. The FeO abundance of the olivine-dominant lithology estimated ranges from 5 to 8 wt.%. Olivine-dominantlithology appears to be present as a basal lithology of the central peak blocks. Olivine dominantlithology is also observed as localized exposures at many small but fresh craters throughout the wall and ejecta region. These fresh craters commonly have a very clear olivine absorption feature, and the FeO abundance of these localized olivine exposures ranges up to 12 wt.%,which corresponds to a nearly pure olivine rock, if Mg# (Mg/(Mg+Fe) in mole per cent) of the olivine is assumed to be similar to the olivine-rich rock types (troctolite and dunite) among the Apollo samples.

**Discussion:** Based on the modal abundance, FeO abundance, distribution, and morphological information of the observed lithologies, we believe that the central peak of Theophilus crater mainly consists of olivine-dominant lithologies with lesser amounts of purest anorthosite (PAN) and Mg-spinel bearing lithologies. Distribution of Mg-spinel bearing lithology is limited in our datasets and they tend to have a relatively sharp vertical boundary with the adjacent lithology. Therefore, we interpret it is not presented as a laterally extensive unit before the formation of the Theophilus crater as suggested [1]. Observed olivine-rich composition comparable to dunite and a sharp boundary with the adjacent PAN lithology suggest that it is not a part of the continuous crustal material. Instead, it is probably mantle (or the lower part of the crustal) origin, which is excavated by the Nectaris basin forming impact as suggested by the global distribution of the olivine-rich sites [2], well before the formation of the Theophlius.

# Observing scenario for the Multi-Band Camera onboard SLIM

*Kazuto Saiki[1], Yuya Igarashi[1], Yusuke Nakauchi[2], Chikatoshi Honda[3], Makiko Ohtake[2], Hiroaki Shiraishi[2], Hiroyuki Satoh[2], Yoshiaki Ishihara[4], Takao Maeda[5], Chihiro Yamanaka[1]

Smart Lander for Investigating Moon (SLIM) is being planned by Japan Aerospace Exploration Agency (JAXA). SLIM aims to research and demonstrate the engineering key issues related to the smart landing on the gravitational planets. They are precise guidance algorithm, vision based navigation, smart landing gear. By doing SLIM mission, we expect to achieve the paradigm shift in the field of celestial body landing from ‘landing where easy to land’ to ‘landing where desire to land’. We proposed Multi-Band Camera (MBC) for SLIM lander. MBC is a compact VIS-NIR camera composed of an imaging sensor (InGaAs), a filter-wheel with 10 band-pass filters, and a movable mirror for panning and tilting. Scientific objectives of MBC are the identification of rocks and rock-forming minerals around the lander and the estimation of Mg#(=Mg/(Mg+Fe)) of olivines that might have come from lunar mantle.

MBC has a telescopic optical system and is a camera with a new concept of spectroscopic observation of rock rather than powder called regolith, so various innovative methods are required for its operation. Among them, we will introduce the methodology of scan operation, on-site calibration, autofocus system, spectroscopic observation of rocks, and Mg # estimation.

Since it is dangerous to land on a place covered with rocks, SLIM landing site was carefully selected. The landing site should be the site where the rock distribution does not become an obstacle to landing and the distribution is as much as rocks can be observed. Since MBC is a telephoto optical system in which the horizontal viewing angle is 4 degrees, rocks would not be observed in random shots. Therefore, it has a function to create a map with a combined low resolution scanned images of around 300 shots that can cover the all observable field of view. After specifying the location of the rock to be observed, we will perform spectroscopic observations efficiently. SLIM, a small unmanned spacecraft, arrives at the moon after a much longer period of time than a manned rocket, so it will be attacked much higher levels of radiation. Because there is a possibility that the background signal of the imaging device increases or the transmittance of the filter changes, we plan to calibrate on the moon. Specifically, MBC has a function to acquire deep space images as dark background data and subtract it from observed image. We also plan to carry out luminance calibration by installing a standard diffuse reflection plate. Since MBC is a telephoto optical system, a focus adjustment mechanism is also indispensable. We realized an automatic focus adjustment function using the fact that the file-size compression rate of the acquired image decreases when approaching the best focus. Although spectroscopic observation of rocks in the near infrared range is thought to be inherently difficult, we are planning to make use of the observable conditions obtained by observation experiments of natural rocks and rock-analogs. In addition, we are planning to spline-fit the data of each band intensity and detect subtle change in wavelength of the absorption peak of $Fe^{2+}$ to estimate Mg # of olivine.

# Current status of a Japanese lunar polar exploration mission

*Takeshi Hoshino[1], Makiko Ohtake[1], Yuzuru Karouji[1], Hiroaki Shiraishi[1]

1. Japan Aerospace Exploration Agency

## Introduction:

Recently, it has been suggested that water ice might be present in the lunar polar region based on spectral measurements of artificial-impact-induced plumes in the permanently shadowed region, and remote sensing observation of the lunar surface using a neutron spectrometer [1], [2] and visible to infrared spectrometer [3]. In addition to the scientific interest about the origin and concentration mechanism of the water ice, there is strong interest in using water ice (if present) as an in-situ resources. Specifically, using water ice as a propellant will significantly affect future exploration scenarios and activities because the propellant generated from the water can be used for ascent from the lunar surface and can reduce the mass of the launched spacecraft of lunar landing missions.

However, currently it is unclear if water ice is really present in the polar region because of the currently limited available data. Therefore, we need to learn that by directly measuring on the lunar surface. If there is water ice, we also need to know it’ s quantity (how much), quality (is it pure water or does it contain other phases such as $CO_2$ and $CH_4$), and usability (how deep do we need to drill or how much energy is required to derive the water) for assessing if we can use it as resources. Therefore, JAXA is studying a lunar polar exploration mission that aims to gain the above information and to establish the technology for planetary surface exploration [4]. JAXA is also studying possibility of implementing it within the framework of international collaboration with Indian Space Research Organisation (ISRO).

## Spacecraft configuration:

The spacecraft system comprises a lander system and a rover system. The system does not have a communication relay satellite but is based on direct communication with the Earth. The minimum target for the landing payload mass is several-hundred kilograms. The launch orbit is the lunar transfer orbit (LTO). After the spacecraft reaches the Moon it is inserted into a circular orbit having a 100km altitude via a few orbital changes. During powered-descent phase, the position of the lander is estimated by landmark navigation using shadows created by the terrain. After landing, the rover is deployed on the lunar surface using ramps. The rover then prospects water ice with its observation instruments..

a few orbital changes. During powered-descent phase, the position of the lander is estimated by landmark navigation using shadows created by the terrain. After landing, the rover is deployed on the lunar surface using ramps. The rover then prospects water ice with its observation instruments..

**Landing site selection:**

Considering the mission objectives and condition of the lunar polar region, we listed the following parameters as constraints.
- Presence of water
- Surface topography
- Communication capability
- Duration of sunshine

As a first trial of the landing site selection, sunshine is simulated using digital elevation models to obtain the sunlight days per year and the number of continuous sunshine periods at each site. Also, slope and the simulated communication visibility map from the Earth are created. These conditions can be superimposed to select the landing site candidate.

**Current status:**
Recently, we finished joint mission definition review (JMDR) with ISRO, in which JAXA provide a launch rocket and a rover while ISRO provide a lander system. Related to the instruments which will be carried on the rover or the lander, JAXA selected several candidate instrument study teams for accelerating development of these instruments. In this presentation, we are going to introduce current status of the mission planning.

# HERACLES mission: Returning to the Moon by an ESA-JAXA-CSA Joint Study

*Yuzuru Karouji[1], Hiroshi Nagaoka[1], Yoshiaki Ishihara[2], Masahiro KAYAMA[3], Satoru Yamamoto[4], Nobuyuki Hasebe[5], Ko Hashizume[6], Yoshiko Ogawa[7], Toru Yada[1], Junichi Haruyama[1], Masanao Abe[1], Makiko Ohtake[1], HERACLES Science Working Group, HERACLES International Science Definition Team

1. Japan Aerospace Exploration Agency, 2. National Institute for Environmental Studies, 3. Faculty of Science, Tohoku University, 4. J-spacesystems, 5. Advanced Research Institute for Science and Engineering, Waseda University, 6. Faculty of Science, Ibaraki University, 7. The University of Aizu

Global Exploration Roadmap published in January 2018 by the International Space Exploration Coordination Group (ISECG) clearly identify the Moon as the next logical destination and defined strategic goals and objectives for its exploration. Returning to the Moon not only yields fundamentally important science opportunities for our understanding of the Solar System but also allows us to test hardware and operational procedures for the exploration and utilization of space beyond Low Earth Orbit (LEO). The Human-Enhanced Robotic Architecture and Capability for Lunar Exploration and Science (HERACLES) is a joint mission under study by European Space Agency (ESA), Japan Aerospace Exploration Agency (JAXA) and Canadian Space Agency (CSA) with NASA and Roscosmos having observer status [e.g., 1]. Thus, HERACLES is an international effort in preparation of returning humans to the Moon and providing opportunities for unprecedented science utilizing the Lunar Orbital Platform-Gateway (Gateway). It is a sub-scale demonstration mission of human lunar exploration aiming for launch in the mid-2020's, and the vehicle is composed to test key components including the three following elements: The Lunar Ascent Element (LAE) will be provided by the ESA, the Lunar Descent Element (LDE) will be provided by the JAXA, and the rover will be provided by the CSA.

The coordination of the planning of science opportunities is performed by the multi-agency HERACLES Science Working Group (SWG). The SWG is also responsible for developing a mission science management plan to describe science themes and science payload instruments selection processes, and data/sample allocation policies. The SWG engaged the science communities of each country and organized the HERACLES international Science Definition Team (iSDT). The iSDT will generate a prioritized list of investigations and will provide input for the landing site selection.

Recently, the iSDT discussed the science scope of the HERACLES mission. The iSDT agreed that the following five non-prioritized topics are the most important lunar science themes that should be addressed by HERACLES; (1) crustal anorthosite composition and crystallization age, (2) mantle composition, (3) improvement of chronology with crater counting of young basalts (<2.5 Ga), (4) internal structure: surface, subsurface, crust, mantle and core, (5) mechanism of material transport (e.g., water) to the Moon. Furthermore, the iSDT has identified several potential landing areas to accomplish these science themes: Jackson crater, Moscoviense basin, Copernicus crater, Schrödinger basin and some young basalts in the Flamsteed region [2, 3].

By the way, the International Space Exploration Program Committee of the Advisory Committee for Space Science and Engineering organized the HERACLES Task Force and independently of SWG, is compiling to recommendations on science and engineering of HERACLES mission. These reports will be submitted at the end of February 2019. These recommentdations will also be taken deeply as opinions of the Japanese scientific community and SWG will discuss how to reflect it in the SWG discussion in the future. In this presentation, we are going to report outcom of previous activities related to the HERACLES SWG and planned discussion within Japanese lunar science community of study in this SWG.

# Lunar Science for Landed Missions –High-Priority Landing Sites Visualized with NASA’ s Moon Trek

*Brian Hamilton Day[1], Emily Law[2]

1. NASA Solar System Exploration Research Virtual Institute, NASA Ames Research Center, 2. NASA Jet Propulsion Laboratory, California Institute of Technology

The Lunar Science for Landed Missions workshop was held on 10–12 January, 2018 at NASA Ames Research Center and was attended by lunar scientists, representatives from commercial companies, and representative of various international space agencies including the Japan Aerospace Exploration Agency and the European Space Agency. The workshop was cosponsored by the Solar System Exploration Research Virtual Institute (SSERVI) and the Lunar Exploration Analysis Group (LEAG). The primary goal of the workshop was to produce a set of high-priority landing site targets, generated by the lunar science community, for near-term lunar missions. The scope of such missions was aimed primarily, but not exclusively, at commercial exploration companies with interests in pursuing ventures on the surface of the Moon. The results of this workshop were published in a report that summarized the findings of the workshop and provided an analysis of priority landing sites and how missions to these sites would meet key science and exploration goals determined by NASA and the scientific community (Jawin, et al, 2019). This presentation for JpGU will review the landing sites advocated by the workshop, highlight characteristics that make them high-priority sites, and showcase the sites using visualizations generated using NASA’ s Moon Trek data visualization and analysis portal (Day and Law, 2017).

# NASA SSERVI: Merging Science and Human Exploration

*Brad Eugene Bailey[1], Kristina Gibbs[1], Gregory Schmidt[1]

1. NASA

NASA's Solar System Exploration Research Virtual Institute (SSERVI) represents a close collaboration between science, technology and exploration, and was created to enable a deeper understanding of the Moon and other airless bodies. SSERVI is supported jointly by NASA’ s Science Mission Directorate and Human Exploration and Operations Mission Directorate. The institute currently focuses on the scientific asp ects of exploration as they pertain to the Moon, Near Earth Asteroids (NEAs) and the moons of Mars, but the institute goals may expand, depending on NASA's needs, in the future. The nine initial teams, selected in late 2013 were funded from 2014 - 2019, have expertise across the broad spectrum of lunar, NEA, and Martian moon sciences. An additional four teams were selected in 2017.

The research includes various aspects of the surface, interior, exosphere, near - space environments, and dynamics of these bodies. In addition, SSERVI has ten International Partners which collaborate with US teams NASA anticipates additional team selections in mid 2019 from the 3rd SSERVI Cooperative Agreement Notice call for proposals. Calls for proposals are issued every 2-3 years to allow overlap between generations of institute teams, but the intent for each team is to provide a stable base of funding for a five-year period.

SSERVI's mission includes acting as a bridge between several groups, joining together researchers from:

1) scientific and exploration communities, 2) multiple disciplines across a wide range of planetary sciences, and 3) domestic and international communities and partnerships.

The SSERVI central office is located at NASA Ames Research Center in Mountain View, CA. The administrative staff at the central office forms the organizational hub for the domestic and international teams and enables the virtual collaborative environment. Interactions with geographically dispersed teams across the U.S., and global partners, occur easily and frequently in a collaborative virtual environment. This talk will consist of an overview of SSERVI’ s mission, current US teams and International Partners.

# Estimation of lava tube cave height below the vertical hole from the surface topography of the Moon

*Tsutomu Honda[1]

1. Vulcano-speleological Society

**[Introduction]** The inclination(sin $\alpha$) and slope angle($\alpha$) of the near surface of the vertical hole and the rille,where the cavity of the lava tube cave is assumed to be under it, can be obtained from the LROC Quick Map[(1)] made from the data of the US LRO. Marius Hills Hole (MHH), Mare Tranquillitatis Hole (MTH), Mare Ingenii Hole (MIH)[(2~5)] discovered by Haruyama et al., furthermore Lacus Mortis vertical holes[(6,7)], Rille structure discovered by Chandrayaan-1[(8)], and Sinus Iridum Pit [(9)] were examined. For the case where the direction of flow of the lava is unknown, the direction showing the angle at which the highest inclination angle of the surrounding is adopted. The cavity height is obtained from the lava (Bingham fluid) flow limit condition H = nfb / ($\rho$ gsin $\alpha$) in the tube [(10~12)], where for n = 4 , H is a tube height with circular section, for n = 3,H is a tube height with finite width rectangular cross section, for n= 2 , H is a tube height with infinite width rectangular section. Here, the gravitational acceleration g = 1.62 m / $sec^2$, the lava density $\rho$ = 2500 kg / $m^3$, and the yield strength values fb = 100 Pa and 200 Pa [(13)].**[Marius Hills Hole (MHH)]** MHH has a diameter of 57 m ×48 m, a depth of 48 m, a ceiling thickness of 31 m, and a cavity height of 17 m. The inclination angle of the rille surface in the vicinity where MHH exists is considered to be in the range of 0.28 degree to 0.69 degree and the tube height was obtained with the lava yield strength value 100 Pa to 200 Pa. For a finite width rectangular section tube, the height is 15.4 m at 100 Pa, which is close to the cavity height of 17 m of MHH.**[Mare Tranquilitatis Hole (MTH)]** MTH has a diameter of 99 m ×84 m, a depth of 107 m, a ceiling thickness of 47 m, and a cave cavity height of 60 m. The inclination angle in the highest direction near MTH was 0.62 degree. A finite width rectangular section tube height is 6.7 m to 13.5 m at 100 Pa to 200 Pa, which is smaller than the cavity height 60 m. The actual angle of the inclination of the tube may be lower.**[Mare Ingenii Hole (MIH)]** MIH has a diameter of 103 mx 66 m and a depth of 37 - 63 m. As the highest inclination angle is 0.21 degree around MIH, the finite width rectangular cross section tube height is estimated as 20 to 40 m at 100 Pa to 200 Pa. As the vertical hole depth is 37 to 63 m, so the ceiling thickness is considered to be about 20 m.**[Pit of Lacus Mortis]** Lacus Mortis's pit has a diameter of 60 m ×100 m and a depth of 114 m. The highest inclination angle around the pit is 1.2 degrees. So,the finite width rectangular cross section tube height is estimated as 3.7 m - 7.4 m at 100 Pa - 200 Pa. As the vertical hole depth is 114 m, so the ceiling thickness seems to be quite thick.**[Rille discovered by Chandrayaan - 1]** The inclination angle of the undamaged portion in the central part of the rille is 0.93 degree. The height of the finite width rectangular cross section tube height is estimated as 4.6 m to 9.2 m at 100 Pa to 200 Pa. Considering that the rille depth at both ends of the undamaged portion is 8 m to 17 m, the ceiling thickness is considered to be extremely thin if there is a cavity under the undeflected ceiling of the rille.**[Pit of Sinus Iridum]** Sinus Iridum Pit has a diameter of 70 m ×30 m and a depth of 20 m. The maximum inclination angle around the Sinus Iridum Pit is 0.83 degree. The height of the finite width rectangular section tube is estimated as 5.1 m to 10.2 m at 100 Pa to 200 Pa. The ceiling thickness will be on the order of 10 to 15 meters.

**[Conclusion]** Table 1 shows a summary of estimates of cavity heights of possible lava tube caves under the holes or pits and rilles. Lava tube cave height was estimated from the LROC Quick Map by measuring the slope of the surface. However, due to the possible lunar crustal deformation after tube formation, there is a possibility that the used slope angle may be different from the actual slope angle of the lava tube below the surface. The estimated cavity height is only a rough estimate and it is expected to be demonstrated by further detailed examination and exploration.

# Detecting mare basalts intruded into the crust on the early Moon

*Ayame Ikeda[1], Tomokatsu Morota[2], Hiroshi Nagaoka[3]

1. Department of Science, Nagoya University, 2. Graduate School of Enviromental Studies, Nagoya University, 3. Japan Aerospace Exploration Agency

To understand the lunar thermal evolution, unraveling the eruption rate of mare basalts and its temporal variation is important. Absolute dating of lunar basalt samples returned by the Apollo and Luna missions indicated that lunar magma eruptions were active from 3.9 to 3.0 Ga [e.g., Nyquist and Shih, 1992]. Also, the age of basalt fragments in the lunar meteorite is estimated to be 4.35 Ga by radiometric dating [Terada et al., 2007], implying that mare magmatism already started at that time. However, the magnitude of magma activity before the basin-forming period (>3.9 Ga) remains unknown, because these magmas could hardly extrude to the surface before topographic lows were formed by basin-forming impacts.

In order to verify the existence of pre-basin basalts and estimate its total volume we investigated the inner ring of the Crisium basin, which consists of deposits of crustal materials ejected by the Crisium-forming impact. In this study, we used topographic data and multiband images obtained by Terrain Camera and Multiband Imager onboard Kaguya. The inner-ring area was defined as area with an altitude higher than -1.3 km. Mare basalts in the inner-ring area were identified based on the optical matuality, the FeO content, and the spectral absorption depths at 950nm, 1050 nm and 1250 nm.

The mean FeO content of the fresh regions in the inner-ring area was calculated to be 6.75 wt%, suggesting the limited amount of basalts in the area. However, we found some basaltic outcrops at interior and ejecta of smaller craters excavating part of the ring materials. The surface area of the basaltic outcrops is estimated to be $1.3\times10^{-3}$ % of the inner-ring area. By assuming that the area abundance of the basalts in the inner ring is equal to the volume abundance, we estimated to be the total volume of basaltic intrusions of $1.2\times10^{5}$ $km^3$. Based on comparison with the total volume of Mare Crisium ($2.0\times10^{5}$–$7.2\times10^{5}$ $km^3$) [Mulis et al., 1992; Solomon and Head, 1980], we conclude that mare volcanism before the Crisium-forming impact was less active than post-Crisium volcanism.

# Searching for lunar swirls with deep learning

*Yurika Iwabuchi[1], Yoshiko Ogawa[1]

1. The University of Aizu

Lunar swirls are winding high albedo patterns not-correlated with topography.They have irregular shapes, distributions, and various spatial scales. About 10 swirls have been discovered so far by visual inspection. However, it is expected there would be more swirls. We have been working on applying Deep Learning to automaticallyfind lunar swirls candidates of small-medium size especially.

The objective of this study is building and updating learning models for automatic identification of lunar swirls and evaluating the models. We aim to search for lunar swirls with Deep Learning. We set the target area in Mare Ingenii area (20˚-50˚S, 150˚-180˚E).

The point to identifying swirl is to distinguish albedo features (swirls) from shading patterns (non-swirls). Therefore, we allocated two kinds of data to the 3 bands in RGB image: Camera imager for R band, and topography data for G and B bands following Kato et al. [2018].As camera image, we use the Multi-band Imager (MI) data from Kaguya satellite. As for DEM data, the data of SLDEM2013 are used. By creating such unique “Combined Image”, we can combine different kinds of information collectively as one image.

We built learning models using the framework of Caffe. We increased variation and quantity of training data to collect data from all confirmed swirl areas and to rotate original images in 3 directions. Totally 212 images (each image covers 1 by 1 deg.) were used as training data. We prepared correct answer data in target area and conduct cross validation for evaluation of results and models. The model building and evaluation were sequentially cycled.

Running the latest learning model, we found 275 images as swirl candidate scenes out of 832 images in the Mare Ingenii. Focusing on True positive rate, the best swirl detection was performed by the learning model built based on training data set which increases variation and quantity of swirl images and ratio of swirl images to non-swirl images.

# Lunar surface feature reconstruction by deep learning using synthetic data

*Koichi Tsuru[1], Toru Kouyama[1], Ryosuke Nakamura[1]

1. National Institute of Advanced Industrial Science and Technology

Various machine learning methods have been proposed to detect lunar surface features such as craters and boulders from satellite imagery. However, many of them need a huge manual effort to create a training data set even to solve one task.

Hence, so far, we have focused on several algorithms based on Generative Adversarial Networks (GANs) that enable highly accurate image generation even from a small amount of training set, and we examined to use Cycle-Consistency Adversarial Networks (CycleGAN) which can learn translation relationship between two image groups, such as a group of Moon surface images and a group of crater maps, for crater detection on the Moon surface. The CycleGAN does not require paired images, whereas it learns the relationship between the two image groups with an unpaired training manner, and images in one of the two groups can be simulated label data.

Initially, we tried to translate a satellite imagery to a labeled image (i.e. crater map), in which the labeled image is produced by simulations based on statistical crater size-frequency distribution. Although it could reduce the annotation cost drastically by the automatic generation of the label data, we found that the learning was not stable and not precise because the texture was too different between the satellite imagery and the simple labeled image. Then, we considered that, in order to improve the performance, it is necessary to train a network with multiple feature labels (i.e. lunar surface elevation, albedo, and shadow maps, and crater and boulder distributions) that characterize the appearance of the Moon surface to be observed.

In this work, we adopted a two-step deep learning framework with fine-tune models trained by 1) generating feature labels from a modeled surface image which is based on given feature labels, and synthesizing the labels to generate a lunar surface image that is compared with the original one to check the network performance (at the same time the generated feature labels are also compared with given ones), and then 2) generating feature labels from actual observed data and again synthesizing the labels to generate a lunar surface image to be compared with the actual image. The good advantage of using modeled data and labels as training data is that it becomes easier to cover complicated and enormous amount of possible observation conditions which is necessary for analyzing actual observation data. In addition, highly precise inference can be possible by the simulation even when the existing observation data of a target object covers only insufficient observation conditions.

In the proposed framework, we employed two generative networks that reconstruct terrain features from satellite imagery and to synthesize satellite imagery from terrain features. By applying cycle-consistency for the training that is measured from similarity between the resynthesized satellite image from “reconstructed” features and the original, the actual terrain features are not required in the training phase.

We prepared DEM, albedo map, crater map, boulder map, and shadow map as features for the reconstruction of a target region. In this presentation, we show the results of feature reconstruction from

# Evaluation of the influence of alkali elements on hydrogen solubility of clinopyroxene for estimating water content of lunar mantle

*Miki Muranushi[1], Akio Suzuki[1], Masahiro KAYAMA[1], Tsuyoshi MIYAMOTO[2]

1. Graduate school of Science, Tohoku university , 2. Center for Northeast Asian Studies, Tohoku university

In the early history of lunar exploration, lunar samples returned by the Apollo missions revealed that volatile elements are depleted on the Moon. Almost all volatile components were thought to be eliminated by the giant impact event that probably led to the formation of the Moon. However, recent microanalyses of lunar samples have discovered hydroxyl or water in the constituent minerals. These observations suggest that the lunar mantle may not be entirely dry and contain water to same extent as the Earth’ s mantle. The lunar volcanic glasses of Apollo 15 and 17 were measured by SIMS and about 4-46 ppm water were detected (Saal et al., 2008). Hui et al. (2013, Nature Geosci.) detected up to 2.7 ppm water in plagioclase grains from the lunar highland crust sample. They suggest that the initial water content of the lunar magma ocean (LMO) reaches approximately 320 ppm water content. As a result of these studies, water content and the process that the moon got water has attracted a lot of attention.
Since no indigenous hydrous minerals have been found in the moon, it is likely that anhydrous mineral possess water as a reservoir in the lunar mantle. Water exists in the Earth’ s mantle as hydrous mineral, anhydrous mineral, silicate melt, liquid water, and their intermediate form. In the Earth’ s mantle, hydrogen may be incorporated as defects in nominally anhydrous minerals (NAMs) such as Olivine, pyroxene and garnet. (e.g., Smyth et al., 1991). Especially, clinopyroxene (Cpx) shows the maximum water content in the upper mantle xenolith (Inglin and Skogby, 2000). Cpx has possibility of being water reservoir in the lunar mantle due to its crystal structure and chemical composition.
Nakamura et al. (2012) confirmed the presence of calcium rich pyroxene in the South Pole-Aitken (SPA). It is possible that the lunar upper mantle has been excavated and exposed in SPA (Cintala and Grieve, 1998; Lucey et al., 1998). Cpx is likely to be one of the major minerals of the lunar mantle as well as the earth.
Since there is less hydrous mineral in the Moon, water should concentrated in KREEPy basalt that assumed to be the final part of the lunar magma ocean solidification. In this study, we target the measurement of hydrogen solubility of Cpx crystallized from alkali-rich magma.
We conducted a high temperature and high pressure experiment at 1 GPa using a piston cylinder apparatus at Bayreiches Geoinstitut, Germany. Starting material is the natural alkali basalt powder (Haku-4 reported by Kuritani et al., 2009), adding ~5 wt. % water with a micro-syringe. For the Fourier Transform Infrared (FT-IR) analysis, it is necessary to produce Cpx crystals larger than 50 μm. Therefore, in order to considerate conditions suitable for sample synthesis, we conducted several experiments that the initial temperature, cooling rate, the temperature after cooling and the retention time were changed. We report the conditions that succeeded in creating the Cpx large enough for FT-IR analysis and the future plans.
Funding acknowledgment: This work was partially supported by the JSPS Japanese-German Graduate Externship.

# Preliminary examination of mineral structure effect on relative permittivity

*Makito Kobayashi[1], Takafumi Niihara[2], Hideaki Miyamoto[2,1]

1. Department of Earth and Planetary Science, School of Science, University of Tokyo, 2. Department of Systems Innovation, School of Engineering, University of Tokyo

The surface of the Moon is covered with regolith formed by the bombardment of meteorites and micro-meteorites. Although drill core samples collected during Apollo missions revealed that the subsurface (1-2 m) structure changes vertically over centimeter to meter scales at landing sites, deeper (> 10 m) structure and spatial continuity is still unknown. Ground Penetrating Radar (GPR) can detect potential variations in subsurface structure which result in permittivity contrasts, therefore, understanding of factors that affect the permittivity of the regolithis important.

Relative permittivity depends on multiple factors such as radar frequency, porosity, temperature, moisture content and chemical composition (e.g., Campbell and Ulrichs, 1969). Correlation between Ti and Fe concentration and the relative permittivity of Apollo samples was previously addressed by Shkuratov and Bondarenko(2001). On the other hand, Fa and Wieczorek (2012) reported that there was no correlation between chemical composition and relative permittivity althoughthe bulk density varied between samples in this study. Because previous workshave not focused specifically on the influence of mineral composition (while keeping bulk density and composition constant), we prepared samples to isolate the influence of mineral composition on relative permittivity.

Bulk density of regolith mostly depends on porosity and the constituent minerals among samples which have the same bulk chemical composition. Lunar regolith contains Fe- and/or Ti-bearing spinel minerals and other oxide minerals (e.g. ilmenite, magnetite, armarcolite), andthe abundance of those minerals depends on the sample. Differences in abundance of constituent minerals indicate different origins of precursor rocks. If we can detect the permittivity contrast resulting from those mineral differences, it could help further our understanding of the subsurface structure and evolution of surface of the Moon. Therefore, we examine whether crystal types of opaque minerals with the samechemicalcomposition affect the relative permittivity.

We prepare a mixture of rutile and iron oxide (II) to create same chemical composition as ilmenite. Porosities of samples are uniform (40%), therefore, densities of the mixture and ilmenite samples are 2.96 and 2.90, respectively. In order to avoid the effect of moisture content, samples are dried for a few days, and we then measure the relative permittivity using a coaxial probe in the range of 1 MHz to 6 GHz at room temperature.

There is a difference of relative permittivity of about 3.6-4.2 when comparing the mixture (10.6-10.7) with ilmenite (6.4-7.0). This result indicates that crystal structure can affect the relative permitivity.In this presentation, we will discuss the effect in more detail.

Education Center on Computational Science and Engineering, Kobe University, 7. Deparment of Earth and Planetary Sciences, Tokyo Institute of Technology, 8. The University of Tokyo

The Moon is classified as a nonmagnetized celestial body that does not hold a global, intrinsic magnetic field and atmosphere, and most of the dayside lunar surface is bombarded by the solar wind plasma. Therefore, most of the solar wind collides with the lunar surface and is absorbed. Meanwhile, some regions called magnetic anomaly of the lunar surface are locally shielded from the solar wind by magnetic fields of crustal origin. The interaction between the lunar crustal magnetic fields and the solar wind is an important topic relevant to the plasma environment around the Moon. Research on the interaction between the solar wind and the strong magnetic anomaly has been advanced so far, but it remains unclear how the magnetic field strength on the dayside lunar surface varies globally.

The global distribution of crustal magnetic field strength has been investigated by electron reflectometry, which remotely infers the surface magnetic field strength from the loss cone angle of reflected electrons from the lunar crustal magnetic field, using the magnetic mirror effect of the moon periphery electron. As the aim of the conventional electron reflectometry is measurements of the strength of the lunar crustal magnetic field itself, a standard practice is to use data obtained on the night side of the Moon and within the terrestrial magnetotail lobes with less influence of the solar wind plasma. Here we apply the electron reflectometry to the data obtained on the day side of the Moon in the solar wind, thereby investigating variations of the surface magnetic field strength caused by the interaction with the solar wind. By applying this method to the data of Kaguya when exposed to the solar wind on the lunar day side, the magnetic field became stronger globally.

We utilized data obtained by the electron spectrum analyzers (MAP-PACE-ESA) and magnetometer (MAP-LMAG) on board Kaguya. We investigated a surface magnetic field intensity by analyzing electron pitch angle distributions of each different energy band measured when the day side lunar surface was exposed to the solar wind. As a result, we revealed energy dependence on the pitch angle distribution of electrons. This suggests that the cutoff pitch angles are influenced by the potential difference between the lunar surface and the satellite and the electric field generated by decoupling of electrons and ions. We will discuss the solar wind dynamic pressure control of the lunar surface magnetic field intensity with energy dependence.

# Objective and Current Development Status of Multi-Band Camera on SLIM

*Yusuke Nakauchi[1], Kazuto Saiki[2], Makiko Ohtake[1], Hiroaki Shiraishi[1], Chikatoshi Honda[3], Hiroyuki Sato[1], Yoshiaki Ishihara[4], Takao Maeda[5], Masatsugu Otsuki[1], Sin-ichiro Sakai[1], Shujiro Sawai[1], SLIM Project Team

1. Japan Aerospace Exploration Agency, 2. Osaka University, 3. Aizu University, 4. National Institute for Environmental Studie, 5. Chuo University

Smart Lander for Investigating Moon (SLIM) project is on going in JAXA. The main objective of this project is to demonstrate various techniques for “pin-point landing” on the moon. SLIM spacecraft is a small lander. It is designed to achieve “pin-point landing” to 100 meter-order error circle. In order to “pin-point landing” of this level, SLIM mission will demonstrate new image-based onboard navigation system and autonomous landing along with several other new technologies (e.g. “tow stage” landing sequence, metal shock absorbers). The SLIM spacecraft weight is ~730 kg wet mass and ~200 kg class dry mass, both of which are more lightweight than previous lunar landers. The spacecraft will be launched with a Japanese rocket H-IIA in 2021 or 2022. Landing on (25.2ºE, 13.3ºS) located in the west of Mare Nectaris is planned.

After landing, SLIM project is planning to observe around landing site using Multi-Band Camera (MBC). The observational mission is positioned as extra success. MBC will observe olivine and estimate Mg# of it. MBC is a compact VIS-NIR camera composed of an imaging sensor (InGaAs), a filter-wheel with 10 band-pass filters, a telephoto optical system, and a movable mirror for panning and tilting. The sensor has sensitivity at wavelength from 700 to 1700 nm, which covers the characteristic ab-sorption bands of lunar minerals. The telephoto optical system can focus on an object from 1.5 to 30 m distance. The imaging sensor has 640 ×512 pixels with 20 $\mu$m pitch. The 4º field of view corresponds to the spatial sampling of 1.3 mm per pixel at 10 m from the lander. Using the movable mirror, observable scanning area is ~50º in azimuth and ~70º in elevation. This makes it possible to observe the size distribution of boulders around the lander. The observation wavelength of band pass filters were selected 10 bands: 750, 920, 950, 970, 1000, 1050, 1100, 1250, 1550, and 1650 nm. The width of their bands is 30nm.

# Monte Carlo simulation of neutron production and transport in the Moon: Effect of lunar subsurface water

*Hiroki Kusano[1], Yuzuru Karouji[1], Hiroshi Nagaoka[1], Naoyuki Yamashita[2], Makoto Hareyama[3]

1. Japan Aerospace Exploration Agency, 2. Planetary Science Institute, 3. St. Marianna University School of Medicine

The intensity of thermal, epithermal, and fast neutrons emitted from a planetary surface provides information on the surface elemental composition, particularly on the hydrogen abundance. In an airless planetary surface, the galactic cosmic rays produce fast neutrons via nuclear interactions in the subsurface materials within a depth of tens centimeters. Then, the fast neutrons are moderated by interactions with subsurface materials including the secondary neutron production. This neutron transport process is terminated at the thermal neutron capture or the neutron leakage from surface. Because the hydrogen atom has a large elastic scattering cross section for a neutron and a nearly identical mass as a neutron, neutrons are efficiently moderated by the elastic scattering with hydrogen atoms. Therefore, the leakage neutron intensity strongly depends on the hydrogen abundance as well as the surface elemental composition. Neutron spectroscopy is thus well suited to detect subsurface water which may present at the lunar polar region. It is essential to obtain the abundance and distribution of lunar subsurface water from the viewpoint of planetary science and space resources for future manned activities.

In this study, the neutron production and transport in the Moon was modeled by Monte Carlo simulation with Geant4 10.3.p03. The effect of subsurface hydrogen abundance and spatial distribution was studied for in-situ water search in future lunar polar landing explorations. The leakage neutron intensity produced by protons and alpha particles in galactic cosmic rays was calculated for the lunar highland composition mixed with various amounts of hydrogen. The production depth and flux of subsurface neutrons, and the production depth of leakage thermal, epithermal, and fast neutrons were also calculated. It was confirmed that the leakage neutron intensity depends on the subsurface hydrogen abundance. The epithermal neutron intensity is particularly sensitive to the presence of subsurface hydrogen. Most of the leakage neutrons were produced within a depth of about 100 g/cm$^2$, which means that the neutron spectroscopy is mainly sensitive to the subsurface water in the top of surface with about 50 cm in depth depending on the surface density. When a dry layer presents at the top of surface, the leakage neutron intensity was found to depend on the dry layer thickness. The variation of leakage neutron intensity was detectable for the dry layer thickness less than about 80 g/cm$^2$. The behavior of lunar subsurface neutrons and its sensitivity for lunar subsurface water will be presented and discussed.

Japan Aerospace Exploration Agency, 9. University of Tokyo, 10. Department of Solid Planetary Sciences Institute of Space and Astronautical Science

We have been designing and developing an active seismic exploration package with seismometers, active seismic source and anchoring system. Our seismic exploration package was designed to investigate from shallow formation (i.e., ice saturation) to deep formation (i.e., thickness of regolith) of the Moon. Here we present the basic concept of our seismic exploration package and its experimental results. We then discuss the possibilities of future space missions. We evaluate the relation between the S-wave velocity and the ice saturation, and found that S-wave velocity largely increase due to ice deposition (low ice saturation). To evaluate our active-source seismic exploration system, furthermore, we conducted seismic exploration in the test field in JAXA. The test field is filled with loose sands of ~50cm thickness. In this experiment, we conducted seismic survey with several acquisition parameters. When we applied the active seismic survey for small-size receiver array, we retrieved clear shot gather. We further calculated dispersion curve from the shot gather and obtained S-wave velocity profile beneath the array using inversion. In addition, we could detect the cushioning material whose S wave velocity is lower than sand by surface wave analysis and compare the result with the dispersion curve which has no buried material. These results demonstrate that S-wave velocity in shallow formation was accurately estimated, suggesting that ice can be identified as anomalous high S-wave velocity via our seismic system. When the seismometer interval is long, the attenuation of the surface wave is large. However, the refracted P-wave can arrive at far offset receivers. Using the refracted wave, we can estimate P-wave velocity of the basement.

# Orbit determination of the Chang’E-5 Test 1 and a new gravity field model

*shanhong liu[1], Jianguo Yan[1]

1. Wuhan University

We introduce the recently Chang’E 5-Test 1 (CE-5T1) mission overall and its orbit characteristic and present the results on precision orbit determination from the radio science investigation of the CE-5T1 spacecraft. We describe the data, modeling and methods used to achieve position knowledge several times better than the required demand (in total position) for most of arcs, over the period from 10 March 2014 to 28 December 2018. In addition to we try to use the near-continuous radiometric tracking data of CE-5T1 to develop a new lunar gravity field up to degree and order 100, which is solved independently using about four years tracking data. The accuracy of the gravity field model is assessed by multi means, such as gravity spectrum, observational residuals after precision orbit determination, lunar surface gravity anomaly character, admittance/coherence with topography model, and the corresponding physical feature and effect are analyzed. We also make a comparison between this model and the previously models we ever solved, CEGM-01 and CEGM-02. The results indicate the effectiveness and reasonability of this solution process. On the basis of current work, with the Chang’E 5, 6, and 7 under implementing and planning, the prospect of future development of Chinese lunar gravity field detection is presented.

Thu. May 30, 2019 5:15 PM - 6:30 PM JST | Thu. May 30, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_1

## [P-PS08] Lunar science and exploration

convener:Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Masahiro KAYAMA(Department of Earth and Planetary Material Sciences, Faculty of Science, Tohoku University), Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Tomokatsu Morota(Graduate School of Environmental Studies, Nagoya University)

Scientific data sets acquired by not only Japanese lunar mission SELENE (Kaguya), but also other countries' missions, have become new standard for lunar science. Analyses of these data have been providing several new knowledge and changing some hypotheses into the truth of the Moon. In concurrence with these studies, some countries including Japan are planning future lunar missions. In this session, we will discuss scientific results based on newly acquired lunar data, strategy for future missions including SLIM, and theoretical and experimental studies for lunar science.<br/>

# Estimation of lava tube cave height below the vertical hole from the surface topography of the Moon

*Tsutomu Honda[1]

1. Vulcano-speleological Society

**[Introduction]** The inclination(sin $\alpha$) and slope angle($\alpha$) of the near surface of the vertical hole and the rille,where the cavity of the lava tube cave is assumed to be under it, can be obtained from the LROC Quick Map[(1)] made from the data of the US LRO. Marius Hills Hole (MHH), Mare Tranquillitatis Hole (MTH), Mare Ingenii Hole (MIH)[(2~5)] discovered by Haruyama et al., furthermore Lacus Mortis vertical holes[(6,7)], Rille structure discovered by Chandrayaan-1[(8)], and Sinus Iridum Pit [(9)] were examined. For the case where the direction of flow of the lava is unknown, the direction showing the angle at which the highest inclination angle of the surrounding is adopted. The cavity height is obtained from the lava (Bingham fluid) flow limit condition H = nfb / ($\rho$ gsin $\alpha$) in the tube [(10~12)], where for n = 4 , H is a tube height with circular section, for n = 3,H is a tube height with finite width rectangular cross section, for n= 2 , H is a tube height with infinite width rectangular section. Here, the gravitational acceleration g = 1.62 m / $sec^2$, the lava density $\rho$ = 2500 kg / $m^3$, and the yield strength values fb = 100 Pa and 200 Pa [(13)].**[Marius Hills Hole (MHH)]** MHH has a diameter of 57 m ×48 m, a depth of 48 m, a ceiling thickness of 31 m, and a cavity height of 17 m. The inclination angle of the rille surface in the vicinity where MHH exists is considered to be in the range of 0.28 degree to 0.69 degree and the tube height was obtained with the lava yield strength value 100 Pa to 200 Pa. For a finite width rectangular section tube, the height is 15.4 m at 100 Pa, which is close to the cavity height of 17 m of MHH.**[Mare Tranquilitatis Hole (MTH)]** MTH has a diameter of 99 m ×84 m, a depth of 107 m, a ceiling thickness of 47 m, and a cave cavity height of 60 m. The inclination angle in the highest direction near MTH was 0.62 degree. A finite width rectangular section tube height is 6.7 m to 13.5 m at 100 Pa to 200 Pa, which is smaller than the cavity height 60 m. The actual angle of the inclination of the tube may be lower.**[Mare Ingenii Hole (MIH)]** MIH has a diameter of 103 mx 66 m and a depth of 37 - 63 m. As the highest inclination angle is 0.21 degree around MIH, the finite width rectangular cross section tube height is estimated as 20 to 40 m at 100 Pa to 200 Pa. As the vertical hole depth is 37 to 63 m, so the ceiling thickness is considered to be about 20 m.**[Pit of Lacus Mortis]** Lacus Mortis's pit has a diameter of 60 m ×100 m and a depth of 114 m. The highest inclination angle around the pit is 1.2 degrees. So,the finite width rectangular cross section tube height is estimated as 3.7 m - 7.4 m at 100 Pa - 200 Pa. As the vertical hole depth is 114 m, so the ceiling thickness seems to be quite thick.**[Rille discovered by Chandrayaan - 1]** The inclination angle of the undamaged portion in the central part of the rille is 0.93 degree. The height of the finite width rectangular cross section tube height is estimated as 4.6 m to 9.2 m at 100 Pa to 200 Pa. Considering that the rille depth at both ends of the undamaged portion is 8 m to 17 m, the ceiling thickness is considered to be extremely thin if there is a cavity under the undeflected ceiling of the rille.**[Pit of Sinus Iridum]** Sinus Iridum Pit has a diameter of 70 m ×30 m and a depth of 20 m. The maximum inclination angle around the Sinus Iridum Pit is 0.83 degree. The height of the finite width rectangular section tube is estimated as 5.1 m to 10.2 m at 100 Pa to 200 Pa. The ceiling thickness will be on the order of 10 to 15 meters.

**[Conclusion]** Table 1 shows a summary of estimates of cavity heights of possible lava tube caves under the holes or pits and rilles. Lava tube cave height was estimated from the LROC Quick Map by measuring the slope of the surface. However, due to the possible lunar crustal deformation after tube formation, there is a possibility that the used slope angle may be different from the actual slope angle of the lava tube below the surface. The estimated cavity height is only a rough estimate and it is expected to be demonstrated by further detailed examination and exploration.

# Detecting mare basalts intruded into the crust on the early Moon

*Ayame Ikeda[1], Tomokatsu Morota[2], Hiroshi Nagaoka[3]

1. Department of Science, Nagoya University, 2. Graduate School of Enviromental Studies, Nagoya University, 3. Japan Aerospace Exploration Agency

To understand the lunar thermal evolution, unraveling the eruption rate of mare basalts and its temporal variation is important. Absolute dating of lunar basalt samples returned by the Apollo and Luna missions indicated that lunar magma eruptions were active from 3.9 to 3.0 Ga [e.g., Nyquist and Shih, 1992]. Also, the age of basalt fragments in the lunar meteorite is estimated to be 4.35 Ga by radiometric dating [Terada et al., 2007], implying that mare magmatism already started at that time. However, the magnitude of magma activity before the basin-forming period (>3.9 Ga) remains unknown, because these magmas could hardly extrude to the surface before topographic lows were formed by basin-forming impacts.

In order to verify the existence of pre-basin basalts and estimate its total volume we investigated the inner ring of the Crisium basin, which consists of deposits of crustal materials ejected by the Crisium-forming impact. In this study, we used topographic data and multiband images obtained by Terrain Camera and Multiband Imager onboard Kaguya. The inner-ring area was defined as area with an altitude higher than -1.3 km. Mare basalts in the inner-ring area were identified based on the optical matuality, the FeO content, and the spectral absorption depths at 950nm, 1050 nm and 1250 nm.

The mean FeO content of the fresh regions in the inner-ring area was calculated to be 6.75 wt%, suggesting the limited amount of basalts in the area. However, we found some basaltic outcrops at interior and ejecta of smaller craters excavating part of the ring materials. The surface area of the basaltic outcrops is estimated to be $1.3\times10^{-3}$ % of the inner-ring area. By assuming that the area abundance of the basalts in the inner ring is equal to the volume abundance, we estimated to be the total volume of basaltic intrusions of $1.2\times10^{5}$ $km^3$. Based on comparison with the total volume of Mare Crisium ($2.0\times10^{5}$–$7.2\times10^{5}$ $km^3$) [Mulis et al., 1992; Solomon and Head, 1980], we conclude that mare volcanism before the Crisium-forming impact was less active than post-Crisium volcanism.

# Searching for lunar swirls with deep learning

*Yurika Iwabuchi[1], Yoshiko Ogawa[1]

1. The University of Aizu

Lunar swirls are winding high albedo patterns not-correlated with topography.They have irregular shapes, distributions, and various spatial scales. About 10 swirls have been discovered so far by visual inspection. However, it is expected there would be more swirls. We have been working on applying Deep Learning to automaticallyfind lunar swirls candidates of small-medium size especially.

The objective of this study is building and updating learning models for automatic identification of lunar swirls and evaluating the models. We aim to search for lunar swirls with Deep Learning. We set the target area in Mare Ingenii area (20˚-50˚S, 150˚-180˚E).

The point to identifying swirl is to distinguish albedo features (swirls) from shading patterns (non-swirls). Therefore, we allocated two kinds of data to the 3 bands in RGB image: Camera imager for R band, and topography data for G and B bands following Kato et al. [2018].As camera image, we use the Multi-band Imager (MI) data from Kaguya satellite. As for DEM data, the data of SLDEM2013 are used. By creating such unique “Combined Image”, we can combine different kinds of information collectively as one image.

We built learning models using the framework of Caffe. We increased variation and quantity of training data to collect data from all confirmed swirl areas and to rotate original images in 3 directions. Totally 212 images (each image covers 1 by 1 deg.) were used as training data. We prepared correct answer data in target area and conduct cross validation for evaluation of results and models. The model building and evaluation were sequentially cycled.

Running the latest learning model, we found 275 images as swirl candidate scenes out of 832 images in the Mare Ingenii. Focusing on True positive rate, the best swirl detection was performed by the learning model built based on training data set which increases variation and quantity of swirl images and ratio of swirl images to non-swirl images.

# Lunar surface feature reconstruction by deep learning using synthetic data

*Koichi Tsuru[1], Toru Kouyama[1], Ryosuke Nakamura[1]

1. National Institute of Advanced Industrial Science and Technology

Various machine learning methods have been proposed to detect lunar surface features such as craters and boulders from satellite imagery. However, many of them need a huge manual effort to create a training data set even to solve one task.

Hence, so far, we have focused on several algorithms based on Generative Adversarial Networks (GANs) that enable highly accurate image generation even from a small amount of training set, and we examined to use Cycle-Consistency Adversarial Networks (CycleGAN) which can learn translation relationship between two image groups, such as a group of Moon surface images and a group of crater maps, for crater detection on the Moon surface. The CycleGAN does not require paired images, whereas it learns the relationship between the two image groups with an unpaired training manner, and images in one of the two groups can be simulated label data.

Initially, we tried to translate a satellite imagery to a labeled image (i.e. crater map), in which the labeled image is produced by simulations based on statistical crater size-frequency distribution. Although it could reduce the annotation cost drastically by the automatic generation of the label data, we found that the learning was not stable and not precise because the texture was too different between the satellite imagery and the simple labeled image. Then, we considered that, in order to improve the performance, it is necessary to train a network with multiple feature labels (i.e. lunar surface elevation, albedo, and shadow maps, and crater and boulder distributions) that characterize the appearance of the Moon surface to be observed.

In this work, we adopted a two-step deep learning framework with fine-tune models trained by 1) generating feature labels from a modeled surface image which is based on given feature labels, and synthesizing the labels to generate a lunar surface image that is compared with the original one to check the network performance (at the same time the generated feature labels are also compared with given ones), and then 2) generating feature labels from actual observed data and again synthesizing the labels to generate a lunar surface image to be compared with the actual image. The good advantage of using modeled data and labels as training data is that it becomes easier to cover complicated and enormous amount of possible observation conditions which is necessary for analyzing actual observation data. In addition, highly precise inference can be possible by the simulation even when the existing observation data of a target object covers only insufficient observation conditions.

In the proposed framework, we employed two generative networks that reconstruct terrain features from satellite imagery and to synthesize satellite imagery from terrain features. By applying cycle-consistency for the training that is measured from similarity between the resynthesized satellite image from “reconstructed” features and the original, the actual terrain features are not required in the training phase.

We prepared DEM, albedo map, crater map, boulder map, and shadow map as features for the reconstruction of a target region. In this presentation, we show the results of feature reconstruction from

# Evaluation of the influence of alkali elements on hydrogen solubility of clinopyroxene for estimating water content of lunar mantle

*Miki Muranushi[1], Akio Suzuki[1], Masahiro KAYAMA[1], Tsuyoshi MIYAMOTO[2]

1. Graduate school of Science, Tohoku university , 2. Center for Northeast Asian Studies, Tohoku university

In the early history of lunar exploration, lunar samples returned by the Apollo missions revealed that volatile elements are depleted on the Moon. Almost all volatile components were thought to be eliminated by the giant impact event that probably led to the formation of the Moon. However, recent microanalyses of lunar samples have discovered hydroxyl or water in the constituent minerals. These observations suggest that the lunar mantle may not be entirely dry and contain water to same extent as the Earth’ s mantle. The lunar volcanic glasses of Apollo 15 and 17 were measured by SIMS and about 4-46 ppm water were detected (Saal et al., 2008). Hui et al. (2013, Nature Geosci.) detected up to 2.7 ppm water in plagioclase grains from the lunar highland crust sample. They suggest that the initial water content of the lunar magma ocean (LMO) reaches approximately 320 ppm water content. As a result of these studies, water content and the process that the moon got water has attracted a lot of attention.
Since no indigenous hydrous minerals have been found in the moon, it is likely that anhydrous mineral possess water as a reservoir in the lunar mantle. Water exists in the Earth’ s mantle as hydrous mineral, anhydrous mineral, silicate melt, liquid water, and their intermediate form. In the Earth’ s mantle, hydrogen may be incorporated as defects in nominally anhydrous minerals (NAMs) such as Olivine, pyroxene and garnet. (e.g., Smyth et al., 1991). Especially, clinopyroxene (Cpx) shows the maximum water content in the upper mantle xenolith (Inglin and Skogby, 2000). Cpx has possibility of being water reservoir in the lunar mantle due to its crystal structure and chemical composition.
Nakamura et al. (2012) confirmed the presence of calcium rich pyroxene in the South Pole-Aitken (SPA). It is possible that the lunar upper mantle has been excavated and exposed in SPA (Cintala and Grieve, 1998; Lucey et al., 1998). Cpx is likely to be one of the major minerals of the lunar mantle as well as the earth.
Since there is less hydrous mineral in the Moon, water should concentrated in KREEPy basalt that assumed to be the final part of the lunar magma ocean solidification. In this study, we target the measurement of hydrogen solubility of Cpx crystallized from alkali-rich magma.
We conducted a high temperature and high pressure experiment at 1 GPa using a piston cylinder apparatus at Bayreiches Geoinstitut, Germany. Starting material is the natural alkali basalt powder (Haku-4 reported by Kuritani et al., 2009), adding ~5 wt. % water with a micro-syringe. For the Fourier Transform Infrared (FT-IR) analysis, it is necessary to produce Cpx crystals larger than 50 μm. Therefore, in order to considerate conditions suitable for sample synthesis, we conducted several experiments that the initial temperature, cooling rate, the temperature after cooling and the retention time were changed. We report the conditions that succeeded in creating the Cpx large enough for FT-IR analysis and the future plans.
Funding acknowledgment: This work was partially supported by the JSPS Japanese-German Graduate Externship.

# Preliminary examination of mineral structure effect on relative permittivity

*Makito Kobayashi[1], Takafumi Niihara[2], Hideaki Miyamoto[2,1]

1. Department of Earth and Planetary Science, School of Science, University of Tokyo, 2. Department of Systems Innovation, School of Engineering, University of Tokyo

The surface of the Moon is covered with regolith formed by the bombardment of meteorites and micro-meteorites. Although drill core samples collected during Apollo missions revealed that the subsurface (1-2 m) structure changes vertically over centimeter to meter scales at landing sites, deeper (> 10 m) structure and spatial continuity is still unknown. Ground Penetrating Radar (GPR) can detect potential variations in subsurface structure which result in permittivity contrasts, therefore, understanding of factors that affect the permittivity of the regolithis important.

Relative permittivity depends on multiple factors such as radar frequency, porosity, temperature, moisture content and chemical composition (e.g., Campbell and Ulrichs, 1969). Correlation between Ti and Fe concentration and the relative permittivity of Apollo samples was previously addressed by Shkuratov and Bondarenko(2001). On the other hand, Fa and Wieczorek (2012) reported that there was no correlation between chemical composition and relative permittivity althoughthe bulk density varied between samples in this study. Because previous workshave not focused specifically on the influence of mineral composition (while keeping bulk density and composition constant), we prepared samples to isolate the influence of mineral composition on relative permittivity.

Bulk density of regolith mostly depends on porosity and the constituent minerals among samples which have the same bulk chemical composition. Lunar regolith contains Fe- and/or Ti-bearing spinel minerals and other oxide minerals (e.g. ilmenite, magnetite, armarcolite), andthe abundance of those minerals depends on the sample. Differences in abundance of constituent minerals indicate different origins of precursor rocks. If we can detect the permittivity contrast resulting from those mineral differences, it could help further our understanding of the subsurface structure and evolution of surface of the Moon. Therefore, we examine whether crystal types of opaque minerals with the samechemicalcomposition affect the relative permittivity.

We prepare a mixture of rutile and iron oxide (II) to create same chemical composition as ilmenite. Porosities of samples are uniform (40%), therefore, densities of the mixture and ilmenite samples are 2.96 and 2.90, respectively. In order to avoid the effect of moisture content, samples are dried for a few days, and we then measure the relative permittivity using a coaxial probe in the range of 1 MHz to 6 GHz at room temperature.

There is a difference of relative permittivity of about 3.6-4.2 when comparing the mixture (10.6-10.7) with ilmenite (6.4-7.0). This result indicates that crystal structure can affect the relative permitivity.In this presentation, we will discuss the effect in more detail.

# Lunar surface magnetic field intensity in the solar wind inferred from electron reflectometry

*Tomoki Kawaguchi[1], Yuki Harada[1], Yoshifumi Saito[2], Shoichiro Yokota[3], Masaki N Nishino[4], Hideyuki Usui[5], Yohei Miyake[6], Hideo Tsunakawa[7], Daiba Kato[8]

The Moon is classified as a nonmagnetized celestial body that does not hold a global, intrinsic magnetic field and atmosphere, and most of the dayside lunar surface is bombarded by the solar wind plasma. Therefore, most of the solar wind collides with the lunar surface and is absorbed. Meanwhile, some regions called magnetic anomaly of the lunar surface are locally shielded from the solar wind by magnetic fields of crustal origin. The interaction between the lunar crustal magnetic fields and the solar wind is an important topic relevant to the plasma environment around the Moon. Research on the interaction between the solar wind and the strong magnetic anomaly has been advanced so far, but it remains unclear how the magnetic field strength on the dayside lunar surface varies globally.

The global distribution of crustal magnetic field strength has been investigated by electron reflectometry, which remotely infers the surface magnetic field strength from the loss cone angle of reflected electrons from the lunar crustal magnetic field, using the magnetic mirror effect of the moon periphery electron. As the aim of the conventional electron reflectometry is measurements of the strength of the lunar crustal magnetic field itself, a standard practice is to use data obtained on the night side of the Moon and within the terrestrial magnetotail lobes with less influence of the solar wind plasma. Here we apply the electron reflectometry to the data obtained on the day side of the Moon in the solar wind, thereby investigating variations of the surface magnetic field strength caused by the interaction with the solar wind. By applying this method to the data of Kaguya when exposed to the solar wind on the lunar day side, the magnetic field became stronger globally.

We utilized data obtained by the electron spectrum analyzers (MAP-PACE-ESA) and magnetometer (MAP-LMAG) on board Kaguya. We investigated a surface magnetic field intensity by analyzing electron pitch angle distributions of each different energy band measured when the day side lunar surface was exposed to the solar wind. As a result, we revealed energy dependence on the pitch angle distribution of electrons. This suggests that the cutoff pitch angles are influenced by the potential difference between the lunar surface and the satellite and the electric field generated by decoupling of electrons and ions. We will discuss the solar wind dynamic pressure control of the lunar surface magnetic field intensity with energy dependence.

# Objective and Current Development Status of Multi-Band Camera on SLIM

*Yusuke Nakauchi[1], Kazuto Saiki[2], Makiko Ohtake[1], Hiroaki Shiraishi[1], Chikatoshi Honda[3], Hiroyuki Sato[1], Yoshiaki Ishihara[4], Takao Maeda[5], Masatsugu Otsuki[1], Sin-ichiro Sakai[1], Shujiro Sawai[1], SLIM Project Team

1. Japan Aerospace Exploration Agency, 2. Osaka University, 3. Aizu University, 4. National Institute for Environmental Studie, 5. Chuo University

Smart Lander for Investigating Moon (SLIM) project is on going in JAXA. The main objective of this project is to demonstrate various techniques for “pin-point landing” on the moon. SLIM spacecraft is a small lander. It is designed to achieve “pin-point landing” to 100 meter-order error circle. In order to “pin-point landing” of this level, SLIM mission will demonstrate new image-based onboard navigation system and autonomous landing along with several other new technologies (e.g. “tow stage” landing sequence, metal shock absorbers). The SLIM spacecraft weight is ~730 kg wet mass and ~200 kg class dry mass, both of which are more lightweight than previous lunar landers. The spacecraft will be launched with a Japanese rocket H-IIA in 2021 or 2022. Landing on (25.2ºE, 13.3ºS) located in the west of Mare Nectaris is planned.

After landing, SLIM project is planning to observe around landing site using Multi-Band Camera (MBC). The observational mission is positioned as extra success. MBC will observe olivine and estimate Mg# of it. MBC is a compact VIS-NIR camera composed of an imaging sensor (InGaAs), a filter-wheel with 10 band-pass filters, a telephoto optical system, and a movable mirror for panning and tilting. The sensor has sensitivity at wavelength from 700 to 1700 nm, which covers the characteristic ab-sorption bands of lunar minerals. The telephoto optical system can focus on an object from 1.5 to 30 m distance. The imaging sensor has 640 ×512 pixels with 20 $\mu$m pitch. The 4º field of view corresponds to the spatial sampling of 1.3 mm per pixel at 10 m from the lander. Using the movable mirror, observable scanning area is ~50º in azimuth and ~70º in elevation. This makes it possible to observe the size distribution of boulders around the lander. The observation wavelength of band pass filters were selected 10 bands: 750, 920, 950, 970, 1000, 1050, 1100, 1250, 1550, and 1650 nm. The width of their bands is 30nm.

# Monte Carlo simulation of neutron production and transport in the Moon: Effect of lunar subsurface water

*Hiroki Kusano[1], Yuzuru Karouji[1], Hiroshi Nagaoka[1], Naoyuki Yamashita[2], Makoto Hareyama[3]

1. Japan Aerospace Exploration Agency, 2. Planetary Science Institute, 3. St. Marianna University School of Medicine

The intensity of thermal, epithermal, and fast neutrons emitted from a planetary surface provides information on the surface elemental composition, particularly on the hydrogen abundance. In an airless planetary surface, the galactic cosmic rays produce fast neutrons via nuclear interactions in the subsurface materials within a depth of tens centimeters. Then, the fast neutrons are moderated by interactions with subsurface materials including the secondary neutron production. This neutron transport process is terminated at the thermal neutron capture or the neutron leakage from surface. Because the hydrogen atom has a large elastic scattering cross section for a neutron and a nearly identical mass as a neutron, neutrons are efficiently moderated by the elastic scattering with hydrogen atoms. Therefore, the leakage neutron intensity strongly depends on the hydrogen abundance as well as the surface elemental composition. Neutron spectroscopy is thus well suited to detect subsurface water which may present at the lunar polar region. It is essential to obtain the abundance and distribution of lunar subsurface water from the viewpoint of planetary science and space resources for future manned activities.

In this study, the neutron production and transport in the Moon was modeled by Monte Carlo simulation with Geant4 10.3.p03. The effect of subsurface hydrogen abundance and spatial distribution was studied for in-situ water search in future lunar polar landing explorations. The leakage neutron intensity produced by protons and alpha particles in galactic cosmic rays was calculated for the lunar highland composition mixed with various amounts of hydrogen. The production depth and flux of subsurface neutrons, and the production depth of leakage thermal, epithermal, and fast neutrons were also calculated. It was confirmed that the leakage neutron intensity depends on the subsurface hydrogen abundance. The epithermal neutron intensity is particularly sensitive to the presence of subsurface hydrogen. Most of the leakage neutrons were produced within a depth of about 100 g/cm$^2$, which means that the neutron spectroscopy is mainly sensitive to the subsurface water in the top of surface with about 50 cm in depth depending on the surface density. When a dry layer presents at the top of surface, the leakage neutron intensity was found to depend on the dry layer thickness. The variation of leakage neutron intensity was detectable for the dry layer thickness less than about 80 g/cm$^2$. The behavior of lunar subsurface neutrons and its sensitivity for lunar subsurface water will be presented and discussed.

Japan Aerospace Exploration Agency, 9. University of Tokyo, 10. Department of Solid Planetary Sciences Institute of Space and Astronautical Science

We have been designing and developing an active seismic exploration package with seismometers, active seismic source and anchoring system. Our seismic exploration package was designed to investigate from shallow formation (i.e., ice saturation) to deep formation (i.e., thickness of regolith) of the Moon. Here we present the basic concept of our seismic exploration package and its experimental results. We then discuss the possibilities of future space missions. We evaluate the relation between the S-wave velocity and the ice saturation, and found that S-wave velocity largely increase due to ice deposition (low ice saturation). To evaluate our active-source seismic exploration system, furthermore, we conducted seismic exploration in the test field in JAXA. The test field is filled with loose sands of ~50cm thickness. In this experiment, we conducted seismic survey with several acquisition parameters. When we applied the active seismic survey for small-size receiver array, we retrieved clear shot gather. We further calculated dispersion curve from the shot gather and obtained S-wave velocity profile beneath the array using inversion. In addition, we could detect the cushioning material whose S wave velocity is lower than sand by surface wave analysis and compare the result with the dispersion curve which has no buried material. These results demonstrate that S-wave velocity in shallow formation was accurately estimated, suggesting that ice can be identified as anomalous high S-wave velocity via our seismic system. When the seismometer interval is long, the attenuation of the surface wave is large. However, the refracted P-wave can arrive at far offset receivers. Using the refracted wave, we can estimate P-wave velocity of the basement.

# Orbit determination of the Chang’E-5 Test 1 and a new gravity field model

*shanhong liu[1], Jianguo Yan[1]

1. Wuhan University

We introduce the recently Chang’E 5-Test 1 (CE-5T1) mission overall and its orbit characteristic and present the results on precision orbit determination from the radio science investigation of the CE-5T1 spacecraft. We describe the data, modeling and methods used to achieve position knowledge several times better than the required demand (in total position) for most of arcs, over the period from 10 March 2014 to 28 December 2018. In addition to we try to use the near-continuous radiometric tracking data of CE-5T1 to develop a new lunar gravity field up to degree and order 100, which is solved independently using about four years tracking data. The accuracy of the gravity field model is assessed by multi means, such as gravity spectrum, observational residuals after precision orbit determination, lunar surface gravity anomaly character, admittance/coherence with topography model, and the corresponding physical feature and effect are analyzed. We also make a comparison between this model and the previously models we ever solved, CEGM-01 and CEGM-02. The results indicate the effectiveness and reasonability of this solution process. On the basis of current work, with the Chang’E 5, 6, and 7 under implementing and planning, the prospect of future development of Chinese lunar gravity field detection is presented.

ICON is an orbiting NASA observatory built to simultaneously observe the characteristics of the ionosphere and thermosphere in order to understand the connection between conditions in space and energy sources in the atmosphere below. Ready for launch in 2019 into a 27 degree inclination, 575 km altitude orbit, it will provide neutral wind, density and temperature products as well as in-situ and remotely-sensed ionospheric densities. These products will inform the conditions of two models that assimilate the data in different ways, and be available on the ICON website. The first is the TIEGCM, where assimilation is accomplished through modification of the winds and temperatures at the lower boundary as prescribed by observations . The second is the IDA4D model, that through a Gauss-Markhov scheme modifies a background ionosphere with actual observations that include many different sources including ICON. Given the expected sampling and data uncertainties from ICON, the expected performance of these models is reported. ICON expects a launch in 2019.

The mid- and low-latitude ionosphere is home to a variety of plasma density irregularities, including depletions (bubbles), enhancements (blobs), and small-scale scintillation, which result in the distortion of radio wave propagation. Recent observations from the C/NOFS satellite suggest that multiple mechanisms are responsible for forming plasma density enhancements, with wave action in the thermosphere as a significant driver of the enhanced densities. Indeed, statistical analysis of enhancements observed from satellites resembles the statistics of Medium-Scale Traveling Ionosphere Disturbances (MSTIDs) with respect to seasonal variability and solar activity. In order to investigate the link between these two phenomena, both in-situ data of the plasma enhancement and remote data of the MSTID at the magnetic footpoint are required. petitSat is a CubeSat mission designed to provide in situ measurements of the plasma density, 3D ion drift, as well as ion and neutral composition. The instrument suite includes a combined retarding potential analyzer and cross-track drift meter and an ion neutral mass spectrometer. This instrument suite will provide comprehensive information about the fluctuations in plasma, as well as changes in the neutral profile. petitSat will launch into a 51 deg inclination orbit at 400 km (consistent with an International Space Station deployment), allowing for numerous conjunctions with the Boston University All-Sky Imager network and GPS receivers from the International Global Navigation Satellite Systems (GNSS) Service (IGS) network over the mission lifetime.

# A three-dimensional ionospheric electrodynamics model

*Astrid I Maute[1], Arthur D Richmond[1]

1. High Altitude Observatory, National Center for Atmospheric Research, Boulder CO, USA.

Ionospheric electric fields and currents are driven by collisional interaction between thermospheric winds and ions, by magnetospherically driven convection and field-aligned currents at high latitudes, by gravitational and pressure-gradient forces on the ionospheric plasma, and by weak currents from the lower atmosphere. The electrodynamics of the ionospheric E and F regions are strongly coupled. For time scales longer than a few minutes the electric field is electrostatic. The electric potential is nearly constant along geomagnetic-field lines, and can be represented in two dimensions in a coordinate system aligned with the magnetic field. The current density, however, varies in all three dimensions. Knowing the ionospheric current flow in three dimension is important for determining the magnetic perturbations at Low Earth Orbit (LEO) satellite height.

We are developing a model of ionospheric electrodynamics that takes into account all of the sources and calculates the three-dimensional structure of currents and their associated magnetic perturbation fields. This model will be used to simulate ionospheric drifts, currents, and ground and LEO geomagnetic perturbations. In this presentation we discuss the modeling principles and present results relevant to the electrodynamics of the middle and low latitude ionosphere, including the effects of coupling with F-region electrodynamics and the expected observable effects at low Earth orbit satellites.

# Spatial Fluctuation of TEC Index: A new index of ionospheric irregularities

*Guanyi Ma[1], Takashi Maruyama[2]

1. National Astronomical Observatories, Chinese Academy of Sciences, 2. National Institute of Information and Communications Technology

This study presents a new spatial fluctuation of total electron content (TEC) index (SFTI) to identify and analyze ionospheric irregularities. SFTI is defined as the dispersion of vertical TEC (VTEC) within a specific area at a given time. With the data from the Global Navigation Satellite System (GNSS) Earth Observation Network of Japan (GEONET), the size of the specific area for SFTI calculation can be chosen as 0.8˚× 0.8˚ in longitude and latitude. An SFTI map generated by sliding window shows the spatial variation of the ionospheric irregularities in two dimensions. It can be used to obtain the size, shape, orientation and intensity distribution of the irregularity structures. With a series of SFTI maps, we analyzed three strong irregularity events on 12 February 2000, 20 March 2001 and 10 November 2004. The irregularities are found to consist of branching structures, which are anisotropic and elongate along longitudinal direction when first seen at low latitudes. The structures can drift and eventually move perpendicular to their orientations. It is concluded that SFTI will provide an unprecedented view of irregularity development and help to understand the process of irregularity generation.

# Coupling of lower thermosphere planetary wave energy into the ionosphere

*Patrick J Espy[1,2], Nora Stray[1,2,3], Robert Hibbins[1,2]

1. Norwegian University of Science and Technology, Trondheim, Norway, 2. Birkeland Centre for Space Science, Bergen, Norway, 3. Teknova AS, Tordenskjolds Gate 9, 4612 Kristiansand, Norway

Neutral atmosphere winds derived from meteor trail drifts observed by a longitudinal chain of Super Dual Auroral Radar Network (SuperDARN) radars have characterized planetary waves with wavenumber 1 and 2 in the lower thermosphere near 95 km. The simultaneous wind observations at stations between 50$^{o}$ and 66$^{o}$ N removes the temporal-spatial aliasing associated with satellite observations and shows the continuous evolution of the planetary waves near the turbopause. A similar technique has been applied to a longitudinal chain of ionosondes in the same latitude band, and the same wavenumber components were observed in $f_{o}$F2. An analysis of the two signals shows them to be highly correlated, with the ionospheric waves lagging behind those in the lower thermosphere. We will describe the technique to extract the waves and compare it with other observations. We will also show the relationship of the ionospheric waves with magnetic and solar activity, and describe a process, commensurate with our measurements, by which planetary wave signals near the turbopause can be transmitted into the ionospheric electron density.

Keywords: dynamics, turbopause, ionosphere

## [P-EM09] Vertical coupling in the atmosphere and Ionosphere

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Loren Chang(Institute of Space Science, National Central University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Jann-Yenq Liu(National Central University, Taiwan), Loren Chang(National Central University, Taiwan)

Vertical coupling mechanisms throughout the whole atmosphere are critical to understanding the near Earth space environment, as well as its sensitivity to the solar, geomagnetic, and atmospheric drivers. This international session focuses on physical/chemical processes occurring in the mesosphere, thermosphere, and ionosphere (MTI). Both quiet and disturbed states in response to lower atmospheric forcing or solar forcing are important for understanding the MTI system and its coupling to other regions. We invite presentations of observations and observational concepts with ground-based and/or space-borne instruments, theoretical studies, numerical simulations, and development of data analysis systems for various kinds of temporal and spatial variations in atmosphere-ionosphere coupled system.

# Modulation of Lightning Occurrence by the Solar Wind

*Omar Angelo Nava[1], Daniel Emmons[1], Robert Loper[1]

1. Air Force Institute of Technology

The connection between terrestrial and space weather phenomena is an emerging field of study with implications for different aspects of operational weather forecasting. This study investigates the influence of solar wind events on the frequency of lightning occurrence over North America. Empirical mode decomposition (EMD) is applied to National Lightning Detection Network (NLDN) data from 1996 to 2012 and correlated against various solar wind parameters. EMD performs operations that partition the lightning time series data into modes or Intrinsic Mode Functions (IMFs). Using composite analysis, we identified an IMF that corresponds to a 27-day co-rotating interaction region (CIR) that results in a statistically significant decrease in thunderstorm occurrence across the entire NLDN for approximately three to nine days. This finding is consistent with previous studies indicating that faster solar wind speeds are correlated with a decrease in galactic cosmic ray (GCR) flux and a reduction in lightning reports. However, the analysis also highlighted a latitudinal stratification in the thunderstorm response. In the mid-latitudes (30-38 deg N), faster solar wind speeds initially increased the number of lightning occurrences before decreasing significantly over the next 14 days. In the upper mid-latitudes (38-46 deg N), the response was reversed with an increase in thunderstorm events followed by a significant decrease. Additional “lightning response reversals” are noted at even higher latitudes. It is hypothesized that solar energetic particles associated with the CIRs are able to penetrate to tropospheric altitudes and increase lightning rates at higher latitudes, while at lower latitudes, the solar wind modulated GCR flux drives the decrease in lightning occurrence. Overall, understanding the electrodynamic connection between the lower and upper atmospheres has important implications for both space physics and atmospheric science communities.

Measurements of mesopause temperature are quite challenging and must rely on remote sensing methods. As part of the Taiwan-Russia joint research cooperation program, we carry out an analysis comparing mesopause temperature measurements made by the Irkutsk spectrophotometer between 2008 - 2018 and those resolved by the SD-WACCM data assimilation model, the empirical MSISE-00 model, and TIMED SABER satellite measurements. Spectral decomposition is performed on the datasets to determine the differences between the different observed and modelled seasonal and inter-annual variability, as well as to resolve long term trends.

# ISS-IMAP observation of the mesospheric disturbances generated by tropical cyclones

*Akinori Saito[1], Takeshi Sakanoi[2], Septi Perwitasari[4], Yuta Hozumi[3], Ryota Okada[1], Ryo Murakami[1]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 3. University of Electro-Communications, 4. Space and Upper Atmospheric Sciences Group, National Institute of Polar Research

Troposphere was investigated to elucidate the vertical atmospheric coupling process using the global observational data from the International Space Station (ISS). The vertical coupling between the lower and the upper atmospheres has been revealed to be significant to control the dynamics and disturbances in the upper atmosphere by recent studies. The phenomena generated by the vertical coupling processes have been detected with various observational instruments, and studied with numerical simulations. TC, such as typhoon, hurricane and cyclone, is regarded as one of the intense sources in the Troposphere to affect the Mesosphere, the Thermosphere and the Ionosphere. There is a plenty of studies that reports the observation of the upper atmospheric disturbances associating with TC using ground-based instruments, such as HF doppler radars, IS radars, GNSS receiver arrays, and optical imagers. Because the ground-based observation cannot track the movement of TC, and TC is much active over the ocean, the observational opportunity is limited for the ground-based instruments. ISS-Ionosphere, Mesosphere, upper Atmosphere, and Plasmasphere (ISS-IMAP) mapping mission made a global observation of the airglow in the mesosphere and the ionosphere for three years. The data set of visible-light and infrared spectrum imager (VISI) of ISS-IMAP is idealistic to investigate the effect of TC on the Mesosphere and the Ionosphere. Mesospheric disturbances were detected by the airglow from the molecular oxygen in 762nm of wavelength, and the ionospheric disturbances were detected by the airglow from the atomic oxygen in 630nm of wavelength. In its three years observation, the number of TC that ISS-IMAP/VISI made the conjugate observation was 171. It was found that more than 20% of TC was associated with the mesospheric disturbances that seems to be generated by TC. The duration of these disturbances was one or two days in spite of the lifetime of TC is longer than a week. The relationship among TC, the mesospheric and the ionospheric disturbances will be discussed in the presentation.

# A fast acoustic wave detected in GNSS total electron content after the foreshock of the 2011 Tohoku Earthquake

*Yoshihiro Kakinami[1], Hiroaki Saito[2], Tetsuo Yamamoto[3], Chia-Hung Chen[4], Masa-yuki Yamamoto[2], Kensuke Nakajima[5], JANN-YENQ Liu[6]

1. Hokkaido Information University, 2. Kochi University of Technology, 3. Hokkaido University, 4. National Cheng Kung University, 5. Kyushu University, 6. National Central University

Acoustic waves are often emitted from large earthquakes, reach the thermosphere and disturb the ionosphere. The disturbances are observed by using of GNSS total electron content (TEC). After the foreshock of the 2011 Tohoku Earthquake, which occurred on 9 March 2011, traveling ionospheric disturbance induced by tsunami was detected. When vertical propagation of acoustic wave from the tsunami source area is assumed, the onset points of co-seismic ionospheric disturbance (CID) must coincide. However, the onset points of the co- CID were detected at different locations in different satellite data assuming that the altitude of CID were the same (ex. at 300 km). Furthermore, we found the onset times were different in the different satellite data. The results suggest that the altitudes of CID are different and timings of observation are also different in the different satellite data. By changing the altitudes of CID, we found coinciding onset point. Once the coinciding onset point is found in the different data sets, the altitudes of the CID are also estimated because the sub-ionospheric point is a function of the altitude of observation. The CID altitude were found at 155.4 and 234.9 km. Considering the time difference of the onset time (399.9 s to the altitude of 155.4 km and 476.1 s to 234.9 km), the acoustic wave velocity is estimated to be 1.04 km/s which is 1.4 times higher than the velocity calculated using the empirical model NRLMSISE-00. The fast acoustic wave would arise from temperature elevated by the limited degrees of freedom of motion of atmospheric molecules, and dissipation of the acoustic wave. Especially, the neutral temperature with heating by the dissipation of the acoustic wave would increase by a factor of 3 for acoustic waves with 0.1 Hz and a pressure at sea level of ~2 Pa, which is on the order of the pressure of the acoustic wave emitted from the sea surface during the observed event. The elevated temperature explains the fast acoustic wave.

# Study of quiet-time high-latitude thermospheric winds using a Fabry-Perot interferometer at Tromsoe: Averages and exceptional events

*Heqiucen XU[1], Kazuo Shiokawa[1], Shin-ichiro Oyama[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

In the previous reports, we studied the dependences of average winds on Kp and F10.7 indices by using a Fabry-Perot interferometer (FPI) at Tromsoe, Norway. In this study, we have further focused on the winds during both globally (Kp < 1+) and locally quiet times in order to provide a baseline wind without magnetic disturbances at latitude of Tromsoe. The wind variations were measured from the Doppler shift of both red-line (630.0 nm, altitudes: 200-300 km, upper thermosphere) and green-line (557.7 nm, altitudes: 90-100 km, mesopause region) emissions with a time resolution of ~13 min. The wind data were collected from 2009 to 2015. In the upper thermosphere, the quiet-time average zonal wind shows westward acceleration at pre-midnight side at ~21-24 LT, while the meridional wind has a minimum around the midnight. In the mesopause region, the average wind tends to show a westward and eastward flow at dusk and dawn side, respectively. By applying sinusoidal regression to the mesospheric average zonal wind, we found that the semidiurnal component has a dominant amplitude of 12.1 m/s. During quiet time, we also found a few exceptional events of more than 100 m/s westward at dusk side in the upper thermosphere. We speculate these exceptional westward winds are related to local plasma convection under quiet time or substorm activities occurred at some other latitudes/local times.

# The longitudinal differences of lunar tidal characteristics between East Asian and American sectors during stratospheric sudden warming events: 2009-2018.

*Jing Liu[1], Donghe Zhang[1]

1. Peking University

With data of total electron content (TEC), equatorial electrojet (EEJ), stratospheric temperature and wind field, variations of the low-latitudinal ionosphere in East Asian and American sectors were investigated during stratospheric sudden warming events from 2009-2018. The lunar tidal amplitudes (M2) were derived with the least-square method. Then their features were compared separately during outstanding major events, moderate major events, minor events, and a non-SSW winter. Brief results are listed as follows: (1) In the American sector, the M2 tides appeared to be dominant over solar tides in all major events since distinct time-shifted semi-diurnal patterns could always be detected during those periods. (2) In the East Asian sector, the M2 characteristics were less clear, and sometimes even hard to identify, which means the relative strengths of lunar and solar tides are more complex in this sector. (3) The M2 amplitudes in TEC tend to be larger in the American sector than in East Asian sector during the same event. (4) The longitudinal differences tend to be lessened in minor SSWs compared to major SSWs. (5) During the non-SSW winter, lunitidal features could still be detected in both sectors. Similar results can be found in previous works for different kinds of parameters. Such longitudinal differences were attributed to combined effects of the geomagnetic field configuration, the latitudinal dependence of lunar and solar tides, the changes of atmospheric circulation, and the coupling process from the lower-atmosphere to the F region ionosphere.

Transpolar Arc (TPA) is an important auroral phenomenon when considering how the energy stored in magnetotail is transported to ionosphere via magnetic reconnection under the northward interplanetary magnetic field. Magnetotail reconnection is considered to play a crucial role in TPA formation. Reconnection X-points are expected to retreat tailward as TPA grows from nightside auroral oval to the dayside. Usually, they straightforwardly retreat tailward, and reconnection-formed TPA morphology is straight-bar shape. However, we wonder how the TPA shape would be expected when traces of the tailward X-point retreats were not straightforward. The Wideband Imaging Camera (WIC), which is a part of Far Ultraviolet (FUV) instrument, onboard the Imager for Magnetopause-to-Aurora Global Exploration (IMAGE) satellite detected an interesting type of TPAs, which are identified as “nightside distorted TPAs”. Their main bar-shaped parts were located at the dawn or dusk sides, and the nightside ends of them got distorted toward pre- or post-midnight sectors. Because these TPAs look like the shape of an alphabetical letter of “J” or “L”, we distinguished the nightside distorted TPAs from “J”- and “L”-shaped TPAs. We followed the time sequence of the evolutions of several nightside distorted TPAs with the IMAGE FUV-WIC imager data. In most cases, the “J” and “L”-shaped TPAs started to grow from the nightside main auroral oval, and protruded to the dayside auroral oval via the experience of distortion, suggesting that magnetotail magnetic reconnection was closely be related with the formation of the nightside distorted TPAs. In this study, we have proposed a model to explain the nightside distorted TPA formation, in order to discuss that TPAs with their nightside ends distorted toward pre- or post-midnight were formed through how physical process. Furthermore, we have tried to verify whether or not our model proposed is appropriate to adequately explain formation process of nightside distorted TPA based on the global MHD simulation using the BATS-R-US codes.

# Ionospheric Conductivity Dependence of the Subauroral Polarization Streams Observed by the SuperDARN HF Radars

Yuting Zhang[1], *Nozomu Nishitani[1], Tomoaki Hori[1], Simon G. Shepherd[2], William A. Bristow[3]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Thayer School of Engineering, Dartmouth College, 3. University of Alaska Fairbanks

We investigate the characteristics of the subauroral polarization stream (SAPS), with a main focus on the solar zenith angle (SZA) dependence using the Super Dual Auroral Radar Network (SuperDARN) HF radars and NOAA POES spacecraft data. In this study, we used 3 SuperDARN radars (HOK / CVE / ADW), and checked data from 2008 to 2017 and found 124 SAPS events where the line-of-sight velocity is larger than 150m/s, magnetic local time is 13 to 19 hours and the flow regions are identified to be equatorward of the auroral precipitation region. For each event, we examined the SZA using the geographic latitude, longitude and the UT span of SAPS. We found that the results of CVE radar are different from the result of HOK and ADW radar, the SAPS observed by CVE radar can happen in high conductivity occasion when both hemispheres are illuminated. However, we found that these illuminated SAPS could only occur under geomagnetically disturbed condition and mostly in spring and fall. In addition, when the geomagnetic activity is low, SAPS tends to appear when the minimum threshold of illuminated ionospheric altitude is 130 km or more, which is near and slightly above the altitude of the peak of Pedersen conductivity. These results suggest that the generation mechanism of SAPS is affected by both geomagnetic activity and the Pedersen conductivity. Results of detailed discussion will be presented.

# Ionospheric convection modeling based on convolution with a localized vector-valued basis function

*Shin ya Nakano[1], Tomoaki Hori[2], Kanako Seki[3], Nozomu Nishitani[2]

1. The Institute of Statistical Mathematics, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Graduate School of Science, University of Tokyo

Divergence free assumption is useful for modeling the flow velocity distribution in the ionosphere where plasma velocity can be assumed to be orthogonal to a potential electric field. If the divergence of two-dimensional plasma velocity is assumed to be zero, we can consider a stream function yielding the plasma velocity distribution. In order to estimate the two-dimensional flow velocity distribution in the ionosphere, we propose a framework which expresses the stream function by a convolution with a spherical Gaussian function. From this spherical Gaussian function, we can obtain a localized vector-valued basis function for flow velocity distribution satisfying the divergence-free condition. Accordingly, flow velocity distribution can be represented by a convolution with the vector-valued basis functions. We combine this model with a state space model and estimate a temporal evolution using the Kalman filter algorithm. Hyperparameters of the model are determined by maximizing marginal likelihood.

The proposed framework is applied for estimating the two-dimensional ionospheric convection pattern from the Super Dual Auroral Radar Network (SuperDARN) data. Although there are some wide gaps in the spatial coverage of the SuperDARN radar network for ionospheric observation, the use of the localized basis function enhances the robustness of the estimate. This basis function also enables us to evaluate the uncertainty of the estimate which would be helpful for incorporating other observations. Some results of the analysis of the SuperDARN data will be demonstrated.

# Occurrence Statistics and Driving Mechanisms of Ionospheric ULF Waves Observed by SuperDARN Radars

*Xueling Shi[1], Joseph B. H. Baker[1], John Michael Ruohoniemi[1], Dong Lin[1], Michael Hartinger[1,2]

1. Virginia Tech, 2. Space Science Institute

Ultra-low frequency (ULF; 1 mHz - 5 Hz) waves are known to play an important role in the transfer of energy from the solar wind to Earth's magnetosphere and ionosphere. The Super Dual Auroral Radar Network (SuperDARN) is an international network consisting of 35 low-power high frequency coherent scatter radars at middle to polar latitudes that look into Earth's upper atmosphere and ionosphere. In this study, we use Doppler velocity measurements obtained by the SuperDARN radars and coordinated spacecraft observations to investigate the occurrence statistics and driving mechanisms of ionospheric ULF waves. Pc3-5 band (1.7-40.0 mHz) ULF waves were surveyed using high time resolution radar data from 2010 to 2016. Specifically, we have investigated the wave spatial occurrence, frequency characteristics, seasonal factors, and dependence on solar wind and geomagnetic conditions. We note two particular findings: (i) an internal wave-particle interaction source is responsible for Pc4 waves at high latitudes in the duskside ionosphere; and, (ii) a source associated with the magnetotail dynamics during active geomagnetic times is suggested for Pc3-4/Pi2 waves at midlatitudes in the nightside ionosphere. A few interesting ULF wave events will be further analyzed for their driving mechanisms via coordinated observations from spacecraft. Collectively, these research findings provide better constraints on where and when ionospheric ULF waves occur and how they might affect magnetospheric and ionospheric dynamics.

# Magnetic Field Oscillations Observed by Swarm Satellites in the Nightside Upper Ionosphere During Low-latitude Pi2 Pulsations

*Khan-Hyuk Kim[1], Jae-Hee Park[1]

1. School of Space Research, Kyung Hee Univ.

Pi2-associated geomagnetic oscillations in the nighside upper ionosphere are studied using magnetic field data acquired by low-Earth orbiting multispacecraft Swarm and at the low-latitude Bohyun (BOH) station located at magnetic shell of L = 1.3 on 22 October 2014. Four Pi2 events were identified from the BOH data near midnight (MLT = 1.5) while Swarm A, B, and C spacecraft were orbiting on the nightside (MLT = 21-22) upper ionosphere from 70˚ to --60˚ in magnetic latitude (MLAT) at 450-500 km altitudes. It is found that the horizontal H component of BOH data is well correlated with the radial ($B_x$) and compressional ($B_z$) components of ionospheric magnetic fields when Swarm spacecraft were at |MLAT| < 30˚. Both $B_x$ and $B_z$ components exhibit in phase or out of phase with the BOH H oscillations depending on the location of the spacecraft (i.e., in the Northern Hemisphere or in the Southern Hemisphere). This indicates that Pi2-associated magnetic oscillation in the ionosphere is the consequence of field line displacement that is symmetric or odd mode about the magnetic equator. We also find that stationary magnetic field perturbation, which is similar to Pi2 oscillation but not associated Pi2 signals, in the upper ionosphere near magnetic equator. A statistical analysis for the global distribution of static/spatial magnetic field perturbations using low-latitude Pi2 oscillation as a reference is a subject of future work.

# Magnetospheric Multiscale observations of ULF waves and correlated low-energy ion monoenergetic acceleration

*Bin Li[1], De-sheng Han[2], Ze-jun Hu[1], Jian-jun Liu[1], Lei Dai[3]

1. Polar Research Institute of China, 2. Tongji University, 3. National Space Science Center, Chinese Academy of Sciences

Low-energy ions of ionospheric origin with energies below tens of eV dominate most of the volume and mass of the terrestrial magnetosphere. However, sunlit spacecraft often become positively charged to several tens of volts, which prevents low-energy ions from reaching the particle detectors on the spacecraft. Magnetospheric multiscale spacecraft (MMS) observations show that ultralow-frequency (ULF) waves drive low-energy ions to drift in the E×B direction with a drift velocity equal to $V_{E\times B}$, and low-energy ions were accelerated to a higher energy level to reach the detection range of the MMS/Fast Plasma Investigation (FPI). The maximum ion flux energy level detected by MMS1 DIS agreed perfectly with the theoretical calculation of $H^+$ ion E×B drift energy. The density of ions in the energy range below 2 eV was between 1 $cm^{-3}$ and 3 $cm^{-3}$ in the magnetosphere subsolar region in this event.

Keywords: low-energy ion monoenergetic acceleration, ultralow-frequency wave, E×B drift

# Statistical study on warm plasma in the magnetotail based on two-component fits of distribution functions

*Kunihiro Keika[1], Ryuta Asami[1], Masahiro Hoshino[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

A large number of observations reported two distinct plasma populations with different temperatures in the Earth's magnetotail: 1-10 keV for the hotter component and <1 keV for the colder. It is well accepted that plasma of solar wind origin can enter into the magnetosphere due to tailward convection of magnetic field lines that were reconnected at the dayside magnetopause, or due to instabilities or waves that develop on the dawn and dusk flanks. Cold plasma of ionospheric origin can be also transported into the plasma sheet predominantly along the field lines. Such cold plasma can be then heated/accelerated to 1 keV or higher. The dominant transport region(s) and heating mechanism(s) are, however, not well understood. This study investigates global characteristics of warm (10-1000 eV) plasma populations observed in the magnetotail in order to better understand transport regions of solar wind and ionospheric plasma.

We use data from plasma observations made by the Hot Plasma Composition Analyzer (HPCA) on board the Magnetospheric Multiscale (MMS) spacecraft. HPCA measures ions with energies of a few eV to ~40 keV with the determination of ion mass. We perform a one-component Maxwellian fit and a two-component Maxwellian fit to a distribution function of the omni-directional proton flux during intervals of slow flow speed (<~70 km/s). The best fit provides density and temperature of one-component Maxwellian plasma or density and temperature for each component of two-component Maxwellian plasma. This study is focused most on the colder (hotter) component of the two-component plasma, which we term a cold (normal) population. We apply this analysis and categorization to HPCA proton data obtained for a period of May 1 to August 31 of Year 2017. MMS dwelled in the magnetotail for the period, and HPCA data are available in the regions of 6 Re < r < 24 Re.

We examine dependence of density and temperature on plasma beta, which is the ratio of plasma thermal pressure to the magnetic pressure and thus represents the distance from the current sheet. The normal population shows clear positive correlations of density and temperature to plasma beta. This indicates adiabatic heating of lobe plasma transported toward the central plasma sheet. The cold population, on the other hand, does not show clear correlations. It is separated into three different types. Type 1 is characterized by positive correlations of density to plasma beta, similar to the normal population. Density is between 0.01 and 0.1 $cm^{-3}$ at a beta range of 0.001 to 0.01, and increases to ~1 $cm^{-3}$ at beta of >0.1. We confirm that the relation between density and temperature is well explained by adiabatic heating with the specific heat ratio of 5/3. Type 2 is seen only in the high beta (>0.1) regions, with density of ~0.01 $cm^{-3}$. Type 3 can be identified by a different relation between density and beta; density is between 0.01 and 1.0 with the highest occurrence frequency at 0.1 $cm^{-3}$, and temperature is a few 10s to 100s eV. Spatial distributions of each type show that Types 1 and 2 are observed at the radial distance of >10 Re. Type 1 shows no clear dawn-dusk asymmetry of occurrence frequency or average temperature, while Type 2 is more frequently observed on the dusk and dawn sides than around midnight. Type 3 occupies the region closer to 10 Re and is also observed at the radial distance of 10-20 Re with lower occurrence.

We interpret that Type 1 is dominated by plasma of solar wind origin transported over the polar regions, through the lobe toward the plasma sheet. Type 2 is likely solar wind plasma that enters through the flank

©2019. Japan Geoscience Union. All Right Reserved. 

magnetopauses. Type 3 is of ionospheric origin, presumably from nightside auroral regions. We suggest that the north-south component of magnetospheric convection over the polar cap becomes dominant at the radial distance of 10 Re or further. Instabilities or waves that allow solar wind plasma to enter the plasma sheet are likely to sufficiently develop on the night side (i.e., $X < 0$).

# Analysis on anisotropy variations for pitch angle distributions of electrons with various parameters at dipolarization sites in the inner plasma sheet

*Kaiti Wang[1], Zhuo-Ren Lang[2], Ching-Huei Lin[3], Tohru Hada[4], Toshi Nishimura[5]

1. Tamkang Univ., 2. National Cheng Kung Univ., 3. Chien-Hsin Univ. of Sci. & Tech., 4. Kyushu Univ., 5. Boston Univ.

During geomagnetic activities, dipolarization of geomagnetic fields can been found to occur at tailside. In this study, we investigate variations in anisotropies of pitch angle distributions for electrons at 63 observed dipolarization sites around distance of 10 $R_E$ (Earth radii) near the magnetic equator in the inner plasma sheet when auroral electrojet AL index decreases. Observational data from 2008 to 2011 for electrons below ~26 keV from the instrument ESA (ElectroStatic Analyzer) onboard of THEMIS mission are adopted. Followed from our previous presentation in which the dependence of these variations on field line lengths (FLL) was focused on [*Wang et al.*, 2018], we present new analysis results concentrating on the dependence of the changes as well as the rates of changes in FLL, magnetic field strengths, and dipolarization angles, during a dipolarizaion period. Comparisons between the anisotropy variations in pitch angle distributions of electrons and the associated bounce time of electrons, event dipolarization time, and measured environmental electric fields will also be presented and discussed.

# Study of slow-mode shock formation in the symmetric magnetic reconnection based on hybrid simulations

*Nehpreet Kaur Walia[1], Kanako Seki[1], Takanobu Amano[1]

1. Department of Earth & Planetary Science, Graduate School of Science, University of Tokyo

Fast magnetic reconnection is achieved in the Petschek' s reconnection theory [1964] via a pair of slow-mode shocks on each side of the diffusion region. The occurrence of these slow-mode shocks has been established in MHD regime by the various MHD and Hall-MHD simulation studies [e.g., e.g., Hoshino and Nishida, 1983; Biernat et al., 1989; Lin and Lee, 1993; Hau and Wang, 2016]. However, in the kinetic regime, their existence is still debated. Some of the hybrid and PIC simulations studies of magnetic reconnection region show slow-shock like structures, where either all the Rankine-Hugoniot (RH) or the Mach number conditions are not satisfied [e.g., Krauss-Varban and Omidi, 1995; Lottermoser et al. 1998; Higashimori and Hoshino, 2012], while some show the presence of Petschek like slow-mode shocks [e.g., Lin and Swift, 1996; Liu et al. 2012; Innocenti et al., 2015]. With satellite observations, the presence of slow-mode shocks have been confirmed for both asymmetric dayside magnetopause reconnection [Walia et al., 2018 and Sonnerup at al., 2016] and symmetric magnetotail reconnection [e.g. Feldman et al., 1987; Saito et al., 1995; Eriksson et al., 2004]. Walia et al. [2018] and Saito et al. [1995] reported that the detection probability of slow-mode shocks at around 20% and 10% in the dayside magnetopause and the magnetotail, respectively. One of the reasons for low detection probability of slow-mode shocks can be that the non-slow mode shock crossings used in the observational studies are very close to the X-point, and hence the slow-mode structure has not developed fully. The error in the determination of the shock normal direction and the shock frame of reference can be another reason for lack of observations of slow-mode shocks. In situ measurements via the use of the satellite data, can help us to look into the detailed structure of a magnetic reconnection crossing, but if one wants to look at the whole structure of magnetic reconnection region, simulation studies are needed. Especially, if one wants to look into the transition from the kinetic scales to MHD scales to find out how the structure of reconnection region changes and slow-mode shocks or other discontinuities form and develop.

In the present study we use 2D hybrid simulations for symmetric magnetic reconnection with isotropic temperature to investigate the formation of slow-mode shocks. The presence of slow-shocks in the magnetic reconnection region is established by checking the satisfaction of the RH conditions and specific conditions of Mach numbers, normal angles etc. [e.g., Seon et al., 1995, 1996]. We check the set of 12 slow-mode shock conditions and use the 30% satisfaction criteria [e.g., Walia et al., 2018; Eriksson et al., 2004] at all distances from the X-point to study the formation of slow-mode shocks from the ion inertial length scales to MHD scale. We found that the Petschek like slow-mode shocks can be identified as close as ~10 $\lambda_i$ ($\lambda_i$ = ion inertial length) to the X-point. Below, 10 $\lambda i$ slow-mode shocks are not fully developed, and rather slow shock-like structure is present. Also, it is found that the slow-mode shock identification is sensitive to the slow-shock normal determination. We will also report the differences in the satisfaction of various conditions (e.g., RH conditions, Mach numbers) and the characteristics of the ion distribution functions between the regions with slow-mode shocks and slow shock-like structures.

Magnetic reconnection is a fundamental plasma process that controls transfer of solar wind energy and mass to planetary magnetospheres and causes explosive energy release associated with solar flares and sudden auroral brightening. NASA's Magnetospheric Multiscale (MMS) mission, which consists of four identical spacecraft launched in March 2015, aims at elucidating how magnetic reconnection works with unprecedented high temporal and spatial resolution measurements of charged particles and electromagnetic fields in space. MMS has been observing Earth's magnetotail since May 2017, and encountered the central region of magnetic reconnection, called the electron diffusion region (EDR), on 11 July 2017 (Torbert et al., Science, 2018). We present results from the reconstruction of the electron diffusion region (EDR) observed in this event. The conditions were suited for the reconstruction technique, developed by Sonnerup et al. (JGR, 2016), that produces magnetic field and electron streamline maps based on a two-dimensional (2-D), time independent, inertia-less form of electron magnetohydrodynamic equation, assuming an approximately symmetric current sheet and negligible guide magnetic field. Our reconstruction results (Hasegawa et al., JGR, 2019) indicate that although the X point was not captured inside its tetrahedron, MMS approached the X point as close as one electron inertial length ~27 km. The opening angle of the recovered separatrix field line, combined with theory, suggests that the dimensionless reconnection rate was 0.17, which is consistent with the measured reconnection electric field 2–4 mV/m. The stagnation point of the reconstructed electron flow is shifted earthward of the X point by ~90 km, one possible interpretation of which is discussed. The energy conversion rate $\mathbf{j}^{*}\mathbf{E}'$ in the electron frame tends to be higher near the stagnation point, consistent with earlier observations and simulations, and is not correlated with the amplitude of broadband electrostatic waves observed in the upper-hybrid frequency range. The latter suggests that the waves did not contribute to energy dissipation in this particular EDR.

# MMS observations of the dense high speed flow in the magnetotail

*Mingyu Wu[1], Tielong Zhang[1]

1. Harbin Insitute of Technology, Shenzhen

With the MMS observations in the magnetotail, we report a earthward, dense, high speed, bulk flow event. In this event, two dense high speed flows (DHSF) are observed. Compared with the plasma sheet, DHSF contains much denser and colder plasma. Ion density of DHSF is about 8 times higher to plasma sheet density, while temperature of DHSF is several times lower to plasma sheet plasma. Due to the high density, DHSF can transport mass more effective than normal bursty bulk flows. Such DHSF can be generated by Magnetic reconnection, but the generation mechanism is still unclear.

# The spatio-temporal development of lightning-induced electron precipitation events

*Robert C Moore[1], Dooyoung Kim[1]

1. University of Florida

Lightning-induced electron precipitation (LEP) events occur when the electromagnetic energy radiated by lightning couples to the magnetosphere and scatters ¬stably trapped radiation belt electrons. A portion of these scattered electrons in turn precipitate into the underlying ionosphere, producing electron density disturbances in the D-region ionosphere which can be detected by VLF remote sensing. When LEP events are observed nearly simultaneously at both the northern and southern ends of a field line, the LEP event is known as a conjugate LEP event. In this paper, an array of VLF receivers in the northern hemisphere is used to measure the spatial-temporal development of the LEP-related ionization patch produced within the D-region ionosphere. During one interesting event, LEP-associated VLF signal perturbations were observed at three receiver sites in the northern hemisphere (Florida, North Carolina, and Connecticut) and at one receiver in the conjugate hemisphere (Palmer Station, Antarctica). The LEP-related disturbance is observed to move poleward with time, consistent with many past observations. A second interesting event indicates the detection of an eastward expansion (with time) of the LEP-related disturbance, however. Together, these observations indicate that previous large-scale statistics compiled for conjugate LEP events may be seriously impacted by the spatio-temporal development of the LEP-associated ionospheric disturbances in the two hemispheres. Perhaps equally importantly, these observations indicate that VLF remote sensing can be used to measure the temporal and spatial development of energetic electron precipitation from the Earth's radiation belts.

## [P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Naritoshi Kitamura(東京大学大学院理学系研究科), Yuka Sato(日本工業大学)

This session provides an opportunity to present recent results from satellite and ground-based observations and theoretical and simulation studies on the magnetosphere, ionosphere, and their coupling processes. We invite talks and posters discussing various phenomena related to the magnetosphere-ionosphere system: solar wind-magnetosphere interaction, magnetosphere-ionosphere convection, field-aligned current, magnetic storms/substorms, neutral-plasma interaction, ionospheric ion inflow and outflow, aurora phenomena, and so forth. Discussions on planetary and satellite ionosphere and magnetospheres, future missions and instrument developments are also welcome.

# Energy flow, dynamo and field-aligned current during a substorm

*Yusuke Ebihara[1], Takashi Tanaka[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Kyushu University

A substorm is one of the most severe disturbances that occur in the magnetosphere. Extremely bright aurora is a great manifestation of the substorm. Since the bright aurora is caused by precipitating electrons, the bright aurora is closely associated with the upward field-aligned currents (FACs). Simultaneously, a large amount of energy, of the order of $10^{11}$ watts, is consumed in the auroral ionosphere due to Joule dissipation during the substorm. The dissipating energy is brought by the FACs that are rapidly intensified. Thus, the formation of the FACs is a key to understand the substorm. The generation of the FACs is accompanied with conversion of energy (dynamo). The energy comes from the solar wind. The purpose of this study is to provide a unified view of a substorm in terms of the energy flow, energy conversion (dynamo) and field-aligned current on the basis of a global magnetohydrodynamics (MHD) simulation. The recent global MHD simulation tells us that, at least, some dynamo regions appear one by one in association with the substorm. The first dynamo region is found in the bow shock where the solar wind kinetic energy is converted to the magnetic energy and the internal energy. However, the role of the bow shock dynamo is suggested to be minor. The second dynamo region is found in the lobe region when the interplanetary magnetic field (IMF) is northward. A complicated structure of the plasma pressure in the lobe gives rise to the generation of FACs that could manifest high-latitude auroral arcs during the growth phase. The third dynamo region appears in the mantle region when IMF is southward. The internal energy is converted to the magnetic energy by way of the kinetic energy in the mantle dynamo. Simultaneously, a large-scale FACs (known as Region 1 FACs) are generated in association with the mantle dynamo, which is probably responsible to the formation of a quiet auroral arc during growth phase. The fourth dynamo appears in the near-Earth magnetosphere on the nightside as a consequence of the formation of the near-Earth neutral line. The magnetic energy (coming from the lobe region) is converted to the internal energy, followed by the kinetic energy and the magnetic energy. The near-Earth dynamo is associated with the onset of the sudden intensification of the upward FACs that are related to the initiation of the auroral breakup. The fifth dynamo is located near the leading/trailing edges of the bright auroral surge where charge separation takes place due to the gradient of the ionospheric Hall conductivity. A localized upward FAC is generated, which probably manifests the bright auroral surge traveling westward. It is concluded that the evolution of the substorm can be understood to the evolution of the dynamo regions in the magnetosphere and the ionosphere.

Pc5 poleward moving auroral arc (PMAA) pulsations observed on the ground in the post-midnight sector exhibit east-west-aligned auroral arcs elongated ~ 1000-3000 km and behave poleward moving form with a recurrence period of ~ 2-10 minutes (Pc5 range). They appear just poleward side of common type pulsating auroras. We examined the space-ground coordinated observations with the THEMIS-A, D, and E spacecraft whose footprints were located near the PMAA observed with the all-sky imager on the ground. The latitudinal wave amplitudes and phase structures are consistent with the field-line resonance (FLR) model, while the period of oscillation was longer at the higher latitude side (not a monochromatic wave). The electron flux in the higher energy range of ~ 2–20 keV showed decreasing modulation in conjunction with the FLR oscillations. The intensity of the electric field and the velocity showed a spatial gradient that suggests the existence of a field-aligned current flow around the region of the satellites. The period of FLR oscillations in the magnetosphere was ~ 15–25% longer than that of the auroral pulsations in the ionosphere, and the enhancement of FLR oscillations was ~ 3–4 minutes ahead of the auroral pulsations. These signals imply that the FLR oscillations could not directly enhance the luminosity oscillation but needed some other process that could enhance the luminosity pulsation. We will examine the mechanism of how to produce the field-aligned electric field in association with the PMAA. In this study we focus on the characteristics of the electron flux variations observed onboard the THEMIS and DMSP satellites. The THEMIS satellites were located near the equatorial plane in the magnetosphere, and the DMSP satellites traversed in the ionosphere and crossed over the field of view of all-sky imager at observatories in Canada and Alaska and Syowa Station in Antarctica. It is found that the DMSP satellites observed the precipitating electron flux that behaved the feature of field-aligned acceleration and also observed the field-aligned currents when the DMSP satellite crossed the region of the PMAA.

# Multiple spots of enhanced electron precipitation near the equatorward boundary of the cusp

*Satoshi Taguchi[1], Satoshi Kose[1], Kohei Takasu[1], Morio Tanaka[1], Keisuke Hosokawa[2], Yasunobu Ogawa[3]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications, 3. National Institute of Polar Research

Localized enhancements of electron precipitation near the equatorward boundary of the cusp is thought to be caused by enhanced fluxes of soft magnetosheath electrons in the flux tube immediately after localized intermitted reconnection on the dayside magnetopause. A recent study based on an all-sky imager has reported an event which shows that enhanced electron precipitation appears in two separate locations along the equatorward boundary of the cusp, and that the distance between them is approximately 0.2 MLT. In this study we have examined if there is any characteristic scale in the distance between neighboring electron precipitation spots near the equatorward of the cusp to understand the characteristics of the occurrence point of intermittent reconnection. We analyzed 630-nm aurora data from an all-sky imager at Longyearbyen, Svalbard, and electron precipitation and field-aligned current data from DMSP spacecraft, which flied in the field-of-view of the auroral imager. A simultaneous observation event shows that six enhanced electron precipitation regions, each of which is accompanied with an upward/downward pair of mesoscale field-aligned currents, were observed along the pass of the DMSP satellite, and that all of those enhanced electron precipitation regions were also identified as auroral spots in the 630-nm auroral image data. By examining auroral image data obtained before the simultaneous observation event, we traced back to the initial brightening for each auroral spot. The result of analysis has shown that the longitudinal distance between the neighboring spots near the equatorward boundary of the cusp lies between 0.15 and 0.4 MLT. The statistical analysis with data obtained for longer period of time on the same day has also shown a similar tendency. We discuss why localized intermittent reconnection tends to occur in such locations.

# Statistical study of auroral/resonant-scattering 427.8-nm emission observed at subauroral latitudes over 14 years

*Kazuo Shiokawa[1], Yuichi Otsuka[1], Martin Connors[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Athabasca University

Auroral emission at 427.8-nm from $N_2^+$ ions is caused by precipitation of energetic electrons, or by resonant scattering of sunlight at high altitudes by $N_2^+$ ions. The latter often causes impressive purple aurora at high altitudes. However, statistical characteristics of auroral 427.8-nm emission have not well been understood. In this paper we report occurrence characteristics of high 427.8-nm emission intensities (more than 100 R) at subauroral latitudes, based on measurements by a filter-tilting photometer over 14 years (2005-2018) at Athabasca, Canada (magnetic latitude: ~62°). We divided the dataset into the elevation angles ($\theta$s) of the sun more than and less than -24° (shadow height of sunlight: 600 km) to separate the 427.8-nm emissions caused by resonant scattering of sunlight and those excited by auroral electrons, respectively. The occurrence rate of 427.8-nm emissions of more than 100 R is 10.6 % and 7.65 % for $\theta$s more than and less than -24°, respectively. The occurrence rate is high in the post-midnight sector, and increases with increasing geomagnetic activity, solar-wind speed, and density. The occurrence rate is highest in summer. A high occurrence rate was also observed in 2015-2018, from the maximum to the declining phase of the 11-year solar activity. Superposed epoch analysis indicates that the 427.8-nm emission exceeds 100 R when solar wind speed increases and solar wind density concurrently decreases, suggesting that the solar wind structures typically observed at the arrival of corotating interaction regions (CIR) can be responsible for the high 427.8-nm emission.

# Antarctic large area network observation of auroral phenomena using unmanned system: Conjugate auroral event studies (2)

*Akira Kadokura[1], Hisao Yamagishi[1], Masaki Okada[1], Yasunobu Ogawa[1], Yoshimasa Tanaka[1], Ryuho Kataoka[1], Herbert Akihito Uchida[1], Yuichi Otsuka[2]

1. National Institute of Polar Research, 2. Nagoya University

Conjugate auroral events observed at Syowa Station, Antarctica and observatories in Iceland on September 28 in 2017 are analyzed. During this period, auroral data obtained by the all-sky auroral imager of the Unmanned Auroral Observation system (UAO) at Amundsen Bay, which is located about 500 km eastward from Syowa Station, are also available. We will discuss development of the conjugate auroral activities in a broader longitudinal area than before.

# Dawn-Dusk Asymmetry in Dayside and Nightside auroral Ovals: Surveys of auroral emissions based on the all-sky imagers in Arctic and Antarctic

*Zejun Hu[1]

1. Polar Research Institute of China

The synoptic distributions of dayside aurora in the Northern and Southern Hemispheres, acquired from all-sky imagers at Yellow River Station in Arctic and South Pole Station in Antarctica, respectively, present the same two-peak structure, namely, the prenoon 09:00 MLT and postnoon 14:00-15:00 MLT peaks. The auroral intensity presents a hemispheric asymmetry, i.e., the postnoon intensity is less than the prenoon intensity in the Southern Hemisphere but more in the Northern Hemisphere. The hemispheric asymmetry is not changed with the change of IMF’ s polarity, although 1) the negative (positive) IMF By favors the postnoon 557.7/630.0-nm auroral emissions, and the positive (negative) By favor to the excitation of 630.0-nm auroral on prenoon oval in the Northern (Southern) Hemisphere; 2) the 630.0-nm auroral intensity in dayside oval increases dramatically during the negative IMF Bz. We suggested that 1) the two-peak structure in the dayside oval are predominantly related with the prenoon/postnoon antiparallel reconnection in high-latitude magnetopause produced to the prenoon and postnoon peaks; 2) the IMF By should modulate the dayside aurora through the inter-hemispheric current, which is produced by a north-south oriented electric field , and changing the distribution of midday R0-R1 current; 3) the opposite prenoon-postnoon asymmetries of dayside auroral distributions in the two hemispheres are the combined effect of the prenoon-postnoon variations of the magnetosheath density and the variation of the local ionospheric conductivity in the two ground-based observatories.

The synoptic distributions of nightside aurora in the Northern Hemisphere, acquired from all-sky imagers at China-Iceland joint Aurora Observatory (CIAO) in Iceland, present that there are different characteristics on 427.8, 557.7, and 630.0 nm: 1) There is a two-peak structure on 427.8 and 557.7 nm, namely the pre-midnight 20:00- 21:00 MLT and post-midnight 04:00 peaks. For 427.8-nm auroral emission, the intensity of two peaks are same. For 557.7-nm emission, the maximal intensity is at peak 21:00 MLT. 2) There is only on peak on 630.0 nm, namely the pre-midnight 20:00-21:00 MLT. The dawn-dusk asymmetry in the nightside auroral oval should be related with the asymmetries of field-aligned currents and plasma waves in magnetosphere.

## [P-EM11] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Tomoaki Hori(Institute for Space-Earth Environmental Research, Nagoya University), Chairperson:Naritoshi Kitamura(東京大学大学院理学系研究科), Yuka Sato(日本工業大学), Masaki Nishino(名古屋大学宇宙地球環境研究所)

This session provides an opportunity to present recent results from satellite and ground-based observations and theoretical and simulation studies on the magnetosphere, ionosphere, and their coupling processes. We invite talks and posters discussing various phenomena related to the magnetosphere-ionosphere system: solar wind-magnetosphere interaction, magnetosphere-ionosphere convection, field-aligned current, magnetic storms/substorms, neutral-plasma interaction, ionospheric ion inflow and outflow, aurora phenomena, and so forth. Discussions on planetary and satellite ionosphere and magnetospheres, future missions and instrument developments are also welcome.

# Enhancement of 10MeV protons associated with a change of magnetic field configuration at geosynchronous orbit

*Takahiro Obara[1]

1. Planetary Plasma and Atmospheric Research Center,Tohoku University

It was found that 10MeV proton flux enhanced at geosynchronous orbit during the thinning of the magnetic field configuration. Since no significant enhancement of 10MeV proton flux was observed outside of the magnetosphere, the 10MeV protons seem to be of magnetospheric origin. Drastic decrease of 2MeV electron flux was observed at the geosynchronous orbit when the thinning of the magnetic field commenced. The 2MeV electron flux recovered when the dipolarization of the magnetic field occurred, while 10MeV proton flux remained almost constant. Three hours before the increase of 10MeV protons, shock structure of the solar wind hit the Earth’ s magnetosphere. At that time, increase of 6.5MeV protons was observed at geosynchronous orbit. Low energy (1~10MeV) protons are thought to be produced by the interaction of the solar wind shock and the magnetopause (Shimazu and Tanaka, 2005). In this event, only 6.5 MeV protons could reach geosynchronous orbit just after the production. Due to the thinning of the magnetic field configuration, 10MeV protons could then reach geosynchronous orbit. Low energy (1~10MeV) protons will be probes of the magnetosphere configuration weather the magnetosphere is truly quiet when the first protons (6.5MeV protons) arrive at geosynchronous orbit altitude and time delay of second protons (10MeV protons) was accompanied by the magnetic field changes in the magnetosphere. This type of event will be interesting from the view of the magnetosphere configuration change during the solar wind shock arrival. We are collecting more events to confirm above mentioned scenario.

# Solar-cycle variations of >30 keV proton flux enhancements under the inner radiation belt

*ALLA SUVOROVA[1]

1. National Central University

Upper atmosphere is continually affected by intense fluxes of energetic electrons and protons penetrating from the magnetosphere to low altitudes. The energetic particles ionize and excite neutral species altering local characteristics of the ionosphere. Continuous monitoring of energetic particles at low heights of ~850 km with the MEPED instrument onboard the NOAA/POES satellites allows studying of particle flux variations with geomagnetic activity and solar cycle. The instrument measures precipitating/trapped electrons and protons in the wide energy range. In the previous study, we revealed enhancements of electrons with energies 30 - 300 keV at low latitudes in a so-called forbidden zone. It was established that the electrons were injected from the inner radiation belt probably due to a mechanism of fast radial transport in the crossed electric and magnetic fields. In the current work, we study fluxes of >30 keV protons in the forbidden zone. We distinguish two types of proton enhancements, which have different spatial-temporal characteristics. One type of proton enhancements occurs due to the charge-exchange mechanism of the ring current and is always observed during magnetic storms. Another type is due to injections from the inner radiation belt. The last enhancements are similar to the electron enhancements. Results of long-term analysis of proton injections will be presented.

# Auroral Imaging with Commercial DSLR Cameras near Athabasca, Canada

*Martin G Connors[1,2], Ian Schofield[1], Mike Noble[2], Alister Ling[2], Ryuho Kataoka[3], Ken Murata[4], Kazunori Yamamoto[4]

1. Athabasca University, 2. Edmonton Centre, Royal Astronomical Society of Canada, 3. National Institute for Polar Research, 4. National Institute for Communications Technology

Commercial DSLR Cameras have permitted a revolution in auroral imaging, due to their digital nature, low cost, high sensitivity, and other advantages. Athabasca University Geophysical Observatory is in the subauroral zone, but due to the high altitude of auroras, usually has optical auroral activity visible on its northern horizon. We have operated mostly northward-pointing DSLR cameras, either with a field of view of about 50 degrees, or nearly allsky coverage. Since the “allsky” cameras we have used in fact do not cover the whole sky, we have tilted them northward to cover that horizon preferentially. We have livestreamed images to http://autumn.athabascau.ca/auroracamhd.htm. Ironically, the northward orientation of cameras at the observatory has precluded us capturing images of the newly-recognized STEVE phenomenon, which is normally located south of our location. However, STEVE events found on auroral imaging campaigns in the Edmonton area can often be identified on EMCCD images from our Keo Scientific intensified allsky camera. Then we can combine the images, showing for example, that STEVE is roughly 200 km above the surface. The auroral imaging campaigns have used three fullframe DSLRs to produce partial sky images that are then stitched together using software to produce approximately 10k-pixel color auroral movies, suited for use with modem planetarium projector systems as impressive high resolution sky shows. Most recently we have used a Sony Alpha 7000 camera, taking advantage of the fiber optic internet link to the Athabasca site, to make livecasting of auroras to Japan possible. Since reliability of cameras with moving parts has been a problem, we hope that the direct imaging Sony Alpha camera will be more reliable than the “reflex” cameras previously used. To get around the problem of moving parts wearing out under the very high frame rate, we also tested inexpensive CMOS-type sensors controlled by single-board computers, and sending a digital image stream, but so far with different, but still present, reliability problems. Another issue faced is that in continuous operation, a large amount of data is produced due to the high pixel count of the cameras. We will discuss technical issues and challenges, but also show some results of DSLR operation over the years, including auroral movies and high resolution still frames.

Keywords: electron microburst precipitation, sounding rocket, pulsating aurora

Bursty precipitations of high-energy electrons into the polar ionopshere have been observed by low-altitude satellite, for example, SAMPEX and FIREBIRD II. These precipitations, called microburst, may contribute to the loss of the terrestrial radiation belt through the collisional energy loss with the dense, cold atmospheric particles. Recent numerical simulations successfully reproduce these microburst precipitations with a few Hz modulations by taking into account the pitch angle scattering with the whistler chorus elements at off-equator regions in the inner magnetosphere. Therefore, one can expect that the miscroburst precipitations have properties depending on auroral activities especially the pulsating auroras. In order to investigate the mechanisms of the microburst precipitations by in-situ observations, we are developing two instrument packages: PARM (Pulsating AuRora and Microbursts; already developed) and PARM-2 (being developed), both of which are designed suitable for sounding rocket experiments. PARM consists of four sensors; HEP (high-energy electron energy spectrometer), MED (medium-energy electron detector), AIC (auroral camera), and AFG (ASIC-based fluxgate magnetometer). PARM was onboard the NASA's RockSat-XN sounding rocket, and launched from Andoya, Norway at 09:13UT, Jan 13, 2019. On the other hand, PARM-2 is under development. It consists of HEP, two AICs, and MIM (magneto-impedance magnetometer). PARM-2 is to be onboard the NASA's LAMP sounding rocket which will fly from Poker Flat, Alaska in the period between the end of 2019 and the

A reduction in weight of instrument, especially optics, is a key technique for explorers or small satellite missions. GEO-X (GEOspace X-ray imager) is a Japanese small satellite mission for X-ray observations of the dayside boundaries of the Earth’ s magnetosphere. An instrument is composed of a X-ray telescope
and a radio hard semiconductor pixel detector. Conventional X-ray optics have a trend that optics with better angular resolution have larger ratio of the weight to effective area. Therefore, it is difficult to utilize them for the X-ray planetary mission which has a severe weight limit. Micro pore optics are being developed based on a concept of a miniature optics. An original micro pore optics based on Si micromachining technologies will be used. A CMOS image sensor and a DEPFET (DEPleted P-Channle FET) are candidates for the X-ray detector. These new type semiconductor detectors are radiation hard and have optical light resistance, which are crucial in GEO-X to observe magnetosheaths and cusps near the dayside of the Earth. We report a summary of the instrument design and development for GEO-X.

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University), Chairperson:Mamoru Yamamoto

The Earth accepts vast input of energy and material from the Sun. The Earth's environment is maintained by the balance between their inputs and outputs. It is therefore important to study energy and mass transport on the Earth. This is an international session that discusses studies of the coupling processes in the Sun-Earth system based on the project "Study of coupling processes in solar-terrestrial system" that was approved by the Master Plan 2011/2014/2017 of Science Council of Japan. We continue proposing the project to the Master Plan 2020. The facilities and networks included are Equatorial MU Radar (EMU) in Indonesia to study the whole equatorial atmosphere, the EISCAT_3D radar system in northern Scandinavia to study detailed structures and elementary processes of the magnetosphere-ionosphere coupling in the polar region, and global networks of various ground-based instruments and observation data. We will show the current status of the project and discuss sciences by soliciting variety papers. This session is open to the world, and we strongly encourage submission of papers related to other facilities and projects, i.e., atmospheric or incoherent scatter radars, observation networks, satellites, and simulation or theoretical studies, etc.

# Status of Equatorial MU Radar project in 2019

*Mamoru Yamamoto[1], Hiroyuki Hashiguchi[1], Tatsuhiro Yokoyama[1], Toshitaka Tsuda[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

Research Institute for Sustainable Humanosphere, Kyoto University (RISH) has been studying the atmosphere and ionosphere by using radars. The first big facility was the MU (Middle and Upper atmosphere) radar installed in Shiga, Japan in 1984. This is one of the most powerful and multi-functional radar, and is successful of revealing importance of atmospheric waves for the dynamical vertical coupling processes. The next big radar was the Equatorial Atmosphere Radar (EAR) installed at Kototabang, West Sumatra, Indonesia in 2001. The EAR was operated under close collaboration with LAPAN (Indonesia National Institute for Aeronautics and Space), and conducted the long-term continuous observations of the equatorial atmosphere/ionosphere. The EAR, however, had a limited sensitivity to the MU radar as the total output power is just 1/10 to the MU radar. Our new project is to establish "Equatorial MU (EMU) Radar" just next to the EAR site in Indonesia. The EMU will have an active phased array antenna with the 163 m diameter and 1055 cross-element Yagis. Total output power of the EMU will be more than 500 kW. The EMU is the "MU radar class" facility, and can detect turbulent echoes from the mesosphere (60-80 km). In the ionosphere incoherent-scatter observations of plasma density, drift, and temperature would be possible. Multi-channel receivers will realizes radar-imaging observations. Preparation for the EMU progress in many aspect including site survey for the construction, discussion with local government, etc. In March 2019, RISH and LAPAN have 1st Internal School on Equatorial Atmosphere (ISQUAR) 2019 with more than 100 participants at Bandung, Indonesia. ISQUAR aims to promote interesting studies of the equatorial atmosphere and use of the atmospheric radar including the EMU. The EMU is one of the key element in the project "Study of coupling processes in the solar-terrestrial system" that is one of the important project in the Master Plan 2014 and 2017 of the Science Council of Japan (SCJ). We continue proposing the project to the SCJ Masterplan 2020.

# Recent Progress and Current Status of EISCAT_3D in 2018-2019

*Hiroshi Miyaoka[1], Yasunobu Ogawa[1], Satonori Nozawa[2], Koji Nishimura[1], Shin-ichiro Oyama[2], Takuji Nakamura[1], Ryoichi Fujii[2], Craig James Heinselman[3]

1. National Institute of Polar Research, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. European Incoherent Scatter Scientific Association

The European Incoherent Scatter(EISCAT) Scientific Association with associate members from Sweden, Norway, Finland, UK, China and Japan, has officially started the construction of the 1st stage of EISCAT_3D from September 2017 toward its completion by the end of 2021, including the commissioning of the radar system. EISCAT 3D is the major upgrade of the existing EISCAT mainland radars, with a multi-static phased array system composed of one central active (transmit-receive) site and 4 receive-only sites to provide us 50-100 times higher temporal resolution than the present system. The construction of EISCAT 3D is planned to implement by 4-staged approach, starting from the core site with half transmitting power about 5MW at Skibotn (Norway) and 2 receiving sites at Kaiseniemi (Sweden) and Karesuvanto (Finland) at the 1st stage. As for site preparation, geotechnical surveys have been completed at three sites, and ground cleaning with trenching for power lines and optical fiber cables have almost finished at the core site, Skibotn. All site buildings are scheduled to be built in 2019 to start installation of the radar system from 2020.

Through the international tendering process led by the EISCAT headquarter, antenna units with housing containers, first stage receiver units, sub-array transmitter units and pulse and steering control units have been completed and contracted providers have just started their preparation for productions to meet the EISCAT_3D implementation plan for sub-systems in 2020.

National Institute of Polar Research has been pursuing the opportunity to contribute in-kind to the construction of EISCAT_3D by supplying radar transmitter units in cooperation with the EISCAT Headquarters and ISEE/Nagoya University. The EISCAT_3D program in Japan was successfully granted as as one of high-priority programs of the Master Plan 2014/2017 and the Roadmap 2014 program, as a core facility of ’Study of Coupling Processes in the Solar-Terrestrial System’ (PI: Prof. Toshitaka Tsuda, ROIS/Kyoto Univ.). Supported by these positive evaluations, high energy-efficient transmitter power amplifiers (SSPAs) has been developed and produced for the engineering verification test at the EISCAT Tromso site with partial fundings for development since 2016.
In this paper, we will overview the recent progress and current status of the project including our strategy for the transmitter units as our national contribution to the EISCAT_3D project.

The Optical Mesosphere Thermosphere Imagers (OMTIs) consist of ~20 all-sky cooled-CCD imagers, 5 Fabry-Perot interferometers, 3 airglow temperature photometers, and 3 meridian-scanning photometers. They measure two-dimensional airglow images in the mesopause region and in the thermosphere, wind and temperatures in the lower thermosphere, and airglow rotational temperatures in the mesopause region. Details of the OMTIs project can be seen at http://stdb2.isee.nagoya-u.ac.jp/omti/. The PWING stands for "study of dynamical variation of Particles and Waves in the INner magnetosphere using Ground-based network observations." The PWING project started on April 2016 as a 5-year project of the Grant-in-Aid for Specially Promoted Research of the Japan Society for the Promotion of Science (JSPS) (16H06286). The PWING project deploy OMTIs all-sky cooled-CCD airglow imagers, 64-Hz sampled induction magnetometers, 40-kHz VLF receivers, and 64-Hz riometers at 8 stations at magnetic latitudes of ~60 degree around the north-pole to cover longitudinal variation of aurora and electromagnetic disturbances in the inner magnetosphere. Details of the PWING project can be seen at http://www.isee.nagoya-u.ac.jp/dimr/PWING/PWING_web_e.htm. These PWING and OMTIs instruments are in automatic operation at various locations from high to equatorial latitudes in Canada, US (Alaska), Russia, Norway, Finland, Iceland, Japan, Thailand, Indonesia, Nigeria, and Australia. In the presentation, we introduce current status and some recent results obtained by these multi-instrument ground networks around the world.

# Development of MAGDAS project: Search for global electromagnetic coupling from polar to equatorial ionosphere

*Akimasa Yoshikawa[1], Taisei Kabasawa[2], Teiji Uozumi[3], Akiko Fujimoto[4], Shuji Abe[3]

1. Department of Earth and Planetary Sciences, Kyushu University, 2. Graduate school of Sciences, Kyushu Univerity, 3. International center for Space weather science and education, Kyushu University, 4. Kyushu Institute of Technology

The equatorial ionosphere is a final destination of electromagnetic energy brought about by energy incidence to the polar ionosphere. Distribution of geomagnetic disturbance accompanying such a coupling phenomenon shows strong asymmetry. Such an aspect suggests that the magnetosphere-ionosphere form a unique transmission and / or propagation system depending on each event.
The MAGDAS project investigates such a global electromagnetic coupling system by combining global geomagnetic field network observation with electric field observation using ionosonde installed at low and dip-equator region.
Recently, by using 250Hz sampling and 10Hz averaged MAGDAS 9 magnetometer data, we found that when the auroral substorm were enhanced during geomagnetic storm, together with enhancement of Pc1 wave at the polar region, the global Pc2 type disturbances (period range from 5 to 20 sec) can be captured from polar to equatorial region. In this talk, we will present recent update of MAGDAS project and of which scientific results.

Keywords: global electromagnetic coupling, Pc2 pulsation, Magnetosphere-ionosphere Coupling

# IUGONET data analysis system for a study of coupling processes in the solar-terrestrial system

*Atsuki Shinbori[1], Yoshimasa Tanaka[2], Norio Umemura[1], Shuji Abe[3], Masahito Nose[1], Satoru UeNo[4]

1. Institute for Space-Earth Environment Research (ISEE), Nagoya University, 2. National institute of Polar Research, 3. International Center for Space Weather Science and Education Kyushu University, 4. Observatory, Kyoto University

The earth’s atmosphere in a height range of more than 80 km is called the upper atmosphere, and the atmospheric layer is influenced by both the solar activity and the atmospheric waves propagating from the lower atmosphere. Therefore, in order to understand the physical mechanism of the short-term and long-term variations in the upper atmosphere, we need to perform an integrated analysis of various kinds of ground-based and satellite observation data taken by different instruments. Since these observation data were separately being managed by each institute, it was difficult for users to effectively find and analyze them for promotion of an interdisciplinary study. In order to solve this problem, the Inter-university Upper atmosphere Global Observation NETwork (IUGONET) project has been initiated in 2009, consisting of five institutes (Tohoku University, National Institute of Polar Research, Nagoya University, Kyoto University, and Kyushu University). In this project, we have added data information (metadata) for various kinds of ground-based observation data in the solar-terrestrial physics and built a practical database (IUGONET Type-A) to share them on the Internet. We have also developed an integrated data analysis tool (IUGONET Data Analysis Software: UDAS) written in an Interactive Data Language (IDL). This analysis tool is a plugin software for Space Physics Environment Data Analysis Software (SPEDAS) to analyze and visualize various kinds of ground-based and satellite observation data. In the IUGONET Type-A, users can easily learn characteristics of observation data through the quick look images/plots and how to use several basic commands to visualize the data. Recently, we developed a UDAS EGG (UDAS Easy Guide to Generate your load routines) to provide users with the templates for IDL procedures that can load their own data in CSV and CDF format into SPEDAS/IDL. In order to enhance an international use of these IUGONET products and to promote an interdisciplinary study of coupling processes on the sun-earth system, we have held tutorial seminars and workshops several times in Japan and foreign countries (India, Indonesia, Nigeria, Malaysia etc.). As a result, many scientific papers [e.g., Dao et al., 2017; Batubara et al., 2018; Koushik et al., 2018] and Master/Doctor theses become published by preparing an analysis environment, and the IUGONET products effectively works as an international platform. This fact suggests that the IUGONET project is in the position enough to serve the subjects of a large research project: Study of coupling processes in the solar-terrestrial system (Master Plan 2014/2017, Load Map 2014) through a collaboration with other ground-based and satellite observation plans and international programs as already planned by Master Plan 2014/2017. Judging from the above situations, the IUGONET project has a potential possibility to extend human development and strong international cooperation to a whole equatorial region (South America, Africa) in addition to India and Indonesia in future. Therefore, it can be concluded that the IUGONET activity effectively promotes the equatorial and polar atmospheric observations, international collaboration and data science (data assimilation), which are three main subjects of Master Plan (2014/2017).

# Discussion on large-scale research project "Study of coupling processes in solar-terrestrial system" (1)

*Mamoru Yamamoto[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

The large-scale research plan "Study of coupling processes in solar-terrestrial system" is recognized in the important projects in Master Plan 2014 and 2017. We are currently preparing for a continuous proposal to Master Plan 2020. In this international session, we will apply discussion time in order to proceed the research plan.

[E] Oral | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Thu. May 30, 2019 10:45 AM - 12:15 PM JST | Thu. May 30, 2019 1:45 AM - 3:15 AM UTC | A01 TOKYO BAY MAKUHARI HALL

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University), Chairperson:Satonori Nozawa

The Earth accepts vast input of energy and material from the Sun. The Earth's environment is maintained by the balance between their inputs and outputs. It is therefore important to study energy and mass transport on the Earth. This is an international session that discusses studies of the coupling processes in the Sun-Earth system based on the project "Study of coupling processes in solar-terrestrial system" that was approved by the Master Plan 2011/2014/2017 of Science Council of Japan. We continue proposing the project to the Master Plan 2020. The facilities and networks included are Equatorial MU Radar (EMU) in Indonesia to study the whole equatorial atmosphere, the EISCAT_3D radar system in northern Scandinavia to study detailed structures and elementary processes of the magnetosphere-ionosphere coupling in the polar region, and global networks of various ground-based instruments and observation data. We will show the current status of the project and discuss sciences by soliciting variety papers. This session is open to the world, and we strongly encourage submission of papers related to other facilities and projects, i.e., atmospheric or incoherent scatter radars, observation networks, satellites, and simulation or theoretical studies, etc.

# Numerical Experiments on Stratosphere-Troposphere Two-Way Dynamical Coupling in the Tropics through Organizations of Moist Convective Systems

*Shigeo Yoden[1], Hai Bui[2], Takahiro Banno[1]

1. Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University, 2. Geophysical Institute, University of Bergen

Recently, we started a new international research activity on Stratospheric And Tropospheric Influences on Tropical Convective Systems (SATIO-TCS) under WCRP/SPARC. It focuses on stratosphere-troposphere (S-T) two-way dynamical coupling in the tropics, where moist convection and its large-scale organization in the troposphere could be influenced by the stratospheric variations, such as stratospheric sudden warming events, the equatorial quasi-biennial oscillation (QBO), or anthropogenic cooling trend in the lower stratosphere, as revealed by some observational studies. For example, Nishimoto and Yoden (2017) made a statistical analysis on the influence of QBO on the Madden-Julian oscillation (MJO) during boreal winter in neutral ENSO periods from 1979 to 2013, and showed that the composite OLR anomaly for a particular MJO phase over the Maritime Continent has a larger negative value and slower eastward propagation with a prolonged period of active convection in the easterly phase of QBO than in the westerly phase.

The tropical dynamics is largely different from the counterpart in the extratropics where dry quasi-geostrophic dynamics prevail. Multi-scale dynamics of moist convection and its organizations are likely to play a vital role in determining the tropospheric response to the stratospheric variations, but numerical model studies from such viewpoint are still limited. Thus, we had performed a series of numerical experiments on radiative-moist convective quasi-equilibrium states in a highly-idealized two-dimensional regional model of an S-T coupled system with explicit moist convection under a periodic lateral boundary condition without Coriolis effects, in which self-sustained oscillations dynamically analogous to the QBO were obtained (Yoden et al. 2014). Modulation of moist convective systems is associated with the QBO-like oscillation of the mean zonal wind, as alternative appearance of squall-line- or back-building-type precipitation patterns, and vertical momentum transports associated with slant-wise moist convection and convectively generated gravity waves are periodically modulated in the oscillation (Nishimoto et al. 2016). Downward influence of the QBO-like oscillation on organized moist convective systems was further investigated in a series of experiments that control the vertical shear of the mean zonal wind with a nudging term (Bui et al. 2017).

Recently, we have performed numerical experiments in a three-dimensional minimal model framework that produces a QBO-like oscillation in a radiative-moist convective quasi-equilibrium state. The computational domain is rectangular (640 km x 160 km, 5 km grid size; Bui et al., 2019), or square (100 km x 100 km, 1 km grid size), without Coriolis effects under doubly periodic boundary conditions. In these experiments, an oscillation with a period of about 300 days emerges in the stratosphere, both in the domain-averaged zonal wind and meridional wind. Synchronization of the zonal and meridional winds is characterized as an anti-clockwise rotation of a skewed spiral feature with height in the horizontal wind hodograph. The QBO-like wind oscillation penetrates into the troposphere with large reduction of oscillation amplitude, and influences tropospheric temperature anomalies and precipitation with an irregular period of about 100 days. Heavy precipitation is associated with positive temperature anomalies.

©2019. Japan Geoscience Union. All Right Reserved. 

The simulation reveals three types of precipitation patterns; fast-moving back-building- and squall-line-type patterns, and isolated quasi-stationary type clusters, which is newly identified in this three-dimensional model. The zonal-height cross sections of the meridionally averaged clouds and relative humidity for this pattern show clear-sky areas with low humidity without shallow clouds, whereas shallow clouds exist over the entire domain including non-precipitating areas with high humidity for the fast-moving two patterns. Intermittent self-organization of convective systems into quasi-stationary type and transition back to the fast-moving back-building- or squall-line-type patterns are fundamental characteristics of self-aggregation in the three-dimensional model.

# Future development of numerical simualtion of equatorial plasma bubbles

*Tatsuhiro Yokoyama[1]

1. Kyoto University

Equatorial plasma bubbles (EPBs) have been a longstanding and increasingly important subject because they cause severe scintillations in radio waves from Global Navigation Satellite System satellites. The phenomenon was found in the 1930s as irregular ionosonde observations and was termed equatorial spread F (ESF). ESF is interpreted as plasma density irregularities associated with EPBs that have nonlinearly evolved into the topside ionosphere. Since late 1970s, numerical simulations have been powerful tools to study the fully nonlinear evolution of EPBs, which cannot be wholly understood from theoretical predictions. The most recent model, High-Resolution Bubble (HIRB) model, could reproduce very turbulent structures inside EPBs such as bufurcation, zonal asymmetry, and two-component power law spectral characteristics. Future directions toward scintillation evaluation and forecasting are discussed.

# Characteristics of CME- and CIR-driven ion upflows in the polar ionosphere

*Yasunobu Ogawa[1], Kanako Seki[2], Kunihiro Keika[2], Yusuke Ebihara[3]

1. National Institute of Polar Research, 2. School of Science, the University of Tokyo, 3. Research Institute for Sustainable Humanosphere, Kyoto University

We investigated how velocity and flux of ionospheric ion upflows vary during magnetic storms driven by corotating interaction regions (CIRs) and coronal mass ejections (CMEs), using data from the European Incoherent Scatter (EISCAT) Tromsø UHF and Svalbard radars between 1996 and 2015. The characteristics of ion upflows were compared with ion and electron temperature variations measured with the EISCAT radars, and also joule heating rate, electric field, and field-aligned current (FAC) distribution derived from the Weimer model. Upward ion velocity increases in the nighttime at Tromsø (66.2 ° N geomagnetic latitude) just after the CIR- and CME-driven storms, corresponding to electron temperature enhancements due to soft particle precipitation and also ion temperature enhancements in the strong westward electric field region. The CME-driven storms have larger upward ion flux (~$1.7\times10^{13}$ $m^{-2}s^{-1}$) than those under the CIR-driven storms (~$0.3\times10^{13}$ $m^{-2}s^{-1}$). In the daytime, ion upflows are seen at Longyearbyen, Svalbard (75.2 ° N geomagnetic latitude), with an upward flux of typically $10^{13}$ $m^{-2}s^{-1}$ for small CIR and CME storm cases. Substantial ion upflows last for a few days after the storm onsets under small CIR storms, whereas they last for only a day under small CME storms. Under both the cases, the substantial ion upflows are associated with an enhancement of the Region 1 FAC, eastward electric field and Joule heating rate. For large CME storms, substantial ion upflows are absent in the daytime probably due to equatorward expansion of the auroral oval.

# SuperDARN Hokkaido Pair of (HOP) radars and mid-latitude SuperDARN: today and future

*Nozomu Nishitani[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

The Super Dural Auroral Radar Network (SuperDARN) is a network of HF radars. At present there are total of 36 SuperDARN radars located in high- to mid-latitude regions of both northern (23) and southern (13) hemispheres. Mid-latitude SuperDARN radars started operation about 15 years ago and have been acquiring scientific data, which could be obtained using the pre-existing high-latitude radars. The SuperDARN Hokkaido Pair of (HOP) radars consisting of Hokkaido East / West radars are located equatorward of 40 degrees geomagnetic latitude (currently located at the lowest geomagnetic latitude) and have been storing important scientific data during quiet to very active periods. In this presentation accomplishments, present status and future directions of the SuperDARN HOP radars and mid-latitude SuperDARN be reviewed.

# Simultaneous observation of Ionospheric Incoherent Scatter and Field Aligned Irregularities using adaptive signal processing techniques by the PANSY radar at Antarctic Syowa Station (39.6˚E, 69.0˚S)

*Taishi Hashimoto[1], Akinori Saito[2], Koji Nishimura[3], Masaki Tsutsumi[3], Kaoru Sato[4], Toru Sato[1]

1. Graduate School of Informatics, Kyoto University, 2. Graduate School of Science, Kyoto University, 3. National Institute of Polar Research, 4. Graduate School of Science, The University of Tokyo

The Program of Antarctic Syowa Mesosphere-Stratosphere-Troposphere (MST) / Incoherent Scatter (IS) radar (the PANSY radar) is a large VHF-band atmospheric radar located at Antarctic Syowa Station. Besides the general functionalities of MST radars, the PANSY radar is also capable of observing IS from 100 km to 500 km in altitude to estimate ionospheric plasma parameters. The ionospheric observation was successfully performed in 2015, which was the first in the Antarctic region.

In contrast to existing IS radars using higher frequencies, the ionospheric observation of the PANSY radar suffers contamination from E-region Field Aligned Irregularities (FAIs). Because the perpendicular condition between the line of sight and the geomagnetic field is satisfied around 100 km in altitude using the VHF-band at this latitude, strong coherent echoes from FAIs fall into the same range gates with the F-region peak of IS.

To mitigate the contamination of FAIs in IS observation of the PANSY radar, we have developed a signal processing procedure using adaptive beamforming techniques [1]. The PANSY radar has two peripheral linear antenna arrays, each with twelve three-element antennas for the Directionally Constrained Minimization of Power approach, to separate signals from different directions. Hence, this technique makes it possible not only to measure the background electron densities accurately, but also to observe the structure and motion of FAIs simultaneously.

In this presentation, we briefly overview the signal processing procedure applied to the ionospheric observation of the PANSY radar, and show recent results from simultaneous observations of IS and FAIs, including some radar images of FAIs obtained by adaptive beamforming techniques.

Recent Studies show that ionosphere influenced by Thunder cloud, Typhoon, Sudden Stratosphere warming, Earth quake, and so on. Possible atmosphere perturbation to generate Radio wave scintillation is still not confirmed by observation in spite of the long history of radio scintillation research. Since 1970’ s, no break through is found in ionosphere physics. The reason is the lack of information of the atmosphere below which is needed simultaneously with ionopshere information. We propose here the satellite constellation of /Pico /mini satellites combined with one /two small satellite (200-500 Kg). Pico/mini satellite should be constellation to measure basic ionosphere parameter. These are electron density, temperature, ion temperature, ion mass, electric field, and neutral wind at ionosphere height. Information on the atmospheric wind down to ground surface below 120 km should be simultaneously measured. This means that we need photometric instruments such as TIDI and SABAR accommodated in TIMED satellite or instruments to measure electromagnetic waves radiated by neutral particles. These observations can be done through international collaboration.

# Statistical study of daily and seasonal variation of the equatorial anomaly in Asia based on satellite-ground beacon experiment

*Yuki Sakamoto[1], Mamoru Yamamoto[1], Kornyanat Hozumi[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. National Institute of Information and Communications Technology

Studies of ionospheric structures by the satellite-ground beacon experiment were conducted in southeast Asia. We have deployed a meridional chain of five beacon receivers from 8S to 27N along 100E meridian, they showed meridional distribution of total-electron content (TEC) of the ionosphere. We revealed time and spatial variabilities of the equatorial anomaly in a certain period of time (Watthanasangmechai et al., 2014, 2015). The data analysis was, however, not easy mainly because of difficulty in estimating bias of the measurement to get the absolute TEC.
In this study, we developed the method of bias estimation. As a result, we can get TEC distribution by computers automatically. Using this method, we analyzed latitude distribution of TEC from Thai to Indonesia in 2012-2015. It is valuable to measure such latitudinal distribution of TEC in the wide latitudinal range from the ground fixed sites.
Using these data, we classified TEC distribution with the equatorial anomaly. It shows some distribution patterns depends on season or time. Classifying the TEC distribution data of LT14-17 and LT20-23, assuming after the formation of the equatorial anomaly (EIA), we take the average in 2012-2015. The plasma fountain makes the 2 peaks (northern and southern of the magnetic equator) in the TEC-Lat graph. In the northern hemisphere summer, the northern peak is larger than the southern one. In winter, the southern peak is larger than the northern one. Classifying the data of LT10-13, assuming the right after formation of the EIA. It shows the opposite result. In summer, the southern one is larger. In winter, the northern one is larger. We will compare these analysis results with atmospheric parameters from the whole atmosphere model GAIA and MSIS.

Keywords: total-electron content, equatorial anomaly

# Latest installation of FM-CW radar in Peru

*Akiko Fujimoto[1], Akihiro Ikeda[2], Akimasa Yoshikawa[3]

1. Kyushu Institute of Technology, 2. National Institute of Technology,Kagoshima College, 3. Kyushu University

An FM-CW (Frequency Modulated Continuous Wave) radar is a type of HF (High Frequency) radar. The FM-CW radar can measure the range of target as well as Doppler shift for reflected radio waves from the target (e.g., ionized layer). From the observed Doppler shift, we can estimate east-west electric field in the ionosphere. Poole (1985) and Poole and Evans (1985) first used FM-CW radar for Doppler observation. Nozaki and Kikuchi (1987, 1988) made improvements to the design. We have installed three FM-CW stations along the Japanese longitude, at Japan, Russia and Philippine, in order to measure the electric fields that penetrate the ionosphere (Yumoto, 2006).

Our goals are, (i) to estimate EEJ (Equatorial Electrojet) structure including the generation, variance and modulation of EEJ, (ii) to understand the electrodynamics of EEJ and the generation mechanism of the Equatorial Spread F (ESF) associated with Plasma Bubbles (PBs) and (iii) to reveal the generation mechanisms of ULF pulsation waves at the lower and equatorial latitudes.

In 2018, the new FM-CW radar has been installed in Peru. This FM-CW observation will give the opportunity of the simultaneous ionospheric observation at the Japan local time and the opposite side of Japan (for example dayside and nightside). ICSWSE (International Center for Space Weather Science and Education, Kyushu University) also have the ground-based magnetometer network (MAGDAS) on the world including Peru MAGDAS chain. With the both magnetometer and FM-CW observations, we try to understand the energy transfer and propagation process from the poles to the equator, in the terms of the coupling the solar-magnetosphere-ionosphere-atmosphere.

We will give the detail and current status of FM-CW radar project.

# Understanding the OH Meinel Band Emissions on the Terrestrial Planets

*Konstantinos S. Kalogerakis[1]

1. Center for Geospace Studies, SRI International, Menlo Park, California, U.S.A.

The OH Meinel band emissions, originating from vibrationally excited hydroxyl radicals, OH(v), represent some of the most important airglow features in the Earth's upper atmosphere. Such emissions were also observed on the night side of Venus during the Venus Express mission [*Piccioni et al.*, A&A 483, L29-L33 (2008)]. Data obtained by CRISM (Compact Reconnaissance Imaging Spectrometer for Mars) aboard the MRO (Mars Reconnaissance Orbiter) revealed OH(v) emissions in the nightglow of Mars [*Clancy et al.*, Icarus 226, 272-281 (2013)]. Modeling studies have shown that the predicted OH(v) emission intensities can vary dramatically depending on the nature of the vibrational relaxation mechanism assumed [e.g., *García Muñoz et al.*, Icarus 176, 75-95 (2005)]. Despite several investigations, the details of all the relevant OH(v) relaxation kinetics and pathways are not well understood.

Our recent studies demonstrated a previously unknown, efficient pathway for vibrational relaxation of OH(v) by O atoms that couples the mesospheric OH(v) emissions with the $CO_2$ 4.3-micron emission and resolves a long-standing problem of severe discrepancies between model predictions and observations of the 4.3-micron emission in the Earth's atmosphere [*Panka et al.* , ACP 17, 9751-9760 (2017); *Kalogerakis et al.*, GRL 43, 8835-8843 (2016)]. This recent breakthrough development highlights the importance of investigating the mechanistic details of OH(v) collisional energy transfer.

We will discuss our efforts to investigate OH(v) vibrational relaxation relevant to the atmospheres of the terrestrial planets. Important areas of interest are the key OH(v) vibrational relaxation rate constants at temperatures relevant to the altitude of the emission layer and the pathways of OH(v) vibrational energy relaxation. The Meinel OH(v) emissions can be used as an indicator of atmospheric composition, variability, circulation, gravity waves, and as a probe of local temperature. A detailed understanding of the sources and sinks of these emissions is a prerequisite before they can be reliably used as a proxy for the aforementioned processes.

# Statistical study of Sporadic Sodium Layer (SSL) observed at Tromsø

*Satonori Nozawa[1], Takuo T. Tsuda[2], Norihito Saito[3], Toru Takahashi[4], Takuya Kawahara[5], Yasunobu Ogawa[4], Hitoshi Fujiwara[6], Satoshi Wada[3], Youhei Ogawa[1], Chris Hall[7], Asgeir Brekke[7]

1. Institute for Space-Earth Environment Research, 2. The University of Electro-Communications, 3. RIKEN Center for Advanced Photonics, 4. National Institute of Polar Research, 5. Faculty of Engineering, Shinshu University, 6. Faculty of Science and Technology, Seikei University, 7. UiT The Arctic University of Norway

Based on about 3000 hours of sodium density data obtained with the Tromsø sodium LIDAR over 7 year seasons between 2012 and 2018, we have identified about 40 events of Sporadic Sodium Layer (SSL) in the polar mesosphere and lower thermosphere (MLT) region. A SSL is a thin sodium layer (about 1-2 km) with high sodium density (usually factor of 2 or more higher than that of a normal layer), and its life time is about a few minutes to a few hours. We have investigated an occurrence rate of sporadic sodium layer (SSL) as well as necessary conditions for a SSL to form in the polar MLT region. SSLs appeared for shorter than 5 % of the overall observational time, indicating it is a rare event. Auroral electron precipitation as well as appearance of a sporadic E layer would be necessary conditions to form a SSL.

The sodium LIDAR at Tromsø (69.6 deg N, 19.2 deg E) has made simultaneous five directional (vertical position, plus 4 horizontal positions with zenith angle = 30 deg or 12.5 deg and azimuth = 0, 90, 180, 270 deg) observations, and has obtained about 3000 hours of temperature, sodium density, and wind data between October 2012 and February 2019. Analyzing the datasets with temporal and height resolutions of 3 min and 500 m, respectively, we have identified about 40 SSL events over the seven winter seasons. By utilizing five point observations, we have determined if a SSL was in-situ generated or was advected. Most SSLs show feature of advection (systematic and similar temporal variations of sodium density), indicating associated sharp rise of sodium density, whose mechanism has long been not understood, can be explained with an advection effect.

Observational results can be summarized as follows:
(1) most SSLs found are probably advected, (2) ionization of aurora would be a necessary condition, (3) sporadic E (Es) layers are almost always associated, (4) local time dependence of appearance of SSL is found, suggesting convectional electric field and semidiurnal tide would play an important role. We will address a generation mechanism of SSL.

Keywords: Sodium layer, Tromso, SSL, Es layer, Sodium LIDAR

# Discussion on large-scale research project "Study of coupling processes in solar-terrestrial system" (2)

*Mamoru Yamamoto[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

The large-scale research plan "Study of coupling processes in solar-terrestrial system" is recognized in the important projects in Master Plan 2014 and 2017. We are currently preparing for a continuous proposal to Master Plan 2020. In this international session, we will apply discussion time in order to proceed the research plan.

[E] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Thu. May 30, 2019 3:30 PM - 5:00 PM JST | Thu. May 30, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University)

The Earth accepts vast input of energy and material from the Sun. The Earth's environment is maintained by the balance between their inputs and outputs. It is therefore important to study energy and mass transport on the Earth. This is an international session that discusses studies of the coupling processes in the Sun-Earth system based on the project "Study of coupling processes in solar-terrestrial system" that was approved by the Master Plan 2011/2014/2017 of Science Council of Japan. We continue proposing the project to the Master Plan 2020. The facilities and networks included are Equatorial MU Radar (EMU) in Indonesia to study the whole equatorial atmosphere, the EISCAT_3D radar system in northern Scandinavia to study detailed structures and elementary processes of the magnetosphere-ionosphere coupling in the polar region, and global networks of various ground-based instruments and observation data. We will show the current status of the project and discuss sciences by soliciting variety papers. This session is open to the world, and we strongly encourage submission of papers related to other facilities and projects, i.e., atmospheric or incoherent scatter radars, observation networks, satellites, and simulation or theoretical studies, etc.

# Study on adaptive clutter rejection system using external receiving antennas for the MU radar

*Hiroyuki Hashiguchi[1], Issei Terada[1], Mamoru Yamamoto[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

Strong clutter echoes from a hard target such as a mountain or building sometimes cause problems of observations with atmospheric radars. In order to reject or suppress ground clutter echoes, it is effective to use NC-DCMP (Norm Constrained- Directionally Constrained Minimum Power) method, which makes null toward the direction of the clutter, if we can receive signals independently from plural antennas [Nishimura et al., JTech., 2012]. It has been demonstrated that the NC-DCMP method is effective to real observation data with the MU (Middle and Upper atmosphere) radar [Hashiguchi et al., Radio Sci., 2018]. Although NC-DCMP method suppresses clutter echoes with almost maintaining the shape of main lobe to add pseudo-noise compared with the conventional DCMP method, the signal-to-noise ratio (S/N) of atmospheric echoes is somewhat degraded. We studied the clutter suppression method with little S/N degradation by using external antennas.

Four turnstile antennas are installed in the MU radar site. The signal from the antenna is sent to the MU radar observation room through the coaxial cable after amplified by the LNA with the limiter and BPF. It is further amplified by the LNA in the observation room, and then down-converted to intermediate frequency (5 MHz) signal to input to the multi-channel receiving system of the MU radar.

We compared the NC-DCMP method using the each received data of 25 channels, which is a conventional clutter suppression method, and the NC-DCMP method using the simple combination of 25 channels and 4 channels of external antennas. In the former case, the S/N of the atmospheric echoes is somewhat degraded, but in the latter case the main lobe shape is guaranteed by 25 channel simple synthesis, so the S/N degradation is not observed. In the latter case, the clutter suppression is sometimes insufficient. This cause is considered to be that the current positions of external antennas are biased to the north side. Antenna positions should be optimized in the future.

We can apply the achievement of this study to the Equatorial MU radar (EMU), which is proposed to be constructed at West Sumatera, Indonesia. The EMU system is the similar as the MU radar, but its antenna consists of 1045 Yagi antennas with 55 groups and it has 64 receiver channels.

# Detached cusp aurora for southward IMF

*Kohei Takasu[1], Satoshi Taguchi[1], Keisuke Hosokawa[2]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications

A poleward-moving aurora is a typical phenomenon in the dayside cusp of the high-latitude ionosphere. This aurora usually originates near the equatorward boundary of the cusp, and diminishes near the poleward boundary of the persistent cusp auroral emissions. In this study we have examined faint poleward-moving auroras that are detached from the persistent cusp emissions by analyzing 630-nm aurora image data from an all-sky imager at Longyearbyen, Svalbard, and precipitating electron data from DMSP spacecraft. These auroras occur for southward IMF, and are located at latitudes higher than 80 MLAT. The intensities are very weak (less than 1 kilo Rayleigh). The result of the analysis shows that the speed of the auroral motion is 1 to 2 km/s, which is faster than typical convection speed in the dayside polar cap. We show the similarities and differences between the faint aurora and the typical poleward moving cusp aurora, and discuss how soft electron precipitation occurs in the region that is well separated from the cusp.

# Motion of the inverted-V structure during an isolated substorm

*Morio Tanaka[1], Satoshi Taguchi[1], Kohei Takasu[1], Tomokazu Oigawa[1], Keisuke Hosokawa[2]

1. Department of Geophysics, Graduate school of science, Kyoto University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications

The inverted-V is an energetic electron precipitation event, which can be seen as a V-shape structure in electron flux spectrograms, and causes intense auroral arcs. Previous studies have suggested that the inverted-V structure can move fast poleward or equatorward. However, we still do not understand what drives its motion. In this study we have investigated the detailed characteristics of an inverted-V structure moving poleward, which occurred during an isolated substorm, using simultaneous observations of auroras, precipitating electrons, and field-aligned currents. We analyzed aurora data (630-nm and 557.7-nm) from an all-sky imager at Longyearbyen, Svalbard, and precipitating electrons and magnetic field data from the DMSP spacecraft (F16, F17, F18, F19). One of the interesting characteristics of the poleward-moving inverted-V is the appearance of a downward field-aligned current equatorward of and adjacent to the inverted-V. We discuss how the region of the downward field-aligned current evolves in association with the motion and growth/decay of the inverted V structure, and possibility of a role of the downward field-aligned current for the latitudinal motion of the inverted V.

Keywords: Field-aligned current, aurora, inverted-V, isolated substorm

# Observation and modeling of Na layer response to energetic particle precipitation

*Takuo T. Tsuda[1], Kyogo Takizawa[1], Ryo Tozu[1], Takuya Kawahara[2], Yoshimasa Tanaka[3], Mitsumu K. Ejiri[3], Takanori Nishiyama[3], Takuji Nakamura[3]

1. The University of Electro-Communications, 2. Shinshu University, 3. National Institute of Polar Research

Metallic layers, such as Na, Fe, Mg, K, and Ca layers, exist in the mesosphere and lower thermosphere (MLT). The height range of the MLT region corresponds to the ionospheric *D* and *E* regions, and in the polar region energetic particles precipitating from the magnetosphere can often penetrate into the *E* region and even into the *D* region. Therefore, the influence of energetic particles on the metallic layers is of interest regarding changes in atmospheric composition accompanied by auroral activity or geomagnetic activity.

In this study, we have performed a statistical investigation on relationship between Na density and cosmic noise absorption (CNA), which were obtained from 2000 to 2002 at Syowa Station, Antarctic (69.0ºS, 39.6ºE). From the investigation, we found the Na density decrease in accordance with the CNA increase, i.e., increase in the energetic particle precipitation. In the presentation, we will show these observational results, and discuss causality about the observed relationship based on numerical caculations using our Na chemistry model.

Keywords: Na layer, Energetic particle precipitation, Syowa Station, Na chemistry model

# Lidar data analysis of the sodium atoms in the thermosphere observed at Tromsoe, Norway

*Takuya Kawahara[1], Satonori Nozawa[2], Norihito Saito[3], Takuo T. Tsuda[4], Toru Takahashi[5], Testuya Kawabata[2], Miki Nishimura[1], Yoshitaka Kobayashi[1]

1. Faculty of Engineering, Shinshu University, 2. ISEE, Nagoya University, 3. RIKEN, Center for Advanced Photonics, 4. The University of Electro-Communications, 5. National Institute of Polar Research

Distribution of low-density Na atoms in the thermosphere is interesting because of the capability of measuring neutral temperature and wind into the lower thermosphere up to 140 km. The thermospheric Na atoms significantly made the altitude range of Na lidar measurements expanded from the 80–105 km to 80–140 km, covering almost the entire E region (Liu et al., GRL, 2016).

The measurements of wind and temperature by a Na lidar in the northern mesosphere (80-105 km) at Tromsoe, Norway (69.6˚N, 19.2˚E) have been carried out in Polar winter season since 2010. However, thermospheric Na has not been seen in our data so far. This is because the automatic analysis program calculates the background signal level using the 140-150 km signals which possibly include a small amount of thermospheric Na signal. Deriving thermospheric Na is done by lowering the background signal level to emphasize thermospheric Na signals. The data at the new moon are selected which have a low background signal. Also, we calculated signal intensity from the Na atoms in the thermosphere based on our lidar parameters such as laser power, a telescope aperture area etc. by using the lidar equation. The results are summarized as follows. (1) Assuming that the Na density is 10 /cm^3, the signal from the Na atoms between 120 and 140 km is expected 300-400 photons, (2) The background signal observed is about 4,400 counts which means the noise level is about 220. So the signal intensity from the Na is nearly comparable to the noise level. (3) Thermospheric Na was not clearly seen in the re-calculated data. However, it depends on the smoothing technique to the original lidar data.

In this talk, we show the results derived by varying the binning time and discuss it.

Keywords: Na lidar, thermosphere, Tromsoe

# Spatial-temporal distribution of anomalous enhancement of ambipolar diffusion coefficient observed by meteor radars installed in the polar region

*Toru Takahashi[1], Masaki Tsutsumi[1,2], Yasunobu Ogawa[1,2,3], Satonori Nozawa[3], Chris Hall[4], Hiroshi Miyaoka[1,2]

1. National Institute of Polar Research, 2. SOKENDAI, 3. Institute for Space-Earth Environmental Research, 4. TGO, The Arctic University of Norway

The meteor radar detected echoes of meteor tails as a tracer of neutral wind from 75 to 100 km altitudes (Hall et al., 2005). In addition, by using a decay time of the echo power, the meteor radar also estimated the ambipolar diffusion coefficient, which depends on the ion and electron temperature. The ambipolar diffusion coefficient was utilized to estimate the neutral temperature because the ion and electron temperature are generally in the thermal equilibrium with the neutral temperature. Recently, an anomalous enhancement of the ambipolar diffusion coefficient which could not be explained by the neutral temperature enhancement (hereafter called the anomalous enhancement) was observed by the meteor radar installed at Tromsoe, Norway (69.6 deg. N, 19.2 deg. E)
A previous study compared the anomalous enhancement with the ion velocity and the ion and electron temperature observed by EISCAT radar (Tsutsumi et al. 2017, Proceedings of the 30th Atmospheric Science Symposium, 2017). They reported that the anomalous enhancement tended to appear with the enhancement of ion velocity and electron temperature and frequently appeared at 16 UT. Furthermore, the anomalous enhancement was not seen during an event of the high energy particle precipitation on November 17, 2012 although one case study. Thus, the anomalous enhancement seems to be generated by the intense electric field and the high energy particle precipitation is not always necessary for its generation. As mentioned above, the previous study revealed a fundamental characteristics of the anomalous enhancement, however the generation mechanisms of the anomalous enhancement is still unclear. To clarify this, the comparison the spatial distribution of the anomalous enhancement with the convective electric field are needed. However, to date the latitudinal and local time occurrence of the anomalous enhancement was not revealed in the polar region.
Three meteor radars have been installed at Tromsoe, Bear island (74.5 deg. N, 19.0 deg. E), and Longyearbyen (78.2 deg. N, 16.2 deg. E). These meteor radars almost align on the same longitude line and can provide the spatial distribution of the anomalous enhancement. All meteor radars are a commercially produced VHF system (ENDR8-20) manufactured by ATRAD Pty Ltd. The antennas were produced by the Arctic University of Norway (Nozawa et al., 2012, JGR; Hall et al., 2002, GRL, Hall et al., 2006, JASTP). In this study, the spatial distribution and the occurrence rate of the anomalous enhancement was derived by these meteor radars.
Peaks of occurrence rate was seen at 20-22, 19-21, 16-19 MLT (~UT+3) at Tromsoe, Bear island, and Longyearbyen latitudes, respectively. This indicates that the anomalous enhancement appeared sequentially from high to low latitudes. In the morning sector, the peak of occurrence rate was only seen at 2-6 MLT above Bear island. In the case of high geomagnetic activity (Kp>3), the evening peaks of the occurrence rate shifted to an earlier time. On the other hand, clear peaks of the occurrence rate in the morning sector appeared at 3-5, 4-8, 7-10 MLT, respectively. Furthermore, the anomalous enhancement appeared with high possibility of 90% around 100 km south of Tromsoe. These characteristics which are seen during the time interval of high geomagnetic activity showed good agreement with the geomagnetic activity dependences of convective electric field.

©2019. Japan Geoscience Union. All Right Reserved. 

We found another interesting characteristic in the geomagnetic dependence of the occurrence of the anomalous enhancement. The peak of occurrence rate in the evening sector was larger than it observed in the morning sector. This is considered to be related that auroral arcs appearing with intense electric field mainly observed in the evening sector. Thus, the generation of anomalous enhancement seems to relate both the convective electric field and the appearance of auroral arcs.
In this presentation, we will show the spatial distribution, MLT and geomagnetic activity dependence of the anomalous enhancement. We will also intend to present the comparison it with the electric filed observed by EISCAT and EISCAT Svalbard radars

# Progress of ICSWSE and MAGDAS project in recent years

*Shuji Abe[1], Akimasa Yoshikawa[2,1], Teiji Uozumi[1], Akiko Fujimoto[3]

1. International Center for Space Weather Science and Education, Japan, 2. Department of Earth and Planetary Sciences, Kyushu University, 3. Kyushu Institute of Technology

International Center for Space Weather Science and Education (ICSWSE), Kyushu University is the research institute for conducting research and education in space weather. Our magnetometer array named as "MAGDAS/CPMN (MAGnetic Data Acquisition System/Circum-pan Pacific Magnetometer Network)" (Principal Investigator: Dr. A. Yoshikawa) has over seventy fluxgate magnetometers, one induction magnetometer, and four FM-CW (Frequency Modulated Continuous Wave) radars around the world. One of our recent research topics is Equatorial Electrojet (EEJ). We calculate EE-index (Uozumi et al, 2008; Fujimoto et al., 2016) for space weather nowcast/forecast using realtime magnetometer data along the magnetic equator, and update it at each hour on the website (http://data.icswse.kyushu-u.ac.jp/eeindex/). To accelerate the understanding of EEJ structure, we constructed dense magnetometer array near magnetic equator at Peru and Malaysia in recent year. In addition, we finished to install new FM-CW radar at Sicaya, Peru. The instrument works well current now. We are providing our observational information and data including old project via our website ( http://data.icswse.kyushu-u.ac.jp/). We also provide them via IUGONET (Inter-university Upper Atmosphere Observation NETwork) Type-A (http://search.iugonet.org/) which is one-stop web service system for researchers to search data, get the information of data, and plot data, and SPEDAS (Space Physics Environment Data Analysis System)/UDAS (iUgonet Data Analysis System). We will provide them via SuperMAG (http://supermag.jhuapl.edu/) in the near future. For accelerating the usage of MAGDAS and its science, we held a tutorial session in International Conference on Space Weather and Satellite Application 2018 at Malaysia, for handling MAGDAS and other data related our research field by using IUGONET system. We believe researchers use MAGDAS data on proper rule and develop their science. We will introduce other research activities in ICSWSE and MAGDAS project, for example, plasma bubble, geomagnetically induced current, and so on.

# Status of GNU Radio Beacon Receiver 2 (GRBR2) development

*Mamoru Yamamoto[1], Mayumi Matsunaga[2], Roland Tsunoda[3]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Tokyo University of Technology, 3. SRI International

GNU Radio Beacon Receiver (GRBR) is the very successful digital receiver developed for dual-band (150/400MHz) beacon experiment. We were successfully conducted observations of total-electron content (TEC) of the ionosphere over Japan and in southeast Asia. However, many beacon satellites is now aging, and its number is decreasing. We now have a project to start new satellite-ground beacon experiment with new satellite constellations. One of them is TBEx (Tandem Beacon Explorer), a project by SRI International, to fly a constellation of two 3U cubesats with triband beacon transmitters. Another one is a project of FORMOSAT-7/COSMIC-2 by Taiwan/USA. Well-known mission of COSMIC-2 is GNSS occultation experiment, but the satellites carry triband beacon transmitters. All of these satellites will be placed into low-inclination orbits by the same launch vehicle in 2018, which will give us great opportunities to enhance studies of the low-latitude ionosphere. We develop a new digital receiver, GRBR2, for these new satellite beacon. GRBR2 is a four channel receiver at 150/400/965/1067MHz beacon signals from two satellite constellations. Now The reveiver system was finally fixed. Problem of the project of delay of the satellite launch. But it is now on schedule for launch by 2019 summer. We start deploying GRBR2 in southeast Asian countries. In this presentaiton, we will report GRBR2 system and its performance including results from test experiment in the field.

# Statistical comparison between plasma bubble day-to-day variability and neutral atmosphere by using GPS scintillation and GAIA model

*Mamoru Yamamoto[1], Keigo Kono[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

Equational plasma bubble is one of the most intense irregularities in the ionosphere. The occurrence of the plasma bubble is considered related to weak changes of the underlying atmosphere which is called large-scale wavelike structure (LSWS). The LSWS is expected formed by penetration of the atmospheric wave into the ionosphere. But its real effect is not yet known in detail. The purpose of this research is to investigate the correlation between the neutral atmosphere and day-to-day variability of equatorial plasma bubbles mainly in the Southeast Asia region. We based on the study by Yamamoto et al (2018) that showed relationship between 40-km height temperature variation and S4 index over Kototabang, Indonesia. In this study we tried to extend the observation region and also tried to elucidate atmospheric waves that are related to the plasma bubble. For indicating activity of the plasma bubble, we used S4 index of GPS scintillation measured by ISEE, Nagoya Univ. at Kototabang, Indonesia. Atmospheric data were taken from GAIA database prepared by NICT. We analyzed data from 2003, 2004, 2012, and 2013 where the solar activity was high. Overall correlation between S4 index and the atmospheric temperature showed similar feature throughout these years. However, even when we tried to extract atmospheric wave components from the GAIA data, the correlation between the wave parameter to S4 index did not show large change. This means that the elucidation of the atmospheric wave component was not very successful so far. Further analyses are required.

# Redevelopment of the MU radar transceiver-module control system

*Mamoru Yamamoto[1], Koki Kurokawa[1], Hiroyuki Hashiguchi[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

The MU radar was installed in Shigaraki, Japan in 1984 as the world first atmospheric radar with active phased-array antenna system. The MU radar consists of 475 Yagi antennas in the circular field of about 100m diameter. By the electronic phase shift of each Yagi, the antenna beam is steered to one of pre-selected 2048 directions in the transmitting pulse-to-pulse basis. Success of the MU radar in the atmospheric/ionospheric research is well known, and its active phased-array configuration was followed by many other radar systems. The phase control of the MU radar is realized by the control of its transceiver-module (TR-module) that are equipped with each Yagi antenna. They are gathered into 25 groups of each 19 modules. One CPU (microcomputer board) is used for control of one group of modules. A weak point of the MU radar exists in this point because we are using the original 8085 CPU board that is connected to the host computer by 1200-baud (!) serial line. This control is very slow, and we could not meet demands for rapid change of observation parameters for long time. This time we tried to re-develop the new TR-module controller by using recent CPU board and electronic devices. In the presentation, we show hardware/software of the newly developed prototype of the MU radar TR-module controller.

Keywords: MU radar, control system, redevelopment

[E] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Thu. May 30, 2019 5:15 PM - 6:30 PM JST | Thu. May 30, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_2

## [P-EM15] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environment Research), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University)

The Earth accepts vast input of energy and material from the Sun. The Earth's environment is maintained by the balance between their inputs and outputs. It is therefore important to study energy and mass transport on the Earth. This is an international session that discusses studies of the coupling processes in the Sun-Earth system based on the project "Study of coupling processes in solar-terrestrial system" that was approved by the Master Plan 2011/2014/2017 of Science Council of Japan. We continue proposing the project to the Master Plan 2020. The facilities and networks included are Equatorial MU Radar (EMU) in Indonesia to study the whole equatorial atmosphere, the EISCAT_3D radar system in northern Scandinavia to study detailed structures and elementary processes of the magnetosphere-ionosphere coupling in the polar region, and global networks of various ground-based instruments and observation data. We will show the current status of the project and discuss sciences by soliciting variety papers. This session is open to the world, and we strongly encourage submission of papers related to other facilities and projects, i.e., atmospheric or incoherent scatter radars, observation networks, satellites, and simulation or theoretical studies, etc.

# Study on adaptive clutter rejection system using external receiving antennas for the MU radar

*Hiroyuki Hashiguchi[1], Issei Terada[1], Mamoru Yamamoto[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

Strong clutter echoes from a hard target such as a mountain or building sometimes cause problems of observations with atmospheric radars. In order to reject or suppress ground clutter echoes, it is effective to use NC-DCMP (Norm Constrained- Directionally Constrained Minimum Power) method, which makes null toward the direction of the clutter, if we can receive signals independently from plural antennas [Nishimura et al., JTech., 2012]. It has been demonstrated that the NC-DCMP method is effective to real observation data with the MU (Middle and Upper atmosphere) radar [Hashiguchi et al., Radio Sci., 2018]. Although NC-DCMP method suppresses clutter echoes with almost maintaining the shape of main lobe to add pseudo-noise compared with the conventional DCMP method, the signal-to-noise ratio (S/N) of atmospheric echoes is somewhat degraded. We studied the clutter suppression method with little S/N degradation by using external antennas.

Four turnstile antennas are installed in the MU radar site. The signal from the antenna is sent to the MU radar observation room through the coaxial cable after amplified by the LNA with the limiter and BPF. It is further amplified by the LNA in the observation room, and then down-converted to intermediate frequency (5 MHz) signal to input to the multi-channel receiving system of the MU radar.

We compared the NC-DCMP method using the each received data of 25 channels, which is a conventional clutter suppression method, and the NC-DCMP method using the simple combination of 25 channels and 4 channels of external antennas. In the former case, the S/N of the atmospheric echoes is somewhat degraded, but in the latter case the main lobe shape is guaranteed by 25 channel simple synthesis, so the S/N degradation is not observed. In the latter case, the clutter suppression is sometimes insufficient. This cause is considered to be that the current positions of external antennas are biased to the north side. Antenna positions should be optimized in the future.

We can apply the achievement of this study to the Equatorial MU radar (EMU), which is proposed to be constructed at West Sumatera, Indonesia. The EMU system is the similar as the MU radar, but its antenna consists of 1045 Yagi antennas with 55 groups and it has 64 receiver channels.

# Detached cusp aurora for southward IMF

*Kohei Takasu[1], Satoshi Taguchi[1], Keisuke Hosokawa[2]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications

A poleward-moving aurora is a typical phenomenon in the dayside cusp of the high-latitude ionosphere. This aurora usually originates near the equatorward boundary of the cusp, and diminishes near the poleward boundary of the persistent cusp auroral emissions. In this study we have examined faint poleward-moving auroras that are detached from the persistent cusp emissions by analyzing 630-nm aurora image data from an all-sky imager at Longyearbyen, Svalbard, and precipitating electron data from DMSP spacecraft. These auroras occur for southward IMF, and are located at latitudes higher than 80 MLAT. The intensities are very weak (less than 1 kilo Rayleigh). The result of the analysis shows that the speed of the auroral motion is 1 to 2 km/s, which is faster than typical convection speed in the dayside polar cap. We show the similarities and differences between the faint aurora and the typical poleward moving cusp aurora, and discuss how soft electron precipitation occurs in the region that is well separated from the cusp.

Keywords: Aurora, cusp, plasma convection, IMF

# Motion of the inverted-V structure during an isolated substorm

*Morio Tanaka[1], Satoshi Taguchi[1], Kohei Takasu[1], Tomokazu Oigawa[1], Keisuke Hosokawa[2]

1. Department of Geophysics, Graduate school of science, Kyoto University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications

The inverted-V is an energetic electron precipitation event, which can be seen as a V-shape structure in electron flux spectrograms, and causes intense auroral arcs. Previous studies have suggested that the inverted-V structure can move fast poleward or equatorward. However, we still do not understand what drives its motion. In this study we have investigated the detailed characteristics of an inverted-V structure moving poleward, which occurred during an isolated substorm, using simultaneous observations of auroras, precipitating electrons, and field-aligned currents. We analyzed aurora data (630-nm and 557.7-nm) from an all-sky imager at Longyearbyen, Svalbard, and precipitating electrons and magnetic field data from the DMSP spacecraft (F16, F17, F18, F19). One of the interesting characteristics of the poleward-moving inverted-V is the appearance of a downward field-aligned current equatorward of and adjacent to the inverted-V. We discuss how the region of the downward field-aligned current evolves in association with the motion and growth/decay of the inverted V structure, and possibility of a role of the downward field-aligned current for the latitudinal motion of the inverted V.

Keywords: Field-aligned current, aurora, inverted-V, isolated substorm

# Observation and modeling of Na layer response to energetic particle precipitation

*Takuo T. Tsuda[1], Kyogo Takizawa[1], Ryo Tozu[1], Takuya Kawahara[2], Yoshimasa Tanaka[3], Mitsumu K. Ejiri[3], Takanori Nishiyama[3], Takuji Nakamura[3]

1. The University of Electro-Communications, 2. Shinshu University, 3. National Institute of Polar Research

Metallic layers, such as Na, Fe, Mg, K, and Ca layers, exist in the mesosphere and lower thermosphere (MLT). The height range of the MLT region corresponds to the ionospheric *D* and *E* regions, and in the polar region energetic particles precipitating from the magnetosphere can often penetrate into the *E* region and even into the *D* region. Therefore, the influence of energetic particles on the metallic layers is of interest regarding changes in atmospheric composition accompanied by auroral activity or geomagnetic activity.

In this study, we have performed a statistical investigation on relationship between Na density and cosmic noise absorption (CNA), which were obtained from 2000 to 2002 at Syowa Station, Antarctic (69.0ºS, 39.6ºE). From the investigation, we found the Na density decrease in accordance with the CNA increase, i.e., increase in the energetic particle precipitation. In the presentation, we will show these observational results, and discuss causality about the observed relationship based on numerical caculations using our Na chemistry model.

# Lidar data analysis of the sodium atoms in the thermosphere observed at Tromsoe, Norway

*Takuya Kawahara[1], Satonori Nozawa[2], Norihito Saito[3], Takuo T. Tsuda[4], Toru Takahashi[5], Testuya Kawabata[2], Miki Nishimura[1], Yoshitaka Kobayashi[1]

1. Faculty of Engineering, Shinshu University, 2. ISEE, Nagoya University, 3. RIKEN, Center for Advanced Photonics, 4. The University of Electro-Communications, 5. National Institute of Polar Research

Distribution of low-density Na atoms in the thermosphere is interesting because of the capability of measuring neutral temperature and wind into the lower thermosphere up to 140 km. The thermospheric Na atoms significantly made the altitude range of Na lidar measurements expanded from the 80–105 km to 80–140 km, covering almost the entire E region (Liu et al., GRL, 2016).

The measurements of wind and temperature by a Na lidar in the northern mesosphere (80-105 km) at Tromsoe, Norway (69.6˚N, 19.2˚E) have been carried out in Polar winter season since 2010. However, thermospheric Na has not been seen in our data so far. This is because the automatic analysis program calculates the background signal level using the 140-150 km signals which possibly include a small amount of thermospheric Na signal. Deriving thermospheric Na is done by lowering the background signal level to emphasize thermospheric Na signals. The data at the new moon are selected which have a low background signal. Also, we calculated signal intensity from the Na atoms in the thermosphere based on our lidar parameters such as laser power, a telescope aperture area etc. by using the lidar equation. The results are summarized as follows. (1) Assuming that the Na density is 10 /cm^3, the signal from the Na atoms between 120 and 140 km is expected 300-400 photons, (2) The background signal observed is about 4,400 counts which means the noise level is about 220. So the signal intensity from the Na is nearly comparable to the noise level. (3) Thermospheric Na was not clearly seen in the re-calculated data. However, it depends on the smoothing technique to the original lidar data.

In this talk, we show the results derived by varying the binning time and discuss it.

Keywords: Na lidar, thermosphere, Tromsoe

# Spatial-temporal distribution of anomalous enhancement of ambipolar diffusion coefficient observed by meteor radars installed in the polar region

*Toru Takahashi[1], Masaki Tsutsumi[1,2], Yasunobu Ogawa[1,2,3], Satonori Nozawa[3], Chris Hall[4], Hiroshi Miyaoka[1,2]

1. National Institute of Polar Research, 2. SOKENDAI, 3. Institute for Space-Earth Environmental Research, 4. TGO, The Arctic University of Norway

The meteor radar detected echoes of meteor tails as a tracer of neutral wind from 75 to 100 km altitudes (Hall et al., 2005). In addition, by using a decay time of the echo power, the meteor radar also estimated the ambipolar diffusion coefficient, which depends on the ion and electron temperature. The ambipolar diffusion coefficient was utilized to estimate the neutral temperature because the ion and electron temperature are generally in the thermal equilibrium with the neutral temperature. Recently, an anomalous enhancement of the ambipolar diffusion coefficient which could not be explained by the neutral temperature enhancement (hereafter called the anomalous enhancement) was observed by the meteor radar installed at Tromsoe, Norway (69.6 deg. N, 19.2 deg. E)
A previous study compared the anomalous enhancement with the ion velocity and the ion and electron temperature observed by EISCAT radar (Tsutsumi et al. 2017, Proceedings of the 30th Atmospheric Science Symposium, 2017). They reported that the anomalous enhancement tended to appear with the enhancement of ion velocity and electron temperature and frequently appeared at 16 UT. Furthermore, the anomalous enhancement was not seen during an event of the high energy particle precipitation on November 17, 2012 although one case study. Thus, the anomalous enhancement seems to be generated by the intense electric field and the high energy particle precipitation is not always necessary for its generation. As mentioned above, the previous study revealed a fundamental characteristics of the anomalous enhancement, however the generation mechanisms of the anomalous enhancement is still unclear. To clarify this, the comparison the spatial distribution of the anomalous enhancement with the convective electric field are needed. However, to date the latitudinal and local time occurrence of the anomalous enhancement was not revealed in the polar region.
Three meteor radars have been installed at Tromsoe, Bear island (74.5 deg. N, 19.0 deg. E), and Longyearbyen (78.2 deg. N, 16.2 deg. E). These meteor radars almost align on the same longitude line and can provide the spatial distribution of the anomalous enhancement. All meteor radars are a commercially produced VHF system (ENDR8-20) manufactured by ATRAD Pty Ltd. The antennas were produced by the Arctic University of Norway (Nozawa et al., 2012, JGR; Hall et al., 2002, GRL, Hall et al., 2006, JASTP). In this study, the spatial distribution and the occurrence rate of the anomalous enhancement was derived by these meteor radars.
Peaks of occurrence rate was seen at 20-22, 19-21, 16-19 MLT (~UT+3) at Tromsoe, Bear island, and Longyearbyen latitudes, respectively. This indicates that the anomalous enhancement appeared sequentially from high to low latitudes. In the morning sector, the peak of occurrence rate was only seen at 2-6 MLT above Bear island. In the case of high geomagnetic activity (Kp>3), the evening peaks of the occurrence rate shifted to an earlier time. On the other hand, clear peaks of the occurrence rate in the morning sector appeared at 3-5, 4-8, 7-10 MLT, respectively. Furthermore, the anomalous enhancement appeared with high possibility of 90% around 100 km south of Tromsoe. These characteristics which are seen during the time interval of high geomagnetic activity showed good agreement with the geomagnetic activity dependences of convective electric field.

©2019. Japan Geoscience Union. All Right Reserved. 

We found another interesting characteristic in the geomagnetic dependence of the occurrence of the anomalous enhancement. The peak of occurrence rate in the evening sector was larger than it observed in the morning sector. This is considered to be related that auroral arcs appearing with intense electric field mainly observed in the evening sector. Thus, the generation of anomalous enhancement seems to relate both the convective electric field and the appearance of auroral arcs.
In this presentation, we will show the spatial distribution, MLT and geomagnetic activity dependence of the anomalous enhancement. We will also intend to present the comparison it with the electric filed observed by EISCAT and EISCAT Svalbard radars

# Progress of ICSWSE and MAGDAS project in recent years

*Shuji Abe[1], Akimasa Yoshikawa[2,1], Teiji Uozumi[1], Akiko Fujimoto[3]

1. International Center for Space Weather Science and Education, Japan, 2. Department of Earth and Planetary Sciences, Kyushu University, 3. Kyushu Institute of Technology

International Center for Space Weather Science and Education (ICSWSE), Kyushu University is the research institute for conducting research and education in space weather. Our magnetometer array named as "MAGDAS/CPMN (MAGnetic Data Acquisition System/Circum-pan Pacific Magnetometer Network)" (Principal Investigator: Dr. A. Yoshikawa) has over seventy fluxgate magnetometers, one induction magnetometer, and four FM-CW (Frequency Modulated Continuous Wave) radars around the world. One of our recent research topics is Equatorial Electrojet (EEJ). We calculate EE-index (Uozumi et al, 2008; Fujimoto et al., 2016) for space weather nowcast/forecast using realtime magnetometer data along the magnetic equator, and update it at each hour on the website (http://data.icswse.kyushu-u.ac.jp/eeindex/). To accelerate the understanding of EEJ structure, we constructed dense magnetometer array near magnetic equator at Peru and Malaysia in recent year. In addition, we finished to install new FM-CW radar at Sicaya, Peru. The instrument works well current now. We are providing our observational information and data including old project via our website ( http://data.icswse.kyushu-u.ac.jp/). We also provide them via IUGONET (Inter-university Upper Atmosphere Observation NETwork) Type-A (http://search.iugonet.org/) which is one-stop web service system for researchers to search data, get the information of data, and plot data, and SPEDAS (Space Physics Environment Data Analysis System)/UDAS (iUgonet Data Analysis System). We will provide them via SuperMAG (http://supermag.jhuapl.edu/) in the near future. For accelerating the usage of MAGDAS and its science, we held a tutorial session in International Conference on Space Weather and Satellite Application 2018 at Malaysia, for handling MAGDAS and other data related our research field by using IUGONET system. We believe researchers use MAGDAS data on proper rule and develop their science. We will introduce other research activities in ICSWSE and MAGDAS project, for example, plasma bubble, geomagnetically induced current, and so on.

# Status of GNU Radio Beacon Receiver 2 (GRBR2) development

*Mamoru Yamamoto[1], Mayumi Matsunaga[2], Roland Tsunoda[3]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Tokyo University of Technology, 3. SRI International

GNU Radio Beacon Receiver (GRBR) is the very successful digital receiver developed for dual-band (150/400MHz) beacon experiment. We were successfully conducted observations of total-electron content (TEC) of the ionosphere over Japan and in southeast Asia. However, many beacon satellites is now aging, and its number is decreasing. We now have a project to start new satellite-ground beacon experiment with new satellite constellations. One of them is TBEx (Tandem Beacon Explorer), a project by SRI International, to fly a constellation of two 3U cubesats with triband beacon transmitters. Another one is a project of FORMOSAT-7/COSMIC-2 by Taiwan/USA. Well-known mission of COSMIC-2 is GNSS occultation experiment, but the satellites carry triband beacon transmitters. All of these satellites will be placed into low-inclination orbits by the same launch vehicle in 2018, which will give us great opportunities to enhance studies of the low-latitude ionosphere. We develop a new digital receiver, GRBR2, for these new satellite beacon. GRBR2 is a four channel receiver at 150/400/965/1067MHz beacon signals from two satellite constellations. Now The reveiver system was finally fixed. Problem of the project of delay of the satellite launch. But it is now on schedule for launch by 2019 summer. We start deploying GRBR2 in southeast Asian countries. In this presentaiton, we will report GRBR2 system and its performance including results from test experiment in the field.

Keywords: Satellite beacon experiment, Digital receiver development, Total electron content

# Statistical comparison between plasma bubble day-to-day variability and neutral atmosphere by using GPS scintillation and GAIA model

*Mamoru Yamamoto[1], Keigo Kono[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

Equational plasma bubble is one of the most intense irregularities in the ionosphere. The occurrence of the plasma bubble is considered related to weak changes of the underlying atmosphere which is called large-scale wavelike structure (LSWS). The LSWS is expected formed by penetration of the atmospheric wave into the ionosphere. But its real effect is not yet known in detail. The purpose of this research is to investigate the correlation between the neutral atmosphere and day-to-day variability of equatorial plasma bubbles mainly in the Southeast Asia region. We based on the study by Yamamoto et al (2018) that showed relationship between 40-km height temperature variation and S4 index over Kototabang, Indonesia. In this study we tried to extend the observation region and also tried to elucidate atmospheric waves that are related to the plasma bubble. For indicating activity of the plasma bubble, we used S4 index of GPS scintillation measured by ISEE, Nagoya Univ. at Kototabang, Indonesia. Atmospheric data were taken from GAIA database prepared by NICT. We analyzed data from 2003, 2004, 2012, and 2013 where the solar activity was high. Overall correlation between S4 index and the atmospheric temperature showed similar feature throughout these years. However, even when we tried to extract atmospheric wave components from the GAIA data, the correlation between the wave parameter to S4 index did not show large change. This means that the elucidation of the atmospheric wave component was not very successful so far. Further analyses are required.

# Redevelopment of the MU radar transceiver-module control system

*Mamoru Yamamoto[1], Koki Kurokawa[1], Hiroyuki Hashiguchi[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

The MU radar was installed in Shigaraki, Japan in 1984 as the world first atmospheric radar with active phased-array antenna system. The MU radar consists of 475 Yagi antennas in the circular field of about 100m diameter. By the electronic phase shift of each Yagi, the antenna beam is steered to one of pre-selected 2048 directions in the transmitting pulse-to-pulse basis. Success of the MU radar in the atmospheric/ionospheric research is well known, and its active phased-array configuration was followed by many other radar systems. The phase control of the MU radar is realized by the control of its transceiver-module (TR-module) that are equipped with each Yagi antenna. They are gathered into 25 groups of each 19 modules. One CPU (microcomputer board) is used for control of one group of modules. A weak point of the MU radar exists in this point because we are using the original 8085 CPU board that is connected to the host computer by 1200-baud (!) serial line. This control is very slow, and we could not meet demands for rapid change of observation parameters for long time. This time we tried to re-develop the new TR-module controller by using recent CPU board and electronic devices. In the presentation, we show hardware/software of the newly developed prototype of the MU radar TR-module controller.

Keywords: MU radar, control system, redevelopment

[J] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Thu. May 30, 2019 3:30 PM - 5:00 PM JST | Thu. May 30, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

## [P-EM16] Physics and Chemistry in the Atmosphere and Ionosphere

convener:Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Takuya Tsugawa(National Institute of Information and Communications Technology), Seiji Kawamura(National Institute of Information and Communications Technology)

This session covers a broad scope of studies of physics and chemistry in the atmosphere and the ionosphere. Coupling processes between plasma and neutral species, and upward and downward coupling among lower/upper atmosphere, and ionosphere/mesosphere/thermosphere including magnetosphere are discussed. We solicit papers based on experiments with ground-based and/or space-borne instruments, theoretical studies, numerical simulations, and development of new observation techniques.

### [PEM16-P01] Temporal and spatial variation of GPS phase scintillation during substorms and auroral breakups

The ionospheric structure caused by precipitation of high energy particles can adversely affect the GPS causing phase scintillation and cycle slip (loss of lock). GPS phase scintillation correlates with the intensity of the aurora, especially the rapid change in the auroral brightness [1,2,3]. Enhancement of the total electron content (TEC) observed during the substorm expansion phase in the night side downward region 1 current seems to be related to intense precipitation particle flux [4]. Such TEC enhancements cause phase scintillation that is most intense just after substorm onsets and auroral breakups. Phase scintillation index is computed for sampling rate of 50 Hz by specialized GPS scintillation receivers from the Canadian High Arctic Ionospheric Network (CHAIN). A proxy scintillation index is obtained from dual frequency measurements of geodetic-quality GPS receivers sampling at 1 Hz, which include globally distributed receivers of RT-IGS network that are monitored by the Canadian Geodetic Survey in near-real-time. Temporal and spatial changes of TEC and phase scintillation are investigated in the context of equivalent ionospheric currents derived from ground magnetometer network using the spherical elementary current method [5,6]. The relation of phase scintillation with auroral emission is also examined. In general, GPS phase scintillation maps to regions of strong westward electrojet and to the poleward edge of the eastward electrojet. Following substorm onsets and auroral breakups, strong phase scintillation associated with TEC enhancements are mapped mainly to the upward region 2 current or the equatorward edge of the downward region 1 current at or near the Harang discontinuity region [7].

# Statistical study of SAPS occurrence characteristics using the SuperDARN Hokkaido HF radar

*Kento Oya[1], Nozomu Nishitani[1], Tomoaki Hori[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

We investigate the occurrence characteristics of Sub-Auroral Polarization Streams (SAPS), using the Super Dual Auroral Radar Network (SuperDARN) Hokkaido East radar. The ultimate goal is to clarify the longitudinal dependence of SAPS occurrence characteristics using the whole SuperDARN radars. In this study, we statistically analyzed about 10-year data from 2007/1/1 to 2016/12/31 and studied the occurrence rate of the flow that can be considered as SAPS, vs MLT and MLAT. Assuming that the flows are east-west oriented, we set the criteria for line of sight velocity of > 80 m/s and echo power of > 3dB. We obtained the overall characteristics of SAPS, i.e., equatorward shift of high occurrence rate region with increasing MLT and geomagnetic activity. Some of the characteristics are different from previous studies. The SAPS regions seem to be located at higher latitudes than the previous studies and the SAPS occurrence peak regions are located at later MLT. These differences might be due to the difference in geographic longitude (Far-East Siberia to Pacific vs North American region). We also found new feature, i.e, westward flows from midnight to morning at relatively low geomagnetic latitudes, that could not be caught in the previous studies probably due to the limitation of radars fields of view, especially lower latitude boundary.

# Spectral investigations of near infrared aurora and airglow at 1.0-1.6 microns: 1-year ground-based imaging spectroscopic observation at Syowa station (69.0˚S, 39.6˚E)

*Takanori Nishiyama[1], Takeshi Sakanoi[2], Makoto Taguchi[3], Hidehiko Suzuki[4]

1. National Institute of Polar Research, 2. Planetary Plasma and Atmospheric Research Center, Tohoku University, 3. Rikkyo University, 4. Department of Physics, Meiji University

The motivation of this study is further understanding of dayside magnetosphere and terrestrial atmosphere coupling system by using continuous observation. Dayside aurora, polar patch, and airglow should be key phenomena for the understanding. In particular, those phenomena in near infrared (NIR) wavelength are crucially important because lower background sky luminosity by Rayleigh scattering may allow us to conduct ground-based optical observation even in dayside. Continuous dayside optical monitoring with high temporal and spatial resolutions in aurora region and cusp give us a clue to understanding of substorm pre-onset sequences at cusp region, magnetopause dynamics related to solar wind shocks, and wave-particle interactions due to electromagnetic ion cyclotron waves and whistler mode chorus. However, NIR aurora has a total lack of its spectral information with enough resolution to make a feasibility study in comparison to that in visible wavelength.

We designed a narrow field spectrometer with medium-high spectral resolution that mainly consists of Czerny-Turner type imaging spectrometer (HORIBA, iHR320) with one entry port and two exit ports. This spectrometer has two mirrors and three diffractive gratings in a rotating turret. A toroidal mirror for collimating corrects for astigmatism so that the tangential (resolution optimized) and sagittal (imaging optimized) focal planes cross at the center of the focal plane. Another larger focus mirror allows the entire flat field to be used without vignetting. Collecting optics, equipped outside the spectrometer, are a gold coated off-axis parabolic mirror and a NIR longpass filter for removal of secondary diffracted light in visible wavelength. Using 1-d InGaAs array (1024 pixels) and 600 gr/mm grating, spectral range and spectral range per pixel are 119 nm and 0.11 nm/pixel, respectively.

We started ground-based spectroscopic observation in NIR wavelength ranging from 1.0 to 1.6 microns, which covers strong OH airglow emissions and auroral emissions in $N_2$1st Positive (1.2 microns) and $N_2^+$ Meinel (1.1 and 1.5 microns) [Jones 1974; Zhou et al., 2007], at Syowa Station (69.0˚S, 39.6˚E) in Antarctica from March 2018. OH airglow spectrum in NIR can be well resolved even in water vapor absorption region. OH rotational temperature is successfully estimated using OH 3-1 band P1(2) and P1(4) emissions. However, auroral emissions were not clearly identified at 1.52 micron (N2+ Meinel) so far. Further investigations are needed including 1.10 micron (N2+ Meinel) and 1.24 micron (N2 1P). In this presentation, we are going to report results in more detail based on one year observation.

# The study of the lower ionosphere in the South Atlantic Anomaly (SAA) Region

*Chih-Yu Chiang[1], Tzu-Fang Chang[2,1], Sunny W. Y. Tam[1]

1. Institute of Space and Plasma Sciences, National Cheng Kung University, Tainan, Taiwan, 2. Institute for Space-Earth Environmental Research, Nagoya University, Japan

South Atlantic Anomaly (SAA) corresponds to a region where the geomagnetic field is relatively weak; such a magnetic field enables energetic particles from the inner radiation belt to penetrate closer to the Earth's surface more easily, thus resulting in relatively high level of radiation in the environment. In this study, we analyze the nighttime airglows in 2007 to 2008 in the SAA region by using the data from the ISUAL (Imager of Sprites and Upper Atmospheric Lightning) experiment aboard the FORMOSAT-2 satellite. We focus specifically on the measurements by the six spectrophotometers and the CCD Imager, which overall cover the spectrum from ultraviolet to infrared wavelengths. Based on our analysis, features of clear enhancements and annual variations at 337 nm, 391.4 nm and 777.4 nm are identified in the SAA region. Through comparing these multiple-band emissions, we can identify energy variation of incident particles and atmospheric compositions of SAA region.

# Multi-GNSS observation of LSTID in Japan and its link with auroral activities

*Mayumi Hashimoto[1], Kosuke Heki[1]

1. Hokkaido University

Interaction between southward magnetic field in solar winds and the Earth’ s magnetosphere causes geomagnetic activities and auroral substorms. The auroral activity is associated with strong electric currents (auroral jet) within the auroral oval. This disturbs the geomagnetic field at high latitude region and is reflected in changes in the AE (Auroral Electrojet) index. At this time, atmospheric gravity waves, generated as a result of the heating of the atmosphere by electric currents, propagate toward the middle and low latitudinal regions and make Large-Scale Traveling Ionospheric Disturbances (LSTID). In this study, we observed ionospheric disturbance in Japan located in middle and low latitudes as the changes in TEC (Total Electron Content). Here we study the relationship between LSTID observed with multiple-GNSS (Global Navigation Satellite System), GPS, GLONASS, Galileo, and QZSS, and short-term changes in the high time resolution AE index time series.

In this study, we used the AE index one minute values from Kyoto University, World Data Center for Geomagnetism (wdc.kugi.kyoto-u.ac.jp). As the GNSS observation point, we used Tsukuba (tskb), one of the IGS observation points in Japan with inter-frequency bias values available. To examine the relationship, we first identified the day when the AE index exceeded 2,000 nT between 2011 and 2017. Then, we converted the RINEX data files of tskb on these days to TEC, removed satellite and receiver biases, and converted them to vertical TEC (VTEC). We compared the AE index and VTEC for 22 cases, and the occurrences of LSTID were confirmed in 5 of them. In these cases, LSTIDs were observed 1 or 2 hours after the peak of the AE index. We estimated the propagation velocity in two ways, i.e. by calculating the time lag between the AE peak and LSTID arrivals in Japan and the distance between the auroral oval and Japan, and by comparing the times of TEC peaks within Japan. Both approaches showed the velocity of ~0.7 km/sec.

Since 2018 summer, the Japanese GNSS network started to track multiple GNSS including the Japanese Quasi-zenith Satellite System (QZSS) and to open the raw data on-line by RINEX 3.02 format. discuss the relationship LSTID and AE index. QZSS includes three satellites with quasi-zenith orbits (PRN01, 02, 03) and one satellite with geostationary orbit (PRN07). Generally speaking, GNSS-TEC data changes by the three reasons, (1) temporal change in ionosphere, (2) spatial change in ionosphere, and (3) apparent change by changes in satellite elevation angle. However, QZSS-TEC includes only (1), and useful in studying ionospheric disturbances without bothering about (2) and (3).

Keywords: LSTID, TEC, GNSS

# Basic development of accurate analytical method in order to determine coordinates of artificial illuminating clouds of Barium and Strontium for chemical-release rocket experiments

*Taro Watanabe[1], Masa-yuki Yamamoto[1], Yoshihiro Kakinami[2]

1. Kochi University of Technology, 2. Hokkaido Information University

In order to investigate neutral atmospheric heating phenomenon in the polar cusp, it is necessary to estimate Joule heating and fluctuation of electric field in the cusp. To accomplish this, we conducted a US-Japan joint rocket experiment called the Cusp Region Experiment 1 (CREX-1) in the Arctic region in November 2014, with releasing Ba (to be ionized in a short time by extreme ultraviolet (EUV) from the Sun) and Sr (not ionized in a short time). And then, we observed resonance scattering emission of $Ba^+$ and Sr simultaneously from two sites on ground so as to obtain fluctuation of the electric field and Joule heating. However, we could not release the gases in the cusp at that time. We are planning additional space experiments, based on the CREX-1 results, using two sounding rockets of the Cusp Region Experiment 2 (CREX-2) and the Joint Japan-US Cusp Heating Investigation (CHI) aiming at observing of the cusp in December 2019.

In this study, we developed a basis of accurate analytical method in order to determine coordinates of artificial illuminating cloud with applying observed data of CREX-1. At the beginning of the analysis, we made calibration data from the RAW images taken at a previous optical system tests. We compared the exposure input-output characteristics of JPEG and RAW to establish an analysis method using RAW images instead of JPEG. Next, we investigated whether it is possible to replace the work of determining centers of the illuminating clouds, which has been carried out by hand, by a method of uniquely determining the luminance maximal by gradient descent method. In addition, we made a background image by a darken composition method and attempted to remove the background brightness gradient trend.

As a result, the characteristics of JPEG image reported by Kakinami et al. (2015) were thought to be arcuate gamma curves, but in RAW images, they were obtained as linear characteristics. Regarding the gradient descent method, although it is possible to uniquely determine the luminance maximal without any human factors, it was found that there is a possibility that the local maximum is not the true center. For background removal by the darken composition method, it is effective for background light gradient removal. However, there is a problem that the shadow of the illuminating clouds appearing in the background image affects the remained shape of the illuminating clouds when removing the background.

Furthermore, we developed an algorithm tracing the three-dimensional position of $Ba^+$/Sr cloud uniquely without any human factors.

# Neutral and plasma density perturbations in the top-/bottom-side ionosphere associated with MSTIDs

*Shin Suzuki[1], Jaeheung Park[2], Yuichi Otsuka[3], Kazuo Shiokawa[3], Huixin Liu[4], Hermann Luehr[5]

1. Faculty of Regional Policy, Aichi University, 2. Korea Astronomy and Space Science Institute, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Earth and Planetary Science Division, Kyushu University SERC, Kyushu University, 5. Helmholtz Centre Potsdam, GFZ, German Research Centre for Geosciences

Medium-scale traveling ionospheric disturbances (MSTIDs) are a well-known wavy structure in the F-region ionosphere. They typically have a horizontal wavelength of several hundred kilometers and a periodicity of about one hour. Although, the MSTIDs were considered to be caused by atmospheric gravity waves, recent studies have suggested that the generation of the MSTID in nighttime is highly associated with coupling processes between the E- and F-region electrodynamics. To confirm the different processes in the MSTID generation in daytime and nighttime, CHAMP satellite measurements would be greatly helpful; CHAMP plasma and neutral density data obtained in the day- and night-side sector can monitor the phase relations between the neutral (i.e., atmospheric gravity wave) and ionospheric plasma perturbations simultaneously at the top-side F-region (approximately 400 km).

As the first step in the abovementioned research, we compared the MSTID signatures between the CHAMP and ground-based 630-nm airglow measurements to validate the MSTID detection by CHAMP. Airglow imaging is a quite useful technique to investigate two-dimensional characteristics of the nighttime MSTIDs. Horizontal parameters of the MSTIDs (such as wavelengths, motions, and their spatial extent) can be estimated directly with a high spatial and temporal resolutions through the 630-nm airglow emission in the bottom-side F-region. Previous study by Park et al. [2009, JGR] made an investigation of spatial signatures regarding one MSTID event using airglow images along the CHAMP orbit. The Institute for Space-Earth Environmental Research, Nagoya University, has operated airglow imaging network, as the OMTI system, around the world since 2000; this network gives much more chance to make coordinated measurements with CHAMP. We found three clear MSTID events (March 15, 2004, February 15, 2007, and January 12, 2007) in which CHAMP passed over the field-of-views of the OMTI camera.

In this presentation, we will report phase relations between the neutral and plasma density perturbations associated with the MSTID events.

# Analysis of ionospheric TEC fluctuation by rocket

*Tsuyoshi Takegawa[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Takuya Tsugawa[2], Michi Nishioka[2]

1. Graduate School of Integrated Science and Technology, Chiba University, 2. National Institute of Information and Communications Technology

It is known that atmospheric waves arised by massive earthquakes, typhoons and volcanic eruptions cause the ionospheric variation. In recent years, ionospheric fluctuations excited by rocket launches have been confirmed (Lin et al., 2014,2017). In case of Taepodong 2, the first wave of TEC fluctuations is confirmed due to the chemical reaction with ionospheric plasmas and the exhaust of the rocket about 5 minutes after the launch and the second wave was confirmed after about 30 minutes from the launch. To examine the ionospheric disturbances apart from the trajectories of rockets, in this study, TEC fluctuation due to the launches of H2A rocket No.25 and No. 29 we examined using GEONET data. The first waves of the TEC fluctuations were confirmed around hundreds kilometers from the rocket trajectory 5 minutes after launch of both of H2A rockets. The first waves appeared as large decreases in VTEC, which is consistent with the previous study of Taepodong 2. Calculating the propagation time of the sound waves from the points on the trajectories of the rockets, the delays correspond to the propagation times from the trajectories to the pierce points of TEC. The second waves were also observed around the 30 minutes after the rocket launches. Calculating the arrival time of sound waves for the second waves, the seconds waves once reflected on the ground were affected by the second waves.

# Examinations of the ionospheric perturbation associated with H-IIA rockets launching

*Junpei Yamazaki[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Keisuke Hosokawa[2], Ichiro Tomizawa[2]

1. Graduate School of Engineering, Chiba University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications

It is reported that ionospheric perturbation are caused by natural hazards, such as giant earthquakes, olcanic eruptions and so on. This is because the infrasound waves generated by natural hazards propagate to the ionospheric. Since rocket launches also generate the atmospheric waves, it is reported that passage and exhaust plumes generate TEC perturbations determined by GEONET data(Lin et al.,2014,2017).
On the other hand, there is few studies about ionospheric perturbation associated with rocket launch away from rocket’ s trajectory. Then, in this study, we analyzed ionospheric perturbations associated with H IIA(No.25 and 26) relatively far trajectory from the Japanese islands using HF Doppler sounding.
The perturbations of Doppler shifts associated with H-IIA No.25 were observed at Kakioka and Sugadaira observatories and those of H-IIA No.26 were observed at Kakioka,Fujisawa and Sugadaira observatories about 35 minutes after the launch. It is confirmed that this delay corresponds to the propagation time of the infrasound wave from the launch site to observation points once reflected on the ground. The frequencies of the disturbance of Doppler shift were 5~10 mHz. Similar disturbances were reported in Lin et al (2014) which examined the TEC disturbances associated with Taepodong. The Doppler shift perturbation is clear when the infrasound wave reached the observation point after reflection on the ground as compared to the case where the infrasound wave reached the observation point directly. When the infrasound wave directly reaches the observation point, it passed through about 200~250km altitude. Where the amplitude of infrasound waves with several 10mHz tend to attenuate. Therefore, ionospheric perturbation at the moment corresponding to the arrived at the direct wave become small.

# Explosion energy derived from the 2015 Kuchinoerabujima eruption: Estimation from infrasound less than 0.01 Hz detected by barometers, seismometers, and TEC

*Yuki Nakashima[1], Kiwamu Nishida[1], Yosuke Aoki[1], Kosuke Heki[2]

1. Earthquake Research Institute, 2. Natural History Sciences, Hokkaido University

This study discusses the amount of energy emitted to the atmosphere as acoustic waves of less than 0.01 Hz by the 2015 Kuchinoerabujima volcano, southwest Japan, eruption derived from barometers, broadband seismometers, and GNSS-TEC observations.
Kuchinoerabujima is one of the volcanic islands of active recently. The volcano erupted at 0:59 UT on 25th May 2015. Many previous studies pointed out that this is a phreatomagmatic eruption and involves a lateral signal (e.g., Kobayashi, 2017; Matsuzawa et al., 2016; Yamada et al., 2017). Yamada et al. (2017) found that barometric data include two phases in about 20 sec. In the first stage, the volcanic plume went up with a pressure pulse, and the second another pulse corresponds to the plume growing laterally. The seismic source time function of that has a component of north-south direction obviously (Matsuzawa et al. 2016).
We found atmospheric disturbances with a characteristic frequency of ~0.01 Hz in all the observations. The frequency range is equivalent to the highest part of the detectable band in the ionosphere. We detected the signal of lower atmospheric perturbation from F-net, an array of broadband seismometers installed by NIED, and a barometer array along the Japanese coastline in front of the Pacific ocean by AIST. As the ionospheric observation, we used GNSS-TEC time series extracted from GEONET 1 Hz sampling data. The waveform feature is very similar to ionospheric disturbances excited by Asama volcano on 1st September 2004 (Heki, 2006; Chonan et al., 2017).
We tried to reproduce the observed signal and estimate the magnitude of the energy source using the ray-tracing method. Atmospheric parameters are inputted from NRLMSISE-00 (Picone et al., 2002), HWM-14 (Drob et al., 2015), IRI2016 (Billitza et al., 2016), and IGRF-12 (Thébault et al., 2015). We put an isotropic energy source on the ground in the windy atmosphere.
The estimated travel time by ray-tracing is consistent with the observation, indicating that the excited atmospheric perturbation simply propagates isotropically without wave broadening due to dispersion discussed in Dautermann et al. (2009a).
If we choose the source energy as $10^8$ J, our model expects about one-third of the observed signal in both the lower atmosphere in the far field and the ionosphere. This amount of energy is $10^{1-2}$ times larger than that of the 2004 Asama eruption estimated from TEC observation (Heki, 2006). It seems to depend on not only the difference of volcanic eruption magnitude but also the crude assumption like ignoring the geomagnetic effect and geometrical spreading same as Dautermann et al. (2009) suggested.
We were not able to find any evidence for anisotropic radiation of energy as stated in some previous studies, suggesting that infrasound of such very low frequencies infrasound (< ~0.01 Hz) responds to with a longer time constant such as the growth of the thermal plume.
Acknowledgment
We would thank GSI, JMA, AIST, and NIED which provide GNSS, barometer, microphone, and broadband seismometer data.

# Detection of spread-F echoes in ionograms using machine learning

*Hiroyuki Nakata[1], Yuta Goto[2], Hiroyo Ohya[1], Toshiaki Takano[1]

1. Graduate School of Engineering, Chiba University, 2. Department of Electrical and Electronics Engineering

Ionospheric irregularities referred to as equatorial spread-F is very important phenomena in terms of radio wave propagation because their spatial scales are from centimeters to tens of kilometer and they affects wide-band radio waves. Therefore, they influence the reliability of satellite-ground communications, navigation systems and so on. The ionogram is one of the important observation system of spread-F. Because the detection of spread-F in the ionogram is done manually, detection of spread-F could be replaced with automatic detection by developing an excellent machine learning system. In this study, therefore, we have developed a method to detect spread-F in the ionogram automatically using machine learning.

In this detection process, we have arranged two classifiers for typical frequency-type and mixed (frequency-type and range-type) spread-F echoes in the ionograms. A number of correct images must be prepared for these classifiers to learn the feature values of spread-F. To do so, ten thousands of correct images were generated by create_samples utility provided by OpenCV library. Using these classifiers, we have detected the both types of spread-F echos in the ionograms observed at 4 observatories (Wakkanai, Kokubunji, Yamagawa, Ogimi) utilized by National Institute of Information and Communications Technology. The detection rates of both types of spread-F echos are from 50% to 73% and both classifier detected both types of spread-F echos similarly. Namely, the classifier for the frequency-type spread-F echo detected both of the frequency-type and mixed-type echos, and vice versa. In case where the two types of spread-F echos are not distinguished, on the other hand, both of classifiers detect 80% of total spread-F echos. In addition, the classifiers also picked up some other phenomenon , such as overlapped traces of O-mode and X-mode, multi-hop trace.

As for the future plan, there might be several way to improve the detection rate; to use more classifiers, to make the classifiers be precisely with more training data, and so on. However, a number of correct images are inevitable in machine learning. In order to prepare such a number of images, it may be effective to generate training data using deep generative model.

# Evaluation of GNSS-TEC receiver performance for sounding rocket installation

*Makoto Okumura[1], Yuki Ashihara[1]

1. National Institute of Technology, Nara College

Earth's atmospheric region ionized electrons by X-rays and ultraviolet rays involved in sunlight is called ionosphere. Ionospheric disturbance causes some problems, e.g., which are terrestrial satellite communication impairment and positioning error of GNSS. For elucidating the generation mechanism of the ionospheric disturbance, we need to observe spatial structure of ionospheric electron density. Ionosphere observation is generally implemented with remote sensing method such as Ionosonde, GNSS-TEC and others. Ionosonde can observe the electron density vertical structure below the altitude of electron density peak in F region, and GNSS-TEC can obtain the total electron content along the radio wave propagation path. However, these methods cannot observe the spatial structure. In this paper, we propose a rocket GNSS-TEC tomography method as a new approach to the ionosphere observation. In this method, we install the GNSS-TEC receiver onboard a sounding rocket, and it is flying the boundary region between the ionospheric E and the F region. It is possible to acquire the TEC data only for the F region.
In case of a combining antenna system installed on the side on sounding rocket, it is simulated that the received signal becomes unstable since the sounding rocket spins at the speed of 1 to 2 Hz. Therefore, we built a structure model of the sounding rocket, and conducted a ground-based rotation experiment. In this experiment, the GNSS carrier phase data was approximately obtained for the steady rotation speed, but TEC value had the variation more than 60 TECU. As the results, we understood that a combining antenna system cannot useful for a rocket GNSS-TEC.

# Relationship between mesosperical airglow disturbance and occurrence of equatorial plasma bubbles

*Ryota Okada[1], Akinori Saito[1], Takafumi Ikeda[1], Hiroyuki Shinagawa[2], Takuya Tsugawa[2], Takeshi Sakanoi[3]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology, 3. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University

762 nm airglow data observed by Ionosphere, Mesosphere, upper Atmosphere and Plasmasphere mapping mission from the ISS / Visible and near Infrared Spectral Imager (ISS-IMAP/VISI) to investigate relationship between mesospheric gravity waves and the occurrence of Equatorial Plasma Bubbles (EPBs). EPBs are depletion of electron density in the equatorial ionosphere. According to the previous study EPBs can be generated through the Rayleigh-Taylor (R-T) instability in the ionosphere. Medium-scale gravity waves with horizontal scales of a few hundred kilometers in the bottom side of the F region have been frequently suggested to play a key role in EPBs seeding. Gravity wave occurrence may depend on seasonal and longitudinal variation and may have oscillation whose period is few days. This several days oscillation of gravity wave may affect the variation of EPBs occurrence that can not be explained only by the R-T growth rate. Previous research of concentric gravity waves (CGWs) using observed by ISS-IMAP/VISI shows more mesospheric CGW events occur in the west side of the African continent than the east side of the African content. It indicate occurrence of CGWs is different between nearby areas. Objective of this study is to elucidate relationship between mesospheric gravity waves and longitudinal dependence of EPB occurrences. ISS-IMAP/VISI was operated for three years from September 2012 to August 2015. ISS-IMAP/VISI observed the airglow in the nadir direction on the nightside with two FOVs facing 45 degrees in the forward and backward of the orbital direction. We analyzed 762nm airglow data and compared with occurrence rate of EPBs and Growth rate of R-T instability. Occurrence rate of EPBs using Rate of TEC Index (ROTI) that is standard deviation of differential of GPS-TEC. Growth rate of R-T instability was calculated by using parameters from Ground-to-topside model of Atmosphere and Ionosphere for Aeronomy (GAIA). In this study, we investigated relationship between occurrence of EPBs observed by GPS-TEC data, linear growth rate of the R-T instability in the ionosphere obtained with GAIA, and mesospheric gravity wave activities observed by ISS-IMAP/VISI.

# Analysis of parameters controlling the occurrence and growth of equatorial plasma bubbles using GAIA

*Hiroyuki Shinagawa[1], Hidekatsu Jin[1], Yasunobu Miyoshi[2], Hitoshi Fujiwara[3], Tatsuhiro Yokoyama[4], Yuichi Otsuka[5]

1. National Institute of Information and Communications Technology, 2. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 3. Faculty of Science and Technology, Seikei University, 4. Kyoto University, 5. Institute for Space-Earth Environmental Research, Nagoya University

In our previous studies, the linear growth rates of the Rayleigh-Taylor (R-T) instability in the ionosphere were obtained with a whole atmosphere-ionosphere coupled model GAIA, and the growth rates were compared with observations [Shinagawa et al., 2018]. We found that a high growth rate of R-T instability tends to correspond to the actual equatorial plasma bubble (EPB) occurrence. The result suggests that the occurrence and growth of EPB are controlled both by atmospheric waves propagating from the lower atmosphere and by geomagnetic activities. However, dependence of various parameters such as electric fields, electron and neutral densities, and neutral wind velocities on the EPB occurrence and growth has not been quantitatively understood. We will discuss how those parameters affect the linear growth rates of the R-T instability using GAIA simulation data, and report the importance of the parameters in controlling the EPB occurrence and growth.

# A three-dimensional numerical model to study the modulation of midlatitude $E_s$-layers

*Satoshi Andoh[1], Akinori Saito[1], Hiroyuki Shinagawa[2], Shin'ichi Miyazaki[1]

1. Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology

We develop a three-dimensional numerical model to shed light on the generation, growth and diffusion mechanisms of the sporadic E layers in the midlatitude.

The Es layer is a high-density layer of plasma formed at around 100 kilometers high. It is affected by both the atmospheric waves generated in the troposphere and mesosphere, and the electromagnetic interaction between the E region and the F region, so that it is a very important phenomena to understand the physics of the upper atmosphere.

The mechanism of Es layer formation is described through the Windshear Theory. According to the theory, factors affecting the Es layer formation are zonal windshears and meridional windshears. Which one can make more effects depends on the altitude of Es layer.

Lately, there has been some new structures of the Es layer detected by several observations (e.g. Lidar observation). They cannot be explained only by Windshear Theory. It is considered that there are three factors of the structures: atmospheric waves, Kelvin-Helmholtz instability and Es layer instability. Several models have been developed to study each factor, but no model includes all three factors. Such a model is necessary to give a consistent explanation for which factor is the most effective for modulation of the Es layers.

Our model includes six kinds of ions of $O^+$, $O_2^+$, $N^+$, $N_2^+$, $NO^+$, $Ca^+$, and in both the transport process and the chemical process of ions in the uniform geomagnetic field solve. In addition, NRLMSISE-00 is used as a background field of neutral atmospheric density. This model uses three-dimensional polar coordinate system. Altitude coverage is from 85 km to 305 km and horizontal domain size is 5 degree ×5 degree in the longitude and latitude direction. The vertical and horizontal resolutions are 1 km and 0.1 degrees, respectively and the time resolution is 1 second.
By inputting latitude, longitude and UT into this model, it is possible to simulate ionosphere in midlatitude within the above calculation area.

In this presentation, as a pseudo-zonal and meridional neutral windshear, we employed a sinusoidal windsear in the vertical direction and reevaluated which component of the neutral windshear will affect more to form Es layers.
As a result, we obtained results consistent with the previous study that the influence of the zonal windshear is large at the low altitude and the influence of the meridional windshear is large at the high altitude.
Moreover, by incorporating the neutral winds of GSWM model and HWM14 model into ours, we examined the mechanism of generation of Es layer in the more real condition.

Based on these, we will introduce the future view in the presentation.

# Statistical analysis of the horizontal phase velocity distribution of mesospheric and ionospheric waves observed in airglow images in Hawaii

*Hideto Naito[1], Kazuo Shiokawa[1], Yuichi Otsuka[1], Takeshi Sakanoi[2], Akinori Saito[3], Takuji Nakamura[4]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 3. Department of Geophysics, Graduate school of science, Kyoto University, 4. National Institute of Polar Research

Matsuda et al. [JGR, 2014] proposed a method of deriving the horizontal phase velocity and propagation direction of the power spectral density of waves found in images using three-dimensional fast Fourier transform. Takeo et al. [JGR, 2017] and Tsuchiya et al. [JGR, 2018] applied this method to the airglow images obtained at Shigaraki and Rikubetsu, Japan, and reported 16-year variability of atmospheric waves at middle latitudes. However, there is no report using this method for analyzing airglow images obtained at low latitudes near the equator. In this study, we applied the analysis method of Matsuda et al. [2014] to airglow images obtained at wavelengths of 557.7 and 630.0 nm during the three years from 2013 to 2016 at Haleakala (20.7°N, 203.7°E) in Hawaii, where the latitude, longitude and orography are greatly different those of Shigaraki (34.8°N, 136.1°E) and Rikubetsu (43.5°N, 143.8°E). We clarified the statistical features of atmospheric gravity waves (AGWs) and medium-scale traveling ionospheric disturbances (MSTIDs) in the low latitude region near the equator, and compared it with features seen in Shigaraki and Rikubetsu (Takeo et al., JGR, 2017 and Tsuchiya et al., JGR, 2018).

The three-year average of the phase velocity spectra of AGWs observed in airglow images at wavelength of 557.7 nm show less propagation in due eastward and due westward in summer. The dominant propagation direction was southward in winter. The power spectral density was strongest in spring and summer, and weakest in winter. In Shigaraki and Rikubetsu, the direction of propagation changes from east in summer to west in winter, while in Haleakala there was no such seasonal change in the propagation in summer and winter. This is probably because Haleakala is located at latitudes away from the peak of the mesospheric jet, so the wind filtering effect by the mesosphere jet is smaller than that at Rikubetsu and Shigaraki.

The MSTIDs observed in airglow images at wavelength of 630.0 nm showed strong spectra in four particular nights, and we found that the average spectra largely affected by these strong spectra. Thus we removed these strong nights and calculated the three-year average horizontal phase velocity spectra for four seasons. From the average spectra, MSTIDs propagate from northwestward to southward in summer and from northward to southeastward in fall. In winter, the power spectral density was strongest, and the MSTIDs propagate mainly in the east-west direction. Spring power spectrum density was weakest. We note that dominant propagation direction of MSTIDs at Shigaraki and Rikubetsu was southwestward regardless of the season, which is very different from Haleakala. The power spectral density was weaker at Haleakala than those at Shigaraki and Rikubetsu. These results may be because polarization electric fields

associated with MSTIDs tends to be attenuated by the equatorial ionization anomaly crest, which exists at low latitudes before midnight and by the MBW (Midnight Brightness Wave) moving poleward from low latitudes associated with the MPB (midnight pressure bulge) even after midnight, as suggested by Narayanan et al. [JGR, 2014].

# Estimation of mesospheric OH temperature by observation data by ISS-IMAP VISI

*Ryo Murakami[1], Akinori Saito[1], Takeshi Sakanoi[2], Yuta Hozumi[3]

1. Kyoto University, 2. Tohoku University, 3. University of Electro-Communications

In general, the data of satellite observation is inferior in resolution to ground observation data and its wavelength resolution is inferior, so it is difficult to analyze. In this research, from 2012 to 2015, data of atmospheric light emission in the mesosphere by the Visible / Near Infrared Spectroscopic Imager (VISI), which is an observation device mounted on the International Space Station in the ISS-IMAP mission, Temperature estimation of the OH luminescent layer in the mesosphere near 85 km is tried. It is known from the previous study that the relative existence distribution of the rotation level when the OH molecule transitions between certain vibration levels follows the Boltzmann distribution and this distribution is determined by the rotation temperature of the OH molecule. Research using this property to try to estimate temperature from OH multiwavelength data has been used only for ground observation data so far. In this research, we apply this method to observation data from outer space and aim to obtain a spatially large temperature distribution map which has never been obtained. For analysis, data in two modes, Calibration mode and Spectral mode are used. In the calibration mode data, the observation data is recorded using the whole light receiving part of the observation equipment in the wavelength range of 500 to 900 nm, and the data of the spectral mode is narrowed down to the wavelength range of six ROI (Region of interest) And observation data are recorded together with spatial position information. Analysis is based on data in Spectral mode. Removal of salt-and-pepper-noise by cosmic rays and removal of artificial noise-containing data using random sample consensus algorithm for multi-wavelength data of OH around 828 nm, In order to compensate for the low resolution of the wavelength resolution, we tried fitting by Gaussian function and tried to estimate the temperature.

# Implementation of photochemical process of NOx and HOx into a whole atmosphere GCM

*Yasunobu Miyoshi[1], Hitoshi Fujiwara[2]

1. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 2. Seikei University

Photochemical process associated with NOx and HOx plays an important role on the energy budged and general circulation in the mesosphere and lower thermosphere (MLT). For example, NO is important for the infrared cooling in the MLT region. Photochemical process associated with HOx is essential for accurate estimate of the O3 distribution in the mesopause region. We implemented photochemical process of HOx and NOx into a whole atmosphere general circulation model (GCM). Using this GCM, effects of the solar activity on the general circulation in the MLT region are studied. Furthermore, this GCM can provide accurate estimate of the energy budget due to the global cooling due to the increase of CO2. In this study, preliminary results will be shown, and further development of the GCM will be discussed.

# Development of a Lagrangian chemical transport model to understand the mechanism of composition change due to change in atmospheric environment

*Shingo Nakanishi[1], Tomoo Nagahama[1], Akira Mizuno[1], Tac Nakajima[1], Riku Ishijima[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

Mesospheric chemical composition largely varies caused by environmental changes from the earth inside and outside. Recent studies reported enhancement of $NO_x$ and $HO_x$ and ozone depletion in the polar mesospheric region at a large solar proton event. These suggest that precipitation of other high energy particles such as a high energy electron from the magnetosphere also has influence on the chemical composition in the mesosphere. For these reasons, we have installed millimeter-wave spectrometers in Rikubetsu-cho, Hokkaido (Japan), Syowa Station (Antarctic), Atacama (Chile), Rio Gallegos (Argentine) and Tromso (Norway), and have been observing steady atmospheric minor molecules such as Ozone, $NO_x$, $HO_x$ and ozone-depleting substances in the stratosphere and mesosphere to understand the atmospheric composition changes caused by natural phenomena such as Energetic Particle Precipitation (EPP).

In addition to these observations, we have been developing a Lagrangian chemical transport model, which is suitable for a simulation of a sudden and a local event to evaluate the influence of the atmospheric composition mechanism in the stratosphere and mesosphere. Our developing model is an extension of the Lagrangian particle dispersion model (FLEXPART) by incorporating meteorological fields data and chemical reactions in the mesosphere. FLEXPART can analyze a trajectory from the ground to about 40 km in altitude using the reanalysis data of NCEP and ECMWF as meteorological fields input data. In this study, we incorporated a new reanalysis dataset (MERRA2) as meteorological fields input data to extend the analysis range toward the mesosphere, and as a result, trajectory a analysis ranging from the ground to about 80 km in altitude can be made. In order to evaluate the analysis accuracy of our developing model, we calculated trajectories for a single position at altitudes of 15, 45, 55, 70 km, and compared the results with another trajectory analysis model. Moreover, only OH reactions are considered in FLEXPART, although it needs to calculate non-linear chemical reactions separately in this study because chemical reactions caused by EPP include not only reactions by natural molecules but also ion-molecular reaction, ionization, dissociation and ion recombination, and so on. For this reason, we incorporated chemical reactions of the stratosphere and mesosphere in FLEXPART using Kinetic Preprocessor (KPP) which is chemical reaction computation software. We previously calculated chemical reactions of the stratosphere and mesosphere using KPP alone and confirmed the amount of mesosphere ozone variation in day and night.
In this presentation, we will report the results of comparison bet between our developing model and other trajectory models as well as the simulation results about some EPP events using our model.

[J] Poster | P (Space and Planetary Sciences )：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

Thu. May 30, 2019 5:15 PM - 6:30 PM JST | Thu. May 30, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_3

## [P-EM16] Physics and Chemistry in the Atmosphere and Ionosphere

convener:Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Takuya Tsugawa(National Institute of Information and Communications Technology), Seiji Kawamura(National Institute of Information and Communications Technology)

This session covers a broad scope of studies of physics and chemistry in the atmosphere and the ionosphere. Coupling processes between plasma and neutral species, and upward and downward coupling among lower/upper atmosphere, and ionosphere/mesosphere/thermosphere including magnetosphere are discussed. We solicit papers based on experiments with ground-based and/or space-borne instruments, theoretical studies, numerical simulations, and development of new observation techniques.

The ionospheric structure caused by precipitation of high energy particles can adversely affect the GPS causing phase scintillation and cycle slip (loss of lock). GPS phase scintillation correlates with the intensity of the aurora, especially the rapid change in the auroral brightness [1,2,3]. Enhancement of the total electron content (TEC) observed during the substorm expansion phase in the night side downward region 1 current seems to be related to intense precipitation particle flux [4]. Such TEC enhancements cause phase scintillation that is most intense just after substorm onsets and auroral breakups. Phase scintillation index is computed for sampling rate of 50 Hz by specialized GPS scintillation receivers from the Canadian High Arctic Ionospheric Network (CHAIN). A proxy scintillation index is obtained from dual frequency measurements of geodetic-quality GPS receivers sampling at 1 Hz, which include globally distributed receivers of RT-IGS network that are monitored by the Canadian Geodetic Survey in near-real-time. Temporal and spatial changes of TEC and phase scintillation are investigated in the context of equivalent ionospheric currents derived from ground magnetometer network using the spherical elementary current method [5,6]. The relation of phase scintillation with auroral emission is also examined. In general, GPS phase scintillation maps to regions of strong westward electrojet and to the poleward edge of the eastward electrojet. Following substorm onsets and auroral breakups, strong phase scintillation associated with TEC enhancements are mapped mainly to the upward region 2 current or the equatorward edge of the downward region 1 current at or near the Harang discontinuity region [7].

# Statistical study of SAPS occurrence characteristics using the SuperDARN Hokkaido HF radar

*Kento Oya[1], Nozomu Nishitani[1], Tomoaki Hori[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

We investigate the occurrence characteristics of Sub-Auroral Polarization Streams (SAPS), using the Super Dual Auroral Radar Network (SuperDARN) Hokkaido East radar. The ultimate goal is to clarify the longitudinal dependence of SAPS occurrence characteristics using the whole SuperDARN radars. In this study, we statistically analyzed about 10-year data from 2007/1/1 to 2016/12/31 and studied the occurrence rate of the flow that can be considered as SAPS, vs MLT and MLAT. Assuming that the flows are east-west oriented, we set the criteria for line of sight velocity of > 80 m/s and echo power of > 3dB. We obtained the overall characteristics of SAPS, i.e., equatorward shift of high occurrence rate region with increasing MLT and geomagnetic activity. Some of the characteristics are different from previous studies. The SAPS regions seem to be located at higher latitudes than the previous studies and the SAPS occurrence peak regions are located at later MLT. These differences might be due to the difference in geographic longitude (Far-East Siberia to Pacific vs North American region). We also found new feature, i.e, westward flows from midnight to morning at relatively low geomagnetic latitudes, that could not be caught in the previous studies probably due to the limitation of radars fields of view, especially lower latitude boundary.

Keywords: magnetosphere-ionosphere coupling, SAPS, SuperDARN, geomagnetic activity

# Spectral investigations of near infrared aurora and airglow at 1.0-1.6 microns: 1-year ground-based imaging spectroscopic observation at Syowa station (69.0˚S, 39.6˚E)

*Takanori Nishiyama[1], Takeshi Sakanoi[2], Makoto Taguchi[3], Hidehiko Suzuki[4]

1. National Institute of Polar Research, 2. Planetary Plasma and Atmospheric Research Center, Tohoku University, 3. Rikkyo University, 4. Department of Physics, Meiji University

The motivation of this study is further understanding of dayside magnetosphere and terrestrial atmosphere coupling system by using continuous observation. Dayside aurora, polar patch, and airglow should be key phenomena for the understanding. In particular, those phenomena in near infrared (NIR) wavelength are crucially important because lower background sky luminosity by Rayleigh scattering may allow us to conduct ground-based optical observation even in dayside. Continuous dayside optical monitoring with high temporal and spatial resolutions in aurora region and cusp give us a clue to understanding of substorm pre-onset sequences at cusp region, magnetopause dynamics related to solar wind shocks, and wave-particle interactions due to electromagnetic ion cyclotron waves and whistler mode chorus. However, NIR aurora has a total lack of its spectral information with enough resolution to make a feasibility study in comparison to that in visible wavelength.

We designed a narrow field spectrometer with medium-high spectral resolution that mainly consists of Czerny-Turner type imaging spectrometer (HORIBA, iHR320) with one entry port and two exit ports. This spectrometer has two mirrors and three diffractive gratings in a rotating turret. A toroidal mirror for collimating corrects for astigmatism so that the tangential (resolution optimized) and sagittal (imaging optimized) focal planes cross at the center of the focal plane. Another larger focus mirror allows the entire flat field to be used without vignetting. Collecting optics, equipped outside the spectrometer, are a gold coated off-axis parabolic mirror and a NIR longpass filter for removal of secondary diffracted light in visible wavelength. Using 1-d InGaAs array (1024 pixels) and 600 gr/mm grating, spectral range and spectral range per pixel are 119 nm and 0.11 nm/pixel, respectively.

We started ground-based spectroscopic observation in NIR wavelength ranging from 1.0 to 1.6 microns, which covers strong OH airglow emissions and auroral emissions in $N_2$1st Positive (1.2 microns) and $N_2^+$ Meinel (1.1 and 1.5 microns) [Jones 1974; Zhou et al., 2007], at Syowa Station (69.0˚S, 39.6˚E) in Antarctica from March 2018. OH airglow spectrum in NIR can be well resolved even in water vapor absorption region. OH rotational temperature is successfully estimated using OH 3-1 band P1(2) and P1(4) emissions. However, auroral emissions were not clearly identified at 1.52 micron (N2+ Meinel) so far. Further investigations are needed including 1.10 micron (N2+ Meinel) and 1.24 micron (N2 1P). In this presentation, we are going to report results in more detail based on one year observation.

# The study of the lower ionosphere in the South Atlantic Anomaly (SAA) Region

*Chih-Yu Chiang[1], Tzu-Fang Chang[2,1], Sunny W. Y. Tam[1]

1. Institute of Space and Plasma Sciences, National Cheng Kung University, Tainan, Taiwan, 2. Institute for Space-Earth Environmental Research, Nagoya University, Japan

South Atlantic Anomaly (SAA) corresponds to a region where the geomagnetic field is relatively weak; such a magnetic field enables energetic particles from the inner radiation belt to penetrate closer to the Earth's surface more easily, thus resulting in relatively high level of radiation in the environment. In this study, we analyze the nighttime airglows in 2007 to 2008 in the SAA region by using the data from the ISUAL (Imager of Sprites and Upper Atmospheric Lightning) experiment aboard the FORMOSAT-2 satellite. We focus specifically on the measurements by the six spectrophotometers and the CCD Imager, which overall cover the spectrum from ultraviolet to infrared wavelengths. Based on our analysis, features of clear enhancements and annual variations at 337 nm, 391.4 nm and 777.4 nm are identified in the SAA region. Through comparing these multiple-band emissions, we can identify energy variation of incident particles and atmospheric compositions of SAA region.

# Multi-GNSS observation of LSTID in Japan and its link with auroral activities

*Mayumi Hashimoto[1], Kosuke Heki[1]

1. Hokkaido University

Interaction between southward magnetic field in solar winds and the Earth’ s magnetosphere causes geomagnetic activities and auroral substorms. The auroral activity is associated with strong electric currents (auroral jet) within the auroral oval. This disturbs the geomagnetic field at high latitude region and is reflected in changes in the AE (Auroral Electrojet) index. At this time, atmospheric gravity waves, generated as a result of the heating of the atmosphere by electric currents, propagate toward the middle and low latitudinal regions and make Large-Scale Traveling Ionospheric Disturbances (LSTID). In this study, we observed ionospheric disturbance in Japan located in middle and low latitudes as the changes in TEC (Total Electron Content). Here we study the relationship between LSTID observed with multiple-GNSS (Global Navigation Satellite System), GPS, GLONASS, Galileo, and QZSS, and short-term changes in the high time resolution AE index time series.

In this study, we used the AE index one minute values from Kyoto University, World Data Center for Geomagnetism (wdc.kugi.kyoto-u.ac.jp). As the GNSS observation point, we used Tsukuba (tskb), one of the IGS observation points in Japan with inter-frequency bias values available. To examine the relationship, we first identified the day when the AE index exceeded 2,000 nT between 2011 and 2017. Then, we converted the RINEX data files of tskb on these days to TEC, removed satellite and receiver biases, and converted them to vertical TEC (VTEC). We compared the AE index and VTEC for 22 cases, and the occurrences of LSTID were confirmed in 5 of them. In these cases, LSTIDs were observed 1 or 2 hours after the peak of the AE index. We estimated the propagation velocity in two ways, i.e. by calculating the time lag between the AE peak and LSTID arrivals in Japan and the distance between the auroral oval and Japan, and by comparing the times of TEC peaks within Japan. Both approaches showed the velocity of ~0.7 km/sec.

Since 2018 summer, the Japanese GNSS network started to track multiple GNSS including the Japanese Quasi-zenith Satellite System (QZSS) and to open the raw data on-line by RINEX 3.02 format. discuss the relationship LSTID and AE index. QZSS includes three satellites with quasi-zenith orbits (PRN01, 02, 03) and one satellite with geostationary orbit (PRN07). Generally speaking, GNSS-TEC data changes by the three reasons, (1) temporal change in ionosphere, (2) spatial change in ionosphere, and (3) apparent change by changes in satellite elevation angle. However, QZSS-TEC includes only (1), and useful in studying ionospheric disturbances without bothering about (2) and (3).

# Basic development of accurate analytical method in order to determine coordinates of artificial illuminating clouds of Barium and Strontium for chemical-release rocket experiments

*Taro Watanabe[1], Masa-yuki Yamamoto[1], Yoshihiro Kakinami[2]

1. Kochi University of Technology, 2. Hokkaido Information University

In order to investigate neutral atmospheric heating phenomenon in the polar cusp, it is necessary to estimate Joule heating and fluctuation of electric field in the cusp. To accomplish this, we conducted a US-Japan joint rocket experiment called the Cusp Region Experiment 1 (CREX-1) in the Arctic region in November 2014, with releasing Ba (to be ionized in a short time by extreme ultraviolet (EUV) from the Sun) and Sr (not ionized in a short time). And then, we observed resonance scattering emission of $Ba^+$ and Sr simultaneously from two sites on ground so as to obtain fluctuation of the electric field and Joule heating. However, we could not release the gases in the cusp at that time. We are planning additional space experiments, based on the CREX-1 results, using two sounding rockets of the Cusp Region Experiment 2 (CREX-2) and the Joint Japan-US Cusp Heating Investigation (CHI) aiming at observing of the cusp in December 2019.

In this study, we developed a basis of accurate analytical method in order to determine coordinates of artificial illuminating cloud with applying observed data of CREX-1. At the beginning of the analysis, we made calibration data from the RAW images taken at a previous optical system tests. We compared the exposure input-output characteristics of JPEG and RAW to establish an analysis method using RAW images instead of JPEG. Next, we investigated whether it is possible to replace the work of determining centers of the illuminating clouds, which has been carried out by hand, by a method of uniquely determining the luminance maximal by gradient descent method. In addition, we made a background image by a darken composition method and attempted to remove the background brightness gradient trend.

As a result, the characteristics of JPEG image reported by Kakinami et al. (2015) were thought to be arcuate gamma curves, but in RAW images, they were obtained as linear characteristics. Regarding the gradient descent method, although it is possible to uniquely determine the luminance maximal without any human factors, it was found that there is a possibility that the local maximum is not the true center. For background removal by the darken composition method, it is effective for background light gradient removal. However, there is a problem that the shadow of the illuminating clouds appearing in the background image affects the remained shape of the illuminating clouds when removing the background.

Furthermore, we developed an algorithm tracing the three-dimensional position of $Ba^+$/Sr cloud uniquely without any human factors.

# Neutral and plasma density perturbations in the top-/bottom-side ionosphere associated with MSTIDs

*Shin Suzuki[1], Jaeheung Park[2], Yuichi Otsuka[3], Kazuo Shiokawa[3], Huixin Liu[4], Hermann Luehr[5]

1. Faculty of Regional Policy, Aichi University, 2. Korea Astronomy and Space Science Institute, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Earth and Planetary Science Division, Kyushu University SERC, Kyushu University, 5. Helmholtz Centre Potsdam, GFZ, German Research Centre for Geosciences

Medium-scale traveling ionospheric disturbances (MSTIDs) are a well-known wavy structure in the F-region ionosphere. They typically have a horizontal wavelength of several hundred kilometers and a periodicity of about one hour. Although, the MSTIDs were considered to be caused by atmospheric gravity waves, recent studies have suggested that the generation of the MSTID in nighttime is highly associated with coupling processes between the E- and F-region electrodynamics. To confirm the different processes in the MSTID generation in daytime and nighttime, CHAMP satellite measurements would be greatly helpful; CHAMP plasma and neutral density data obtained in the day- and night-side sector can monitor the phase relations between the neutral (i.e., atmospheric gravity wave) and ionospheric plasma perturbations simultaneously at the top-side F-region (approximately 400 km).

As the first step in the abovementioned research, we compared the MSTID signatures between the CHAMP and ground-based 630-nm airglow measurements to validate the MSTID detection by CHAMP. Airglow imaging is a quite useful technique to investigate two-dimensional characteristics of the nighttime MSTIDs. Horizontal parameters of the MSTIDs (such as wavelengths, motions, and their spatial extent) can be estimated directly with a high spatial and temporal resolutions through the 630-nm airglow emission in the bottom-side F-region. Previous study by Park et al. [2009, JGR] made an investigation of spatial signatures regarding one MSTID event using airglow images along the CHAMP orbit. The Institute for Space-Earth Environmental Research, Nagoya University, has operated airglow imaging network, as the OMTI system, around the world since 2000; this network gives much more chance to make coordinated measurements with CHAMP. We found three clear MSTID events (March 15, 2004, February 15, 2007, and January 12, 2007) in which CHAMP passed over the field-of-views of the OMTI camera.

In this presentation, we will report phase relations between the neutral and plasma density perturbations associated with the MSTID events.

# Analysis of ionospheric TEC fluctuation by rocket

*Tsuyoshi Takegawa[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Takuya Tsugawa[2], Michi Nishioka[2]

1. Graduate School of Integrated Science and Technology, Chiba University, 2. National Institute of Information and Communications Technology

It is known that atmospheric waves arised by massive earthquakes, typhoons and volcanic eruptions cause the ionospheric variation. In recent years, ionospheric fluctuations excited by rocket launches have been confirmed (Lin et al., 2014,2017). In case of Taepodong 2, the first wave of TEC fluctuations is confirmed due to the chemical reaction with ionospheric plasmas and the exhaust of the rocket about 5 minutes after the launch and the second wave was confirmed after about 30 minutes from the launch. To examine the ionospheric disturbances apart from the trajectories of rockets, in this study, TEC fluctuation due to the launches of H2A rocket No.25 and No. 29 we examined using GEONET data. The first waves of the TEC fluctuations were confirmed around hundreds kilometers from the rocket trajectory 5 minutes after launch of both of H2A rockets. The first waves appeared as large decreases in VTEC, which is consistent with the previous study of Taepodong 2. Calculating the propagation time of the sound waves from the points on the trajectories of the rockets, the delays correspond to the propagation times from the trajectories to the pierce points of TEC. The second waves were also observed around the 30 minutes after the rocket launches. Calculating the arrival time of sound waves for the second waves, the seconds waves once reflected on the ground were affected by the second waves.

# Examinations of the ionospheric perturbation associated with H-IIA rockets launching

*Junpei Yamazaki[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano[1], Keisuke Hosokawa[2], Ichiro Tomizawa[2]

1. Graduate School of Engineering, Chiba University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications

It is reported that ionospheric perturbation are caused by natural hazards, such as giant earthquakes, olcanic eruptions and so on. This is because the infrasound waves generated by natural hazards propagate to the ionospheric. Since rocket launches also generate the atmospheric waves, it is reported that passage and exhaust plumes generate TEC perturbations determined by GEONET data(Lin et al.,2014,2017).
On the other hand, there is few studies about ionospheric perturbation associated with rocket launch away from rocket’ s trajectory. Then, in this study, we analyzed ionospheric perturbations associated with H IIA(No.25 and 26) relatively far trajectory from the Japanese islands using HF Doppler sounding.
The perturbations of Doppler shifts associated with H-IIA No.25 were observed at Kakioka and Sugadaira observatories and those of H-IIA No.26 were observed at Kakioka,Fujisawa and Sugadaira observatories about 35 minutes after the launch. It is confirmed that this delay corresponds to the propagation time of the infrasound wave from the launch site to observation points once reflected on the ground. The frequencies of the disturbance of Doppler shift were 5~10 mHz. Similar disturbances were reported in Lin et al (2014) which examined the TEC disturbances associated with Taepodong. The Doppler shift perturbation is clear when the infrasound wave reached the observation point after reflection on the ground as compared to the case where the infrasound wave reached the observation point directly. When the infrasound wave directly reaches the observation point, it passed through about 200~250km altitude. Where the amplitude of infrasound waves with several 10mHz tend to attenuate. Therefore, ionospheric perturbation at the moment corresponding to the arrived at the direct wave become small.

# Explosion energy derived from the 2015 Kuchinoerabujima eruption: Estimation from infrasound less than 0.01 Hz detected by barometers, seismometers, and TEC

*Yuki Nakashima[1], Kiwamu Nishida[1], Yosuke Aoki[1], Kosuke Heki[2]

1. Earthquake Research Institute, 2. Natural History Sciences, Hokkaido University

This study discusses the amount of energy emitted to the atmosphere as acoustic waves of less than 0.01 Hz by the 2015 Kuchinoerabujima volcano, southwest Japan, eruption derived from barometers, broadband seismometers, and GNSS-TEC observations.
Kuchinoerabujima is one of the volcanic islands of active recently. The volcano erupted at 0:59 UT on 25th May 2015. Many previous studies pointed out that this is a phreatomagmatic eruption and involves a lateral signal (e.g., Kobayashi, 2017; Matsuzawa et al., 2016; Yamada et al., 2017). Yamada et al. (2017) found that barometric data include two phases in about 20 sec. In the first stage, the volcanic plume went up with a pressure pulse, and the second another pulse corresponds to the plume growing laterally. The seismic source time function of that has a component of north-south direction obviously (Matsuzawa et al. 2016).
We found atmospheric disturbances with a characteristic frequency of ~0.01 Hz in all the observations. The frequency range is equivalent to the highest part of the detectable band in the ionosphere. We detected the signal of lower atmospheric perturbation from F-net, an array of broadband seismometers installed by NIED, and a barometer array along the Japanese coastline in front of the Pacific ocean by AIST. As the ionospheric observation, we used GNSS-TEC time series extracted from GEONET 1 Hz sampling data. The waveform feature is very similar to ionospheric disturbances excited by Asama volcano on 1st September 2004 (Heki, 2006; Chonan et al., 2017).
We tried to reproduce the observed signal and estimate the magnitude of the energy source using the ray-tracing method. Atmospheric parameters are inputted from NRLMSISE-00 (Picone et al., 2002), HWM-14 (Drob et al., 2015), IRI2016 (Billitza et al., 2016), and IGRF-12 (Thébault et al., 2015). We put an isotropic energy source on the ground in the windy atmosphere.
The estimated travel time by ray-tracing is consistent with the observation, indicating that the excited atmospheric perturbation simply propagates isotropically without wave broadening due to dispersion discussed in Dautermann et al. (2009a).
If we choose the source energy as $10^8$ J, our model expects about one-third of the observed signal in both the lower atmosphere in the far field and the ionosphere. This amount of energy is $10^{1-2}$ times larger than that of the 2004 Asama eruption estimated from TEC observation (Heki, 2006). It seems to depend on not only the difference of volcanic eruption magnitude but also the crude assumption like ignoring the geomagnetic effect and geometrical spreading same as Dautermann et al. (2009) suggested.
We were not able to find any evidence for anisotropic radiation of energy as stated in some previous studies, suggesting that infrasound of such very low frequencies infrasound (< ~0.01 Hz) responds to with a longer time constant such as the growth of the thermal plume.
Acknowledgment
We would thank GSI, JMA, AIST, and NIED which provide GNSS, barometer, microphone, and broadband seismometer data.

# Detection of spread-F echoes in ionograms using machine learning

*Hiroyuki Nakata[1], Yuta Goto[2], Hiroyo Ohya[1], Toshiaki Takano[1]

1. Graduate School of Engineering, Chiba University, 2. Department of Electrical and Electronics Engineering

Ionospheric irregularities referred to as equatorial spread-F is very important phenomena in terms of radio wave propagation because their spatial scales are from centimeters to tens of kilometer and they affects wide-band radio waves. Therefore, they influence the reliability of satellite-ground communications, navigation systems and so on. The ionogram is one of the important observation system of spread-F. Because the detection of spread-F in the ionogram is done manually, detection of spread-F could be replaced with automatic detection by developing an excellent machine learning system. In this study, therefore, we have developed a method to detect spread-F in the ionogram automatically using machine learning.

In this detection process, we have arranged two classifiers for typical frequency-type and mixed (frequency-type and range-type) spread-F echoes in the ionograms. A number of correct images must be prepared for these classifiers to learn the feature values of spread-F. To do so, ten thousands of correct images were generated by create_samples utility provided by OpenCV library. Using these classifiers, we have detected the both types of spread-F echos in the ionograms observed at 4 observatories (Wakkanai, Kokubunji, Yamagawa, Ogimi) utilized by National Institute of Information and Communications Technology. The detection rates of both types of spread-F echos are from 50% to 73% and both classifier detected both types of spread-F echos similarly. Namely, the classifier for the frequency-type spread-F echo detected both of the frequency-type and mixed-type echos, and vice versa. In case where the two types of spread-F echos are not distinguished, on the other hand, both of classifiers detect 80% of total spread-F echos. In addition, the classifiers also picked up some other phenomenon , such as overlapped traces of O-mode and X-mode, multi-hop trace.

As for the future plan, there might be several way to improve the detection rate; to use more classifiers, to make the classifiers be precisely with more training data, and so on. However, a number of correct images are inevitable in machine learning. In order to prepare such a number of images, it may be effective to generate training data using deep generative model.

# Evaluation of GNSS-TEC receiver performance for sounding rocket installation

*Makoto Okumura[1], Yuki Ashihara[1]

1. National Institute of Technology, Nara College

Earth's atmospheric region ionized electrons by X-rays and ultraviolet rays involved in sunlight is called ionosphere. Ionospheric disturbance causes some problems, e.g., which are terrestrial satellite communication impairment and positioning error of GNSS. For elucidating the generation mechanism of the ionospheric disturbance, we need to observe spatial structure of ionospheric electron density. Ionosphere observation is generally implemented with remote sensing method such as Ionosonde, GNSS-TEC and others. Ionosonde can observe the electron density vertical structure below the altitude of electron density peak in F region, and GNSS-TEC can obtain the total electron content along the radio wave propagation path. However, these methods cannot observe the spatial structure. In this paper, we propose a rocket GNSS-TEC tomography method as a new approach to the ionosphere observation. In this method, we install the GNSS-TEC receiver onboard a sounding rocket, and it is flying the boundary region between the ionospheric E and the F region. It is possible to acquire the TEC data only for the F region.
In case of a combining antenna system installed on the side on sounding rocket, it is simulated that the received signal becomes unstable since the sounding rocket spins at the speed of 1 to 2 Hz. Therefore, we built a structure model of the sounding rocket, and conducted a ground-based rotation experiment. In this experiment, the GNSS carrier phase data was approximately obtained for the steady rotation speed, but TEC value had the variation more than 60 TECU. As the results, we understood that a combining antenna system cannot useful for a rocket GNSS-TEC.

# Relationship between mesosperical airglow disturbance and occurrence of equatorial plasma bubbles

*Ryota Okada[1], Akinori Saito[1], Takafumi Ikeda[1], Hiroyuki Shinagawa[2], Takuya Tsugawa[2], Takeshi Sakanoi[3]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology, 3. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University

762 nm airglow data observed by Ionosphere, Mesosphere, upper Atmosphere and Plasmasphere mapping mission from the ISS / Visible and near Infrared Spectral Imager (ISS-IMAP/VISI) to investigate relationship between mesospheric gravity waves and the occurrence of Equatorial Plasma Bubbles (EPBs). EPBs are depletion of electron density in the equatorial ionosphere. According to the previous study EPBs can be generated through the Rayleigh-Taylor (R-T) instability in the ionosphere. Medium-scale gravity waves with horizontal scales of a few hundred kilometers in the bottom side of the F region have been frequently suggested to play a key role in EPBs seeding. Gravity wave occurrence may depend on seasonal and longitudinal variation and may have oscillation whose period is few days. This several days oscillation of gravity wave may affect the variation of EPBs occurrence that can not be explained only by the R-T growth rate. Previous research of concentric gravity waves (CGWs) using observed by ISS-IMAP/VISI shows more mesospheric CGW events occur in the west side of the African continent than the east side of the African content. It indicate occurrence of CGWs is different between nearby areas. Objective of this study is to elucidate relationship between mesospheric gravity waves and longitudinal dependence of EPB occurrences. ISS-IMAP/VISI was operated for three years from September 2012 to August 2015. ISS-IMAP/VISI observed the airglow in the nadir direction on the nightside with two FOVs facing 45 degrees in the forward and backward of the orbital direction. We analyzed 762nm airglow data and compared with occurrence rate of EPBs and Growth rate of R-T instability. Occurrence rate of EPBs using Rate of TEC Index (ROTI) that is standard deviation of differential of GPS-TEC. Growth rate of R-T instability was calculated by using parameters from Ground-to-topside model of Atmosphere and Ionosphere for Aeronomy (GAIA). In this study, we investigated relationship between occurrence of EPBs observed by GPS-TEC data, linear growth rate of the R-T instability in the ionosphere obtained with GAIA, and mesospheric gravity wave activities observed by ISS-IMAP/VISI.

In our previous studies, the linear growth rates of the Rayleigh-Taylor (R-T) instability in the ionosphere were obtained with a whole atmosphere-ionosphere coupled model GAIA, and the growth rates were compared with observations [Shinagawa et al., 2018]. We found that a high growth rate of R-T instability tends to correspond to the actual equatorial plasma bubble (EPB) occurrence. The result suggests that the occurrence and growth of EPB are controlled both by atmospheric waves propagating from the lower atmosphere and by geomagnetic activities. However, dependence of various parameters such as electric fields, electron and neutral densities, and neutral wind velocities on the EPB occurrence and growth has not been quantitatively understood. We will discuss how those parameters affect the linear growth rates of the R-T instability using GAIA simulation data, and report the importance of the parameters in controlling the EPB occurrence and growth.

# A three-dimensional numerical model to study the modulation of midlatitude $E_s$-layers

*Satoshi Andoh[1], Akinori Saito[1], Hiroyuki Shinagawa[2], Shin'ichi Miyazaki[1]

1. Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology

We develop a three-dimensional numerical model to shed light on the generation, growth and diffusion mechanisms of the sporadic E layers in the midlatitude.

The Es layer is a high-density layer of plasma formed at around 100 kilometers high. It is affected by both the atmospheric waves generated in the troposphere and mesosphere, and the electromagnetic interaction between the E region and the F region, so that it is a very important phenomena to understand the physics of the upper atmosphere.

The mechanism of Es layer formation is described through the Windshear Theory. According to the theory, factors affecting the Es layer formation are zonal windshears and meridional windshears. Which one can make more effects depends on the altitude of Es layer.

Lately, there has been some new structures of the Es layer detected by several observations (e.g. Lidar observation). They cannot be explained only by Windshear Theory. It is considered that there are three factors of the structures: atmospheric waves, Kelvin-Helmholtz instability and Es layer instability. Several models have been developed to study each factor, but no model includes all three factors. Such a model is necessary to give a consistent explanation for which factor is the most effective for modulation of the Es layers.

Our model includes six kinds of ions of $O^+$, $O_2^+$, $N^+$, $N_2^+$, $NO^+$, $Ca^+$, and in both the transport process and the chemical process of ions in the uniform geomagnetic field solve. In addition, NRLMSISE-00 is used as a background field of neutral atmospheric density. This model uses three-dimensional polar coordinate system. Altitude coverage is from 85 km to 305 km and horizontal domain size is 5 degree ×5 degree in the longitude and latitude direction. The vertical and horizontal resolutions are 1 km and 0.1 degrees, respectively and the time resolution is 1 second.
By inputting latitude, longitude and UT into this model, it is possible to simulate ionosphere in midlatitude within the above calculation area.

In this presentation, as a pseudo-zonal and meridional neutral windshear, we employed a sinusoidal windsear in the vertical direction and reevaluated which component of the neutral windshear will affect more to form Es layers.
As a result, we obtained results consistent with the previous study that the influence of the zonal windshear is large at the low altitude and the influence of the meridional windshear is large at the high altitude.
Moreover, by incorporating the neutral winds of GSWM model and HWM14 model into ours, we examined the mechanism of generation of Es layer in the more real condition.

Based on these, we will introduce the future view in the presentation.

# Statistical analysis of the horizontal phase velocity distribution of mesospheric and ionospheric waves observed in airglow images in Hawaii

*Hideto Naito[1], Kazuo Shiokawa[1], Yuichi Otsuka[1], Takeshi Sakanoi[2], Akinori Saito[3], Takuji Nakamura[4]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 3. Department of Geophysics, Graduate school of science, Kyoto University, 4. National Institute of Polar Research

Matsuda et al. [JGR, 2014] proposed a method of deriving the horizontal phase velocity and propagation direction of the power spectral density of waves found in images using three-dimensional fast Fourier transform. Takeo et al. [JGR, 2017] and Tsuchiya et al. [JGR, 2018] applied this method to the airglow images obtained at Shigaraki and Rikubetsu, Japan, and reported 16-year variability of atmospheric waves at middle latitudes. However, there is no report using this method for analyzing airglow images obtained at low latitudes near the equator. In this study, we applied the analysis method of Matsuda et al. [2014] to airglow images obtained at wavelengths of 557.7 and 630.0 nm during the three years from 2013 to 2016 at Haleakala (20.7°N, 203.7°E) in Hawaii, where the latitude, longitude and orography are greatly different those of Shigaraki (34.8°N, 136.1°E) and Rikubetsu (43.5°N, 143.8°E). We clarified the statistical features of atmospheric gravity waves (AGWs) and medium-scale traveling ionospheric disturbances (MSTIDs) in the low latitude region near the equator, and compared it with features seen in Shigaraki and Rikubetsu (Takeo et al., JGR, 2017 and Tsuchiya et al., JGR, 2018).

The three-year average of the phase velocity spectra of AGWs observed in airglow images at wavelength of 557.7 nm show less propagation in due eastward and due westward in summer. The dominant propagation direction was southward in winter. The power spectral density was strongest in spring and summer, and weakest in winter. In Shigaraki and Rikubetsu, the direction of propagation changes from east in summer to west in winter, while in Haleakala there was no such seasonal change in the propagation in summer and winter. This is probably because Haleakala is located at latitudes away from the peak of the mesospheric jet, so the wind filtering effect by the mesosphere jet is smaller than that at Rikubetsu and Shigaraki.

The MSTIDs observed in airglow images at wavelength of 630.0 nm showed strong spectra in four particular nights, and we found that the average spectra largely affected by these strong spectra. Thus we removed these strong nights and calculated the three-year average horizontal phase velocity spectra for four seasons. From the average spectra, MSTIDs propagate from northwestward to southward in summer and from northward to southeastward in fall. In winter, the power spectral density was strongest, and the MSTIDs propagate mainly in the east-west direction. Spring power spectrum density was weakest. We note that dominant propagation direction of MSTIDs at Shigaraki and Rikubetsu was southwestward regardless of the season, which is very different from Haleakala. The power spectral density was weaker at Haleakala than those at Shigaraki and Rikubetsu. These results may be because polarization electric fields

associated with MSTIDs tends to be attenuated by the equatorial ionization anomaly crest, which exists at low latitudes before midnight and by the MBW (Midnight Brightness Wave) moving poleward from low latitudes associated with the MPB (midnight pressure bulge) even after midnight, as suggested by Narayanan et al. [JGR, 2014].

# Estimation of mesospheric OH temperature by observation data by ISS-IMAP VISI

*Ryo Murakami[1], Akinori Saito[1], Takeshi Sakanoi[2], Yuta Hozumi[3]

1. Kyoto University, 2. Tohoku University, 3. University of Electro-Communications

In general, the data of satellite observation is inferior in resolution to ground observation data and its wavelength resolution is inferior, so it is difficult to analyze. In this research, from 2012 to 2015, data of atmospheric light emission in the mesosphere by the Visible / Near Infrared Spectroscopic Imager (VISI), which is an observation device mounted on the International Space Station in the ISS-IMAP mission, Temperature estimation of the OH luminescent layer in the mesosphere near 85 km is tried. It is known from the previous study that the relative existence distribution of the rotation level when the OH molecule transitions between certain vibration levels follows the Boltzmann distribution and this distribution is determined by the rotation temperature of the OH molecule. Research using this property to try to estimate temperature from OH multiwavelength data has been used only for ground observation data so far. In this research, we apply this method to observation data from outer space and aim to obtain a spatially large temperature distribution map which has never been obtained. For analysis, data in two modes, Calibration mode and Spectral mode are used. In the calibration mode data, the observation data is recorded using the whole light receiving part of the observation equipment in the wavelength range of 500 to 900 nm, and the data of the spectral mode is narrowed down to the wavelength range of six ROI (Region of interest) And observation data are recorded together with spatial position information. Analysis is based on data in Spectral mode. Removal of salt-and-pepper-noise by cosmic rays and removal of artificial noise-containing data using random sample consensus algorithm for multi-wavelength data of OH around 828 nm, In order to compensate for the low resolution of the wavelength resolution, we tried fitting by Gaussian function and tried to estimate the temperature.

# Implementation of photochemical process of NOx and HOx into a whole atmosphere GCM

*Yasunobu Miyoshi[1], Hitoshi Fujiwara[2]

1. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 2. Seikei University

Photochemical process associated with NOx and HOx plays an important role on the energy budged and general circulation in the mesosphere and lower thermosphere (MLT). For example, NO is important for the infrared cooling in the MLT region. Photochemical process associated with HOx is essential for accurate estimate of the O3 distribution in the mesopause region. We implemented photochemical process of HOx and NOx into a whole atmosphere general circulation model (GCM). Using this GCM, effects of the solar activity on the general circulation in the MLT region are studied. Furthermore, this GCM can provide accurate estimate of the energy budget due to the global cooling due to the increase of CO2. In this study, preliminary results will be shown, and further development of the GCM will be discussed.

Keywords: the general circulation of the atmosphere, photochemical process

# Development of a Lagrangian chemical transport model to understand the mechanism of composition change due to change in atmospheric environment

*Shingo Nakanishi[1], Tomoo Nagahama[1], Akira Mizuno[1], Tac Nakajima[1], Riku Ishijima[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

Mesospheric chemical composition largely varies caused by environmental changes from the earth inside and outside. Recent studies reported enhancement of $NO_x$ and $HO_x$ and ozone depletion in the polar mesospheric region at a large solar proton event. These suggest that precipitation of other high energy particles such as a high energy electron from the magnetosphere also has influence on the chemical composition in the mesosphere. For these reasons, we have installed millimeter-wave spectrometers in Rikubetsu-cho, Hokkaido (Japan), Syowa Station (Antarctic), Atacama (Chile), Rio Gallegos (Argentine) and Tromso (Norway), and have been observing steady atmospheric minor molecules such as Ozone, $NO_x$, $HO_x$ and ozone-depleting substances in the stratosphere and mesosphere to understand the atmospheric composition changes caused by natural phenomena such as Energetic Particle Precipitation (EPP).

In addition to these observations, we have been developing a Lagrangian chemical transport model, which is suitable for a simulation of a sudden and a local event to evaluate the influence of the atmospheric composition mechanism in the stratosphere and mesosphere. Our developing model is an extension of the Lagrangian particle dispersion model (FLEXPART) by incorporating meteorological fields data and chemical reactions in the mesosphere. FLEXPART can analyze a trajectory from the ground to about 40 km in altitude using the reanalysis data of NCEP and ECMWF as meteorological fields input data. In this study, we incorporated a new reanalysis dataset (MERRA2) as meteorological fields input data to extend the analysis range toward the mesosphere, and as a result, trajectory a analysis ranging from the ground to about 80 km in altitude can be made. In order to evaluate the analysis accuracy of our developing model, we calculated trajectories for a single position at altitudes of 15, 45, 55, 70 km, and compared the results with another trajectory analysis model. Moreover, only OH reactions are considered in FLEXPART, although it needs to calculate non-linear chemical reactions separately in this study because chemical reactions caused by EPP include not only reactions by natural molecules but also ion-molecular reaction, ionization, dissociation and ion recombination, and so on. For this reason, we incorporated chemical reactions of the stratosphere and mesosphere in FLEXPART using Kinetic Preprocessor (KPP) which is chemical reaction computation software. We previously calculated chemical reactions of the stratosphere and mesosphere using KPP alone and confirmed the amount of mesosphere ozone variation in day and night.
In this presentation, we will report the results of comparison bet between our developing model and other trajectory models as well as the simulation results about some EPP events using our model.

1. Graduate School of Science, Kyoto University, 2. National Insititute for Fusion Science

Instabilities driven by energetic ions are important issues both for space plasmas and magnetic fusion plasmas. Radio Frequency (RF) waves in the range from the ion cyclotron frequency to the lower hybrid resonance frequency are often observed during the period of neutral beam injection (NBI) in Large Helical Device (LHD) plasmas. The experimental results showed that the peak frequency in the Lower Hybrid Wave (LHW) region has a positive correlation with the electron density and the ion cyclotron emissions (ICEs) have much larger amplitudes than LHW. These waves can be excited by instabilities due to energetic ions generated by the NBI perpendicular to the magnetic field.

Using a one-dimensional, electromagnetic, Particle-In-Cell (PIC) code, we study instabilities driven by energetic ions assuming that the energetic ions have a non-Maxwellian ring-like distribution in the velocity space perpendicular to the magnetic field. This PIC code enables us to self-consistently simulate full dynamics of electrons and ions and evolution of electromagnetic fields, using the full Maxwell's equations and the equations of motion of particles. We focus on the nonlinear evolution of LHW and ICEs caused by continuous energetic-ion injection into a plasma.

The simulation results are as follows. After the rapid growth of the LHW in the early stage, the ICEs gradually become intense. Finally, the ICEs have larger amplitudes than LHW.

# Study of Kinetic Alfven waves in space plasmas with electron having Kappa distribution

*SATYAVIR SINGH[1], Krushna Chandra Barik[1], Yoshiharu Omura[2], Gurbax Singh Lakhina[1]

1. Indian Institute of Geomagnetism, New Panvel, India, 2. Research Institute for Sustainable Humanosphere, Kyoto University, Kyoto, Japan

A theoretical model is developed by assuming a three component plasma comprising of the cold background ions, hot electrons having kappa distribution and hot ion beams to study the generation of kinetic Alfvén waves (KAWs).The background ions and beam ions are considered Maxwellian and the ion beam is only allowed to have velocity shear and non-uniform streaming. A dispersion relation for the excitation of the kinetic Alfven waves (KAWs) is analyzed. The effect of plasma parameters like number density, propagation angle, temperature, kappa etc. on the excitation of KAWs is examined. A comparative study of the results obtained from this model will be carried out with a plasma model having all the three species as Maxwellian. Further, an application of the theoretical model will be discussed relevant in the Earth’ s magnetosphere.

# A high-order divergence-free weighted finite difference scheme for the two-fluid plasma equations

*Takahiro Miyoshi[1], Takashi Minoshima[2], Yosuke Matsumoto[3]

1. Graduate School of Science, Hiroshima University, 2. Department of Mathematical Science and Advanced Technology, Japan Agency for Marine-Earth Science and Technology, 3. Graduate School of Science, Chiba University

Recent development of numerical techniques for magnetohydrodynamics (MHD) enables us to simultaneously simulate fine structures created by shock-vortex interactions and a large-scale MHD structure. On the other hand, the scales of the fine structures can become so small that the MHD approximation breaks down. Thus, a new macroscopic plasma simulation model beyond MHD is strongly required. In particular, the full two-fluid plasma model including local charge separation is considered in this study. According to the growth of computing power, the full two-fluid plasma simulation model will be scope of a standard model in the near future.

Since the full two-fluid plasma equations are hyperbolic conservation laws with stiff source terms, i.e., hyperbolic balance laws, state-of-the-art numerical techniques for the neutral fluid and MHD models can be applied. Recently, Minoshima et al. [1] developed high-order, non-oscillatory, and divergence-free finite difference schemes for MHD. In their schemes, the magnetic fields are defined on staggered grids, and the induction equation is discretized using high-order centered finite differences of the electric fields that correspond to numerical fluxes for the induction equation weightedly interpolated to the vertices of the grids. We apply this approach such that the Maxwell equations are discretized on the staggered grids using high-order centered finite differences of the electric and magnetic fields interpolated to the grid vertices and construct a high-order non-oscillatory divergence-free scheme for the full two-fluid plasma equations. A comparative study with other schemes is presented in this talk. We also discuss the time integration method.

# Electromagnetic linear dispersion relation for plasma with a drift across magnetic field

*Takayuki Umeda[1], Takuma Nakamura[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Space Research Institute, Austrian Academy of Sciences

A current across the magnetic field is formed in various situations in plasma. The relative drift between ions and electrons due to the cross-field current becomes a source of various microscopic instabilities. A fully electromagnetic and kinetic linear dispersion relation for plasma with a drift across magnetic field is derived by assuming a uniform background plasma. The dielectric permittivity tensor for shifted Maxwellian velocity distributions is also presented.

1. Graduate School of Science, Chiba University

Magnetohydrodynamic simulations have played important roles for understanding space and astrophysical phenomena. In such circumstances, shock waves and turbulence are inherent properties, and both aspects equally affect evolution of the whole system. Therefore development of numerical algorithms capable of solving both shock waves (discontinuities) and turbulence (waves) with high resolution is a challenging task to tackle violent phenomena in space and astrophysical plasmas.

High-order (greater than the fifth) spatial interpolation coupled with approximate Riemann solvers is a promising solution to such problems (Matsumoto et al., 2016; Minoshima, Miyoshi, Matsumoto, 2019). CANS+ (Matsumoto et al., 2016) employs the fifth order MP5 reconstruction scheme coupled with the HLLD approximate Riemann solver (Miyoshi and Kusano, 2005), and it successfully provided highly resolved solutions for both shock waves and turbulence. A drawback of adopting high-order schemes is its large and complex floating-point operations for obtaining the numerical flux at the cell surface, including minmod (with four arguments) limiters and conversion from the primitive to the characteristic variables. These numerical operations in addition to calculation of the HLLD numerical flux dominated overall computational loads.

In this paper, we propose a different way of calculating the numerical flux by adopting supervised learning algorithms. A deep (multilayer) neural network consists of input and output layers, whose sizes are determined by the problem of interest, and arbitrary numbers and sizes of hidden layers. These layers are connected by linear operations followed by a mapping through nonlinear functions such as a sigmoid function (fully connected networks). Weighting parameters used in the linear operations in each layer are updated repeatedly so that the loss function between the output and the label data (true value) becomes a minimum value. In the present particular problem, we prepared learning data by examining a 1-D shock tube problem which contains rarefaction waves and discontinuities by using CANS+. The input and label data are cell states for all primitive variables in six-point stencils centered on a cell and the numerical flux on the right-hand side of the cell, respectively. We have implemented a multi-layer, fully-connected network by using the Chainer framework for the prepared learning data. With the given data set we successfully obtained a network that can predict the numerical flux with 99% accuracy. In this talk we present detailed algorithms and learning data, and discuss future perspectives including application to multidimensional simulations.

# Multiple Boris integrators for particle-in-cell simulation

*Seiji Zenitani[1], Tsunehiko N Kato[2]

1. Kyoto University, 2. National Astronomical Observatory of Japan

We construct Boris-type schemes for integrating the gyration of charged particles in particle-in-cell (PIC) simulation. The new solvers virtually combine the classic 2-step Boris solver arbitrary $n$ times, and then they provide $n^2$ times smaller errors. We derive a single-step form of the multiple Boris solvers, whose coefficients are given by polynomials. We carry out numerical tests of the new solvers, in comparison with other particle integrators.

# Contour Dynamics for Vlasov–Poisson Plasma with the Periodic Boundary

*Hiroki Sato[1], Tomo-Hiko Watanabe[1], Shinya Maeyama[1]

1. Nagoya University

Zabusky, Hughes, and Roberts presented a contour dynamics algorithm for the Euler equations of fluid dynamics in two dimensions [1].On the paper, they succeed in calculating time development of contours of vorticity on the x-y plane with the contour dynamics(CD) algorithm, which is a method by using contours of vorticity, piece-wise constant function, and line integrals of Green’ s function on the contours. The CD method does not use underlying lattice, but uses nodes on the contours, and it can lead to more accurate calculation for complex deformation of vorticity.

This method is also applied to Vlasov–Poisson system. In order to study the CD in the Vlasov–Poisson plasma, we have developed a method to implement the periodic of potential and its derivative are satisfied.To check validity of out method, we test the Linear Landau damping by means of the CD scheme.While discretization of the distribution function might lead to some difference from that with continuous distribution, soundness of our new scheme is confirmed in comparison with analytical solutions.

We are also investigating in behaviors of the CD in the continuous limit, and in the nonlinear Landau damping as well.

# Simulation methods and visualization tools for MHD simulations in a sphere

*Akira Kageyama[1], Kumiko Hori[1], Naohisa Sakamoto[1]

1. Graduate School of System Informatics, Kobe University

In recent years, we have been developing a set of simulation and visualization tools for magnetohydrodynamics (MHD) simulations in the spherical geometry. The adopted numerical scheme is a finite-difference method on the Yin-Yang-Zhong grid [1], which is an overset grid system in the spherical geometry.

The codes are written in Fortran 2003 or in eFortran [2], which is a dialect of Fortran 2008 language. The features of eFortran include; the period "." as the member access operator; block comments, addition/subtraction/multiplication assignment, pre-defined and user-defined aliases, automatic check of "implicit none" call, "just once" block, and "skip" block. We have developed a preprocessor to convert the dialect into the legitimate Fortran. It is a simple text converter in Python that keeps the line numbers of the input dialect and the output standard codes.

We have performed MHD simulations of relaxation process in a sphere [5]. Since the spherical geometry is free from the lateral dynamic pressure on the spherical boundary, we can observe MHD relaxation process in which flow and the magnetic field coexist. Intriguing structures of magnetic/flow fields are observed after relaxations.

One of interesting applications of the spherical MHD solver is the spherical shell convection with resistive inner core. Magnetic field generated by dynamo process in the convective spherical layer can diffuse into the inner solid core. We have solved slowly rotating spherical thin shell convection system and confirmed that the resistive inner core plays important roles to keep the dynamo operating in convection rolls in the ring- or spiral-shape.

We have also applied the Yin-Yang-Zhong simulation code to simulate MHD flows in a precessing sphere. We have confirmed that magnetic field is generated in spherical precession flows in some parameter regimes that are reported in previous studies. The structure and the generation mechanism of the magnetic field is analyzed in detail.

For the visualization purposes, we have developed two kinds of visualization tools for simulation data produced on the Yin-Yang or Yin-Yang-Zhong grid : (a) Two dimensional (cross sectional) in-situ visualization library with vector graphics format (EPS) [3], and (b) three dimensional visualization methods based on an advanced visualization framework KVS (Kyoto Visualization System) [4].

# Kármán Vortex Street, Strouhal Number, Hairpin Vortex in 3D global Magnetohydrodynamic MHD simulations in Northward IMF

*DongSheng CAI[1]

1. University of Tsukuba

A Kármán vortex street is a repeating pattern of two rows of paired swirling vortices and appears after some obstacles or stagnation areas in fluid or plasma flows. It is caused by a process known as a vortex shedding where vortices leave the shear layer. Recently, several studies have discussed the Kelvin-Helmholtz (K-H) instability and its related waves and vortex structures by using 2D / 3D global (Magneto Hydro Dynamics) MHD simulations in the northward IMF (Interplanetary Magnetic Field). These found a double-vortex sheet in which a vortex train propagates, respectively, along the inner and outer edges of the magnetopause. In the present paper, we show that these two rows of vortices form the Kármán vortex street, and we discuss its generation mechanism with the help of 3D global MHD simulations. These Kármán vortex stretches and elongates in the night side and becomes to be the so-called the Hairpin vortex that is essential for the coherent structure. We also identify the non-dimensional number vortex so-called the Strouhal number in our simulation. The Stouhal number is ubiquitous and represents one of the most significant features in the Kármán vortex street.

# Correlations between plasma density and magnetic field strength in MHD turbulence in space

*Tohru Hada[1], Yasuhito Narita[2], Yasuhiro Nariyuki[3]

1. Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2. Space Research Institute, Austrian Academy of Sciences, 3. Faculty of Human Development, University of Toyama

Large amplitude magnetohydrodynamic (MHD) turbulence is ubiquitous in space plasma, for example, in the solar wind, in the foreshock region (Narita, World Scientific, 2010) and in the sheath region of the earth's bowshock (e.g., Pollock et al., J. Atmosph. Solar Terr. Phys, 2018). Moreover, recent Voyager observations of large amplitude density and magnetic field fluctuations in the heliosheath behind the termination shock arouse a vivid discussion on the compressible nature and the origin of the observed turbulence (Burlaga and Ness, ApJ, 2009; Gutynska et al., ApJ, 2010). An obvious way of generating the density fluctuations is via the presence of compressive wave modes, such as obliquely propagating MHD waves. The density response is linear to the magnetic field perturbations in this case, and it vanishes in the limit of parallel wave propagation. In a finite (large) amplitude Alfvenic turbulence the density perturbation may be mainly generated via the "frozen-in" of the magnetic field to the plasma or the static balance between the plasma pressure and the magnetic field. Both of these processes result in the quadratic response of the density to the magnetic field perturbations, although their correlation is positive for the former and negative for the latter. This simple fluid picture, sometimes referred to as the "quasi-static" approximation, is known to be significantly modified when the ion response to the turbulence is kinetically treated (Mjolhus and Wyller, Phys. Scripta, 1986; Medvedev and Diamond, Phys. Plasmas, 1996). In this presentation, we address this unsolved issue of the correlations between the plasma density and the magnetic field amplitude in the presence of finite amplitude MHD turbulence by performing hybrid simulations (kinetic ions + fluid electrons), and by examining the in situ Cluster spacecraft data of the foreshock plasma (Narita and Hada, Earth, Planets and Space, 2018).

# Stochastic models of phase space diffusion via wave-particle interaction with parallel propagating electromagnetic waves

*Yasuhiro Nariyuki[1]

1. Faculty of Human Development, University of Toyama

Particle diffusion due to electromagnetic waves is one of fundamental processes in various phenome in space plasms such as electron acceleration in the outer radiation belt [e.g., Saito et al, JGR, 2016], astrophysical shock [e.g., Yamazaki, JHEA, 2015], and solar wind [e.g., Seough et al, APJ, 2015]. Although quasi-linear theories are widely used as a standard theory of particle scattering, nonlinear wave-particle interactions such as particle trapping also affect particle diffusions in the presence of finite amplitude waves. Saito et al [JGR, 2016] demonstrated that nonlinearity of whistler chorus waves plays a significant role in electron diffusion though nonlinear wave-particle interactions.

In Saito et al [JGR, 2016], the artificial randomization of gyrophases (phase breaking) is incorporated to discuss suppression of coherent wave-particle interactions. Remark that such a randomization corresponds to a noise term in equations of motion of each particles. In this sense, phase breaking causes not only the suppression of coherent processes but also diffusions in phase space. In the present study, we discuss the generalization of phase breaking. It is shown that particle diffusion depends on probability density functions of noises and their parameters. Noise terms in equations of the pitch angle are also necessary to describe diffusion in phase space. Treatment of phase breaking as a stochastic differential equation is also discussed.

# Electron beam instability in collisionless magnetic reconnection with a strong guide field

*Kazuya Shimomura[1], Tomo-Hiko Watanabe[1], Shinya Maeyama[1], Akihiro Ishizawa[2]

1. Nagoya Univertsity, 2. Kyoto University

Magnetic reconnection is a fundamental physics mechanism in magnetized plasma that causes a topological change of magnetic field lines and a conversion of magnetic energy to kinetic energy, leading to a self-organization of plasmas in laboratory and space. It is considered that the two-fluid effects or the kinetic effects facilitate the fast reconnection of magnetic field lines in colllisionless plasmas. Anomalous resistivity (AR) is one of the candidates that contributes to continuously drive the magnetic reconnection. A recent simulation study reports that AR induced by the Buneman instability accelerates the magnetic reconnection [1]. However, it is not clear how the instability causing the AR is spontaneously driven during the reconnection.
In our study so far, we have carried out numerical simulations of the collisionless magnetic reconnection by means of the gyrokinetic model of a slab plasma with a strong guide field [2][3]. During the reconnection, the parallel electric field is induced by the electron inertia at the X-point where electrons are acccelerated along the guide field. A liner analysis by use of the dispersion releation shows that the kinetic Alfvén waves (KAWs) are destabilized when the electron beam velocity exceeds the Alfvén speed, where, we assumed a plane wave in an uniform background profile. Furthermore, in this $\delta f$ gyrokinetic model, the total distribution function F is approximately described as $F=FM+\delta f=(1+Uv)FM\tilde{}1/2pi\ exp(-(v-U)^2/2)$, where $FM$, $\delta f$ and $U$ are the Maxwellian, perturbed distribution function, and a beam velocity component, respectively. In order to analyze a stability of the KAWs in an inhomogeneous background profile during the collisionless magnetic reconnection, we must use the total distribution function rather than $\delta f$, since the KAWs are stable for $(1+Uv)FM$, according to the Nyquist criteria. Therefore, in this study, the magnetic reconnection process triggered by the electron inertia is simulated by use of a full-f gyrokinetic model of a slab plasma with the guide field. As a result, the shifted Maxwellian is formed at the X-point self-consistently by the parallel electric field. The attached figure shows distribution of the parallel electron beam on the reconnection plane in the nonlinear phase during the reconnection. It is possible to carry out the stability analysis in an inhomogeneous background by use of this simulation results. Results of the stability analysis will also be discussed at the meeting.

# Particle acceleration with precursor wave driven wakefield in relativistic shocks

*Masanori Iwamoto[1], Takanobu Amano[1], Masahiro Hoshino[1], Yosuke Matsumoto[2]

1. Graduate School of Science,The University of Tokyo, 2. Graduate School of Science, Chiba University

The acceleration mechanism for generating ultra-high-energy cosmic rays (UHECRs) with energies above $10^{18}$eV is one of the most important unsolved problems in astrophysics. Relativistic shocks in extragalactic astrophysical objects such as jets from active galactic nuclei (AGNs) and gamma-ray bursts (GRBs) are considered as efficient acceleration sites and commonly proposed sources for UHECRs. Observations of anisotropy in the arrival direction of the UHECRs favor the extragalactic origin.

In relativistic shocks, large-amplitude electromagnetic waves are excited by synchrotron maser instability (SMI) in the shock transition and propagate upstream (Hoshino & Arons 1991). The precursor wave emission via the SMI is widely studied by means of 1D particle-in-cell (PIC) simulations. Hoshino (2008) demonstrated that the pump electromagnetic wave decays into a Langmuir wave via parametric decay instability and found that nonthermal particles are generated in the manner analogous to wakefield acceleration (WFA) during the nonlinear process of the Langmuir wave collapse. The WFA is first proposed in laboratory plasmas (Tajima & Dawson 1979) and recently applied for UHECR acceleration (e.g., Chen et al. 2002). The WFA in the context of relativistic shocks is considered a promising candidate for UHECR acceleration.

It was believed that in multidimensional shocks, the intense wave emission via the SMI would cease soon due to inhomogeneity along the shock surface. Recently, however, our high-resolution 2D PIC simulations in pair plasmas showed that the wave emission continues (Iwamoto et al. 2017, 2018). Although our studies give positive results for the WFA in relativistic shocks, we could not directly demonstrate it because finite mass difference of two opposite charges is essential for exciting the wakefield.

In this presentation, by performing 2D PIC simulation of ion-electron shocks, we will demonstrate that the wakefield is indeed induced by the large-amplitude precursor wave. Especially for relatively high magnetization, the precursor wave amplitude is significantly amplified and exceeds that in pair plasmas due to a positive feedback process associated with ion-electron coupling through the wakefield. Nonthermal electrons and ions are generated during the nonlinear process of the wakefield collapse and the particle energy spectrum shows a power-law distribution. We will discuss the particle acceleration mechanism in details.

Keywords: cosmic rays, shock waves, acceleration of particles

# Stochastic Shock Drift Acceleration in the Shock Transition Region with Finite Pitch-Angle Anisotropy

*Takuma Katou[1], Takanobu Amano[1]

1. The University of Tokyo

The acceleration of non-thermal electrons is one of the important subjects in space physics. The shock accelerated non-thermal electrons have been observed at Earth's bow shocks (Gostling et al. 1989). These electrons are supra-thermal (with energies from 1keV to 100keV), and their distribution is power-law. However, acceleration models proposed in the past could not reproduce such observed spectra. Recent in-situ satellite observations of Earth's bow shock found wave-particle interactions between whistler waves and electrons at the shock transition region (Oka et.al. 2017). These results indicate that whistler waves play an important role for the acceleration of supra-thermal electrons.

We propose the stochastic shock drift acceleration (SSDA) model as a new acceleration mechanism for non-thermal electrons. It takes into account the effect of stochastic pitch-angle scatterings by whistler waves during the course of the Shock Drift Accelerations (SDA), which is a classical acceleration model for supra-thermal electrons at the shock transition region (Wu 1984, Leroy and Mangeney 1984). By introducing stochasticity with pitch-angle scatterings, the acceleration efficiency may be improved. We theoretically analyzed this acceleration model. We showed that the electron energy spectrum becomes a power-law consistent with observations in the limit of strong scatterings. We also found the maximum energy attainable through the proposed model, and it scales linearly with the pitch-angle scattering coefficient which represents the strength of scatterings. In our previous study, we have assumed the electron pitch-angle distribution is isotropic, and an effective shock speed $u/\cos\theta$ (u: shock speed, $\theta$: shock normal angle) is non-relativistic. The SSDA model cannot consider an anisotropy of the electron pitch-angle distribution. It is well known that the shock with a relativistic effective shock speed has a finite pitch-angle anisotropy. Therefore it is difficult to compare the SSDA model with full particle-in-cell (PIC) simulations which can reproduce only the shock with a relativistic effective shock speed because of the limitation of parameters we can take. To fix this problem, we extend the SSDA model so that it can be applied to such a shock. In this presentation, we discuss the consistency between the extended SSDA model and PIC simulation results.

Keywords: acceleration of particle, Earth, shock waves

# Near-fields and its Applications in Space Plasmas

*Tadas Nakamura[1]

1. Fukui Prefectural University

Solutions to Maxwell's equations consists of two parts: propagating components (electromagnetic waves) and the so-called near-field. Unfortunately, there seems to be considerable confusion on the latter, and the words "near-field" have different meanings depending on authors. For example, Coulomb interaction is often explained as the result of the interchange of virtual photons, however, the Coulomb field is not a photon but a near-field in the sense of this talk. Also, little attention is paid to the difference between propagating plasma waves and plasma near-fields in space physics.

The near-field in the present talk is understood as the off-shell solution to the inhomogeneous linear equations; the term "off-shell" means solutions that do not satisfy the dispersion relation. When the field source is static (Coulomb field or magnetic dipole, for example), it is easy to decompose the field into waves and off-shell near-fields. Here in this talk, the way to do this decomposition for time-dependent field source is explained. When we solve Maxwell's equations, usually we make use of Fourier-Laplace transform to obtain the dispersion relation. The time dependence of the fields is obtained by the inverse Laplace transform using the residue theorem; the wave components are obtained from the residue at the pole of the dispersion relation. One can obtain the near-field component by subtracting this residue contribution from the solution of the inhomogeneous equations.

The author reported the derivation of this result at the fall meeting of SGEPSS last year, and will report its application to space physics this time. The talk at the fall meeting was mainly about the electromagnetic fields in a vacuum; fields in plasmas will be discussed this time. The athematical structure of the fields in plasmas are essentially the same as that in a vaccum, however, currents and charges in plasmas cause a wide variety of phenomena in space. Phenomena such as current generation around small bodies in space plasma flows, the return currents genereted by energetic auroral electrons, and several others will be examined as examples.

Keywords: plasma waves, Laplace transform, near field

# Problems of Gravitational Waves and Origin of Gravitational Fields Raised by Studies on Binary Black Hole

*Hiroshi Oya[1]

1. Department of Geophysics Graduate School for Science Tohoku University

1.INTRODUCTION
As results of a study on the observations and analyses of the decameter radio wave pulses from the center of our Galaxy, it has been concluded that the super massive objects at the center of our Galaxy consist of two black holes which are forming a binary system rotating with common period of 2200sec; two black holes called Gaa and Gab, here, are associated with spin with rotation periods of 176.4±1.7 sec and 148.6±1.0 sec with orbiting velocities 18% and 21% of the light velocity, respectively. The radius of the orbits of Gaa and Gab are 0.13 AU and 0.15 AU ; applying Newtonian dynamics with assumption of coincidence of the orbital plane surfaces with the observing direction, it has been concluded that Gaa and Gab have masses of (2.27±0.06)x10∧6 SM and 1.94±0.03)x10∧6 SM with unit of solar mass ( SM).
2.THE THEORETICAL INVESTIGATION OF THE GRAVITATIONAL WAVE PROPAGATION
Considering the all parameters deduced for the Gaa and Gab binary system, fast reduction of the radii of the orbits of the binary due to emissions of gravitational waves is inevitable in so far as we follow the traditional theory of the generation of the gravitational wave from the black hole. In the present studies, the propagation of wave general across the event horizon have been theoretically investigated using the spacetime of Minkowski which is realized in the frame that is making free fall in the black hole space time. The results has indicated, both for Shwarzschild and Kerr black holes, that the waves are ceased to propagate at the event horizon. Then we concluded that black hole is not able to be origin of the gravitational wave.
3.DISCUSSION AND CONCLUSION
For the LIGO results that reported observations of the gravitational wave from the stellar mass black hole mergers, an alternative interpretation of the possible origin of the merger is the merger of the compact stars which have no event horizon. By the result of our study, the existence of the graviton which is currently assumed as origin of gravitational force meets problem because the graviton is also a wave in the regime of the quantum mechanics. We suggest the necessity of new concept otherwise than graviton hypothesis for origin of the gravitational fields.

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University), Chairperson:Sachie Kanada(Nagoya University), Akiyoshi Wada(Meteorological Research Institute)

Tropical cyclones (TC) sometimes cause destructive disasters in many countries by torrential rainfall, strong wind, storm surge, and high surf. In 2008, the western Japan suffered a record-breaking heavy rainfall related to Typhoon Prapirooon (2018) in July. Furthermore, two Category 4 typhoons, typhoons Jebi (2018) and Trami (2018), made landfalls on the western Japan in September and caused devastating disasters over the Japanese Islands. In the Northern Atlantic, Hurricane Florence caused catastrophic damage in the eastern side of U.S. Recent studies reported a northward shift of the location where a TC achieved the peak intensity and also reported increases in the frequency of rapidly intensifying storms. Thus, understanding the TC processes related to translation, intensity change and precipitation in the changing climate, and to provide more accurate forecasts and long-term projections are essential for the earth and planetary science.<br/>Advances in innovative observations such as meteorological aircraft, weather satellite, supercomputer systems such as the Earth Simulator and K-computer, and introduction of new methods such as the deep-learning, have led to novel development of numerical weather forecasting and understanding of the phenomena related to TCs in the past, present and future climates. In this session, we welcome papers on various aspects of TC studies. We hope that the session will provide a new direction for future TC researches.

# A GRAPES-based mesoscale EPS for TC forecasting: configuration and performance

*Xubin Zhang[1]

1. Institute of Tropical and Marine Meteorology, CMA

To improve short-range tropical cyclone (TC) forecasting in China from both deterministic and probabilistic standpoints, a mesoscale ensemble prediction system (TREPS) based on the Global/Regional Assimilation and Prediction System (GRAPES) is constructed as a planned operational system. TREPS comprises one unperturbed and 30 perturbed forecasts ranging up to 60 h at horizontal resolution of 9 km. Downscaling perturbations from the ECMWF ensemble prediction system (ENS) are used to generate initial perturbations by blending them with balanced random perturbations implemented around the TC and to generate perturbations for lateral boundary conditions. The surface temperature around the TC is also perturbed, with a combination of multi-physics and stochastically perturbed parametrization tendencies considered to represent uncertainties in the model physics. These perturbation methods contribute a full-area, multi-scale and multi-variable mutual complement to increasing forecast perturbations. TREPS is evaluated for 19 TCs making landfall in China during 2014–2016. For deterministic guidance, TREPS significantly improves TC forecasting for intensity, rainfall and wind compared to ECMWF deterministic and ensemble forecasts. TREPS demonstrates significant advantages over its deterministic forecasts in predicting track, intensity, (extremely) heavy rainfall and wind. Furthermore, TREPS effectively reduces the degree of underdispersion in intensity forecasting compared to ENS. For probabilistic forecasting, TREPS outperforms ENS in accurately predicting extremely heavy rainfall and (extremely) strong wind owing to its better discriminating ability, but performs worse in predicting modest wind, light and heavy rainfall. Two post-processing techniques –optimal member and optimal probability –to improve, respectively, deterministic and probabilistic guidance of TREPS in rainfall and wind forecasting are proposed. The former is shown to be effective only for light rainfall, while the latter demonstrates consistent (partial) improvements in rainfall (wind). The superiorities and inferiorities of TREPS, as well as possible reasons for these, are intuitively illustrated in a case-study for Rammasun.

# Evaluation of operational Ensemble based Global Forecast System prediction for Tropical Cyclones over the North Indian Ocean

*Medha Deshpande[1], Radhika Kanase[1], R P M Krishna[1], Emmanuel Rongmie[1], P Mukhopadhyay[1]

1. IITM, Pune, INDIA

The importance of accurate prediction of Tropical Cyclone (TC) genesis, rapid intensity changes, location and intensity during landfall is well known. Reliable prediction of these at 3-5 days lead time is crucial for disaster managing point of view. Bearing in mind the uncertainty in initial condition and model physics there was a need for high resolution ensemble based forecast system for region specific probabilistic prediction of weather over India. Considering this along with the existing Global Forecast System deterministic model (GFS T1534), the ensemble forecast system GEFS (T 1534) with 20 members is implemented and is in operation since June 2018 for the probabilistic prediction.

This paper evaluates the skill of operational high resolution (12.5 km) modelling system in predicting track and intensity of recent cases of TCs over North Indian Ocean at various lead time. Ensemble prediction of tracks of cyclones and its strike probability are evaluated. Ensemble mean track is better than the deterministic track particularly at longer lead time (figure 1). The vertical thermo-dynamic structure at the mature stage of the cyclone is well captured by the deterministic model. Evaluation of deterministic model (figure 2) specify average track error is ranging from < 100 km at Day 1 lead up to about 280 km at day 5 lead time and average error in intensity prediction is ranging from 10 kt –20 kts. In general model indicates early intensification and slightly overestimates the peak intensity in majority of the cases. It is challenging to predict the variation in the intensity. Skill in the prediction of genesis is also evaluated by calculating Genesis Potential Index (GPI). Further developments like improving the physics and dynamics of the model along with use of proper land use land cover data are underway.

# Structural Changes Preceding Rapid Intensification in Tropical Cyclones as shown in a Large Ensemble of Idealized Simulations

*Yoshiaki Miyamoto[1], David S Nolan[2]

1. Faculty of Environment and Information Studies, Keio University, 2. Rosenstiel School of Marine and Atmospheric Science, University of Miami

Structural changes that precede rapid intensification (RI) of tropical cyclones (TCs) are examined in a full physics model by conducting a large ensemble (270) of simulations.

The processes leading to RI in a representative case with moderate shear are consistent with previous studies for weakly sheared cases. The most distinct changes are that the vortex tilt and the vortex size begin to decrease more rapidly 6 h before the onset of RI.

A vorticity budget analysis for the upper layer around the low--level center reveals that the vertical vorticity is increased by vertical advection, stretching, and tilting terms before RI, whereas the horizontal advection is small. Thus, the upright vortex structure is not achieved through a vortex alignment process, but rather is built upward by deep convection.

The ensemble simulations are generated by changing the intensity and size of the initial vortex, the magnitude of vertical wind shear, and the translation speed. The ensemble members that show RI are consistent with the control case and many previous studies:

before the onset of RI, the intensity gradually increases, the radius of maximum tangential velocity (RMW) decreases, the flow structure becomes more symmetric, the vortex tilt decreases, and the radius of maximum convergence approaches the radius of maximum winds.

A dimensionless parameter representing a tendency for the formation of the vertically upright structure is considered.

The product of this parameter and the local Rossby number is significantly larger for TCs that exhibit RI in the next 24 hours.

# Potential impacts of tropical cyclone inner-core convective activity on the predictability of rapid intensification

*Masashi Minamide[1], Derek J. Posselt[1]

1. Jet Propulsion Laboratory, california institute of technology

Predictions of significant changes in tropical cyclone (TC) intensity, such as rapid intensification (RI), have emerged as a more challenging topic than forecasting TC tracks, since intensification of TCs involves multi-scale physical processes with significant contributions from convective-scale phenomena. Before the onset of RI, intensifying TCs are known to experience a precession process, in which tilted vortex rotates counter-clockwise to develop axisymmetric structure. From both modeling and observational studies, there is an agreement in the qualitative features of precession process among TCs, but the quantitative features, such as the vortex tilt magnitude, the duration of the precession process and whether or not the vortex is able to complete the precession process, vary among TCs. The predictability of the variety of precession process and subsequent RI is reported to be ultimately dominated by the chaotic nature of moist convection. Given the large influence of RI on the TC intensity forecasts, the further understandings in its uncertainty sources are necessary.

In this study, mechanisms that determine the variability of these precession processes are explored through sets of sensitivity and ensemble forecast experiments. We have used the Pennsylvania State University's experimental real-time ensemble Kalman filter analysis of Hurricane Harvey (2017) that assimilated GOES-16 all-sky satellite radiances (which has an equivalent monitoring capability to Himawari-8) in convection-permitting Weather Research and Forecasting model (WRF-ARW) simulations. This analysis resulted in a highly accurate forecast of intensity and track, and realistically represented the storm's rapid intensification. Starting with an analysis based on 18 hours of cycling data assimilation, we have conducted sensitivity experiments in which we reduced the initial atmospheric moisture amount by 5 to 20 %. Even initialized with the same wind field, and with fully developed convective updrafts and organization, the vortex tilt magnitude and the duration of precession are significantly modified by the inner-core moist processes. We explore the characteristics of the vortex structures that underwent short/long/uncompleted precession process, together with the theoretical background for these varieties of precession process by using a simplified toy-model. The results have implications for the design of future observation networks tasked with providing constraint on predictions of convections and rapidly intensifying tropical cyclones.

# A link between high-speed solar wind streams and rapid intensification of tropical cyclones

*Paul Prikryl[1,2], Lidia Nikitina[2], Vojto Rušin[3]

1. Physics Department, University of New Brunswick, Fredericton, NB, Canada, 2. Geomagnetic Laboratory, Natural Resources Canada, Ottawa, ON, Canada, 3. Astronomical Institute, Slovak Academy of Sciences, Tatranská Lomnica, Slovak Republic

Physical processes responsible for changes of tropical cyclone intensity are not well understood [1]. To improve the current understanding of tropical cyclone structure and intensity changes the future research needs to focus on response to all external forcing [2]. We examined rapid intensification of tropical storms in the context of solar wind coupling to the magnetosphere-ionosphere-atmosphere system. Tropical cyclone “best tracks” in the southern and northern hemispheres are used in the superposed epoch analysis of time series of solar wind parameters. The results indicate that rapid intensification of tropical storms tends to follow arrivals of high-speed solar wind from coronal holes and coronal mass ejections [3]. The ensuing auroral and polar cap activity including ionospheric currents and ionospheric convection generates atmospheric gravity waves that propagate from the high-latitude lower thermosphere both upward and downward [4,5,6]. If ducted in the lower atmosphere, they can reach tropical troposphere. Despite significantly reduced wave amplitude, but subject to amplification upon reflection in the upper troposphere, these gravity waves can trigger/release moist instabilities to initiate convective bursts, with the latent heat release leading to intensification of storms [7]. Convective bursts have been linked to rapid intensification of tropical cyclones. Tropical cyclone intensifications are preceded by atmospheric gravity waves generated by the solar wind magnetosphere-ionosphere-atmosphere coupling process. The gravity waves are observed in the ionosphere as traveling ionospheric disturbances. Their propagation in the lower atmosphere is examined by ray tracing in a model atmosphere to show that they can reach tropical cyclones. It is suggested that the interaction of aurorally-generated gravity waves with the tropical cyclone vortex and the inner primary eyewall could play a role in the intensification process. Assuming that quasi-periodic convective bursts lead to vortex waves, a two-dimensional barotropic approximation [8] is used to obtain asymptotic solutions representing propagation of vortex waves. The absorption of vortex waves by the mean flow in the critical layer leads to formation of the secondary eyewall and ultimately to a process of eyewall replacement cycle, one of the well-established paradigms of intensity changes in tropical cyclones [9].

# Influence of Tropical Lower Stratospheric Cooling on Extreme Deep Convective Activity and Tropical Cyclones

*Kunihiko Kodera[1], Nawo Eguchi[2], Rei Ueyama[3], Beatriz M Funatsu[4], Chantal Claud[5]

1. Meteorological Research Institute, 2. Kyushu University, 3. NASA Ames Research Center, 4. Université de Nantes, 5. Ecole Polytechnique

In previous studies we showed that stratospheric sudden warming (SSW) event can induce rapid cooling in the tropical stratosphere and impact on the tropical convective activity. Case studies on two large SSWs in January 2009 and January 2010, showed that convective activity increased along ascending branch of the Hadley circulation in the austral summer hemisphere. It is also found that frequency of the convective overshooting clouds, and the tropical cyclones (TCs) increased following the tropical stratospheric cooling. Detailed analysis on the relationship between the tropical stratospheric cooling and tropical cyclones are made for 2010 January case. In January 2010, TCs have been generated one after another over Indian Ocean, Maritime continent, and Pacific sectors following a eastward propagation of convective active center associated with the Madden-Julian Oscillation (MJO) until rapid cooling started in the tropical stratosphere in late January. Then, after that, MJO became stationary over the central Pacific and TCs developed or re-developed simultaneously over 3 different sectors: Southwest Indian Ocean, Australia, and central Pacific. TC does not form over the lands, however, extreme deep convective activity simultaneously enhanced with the TCs over African and South American continents. It is suggested that a decrease of static stability in the tropical tropopause layer (TTL) due to a cooling in the lower stratosphere, produced favorable condition for the development of extreme deep convection. The increase of extreme deep convection around 15° S latitudinal zone following the tropical stratospheric cooling can be characterized as a strengthening of deep ascending branch of the Hadley circulation connected to the Brewer-Dobson circulation.

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University), Chairperson:Yoshiaki Miyamoto, Kosuke Ito(University of Ryukyus)

Tropical cyclones (TC) sometimes cause destructive disasters in many countries by torrential rainfall, strong wind, storm surge, and high surf. In 2008, the western Japan suffered a record-breaking heavy rainfall related to Typhoon Prapirooon (2018) in July. Furthermore, two Category 4 typhoons, typhoons Jebi (2018) and Trami (2018), made landfalls on the western Japan in September and caused devastating disasters over the Japanese Islands. In the Northern Atlantic, Hurricane Florence caused catastrophic damage in the eastern side of U.S. Recent studies reported a northward shift of the location where a TC achieved the peak intensity and also reported increases in the frequency of rapidly intensifying storms. Thus, understanding the TC processes related to translation, intensity change and precipitation in the changing climate, and to provide more accurate forecasts and long-term projections are essential for the earth and planetary science.<br/>Advances in innovative observations such as meteorological aircraft, weather satellite, supercomputer systems such as the Earth Simulator and K-computer, and introduction of new methods such as the deep-learning, have led to novel development of numerical weather forecasting and understanding of the phenomena related to TCs in the past, present and future climates. In this session, we welcome papers on various aspects of TC studies. We hope that the session will provide a new direction for future TC researches.

Upper-tropospheric aircraft reconnaissance with dropsonde deployment using a Gulfstream-II aircraft was carried out for the inner core of Typhoon Trami on four successive days since 25 September 2018. According to the JMA best track, the central pressure reached its minimum value of 915 hPa on the first day and was subsequently maintained at 950 hPa for three days. Using dropsonde data, this study examined the change in the inner-core structure associated with the intensity change. Based on satellite imagery, this intensity change was associated with the rapid expansion of the eye (with radius increasing from 35 to 90 km) and the gradual increase in the eyewall cloud-top height. A composite analysis of dropsonde profiles in the radius-height domain on each day revealed a change in the flow structure, with the decrease (increase) in the tangential wind component near the radius of 40 km (120 km). This caused an increase in the radial gradient of angular momentum, corresponding to an increase in inertial stability. These results suggest that this typhoon underwent the structural change similar to eyewall replacement cycle while the central pressure was maintained.

# Dramatic changes in the inner-core structure of Typhoon Jebi (2018) at landfall and relationship between a mesovortex and strong wind gusts

*Udai Shimada[1], Ryo OYAMA[1], shingo shimizu[2]

1. Meteorological Research Institute, 2. National Research Institute for Earth Science and Disaster Prevention

Landfalling tropical cyclones experience dramatic structural changes due to increased friction, topography, reduced surface heat fluxes, and reduced moisture supply. Typhoon Jebi (2018) made landfall in Shikoku Island on September 4, 2018, and then it caused record-breaking gust wind speeds greater than 40 m $s^{-1}$ and heavy rainfall greater than 50 mm $h^{-1}$ along its track. Dramatic changes in the inner-core structure of Jebi at landfall and the relationship between heavy rainfall and strong wind gusts, and structural features were examined by using observations. The azimuthal-mean structure of Jebi after landfall shows that while the tangential wind at 1-km altitude decreased from 45 m $s^{-1}$ to 30 m $s^{-1}$, the structure became more compact, with the radius of maximum wind (RMW) at ~50 km and radar reflectivity increasing inside the RMW at altitudes from 1 to 5 km. Because of increasing forward speed and active convection inside the RMW, maximum wind speed below 6-km altitude did not decrease significantly even after landfall. Inside the RMW, a mesovortex with a scale of 50 km formed in the downshear-left quadrant. The formation of the mesovortex was likely attributed to dynamically forced updraft associated with the storm vortex tilted by vertical wind shear and attributed to tilting of horizontal vorticity associated with the convergence of enhanced frictional inflow. The mesovortex contributed to the strong wind gusts and heavy rainfall. Also, the fast forward speed of more than 15 m $s^{-1}$ increased wind gusts on the right-hand side of Jebi’ s track.

# Revisiting Asymmetric CAPE in Sheared Tropical Cyclones

*Qingqing Li[1]

1. NUIST Nanjing University of Information Science and Technology

This study numerically revisits the characteristics and physical processes of azimuthally asymmetric convective available potential energy (CAPE) in the outer cores of vertically sheared tropical cyclones (TCs), which has been observed previously. The results indicate that a downshear-upshear contrast in CAPE occurs in weakly sheared TCs as pointed out in prior studies, while an enhanced downshear left-downshear right contrast is found in strongly sheared storms. Specifically, less (larger) CAPE values arise downshear left (right) under large shear environments. Downward transport of low entropy by the convective and mesoscale downdrafts in principal rainbands reduces the equivalent potential temperature ($\theta e$) in the downshear-left boundary layer, whereas positive horizontal advection by the asymmetric outflow contributes to the presence of a mid-level maximum of $\theta e$ in the same quadrant. Resultantly, lower outer-core CAPE is present downshear left. In the downshear-right quadrant, a lack of convective downdrafts together with surface fluxes leads to higher $\theta e$ in the boundary layer. The intrusion of dry air by ventilation produces lower $\theta e$ in the upper troposphere on the right of the shear. Larger CAPE values thus arise downshear right. The effects of such azimuthally asymmetric CAPE on TC structure and intensity are also discussed.

# Observed rainfall asymmetry of tropical cyclone in the process of making landfall in Guangdong, South China

*Guanhuan Wen[1]

1. Guangzhou Institute of Tropical and Marine Meteorology, China Meteorological Administation

This study investigates the rainfall asymmetry of tropical cyclones (TCs) in the process of making landfall in Guangdong (GD), South China, on the basis of satellite-based and reanalysis precipitation data. We mainly focus on TC rainfall asymmetry, its main influencing factor, and its change in the process of landfall, and the difference between different ENSO phases. The results reveal that vertical wind shear (VWS) is the dominant influencing factor of TC rainfall asymmetry in GD. The rainfall maximum is located in downshear left of VWS. The TC rainfall asymmetry has little change in the process of making landfall, though the rain rate decreases. Both the phase and amplitude of TC rainfall asymmetry have no significant change from 24 hours prior to landfall to 12 hours after landfall. The rainfall maximum steadily lies in downshear left. The amplitude of rainfall asymmetry is about 50%, suggesting that the asymmetric rainfall is about half of the axisymmetric rainfall. There is no obvious difference in TC rainfall asymmetry between El Niño, La Niña, and neutral years.

# Volumetric Detection of Tornadic Vortices Associated with Typhoon Nanmadol (2017) Using PAWR and Deep Learning

*Toru Adachi[1], Naoki Ishitsu[2], Kenichi Kusunoki[1], Hanako Inoue[1], Ken-ichiro Arai[2], Chusei Fujiwara[3], Hiroto Suzuki[3]

1. Meteorological Research Institute, 2. Alpha Denshi/Meteorological Research Institute, 3. East Japan Railway Company

Tornadoes spawned by miniature supercells associated with typhoon are one of critical issues for disaster risk reduction in Japan. However, it is not easy to monitor and predict their occurrence because the parent storm is considerably small compared with classic-type tornadic supercell. We try to overcome this problem by combining cutting-edge technologies using rapid-scan phased array weather radar (PAWR) and deep learning analysis. We present a case study of tornado-like vortices which caused damages in Souka city, Saitama, during the approach of Typhoon Nanmadol (2017). We performed data analysis of two rapid-scan phased array weather radars operated by Meteorological Research Institute in Tsukuba and operated by Japan Radio Co., Ltd. in Chiba. To detect vortices from the PAWR-observed Doppler velocity data, we employed a vortex pattern finding scheme using convolutional neural network. Since PAWR carries out quasi-simultaneous observation of multi-elevational angles, we considered a group of vortices located in a radius of 4-km as a single vertically-extending volumetric vortex. By analyzing the spatiotemporal structure, we found a significant growth of a tornadic vortex about five minutes prior to its passage over the ground damage area. This finding suggests that a combination of rapid-scan PAWR observation and deep learning analysis is useful for monitoring and short-term forecasting of tornadoes associated with typhoon.

# Numerical study on lightning frequency in a tropical cyclone

*Yousuke Sato[1,3], Yoshiaki Miyamoto[2,3], Tomita Hirofumi[3]

1. Department of Applied Energy, Nagoya University, 2. Faculty of Environment and Information Studies, Keio University, 3. RIKEN Center for Computational Science

This study investigates frequency of lightning in each stage of lifecycle of tropical cyclone (TC) using the next generation weather and climate library called Scalable Computing for Advanced Library and Environment (SCALE; Sato et al. 2015, Nishizawa et al. 2015). Lightning component was developed and implemented into SCALE in this study. An idealized experiment based on an experimental setup of Miyamoto and Takemi (2013) was conducted by SCALE coupled with lightning component. The results of the simulation indicate that the lightning frequency is maximum before rapid intensification (RI) of TC, which supports the report of Price et al. (2009) derived from satellite observation. The frequency of lightning decreases after RI and it keeps small until the TC reaches steady state. Our analyses elucidate that the dependency of the lightning frequency upon the developing stage of TC is originated from the type of convection dominating at each growth stage. Before the RI, the convection generated by consuming convective available potential energy (CAPE) transport hydrometeors upward, and the charge split and the lightning frequently occur. During the steady state, the hydrometeors are mainly transported by the fast rotating flow in the simulated TC, which resulted in the weak charge split and small frequency of lightning.

# Sensitivity of Numerical Simulation of Typhoon Nepartak (2016) to Cloud Condensation Nuclei Concentration

*Yu-De Wu[1], Jian-Liang Wang[1]

1. Dept. of Environmental Informational and Engineering, Chung Cheng Institute of Technology, National Defense University, Taiwan

The study is carried out using the WRF model and the Cloud Condensation Nuclei, CCN, in the WDM6 microphysics scheme has been modified to test its impacts on typhoon simulations. The simulated track, intensity, and rainfall distribution of Typhoon Nepartak (2016) over Pacific Ocean are compared among numerical experiments of different initial concentration of CCN (wdm6_ctr, wdm6_10, and wdm6_50, where wdm6_10 and wdm6_50 represent that CCN are respectively 10 and 50 times of the value used in wdm6_ctr).

The simulated tracks in three runs are similar, but the intensity and the maximum dBz increase both in wdm6_10 and wdm6_50, but it takes more time for wdm6_50 to intensify. The comparison of mixing ratios of five water species shows that the cloud droplets mixing ratios increase as CCN is increased. The mixing ratios of rain, cloud ice, snow and graupel are enhanced more rapidly in wdm6_10 compared with wdm6_50. The same situation happens in the divergence field and upward motions. It is suggested that the increase of CCN will result in stronger typhoon, but the intensification will be slowed down with too much CCN.

# Moisture Budget Analysis for Hurricane Precipitation on Texas

*Satoshi Iizuka[1], Naoki Sakai[1]

1. National Research Institute for Earth Science and Disaster Resilience

In August 2017, Hurricane Harvey brought the unprecedented amount of rainfall and catastrophic flooding on the Houston metropolitan area, as it stagnated near the coast of Texas for several days after its decline to a tropical storm intensity. The present study compares the moisture budget for rainfall associated with Harvey with those of past hurricanes making landfall on Texas. It seems that the high pressure over the west coast region of the US, along with the meandering of the subtropical jet starting from the periphery of Hawaii and toward the south in Texas, stagnated Hurricane Harvey around the coast of Texas for several days. The meandering of the subtropical jet toward the south in Texas also caused the largest convergence of moisture advected from the Gulf of Mexico efficiently over Texas, although the accompanied high pressure was not extraordinary event. Therefore, it is suggested that surrounding meteorological conditions can greatly affect rainfall related to tropical cyclones.

# Remote response of a developing tropical cyclone over the western North Pacific to large-scale vapor transport from the Kuroshio in boreal fall

*Keita Fujiwara[1], Ryuichi Kawamura[2], Tetsuya Kawano[2]

1. Graduate School of Science, Kyushu University, 2. Faculty of Science, Kyushu University

A remote linkage between the development of tropical cyclone (TC) over the western North Pacific and moisture transport from the Kuroshio Current due to environmental flow toward TC was examined by using regional cloud resolving model and Lagrangian diagnostics. In this study, we specially highlighted a prototypical TC (Typhoon Chaba 2010), which developed and migrated northward over the Philippines Sea in boreal fall, and conducted sensitivity experiments that modified surface turbulent latent heat flux (LHF) over the Kuroshio. The large-scale environment was characterized by a combination of two synoptic systems, eastward-migrating anticyclone from the Asian continent and TC approaching Japan, bringing low-level northeasterly flows over the Kuroshio through an enhanced meridional pressure gradient in that region. Trajectory analyses suggested that air parcels along the northeasterlies modified by receiving abundant water vapor from the underlying Kuroshio may contribute to latent heating within Chaba’s inner core region as a remote effect, leading to TC development.

When LHF was removed or reduced over the Kuroshio under the dominance of the northwesterly flow, TC intensity attenuated during its developing stage even though TC was fairly far away from the Kuroshio. Since no or little modification of dry air parcels occurred in the atmospheric boundary layer over the Kuroshio, contribution of those parcels to latent heat release around Chaba’s eyewall become small. Furthermore, dry air penetration into TC’s inner core region may act as an inhibitor of convection within that region, resulting in deceleration of the TC development. These findings were consistent with another TC (Typhoon Toakge 2004) with a similar synoptic environment, increasing reliability of remote impact of moisture import from the Kuroshio on TC development.

# Asymmetrically Intensifying Processes of a Category 4 Super Typhoon Lan (2017) during High Vertical Wind Shear

*Sachie Kanada[1], Akiyoshi Wada[2], Kazuhisa Tsuboki[1]

1. Nagoya University, 2. Meteorological Research Institute

On 21 October 2017, Typhoon Lan developed to a Category 4 super typhoon with the minimum central pressure (MCP) of 915 hPa at 25.6 degrees north latitude and maintained the peak intensity until the storm arrived at 29.9˚N under a strong environmental vertical wind shear (VWS) of 14 m $s^{-1}$. To understand the intensification processes of an intense typhoon with such high VWS, numerical simulations on Typhoon Lan were conducted using a high-resolution three-dimensional atmosphere regional model, the Cloud Resolving Storm Simulator (CReSS; Tsuboki and Sakakibara, 2002). Two sensitivity experiments, 1dO and FO, were conducted with different SST representations. In the 1dO experiment, a simple thermal diffusion model was used to express temperature changes due to ocean vertical mixing. The FO experiment with a time-fixed SST did not consider the evolution of SST. Both experiments used the same initial and boundary conditions and model specifications for the atmosphere, started at 0000 UTC 18 October 2017, and had an integration time of 5 days. The computational domain was 2˚N–37.8˚N and 115˚E–145˚E. The number of horizontal grids in the computational domain was 752×896 with the horizontal grid size of 0.04 longitude by 0.04 latitude.

The typhoon simulated in the 1dO experiment successfully achieved the MCP of 910 hPa at 29.5˚N, exhibiting strong asymmetric precipitation pattern as observed by the satellites. The intensification processes were accompanied by rapid developments of the strong winds and warm core in the low-levels. The strong northeast VWS forced to tilt the storm axis to downshear side (northeast) and, in the downshear quadrants, tall, intense and upstanding eyewall updrafts (CBs) formed from the low-level convergence of the storm travelling northeastward with a relatively fast translation speed of 10 m $s^{-1}$. Meanwhile, dry subsidence from the upper-levels intensified the low-level warm core in the upshear side of the eye. Despite the inner-core convection and precipitation exhibited strong asymmetric structures, the axisymmetricity of the storm circulation was maintained in the mid-to-low levels and abundant water vapor enclosed in the eye allowed to develop CBs around the radius of the maximum wind speeds. Although the FO storm overestimated the MCP of 879hPa, the similar asymmetric patterns in precipitation and convection were also found in the FO storm. The results indicated that the storm structures of typhoon Lan would be less sensitive to the SST-cooling effect.

# Roles of preexisting oceanic condition and ocean coupling processes in the intensity prediction during the mature phase of Typhoon Trami (2018)

*Akiyoshi Wada[1]

1. Typhoon Research Department Meteorological Research Institute

Typhoon Trami (2018) is one of the typhoons that made landfall in Japan. According to the Regional Specialized Meteorological Center (RSMC) Tokyo best track analysis, the central pressure reached 915 hPa at 18 UTC on 24 September around 20˚N and then rapidly increased by 950 hPa in 18 hours. After the rapid increases in the central pressure, intensity forecasts announced further intensification to 935 hPa, but the typhoon could not intensify again. In order to clarify the impact of the cold eddies over the ocean on this forecast error, we conducted numerical simulations with different oceanic initial conditions (daily data from 19 to 25 September were used so that the number of ensemble members is seven) using a 2 km-mesh nonhydrostatic atmosphere model coupled with ocean surface wave and multilayer ocean models with the Japan Meteorological Agency (JMA) global objective analysis with horizontal resolution of 20 km and the JMA North Pacific Ocean analysis with horizontal resolution of 0.5˚. In addition, a sensitivity numerical experiment was conducted with the oceanic initial condition on 23 September merged with an artificial cold vortex centered at 21˚N, 129˚E of which both a mixed layer and thermocline was 50 m shallower than the control experiment. Moreover, a simulation with a 2 km-mesh nonhydrostatic atmosphere model was performed with the oceanic initial condition on 23 September. The initial time and integration period are 00 UTC on 23 September and 180 hours with the time interval of 3 seconds.

The results of simulated tracks were reasonable compared with the RSMC best track analysis, while the rapid decrease in the central pressure could not be simulated due to a large difference in central pressure at the initial time so that the simulated minimum central pressure was higher than the best track central pressure. From the analysis with the ratio of a difference to the standard deviation obtained from the ensemble experiments, the impact of different oceanic initial conditions on central pressure was different from that on the maximum wind speed particularly from 25 to 27 September when the typhoon passed near the cold eddy. The impact of ocean coupling on simulated central pressure and maximum wind speed was considerably greater than that of the artificial cold eddy and that of different oceanic initial conditions. The impact of the artificial cold eddy was a few times greater than that of different oceanic initial conditions around 26 September. The result indicates that more detailed observation and more accurate analysis regarding the cold eddy over the ocean will contribute to the improvement of typhoon intensity predictions.

# Development and assessment of the probabilistic storm surge forecast system in Taiwan: Case Study of Typhoon Maria in 2018

*Chun-Wei Lin[1], Tso-Ren Wu[1], Yu-Lin Tsai[1], Shu-Chun Chuang[1], Chi-Hao Chu[2], Chuen-Teyr Terng[2]

1. Graduate Institute of Hydrological and Oceanic Sciences, National Central University, Chungli, Taiwan, 2. Marine Meteorology Center, Central Weather Bureau, Taipei, Taiwan

From the forecast and the analyzed typhoon tracks in Taiwan, it is found that if the forecast track errors are greater than 100 km, roughly a quarter of the length of Taiwan, significant variability of storm surge elevation can be seen.
In order to consider the uncertainty of the atmospheric forecast, this study aims to develop the probabilistic storm surge forecast system. The coastal storm surge model applied in this study is COMCOT-SS (COrnell Multi-Grid COupled Tsunami Model –Storm Surge), which is the kernel of the operating deterministic storm surge forecast system in CWB, Taiwan. It solves nonlinear shallow water equations in the nested-grid scheme. Two ensemble methods are adopted in this study, one is Deterministic Track Error Distribution Method, D-TED Method. The other one is the Ensemble Track Analysis Method, ETA Method. D-TED Method is generated from the deterministic forecast, while the ETA Method obtains typhoon tracks and parameters from the CWB WEPS (CWB WRF Ensemble Prediction System).
From the case study of typhoon Maria in 2018, it shows that as the typhoon approaching Taiwan, the coverage of the tracks from ETA Method would be more convergence comparing to the tracks from D-TED Method, and it provides a more concentrated surge elevation distribution.

# Basic Data Construction for a Typhoon Disaster Prevention Model : Analysis and Changes by El Nino and La Nina year

*HANA NA[1], Woo-Sik Jung[1]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea

Among the typhoons that affected the Korean Peninsula for approximately 110 years from 1904, when weather observation began until 2018, all of the top five typhoons in terms of the maximum wind speed and property damage record occurred after 2000. This implies that the intensity of typhoons is becoming stronger and the damage is more severe compared to the past. Moreover, typhoons are significantly affected by the sea temperature. The El Nino and La Nina phenomena, in which significant changes in the sea temperature occur, may significantly affect the occurrence and intensity of typhoons affecting the Korean Peninsula. Therefore, this study aims to analyze changes by year, and the years of El Nino and La Nina occurrences by estimating the maximum wind speed that can be generated during typhoon period based on the typhoons that affected the Korean Peninsula. This study was conducted for the period between 2002 and 2015. As a result of analyzing the maximum wind speed of the typhoons that affected the Korean Peninsula by year, high 3-second gusts tended to occur in the Gyeongsang-do area including the southeast coast of the Korean Peninsula from 2002 to 2006. Subsequently, the strong wind area of the 3-second gusts expanded, and high 3-second gusts occurred in the Seoul metropolitan area. Moreover, as a result of investigating the 3-second gust characteristics for the years of El Nino and La Nina occurrences, a higher maximum wind speed was observed from the typhoons that affected the Korean Peninsula in the years of El Nino occurrence.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

# Basic Data Construction for a Typhoon Disaster Prevention Model : Analysis According to the Typhoon Path Type

*HANA NA[1], Woo-Sik JUNG[1]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea

In this study, a typhoon disaster prevention model was used to estimate the maximum wind speed during typhoon period by path type from all typhoons that affected the Korean Peninsula from 2002 to 2015. For the typhoon information and upper wind information used as input data, the results of the WRF numerical model, which utilized the Best Track data of the RSMC Tokyo Typhoon Center and the RDAPS data of the Korea Meteorological Administration, were applied. From analyzing the path type impact frequency using all typhoons that affected the Korean Peninsula during the study period (2002–2015), Type 7 that affected the Korean Peninsula through Japan was the most frequent, followed by Type 2 that directly landed on the Korean Peninsula through the southern coast. From analyzing the monthly path types of the typhoons that affected the Korean Peninsula, Type 2 that affected the Korean Peninsula by landing on the southern coast and Type 7 that affected the Korean Peninsula through Japan were the most frequent for the recently increasing September typhoons. The analysis of the maximum wind speed of the 3-second gust that may occur during typhoon period by path type revealed that Type 2 that affected the Korean Peninsula by landing on the southern coast exhibited the highest 3-second gust. As a result of examining the distribution of Type 2, high 3-second gusts occurred throughout the Korean Peninsula, including the southeast coast. As for the path of Type 2 that directly affected the Korean Peninsula by landing on the southern coast, the occurrence frequency was the second highest during the entire study period and the value of the 3-second gust, which was the maximum wind speed that may occur during typhoon period, was the highest.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

# Basic Data Construction for a Typhoon Disaster Prevention Model : Monthly Characteristics of Typhoon Rusa, Maemi, Kompasu, and Bolaven

*HANA NA[1], Woo-Sik Jung[1]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea

According to a typhoon report that summarized the typhoons that had affected the Korean Peninsula for approximately 100 years since the start of weather observation in the Korean Peninsula, the number of typhoons that affected the Korean Peninsula was the highest in August, followed by July, and September. A study that analyzed the period between 1953 and 2003 revealed that the number of typhoons that affected the Korean Peninsula was 62 in August, 49 in July, and 45 in September. As shown, previous studies that analyzed the typhoons that affected the Korean Peninsula by month were primarily focused on the impact frequency. This study aims to estimate the monthly impact frequency of the typhoons that affected the Korean Peninsula as well as the maximum wind speed that accompanied the typhoons. It also aims to construct the basic data of a typhoon disaster prevention model by estimating the maximum wind speed during typhoon period using Typhoon Rusa that resulted in the highest property damage, Typhoon Maemi that recorded the maximum wind speed, Typhoon Kompasu that significantly affected the Seoul metropolitan area, and Typhoon Bolaven that recently recorded severe damages. A typhoon disaster prevention model was used to estimate the maximum wind speed of the 3-second gust that may occur, and the 700 hPa wind speed estimated through WRF(Weather Research and Forecasting) numerical simulation was used as input data.

Unlike the target period reported in the white paper on typhoons (1904–2010), this study analyzed the monthly impact frequency of the typhoons that affected the Korean Peninsula from 2002 and 2015. The result indicated that the impact frequency was the highest in August, followed by July and September. This result was the same as that of the typhoon report. An analysis by year revealed that typhoon period increased in September. The 3-second gust was found to be the highest in September, followed by August and July. When this result was analyzed in relation to the recently increasing autumn typhoons (September and October), the 3-second gust result was the highest in September, indicating disaster prevention must be emphasized. By additionally analyzing the maximum wind speed distributions of Typhoon Rusa, Maemi, Kompasu, and Bolaven, the area with the maximum wind speed varied depending on the typhoon path, and the 3-second gust was higher than 44 m/s based on the typhoon intensity classification and accounted for approximately10%.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

# The mechanism of typhoon generated in the earth that rotates in the space where the solar wind blows

*Shinji Karasawa[1]

1. Miyagi National College of Technology Professor emeritus

The atmosphere in the upper tropical cyclone (TC) rotates the clock-wise direction by the trade winds and westerlies. The rotation speed near the center increases, because the angular momentum of the atmospheric molecule is transported. The eye of the typhoon is appeared at the place where the centrifugal force of the rotation on the flow exceeds compared with the difference of the pressure. The atmosphere including the vapor of water in the cumulonimbus are mixed with the cold air flow swirling in the clockwise direction at the eye of typhoon, where the water vapors become to the rain, and the cumulonimbus rotates in anticlockwise direction.
The solar wind includes rotational momentum and the rotational momentum of the solar wind generates the trade winds. On the other hand, the westerlies are caused by the solar wind that rotates the tail of Earth's magnetosphere on the opposite side of the Sun in anticlockwise rotation, and it gives the driving force of the westerlies. Ref. S. Karasawa.

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University)

Tropical cyclones (TC) sometimes cause destructive disasters in many countries by torrential rainfall, strong wind, storm surge, and high surf. In 2008, the western Japan suffered a record-breaking heavy rainfall related to Typhoon Prapirooon (2018) in July. Furthermore, two Category 4 typhoons, typhoons Jebi (2018) and Trami (2018), made landfalls on the western Japan in September and caused devastating disasters over the Japanese Islands. In the Northern Atlantic, Hurricane Florence caused catastrophic damage in the eastern side of U.S. Recent studies reported a northward shift of the location where a TC achieved the peak intensity and also reported increases in the frequency of rapidly intensifying storms. Thus, understanding the TC processes related to translation, intensity change and precipitation in the changing climate, and to provide more accurate forecasts and long-term projections are essential for the earth and planetary science.<br/>Advances in innovative observations such as meteorological aircraft, weather satellite, supercomputer systems such as the Earth Simulator and K-computer, and introduction of new methods such as the deep-learning, have led to novel development of numerical weather forecasting and understanding of the phenomena related to TCs in the past, present and future climates. In this session, we welcome papers on various aspects of TC studies. We hope that the session will provide a new direction for future TC researches.

# Numerical study on lightning frequency in a tropical cyclone

*Yousuke Sato[1,3], Yoshiaki Miyamoto[2,3], Tomita Hirofumi[3]

1. Department of Applied Energy, Nagoya University, 2. Faculty of Environment and Information Studies, Keio University, 3. RIKEN Center for Computational Science

This study investigates frequency of lightning in each stage of lifecycle of tropical cyclone (TC) using the next generation weather and climate library called Scalable Computing for Advanced Library and Environment (SCALE; Sato et al. 2015, Nishizawa et al. 2015). Lightning component was developed and implemented into SCALE in this study. An idealized experiment based on an experimental setup of Miyamoto and Takemi (2013) was conducted by SCALE coupled with lightning component. The results of the simulation indicate that the lightning frequency is maximum before rapid intensification (RI) of TC, which supports the report of Price et al. (2009) derived from satellite observation. The frequency of lightning decreases after RI and it keeps small until the TC reaches steady state. Our analyses elucidate that the dependency of the lightning frequency upon the developing stage of TC is originated from the type of convection dominating at each growth stage. Before the RI, the convection generated by consuming convective available potential energy (CAPE) transport hydrometeors upward, and the charge split and the lightning frequently occur. During the steady state, the hydrometeors are mainly transported by the fast rotating flow in the simulated TC, which resulted in the weak charge split and small frequency of lightning.

# Sensitivity of Numerical Simulation of Typhoon Nepartak (2016) to Cloud Condensation Nuclei Concentration

*Yu-De Wu[1], Jian-Liang Wang[1]

1. Dept. of Environmental Informational and Engineering, Chung Cheng Institute of Technology, National Defense University, Taiwan

The study is carried out using the WRF model and the Cloud Condensation Nuclei, CCN, in the WDM6 microphysics scheme has been modified to test its impacts on typhoon simulations. The simulated track, intensity, and rainfall distribution of Typhoon Nepartak (2016) over Pacific Ocean are compared among numerical experiments of different initial concentration of CCN (wdm6_ctr, wdm6_10, and wdm6_50, where wdm6_10 and wdm6_50 represent that CCN are respectively 10 and 50 times of the value used in wdm6_ctr).

The simulated tracks in three runs are similar, but the intensity and the maximum dBz increase both in wdm6_10 and wdm6_50, but it takes more time for wdm6_50 to intensify. The comparison of mixing ratios of five water species shows that the cloud droplets mixing ratios increase as CCN is increased. The mixing ratios of rain, cloud ice, snow and graupel are enhanced more rapidly in wdm6_10 compared with wdm6_50. The same situation happens in the divergence field and upward motions. It is suggested that the increase of CCN will result in stronger typhoon, but the intensification will be slowed down with too much CCN.

# Moisture Budget Analysis for Hurricane Precipitation on Texas

*Satoshi Iizuka[1], Naoki Sakai[1]

1. National Research Institute for Earth Science and Disaster Resilience

In August 2017, Hurricane Harvey brought the unprecedented amount of rainfall and catastrophic flooding on the Houston metropolitan area, as it stagnated near the coast of Texas for several days after its decline to a tropical storm intensity. The present study compares the moisture budget for rainfall associated with Harvey with those of past hurricanes making landfall on Texas. It seems that the high pressure over the west coast region of the US, along with the meandering of the subtropical jet starting from the periphery of Hawaii and toward the south in Texas, stagnated Hurricane Harvey around the coast of Texas for several days. The meandering of the subtropical jet toward the south in Texas also caused the largest convergence of moisture advected from the Gulf of Mexico efficiently over Texas, although the accompanied high pressure was not extraordinary event. Therefore, it is suggested that surrounding meteorological conditions can greatly affect rainfall related to tropical cyclones.

# Remote response of a developing tropical cyclone over the western North Pacific to large-scale vapor transport from the Kuroshio in boreal fall

*Keita Fujiwara[1], Ryuichi Kawamura[2], Tetsuya Kawano[2]

1. Graduate School of Science, Kyushu University, 2. Faculty of Science, Kyushu University

A remote linkage between the development of tropical cyclone (TC) over the western North Pacific and moisture transport from the Kuroshio Current due to environmental flow toward TC was examined by using regional cloud resolving model and Lagrangian diagnostics. In this study, we specially highlighted a prototypical TC (Typhoon Chaba 2010), which developed and migrated northward over the Philippines Sea in boreal fall, and conducted sensitivity experiments that modified surface turbulent latent heat flux (LHF) over the Kuroshio. The large-scale environment was characterized by a combination of two synoptic systems, eastward-migrating anticyclone from the Asian continent and TC approaching Japan, bringing low-level northeasterly flows over the Kuroshio through an enhanced meridional pressure gradient in that region. Trajectory analyses suggested that air parcels along the northeasterlies modified by receiving abundant water vapor from the underlying Kuroshio may contribute to latent heating within Chaba’s inner core region as a remote effect, leading to TC development.

When LHF was removed or reduced over the Kuroshio under the dominance of the northwesterly flow, TC intensity attenuated during its developing stage even though TC was fairly far away from the Kuroshio. Since no or little modification of dry air parcels occurred in the atmospheric boundary layer over the Kuroshio, contribution of those parcels to latent heat release around Chaba’s eyewall become small. Furthermore, dry air penetration into TC’s inner core region may act as an inhibitor of convection within that region, resulting in deceleration of the TC development. These findings were consistent with another TC (Typhoon Toakge 2004) with a similar synoptic environment, increasing reliability of remote impact of moisture import from the Kuroshio on TC development.

# Asymmetrically Intensifying Processes of a Category 4 Super Typhoon Lan (2017) during High Vertical Wind Shear

*Sachie Kanada[1], Akiyoshi Wada[2], Kazuhisa Tsuboki[1]

1. Nagoya University, 2. Meteorological Research Institute

On 21 October 2017, Typhoon Lan developed to a Category 4 super typhoon with the minimum central pressure (MCP) of 915 hPa at 25.6 degrees north latitude and maintained the peak intensity until the storm arrived at 29.9˚N under a strong environmental vertical wind shear (VWS) of 14 m $s^{-1}$. To understand the intensification processes of an intense typhoon with such high VWS, numerical simulations on Typhoon Lan were conducted using a high-resolution three-dimensional atmosphere regional model, the Cloud Resolving Storm Simulator (CReSS; Tsuboki and Sakakibara, 2002). Two sensitivity experiments, 1dO and FO, were conducted with different SST representations. In the 1dO experiment, a simple thermal diffusion model was used to express temperature changes due to ocean vertical mixing. The FO experiment with a time-fixed SST did not consider the evolution of SST. Both experiments used the same initial and boundary conditions and model specifications for the atmosphere, started at 0000 UTC 18 October 2017, and had an integration time of 5 days. The computational domain was 2˚N–37.8˚N and 115˚E–145˚E. The number of horizontal grids in the computational domain was 752×896 with the horizontal grid size of 0.04 longitude by 0.04 latitude.

The typhoon simulated in the 1dO experiment successfully achieved the MCP of 910 hPa at 29.5˚N, exhibiting strong asymmetric precipitation pattern as observed by the satellites. The intensification processes were accompanied by rapid developments of the strong winds and warm core in the low-levels. The strong northeast VWS forced to tilt the storm axis to downshear side (northeast) and, in the downshear quadrants, tall, intense and upstanding eyewall updrafts (CBs) formed from the low-level convergence of the storm travelling northeastward with a relatively fast translation speed of 10 m $s^{-1}$. Meanwhile, dry subsidence from the upper-levels intensified the low-level warm core in the upshear side of the eye. Despite the inner-core convection and precipitation exhibited strong asymmetric structures, the axisymmetricity of the storm circulation was maintained in the mid-to-low levels and abundant water vapor enclosed in the eye allowed to develop CBs around the radius of the maximum wind speeds. Although the FO storm overestimated the MCP of 879hPa, the similar asymmetric patterns in precipitation and convection were also found in the FO storm. The results indicated that the storm structures of typhoon Lan would be less sensitive to the SST-cooling effect.

# Roles of preexisting oceanic condition and ocean coupling processes in the intensity prediction during the mature phase of Typhoon Trami (2018)

*Akiyoshi Wada[1]

1. Typhoon Research Department Meteorological Research Institute

Typhoon Trami (2018) is one of the typhoons that made landfall in Japan. According to the Regional Specialized Meteorological Center (RSMC) Tokyo best track analysis, the central pressure reached 915 hPa at 18 UTC on 24 September around 20˚N and then rapidly increased by 950 hPa in 18 hours. After the rapid increases in the central pressure, intensity forecasts announced further intensification to 935 hPa, but the typhoon could not intensify again. In order to clarify the impact of the cold eddies over the ocean on this forecast error, we conducted numerical simulations with different oceanic initial conditions (daily data from 19 to 25 September were used so that the number of ensemble members is seven) using a 2 km-mesh nonhydrostatic atmosphere model coupled with ocean surface wave and multilayer ocean models with the Japan Meteorological Agency (JMA) global objective analysis with horizontal resolution of 20 km and the JMA North Pacific Ocean analysis with horizontal resolution of 0.5˚. In addition, a sensitivity numerical experiment was conducted with the oceanic initial condition on 23 September merged with an artificial cold vortex centered at 21˚N, 129˚E of which both a mixed layer and thermocline was 50 m shallower than the control experiment. Moreover, a simulation with a 2 km-mesh nonhydrostatic atmosphere model was performed with the oceanic initial condition on 23 September. The initial time and integration period are 00 UTC on 23 September and 180 hours with the time interval of 3 seconds.

The results of simulated tracks were reasonable compared with the RSMC best track analysis, while the rapid decrease in the central pressure could not be simulated due to a large difference in central pressure at the initial time so that the simulated minimum central pressure was higher than the best track central pressure. From the analysis with the ratio of a difference to the standard deviation obtained from the ensemble experiments, the impact of different oceanic initial conditions on central pressure was different from that on the maximum wind speed particularly from 25 to 27 September when the typhoon passed near the cold eddy. The impact of ocean coupling on simulated central pressure and maximum wind speed was considerably greater than that of the artificial cold eddy and that of different oceanic initial conditions. The impact of the artificial cold eddy was a few times greater than that of different oceanic initial conditions around 26 September. The result indicates that more detailed observation and more accurate analysis regarding the cold eddy over the ocean will contribute to the improvement of typhoon intensity predictions.

# Development and assessment of the probabilistic storm surge forecast system in Taiwan: Case Study of Typhoon Maria in 2018

*Chun-Wei Lin[1], Tso-Ren Wu[1], Yu-Lin Tsai[1], Shu-Chun Chuang[1], Chi-Hao Chu[2], Chuen-Teyr Terng[2]

1. Graduate Institute of Hydrological and Oceanic Sciences, National Central University, Chungli, Taiwan, 2. Marine Meteorology Center, Central Weather Bureau, Taipei, Taiwan

From the forecast and the analyzed typhoon tracks in Taiwan, it is found that if the forecast track errors are greater than 100 km, roughly a quarter of the length of Taiwan, significant variability of storm surge elevation can be seen.
In order to consider the uncertainty of the atmospheric forecast, this study aims to develop the probabilistic storm surge forecast system. The coastal storm surge model applied in this study is COMCOT-SS (COrnell Multi-Grid COupled Tsunami Model –Storm Surge), which is the kernel of the operating deterministic storm surge forecast system in CWB, Taiwan. It solves nonlinear shallow water equations in the nested-grid scheme. Two ensemble methods are adopted in this study, one is Deterministic Track Error Distribution Method, D-TED Method. The other one is the Ensemble Track Analysis Method, ETA Method. D-TED Method is generated from the deterministic forecast, while the ETA Method obtains typhoon tracks and parameters from the CWB WEPS (CWB WRF Ensemble Prediction System).
From the case study of typhoon Maria in 2018, it shows that as the typhoon approaching Taiwan, the coverage of the tracks from ETA Method would be more convergence comparing to the tracks from D-TED Method, and it provides a more concentrated surge elevation distribution.

# Basic Data Construction for a Typhoon Disaster Prevention Model : Analysis and Changes by El Nino and La Nina year

*HANA NA[1], Woo-Sik Jung[1]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea

Among the typhoons that affected the Korean Peninsula for approximately 110 years from 1904, when weather observation began until 2018, all of the top five typhoons in terms of the maximum wind speed and property damage record occurred after 2000. This implies that the intensity of typhoons is becoming stronger and the damage is more severe compared to the past. Moreover, typhoons are significantly affected by the sea temperature. The El Nino and La Nina phenomena, in which significant changes in the sea temperature occur, may significantly affect the occurrence and intensity of typhoons affecting the Korean Peninsula. Therefore, this study aims to analyze changes by year, and the years of El Nino and La Nina occurrences by estimating the maximum wind speed that can be generated during typhoon period based on the typhoons that affected the Korean Peninsula. This study was conducted for the period between 2002 and 2015. As a result of analyzing the maximum wind speed of the typhoons that affected the Korean Peninsula by year, high 3-second gusts tended to occur in the Gyeongsang-do area including the southeast coast of the Korean Peninsula from 2002 to 2006. Subsequently, the strong wind area of the 3-second gusts expanded, and high 3-second gusts occurred in the Seoul metropolitan area. Moreover, as a result of investigating the 3-second gust characteristics for the years of El Nino and La Nina occurrences, a higher maximum wind speed was observed from the typhoons that affected the Korean Peninsula in the years of El Nino occurrence.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

# Basic Data Construction for a Typhoon Disaster Prevention Model : Analysis According to the Typhoon Path Type

*HANA NA[1], Woo-Sik JUNG[1]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea

In this study, a typhoon disaster prevention model was used to estimate the maximum wind speed during typhoon period by path type from all typhoons that affected the Korean Peninsula from 2002 to 2015. For the typhoon information and upper wind information used as input data, the results of the WRF numerical model, which utilized the Best Track data of the RSMC Tokyo Typhoon Center and the RDAPS data of the Korea Meteorological Administration, were applied. From analyzing the path type impact frequency using all typhoons that affected the Korean Peninsula during the study period (2002–2015), Type 7 that affected the Korean Peninsula through Japan was the most frequent, followed by Type 2 that directly landed on the Korean Peninsula through the southern coast. From analyzing the monthly path types of the typhoons that affected the Korean Peninsula, Type 2 that affected the Korean Peninsula by landing on the southern coast and Type 7 that affected the Korean Peninsula through Japan were the most frequent for the recently increasing September typhoons. The analysis of the maximum wind speed of the 3-second gust that may occur during typhoon period by path type revealed that Type 2 that affected the Korean Peninsula by landing on the southern coast exhibited the highest 3-second gust. As a result of examining the distribution of Type 2, high 3-second gusts occurred throughout the Korean Peninsula, including the southeast coast. As for the path of Type 2 that directly affected the Korean Peninsula by landing on the southern coast, the occurrence frequency was the second highest during the entire study period and the value of the 3-second gust, which was the maximum wind speed that may occur during typhoon period, was the highest.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

# Basic Data Construction for a Typhoon Disaster Prevention Model : Monthly Characteristics of Typhoon Rusa, Maemi, Kompasu, and Bolaven

*HANA NA[1], Woo-Sik Jung[1]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea

According to a typhoon report that summarized the typhoons that had affected the Korean Peninsula for approximately 100 years since the start of weather observation in the Korean Peninsula, the number of typhoons that affected the Korean Peninsula was the highest in August, followed by July, and September. A study that analyzed the period between 1953 and 2003 revealed that the number of typhoons that affected the Korean Peninsula was 62 in August, 49 in July, and 45 in September. As shown, previous studies that analyzed the typhoons that affected the Korean Peninsula by month were primarily focused on the impact frequency. This study aims to estimate the monthly impact frequency of the typhoons that affected the Korean Peninsula as well as the maximum wind speed that accompanied the typhoons. It also aims to construct the basic data of a typhoon disaster prevention model by estimating the maximum wind speed during typhoon period using Typhoon Rusa that resulted in the highest property damage, Typhoon Maemi that recorded the maximum wind speed, Typhoon Kompasu that significantly affected the Seoul metropolitan area, and Typhoon Bolaven that recently recorded severe damages. A typhoon disaster prevention model was used to estimate the maximum wind speed of the 3-second gust that may occur, and the 700 hPa wind speed estimated through WRF(Weather Research and Forecasting) numerical simulation was used as input data.

Unlike the target period reported in the white paper on typhoons (1904–2010), this study analyzed the monthly impact frequency of the typhoons that affected the Korean Peninsula from 2002 and 2015. The result indicated that the impact frequency was the highest in August, followed by July and September. This result was the same as that of the typhoon report. An analysis by year revealed that typhoon period increased in September. The 3-second gust was found to be the highest in September, followed by August and July. When this result was analyzed in relation to the recently increasing autumn typhoons (September and October), the 3-second gust result was the highest in September, indicating disaster prevention must be emphasized. By additionally analyzing the maximum wind speed distributions of Typhoon Rusa, Maemi, Kompasu, and Bolaven, the area with the maximum wind speed varied depending on the typhoon path, and the 3-second gust was higher than 44 m/s based on the typhoon intensity classification and accounted for approximately10%.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

# The mechanism of typhoon generated in the earth that rotates in the space where the solar wind blows

*Shinji Karasawa[1]

1. Miyagi National College of Technology Professor emeritus

The atmosphere in the upper tropical cyclone (TC) rotates the clock-wise direction by the trade winds and westerlies. The rotation speed near the center increases, because the angular momentum of the atmospheric molecule is transported. The eye of the typhoon is appeared at the place where the centrifugal force of the rotation on the flow exceeds compared with the difference of the pressure. The atmosphere including the vapor of water in the cumulonimbus are mixed with the cold air flow swirling in the clockwise direction at the eye of typhoon, where the water vapors become to the rain, and the cumulonimbus rotates in anticlockwise direction.
The solar wind includes rotational momentum and the rotational momentum of the solar wind generates the trade winds. On the other hand, the westerlies are caused by the solar wind that rotates the tail of Earth's magnetosphere on the opposite side of the Sun in anticlockwise rotation, and it gives the driving force of the westerlies. Ref. S. Karasawa.

## [A-AS02] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus), Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University), Chairperson:Sachie Kanada(Nagoya University), Yoshiaki Miyamoto

Tropical cyclones (TC) sometimes cause destructive disasters in many countries by torrential rainfall, strong wind, storm surge, and high surf. In 2008, the western Japan suffered a record-breaking heavy rainfall related to Typhoon Prapirooon (2018) in July. Furthermore, two Category 4 typhoons, typhoons Jebi (2018) and Trami (2018), made landfalls on the western Japan in September and caused devastating disasters over the Japanese Islands. In the Northern Atlantic, Hurricane Florence caused catastrophic damage in the eastern side of U.S. Recent studies reported a northward shift of the location where a TC achieved the peak intensity and also reported increases in the frequency of rapidly intensifying storms. Thus, understanding the TC processes related to translation, intensity change and precipitation in the changing climate, and to provide more accurate forecasts and long-term projections are essential for the earth and planetary science.<br/>Advances in innovative observations such as meteorological aircraft, weather satellite, supercomputer systems such as the Earth Simulator and K-computer, and introduction of new methods such as the deep-learning, have led to novel development of numerical weather forecasting and understanding of the phenomena related to TCs in the past, present and future climates. In this session, we welcome papers on various aspects of TC studies. We hope that the session will provide a new direction for future TC researches.

# Evaluation of the monthly Potential of the 2018 typhoon activity and the effect of the positive PMM and SST of the eastern northwestern Pacific

*Takahiro Ishiyama[1], Masaki Satoh[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo

Typhoons in the northwest Pacific in 2018 exceeded the average for 29 occurrences, the number of landings to Japan to 5, and for the typhoon which became extreme strength it was updated with the most record and the activity was active. In the ENSO phase, La Niña phenomenon occurred in the beginning of 2018 but converged by early spring and El Niño phenomenon occurred in October. However, during the most active period of the typhoon (from June to November), the ENSO phase was still in a neutral state. Therefore, Pacific Meridional Mode (hereafter PMM) (Chiang and Vimont 2004) is focused recently. At the positive phase of PMM, a zone of warming sea surface temperature (hereafter SST) is formed in the northeast - southwest direction of 20 degrees north latitude, 120 degrees west latitude to 0 degrees north latitude and 180 degrees west longitude. Previous studies have pointed out that this positive PMM favors TC activities in the northwest Pacific (Zhang et al. 2016). Looking at the PMM index (SST) from 1948 to 2018, there was positive PMM in 2018 and the intensity was strong enough to be within 15th place of 71 in each month of active typhoon season. Especially, in August and September, strong positive PMM phenomenon was developed in 4th place and 2nd place.

The purpose of this research is to focus on the monthly SST variation such as ENSO and PMM and to evaluate the Potential of the 2018 typhoon activity. We also focus on the PMM and the SST over the eastern of northwest Pacific, and investigate how they affect the 2018 typhoon activity.

For the above purpose, we conducted perpetual experiments in which boundary conditions were fixed from July to October, respectively, using a nonhydrostatic model NICAM. The horizontal resolution was 56 km, and the number of vertical layers was 38 layers. In sensitivity experiments, PMM region and PMM + eastern northwest Pacific regions of SST in July 2018 sensitivity experiment 1 and sensitivity experiment 2 replaced with climate value were conducted. Comparing the experimental result of sea level pressure (hereafter SLP) with JRA-55, although the position of the maximum value of the high pressure in July is misaligned, the position and overhang of the high pressure does not differ greatly in each month, and perpetual experiments also reproduce the reality well. Both reanalysis and perpetual experiments have more typhoons in July and August than in September and October. Also, the occurrence position of the typhoon occurs more frequently in the eastern side of the northwestern Pacific in order of July, August, September. The same tendency was observed. Such differences in active areas of typhoon activity had an effect on the monsoon trough.
Subsequently, the SLPs of the 2018 experiment, sensitivity experiment 1 and sensitivity experiment 2 were compared. In comparison with the sensitivity experiment 1, the sensitivity experiment 1 became a lower pressure deviation in the west side of the northwest Pacific than 2018 experiment, whereas in the sensitivity experiment 2, the sensitivity experiment 2 had higher SLP in the whole northwest Pacific than 2018 experiment. From this, it was found that the positive SST deviation in the eastern northwest Pacific was more involved in the typhoon activity of 2018.

# Contributions of different time scale variations to tropical cyclogenesis over the western North Pacific

*Xi Cao[1]

1. Institute of Atmospheric Physics, Chinese Academy of Sciences

The present study investigates relative contributions of different time scale variations of environmental factors to the tropical cyclone (TC) genesis over the western North Pacific (WNP) during July-August-September-October (JASO). Distinct from previous studies that are concerned with large-scale spatial patterns during a certain period, the present study focuses on local and instantaneous conditions of the TC genesis. Analysis shows that the contribution of convection and lower-level vorticity to the TC genesis is mainly due to intraseasonal and synoptic variations. The contribution of vertical wind shear is largely related to synoptic variations. The contribution of mid-level specific humidity is almost two times more from intraseasonal variations than from synoptic variations. The contribution of sea surface temperature (SST) to the TC genesis is mainly due to interannual and intraseasonal variations. The barotropic energy for synoptic-scale disturbances during the TC genesis comes mainly from climatological mean flows over the southwest quadrant and from intraseasonal wind variations over the northeast quadrant of the WNP, respectively. The contribution of interannual variations to the TC genesis is enhanced over the southeast quadrant of the WNP. More TCs form under weak easterly and westerly vertical shears, respectively, during El Niño developing and decaying JASO. The contribution of interannual variations of SST tends to be larger during the El Niño decaying than developing JASO.

# Binary interaction between TC Chanthu (2016) and a nearby cold low

*Kosuke Ito[1], Miyabi Higa[1], Johnny Chan[2]

1. University of the Ryukyus, 2. City University of Hong Kong

Tropical cyclone (TC) Chanthu (2016) caused the heavy rainfall and strong wind on Hokkaido Prefecture, Japan. However, this was one of the "busted" cases in which the track forecast error reached up to 900 km in a 72-h forecast by the Regional Specialized Meteorological Center (RSMC) Tokyo. In fact, the re-forecast experiment with Japan Meterological Agency Non-Hydrostatic Model (JMA-NHM) that employed Kain-Fritsch scheme as a convective parameterization correctly captured the observed northward translation speed of TC Chanthu, while the JMA Global Spectral Model (JMA-GSM) and JMA-NHM that employed Arakawa-Schubert scheme failed to predict the accurate northward translation speed. The mesoscale analysis showed that there was a cold low located at 200km west of TC Chanthu (2016). With Kain-Frische scheme, the binary interaction between TC Chanthu and the nearby cold low was reproduced so that it contributed the faster translation to the north as consistent with the best track. In contrast, the binary interaction was not reproduced in the simulations with Arakawa-Schubert scheme because a triggered large-scale convection made TC Chanthu and the nearby cold low merged. It exemplifies that the reproduction of fine-scale features diminishes "busted" cases, which contributes to the disaster prevention and mitigation.

# Response of landfalling North Indian Ocean cyclonic disturbances to warming climate and associated environmental parameters

*JAGABANDHU PANDA[1], KASTURI SINGH[1]

1. Department of Earth and Atmospheric Sciences, National Institute of Technology Rourkela, India

Most of the studies focusing on cyclonic disturbances (CDs) concentrate on their frequency. However, the system that causes destruction to nearby coastal areas is the landfalling one. The impact of warming climate on landfalling CD activity is an interesting topic. Thus, the present study focuses on the landfalling activity of CDs formed over North Indian Ocean (NIO) and associated environmental parameters responsible for the same. The study is divided into two epochs i.e. pre-warming period (PWP) 1891-1946 and current warming period (CWP) 1947-2016 based on the sea surface temperature anomaly variation.

Over NIO, nearly 88 and 84.80% of systems made landfall over coastal areas associated with Bay of Bengal (BOB) basin and the respective percentages are 53.03 and 39% for AS during PWP and CWP respectively. The percentage of landfalling CDs shows a decreasing and stable trend respectively during PWP and CWP for BOB sub-basin. Over AS, the Kendall’ s coefficients are found to be −0.255 and −0.0024 during PWP and CWP respectively. The study reveals that Bangladesh, Andhra Pradesh (AP), and Tamil Nadu (TN) are more vulnerable to severe cyclones formed over BOB during the current warming climate. Whereas, for Arabian Sea (AS) region, Gujrat (GJ) is prone to severe cyclones and Arabian Peninsula countries are vulnerable to cyclonic storms during the current warming climate. For pre-monsoon season, among all NIO coastal states, Bangladesh and Arakan face a greater number of CD landfalls during CWP for BOB systems. Whereas, for post-monsoon season, AP, TN and Bangladesh suffered maximum landfalls. The seasonal landfalling activity of CDs over AS shows that Arabian Peninsula is more vulnerable than GJ in pre-monsoon season during CWP. However, for post-monsoon season, both Arabian Peninsula and GJ are significantly prone to landfalling CDs. During PWP, most of the systems formed over middle sector of BOB recurve in north-eastward direction. Whilst, one climatological track is found to be recurving towards Bangladesh, another one is towards AP during CWP. CDs formed over southern sector of BOB prefers two tracks, one being westward towards TN and the other is in north-east direction towards Bangladesh during CWP. The enhanced genesis over southern and middle sector of BOB is mainly responsible for more landfalls over AP, TN and Bangladesh. The CDs formed over the eastern AS basin recurve to make landfall over GJ or Oman during PWP. However, during CWP, another preferable track towards Yemen is also seen for the systems formed over eastern AS.

The climatological vertically integrated (mass-weighted) tropospheric wind pattern near TN coast has changed direction from westward during PWP to north-westward during CWP (Figure 1), favouring more landfall over AP and TN. Over the central part near the latitude 14˚N, change in the magnitude has occurred with change in the direction of the winds from NW-N to NE. Because of the prevailing wind steering pattern, the systems that formed over the middle and southern BOB do not prefer to make landfall to WB and Odisha during CWP. Over AS, the wind is mostly directed towards GJ irrespective of the period considered, which favours more landfalling of CDs over the place. These winds are primarily part of mid-latitude westerly troughs. For BOB, the SST gradient is in meridional direction and hence most of the systems formed, suffer landfall over Indian coastal states and other rim countries face less landfalls. Over AS, SST gradient is zonally distributed and therefore, the eastward deflection of CDs is more observed, making the Indian state of GJ to be the most affected region. The study is expected to be helpful in the decision-making process in view of socio-economic impacts of landfalling CDs.

# Rainfall contribution of North Indian Ocean cyclonic disturbances over India in a warming climate

*KASTURI SINGH[1], JAGABANDHU PANDA[1]

1. Department of Earth and Atmospheric Sciences, National Institute of Technology Rourkela, India

Rainfall associated with cyclonic disturbances (CDs) poses mostly significant threat to the society. Such type of systems and their remnants are capable of producing heavy rainfall, which often produce flash flooding. The warming climate is considered from 1947 onwards based on sea surface temperature anomaly variation over North Indian Ocean (NIO) basin. Nearly 71.42% of CDs in pre-monsoon and 87.07% CDs in post-monsoon season crossed or gazed the Indian coast during 140 cyclone seasons of the warming climate. The trend for annual variation of CD rainfall (CDR) anomaly is decreasing along with CD anomaly during pre-monsoon season (P=4.89901E-15). The trend for CDR anomaly is observed to be almost stable while the CD anomaly is decreasing drastically (P=1) in the post-monsoon season, indicating increased amount of rainfall is contributed by CDs over India in this period.

Among eastern coastal states, Andhra Pradesh (AP), Tamil Nadu (TN), Mizoram, Tripura and among western coastal states, Kerala (KL), Karnataka (KA) and Gujarat (GJ) received most of the accumulated rainfall in pre-monsoon season. The rainfall contributed by CDs during pre-monsoon season is limited to the coastal districts of India only. However, the rainfall occurrences during post-monsoon season could penetrate up to very interior districts. During post-monsoon season, Odisha (OD), AP and TN received the highest rainfall contribution from CDs. Jharkhand, KL, KA, parts of Maharashtra (MH) and coastal GJ received significantly higher amount of rainfall in comparison to other interior places. Up to ~70% of rainfall is contributed by CDs over GJ, nearly 20-30% over AP and 15-18% over western Rajasthan during pre-monsoon (Figure 1). During post-monsoon season, considerable rainfall (60% of annual value) contribution is seen over all states. The trend in CD rainfall is observed to be increasing over western GJ, western Rajasthan, northeast AP and southeast OD during pre-monsoon months. The spatio-temporal trend of CD rainfall over Bihar, Jharkhand, northern OD, northern Chhattisgarh, eastern Madhya Pradesh, Sikkim and Meghalaya are observed to be increasing during post-monsoon months. The rainfall contributed by CDs over the border regions of AP and TN is observed to be decreasing. Among eastern coastal states, AP has received 200cm of accumulated rainfall contribution during pre-monsoon season. The corresponding values for TN, OD and WB are 180, 140 and 140cm respectively. During post-monsoon season, AP received 1100cm of rainfall, OD and TN with 900cm of rainfall each, and WB received 450cm of accumulated rainfall contributed by CDs. For western coastal states, during pre-monsoon season, the maximum amount of accumulated rainfall contributions over GJ, MH, KA and KL are about 85, 75, 110 and 160cm respectively. During post-monsoon season, the corresponding values are nearly 134, 145, 320 and 350cm. Comparing the trend for maximum and minimum rainfall received by a coastal state, it can be concluded that even though the maximum values for some years are slightly less in comparison to other years, the minimum contribution is quite significant for those particular years. The possible reason can be due to larger and faster moving storms those result in longer precipitation durations with greater area coverage.

Further, the association of such rainfall contributions with ENSO, MJO and IOD cannot be undermined and thus, analyzed using observations and modeling output. The preliminary results indicate relative dominance of MJO in determining the CDR over Indian region during pre-monsoon months. During IOD –ve, heavy rainfall is contributed by CDs over AP and TN. The explicit discussion regarding the same will

# Analysis of typhoon tracks and associated precipitation amount over western Japan: A case study with Typhoon Nancy and Typhoon Jebi

*Sridhara Nayak[1], Tetsuya Takemi[1]

1. Disaster Prevention Research Institute, Kyoto University

Recent research suggests that typhoons under future warming climate will be more powerful and bring excessive precipitations to the landfall areas. In our study, we downscaled two very strong Typhoons [Typhoon Nancy (international #196118) and Typhoon Jebi (international #201821)] at 1-km grid resolution in present climate and with pseudo global warming (PGW) conditions by using Weather Research and Forecasting (WRF) model. An attempt is also made to examine whether the precipitation amounts carried by Typhoon Jebi can be projected from Typhoon Nancy with PGW conditions, because both typhoons made landfall over same region of Japan with a difference of 57 years. Our results indicate that the typhoon tracks in present climate simulation have good agreement with that of from the RSMC, Tokyo’ s best track datasets. The precipitation amounts over western Japan in the present climate simulation also follows the Radar-AMeDAS observed precipitation amounts. We again find similar typhoon tracks under PGW conditions for both typhoons with higher winds and precipitations compared to that of in present climate simulation. The precipitation amounts associated with the Typhoon Nancy in future climate is found to be higher than that of with Typhoon Jebi during the landfall. However, the 24 hours accumulated precipitation amount brought by Typhoon Nancy with PGW conditions has an overall good agreement with that of by Typhoon Jebi in present climate simulation especially over landfall region. Closer investigation on the typhoon tracks and typhoon induced precipitation amounts suggests that Typhoon Jebi is a possible projection of Typhoon Nancy although it was formed over different location.

[J] Oral | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

Thu. May 30, 2019 9:00 AM - 10:30 AM JST | Thu. May 30, 2019 12:00 AM - 1:30 AM UTC | 102 1F

## [A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Hisahiro Takashima(福岡大学)

This session provides a forum for the presentation of the broad spectrum of tropospheric and stratospheric chemistry, including various research topics (e.g., dynamical processes, air quality and climate), approaches (modeling, field measurements, remote sensing, and laboratory studies), and species (gas and aerosol). This session also provides an opportunity for discussing possible future collaboration with other research fields relevant to atmospheric chemistry. We strongly encourage authors to prepare presentation slides and a poster in English.

# Toward the Reduction of Radiative Forcing of Methane and Tropospheric Ozone: Aiming at the Emission Control of $CH_4$, $NO_x$and NMVOC in Asia

*Hajime Akimoto[1], Tatsuya NNagashima[1], Hiroshi Tanimoto[1], Zig Klimont[2], Markus Amann[2]

1. National Institute for Environmental Studies, 2. International Institute for Applied Systems Analysis

In order to reduce impacts of climate change, including potential further increase of damages due to extreme events related to global warming, reduction of burdens of $CH_4$and tropospheric ozone in Asia are discussed. In order to mitigate the inevitable further increase of radiative forcing (RF) of ca. 0.8 W $m^{-2}$by 2040 caused by the increase of $CO_2$in 2040, feasible reduction of the industrial RF of methane ($CH_4$) and tropospheric ozone (trop-$O_3$) to the 50% of the values in 2011 are targeted to compensate 50% of the RF increase of $CO_2$. The remaining RF of $CH_4$and trop-$O_3$(0.26 and 0.22 W $m^{-2}$, respectively) correspond to the historical levels in 1960-1970. The necessary reductions of anthropogenic emissions of $CH_4$, $NO_x$and NMVOC in Asia in 2040 to the level of 1970 from that of 2010 have been estimated to be 35% $CH_4$, 44% $NO_2$, and 22% NMVOC from those of 2010 assuming the same necessary reduction ratio as for the global emissions. The estimated reductions have been compared with the reduction amount proposed in the Solution Report prepared under UN Environment Asia Pacific Office in 2018. The presumed reduction of the Asian emissions by 2030 through introducing of proven control measures are 27, 57 and 55% for $CH_4$ , $NO_x$and NMVOC. Thus, the reduction of RF of more than 50% from the reference year of 2010 is feasible for trop-$O_3$if the emissions of $NO_x$and NMVOC from other part of the world could be reduced coherently. Further efforts would be necessary for the reduction RF of $CH_4$by more than 50% of the present value.

# Determination of atmospheric $NO_2$ column densities using a Pandora instrument measuring direct-sun spectra at Yokosuka, Japan: Improved validation of TROPOMI satellite observations

*Yugo Kanaya[1], Hisahiro Takashima[2,1], Masato I. Nodzu[3], Takashi Sekiya[7], Kazuyuki Miyazaki[1], Henk Eskes[4], Gaia Pinardi[5], Daniel Santana Diaz[6], Moritz Müller[6], Alexander Cede[6]

1. Research and Development Center for Global Change, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Fukuoka University, 3. Tokyo Metropolitan University, 4. KNMI, 5. BIRA-IASB, 6. LuftBlick, 7. Japan Agency for Marine-Earth Science and Technology (JAMSTEC)

Satellite observations of $NO_2$, a key atmospheric pollutant, have provided critical information on global distribution of $NO_x$ sources and their temporal changes since 1995, and advanced understanding of atmospheric chemistry. A recent remarkable improvement is with their spatial resolution, reaching 7×3.5 km for TROPOMI (Sentinel-5P), launched in 2017. However, there is still a fundamental issue of low bias in the determined tropospheric $NO_2$ column densities (e.g., 25-50% for TROPOMI), when evaluated against ground-based spectroscopic observations. Potential causes would be (1) a-priori vertical profile shapes, (2) co-present aerosols and/or surface albedo, and (3) spatial inhomogeneity of $NO_2$, while (4) uncertainty in the ground-based observations could also be important. At Yokosuka (32.32˚N, 139.65˚E), located on the south edge of Tokyo-Yokohama metropolitan area, we newly started direct-sun Pandora spectrometer observations in November 2018 and strengthened validation capability, where the scattered-sun MAX-DOAS observations (from a JAMSTEC original instrument) had been solely referenced before. Results during winter 2018/2019 showed TROPOMI (within 0.1˚ from Yokosuka) had ~40% low bias against MAX-DOAS. The magnitude of difference was similar to the results from longer comparison during Feb-Sep 2018 for TROPOMI and earlier comparisons for OMI (QA4ECV). Pandora (in direct-sun mode) gave values ~24 % less than MAX-DOAS; the cause of difference was likely spatial inhomogeneity, as pollution levels were higher in the northeast for the sight of MAX-DOAS than in south for Pandora. This was consistent with the fact that TROPOMI gave ~18% higher values, when the averaging area was shifted to northeast by 10 km. As such, the importance of factors (3) and (4) was newly evaluated. By considering MAX-DOAS profile shapes in the recalculation of satellite products, we will discuss on factor (1), and the possibility to derive near-surface $NO_2$ concentrations from satellite observations.

# A high-resolution global data assimilation for air pollution analysis on megacity scale using multi-sensor satellite measurements including TROPOMI $NO_2$ data

*Takashi Sekiya[1], Kazuyuki Miyazaki[2,1], Henk Eskes[3], Folkert Boersma[3], Koji Ogochi[1], Kengo Sudo[4,1], Masayuki Takigawa[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Jet Propulsion Laboratory/California Institute for Technology, 3. Royal Netherlands Meteorological Institute (KNMI), 4. Graduate School of Environmental Studies, Nagoya University

Intensive human activities lead to high emissions of air pollutants at megacities, causing severe damages to human health. The number of megacities is expected to rise in developing regions in the near future. Thus, it is important to provide information on air pollutants and their emissions on a megacity scale for the globe in a consistent way. In this study, we present the results from global chemical data assimilation of multi-species satellite observations with a resolution of 0.56 degree using an ensemble Kalman filter approach (Miyazaki et al., 2015) and high-resolution global chemical transport model, CHASER (Sekiya et al., 2018). Assimilated data were obtained from the OMI, GOME-2, and SCIAMACHY for tropospheric $NO_2$ column, the TES for $O_3$ profile, the MOPITT for total CO column, the MLS for $O_3$ and $HNO_3$ profiles, and the OMI for total $SO_2$ column. Data assimilation at 0.56-degree resolution largely improved agreements with the observed surface $NO_2$ pollutions on megacity scale, with reductions of the root mean square errors (RMSEs) relative to in-situ measuring networks (AirBase, AQS, Hong Kong EPD, and NIES) by 33% for Europe, by 67% for the U.S., and by 75% for East Asia, compared to the model simulations without data assimilation. With increasing horizontal resolution from 2.8 to 0.56 degree, the global total $NO_x$emission estimates became lower by 10% mainly because of the effects of non-linear $O_3$-$HO_x$-$NO_x$ chemistry, while resolving higher NOx emissions by a factor of 4-5 in most of the megacities than their surrounding areas. Using the high-resolution data assimilation system and applying advanced super-observation approach, we demonstrated that assimilation of tropospheric $NO_2$ retrievals from TROPOMI improved agreements of tropospheric $NO_2$ column with the assimilated TROPOMI data itself by 62% and with OMI by 40% (not used for data assimilation) compared to model simulation at 1.1-degree resolution for April 2018. These improvements primarily resulted from substantial emission reductions over the U.S., China and India and increases over rural regions relative to the a priori emissions (HTAP_v2.2+GFED4 +GEIA). These results demonstrated the potentials of the high-resolution global data assimilation with the combined use of advanced satellite observations to provide valuable information on spatial and temporal variations of air pollution on a megacity scale globally.

# Recent trends of $NO_2$, VOC, and tropospheric ozone concentrations observed around Chiba, Japan in 2013-2018

*Daichi Yonekawa[1], Hitoshi Irie[2]

1. Chiba university Graduate school, 2. Chiba university

Tropospheric ozone ($O_3$) is not only a major photochemical oxidant but also the third important greenhouse gas. In recent years its importance is widely recognized as a short-lived climate pollutant (SLCP). As nitrogen dioxide ($NO_2$) and volatile organic compounds (VOC) are both important precursors of $O_3$, they play a central role in photochemical chemistry in the atmosphere. In addition, they have negative direct effects on human health. However, recent trends of $O_3$, $NO_2$, and VOC have not been fully understood yet even in Japan.
Using the multi-axis differential optical absorption spectroscopy (MAX-DOAS), we conducted continuous observations of $NO_2$, formaldehyde (HCHO; as a substitute for VOC) and $O_3$ concentrations for altitudes of 0-1 km at the SKYNET Chiba site (35.63ºN, 140.10ºE, 21 m asl) for 6 years from 2013 to 2018. Analysis of the data showed that $NO_2$ and HCHO concentrations decreased by about 30%, but a systematic decrease in $O_3$ concentration was not observed. Similar trends were seen in tropospheric $NO_2$ column data obtained by the Ozone Monitoring Instrument (OMI) onboard the Aura satellite of the National Aeronautics and Space Administration (NASA), and concentration data of $NO_2$, non-methane hydrocarbon (NMHC; as a substitute for VOC), and photochemical oxidant (Ox; as a substitute for $O_3$) observed by the atmospheric environmental regional observation system (AEROS) called Soramamekun. These results are consistent with previous reports. In this presentation, the observed trends and their causes will also be discussed by utilizing our unique MAX-DOAS system that was directed to 4 different azimuth directions (north, east, west, and south), while traffic is heavy at the north, a residential area is located at the east, there is a sea at the west, and a factory area is located at the south around the SKYNET Chiba site.

# Long-term seasonal changes in tropospheric ozone over Japan

*Natsumi Kawano[1], Tatsuya Nagashima[1], Seiji Sugata[1]

1. National Institute for Environmental Studies

Tropospheric $O_3$ is the primary source of OH radicals in the troposphere that contribute to the oxidation capacity of the atmosphere. According to the seasonal cycles of surface $O_3$, different behaviors at the remote and metropolitan areas in northern midlatitude have been pointed out (Parrish et al., 2013; Cooper et al., 2014; McGlynn et al., 2018; Jung et al., 2018). For example, European, American and Asian continental remote sites indicated that the seasonal cycle in the present decade had earlier annual maximum peaks than the maximum in the past decades. On the other hand, delayed maximum peaks appeared in urban locations. In spite of lots of monitoring stations, research for changes in seasonal $O_3$ cycles in Japan is still unclear. In this study, we investigate the seasonal cycle changes by using long-term continuous $O_3$ monitoring data at 265 ambient sites.
First, to clarify the annual $O_3$ maximum, sine function fitting examined by Parrish et al. (2013) was applied to monitoring data between the 1980s and 2010s. Regarding the spatial distribution of seasonal shifting between the 1980s and 2010s, most monitoring sites showed changes in a delayed shift. In particular, the stations with more than 0.2 days/decade delay belong to eastern and southwestern parts of Japan. Next, sine function was fitted to 5-years moving average over the entire data record to acquire the long-term trends of seasonal maximum in each region. All monitoring station were classified based on the 35-years averaged NOx concentration: urban, suburban and rural (Kurokawa et al., 2009). Results in all classifications showed delayed trends over analysis periods. In rural sites, $O_3$ mixing ratio reached the annual maximum in 5-days earlier than urban and suburban sites. In future work, we will conduct long-term air quality simulation and investigate the mechanism of seasonal cycle delaying.

# Characteristics of Atmospheric Photochemical Pollution at a Comprehensive Site in Guangzhou, China

*Yu Zou[1]

1. Institute of Tropical and Marine Meteorology, CMA,Guangzhou,China

Guangzhou, one of China’ s megacities, is beset with frequent occurrence of atmospheric photochemistry events. In this study, online instruments were used to simultaneously monitor NMHCs, NO*x* and $O_3$ at Guangzhou Panyu Atmospheric Composition Station (GPACS) of the China Meteorological Administration (CMA), from June 2011 to May 2012, in order to obtain their characteristics, NMHCs reactivity and the control strategies for atmospheric photochemistry. The results showed that during the observation period, the seasonal variation of $O_3$ mixing ratio was lower in spring and winter compared to summer and autumn, which was opposite that for NMHCs and NO*x*. $O_3$ mixing ratio began to show a net increase at 8:00LT, likely due to the breakup of the nocturnal boundary layer and increased photochemistry, while a net decrease in $O_3$ mixing ratio occurred at about 15:00LT, due to the fact that sunlight and its associated photochemistry begin to decrease, leading to low OH radicals and the titration of $O_3$ by emissions of NO*x*. In terms of NMHCs, aromatics had the largest $O_3$ formation potential, among which toluene, xylenes, ethylbenzene, 1,2,4-trimethylbenzene and 1,3,5-trimethybenzene were the most important species, with a total contribution of about 44%. Weekday/weekend $O_3$ differences in the morning and at midday largely depend on how much the $O_3$ precursors are affected by the different intensity of anthropogenic activities. Although the increase of biogenic NMHCs emissions at midday reverses the sensitivity of $O_3$ production from NMHCs-sensitive to NO*x*-sensitive, high-reactive NMHCs and NO*x* control can be effective for reducing peak $O_3$ mixing ratios in Guangzhou. Further investigation based on numerical models is required to reach more robust conclusions.

# LC/MS analysis of molecular markers present in biogenic secondary organic aerosols collected during year-round observations at a cool-temperature forest

*Kei Sato[1], Sathiyamurthi Ramasamy[1], Satoshi Inomata[1], Yuzo Miyazaki[2]

1. National Institute for Environmental Studies, 2. Hokkaido University

To understand formation processes for organic nitrogen and dimeric compounds present in forest aerosols, we analyzed molecular markers present in forest aerosols collected during year-round observations using negative/mode electrospray ionization-liquid chromatography-mass spectrometry (ESI-LC/MS). Thirty-seven aerosol filter samples were collected at Tomakomai Experimental Forest between January and December in 2013, and 33 of the collected samples were analyzed in this study. Molecular markers analyzed in this study were cis-pinic acid, 3-methyl-1,2,3-butanetricarboxylic acid (3-MBTCA), α-pinene-derived dimer detected by ESI at m/z 357 (α-pinene dimer), isoprene-derived olganosulfate detected at m/z 215 (isoprene OS), and isoprene-derived nitrooxyorganosulfate detected at m/z 260 (isoprene NOS). Each aerosol filter sample was extracted in methanol; the extract was concentrated under gentle stream of nitrogen; the concentrated extract was dissolved in an analytical solvent to obtain an analytical sample; and the analytical sample was analyzed by an LC/MS instrument (Sato et al., 2007). The seasonal change in the concentration of cis-pinic acid, formed from α-pinene oxidation, was peaked in spring and fall, whereas the seasonal change in the concentration of 3-MBTCA, formed from oxidation of pinonic acid, was peaked in summer. Very similar results were reported in a previous paper on the GC/MS analysis of the same samples (Müller et al., 2017). The seasonal change in the concentration of α-pinene dimer was similar to that of cis-pinic acid, suggesting that a major formation process of the detected dimers was the atmospheric oxidation of α-pinene. The seasonal changes in the concentrations of isoprene OS and isoprene NOS, which are derived from isoprene epoxydiol (IEPOX), were peaked at fall and summer, respectively. The seasonal change in the concentration of isoprene NOS agreed well with that of 2-methyltetrols, molecular markers of isoprene secondary organic aerosol. These results suggest that a major formation process of isoprene NOS is secondary organic aerosol formation from isoprene in the presence of air pollutants.

# Surfactant Effects on Acid-Catalyzed Reactions at Aqueous Aerosol Surfaces

*Shinnosuke Ishizuka[1], Tetsuya Hama[2], Shinichi Enami[1]

1. National Institute for Environmental Studies, 2. Institute for Low Temperature Science, Hokkaido University

The outermost layer of atmospheric aqueous aerosol is covered with amphiphilic organic compounds. Volatile organic compounds (VOCs) in the gas phase should encounter them first at the air/aerosol interface, rather than solute molecules homgeneously distributed in the bulk. It may control the whole reactivity of the aqueous aerosol and play key roles in birth, growth and degradation processes of atmospheric aerosols. Here we studied activities of quaternary alkyl trimethyl ammonium cations $CH_3(CH_2)_{n-1}(CH_3)_3N^+$ (n = 1, 4, 8, 10, 12, 14) at the surfaces of water using surface-sensitive spraying ionization mass spectrometry. The longer-chain alkyl ammonium cations are detected more prominently at the water surface of the equimolar solution, expressed as an exponential function of the alkyl chain length. We suggest the occurrence of competitive adsorption among the quaternary ammonium cations at water surface. Then, the surfactant effects on the gaseous uptake and subsequent reactions of VOCs was investigated. When isoprene is exposed to acidified water surfaces, proton transfer reaction from $H_3O^+$ to isoprene occurs, which is followed by chain-propagation reactions. We found that the longer-chain ammonium cations suppressed isoprene oligomer signals but rarely hindered chain-propagation reactions even at larger concentrations, e.g., the higher surface coverage. It suggests that gaseous isoprene is directly added to the protonated species at water surface. We conclude that competitive adsorption between isoprene oligomers and the ammonium cations suppressed the acid-catalyzed reactions. Driving force leading to the adsorptive competition will be argued based on experiments performed by adding anionic and neutral surfactants.

# Roles of heterogeneous reactions in the tropospheric chemistry: a global modeling study

*Phuc Thi Minh Ha[1], Fumikazu Taketani[2], Yugo Kanaya[2], Kengo Sudo[1,2]

1. Graduate School of Environmental Studies, Nagoya University, 2. Research and Development Center for Global Change, JAMSTEC

Heterogeneous reactions in the atmosphere largely affect air quality and climate by changing tropospheric photochemical processes involving gases like $O_3$, $HO_x$, $NO_x$, $HNO_3$, CO, VOCs, and aerosols. There are many previous studies on the effects of heterogeneous reactions at regional to global scales using direct measurements, remote sensing, and simulation. For the atmospheric chemistry simulation, there is a large uncertainty from the treatment of the heterogeneous reactions in the model due to the still insufficient understanding of the mechanism of heterogeneous reactions.
This study is intended to understand the roles of the heterogeneous reactions in the global tropospheric chemistry using a chemistry-climate model CHASER (MIROCESM) (Sudo et al., 2011) which includes more than 250 chemical reactions in the troposphere and stratosphere with more than 70 chemical species. This model also includes aerosol components (SPRINTARS) for sulfate, nitrate, BC, POA/SOA, dust, and sea-salt; formation of nitrate and SOA, and ageing of BC are calculated tightly linked to the chemistry in CHASER. The present version of CHASER considers heterogeneous reactions of $N_2O_5$, $HO_2$, $RO_2$, and HCHO for surfaces of the individual aerosol components and cloud particles.
The model simulation is validated with the observational data from EANET, EMEP and the ship-based observation. Our performed sensitivity simulations with respect to the heterogeneous reactions show that the impacts of the $N_2O_5$ heterogeneous reaction may not be as large as previously reported; surface concentrations of $NO_x$, $O_3$ and OH are only reduced by 1.6%, 2.2%, 2.6%, respectively, in global mean (in regional, at most, 23%, 5.4%, and 12.8%). Whereas, the $HO_2$ reaction (to form $H_2O_2$) can cause a significant effect on distributions of $O_3$ and related species ($NO_x$, $O_3$, OH are changed by 68.7%, -21.5% and -70.1%). In addition to the polluted areas in China and India, we found that in the North Pacific region the heterogeneous reactions can play a critical role in the concentrations of $NO_x$, $O_3$, CO, OH, $HO_2$ (up to 69%, 21%, 7%, 70%, 81%, respectively). The possible large impacts of the heterogeneous reactions are also verified with the ship-based observational data for the North Pacific and Alaska regions.

# Sensitivity of regional deposition of inhaled atmospheric aerosols in human respiratory tract to their size distribution and hygroscopicity: A case study

*Minrui Wang[1], Toshiyuki Mihara[2,4], Mizuo Kajino[5], Kaori Kawana[2,6], Michihiro Mochida[1,2,3]

1. Institute for Space Earth Environmental Research, 2. Graduate School of Environmental Studies, Nagoya University, 3. Institute for Advanced Research, Nagoya University, 4. Now at Gifu Prefectural Industrial Research Institute, 5. Meteorological Research Institute, Japan Meteorological Agency, 6. Now at Research and Development Center for Global Change, JAMASTEC

Aerosols, which inhaled to human respiratory tract, can cause various diseases that threaten one's health. In order to estimate aerosol's health risk, it is significant to elucidate the sensitivity of regional deposition of inhaled aerosols.

In this study, by applying size distribution and hygroscopic growth factor data of aerosol (measured by a scanning mobility particle sizer in September 2009 and July-August 2010) to an MPPD (Multiple-Path Particle Dosimetry) model, we calculated the regional deposition differentiated by size diameter/hygroscopicity for a resting/light exercising adult male. As a result, regional deposition ratio in intrathoracic region (both tracheobronchial airway and alveolar interstitium) showed a bimodal distribution among particle size diameter ranging between 24.1~359.0 nm, in which the maximum value was 50.1%/50.0% at 24.1 nm (during light exercise). In general, there was a decreasing trend in deposition ratio when particle size diameter increased. For mode particles (dry diameter $d_{p,dry} < 100$ nm), the regional deposition of particles that have low hygroscopicity parameter ($\kappa$) tent to be larger than those with higher $\kappa$. However, for larger particles (especially when $d_{p,dry} > 200$ nm), this trend became reversed.

In 2009 the measurement was continuous for 10 days, while daily variation was found in aerosol number-size distribution and regional deposition. Therefore, we analyzed the meteorological data of the measurement period in 2009, comparing daytime (12:00-18:00 LST) and nighttime (00:00-06:00 LST) in order to indicate meteorological matters that affect the temporal variation of regional deposition. The result showed that the relative humidity (RH) during daytime was basically lower than 50% except September 15 and September 22~23 due to continuous rain, and the distribution of regional deposition was maximum for relatively hydrophobic mode particles ($d_{p,dry} < 100$ nm, hygroscopic growth factor $g$ ranges between 1.0~1.2). On the other hand, RH during nighttime was mostly higher than 60%, and a bimodal distribution of both hydrophobic and hydrophilic ($g$ ranges between 1.2~1.4) particles was found. Meanwhile, on September 23 RH was high (over 75%) during whole day, we found a monomodal distribution of regional deposition with a maximum value for hydrophilic particles that last about 6 hours in the afternoon.

According to our results we suggested that along with the temporal variation of artificial emission, changes in ambient humidity could also influence the composition of inhaled aerosol particles to a great extent, and therefore affected the regional deposition.

# Biogeochemical cycle between atmosphere and ocean via particulate matters
# -Award lecture for JpSAC Young Scientist Award-

*Yoko Iwamoto[1]

1. Graduate School of Biosphere Science, Hiroshima University

The oceans absorbs carbon dioxide which is increasing in the atmosphere and has the ability to mitigate sudden climate change. The biological pump driven by marine phytoplankton play an important role in the global carbon cycle. In order to accurately estimate the carbon absorptive capacity of the oceans, it is important to know the supply amount of nutrient elements that support the growth of phytoplankton. Despite the fact that iron is an essential element for marine phytoplankton, the concentration of dissolved iron in the surface ocean is extremely low. Iron containing aerosols such as mineral dust in the atmosphere could be important as a source of iron to the surface ocean.

In my previous work, the sporadic deposition of atmospheric mineral dust by sea fog over the North Pacific was observed during an Asian dust event. By using bulk and individual particle analyses for suspended particulate matters in seawater, the biogeochemical impact of the dust deposition was investigated. As a result, it was found that the bioavailable iron supply to the surface ocean by an Asian dust event was sufficient to promote the growth of phytoplankton, and it also contribute the carbon absorption to the northern North Pacific. In addition, from a mapping data covering the North Pacific and its marginal seas, it was revealed that mineral particles of atmospheric origin existed ubiquitously in the surface ocean even during summer when the influence of Asian dust event is small.

On the other hand, the growth of marine phytoplankton causes changes in the atmospheric environment through aerosol generation. My current research focuses on oceanic aerosols acting as cloud condensation nuclei. From the continuous observation conducted at Noto ground-based research observatory (NOTOGRO) facing the Sea of Japan, it was found that the growth rate of cloud droplets delayed when the organic mass fraction of the aerosol was high. Currently, researches on the linkage between phytoplankton species and marine biogenic aerosol and the climate effect of aerosol generated by bubble bursting at the air-sea interface are conducted.

# Kinetic Studies for Quantitative Elucidation of Heterogeneous Halogen Chemistry in the Troposphere
# -JpSAC Early Career Scientist Award Lecure-

*Yosuke Sakamoto[1,2]

1. Graduate School of Global Environmental Studies, Kyoto University , 2. Graduate School of Human and Environmental Studies, Kyoto University

Ozone is one of the most important species in the troposphere since it has health and environmental effects, and relates to atmospheric oxidation capacity and climate change. Halogen species are deeply involved in the tropospheric ozone chemistry by forming catalytic reaction cycles. Observations, model simulations and laboratory experiments have suggested that heterogeneous reactions of gaseous oxidants such as ozone and OH radical with halide ions in sea water/ice and sea salt aerosol are important halogen emission sources. However, quantitatively we still have not had conclusions of their importance in many cases due to experimental difficulties to determine kinetic parameters for the heterogeneous reactions. To obtain quantitative kinetic parameters of gas-liquid heterogeneous oxidation reactions of halide ions which are difficult for conventional methods, this study has developed original approaches using laser spectroscopy or mass spectrometry, and applied them to kinetic studies. This presentation includes results of three reaction systems: 1. gaseous ozone with iodide solution (Sakamoto et al. 2009, 2013), 2. gaseous ozone with bromide solution (Sakamoto et al. 2018a), 3. gaseous OH radical with chloride containing deliquesced aerosol (Sakamoto et al. 2018b), and also discussion on contribution of interfacial process to total reaction rate.

# Validation of GOSAT cloud judgement by using Himawari-8 data

*Kitamura Katsuki[1], Naoko Saitoh[2]

1. Chiba University Graduate School of Science and Engineering Division of Earth Environmental Science , 2. Center for Environmental Remote Sensing Chiba University

In the retrieval processing of greenhouse gases from the Thermal and Near Infrared Sensor for Carbon Observation (TANSO)−Fourier Transform Spectrometer (FTS) on board Greenhouse Gases Observing Satellite (GOSAT), cloud contamination in the field of views (FOVs) of TANSO−FTS has been judged by TANSO−Cloud and Aerosol Imager (CAI) in the daytime and by the thermal infrared (TIR) band of TANSO−FTS in the nighttime. This study has compared the cloud detections in the TANSO−FTS FOVs by TANSO−CAI or TANSO−FTS TIR band with cloud detections by the Advanced Himawari Imager (AHI) on board Himawari−8.

For each of all TANSO−FTS observations over the ocean in January and July in 2016, we first selected all coincident Himawari−8 data when their center positions were located in the TANSO−FTS FOVs and they were obtained within one minute before or after the TANSO−FTS observations. Next, we conducted cloud detection tests for each of the selected Himawari−8 data based on their reflectance and brightness temperature values, and then judged each of TANSO−FTS FOVs as a clear or cloudy scene by combining the cloud detection tests of the Himawari−8 data in the TANSO−FTS FOVs.

About 90% of cloud judgements by TANSO−CAI and Himawari−8 agreed with each other. TANSO−CAI used only reflectance data in visible bands for their cloud detections, whereas Himawari−8 used both reflectance and brightness temperature data in visible and infrared bands, respectively, which may cause their ~10% disagreements. In contrast, agreements in cloud judgements between TANSO−FTS TIR band and Himawari−8 got worse by 13−20% compared to the TANSO−CAI and Himawari−8 cloud judgements. This is because that the FOVs of TANSO−FTS (10.5 km) is larger than those of TANSO−CAI and Himawari−8 (0.5 km and 2 km), and cloud detections by TANSO−FTS TIR band used only brightness temperature data.

In addition, GOSAT cloud judgements (TANSO−CAI or TANSO−FTS TIR band) tended to judge TANSO−FTS FOVs as “clear”, whereas Himawari−8 judged the same TANSO−FTS FOVs as “cloud” in most cases of disagreements in their cloud judgements. This is partly because of “clear conservativeness” of our cloud detection algorithm by Himawari−8. As for TANSO−FTS FOVs judged as “clear” by TANSO−FTS TIR band and “cloud” by Himawari−8, small-scale clouds partly existed in the TANSO−FTS FOVs judging from relatively low brightness temperature values of the coincident Himawari−8 data. This suggests the possibility that TANSO−FTS TIR band cannot detect such small-scale clouds.

# Measurement of temperature that fungal spores form ice nuclei

*Kazuyuki Kita[1], Kansei Sasaki[1], Koutaro Minami[1], Takeshi Kinase[2], Kouji Adachi[2], Yuji Zaizen[2], Kentaro Hosaka[3], Teruya Maki[4], Yasuhito Igarashi[1,5]

## 1. Background

Aerosols act as condensation nuclei and ice nuclei for the cloud particle formation in the atmosphere. In recent years, it was discovered that some bioaerosols can be ice-nuclei at relatively high temperatures of -15 ˚C or higher, indicating the possibility they could form ice clouds and precipitation at lower altitudes where formation mechanism of ice clouds has not been understood, and their significance in the meteorology and climate has been recognized. Although there have been many studies that measure ice nuclei formation temperature for general aerosols, it has been measured for very limited number of fungal spores in those studies. Thus, it has been not yet understood what kind of fungal spores can work as ice nuclei at relatively high temperatures.

In this research, we measured ice nucleation of spores of various kinds of fungi sampled in Japanese forests and examined the relationship between ice nucleation temperature and biological classification. We also classified patterns of ice nuclei formation, which may have information on ice nuclei formation temperature and process.

## 2. Method

In this research, spores were sampled from fungi collected during fungi surveys conducted every month from May to October in various types of woods in the Tsukuba Botanical Garden. Some fungi were also collected in the forests of Namie Town, Fukushima Prefecture. Using an optical microscope equipped with a cooling stage, ice nuclei form of generation of ice nuclei is observed.

## 3. Results and discussion

The ice nucleation temperatures of fungal spores showed large diversity, depending on their species. The ice nucleation temperature depends on the biological classification of fungi. Although there were a large variation, ice nucleation temperatures of spores of *Russulales*, ranged from -20 to -30 ˚C. The temperatures of *Boletales* spores were about -30 ˚C, and they of *Polyporales* spores were -22 ˚C. *Agaricales* can be divided into two groups: spore ice nucleation temperature was about -15 ˚C and about - 30 ˚C. The generation form of ice nuclei in spores can be categorized into 4 groups: A: ice grows from the whole spore surface after its swelling, B: ice grows suddenly from the spore surface, C: ice grows from a particular part of spores, D: ice generated around spores. Although there are a few exceptions, most of the spores that could be classified as “A” became ice nucleus at a relatively high temperature of -15 ˚C or higher. For other developmental forms, the relationship with ice nucleation temperature is not clear. Measuring the ice nucleation temperatures of various kinds of fungal spores this study found that some

©2019. Japan Geoscience Union. All Right Reserved. 

fungal spores can become ice nuclei at a relatively high temperature of -15 ˚C or so, showing a possibility that fungal spore can produce ice clouds in relatively lower atmosphere. It is also found that fungal spores forming ice at relatively high temperature mostly classified as *Agaricales* , and that they swelled just before they made ice particles. These results may have information on factors determining the ice formation temperature of spores.

# Investigation of Atmospheric Aerosol Particles and gases by R/V Mirai cruise over the Arctic Ocean on 2017

*Fumikazu Taketani[1], Saki Kato[1,2], Takuma Miyakawa[1], Masayuki Takigawa[1], Masahiro Yamaguchi[1], Hisahiro Takashima[1,2], Petr Mordovskoi[1], Yugo Kanaya[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Fukuoka University

Atmospheric aerosol particles play an important role in Arctic climate through the absorbing and scattering of solar radiation. Also, the deposition of light-absorbing particles on the surface reduces the Earth’ s albedo and accelerates snow/ice melting by absorbing the sunlight. However, the observational information has been still insufficient to assess their contribution over the Arctic region. In this study, we conducted the ship-based measurements of marine aerosol particles (black carbon (BC), and fluorescent property) and trace gases (ozone and carbon monoxide) using R/V Mirai during a cruise across the Arctic Ocean and Bering Sea (23 August –4 October 2017). The measured BC mass concentration over the Arctic Ocean in the latitudinal region > 70˚N was an overall mean value of 3.5 ±2.0 ng/$m^3$ . This value was almost same to the levels recorded during our previous observations in the Arctic cruise on September during 2014 -2016. We captured relatively high BC mass concentration and/or CO mixing ratio events at 4 and 7-12 September 2017. The trajectory and BC property suggested that the source of BC on 4 September could be oil field at north of Alaska. We will present further analysis on the size distribution, BC mixing state, during the cruise in the presentation.

# Characterization of carbonaceous aerosols in East Asia in the spring of 2015: Importance of non-fossil fuel sources

*Takuma Miyakawa[1], Yuichi Komazaki[1], Fumikazu Taketani[1], Xiaole PAN[2], Zifa Wang[2], Yugo Kanaya[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Institute for Atmospheric Physics, Chinese Academy of Science

The sources of elemental (EC) and organic carbon (OC) aerosols in the spring of 2015 in Asian outflow were investigated in terms of the radiocarbon ($^{14}C$) for carbonaceous aerosols and organic molecular marker analyses. The contribution of fossil fuel (FF) sources to total carbonaceous aerosols (TC) significantly increased in polluted air masses with enhancements of carbon monoxide concentrations. For EC, FF sources dominated in the polluted air masses. For OC, the contributions of non-FF and non-biomass burning (BB) sources were found to be significant (comparable to or higher than those of FF sources), especially in the air masses with higher values of both the ratio of water-soluble fraction of OC ($f_{WSOC}$) and $^{14}C$ concentrations ($F^{14}C$). Positive correlation between $f_{WSOC}$ and $F^{14}C$ indicates that the origins of TC (mainly OC) have great effects on the variabilities in the water solubility and the following climatic impacts (i.e., cloud formation process) of OC in the regional scale within the time scale of a week. Multivariate analyses using metallic and ionic tracers revealed the insights into the characteristics of classified carbonaceous aerosols in Asian outflow.

# Analyzing the influence of biomass burning on ambient air pollution in mainland Southeast Asia from 2001 to 2016

*Shuai Yin[1]

1. National Institute for Environmental Studies

In this study, various remote sensing data, modeling data and emission inventories were integrated to analyze the tempo-spatial distribution of biomass burning in mainland Southeast Asia and its effects on the local ambient air quality from 2001 to 2016. With such a long time span, land cover changes have been considered in dividing the biomass burning into four types: forest fires, shrubland fires, crop residue burning and other fires. The results show that the monthly average number of fire spots peaked at 34,512 in March and that the monthly variation followed a strong seasonal pattern, which was closely related to precipitation and farming activities. The four kinds of biomass burning fires presented totally different tempo-spatial distributions and forest fires and shrubland fires are more dominant than other types. Moreover, the monthly Aerosol Optical Depth (AOD), particulate matter with a diameter less than 2.5 $\mu$m ($PM_{2.5}$) and carbon monoxide (CO) concentrations also peaked in March with values of 0.62, 73.97 $\mu g/m^3$ and 426 ppb, respectively. There are significant correlations between the monthly AOD, $PM_{2.5}$, and CO concentrations and the number of fire spots. On an annual scale, we also found certain correlations between the AOD and $PM_{2.5}$ concentrations and the number of fire spots. With respect to the spatial distribution, the AOD, $PM_{2.5}$ and CO concentrations are always higher in intense biomass burning regions. Southeast Asia is one of the most populated and fastest growing economic regions in the world. Therefore, in order to objectively and accurately analyze the influence of biomass burning on local air quality over a long time span, it is imperative for this study to consider the effects of anthropogenic activities. Two anthropogenic $CO_2$ emission inventories, the Emission Database for Global Atmosphere Research (EDGAR) and the Carbon Dioxide Information Analysis Center (CDIAC), were used. The results further prove that biomass burning is the dominant cause of the variation in the local air quality in mainland Southeast Asia. Although government authorities have taken measures to control biomass burning, the number of fire spots did not decrease; the numbers exceeded 100,000 each year from 2012 to 2016.

# High-resolution and multi-year inventory of mercury emissions from biomass burning in tropical continents during 2001–2017

*Yusheng Shi[1]

1. Aerospace Information Research Institute, Chinese Academy of Sciences

Mercury emissions from biomass burning contribute significantly to the atmospheric mercury budget and the interannual variations of mercury concentrations in the troposphere. This study developed a high-resolution (0.1 deg) and multi-year (2001-2017) monthly inventory of mercury emissions from biomass burning in five fire types in the tropical continents (Central and South America, Africa, and South and Southeast Asia). The inventory estimates of mercury emissions from biomass burning are based on the newly released MCD61A1 version 6 Burned Area data product, satellite and observational data of biomass density, and spatial and temporal variable combustion factors. Results from the inventory demonstrated that during 2001-2017, the average annual mercury emissions from biomass burning in tropical continents was 497 Mg and ranged from 289 Mg to 681 Mg. Forest fires were the largest contributor, accounting for 61% (300 Mg) of the total mercury emissions from biomass burning, followed by fires in shrubland (30%, 151 Mg), savanna (7%, 35 Mg), peatland (1%, 6 Mg), and cropland (1%, 5 Mg). However, these proportions varied between the continents; in the Americas and Asia, the largest biomass burning emissions came from forest fires, and in Africa the largest emissions were from shrubland fires. Between the three continents, Africa released 41% of the mercury emissions from biomass burning (202 Mg $year^{-1}$), Asia released 31% (154 Mg $year^{-1}$), and the Americas released 28% (141 Mg $year^{-1}$). The total mercury emissions from biomass burning in these tropical continents exhibited strong interannual variations from 2001 to 2017, with peak emissions in March and Agust to September, and forest fires were the primary land fire type controlling the interannual variations. Soil mercury emissions released during biomass burning was determined to be 495 Mg $year^{-1}$ during 2001-2017. The biomass burning mercury emissions data in this inventory agrees with results by other studies, which suggests that it could be used as an input for atmospheric transport models.

# Simultaneous observations by sky radiometer and MAX-DOAS for characterization of biomass burning plumes in central Thailand in January-April 2016

*Hitoshi Irie[1], Syedul Hoque[1], Alessandro Damiani[1], Al Mashroor Fatmi[1], Pradeep Khatri[2], Tamio Takamura[1], Thanawat Jarupongsakul[3]

1. Chiba University, 2. Tohoku University, 3. Chulalongkorn University

The first intensive multi-component ground-based remote sensing observations by sky radiometer and Multi-Axis Differential Optical Absorption Spectroscopy (MAX-DOAS) were performed simultaneously at the SKYNET/Phimai site located in central Thailand (15.18˚N, 102.56˚E) from January to April 2016. The period corresponds to the dry season associated with the intense biomass burning (BB) activity around the site. The near-surface concentration of formaldehyde (HCHO) retrieved from MAX-DOAS was found to be a useful tracer for absorption aerosols from BB plumes, when BB was the dominant sources of HCHO and absorption aerosols over other sources. As the HCHO concentration tripled from 3 to 9 ppbv, the ratio of gaseous glyoxal to HCHO concentrations in daytime decreased from ~0.04 to ~0.03, responding presumably to the increased contribution of volatile organic compound emissions from BB. In addition, clear increases in aerosol absorption optical depths (AAODs) retrieved from sky radiometer observations were seen with the HCHO enhancement. At a HCHO of 9 ppbv, AAOD at a wavelength of 340 nm reached as high as ~0.15±0.03. The wavelength dependence of AAODs at 340-870 nm was quantified by the absorption Ångström exponent (AAE), providing evidence for the presence of brown carbon aerosols at an AAE of 1.5±0.2. Thus, our multi-component observations around central Thailand are expected to provide unique constraints for understanding physical/chemical/optical properties of BB plumes.

# Quantifying PM2.5 from long-range transport and local pollution in Taiwan during winter monsoon.

*Ming-Tung Chuang[1]

1. Research Center for Environmental Changes, Academia Sinica

From autumn to the following spring, annually, the northeast monsoon transports PM2.5 (particles less than
2.5 μm in aerodynamic diameter) from the Asian continent to downstream areas. Naturally, this triggered a
question: What are the contributions of PM2.5 from long-range transport (LRT) and local pollution (LP) at any
downstream location? To answer that question, the present study developed an economical and efficient method
that can easily estimate the contribution of PM2.5 from LRT (LRT-PM2.5) and PM2.5 from LP (LP-PM2.5). The
method used PM2.5 and meteorological observation data in Taiwan from 2006 to 2015 and a short-term simulation
from January to May in 2010. The analysis classified the data into three types of PM2.5 source patterns:
LRT-Event (high concentration plume at the front edge of southward moving anticyclones/strong northeast
wind), LRT-Ordinary (less concentration in common strong northeast wind), and LRT/LP Mix or Pure LP (PM2.5
was from both LRT and LP or from only LP under weak northeast wind). During the ten-year period, the average
LRT-PM2.5 values at the northern tip of Taiwan were 31–39 μgm−3, 12–16 μgm−3, and 4–13 μgm−3 for the
LRT-Event, LRT-Ordinary, and LRT/LP Mix or Pure LP patterns, respectively. The 10-year average LRT-PM2.5
and LP-PM2.5 contributions were approximately 70:30 in northern Taiwan, 50:50 in central Taiwan, and 30:70 in
southern Taiwan for the LRT-Event pattern; 60:40 in northern and 40:60 in central and southern Taiwan for the
LRT-Ordinary pattern; and 30:70 in northern and 25:75 in central and southern Taiwan for the LRT/LP Mix or
Pure LP pattern. Interestingly, LRT-PM2.5 peaked in 2013 but has decreased annually since then, whereas LPPM2.5
has roughly decreased in the past ten years.

# Vertical characterization of $PM_{2.5}$ based on observation using compact sensors on and around Mt. Unzen in Nagasaki Prefecture

*Tomoki Nakayama[1], Ayane Ueno[1], Kenta Kanegae[1], Kazuaki Kawamoto[1], Kodo Umakoshi[1], Takayuki Yamasaki[2], Wataru Okamoto[2], Yutaka Matsumi[2]

1. Faculty of Environmental Science, Nagasaki University, 2. ISEE, Nagoya University

Aerosol particles in the atmosphere, including $PM_{2.5}$, are known to have significant impacts on climate, the atmospheric environment, ecosystems, and human health. Whereas both of domestic sources and transboundary pollution from Asian Continent possibly contribute to the $PM_{2.5}$ mass concentrations in Japan, high $PM_{2.5}$ events owing to the transboundary pollution are often observed, especially in north-western part of Kyushu region (including Nagasaki Prefecture). Although $PM_{2.5}$ mass concentrations are observed at the observatories of the Atmospheric Environmental Regional Observation System (AEROS) of the Ministry of the Environment, Japan (MOEJ), the observatory on mountain is very limited, and widely used large and expensive bate attenuation monitor (BAM) is not suitable for the multi-point observations.

We developed a compact $PM_{2.5}$ sensor with Panasonic Corporation [Nakayama et al. 2018]. This sensor can measure $PM_{2.5}$ mass concentrations by detecting light scattering intensities from individual aerosol particles with diameters greater than 0.3 $\mu$m. In this study, this sensor was applied for the observations of $PM_{2.5}$ mass concentrations around Mt. Unzen in Nagasaki Prefecture from December 2018. The $PM_{2.5}$ sensors were installed at six sites with different altitudes from 20 m to 1300 m to analyze vertical and horizontal distributions of $PM_{2.5}$. During high $PM_{2.5}$ events (>35 $\mu g/m^3$) in winter, the $PM_{2.5}$ mass concentrations at an altitude above 1000 m are similar to those at 20 m in most cases. However, in some cases, high $PM_{2.5}$ was observed only at low altitude sites, likely because of inflow of clean air with lower aerosol burden from higher altitude to the mountain sites and/or low boundary layer height. The vertical profile data obtained in this work will be compared with the lidar data obtained by NIES at Omura city, which is located 38 km north-west of Mt. Unzen, to discuss the possible sources and transport patterns of $PM_{2.5}$.

# Observation of NPF events at the summit of Mt. Fuji during daytime and nighttime

*Hiroki Igarashi[1], Takenori Sato[1], Tatsuhiro Mori[1], Kazuhiko Miura[1], Yoko Iwamoto[2], Ryuichi Wada[3], Shungo Kato[4], Hiroshi Okochi[5]

1. Tokyo University of Science, 2. Hiroshima University, 3. Teikyo University of Science, 4. Tokyo Metropolitan University, 5. Waseda University

An improved understanding of a new particle formation (NPF), which is a key process controlling the spatial and temporal distributions of aerosol concentration, is needed to estimate the direct radiative forcing. However, it is difficult to quantitatively understand the mechanism of NPF because the frequency of the NPF depends on the aerosol concentration, gases, and meteorological condition. In this study, we measured number concentrations (*N*) of aerosol particles (10 to 487 nm) at the summit of Mt. Fuji (35.360˚N, 138.727˚E, 3776 m a.s.l.) between July and August during 2011-2017. We report the annual and diurnal variations of the frequency of the NPF for a long-term period. The summit of Mt. Fuji is usually located in the free troposphere and enable us to observe the long-range transport of aerosol particles. The NPF event was defined as the event that *N* increases over 1 hour for diameter smaller than 25 nm. We observed 172 NPF events (daytime and nighttime events were 90 times and 82 times, respectively) during the observation period. Most events occurred at 8 o'clock (at the peak of daytime events) and 20 to 21 o'clock (at peaks of nighttime events) in local time. In addition, the growth rate of aerosol particles was calculated. The median value of the growth rate was estimated to be 5.27 nm/h (6.03 nm/h for daytime and 4.56 nm/h for nighttime) at 40 NPF events, suggesting that aerosol particles are easily grown during daytime. Finally, using a back trajectory analysis (NOAA HYSPLIT version 4), we investigated when and where the NPF occurred. As a result, it is suggested that 62.5% of the total NPF occurred during the daytime, and the rest occurred during the nighttime (37.5%). The NPF frequently occurred during daytime over Japan although a few NPF occurred over the sea during nighttime.

# Measurement of atmospheric metal particles using an ICP-MS and TEM.

*Takeshi Kinase[1], Kouji Adachi[1], Mizuo Kajino[1], Masahiko Hayashi[2], Keiichiro Hara[2]

1. Meteorological Research Institute, 2. Fukuoka

Particles containing transition metal components (hereafter, metal particle) are one of the major aerosols. Some of these metal particles have strong oxidation potential and have health effects by deposition into the human body through generating reactive oxygen and free-radical in and on cells. These reactive oxygen and free radicals cause various effects such as oxidative stress, inflammatory cell, DNA oxidative damages and cell death. However, oxidation potential for each metal particle and the magnitude of hazard to human health are not well known. In addition, colored metal particles, such as iron oxide, absorb solar radiation and contribute to the global warming. However, these effects of metal particles are not clarified because their observations and detailed features are not well known.

In this study, we measured atmospheric metal particle concentrations using an inductively coupled plasma-mass spectrometry (ICP-MS) and collected aerosol samples on the Cu grids using impactors to observe each aerosol particle using a transmission electron microscope (TEM) and an energy-dispersive X-ray spectrometry detector (EDS) with the scanning transmission electron microscopy (STEM). The ICP-MS instrument was coupled with a gas changer for air replacement in argon gas atmosphere, so that aerosol particles were directly measured using the ICP-MS in real-time. As a result, we could measure time trends of atmospheric metal particle concentrations quantitatively with high time resolutions together with their shape and mixing states by the TEM and STEM-EDS analysis.

We measured atmospheric metal particles in winter (2018/1/17–2/8) and in spring (2018/5/8–5/30) at Fukuoka University. We measured increasing events of metal particles by ICP-MS. Fe and Al were the highest concentration followed by Zn, Mn, Cr and Pb. Two different slopes were observed in relation between Fe and other metal elements such as Mn, V, and Al. On the other hand, Ag, Au, Mo and Tc did not correlate with Fe. From TEM observation of samples with high concentrations of metal particles, we found aggregated metal particles as ultrafine metal spheres (for smaller particles were several nm). These particles contained Fe, Mn and Cr as major metal elements, and most particles were internally mixed with a sulphate. Furthermore, some metal particles contained many ultrafine metal particles that distributed separately in a sulphate. Zn and Pb containing particles were also internally mixed with sulphate, however, they were observed as dissolved substances (not particle state) or crystallized state, which were decomposed by electron beam.
We found other metal particles which contained such as Ag, Sb, and Cu during their increasing periods. Our results are useful for understanding of atmospheric metal particles behaviors.

# Experimental results on measuring device of complex refractive index using the single particle extinction and scattering method

*TAKASAGO YUYA[1]

1. Tokyo university

Changes in the type and amount of atmospheric aerosol alter the albedo, resulting in radiation budget and climate change. However, the prediction accuracy of the fluctuation range is not high at the present. The complex refractive index can estimate the type of atmospheric aerosol. In the existing method, a method of measuring the complex refractive index for each bulk is mainstream, and there are few cases to measure for each single particle. If accurate measurement data of complex refractive index for each particle type can be obtained, it is possible to improve prediction accuracy of climate change width of particle type, so measurement with complex refractive index for each single particle is important. In this study, we conducted an experiment using single particle extinction and scattering method as a method to measure the complex refractive index. The single particle extinction and scattering method is a method of measuring forward scattered light intensity generated by projecting a laser on fine particles and interference between scattered light and incident light and estimating the value of the complex refractive index of the particle from these data. We developed an experimental apparatus using this method and conducted experiments with polystyrene, BC standard particles and precipitation samples (Okinawa, Happo, Fukui). Currently, I am thinking a method to solve the inverse problem that estimates particle characteristics such as particle type and complex refractive index from forward scattering intensity obtained from experiment and interference data of incident light and scattered light. For this purpose, we are developing a method of classifying samples mixed with plural types of particles into particle type by using clustering method of machine learning.

Institute of Nature and Environmental Technology, Kanazawa University, 4. Department of Applied Chemistry, Graduate School of Engineering, Osaka Prefecture University, 5. School of Earth and Environmental Sciences, Seoul National University, Seoul, Korea, 6. Research Institute for Applied Mechanics, Kyushu University, 7. Institute of Atmospheric Physics, CAS, Beijing, China

Compared to carbon dioxide ($CO_2$), which is a major long-lived greenhouse gas, the influence of black carbon (BC) to global warming is not negligible among the short-lived components. To improve the bottom-up emission inventory for enhancing the understanding level of BC, the measured ΔBC/ΔCO ratios were compared with those from the Regional Emission inventory in Asia (REAS) version 2.1 bottom-up inventory. The measurements were conducted at two sites in Korea (Baengnyeong; 124.63˚ E, 37.97˚ N, and Gosan; 126.17˚ E, 33.28˚ N) and two sites in Japan (Noto; 137.36˚ E, 37.45˚ N, and Fukuoka; 130.47˚ E, 33.52˚ N). The instruments for measuring CO concentration are same at all sites as Model 48i (Thermo Fisher Scientific), however, the instruments for BC were different depends on the sites (sunset EC/OC analyzer in Baengnyeong, Continuous Light Absorption Photometer in Gosan, Multi-Angle Absorption Photometer in Noto and Fukuoka). Based on the backward trajectories during past 120 hours calculated from HYSPLIT model, all trajectories were assigned to six study domains which divided by country and/or administrative district (East China, North China, Northeast China, South Korea, North Korea, and Japan). To exclude the wet-removal effect, the ΔBC/ΔCO ratio was considered only when the accumulated precipitation along a backward trajectory (APT) for three days is equal to zero. Also, we confirmed that the comparison of ΔBC/ΔCO by six study domains could be reasonable since there were no significant differences in ΔBC/ΔCO ratio depending on traveling time (dry deposition effects) and residence time over the emission source areas. Compared to measured ΔBC/ΔCO ratio (6.6 –8.4 ng/$m^3$·ppb), ΔBC/ΔCO from REAS emission inventory (8.0 ng/$m^3$·ppb for East China –23.2 ng/$m^3$·ppb for South Korea) were overestimated by factor 1.2 for East China to 2.9 for South Korea whereas those for North Korea (3.7 ng/$m^3$·ppb from REAS) was underestimated by factor 2.0. The measured ΔBC/ΔCO ratios in Japan (6.8 ng/$m^3$·ppb) were similar to those from REAS emission inventory (6.5 ng/$m^3$·ppb). The seasonal and spatial differences of ΔBC/ΔCO ratios between measured and emission inventory will be examined to identify the over- and under-estimated administrative districts.

# Inverse modeling of black carbon emissions over China using ensemble data assimilation

*Ping Wang[1]

1. Chinese Academy of Meteorological Sciences

Emissions inventories of black carbon (BC), which are traditionally constructed using a “bottom-up” approach based on activity data and emissions factors, are considered to contain a large level of uncertainty. In this paper, an ensemble optimal interpolation (EnOI) data assimilation technique is used to investigate the possibility of optimally recovering the spatially resolved emissions bias of BC. An inverse modeling system for emissions is established for an atmospheric chemistry aerosol model and two key problems related to ensemble data assimilation in the top-down emissions estimation are discussed: 1) how to obtain reasonable ensembles of prior emissions; and 2) establishing a scheme to localize the background-error matrix. An experiment involving one year long simulation cycle with EnOI inversion of BC emissions is performed for 2008. The bias of the BC emissions intensity in China at each grid point is corrected by this inverse system. The inversed emission over China in January is 240.1 Gg, and annual emission is about 2539.3 Gg, which is about 1.8 times of bottom-up emission inventory. The results show that, even though only monthly mean BC measurements are employed to inverse the emissions, the accuracy of the daily model simulation improves. Using top-down emissions, the average root-mean-square error of simulated daily BC is decreased by nearly 30%. These results are valuable and promising for a better understanding of aerosol emissions and distributions, as well as aerosol forecasting.

# Analysis of BC emissions in East Asia using inverse model

*Takashi Maki[1], Taichu Y Tanaka[1], Naga Oshima[1], Thomas Sekiyama[1], Keiichi Kondo[1], Jun-ichi Kurokawa[2], Keiya Yumimoto[3], Toshimasa Ohara[4]

1. Meteorological Research Institute, 2. Asia Center for AirPollution Research, 3. Kyushu University, 4. National Institute for Environmental Studies

In addition to affecting climate change and global warming, Black Carbon (BC) brings impact on society and human health as well. However, changes in BC emissions in east Asia have yet to be fully understood. Attempts have been made by various institutions and researchers to estimate BC emission inventories from various statistics but there are problems such as lack of rapid reporting. In order to modify black carbon emissions inventory based on this statistic, we have constructed an BC emission inversion system for east Asia using aerosol transport model and surface observations. The analysis period for emissions is from 2011 to 2014. We adopt global aerosol transport model named MASINGAR mk-2 (Tanaka et al.). The model is a subset of MRI (Meteorological Research Institute) earth system model for climate research and can treat BC, OC, mineral dust, sulfate and sea-salt with external mixing. We divided tags of each province of China, South Korea, Japan into 33 regions and carried out tagged tracer transport experiments. We collected 5 surface sites daily observation data (Hedo, Fukue, Echizen, Happo and Lulin). A priori BC emission is provided by REAS 2.2 (Kurokawa et al.) at 2010. Inversion results suggested that BC emissions in East Asia between 2011 and 2014 are decreasing especially in China about 10%, compared to the 2010 emissions. There was no significant change in BC emissions in Japan and South Korea during the analysis period. However, the observation network could constrain mainly northern part of China. We need more observation data (ex. satellite data) to constrain BC emission amount.

# Source attribution of BC in the northern Pacific and Arctic Ocean by chemistry climate model

*Takato Onishi[1], Kengo Sudo[1,2], Yugo Kanaya[2], Fumikazu Taketani[2]

1. Graduate School of Environmental Studies, Nagoya University, 2. Japan Agency for Marine-Earth Science and Technology

Black Carbon (BC) is emitted from combustion of biomass and fossil fuel into the atmosphere. BC in the atmosphere absorbs visible light and heats the atmosphere contributing to global warming. The emitted BC being originally hydrophobic with low CCN activity, is not easily scavenged by precipitation allowing long-range transport of BC to remote areas. Snow or ice surfaces, when affected by deposition of BC, decrease their albedo causing further warming in the high latitudes.
This study focuses on long-range transport of BC in the northern high latitude regions and investigates BC origins (source regions and types) with a tagged tracer simulation by a global chemistry climate model CHASER. The modeled BC concentrations are validated with the BC observational data obtained from the JAMSTEC research vessel Mirai (from August to September). The model is found to be overestimating the observed BC by a factor of 1.2 to 7 in the south of 70°N in the northern Pacific. Differences between the model and observation are relatively small near Japan, but a bit larger between 160°E to 180°E in the Pacific Ocean. For the Arctic Ocean, on the other hand, the model severely overestimates BC by a factor of 13 to 70. In the model, BC in the North Pacific and Arctic Ocean is originated mainly from Siberia, North America and China.
The overestimated BC in the model probably shows an underestimate of wet deposition by precipitation. However, it is found that CHASER tends to overestimate precipitation amount when compared to the reanalysis data as the ERA-interim. This suggests that there is an inconsistency in the BC wet deposition scheme such as underestimation of BC uptake to cloud droplets. We considered correlation between precipitation and BC wet deposition flux normalized by columnar BC mass for checking relation of precipitation and BC wet removal. The correlation coefficient is about 0.4 suggesting that BC removal by precipitation is weak in the model. In addition, the ratios of internal BC to total BC for the surface to lower troposphere are calculated for the years of 2014 to 2017. In the northern pacific and Arctic Ocean, the ratios are about 30 percent indicating that the hydrophobic type of BC is dominant in the region for which CHASER overestimates BC.
As a result, it is suggested that there is much room for improvement in the simulation of aging process of BC (hydrophobic to hydrophilic conversion) and the scheme for wet deposition of external BC. In the presentation, the results from the further improved model simulations will be introduced and discussed.

# Evaluation of a mobile $PM_{2.5}$ sensor and application to the measurements along the National route 1 and around Nagasaki University

*Kenta Kanegae[1], Takayuki Yamasaki[2], Wataru Okamoto[2], Yutaka Matsumi[2], Tomoki Nakayama[1]

1. Nagasaki University, 2. Nagoya University

Short-term exposure of $PM_{2.5}$, negatively impacts human health through respiratory disease (such as asthma and bronchitis) and cardiovascular diseases, and leads to premature death. Because $PM_{2.5}$ is spatially and temporally variable and individuals also move in time and space, it is important to understand personal exposures of $PM_{2.5}$ for better assessment of the health impact. We developed a palm-sized optical $PM_{2.5}$ sensor with and Panasonic Corporation, and evaluated the performance for environmental monitoring at fixed sites [Nakayama et al. 2018]. This sensor was designed to measure $PM_{2.5}$ mass concentrations by detecting light scattering intensities from individual aerosol particles with diameters greater than 0.3 $\mu$m. The small size, light weight, and low power consumption of the sensor are suitable for mobile personal exposure measurement. However, the sensitivity of the sensor can be change if the sensor is tilted or swung, because aerosol particles flow into the sensor via an updraft generated by a heater and flow rate may be change during tinting or swinging.
In this study, we investigate the performance of the $PM_{2.5}$ sensor for mobile exposure measurements. The changes in the sensitivity of the sensor during tilting or swinging have been tested. Moreover, the change in the sensitivity of the sensor during walking has been investigated, by comparing the $PM_{2.5}$ data during walking with those during standing. From the results of these tests, it was found that the sensor can be applied for mobile exposure measurements of $PM_{2.5}$ mass concentration. We applied this sensor for the mobile measurements during walking along the National Route 1 (from Tokyo to Kyoto) for two weeks, and around Nagasaki University. The obtained $PM_{2.5}$ data will be compared with those obtained at the surrounding ambient air monitoring stations (AEROS) and meteorological data to discuss the sources and transportation of $PM_{2.5}$. We believe that this research will provide useful information for applications of the compact sensor to epidemiological research of health effects of $PM_{2.5}$.

# Analysis on the Relationship between the Concentration of Particulate Matter and Mortality from Respiratory and Cardiovascular Diseases

*Woo-Sik JUNG[1], Woo-Gon Do[2]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea, 2. Busan Metropolitan City of Institute of Health and Environment Busan, Korea

Concerns over particulate matter are growing rapidly as the number high concentration days are increasing. Since 2015, PM2.5 has been set as a national ambient air quality standard and frequency of Asian dust or mists and precursors coming from the west of Korea has increased. Various studies have been conducted on the distribution and composition of particulate matter. The particulate matter is known to be the main cause of respiratory and cardiovascular disease, such as vascular dysfunction, asthma and the occurrence of chronic bronchitis. As the paradigm of air quality management policy changes from controlling, treating and reducing sources to taking into account the damage of a receptor including assessing health risks, it is necessary to establish scientific policies by quantitatively assessing the health effects of the particulate matter and calculating health benefits. To do this, a quantitative assessment of the health risks of particulate matter is essential. The purpose of this study is to analyze the effects of changes in the daily average concentration of particulate matter on the mortality of respiratory and cardiovascular diseases in Busan, Korea. In this study, we employed a generalized additive model (GAM) with a quasi-Poisson to assess the association between daily mean particulate matter and mortality. A penalized spline function was used to adjust the seasonal pattern and long-term trend in daily mortality and the nonlinear mortality effects of the weather. Based on this, a model between the death rate and daily average particulate matter was established and the change in the mortality rate of respiratory and cardiovascular diseases was analyzed according to the change in particulate concentration. The daily mean particulate matter were calculated using hourly PM2.5 and PM10 data provided the Environment Ministry of Korea and the causes of death from 2015 to 2017 were provided by the National Statistical Office's 'Micro Data Service'.

# A Study on the Estimation of Contribution Rate of Odour Substances Using CALPUFF model

*Woo-Sik JUNG[1], Woo-Gon Do[2]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea, 2. Busan Metropolitan City of Institute of Health and Environment Busan, Korea

The environmental odours produced by anthropogenic origin according to urbanization and industrialization continue to increase. These odours cause mental and physiological stress and have a variety of adverse health effects, including nausea, headaches, loss of appetite, gastrointestinal disorders, difficulty in breathing, and allergy. Therefore, the odours are degrading the quality of life for residents in nearby residential areas, causing health hazards and eventually causing economic loss in the community. Miscellaneous approaches are used internationally within odour regulatory systems, with methods and tools for management and control supported by ambient air odour concentration and individual chemicals(maximum impact standard); fixed and variable separation distances(separation distance standard); maximum emission rate for odours and individual chemicals(maximum emission standard); number of complaints or annoyance level(maximum annoyance standard); best available technologies e BAT (technology standard). However, the occurrence of odors is a very local issue that reflects the characteristics of individual sources and the subjective impact of nearby residents. Therefore, prior to these regulations, it is very important to assess the impact of individual emissions quantitatively. The CALPUFF model is a typically used model for assessing the dispersion of air pollutants or odours in various research institutes, including the U.S. EPA. This model is an optimal method for calculating the contribution rate of individual emission sources in area where odour sources are concentrated. In this study, the CALPUFF model was used to identify the contribution rate of the four adjacent emission facilities to the surrounding areas in Saenggok Industrial Complex located in Saenggok-dong, Gangseo-gu, Busan in Korea. In order to estimate the contribution rate of individual emission sources, the predicted odour concentration of each emission source was calculated respectively(S1-S4). Next, the predicted odour concentration was calculated considering four emission sources together(Base). Finally, the contribution rates of individual emission sources within the modeling domain were calculated as the ratio of S1-S4 to Base. The amount of area sources in each emission facility was indirectly calculated using the concentration measured near the emission facility. Meterological input data produced by applying the results of the WRF model to the CALMET model. As a result of the CALPUFF model, the contribution rate of sludge treatment facility was the highest at 76%, and the rest of the facilities were shown to contribute about 10% to the surrounding area.

# Stepwise decrease in atmospheric trace gases near the ground associated with rapid vertical mixing observed by 3-D coherent Doppler lidar and in-situ gas measurements

*Hisahiro Takashima[1], Keiichiro Hara[1], Yuki Ohira[1], Akinori Takami[2], Ayako Yoshino[2], Yasushi Fujiyoshi[3]

1. Fukuoka University, 2. National Institute for Environmental Studies, 3. Hokaido University

Stepwise decreases, which occur over several minutes, in nitrogen oxides (NOx) and carbon monoxide (CO) concentrations, in which the main source of these gases is supposed to be near the surface, are sometimes observed in Fukuoka, urban site in Japan, during the summer-winter seasons. In the most cases, ozone ($O_3$) content, which could be higher at higher altitudes, increases. Wind observations by 3-D coherent Doppler lidar suggest there is a thin surface layer (up to ~50-300 m thickness) near the ground before the stepwise change, and then rapid vertical mixing associated with the local meteorological system occurs. The surface thin layer plays a role as a cover of pollutants near the ground, and the vertical mixing within the boundary layer rapidly dilutes/reduces the pollutant contents near the ground.

# Spatiotemporal variations of nitrogen dioxide ($NO_2$) over Fukuoka , observed by multiple MAX-DOAS instruments and 3-D coherent Doppler lidar

*Hironobu Ueki[1], Hisahiro Takashima[1], Martina M. Friedrich[2]

1. Fukuoka university, 2. Belgian Institute for Space Aeronomy (BIRA-IASB), Belgium

To understand spatiotemporal variations and transport/mixing processes in nitrogen dioxide ($NO_2$) over Fukuoka, an urban area in Japan, continuous $NO_2$ profile observations with a high temporal resolution of four minutes by MAX-DOAS (Multi Axis Differential Optical Absorption Spectroscopy) at three sites in Fukuoka have been conducted from October 2018 to January 2019. Two sites (Yakuin (33.580˚N, 130.396˚E) and Sohara (33.580˚N, 130356˚E)) are located near the city center and pointing towards the north(towards the sea), and one site (Fukuoka University (33.550˚N, 130.364˚E)) is located outside of the city center pointing towards the city center.

In the case of 29 November 2018, an air mass with a high $NO_2$ concentration was observed near the ground in the morning (until 10:30 am) and later, around 10:30 to 11:30 am, an increased concentration of $NO_2$ gradually appeared at a higher altitude over the city center. This increased $NO_2$ concentration disappeared around 13:30-14:00 pm. From the simultaneous three-dimensional (3-D) wind observations by 3-D coherent Doppler lidar installed at Fukuoka University, it is suggested that the air mass with high $NO_2$ concentration was transported upward from the ground by vertical convection, and after that, a clean air-mass was advected from sea by sea-breeze. In this presentation, we will show several results observed by the multipoint MAX-DOAS and 3-D wind observations, focusing on the 3-D transport over Fukuoka using the high $NO_2$ air mass as a tracer.

# Measurement on the $^{17}O$-excess of tropospheric nitrogen oxides

*Fumiko Nakagawa[1], Dong Ding[1], Urumu Tsunogai[1], Takashi Yamaguchi[2], Izumi Noguchi[2]

1. Graduate School of Environmental Studies, Nagoya University, 2. Institute of Environment Sciences, Hokkaido Research Organization

Nitrogen oxides are important trace gases that influence the concentrations of atmospheric oxidants that drive tropospheric and stratospheric chemistry. Triple oxygen isotopes ($\Delta^{17}O$ values; deviation of $^{17}O$ from the mass dependent fractionation line) have been used to understand complex chemical systems such as the cycling and oxidation of NOx. For example, $\Delta^{17}O$ valuesof atmospheric nitrate ($HNO_3$, $NO_3^-$, and p-$NO_3^-$), indicates the proportion of NOx that reacts with ozone ($O_3$) during its oxidation (Michalski *et al.*, 2003; Tsunogai *et al.*, 2010; Nelson et al., 2018). $\Delta^{17}O$ values of atmospheric nitrous acid (HONO; recognized as a potentially important source of OH radicals) have also been used recently to decipher their production pathways. In these studies, however, predicted $\Delta^{17}O$ values were used for $NO_2$. Here, we tried to establish a method to determine $\Delta^{17}O$ values of atmospheric $NO_2$.

$\Delta^{17}O$ value of $NO_2$ was determined, together with $\Delta^{17}O$ value of HONO, by combining sensitive determination method on isotope compositions of $NO_2^-$(Komatsu *et al.*, 2008; Tsunogai *et al.*, 2010) with a slightly modified filter-pack method (Noguchi *et al.*, 2007), in which both $NO_2$ and HONO were collected simultaneously as $NO_2^-$on triethanolamine (TEA)-coated filter and alkaline ($K_2CO_3$) impregnated filter, respectively. Periodical sampling of atmospheric $NO_2$ and HONO was carried out at Hokkaido Institute of Environmental Sciences, Sapporo and at Nagoya University, which is located in a suburban area of Nagoya City. The sample collection period was fixed to one week with a flow rate of 10 L/min. In order to determine diurnal variation in $\Delta^{17}O$ value of $NO_2$ and HONO, an automated system for time-interval air sampling equipped with 6 four-stage-filter-packs were made and used it to collect atmospheric samples every 4 hours.The $\Delta^{17}O$ values of $NO_2$ and HONO showed similar diurnal variations; higher value on the day time than the night time. The result suggests that the atmospheric HONO is formed mainly by chemical reaction of NOx in the urban atmosphere.

# Long-term measurements of the column-averaged mixing ratios of tropospheric substances related to the air pollution using ground-based FTIRs at Rikubetsu, Japan

*Tomoo Nagahama[1], Isamu Morino[2], Shingo Nakanishi[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. National Institute for Environmental Studies

Air pollutants originating from carbon compounds such as reactive volatile organic compounds (VOCs) cause a serious degrading of the air quality near their sources. In addition, these are transported to remote areas with chemical composition changes, and affect air quality in urban areas and their surrounding areas, and therefore, are one of major issues in preserving the air quality. Especially, HCHO and HCOOH originating from forest fires and biogenic VOCs are distributed near their sources since their chemical lifetime is within a few days, and therefore, their distributions and time variations are one of important keys in associating the sources with the impact to the global environment. In order to understand the characteristics of long-term variation of the air quality and its influence on the global environment, the temporal variation of tropospheric substances related to the air pollution are measured with ground-based Fourier Transform InfraRed (FTIR) instrument (Bruker IFS120M and IFS120/5HR) installed at Rikubetsu observatory in Hokkaido, Japan. The cooperative measurements of solar absorption spectra using the FTIRs are conducted by the Institute for Space-Earth Environmental Research (ISEE) of Nagoya University and the National Institute for Environmental Studies (NIES) since 1995. The spectrum is obtained in a 3-15 $\mu$m band with a resolution of 0.0035 $cm^{-1}$. The vertical distribution of trace gases in troposphere and stratosphere is retrieved from the measured spectrum by using the SFIT4 (version 0.944) software. Using SFIT4, we have retrieved the total column amounts and tropospheric column-averaged mixing ratio of $O_3$, $CH_4$, $C_2H_6$, N2O, CO, HCN, HCHO, HCOOH, $C_2H_2$, $CH_3OH$, and find their seasonal and long-term variations from 1995 to 2018. The observed tropospheric column-averaged mixing ratios of $O_3$, $C_2H_6$ and CO show the maximum in March and April, although that of HCHO peaks in July and that of HCN is in May and August, respectively. These differences among the substances may reflect the source and sink processes. Especially, HCHO having a short lifetime may reflect oxidation of biogenic VOCs in summer as well as forest fires.
In the presentation, we will report the detailed features of temporal variations of these substances in troposphere and will discuss its influence on the global environment.

# Impacts of Biogenic and Anthropogenic Emissions on Summertime Ozone Formation in the Guanzhong Basin, China

*Nan Li[1]

1. Nanjing University of Information Science & Technology

This study is the first attempt to understand the synergistic impact of anthropogenic and biogenic emissions on summertime ozone ($O_3$) formation in the Guanzhong (GZ) basin where Xi’ an, the oldest and the most populous city (with a population of 9 million) in the northwest China, is located. Month-long (August 2011) WRF-Chem simulations with different sensitivity experiments were conducted and compared with near-surface measurements. Biogenic volatile organic compounds (VOCs) concentrations were characterized from 6 surface sites among the Qinling Mountains, and urban air composition was measured in the Xi’ an city at a tower 100 m above the surface. The WRF-Chem control experiment reasonably reproduced the magnitudes and variations of observed $O_3$, VOCs, $NO_x$, $PM_{2.5}$ and meteorological parameters, with normalized mean biases for each parameter within ±21%. Subsequent analysis employed the factor separation approach (FSA) to quantitatively disentangle the pure and synergistic impacts of anthropogenic and/or biogenic sources on summertime $O_3$ formation. The impact of anthropogenic sources alone was found to be dominant for $O_3$ formation. Although anthropogenic particles reduced $NO_2$ photolysis by up to 60%, the anthropogenic sources contributed 19.1 ppb $O_3$ formation on average for urban Xi’ an. The abundant biogenic VOCs from the nearby forests promoted $O_3$ formation in urban areas by interacting with the anthropogenic $NO_x$. The calculated synergistic contribution (from both biogenic and anthropogenic sources) was up to 14.4 ppb in urban Xi’ an, peaking in the afternoon. Our study reveals that the synergistic impact of individual source contributions to $O_3$ formation should be considered in the formation of air pollution control strategies, especially for big cities in the vicinity of forests.

# Comprehensive monitoring project of greenhouse gases and air pollutants around Jakarta megacity in Indonesia

*Masahide Nishihashi[1], Hitoshi Mukai[1], Yukio Terao[1], Shigeru Hashimoto[1], Rizaldi Boer[2], Muhammad Ardiansyah[2], Bregas Budianto[2], Gito Sugih Immanuel[2], Adi Rakhman[2], Rudi Nugroho[3], Nawa Suwedi[3], Agus Rifai[3], Iif Miftahul Ihsan[3], Anies Marufatin[3], Albert Sulaiman[3], Dodo Gunawan[4], Eka Suharguniyawan[4], Asep Firman Ilahi[4], Muharam Syam Nugraha[4], Ronald Christian Wattimena[4], Bayu Feriaji[4], Thomas Lauvaux[5], Tomohiro Oda[6]

1. National Institute for Environmental Studies, 2. Bogor Agricultural University (IPB), Indonesia, 3. Agency for the Assessment and Application of Technology (BPPT), Indonesia, 4. Meteorological, Climatological, and Geophysical Agency (BMKG), Indonesia, 5. Laboratory for Sciences of Climate and Environment (LSCE), France, 6. Universities Space Research Association/NASA Goddard Space Flight Center, USA

The emission increases of greenhouse gases (GHGs) and air pollutants in megacities have been recognized as one of the important issues as a concern for health and climate change. Jakarta, the capital city of Indonesia, including suburban cities (Bogor, Depok, Tangerang, and Bekasi; locally known as “Jabodetabek”), has a population of 32 million people and has been listed as the second largest megacity in the world and the largest megacity in Southeast Asia. Several air quality monitoring campaigns were conducted in Jakarta. However, previous studies lacked continuous high-accuracy monitoring stations due to the limitations of environmental monitoring budgets and experts. We present here a new interdisciplinary project to expand our current understanding of the interactions between emissions, air quality, and regional/global climates.

To estimate the amount of anthropogenic emissions from Jakarta megacity and compare with city activities, we developed a ground-based comprehensive monitoring system of GHGs and air pollutants controlled remotely in addition to automated start-and-stop operations during power failures. Monitoring systems were installed at Bogor (center of Bogor city), Serpong (Jakarta suburb), and Cibeureum (mountainous area) in 2016–2017. Each monitoring system consists of system control/data acquisition units controlling multiple instruments and collecting continuously and continuous monitoring instruments of $CO_2$, $CH_4$, CO, $NO_x$, $SO_2$, $O_3$, aerosol concentrations ($PM_{2.5}$, $PM_{10}$, BC) and the chemical components ($NO_3^-$, $SO_4^{2-}$) of $PM_{2.5}$ and $PM_{10}$, and meteorological parameters. Flask sampling of air is also performed automatically once a week to analyze $N_2O$, $SF_6$, and carbon isotopes ($^{13}C$, $^{14}C$) in $CO_2$ in NIES and to validate the continuous measurement data of $CO_2$, $CH_4$, and CO.

The results show that the daytime values of $CO_2$, three hours averages from 12 to 15 local time, at Bogor and Serpong are 6.8 and 7.1 ppm higher than Cibeureum, respectively. These features are also presented in the other species, i.e., CO, $NO_x$, $SO_2$, $PM_{2.5}$, $PM_{10-2.5}$, and BC. Moreover, we found 5–10 ppm lower values of $CO_2$ during daytime at Bogor and Serpong in December and January, mid-rainy season in Jakarta, compared with the other months and frequent and extremely high $CH_4$ enhancements during nighttime (i.e., 3 to 5 ppm) at Serpong.

We present here the temporal variability observed at three monitoring sites and some preliminary results based on high-resolution $CO_2$ simulations using Weather Research and Forecasting model coupled to Chemistry (WRF-Chem).

# Seasonality of short-term variations in atmospheric $CH_4$ observed at Hateruma and relationship with the reginal emissions from East Asia

*Yasunori Tohjima[1], Jiye Zeng[1], Tomoko Shirai[1], Akihiko Ito[1], Motoki Sasakawa[1], Toshinobu Machida[1]

1. National Institute for Environmental Studies

National Institute of Environmental Studies (NIES), Japan, has been carrying out in-situ observation of atmospheric $CH_4$ at Hateruma Island (HAT; lat. 24.1˚N, long. 123.8˚E) since 1996 by using a gas chromatographic system. Since HAT is in the marginal region of the East Asia, air masses from the continental region would cause elevated concentrations of a variety of species including $CH_4$. Such events were often observed especially during late autumn to early spring due to the Asian monsoon. In the previous studies, we revealed a secular increase in the short-term variations of $CH_4$ and its relationship with the emission increase from the continental China. Here, we examined the seasonality of the short-term variations of $CH_4$ in 1996 to 2017. First, we computed the increment of the hourly $CH_4$ ($\Delta CH_4$) over the baseline, which was the smoothed averages of $CH_4$ below the 20 percentile in a 101-hour moving time-window. Then the standard deviation of $\Delta CH_4$ for each month of each year was computed. The average monthly standard deviations of $\Delta CH_4$ show rather stable values in winter (November-February, 18~20 ppb), peaks in May (28 ppb) and September (26 ppb), and a dip in July (11 ppb). We simulated $\Delta CH_4$ by a Lagrangian particle dispersion model (LPDM) using the monthly $CH_4$ emission maps of Patra et al. (2009) and EDGAR v4.3.2, respectively. Although the monthly variability of the simulated $\Delta CH_4$ based on the Patra et al. (2009) emission maps well reconstructed the observed pattern of the monthly standard deviations, that based on the EDGAR v4.3.2 emission maps showed a maximum in March, which was not consistent with the observed pattern. The simulated maximum variability in March is related to the emission peak in March of the EDGAR v4.3.2 inventory, which is attributed to the maximum emissions from agricultural and livestock sectors. The lack of the spring peak in the observation suggests that the anthropogenic $CH_4$ emission in March of EDGAR v4.3.2 may be overestimated.

# A cryogen-free automated measurement system of stable carbon isotope ratio of atmospheric methane

*Taku Umezawa[1], Takuya Saito[1]

1. National Institute of Environmental Studies

Methane is an important greenhouse gas emitted from both natural and anthropogenic sources. Accurate understanding of various methane sources is needed for effective reduction of its emissions. Measurement of stable carbon isotope ratio of atmospheric methane is useful for top-down evaluation of relative contributions of various types of methane sources, because individual methane sources have characteristic isotope signatures. Isotope ratio data for atmospheric methane therefore receive increasing attention for constraining the global methane budget. To meet research community demand, it is imperative for measurement systems to achieve adequate precision and traceability as well as high measurement throughput to process number of air samples that are routinely shipped from monitoring sites to laboratory. Stable carbon isotope ratio has been measured by continuous-flow isotope ratio mass spectrometry where methane in sample air is preconcentrated in a trap filled with an adsorbent cooled by liquid nitrogen. By using a stirring cooler instead, we set up a cryogen-free measurement system, and our configuration attained reproducibility of ~0.1 per mil. This precision is comparable to those previously achieved by using liquid nitrogen; our system is however advantageous for unattended and automated measurement operation. We examined measurements for air sampled outside our laboratory, and the preliminary measurement data at ~1-hour intervals show a clear diurnal variation.

DISTABIF, Università degli studi della Campania Luigi Vanvitelli, 11. Department Landscape Design & Sustainable Ecosystems RUDN University, 12. IAFES, Euro-Mediterranean Center on Climate Change, 13. Global Carbon Project, CSIRO Oceans and Atmosphere

Atmospheric methane ($CH_4$) is the most important greenhouse gas after carbon dioxide. Because $CH_4$ has a relatively short lifetime due to chemical losses in the atmosphere, it is expected that reducing $CH_4$ emissions would mitigate global warming in a relatively short timeframe. However, sources of atmospheric $CH_4$ are associated with a wide variety of processes such as fossil fuel production and consumption, agriculture, natural wetlands, and biomass burning, and our understanding of the full $CH_4$ budget is limited. To better understand $CH_4$ sources, an inverse analysis is one prominent methodology that estimates spatiotemporal variations of $CH_4$ sources consistent with their prior estimates and atmospheric observations within specified uncertainties. In this study, we performed a long-term inverse analysis of $CH_4$ fluxes with an inversion system named NICAM-TM 4D-Var (Niwa et al., 2017a,b). The inversion system is based on the atmospheric transport model NICAM-TM (Niwa et al., 2011), which has a homogeneous icosahedral grid system and mass conserving property. The horizontal model grid resolution was set to 223 km and the $CH_4$ flux estimation was performed at the same resolution, though some spatial error correlations were introduced. The prior flux dataset includes wetland/rice cultivation emission and soil uptake estimated by the terrestrial ecosystem model VISIT (Ito and Inatomi, 2012). The other emission categories are provided from the ongoing Global Carbon Project (GCP)–$CH_4$. In the inversion, several emission categories are separately estimated according to their seasonal and interannual variabilities. Compared with the prior estimates, the inverse analysis with ground-based station data estimated smaller emissions from East Asia and Europe, larger and smaller northern summer emissions from West Siberia and Hudson Bay Lowlands, respectively, and larger emissions from Bengal and Indochina areas. These changes estimated by the inversion are attributed to emissions from anthropogenic categories (mainly fossil fuel related), natural wetlands, and rice cultivation, respectively. The presentation will also address the reliability of the inversion estimates using independent aircraft data and examine the independence of each category emission estimate.

# Scientific findings from observations of GOSAT/TANSO–FTS TIR band

*Naoko Saitoh[1], Shingo Kosaka[1], Masato Shiraki[1], Hinako Kobayashi[1]

1. Center for Environmental Remote Sensing

Greenhouse Gases Observing Satellite (GOSAT) has continued its observations of greenhouse gases for more than 10 years since its launch on 23 January 2009. The thermal infrared (TIR) band of the Thermal and Near Infrared Sensor for Carbon Observation (TANSO)–Fourier Transform Spectrometer (FTS) on board GOSAT has observed concentrations of $CO_2$, $CH_4$ and other greenhouse gases in several atmospheric layers. In the latest TANSO–FTS TIR Level 2 retrieval algorithm, Version 1 (V1), ozone, water vapor, and temperature have been retrieved as by-products of the $CO_2$ and $CH_4$ products (Saitoh et al., 2016). We have already evaluated the data quality of the TANSO–FTS TIR V1 $CO_2$ and $CH_4$ products (Saitoh et al., 2016, 2017; Holl et al., 2016; Zou et al., 2016; Olsen et al., 2017). We applied the evaluated bias-correction values to the TANSO–FTS TIR V1 $CO_2$ data and compared variations in concentrations of the TIR $CO_2$ data with those of Measurement Of Pollution In The Troposphere (MOPITT) CO data [Deeter et al., 2014] in upper troposphere over the northern Africa. The comparison result showed that both TANSO–FTS TIR $CO_2$ and MOPITT CO concentrations became larger there almost at the same time in March through May, which suggests air mass with high CO and $CO_2$ emitted due to biomass burning was transported to upper atmosphere. As TANSO–FTS TIR V1 $CH_4$ profiles generally agreed with aircraft $CH_4$ profiles to within ~1% in the troposphere in low and middle latitudes, we analyzed seasonal variations in $CH_4$ concentrations in each altitude layer over India by using the TIR V1 $CH_4$ data. Our results were similar to the results reported in Chandra et al. (2017), but showed larger impact of $CH_4$ variations in lower troposphere on seasonal variations in $XCH_4$ concentrations. We have conducted validation analysis of TANSO–FTS TIR $O_3$ profiles simultaneously retrieved with the TIR V1 $CO_2$ product using Atmospheric Chemistry Experiment (ACE)–FTS and ozonesonde data. Although there was slightly high bias in the TANSO–FTS TIR $O_3$ data in the lower troposphere in summer, they showed better agreements with ACE–FTS and ozonesonde data than their a priori data taken from MacPeters et al. (2007). The TANSO–FTS TIR $O_3$ data in the lowest retrieval layer (surface–857 hPa) showed clear enhancements in $O_3$ concentrations over Mainland China compared to eastern Japan, which could demonstrate the detectability of tropospheric pollutants by the TANSO–FTS TIR band.

# Continuous measurements of atmospheric $CO_2$ and its $\delta^{13}C$ and $\delta^{18}O$ at Minamitorishima Island

*Shohei Murayama[1], Kazuhiro Tsuboi[2], Shigeyuki Ishidoya[1], Hidekazu Matsueda[2], Yosuke Niwa[3], Yousuke Sawa[2], Kentaro Ishijima[2], Kentaro Kozumi[4], Genta Umezawa[4], Kazuya Yukita[4], Shigeharu Nishida[4], Megumi Yamamoto[4], Tetsuyuki Usami[1], Shinji Morimoto[5]

1. National Institute of Advanced Industrial Science and Technology (AIST), 2. Meteorological Research Institute, 3. National Institute for Environmental Studies, 4. Japan Meteorological Agency, 5. Tohoku University

The Minamitorishima (MNM; 24°17’ N, 153°59’ E) station is uniquely located to monitor background air at northern mid latitudes; the site is located on a remote coral island in the western North Pacific, about 1,950 km southeast of Tokyo. The Japan Meteorological Agency has been making long-term continuous observations of atmospheric concentrations of major greenhouse gases at MNM. For a better understanding of mechanisms governing the observed $CO_2$ variation, systematic measurements of atmospheric $CO_2$ and its $\delta^{13}C$ and $\delta^{18}O$ have been carried out at MNM by analyzing discrete flask air samples taken at the site since 2011. The existing measurement program was enhanced by initiating continuous measurements of $CO_2$ and its $\delta^{13}C$ and $\delta^{18}O$ using a laser spectroscopy (Off-Axis Integrated-Cavity Output Spectroscopy) in March 2018.

Sample air is drawn from an air intake mounted on a tower at 20-m height above the ground surface, and introduced into a continuous isotope analyzer (Model CCIA-48, Los Gatos Research) after removing water vapor and aerosol particles. The analyzer is calibrated hourly for the concentrations of each $CO_2$ isotopologue, using 3 air-based $CO_2$ standard gases with isotopic ratios of industrial $CO_2$ and different total $CO_2$ concentrations. The isotopic ratios of these standards were determined by a mass spectrometer, and the concentrations of each $CO_2$ isotopologue of the standards were obtained from the isotopic ratios. The total $CO_2$ concentration and its $\delta^{13}C$ and $\delta^{18}O$ of sample air are calculated from the measured concentrations of each isotopologue.

The obtained $CO_2$ isotopic data are scattered, and the precisions of the $\delta^{13}C$ and $\delta^{18}O$ values measured by this analyzer estimated from hourly measurements of a target gas, which is dried natural air compressed into a 48-L gas cylinder, are about 10 times and 5 times worse than those achieved by our mass spectrometer, respectively. However, the daily mean values of atmospheric $\delta^{13}C$ and $\delta^{18}O$ show day-to-day variations in concert with those of the total $CO_2$ concentration and prominent seasonal variations. The daily mean $\delta^{13}C$ and $\delta^{18}O$ show systematic difference from the isotopic values obtained from flask sampling on the same day. However, since the differences are almost constant, the nature of the variations are very similar in both cases.

In this presentation, results of the preliminary analyses of the daily mean $CO_2$, $\delta^{13}C$ and $\delta^{18}O$ data obtained from the continuous measurement will be presented. From comparison with the flask sampling results, the effectiveness of the continuous measurement will also be discussed.

# Variations of atmospheric Radon-222 concentration observed at JMA stations

*Kentaro Ishijima[1], Kazuhiro Tsuboi[1], Hidekazu Matsueda[1], Yousuke Sawa[1], Yosuke Niwa[2,1], Takashi Maki[1], Takashi Nakamura[3]

1. Meteorological Research Institute, 2. National Institute for Environmental Studies, 3. Japan Meteorological Agency

Japan Meteorological Agency (JMA) has been operating several stations to monitor atmospheric greenhouse gases since the late 1980s under the Global Atmosphere Watch programme of the World Meteorological Organization (WMO/GAW). They show synoptic, seasonal, interannual variations, and trends due to changes in atmospheric transport and source/sink strength. To know their transport from land regions, we started the monitoring of atmospheric Radon-222 ($^{222}$Rn) in the 2000s at the JMA stations. Because $^{222}$Rn is emitted from almost only lands and chemically inert, it is useful to identify temporal variability of atmospheric greenhouse gases due to sources/sinks on land. $^{222}$Rn also radioactively decays with the half-life of 3.8 days, so is widely utilized to validate regional transport of atmospheric transport model through the model-observation comparisons. Understanding such transport process is also supported by using an atmospheric transport model. We have just started to use a newly developed on-line atmospheric tracer transport model (GSAM-TM). The tracer transport process is driven by a low-resolution version (TL95) of JMA's operational global numerical weather prediction model (GSAM).
In this study, we analyze the observed and model simulated atmospheric $^{222}$Rn concentration, to understand the transport process of land-origin atmospheric tracer as well as to validate the GSAM-TM. For example, the model well reproduces high $^{222}$Rn peaks, which are frequently observed at Minamitorishima (MNM; 24.28˚N, 153.98˚E) and Chichijima (CCJ; 27.09˚N, 142.19˚E) in winter to spring. Especially in winter, there are many cases that a high peak is first observed at CCJ and one day after at MNM. They are mainly produced by a cold front moving eastward with dense $^{222}$Rn behind the frontal line. The peak height at MNM is about two-thirds of that at CCJ. It is slightly smaller than that expected from decay by the 3.8 days half-life (about four-fifths), because dense $^{222}$Rn trapped by the front is diluted mainly by diffusion while transported. The model also well reproduces such peak attenuation degree. More details and results of $^{222}$Rn-age tracer simulations as well as of other JMA station will also be discussed in our presentation.

*Acknowledgements.* We sincerely thank all members of the JMA for operating $^{222}$Rn measurement systems at JMA monitoring stations

# Long-term variations of CFCs and HCFCs observed with ground-based FTIR spectrometers at Rikubetsu, Syowa Station, and Tsukuba since 1995

*Hideaki Nakajima[1,2], Masanori Takeda[2,1], Isao Murata[2], Takafumi Sugita[1], Tomoo Nagahama[3], Isamu Morino[1], Takeshi Kinase[4]

1. National Institute for Environmental Studies, 2. Graduate School of Environmental Studies, Tohoku University, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Meteorological Research Institute

We have been observing atmospheric minor constituents with ground-based Fourier-Transform InfraRed spectrometer (FTIR) at Rikubetsu (43.5N, 143.8E) since 1995, at Syowa Station, Antarctica (69.0S, 39.6E) in 2007, 2011, and 2016 with Bruker IFS-120M, and at Tsukuba (36.1N, 140.1E) since 2018 with Bruker IFS-125HR. We have analyzed vertical profiles and total columns of CFC-11, CFC-12, and HCFC-22 with SFIT4 retrieval algorithm. Production and consumption of CFCs and HCFCs have been regulated under the Montreal Protocol since 1987. Substitution to HCFCs and HFCs which do not destroy ozone layer is underway. However, illegal production of CFC-11 somewhere in Asia was recently reported (Montzka et al., Nature, 2018). Monitoring of these gases are possible not only by ground-based gas-chromatogram/mass-spectroscopy technique, but also by infrared spectroscopic measurements. Ground-based FTIR measurement has a capability to monitor multiple gas species simultaneously with vertical profile information for some gases. We retrieved vertical profiles and column amounts of CFC-11, CFC-12, and HCFC-22 since 1995 from FTIR spectra. Figure 1 shows total column amounts of HCFC-22 since 1995, while Figure 2 shows partial column amounts of HCFC-22 between 0 and 8 km. Seasonal variation which are seen in Figure 1 might be due to the change of tropopause height. However, it is removed in partial column amount in Figure 2. Trajectory calculation results of CFC-11 and other gases will be presented at the meeting.

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. National Institute for Environmental Studies, 3. Laser and Applications Research Center, UNIDEF (CITEDEF-CONICET)

We had been carried out a trilateral international collaboration among Japan, Chile, and Argentina called SAVER-Net (South American Environmental Risk Management Network) project for five years under the JST-JIICA SATREPS program. The major aim of the project was establishing an observation network of UV/ozone and aerosols over Chile and Argentina where was a blank area of the measurement stations on a global scale. The southern tip region of South America is the southernmost habitable area in the world, and the local residents in this region directly suffers from the influence of ozone hole that sometimes overpasses the region. Although the project was terminated in March 2018, we continue collaboration to develop forecast system of ozone hole and UV indices.

In this presentation, we will report the results of ozone observation by using a millimeter-wave spectrometer installed at the atmospheric observatory in southern Patagonia (OAPA) in Rio Gallegos, Argentina. The observation period was from April 2015 to March 2016 and September 2016 to August 2017, and we obtained ~ 9,400 1-hour averaged vertical profiles. We compared the time series of ozone volume mixing ratio (VMR) profile obtained in September and October when the ozone hole passes over the southern tip with the meteorological parameters, such as atmospheric temperature, potential temperature, and potential vorticities that are derived from MERRA-2 reanalysis data. As a result of the comparisons, we revealed that

・Ozone VMRs and the absolute value of potential vorticities show a good correlation below ~ 1000 K in potential temperature corresponding to ~ 35 km in altitude.

・As the ozone hole reaches above Rio Gallegos, atmospheric temperature decreases around ~ 25 km due to the horizontal advection of cool air in the polar vortex, and the temperature above ~35 km increases due to atmospheric descent inside of the polar vortex,

and we can use these quantities to easily distinguish whether Rio Gallegos is located at inside or outside of the ozone hole.

We will also present more detailed results about the ozone hole activities in 2015 and 2016.

Keywords: ozone hole, millimeter-wave spectroscopy, South America, polar vortex

[J] Poster | A (Atmospheric and Hydrospheric Sciences )：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

Thu. May 30, 2019 5:15 PM - 6:30 PM JST | Thu. May 30, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_6

## [A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University)

This session provides a forum for the presentation of the broad spectrum of tropospheric and stratospheric chemistry, including various research topics (e.g., dynamical processes, air quality and climate), approaches (modeling, field measurements, remote sensing, and laboratory studies), and species (gas and aerosol). This session also provides an opportunity for discussing possible future collaboration with other research fields relevant to atmospheric chemistry. We strongly encourage authors to prepare presentation slides and a poster in English.

# Validation of GOSAT cloud judgement by using Himawari-8 data

*Kitamura Katsuki[1], Naoko Saitoh[2]

1. Chiba University Graduate School of Science and Engineering Division of Earth Environmental Science , 2. Center for Environmental Remote Sensing Chiba University

In the retrieval processing of greenhouse gases from the Thermal and Near Infrared Sensor for Carbon Observation (TANSO)−Fourier Transform Spectrometer (FTS) on board Greenhouse Gases Observing Satellite (GOSAT), cloud contamination in the field of views (FOVs) of TANSO−FTS has been judged by TANSO−Cloud and Aerosol Imager (CAI) in the daytime and by the thermal infrared (TIR) band of TANSO−FTS in the nighttime. This study has compared the cloud detections in the TANSO−FTS FOVs by TANSO−CAI or TANSO−FTS TIR band with cloud detections by the Advanced Himawari Imager (AHI) on board Himawari−8.

For each of all TANSO−FTS observations over the ocean in January and July in 2016, we first selected all coincident Himawari−8 data when their center positions were located in the TANSO−FTS FOVs and they were obtained within one minute before or after the TANSO−FTS observations. Next, we conducted cloud detection tests for each of the selected Himawari−8 data based on their reflectance and brightness temperature values, and then judged each of TANSO−FTS FOVs as a clear or cloudy scene by combining the cloud detection tests of the Himawari−8 data in the TANSO−FTS FOVs.

About 90% of cloud judgements by TANSO−CAI and Himawari−8 agreed with each other. TANSO−CAI used only reflectance data in visible bands for their cloud detections, whereas Himawari−8 used both reflectance and brightness temperature data in visible and infrared bands, respectively, which may cause their ~10% disagreements. In contrast, agreements in cloud judgements between TANSO−FTS TIR band and Himawari−8 got worse by 13−20% compared to the TANSO−CAI and Himawari−8 cloud judgements. This is because that the FOVs of TANSO−FTS (10.5 km) is larger than those of TANSO−CAI and Himawari−8 (0.5 km and 2 km), and cloud detections by TANSO−FTS TIR band used only brightness temperature data.

In addition, GOSAT cloud judgements (TANSO−CAI or TANSO−FTS TIR band) tended to judge TANSO−FTS FOVs as “clear”, whereas Himawari−8 judged the same TANSO−FTS FOVs as “cloud” in most cases of disagreements in their cloud judgements. This is partly because of “clear conservativeness” of our cloud detection algorithm by Himawari−8. As for TANSO−FTS FOVs judged as “clear” by TANSO−FTS TIR band and “cloud” by Himawari−8, small-scale clouds partly existed in the TANSO−FTS FOVs judging from relatively low brightness temperature values of the coincident Himawari−8 data. This suggests the possibility that TANSO−FTS TIR band cannot detect such small-scale clouds.

# Measurement of temperature that fungal spores form ice nuclei

*Kazuyuki Kita[1], Kansei Sasaki[1], Koutaro Minami[1], Takeshi Kinase[2], Kouji Adachi[2], Yuji Zaizen[2], Kentaro Hosaka[3], Teruya Maki[4], Yasuhito Igarashi[1,5]

1. Ibaraki University, 2. Meteorological Research Laboratory, 3. National Musium of Nature and Science, 4. Kanazawa University, 5. Kyoto University

## 1. Background

Aerosols act as condensation nuclei and ice nuclei for the cloud particle formation in the atmosphere. In recent years, it was discovered that some bioaerosols can be ice-nuclei at relatively high temperatures of -15 ˚C or higher, indicating the possibility they could form ice clouds and precipitation at lower altitudes where formation mechanism of ice clouds has not been understood, and their significance in the meteorology and climate has been recognized. Although there have been many studies that measure ice nuclei formation temperature for general aerosols, it has been measured for very limited number of fungal spores in those studies. Thus, it has been not yet understood what kind of fungal spores can work as ice nuclei at relatively high temperatures.

In this research, we measured ice nucleation of spores of various kinds of fungi sampled in Japanese forests and examined the relationship between ice nucleation temperature and biological classification. We also classified patterns of ice nuclei formation, which may have information on ice nuclei formation temperature and process.

## 2. Method

In this research, spores were sampled from fungi collected during fungi surveys conducted every month from May to October in various types of woods in the Tsukuba Botanical Garden. Some fungi were also collected in the forests of Namie Town, Fukushima Prefecture. Using an optical microscope equipped with a cooling stage, ice nuclei form of generation of ice nuclei is observed.

## 3. Results and discussion

The ice nucleation temperatures of fungal spores showed large diversity, depending on their species. The ice nucleation temperature depends on the biological classification of fungi. Although there were a large variation, ice nucleation temperatures of spores of *Russulales*, ranged from -20 to -30 ˚C. The temperatures of *Boletales* spores were about -30 ˚C, and they of *Polyporales* spores were -22 ˚C. *Agaricales* can be divided into two groups: spore ice nucleation temperature was about -15 ˚C and about - 30 ˚C. The generation form of ice nuclei in spores can be categorized into 4 groups: A: ice grows from the whole spore surface after its swelling, B: ice grows suddenly from the spore surface, C: ice grows from a particular part of spores, D: ice generated around spores. Although there are a few exceptions, most of the spores that could be classified as “A” became ice nucleus at a relatively high temperature of -15 ˚C or higher. For other developmental forms, the relationship with ice nucleation temperature is not clear. Measuring the ice nucleation temperatures of various kinds of fungal spores this study found that some

©2019. Japan Geoscience Union. All Right Reserved. 

fungal spores can become ice nuclei at a relatively high temperature of -15 ˚C or so, showing a possibility that fungal spore can produce ice clouds in relatively lower atmosphere. It is also found that fungal spores forming ice at relatively high temperature mostly classified as *Agaricales* , and that they swelled just before they made ice particles. These results may have information on factors determining the ice formation temperature of spores.

# Investigation of Atmospheric Aerosol Particles and gases by R/V Mirai cruise over the Arctic Ocean on 2017

*Fumikazu Taketani[1], Saki Kato[1,2], Takuma Miyakawa[1], Masayuki Takigawa[1], Masahiro Yamaguchi[1], Hisahiro Takashima[1,2], Petr Mordovskoi[1], Yugo Kanaya[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Fukuoka University

Atmospheric aerosol particles play an important role in Arctic climate through the absorbing and scattering of solar radiation. Also, the deposition of light-absorbing particles on the surface reduces the Earth’ s albedo and accelerates snow/ice melting by absorbing the sunlight. However, the observational information has been still insufficient to assess their contribution over the Arctic region. In this study, we conducted the ship-based measurements of marine aerosol particles (black carbon (BC), and fluorescent property) and trace gases (ozone and carbon monoxide) using R/V Mirai during a cruise across the Arctic Ocean and Bering Sea (23 August –4 October 2017). The measured BC mass concentration over the Arctic Ocean in the latitudinal region > 70˚N was an overall mean value of 3.5 ±2.0 ng/$m^3$ . This value was almost same to the levels recorded during our previous observations in the Arctic cruise on September during 2014 -2016. We captured relatively high BC mass concentration and/or CO mixing ratio events at 4 and 7-12 September 2017. The trajectory and BC property suggested that the source of BC on 4 September could be oil field at north of Alaska. We will present further analysis on the size distribution, BC mixing state, during the cruise in the presentation.

# Characterization of carbonaceous aerosols in East Asia in the spring of 2015: Importance of non-fossil fuel sources

*Takuma Miyakawa[1], Yuichi Komazaki[1], Fumikazu Taketani[1], Xiaole PAN[2], Zifa Wang[2], Yugo Kanaya[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Institute for Atmospheric Physics, Chinese Academy of Science

The sources of elemental (EC) and organic carbon (OC) aerosols in the spring of 2015 in Asian outflow were investigated in terms of the radiocarbon ($^{14}C$) for carbonaceous aerosols and organic molecular marker analyses. The contribution of fossil fuel (FF) sources to total carbonaceous aerosols (TC) significantly increased in polluted air masses with enhancements of carbon monoxide concentrations. For EC, FF sources dominated in the polluted air masses. For OC, the contributions of non-FF and non-biomass burning (BB) sources were found to be significant (comparable to or higher than those of FF sources), especially in the air masses with higher values of both the ratio of water-soluble fraction of OC ($f_{WSOC}$) and $^{14}C$ concentrations ($F^{14}C$). Positive correlation between $f_{WSOC}$ and $F^{14}C$ indicates that the origins of TC (mainly OC) have great effects on the variabilities in the water solubility and the following climatic impacts (i.e., cloud formation process) of OC in the regional scale within the time scale of a week. Multivariate analyses using metallic and ionic tracers revealed the insights into the characteristics of classified carbonaceous aerosols in Asian outflow.

# Analyzing the influence of biomass burning on ambient air pollution in mainland Southeast Asia from 2001 to 2016

*Shuai Yin[1]

1. National Institute for Environmental Studies

In this study, various remote sensing data, modeling data and emission inventories were integrated to analyze the tempo-spatial distribution of biomass burning in mainland Southeast Asia and its effects on the local ambient air quality from 2001 to 2016. With such a long time span, land cover changes have been considered in dividing the biomass burning into four types: forest fires, shrubland fires, crop residue burning and other fires. The results show that the monthly average number of fire spots peaked at 34,512 in March and that the monthly variation followed a strong seasonal pattern, which was closely related to precipitation and farming activities. The four kinds of biomass burning fires presented totally different tempo-spatial distributions and forest fires and shrubland fires are more dominant than other types. Moreover, the monthly Aerosol Optical Depth (AOD), particulate matter with a diameter less than 2.5 $\mu$m ($PM_{2.5}$) and carbon monoxide (CO) concentrations also peaked in March with values of 0.62, 73.97 $\mu g/m^3$ and 426 ppb, respectively. There are significant correlations between the monthly AOD, $PM_{2.5}$, and CO concentrations and the number of fire spots. On an annual scale, we also found certain correlations between the AOD and $PM_{2.5}$ concentrations and the number of fire spots. With respect to the spatial distribution, the AOD, $PM_{2.5}$ and CO concentrations are always higher in intense biomass burning regions. Southeast Asia is one of the most populated and fastest growing economic regions in the world. Therefore, in order to objectively and accurately analyze the influence of biomass burning on local air quality over a long time span, it is imperative for this study to consider the effects of anthropogenic activities. Two anthropogenic $CO_2$ emission inventories, the Emission Database for Global Atmosphere Research (EDGAR) and the Carbon Dioxide Information Analysis Center (CDIAC), were used. The results further prove that biomass burning is the dominant cause of the variation in the local air quality in mainland Southeast Asia. Although government authorities have taken measures to control biomass burning, the number of fire spots did not decrease; the numbers exceeded 100,000 each year from 2012 to 2016.

# High-resolution and multi-year inventory of mercury emissions from biomass burning in tropical continents during 2001–2017

*Yusheng Shi[1]

1. Aerospace Information Research Institute, Chinese Academy of Sciences

Mercury emissions from biomass burning contribute significantly to the atmospheric mercury budget and the interannual variations of mercury concentrations in the troposphere. This study developed a high-resolution (0.1 deg) and multi-year (2001-2017) monthly inventory of mercury emissions from biomass burning in five fire types in the tropical continents (Central and South America, Africa, and South and Southeast Asia). The inventory estimates of mercury emissions from biomass burning are based on the newly released MCD61A1 version 6 Burned Area data product, satellite and observational data of biomass density, and spatial and temporal variable combustion factors. Results from the inventory demonstrated that during 2001-2017, the average annual mercury emissions from biomass burning in tropical continents was 497 Mg and ranged from 289 Mg to 681 Mg. Forest fires were the largest contributor, accounting for 61% (300 Mg) of the total mercury emissions from biomass burning, followed by fires in shrubland (30%, 151 Mg), savanna (7%, 35 Mg), peatland (1%, 6 Mg), and cropland (1%, 5 Mg). However, these proportions varied between the continents; in the Americas and Asia, the largest biomass burning emissions came from forest fires, and in Africa the largest emissions were from shrubland fires. Between the three continents, Africa released 41% of the mercury emissions from biomass burning (202 Mg $year^{-1}$), Asia released 31% (154 Mg $year^{-1}$), and the Americas released 28% (141 Mg $year^{-1}$). The total mercury emissions from biomass burning in these tropical continents exhibited strong interannual variations from 2001 to 2017, with peak emissions in March and Agust to September, and forest fires were the primary land fire type controlling the interannual variations. Soil mercury emissions released during biomass burning was determined to be 495 Mg $year^{-1}$ during 2001-2017. The biomass burning mercury emissions data in this inventory agrees with results by other studies, which suggests that it could be used as an input for atmospheric transport models.

# Simultaneous observations by sky radiometer and MAX-DOAS for characterization of biomass burning plumes in central Thailand in January-April 2016

*Hitoshi Irie[1], Syedul Hoque[1], Alessandro Damiani[1], Al Mashroor Fatmi[1], Pradeep Khatri[2], Tamio Takamura[1], Thanawat Jarupongsakul[3]

1. Chiba University, 2. Tohoku University, 3. Chulalongkorn University

The first intensive multi-component ground-based remote sensing observations by sky radiometer and Multi-Axis Differential Optical Absorption Spectroscopy (MAX-DOAS) were performed simultaneously at the SKYNET/Phimai site located in central Thailand (15.18˚N, 102.56˚E) from January to April 2016. The period corresponds to the dry season associated with the intense biomass burning (BB) activity around the site. The near-surface concentration of formaldehyde (HCHO) retrieved from MAX-DOAS was found to be a useful tracer for absorption aerosols from BB plumes, when BB was the dominant sources of HCHO and absorption aerosols over other sources. As the HCHO concentration tripled from 3 to 9 ppbv, the ratio of gaseous glyoxal to HCHO concentrations in daytime decreased from ~0.04 to ~0.03, responding presumably to the increased contribution of volatile organic compound emissions from BB. In addition, clear increases in aerosol absorption optical depths (AAODs) retrieved from sky radiometer observations were seen with the HCHO enhancement. At a HCHO of 9 ppbv, AAOD at a wavelength of 340 nm reached as high as ~0.15±0.03. The wavelength dependence of AAODs at 340-870 nm was quantified by the absorption Ångström exponent (AAE), providing evidence for the presence of brown carbon aerosols at an AAE of 1.5±0.2. Thus, our multi-component observations around central Thailand are expected to provide unique constraints for understanding physical/chemical/optical properties of BB plumes.

# Quantifying PM2.5 from long-range transport and local pollution in Taiwan during winter monsoon.

*Ming-Tung Chuang[1]

1. Research Center for Environmental Changes, Academia Sinica

From autumn to the following spring, annually, the northeast monsoon transports PM2.5 (particles less than
2.5 μm in aerodynamic diameter) from the Asian continent to downstream areas. Naturally, this triggered a
question: What are the contributions of PM2.5 from long-range transport (LRT) and local pollution (LP) at any
downstream location? To answer that question, the present study developed an economical and efficient method
that can easily estimate the contribution of PM2.5 from LRT (LRT-PM2.5) and PM2.5 from LP (LP-PM2.5). The
method used PM2.5 and meteorological observation data in Taiwan from 2006 to 2015 and a short-term simulation
from January to May in 2010. The analysis classified the data into three types of PM2.5 source patterns:
LRT-Event (high concentration plume at the front edge of southward moving anticyclones/strong northeast
wind), LRT-Ordinary (less concentration in common strong northeast wind), and LRT/LP Mix or Pure LP (PM2.5
was from both LRT and LP or from only LP under weak northeast wind). During the ten-year period, the average
LRT-PM2.5 values at the northern tip of Taiwan were 31–39 μgm−3, 12–16 μgm−3, and 4–13 μgm−3 for the
LRT-Event, LRT-Ordinary, and LRT/LP Mix or Pure LP patterns, respectively. The 10-year average LRT-PM2.5
and LP-PM2.5 contributions were approximately 70:30 in northern Taiwan, 50:50 in central Taiwan, and 30:70 in
southern Taiwan for the LRT-Event pattern; 60:40 in northern and 40:60 in central and southern Taiwan for the
LRT-Ordinary pattern; and 30:70 in northern and 25:75 in central and southern Taiwan for the LRT/LP Mix or
Pure LP pattern. Interestingly, LRT-PM2.5 peaked in 2013 but has decreased annually since then, whereas LPPM2.5
has roughly decreased in the past ten years.

# Vertical characterization of $PM_{2.5}$ based on observation using compact sensors on and around Mt. Unzen in Nagasaki Prefecture

*Tomoki Nakayama[1], Ayane Ueno[1], Kenta Kanegae[1], Kazuaki Kawamoto[1], Kodo Umakoshi[1], Takayuki Yamasaki[2], Wataru Okamoto[2], Yutaka Matsumi[2]

1. Faculty of Environmental Science, Nagasaki University, 2. ISEE, Nagoya University

Aerosol particles in the atmosphere, including $PM_{2.5}$, are known to have significant impacts on climate, the atmospheric environment, ecosystems, and human health. Whereas both of domestic sources and transboundary pollution from Asian Continent possibly contribute to the $PM_{2.5}$ mass concentrations in Japan, high $PM_{2.5}$ events owing to the transboundary pollution are often observed, especially in north-western part of Kyushu region (including Nagasaki Prefecture). Although $PM_{2.5}$ mass concentrations are observed at the observatories of the Atmospheric Environmental Regional Observation System (AEROS) of the Ministry of the Environment, Japan (MOEJ), the observatory on mountain is very limited, and widely used large and expensive bate attenuation monitor (BAM) is not suitable for the multi-point observations.

We developed a compact $PM_{2.5}$ sensor with Panasonic Corporation [Nakayama et al. 2018]. This sensor can measure $PM_{2.5}$ mass concentrations by detecting light scattering intensities from individual aerosol particles with diameters greater than 0.3 $\mu$m. In this study, this sensor was applied for the observations of $PM_{2.5}$ mass concentrations around Mt. Unzen in Nagasaki Prefecture from December 2018. The $PM_{2.5}$ sensors were installed at six sites with different altitudes from 20 m to 1300 m to analyze vertical and horizontal distributions of $PM_{2.5}$. During high $PM_{2.5}$ events (>35 $\mu g/m^3$) in winter, the $PM_{2.5}$ mass concentrations at an altitude above 1000 m are similar to those at 20 m in most cases. However, in some cases, high $PM_{2.5}$ was observed only at low altitude sites, likely because of inflow of clean air with lower aerosol burden from higher altitude to the mountain sites and/or low boundary layer height. The vertical profile data obtained in this work will be compared with the lidar data obtained by NIES at Omura city, which is located 38 km north-west of Mt. Unzen, to discuss the possible sources and transport patterns of $PM_{2.5}$.

# Observation of NPF events at the summit of Mt. Fuji during daytime and nighttime

*Hiroki Igarashi[1], Takenori Sato[1], Tatsuhiro Mori[1], Kazuhiko Miura[1], Yoko Iwamoto[2], Ryuichi Wada[3], Shungo Kato[4], Hiroshi Okochi[5]

1. Tokyo University of Science, 2. Hiroshima University, 3. Teikyo University of Science, 4. Tokyo Metropolitan University, 5. Waseda University

An improved understanding of a new particle formation (NPF), which is a key process controlling the spatial and temporal distributions of aerosol concentration, is needed to estimate the direct radiative forcing. However, it is difficult to quantitatively understand the mechanism of NPF because the frequency of the NPF depends on the aerosol concentration, gases, and meteorological condition. In this study, we measured number concentrations (*N*) of aerosol particles (10 to 487 nm) at the summit of Mt. Fuji (35.360˚N, 138.727˚E, 3776 m a.s.l.) between July and August during 2011-2017. We report the annual and diurnal variations of the frequency of the NPF for a long-term period. The summit of Mt. Fuji is usually located in the free troposphere and enable us to observe the long-range transport of aerosol particles. The NPF event was defined as the event that *N* increases over 1 hour for diameter smaller than 25 nm. We observed 172 NPF events (daytime and nighttime events were 90 times and 82 times, respectively) during the observation period. Most events occurred at 8 o'clock (at the peak of daytime events) and 20 to 21 o'clock (at peaks of nighttime events) in local time. In addition, the growth rate of aerosol particles was calculated. The median value of the growth rate was estimated to be 5.27 nm/h (6.03 nm/h for daytime and 4.56 nm/h for nighttime) at 40 NPF events, suggesting that aerosol particles are easily grown during daytime. Finally, using a back trajectory analysis (NOAA HYSPLIT version 4), we investigated when and where the NPF occurred. As a result, it is suggested that 62.5% of the total NPF occurred during the daytime, and the rest occurred during the nighttime (37.5%). The NPF frequently occurred during daytime over Japan although a few NPF occurred over the sea during nighttime.

# Measurement of atmospheric metal particles using an ICP-MS and TEM.

*Takeshi Kinase[1], Kouji Adachi[1], Mizuo Kajino[1], Masahiko Hayashi[2], Keiichiro Hara[2]

1. Meteorological Research Institute, 2. Fukuoka

Particles containing transition metal components (hereafter, metal particle) are one of the major aerosols. Some of these metal particles have strong oxidation potential and have health effects by deposition into the human body through generating reactive oxygen and free-radical in and on cells. These reactive oxygen and free radicals cause various effects such as oxidative stress, inflammatory cell, DNA oxidative damages and cell death. However, oxidation potential for each metal particle and the magnitude of hazard to human health are not well known. In addition, colored metal particles, such as iron oxide, absorb solar radiation and contribute to the global warming. However, these effects of metal particles are not clarified because their observations and detailed features are not well known.

In this study, we measured atmospheric metal particle concentrations using an inductively coupled plasma-mass spectrometry (ICP-MS) and collected aerosol samples on the Cu grids using impactors to observe each aerosol particle using a transmission electron microscope (TEM) and an energy-dispersive X-ray spectrometry detector (EDS) with the scanning transmission electron microscopy (STEM). The ICP-MS instrument was coupled with a gas changer for air replacement in argon gas atmosphere, so that aerosol particles were directly measured using the ICP-MS in real-time. As a result, we could measure time trends of atmospheric metal particle concentrations quantitatively with high time resolutions together with their shape and mixing states by the TEM and STEM-EDS analysis.

We measured atmospheric metal particles in winter (2018/1/17–2/8) and in spring (2018/5/8–5/30) at Fukuoka University. We measured increasing events of metal particles by ICP-MS. Fe and Al were the highest concentration followed by Zn, Mn, Cr and Pb. Two different slopes were observed in relation between Fe and other metal elements such as Mn, V, and Al. On the other hand, Ag, Au, Mo and Tc did not correlate with Fe. From TEM observation of samples with high concentrations of metal particles, we found aggregated metal particles as ultrafine metal spheres (for smaller particles were several nm). These particles contained Fe, Mn and Cr as major metal elements, and most particles were internally mixed with a sulphate. Furthermore, some metal particles contained many ultrafine metal particles that distributed separately in a sulphate. Zn and Pb containing particles were also internally mixed with sulphate, however, they were observed as dissolved substances (not particle state) or crystallized state, which were decomposed by electron beam.
We found other metal particles which contained such as Ag, Sb, and Cu during their increasing periods. Our results are useful for understanding of atmospheric metal particles behaviors.

# Experimental results on measuring device of complex refractive index using the single particle extinction and scattering method

*TAKASAGO YUYA[1]

1. Tokyo university

Changes in the type and amount of atmospheric aerosol alter the albedo, resulting in radiation budget and climate change. However, the prediction accuracy of the fluctuation range is not high at the present. The complex refractive index can estimate the type of atmospheric aerosol. In the existing method, a method of measuring the complex refractive index for each bulk is mainstream, and there are few cases to measure for each single particle. If accurate measurement data of complex refractive index for each particle type can be obtained, it is possible to improve prediction accuracy of climate change width of particle type, so measurement with complex refractive index for each single particle is important. In this study, we conducted an experiment using single particle extinction and scattering method as a method to measure the complex refractive index. The single particle extinction and scattering method is a method of measuring forward scattered light intensity generated by projecting a laser on fine particles and interference between scattered light and incident light and estimating the value of the complex refractive index of the particle from these data. We developed an experimental apparatus using this method and conducted experiments with polystyrene, BC standard particles and precipitation samples (Okinawa, Happo, Fukui). Currently, I am thinking a method to solve the inverse problem that estimates particle characteristics such as particle type and complex refractive index from forward scattering intensity obtained from experiment and interference data of incident light and scattered light. For this purpose, we are developing a method of classifying samples mixed with plural types of particles into particle type by using clustering method of machine learning.

Institute of Nature and Environmental Technology, Kanazawa University, 4. Department of Applied Chemistry, Graduate School of Engineering, Osaka Prefecture University, 5. School of Earth and Environmental Sciences, Seoul National University, Seoul, Korea, 6. Research Institute for Applied Mechanics, Kyushu University, 7. Institute of Atmospheric Physics, CAS, Beijing, China

Compared to carbon dioxide ($CO_2$), which is a major long-lived greenhouse gas, the influence of black carbon (BC) to global warming is not negligible among the short-lived components. To improve the bottom-up emission inventory for enhancing the understanding level of BC, the measured ΔBC/ΔCO ratios were compared with those from the Regional Emission inventory in Asia (REAS) version 2.1 bottom-up inventory. The measurements were conducted at two sites in Korea (Baengnyeong; 124.63˚ E, 37.97˚ N, and Gosan; 126.17˚ E, 33.28˚ N) and two sites in Japan (Noto; 137.36˚ E, 37.45˚ N, and Fukuoka; 130.47˚ E, 33.52˚ N). The instruments for measuring CO concentration are same at all sites as Model 48i (Thermo Fisher Scientific), however, the instruments for BC were different depends on the sites (sunset EC/OC analyzer in Baengnyeong, Continuous Light Absorption Photometer in Gosan, Multi-Angle Absorption Photometer in Noto and Fukuoka). Based on the backward trajectories during past 120 hours calculated from HYSPLIT model, all trajectories were assigned to six study domains which divided by country and/or administrative district (East China, North China, Northeast China, South Korea, North Korea, and Japan). To exclude the wet-removal effect, the ΔBC/ΔCO ratio was considered only when the accumulated precipitation along a backward trajectory (APT) for three days is equal to zero. Also, we confirmed that the comparison of ΔBC/ΔCO by six study domains could be reasonable since there were no significant differences in ΔBC/ΔCO ratio depending on traveling time (dry deposition effects) and residence time over the emission source areas. Compared to measured ΔBC/ΔCO ratio (6.6 –8.4 ng/$m^3$·ppb), ΔBC/ΔCO from REAS emission inventory (8.0 ng/$m^3$·ppb for East China –23.2 ng/$m^3$·ppb for South Korea) were overestimated by factor 1.2 for East China to 2.9 for South Korea whereas those for North Korea (3.7 ng/$m^3$·ppb from REAS) was underestimated by factor 2.0. The measured ΔBC/ΔCO ratios in Japan (6.8 ng/$m^3$·ppb) were similar to those from REAS emission inventory (6.5 ng/$m^3$·ppb). The seasonal and spatial differences of ΔBC/ΔCO ratios between measured and emission inventory will be examined to identify the over- and under-estimated administrative districts.

# Inverse modeling of black carbon emissions over China using ensemble data assimilation

*Ping Wang[1]

1. Chinese Academy of Meteorological Sciences

Emissions inventories of black carbon (BC), which are traditionally constructed using a “bottom-up” approach based on activity data and emissions factors, are considered to contain a large level of uncertainty. In this paper, an ensemble optimal interpolation (EnOI) data assimilation technique is used to investigate the possibility of optimally recovering the spatially resolved emissions bias of BC. An inverse modeling system for emissions is established for an atmospheric chemistry aerosol model and two key problems related to ensemble data assimilation in the top-down emissions estimation are discussed: 1) how to obtain reasonable ensembles of prior emissions; and 2) establishing a scheme to localize the background-error matrix. An experiment involving one year long simulation cycle with EnOI inversion of BC emissions is performed for 2008. The bias of the BC emissions intensity in China at each grid point is corrected by this inverse system. The inversed emission over China in January is 240.1 Gg, and annual emission is about 2539.3 Gg, which is about 1.8 times of bottom-up emission inventory. The results show that, even though only monthly mean BC measurements are employed to inverse the emissions, the accuracy of the daily model simulation improves. Using top-down emissions, the average root-mean-square error of simulated daily BC is decreased by nearly 30%. These results are valuable and promising for a better understanding of aerosol emissions and distributions, as well as aerosol forecasting.

# Analysis of BC emissions in East Asia using inverse model

*Takashi Maki[1], Taichu Y Tanaka[1], Naga Oshima[1], Thomas Sekiyama[1], Keiichi Kondo[1], Jun-ichi Kurokawa[2], Keiya Yumimoto[3], Toshimasa Ohara[4]

1. Meteorological Research Institute, 2. Asia Center for AirPollution Research, 3. Kyushu University, 4. National Institute for Environmental Studies

In addition to affecting climate change and global warming, Black Carbon (BC) brings impact on society and human health as well. However, changes in BC emissions in east Asia have yet to be fully understood. Attempts have been made by various institutions and researchers to estimate BC emission inventories from various statistics but there are problems such as lack of rapid reporting. In order to modify black carbon emissions inventory based on this statistic, we have constructed an BC emission inversion system for east Asia using aerosol transport model and surface observations. The analysis period for emissions is from 2011 to 2014. We adopt global aerosol transport model named MASINGAR mk-2 (Tanaka et al.). The model is a subset of MRI (Meteorological Research Institute) earth system model for climate research and can treat BC, OC, mineral dust, sulfate and sea-salt with external mixing. We divided tags of each province of China, South Korea, Japan into 33 regions and carried out tagged tracer transport experiments. We collected 5 surface sites daily observation data (Hedo, Fukue, Echizen, Happo and Lulin). A priori BC emission is provided by REAS 2.2 (Kurokawa et al.) at 2010. Inversion results suggested that BC emissions in East Asia between 2011 and 2014 are decreasing especially in China about 10%, compared to the 2010 emissions. There was no significant change in BC emissions in Japan and South Korea during the analysis period. However, the observation network could constrain mainly northern part of China. We need more observation data (ex. satellite data) to constrain BC emission amount.

Keywords: Inverse model, BC emission, Aerosol model

# Source attribution of BC in the northern Pacific and Arctic Ocean by chemistry climate model

*Takato Onishi[1], Kengo Sudo[1,2], Yugo Kanaya[2], Fumikazu Taketani[2]

1. Graduate School of Environmental Studies, Nagoya University, 2. Japan Agency for Marine-Earth Science and Technology

Black Carbon (BC) is emitted from combustion of biomass and fossil fuel into the atmosphere. BC in the atmosphere absorbs visible light and heats the atmosphere contributing to global warming. The emitted BC being originally hydrophobic with low CCN activity, is not easily scavenged by precipitation allowing long-range transport of BC to remote areas. Snow or ice surfaces, when affected by deposition of BC, decrease their albedo causing further warming in the high latitudes.
This study focuses on long-range transport of BC in the northern high latitude regions and investigates BC origins (source regions and types) with a tagged tracer simulation by a global chemistry climate model CHASER. The modeled BC concentrations are validated with the BC observational data obtained from the JAMSTEC research vessel Mirai (from August to September). The model is found to be overestimating the observed BC by a factor of 1.2 to 7 in the south of 70°N in the northern Pacific. Differences between the model and observation are relatively small near Japan, but a bit larger between 160°E to 180°E in the Pacific Ocean. For the Arctic Ocean, on the other hand, the model severely overestimates BC by a factor of 13 to 70. In the model, BC in the North Pacific and Arctic Ocean is originated mainly from Siberia, North America and China.
The overestimated BC in the model probably shows an underestimate of wet deposition by precipitation. However, it is found that CHASER tends to overestimate precipitation amount when compared to the reanalysis data as the ERA-interim. This suggests that there is an inconsistency in the BC wet deposition scheme such as underestimation of BC uptake to cloud droplets. We considered correlation between precipitation and BC wet deposition flux normalized by columnar BC mass for checking relation of precipitation and BC wet removal. The correlation coefficient is about 0.4 suggesting that BC removal by precipitation is weak in the model. In addition, the ratios of internal BC to total BC for the surface to lower troposphere are calculated for the years of 2014 to 2017. In the northern pacific and Arctic Ocean, the ratios are about 30 percent indicating that the hydrophobic type of BC is dominant in the region for which CHASER overestimates BC.
As a result, it is suggested that there is much room for improvement in the simulation of aging process of BC (hydrophobic to hydrophilic conversion) and the scheme for wet deposition of external BC. In the presentation, the results from the further improved model simulations will be introduced and discussed.

# Evaluation of a mobile $PM_{2.5}$ sensor and application to the measurements along the National route 1 and around Nagasaki University

*Kenta Kanegae[1], Takayuki Yamasaki[2], Wataru Okamoto[2], Yutaka Matsumi[2], Tomoki Nakayama[1]

1. Nagasaki University, 2. Nagoya University

Short-term exposure of $PM_{2.5}$, negatively impacts human health through respiratory disease (such as asthma and bronchitis) and cardiovascular diseases, and leads to premature death. Because $PM_{2.5}$ is spatially and temporally variable and individuals also move in time and space, it is important to understand personal exposures of $PM_{2.5}$ for better assessment of the health impact. We developed a palm-sized optical $PM_{2.5}$ sensor with and Panasonic Corporation, and evaluated the performance for environmental monitoring at fixed sites [Nakayama et al. 2018]. This sensor was designed to measure $PM_{2.5}$ mass concentrations by detecting light scattering intensities from individual aerosol particles with diameters greater than 0.3 $\mu$m. The small size, light weight, and low power consumption of the sensor are suitable for mobile personal exposure measurement. However, the sensitivity of the sensor can be change if the sensor is tilted or swung, because aerosol particles flow into the sensor via an updraft generated by a heater and flow rate may be change during tinting or swinging.
In this study, we investigate the performance of the $PM_{2.5}$ sensor for mobile exposure measurements. The changes in the sensitivity of the sensor during tilting or swinging have been tested. Moreover, the change in the sensitivity of the sensor during walking has been investigated, by comparing the $PM_{2.5}$ data during walking with those during standing. From the results of these tests, it was found that the sensor can be applied for mobile exposure measurements of $PM_{2.5}$ mass concentration. We applied this sensor for the mobile measurements during walking along the National Route 1 (from Tokyo to Kyoto) for two weeks, and around Nagasaki University. The obtained $PM_{2.5}$ data will be compared with those obtained at the surrounding ambient air monitoring stations (AEROS) and meteorological data to discuss the sources and transportation of $PM_{2.5}$. We believe that this research will provide useful information for applications of the compact sensor to epidemiological research of health effects of $PM_{2.5}$.

# Analysis on the Relationship between the Concentration of Particulate Matter and Mortality from Respiratory and Cardiovascular Diseases

*Woo-Sik JUNG[1], Woo-Gon Do[2]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea, 2. Busan Metropolitan City of Institute of Health and Environment Busan, Korea

Concerns over particulate matter are growing rapidly as the number high concentration days are increasing. Since 2015, PM2.5 has been set as a national ambient air quality standard and frequency of Asian dust or mists and precursors coming from the west of Korea has increased. Various studies have been conducted on the distribution and composition of particulate matter. The particulate matter is known to be the main cause of respiratory and cardiovascular disease, such as vascular dysfunction, asthma and the occurrence of chronic bronchitis. As the paradigm of air quality management policy changes from controlling, treating and reducing sources to taking into account the damage of a receptor including assessing health risks, it is necessary to establish scientific policies by quantitatively assessing the health effects of the particulate matter and calculating health benefits. To do this, a quantitative assessment of the health risks of particulate matter is essential. The purpose of this study is to analyze the effects of changes in the daily average concentration of particulate matter on the mortality of respiratory and cardiovascular diseases in Busan, Korea. In this study, we employed a generalized additive model (GAM) with a quasi-Poisson to assess the association between daily mean particulate matter and mortality. A penalized spline function was used to adjust the seasonal pattern and long-term trend in daily mortality and the nonlinear mortality effects of the weather. Based on this, a model between the death rate and daily average particulate matter was established and the change in the mortality rate of respiratory and cardiovascular diseases was analyzed according to the change in particulate concentration. The daily mean particulate matter were calculated using hourly PM2.5 and PM10 data provided the Environment Ministry of Korea and the causes of death from 2015 to 2017 were provided by the National Statistical Office's 'Micro Data Service'.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

# A Study on the Estimation of Contribution Rate of Odour Substances Using CALPUFF model

*Woo-Sik JUNG[1], Woo-Gon Do[2]

1. Department of Atmospheric Environment Information Engineering, Atmospheric Environment Information Research Center, Inje University, Gimhae 50834, Korea, 2. Busan Metropolitan City of Institute of Health and Environment Busan, Korea

The environmental odours produced by anthropogenic origin according to urbanization and industrialization continue to increase. These odours cause mental and physiological stress and have a variety of adverse health effects, including nausea, headaches, loss of appetite, gastrointestinal disorders, difficulty in breathing, and allergy. Therefore, the odours are degrading the quality of life for residents in nearby residential areas, causing health hazards and eventually causing economic loss in the community. Miscellaneous approaches are used internationally within odour regulatory systems, with methods and tools for management and control supported by ambient air odour concentration and individual chemicals(maximum impact standard); fixed and variable separation distances(separation distance standard); maximum emission rate for odours and individual chemicals(maximum emission standard); number of complaints or annoyance level(maximum annoyance standard); best available technologies e BAT (technology standard). However, the occurrence of odors is a very local issue that reflects the characteristics of individual sources and the subjective impact of nearby residents. Therefore, prior to these regulations, it is very important to assess the impact of individual emissions quantitatively. The CALPUFF model is a typically used model for assessing the dispersion of air pollutants or odours in various research institutes, including the U.S. EPA. This model is an optimal method for calculating the contribution rate of individual emission sources in area where odour sources are concentrated. In this study, the CALPUFF model was used to identify the contribution rate of the four adjacent emission facilities to the surrounding areas in Saenggok Industrial Complex located in Saenggok-dong, Gangseo-gu, Busan in Korea. In order to estimate the contribution rate of individual emission sources, the predicted odour concentration of each emission source was calculated respectively(S1-S4). Next, the predicted odour concentration was calculated considering four emission sources together(Base). Finally, the contribution rates of individual emission sources within the modeling domain were calculated as the ratio of S1-S4 to Base. The amount of area sources in each emission facility was indirectly calculated using the concentration measured near the emission facility. Meterological input data produced by applying the results of the WRF model to the CALMET model. As a result of the CALPUFF model, the contribution rate of sludge treatment facility was the highest at 76%, and the rest of the facilities were shown to contribute about 10% to the surrounding area.

# A Study on the Estimation of Contribution Rate of Odour Substances Using CALPUFF model

**Woo-Sik Jung*, Woo-Gon Do,**

*Dept. of Atmospheric Environment Information Engineering, Inje University, Gimhae, Korea
Busan Metropolitan City of Institute of Health and Environment Busan, Korea

The environmental odours produced by anthropogenic origin according to urbanization and industrialization continue to increase. These odours cause mental and physiological stress and have a variety of adverse health effects, including nausea, headaches, loss of appetite, gastrointestinal disorders, difficulty in breathing, and allergy. Therefore, the odours are degrading the quality of life for residents in nearby residential areas, causing health hazards and eventually causing economic loss in the community. Miscellaneous approaches are used internationally within odour regulatory systems, with methods and tools for management and control supported by ambient air odour concentration and individual chemicals(maximum impact standard); fixed and variable separation distances(separation distance standard); maximum emission rate for odours and individual chemicals(maximum emission standard); number of complaints or annoyance level(maximum annoyance standard); best available technologies e BAT (technology standard). However, the occurrence of odors is a very local issue that reflects the characteristics of individual sources and the subjective impact of nearby residents. Therefore, prior to these regulations, it is very important to assess the impact of individual emissions quantitatively. The CALPUFF model is a typically used model for assessing the dispersion of air pollutants or odours in various research institutes, including the U.S. EPA. This model is an optimal method for calculating the contribution rate of individual emission sources in area where odour sources are concentrated. In this study, the CALPUFF model was used to identify the contribution rate of the four adjacent emission facilities to the surrounding areas in Saenggok Industrial Complex located in Saenggok-dong, Gangseo-gu, Busan in Korea. In order to estimate the contribution rate of individual emission sources, the predicted odour concentration of each emission source was calculated respectively(S1-S4). Next, the predicted odour concentration was calculated considering four emission sources together(Base). # Stepwise decrease in atmospheric trace gases near the ground associated with rapid vertical mixing observed by 3-D coherent Doppler lidar and in-situ gas measurements

*Hisahiro Takashima[1], Keiichiro Hara[1], Yuki Ohira[1], Akinori Takami[2], Ayako Yoshino[2], Yasushi Fujiyoshi[3]

1. Fukuoka University, 2. National Institute for Environmental Studies, 3. Hokaido University

Stepwise decreases, which occur over several minutes, in nitrogen oxides (NOx) and carbon monoxide (CO) concentrations, in which the main source of these gases is supposed to be near the surface, are sometimes observed in Fukuoka, urban site in Japan, during the summer-winter seasons. In the most cases, ozone ($O_3$) content, which could be higher at higher altitudes, increases. Wind observations by 3-D coherent Doppler lidar suggest there is a thin surface layer (up to ~50-300 m thickness) near the ground before the stepwise change, and then rapid vertical mixing associated with the local meteorological system occurs. The surface thin layer plays a role as a cover of pollutants near the ground, and the vertical mixing within the boundary layer rapidly dilutes/reduces the pollutant contents near the ground.

# Spatiotemporal variations of nitrogen dioxide ($NO_2$) over Fukuoka , observed by multiple MAX-DOAS instruments and 3-D coherent Doppler lidar

*Hironobu Ueki[1], Hisahiro Takashima[1], Martina M. Friedrich[2]

1. Fukuoka university, 2. Belgian Institute for Space Aeronomy (BIRA-IASB), Belgium

To understand spatiotemporal variations and transport/mixing processes in nitrogen dioxide ($NO_2$) over Fukuoka, an urban area in Japan, continuous $NO_2$ profile observations with a high temporal resolution of four minutes by MAX-DOAS (Multi Axis Differential Optical Absorption Spectroscopy) at three sites in Fukuoka have been conducted from October 2018 to January 2019. Two sites (Yakuin (33.580˚N, 130.396˚E) and Sohara (33.580˚N, 130356˚E)) are located near the city center and pointing towards the north(towards the sea), and one site (Fukuoka University (33.550˚N, 130.364˚E)) is located outside of the city center pointing towards the city center.

In the case of 29 November 2018, an air mass with a high $NO_2$ concentration was observed near the ground in the morning (until 10:30 am) and later, around 10:30 to 11:30 am, an increased concentration of $NO_2$ gradually appeared at a higher altitude over the city center. This increased $NO_2$ concentration disappeared around 13:30-14:00 pm. From the simultaneous three-dimensional (3-D) wind observations by 3-D coherent Doppler lidar installed at Fukuoka University, it is suggested that the air mass with high $NO_2$ concentration was transported upward from the ground by vertical convection, and after that, a clean air-mass was advected from sea by sea-breeze. In this presentation, we will show several results observed by the multipoint MAX-DOAS and 3-D wind observations, focusing on the 3-D transport over Fukuoka using the high $NO_2$ air mass as a tracer.

# Measurement on the $^{17}O$-excess of tropospheric nitrogen oxides

*Fumiko Nakagawa[1], Dong Ding[1], Urumu Tsunogai[1], Takashi Yamaguchi[2], Izumi Noguchi[2]

1. Graduate School of Environmental Studies, Nagoya University, 2. Institute of Environment Sciences, Hokkaido Research Organization

Nitrogen oxides are important trace gases that influence the concentrations of atmospheric oxidants that drive tropospheric and stratospheric chemistry. Triple oxygen isotopes ($\Delta^{17}O$ values; deviation of $^{17}O$ from the mass dependent fractionation line) have been used to understand complex chemical systems such as the cycling and oxidation of NOx. For example, $\Delta^{17}O$ valuesof atmospheric nitrate ($HNO_3$, $NO_3^-$, and p-$NO_3^-$), indicates the proportion of NOx that reacts with ozone ($O_3$) during its oxidation (Michalski *et al.*, 2003; Tsunogai *et al.*, 2010; Nelson et al., 2018). $\Delta^{17}O$ values of atmospheric nitrous acid (HONO; recognized as a potentially important source of OH radicals) have also been used recently to decipher their production pathways. In these studies, however, predicted $\Delta^{17}O$ values were used for $NO_2$. Here, we tried to establish a method to determine $\Delta^{17}O$ values of atmospheric $NO_2$.

$\Delta^{17}O$ value of $NO_2$ was determined, together with $\Delta^{17}O$ value of HONO, by combining sensitive determination method on isotope compositions of $NO_2^-$(Komatsu *et al.*, 2008; Tsunogai *et al.*, 2010) with a slightly modified filter-pack method (Noguchi *et al.*, 2007), in which both $NO_2$ and HONO were collected simultaneously as $NO_2^-$on triethanolamine (TEA)-coated filter and alkaline ($K_2CO_3$) impregnated filter, respectively. Periodical sampling of atmospheric $NO_2$ and HONO was carried out at Hokkaido Institute of Environmental Sciences, Sapporo and at Nagoya University, which is located in a suburban area of Nagoya City. The sample collection period was fixed to one week with a flow rate of 10 L/min. In order to determine diurnal variation in $\Delta^{17}O$ value of $NO_2$ and HONO, an automated system for time-interval air sampling equipped with 6 four-stage-filter-packs were made and used it to collect atmospheric samples every 4 hours.The $\Delta^{17}O$ values of $NO_2$ and HONO showed similar diurnal variations; higher value on the day time than the night time. The result suggests that the atmospheric HONO is formed mainly by chemical reaction of NOx in the urban atmosphere.

# Long-term measurements of the column-averaged mixing ratios of tropospheric substances related to the air pollution using ground-based FTIRs at Rikubetsu, Japan

*Tomoo Nagahama[1], Isamu Morino[2], Shingo Nakanishi[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. National Institute for Environmental Studies

Air pollutants originating from carbon compounds such as reactive volatile organic compounds (VOCs) cause a serious degrading of the air quality near their sources. In addition, these are transported to remote areas with chemical composition changes, and affect air quality in urban areas and their surrounding areas, and therefore, are one of major issues in preserving the air quality. Especially, HCHO and HCOOH originating from forest fires and biogenic VOCs are distributed near their sources since their chemical lifetime is within a few days, and therefore, their distributions and time variations are one of important keys in associating the sources with the impact to the global environment. In order to understand the characteristics of long-term variation of the air quality and its influence on the global environment, the temporal variation of tropospheric substances related to the air pollution are measured with ground-based Fourier Transform InfraRed (FTIR) instrument (Bruker IFS120M and IFS120/5HR) installed at Rikubetsu observatory in Hokkaido, Japan. The cooperative measurements of solar absorption spectra using the FTIRs are conducted by the Institute for Space-Earth Environmental Research (ISEE) of Nagoya University and the National Institute for Environmental Studies (NIES) since 1995. The spectrum is obtained in a 3-15 $\mu$m band with a resolution of 0.0035 $cm^{-1}$. The vertical distribution of trace gases in troposphere and stratosphere is retrieved from the measured spectrum by using the SFIT4 (version 0.944) software. Using SFIT4, we have retrieved the total column amounts and tropospheric column-averaged mixing ratio of $O_3$, $CH_4$, $C_2H_6$, N2O, CO, HCN, HCHO, HCOOH, $C_2H_2$, $CH_3OH$, and find their seasonal and long-term variations from 1995 to 2018. The observed tropospheric column-averaged mixing ratios of $O_3$, $C_2H_6$ and CO show the maximum in March and April, although that of HCHO peaks in July and that of HCN is in May and August, respectively. These differences among the substances may reflect the source and sink processes. Especially, HCHO having a short lifetime may reflect oxidation of biogenic VOCs in summer as well as forest fires.
In the presentation, we will report the detailed features of temporal variations of these substances in troposphere and will discuss its influence on the global environment.

# Impacts of Biogenic and Anthropogenic Emissions on Summertime Ozone Formation in the Guanzhong Basin, China

*Nan Li[1]

1. Nanjing University of Information Science & Technology

This study is the first attempt to understand the synergistic impact of anthropogenic and biogenic emissions on summertime ozone ($O_3$) formation in the Guanzhong (GZ) basin where Xi’ an, the oldest and the most populous city (with a population of 9 million) in the northwest China, is located. Month-long (August 2011) WRF-Chem simulations with different sensitivity experiments were conducted and compared with near-surface measurements. Biogenic volatile organic compounds (VOCs) concentrations were characterized from 6 surface sites among the Qinling Mountains, and urban air composition was measured in the Xi’ an city at a tower 100 m above the surface. The WRF-Chem control experiment reasonably reproduced the magnitudes and variations of observed $O_3$, VOCs, $NO_x$, $PM_{2.5}$ and meteorological parameters, with normalized mean biases for each parameter within ±21%. Subsequent analysis employed the factor separation approach (FSA) to quantitatively disentangle the pure and synergistic impacts of anthropogenic and/or biogenic sources on summertime $O_3$ formation. The impact of anthropogenic sources alone was found to be dominant for $O_3$ formation. Although anthropogenic particles reduced $NO_2$ photolysis by up to 60%, the anthropogenic sources contributed 19.1 ppb $O_3$ formation on average for urban Xi’ an. The abundant biogenic VOCs from the nearby forests promoted $O_3$ formation in urban areas by interacting with the anthropogenic $NO_x$. The calculated synergistic contribution (from both biogenic and anthropogenic sources) was up to 14.4 ppb in urban Xi’ an, peaking in the afternoon. Our study reveals that the synergistic impact of individual source contributions to $O_3$ formation should be considered in the formation of air pollution control strategies, especially for big cities in the vicinity of forests.

Meteorological, Climatological, and Geophysical Agency (BMKG), Indonesia, 5. Laboratory for Sciences of Climate and Environment (LSCE), France, 6. Universities Space Research Association/NASA Goddard Space Flight Center, USA

The emission increases of greenhouse gases (GHGs) and air pollutants in megacities have been recognized as one of the important issues as a concern for health and climate change. Jakarta, the capital city of Indonesia, including suburban cities (Bogor, Depok, Tangerang, and Bekasi; locally known as “Jabodetabek”), has a population of 32 million people and has been listed as the second largest megacity in the world and the largest megacity in Southeast Asia. Several air quality monitoring campaigns were conducted in Jakarta. However, previous studies lacked continuous high-accuracy monitoring stations due to the limitations of environmental monitoring budgets and experts. We present here a new interdisciplinary project to expand our current understanding of the interactions between emissions, air quality, and regional/global climates.

To estimate the amount of anthropogenic emissions from Jakarta megacity and compare with city activities, we developed a ground-based comprehensive monitoring system of GHGs and air pollutants controlled remotely in addition to automated start-and-stop operations during power failures. Monitoring systems were installed at Bogor (center of Bogor city), Serpong (Jakarta suburb), and Cibeureum (mountainous area) in 2016–2017. Each monitoring system consists of system control/data acquisition units controlling multiple instruments and collecting continuously and continuous monitoring instruments of $CO_2$, $CH_4$, CO, $NO_x$, $SO_2$, $O_3$, aerosol concentrations ($PM_{2.5}$, $PM_{10}$, BC) and the chemical components ($NO_3^-$, $SO_4^{2-}$) of $PM_{2.5}$ and $PM_{10}$, and meteorological parameters. Flask sampling of air is also performed automatically once a week to analyze $N_2O$, $SF_6$, and carbon isotopes ($^{13}C$, $^{14}C$) in $CO_2$ in NIES and to validate the continuous measurement data of $CO_2$, $CH_4$, and CO.

The results show that the daytime values of $CO_2$, three hours averages from 12 to 15 local time, at Bogor and Serpong are 6.8 and 7.1 ppm higher than Cibeureum, respectively. These features are also presented in the other species, i.e., CO, $NO_x$, $SO_2$, $PM_{2.5}$, $PM_{10-2.5}$, and BC. Moreover, we found 5–10 ppm lower values of $CO_2$ during daytime at Bogor and Serpong in December and January, mid-rainy season in Jakarta, compared with the other months and frequent and extremely high $CH_4$ enhancements during nighttime (i.e., 3 to 5 ppm) at Serpong.

We present here the temporal variability observed at three monitoring sites and some preliminary results based on high-resolution $CO_2$ simulations using Weather Research and Forecasting model coupled to Chemistry (WRF-Chem).

# Seasonality of short-term variations in atmospheric $CH_4$ observed at Hateruma and relationship with the reginal emissions from East Asia

*Yasunori Tohjima[1], Jiye Zeng[1], Tomoko Shirai[1], Akihiko Ito[1], Motoki Sasakawa[1], Toshinobu Machida[1]

1. National Institute for Environmental Studies

National Institute of Environmental Studies (NIES), Japan, has been carrying out in-situ observation of atmospheric $CH_4$ at Hateruma Island (HAT; lat. 24.1˚N, long. 123.8˚E) since 1996 by using a gas chromatographic system. Since HAT is in the marginal region of the East Asia, air masses from the continental region would cause elevated concentrations of a variety of species including $CH_4$. Such events were often observed especially during late autumn to early spring due to the Asian monsoon. In the previous studies, we revealed a secular increase in the short-term variations of $CH_4$ and its relationship with the emission increase from the continental China. Here, we examined the seasonality of the short-term variations of $CH_4$ in 1996 to 2017. First, we computed the increment of the hourly $CH_4$ ($\Delta CH_4$) over the baseline, which was the smoothed averages of $CH_4$ below the 20 percentile in a 101-hour moving time-window. Then the standard deviation of $\Delta CH_4$ for each month of each year was computed. The average monthly standard deviations of $\Delta CH_4$ show rather stable values in winter (November-February, 18~20 ppb), peaks in May (28 ppb) and September (26 ppb), and a dip in July (11 ppb). We simulated $\Delta CH_4$ by a Lagrangian particle dispersion model (LPDM) using the monthly $CH_4$ emission maps of Patra et al. (2009) and EDGAR v4.3.2, respectively. Although the monthly variability of the simulated $\Delta CH_4$ based on the Patra et al. (2009) emission maps well reconstructed the observed pattern of the monthly standard deviations, that based on the EDGAR v4.3.2 emission maps showed a maximum in March, which was not consistent with the observed pattern. The simulated maximum variability in March is related to the emission peak in March of the EDGAR v4.3.2 inventory, which is attributed to the maximum emissions from agricultural and livestock sectors. The lack of the spring peak in the observation suggests that the anthropogenic $CH_4$ emission in March of EDGAR v4.3.2 may be overestimated.

# A cryogen-free automated measurement system of stable carbon isotope ratio of atmospheric methane

*Taku Umezawa[1], Takuya Saito[1]

1. National Institute of Environmental Studies

Methane is an important greenhouse gas emitted from both natural and anthropogenic sources. Accurate understanding of various methane sources is needed for effective reduction of its emissions. Measurement of stable carbon isotope ratio of atmospheric methane is useful for top-down evaluation of relative contributions of various types of methane sources, because individual methane sources have characteristic isotope signatures. Isotope ratio data for atmospheric methane therefore receive increasing attention for constraining the global methane budget. To meet research community demand, it is imperative for measurement systems to achieve adequate precision and traceability as well as high measurement throughput to process number of air samples that are routinely shipped from monitoring sites to laboratory. Stable carbon isotope ratio has been measured by continuous-flow isotope ratio mass spectrometry where methane in sample air is preconcentrated in a trap filled with an adsorbent cooled by liquid nitrogen. By using a stirring cooler instead, we set up a cryogen-free measurement system, and our configuration attained reproducibility of ~0.1 per mil. This precision is comparable to those previously achieved by using liquid nitrogen; our system is however advantageous for unattended and automated measurement operation. We examined measurements for air sampled outside our laboratory, and the preliminary measurement data at ~1-hour intervals show a clear diurnal variation.

Keywords: Methane, Stable carbon isotope ratio

Massachusetts Institute of Technology, 9. Laboratoire des Sciences du Climat et de l'Environnement, LSCE-IPSL (CEA-CNRS-UVSQ), 10. DISTABIF, Università degli studi della Campania Luigi Vanvitelli, 11. Department Landscape Design & Sustainable Ecosystems RUDN University, 12. IAFES, Euro-Mediterranean Center on Climate Change, 13. Global Carbon Project, CSIRO Oceans and Atmosphere

Atmospheric methane ($CH_4$) is the most important greenhouse gas after carbon dioxide. Because $CH_4$ has a relatively short lifetime due to chemical losses in the atmosphere, it is expected that reducing $CH_4$ emissions would mitigate global warming in a relatively short timeframe. However, sources of atmospheric $CH_4$ are associated with a wide variety of processes such as fossil fuel production and consumption, agriculture, natural wetlands, and biomass burning, and our understanding of the full $CH_4$ budget is limited. To better understand $CH_4$ sources, an inverse analysis is one prominent methodology that estimates spatiotemporal variations of $CH_4$ sources consistent with their prior estimates and atmospheric observations within specified uncertainties. In this study, we performed a long-term inverse analysis of $CH_4$ fluxes with an inversion system named NICAM-TM 4D-Var (Niwa et al., 2017a,b). The inversion system is based on the atmospheric transport model NICAM-TM (Niwa et al., 2011), which has a homogeneous icosahedral grid system and mass conserving property. The horizontal model grid resolution was set to 223 km and the $CH_4$ flux estimation was performed at the same resolution, though some spatial error correlations were introduced. The prior flux dataset includes wetland/rice cultivation emission and soil uptake estimated by the terrestrial ecosystem model VISIT (Ito and Inatomi, 2012). The other emission categories are provided from the ongoing Global Carbon Project (GCP)–$CH_4$. In the inversion, several emission categories are separately estimated according to their seasonal and interannual variabilities. Compared with the prior estimates, the inverse analysis with ground-based station data estimated smaller emissions from East Asia and Europe, larger and smaller northern summer emissions from West Siberia and Hudson Bay Lowlands, respectively, and larger emissions from Bengal and Indochina areas. These changes estimated by the inversion are attributed to emissions from anthropogenic categories (mainly fossil fuel related), natural wetlands, and rice cultivation, respectively. The presentation will also address the reliability of the inversion estimates using independent aircraft data and examine the independence of each category emission estimate.

# Scientific findings from observations of GOSAT/TANSO–FTS TIR band

*Naoko Saitoh[1], Shingo Kosaka[1], Masato Shiraki[1], Hinako Kobayashi[1]

1. Center for Environmental Remote Sensing

Greenhouse Gases Observing Satellite (GOSAT) has continued its observations of greenhouse gases for more than 10 years since its launch on 23 January 2009. The thermal infrared (TIR) band of the Thermal and Near Infrared Sensor for Carbon Observation (TANSO)–Fourier Transform Spectrometer (FTS) on board GOSAT has observed concentrations of $CO_2$, $CH_4$ and other greenhouse gases in several atmospheric layers. In the latest TANSO–FTS TIR Level 2 retrieval algorithm, Version 1 (V1), ozone, water vapor, and temperature have been retrieved as by-products of the $CO_2$ and $CH_4$ products (Saitoh et al., 2016). We have already evaluated the data quality of the TANSO–FTS TIR V1 $CO_2$ and $CH_4$ products (Saitoh et al., 2016, 2017; Holl et al., 2016; Zou et al., 2016; Olsen et al., 2017). We applied the evaluated bias-correction values to the TANSO–FTS TIR V1 $CO_2$ data and compared variations in concentrations of the TIR $CO_2$ data with those of Measurement Of Pollution In The Troposphere (MOPITT) CO data [Deeter et al., 2014] in upper troposphere over the northern Africa. The comparison result showed that both TANSO–FTS TIR $CO_2$ and MOPITT CO concentrations became larger there almost at the same time in March through May, which suggests air mass with high CO and $CO_2$ emitted due to biomass burning was transported to upper atmosphere. As TANSO–FTS TIR V1 $CH_4$ profiles generally agreed with aircraft $CH_4$ profiles to within ~1% in the troposphere in low and middle latitudes, we analyzed seasonal variations in $CH_4$ concentrations in each altitude layer over India by using the TIR V1 $CH_4$ data. Our results were similar to the results reported in Chandra et al. (2017), but showed larger impact of $CH_4$ variations in lower troposphere on seasonal variations in $XCH_4$ concentrations. We have conducted validation analysis of TANSO–FTS TIR $O_3$ profiles simultaneously retrieved with the TIR V1 $CO_2$ product using Atmospheric Chemistry Experiment (ACE)–FTS and ozonesonde data. Although there was slightly high bias in the TANSO–FTS TIR $O_3$ data in the lower troposphere in summer, they showed better agreements with ACE–FTS and ozonesonde data than their a priori data taken from MacPeters et al. (2007). The TANSO–FTS TIR $O_3$ data in the lowest retrieval layer (surface–857 hPa) showed clear enhancements in $O_3$ concentrations over Mainland China compared to eastern Japan, which could demonstrate the detectability of tropospheric pollutants by the TANSO–FTS TIR band.

# Continuous measurements of atmospheric $CO_2$ and its $\delta^{13}C$ and $\delta^{18}O$ at Minamitorishima Island

*Shohei Murayama[1], Kazuhiro Tsuboi[2], Shigeyuki Ishidoya[1], Hidekazu Matsueda[2], Yosuke Niwa[3], Yousuke Sawa[2], Kentaro Ishijima[2], Kentaro Kozumi[4], Genta Umezawa[4], Kazuya Yukita[4], Shigeharu Nishida[4], Megumi Yamamoto[4], Tetsuyuki Usami[1], Shinji Morimoto[5]

1. National Institute of Advanced Industrial Science and Technology (AIST), 2. Meteorological Research Institute, 3. National Institute for Environmental Studies, 4. Japan Meteorological Agency, 5. Tohoku University

The Minamitorishima (MNM; 24°17’ N, 153°59’ E) station is uniquely located to monitor background air at northern mid latitudes; the site is located on a remote coral island in the western North Pacific, about 1,950 km southeast of Tokyo. The Japan Meteorological Agency has been making long-term continuous observations of atmospheric concentrations of major greenhouse gases at MNM. For a better understanding of mechanisms governing the observed $CO_2$ variation, systematic measurements of atmospheric $CO_2$ and its $\delta^{13}C$ and $\delta^{18}O$ have been carried out at MNM by analyzing discrete flask air samples taken at the site since 2011. The existing measurement program was enhanced by initiating continuous measurements of $CO_2$ and its $\delta^{13}C$ and $\delta^{18}O$ using a laser spectroscopy (Off-Axis Integrated-Cavity Output Spectroscopy) in March 2018.

Sample air is drawn from an air intake mounted on a tower at 20-m height above the ground surface, and introduced into a continuous isotope analyzer (Model CCIA-48, Los Gatos Research) after removing water vapor and aerosol particles. The analyzer is calibrated hourly for the concentrations of each $CO_2$ isotopologue, using 3 air-based $CO_2$ standard gases with isotopic ratios of industrial $CO_2$ and different total $CO_2$ concentrations. The isotopic ratios of these standards were determined by a mass spectrometer, and the concentrations of each $CO_2$ isotopologue of the standards were obtained from the isotopic ratios. The total $CO_2$ concentration and its $\delta^{13}C$ and $\delta^{18}O$ of sample air are calculated from the measured concentrations of each isotopologue.

The obtained $CO_2$ isotopic data are scattered, and the precisions of the $\delta^{13}C$ and $\delta^{18}O$ values measured by this analyzer estimated from hourly measurements of a target gas, which is dried natural air compressed into a 48-L gas cylinder, are about 10 times and 5 times worse than those achieved by our mass spectrometer, respectively. However, the daily mean values of atmospheric $\delta^{13}C$ and $\delta^{18}O$ show day-to-day variations in concert with those of the total $CO_2$ concentration and prominent seasonal variations. The daily mean $\delta^{13}C$ and $\delta^{18}O$ show systematic difference from the isotopic values obtained from flask sampling on the same day. However, since the differences are almost constant, the nature of the variations are very similar in both cases.

In this presentation, results of the preliminary analyses of the daily mean $CO_2$, $\delta^{13}C$ and $\delta^{18}O$ data obtained from the continuous measurement will be presented. From comparison with the flask sampling results, the effectiveness of the continuous measurement will also be discussed.

# Variations of atmospheric Radon-222 concentration observed at JMA stations

*Kentaro Ishijima[1], Kazuhiro Tsuboi[1], Hidekazu Matsueda[1], Yousuke Sawa[1], Yosuke Niwa[2,1], Takashi Maki[1], Takashi Nakamura[3]

1. Meteorological Research Institute, 2. National Institute for Environmental Studies, 3. Japan Meteorological Agency

Japan Meteorological Agency (JMA) has been operating several stations to monitor atmospheric greenhouse gases since the late 1980s under the Global Atmosphere Watch programme of the World Meteorological Organization (WMO/GAW). They show synoptic, seasonal, interannual variations, and trends due to changes in atmospheric transport and source/sink strength. To know their transport from land regions, we started the monitoring of atmospheric Radon-222 ($^{222}$Rn) in the 2000s at the JMA stations. Because $^{222}$Rn is emitted from almost only lands and chemically inert, it is useful to identify temporal variability of atmospheric greenhouse gases due to sources/sinks on land. $^{222}$Rn also radioactively decays with the half-life of 3.8 days, so is widely utilized to validate regional transport of atmospheric transport model through the model-observation comparisons. Understanding such transport process is also supported by using an atmospheric transport model. We have just started to use a newly developed on-line atmospheric tracer transport model (GSAM-TM). The tracer transport process is driven by a low-resolution version (TL95) of JMA's operational global numerical weather prediction model (GSAM).
In this study, we analyze the observed and model simulated atmospheric $^{222}$Rn concentration, to understand the transport process of land-origin atmospheric tracer as well as to validate the GSAM-TM. For example, the model well reproduces high $^{222}$Rn peaks, which are frequently observed at Minamitorishima (MNM; 24.28˚N, 153.98˚E) and Chichijima (CCJ; 27.09˚N, 142.19˚E) in winter to spring. Especially in winter, there are many cases that a high peak is first observed at CCJ and one day after at MNM. They are mainly produced by a cold front moving eastward with dense $^{222}$Rn behind the frontal line. The peak height at MNM is about two-thirds of that at CCJ. It is slightly smaller than that expected from decay by the 3.8 days half-life (about four-fifths), because dense $^{222}$Rn trapped by the front is diluted mainly by diffusion while transported. The model also well reproduces such peak attenuation degree. More details and results of $^{222}$Rn-age tracer simulations as well as of other JMA station will also be discussed in our presentation.

*Acknowledgements.* We sincerely thank all members of the JMA for operating $^{222}$Rn measurement systems at JMA monitoring stations

# Long-term variations of CFCs and HCFCs observed with ground-based FTIR spectrometers at Rikubetsu, Syowa Station, and Tsukuba since 1995

*Hideaki Nakajima[1,2], Masanori Takeda[2,1], Isao Murata[2], Takafumi Sugita[1], Tomoo Nagahama[3], Isamu Morino[1], Takeshi Kinase[4]

1. National Institute for Environmental Studies, 2. Graduate School of Environmental Studies, Tohoku University, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Meteorological Research Institute

We have been observing atmospheric minor constituents with ground-based Fourier-Transform InfraRed spectrometer (FTIR) at Rikubetsu (43.5N, 143.8E) since 1995, at Syowa Station, Antarctica (69.0S, 39.6E) in 2007, 2011, and 2016 with Bruker IFS-120M, and at Tsukuba (36.1N, 140.1E) since 2018 with Bruker IFS-125HR. We have analyzed vertical profiles and total columns of CFC-11, CFC-12, and HCFC-22 with SFIT4 retrieval algorithm. Production and consumption of CFCs and HCFCs have been regulated under the Montreal Protocol since 1987. Substitution to HCFCs and HFCs which do not destroy ozone layer is underway. However, illegal production of CFC-11 somewhere in Asia was recently reported (Montzka et al., Nature, 2018). Monitoring of these gases are possible not only by ground-based gas-chromatogram/mass-spectroscopy technique, but also by infrared spectroscopic measurements. Ground-based FTIR measurement has a capability to monitor multiple gas species simultaneously with vertical profile information for some gases. We retrieved vertical profiles and column amounts of CFC-11, CFC-12, and HCFC-22 since 1995 from FTIR spectra. Figure 1 shows total column amounts of HCFC-22 since 1995, while Figure 2 shows partial column amounts of HCFC-22 between 0 and 8 km. Seasonal variation which are seen in Figure 1 might be due to the change of tropopause height. However, it is removed in partial column amount in Figure 2. Trajectory calculation results of CFC-11 and other gases will be presented at the meeting.

# Millimeter-wave observation of stratospheric ozone in 2015-2017 in Rio Gallegos at the southern tip of South America

*Akira Mizuno[1], Hironori Seki[1], Tomoo Nagahama[1], Hirofumi Ohyama[2], Jacobo Salvador[3], Facundo Orte[3], Elian Walfram[3]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. National Institute for Environmental Studies, 3. Laser and Applications Research Center, UNIDEF (CITEDEF-CONICET)

We had been carried out a trilateral international collaboration among Japan, Chile, and Argentina called SAVER-Net (South American Environmental Risk Management Network) project for five years under the JST-JIICA SATREPS program. The major aim of the project was establishing an observation network of UV/ozone and aerosols over Chile and Argentina where was a blank area of the measurement stations on a global scale. The southern tip region of South America is the southernmost habitable area in the world, and the local residents in this region directly suffers from the influence of ozone hole that sometimes overpasses the region. Although the project was terminated in March 2018, we continue collaboration to develop forecast system of ozone hole and UV indices.

In this presentation, we will report the results of ozone observation by using a millimeter-wave spectrometer installed at the atmospheric observatory in southern Patagonia (OAPA) in Rio Gallegos, Argentina. The observation period was from April 2015 to March 2016 and September 2016 to August 2017, and we obtained ~ 9,400 1-hour averaged vertical profiles. We compared the time series of ozone volume mixing ratio (VMR) profile obtained in September and October when the ozone hole passes over the southern tip with the meteorological parameters, such as atmospheric temperature, potential temperature, and potential vorticities that are derived from MERRA-2 reanalysis data. As a result of the comparisons, we revealed that

・Ozone VMRs and the absolute value of potential vorticities show a good correlation below ~ 1000 K in potential temperature corresponding to ~ 35 km in altitude.

・As the ozone hole reaches above Rio Gallegos, atmospheric temperature decreases around ~ 25 km due to the horizontal advection of cool air in the polar vortex, and the temperature above ~35 km increases due to atmospheric descent inside of the polar vortex,

and we can use these quantities to easily distinguish whether Rio Gallegos is located at inside or outside of the ozone hole.

We will also present more detailed results about the ozone hole activities in 2015 and 2016.

Keywords: ozone hole, millimeter-wave spectroscopy, South America, polar vortex

## [A-AS04] Atmospheric Chemistry

convener:Tomoki Nakayama(Graduate School of Fisheries and Environmental Sciences, Nagasaki University), Yoko Iwamoto(Graduate School of Biosphere Science, Hiroshima University), Sakae Toyoda(Department of Chemical Science and Engineering, Tokyo Institute of Technology), Nawo Eguchi(Kyushu University), Chairperson:Hideaki Nakajima(国立環境研究所)

This session provides a forum for the presentation of the broad spectrum of tropospheric and stratospheric chemistry, including various research topics (e.g., dynamical processes, air quality and climate), approaches (modeling, field measurements, remote sensing, and laboratory studies), and species (gas and aerosol). This session also provides an opportunity for discussing possible future collaboration with other research fields relevant to atmospheric chemistry. We strongly encourage authors to prepare presentation slides and a poster in English.

# Planetary atmosphere - Mars and Venus -

*Hiroyuki Maezawa[1]

1. Department of Physical Science Osaka Prefecture University

Recently, research on extraterrestrial planets and protoplanetary disks has been rapidly increasing. Mars and Venus, lacking intrinsic magnetic fields, are valuable research targets for further understanding atmospheric environments, habitability of earth-type planets, and the influence of activity of the central star on planetary atmospheres.

On Mars, methane has been detected and research continues to investigate its originand destruction processes by oxidation reaction networks in the atmosphere and on the surface. For an Earth-type planet with an atmosphere mainly of $CO_2$, the $CO_2$ is photo-dissociated into CO and oxygen by UV radiation from the sun. Mars and Venus have small percentages of CO and oxygen, and how they are oxidized back into $CO_2$ has not yet been fully elucidated. This is known as the “$CO_2$ stability problem”. Also, in order to understand the evolutionary processes of the Martian atmosphere, detailed and systematic observations of the spatial and temporal fluctuations of $H_2O$ and oxidants, including $H_2O_2$, $O_3$, $O_2$, etc., and their altitudinal distributions are important.

Venus experiences high-speed super-rotation winds at approximately the cloud altitude and day to night circulation at higher altitudes. Recently, for example, it has gradually become clear that the latter convection does not show a similar pattern in the morning and afternoon. In addition, the Akatsuki satellite (JAXA) has captured large-scale, bow-shaped patterns induced by atmospheric gravity waves. It is also important to investigate how the complex dynamics seen in the Venusian atmosphere drive material circulations and oxidation reaction networks including those with respect to minor species such as $SO_x$, $HO_x$, $CO_x$, chloride, aerosol, sulfuric acid, etc. Venus and Mars also provide important insights into how abiotically the biomarkers, $O_2$ and $O_3$, are formed in typical terrestrial planets with mainly $CO_2$ atmospheres.

In this talk, the observations of planetary atmospheres, explored via heterodyne spectroscopy with radio telescopes such as the Atacama Large Millimeter/submillimeter-wave Array (ALMA) interferometer, as well as measurements of various wavelengths with ground-based telescopes and satellites will be also discussed. Since the wavelengths of milli/submillimeter waves are comparatively long, they are less attenuated by absorption and scattering by aerosols/dust. In addition, the Doppler shift of the spectrum obtained with heterodyne spectroscopy provides important information about the velocity fields of the mesosphere and lower thermosphere. Also, regardless of the presence or absence of background light sources such as the sun heterodyne spectroscopy allows us to observe day and night-side atmospheres of planets.

# Validation of methane profile observed with FTIR at Tsukuba

Yuki Dai[2], *Isao Murata[1], Hideaki Nakajima[3], Isamu Morino[3]

1. Graduate School of Environmental Studies, Tohoku University, 2. Graduate School of Science, Tohoku University, 3. National Institute for Environmental Studies

$CH_4$ is the second greenhouse gas and the concentration near the surface is increasing. But there are many emission sources and the increasing rate is varying year by year. The profile of $CH_4$ can be observed with a ground-based high-resolution Fourier transform spectrometer using spectral inversion analysis. However, the validation of the retrieved profile doesn't have been performed enough. Then, we compared some retrieval parameters and validated the retrieved tropospheric partial columns using aircraft sampling measurements.
We analyzed the spectra taken at Tsukuba between 2012 and 2017. SFIT4 spectral fitting program was used to derive the profiles from spectra in 3 micrometer region. $H_2O$ as interference species affects the accuracy of the retrieved $CH_4$ profiles. Two initial profiles of $H_2O$ are provided: monthly mean (v1) and daily analyzed (v5). Two kinds of microwindows for the retrieval are also provided according to Sussmann et al. (2011): 5 microwindows (5MW) and 3 microwindows (3MW). Fitting results were compared based on the root mean square residual (RMS) and degree of freedoms (DOFs). As a result, 5MWv1 is worse for both RNS and DOFs than other 3. Then, we compared the results of 5MWv5, 3MWv1, and 3MWv5 with aircraft sampling.
The monthly mean tropospheric partial columns integrated from 0 to 8 km were compared with those calculated from aircraft sampling observed by the center for atmospheric and oceanic studies, Tohoku University near Sendai from 2012 to 2017. When all derived partial columns were compared with aircraft results, all 3 cases (5MWv5, 3MWv1, and 3MWv5) showed 5 -10 % differences in summer when $H_2O$ concentration is high. But when the derived partial columns for which RMS is less than 0.15 were compared, all 3 cases agreed with aircraft results within the uncertainty besides for the -2.9 % bias.

# Retrieval of HFC-23 from FTIR observations at Syowa Station, Rikubetsu and Tsukuba

*Masanori Takeda[1,2], Hideaki Nakajima[2,1], Isao Murata[1], Tomoo Nagahama[3], Isamu Morino[2]

The Montreal Protocol on Substances that Deplete the Ozone Layer has successfully been regulated production and consumption of chlorofluorocarbons (CFCs) and global atmospheric CFCs concentration have kept decreasing. On the other hand, production and consumption of hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs) as alternatives for CFCs are expanding up to the present. Especially, HFC-23 ($CHF_3$) which has very high global warming potential (100yr-GWP: 12,400) is generated as unavoidable by-product of HCFC-22 ($CHClF_2$) production and their emissions into atmosphere have been increasing relevant to production of HCFC-22. Observations of these gases are possible not only by in-situ gas-chromatogram/mass-spectroscopy systems, but also by infrared spectroscopic measurements. Ground-based Fourier Transform Infrared spectrometer (FTIR) has a capability to monitor multiple gas species simultaneously. In this study, we retrieved total column abundances and vertical profiles of HFC-23 from ground-based FTIR observations with the SFIT4 version 0.9.4.4 based on the optimal estimate method (Rodgers, 2000).
We operated atmospheric solar absorption measurements using ground-based FTIR instrument at Antarctic Syowa Station (69.0ºS, 39.6ºE) in 2007, 2011 and 2016. We used two micro-windows (MWs) of 1138.5-1148.0 $cm^{-1}$(MW1) and 1154.0-1160.0 $cm^{-1}$(MW2) in this study. As the spectroscopic parameters of HFC-23, the pseudo line lists produced by G. C. Toon (NASA/JPL) were used. For other interfering species, the line parameters from HITRAN2008 were used. Temperature and pressure vertical information from surface to 40 km a.s.l. were taken by the daily temperature and pressure profiles from NCEP (National Centers for Environmental Prediction) Reanalysis-1 dataset. Meteorological information above 40 km a.s.l. were adopted from the monthly climatological profiles from the COSPAR International Reference Atmosphere (CIRA-86) dataset. The HFC-23 a priori profile was taken fromthe simulated profile by Naik et al. (2000), but that was scaled to make the concentration of the lowest level equal to 20 pptv which is the approximate value of surface concentration in southern hemisphere in 2007. For $H_2O$ and its isotopologues, the a priori profiles were taken from independent preliminarily profile retrievals for each observed spectra. For other interfering species, 40 years (1980-2020) mean profiles of the monthly profiles provided from WACCM (Whole Atmosphere Community Climate Model) version 6 were used as a priori profiles. Figure 1 shows the timeseries of the FTIR-retrieved total columns of HFC-23. According to the error analysis, mean systematic and random errors on the HFC-23 retrievals were ~40% and ~10% to retrieved HFC-23 total column, respectively. The FTIR observation is practicable to estimate the trend of atmospheric HFC-23, because the random uncertainty is relatively small.
In addition, we performed retrievals of HFC-23 from FTIR spectra at Rikubetsu (43.46ºN, 143.77ºE) and Tsukuba (36.05ºN, 140.12ºE) in Japan in the same way as the retrieval strategy at Syowa Station. In the presentation, we will discuss on the differences of HFC-23 trends among these three FTIR sites, along with the trends of HCFC-22 from FTIR observations.

# Roles of cloud distribution in global atmospheric photochemistry

*Ryoki Matsuda[1], Kengo Sudo[1,2]

1. Graduate School of Environmental Studies, Nagoya University , 2. Japan Marine-Earth Science and Technology

Chemical reactions in the atmosphere directly affect formation and loss of ozone, methane, nitrogen oxides, sulfur oxides and aerosols, and have a great influence on the atmospheric environment and climate change. Since these reactions are driven by photodissociation of ozone and related species caused by ultraviolet radiation, they can be largely modulated by distribution of clouds. This study quantitatively investigates the photolytic impacts of clouds on atmospheric chemistry by using a global chemical transport model (chemical climate model) and observational (satellite and aircraft) data.
First, verification with satellite data (ISCCP D2) shows that the model (CHASER) reproduced well the global distribution of cloud amount as in the satellite data.
Sensitivity experiments were also performed to estimate clouds impacts on the photolytic processes and global photochemical field in the atmosphere. As a result, it was shown that OH radical (OH) concentrations decrease by 10 to 20% near the surface and increase by 10 to 20% in the upper troposphere. The changes basically reflect scattering and reflection of solar UV radiation by low-middle clouds, which is consistent with the previous studies. The global mean OH concentration, proxy of the oxidizing capacity of the atmosphere, increased by about 12% due to clouds while the global mean tropospheric ozone ($O_3$) concentration increased by about 0.7%.
The above results for clouds impacts on the atmospheric chemical field calculated in the model were verified by using aircraft observation (NASA ATOM-1). The result shows that the observed OH and $O_3$ concentrations are reproduced more accurately when clouds are properly considered in the model.
These results indicate that clouds have significant influences on the global atmospheric chemistry (especially on the OH concentration field). Since OH determines the concentrations of chemical species such as methane, carbon monoxide (CO), fluorocarbons (CFCs), etc. which are important for climate and stratospheric ozone, this study suggests that the variation and trends in clouds can largely affect the chemical species, which may give an additional influence on climate and atmospheric environment.

# Evaluating global distribution and interannual variation of stratosphere-troposphere exchange of ozone: impacts of climate variabilities

*Kengo Sudo[1,2], Xin Li[1]

1. Graduate School of Environmental Studies, Nagoya University, 2. Research and Development Center for Global Change, JAMSTEC

The stratosphere-troposphere exchange (STE) of ozone ($O_3$) can have significant impacts on the interannual variability and long-term trend of global tropospheric ozone and radiation budget. This study investigates global STE of $O_3$ particularly focusing on the roles of major climate variabilities such as ENSO, PDO, and QBO and climate trend (surface temperature). Using a chemistry coupled climate model, this study estimates temporal variation in the vertical and meridional STE $O_3$ fluxes during the years of 2000-2016. For the major climate variabilities of ENSO and PDO, associated STE changes are assessed in detail using a composite analysis. The model validation shows that the model well captures the OMI-observed tropospheric column ozone (TCO) abundances (r~0.55), especially around the tropical Pacific (r~0.8). It is shown that in the tropics there is upward $O_3$ transport to the stratosphere (troposphere to stratosphere transport, TST) while in the extratropics, $O_3$ transport is downward (stratosphere to troposphere transport, STT), consistent with the Brewer-Dobson circulation in the stratosphere. Although geographical distributions of vertical and meridional STE fluxes are not changed largely by ENSO or PDO, the STE fluxes are significantly amplified by the ENSO events. Horizontal patterns of STE flux anomaly are found to be similar with respect to the El Niño episodes and the PDO warm phases (STT increased by 21% and 10%, respectively, in the northwest Pacific). These anomalies are reversed during the La Niña and PDO cold phases (STT decreased by 16% and 3%, respectively, in northeast Pacific). The anomaly of global net STE $O_3$ flux is interpreted as several key factors using a multiple-regression analysis. The result shows that the STE anomaly is explained largely by the combination of ONI, PDO, QBO, and global mean surface temperature ($R^2$~43%). Contributions of ONI and PDO to STE anomaly are estimated to be 22.3% and 23.1%, respectively. This study quantitatively reveals the possible connection between climate condition and STE.

## [A-OS07] Climate variability and predictability on subseasonal to decadal timescales

convener:Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL), Doug Smith(Met Office), Yushi Morioka(Japan Agency for Marine-Earth Science and Technology)

Climate variability poses growing threats to human lives and socio-economic activities through changes in frequency and intensity of abnormal weather such as cold/heat waves and floods/droughts. This involves several climate phenomena with a wide range of timescales from subseasonal to decadal variations (e.g. MJO, IOD, ENSO, PDV, AMV). Many efforts have been made for understanding and predicting climate variations on each timescale, but there remain large uncertainties in simulation and prediction of subseasonal to decadal climate variations. This highlights lack of understanding of weather and climate interaction across different spatial and temporal timescales (e.g. tropical cyclones and ENSO) as well as multiple physical processes underlying climate variations (e.g. troposphere-stratosphere coupling, air-sea-ice interaction). This session aims to share current knowledge of subseasonal to decadal climate variability and predictability in order to identify the unresolved issues for better understanding and accurate prediction. This session invites all the abstracts related to the observational, theoretical, process-level and modelling research on subseasonal to decadal climate variability and predictability.

# Changes in North American and European Heatwave Characteristics

*Szandra A. Peter[1], Ben Kirtman[1]

1. Rosenstiel School of Marine and Atmospheric Science

Heat waves are a serious threat to ecosystems, society and the economies of the world. By calculating specific threshold values from daily maximum 2 m temperatures of the NCEP/NCAR reanalysis data (Kalnay et al. 1996), the frequency of heat waves during summer months (JJA) in Europe and the US is determined for the period of 1982 to 2017. The differences between the first and the second half of the 36-year period are discussed, and the results are compared to the North American Multi-Model Ensemble (NMME) forecast with specific focus on recent heat waves in the Pacific Northwest of North America and Central Europe. The connection between heat waves and known climate variability (i.e., the NAO, PNA) is analyzed. We strive to assess the importance of natural variability, such as the NAO, in the frequency of heat waves by comparing the first and last half of the studied 36-year period. We also examine how well the NMME retrospective and real-time forecasts capture heat waves (and cold spells), and the sources of predictability (i.e., sea surface temperature anomalies, land surface conditions), and how the predictability connects to the various modes of climate variability.

# The effects of the "New Climate" Warming on Western Mediterranean: Situation of the Recent Extreme Events

*Mohammed-Said KARROUK[1]

1. Hassan II University of Casablanca

Since the nineties of the last century, climatological research following a great scientific advance in the field of prediction, not the variability and evolution of the different climatic parameters was beginning to be clearer!

But today, since the beginning of 2005, certainly due to oceanic thermal cumulations, and the shift of climatic zones towards poles in selective forms (more intense on the oceans present on the continents); Climatic events do not evolve according to the usual and expected rhythms: atmospheric circulation, precipitation, temperatures, seasonal phenomena, etc. These conditions are a spatiotemporal evolution and distribution, which characterize the new "global climate", by the new atmospheric regime imposing the Meridian Atmospheric Circulation (MAC), alternating the conditions of Freshness (humidity) and Heat (drought) along the year.

In this new situation, Western Mediterranean, located in the climate transition zone, is fully affected by the "New Climate". Usually, the atmospheric response to major climatic events (ENSO) in this region such as "El Niño" was characterized by the establishment of the NAO positive index, stability and drought, due to dominance Zonal Atmospheric Circulation in winter. On the other hand, in the "La Niña" episode, the negative index of the NAO and the predominant Meridian Atmospheric Circulation and precipitation became abundant.

Since the beginning of this century, qualified meteorological events of "exceptional !" causing floods have continued to occur in Western Mediterranean, with increasing recurrence, prompting us to wonder about the "new" mode of hydro-thermal function of the climate system that induces torrential rains, as well as its effect on environments and societies.

Thanks to spatial observation and monitoring of meteorological conditions over the last 15 years, these types of alternating Heat / Cold conditions have become predictable, enabling decision-makers today to prepare adequately for the management of related risks to the "New Climate" warmed.

# Month-to-month Difference of the Western Pacific Subtropical High Simulated by CMIP5 Models

*Xiao Dong[1], Renping Lin[1]

1. Institute of Atmospheric Physics

The western Pacific subtropical high (WPSH) is an important circulation system of the East Asian summer monsoon (EASM). Most previous studies have focused on the variability of summer mean WPSH. Note that the WPSH also experiences subseasonal variation from early to late summer. In this study we examined the month-to-month shift of the WPSH in boreal summer, that is, from June to July and from July to August, simulated by CMIP5 Atmospheric General Circulation Models (AGCMs) and coupled models. Results show that climatologically AGCMs can reproduce the northward shift of the WPSH better than eastward retreat from July to August. Compared with AGCMs, coupled models can improve the month-to-month shift simulation to some extent, indicating that the air-sea coupling processes are also important in subseasonal timescale.

# Potential regulation on the climatic effect of Tibetan Plateau heating by tropical air–sea coupling

*Ziqian Wang[1], Anmin Duan[2], Song Yang[1]

1. School of Atmospheric Sciences, Sun Yat-sen University, 2. Institute of Atmospheric Physics, Chinese Academy of Sciences

Based on the conventional weather research and forecasting (WRF) model and the air–sea coupled mode WRF-OMLM, we investigate the potential regulation on the climatic effect of Tibetan Plateau (TP) heating by the air–sea coupling over the tropical Indian Ocean and western Pacific. Results indicate that the TP heating significantly enhances the southwesterly monsoon circulation over the northern Indian Ocean and the South Asia subcontinent. The intensified southwesterly wind cools the sea surface mainly through the wind-evaporation-SST (sea surface temperature) feedback. Cold SST anomaly then weakens monsoon convective activity, especially that over the Bay of Bengal, and less water vapor is thus transported into the TP along its southern slope from the tropical oceans. As a result, summer precipitation decreases over the TP, which further weakens the TP local heat source. Finally, the changed TP heating continues to influence the summer monsoon precipitation and atmospheric circulation. To a certain extent, the air–sea coupling over the adjacent oceans may weaken the effect of TP heating on the mean climate in summer. It is also implied that considerations of air–sea interaction are necessary in future simulation studies of the TP heating effect.

# Intraseasonal variation of the South Asian high and its role in connecting the Indian and East Asian summer monsoons

*Wei Wei[1]

1. Sun Yat-sen University

The South Asian high (SAH) is the most intense and persistent upper-level circulation system in the Asian monsoon region during boreal summer. It plays a crucial role in the onset and variation of the Asian summer monsoon. Ample evidence shows that the monsoon onset and activities are closely related to the intraseasonal oscillation (ISO). Previous studies have found that the ISO in the East Asian summer monsoon (EASM) is impacted by the northward or northwestward propagation of the ISO in the South China Sea and the western North Pacific, and the northeastward propagation of the ISO in the tropical Indian Ocean. However, seldom research mentioned the effect of the ISO in the SAH. Our previous studies have shown that the SAH plays an important role in connecting the Indian summer monsoon (ISM) and the EASM on the interannual time scale. However, the effect of the SAH on the connection of the ISM and the EASM on the intraseasonal time scale is still not clear. Actually, the ISO in the SAH is significant in its zonal variation. In this study, we firstly figured out the intraseasonal variation feature of the SAH. And then, we explored the upper-level signal which will lead to the onset, advance and retreat of the EASM. Considering significant ISO in the ISM, we investigated the ISO feature in the ISM and its effect on the ISO in the SAH. Finally, we addressed a new physical process that the ISO in the ISM will impact the ISO in the SAH, and further influence the advance and retreat of the EASM on the intraseasonal time scale. We try to learn about the intraseasonal variation of the EASM in a new view, and propose a new way to improve the short-term climate prediction and the extended-range weather forecast.

# Mean Surface Air Temperatures in Japan - Regional Classification and Interranual Variability

*Pascal Oettli[1], Masami Nonaka[1], Swadhin Behera[1]

1. Japan Agency for Marine-Earth Science and Technology

Back to the year 1886, several divisions of the climate of Japan into homogeneous climatic regions have been proposed, following different approaches of the question. This includes the Köppen climate classification (Fukui in 1933; Sekiguchi in 1949), the new Thornthwaite climate classification (Isozaki in 1933; Fukui in 1957) or the similarities of weather conditions. The latter is performed either throughout the year (Nakagawa in 1899; Sekiguchi in 1959; Yoshino in 1980) or during specific seasons (Iwakiri in 1967; Murata and Yoshino in 1988), sometimes with the help of statistical techniques, such as principal component analysis and the cluster analysis (Mikami in 1975; Koizumi and Kato in 2012.)

Using a type of artificial neural network called Self-Organizing Map, or SOM, we propose another division of the climate of Japan, solely based on the mean areal surface air temperature anomalies. SOM has been successfully employed in climate studies for more than a decade and has showed its ability to extract simple features from high-dimensional data. Here, SOM is applied to group 762 AMeDAS stations, taken throughout Japan for the last 30 years, into homogeneous clusters (=regions). Clustering is performed seasonally, with a focus on boreal winter (December to February) and boreal summer (June to August). As a result, eight regions are defined and associated time series of temperature anomalies (=indices) are computed.

Subsequently, possible source(s) of the interannual variability of mean surface air temperature anomalies are explored, for a better understanding of the regional differences. For this, correlation coefficients between indices previously defined and different climatic variable anomaly fields (sea-surface temperatures, outgoing longwave radiation, geopotential height...) are calculated. Hopefully, this work would also lead to a better seasonal forecast, taking into account the specificity of each region in regard to their link to the large-scale variability.

# Inter-Annual Variability of the Indonesian Rainfall and Air-Sea Interaction over the Indian-Pacific Ocean Associated with Regime Shift

*Murni Ngestu Nurutami[1], Tadahiro Hayasaka[1]

1. Center for Atmospheric and Oceanic Studies, Graduate School of Science, Tohoku University

The inter-annual and inter-decadal variability of the Indonesian rainfall are investigated in association with the interannual climate modes over Indian-Pacific Oceans and the inter-decadal modulation on inter-annual climate variability impact. Rainfall data of the Climate Research Unit (CRU) from 1901 to 2016 and the Global Precipitation Climatology Project (GPCP) from 1979 to 2016 for June –November (JJASON) are used. The empirical orthogonal function (EOF) is used to identify the dominant spatial and temporal variability patterns of rainfall and the standard and partial correlation techniques are used to compare and to quantify the linear relationship between two or more time-series datasets. Based on the first principle component (PC1) of both CRU and GPCP data, the results show that canonical El Niño Southern-Oscillation (canonical ENSO), ENSO Modoki, and Indian Ocean Dipole (IOD) are the major climate modes influencing the inter-annual variability of the Indonesian rainfall, and the Inter-decadal Pacific Oscillation (IPO) is the major decadal phenomenon which affects the decadal variability of Indonesian rainfall. All of the inter-annual climate modes and IPO have negative correlation with the Indonesian rainfall, but the spatial distributions of Indonesian rainfall change associated with each phenomenon are different. During 1970 to 2016, three phases of IPO have been identified which are strongly related to Indonesian rainfall with the correlation coefficient of -0.75. The three phases are a negative phase in 1970-1978, a positive phase in 1979-1997, and another negative phase in 1998-2015. Mostly, these climate modes occur simultaneously, and the impacts of them on rainfall are combined. The driest condition of rainfall occurs when El Niño coincides with positive IOD during positive IPO, and the wettest condition occurs when La Niña –La Niña Modoki coincides with negative IOD during negative IPO over the whole region of Indonesia. The IPO plays a role in modulating the impact of these inter-annual climate modes on their frequencies and magnitudes to Indonesian rainfall from 1970s until present. The responses of the Indonesian rainfall to each inter-annual climate mode modulated by IPO are different as based on their time series correlation coefficient. The negative correlation between canonical ENSO and Indonesian rainfall weakens during negative IPO from early 2000s and intensifies during positive IPO. On the other hand, the negative correlation between ENSO Modoki and Indonesian rainfall and between IOD and Indonesian rainfall increases during negative phase of IPO from late 1990s, and the negative correlation between ENSO Modoki and Indonesian rainfall weakens during positive IPO. Recently, the frequency of ENSO Modoki and IOD and their impacts on Indonesian rainfall increase.

# Exploring synoptic-scale drivers of interannual rainfall variability over Africa

*Piotr Wolski[1], Chris Jack[1], Waarith Abrahams[1], Stefaan Conradie[1]

1. University of Cape Town

Variability in local climate is a result of an interplay of multi-scale drivers –processes and feedbacks - intertwined within dependency or conditioning chain across spatial scales: from global to synoptic to meso- to local. Resolving these drivers and dependencies can be framed through the following questions: where does a deterministic signal at a particular time scale arise, how does it propagate through space and scales, and how can we maximize our ability to capture it? Here, we report on an exploratory study focusing on the synoptic-scale forcing underlying rainfall variability at the interannual time scale over Africa. In that, we systematically map, over the continent, variables and spatial scales which provide the strongest explanatory power of interannual rainfall variability. In addition, we constrast the explanatory power of mean state of synoptic fields with that of their variance, and of frequency of individual (daily) states. The analyses utilize multiple regression and CCA performed on mean de-orthogonalized fields of q,t,u,v,z at various pressure levels, with daily states of synoptic variables classified using self-organizing maps (SOM). The results are interpreted from the process perspective in terms of their agreement with the current understanding of the role of process chains affecting rainfall over various regions of the contient, and in terms of their implications to statistical downscaling of climate projections and seasonal forecasts.

# Effect of El Niño on the response ratio of Hadley circulation to different SST meridional structures

*Juan Feng[1]

1. Beijing Normal University

The role of El Niño in influencing the response ratio of the Hadley circulation (HC) to different tropical sea surface temperature (SST) meridional structures is investigated over the period 1979–2016. The explained variance of the equatorially asymmetric principal mode of HC variability is enhanced during El Niño events that are characterized by equatorially symmetric El Niño SST anomalies. The reason for the enhanced explained variance is examined. It is shown that the response ratio of the HC to different SST meridional structures is greatly enhanced in El Niño events; this is because the SST over the Indo-Pacific warm pool (IPWP) shows inhomogeneous warming in El Niño events, with greater values in the southern IPWP. The asymmetric warming over the IPWP is opposite to the climatological meridional structure of the SST over the IPWP, which intensifies the equatorially symmetric variation of SST, and contributes to the enhanced response ratio of the HC to SST. This point is further verified by the suppression of this enhanced response ratio in El Niño events of the HC to SST when the effects of SST over the IPWP are removed, implying the different warming amplitude within the IPWP during the El Niño events contributes to the enhanced response ratio. The response in La Niña events is also explored, indicating a difference between El Niño and La Niña events. These results may help explain the corresponding variations of the HC during the El Niño events, and highlight the different influences of the El Niño and La Niña events on the response of the HC to SST.

# Novel data-driven approach for ENSO prediction

*Dmitri Kondrashov[1], Evgeniy Loskutov[2], Andrei Gavrilov[2], Dmitry Mukhin[2], Alexander Feigin[2]

1. University of California, Los Angeles, United States, 2. Institute of Applied Physics of the Russian Academy of Sciences, Nizhny Novgorod, Russian Federation

We have developed novel data-driven technique for ENSO prediction that combines two existing approaches: linear dynamical mode (LDM) decomposition of spatially distributed data, and multilevel empirical model reduction (EMR) stochastic modeling approach. The nonlinear EMR model that utilizes dynamical variables obtained by empirical orthogonal function (EOF) decomposition of tropical Pacific SST’ s (Kondrashov et al. 2005), had already achieved a very competitive skill in International Research Institute for Climate and Society (IRI) ENSO real-time multi-model plume (Barnston et al. 2012). On the other hand, Gavrilov et al. (2018) have shown that LDM decomposition provides better modes for ENSO forecast than EOFs.

In the presented results we have used LDM modes as dynamical variables at the main level of multilevel linear EMR model. The model was trained on monthly 1960 -- 2014 sea surface temperatures (30S to 30N, 2x2 deg). The results of comparing skill of the retrospective predictions of the SST-based ENSO indices obtained by EMR model with LDM and EOF modes, will be discussed.

# Experimental seasonal climate prediction using CFES: Comparison with the SINTEX-F systems

*Nobumasa Komori[1], Bunmei Taguchi[2], Akira Kuwano-Yoshida[3,1], Takeshi Doi[1], Masami Nonaka[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Research Center for Advanced Science and Technology, The University of Tokyo, 3. Disaster Prevention Research Institute, Kyoto University

An experimental seasonal climate prediction system has been developed based on the Coupled atmosphere-ocean general circulation model for the Earth Simulator (CFES). Following the well-established systems based on the SINTEX-F model, initial conditions for seasonal climate prediction are constructed by strongly nudging sea surface temperature (SST) to observed one.

At this stage, 12-member ensemble 6-month predictions from the 1st day of March, June, September, and December have been conducted from 1983 through 2018, after 32-years of coupled spin-up integration with SST-nudging to the observed climatology. The experimental system exhibits skill in predicting variability of seasonal-mean 2-m air temperature over the tropical Pacific, and contributes to the improvement of multi-model ensemble prediction with the SINTEX-F systems.

# Exploring the SST error growth during ENSO developing phase by using BCC_CSM1.1(m)

*Ben Tian[1], Hongli Ren[1]

1. National Climate Center, China Meteorological Administration

Here we assess the ENSO prediction errors as a function of lead time using the seasonal hindcast of the Beijing Climate Center System Model, BCC_CSM1.1(m). The ensemble mean forecasts seems to be more challenging during the developing years of ENSO, compared with those made towards the decay phase. The composites of SST prediction errors are significantly negative and cover a large area in central-eastern tropical Pacific, thus limiting the model in forecasting the onset and intensity of El Niño. The large-scale errors, at their early stage, are generated gradually by negative anomalies in the subsurface temperature of the central-western equatorial Pacific, a process similar to El Niño decay and then transition to La Nina growth phase. Our results support others' work of "sensitive areas" for ENSO predictions, and emphasize the essential accuracy of initial fields and their early evolution, providing information for further improving the forecasting skill of ENSO.

# Role of sea-ice initialization in climate predictability over the Weddell Sea

*Yushi Morioka[1], Takeshi Doi[1], Doroteaciro Iovino[2], Simona Masina[2], Swadhin Behera[1]

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Centro Euro-Mediterraneo sui Cambiamenti Climatici (CMCC)

Potential impact of sea-ice initialization on the interannual climate predictability over the Weddell Sea is investigated using a coupled general circulation model. Climate variability in the Weddell Sea is generally believed to have association with remote forcing such as El Niño-Southern Oscillation and the Southern Annual Mode. However, sea-ice variability in the Weddell Sea has been recently suggested to play additional roles in modulating local atmospheric variability through changes in surface air temperature and near-surface baroclinicity. When both the model’s sea-surface temperature (SST) and sea-ice concentration (SIC) are initialized with observations using nudging schemes, reforecast experiments from September 1st show improvements in predicting the observed SIC anomalies in the Weddell Sea up to four months ahead, compared to the other experiments with only SST initialization. During austral spring (Oct-Dec) of lower-than-normal sea-ice years in the Weddell Sea, reforecast experiments with the SST and SIC initializations reasonably predict high surface air temperature anomalies in the Weddell Sea and high sea-level pressure anomalies over the Atlantic sector of the Southern Ocean. These results suggest that accurate initialization of sea-ice conditions during austral winter is necessary for skillful prediction of climate variability over the Weddell Sea during austral spring.

# Observed and hindcasted subdecadal variability of the tropical Pacific climate

*Takashi Mochizuki[1], Masahiro Watanabe[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere-Ocean Research Institute, The University of Tokyo

The tropical Pacific is highly responsible for controlling the tendencies of global climate. Here, we have found a subdecadal (i.e., 3-year-running means) variation that has been distinctively observed in the 2000s over the tropical Pacific. The warm water that originated from the positive ocean-heat-content (OHC) anomaly over the western Pacific in 2000 slowly extended eastward and stayed at the central equatorial Pacific between 2002-2005, rather than reaching the eastern edge. At the same time, an accompanying anti-cyclonic surface wind anomaly was observed in the off-equatorial North Pacific. This dynamical response of the upper ocean may have contributed to the subsequent warming in the western Pacific. In the preceding decades, in contrast, the observed OHC has usually represented a periodic fluctuation in the tropical Pacific, characterized by anomalous heat input/output in the meridional direction and slow eastward adjustment in the equatorial ocean thermocline. This subdecadal variation in the 2000s is quite distinct from our decadal hindcasts with initialization in Coupled Model Intercomparison Project Phase 5. The model predominantly simulates periodic-type fluctuations in any decade, and the resultant low predictability of the subdecadal variation in the 2000s can work to modulate the predictive skills at a lead time of several years.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-OS Ocean Sciences & Ocean Environment

Thu. May 30, 2019 5:15 PM - 6:30 PM JST | Thu. May 30, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_7

## [A-OS07] Climate variability and predictability on subseasonal to decadal timescales

convener:Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL), Doug Smith(Met Office), Yushi Morioka(Japan Agency for Marine-Earth Science and Technology)

Climate variability poses growing threats to human lives and socio-economic activities through changes in frequency and intensity of abnormal weather such as cold/heat waves and floods/droughts. This involves several climate phenomena with a wide range of timescales from subseasonal to decadal variations (e.g. MJO, IOD, ENSO, PDV, AMV). Many efforts have been made for understanding and predicting climate variations on each timescale, but there remain large uncertainties in simulation and prediction of subseasonal to decadal climate variations. This highlights lack of understanding of weather and climate interaction across different spatial and temporal timescales (e.g. tropical cyclones and ENSO) as well as multiple physical processes underlying climate variations (e.g. troposphere-stratosphere coupling, air-sea-ice interaction). This session aims to share current knowledge of subseasonal to decadal climate variability and predictability in order to identify the unresolved issues for better understanding and accurate prediction. This session invites all the abstracts related to the observational, theoretical, process-level and modelling research on subseasonal to decadal climate variability and predictability.

# Changes in North American and European Heatwave Characteristics

*Szandra A. Peter[1], Ben Kirtman[1]

1. Rosenstiel School of Marine and Atmospheric Science

Heat waves are a serious threat to ecosystems, society and the economies of the world. By calculating specific threshold values from daily maximum 2 m temperatures of the NCEP/NCAR reanalysis data (Kalnay et al. 1996), the frequency of heat waves during summer months (JJA) in Europe and the US is determined for the period of 1982 to 2017. The differences between the first and the second half of the 36-year period are discussed, and the results are compared to the North American Multi-Model Ensemble (NMME) forecast with specific focus on recent heat waves in the Pacific Northwest of North America and Central Europe. The connection between heat waves and known climate variability (i.e., the NAO, PNA) is analyzed. We strive to assess the importance of natural variability, such as the NAO, in the frequency of heat waves by comparing the first and last half of the studied 36-year period. We also examine how well the NMME retrospective and real-time forecasts capture heat waves (and cold spells), and the sources of predictability (i.e., sea surface temperature anomalies, land surface conditions), and how the predictability connects to the various modes of climate variability.

# The effects of the "New Climate" Warming on Western Mediterranean: Situation of the Recent Extreme Events

*Mohammed-Said KARROUK[1]

1. Hassan II University of Casablanca

Since the nineties of the last century, climatological research following a great scientific advance in the field of prediction, not the variability and evolution of the different climatic parameters was beginning to be clearer!

But today, since the beginning of 2005, certainly due to oceanic thermal cumulations, and the shift of climatic zones towards poles in selective forms (more intense on the oceans present on the continents); Climatic events do not evolve according to the usual and expected rhythms: atmospheric circulation, precipitation, temperatures, seasonal phenomena, etc. These conditions are a spatiotemporal evolution and distribution, which characterize the new "global climate", by the new atmospheric regime imposing the Meridian Atmospheric Circulation (MAC), alternating the conditions of Freshness (humidity) and Heat (drought) along the year.

In this new situation, Western Mediterranean, located in the climate transition zone, is fully affected by the "New Climate". Usually, the atmospheric response to major climatic events (ENSO) in this region such as "El Niño" was characterized by the establishment of the NAO positive index, stability and drought, due to dominance Zonal Atmospheric Circulation in winter. On the other hand, in the "La Niña" episode, the negative index of the NAO and the predominant Meridian Atmospheric Circulation and precipitation became abundant.

Since the beginning of this century, qualified meteorological events of "exceptional !" causing floods have continued to occur in Western Mediterranean, with increasing recurrence, prompting us to wonder about the "new" mode of hydro-thermal function of the climate system that induces torrential rains, as well as its effect on environments and societies.

Thanks to spatial observation and monitoring of meteorological conditions over the last 15 years, these types of alternating Heat / Cold conditions have become predictable, enabling decision-makers today to prepare adequately for the management of related risks to the "New Climate" warmed.

# Month-to-month Difference of the Western Pacific Subtropical High Simulated by CMIP5 Models

*Xiao Dong[1], Renping Lin[1]

1. Institute of Atmospheric Physics

The western Pacific subtropical high (WPSH) is an important circulation system of the East Asian summer monsoon (EASM). Most previous studies have focused on the variability of summer mean WPSH. Note that the WPSH also experiences subseasonal variation from early to late summer. In this study we examined the month-to-month shift of the WPSH in boreal summer, that is, from June to July and from July to August, simulated by CMIP5 Atmospheric General Circulation Models (AGCMs) and coupled models. Results show that climatologically AGCMs can reproduce the northward shift of the WPSH better than eastward retreat from July to August. Compared with AGCMs, coupled models can improve the month-to-month shift simulation to some extent, indicating that the air-sea coupling processes are also important in subseasonal timescale.

# Potential regulation on the climatic effect of Tibetan Plateau heating by tropical air–sea coupling

*Ziqian Wang[1], Anmin Duan[2], Song Yang[1]

1. School of Atmospheric Sciences, Sun Yat-sen University, 2. Institute of Atmospheric Physics, Chinese Academy of Sciences

Based on the conventional weather research and forecasting (WRF) model and the air–sea coupled mode WRF-OMLM, we investigate the potential regulation on the climatic effect of Tibetan Plateau (TP) heating by the air–sea coupling over the tropical Indian Ocean and western Pacific. Results indicate that the TP heating significantly enhances the southwesterly monsoon circulation over the northern Indian Ocean and the South Asia subcontinent. The intensified southwesterly wind cools the sea surface mainly through the wind-evaporation-SST (sea surface temperature) feedback. Cold SST anomaly then weakens monsoon convective activity, especially that over the Bay of Bengal, and less water vapor is thus transported into the TP along its southern slope from the tropical oceans. As a result, summer precipitation decreases over the TP, which further weakens the TP local heat source. Finally, the changed TP heating continues to influence the summer monsoon precipitation and atmospheric circulation. To a certain extent, the air–sea coupling over the adjacent oceans may weaken the effect of TP heating on the mean climate in summer. It is also implied that considerations of air–sea interaction are necessary in future simulation studies of the TP heating effect.

# Intraseasonal variation of the South Asian high and its role in connecting the Indian and East Asian summer monsoons

*Wei Wei[1]

1. Sun Yat-sen University

The South Asian high (SAH) is the most intense and persistent upper-level circulation system in the Asian monsoon region during boreal summer. It plays a crucial role in the onset and variation of the Asian summer monsoon. Ample evidence shows that the monsoon onset and activities are closely related to the intraseasonal oscillation (ISO). Previous studies have found that the ISO in the East Asian summer monsoon (EASM) is impacted by the northward or northwestward propagation of the ISO in the South China Sea and the western North Pacific, and the northeastward propagation of the ISO in the tropical Indian Ocean. However, seldom research mentioned the effect of the ISO in the SAH. Our previous studies have shown that the SAH plays an important role in connecting the Indian summer monsoon (ISM) and the EASM on the interannual time scale. However, the effect of the SAH on the connection of the ISM and the EASM on the intraseasonal time scale is still not clear. Actually, the ISO in the SAH is significant in its zonal variation. In this study, we firstly figured out the intraseasonal variation feature of the SAH. And then, we explored the upper-level signal which will lead to the onset, advance and retreat of the EASM. Considering significant ISO in the ISM, we investigated the ISO feature in the ISM and its effect on the ISO in the SAH. Finally, we addressed a new physical process that the ISO in the ISM will impact the ISO in the SAH, and further influence the advance and retreat of the EASM on the intraseasonal time scale. We try to learn about the intraseasonal variation of the EASM in a new view, and propose a new way to improve the short-term climate prediction and the extended-range weather forecast.

# Mean Surface Air Temperatures in Japan - Regional Classification and Interranual Variability

*Pascal Oettli[1], Masami Nonaka[1], Swadhin Behera[1]

1. Japan Agency for Marine-Earth Science and Technology

Back to the year 1886, several divisions of the climate of Japan into homogeneous climatic regions have been proposed, following different approaches of the question. This includes the Köppen climate classification (Fukui in 1933; Sekiguchi in 1949), the new Thornthwaite climate classification (Isozaki in 1933; Fukui in 1957) or the similarities of weather conditions. The latter is performed either throughout the year (Nakagawa in 1899; Sekiguchi in 1959; Yoshino in 1980) or during specific seasons (Iwakiri in 1967; Murata and Yoshino in 1988), sometimes with the help of statistical techniques, such as principal component analysis and the cluster analysis (Mikami in 1975; Koizumi and Kato in 2012.)

Using a type of artificial neural network called Self-Organizing Map, or SOM, we propose another division of the climate of Japan, solely based on the mean areal surface air temperature anomalies. SOM has been successfully employed in climate studies for more than a decade and has showed its ability to extract simple features from high-dimensional data. Here, SOM is applied to group 762 AMeDAS stations, taken throughout Japan for the last 30 years, into homogeneous clusters (=regions). Clustering is performed seasonally, with a focus on boreal winter (December to February) and boreal summer (June to August). As a result, eight regions are defined and associated time series of temperature anomalies (=indices) are computed.

Subsequently, possible source(s) of the interannual variability of mean surface air temperature anomalies are explored, for a better understanding of the regional differences. For this, correlation coefficients between indices previously defined and different climatic variable anomaly fields (sea-surface temperatures, outgoing longwave radiation, geopotential height...) are calculated. Hopefully, this work would also lead to a better seasonal forecast, taking into account the specificity of each region in regard to their link to the large-scale variability.

# Inter-Annual Variability of the Indonesian Rainfall and Air-Sea Interaction over the Indian-Pacific Ocean Associated with Regime Shift

*Murni Ngestu Nurutami[1], Tadahiro Hayasaka[1]

1. Center for Atmospheric and Oceanic Studies, Graduate School of Science, Tohoku University

The inter-annual and inter-decadal variability of the Indonesian rainfall are investigated in association with the interannual climate modes over Indian-Pacific Oceans and the inter-decadal modulation on inter-annual climate variability impact. Rainfall data of the Climate Research Unit (CRU) from 1901 to 2016 and the Global Precipitation Climatology Project (GPCP) from 1979 to 2016 for June –November (JJASON) are used. The empirical orthogonal function (EOF) is used to identify the dominant spatial and temporal variability patterns of rainfall and the standard and partial correlation techniques are used to compare and to quantify the linear relationship between two or more time-series datasets. Based on the first principle component (PC1) of both CRU and GPCP data, the results show that canonical El Niño Southern-Oscillation (canonical ENSO), ENSO Modoki, and Indian Ocean Dipole (IOD) are the major climate modes influencing the inter-annual variability of the Indonesian rainfall, and the Inter-decadal Pacific Oscillation (IPO) is the major decadal phenomenon which affects the decadal variability of Indonesian rainfall. All of the inter-annual climate modes and IPO have negative correlation with the Indonesian rainfall, but the spatial distributions of Indonesian rainfall change associated with each phenomenon are different. During 1970 to 2016, three phases of IPO have been identified which are strongly related to Indonesian rainfall with the correlation coefficient of -0.75. The three phases are a negative phase in 1970-1978, a positive phase in 1979-1997, and another negative phase in 1998-2015. Mostly, these climate modes occur simultaneously, and the impacts of them on rainfall are combined. The driest condition of rainfall occurs when El Niño coincides with positive IOD during positive IPO, and the wettest condition occurs when La Niña –La Niña Modoki coincides with negative IOD during negative IPO over the whole region of Indonesia. The IPO plays a role in modulating the impact of these inter-annual climate modes on their frequencies and magnitudes to Indonesian rainfall from 1970s until present. The responses of the Indonesian rainfall to each inter-annual climate mode modulated by IPO are different as based on their time series correlation coefficient. The negative correlation between canonical ENSO and Indonesian rainfall weakens during negative IPO from early 2000s and intensifies during positive IPO. On the other hand, the negative correlation between ENSO Modoki and Indonesian rainfall and between IOD and Indonesian rainfall increases during negative phase of IPO from late 1990s, and the negative correlation between ENSO Modoki and Indonesian rainfall weakens during positive IPO. Recently, the frequency of ENSO Modoki and IOD and their impacts on Indonesian rainfall increase.

# Exploring synoptic-scale drivers of interannual rainfall variability over Africa

*Piotr Wolski[1], Chris Jack[1], Waarith Abrahams[1], Stefaan Conradie[1]

1. University of Cape Town

Variability in local climate is a result of an interplay of multi-scale drivers –processes and feedbacks - intertwined within dependency or conditioning chain across spatial scales: from global to synoptic to meso- to local. Resolving these drivers and dependencies can be framed through the following questions: where does a deterministic signal at a particular time scale arise, how does it propagate through space and scales, and how can we maximize our ability to capture it? Here, we report on an exploratory study focusing on the synoptic-scale forcing underlying rainfall variability at the interannual time scale over Africa. In that, we systematically map, over the continent, variables and spatial scales which provide the strongest explanatory power of interannual rainfall variability. In addition, we constrast the explanatory power of mean state of synoptic fields with that of their variance, and of frequency of individual (daily) states. The analyses utilize multiple regression and CCA performed on mean de-orthogonalized fields of q,t,u,v,z at various pressure levels, with daily states of synoptic variables classified using self-organizing maps (SOM). The results are interpreted from the process perspective in terms of their agreement with the current understanding of the role of process chains affecting rainfall over various regions of the contient, and in terms of their implications to statistical downscaling of climate projections and seasonal forecasts.

# Effect of El Niño on the response ratio of Hadley circulation to different SST meridional structures

*Juan Feng[1]

1. Beijing Normal University

The role of El Niño in influencing the response ratio of the Hadley circulation (HC) to different tropical sea surface temperature (SST) meridional structures is investigated over the period 1979–2016. The explained variance of the equatorially asymmetric principal mode of HC variability is enhanced during El Niño events that are characterized by equatorially symmetric El Niño SST anomalies. The reason for the enhanced explained variance is examined. It is shown that the response ratio of the HC to different SST meridional structures is greatly enhanced in El Niño events; this is because the SST over the Indo-Pacific warm pool (IPWP) shows inhomogeneous warming in El Niño events, with greater values in the southern IPWP. The asymmetric warming over the IPWP is opposite to the climatological meridional structure of the SST over the IPWP, which intensifies the equatorially symmetric variation of SST, and contributes to the enhanced response ratio of the HC to SST. This point is further verified by the suppression of this enhanced response ratio in El Niño events of the HC to SST when the effects of SST over the IPWP are removed, implying the different warming amplitude within the IPWP during the El Niño events contributes to the enhanced response ratio. The response in La Niña events is also explored, indicating a difference between El Niño and La Niña events. These results may help explain the corresponding variations of the HC during the El Niño events, and highlight the different influences of the El Niño and La Niña events on the response of the HC to SST.

# Novel data-driven approach for ENSO prediction

*Dmitri Kondrashov[1], Evgeniy Loskutov[2], Andrei Gavrilov[2], Dmitry Mukhin[2], Alexander Feigin[2]

1. University of California, Los Angeles, United States, 2. Institute of Applied Physics of the Russian Academy of Sciences, Nizhny Novgorod, Russian Federation

We have developed novel data-driven technique for ENSO prediction that combines two existing approaches: linear dynamical mode (LDM) decomposition of spatially distributed data, and multilevel empirical model reduction (EMR) stochastic modeling approach. The nonlinear EMR model that utilizes dynamical variables obtained by empirical orthogonal function (EOF) decomposition of tropical Pacific SST’ s (Kondrashov et al. 2005), had already achieved a very competitive skill in International Research Institute for Climate and Society (IRI) ENSO real-time multi-model plume (Barnston et al. 2012). On the other hand, Gavrilov et al. (2018) have shown that LDM decomposition provides better modes for ENSO forecast than EOFs.

In the presented results we have used LDM modes as dynamical variables at the main level of multilevel linear EMR model. The model was trained on monthly 1960 -- 2014 sea surface temperatures (30S to 30N, 2x2 deg). The results of comparing skill of the retrospective predictions of the SST-based ENSO indices obtained by EMR model with LDM and EOF modes, will be discussed.

# Experimental seasonal climate prediction using CFES: Comparison with the SINTEX-F systems

*Nobumasa Komori[1], Bunmei Taguchi[2], Akira Kuwano-Yoshida[3,1], Takeshi Doi[1], Masami Nonaka[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Research Center for Advanced Science and Technology, The University of Tokyo, 3. Disaster Prevention Research Institute, Kyoto University

An experimental seasonal climate prediction system has been developed based on the Coupled atmosphere-ocean general circulation model for the Earth Simulator (CFES). Following the well-established systems based on the SINTEX-F model, initial conditions for seasonal climate prediction are constructed by strongly nudging sea surface temperature (SST) to observed one.

At this stage, 12-member ensemble 6-month predictions from the 1st day of March, June, September, and December have been conducted from 1983 through 2018, after 32-years of coupled spin-up integration with SST-nudging to the observed climatology. The experimental system exhibits skill in predicting variability of seasonal-mean 2-m air temperature over the tropical Pacific, and contributes to the improvement of multi-model ensemble prediction with the SINTEX-F systems.

# Exploring the SST error growth during ENSO developing phase by using BCC_CSM1.1(m)

*Ben Tian[1], Hongli Ren[1]

1. National Climate Center, China Meteorological Administration

Here we assess the ENSO prediction errors as a function of lead time using the seasonal hindcast of the Beijing Climate Center System Model, BCC_CSM1.1(m). The ensemble mean forecasts seems to be more challenging during the developing years of ENSO, compared with those made towards the decay phase. The composites of SST prediction errors are significantly negative and cover a large area in central-eastern tropical Pacific, thus limiting the model in forecasting the onset and intensity of El Niño. The large-scale errors, at their early stage, are generated gradually by negative anomalies in the subsurface temperature of the central-western equatorial Pacific, a process similar to El Niño decay and then transition to La Nina growth phase. Our results support others' work of "sensitive areas" for ENSO predictions, and emphasize the essential accuracy of initial fields and their early evolution, providing information for further improving the forecasting skill of ENSO.

# Role of sea-ice initialization in climate predictability over the Weddell Sea

*Yushi Morioka[1], Takeshi Doi[1], Doroteaciro Iovino[2], Simona Masina[2], Swadhin Behera[1]

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Centro Euro-Mediterraneo sui Cambiamenti Climatici (CMCC)

Potential impact of sea-ice initialization on the interannual climate predictability over the Weddell Sea is investigated using a coupled general circulation model. Climate variability in the Weddell Sea is generally believed to have association with remote forcing such as El Niño-Southern Oscillation and the Southern Annual Mode. However, sea-ice variability in the Weddell Sea has been recently suggested to play additional roles in modulating local atmospheric variability through changes in surface air temperature and near-surface baroclinicity. When both the model’s sea-surface temperature (SST) and sea-ice concentration (SIC) are initialized with observations using nudging schemes, reforecast experiments from September 1st show improvements in predicting the observed SIC anomalies in the Weddell Sea up to four months ahead, compared to the other experiments with only SST initialization. During austral spring (Oct-Dec) of lower-than-normal sea-ice years in the Weddell Sea, reforecast experiments with the SST and SIC initializations reasonably predict high surface air temperature anomalies in the Weddell Sea and high sea-level pressure anomalies over the Atlantic sector of the Southern Ocean. These results suggest that accurate initialization of sea-ice conditions during austral winter is necessary for skillful prediction of climate variability over the Weddell Sea during austral spring.

# Observed and hindcasted subdecadal variability of the tropical Pacific climate

*Takashi Mochizuki[1], Masahiro Watanabe[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere-Ocean Research Institute, The University of Tokyo

The tropical Pacific is highly responsible for controlling the tendencies of global climate. Here, we have found a subdecadal (i.e., 3-year-running means) variation that has been distinctively observed in the 2000s over the tropical Pacific. The warm water that originated from the positive ocean-heat-content (OHC) anomaly over the western Pacific in 2000 slowly extended eastward and stayed at the central equatorial Pacific between 2002-2005, rather than reaching the eastern edge. At the same time, an accompanying anti-cyclonic surface wind anomaly was observed in the off-equatorial North Pacific. This dynamical response of the upper ocean may have contributed to the subsequent warming in the western Pacific. In the preceding decades, in contrast, the observed OHC has usually represented a periodic fluctuation in the tropical Pacific, characterized by anomalous heat input/output in the meridional direction and slow eastward adjustment in the equatorial ocean thermocline. This subdecadal variation in the 2000s is quite distinct from our decadal hindcasts with initialization in Coupled Model Intercomparison Project Phase 5. The model predominantly simulates periodic-type fluctuations in any decade, and the resultant low predictability of the subdecadal variation in the 2000s can work to modulate the predictive skills at a lead time of several years.

## [A-OS07] Climate variability and predictability on subseasonal to decadal timescales

convener:Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL), Doug Smith(Met Office), Yushi Morioka(Japan Agency for Marine-Earth Science and Technology), Chairperson:V Ramaswamy(NOAA GFDL), Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology)

Climate variability poses growing threats to human lives and socio-economic activities through changes in frequency and intensity of abnormal weather such as cold/heat waves and floods/droughts. This involves several climate phenomena with a wide range of timescales from subseasonal to decadal variations (e.g. MJO, IOD, ENSO, PDV, AMV). Many efforts have been made for understanding and predicting climate variations on each timescale, but there remain large uncertainties in simulation and prediction of subseasonal to decadal climate variations. This highlights lack of understanding of weather and climate interaction across different spatial and temporal timescales (e.g. tropical cyclones and ENSO) as well as multiple physical processes underlying climate variations (e.g. troposphere-stratosphere coupling, air-sea-ice interaction). This session aims to share current knowledge of subseasonal to decadal climate variability and predictability in order to identify the unresolved issues for better understanding and accurate prediction. This session invites all the abstracts related to the observational, theoretical, process-level and modelling research on subseasonal to decadal climate variability and predictability.

We conduct real-time seasonal forecast using high-resolution global models (GFDL-FLOR, GFDL-HiFLOR, and NICAM) that have skill in predicting tropical cyclone statistics over the global ocean basins. The seasonal predictions starting from 2018 July initial conditions show above normal frequency of tropical cyclones in the Western North Pacific and Central Pacific Oceans as observed. To understand physical mechanisms behind the active storm season in the Pacific, we conducted idealized seasonal forecasts by changing sea surface temperature spatial patterns, which is so called "real-time attribution" simulations. We find out that warmer subtropical Pacific associated with positive Pacific Meridional Mode (PMM), rather than central Pacific El Nino, was responsible for the active storm season. In the presentation, we will also show preliminary results for impact of anthropogenic forcing on the 2018 active storm season.

# Future change of tropical cyclone-induced waves in the Indian Ocean; An analysis based on super-high-resolution MRI-AGCM3.2 climate model

*Bahareh Kamranzad[1,2], Nobuhito Mori[1]

1. Disaster Prevention Research Institute, Kyoto University, 2. Hakubi Center for Advanced Research, Kyoto University

Indian Ocean experiences intensive tropical cyclones in both northern and southern parts. The Northern Indian Ocean (NIO) includes 7% of the global tropical cyclones which results in generating severe wave climate during the extreme events. In this study, future change of tropical cyclone-induced waves due to climate change is assessed in terms of change in the spatial distribution patterns and magnitude. The cyclone seasons in NIO are divided by pre-monsoon (especially May) and northeast monsoon (October–December). Moreover, there are few cyclones form the southwest monsoon during June and September. Hence, the assessment of future change of intensity of tropical cyclones and the generated waves is necessary to be performed on a monthly scale. For this purpose, wind field obtained from super-high-resolution atmospheric global climate model MRI-AGCM3.2S of the Japan Meteorological Agency (JMA) -with horizontal spatial and temporal output resolutions of 20 km and 1 hr., respectively- was used to force a numerical wave model (SWAN) in historical (1979-2003) and future (2075-2099) periods (based on Representative Concentration Pathway (RCP) 8.5 scenario).
Spatial distribution of annual extreme events in the domain shows that the concentration of tropical cyclones is in the NIO and around Madagascar (located in the Southern Indian Ocean (SIO)) generating high waves of the magnitudes of around 20 m during the events. Spatial distribution of monthly maximum values of the historical and future wind speed (WS) and significant wave height (SWH) indicates that according to historical projection, intense cyclones happen during May and June in NIO, while they can be observed mostly during December to April in the SIO. The future monthly distribution of cyclone induced waves in SIO shows a similar pattern to the historical events, except for winter tropical cyclones (November and December), which are decreased in the future, while increasing in the intensity can be observed during October and April in NIO.
Monthly variation of maximum events in the domain was assessed in the NIO and SIO, separately. According to the past studies, due to the global warming, tropical cyclones of hurricane intensity -which currently occur only in the pre and post-monsoon seasons- will likely be formed even during the summer monsoon in NIO. Our results illustrate an increase in the intensity of cyclones in the future, not only during the summer monsoon (July) but also during the winter monsoon (September and October). Results show that the range of change in the highest SWH in NIO is between -27% (in February) and +26% (in October). In the northern part of SIO, the intensity of future tropical cyclones will increase during the southwestern inter-monsoon season (March and April), whereas it will decrease at the end of southwestern monsoon season (September). In the southern part of SIO, the intensity of tropical cyclones will increase around 20% during northeastern monsoon (February and March), which results in a future increase of 40% in maximum SWH in February. Generally, change in highest SWH in the future follows the pattern of WS except for the northern parts of SIO when the highest increase in maximum SWH (21%) occurs in March whereas the highest increase in maximum WS occurs in April (25%). There is a 20% increase in maximum WS during February in southern parts of SIO which can be a reason for the increase of SWH during March in northern parts. It can be concluded that the change in the intensity of future tropical cyclones in NIO is higher than SIO. The range of change in highest SWH in NIO is larger than SIO, except for February when the maximum wave height in southern parts of SIO will increase about 40% in

©2019. Japan Geoscience Union. All Right Reserved. 

the future. Furthermore, the change in maximum SWH in northern parts of SIO seems to be affected by the change of tropical cyclones in southern parts of SIO.

# The ocean-coupled global cloud-resolving modeling era

*Tomoki Miyakawa[1]

1. Atmosphere and Ocean Research Institute University of Tokyo

Developments of global cloud/cloud-system resolving models are recently in full activity in many modeling centers, with 9 members participating in a model inter-comparison project called the DYnamics of the Atmospheric general circulation Modeled On Non-hydrostatic Domains (DYAMOND). With the aid of the supercomputers, they are eyeing to become the main-stream in the next generation models for global simulations in the seasonal to multi-decadal range. Implementation of a fully dynamical ocean model is certainly an essential component in these developments. NICAM, a front-runner in DYAMOND project, can be coupled to COCO, the ocean component of a global climate model MIROC. The coupled version is called NICAM-COCO, or NICOCO, and is now being tested in pilot studies that involve atmosphere-ocean interactions.

An overview of these early studies will be presented, including how convection is affected by the existence of fine-scale ocean fronts, and how the Madden-Julian oscillation affects the initiation and termination of ENSO.

Keywords: ocean-coupled model, global cloud-resolving model, seasonal prediction

# Westerly Wind Burst (WWB)/Easterly Wind Surge (EWS)-like stochastic forcing and the effects on ENSO prediction by the SINTEX-F system

*Takeshi Doi[1], Swadhin Behera[1], Toshio Yamagata[1]

1. JAMSTEC

Intra-seasonal surface westerly wind bursts (WWB)/easterly wind surges (EWS) in the tropical Pacific play important roles in the onset of El Nino/La Nina. However, the latest version of the SINTEX-F seasonal prediction system tends to underestimate the chance of occurrence of those winds. This problem may cause the relatively low skill of predicting the onset of ENSO, and the over-confident problems of ENSO prediction. In this study, we developed the WWB/EWS-like stochastic forcing parameterization, and examined the effects on ENSO prediction by the SINTEX-F system. In my talk, failure of 2014 El Nino prediction is the focus.

# The life-cycle of annual waves in the Pacific Ocean as identified by a seamless diagnosis for the energy flux

*Hidenori AIKI[1], Takahiro Shimura[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School for Environmental Studies, Nagoya University

Synoptic-scale waves play an important role in tropical-extratropical interactions, that has been little investigated in terms of the transfers of wave energy owing to the lack of an appropriate diagnosis scheme in previous studies. A recent theoretical study has derived a seamless scheme that is able to identify the direction of group velocity for both gravity and planetary waves at all latitudes. This new scheme has been used in the present study to provide a first-ever energetic view for the life-cycle of annual waves in the Pacific Ocean in a set of shallow-water model experiments with climatological wind forcing. The new scheme is able to show, in particular for the third baroclinic mode, the signals of eastward energy flux associated with equatorial Kelvin waves that are distributed in the eastern part of the tropical Pacific Ocean. Waves in the tropical and subtropical regions are connected each other at the eastern boundary of the Pacific Ocean that has been viewed, for the first time in the history of geophysical fluid dynamics, in terms of the circulation of wave energy. Concerning the low-pass filtered time evolution of the energy flux, the reflection of equatorial waves at the western boundary is more clearly identified than that at the eastern boundary. These results for the analysis of climatological annual waves provide a basis for the analysis of waves with interannual variations in a future study to better understand, for example, tropical-extratropical interactions during El Nino and La Nina.

# Development of weakly coupled atmosphere-ocean data assimilation system and the evaluation of the coupled reanalysis in JMA/MRI

*Yosuke Fujii[1], Chiaki Kobayashi[1], Toshiyuki Ishibashi[1], Yuhei Takaya[1]

1. Meteorological Research Institute, Japan Meteorological Agency

JMA/MRI have developed a weakly-coupled Data Assimilation (DA) system, MRI-CDA1, based on JMA's operational systems. MRI-CDA1 is composed of the global atmosphere Four-Dimensional Variational (4DVAR) system for numerical weather predictions, the global ocean Three-Dimensional Variational (3DVAR) system for seasonal predictions, and the coupled atmosphere-ocean model for seasonal predictions. The coupled atmosphere-ocean model is adopted as the outer model of the atmospheric 4DVAR routine although the uncoupled atmospheric model is used as the inner model. While the atmospheric 4DVAR analysis is performed every 6 hours, the oceanic 3DVAR analysis is performed every 10 days and the oceanic analysis increments are applied in the integrations of the outer (coupled) model.

Coupled reanalysis experiments based on MRI-CDA1 are conducted for the period from November 2013 to December 2015. In the coupled reanalysis the excess rainfall found in the tropics in Japanese 55-year Reanalysis (JRA-55) is effectively suppressed, particularly in the Intertropcal Convergence Zone (ITCZ) in the Pacific. We also confirmed that the coupled DA system properly reproduces the lagged-correlated variations of Sea Surface Temperature (SST) and precipitation in the far western tropical North Pacific which is not reproduced by a regular uncoupled DA system. The variation of the precipitation is improved in the coupled reanalysis over the uncoupled one when only conventional data and oceanic data are assimilated. But the coupled DA system adjusts SST to the change of precipitation, instead of correcting the precipitation field, when atmospheric data from satellite are additionally assimilated. We also conducted another coupled reanalysis experiment in which the atmospheric observation error variances set larger than the original, and found that the variation of the precipitation in the tropics is roughly improved over the original coupled reanalysis.

## [A-OS07] Climate variability and predictability on subseasonal to decadal timescales

convener:Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL), Doug Smith(Met Office), Yushi Morioka(Japan Agency for Marine-Earth Science and Technology), Chairperson:Yushi Morioka(Japan Agency for Marine-Earth Science and Technology), Takashi Mochizuki(Japan Agency for Marine-Earth Science and Technology)

Climate variability poses growing threats to human lives and socio-economic activities through changes in frequency and intensity of abnormal weather such as cold/heat waves and floods/droughts. This involves several climate phenomena with a wide range of timescales from subseasonal to decadal variations (e.g. MJO, IOD, ENSO, PDV, AMV). Many efforts have been made for understanding and predicting climate variations on each timescale, but there remain large uncertainties in simulation and prediction of subseasonal to decadal climate variations. This highlights lack of understanding of weather and climate interaction across different spatial and temporal timescales (e.g. tropical cyclones and ENSO) as well as multiple physical processes underlying climate variations (e.g. troposphere-stratosphere coupling, air-sea-ice interaction). This session aims to share current knowledge of subseasonal to decadal climate variability and predictability in order to identify the unresolved issues for better understanding and accurate prediction. This session invites all the abstracts related to the observational, theoretical, process-level and modelling research on subseasonal to decadal climate variability and predictability.

# Decadal variability and predictability of the North Atlantic Oscillation

*Rosemary Eade[1,2], David Stephenson[2], Doug Smith[1], Adam Scaife[1,2], Leon Hermanson[1], Nick Dunstone[1]

1. Met Office Hadley Centre, 2. University of Exeter

The winter of 1962/63 was the coldest in the UK in over a century while the mildest winter occurred in 1988/89. For countries to be resilient against the impacts of large weather variations in the future, it is important to assess the likelihood of seeing such extreme fluctuations and understand the physical drivers. In Europe and North America, these fluctuations are related to a combination of year-to-year variability and low-frequency variability of the North Atlantic Oscillation (NAO). The NAO is now a significant source of predictability for seasonal forecasts in these regions, however the signal-to-noise ratio of the ensemble mean to total variability in these ensemble predictions has been shown to be anomalously small, which means the real world is more predictable than our climate models suggest. Here we provide a new evaluation of the ability of climate models to simulate and predict longer-term variability and extreme trends in the NAO. For this we use statistical analyses of the observations and climate model simulations, and assess predictability with a large multi-model ensemble of decadal predictions. We also investigate the drivers of NAO variability and trends using new results from the CMIP6 Decadal Climate Prediction Project and the Polar Amplification MIP.

# Seasonal to multi-year climate predictability in a climate model MIROC6

*Takahito Kataoka[1], Hiroaki Tatebe[1], Hiroshi Koyama[1], Takashi Mochizuki[1]

1. JAMSTEC Japan Agency for Marine-Earth Science and Technology

Seasonal to multi-year climate predictability is examined in hindcast experiments using the latest version of a climate model MIROC (MIROC6). The model is initialized by assimilating observed ocean temperature and salinity anomaly fields and full-filed of sea ice concentration. In addition, the atmospheric initial conditions are replaced with variables from JRA55 reanalysis and the hindcasts are issued on November 1st. On seasonal timescales, the MIROC6 prediction system shows an improvement in Niño3.4 prediction skill from that of MIROC5, though the skill itself is still modest. SLP variability around Japan appears to have predictive skill up to second winter (lead time of about 15 month) and summer (lead time of about 21 month) possibly due to the improved ENSO prediction skill and the better representation of East Asian monsoon. On longer timescales, although the predictive component largely originates from the externally forced variability, MIROC6 shows predictive skills in the surface air temperature particularly in the North Pacific and the North Atlantic.

# Identifying the early 2000s hiatus associated with internal climate variability

*Xin-Gang Dai[1], Ping Wang[2]

1. Institute of Atmospheric Physics, Chinese Academy of Sciences, 2. Chinese Academy of Meteorological Sciences

This study focuses on re-examining the early 2000s hiatus and the associated key components of the global mean surface temperature (GMST) using multiscale statistics for five well-known gridded surface temperature and two reanalysis datasets. The hiatus is characterized as a near-zero trend on the decadal scale corresponding to the maximum P-value via an F-test in statistics. The results reveal that the hiatus exists in both the GMST and global mean air temperature (GMAT) time series, rather than in global warming component, which has maintained an approximately constant rate of change of approximately 0.08ºC/decade over the past three decades. The hiatus' s duration is different from that of time series such as 2002-2012/2001-2013/2002-2014 in HadCRUT4, NOAA-old, ERA-Interim and NCEP-R2. The newly gridded datasets with data infilling or bias correction for interpreting the sea surface temperature (SST) measurement from the old versions show a slightly higher trend from for 2002-2012 than the hiatus, which is thus regarded as a slowdown. Comparison suggests that the hiatus should be during the period 2002-2012. Orthogonal wavelet decomposition of the temperature time series shows that the hiatus was merely a decadal balance between cooling from interannual variability and global warming, in addition to weak warming from interdecadal and multidecadal climate oscillations. In addition, the evolutions of the GMST' s interannual composite well coincided with Niño3.4 SST anomalies, which is consistent with the numerical simulation performed by Kosaka and Xie in 2013. Hence, it is the anomalous El Niño Southern Oscillation (ENSO) events in the early 2000s that caused the hiatus despite a constant rate of global warming and the maximum magnitude of the multidecadal composite that led to the limited contribution to the trend during this period. The multidecadal composite follows a downward path, which implies that future climate conditions will likely rely on competition between multidecadal cooling and global warming if the multidecadal climate cycle repeats, as was experienced during the second half of the twentieth century.

# Decadal Evolution of the Surface Energy Budget during the Fast Warming and Global Warming Hiatus Periods in the ERA-Interim

*XIAOMING HU[1]

1. Sun Yat-sen University

The global-mean surface temperature has experienced a rapid warming from the 1980s to early-2000s but a muted warming since, referred to as the global warming hiatus in the literature. Decadal changes in deep ocean heat uptake are thought to primarily account for the accelerated warming rate and subsequent slowdown. Here, we examine the role of ocean heat uptake in establishing the fast warming and warming hiatus periods in the ERA-Interim through a decomposition of the global-mean surface energy budget. We find the increase of carbon dioxide alone yields a nearly steady increase of the downward longwave radiation at the surface from the 1980s to the present, but neither accounts for the fast warming nor warming hiatus periods. During the global warming hiatus period, the transfer of latent heat energy from the ocean to atmosphere increases and the total downward radiative energy flux to the surface decreases due to a reduction of solar absorption caused primarily by an increase of clouds. The reduction of radiative energy into the ocean and the surface latent heat flux increase cause the ocean heat uptake to decrease and thus contribute to the slowdown of the global-mean surface warming. Our analysis also indicates that in addition to a reduction of deep ocean heat uptake, the fast warming period is also driven by enhanced solar absorption due predominantly to a decrease of clouds and by enhanced longwave absorption mainly attributed to the air temperature feedback.

# The role of ocean variability for multi-year droughts in Australia

*Andrea Taschetto[1,2], Alex Sen Gupta[1,2], Caroline C Ummenhofer[3], Matthew H England[1,2]

1. Climate Change Research Centre, University of New South Wales, Sydney, Australia, 2. ARC Centre of Excellence for Climate Extremes, University of New South Wales, Sydney, Australia, 3. Department of Physical Oceanography, Woods Hole Oceanographic Institution, Woods Hole, MA, USA

Australian climate is strongly affected by variations in sea surface temperature in the Pacific, Indian and Southern Oceans. Over the northern and eastern regions of Australia, the El Niño –Southern Oscillation (ENSO) is the main phenomenon causing profound impacts in rainfall. On the southern regions, a large proportion of rainfall comes from synoptic weather systems at the mid-latitudes, such as cold fronts and cut-off lows. The interaction between the tropical modes of variability and the atmosphere dynamics at mid-latitudes makes difficult to understand the role of the oceans for droughts relative to the atmosphere internal variability.

The contribution of ocean versus atmosphere variability for Australian rainfall is investigated in this study. Numerical experiments are performed using the National Center for Atmospheric Research (NCAR) Community Earth System Model (CESM). Three multi-century simulations are integrated to address the role of the oceans for rainfall variability: (i) a fully coupled climate system run, (ii) an run forced with climatological cycle of SST, i.e. no SST variability beyond one year, and (iii) a run forced with varying SST, i.e. containing SST variability but no air-sea feedback.

Our results show that interannual variations in sea surface temperature has a significant impact on rainfall variability and extremes, such as multi-year droughts and pluvials. Ocean variability makes droughts more intense and modulates the duration of short-term dry spells. However, interannual variability in the oceans does not significantly affect the duration of droughts longer than 3 years. On the other hand, in a world with no year-to-year ocean variability, multi-year dry spells can last longer than oceanic-driven droughts. This can be explained by the influence that ENSO has over the tropics:ENSO is a crucial phenomenon for restoring droughts and pluvials. In the absence of ocean variability, there is no dominant climate driver that can act to terminate extended dry or wet periods.

# Decadal variability and predictability in the Southern Ocean - implications for interpreting recent observed trends

*Liping Zhang[1,2], Thomas L Delworth[2], William Cooke[2,3], Xiaosong Yang[2,3]

1. Princeton University, 2. Geophysical Fluid Dynamics Laboratory, 3. UCAR

While decadal variability and predictability in the North Atlantic and North Pacific have received considerable attention, there has been less work on decadal variability and predictability in the Southern Ocean. As shown previously, a coherent mode of decadal to centennial variability exists in multiple climate models. The mechanism involves a multidecadal accumulation of heat in the subsurface of the Southern Ocean, which is then rapidly discharged through intense oceanic convection when the accumulation of subsurface heat reduces the stratification of the water column. The release of this accumulated subsurface heat can have considerable regional scale climatic impacts, along with substantial impacts on ocean heat uptake. Using a large suite of perfect predictability experiments, in concert with long control simulations, we show that this variability has a high degree of predictability. We present further results that show this type of variability may play an important role for interpreting recently observed trends of sea ice and temperature in the Southern Ocean. Specifically, observed trends over the last several decades resemble a particular phase of this variability in which reduced oceanic convection leads to subsurface warming and surface cooling, with associated increases in sea ice extent. This phase of natural variability may substantially contribute to observed decadal trends, working in concert with other factors.

## [A-OS10] Atlantic climate variability, and its global impacts and predictability

convener:Ingo Richter(JAMSTEC Japan Agency for Marine-Earth Science and Technology), Hiroki Tokinaga(Research Institute for Applied Mechanics, Kyushu University), Noel S Keenlyside(Geophysical Institute Bergen), Carlos R Mechoso(University of California Los Angeles), Chairperson:Hiroki Tokinaga(京都大学白眉センター), Ingo Richter

The Atlantic Ocean is subject to pronounced climate variations that occur on a wide range of time scales, including interannual variability in the equatorial and subtropical regions, and Atlantic multi-decadal variability (AMV), which has been linked with the Atlantic meridional overturning circulation (AMOC). These are connected to other climate variations across the globe. The AMV, e.g., has long been known to have global impacts, such as changes in the Indian, Asian and South American summer monsoons, and changes in the Pacific associated with the "global hiatus". Interannual variability in the equatorial and subtropical Atlantic has also been shown to influence global climate, including over Asia, while the freshening of the North Atlantic by melting of the Greenland ice cap is expected to influence all ocean basins via atmospheric bridges. Likewise, misrepresentation of the Atlantic can have global ramifications in climate models. Misrepresentation of the AMOC, e.g., has been associated with model biases in the entire Northern Hemisphere.<br/><br/>This session seeks observational, modeling, and theoretical studies on the mechanisms that determine the Atlantic mean climate and variability, as well as the predictability and global impacts of such variability. We also seek studies that evaluate climate model performance in the region. Topics include atmosphere-ocean-cloud interactions in the tropical Atlantic and their remote impacts; relationships between tropical and mid/high latitude variability; air-sea interaction along the Gulf Stream and its influence on cyclones and storm track evolution; variability in the Benguela upwelling region; influence of Agulhas leakage on the South Atlantic; coupled climate models biases in the region and their impacts; AMOC and long-term climate change.

A subdecadal (i.e., 3-year-running means) variation over the tropical Pacific is very distinctively observed in the 2000s. Here, we have demonstrated that sea surface temperature (SST) anomalies in the tropical Atlantic contribute to forming high ocean temperature anomalies of the tropical Pacific in the early-2000s, by performing partial data assimilation of global climate model. Low SST over the equatorial Atlantic changes the Walker circulation and the associated weakening of the Pacific trade wind raises the equatorial SST on the subdecadal timescales. At the same time, high SST anomaly is generated also in the off-equatorial North Pacific through deepening of the upper ocean thermocline due to an accompanying anti-cyclonic surface wind anomaly aloft. In addition, the north tropical Atlantic SST may help the subdecadal warming in the equatorial Pacific, similar to the common changes working as a seasonal trigger of the so-called central Pacific El Nino Southern Oscillation event.

# Recent acceleration of Arabian Sea warming induced by the Atlantic-western Pacific trans-basin multidecadal variability

*Cheng Sun[1]

1. Beijing Normal University

The rapid warming of the Arabian Sea (AS) brings an increased risk of extreme weather and climate events,
e.g., flood, heat wave and cyclone. AS warming has significantly accelerated since the 1990s, in particular in the
spring season, stemming from the multidecadal variability of AS sea surface temperature (SST). Here, we show
that this variability is closely related to the Atlantic multidecadal oscillation (AMO). A set of Atlantic pacemaker
experiments with slab mixed-layer ocean model successfully reproduce the AS spring multidecadal variability and
its connection with the AMO. An atmospheric teleconnection from the Atlantic to the AS in the preceding winter
and associated thermodynamic air-sea feedback are found important. The teleconnection can be recreated by the
atmospheric model when the SSTs of AMO and its trans-basin footprint over western Pacific (WP) are prescribed
simultaneously. The WP SST warming associated with AMO positive phase induces a Gill-type Rossby wave
response over the AS, showing an anomalous low and converging southerlies that weaken the winter northerly.
A positive wind-evaporation-SST feedback further develops, leading to the AS SST anomalies being formed and
maintained to the subsequent spring. The concurrent cold-to-warm phase shift of AMO and its WP SST footprint
since the 1990s contributes constructively to the rapid warming of AS. Our results suggest a key role of trans-basin
interactions in the attribution of historical regional SST warming and constraint of projected future warming.

# Westward Wind Changes over the Tropical and Mid-latitude Pacific in the Past Three Decades Driven by the Inter-basin Teleconnections

*Xichen Li[1]

1. Institute of Atmospheric Physics

Due to its active role in the atmosphere-ocean interactions and in the global climate variability, the trade wind regime over the Pacific Ocean has been receiving increased attention. Although the intensification of the equatorial trade wind in recent decades has been widely investigated, the meridional extension of this easterly wind change and the associated mechanism remain unclear. To untangle this problem, we combine observations, reanalysis datasets, and a hierarchy of climate model simulations. Analysis based on measurements and reanalysis datasets show that the intensified easterly wind anomaly is not only confined within the tropical basin, but also extends to the mid-latitude Pacific, from 40˚S to 40˚N. In the tropics, the trade wind change is primarily attributed to the enhanced Walker circulation driven by the inter-basin teleconnection and further the decadal variability over the Atlantic and the Pacific oceans, whereas in the mid-latitudes, the changes in sub-tropical highs and Aleutian Low become more dominant. While the altered winds can contribute to the observed sea surface temperature (SST) changes in both tropical and mid-latitude Pacific, they are not driven by the regional Pacific SST changes. Instead, the wind changes are mostly caused by remote influences originated from the tropical Atlantic and Indian Ocean SST changes through stationary Rossby waves. This finding builds a direct pathway linking the tropical Atlantic and Indian Ocean to the mid-latitude Pacific. This pathway has a broad implication for understanding air-sea interactions and sea level changes over the Pacific, and may have an important impact on the interannual and decadal predictability of the Pacific climate variability, such as Pacific Decadal Oscillation and El Niño –Southern Oscillation.

# On the Usefulness of the Atlantic Multidecadal Oscillation Index for Identifying Origins of North Atlantic Sea Surface Temperature Variability

*Jing Sun[1,2], Mojib Latif[1,3], Wonsun Park[1], Taewook Park[1,4]

1. GEOMAR Helmholtz Centre for Ocean Research Kiel, 2. Ocean University of China, 3. University of Kiel, 4. Korea Polar Research Institute

We provide, on the basis of observations and climate models, an interpretation of the Atlantic Multidecadal Oscillation (AMO) index which is widely used in studies addressing sea surface temperature (SST) variability over the North Atlantic (NA). In particular, the AMO index is often used as an index of the Atlantic Meridional Overturning Circulation (AMOC). The AMO index, defined here as the anomalous North Atlantic SST averaged over 0˚ - 60˚ N, accounts for significant SST variability over the tropical and subpolar NA. Climate models analyzed in this study suggest that the AMOC only accounts for significant SST variability over the subpolar NA. In these models, a low-pass filtered AMO index also is associated with SST variability only over the subpolar NA and tracks well multidecadal AMOC variability. SST variability over the tropical NA has previously been suggested to be largely governed by local surface wind variability, which can be amplified the wind-evaporation-SST feedback, and remote forcing by El Niñ o/Southern Oscillation, the leading mode of interannual variability over the tropical Pacific. The AMO index lumps together SST variability associated with different physical mechanisms, which limits the usefulness of the index to understand the origins of NA SST variability. Our results may help to reconcile seemingly competing results about the role of ocean dynamics in NA SST variability.

# Atlantic Multidecadal SST Signal Modulated by the Low-Frequency Mixed Layer Depth Variability

*Ayako Yamamoto[1], Hiroaki Tatebe[1], Masami Nonaka[1]

1. Japan Agency for Marine-Earth Science and Technology

Atlantic Multidecadal Oscillation (AMO) has conventionally been attributed to the heat transport associated with the Atlantic Meridional Overturning Circulation. A recent study, however, challenged this paradigm and indicated that the North Atlantic basin-wide sea surface temperature (SST) pattern analogous to AMO can emerge owing to the atmospheric stochastic forcings in slab ocean models, without an active ocean. Subsequent studies have disputed this finding, arguing that the cause of the SST warming differ between the slab ocean models and fully-coupled models; however, a consensus is yet to be reached.

In this study, we take an approach to resolve this conundrum, by partitioning the multidecadal SST tendency into a part that is induced by the surface heat fluxes and another by the ocean, using a latest version of a fully-coupled climate model, MIROC6. We found that the heat flux term is primarily responsible for the North Atlantic subpolar SST warming, opposing the cooling caused by the oceanic term, despite that the associated heat flux anomalies are upward. Further decomposition of the heat flux term indicates that it is the mixed layer depth (MLD) deepening that makes the ocean less susceptible for cooling. This MLD variability is essentially induced by the anomalous salinity transport by the Gulf Stream modulated by the multidecadal North Atlantic Oscillation. The tropical North Atlantic SST signal, in contrast, arises due to the surface heat fluxes. Our study thus implies the key role of both air-sea fluxes and the ocean dynamics in the emergence of the AMO signal.

# A High-Resolution Future Wave Climate Projection for the Northwestern Atlantic

*Adrean Webb[1], Tomoya Shimura[1], Nobuhito Mori[1]

1. Kyoto University, Disaster Prevention Research Institute

A high-resolution wave climate projection for the Northwestern Atlantic has been conducted to help assess possible regional impacts under an RCP8.5 climate forcing scenario. Here, NOAA WAVEWATCH III is utilized to resolve the Northwestern Atlantic and US Eastern Coast at approximately 21 km and 7 km, respectively. Hourly wind field forcings are provided by MRI-AGCM 3.2S at a 21 km/lat resolution and the increased temporal frequency and spatial resolution allow for better modeling of large storm events. Climatological (25-year) significant wave height differences between future and historical periods indicate that a seesaw effect will occur, with decreases occurring in the Northwest Atlantic and Gulf of Mexico and increases occurring in the Caribbean Sea. Other notable changes include decreases in incident shoreline energy along the US East Coast. Further details of the projection will be discussed, including underlying wind field changes and extreme wave statistics.

## [A-OS10] Atlantic climate variability, and its global impacts and predictability

convener:Ingo Richter(JAMSTEC Japan Agency for Marine-Earth Science and Technology), Hiroki Tokinaga(Research Institute for Applied Mechanics, Kyushu University), Noel S Keenlyside(Geophysical Institute Bergen), Carlos R Mechoso(University of California Los Angeles), Chairperson:Ingo Richter, Hiroki Tokinaga(京都大学白眉センター)

The Atlantic Ocean is subject to pronounced climate variations that occur on a wide range of time scales, including interannual variability in the equatorial and subtropical regions, and Atlantic multi-decadal variability (AMV), which has been linked with the Atlantic meridional overturning circulation (AMOC). These are connected to other climate variations across the globe. The AMV, e.g., has long been known to have global impacts, such as changes in the Indian, Asian and South American summer monsoons, and changes in the Pacific associated with the "global hiatus". Interannual variability in the equatorial and subtropical Atlantic has also been shown to influence global climate, including over Asia, while the freshening of the North Atlantic by melting of the Greenland ice cap is expected to influence all ocean basins via atmospheric bridges. Likewise, misrepresentation of the Atlantic can have global ramifications in climate models. Misrepresentation of the AMOC, e.g., has been associated with model biases in the entire Northern Hemisphere.<br/><br/>This session seeks observational, modeling, and theoretical studies on the mechanisms that determine the Atlantic mean climate and variability, as well as the predictability and global impacts of such variability. We also seek studies that evaluate climate model performance in the region. Topics include atmosphere-ocean-cloud interactions in the tropical Atlantic and their remote impacts; relationships between tropical and mid/high latitude variability; air-sea interaction along the Gulf Stream and its influence on cyclones and storm track evolution; variability in the Benguela upwelling region; influence of Agulhas leakage on the South Atlantic; coupled climate models biases in the region and their impacts; AMOC and long-term climate change.

Observational studies have identified periods of enhanced ENSO predictability from tropical Atlantic variability. Some works have found that this enhancement is provided by the boreal summer Atlantic Equatorial Mode (EM) impact on the atmospheric processes that trigger the following winter ENSO phenomenon. Other works have found how the variability of sea surface temperature (SST) in the northern tropical Atlantic (NTA) during boreal spring acts as ENSOs optimal predictor. The periods of enhanced ENSO predictability appear in phase with the Atlantic Multidecadal Variability (AMV) but no physical explanation has been posed so far. Here we present a hypothesis that conciliates for the first time the existence of both relationships in observations . The results are tested in CMIP5 PI-Control simulations, which allows consideration of a large number of time-periods in which either the NTA or the EM impact ENSO are tested. Model results are consistent with our hypothesis about the switch for the inter-basin connections and the proposed mechanisms. In addition, the model bias in global SST consisting of too high values south of the equator favors some interbasin teleconnections more than others.

# Interannual variability of Antarctic Intermediate Water in the tropical North Atlantic

*Yao Fu[1], Chunzai Wang[1], Peter Brandt[2,3], Richard J. Greatbatch[2,3]

1. State Key Laboratory of Tropical Oceanography, South China Sea Institute of Oceanology, Chinese Academy of Sciences, Guangzhou, China, 2. GEOMAR Helmholtz Centre for Ocean Research Kiel, Kiel, Germany , 3. Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Interannual variability of Antarctic Intermediate Water (AAIW) in the tropical North Atlantic is investigated using the GECCO2 ocean state estimate and Argo data. AAIW salinity variability near the western boundary is shown to be highly correlated with the western boundary current (WBC) transport on interannual timescales. Northward propagating anomalies are associated with the WBC variability that, in turn, is related to the large-scale wind stress curl forcing by means of the Sverdrup balance. AAIW anomalies also propagate westward with the speed of baroclinic Rossby waves, indicating that the westward propagation of baroclinic Rossby waves also plays a role in the variability of AAIW characteristics. Slow eastward spreading of AAIW anomalies is also identified on decadal timescales. Understanding the observed interannual and decadal variability of AAIW salinity is important to properly interpret salinity changes with respect to changes in the hydrological cycle.

# Understanding the mechanisms of the Atlantic meridional climate variability

*Hyacinth C Nnamchi[1], Riccardo Farneti[2], Noel S Keenlyside[3], Fred Fred Kucharski[2], Mojib Latif[1]

1. GEOMAR Helmholtz Centre for Ocean Research Kiel, Kiel, Germany, 2. Abdus Salam International Centre for Theoretical Physics, Trieste, Italy, 3. Geophysical Institute, University of Bergen, and Bjerknes Centre for Climate Research, Bergen, Norway

Decadal climate variability over tropical Atlantic is dominated by the Atlantic meridional mode (AMM). The AMM is characterized by opposite sea surface temperature anomalies to the north and south of the equator, anomalous wind flow from the cooler to the warmer hemisphere and meridional shift of the inter-tropical convergence zone. The tropical variability has also been linked to meridional variability in the South Atlantic and the extratropics of North Atlantic, with far-reaching impacts over the adjacent continents. The AMM is primarily understood in terms of the thermodynamic ocean-atmosphere interactions, particularly, the wind-evaporation sea surface feedback. Using a global ocean model forced by atmospheric observations, this study suggests that the Atlantic meridional overturning circulation may affect the Atlantic-scale meridional climate variability.

# The corss-equatorical gradient variability: The role of heat, momentum, and freshwater flux

*Takahito Kataoka[1]

1. JAMSTEC Japan Agency for Marine-Earth Science and Technology

The ocean-atmosphere feedback associated with the thermodynamic coupling among wind speed, evaporation, and sea surface temperature (SST), called the wind-evaporation-SST (WES) feedback, contributes to the cross-equatorial SST gradient over the tropical oceans. By conducting an eigenanalyses of simple linear air-sea coupled models, it is shown that three additional feedback processes are present when the variable oceanic mixed layer depth (MLD) is considered. The horizontal structures of the leading modes are similar to the WES mode, which shows a meridional dipole in the SST anomalies straddling the equator with cross-equatorial wind anomalies that represent the weakening/strengthening of the trade winds over the warm/cool SST anomalies.
In the presence of the damping term, the WES mode exists as a least damped mode consistent with previous studies. When the buoyancy flux anomaly associated with the latent heat flux anomaly is considered, a similar dipole mode in obtained, but the decaying time scale is about 40 % smaller. The freshwater flux coupling also gives a cross-equatorial gradient mode, but its stability is even smaller (decaying time scale is about 30 % of that of the WES). On the other hand, the momentum coupling allows a strongest meridional dipole variability, which is weakly unstable, indicating the importance of the wind mixing effect on the tropical meridional modes.

# Generation mechanisms of the Benguela Nino with a focus on local amplification

*Tomoki Tozuka[1], Ryo Kobayashi[1]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Benguela Nino is associated with positive sea surface temperature (SST) anomalies off the west coast of Angola and Namibia in the South Atlantic. Although both local and remote forcing have been indicated to contribute to the development of Benguela Nino, the reason why their relative contribution varies among the events has not been clarified. Thus, the generation mechanisms of the Benguela Nino are investigated in this study by categorizing the events into locally amplified and non-locally amplified events depending on whether alongshore wind anomalies contribute to the development of the Benguela Nino. It is found that the locally events are associated with alongshore northerly wind anomalies related to anomalous weakening of the subtropical anticyclone in the South Atlantic known as St. Helena High and the continental low named Angola Low. On other hands, no alongshore wind anomalies that favor the development of SST anomalies exist in the non-locally amplified events. A mixed layer heat budget analysis reveals that the surface heat flux term is greater in the locally amplified events owing to smaller latent heat release associated with the weakening of the climatological southerly winds, while the anomalous warming by the advection term is stronger in the non-locally amplified events.

# Seasonal energy analysis for baroclinic waves in equatorial Atlantic through a diagnostic scheme for energy flux

*Qingyang Song[1], Hidenori AIKI[1]

1. Institute of space-earth environmental research, Nagoya University

This study applied a gravity-reduced ocean model to simulate three baroclinic normal modes covering 20 years for energy analysis in Atlantic Ocean. The model, considering lateral mixing, is driven by decomposed wind forcing for each mode. Energy flux were calculated through a recently proposed diagnostic scheme with model output for all the three modes. The scheme is capable of altering pressure flux to the direction parallel to group velocities of Rossby and mixed Rossby waves in equatorial region (4° N to 4°S) without affecting the divergence. The obtained annual energy flux confirmed the dominant of westward Rossby waves in the northern and southern part of the equatorial region, while eastward Kelvin and mixed Rossby waves are most prevail in central and eastern part. The results are consistent with the fact that in the west tropical Atlantic, the most prominent signal is annual and in the central and east Atlantic, is semi-annual. Additionally, three monthly averaged energy flux revealed the seasonal energy cycle of baroclinic waves in equatorial Atlantic. Two energy sources in August and April emerged in western (around 35°W) and central part (around 15°W) of the equator in Atlantic ocean respectively. Those results suggested that the energy flux calculated by new proposed scheme in Atlantic Ocean can provide a powerful tool for energy analysis making significant contributions for further climate predictions.

Amazonian rainfall plays a critical role in the global climate system and the hydrological cycle. It is thus important to quantify changes in the Amazonian rainfall and clarify its mechanism. Previous studies indicate that the interannual variability of Amazonian precipitation could be largely attributed to variabilities in the South American monsoon system and the El Niño Southern Oscillation. However, the trend of the wet season tropical Amazonian precipitation during recent decades is not very well investigated. In this study, by combining both satellite and in situ observations, it is revealed that tropical Amazonian precipitation has significantly increased by~180 to 600 mm (in different datasets) in the wet season during the satellite era from 1979 to 2015. We then use a state-of-the-art atmospheric model to simulate the impact of the tropical sea surface temperatures (SSTs) on the precipitation changes. Results show that the multidecadal warming of the tropical Atlantic has contributed more than half of this precipitation change over the past three decades, while the east Pacific cooling plays a secondary role. We finally combine the simulation results and the reanalysis data to investigate the mechanisms of this process, i.e. the SST variability dramatically increases the convergence of the moisture transport over the Amazon region. The precipitation changes over the Amazon region largely impact on the local hydrological cycle and the ecosystem, and have important impacts on the global climate system by mediating the teleconnection between the Pacific and the Atlantic oceans. Our results show that the long-term change in the wet season Amazonian precipitation is important and deserves further investigation and discussion.

# Linear inverse modeling of the tropical Atlantic

*Ingo Richter[1], Ping Chang[2]

1. JAMSTEC Japan Agency for Marine-Earth Science and Technology, 2. Texas A&M University

The tropical Atlantic features variability at interannual and decadal time scales that is known to have a strong influence on the surrounding continents and possibly other ocean basins. Current prediction systems, however, struggle to skillfully predict sea-surface temperature (SST), let alone its impact on rainfall over the adjacent continents. It is often assumed that this poor prediction skill is due to the severe SST biases and misrepresented variability patterns that most models feature in the region but this has recently been called into question.

In the present study, we construct a simple statistical model of the tropical Atlantic to 1) investigate the influence of model biases on prediction skill, and 2) establish a benchmark to evaluate dynamical model against. Using 35 fully coupled ocean-atmosphere GCMs from the pre-industrial control experiment (piControl) of the Coupled Model Intercomparison Project Phase 5 (CMIP5) we construct a linear inverse model (LIM) for each GCM based on tropical SSTs only. The LIM thus constructed is then used to predict SSTs for the period 2000-2017 from the NCEP/NCAR reanalysis. These predictions are compared to those from a LIM constructed using the NCEP/NCAR reference for the period 1948-1999 as training data. Since each of the model LIMs is constructed from more or less unrealistic variability patterns one would expect to see a clear impact on prediction skill.

The results, however, indicate that prediction skill in the tropical Atlantic is relatively insensitive to the tropical variability patterns of each model. Only some cases see a marked deterioration of prediction skill relative to the reference model. The LIM performs well in the subtropical north and south Atlantic. In the equatorial Atlantic, on the other hand, skill is rather poor at 3 months lead time, though clearly above persistence. Our analysis suggests that in many CMIP5 models misrepresentation of variability should not be a major stumbling block toward skillful prediction. This indicates that the current lack of prediction skill in the region is due to other factors, such as model initialization or inherent predictability limits due to noise.
Comparing several dynamical hindcast experiments with the LIM constructed from observations, we find that the LIM generally has superior prediction skill over most parts of the tropical Atlantic.

# Relationships Among Inter-model Spread and Biases in Tropical Atlantic Sea Surface Temperatures

Elsa - Mohino Harris[1], *Belen Rodriguez-Fonseca[1,2], Teresa - Losada[1], Irene - Polo[1], Roberto - Mechoso[3]

1. Department of Physics of the Earth and Astrophysics, Universidad Complutense de Madrid, 28040, Madrid, Spain. , 2. Institute of Geosciences IGEO,UCM-CSIC, 28040, Madrid, Spain., 3. Department of Atmospheric and Oceanic Sciences, UCLA, Los Angeles, USA

State-of-the-art general circulation models show important systematic errors in their simulation of sea surface temperatures (SST), especially in the Tropical Atlantic. In this work the spread in the simulation of climatological SST in the Tropical Atlantic by 24 CMIP5 models is examined, and its relationship with the mean systematic biases in the region is explored. The modes of inter-model variability are estimated by applying Principal Component (PC) analysis to the SSTs in the region 70ºW-20ºE, 20ºS-20ºN. The inter-model variability is approximately explained by the first three modes. The first mode is related to warmer SSTs in the basin, shows worldwide connections with same-signed loads over most of the tropics and is connected with lower low cloud cover over the eastern parts of the subtropical oceans. The second mode is restricted to the Atlantic, where it shows negative and positive loads to the north and south of the equator, respectively, and is connected to a too weak Atlantic Meridional Overturning Circulation (AMOC). The third mode is related to the double Intertropical Convergence Zone bias in the Pacific and to an interhemispheric asymmetry in the net radiation at the top of the atmosphere. According to the results, the most important of these contributors for SST biases spread in the Tropical Atlantic is the second mode, with models having stronger biases simulating weaker AMOCs.

# Revisiting the CMIP5 Thermocline in the Equatorial Pacific and Atlantic Oceans

Antonio - Castaño[1,2], Elsa - Mohino[1], *Belen Rodriguez-Fonseca[1,2], Teresa - Losada[1]

1. Department of Physics of the Earth and Astrophysics, Universidad Complutense de Madrid, 28040, Madrid, Spain., 2. Institute of Geosciences, IGEO, UCM-CSIC 28040, Madrid, Spain.

The thermocline is defined as the ocean layer for which the vertical thermal gradient is maximum. In the equatorial ocean, observations led to the use of the 20˚C isotherm depth (z20) as an estimate of the thermocline. This work compares z20 against the physical thermocline in the Equatorial Atlantic and Pacific Oceans, using SODA reanalysis and CMIP5 Pre-Industrial Control simulations. Our results show that in models z20 is systematically deeper and flatter than the thermocline and does not respond correctly to surface wind stress variations. It is also shown that the annual cycle of z20 is much weaker than that of the physical thermocline. This happens in both equatorial basins and indicates that z20 does not react to the same mechanisms as the thermocline. Possible consequences in the assessment of air-sea coupling in current GCMs and bias reduction strategies are also suggested, as well as possible effects in the representation of upwelling systems in the tropical region.

Keywords: CMIP5, defining thermocline, tropical atlantic, air-sea interactions

# Lagged Effects of North Atlantic SST Anomalies on Weather in Remote Areas

*Natalia Gnatiuk[1], Timo Vihma[2], Leonid Bobylev[1]

1. Nansen International Environmental and Remote Sensing Centre, 2. Finnish Meteorological Institute

Polar climate has experienced dramatic changes during observed global warming. These changes in turn have, as hypothesised, strong influences on the mid-latitude weather. Many proposed linkages focus on the effects of changes in sea ice, sea surface temperature or terrestrial snow pack on the air temperature in selected mid-latitude areas. Our hypothesis is that from the point of view of the atmosphere, it does not matter whether the thermal forcing from the surface originates from sea ice melt, terrestrial snow melt, or changes in SST. Most important is to quantify how the atmosphere responds to anomalies in surface temperature, and how the local/regional responses may affect weather patterns in remote areas. By analysing these responses systematically in global scale, we can identify the regions and seasons where/when the response is strongest. Comparing these regions/seasons to observed changes in sea ice, terrestrial snow, and open ocean SST, we will obtain information on the relative importance of forcing from these three factors. For this purpose, we studied the relationships between anomalies in the surface temperature (Ts) in the Northern Hemisphere (on grid $1.5^{o}$-$1.5^{o}$) and 2-m air temperature (T2m) in selected 13 study regions in Europe, Greenland, and parts of Asia and North Africa for the period 1979-2018 based on the ERA-Interim reanalysis. Applying also detrended data, we eliminated spurious correlations resulting from similar trends in the two variables.

We detected significant correlations between the surface temperature over the Labrador Sea, Canadian archipelago and North Atlantic and 2-m air temperature in different study regions for inter-seasonal spring - summer (MAM-JJA) and autumn - winter (SON-DJF) relationships. Among the strongest correlations between the spring Ts and summer T2m were the positive correlations found between Ts in the North Atlantic and T2m in Scandinavia, Ts in the Labrador Sea and T2m in Northeast Europe, and Ts in Norther Sahara and T2m in Urals. As well, among the strongest correlations between the autumn Ts and winter T2m were the positive correlations found between Ts in the North Atlantic and the Labrador Sea and T2m in Scandinavia and Northwest Africa; and the negative correlations found between Ts in the Labrador Sea and the North Atlantic and T2m in Scandinavia, Northeast Europe, Urals, Black Sea region and Northcentral Asia.

In order to identify thermal forcing factors and to assess their relative importance, we analysed the multiyear averages and anomalies of sea-ice concentration, snow cover and surface heat fluxes. According to the results, in all identified cases, changes in SST mostly were an influencing factor.

Another big challenge was to understand the physical mechanisms responsible for the obtained statistical results. For this purpose, we analysed surface pressure, geopotential heights, wind components, air-mass trajectories, incoming solar radiation, cloud cover, and total precipitation for sub-sets of 10 coldest and 10 warmest seasons in the period 1979-2018. There is a detectable effect on anomalies in the atmospheric pressure field and wind components in these regions.

The research is granted by the “ERA.Net RUS Plus” Initiative, ID 166 and national RFBR project No. 18-55-76004; and partly by RSF grant №. 17-17-01151.

It has been known for some time that SST anomalies in the equatorial Pacific induce same-signed anomalies in the northern tropical Atlantic (NTA) through changes in the Atlantic trade winds. More recently, it has been suggested that the NTA, in turn, can influence the equatorial Pacific through changes in the surface zonal winds over the western part of the basin. The sign of these wind anomalies, however, would act to force equatorial Pacific SST anomalies that are opposite to those in the NTA. The present study takes a closer look at this apparent conundrum by conducting GCM experiments with prescribed SSTs for the period 1982-2014. In the control experiment, observed SSTs are prescribed globally, while in two sensitivity experiments SST anomalies are removed from either the tropical Atlantic or the tropical Pacific. For the control experiment, analysis suggests that NTA warming is accompanied by SST warming and westerly wind anomalies in the equatorial Pacific. When tropical Pacific SST anomalies are removed, on the other hand, NTA warming coincides with easterly anomalies. Moreover, when SST anomalies are removed from the tropical Atlantic, wind variability over the western equatorial Pacific is enhanced. These results suggest that SST anomalies in the NTA, which are strongly influenced by the tropical Pacific, act as a negative feedback to ENSO development. This interbasin link may be further complicated by other influences on the NTA, such as local air-sea coupling and the North Atlantic Oscillation.

## [A-OS10] Atlantic climate variability, and its global impacts and predictability

convener:Ingo Richter(JAMSTEC Japan Agency for Marine-Earth Science and Technology), Hiroki Tokinaga(Research Institute for Applied Mechanics, Kyushu University), Noel S Keenlyside(Geophysical Institute Bergen), Carlos R Mechoso(University of California Los Angeles)

The Atlantic Ocean is subject to pronounced climate variations that occur on a wide range of time scales, including interannual variability in the equatorial and subtropical regions, and Atlantic multi-decadal variability (AMV), which has been linked with the Atlantic meridional overturning circulation (AMOC). These are connected to other climate variations across the globe. The AMV, e.g., has long been known to have global impacts, such as changes in the Indian, Asian and South American summer monsoons, and changes in the Pacific associated with the "global hiatus". Interannual variability in the equatorial and subtropical Atlantic has also been shown to influence global climate, including over Asia, while the freshening of the North Atlantic by melting of the Greenland ice cap is expected to influence all ocean basins via atmospheric bridges. Likewise, misrepresentation of the Atlantic can have global ramifications in climate models. Misrepresentation of the AMOC, e.g., has been associated with model biases in the entire Northern Hemisphere.<br/><br/>This session seeks observational, modeling, and theoretical studies on the mechanisms that determine the Atlantic mean climate and variability, as well as the predictability and global impacts of such variability. We also seek studies that evaluate climate model performance in the region. Topics include atmosphere-ocean-cloud interactions in the tropical Atlantic and their remote impacts; relationships between tropical and mid/high latitude variability; air-sea interaction along the Gulf Stream and its influence on cyclones and storm track evolution; variability in the Benguela upwelling region; influence of Agulhas leakage on the South Atlantic; coupled climate models biases in the region and their impacts; AMOC and long-term climate change.

Amazonian rainfall plays a critical role in the global climate system and the hydrological cycle. It is thus important to quantify changes in the Amazonian rainfall and clarify its mechanism. Previous studies indicate that the interannual variability of Amazonian precipitation could be largely attributed to variabilities in the South American monsoon system and the El Niño Southern Oscillation. However, the trend of the wet season tropical Amazonian precipitation during recent decades is not very well investigated. In this study, by combining both satellite and in situ observations, it is revealed that tropical Amazonian precipitation has significantly increased by~180 to 600 mm (in different datasets) in the wet season during the satellite era from 1979 to 2015. We then use a state-of-the-art atmospheric model to simulate the impact of the tropical sea surface temperatures (SSTs) on the precipitation changes. Results show that the multidecadal warming of the tropical Atlantic has contributed more than half of this precipitation change over the past three decades, while the east Pacific cooling plays a secondary role. We finally combine the simulation results and the reanalysis data to investigate the mechanisms of this process, i.e. the SST variability dramatically increases the convergence of the moisture transport over the Amazon region. The precipitation changes over the Amazon region largely impact on the local hydrological cycle and the ecosystem, and have important impacts on the global climate system by mediating the teleconnection between the Pacific and the Atlantic oceans. Our results show that the long-term change in the wet season Amazonian precipitation is important and deserves further investigation and discussion.

# Linear inverse modeling of the tropical Atlantic

*Ingo Richter[1], Ping Chang[2]

1. JAMSTEC Japan Agency for Marine-Earth Science and Technology, 2. Texas A&M University

The tropical Atlantic features variability at interannual and decadal time scales that is known to have a strong influence on the surrounding continents and possibly other ocean basins. Current prediction systems, however, struggle to skillfully predict sea-surface temperature (SST), let alone its impact on rainfall over the adjacent continents. It is often assumed that this poor prediction skill is due to the severe SST biases and misrepresented variability patterns that most models feature in the region but this has recently been called into question.

In the present study, we construct a simple statistical model of the tropical Atlantic to 1) investigate the influence of model biases on prediction skill, and 2) establish a benchmark to evaluate dynamical model against. Using 35 fully coupled ocean-atmosphere GCMs from the pre-industrial control experiment (piControl) of the Coupled Model Intercomparison Project Phase 5 (CMIP5) we construct a linear inverse model (LIM) for each GCM based on tropical SSTs only. The LIM thus constructed is then used to predict SSTs for the period 2000-2017 from the NCEP/NCAR reanalysis. These predictions are compared to those from a LIM constructed using the NCEP/NCAR reference for the period 1948-1999 as training data. Since each of the model LIMs is constructed from more or less unrealistic variability patterns one would expect to see a clear impact on prediction skill.

The results, however, indicate that prediction skill in the tropical Atlantic is relatively insensitive to the tropical variability patterns of each model. Only some cases see a marked deterioration of prediction skill relative to the reference model. The LIM performs well in the subtropical north and south Atlantic. In the equatorial Atlantic, on the other hand, skill is rather poor at 3 months lead time, though clearly above persistence. Our analysis suggests that in many CMIP5 models misrepresentation of variability should not be a major stumbling block toward skillful prediction. This indicates that the current lack of prediction skill in the region is due to other factors, such as model initialization or inherent predictability limits due to noise.
Comparing several dynamical hindcast experiments with the LIM constructed from observations, we find that the LIM generally has superior prediction skill over most parts of the tropical Atlantic.

# Relationships Among Inter-model Spread and Biases in Tropical Atlantic Sea Surface Temperatures

Elsa - Mohino Harris[1], *Belen Rodriguez-Fonseca[1,2], Teresa - Losada[1], Irene - Polo[1], Roberto - Mechoso[3]

1. Department of Physics of the Earth and Astrophysics, Universidad Complutense de Madrid, 28040, Madrid, Spain. , 2. Institute of Geosciences IGEO,UCM-CSIC, 28040, Madrid, Spain., 3. Department of Atmospheric and Oceanic Sciences, UCLA, Los Angeles, USA

State-of-the-art general circulation models show important systematic errors in their simulation of sea surface temperatures (SST), especially in the Tropical Atlantic. In this work the spread in the simulation of climatological SST in the Tropical Atlantic by 24 CMIP5 models is examined, and its relationship with the mean systematic biases in the region is explored. The modes of inter-model variability are estimated by applying Principal Component (PC) analysis to the SSTs in the region 70ºW-20ºE, 20ºS-20ºN. The inter-model variability is approximately explained by the first three modes. The first mode is related to warmer SSTs in the basin, shows worldwide connections with same-signed loads over most of the tropics and is connected with lower low cloud cover over the eastern parts of the subtropical oceans. The second mode is restricted to the Atlantic, where it shows negative and positive loads to the north and south of the equator, respectively, and is connected to a too weak Atlantic Meridional Overturning Circulation (AMOC). The third mode is related to the double Intertropical Convergence Zone bias in the Pacific and to an interhemispheric asymmetry in the net radiation at the top of the atmosphere. According to the results, the most important of these contributors for SST biases spread in the Tropical Atlantic is the second mode, with models having stronger biases simulating weaker AMOCs.

# Revisiting the CMIP5 Thermocline in the Equatorial Pacific and Atlantic Oceans

Antonio - Castaño[1,2], Elsa - Mohino[1], *Belen Rodriguez-Fonseca[1,2], Teresa - Losada[1]

1. Department of Physics of the Earth and Astrophysics, Universidad Complutense de Madrid, 28040, Madrid, Spain., 2. Institute of Geosciences, IGEO, UCM-CSIC 28040, Madrid, Spain.

The thermocline is defined as the ocean layer for which the vertical thermal gradient is maximum. In the equatorial ocean, observations led to the use of the 20˚C isotherm depth (z20) as an estimate of the thermocline. This work compares z20 against the physical thermocline in the Equatorial Atlantic and Pacific Oceans, using SODA reanalysis and CMIP5 Pre-Industrial Control simulations. Our results show that in models z20 is systematically deeper and flatter than the thermocline and does not respond correctly to surface wind stress variations. It is also shown that the annual cycle of z20 is much weaker than that of the physical thermocline. This happens in both equatorial basins and indicates that z20 does not react to the same mechanisms as the thermocline. Possible consequences in the assessment of air-sea coupling in current GCMs and bias reduction strategies are also suggested, as well as possible effects in the representation of upwelling systems in the tropical region.

# Lagged Effects of North Atlantic SST Anomalies on Weather in Remote Areas

*Natalia Gnatiuk[1], Timo Vihma[2], Leonid Bobylev[1]

1. Nansen International Environmental and Remote Sensing Centre, 2. Finnish Meteorological Institute

Polar climate has experienced dramatic changes during observed global warming. These changes in turn have, as hypothesised, strong influences on the mid-latitude weather. Many proposed linkages focus on the effects of changes in sea ice, sea surface temperature or terrestrial snow pack on the air temperature in selected mid-latitude areas. Our hypothesis is that from the point of view of the atmosphere, it does not matter whether the thermal forcing from the surface originates from sea ice melt, terrestrial snow melt, or changes in SST. Most important is to quantify how the atmosphere responds to anomalies in surface temperature, and how the local/regional responses may affect weather patterns in remote areas. By analysing these responses systematically in global scale, we can identify the regions and seasons where/when the response is strongest. Comparing these regions/seasons to observed changes in sea ice, terrestrial snow, and open ocean SST, we will obtain information on the relative importance of forcing from these three factors. For this purpose, we studied the relationships between anomalies in the surface temperature (Ts) in the Northern Hemisphere (on grid $1.5^{o}$-$1.5^{o}$) and 2-m air temperature (T2m) in selected 13 study regions in Europe, Greenland, and parts of Asia and North Africa for the period 1979-2018 based on the ERA-Interim reanalysis. Applying also detrended data, we eliminated spurious correlations resulting from similar trends in the two variables.

We detected significant correlations between the surface temperature over the Labrador Sea, Canadian archipelago and North Atlantic and 2-m air temperature in different study regions for inter-seasonal spring - summer (MAM-JJA) and autumn - winter (SON-DJF) relationships. Among the strongest correlations between the spring Ts and summer T2m were the positive correlations found between Ts in the North Atlantic and T2m in Scandinavia, Ts in the Labrador Sea and T2m in Northeast Europe, and Ts in Norther Sahara and T2m in Urals. As well, among the strongest correlations between the autumn Ts and winter T2m were the positive correlations found between Ts in the North Atlantic and the Labrador Sea and T2m in Scandinavia and Northwest Africa; and the negative correlations found between Ts in the Labrador Sea and the North Atlantic and T2m in Scandinavia, Northeast Europe, Urals, Black Sea region and Northcentral Asia.

In order to identify thermal forcing factors and to assess their relative importance, we analysed the multiyear averages and anomalies of sea-ice concentration, snow cover and surface heat fluxes. According to the results, in all identified cases, changes in SST mostly were an influencing factor.

Another big challenge was to understand the physical mechanisms responsible for the obtained statistical results. For this purpose, we analysed surface pressure, geopotential heights, wind components, air-mass trajectories, incoming solar radiation, cloud cover, and total precipitation for sub-sets of 10 coldest and 10 warmest seasons in the period 1979-2018. There is a detectable effect on anomalies in the atmospheric pressure field and wind components in these regions.

The research is granted by the “ERA.Net RUS Plus” Initiative, ID 166 and national RFBR project No. 18-55-76004; and partly by RSF grant №. 17-17-01151.

Thu. May 30, 2019 9:00 AM - 10:30 AM JST | Thu. May 30, 2019 12:00 AM - 1:30 AM UTC | 201B 2F

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz), Chairperson:Adina Paytan(University of California, Santa Cruz)

This session aims to synthetize watershed sciences in order to understand dynamical processes of materials transport and nutrient cycles in watersheds from headwaters to coastal seas. The session will be integrating a variety of research disciplines including limnology, ground water hydrology, coastal oceanography, meteorology, pedology, sedimentology, forestry, agriculture, fishery, ecology, social science and more. This session calls for ideas on new methods for the watershed sciences, such as tracer and molecular technique, hydrological modeling, paleontological approaches, laboratory and field experiments, social-scientific evaluation of ecosystem services and social-ecological systems, and so on, in order to elucidate physical, chemical and biological mechanisms for shedding light on natural phenomena and their changes over time in complex and dynamic watershed systems under human and climate impacts. Through this session, we would like to facilitate interdisciplinary collaboration among participants to create new knowledge on watershed sciences.

## Introduction

Study on relationships between biodiversity and ecosystem functioning (BEF) has attracted social as well as ecological interests because the biodiversity can affect ecosystem processes, especially productivity, which determines provisioning service for humanity. Because of difficulty in accurate measurement of the productivity, however, biomass has been traditionally used as its proxy to assess the BEF. Positive correlations between biodiversity and biomass-based productivity indices have been reported for many plants both in terrestrial and aquatic ecosystems. Such correlations are also true for consumers in terrestrial systems. In aquatic ecosystems, in contrast, the biomass-based BEF relationships are inconsistent among consumer communities: some are positive or convex and others non-significant (Waide et al. 1999).

Such an inconsistency can be explained by vertical diversity, i.e., diversity of trophic positions. In systems with multitrophic interactions, in theory, consumer biomass exponentially decreases with the increasing trophic position, while underlying more primary products. The use of the consumer biomass as a proxy of its productivity is, therefore, inappropriate to view the BEF relationships in complex multitrophic systems, as in the case of aquatic food webs. Considering the multitrophic and multifunctional nature of real food webs, Wang & Brose (2018) recently have constructed a theoretical model to test vertical diversity hypothesis (VDH), predicting that functional diversity across the TPs can enhance trophic biomass flows from basal resources to top predators.

In the multitrophic and multifunctional systems, one of better ways for full-understanding of the BEF is to estimate trophic biomass flows, using carbon ( $\delta^{13}$C) and nitrogen ( $\delta^{15}$N) stable isotope analysis, which is a powerful tool for the food web analysis. Taking advantage of this analysis, Ishikawa et al. (2017) have proposed a novel index of food web properties, integrated trophic position (hereafter, *i*TP), defined as the summed TPs of all taxa in a focal food web weighed by the relative biomass of each taxon. The *i*TP can provide appropriate estimate for ecosystem functioning of vertical diversity because it indicates how many times consumer biomass experiences metabolic turnover as a whole of community within its food web. Here we test how the biodiversity can affect *i*TP for benthic macroinvertebrates in coastal waters of Lake Biwa, focusing on within-lake variation in coastal environments which can alter their local communities and thus food web properties.

## Materials & Methods

We collected benthic macroinvertebrates and their basal food sources from 33 shallow coastal waters of Lake Biwa. For each sampling site, the macroinvertebrates were sorted, identified and counted to

©2019. Japan Geoscience Union. All Right Reserved. 

calculate Shannon-Wiener diversity index ($H'$). For each taxon at each site, its dry mass was measured to calculate its biomass per unit area. Individual taxa and their basal foods at each site were provided for $\delta^{13}C$ and $\delta^{15}N$ stable isotope analysis. After this analysis, we calculated *i*TP, according to Ishikawa et al. (2017).

## Results & Discussion

A total of 27 benthic macroinvertebrate taxa were found in coastal waters of Lake Biwa. In the coastal communities, oligochaetes and chironomids are the most dominant taxa in numerical abundance, while gazing snails and a suspension-feeding bivalve were the most dominant in biomass abundance. Most taxa of grazers and deposit feeders located around TP=2, while carnivorous leeches and a freshwater prawn had the highest TP, regarded as top predators of macroinvertebrate communities.
The community biomass tended to increase significantly but weakly with macroinvertebrate diversity $H'$. By contrast, *i*TP of coastal macroinvertebrate communities markedly increased when they have the higher $H'$ (Fig. 1). The within-lake variation in their *i*TPs was better accounted for not only by the relative biomass abundance of top predators with highest TPs and lower numerical abundance but also by that of deposit feeders with lower TP and highest numerical abundance: the former can increase the relative contribution of predator TPs to the *i*TP, while the latter can have negative effects not only on the *i*TP but also on $H'$ because of its numerical abundance. This is possible explanation for such a correlational pattern of BEF found in the coastal macroinvertebrate communities, empirically supporting the VDH. Our study demonstrated that the *i*TP rather than the consumer community biomass can be a promising indicator for BEF related to vertical diversity in aquatic food webs with multitrophic interactions.

PRESTO, Japan Science and Technology Agency, 6. National Taiwan University, 7. University of Santo Tomas, 8. Department of Biogeochemistry, Japan Agency for Marine-Earth Science and Technology, 9. Faculty of Life and Environmental Sciences, Yamanashi University

The previous our analysis based on the community composition of microalgae and bacteria have shown that; 1) the beta diversity distances of algae and bacteria were significantly different between the four categories of land use in the Yasu River, 2) the ordinations of the sampling sites by the riverine microbial composition can be regressed by the environmental gradients between the sites in the watershed, 3) the diversity indices of bacteria increased with diversity index of algae. The further analyses of elemental composition of epilithic matter, most of which may be constituted from algae and bacteria, were made in order the assess the internal nutrient status of the epilithon. Both phosphorus amount per unit area and chlorophyll per carbon showed a significant positive correlation with phosphorus per carbon ($P < 10^{-8}$). Such ordination may help to realize whether phosphorus availability is limited to sustain the biofilm abundance or microbial activities so as to consider the possible impact of land use on the community composition and diversity of algae and bacteria. The richness of algae decreased with the decline of phosphorus per carbon of epilithic matter whereas that of bacteria was bifurcated. So, the richness and the Shannon diversity index ($H'$) of algae showed a significant positive relationship with the phosphorus per carbon (possible index of phosphorus availability) ($P < 10^{-4}$), whereas those of bacteria showed insignificant relationship ($P > 0.2$). Most of low bacteria richness sites at low phosphorus per carbon corresponded to those where chlorophyll abundance per unit area is relatively high in spite of low phosphorus availability.

Among developing countries in the tropics, urban stream syndrome is primarily driven by multiple environmental stressors, such as nutrient pollution and habitat degradation, due to social-economic developments in the catchment. To aid in environmental mitigation, improved conservation effort was recently set based on the Convention of Biological Diversity Aichi Target 11 that underscores global expansion of protected areas in terrestrial and aquatic environments. As such, this study aims to disentangle the overlaying effects of nutrient pollution and deforestation on benthic macroinvertebrate communities and assess the recent protection efforts in the watersheds of Laguna de Bay, Philippines. Study sites in Silang-Santa Rosa Subwatershed (13) and Marikina Watershed (16) were sampled for benthic macroinvertebrates and surveyed for environmental factors such as land cover and land use patterns, human population density (HPD), and stream physicochemistry including nutrient concentrations. Multivariate and multiple regression analyses on macroinvertebrate assemblages and environmental variables efficiently delineated sites according to degree of human impacts in Silang-Santa Rosa Subwatershed and the status of protection in Marikina Watershed. Canopy openness, HPD, conductivity, dissolved oxygen, and nutrients (total phosphorus, nitrates, ammonia) appeared to be the most important variables in predicting assemblages of benthic macroinvertebrates. This study effectively demonstrated how Silang-Santa Rosa Subwatershed's HPD and canopy openness, as proxies for human activities and deforestation, respectively, impact stream environments and the benthic communities. Furthermore, the recent establishment of Upper Marikina River Basin Protected Landscape inside Marikina Watershed was successfully used to show how freshwater protected areas are effective in combatting stream habitat destruction and biodiversity loss. Our findings timely show the crucial role of freshwater protected areas in conserving stream ecosystems from the effects of unsustainable urbanization in a developing country like the Philippines.

# Ammonium contamination of shallow groundwater beneath vegetable fields in Central Vietnam

*Maeda Morihiro[1], Takuya Fujimura[1], Van Ngoc Tuong Hoang[2], Daisuke Inoue[3], Hidetaka Chikamori[1], Fujio Hyodo[1]

1. Okayama University, 2. Hue University, 3. Osaka University

Nitrogen contamination in shallow groundwater occurs in a coastal area in Central Vietnam. In agricultural fields close to the residential area, high concentrations of $NH_4^+$ and $NO_3^-$ in groundwater was attributed to unintended inflow of livestock wastes and/or domestic wastewater. On the other hand, $NH_4^+$ concentration reaches to several milligrams N per liter even in vegetable fields away from the residential area. The objective of this study was to determine $NH_4^+$ contamination mechanisms of the shallow groundwater without domestic wastewater inflow. In this study, we tested three hypotheses: (i) $NH_4^+$ derived from fertilizer or manure applied to the fields was transported to groundwater thorough soil, (ii) nitrate ($NO_3^-$) produced as a result of nitrification in topsoil was transferred to deep soil and again transformed to $NH_4^+$, or (iii) nitrogen mineralization occurred in deep soil. Soil samples were collected up to 240 cm from a vegetable production field in Quang Thang Commune, Central Vietnam in June (dry season) and November (rainy season) of 2016 and 2017. The groundwater table existed at 57 or 67 cm in June and 33 cm from the soil surface in November. Concentrations of $NH_4^+$ in PVC pipe wells fluctuated between 1 and 3 mg N $L^{-1}$ in accordance with the detection of soil $NH_4^+$ content (5-20 mg $kg^{-1}$) in the 150-240 cm layer. On the other hand, soil $NH_4^+$ was not detected in the 30-80 cm layer whereas it was 2-6 mg $kg^{-1}$ in the 0-10 cm layers, indicating that $NH_4^+$ was not transferred to layers deeper than 30 cm. The absence of a functional gene of dissimilatory nitrate reduction to $NH_4^+$ (DNRA) in the 150-240 cm soil layer shows that DNRA did not occur in this deep layer. Natural abundance values of $^{15}N$ ($\delta^{15}N$) for soil $NH_4^+$ (+3.6 to 5.5‰) were similar to those in soil total N (+1.9 to 3.6‰) in the 150-240 cm layer. In addition, anaerobically incubated soil from the 140-160 cm layer was mineralized by 1-2 mg $NH_4^+$-N $kg^{-1}$ for 8 weeks. These experimental results suggest that the high concentration of $NH_4^+$ found in wells was originated from mineralization of deep soil.

Keywords: ammonium , dissimilatory nitrate reduction to ammonium, nitrogen mineralization

# Modelling nutrient and organic waste behaviour in a tropical wetland in Singapore under projected anthropogenic scenarios

*Swee Yang Edmund Low[1], Dong Eon Kim[1], Canh Tien Trinh Nguyen[1], Yixiong Cai, Shie-Yui Liong[1]

1. National University of Singapore

Nee Soon swamp forest is one of the last vestiges of tropical wetland in Singapore, and is important both as a site for ecological preservation, as well as a source of water for potable treatment. Understanding the hydrological regime of the swamp forest and implications for water quality is critical to guide stakeholders in implementing effective measures to preserve the wetland against anthropogenic impacts. In particular, although current field measurement data do not indicate a concern with organic or nutrient pollution, reviewing the ways in which the wetland responds to elevated waste discharges can help identify potential hotspots, and the impact on the outflow from the catchment which drains into downstream controlled watercourses. An integrated water quality model is therefore developed in this study to investigate spatial and temporal concentrations of DO levels, organic pollution (as quantified by biochemical oxygen demand, BOD), and nutrient pollution (NH3-N and NO3-N) within the catchment’s river network under projected scenarios of upstream wastewater inflow. The model was developed using MIKE HYDRO for modelling the study domain, as well as the MIKE ECO Lab numerical laboratory for characterising water quality processes. Model parameters are calibrated against time series of observed discharges and dissolved oxygen levels at measurement stations along the river network. The calibrated model was then applied to study downstream impact due to elevated BOD and ammonia from upstream wastewater discharge. Over a simulation period of April 2014 to December 2015, the model predicted that a spiked inflow of 400 mg/l BOD and 30 mg/l NH3-N upstream will elevate downstream concentrations at the catchment outlet to an average of 13 mg/l BOD, and 0.7 mg/l nitrogen (NH3-N, NO3-N), from a baseline of 0.4 mg/l BOD, 0.03 mg/l NH3-N, and 0.07 mg/l NO3-N. Levels of DO were decreased from an initial 5.4 mg/l to 3.6 mg/l. Though a scenario of spiked pollutant influx at the swamp forest’s undeveloped upstream sub-catchments is currently unlikely to occur, the outcomes nevertheless will be beneficial for future planning studies in understanding how the water quality of the catchment will be impacted should urban redevelopment works be considered around the swamp forest.

Watershed systems provide various ecological services such as good water quality, regulate water flow, maintain water balance and biodiversity conservation. However, human disturbances greatly affect the water quality and composition of biotic communities. Although anthropogenic changes in freshwater systems were truly evident, studies focusing on the human impacts on tropical watersheds are still limited in developing countries. Thus, this study aims to investigate the response of freshwater macroinvertebrates to varying land use patterns and land cover characteristics in Marikina Watershed, Philippines. For a total of 30 streams, which were categorized into 7 protected, 3 forested, 8 agricultural, and 12 residential streams based on land use and cover in their catchments, were collected benthic macroinvertebrates and measured environmental variables. PCA plots were not able to classify water quality according to land use and was supported with no significant difference in Kruskal –Wallis test. However, water quality of primarily vegetated and primarily non-vegetated sites as well as protected and protected streams had delineation, as accorded with the results of independent *t* - tests with significant differences ($p<0.05$) on dissolved oxygen, conductivity, total dissolved solids and salinity. While the forested streams are clustered together in the NMDS plot but there is no clear pattern in the assemblage of benthic macroinvertebrates. The similarities in the composition of macroinvertebrates could be attributed to the similar magnitude and intensity of landscape alteration of each land use among the streams. Interestingly, the nMDS plot shows strong separation of macroinvertebrate assemblages across gradient of vegetation area (Global $R = 0.388$, $P = 0.001$) and were supported independent *t*- test where with macroinvertebrate diversity, density and abundance of pollution-sensitive taxa on primarily vegetated areas exhibited significant differences from non-vegetated areas ($p < 0.05$). Additionally, biotic indices such as such as SingScore, Average Score per Taxon THAI ($ASPT^{THAI}$), Biological Monitoring Working Party ($BMWP^{THAI}$), and Stream Invertebrate Grade Number Average Level version 2 (SIGNAL 2) reveal significant differences among protection status, land use types and land cover ($p<0.05$). CCA plot also revealed pollution –sensitive taxa with primarily vegetated sites were associated with pollution-sensitive taxa and primarily non-vegetated sites are associated with pollution-tolerant organisms to on CCA plot. The findings of this study demonstrate the effects of land alteration to the macroinvertebrate community and water quality. Furthermore, it emphasizes the importance of vegetation cover and designation of protected areas to have better ecological quality in a watershed. This study thus suggests for an extensive and improved policy development and implementation. Furthermore, extensive biomonitoring and formulation of Marikina Watershed Biotic Index are recommended.

Thu. May 30, 2019 10:45 AM - 12:15 PM JST | Thu. May 30, 2019 1:45 AM - 3:15 AM UTC | 201B 2F

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz), Chairperson:Yasumoto Jun(University of the Ryukyus, Faculty of Agriculuture Department of Regional Agricultural Engineering)

This session aims to synthetize watershed sciences in order to understand dynamical processes of materials transport and nutrient cycles in watersheds from headwaters to coastal seas. The session will be integrating a variety of research disciplines including limnology, ground water hydrology, coastal oceanography, meteorology, pedology, sedimentology, forestry, agriculture, fishery, ecology, social science and more. This session calls for ideas on new methods for the watershed sciences, such as tracer and molecular technique, hydrological modeling, paleontological approaches, laboratory and field experiments, social-scientific evaluation of ecosystem services and social-ecological systems, and so on, in order to elucidate physical, chemical and biological mechanisms for shedding light on natural phenomena and their changes over time in complex and dynamic watershed systems under human and climate impacts. Through this session, we would like to facilitate interdisciplinary collaboration among participants to create new knowledge on watershed sciences.

# Characterization, distribution and degradation of environmental plastics in inland river system of Mongolia

*Batdulam Battulga[1], Masayuki Kawahigashi[1], Bolormaa Oyuntsetseg[2]

1. Department of Geography, Tokyo Metropolitan University, Tokyo, 192-0397, Japan , 2. Department of Chemistry, National University of Mongolia, Ulaanbaatar, 210646, Mongolia

Marine plastic abundance and distribution have been reported toward increasing importance of their behavior as anthropogenic influences on aquatic environment. However, remains of plastics particularly in freshwater are largely unknown. Tributaries in the Selenga River system are important sources of fresh water in Central and Northern Mongolia, although the river system has been alarmed by various kinds of pollution because of growing population and increasing demand of land and resources. Evaluating fate of plastics in the river is vital to assess how the urban system affects plastic pollution in Selenga River. This study aimed to identify the fate of environmental plastics in the Selenga River system of Mongolia.
In 2017 and 2018, totally 18 sampling sites have been surveyed according to geographical locations from the capital city, Ulaanbaatar. Collected plastics were classified as their sizes (micro, meso, macro and mega) and materials such as films, foams, fragments and fibers. Visually sorted plastics identified by FTIR micro-spectroscopy to determine chemical characterization. Furthermore, a degradation index of collected plastics was examined using a ratio of two specific IR absorptions. Invisible microplastics (MP) attached onto the collected plastics were separated mainly from polystyrene foam (PSF), which was the most dominant environmental plastics in the research field. Characterization of the invisible MP was conducted using a digital microscope and an FTIR micro-spectroscopy.
Plastic films and foams were largely occupied in the collected plastics from the researched rivers. Surprisingly great amount of PSF were found in micro and meso size ranges. The results illustrate that on-site fragmentation and degradation of bulk PSF occurred in the research sites probably due to solar radiation and freeze-thaw cycles. A broad range of the degradation index was recorded in micro, meso and macro sized PSF, indicating that various stages of degradation occurred in the river environment. Apart from the other plastics types, PSF was considered as a carrier of invisible MP. A greater diversity of invisible MP types and numbers were found in a microscopic view using a digital microscope on the surface of PSF. Polyethylene (PE) and polystyrene (PS) were major components of the sorbed MP.
This study represents the first detailed examination of the distribution, types and degradation processes of plastics in the Mongolian river system. Environmental plastics were widespread litter in the investigated Mongolian river shores due to low-level of waste management with rapidly growing population and urbanization.

# Multi-site and multi-approach sediment transport modeling in tropical watersheds

*Assefa M Melesse[1], Alemu Osore Aga[2], Hagos Gebreselassie[2]

1. Florida International University, 2. Addis Ababa University

Land degradation and poor watershed management have been the major factors that led to severe soil erosion and hence sedimentation in receiving water bodies and reservoirs. The environmental impacts of sediment transport and loading is highly pronounced in tropical watersheds where rainfall is erratic and torrential and soil and conservation measures are poor. In this study, a soil erosion, sediment yield and transport modeling were conducted in three tropical watersheds in Ethiopia and Kenya. Field plot experiment, model development and evaluation were conducted. The impact of land use, rainfall intensity and slope were evaluated at plot and watershed scales. Three models (WEPP, SWAT and Erosion 3D) were tested and compared. The results indicate that the models performed differently with Erosion 3D and WEPP performed better in sediment load simulation. In the absence of the observed sediment data, sediment rating curves developed and validated were useful and are promising.

Keywords: Sediment flux, Sediment modeling, Erosion 3D, SWAT, WEPP, Tropical watersheds

# Calculation of SS concentration coefficients of river water for each land use by a simple watershed model.

*Seiko Yoshikawa[1], Donglai Ma[1,2], Tadamasa Saito[1,3], Kenji Matsumori[4], Yuko Itoh[5], Masahiro Kobayashi[5]

1. Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization, 2. Graduate Scool, Tsukuba University , 3. Faculty of Agriculture, Ibaraki University , 4. Western Region Agricultural Research Center, National Agriculture and Food Research Organization, 5. Forestry and Forest Products Research Institute

In recent years, sediment-related disasters are increasing due to intensification and localization of rainfall caused by climate change. Although it is difficult to predict the place and extent of sediment-related disasters, we firstly grasp the average concentrations of sediment discharge in recent years and predict increase and decrease in the sediment concentrations when the way of rain changes. Sediment runoff is depend on land use and land cover, conservative measures, topography, climate condition mainly rainfall etc.. Among them, the land use and land cover is expected to be great in normal climate conditions. Here, in order to contribute to the prediction of sediment-related disasters in the future, coefficients that indicate the SS load intensity to rivers of each land use for the river watersheds across the country are calculated using a simple watershed land use model.
Watersheds whose lower ends are observation points of water quality, and whose land use ratios were determined by GIS technique using published database of DEM (GSI, 10B, raster data) and LULC mesh data (JAXA , ALOS AVNIR-2, 10m mesh data). The SS concentration coefficients of paddy, upland, forest, and urban were calculated by applying the below multiple regression equation using the land use ratios and published SS data( Ministry of Environment).

$C = a_1 x_1 + a_2 x_2 + a_3 x_3 + a_4 x_4$

$C$: SS concentration (mg $L^{-1}$) $a_i$ : SS concentration coefficient for land use $i$, $x_i$ : ratio of land use $i$, Land use $i$ : 1;paddy 2;upland fields 3;forest 4;urban

The SS concentration coefficient is 15.4 (lower limit 95% value 12.0 to upper limit 95% value 18.8), 11.5 (7.4 to 15.6), 3.9 (2.6 to 5.1), 11.2 (9.2 to 13.2) for paddy fields, upland fields, forests and urban areas respectively (n=5103).
In order to investigate further in detail, it is necessary to analyze fertilization, soil properties, livestock industry in the watershed, climatic conditions (especially rainfall amount), topographical and geographical features and so on.

# Evaluation of long term variation in water balance and discharge of sediment and nitrogen in the urbanized catchment of Yamato River, using SWAT model

*Kunyang Wang[1,2], Yuta Shimizu[3], Shin-ichi Onodera[1], Mitsuyo Saito[4], Yusuke Tomozawa[1]

1. Graduate School of Integrated Arts and Science, Hiroshima University, 2. Capital Normal University, 3. National Agriculture and Food Research Organization, 4. Okayama University

Land-use changes, freshwater use, and the biochemical flow are important factors affecting the Earth's environmental threshold. In the research topics of Planetary Boundaries (PB), these factors have been defined as entering high-risk levels. One-third of the planet's freshwater resources come from groundwater, and now, in some countries and regions, it is also exposed to the risk of groundwater depletion. Large-scale urbanization brings economic development but also increases the possibility of urban waterlogging.

Yamato river is the highest-level river in Japan. It has a watershed area of 1067 square kilometers, covering almost half area of Nara prefecture. Yamato river catchment includes Nara basin which as an important agricultural base, Nara city and part of Sakai city. The water environment in the catchment is closely related to the healthy life of human beings. Especially in recent years, there are frequent flooding in the catchment. Therefore, the study of Yamato river is very necessary.

This thesis uses the SWAT (Soil and Water Assessment Tool) model and Geographic Information System (GIS) methodology. The SWAT model can not only simulate the water discharge and nutrient load but also find the essence of the change of water environment through the change of parameter sensitivity. Select Coefficient of determination (R2), Nash–Sutcliffe efficiency (NSE), and percentage of bias (PBIAS) as a factor of assessing results and obtained the experimental results with credibility.

It is found that the land use in the basin is mainly manifested in the change from farmland to urban land use type, which probably accounts for 1/3 of the total area of land use type changed. Over a period of 2009-2016, the average of water discharge from the total outlet in the main channel is 2.37 million m3/day while it's 2.06 million m3/day in 1971-1978. As a result of changes in land use, water yield from farmland decreased by 45% compared with the 1970s, while the yield from the city increased by 43%. Among them, Surface runoff generated increase by about 70%. In Sakai and its surrounding cities, surface runoff generated increased by 18% per 100 mm precipitation. Curb length density in the high-density urban area increased about one time. That means Sakai now, in the face of flooding caused by torrential rains, needs to take on higher risks.

Sediment yield reducing by more than 70% from 1988 to 2014. The change comes mainly from the management of the river channel. The non-point source load of nitrate increased from 1096 tons to 1534 tons, this is mainly due to the increase in precipitation and the increase in population. The growth of forests also has a certain impact. This is because the type of land used in farmland and forests, there has a large number of fertilizers on the surface of the soil from human agriculture activities or the decay of animal and plant debris. Under the driving effect of precipitation, it mainly transported by the lateral flow in farmland and forest area and the surface runoff in the urban area, a large part will enter the river channel.

# Causal correlation between water-use of the Tedori River and coastal erosion of Chirihama Nagisa Driveway, Ishikawa, Japan

*Toshihiko Momose[1]

1. Ishikawa Prefectural University

Awarded as the best beach of Japan (Reported by TripAdvisor, Inc. 2016), Chirihama Nagisa Driveway is a sandy beach located in Ishikawa, attracting people as the place that allows for driving cars and even large tourist buses along the shore. The source of the Chirihama sand is debris from Mt. Haku-san, which is transferred by the Tedori River and the Tsushima Current. At the river mouth, the finer sands are transferred to further offshore, and then drifted to further beach such as the Chirihama coast (50 km far from the river mouth). Due to the natural sand drifting process, the Chirihama coast is composed of the sands with fine and uniform grain size, the feature which guarantees for comfortable drive on the beach. The Chirihama coast is a treasure of Ishikawa; however, it faces a crisis of disappearance due to beach erosion.

According to Ishikawa prefectural government, the amount of sand loss of the Chirihama coast is 70000 $m^3$/year and its width decreases at 1 m/year. While the Chirihama coast is disappearing, a large-scale landslide of 1300000 $m^3$ occurred at upstream region of the Todori River in 2015 and the massive derbies moved downstream. The turbid water released for the ocean seemed to contribute to the formation of the Chirihama coast, but there are no reports on the recovery of the Chirihama coast. Where do the sands released from the Tedori River move?

Field investigations along the coast have found that the beach sediment at 4 –5 km far from the river mouth has the same feature as the Chirihama sand. From the viewpoint of recent water-use of the Tedori river, this presentation explains a possible reason why the fine sand released from the Tedori River cannot move to the Chirihama coast.

Keywords: Chirihama Nagisa Driveway, Coastal erosion, Tedori River, River structure

# Role of suspended solids on elemental dynamics in the Selenga River system

*Masayuki Kawahigashi[1], Orgilbold Myangan[2], Bolormaa Oyuntsetseg[2]

1. Tokyo Metropolitan University, 2. National University of Mongolia

Lake Baikal is one of the cleanest lake in the world. However, there are many sources of pollution such as mining, industry and agriculture in the river basin of the main tributary, Selenga River which is flowing into Lake Baikal. Lake Baikal actually face to severe pollution affected by anthropogenic activities in the watershed. Natural cleaning mechanism can still be functioning to prevent pollutants flow into the Baikal. Since suspended solids (SS) in the Selenga River can play a role as carriers of heavy metals and organic pollutants, their dynamics should be addressed to know the mechanism.

Water and sediment samples were collected in the Russian territory from the Mongolian border to the shore of the Baikal including the Selenga Delta. SS samples were further recovered using a glass fiber filter from the water samples. Surface sediments and SS samples were digested with the mixture of nitric acid and perchloric acid for determination of elements using Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES).

Elemental concentrations were changeable depending on SS concentration along the tributary. Changes in SS concentration can be controlled by flow rate of the tributary. The significant relationship were observed between SS and sesquioxides mainly consisting of Fe and Al. Both of Mn and Cr were also common constituents of the SS oxides despite of their low concentration in SS. In contrast, Zn and Cu have no correlation with SS, indicating that they are specifically accumulated onto SS surface at a point where the two elements were released. The concentration of SS gradually decreased accompanied by decrease in heavy metals in SS in the delta region. On the contrary, those elements in the surface sediments increased to downstream in the delta region. Deposition process of SS in the delta can be occurred due to decrease in flow rate by channel bifurcation of tributaries, back water effect from Lake Baikal and SS trapping by vegetation in the delta. The delta has a potential to trap SS, resulting that water quality in the Lake Baikal has been protected of water quality in Lake Baikal.

Keywords: Lake Baikal, SS deposition, channel bifurcation

Discussion

# Relationship between topographical characteristics in catchment area and dissolved iron concentration of river in permafrost area

*Yuto Tashiro[1], Muneoki Yoh[1], Takayuki Shiraiwa[2], Takeo Onishi[3]

1. Tokyo University of Agriculture and Technology, 2. Hokkaido University, 3. Gifu University

[Background]
Dissolved iron flowing out from the wetlands in the Amur River basin is an important nutrient that supports the primary production of phytoplankton in the Sea of Okhotsuk. Therefore, the amount of iron supplied to the sea is supposed to change due to the increase and/or decrease of the wetland area within the Amur basin. However, in the longterm observation of the dissolved iron concentration in the Amur River, the considerably high concentration, which can not be explained by the land-use change of the wetland, was observed in the latter of the 1990s. In the 1990s, because the relatively higher temperature had been continued, Shamov et al.,2014 speculated that permafrost thawing might be caution. Therefore, we hypothesized that permafrost thawing might promote the forming of humid and reductive condition which was suited to dFe generation in active layer, and have been conducting research on the mechanism of dissolved iron production and the distribution of permafrost. It has become clear that permafrost exists under the vegetation called Mari. Mari is the wetland which is covered by hygrophyte and sphagnum in a valley, and thick peat soil is accumulated underground.On the other hand, forest areas where birch or larch are densely spread with thin peat layers on the slope and ridge. Thus, the topographical features such as valley, slope and ridge in the catchment area dominate the vegetation and soil properties, and the dissolved iron cycling. In this study, we focused on the area of the valley as a topographical feature within the catchment area, and researched with the aim to discover the relationship to dissolved iron concentration in the river.
[Materials and Methods]
The research was conducted in the Tyrma River basin, which is a further tributary of the Tributary of the Amur River, in Khabarovsk. This area corresponds to the sporadic permafrost zone. In September 2018, we collected the water from 12 rivers in total; 5 rivers flowing into the Tyrma River and 5 rivers flowing into the Gujar river which is a tributary of the Tyrma River (basin area 7 to 200 km2). After sampling the water, immediately filtration was carried out with a disposable 0.45 $\mu$m filter and stored in polyethylene containers. Dissolved iron concentration was measured by the phenanthroline method after adding a few drops of HNO3- to the sample water to adjust pH <2.
We extracted the valley area using GIS soft "QGIS". The altitude data of field site, a global numerical surface model (DSM) corresponding to a resolution of 30 m by a panchromatic stereoscopic sensor (PRISM) equipped with JAXA 's Land Observing Satellite "ALOS" was used. The catchment area on the upstream side from the sampling point of each river was extracted and the Topographic Position Index (TPI) and the inclination (degree) were calculated. Next, the cells with TPI <0 - [standard deviation of TPI ×1/2] and inclination <3 (degree) were judged as a valley and these areas were calculated. The radius(R) of TPI was set to R = 500 m or R = 1000 m according to the valley width of the river. The reason why the condition of inclination <3 (degree) was added was that if only the condition of TPI was included, even the lower part of the slope was included, so that the valley area could be overestimated.
[Results and Discussion]
Dissolved iron concentrations in some rivers showed a very low concentration of <0.02 mg / L, which is below the detection limit, while others showed high concentrations of 0.37 mg / L. The relationship between these concentration differences and the valley area in the catchment area is shown in Fig.1. In the rivers whose valley area was less than 1 km2, the concentration of dissolved iron was less than 0.05

©2019. Japan Geoscience Union. All Right Reserved. 

mg / L. On the other hand, it was revealed that the concentration of dissolved iron tended to be higher with larger valley area in the catchment area. For the rivers with the low dFe concentrations, the catchment areas ware less than 15 km2, and the valley area occupied as low as 3% or less. The other rivers whose the dissolved iron concentration higher than 0.1 mg / L, the valley area accounted for 5-8% of the catchment area. The flat valley exists along the river is a typical topography in the Tyrma basin. In such places where the inclination is small, since the movement of water is also limited and make the residence time longer, the moisture and reductive environment can be maintained in the active layer on the permafrost, and wetland like Mari which is taken precedence by hygrophyte is widely formed in the valley. As the result, this study showed that Mari covering the valley has the function of dissolved iron generation and dissolved iron flow out into rivers.

Fluoride is leaching to natural water system from volcanic rocks and ashes with alkali volcanic activity along Great Lift Valley in east Africa. Tanzanian people in Great Lift Valley are also suffering drinking water including high fluoride ( > 1.5 mgF/L of WHO) and water shortage. We investigated the groundwater and river water fluoride pollutions in area between Arusha of Mt. Meru watershed and Moshi of Mt. Kilimanjaro watershed in September, 2018 to provide the solutions to these issues as No. 6 of SDGs. We find some results below:

1. Average fluoride content is 4.0 mgF/L in Mt. Meru watershed, and 0.5 mgF/L in Mt. Kilimanjaro watershed.

2. Fluoride concentrates in Na-$HCO_3$ type water, and Fluoride tend to increase with Na and pH.

3. Groundwater fluoride tends to be increasing with residence time, but in recent twenty five years, fluoride is
higher in younger groundwater.
4. Well waters supplied to Arusha city come from the recharge zone of 2,000 m to 3,000 m in altitude of Mt. Meru, and the fluoride content tend to increase with the recharge altitude.

# Development and Application of a System for Measurement of Total Load of Water Quality

*Keiji Takase[1], Yuko Itoh[2]

1. Ishikawa Prefectual University, 2. Forestry and Forest Products research Institute, Japan

Conservation and management of water quality is most important to conserve the water environment as well as to secure good water resource. Water quality has been conventionally controlled by regulation of emission concentration. On the other hand, divergence of emission material and increase of waste water in recent years indicates that the regulation of total emission will be most important. In addition, the knowledge of total load of a material such as nitrogen and phosphorous is fundamental to understand a cycle and mass balance of the material. However, the measurement of water quality load is not so easy because it requires much of time and labor well as high cost. So, we established a new system by which we could easily determine the total load of water quality. In this paper, the system is applied in a forested watershed to discuss validity of the system.

# Water infiltration and uptake around a Japanese cypress growing on a flat upland

*Masahiro Kobayashi[1], Shin-ichi Onodera[2], Yuko Itoh[1], Tadashi Sakata[1]

1. Forestry and Forest Products Research Institute, 2. Graduate School of Integrated and Arts Sciences, Hiroshima University

In forest ecosystems, trees strongly influence the water movement above and below the ground. During rainfall events, some rainwater flows as stemflow, which provides concentrated water input into soil. The redistribution of soil water during periods without rainfall is affected by water uptake by roots. To clarify the effects of trees on soil water dynamics during and after rainfall events, we monitored the distribution and temporal dynamics of the soil water potential around the stem of a Japanese cypress (*Chamaecyparis obtusa*) using a two-dimensional array of tensiometers installed at multiple soil depths and distances from the tree. During rainfall events with wet antecedent moisture conditions, stemflow infiltrated into the soil and recharged the shallow groundwater near the stem. The matric potential often increased at lower positions before upper positions, indicating bypass flow through macropores. After large rainfall events, once the matric potential distribution became uniform horizontally, gravity-driven drainage proceeded. During the drying process, the matric potential decreased markedly proximal to the stem compared to distally. A horizontal gradient in the matric potential was observed in both the shallow and deeper soil layers. This indicates an intense sink caused by water uptake by roots from the deeper soil layer. Upon excavating the roots after monitoring the matric potential, dense fine roots were observed in the deeper soil layer. The tree studied may feed the deeper soil around its root zone with rainwater as stemflow and use the water advantageously following the drying process.

# Innovative Rainfall Simulator Design for Moving Storm Scenarios with Different Storm Patterns

*RAVI KUMAR MEENA[1], SUMIT SEN[2]

1. M.Tech Student, Department of Hydrology, Indian Institute of Technology Roorkee, Roorkee, Uttarakhand, India, 2. Associate Professor, Department of Hydrology, Indian Institute of Technology Roorkee, Roorkee, Uttarakhand, India

Rainfall simulators are widely used in the field of hydrology, biosystem engineering, agronomy, and geomorphology to understand the processes involved in these disciplines. Usually, rainfall simulators are not able to generate spatio-temporal variation in rainfall intensity simultaneously unlike natural conditions. Majority of methods used in rainfall simulator studies assumes that the rainstorm reaches instantaneously and remains steady over an area for a certain time period. Hence, most of the rainfall experiments ignore the effect of runoff response caused by moving storm across a watershed which results in under or over estimation of runoff peaks. Considering these limitations of traditional rainfall simulators, we are developing an advanced rainfall simulator using eleven full cone nozzles to simulate moving front storm. These nozzles can generate rainfall intensity in the range of 65 to 190 mm/hr at a pressure range of 50 kPa to 180 kPa with a varying height from 1.5m to 4m above the ground surface. All the eleven nozzles are controlled by flow control valves and the valves are individually regulated by servo motors. Arduino Mega microcontroller system is used to control all the servo motors to generate variable rainfall intensities. Further, we have developed a mobile application for Android users to regulate all the valves of rainfall simulator. This simulator is able to simulate nearly natural rainfall conditions in the controlled environment in four different patterns i.e. uniform, advanced, delayed and intermediate. A tray of 250cm×140cm×50cm has also being designed and fabricated to conduct different hydrological experiments. This tray is designed with a provision to generate and record overland, subsurface and base flow. Tray area can also be divided in three partition to analyze three different soil conditions simultaneously. Slope adjustment, leachate collection unit and piezo metric head measurement unit are also incorporated in this experimental tray. Overall, the whole rainfall simulator with tray can be used to study the impact of moving storm on soil erosion, infiltration, and runoff in the simulated near natural environment along with pollutant transport mechanisms. This study is being focused on detailed analysis of moving storms and their impact on hydrograph characteristics, especially in terms of time of concentration (tc), time to peak (tp), and peak discharge (Qp) for two different storm directions (upstream and downstream) with different storm movement velocity and rainfall intensity.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

Thu. May 30, 2019 3:30 PM - 5:00 PM JST | Thu. May 30, 2019 6:30 AM - 8:00 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_5

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz)

This session aims to synthetize watershed sciences in order to understand dynamical processes of materials transport and nutrient cycles in watersheds from headwaters to coastal seas. The session will be integrating a variety of research disciplines including limnology, ground water hydrology, coastal oceanography, meteorology, pedology, sedimentology, forestry, agriculture, fishery, ecology, social science and more. This session calls for ideas on new methods for the watershed sciences, such as tracer and molecular technique, hydrological modeling, paleontological approaches, laboratory and field experiments, social-scientific evaluation of ecosystem services and social-ecological systems, and so on, in order to elucidate physical, chemical and biological mechanisms for shedding light on natural phenomena and their changes over time in complex and dynamic watershed systems under human and climate impacts. Through this session, we would like to facilitate interdisciplinary collaboration among participants to create new knowledge on watershed sciences.

# Phosphate Enrichment Hampers Development of Juvenile Acropora digitifera Coral by Inhibiting Skeleton Formation

Mariko Iijima[1], *Yasumoto Ko[1], Jun Yasumoto[2], Mina Hirose[3], Mitsuru Jimbo[1], Shugo Watabe[1]

1. Kitasato University School of Marine Biosciences, 2. Faculty of Agriculture, University of the Ryukyus, 3. Tropical Technology Plus

Coral reef degradation resulting from various types of local stress on corals such as excessive nutrient enrichment in and gravel inflow into coastal waters is of an increasing global concern. Because tropical and subtropical seawaters are generally poor in nutrients and thus oligotrophic, these stresses are thought to result in the decline of environments favorable to coral growth. Inorganic phosphates have been especially considered to possibly inhibit the formation of coral skeleton. Despite many studies available on the effects of nutrients on corals, a clear consensus for how nutrients exert deteriorative effects on the corals has not been established satisfactorily. Recently, we found that biogenic polyamines react with carbon dioxide ($CO_2$) and accelerate an aragonite formation of calcium carbonate ($CaCO_3$) in seawater. In this study, we examined the effects of phosphates and nitrates on *in vitro* aragonite formation of $CaCO_3$ by using biogenic polyamines and *in vivo* aragonite formation of juvenile coral *Acropora digitifera* skeletons, showing that phosphates clearly inhibited both *in vitro* and *in vivo* $CaCO_3$ formations at similar concentrations. In contrast, nitrates inhibited neither *in vitro* aragonite formation of $CaCO_3$ nor *in vivo* aragonite formation of juvenile coral skeletons. These findings indicate that phosphates have a detrimental effect on bioinorganic coral calcification. Furthermore, the findings that phosphate enrichment inhibits coral skeleton formation led us to conclude that enriched phosphate is adsorbed on juvenile coral skeleton surface and inhibits inorganically normal development of juvenile coral skeleton.

# Modeling chlorophyll-a concentration using remote sensing in shallow water systems: Comparison of sensors

*Assefa M Melesse[1], Tara Blakey[1], Mohammad Haji Gholizadeh[1], Mohd Manzar Abbas[1]

1. Florida International University

The level of productivity in the upland and coastal water bodies is highly linked to land processes (land use, water management, water and nutrient fluxes). Understanding the linkage between these processes and the level of algal blooms in the water bodies is crucial for improving water quality. A comparative study was conducted using remote sensing data from three different sensors (SeaWIFS, MoDIS and Landsat) to evaluate the capability of reflectance data from these sensors for estimation of chl-a concentrations in three water bodies in the USA (Lake Okeechobee, Florida Bay and Chesapeake Bay). Observed chl-a data were gathered and compared with simulation results. The analysis found that all of the sensors have performed well in deeper water bodies than in shallow sections due to the bottom reflectance from non-algal blooms. For shallow water bodies, selection of the proper bands and band combinations, identification of the non-algal bloom reflectance and the corresponding algorithms can improve the simulation. Seasonality as well as spatial variability (using cross-sections) were evaluated and the results showed that chl-a values were highly variable for the selected summer months. Indicative of the effect of land surface fluxes of nutrients, chl-a values were higher closer to coastal areas in the Florida bay and Chesapeake Bay. The chl-a in the freshwater lake of Okeechobee was simulated using Landsat 8 data and the results found were very good. Comparison of the SeaWIFS and MoDIS chl-a value to that of the measured concentrations in the deeper section of Florida Bay and Chesapeake Bay, respectively showed very good agreement.

Keywords: Chl-a, SeaWIFS, Water qulity modeling, South Florida, Remote sensing

# Dynamics in groundwater flow system with seasonal water table variation in a coastal and island

*Yusuke Tomozawa[1], Shin-ichi Onodera[1], Mitsuyo Saito[2]

1. Graduate School of Integrated Arts and Sciences Hiroshima University, 2. Graduate School of Environmental and Life Science, Okayama University

In islands, freshwater water resources are valuable as living and agricultural use, and dug wells water and reservoirs had been utilized for more than 100 years. In order to use such water resources sustainably, it is important to evaluate groundwater flow as well as water budget.

In this research, we examined to confirm the seasonal variation in water stable isotopic ratios in observation boreholes at the coastal lowland in Ikuchi Island Hiroshima prefecture. Moreover, considering that the target area is coastal, $Cl^-$ concentration was analyzed to evaluate the influence of salt fresh water boundary.

The experimental site is located on Ikuchi Island in Hiroshima prefecture. The highest altitude is 456 m. The basement rock is mainly composed of granite. Annual average precipitation is 1058.8 mm. Observation boreholes are located at the coastal lowland in the southeastern part of the island. The upper site (Site U) with the altitude of 5.1 m asl has 3 boreholes with the depths of 2 m, 15 m, 30 m, the lower site (Site D) with 2.5 m asl has 8 with the depth of 1 m, 2 m, 3 m, 10 m, 15 m, 20 m, 30 m, 40 m, respectively. The water sampling was carried out from monthly to half year interval since 2015. Every samples were analyzed for water isotopic ratios by PICARO and anion component by ion chromatography. Especially samples in January in 2019 were analyzed for CFCs and SF6.

Based on the previous study (Saito and Onodera, 2007), the distinct altitude effect of isotopic ratio in precipitation has been confirmed. Due to spatial and temporal variations in isotopic ratios, recharge process to groundwater was suggested as follows, 1) recharge on site to shallow groundwater (2-3m deep) at D ( $\delta^{18}O$: -7.8 to - 7.4 ‰), 2) river water contribution to the shallow groundwater (2-15m) at U ( $\delta^{18}O$: - 8.3 to - 7.5 ‰), 3) recharge in the mountain slope with the altitude of about 360 m to deep groundwater (30m) at U ( $\delta^{18}O$: - 8.4 to - 8.1 ‰), 4) recharge at 400 m on near the mountain top to deep groundwater (10-30 m) at D( $\delta^{18}O$: - 8.7 to - 8.4 ‰), 5) recharge of precipitation with lower isotope than in present to deeper groundwater (40 m) at D ( $\delta^{18}O$: -8.9 to - 8.8 ‰)

The deepest groundwater (40m) at D had lower isotopic ratios with higher $Cl^-$ concentration (250 to 584 mg / L) during a lower water table in the winter. This indicated the seawater –fresh water boundary rose with water table according to Gyben-Hrzberg concept. These phenomena also suggest to cause the rise of deeper and older groundwater flow line. Consequently, we suggest the lower isotopic ratio in deeper groundwater indicates the immobile water which were recharged in the glacial period. Based on other tracers (CFC, SF 6), we will discuss more.

# The Tracing of Groundwater Contamination Sources in Indonesian Coastal Alluvial Groundwater using $\delta^{34}S$ and $\delta^{15}N$ Isotopes

*Anna Fadliah Rusydi[1,4], Mitsuyo Saito[2], Seiichiro Ioka[3], Shin-ichi Onodera[1]

1. Graduate School of Integrated Arts and Sciences, Hiroshima University, Japan, 2. Graduate School of Environmental and Life Sciences, Okayama University, Japan, 3. Research Institute for Sustainable Energy, Hirosaki University, Japan, 4. Research Center for Geotechnology, Indonesian Institute of Sciences, Indonesia

The coastal area is one of the Indonesian Government priorities as an archipelago country. The groundwater in the area is one of the most reliable clean water resources, therefore it is crucial to understanding the vulnerability of this resource. Our research area was located at Indramayu, a developing rural coastal area in Indonesia, where, the environment was relatively pristine. This research aimed was to identify the effect of natural condition and human activity to groundwater quality by using stable isotope $\delta^{34}S$ and $\delta^{15}N$.

Totally, there were 20 samples taken from groundwater (18) and river (2). The nitrate and sulfate were detected in a total of 5 and 19 samples, respectively. The isotopes composition for isotope nitrate were -11.2 ‰–+22.22‰ for $\delta^{15}N\text{-}NO_3$ and -3.4 ‰–+17.1‰ for $\delta^{18}O\text{-}NO_3$. Moreover, the values of $\delta^{34}S\text{-}SO_4$ and $\delta^{18}O\text{- }SO_4$ were varied from -4.2 ‰–+28.4‰ and +7.3 ‰–+18.8 ‰, respectively. The isotopic signatures of nitrate suggested that the used of inorganic fertilizer and animal manure give the impact to both groundwater and river. Similarly, the isotopic signatures of sulfur were showing that those detected sulfate in the groundwater were mostly coming from fertilizer. Moreover, the soil was mineralized by organic sulfate as well. At one point, located in the fishery area, the groundwater was indicated the seawater contamination. It was shown by the heavy composition of sulfur isotope (28.4‰ for $\delta^{34}S$ and 18.8‰ for $\delta^{18}O$). Lastly, our results showed those combined isotopes of $\delta^{34}S$ and $\delta^{15}N$ along with land-use evaluation could explain the possible sources of groundwater in coastal area at very early urbanization stage.

# Spatio-temporal dynamics of orthophosphate with implications for limitation of phytoplankton growth in north basin of Lake Biwa, Japan

*Xin Liu[1], Rong Yi[1], Masahiro Maruo[1], Syuhei Ban[1]

1. The University of Shiga Prefecture

Orthophosphate ($PO_4$-P) is the main chemical form of phosphorus (P) for phytoplankton growth, often considered as a limiting nutrient for primary production in freshwater ecosystems. However, few information on accurate measurements for $PO_4$-P concentrations in epilimnion of meso- and oligotrophic lakes due to lower than the detection limit (60 nM) of soluble reactive P using traditional spectrophotometrical method. In the present study, we measured $PO_4$-P concentrations using ion chromatography with a detection limit of 5 nM, and determined truly vertical distribution of $PO_4$-P throughout the year with other abiotic and biotic environmental factors in north basin of Lake Biwa, to accurately understand biogeochemical processes of P in this mesotrophic lake.

Field investigations were conducted monthly from April to December 2018 at station K4 (35º19'9.6"N, 136º11'2.7"E; 50 m deep). Phosphate enrichment experiments were also made at each sampling occasion to clarify P limitation for phytoplankton growth. Lake water including phytoplankton assemblage collected from epilimnion (0–20 m) was enriched with 1 $\mu$M of $PO_4$-P (+P) and incubated together with untreated one (control) for 2 days under ambient light and temperature conditions. To evaluate the effect of potentially nutrient-rich bottom water, the filtered bottom water was mixed with untreated epilimnion water including phytoplankton at 1:1 (+B) was incubated at the same conditions as the +P treatment. Phytoplankton growth rate ($g$) was calculated with equation of $g=\ln(C_t/C_0)/2$, where $C_0$ and $C_t$ are chlorophyll *a* (chl. *a*) concentrations at start and end of the experiment, respectively.

Water temperature increased in the epilimnion from May, and strict thermocline was developed from June to September. Chl. *a* concentrations increased from June to July in 10–20 m, and from October to November in 0–20 m. $PO_4$-P concentrations were always low, <20 nM, in the epilimnion from April to June. The concentrations below 30 m increased up to 140 nM in May, but decreased after that until July. In August and September, the concentrations increased up to 30–40 nM even in the epilimnion probably due to disturbance by typhoon. The concentrations below 30 m increased with depth, and the highest values were frequently observed near the bottom, up to 220 nM. On average throughout the water column, $PO_4$-P concentrations were 24–48 nM from April to June, then slightly increased up to 73 nM until September, being constant, 50–63 nM until December.

Total P, total dissolved P, dissolved organic P and particulate P exhibited similar spatio-temporal distributions, but different pattern from those of $PO_4$-P. $NH_4$-N increased in 10–20 m from May to July, whereas the $NO_3$-N increased in the hypolimnion as season progressed. Sestonic C:N:P ratios suggested a terrible P deficiency in July and October when phytoplankton biomass increased.

Phosphate enrichment experiments showed that phytoplankton in the epilimnion was mostly limited with P for its growth. Phytoplankton $g$ in control varied −0.05-0.08 $d^{-1}$, being always lower than those in +P (−0.04-0.44 $d^{-1}$) and/or +B (−0.04-0.49 $d^{-1}$) treatments except for November and December. In November, no growth was found even in +P treatment. This might be caused by nitrogen limitation because of <6 $\mu$M of $NO_3$-N in the epilimnion. The $g$ of control was similar as that of +P and +B (ca. 0.1 $d^{-1}$) in December, indicating that P deficiency for phytoplankton growth was relaxed until December by vertical convection.

©2019. Japan Geoscience Union. All Right Reserved. 

We firstly determined completely vertical distributions of $PO_4$-P in north basin of Lake Biwa from spring to winter, and detected 20–40 nM of $PO_4$-P in the epilimnion. Phosphate enrichment experiments showed that 20 nM of $PO_4$-P might be critical concentration for phytoplankton growth in the lake. No phytoplankton growth even in +P treatment in November implied that nitrogen limitation for phytoplankton growth will be possible in Autumn. Further study for clarify this will be needed.

National Institute of Advanced Industrial Science and Technology, 5. University of the Ryukyus, Faculty of Agriculuture Department of Subtropical Agro-Environmental Sciences

Clean water and sanitation (Sustainable development Goals (6)) is one of the world's important issues. People use groundwater in many areas as a water source, but various cases of contamination by agricultural activities and substances derived from human and animal excrements have been reported.

On the other hand, genetic analysis techniques using molecular biological methods have been applied to the analysis of microbial phase in the water environment.

In recent years, the method using the latest analysis equipment of next generation Sequencer is established, mainly for microorganisms. In addition, new monitoring indices such as environmental DNA have been developed. It is thought that the microbial phase in groundwater varies depending on the influence of various environmental factors and human activity, but the actual condition is not clear.

The next generation Sequencer is a very powerful tool used to grasp the microbial phase in groundwater. It is thought that the microbial phase can be an important indicator in water resource management of basins in the future.

The purpose of this study is to investigate the microbial species and their coexistence in groundwater in the Ryukyu Limestone area using the next generation sequencer.

# Evaluation for temporal variation in groundwater inflow to the lagoons connected to Lake Biwa by radon ($^{222}$Rn) tracer analysis

*Mitsuyo Saito[1], Shin-ichi Onodera[2], Yusuke Tomozawa[2], Kunyang Wang[2], Syuhei Ban[3], Noboru Okuda[4]

1. Graduate School of Environmental and Life Science, Okayama University, 2. Graduate School of Integrated Arts and Sciences, Hiroshima University, 3. School of Environmental Sciences, The University of Shiga Prefecture, 4. Research Institute for Humanity and Nature

Primary production in freshwater lakes and reservoirs are usually controlled by phosphorus (P). Lacustrine groundwater discharge (LGD), direct discharge of subsurface water to lake, is regarded as a potential nutrient paths, including phosphorus from a catchment to lake water environment. There are more than 20 lagoons around Lake Biwa which were originally a part of the lake. These lagoons are regarded to have important functions as settling ponds of inflowing loads from the catchments to Lake Biwa, refuges for shallow water ecosystems and so on. Because these lagoons are connected to Lake Biwa, evaluation of nutrient budget is important for the nutrient cycle in the lake. Some researchers have pointed out the presence of LGD in littoral area of Lake Biwa. However, it has not been evaluated for the lagoons around the lake. In the present research, we aimed to evaluate the temporal variation in groundwater inflow to a lagoon connected to Lake Biwa by radon ($^{222}$Rn) tracer analysis.

The field campaigns were conducted in December 2017, August and October 2018 for the lagoons (Noda-Numa and Hasu-Ike) located on northeastern shore of Lake Biwa. The volume of inflow and outflow, water temperature, electric conductivity, chlorophyll-a and radon ($^{222}$Rn) concentration were measured in the lagoon. $^{222}$Rn is a radioactive element of uranium ($^{238}$U) series with 3.8 day of half-life. $^{222}$Rn is a useful tracer of groundwater discharge because it generally enriched in groundwater than surface water. To examine the temporal variation in groundwater inflow, the time-series $^{222}$Rn concentration in water was obtained. Water samples were collected at the inlet, outlet and near the center of the lagoons and natural springs and groundwater wells around the lagoons. Water and $^{222}$Rn balance suggest that groundwater inflow is larger in Noda-Numa than Hasu-Ike. The catchment topography may influence on this difference. $^{222}$Rn balance-based residence time of lagoon water was estimated 10-20 days in Noda-Numa, and 4-5 days in Hasu-Ike, were similar with that based on water balance. These results suggest the groundwater inflow is a potential phosphorus path to Noda-Numa.

# Br/Cl ratio characteristics of groundwater in coastal areas in Indonesia

*Seiichiro Ioka[1], Shin-ichi Onodera[2], Mitsuyo Saito[3], Anna Fadliah Rusydi[2,4]

1. Institute of Regional Innovation, Hirosaki University, Japan, 2. Graduate School of Integrated Arts and Sciences, Hiroshima University, Japan, 3. Graduate School of Environmental and Life Sciences, Okayama University, Japan, 4. Research Center for Geotechnology, Indonesian Institute of Sciences, Indonesia

The urban development in Indonesia’ s coastal areas has led to an increase of groundwater demand, which then has resulted in groundwater salinization. In this study, we analyze bromide and Br/Cl ratio characteristics, as index of groundwater salinization, in three cities of Indonesian coastal areas, namely: Indramayu, Mataram, and Semarang. Each research site is at different stage of urbanization. Indramayu is in very early stage of urbanization, followed by Mataram as a developing tourism area, and the last one Semarang as a heavy urbanization city. The results show that concentrations of bromide in groundwater are ranged from 0.05 to 38 mg/L in Indramayu, 0.01 to 0.8 mg/L in Mataram, and 0.02 to 8.0 mg/L in Semarang. Furthermore, the occurrence of Br is described in terms of the Br/Cl weight ratio, which allows for small changes in bromide concentrations to be assessed in terms of salinity. Median values of Br/Cl weight ratio in the groundwater of Indramayu, Mataram, and Semarang were approximately 0.0035, 0.0027, and 0.0025, respectively, while the ratio in seawater is generally around 0.0035. The relationship between Br/Cl weight ratio and chloride concentration indicate the groundwater in Indramayu is undergoing salinization due to seawater intrusion compared to the other two areas, meanwhile the groundwater in Semarang is experiencing chloride contamination due to anthropogenic activities based on the study by Andreasen and Fleck (1997).

# Estimation of groundwater recharge and phosphorus transport under different precipitation conditions in a suburban catchment, using SWAT model

*Kunyang Wang[1,2], Shin-ichi Onodera[1], Mitsuyo Saito[3], Noboru Okuda[4], Takuya Okubo[5]

1. Graduate School of Integrated Arts and Science, Hiroshima University, 2. Capital Normal University, 3. Okayama University, 4. Research Institute for Humanity and Nature, 5. University of the Shiga Prefecture

The quantification of the groundwater recharge and phosphorus transport in water is one of the most important indicators of the water cycle in lakes because these processes are related to the transport of large nutrient loads. The Yasu River is one of the important water sources of the Biwa Lake. In this paper, Geographic Information System technology is used to analyze and predict the land use change in the Yasu River Basin. The water balance was simulated using the Soil and Water Assessment Tool. Simulations of different years in different precipitation seasons were carried out. The correlation coefficient and the Nash Sutcliffe coefficient are higher than the reference values. The sensitivity analysis of the parameters reveals the different degrees of sensitivity of the parameters in different water seasons, CN2 always has a high sensitivity during all kinds of water season. The total groundwater recharge and discharge are 180 million $m^3$ and 179 million $m^3$ in the normal precipitation season, respectively. The trends differ in the dry and wet seasons. In the dry season of 2007, the groundwater recharge was below 140 million $m^3$, while it exceeded 240 million $m^3$ in the rainy season in 2003. In addition, the process of phosphorus loss in the basin and release into Lake Biwa are explained from the perspective of space and time. This is closely related to the spatial distribution of the main channel and the time distribution of precipitation. The total amount of nonpoint source pollution of phosphorus in three years is equivalent to 4.08 kg/ha of paddy fields in the watershed. The spatial distribution of phosphorus loss is related to the stream flow, it is mainly concentrated in the area with paddy fields and urban. The time distribution is related to the distribution of the precipitation. With increasing precipitation, the nonpoint source pollution of phosphorus slightly increases. This is due to the driving effect of precipitation on the phosphorus transfer and erosion of soil.

# Losses of phosphorus with soil erosion and nitrate with groundwater recharge in an agricultural catchment, subtropical small island

*Shin-ichi Onodera[1], Mitsuyo Saito[2], Yang Cao[1], Anna Fadliah Rusydi[1], Hide Omae[3], Yoshiko Iizumi[4], Yusuke Tomozawa[1]

1. Graduate School of Integrated and Arts Sciences, Hiroshima University, 2. Graduate School of Environmental and Life Science, Okayama University, 3. JIRCAS TARF, 4. JIRCAS HQ

In tropical and subtropical region, the rainfall intensity is strong and soil erosion in an agricultural land is one of big environmental issues. Especially, the impact of large sediment discharge on the coral reef is serious around small islands, such as Okinawa and Philippines. In case of Okinawa Prefecture, to reduce the sediment discharge and conserve corals, many sediment trap ponds are constructed in a downstream area of agricultural lands. However, sediment deposition rate, variation of trap effect, and component of sediment in a pond have not been confirmed.

To estimate of erosion rate and deposition process of a small pond in an agricultural catchment of a subtropical small island, we examine to observe the sediment deposition in a small pond and monitor water level and chlorophyll a in a pond and runoff and turbidity of an inflow stream in a small catchment with the area of 300m2 in Ishigaki Island, Okinawa Prefecture, Subtropical region. Our monitoring was started from February 2017 after removing all sediment in a pond in January, and up to April 2018. Observation of sediment deposition was conducted with collecting the samples at 5 sites in June 2017 and January 2018. Inflow and outflow water samples were collected every one month.
The sediment deposition was extremely large from January to May 2017, the average erosion rate in all catchment area was estimated to be 6mm. On the other hand, the sediment deposition was nothing from June 2017 to January 2018. Based on the monitoring of stream runoff and turbidity, one big storm event in April with strong intensity mainly contributes to sediment discharge and overflow of the pond occurred. On the other hand, the later period had also big events. This difference is suggested to be the difference of land cover by crops and availability of sediment trap in this pond. In addition, the sediment component mainly was composed of surface soft layer, subsurface sandy layer, and bottom gravel layer. The average thickness was 2cm in surface layer, 100cm in mid sandy layer, and 10cm in gravel layer, respectively. Especially, the surface soft layer had high nutrient content. The dissolved nutrient of inflow stream water and pond water were high concentration. But the 10% of nutrient in the inflow decreased in pond. This means the plankton was produced, using this nutrient and that was deposited later. The soft layer is suggested to be effect of organic fertilizer, it is expected to apply to agricultural lands.

# Phosphate solubilizing bacteria as an indicator of sediment phosphorus in freshwater lakes

*Sreekumari Kurissery[1], Katelynn Crawford[1], Nandakumar Kanavillil[1]

1. Lakehead University, Canada

It has been well documented that phosphorus pollution is one of the most significant factors impeding the overall health of freshwater lakes. Various measures are being taken to reduce phosphorus input into the lakes by anthropogenic activities and thus to maintain a healthy ecosystem. However, it is well known that bioavailable phosphorus tends to bind with substances such as ferric iron and calcium present in the water, become insoluble, and settles into the sediments. The presentstudy has been carried out to understand the relationship between the sediment phosphorus concentration and density of phosphate solubilizing bacteria (PSB) in two lakes in Ontario, Canada, namely, Lake Simcoe and Sparrow Lake. In September 2017, 20cm sediment cores were collected from the nearshore sites of these two lakes to determine the presence of PSB in relation to the sediment phosphorus concentration. PSB could potentially release phosphorus back into the water column through a process called internal phosphorus loading from the inorganic phosphates in the sediment when the right conditions are present. PSB were isolated from the sediment cores at 5 cm intervals by plating on to Pikovskaya’ s agar. Five grams of sediment was used to analyze total reactive phosphorus in the sediment. In Lake Simcoe, PSB ranged from $3x10^1$ to $1.1x10^1$ cfu/g, and the amount of total reactive phosphorus ranged from 0.19 to 0.46 mg/g. In Sparrow Lake, PSB ranged from $4x10^0$ to $3x10^1$ cfu/g and the amount of total reactive phosphorus ranged from 0.21 to 0.39 mg/g. A linear regression was completed to determine the relationship between total reactive phosphorus and PSB for each core. The results showed a negative relationship between these two tested parameters (Lake Simcoe: $r^2$=0.23, $y = -35.34x + 30.811$ $p$=0.5206, and Sparrow Lake: $r^2$ =0.87, $y = -155.9x + 62.322$, $p$=0.067). While PSB density decreased with core depth, the concentration of reactive phosphorus increased. This indicates that the density of PSB in lake sediment may indicate the concentration of total reactive phosphorus and thus the internal phosphorus loading. More study is recommended to confirm the results.

# A Study on the dynamics of various phosphate forms in soil and groundwater in Ryukyu limestone regions

*Masashi Nozaki[1], Jun Yasumoto[2], Yasumoto Ko[3], Hirose Mina[4], Iijima Mariko[3], Ryuichi Shinjo[5], Bam H.N. Razafindrabe[6]

1. University of The Ryukyus, Graduate School of Agriculture,, 2. University of the Ryukyus, Faculty of Agriculture, Department of Regional Agricultural Engineering, 3. Kitasato University School of Marine Biosciences, 4. Tropical Technology Plus, 5. Department of Physics and Earth Sciences, University of the Ryukyus, 6. University of the Ryukyus, Faculty of Agriculture, Department of Subtropical Agro-Environmental Sciences

Phosphorus in water environment exists in various forms and size, such as dissolved, particulate, organic and inorganic forms. However, there are many unclear points in Phosphorus in groundwater. In this study, we tried to understand the dynamics of various phosphate forms in soil and groundwater in Ryukyu limestone regions by combining Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES) and $^{31}$P Nuclear Magnetic Resonance ($^{31}$P-NMR), in addition to Colorimetric (molybdenum blue method). From August 2017 to August 2018, we took groundwater samples in southern part of Okinawa, Japan, with Ryukyu limestone distribution on a monthly basis. We measured pH, electronic conductivity (EC), Oxidation-Reduction Potential (ORP), dissolved oxygen (DO) and alkalinity ($HCO_3^-$) on site, and analyzed major dissolved ion ($Cl^-$, $HCO_3^-$, $NO_2^-$, $NO_3^-$, $SO_4^{2-}$, $Na^+$, $K^+$, $Mg^{2+}$, $Ca^{2+}$), suspended solid (SS) and phosphorus concentration. Phosphorus concentration analyzed 3 different method to molybdenum blue method (Col-P), ICP-AES (ICP-P) and Total P (T-P). Phosphate form analysis used $^{31}$P-NMR.
We compared Col-P and ICP-P in order to understand dissolved phosphorus spatial distribution. The results show that ICP-P is 1.06~49.24 times larger than Col-P. It is inferred that ICP-P is also measuring fine particulate phosphorus and organic phosphorus. As a result, several forms of phosphate without orthophosphate were found in groundwater. Particulate phosphorus was determined by subtracting ICP-P from T-P. A positive correlation (r= 0.78) was found between P-P and SS. According to these results, it is thought that PP adsorbs various forms of phosphate including orthophosphate. We analyzed the correlation between dissolved phosphorus (Col-P, ICP-P) and all measured value in order to understand the characteristics of seasonal variation to dissolved phosphorus. There was a negative correlation between Col-P to water temperature. When focusing on seasonal variation of Col-P, we found that Col-P concentration decreases when water temperature increases. Moreover, Col-P concentration increases as water temperature increases. Through the analysis of various forms of phosphate in soil and SS by using $^{31}$P-NMR, along with orthophosphate, pyrophosphate, pyrophosphate ester, orthophosphate monoester were also detected. It is thus suggested that the phosphate of polymeric or organic forms other than orthophosphate are from plant origin, as a result of microbial activities and microorganism decomposition.

# Impacts of highly concentrated turbid water on the groundwater in the Tedori River alluvial fan, Japan

*Yoichi Fujihara[1], Shunsuke Chono[1], Keiji Takase[1], Eiji Ichion[1]

1. Department of Environmental Science, Ishikawa Prefectural University

The Tedori River alluvial fan in the Ishikawa prefecture is a representative alluvial fan in the Hokuriku region in Japan. The river water is taken by a headworks located at the top of the alluvial fan and is used for irrigation in paddy fields with a total area of about 7,500 ha. Seepages from the riverbed and percolations from the paddy area are the main sources of groundwater in the Tedori River alluvial fan. In 2015, large-scale landslides in the upper reaches of the Tedori River caused a long period of high turbidity in the river. Highly concentrated turbid water with an average concentration of 585 mg/L (a maximum of 4,012 mg/L) has been discharged continuously into the river since May, 2015. This turbidity has caused concerns about the recharge functions of groundwater in the alluvial fan.

In this study, the measurements of paddy percolations and riverbed seepages, before and after the occurrence of high turbidity, were used to examine the influence of these phenomena on groundwater recharge functions in the alluvial fan. We measured water requirement rates in the paddy area in the Tedori River alluvial fan. The measurements were conducted before and after the midsummer-drainage period at >100 paddy fields. We also measured the river discharges in the cross-sections of the river throughout the alluvial fan. The number of cross-sections was 16 and we estimated the riverbed seepages by calculating the discharge differences between the cross-sections.

The results revealed that the amount of paddy percolation decreased significantly due to the turbidity of the river water. The average percolation in the paddy area was found to be 12.4 mm/day in 2014 and 7.9 mm/day in 2016 before the midsummer-drainage period. Moreover, the average percolation in the paddy was found to be 19.6 mm/day in 2014 and 13.7 mm/day in 2016 after the midsummer-drainage period. The volume of the riverbed seepage was observed to have reduced and the seepage section were also observed to have shortened. The observed seepages from the river bed were 4.72 m3/s in 2009 and 3.33 m3/s in 2016 for the irrigation period, whereas for the non-irrigation period, these values were 5.92 m3/s in 2009 and 1.25 m3/s in 2016. Furthermore, the seepage section was found to shorten from 14.2 km to 8.0 km, due to the high turbidity of the water.

Finally, we estimated the amount of groundwater recharge based on these measurements, which revealed that the groundwater recharge from paddy percolation decreased by 270 mm/year (36%), and the recharge from riverbed decreased by 591 mm/year (61%). The total groundwater recharge decreased by 861 mm/year (36%), a value that corresponded to the groundwater level measurements. From these results, we can conclude that the effects of highly concentrated turbid water on the groundwater are quite serious in the Tedori River alluvial fan.

# Altitude effect of water stable isotopic ratio of ravine water and its contribution to groundwater in alluvial plains - Comparison in east and west side catchments of Lake Biwa –

*Yusuke Tomozawa[1], Kunyang Wang[1], Mitsuyo Saito[2], Syuhei Ban[3], Noboru Okuda[4], Shin-ichi Onodera[1]

1. Graduate School of Integrated Arts and Sciences Hiroshima University, 2. Graduate School of Environmental and Life Science, Okayama University, 3. School of Environmental Science, The University of Shiga Prefecture, 4. Research Institute for Humanity and Nature

The stable isotope ratio of hydrogen and oxygen in water is one of useful tracers for hydrological cycle and processes in the catchment scale as well as global. The typical characteristics are spatial or geographical distribution trend such as “altitude effect” or “inland effect”, which are lower in the higher altitude or more inland. Based on these trend, the groundwater recharge area had been estimated. However, the merger of these effects and additional effect such as the seasonal variation of isotopic ratio in precipitation or vapor causes various trend.
In this study, we examined to confirm the altitude effect of water stable isotope ratio and estimate recharge altitude to groundwater in alluvial plains, with comparing in the east and west side catchments of Lake Biwa .
Sampling of spring water in the Serikawa upstream area on the east side of Lake Biwa was conducted in July 2017, December 2017, August 2018. Sampling of ravine water in the Adogawa / Ukawa upstream area on the west side of Lake Biwa was conducted in August 2018. Water samples of spring in the head water and groundwater in the alluvial plain were collected at 11 and 2 sites in the east and at 13 and 2 in the west with measuring EC, pH and DO, respectively. The water stable isotopic ratios were analyzed by PICARO.
Stable isotopic ratios in groundwater were lower than surface water in both east and west. Altitude effects of spring water in the head water were recognizable. This means the surface water in the alluvial plain was mainly contributed from Lake Biwa, whereas groundwater was from the head water. The altitude effect of oxygen stable isotopic ratio was 0.15 - 0.13 ‰/ 100 m on the east side and 0.15 ‰/ 100 m on the west side (only in the upper stream of the Ado River). In addition, the d value of isotopic ratio in the precipitation was 23‰ in the upper Adokawa in August 2018, 18 ‰in Ugawa, and 20 ‰in Serikawa.
We also estimated groundwater recharge elevation and water contribution rate in the upstream region based on these.

Western Region Agricultural Research Center, National Agriculture and Food Research Organization, 3. Forestry and Forest Products Research Institute, 4. Graduate school,Tsukuba University, 5. Faculty of Agriculture, Ibaraki University

Water quality deterioration of rivers caused by leakage of fertilizer components such as nitrogen and phosphorus from paddy and upland fields is a environmental problem. Also, runoff of fertilizer components are expected to increase with the accelerated water and sediment runoff by intensification and localization of rainfall caused by climate change. Although it is difficult to predict the place and extent of heavy-rainfall-related disasters, we firstly grasp the average concentrations of nitrogen and phosphorus and predict increase and decrease in those concentrations when the way of rain changes. Nitrogen and phosphorus runoff is depend on land use and land cover, conservative measures, topography, climate condition mainly rainfall etc.. Among them, the land use and land cover is expected to be a main factor in normal climate conditions. In order to contribute to the prediction of heavy-rain related disasters in the future, coefficients that indicate the total nitrogen (TN) and total phosphorus (TP) load intensity to rivers of each land use for the river watersheds across the country are calculated using a simple watershed land use model. Watersheds whose lower ends are observation points of water quality, and whose land use ratios were determined by GIS technique using published database of DEM (GSI, 10B) and LULC mesh data (JAXA , ALOS AVNIR-2). The TN and TP concentration coefficients of paddy, upland, forest, and urban were calculated by applying the below multiple regression equation using the land use ratios and published TN and TP data( Ministry of Environment).

$c = a_1 x_1 + a_2 x_2 + a_3 x_3 + a_4 x_4$

*C:* TN or TP concentration (mg $L^{-1}$) $a_i$ : TN or TP concentration coefficient for land use *I,* $x_i$ : ratio of land use *I,* Land use: 1;paddy, 2;upland fields, 3;forest, 4;urban

TN concentration coefficient across Japan is 1.67 (from lower limit 95% value 1.34 to upper limit 95% value 2.01), 4.08 (from 3.64 to 4.51), 0.76 (from 0.67 to 0.90), 3.57 (from 3.38 to 3.76) for paddy fields, upland fields, forests and urban areas respectively (n=3256). The TP concentration coefficient is 0.146 (lower limit 95% value 0.119 to upper limit 95% value 0.172), 0.172 (0.138 to 0.206), 0.044 (0.033 to 0.055), 0.267 (0.253 to 0.282) for paddy fields, upland fields, forests and urban areas respectively (n=3256,). Prefectural TN and TP concentration coefficients for paddy and upland fields related only loosely to prefectural surplus N and surplus P. On the other hand, prefectural TN and TP concentration coefficients for forests and urban related to prefectural population densities by logarithmic functions with determination coefficients $R^2$ from 0.45 to 0.48.

# Possibility of nutrients transportation from littoral slope for enhancement of phytoplankton growth in north basin of Lake Biwa

*Syuhei Ban[1], Rong YI[1], Xin Liu[1], Masahiro Maruo[1], Miki Sudo[1], Naoshige Goto[1], Jun Murase[2]

1. The University of Shiga Prefecture, 2. Nagoya University

Nutrient loading from non-point source in a lake ecosystem has not been well recognized yet. In Lake Biwa, total phosphorus (TP) does not decline to the level before eutrophication period, 1960s to 1970s, despite of decreasing the loading from point sources surrounding the lake after that. One of the reasons for no well lowering TP in the lake is attributed to agricultural runoff, in which suspended materials including phosphorus would be deposited to the littoral bottom. In our previous study, subsurface maximum of ammonium as a proxy of dissolved materials from anaerobic interstitial waters in the littoral bottom sediments was found along a transect from littoral to pelagic regions, implying horizontal transportation of nutrients from littoral sediments. There were no such evidences of soluble reactive phosphorus (SRP) yet due to always below the detection limit in the pelagic waters. Recently, we developed modified protocol using an ion chromatography for measuring orthophosphate concentration at nano-molar levels. In this presentation, we’ d like to provide several evidences for horizontal transportation of dissolved nutrients including orthophosphate along a transect from littoral to pelagic sites in north basin of Lake Biwa.

Total of the 6 times transect surveys for determining vertical profiles of nutrients, methane and herbicides were made in 2010-2011. Additional two transect surveys for determining those of nutrients including orthophosphate were made in 16 May and 25 July of 2018. During the 2010-2011 campaigns, *in situ* phytoplankton primary production was measured during the stagnation period using light intensity and chlorophyll *a*concentration monitored by sensors attached to a mooring buoy situated at an offshore station in north basin of Lake Biwa and an equation of photosynthesis - light intensity (P-I) curve.

In 2010-2011 campaigns, we detected sub-surface maximum layer, 20-30 m, of ammonium and methane as a proxy of dissolved materials transported from interstitial water in the sediment of littoral slope. Herbicides, which were used in rice paddy during the rice planting and proxy of materials transported from terrestrial environments surrounding the lake, were also detected in 20-30 m even at the offshore regions in the lake. Primary production monitoring suggested that phytoplankton production depended on some environmental variables other than solar irradiance, e.g. nutrients, until summer months. These results suggested that nutrients for enhancing algal growth might be horizontally transported from sediment in the littoral slope, and that the source of the nutrients might be provided from the drainage of rice paddy.

In 2018 campaigns, sub-surface maximum of ammonium was clearly found along a transect from littoral to pelagic sites in both May and July, but no such sub-surface maximum of orthophosphate was found. Several reasons for failure to find sub-surface maximum of orthophosphate might be proposed. Phosphate would be used by both phytoplankton and bacteria, while ammonium would be used by phytoplankton alone in the euphotic layer. In phosphate limited environment, such as pelagic areas in north basin of Lake Biwa, sub-surface maximum could not be easily detected due to rapid absorption by both phytoplankton and bacteria. Or, a transportation of nutrients from the littoral sloop would sporadically occur, and then we simply missed to detect it. This is on-going research project, and then further studies will be conducted to clarify this issue.

# SWAT model analysis for confirming the effects of crop growth on the suspended sediment concentration from a settling basin catchment on Ishigaki island

*Yang Cao[1], Shin-ichi Onodera[1], Mitsuyo Saito[2], Hide Omae[3], Yoshiko Iizumi[3]

1. Graduate School of Integrate Arts and Sciences, Hiroshima University, 2. Graduate School of Environmental and life Science, Okayama University, 3. Tropical Agriculture Research Front (TARF), Japan International Research Center for Agricultural Sciences (JIRCAS)

Crop growth has a significant effect on soil erosion in small watersheds. Exploring the characteristics and occurrences of soil erosion in small watersheds assists in our understanding of the water and material cycles in agricultural areas. The small catchment on the tropical island of Ishigaki, Japan, was chosen as the research area. The effects of sugarcane growth at different stages on the suspended sediment concentration in the basin from January 2017 to July 2018 were analyzed based on the Soil and Water Assessment Tool (SWAT) model. This study will explore the possible driving factors of these phenomena. The results show that the suspended sediment concentration in the basin reached its highest value on a rainy day near the sugarcane planting period because of the soil relaxation caused by tillage and cultivation. At the end of the sugarcane growth period, the sediment concentration was not at a high level when the rainfall reached 150 mm, because of the effective protection of the soil by sugarcane. The simulated sediment concentration of precipitation per mm showed that the simulated sediment concentration was at its highest during the crop planting period, followed by the period of bare land, and at the lowest during the crop growth period.

# Estimating the runoff of water, sediment, and nutrient using SWAT model in Kikuchi-river watershed, Kumamoto, and the influence of the forest

*Soichiro Fujii[1], Masahiko Kanamori[1], Yuko Nagano[1], Maki Kinoshita[2], Yuta Shimizu[3], Shin-ichi Onodera[4]

1. Japan Forest Technology Association, 2. PASCO Corporation, 3. Western Region Agricultural Research Center, National Agriculture and Food Research Organization, 4. Graduate School of Integrated and Arts Sciences, Hiroshima University

Recently, enclosed sea area such as Ariake-sea have severe nutrient enrichment problem and is decreasing the produce of fishery industry. Such enclosed sea area is commonly affected by river water quality discharged from the land area. Therefore, estimating the load of sediment and nutrient from its land area is important. However, most of researches estimating discharge from land area is conducted by simple method using primary load factor. These method only can provide the estimates in annual scale regardless of the land use. On the other hand, the positive effect of forest to water quality in the river, so-called green dam, is paid attention recently, and supposed to play important roll on improvement to sea environment. However, the effect of forest to water quality is not explained enough, and few research has conducted in watershed scale. In this study, we aim to simulate water, sediment, and nutrient runoff in order to provide more detail information about discharge from land area, and to estimate the influence of the forest to water quality. We use Soil and Water Assessment Tool (SWAT) and chose Kikuchi-river as a model watershed, which has the third largest watershed area among the rivers drain into Ariake-sea.

We set Komoda observatory as the most downstream point of Kikuchi-river and the model watershed is the upstream side from there. More than half of this watershed is covered by forest. We collected land use data, soil data, climate data and 30m mesh digital elevation model (DEM) data of this watershed in order to establish the model. In order to calibrate and validate the model performance, observed data of daily stream flow from 2008 to 2016, and sampling data of sediment and nutrient were collected. Moreover, we measured the amount of sediment, phosphorus and nitrogen during flood situation in 2016 and 2017. The parameters in the model were modified according to the result of calibration, and the performance of the model was evaluated from three indices such as Nash-Sutcliffe index.

The model performance was evaluated as more than satisfactory for all materials: water, sediment, phosphorus and nitrogen. Therefore, this model can simulate daily runoff from 2008 to 2017. The runoff rate of sediment and most of nutrient from forest was less than 30% of the annual average in whole watershed, although water discharge was the same level to the rate of forest area, which indicates the function of forest to provide low concentrate water of sediment and nutrient to the river. In conclusion, modelling the runoff from land area using SWAT model has potential to provide detail information about land area discharge and estimate the influence of forest to river water quality.

# Atmospheric depositions on forest ecosystems in areas along the Sea of Japan

*Yuko Itoh[1], Keiji Takase[2], Yoichi Fujihara[2], Toru Okamoto[1]

1. Forestry and Forest Products Research Institute, Japan, 2. Ishikawa Prefectural University

In recent years, concerns about the effects of excess-nitrogen usage by human activities on terrestrial environment, including forest ecosystems, have been increasing at a global scale. The phenomenon of high-nitrate efflux from several forest watersheds has already been reported in the surroundings of metropolitan areas in Japan. Furthermore, concerns regarding the effects of transboundary air pollution on areas along the Sea of Japan with expanding economic activities have been increasing in Asian countries. However, on-site monitoring throughout the year is difficult in most of these areas because of heavy snow, especially in the mountainous area. Therefore, the behaviors of elements within forest ecosystems throughout a year have primarily not yet been elucidated in this district. This study was conducted to determine the influxes and effluxes of elements in this heavy snowy region and to understand the contribution of transboundary air pollution to the quantity of atmospheric deposition. We also carried out rainfall and stream water investigations from the headwater area to the lower stream area in the Tedori River Basin and an inland mountainous area to understand the geographical distribution of the actual conditions of elements' influxes and effluxes in this region. We started monitoring the major and minor elements in a small forested watershed in the middle part of the Tedori River Basin, Ishikawa prefecture, Japan, in 2013. In this study site, we observed a large amount of precipitation throughout the year. Regarding the annual snowfall amount, there were extensive variations among the years. Seasonal fluctuations were observed in the influx of atmospheric deposition; in particular, the distribution of most of the elements increased during winter. The annual deposition average of inorganic nitrogen ($NH_4$-N + $NO_3$-N) in this site was 15.8 kg $ha^{-1}$. The contribution of winter season deposition to the annual inputs was high. The influx of nitrogen by bulk precipitation during winter season was 2.3 times that of summer, and that of sulfur sulfate was 3.7 times. The nitrogen influx quantity was similar to or more than that reported in nitrogen-saturated forested areas of the Kanto district. Therefore, similar to that in the Kanto district, higher nitrogen deposition loads from the atmosphere could also be influenced on the effect of nitrogen dynamics and the increase in nitrogen efflux at these forest watersheds. However, the efflux concentrations of most of the dissolved elements in stream water did not show clear seasonal fluctuations. Stream water nitrate concentration was stable and low. In addition to the seasonal fluctuation of nitrogen and sulfur, the ratios among some trace elements, which are anthropogenic substances (Pb, V, As, etc.), and sea salts and yellow sand could be useful indicators to elucidate the contribution of transboundary air pollution to these regions. We compared the element inputs associated with precipitation during the non-snowy season (July–November) at six locations in the Tedori River Basin and one location in the inland area. The inorganic nitrogen and sulfuric acid sulfur influxes were the largest at the middle reaches of the Tedori River Basin. The inflow amount of inorganic nitrogen and sulfuric acid sulfur at two points in the mountainous area was approximately half or less than that at the middle region and was approximately the same as the inflow amount at the inland mountainous area. Furthermore, we investigated stream water, spring water, and ground water samples from the headwater area to the lower stream area in the Tedori River Basin. The nitrate concentrations in all the samples ranged from 0.00 to 2.93 $mgL^{-1}$ (median value: 0.69 $mgL^{-1}$). In contrast, the nitrate concentrations of stream water in the Tsukuba experimental forest watershed, which has been reported as a nitrogen-saturated forested area of the Kanto district, were much higher (average value: 7.56 $mgL^{-1}$) than those in the Tedori River Basin. Compared with the influx, the efflux concentrations of nitrate in the water

©2019. Japan Geoscience Union. All Right Reserved. 

samples were generally very low around this basin. Therefore, higher nitrogen depositions have not yet distinctly influenced the nitrate concentrations of stream water in this area. To elucidate the influence of transboundary air pollutant influx on the entire Tedori River Basin, it is necessary to evaluate the inflow amount during the snowy season in the mountainous area. Therefore, it is important to establish a method that can be used to observe the influx and efflux of elements throughout the year even in mountainous areas with heavy snow.

# Continuous and simultaneous flux measurement of $N_2O$ and $CO_2$ from agricultural soil using a portable multi-turn time-of-flight mass spectrometer

*Noriko Nakayama[1], Yusuke Iwai[1], Yo Toma[2], Hiroshi Furutani[1], Ryusuke Hatano[3], Michisato Toyoda[1]

Agricultural soil is one of the important sources/sinks of greenhouse gases such as $N_2O$, $CO_2$, and $CH_4$. The formation and consumption of such greenhouse gases in agricultural soils are dependent on not only the chemical and biological properties of the soil, but also their variations. Hence continuous monitoring of such greenhouse gases as tracer gases are quite useful to track chemical and biological processes and variations of soil properties.

In this paper, we describe a new field-deployable gas flux measurement system for the continuous monitoring of multiple agricultural soil gases ($N_2O$, $CO_2$, and $CH_4$) using a high resolution multi-turn time-of-flight mass spectrometer (MULTUM) combined with an automated flux chamber system. The new system measured the soil gases every 2.5 min with the precisions of ~6% for $N_2O$, $CH_4$, and 2% or better for $CO_2$ and $O_2$ at atmospheric concentrations with one relative standard deviation (RSD) for n = 10.

To demonstrate the utility of the continuous multi-gas flux measurement system, we conducted a field study at the Ehime University farm (Ehime, Japan) from September 3$^{rd}$ to 8$^{th}$, 2018. In the field study, an automated flux chamber was placed in the agricultural field and the soil gas concentrations in the chamber were continuously monitored by the MULTUM system. Soil temperature/moisture sensor were also monitored at the depth of 7.5 cm underground in addition to a weather information (wind speed, precipitation, solar radiation). The continuous measurement had been continued with operators almost unattended except for a daily system check.

For one flux measurement (20 min), eight gas samples were taken every 2.5 min with the flux chamber closed. Gas flux of $N_2O$ and $CO_2$ had been carried out by applying linear regression to the eight gas measurements. We found that a significant correlation of $N_2O$ flux with soil electrical conductivity and water content, although no significant correlation of $CO_2$ flux to soil electrical conductivity was observed. Significant and rapid decreases in $N_2O$ and $CO_2$ flux during rainfall events were also observed. Our preliminary result shows that high time-resolution flux data obtained by MULTUM system is quite useful for tracking the variation in soil properties and biological processes and their activity in soil environment.

# Effects of introduction of cyclic irrigation system on mass balances of SS and T-P in Lake Inbanuma, Chiba, Japan

*Tomijiro Kubota[1]

1. National Agriculture and Food Research Organization, Institute for Rural Engineering

## Introduction

The introduction of cyclic irrigation has been advanced since 2010 in the Lake Inbanuma as part of the update project of the irrigation facilities. In the present study, mass balances of SS and T-P were examined before and after the introduction of the cyclic irrigation.

## Materials and methods

The irrigation block where the cyclic irrigation began in 2015 was selected as the investigation site, and the investigation was executed to the irrigation period in 2014 and 2015. The hydrological and water quality investigation was executed at ① division works of irrigation canal and ② drainage pumping station. Water samples were taken at the two points and the TOC, SS, TN, NO3-N, NO2-N, NH4-N, TP, and PO4-P were analyzed in the regular investigation executed about once a month. Besides regular investigation, water samples were taken once a day (8:00AM or noon) by the automatic water sampler and SS and T-P were analysed. The turbidity and water level were measured every ten minutes by using data loggers at same sites. The turbidity data were converted into the concentration of SS and TP by using the regression curve. The quantity of water intaken from the lake and drainage to the lake were obtained from the records of the facility manager.

## Result and discussion

The inflow and outflow loads and the balance were calculated before and after the introduction of the cyclic irrigation. In 2014, before the start of cyclic irrigation, both the outflow loads of SS and T-P were small to compare with those inflow loads. The amount of accumulation of SS and T-P were about 1.3t and 2kg respectively when having no rainfall in the irrigation block. On the other hand, the outflow of SS and T-P were about 3.5t/day and 20kg/day respectively in rainy days. If 2015 year is compared to 2014, it had increased in T-P though the load of irrigation water each day at no rainfall periods and it had not been change in SS though an accurate comparison is difficult according to the missing value. However, after the cyclic irrigation had been started, the amount of the outflow loads had decreased greatly like 35% in SS and 38% in T-P. The balance of the outflow loads during the irrigation periods of 2014 were -470kg/day in SS, which meant the purification type, while +2.6kg/day in T-P. as a result, it was found that the introduction of cyclic irrigation system had worked for water purification in SS and T-P effectively.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

Thu. May 30, 2019 5:15 PM - 6:30 PM JST | Thu. May 30, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_9

## [A-HW22] Materials transport and nutrient cycles in watersheds; from headwaters to coastal seas

convener:Masahiro Kobayashi(Forestry and Forest Products Research Institute), Seiko Yoshikawa(Institute for Agro-environmental Sciences, National Agriculture and Food Research Organization), Jun Yasumoto(University of the Ryukyus, Faculty of Agriculuture), Adina Paytan(University of California Santa Cruz)

This session aims to synthetize watershed sciences in order to understand dynamical processes of materials transport and nutrient cycles in watersheds from headwaters to coastal seas. The session will be integrating a variety of research disciplines including limnology, ground water hydrology, coastal oceanography, meteorology, pedology, sedimentology, forestry, agriculture, fishery, ecology, social science and more. This session calls for ideas on new methods for the watershed sciences, such as tracer and molecular technique, hydrological modeling, paleontological approaches, laboratory and field experiments, social-scientific evaluation of ecosystem services and social-ecological systems, and so on, in order to elucidate physical, chemical and biological mechanisms for shedding light on natural phenomena and their changes over time in complex and dynamic watershed systems under human and climate impacts. Through this session, we would like to facilitate interdisciplinary collaboration among participants to create new knowledge on watershed sciences.

# Phosphate Enrichment Hampers Development of Juvenile Acropora digitifera Coral by Inhibiting Skeleton Formation

Mariko Iijima[1], *Yasumoto Ko[1], Jun Yasumoto[2], Mina Hirose[3], Mitsuru Jimbo[1], Shugo Watabe[1]

1. Kitasato University School of Marine Biosciences, 2. Faculty of Agriculture, University of the Ryukyus, 3. Tropical Technology Plus

Coral reef degradation resulting from various types of local stress on corals such as excessive nutrient enrichment in and gravel inflow into coastal waters is of an increasing global concern. Because tropical and subtropical seawaters are generally poor in nutrients and thus oligotrophic, these stresses are thought to result in the decline of environments favorable to coral growth. Inorganic phosphates have been especially considered to possibly inhibit the formation of coral skeleton. Despite many studies available on the effects of nutrients on corals, a clear consensus for how nutrients exert deteriorative effects on the corals has not been established satisfactorily. Recently, we found that biogenic polyamines react with carbon dioxide ($CO_2$) and accelerate an aragonite formation of calcium carbonate ($CaCO_3$) in seawater. In this study, we examined the effects of phosphates and nitrates on *in vitro* aragonite formation of $CaCO_3$ by using biogenic polyamines and *in vivo* aragonite formation of juvenile coral *Acropora digitifera* skeletons, showing that phosphates clearly inhibited both *in vitro* and *in vivo* $CaCO_3$ formations at similar concentrations. In contrast, nitrates inhibited neither *in vitro* aragonite formation of $CaCO_3$ nor *in vivo* aragonite formation of juvenile coral skeletons. These findings indicate that phosphates have a detrimental effect on bioinorganic coral calcification. Furthermore, the findings that phosphate enrichment inhibits coral skeleton formation led us to conclude that enriched phosphate is adsorbed on juvenile coral skeleton surface and inhibits inorganically normal development of juvenile coral skeleton.

# Modeling chlorophyll-a concentration using remote sensing in shallow water systems: Comparison of sensors

*Assefa M Melesse[1], Tara Blakey[1], Mohammad Haji Gholizadeh[1], Mohd Manzar Abbas[1]

1. Florida International University

The level of productivity in the upland and coastal water bodies is highly linked to land processes (land use, water management, water and nutrient fluxes). Understanding the linkage between these processes and the level of algal blooms in the water bodies is crucial for improving water quality. A comparative study was conducted using remote sensing data from three different sensors (SeaWIFS, MoDIS and Landsat) to evaluate the capability of reflectance data from these sensors for estimation of chl-a concentrations in three water bodies in the USA (Lake Okeechobee, Florida Bay and Chesapeake Bay). Observed chl-a data were gathered and compared with simulation results. The analysis found that all of the sensors have performed well in deeper water bodies than in shallow sections due to the bottom reflectance from non-algal blooms. For shallow water bodies, selection of the proper bands and band combinations, identification of the non-algal bloom reflectance and the corresponding algorithms can improve the simulation. Seasonality as well as spatial variability (using cross-sections) were evaluated and the results showed that chl-a values were highly variable for the selected summer months. Indicative of the effect of land surface fluxes of nutrients, chl-a values were higher closer to coastal areas in the Florida bay and Chesapeake Bay. The chl-a in the freshwater lake of Okeechobee was simulated using Landsat 8 data and the results found were very good. Comparison of the SeaWIFS and MoDIS chl-a value to that of the measured concentrations in the deeper section of Florida Bay and Chesapeake Bay, respectively showed very good agreement.

Keywords: Chl-a, SeaWIFS, Water qulity modeling, South Florida, Remote sensing

# Dynamics in groundwater flow system with seasonal water table variation in a coastal and island

*Yusuke Tomozawa[1], Shin-ichi Onodera[1], Mitsuyo Saito[2]

1. Graduate School of Integrated Arts and Sciences Hiroshima University, 2. Graduate School of Environmental and Life Science, Okayama University

In islands, freshwater water resources are valuable as living and agricultural use, and dug wells water and reservoirs had been utilized for more than 100 years. In order to use such water resources sustainably, it is important to evaluate groundwater flow as well as water budget.

In this research, we examined to confirm the seasonal variation in water stable isotopic ratios in observation boreholes at the coastal lowland in Ikuchi Island Hiroshima prefecture. Moreover, considering that the target area is coastal, $Cl^-$ concentration was analyzed to evaluate the influence of salt fresh water boundary.

The experimental site is located on Ikuchi Island in Hiroshima prefecture. The highest altitude is 456 m. The basement rock is mainly composed of granite. Annual average precipitation is 1058.8 mm. Observation boreholes are located at the coastal lowland in the southeastern part of the island. The upper site (Site U) with the altitude of 5.1 m asl has 3 boreholes with the depths of 2 m, 15 m, 30 m, the lower site (Site D) with 2.5 m asl has 8 with the depth of 1 m, 2 m, 3 m, 10 m, 15 m, 20 m, 30 m, 40 m, respectively. The water sampling was carried out from monthly to half year interval since 2015. Every samples were analyzed for water isotopic ratios by PICARO and anion component by ion chromatography. Especially samples in January in 2019 were analyzed for CFCs and SF6.

Based on the previous study (Saito and Onodera, 2007), the distinct altitude effect of isotopic ratio in precipitation has been confirmed. Due to spatial and temporal variations in isotopic ratios, recharge process to groundwater was suggested as follows, 1) recharge on site to shallow groundwater (2-3m deep) at D ( $\delta^{18}O$: -7.8 to - 7.4 ‰), 2) river water contribution to the shallow groundwater (2-15m) at U ( $\delta^{18}O$: - 8.3 to - 7.5 ‰), 3) recharge in the mountain slope with the altitude of about 360 m to deep groundwater (30m) at U ( $\delta^{18}O$: - 8.4 to - 8.1 ‰), 4) recharge at 400 m on near the mountain top to deep groundwater (10-30 m) at D( $\delta^{18}O$: - 8.7 to - 8.4 ‰), 5) recharge of precipitation with lower isotope than in present to deeper groundwater (40 m) at D ( $\delta^{18}O$: -8.9 to - 8.8 ‰)

The deepest groundwater (40m) at D had lower isotopic ratios with higher $Cl^-$ concentration (250 to 584 mg / L) during a lower water table in the winter. This indicated the seawater –fresh water boundary rose with water table according to Gyben-Hrzberg concept. These phenomena also suggest to cause the rise of deeper and older groundwater flow line. Consequently, we suggest the lower isotopic ratio in deeper groundwater indicates the immobile water which were recharged in the glacial period. Based on other tracers (CFC, SF 6), we will discuss more.

# The Tracing of Groundwater Contamination Sources in Indonesian Coastal Alluvial Groundwater using $\delta^{34}S$ and $\delta^{15}N$ Isotopes

*Anna Fadliah Rusydi[1,4], Mitsuyo Saito[2], Seiichiro Ioka[3], Shin-ichi Onodera[1]

1. Graduate School of Integrated Arts and Sciences, Hiroshima University, Japan, 2. Graduate School of Environmental and Life Sciences, Okayama University, Japan, 3. Research Institute for Sustainable Energy, Hirosaki University, Japan, 4. Research Center for Geotechnology, Indonesian Institute of Sciences, Indonesia

The coastal area is one of the Indonesian Government priorities as an archipelago country. The groundwater in the area is one of the most reliable clean water resources, therefore it is crucial to understanding the vulnerability of this resource. Our research area was located at Indramayu, a developing rural coastal area in Indonesia, where, the environment was relatively pristine. This research aimed was to identify the effect of natural condition and human activity to groundwater quality by using stable isotope $\delta^{34}S$ and $\delta^{15}N$.

Totally, there were 20 samples taken from groundwater (18) and river (2). The nitrate and sulfate were detected in a total of 5 and 19 samples, respectively. The isotopes composition for isotope nitrate were -11.2 ‰–+22.22‰ for $\delta^{15}N\text{-}NO_3$ and -3.4 ‰–+17.1‰ for $\delta^{18}O\text{-}NO_3$. Moreover, the values of $\delta^{34}S\text{-}SO_4$ and $\delta^{18}O\text{- }SO_4$ were varied from -4.2 ‰–+28.4‰ and +7.3 ‰–+18.8 ‰, respectively. The isotopic signatures of nitrate suggested that the used of inorganic fertilizer and animal manure give the impact to both groundwater and river. Similarly, the isotopic signatures of sulfur were showing that those detected sulfate in the groundwater were mostly coming from fertilizer. Moreover, the soil was mineralized by organic sulfate as well. At one point, located in the fishery area, the groundwater was indicated the seawater contamination. It was shown by the heavy composition of sulfur isotope (28.4‰ for $\delta^{34}S$ and 18.8‰ for $\delta^{18}O$). Lastly, our results showed those combined isotopes of $\delta^{34}S$ and $\delta^{15}N$ along with land-use evaluation could explain the possible sources of groundwater in coastal area at very early urbanization stage.

# Spatio-temporal dynamics of orthophosphate with implications for limitation of phytoplankton growth in north basin of Lake Biwa, Japan

*Xin Liu[1], Rong Yi[1], Masahiro Maruo[1], Syuhei Ban[1]

1. The University of Shiga Prefecture

Orthophosphate ($PO_4$-P) is the main chemical form of phosphorus (P) for phytoplankton growth, often considered as a limiting nutrient for primary production in freshwater ecosystems. However, few information on accurate measurements for $PO_4$-P concentrations in epilimnion of meso- and oligotrophic lakes due to lower than the detection limit (60 nM) of soluble reactive P using traditional spectrophotometrical method. In the present study, we measured $PO_4$-P concentrations using ion chromatography with a detection limit of 5 nM, and determined truly vertical distribution of $PO_4$-P throughout the year with other abiotic and biotic environmental factors in north basin of Lake Biwa, to accurately understand biogeochemical processes of P in this mesotrophic lake.

Field investigations were conducted monthly from April to December 2018 at station K4 (35º19'9.6"N, 136º11'2.7"E; 50 m deep). Phosphate enrichment experiments were also made at each sampling occasion to clarify P limitation for phytoplankton growth. Lake water including phytoplankton assemblage collected from epilimnion (0–20 m) was enriched with 1 $\mu$M of $PO_4$-P (+P) and incubated together with untreated one (control) for 2 days under ambient light and temperature conditions. To evaluate the effect of potentially nutrient-rich bottom water, the filtered bottom water was mixed with untreated epilimnion water including phytoplankton at 1:1 (+B) was incubated at the same conditions as the +P treatment. Phytoplankton growth rate ($g$) was calculated with equation of $g=\ln(C_t/C_0)/2$, where $C_0$ and $C_t$ are chlorophyll *a* (chl. *a*) concentrations at start and end of the experiment, respectively.

Water temperature increased in the epilimnion from May, and strict thermocline was developed from June to September. Chl. *a* concentrations increased from June to July in 10–20 m, and from October to November in 0–20 m. $PO_4$-P concentrations were always low, <20 nM, in the epilimnion from April to June. The concentrations below 30 m increased up to 140 nM in May, but decreased after that until July. In August and September, the concentrations increased up to 30–40 nM even in the epilimnion probably due to disturbance by typhoon. The concentrations below 30 m increased with depth, and the highest values were frequently observed near the bottom, up to 220 nM. On average throughout the water column, $PO_4$-P concentrations were 24–48 nM from April to June, then slightly increased up to 73 nM until September, being constant, 50–63 nM until December.

Total P, total dissolved P, dissolved organic P and particulate P exhibited similar spatio-temporal distributions, but different pattern from those of $PO_4$-P. $NH_4$-N increased in 10–20 m from May to July, whereas the $NO_3$-N increased in the hypolimnion as season progressed. Sestonic C:N:P ratios suggested a terrible P deficiency in July and October when phytoplankton biomass increased.

Phosphate enrichment experiments showed that phytoplankton in the epilimnion was mostly limited with P for its growth. Phytoplankton $g$ in control varied −0.05-0.08 $d^{-1}$, being always lower than those in +P (−0.04-0.44 $d^{-1}$) and/or +B (−0.04-0.49 $d^{-1}$) treatments except for November and December. In November, no growth was found even in +P treatment. This might be caused by nitrogen limitation because of <6 $\mu$M of $NO_3$-N in the epilimnion. The $g$ of control was similar as that of +P and +B (ca. 0.1 $d^{-1}$) in December, indicating that P deficiency for phytoplankton growth was relaxed until December by vertical convection.

©2019. Japan Geoscience Union. All Right Reserved. 

We firstly determined completely vertical distributions of $PO_4$-P in north basin of Lake Biwa from spring to winter, and detected 20–40 nM of $PO_4$-P in the epilimnion. Phosphate enrichment experiments showed that 20 nM of $PO_4$-P might be critical concentration for phytoplankton growth in the lake. No phytoplankton growth even in +P treatment in November implied that nitrogen limitation for phytoplankton growth will be possible in Autumn. Further study for clarify this will be needed.

National Institute of Advanced Industrial Science and Technology, 5. University of the Ryukyus, Faculty of Agriculuture Department of Subtropical Agro-Environmental Sciences

Clean water and sanitation (Sustainable development Goals (6)) is one of the world's important issues. People use groundwater in many areas as a water source, but various cases of contamination by agricultural activities and substances derived from human and animal excrements have been reported.

On the other hand, genetic analysis techniques using molecular biological methods have been applied to the analysis of microbial phase in the water environment.

In recent years, the method using the latest analysis equipment of next generation Sequencer is established, mainly for microorganisms. In addition, new monitoring indices such as environmental DNA have been developed. It is thought that the microbial phase in groundwater varies depending on the influence of various environmental factors and human activity, but the actual condition is not clear.

The next generation Sequencer is a very powerful tool used to grasp the microbial phase in groundwater. It is thought that the microbial phase can be an important indicator in water resource management of basins in the future.

The purpose of this study is to investigate the microbial species and their coexistence in groundwater in the Ryukyu Limestone area using the next generation sequencer.

# Evaluation for temporal variation in groundwater inflow to the lagoons connected to Lake Biwa by radon ($^{222}$Rn) tracer analysis

*Mitsuyo Saito[1], Shin-ichi Onodera[2], Yusuke Tomozawa[2], Kunyang Wang[2], Syuhei Ban[3], Noboru Okuda[4]

1. Graduate School of Environmental and Life Science, Okayama University, 2. Graduate School of Integrated Arts and Sciences, Hiroshima University, 3. School of Environmental Sciences, The University of Shiga Prefecture, 4. Research Institute for Humanity and Nature

Primary production in freshwater lakes and reservoirs are usually controlled by phosphorus (P). Lacustrine groundwater discharge (LGD), direct discharge of subsurface water to lake, is regarded as a potential nutrient paths, including phosphorus from a catchment to lake water environment. There are more than 20 lagoons around Lake Biwa which were originally a part of the lake. These lagoons are regarded to have important functions as settling ponds of inflowing loads from the catchments to Lake Biwa, refuges for shallow water ecosystems and so on. Because these lagoons are connected to Lake Biwa, evaluation of nutrient budget is important for the nutrient cycle in the lake. Some researchers have pointed out the presence of LGD in littoral area of Lake Biwa. However, it has not been evaluated for the lagoons around the lake. In the present research, we aimed to evaluate the temporal variation in groundwater inflow to a lagoon connected to Lake Biwa by radon ($^{222}$Rn) tracer analysis.

The field campaigns were conducted in December 2017, August and October 2018 for the lagoons (Noda-Numa and Hasu-Ike) located on northeastern shore of Lake Biwa. The volume of inflow and outflow, water temperature, electric conductivity, chlorophyll-a and radon ($^{222}$Rn) concentration were measured in the lagoon. $^{222}$Rn is a radioactive element of uranium ($^{238}$U) series with 3.8 day of half-life. $^{222}$Rn is a useful tracer of groundwater discharge because it generally enriched in groundwater than surface water. To examine the temporal variation in groundwater inflow, the time-series $^{222}$Rn concentration in water was obtained. Water samples were collected at the inlet, outlet and near the center of the lagoons and natural springs and groundwater wells around the lagoons. Water and $^{222}$Rn balance suggest that groundwater inflow is larger in Noda-Numa than Hasu-Ike. The catchment topography may influence on this difference. $^{222}$Rn balance-based residence time of lagoon water was estimated 10-20 days in Noda-Numa, and 4-5 days in Hasu-Ike, were similar with that based on water balance. These results suggest the groundwater inflow is a potential phosphorus path to Noda-Numa.

# Br/Cl ratio characteristics of groundwater in coastal areas in Indonesia

*Seiichiro Ioka[1], Shin-ichi Onodera[2], Mitsuyo Saito[3], Anna Fadliah Rusydi[2,4]

1. Institute of Regional Innovation, Hirosaki University, Japan, 2. Graduate School of Integrated Arts and Sciences, Hiroshima University, Japan, 3. Graduate School of Environmental and Life Sciences, Okayama University, Japan, 4. Research Center for Geotechnology, Indonesian Institute of Sciences, Indonesia

The urban development in Indonesia’ s coastal areas has led to an increase of groundwater demand, which then has resulted in groundwater salinization. In this study, we analyze bromide and Br/Cl ratio characteristics, as index of groundwater salinization, in three cities of Indonesian coastal areas, namely: Indramayu, Mataram, and Semarang. Each research site is at different stage of urbanization. Indramayu is in very early stage of urbanization, followed by Mataram as a developing tourism area, and the last one Semarang as a heavy urbanization city. The results show that concentrations of bromide in groundwater are ranged from 0.05 to 38 mg/L in Indramayu, 0.01 to 0.8 mg/L in Mataram, and 0.02 to 8.0 mg/L in Semarang. Furthermore, the occurrence of Br is described in terms of the Br/Cl weight ratio, which allows for small changes in bromide concentrations to be assessed in terms of salinity. Median values of Br/Cl weight ratio in the groundwater of Indramayu, Mataram, and Semarang were approximately 0.0035, 0.0027, and 0.0025, respectively, while the ratio in seawater is generally around 0.0035. The relationship between Br/Cl weight ratio and chloride concentration indicate the groundwater in Indramayu is undergoing salinization due to seawater intrusion compared to the other two areas, meanwhile the groundwater in Semarang is experiencing chloride contamination due to anthropogenic activities based on the study by Andreasen and Fleck (1997).

# Estimation of groundwater recharge and phosphorus transport under different precipitation conditions in a suburban catchment, using SWAT model

*Kunyang Wang[1,2], Shin-ichi Onodera[1], Mitsuyo Saito[3], Noboru Okuda[4], Takuya Okubo[5]

1. Graduate School of Integrated Arts and Science, Hiroshima University, 2. Capital Normal University, 3. Okayama University, 4. Research Institute for Humanity and Nature, 5. University of the Shiga Prefecture

The quantification of the groundwater recharge and phosphorus transport in water is one of the most important indicators of the water cycle in lakes because these processes are related to the transport of large nutrient loads. The Yasu River is one of the important water sources of the Biwa Lake. In this paper, Geographic Information System technology is used to analyze and predict the land use change in the Yasu River Basin. The water balance was simulated using the Soil and Water Assessment Tool. Simulations of different years in different precipitation seasons were carried out. The correlation coefficient and the Nash Sutcliffe coefficient are higher than the reference values. The sensitivity analysis of the parameters reveals the different degrees of sensitivity of the parameters in different water seasons, CN2 always has a high sensitivity during all kinds of water season. The total groundwater recharge and discharge are 180 million $m^3$ and 179 million $m^3$ in the normal precipitation season, respectively. The trends differ in the dry and wet seasons. In the dry season of 2007, the groundwater recharge was below 140 million $m^3$, while it exceeded 240 million $m^3$ in the rainy season in 2003. In addition, the process of phosphorus loss in the basin and release into Lake Biwa are explained from the perspective of space and time. This is closely related to the spatial distribution of the main channel and the time distribution of precipitation. The total amount of nonpoint source pollution of phosphorus in three years is equivalent to 4.08 kg/ha of paddy fields in the watershed. The spatial distribution of phosphorus loss is related to the stream flow, it is mainly concentrated in the area with paddy fields and urban. The time distribution is related to the distribution of the precipitation. With increasing precipitation, the nonpoint source pollution of phosphorus slightly increases. This is due to the driving effect of precipitation on the phosphorus transfer and erosion of soil.

# Losses of phosphorus with soil erosion and nitrate with groundwater recharge in an agricultural catchment, subtropical small island

*Shin-ichi Onodera[1], Mitsuyo Saito[2], Yang Cao[1], Anna Fadliah Rusydi[1], Hide Omae[3], Yoshiko Iizumi[4], Yusuke Tomozawa[1]

1. Graduate School of Integrated and Arts Sciences, Hiroshima University, 2. Graduate School of Environmental and Life Science, Okayama University, 3. JIRCAS TARF, 4. JIRCAS HQ

In tropical and subtropical region, the rainfall intensity is strong and soil erosion in an agricultural land is one of big environmental issues. Especially, the impact of large sediment discharge on the coral reef is serious around small islands, such as Okinawa and Philippines. In case of Okinawa Prefecture, to reduce the sediment discharge and conserve corals, many sediment trap ponds are constructed in a downstream area of agricultural lands. However, sediment deposition rate, variation of trap effect, and component of sediment in a pond have not been confirmed.

To estimate of erosion rate and deposition process of a small pond in an agricultural catchment of a subtropical small island, we examine to observe the sediment deposition in a small pond and monitor water level and chlorophyll a in a pond and runoff and turbidity of an inflow stream in a small catchment with the area of 300m2 in Ishigaki Island, Okinawa Prefecture, Subtropical region. Our monitoring was started from February 2017 after removing all sediment in a pond in January, and up to April 2018. Observation of sediment deposition was conducted with collecting the samples at 5 sites in June 2017 and January 2018. Inflow and outflow water samples were collected every one month.
The sediment deposition was extremely large from January to May 2017, the average erosion rate in all catchment area was estimated to be 6mm. On the other hand, the sediment deposition was nothing from June 2017 to January 2018. Based on the monitoring of stream runoff and turbidity, one big storm event in April with strong intensity mainly contributes to sediment discharge and overflow of the pond occurred. On the other hand, the later period had also big events. This difference is suggested to be the difference of land cover by crops and availability of sediment trap in this pond. In addition, the sediment component mainly was composed of surface soft layer, subsurface sandy layer, and bottom gravel layer. The average thickness was 2cm in surface layer, 100cm in mid sandy layer, and 10cm in gravel layer, respectively. Especially, the surface soft layer had high nutrient content. The dissolved nutrient of inflow stream water and pond water were high concentration. But the 10% of nutrient in the inflow decreased in pond. This means the plankton was produced, using this nutrient and that was deposited later. The soft layer is suggested to be effect of organic fertilizer, it is expected to apply to agricultural lands.

# Phosphate solubilizing bacteria as an indicator of sediment phosphorus in freshwater lakes

*Sreekumari Kurissery[1], Katelynn Crawford[1], Nandakumar Kanavillil[1]

1. Lakehead University, Canada

It has been well documented that phosphorus pollution is one of the most significant factors impeding the overall health of freshwater lakes. Various measures are being taken to reduce phosphorus input into the lakes by anthropogenic activities and thus to maintain a healthy ecosystem. However, it is well known that bioavailable phosphorus tends to bind with substances such as ferric iron and calcium present in the water, become insoluble, and settles into the sediments. The presentstudy has been carried out to understand the relationship between the sediment phosphorus concentration and density of phosphate solubilizing bacteria (PSB) in two lakes in Ontario, Canada, namely, Lake Simcoe and Sparrow Lake. In September 2017, 20cm sediment cores were collected from the nearshore sites of these two lakes to determine the presence of PSB in relation to the sediment phosphorus concentration. PSB could potentially release phosphorus back into the water column through a process called internal phosphorus loading from the inorganic phosphates in the sediment when the right conditions are present. PSB were isolated from the sediment cores at 5 cm intervals by plating on to Pikovskaya’ s agar. Five grams of sediment was used to analyze total reactive phosphorus in the sediment. In Lake Simcoe, PSB ranged from $3x10^1$ to $1.1x10^1$ cfu/g, and the amount of total reactive phosphorus ranged from 0.19 to 0.46 mg/g. In Sparrow Lake, PSB ranged from $4x10^0$ to $3x10^1$ cfu/g and the amount of total reactive phosphorus ranged from 0.21 to 0.39 mg/g. A linear regression was completed to determine the relationship between total reactive phosphorus and PSB for each core. The results showed a negative relationship between these two tested parameters (Lake Simcoe: $r^2$=0.23, $y = -35.34x + 30.811$ $p$=0.5206, and Sparrow Lake: $r^2$ =0.87, $y = -155.9x + 62.322$, $p$=0.067). While PSB density decreased with core depth, the concentration of reactive phosphorus increased. This indicates that the density of PSB in lake sediment may indicate the concentration of total reactive phosphorus and thus the internal phosphorus loading. More study is recommended to confirm the results.

# A Study on the dynamics of various phosphate forms in soil and groundwater in Ryukyu limestone regions

*Masashi Nozaki[1], Jun Yasumoto[2], Yasumoto Ko[3], Hirose Mina[4], Iijima Mariko[3], Ryuichi Shinjo[5], Bam H.N. Razafindrabe[6]

1. University of The Ryukyus, Graduate School of Agriculture,, 2. University of the Ryukyus, Faculty of Agriculture, Department of Regional Agricultural Engineering, 3. Kitasato University School of Marine Biosciences, 4. Tropical Technology Plus, 5. Department of Physics and Earth Sciences, University of the Ryukyus, 6. University of the Ryukyus, Faculty of Agriculture, Department of Subtropical Agro-Environmental Sciences

Phosphorus in water environment exists in various forms and size, such as dissolved, particulate, organic and inorganic forms. However, there are many unclear points in Phosphorus in groundwater. In this study, we tried to understand the dynamics of various phosphate forms in soil and groundwater in Ryukyu limestone regions by combining Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES) and $^{31}$P Nuclear Magnetic Resonance ($^{31}$P-NMR), in addition to Colorimetric (molybdenum blue method). From August 2017 to August 2018, we took groundwater samples in southern part of Okinawa, Japan, with Ryukyu limestone distribution on a monthly basis. We measured pH, electronic conductivity (EC), Oxidation-Reduction Potential (ORP), dissolved oxygen (DO) and alkalinity ($HCO_3^-$) on site, and analyzed major dissolved ion ($Cl^-$, $HCO_3^-$, $NO_2^-$, $NO_3^-$, $SO_4^{2-}$, $Na^+$, $K^+$, $Mg^{2+}$, $Ca^{2+}$), suspended solid (SS) and phosphorus concentration. Phosphorus concentration analyzed 3 different method to molybdenum blue method (Col-P), ICP-AES (ICP-P) and Total P (T-P). Phosphate form analysis used $^{31}$P-NMR.
We compared Col-P and ICP-P in order to understand dissolved phosphorus spatial distribution. The results show that ICP-P is 1.06~49.24 times larger than Col-P. It is inferred that ICP-P is also measuring fine particulate phosphorus and organic phosphorus. As a result, several forms of phosphate without orthophosphate were found in groundwater. Particulate phosphorus was determined by subtracting ICP-P from T-P. A positive correlation (r= 0.78) was found between P-P and SS. According to these results, it is thought that PP adsorbs various forms of phosphate including orthophosphate. We analyzed the correlation between dissolved phosphorus (Col-P, ICP-P) and all measured value in order to understand the characteristics of seasonal variation to dissolved phosphorus. There was a negative correlation between Col-P to water temperature. When focusing on seasonal variation of Col-P, we found that Col-P concentration decreases when water temperature increases. Moreover, Col-P concentration increases as water temperature increases. Through the analysis of various forms of phosphate in soil and SS by using $^{31}$P-NMR, along with orthophosphate, pyrophosphate, pyrophosphate ester, orthophosphate monoester were also detected. It is thus suggested that the phosphate of polymeric or organic forms other than orthophosphate are from plant origin, as a result of microbial activities and microorganism decomposition.

# Impacts of highly concentrated turbid water on the groundwater in the Tedori River alluvial fan, Japan

*Yoichi Fujihara[1], Shunsuke Chono[1], Keiji Takase[1], Eiji Ichion[1]

1. Department of Environmental Science, Ishikawa Prefectural University

The Tedori River alluvial fan in the Ishikawa prefecture is a representative alluvial fan in the Hokuriku region in Japan. The river water is taken by a headworks located at the top of the alluvial fan and is used for irrigation in paddy fields with a total area of about 7,500 ha. Seepages from the riverbed and percolations from the paddy area are the main sources of groundwater in the Tedori River alluvial fan. In 2015, large-scale landslides in the upper reaches of the Tedori River caused a long period of high turbidity in the river. Highly concentrated turbid water with an average concentration of 585 mg/L (a maximum of 4,012 mg/L) has been discharged continuously into the river since May, 2015. This turbidity has caused concerns about the recharge functions of groundwater in the alluvial fan.

In this study, the measurements of paddy percolations and riverbed seepages, before and after the occurrence of high turbidity, were used to examine the influence of these phenomena on groundwater recharge functions in the alluvial fan. We measured water requirement rates in the paddy area in the Tedori River alluvial fan. The measurements were conducted before and after the midsummer-drainage period at >100 paddy fields. We also measured the river discharges in the cross-sections of the river throughout the alluvial fan. The number of cross-sections was 16 and we estimated the riverbed seepages by calculating the discharge differences between the cross-sections.

The results revealed that the amount of paddy percolation decreased significantly due to the turbidity of the river water. The average percolation in the paddy area was found to be 12.4 mm/day in 2014 and 7.9 mm/day in 2016 before the midsummer-drainage period. Moreover, the average percolation in the paddy was found to be 19.6 mm/day in 2014 and 13.7 mm/day in 2016 after the midsummer-drainage period. The volume of the riverbed seepage was observed to have reduced and the seepage section were also observed to have shortened. The observed seepages from the river bed were 4.72 m3/s in 2009 and 3.33 m3/s in 2016 for the irrigation period, whereas for the non-irrigation period, these values were 5.92 m3/s in 2009 and 1.25 m3/s in 2016. Furthermore, the seepage section was found to shorten from 14.2 km to 8.0 km, due to the high turbidity of the water.

Finally, we estimated the amount of groundwater recharge based on these measurements, which revealed that the groundwater recharge from paddy percolation decreased by 270 mm/year (36%), and the recharge from riverbed decreased by 591 mm/year (61%). The total groundwater recharge decreased by 861 mm/year (36%), a value that corresponded to the groundwater level measurements. From these results, we can conclude that the effects of highly concentrated turbid water on the groundwater are quite serious in the Tedori River alluvial fan.

# Altitude effect of water stable isotopic ratio of ravine water and its contribution to groundwater in alluvial plains - Comparison in east and west side catchments of Lake Biwa –

*Yusuke Tomozawa[1], Kunyang Wang[1], Mitsuyo Saito[2], Syuhei Ban[3], Noboru Okuda[4], Shin-ichi Onodera[1]

1. Graduate School of Integrated Arts and Sciences Hiroshima University, 2. Graduate School of Environmental and Life Science, Okayama University, 3. School of Environmental Science, The University of Shiga Prefecture, 4. Research Institute for Humanity and Nature

The stable isotope ratio of hydrogen and oxygen in water is one of useful tracers for hydrological cycle and processes in the catchment scale as well as global. The typical characteristics are spatial or geographical distribution trend such as “altitude effect” or “inland effect”, which are lower in the higher altitude or more inland. Based on these trend, the groundwater recharge area had been estimated. However, the merger of these effects and additional effect such as the seasonal variation of isotopic ratio in precipitation or vapor causes various trend.
In this study, we examined to confirm the altitude effect of water stable isotope ratio and estimate recharge altitude to groundwater in alluvial plains, with comparing in the east and west side catchments of Lake Biwa .
Sampling of spring water in the Serikawa upstream area on the east side of Lake Biwa was conducted in July 2017, December 2017, August 2018. Sampling of ravine water in the Adogawa / Ukawa upstream area on the west side of Lake Biwa was conducted in August 2018. Water samples of spring in the head water and groundwater in the alluvial plain were collected at 11 and 2 sites in the east and at 13 and 2 in the west with measuring EC, pH and DO, respectively. The water stable isotopic ratios were analyzed by PICARO.
Stable isotopic ratios in groundwater were lower than surface water in both east and west. Altitude effects of spring water in the head water were recognizable. This means the surface water in the alluvial plain was mainly contributed from Lake Biwa, whereas groundwater was from the head water. The altitude effect of oxygen stable isotopic ratio was 0.15 - 0.13 ‰/ 100 m on the east side and 0.15 ‰/ 100 m on the west side (only in the upper stream of the Ado River). In addition, the d value of isotopic ratio in the precipitation was 23‰ in the upper Adokawa in August 2018, 18 ‰in Ugawa, and 20 ‰in Serikawa.
We also estimated groundwater recharge elevation and water contribution rate in the upstream region based on these.

Western Region Agricultural Research Center, National Agriculture and Food Research Organization, 3. Forestry and Forest Products Research Institute, 4. Graduate school,Tsukuba University, 5. Faculty of Agriculture, Ibaraki University

Water quality deterioration of rivers caused by leakage of fertilizer components such as nitrogen and phosphorus from paddy and upland fields is a environmental problem. Also, runoff of fertilizer components are expected to increase with the accelerated water and sediment runoff by intensification and localization of rainfall caused by climate change. Although it is difficult to predict the place and extent of heavy-rainfall-related disasters, we firstly grasp the average concentrations of nitrogen and phosphorus and predict increase and decrease in those concentrations when the way of rain changes. Nitrogen and phosphorus runoff is depend on land use and land cover, conservative measures, topography, climate condition mainly rainfall etc.. Among them, the land use and land cover is expected to be a main factor in normal climate conditions. In order to contribute to the prediction of heavy-rain related disasters in the future, coefficients that indicate the total nitrogen (TN) and total phosphorus (TP) load intensity to rivers of each land use for the river watersheds across the country are calculated using a simple watershed land use model. Watersheds whose lower ends are observation points of water quality, and whose land use ratios were determined by GIS technique using published database of DEM (GSI, 10B) and LULC mesh data (JAXA , ALOS AVNIR-2). The TN and TP concentration coefficients of paddy, upland, forest, and urban were calculated by applying the below multiple regression equation using the land use ratios and published TN and TP data( Ministry of Environment).

$c = a_1 x_1 + a_2 x_2 + a_3 x_3 + a_4 x_4$

*C:* TN or TP concentration (mg $L^{-1}$) $a_i$ : TN or TP concentration coefficient for land use *I,* $x_i$ : ratio of land use *I,* Land use: 1;paddy, 2;upland fields, 3;forest, 4;urban

TN concentration coefficient across Japan is 1.67 (from lower limit 95% value 1.34 to upper limit 95% value 2.01), 4.08 (from 3.64 to 4.51), 0.76 (from 0.67 to 0.90), 3.57 (from 3.38 to 3.76) for paddy fields, upland fields, forests and urban areas respectively (n=3256). The TP concentration coefficient is 0.146 (lower limit 95% value 0.119 to upper limit 95% value 0.172), 0.172 (0.138 to 0.206), 0.044 (0.033 to 0.055), 0.267 (0.253 to 0.282) for paddy fields, upland fields, forests and urban areas respectively (n=3256,). Prefectural TN and TP concentration coefficients for paddy and upland fields related only loosely to prefectural surplus N and surplus P. On the other hand, prefectural TN and TP concentration coefficients for forests and urban related to prefectural population densities by logarithmic functions with determination coefficients $R^2$ from 0.45 to 0.48.

# Possibility of nutrients transportation from littoral slope for enhancement of phytoplankton growth in north basin of Lake Biwa

*Syuhei Ban[1], Rong YI[1], Xin Liu[1], Masahiro Maruo[1], Miki Sudo[1], Naoshige Goto[1], Jun Murase[2]

1. The University of Shiga Prefecture, 2. Nagoya University

Nutrient loading from non-point source in a lake ecosystem has not been well recognized yet. In Lake Biwa, total phosphorus (TP) does not decline to the level before eutrophication period, 1960s to 1970s, despite of decreasing the loading from point sources surrounding the lake after that. One of the reasons for no well lowering TP in the lake is attributed to agricultural runoff, in which suspended materials including phosphorus would be deposited to the littoral bottom. In our previous study, subsurface maximum of ammonium as a proxy of dissolved materials from anaerobic interstitial waters in the littoral bottom sediments was found along a transect from littoral to pelagic regions, implying horizontal transportation of nutrients from littoral sediments. There were no such evidences of soluble reactive phosphorus (SRP) yet due to always below the detection limit in the pelagic waters. Recently, we developed modified protocol using an ion chromatography for measuring orthophosphate concentration at nano-molar levels. In this presentation, we’ d like to provide several evidences for horizontal transportation of dissolved nutrients including orthophosphate along a transect from littoral to pelagic sites in north basin of Lake Biwa.

Total of the 6 times transect surveys for determining vertical profiles of nutrients, methane and herbicides were made in 2010-2011. Additional two transect surveys for determining those of nutrients including orthophosphate were made in 16 May and 25 July of 2018. During the 2010-2011 campaigns, *in situ* phytoplankton primary production was measured during the stagnation period using light intensity and chlorophyll *a*concentration monitored by sensors attached to a mooring buoy situated at an offshore station in north basin of Lake Biwa and an equation of photosynthesis - light intensity (P-I) curve.

In 2010-2011 campaigns, we detected sub-surface maximum layer, 20-30 m, of ammonium and methane as a proxy of dissolved materials transported from interstitial water in the sediment of littoral slope. Herbicides, which were used in rice paddy during the rice planting and proxy of materials transported from terrestrial environments surrounding the lake, were also detected in 20-30 m even at the offshore regions in the lake. Primary production monitoring suggested that phytoplankton production depended on some environmental variables other than solar irradiance, e.g. nutrients, until summer months. These results suggested that nutrients for enhancing algal growth might be horizontally transported from sediment in the littoral slope, and that the source of the nutrients might be provided from the drainage of rice paddy.

In 2018 campaigns, sub-surface maximum of ammonium was clearly found along a transect from littoral to pelagic sites in both May and July, but no such sub-surface maximum of orthophosphate was found. Several reasons for failure to find sub-surface maximum of orthophosphate might be proposed. Phosphate would be used by both phytoplankton and bacteria, while ammonium would be used by phytoplankton alone in the euphotic layer. In phosphate limited environment, such as pelagic areas in north basin of Lake Biwa, sub-surface maximum could not be easily detected due to rapid absorption by both phytoplankton and bacteria. Or, a transportation of nutrients from the littoral sloop would sporadically occur, and then we simply missed to detect it. This is on-going research project, and then further studies will be conducted to clarify this issue.

# SWAT model analysis for confirming the effects of crop growth on the suspended sediment concentration from a settling basin catchment on Ishigaki island

*Yang Cao[1], Shin-ichi Onodera[1], Mitsuyo Saito[2], Hide Omae[3], Yoshiko Iizumi[3]

1. Graduate School of Integrate Arts and Sciences, Hiroshima University, 2. Graduate School of Environmental and life Science, Okayama University, 3. Tropical Agriculture Research Front (TARF), Japan International Research Center for Agricultural Sciences (JIRCAS)

Crop growth has a significant effect on soil erosion in small watersheds. Exploring the characteristics and occurrences of soil erosion in small watersheds assists in our understanding of the water and material cycles in agricultural areas. The small catchment on the tropical island of Ishigaki, Japan, was chosen as the research area. The effects of sugarcane growth at different stages on the suspended sediment concentration in the basin from January 2017 to July 2018 were analyzed based on the Soil and Water Assessment Tool (SWAT) model. This study will explore the possible driving factors of these phenomena. The results show that the suspended sediment concentration in the basin reached its highest value on a rainy day near the sugarcane planting period because of the soil relaxation caused by tillage and cultivation. At the end of the sugarcane growth period, the sediment concentration was not at a high level when the rainfall reached 150 mm, because of the effective protection of the soil by sugarcane. The simulated sediment concentration of precipitation per mm showed that the simulated sediment concentration was at its highest during the crop planting period, followed by the period of bare land, and at the lowest during the crop growth period.

# Estimating the runoff of water, sediment, and nutrient using SWAT model in Kikuchi-river watershed, Kumamoto, and the influence of the forest

*Soichiro Fujii[1], Masahiko Kanamori[1], Yuko Nagano[1], Maki Kinoshita[2], Yuta Shimizu[3], Shin-ichi Onodera[4]

Recently, enclosed sea area such as Ariake-sea have severe nutrient enrichment problem and is decreasing the produce of fishery industry. Such enclosed sea area is commonly affected by river water quality discharged from the land area. Therefore, estimating the load of sediment and nutrient from its land area is important. However, most of researches estimating discharge from land area is conducted by simple method using primary load factor. These method only can provide the estimates in annual scale regardless of the land use. On the other hand, the positive effect of forest to water quality in the river, so-called green dam, is paid attention recently, and supposed to play important roll on improvement to sea environment. However, the effect of forest to water quality is not explained enough, and few research has conducted in watershed scale. In this study, we aim to simulate water, sediment, and nutrient runoff in order to provide more detail information about discharge from land area, and to estimate the influence of the forest to water quality. We use Soil and Water Assessment Tool (SWAT) and chose Kikuchi-river as a model watershed, which has the third largest watershed area among the rivers drain into Ariake-sea.

We set Komoda observatory as the most downstream point of Kikuchi-river and the model watershed is the upstream side from there. More than half of this watershed is covered by forest. We collected land use data, soil data, climate data and 30m mesh digital elevation model (DEM) data of this watershed in order to establish the model. In order to calibrate and validate the model performance, observed data of daily stream flow from 2008 to 2016, and sampling data of sediment and nutrient were collected. Moreover, we measured the amount of sediment, phosphorus and nitrogen during flood situation in 2016 and 2017. The parameters in the model were modified according to the result of calibration, and the performance of the model was evaluated from three indices such as Nash-Sutcliffe index.

The model performance was evaluated as more than satisfactory for all materials: water, sediment, phosphorus and nitrogen. Therefore, this model can simulate daily runoff from 2008 to 2017. The runoff rate of sediment and most of nutrient from forest was less than 30% of the annual average in whole watershed, although water discharge was the same level to the rate of forest area, which indicates the function of forest to provide low concentrate water of sediment and nutrient to the river. In conclusion, modelling the runoff from land area using SWAT model has potential to provide detail information about land area discharge and estimate the influence of forest to river water quality.

# Atmospheric depositions on forest ecosystems in areas along the Sea of Japan

*Yuko Itoh[1], Keiji Takase[2], Yoichi Fujihara[2], Toru Okamoto[1]

1. Forestry and Forest Products Research Institute, Japan, 2. Ishikawa Prefectural University

In recent years, concerns about the effects of excess-nitrogen usage by human activities on terrestrial environment, including forest ecosystems, have been increasing at a global scale. The phenomenon of high-nitrate efflux from several forest watersheds has already been reported in the surroundings of metropolitan areas in Japan. Furthermore, concerns regarding the effects of transboundary air pollution on areas along the Sea of Japan with expanding economic activities have been increasing in Asian countries. However, on-site monitoring throughout the year is difficult in most of these areas because of heavy snow, especially in the mountainous area. Therefore, the behaviors of elements within forest ecosystems throughout a year have primarily not yet been elucidated in this district. This study was conducted to determine the influxes and effluxes of elements in this heavy snowy region and to understand the contribution of transboundary air pollution to the quantity of atmospheric deposition. We also carried out rainfall and stream water investigations from the headwater area to the lower stream area in the Tedori River Basin and an inland mountainous area to understand the geographical distribution of the actual conditions of elements' influxes and effluxes in this region. We started monitoring the major and minor elements in a small forested watershed in the middle part of the Tedori River Basin, Ishikawa prefecture, Japan, in 2013. In this study site, we observed a large amount of precipitation throughout the year. Regarding the annual snowfall amount, there were extensive variations among the years. Seasonal fluctuations were observed in the influx of atmospheric deposition; in particular, the distribution of most of the elements increased during winter. The annual deposition average of inorganic nitrogen ($NH_4$-N + $NO_3$-N) in this site was 15.8 kg $ha^{-1}$. The contribution of winter season deposition to the annual inputs was high. The influx of nitrogen by bulk precipitation during winter season was 2.3 times that of summer, and that of sulfur sulfate was 3.7 times. The nitrogen influx quantity was similar to or more than that reported in nitrogen-saturated forested areas of the Kanto district. Therefore, similar to that in the Kanto district, higher nitrogen deposition loads from the atmosphere could also be influenced on the effect of nitrogen dynamics and the increase in nitrogen efflux at these forest watersheds. However, the efflux concentrations of most of the dissolved elements in stream water did not show clear seasonal fluctuations. Stream water nitrate concentration was stable and low. In addition to the seasonal fluctuation of nitrogen and sulfur, the ratios among some trace elements, which are anthropogenic substances (Pb, V, As, etc.), and sea salts and yellow sand could be useful indicators to elucidate the contribution of transboundary air pollution to these regions. We compared the element inputs associated with precipitation during the non-snowy season (July–November) at six locations in the Tedori River Basin and one location in the inland area. The inorganic nitrogen and sulfuric acid sulfur influxes were the largest at the middle reaches of the Tedori River Basin. The inflow amount of inorganic nitrogen and sulfuric acid sulfur at two points in the mountainous area was approximately half or less than that at the middle region and was approximately the same as the inflow amount at the inland mountainous area. Furthermore, we investigated stream water, spring water, and ground water samples from the headwater area to the lower stream area in the Tedori River Basin. The nitrate concentrations in all the samples ranged from 0.00 to 2.93 $mgL^{-1}$ (median value: 0.69 $mgL^{-1}$). In contrast, the nitrate concentrations of stream water in the Tsukuba experimental forest watershed, which has been reported as a nitrogen-saturated forested area of the Kanto district, were much higher (average value: 7.56 $mgL^{-1}$) than those in the Tedori River Basin. Compared with the influx, the efflux concentrations of nitrate in the water

©2019. Japan Geoscience Union. All Right Reserved. 

samples were generally very low around this basin. Therefore, higher nitrogen depositions have not yet distinctly influenced the nitrate concentrations of stream water in this area. To elucidate the influence of transboundary air pollutant influx on the entire Tedori River Basin, it is necessary to evaluate the inflow amount during the snowy season in the mountainous area. Therefore, it is important to establish a method that can be used to observe the influx and efflux of elements throughout the year even in mountainous areas with heavy snow.

# Continuous and simultaneous flux measurement of $N_2O$ and $CO_2$ from agricultural soil using a portable multi-turn time-of-flight mass spectrometer

*Noriko Nakayama[1], Yusuke Iwai[1], Yo Toma[2], Hiroshi Furutani[1], Ryusuke Hatano[3], Michisato Toyoda[1]

1. Osaka University, 2. Ehime University, 3. Hokkaido University

Agricultural soil is one of the important sources/sinks of greenhouse gases such as $N_2O$, $CO_2$, and $CH_4$. The formation and consumption of such greenhouse gases in agricultural soils are dependent on not only the chemical and biological properties of the soil, but also their variations. Hence continuous monitoring of such greenhouse gases as tracer gases are quite useful to track chemical and biological processes and variations of soil properties.

In this paper, we describe a new field-deployable gas flux measurement system for the continuous monitoring of multiple agricultural soil gases ($N_2O$, $CO_2$, and $CH_4$) using a high resolution multi-turn time-of-flight mass spectrometer (MULTUM) combined with an automated flux chamber system. The new system measured the soil gases every 2.5 min with the precisions of ~6% for $N_2O$, $CH_4$, and 2% or better for $CO_2$ and $O_2$ at atmospheric concentrations with one relative standard deviation (RSD) for n = 10.

To demonstrate the utility of the continuous multi-gas flux measurement system, we conducted a field study at the Ehime University farm (Ehime, Japan) from September 3$^{rd}$ to 8$^{th}$, 2018. In the field study, an automated flux chamber was placed in the agricultural field and the soil gas concentrations in the chamber were continuously monitored by the MULTUM system. Soil temperature/moisture sensor were also monitored at the depth of 7.5 cm underground in addition to a weather information (wind speed, precipitation, solar radiation). The continuous measurement had been continued with operators almost unattended except for a daily system check.

For one flux measurement (20 min), eight gas samples were taken every 2.5 min with the flux chamber closed. Gas flux of $N_2O$ and $CO_2$ had been carried out by applying linear regression to the eight gas measurements. We found that a significant correlation of $N_2O$ flux with soil electrical conductivity and water content, although no significant correlation of $CO_2$ flux to soil electrical conductivity was observed. Significant and rapid decreases in $N_2O$ and $CO_2$ flux during rainfall events were also observed. Our preliminary result shows that high time-resolution flux data obtained by MULTUM system is quite useful for tracking the variation in soil properties and biological processes and their activity in soil environment.

# Effects of introduction of cyclic irrigation system on mass balances of SS and T-P in Lake Inbanuma, Chiba, Japan

*Tomijiro Kubota[1]

1. National Agriculture and Food Research Organization, Institute for Rural Engineering

## Introduction

The introduction of cyclic irrigation has been advanced since 2010 in the Lake Inbanuma as part of the update project of the irrigation facilities. In the present study, mass balances of SS and T-P were examined before and after the introduction of the cyclic irrigation.

## Materials and methods

The irrigation block where the cyclic irrigation began in 2015 was selected as the investigation site, and the investigation was executed to the irrigation period in 2014 and 2015. The hydrological and water quality investigation was executed at ① division works of irrigation canal and ② drainage pumping station. Water samples were taken at the two points and the TOC, SS, TN, NO3-N, NO2-N, NH4-N, TP, and PO4-P were analyzed in the regular investigation executed about once a month. Besides regular investigation, water samples were taken once a day (8:00AM or noon) by the automatic water sampler and SS and T-P were analysed. The turbidity and water level were measured every ten minutes by using data loggers at same sites. The turbidity data were converted into the concentration of SS and TP by using the regression curve. The quantity of water intaken from the lake and drainage to the lake were obtained from the records of the facility manager.

## Result and discussion

The inflow and outflow loads and the balance were calculated before and after the introduction of the cyclic irrigation. In 2014, before the start of cyclic irrigation, both the outflow loads of SS and T-P were small to compare with those inflow loads. The amount of accumulation of SS and T-P were about 1.3t and 2kg respectively when having no rainfall in the irrigation block. On the other hand, the outflow of SS and T-P were about 3.5t/day and 20kg/day respectively in rainy days. If 2015 year is compared to 2014, it had increased in T-P though the load of irrigation water each day at no rainfall periods and it had not been change in SS though an accurate comparison is difficult according to the missing value. However, after the cyclic irrigation had been started, the amount of the outflow loads had decreased greatly like 35% in SS and 38% in T-P. The balance of the outflow loads during the irrigation periods of 2014 were -470kg/day in SS, which meant the purification type, while +2.6kg/day in T-P. as a result, it was found that the introduction of cyclic irrigation system had worked for water purification in SS and T-P effectively.

Discussion

# Humic substances in deep sedimentary groundwater

*Takumi Saito[1]

1. School of Engineering, The University of Tokyo

Humic substances (HSs) are ubiquitous in various environments and play important roles for the fate of nutrients and pollutants. Deep underground environment is not an exception, although the properties of HSs there are largely unknown due to their limited availability. Recently, we reported the physicochemical and ion-binding properties of HSs extracted from sedimentary groundwater at -250 m below ground surface of the Horonobe underground research center operated by the Japan Atomic Energy Agency. The Horonobe HSs (HHSs) consist of relatively small organic molecules rich in aliphatic carbon and reduced sulfur. The densities of acidic functional groups such as carboxylic groups are relatively high for HHSs, and they are chemically homogenous. Nevertheless, the binding of $Cu^{2+}$ to HHSs are smaller than that to surface HSs, suggesting the presence of different coordination environments for $Cu^{2+}$ in HHSs. Cadmium, a thiophilic metal, tends to form CdS(s) nano-particles with HHSs likely due to the high concentrations of reduced sulfur. In this talk, the particularity of the HHSs will be discussed, comparing their properties with those of their counterparts in surface environments.

# Nano-Bubble Retention in Saturated Porous Media under Different Solution Chemistry

*Shoichiro Hamamoto[1], Takuya Sugimoto[1], Takato Takemura[2], Taku Nishimura[1], Scott A Bradford[3]

1. Department of Biological and Environmental Engineering, The University of Tokyo, 2. College of Humanities and Sciences, Nihon University, 3. U. S. Salinity Laboratory

An understanding of nano-bubble (NB) migration in porous media is needed for potential environmental applications. This research investigates factors that control the transport, retention, and release of air NBs in repacked glass beads. One-dimensional column transport studies with air NBs were conducted under different solution IS, ionic composition, and pH conditions. Collected data were simulated using a mathematical model that considered advective and dispersive transport, first-order kinetic retention, and transient release. Results were interpreted with the aid of interaction energy calculations that considered electric double layer, van der Waals, and Lewis acid-base interactions on surfaces with different amounts of nanoscale roughness. NB concentrations in the effluent were reduced with an increase in ionic strength (IS) or a decrease in pH due to a reduction in the repulsive force between the glass surface and NBs, especially when the solution contained $Ca^{2+}$ as compared to $Na^{+}$ and for larger NBs. NB retention on the surface was explained by ubiquitous nanoscale roughness on the glass beads that significantly lowered the energy barrier, and localized attractive charge heterogeneity and/or hydrophobic interactions.

# Geochemical Investigation of Metals and Trace Elements around the Abandoned Cu –Ni Mine Site in Selibe Phikwe, Botswana

*Fiona Segolame Motswaiso[1], Kengo - Nakamura[1], Noriaki - Watanabe[1], Takeshi - Komai[1]

1. Tohoku Univeristy Graduate School of Environmental Studies

Metals and trace elements may occur naturally in rocks and soils, but elevated quantities of them are gradually released into the environment by anthropogenic activities such as mining. In order to address issues of trace element water and soil pollution, a distinction needs to be made between natural and anthropogenic anomalies. The current study aims at characterizing the spatial distribution of trace elements and evaluate site-specific geochemical background concentrations of trace elements in the mine soils and river sediments and also to discriminate between lithogenic and anthropogenic sources of enrichment around a copper-nickel mining town in Selibe-Phikwe, Botswana.

A total of 43 soil, 30 river sediments, and 9 river water samples were collected from an area of 500m2 within the precincts of the mine. The total concentration of Cu, Ni, Pb, Cr, As, and Co in soils and sediments were determined using ED-XRF while river water samples were analyzed by ICP-AES. Geochemical pollution indices such as Geo-accumulation Index (Igeo), Enrichment Factor (EF) and Integrated Pollution Index (IPI) were employed for the assessment of metal and trace element contamination. The average metal concentration in soil of Cu, Ni, Pb, Cr, As, and Co in the study area were 73.27, 78.10, 25.83, 61.43, 4.28 and 6.43 mg/kg, respectively. To calculate the geochemical baseline, Relative cumulative frequency curves and the 4 s -outlier test methods suggested by Matschullat (2000) were incorporated. The estimated average baseline concentrations of Cr, Cu, Ni, Co, Zn and As are 53.8, 51.85, 53.95, 5.6, 32.36 and 4.27 mg kg 1, respectively. Soil leachate, sediment leachate, and river water pH levels ranged from basic (9) to very acidic (3) in areas closer to the mine. There is high variation in heavy metal concentration, eg. Cu, depicting regional natural background concentrations while others depict anthropogenic sources. The calculated Igeo values revealed moderate pollution level by the same metals. The result of integrated pollution indices suggested a generally deteriorating site quality. The results of chemical analysis also indicate that the trace elements in soils decreased with respect to distance from the mine; controlled mainly by water movement, wind direction, and topography.

# Removal of Arsenic (III) From Aqueous Solution Using Pumice and Zeolite Supported Zero-Valent Iron Nanoparticle

*Shashi Ranjan[1], Brijesh kumar yadav[1], Himanshu Joshi[1]

1. Indian Institute of Technology Roorkee

Arsenic is a naturally occurring toxic element and is widely distributed in natural ecosystems. Due to the natural as well as human-induced actions, its presence in groundwater is expanding its horizons and is becoming a major concern in lower Gangetic plains. Large active surface area and high arsenic adsorption capacity make nano-zero valent iron nanoparticle (nZVI) a promising adsorbent to remove arsenic species but due to high surface energy and the inherent magnetic forces of nZVI, it gets agglomerated and reduces its efficiency for adsorption. The objective of the present study was to develop supported nZVI over the porous material (pumice and zeolite) and their use for As (III) removal from aqueous solution. The chemical approach, i.e., Liquid Phase Synthesis, was used to infuse the iron nanoparticle on the surface of the porous material via reduction of iron in the presence of the base material by sodium borohydride. The shape, size, and surface morphology studied by Fe-SEM and shows a uniform distribution of nZVI over the surface of granular (0.5-1 mm) base materials. Batch studies were performed to determine the applicability of prepared composites as an adsorbent for As (III) removal at varying initial As (III) concentration (0.5 -5 mg/L), adsorbent dose (1-10 g/L) and pH (3-12). Adsorption kinetics and isotherms were studied in detail for the synthesized adsorbent to deduce the overall performance. Batch experiments demonstrated the quick removal of As (III) at initial stages followed by a slower removal rate, making it a two-stage process. The supported nZVI was found to be an effective adsorbent for As (III) removal and due to its mechanical strength, it can be applied for in-situ remediation of arsenic-polluted groundwater

# Unsaturated Hydraulic Conductivity Estimation from Multi-step Centrifuge Outflow

*Thanh Long Bui[1], Yasushi Mori[1]

1. Graduate School of Environmental and Life Science, Okayama University

In the age of blooming technologies, direct and indirect laboratory methods, which identified soil function, are developed to shorten experiment time. In developing countries of Asia area, research on soil physic is sometimes limited because it is not easy to bring samples from those countries. In addition, it is impossible to identify soil function from the soil sample without original structure. Therefore if we can measure soil hydraulic conductivity or water holding capacity with small volume of samples, it is very beneficial for the region where soil data is limited. In this study, centrifuge multi-step outflow method was examined to estimate drainage process, i.e., unsaturated hydraulic properties.

The experiment was conducted using 2-mL centrifuge tube with two pin-holes at the top and bottom of the tube. After saturated from the bottom, multi-step pressurized outflow was performed on four kinds of soil samples including standard soil, granite decomposed soil, rice paddy field soil and volcanic ash soil. Transient outflow volume was measured using small centrifuge machine within 5 and 15 minutes at room temperature (25oC). The centrifuge pressure step was 1000, 2000, 3000, 4000, and 5000rpm, which was approximately 90, 360, 810, 1400, and 2250cmH2O respectively. Based on the outflow volume and accumulated time as input data for inverse solution model (HYDRUS 1D v4.6), hydraulic conductivity was optimized.

We found out that the optimization was successful with clayey soils and volcanic ash soils, but not with granite decomposed soil and standard sandy soils. The more sand particles it contained, the less convergence for hydraulic conductivity optimization we had obtained.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

Thu. May 30, 2019 5:15 PM - 6:30 PM JST | Thu. May 30, 2019 8:15 AM - 9:30 AM UTC | Poster Hall International Exhibition Hall8, Makuhari Messe_10

## [A-GE28] Subsurface Mass Transport, Material Cycle, and Environmental Assessment

convener:Yuki Kojima(Department of Civil Engineering, Gifu University), Shoichiro Hamamoto(Department of Biological and Environmental Engineering, The University of Tokyo), Hirotaka Saito(Department of Ecoregion Science, Tokyo University of Agriculture and Technology), Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University)

This session covers the topics on mass transport, water and energy cycles in geoenvironment. Subjects related to laboratory and field measurements, theoretical analysis, and numerical modeling will be discussed. Presentations on geo-pollution, remediation, geological disposal of hazardous wastes, ground source heat utilization, mass transport in vadose zone, soil-water monitoring, and environmental assessment are encouraged.

Frequent disturbances of typhoons, earthquakes and heavy rains have resulted in many landslides scattering over steep terrains and remote areas of Taiwan. As a result, the general engineering methods may not work well.

In the past, helicopters were used for aerial hydroseeding on such landslides. However, the remediation method with helicopters is complicated. This method takes a lot of manpower and materials. Additionally, the remediation timing is often missed because its preparation is time-consuming.

In recent years, the relevant research and technology of unmanned aerial vehicles (UAVs) are approaching maturity. Compare to helicopters, UAVs have the advantages of mobility and instantaneity. UAVs has many potentials to deliver vegetating materials to landslides.

Traditionally, vegetating materials (liquid or dry powder types) are sprayed to landslide sites through compressors. However, the load of UAVs is limited. They can't carry too much liquid or compressors. In other words, traditional vegetating materials won’ t work for UAV methods.

This study was to develop several types of agglomerates by mixing vegetating materials. The agglomerates look like a pellet, so it is called "vegetation pellet". To make sure which pellets can be applied to what environmental conditions, the water characteristics, pH value, nutrient content and seed germination rate of pellets with different ingredients were analyzed. In the field experiment, seed germination of pellets was monitored after pellets were applied to three different landslide sites.

Results showed that seed germination of pellets is directly related to the level of environmental moisture. If pellets were applied to landslides where rainfall and soil moisture were high, seed germination rates of pellets could reach 80% within three weeks. There were 1~3 germinating woody plants per square meter. Although germination rates of pellets applied during the dry season were nearly nill, seeds in pellets could germinate vigorously after the first wave of rainfall.

Although this study is still in the initial phase of the pellet development, the preliminary experiments showed that using UAVs to deliver vegetation pellets has considerable potentials for landslide remediation. Further studies can vary the fraction of ingredients and the size of pellets to maximize remediation effects.

# Characterizing Soil Environment in The Rice Terraces of the Philippine Cordilleras

*Tomoyo Kurozumi[1], Yasushi Mori[2], Hiroaki Somura[2], Milagros Ong How[3]

1. Faculty of Environmental Science and Technology, Okayama University, 2. Graduate School of Environmental and Life Science, Okayama University , 3. Universal Harvested Incorporated

Rice terraces of the Philippine Cordilleras, located in northern Luzon Island, are contribute to the food production as well as water and carbon storage. The rice terraces, which have been designated as the World Heritage and should be protected as a cultural heritage, were in danger of collapse. Thus we need to clarify the mechanism of collapse from the perspective of natural science and protect them efficiently. We made a hypothesis that rice terraces are water storage structures physically, so the weight of paddy affects the stability, which determined by levee length, the depth of hardpan, and water ponding depth. Mainly in Banaue, rice terraces in three location: Viewdeck; Bangaan; and Hapao were investigated. Sometimes, ponding water on the rice terraces had fermentation odor, and the hard pan was detected at deeper depth. During the in situ infiltration test, gas was coming up from the soil and the hydraulic conductivity was low or unmeasurable. Excess amount of organic matter was considered to cause the gas emission which disturbs the soil sedimentation and compression, resulting in hardpan formation failure. Although organic matter application was important to soil nutrition and high crop yields, it might result in reductive condition which causes mineral leaky paddy and harmful gas emission.

# Web-based interactive platform for analysis of regional-scale groundwater resources

*Chuen-Fa Ni[1], I-Hsien Lee[1], Chi-Ping Lin[1], Wi-Ci Li[1]

1. National Central University

With the increasing variability of climate conditions, the sustainable management of groundwater resources has become a challenging task. Accurate assessment of groundwater resources relies on sufficient measurements and efficient analysis tools. The integrated technologies and multidisciplinary knowledge for groundwater have enhance the understanding of dynamics in groundwater systems. Taking advantages of widely developments in computer sciences and web service, the web platform provides an excellent open environment for groundwater investigations. However, most groundwater relevant web platforms are mainly focusing on the data visualization. The data (points, polylines, and polygons) and pre-analysis results (i.e., the figures) overlap a street map to indicate the location of interests and quantify the influenced regions of groundwater hazards. Such one-way interaction framework has significantly limited the implementations of measurement data and groundwater relevant applications. The study aims to develop an online web-based platform for groundwater data visualization, temporal and spatial data analysis, mesh generation and flow modeling. The study integrates multiple program languages such as Java, C, Python, and FORTRAN to bridge the data flow and online visualization. The interactive real-time web environment enables users to screen temporal and spatial measurements on the web map, conduct online data analyses, and develop numerical groundwater models. With well-designed database and numerous modules for data analyses and modeling, the platform allows users to share data and develop collaborative activities. The built-in analysis tools can also improve the efficiency of groundwater management and decision-making processes.

# Development of simultaneous measurement system of viscosity and permeability for highly accurate evaluation of flow characteristic of Geofluid

*Tomoya Muramoto[1], Yoshitaka Fujita[1], Hiroaki Kajikawa[1], Hideaki Iizumi[1], Kazunori Ide[1]

1. National Institute of Advanced Industrial Science and Technology, National Metrology Institute of Japan

In this study, we will develop a high precision simulutaneous measurement system of high temperature - high pressure viscosity and permeability to strictly evaluate the behavior of Geofluid. In this system, we combine high precision viscosity measurement technique and high pressure generation technique of National Metrology Institute of Japan. One of the features of the porous medium like crust is that the fluid can be transmitted through a cavity having a complicated geometric shape inside it. That is, the porous medium has hydraulic properties. Recently, in evaluating the long-term stability of disposal system for high-level radioactive wastes, and also, to reveal the relationship between fluid characteristic and tectonic deformation of crust, the need to know the permeability / substance transport characteristics of the target rock or stratum in detail has been emphasized. A lot of research and development has been done to grasp the flow characteristics of the Geofluid under high pressure, however, the pressure dependence of the viscosity of the crustal fluid tends to be overlooked, and also the permeability coefficient of the rock accompanying it tends to be ignored. So, there are few studies which strictly evaluated of it. Technical development of high precision measurement of permeability in terms of Metrology has not been done so far. In addition, no quantitive study has been done on the generally used Darcy’ s law from Metrology viewpoint. In this study, we focus on the similarity between flow field descriptions beased on Hagen-Poiseulle’ s law used for highly accurate viscosity measurements by capillary method and Darcy’ s law. We will develop simultaneous measurement system of high temperature - high pressure viscosity and permeability, leading to an essential understanding of flow characteristics of Geofluid.

# Soil hydraulic parameter estimation by evaporation method

Shintaro Kubota[1], *Hirotaka Saito[1]

1. Graduate School of Agriculture, Tokyo University of Agriculture and Technology

An evaporation method to estimate soil hydraulic properties, such as soil water retention curve and unsaturated hydraulic conductivity, has been receiving attention because of its simplicity and flexibility. Depending upon experimental setup, there are several approaches available for data analysis. In this study, a so-called simplified method and a more common but more involved inverse method were compared in terms of estimating soil hydraulic parameters. In the simplified method, soil water retention curve and unsaturated hydraulic conductivity were approximated by assuming that soil water pressure heads measured at two locations within the soil sample were linearly distributed. Parameter $\alpha$ and $n$ which were used in the van Genuchten (VG) soil water retention model were determined by fitting it to the curve obtained by the simplified method. Unsaturated hydraulic conductivity function was then predicted by the van Genuchten-Maulen model with the obtained $\alpha$ and $n$. For the inverse method, the $\alpha$ and $n$ parameters were directly optimized using a numerical analysis by fitting to measured pressure heads.
In this study, Toyoura sand, Tottori dune sand, glass beads and silt were used. After soil water retention curves were determined using the simplified method, the VG parameters were estimated to predict unsaturated hydraulic conductivity. With the inverse method, the VG parameters were inversely estimated using HYDRUS-1D program. Results showed that the parameters estimated from both the simplified and inverse methods predicted unsaturated hydraulic conductivity well compared to that determined from the simplified method. On the other hand, those for Toyoura sand, Tottori dune sand and glass beads were not well predicted. In general, the unsaturated hydraulic conductivity in the wet region was overpredicted, while that in the dry region was underestimated when the simplified method was used. Overall, this study shows that the simplified method needs to be carefully used especially for coarse materials, such as sand and glass beads.

# Measurement of apparent gas diffusion coefficient in poorly tilled seedbed under windy condition.

*Yoshihiro Matsumoto[1], Shuichiro Yoshida[1], Hiroyuki Sekiya[2], Kazuhiro Nishida[1]

1. Graduate School of Agricultural and Life Sciences, The University of Tokyo, 2. National Agricultural Research Center NARO

In the cultivation of soybean in clayey paddy fields, huge clods with diameters of some centimeters are formed by tillage. In soil, movement of gas is usually assumed to be governed by molecular diffusion. On the other hand, in soil layer with huge clods, movement of gas can be enhanced by wind-induced pressure-pumping through large inter-clod pore space under windy condition. Although pressure-pumping is not a diffusive process, this phenomenon can be represented as a diffusive process by the Fick's law with the apparent gas diffusion coefficient under windy condition ($D_a$). However, little work has been done on $D_a$ in poorly tilled soil, especially in situ. This study aimed to compare $D_a$ and molecular gas diffusion coefficient ($D_m$) in poorly tilled seedbed and quantify how many times $D_a$ is larger than $D_m$.

The undisturbed poorly tilled soil was sampled on June 2018 just after tillage from the surface of the clayey field where conversion from flooded rice to soybean was conducted this year using the soil column with a diameter of 15.3 cm and a height of 9.7 cm. The porosity and mean clod diameter of the soil were 0.69 and 2.8 cm, respectively. As a control, Mikawa silica sand was packed into the column with a porosity of 0.49. The empty cap with a height of 2.9 cm were attached to the lower end of the column to conduct gas diffusion experiments. The oxygen concentration sensors were installed to the column and cap at 4.7 and 11.7 cm depth from the top of the column, respectively. The top of the column was closed, and then $CO_2$ gas was injected from the cap to saturate the column with $CO_2$. After opening the top of the column, $O_2$ concentration was continuously measured. The gas diffusion coefficient ($D_a$ or $D_m$) was estimated by fitting the measured $O_2$ concentration at 4.7 cm and 11.7 cm depth to the numerical solution of the diffusion equation. The diffusion tests under the wind for evaluating $D_a$ was conducted on November 2018 at the field where the soil specimen were taken. Three-dimensional wind velocity at 2 m above the column ($U_2$) was measured by the ultrasonic anemometer. The diffusion tests without the effect of wind for evaluating $D_m$ was conducted in the laboratory in the same manner.

Under the wind speed $U_2$ of 1.0 and 1.4 m $s^{-1}$, the apparent diffusion coefficients $D_a$ for the sand column were both 0.020 $cm^2$ $s^{-1}$, which was close to the measured $D_m$ for the column: 0.019 $cm^2$ $s^{-1}$. Thus, the gas diffusion in the sand column was governed by the molecular diffusion alone. On the other hand, the $D_a$s for the poorly tilled soil column under $U_2$ of 1.5, 2.3, and 4.1 m $s^{-1}$ were 0.065, 0.075, and 0.097 $cm^2$ $s^{-1}$, respectively, while the $D_m$ for the column was 0.036 $cm^2$ $s^{-1}$. This result shows the wind induced two to three-fold increase of apparent gas diffusion coefficient through the inter-clod pores of the poorly tilled soil, while the effect does not work on the sand layer.

# Evaluating improvement techniques for phytosuction separation method to remove heavy metals from contaminated soils

*Yuki Kojima[1], Hayata Terada[1], Masahiko Katoh[2], Kohji Kamiya[1]

1. Department of Civil Engineering, Gifu University, 2. School of Agriculture, Meiji University

Soil contamination by heavy metals has been a critical issue because heavy metals are bonded with soil particles tightly and are difficult to remove. Phytoextraction is one of the soil decontamination methods that plants growing at contaminated sites extract contaminants with soil moisture. Although the phytoextraction is environmentally friendly and low in cost, removal rates of contaminants are limited because plants growth is inhibited due to the toxicity of contaminants. Katoh et al. (2016) proposed a new method for heavy metal decontamination, phytosuction separation (PSS), which utilizes plant water uptake and an immobilization material (they used hydroxyapatite). In PSS, a immobilization material for heavy metals was placed on a contaminated soil, and plants grow in non-contaminated soil mounded on the immobilization material. Plant water uptake induces heavy metal transfer from contaminated soil toward the immobilization materials. Since plants are protected from the toxicity of heavy metals in this method, the removal rates of heavy metals are much higher than that with phytoextraction. In this study, we aimed to improve the PSS method by i) using new immobilization materials, ii) inducing soil water cycle between the contaminated and non-contaminated soils, and iii) applying organic fertilizer to enhance plant growth and to increase mobility of heavy metals.

We performed pot experiments to evaluate each improvement techniques with lead contaminated soil collected from a shooting range. As a new immobilization material, we examined iron slag and commercialized adsorption sheet. Water cycle between contaminated and non-contaminated soils are induced by changing position of water supply. Katoh et al. (2016) supplied water from contaminated soil, but we supplied from non-contaminated soils. The water supplied to non-contaminated soil move downward by gravity and reach contaminated soil, and then go back to the non-contaminated soil by plant water uptake. Plant roots produce organic acid and it will be transferred to the contaminated soil with water. Since organic acid increase mobility of lead, the water cycle possibly improve the efficiency of PSS method.

The results showed poor plant growth when slag and commercialized sheet are used as a immobilization material compared with when hydroxyapatite was used. Obviously the plants growth was inhibited by the toxicity of lead. The slag did not have enough ability to immobilize the lead, possibly due to the small soil moisture content in PSS method. The commercialized sheet allowed plant roots penetrate itself and the roots reached contaminated soil. The water cycle increased soluble lead content in contaminated. It means that organic acid produced by roots reached the contaminated soil. Applying organic fertilizer did not increase soluble lead content in the contaminated soil, but it improved plant growth. Therefore, water cycle and organic fertilizer improves the PSS method, but immobilization materials still need to be investigated.

# Transport of Colloidal Particles in Saturated Toyoura Sand: Effects of Flow Rate on Importance of Electrostatic Repulsion

*Takuya Sugimoto[1], Shoichiro Hamamoto[1], Taku Nishimura[1], Yasuhisa Adachi[2], Motoyoshi Kobayashi[2]

1. Graduate School of Agricultural and Life Sciences, The University of Tokyo, 2. Faculty of Life and Environmental Sciences, University of Tsukuba

There are substantial colloidal particles such as clay minerals and metal oxides in soil environments. Such colloidal particles have been considered as a potential carrier of contaminants in vadose zone and aquifer, due to their surface charges and high specific surface area. Therefore, understanding the transport mechanisms of colloidal particles in soils is essential to predict the fate of the contaminants in the environments. In this study, we analyze deposition rate coefficients of polystyrene latex particles with a diameter of 1 $\mu$m in a column packed with Toyoura sand with an average diameter of 0.274 mm as a function of NaCl concentration at three different flow rates. The concentration of the colloids in the effluent was quantified using a spectrometer photometer. The experimental results showed that the deposition rate coefficients of the colloids increased with increasing NaCl concentrations and reached a plateau above a certain NaCl concentration, called the critical deposition concentration (CDC). The CDCs shifts to higher salt concentrations with increasing injected flow rates. We show that this experimental trend can be captured by a simplified model including physico-chemical interactions based on the DLVO theory.

# Leaching behavior of As, Pb, Cd and Se in subsurface marine and nonmarine sedimentary environment in central Kanto plain, Japan

*SUSHMITA HOSSAIN[1], Takashi Ishiyama[2], Shoichi Hachinohe[2], Chiaki T. Oguchi[1]

1. Graduate school of Science and Engineering, Saitama University, 2. Center for Environmental Science in Saitama

Leaching behavior of trace element and heavy metal strongly depends on the physicochemical form termed as chemical speciation in soil and sediment. So that, sediment and soil act as scavenger to transfer naturally or anthropogenically occurring element to subsurface environment with changing environmental conditions. In this research, total 25 boring core sediment samples were investigated at 1 m interval from lowland valley of Yono area, Saitama in Kanto Plain for chemical speciation and potential risk assessment of arsenic (As), lead (Pb), cadmium (Cd) and Selenium (Se) with other metals. Samples were kept in near natural or not oxidized condition applying special preservation technique. A four steps sequential extraction method was adopted to determine chemical speciation. Boring core consist of surface clayey silt, peat, organic rich silt and clay, tuffaceous clay and medium to coarse sand with gravel layer of nonmarine sediment up to 17 m depth, where as from depth of 17 to 20 m transitional sediment are underlain by marine sediment up to 26 m. Total metal concentration, mineral content and chemical speciation concentration were determined by using X-ray Florescence(XRF), X-ray diffractometer (XRD), Inductively coupled plasma mass spectrometer (ICP-MS) and Inductively coupled plasma atomic emission spectrometer (ICP-AES) respectively. Clay minerals distributions were determined specially after application of heat and ethylene glycol treatment and XRD peak analysis. Pore water were collected from each samples and element concentration were measured by ICP-MS and ICP-AES. Under natural condition, pH of the leachate from sediment are not significantly different in nonmarine and marine environment which are ranged from pH 6.55 to 8.04. However, the electrical conductivity (EC) concentration range 53.9 to 72.1 μS/cm in marine and 77.9 to 104.7 μS/cm in surface silty clay sediment, that is quite higher than (7.83 to 25.4 μS/cm) of nonmarine fluvial, peat and tuffaceous clay. Chemical speciation trend for As in marine and nonmarine sediment is Fe-Mn oxide bound > Carbonate bound > Ion-exchangeable bound > water soluble where more than 95-98 % are consist of residual and organic bound in all samples indicates their occurrence are of natural origin. The potential mobile fractions (Fe-Mn oxide bound + Carbonate bound + Ion-exchangeable bound + water soluble) of Se and Cd are less than 5 % of total concentration whereas for Pb, it is less than 1%. Chemical speciation trend for Se is Fe-Mn oxide bound > Carbonate bound > Ion-exchangeable bound > water soluble in fluvial nonmarine sediment differs from the trend in marine environment which seems more bioavailable. For Cd, the trend is Carbonate bound > Ion exchangeable bound > Fe- Mn oxide bound >> water soluble. The speciation trend of Pb and As is similar. In pore water also, the concentration trend is As > Se > Cd >Pb. However, only As conc. in pore water exceeds several times from environmental standard (10 μg/l) of WHO and Japan in leachate and drinking water of both non marine and marine sediment. The highest concentration is 116.42 μg/l at depth of 17.2-17.4 m, 86.14 μg/l at 24.2-24.4 m and 63.12 μg/l at 10.2-10.4 m in transitional, marine and fluvial environment respectively. Pore water concentration of Pb, Cd and Se have not exceeded the environmental standard of leachate and drinking water quality. According to risk assessment, the bioavailable fraction of As, Pb, Se and Cd in both marine and nonmarine sediment is less than 1-5 % of the total concentration indicating low or no risk. However, results suggest that leaching behavior of As differs from Se, Cd and Pb even though according to risk assessment on speciation, they have similar conditions. Pore water as well as groundwater As in fluvial aquifer shows higher concentration which is related to higher potential mobile fractions and enrichment.

# Colloid transport in a quasi-saturated porous media

*Yushi Ooko[1], Takuya Sugimoto[2], Shoichiro Hamamoto[2], Taku Nishimura[2]

1. The University of Tokyo, 2. Graduate School of Agricultural and Life Sciences, The University of Tokyo

Colloidal particles in soils have been considered as one of the transport carriers for contaminants through groundwater (saturated zone). In natural soil system, repeated wetting-drying cycles often leads to entrapped air in the pores of a water-saturated zone, namely, quasi-saturated condition. However, there are few studies on colloidal transport process in quasi-saturated condition. Therefore, studying the colloidal transport in such quasi-saturated condition is important to understand the phenomenon of colloidal migration in the environments. In this study, we aimed to investigate the effects of entrapped air on colloid transport in porous media based on one-dimensional column experiments. We also characterized entrapped air in the porous media by X-ray CT measurements.
Two different sand columns (1. i.d. 0.9-cm, height 10-cm, 2. i.d. 5-cm, height 10-cm) were prepared for X-ray CT measurements and column transport experiments, respectively. Columns repacked with Toyoura sand were completely water-saturated by applying degassed water to the dry-sand repacked column under vacuum condition. The soil water was drained by applying a suction of 70-cm H2O to the column. By hanging water table, the sand columns were then re-saturated by immersing them in water tank, resulting in quasi-saturated sand columns. In the X-ray CT measurements, the sand column was scanned by X-ray CT device (Metrotom 1500, Carl Zeiss) with spatial resolution of 11.3 micron. In the column transport experiments, the suspension of silica particles (SL) with a diameter of 100 nm in diameter was injected to the columns under saturated and quasi-saturated condition at a constant flow rate. Effluents were collected periodically to measure the turbidity, which represents SL concentrations.
X-ray- CT measurements and subsequent CT image analysis showed the decreased fraction of entrapped air in pore volume and the increased fraction of smaller entrapped air at lower part of the column. Pore-network tortuosity analysis based on the CT images revealed that more tortuous liquid-phase network formed in the quasi-saturated condition as compared to the one under water-saturated condition. As a result of column experiments, the colloid transport was facilitated in the presence of entrapped air compared to the fully -saturated condition. It was suggested that the presence of entrapped air would inhibit the deposition of silica particles at the favorable site on the sand particles.

## [A-GE29] Energy-Environment-Water Nexus and Sustainable Development

convener:Ming Zhang(Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST), Ken Kawamoto(Graduate School of Science and Engineering, Saitama University), Jet-Chau Wen(National Yunlin University of Science and Technology), Yonghong Hao(Tianjin Normal University), Chairperson:Ming Zhang(AIST), Hirotaka Saito(Tokyo University of Agriculture and Technology), Yonghong Hao(Tianjin Normal University)

This session provides a broad platform for discussion and presentation of fundamental and up-to-date scientific results related to clean energy production, environmental remediation and restoration, waste management, water cycle, monitoring of water quality, management of water resources and interconnections among them for sustainable development. Presentations on the topics associated with social science that enhance public awareness, stakeholder empowerment and involvement, and policy decisions regarding the management of water, energy and the environment are also encouraged.

Discussion

# Input-Output Analysis of Taiwan’s Food-Energy-Water Risk

*CHU-CHUN YAO[1], Gene Jiing-yun You[1]

1. National Taiwan University

The water, energy, and food (WEF) nexus means that the three sectors are inextricably linked and that actions in one area more often than not have impacts in one or both of the others. From a national planning perspective, it is necessary to more precisely investigate the relationships among food-energy-water sectors. This study applies input-output analysis based on interdependencies between economic sectors or industries in Taiwan’s food-energy-water challenge and risk. In this study, the research data is based on Taiwan’s trade association tables of 52 economic sectors (including food, energy, and water-related sectors) for the year 1996, 2001, 2006, and 2011. We develop the extrapolation method to produce available I-O table. The future I-O table can be forecasted by applying different predictive models (e.g., linear or nonlinear regressions). We will observe the changes in Taiwan’s economic structures during the time period (e.g., between 1996 and 2001) and also investigate the uncertainty of economic impact focusing on food, energy, and water. Based on the results of analysis of Taiwan’s trade association tables, we can predict the risks that Taiwan’s industries may face under different conditions in the future and might provide some useful information to the government for taking countermeasures.

# Groundwater potential analysis using the multiple spatiotemporal remote sensing approach in fractured rock of mountainous region

*Jung-Jun Lin[1,2], Yuei-An Liou[1], Chien-Chung Ke[2], Su-Yun Chi[2], Jia-Hung Liang[3]

1. National Central Univ., 2. Sinotech Engineering Consultants, Inc., 3. Ministry of Economic Affairs

Because of the costly field investigation, an optimum benefit technique, the multiple spatiotemporal remote sensing analysis, was used for long-term monitoring and assessment of groundwater potential capacity. In this study, we used the mentioned approach to derive the spatiotemporal index from Landsat imagery for identifying the land use change and understanding the regional hydrogeological characteristics, such as normalized difference vegetation index (NDVI), soil moisture index (SMI), land surface temperature (LST) and so on. To verify the index evaluation results, the hydrogeological properties including the core inspection, geophysical logging and hydraulic testing of totally 108 boreholes drilling in the fractured rock mass in mountainous region were collected. The pumping test results such as well capacity from 76 groundwater monitoring wells were also used to compare the potential groundwater capacity evaluated from remote sensing analysis. It was found a good agreement between the field investigation data and remote sensing analysis results. Therefore, the multi-scaled comprehensive analyses of natural and anthropogenic geomorphic features are suitable for providing more information to qualify and estimate the selections of investigated sites in the future.
