[U-02] Assessment and Accountability of Scientific Knowledge Creation

convener:Michiyo SHIMAMURA(Japan Agency for Marine-Earth Science and Technology), Yasuhiro Yamanaka(Faculty of Environmental Earth Science, Hokkaido University), Kiyoshi Suyehiro(Japan Agency for Marine-Earth Science and Technology), Brooks Hanson(American Geophysical Union)

[U02-P01] Let's start the discussion of the international tuning of research assessment in earth science to create a culture and indicators of “creation of knowledge”

*Yasuhiro Yamanaka[1], Michiyo SHIMAMURA[2], Kiyoshi Suyehiro[2] (1.Faculty of Environmental Earth Science, Hokkaido University, 2. Japan Agency for Marine-Earth Science and Technology)

[E] Poster | U (Union)：Union

[U-03] Sustainable global groundwater management for human security

convener:Yoshihide Wada(International Institute for Applied Systems Analysis), Makoto Taniguchi(Research Institute for Humanity and Nature)

[U03-P01] **Estimating yield is key to obtaining global material flux via the submarine groundwater discharge**

*Chen-Tung Arthur Chen[1,2], Ting-Hsuan Huang[1], Hon-Kit Lui[1], JING ZHANG[3] (1.National Sun Yat Sen University, 2.Zhejiang University, 3.University of Toyama)

[U03-P02] Quantitative assessment of the impacts of sustainable irrigation on global bioenergy production

*Zhipin Ai[1], Naota Hanasaki[1] (1.National Institute for Environmental Studies, Japan)

[U03-P03] Integrated structural, geophysical and hydrogeological approaches for sustainable groundwater resources in Precambrian basement rock terranes, India

*Rudra Mohan Pradhan[1], Tapas Kumar Biswal[1] (1.Department of Earth Sciences, Indian Institute of Technology Bombay, India)

[E] Poster | U (Union)：Union

[U-04] International Efforts Supporting Global Navigation Satellite System-Enhanced Tsunami Early Warning

convener:Rundle John B(University of California Davis), Kazuyoshi Nanjo(University of Shizuoka), Eiichi Fukuyama(Kyoto University / National Research Institute for Earth Science and Disaster Resilience)

[U04-P01] **GNSS total electron content for ionospheric tsunami early warning**

Tien-Chi Liu[1], Katsumi Hattori[2], *JANN-YENQ Liu[3,4,5], CHIYEN LIN[3,4], Yu-Lin Tsai[1], Tso-Ren Wu[1] (1.Graduate Institute of Hydrological and Oceanic Sciences, National Central University, Taiwan, 2.Graduate School of Science, Chiba University, Japan, 3.Center for Astronautical Physics and Engineering, National Central University, Taiwan, 4.Department of Space Science and Engineering, National Central University, Taiwan, 5.Center for Space and Remote Sensing Research, National Central University, Taiwan)

[E] Poster | U (Union)：Union

[U-05] Advanced understanding of Quaternary and Anthropocene hydroclimate changes in East Asia

convener:Chuan-Chou Shen(High-Precision Mass Spectrometry and Environment Change Laboratory, Department of Geosciences, National Taiwan University), Yusuke Yokoyama(Atmosphere and Ocean Research Institute, University of Tokyo), Kaoru Kubota(Graduate School of Human Development and Environment, Kobe University), Li Lo(Department of Geosciences, National Taiwan University)

[U05-P01] Precessionally Paced Foraminifera-bound Nitrogen Isotope Variations in the Solomon Sea Influenced by Eastern Equatorial Pacific Upwelling Intensity

★Invited Papers

*Haojia Abby Ren[1], Wei-Ning Fang[1], Yi-Chi Chen[1], Kuo-Yen Wei[1], Chuan-Chou Shen[1] (1.National Taiwan University)

[U05-P02] Annual record of boron isotopes of massive *Porites* coral skeleton from Chichijima Island in the western North Pacific

*Kaoru Kubota[1], Ryo Nakano[2], Masafumi MURAYAMA[2], Tsuyoshi Ishikawa[1], Yusuke Yokoyama[3], Atsushi Suzuki[4] (1.Kochi Institute for Core Sample Research, JAMSTEC, 2.Faculty of Agriculture and Marine Science, Graduate School of Integrated Arts and Sciences, Kochi University, 3.Atmosphere and Ocean Research Institute, The University of Tokyo, 4.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[U05-P03] Gauging Quaternary Sea Level Changes using various sea level indicators and GIA model

*Yusuke Yokoyama[1], Anthony Purcell[2], Takeshige Ishiwa[3] (1.Atmosphere and Ocean Research Institute, University of Tokyo, 2.Research School of Earth Sciences, The Australian National University, 3.National Institute of Polar Research)

[U05-P04] Sea-level change in Tongatapu, the Kingdom of Tonga for the last 3000 years based on local marine reservoir effect and geophysical modeling

*Naoto Fukuyo[1,2], Anthony Purcell[3], Geoffrey Clark[4], Phillip Parton[4], Yusuke Yokoyama[1,2] (1.Atmosphere and Ocean Research Institute, The University of Tokyo, 2.Department of Earth and Planetary Sciences, Faculty of Science, The University of Tokyo, 3.Research School of Earth Sciences, The Australian National University, 4.College of Asia and the Pacific, Australian National University)

[U05-P05] High-resolution Holocene records of a stalagmite from maritime Japan

*Shota Amekawa[1], Akihiro Kano[1], Kenji Kashiwagi[2], Taiki Mori[3], Fumito Shiraishi[4], Chuan-Chou Shen[5,6,7] (1.Graduate School of Science, The University of Tokyo, 2.Department of Environmental Biology and Chemistry, Faculty of Science, University of Toyama, 3.Graduate School of Integrated Sciences for Global Society, Kyushu University, 4.Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 5.High-precision Mass Spectrometry and Environment Change Laboratory (HISPEC), Department of Geosciences, National Taiwan University, 6.Global Change Research Center, National Taiwan University, 7.Research Center for Future Earth, National Taiwan University)

[U05-P06] Mg/Ca and stable oxygen isotopes of individual foraminifera in the tropics: Climate variability or ecology?

★Invited Papers

*Sze Ling Ho[1], Jeroen Groeneveld[2,3], Andreas Mackensen[4], Mahyar Mohtadi[3], Thomas Laepple[2] (1.Institute of Oceanography, National Taiwan University, 10617 Taipei, Taiwan, 2.Alfred Wegener Institute, Helmholtz Center for Polar and Marine Research, Telegrafenberg A45, D-14473 Potsdam, Germany, 3.MARUM-Center for Marine Environmental Sciences, University of Bremen, Klagenfurter Strasse 2-4, D-28359 Bremen, Germany, 4.Alfred Wegener Institute, Helmholtz Center for Polar and Marine Research, Am Alten Hafen 26, D-27568 Bremerhaven, Germany)

[U05-P07] Insight to Western Pacific circulation from coral skeletal radiocarbon

*Shoko Hirabayashi[1,2,3], Yusuke Yokoyama[2,3], Atsushi Suzuki[4], Tezer Esat[5], Yosuke Miyairi[2], Takahiro Aze[2], Fernando Siringan[6], Yasuo Maeda[7], Hironobu Kan[1] (1.Faculty of Social and Cultural Studies, Kyushu University, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 4.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST), 5.Research School of Earth Sciences, The Australian National University, 6.Marine Science Institute, University of the Philippines, 7.Institute of Natural and Environmental Sciences, University of Hyogo)

[U05-P08] Surface productivity and potential terrestrial ecology system in the central Okhotsk Sea during the middle-early Pleistocene

*Li Lo[1], Lukas Smik[2], Simon T. Belt[2] (1.Department of Geosciences, National Taiwan University, 2.School of Geography, Earth and Environmental Sciences, University of Plymouth)

[U05-P09] **Lake water distribution derived from surface water oxygen and hydrogen isotopes around Fuji Five Lakes**

*Ota Kosuke[1,2], Yusuke Yokoyama[1,2], Yosuke Miyairi[2], Shinya Yamamoto[3], Toshihiro Miyajima[2] (1.University of Tokyo, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.Mount Fuji Research Institute, Yamanashi Prefectural Government,)

[U05-P10] Carbon and oxygen isotopes and ^{14}C age of travertine and spring water in NW Iran

*Yubo Zhang[1], Yoshihiro Asahara[1], Masayo Minami[2], Masaki kaneko[1], Hadi Amin-Rasouli[3], Hossein Azizi[3] (1.Graduate School of Environmental Studies, Nagoya Univercity , 2.Institute for Space Earth Environmental Research, Nagoya University, 3.University of Kurdistan)

[E] Poster | U (Union)：Union

[U-10] Linking Education and Research Communities in Geosciences: Engaging the Public and Local Communities

convener:Vincent Tong(University College London), Takashi Oguchi(Center for Spatial Information Science, The University of Tokyo), Renee M Clary(Mississippi State University), Keiko Kuge(Department of Geophysics, Graduate School of Science, Kyoto University)

[U10-P01] Activities of the Committee for School Education, Seismological Society of Japan: Communicating with educators

*Makoto Yamano[1], Ken'ichi Arai[2], Akihiko Ito[3], Yasuyuki Kano[1], Osamu Kuwano[4], Masashige Minamishima[5], Ayako Misawa[6], Eiichi Misawa[7], Hiroo Nemoto[8], Akiko Sato[9], Nobuyuki Yamada[10] (1.The University of Tokyo, 2.Sakae Higashi High School, 3.Utsunomiya University, 4.JAMSTEC, 5.Tokyo Metropolitan High School of Ryogoku, 6.Shizuoka Prefectural Shizuoka Senior High School, 7.Chiba Prefectural Keiyo Senior High School, 8.Ritsumeikan University, 9.Hiratsuka City Nakahara Junior High School, 10.Kochi University)

[U10-P02] Activities of Education and Outreach by the Seismological Society of Japan

*Keiko Kuge[1], Takashi Furumura[2], Mitsuyuki Hoshiba[3], Naoji Koizumi[4], Kazuyuki Nakagawa[5], Masayuki Obayashi[6], Shin'ichi Sakai[2], Katsuhiko Shiomi[7], Keiichi Tadokoro[8], Satoru Tanaka[6], Hiroshi Tsuruoka[2], Takahiko Uchide[9], Makoto Yamano[2] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.Earthquake Research Institute, The University of Tokyo, 3.Meterological Research Institute, 4.School of Environmental Science, The University of Shiga Prefecture, 5.Jiji Press, 6.Japan Agency for Marine-Earth Science and Technology, 7.National Research Institute for Earth Science and Disaster Resilience, 8.Earthquake and Volcano Research Center, Nagoya University, 9.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[U10-P03] 20th Children's Summer School on Seismology and Volcanology in the Tango Peninsula, Japan

*Yasuyuki Kano[1], 20th School Children's Summer Course on Seismology and Volcanology (1.Earthquake Research Institute, The University of Tokyo)

[U10-P04] Development of e-learning materials for GIS exercises in Japan and their outcomes

*Hiroyuki Yamauchi[1], Takashi Oguchi[2], Yuichi S. Hayakawa[3,2], Toshikazu Seto[2] (1.Department of Natural Environmental Studies, Graduate School of Frontier Sciences, The University of Tokyo, 2.Center for Spatial Information Science, The University of Tokyo, 3.Environmental Geography, Faculty of Environmental Earth Science, Hokkaido University)

[U10-P06] Enhancing the impact of sustainability research and education: Distributed leadership as a guiding model

*Vincent Tong[1] (1.University College London)

[E] Poster | U (Union)：Union

[U-20] "Open Colloquium" Exploring the Earth's interior using cutting edge science and technology

convener:Hiroko Watanabe(Research Center for Neutrino Science, Tohoku University), William F McDonough(Department of Earth Science and Research Center for Neutrino Science, Tohoku University, Sendai, Miyagi 980-8578, Japan), Kenta Ueki(Japan Agency for Marine-Earth Science and Technology), Eiichiro Araki(Japan Agency for Marine-Earth Science and Technology)

[U20-P01] **Study of Ocean Bottom Detector for observation of geo-neutrinos from mantle**

*Taichi Sakai[1], Kunio Inoue[1], Hiroko Watanabe[1], William F McDonough[2,3], Kenta Ueki[4], Natsue Abe[4], Noriaki Sakurai[4], Masanori Kyo[4], Eiichiro Araki[4], Takafumi Kasaya[4], Hiroshi Yoshida[4] (1.Tohoku university,Research Center for Neutrino Science, 2.Tohoku university, 3.University of Maryland, 4.JAMSTEC)

[E] Poster | U (Union)：Union

[U-22] Environmental drivers and impacts of the evolving COVID-19 pandemic

convener:Benjamin F Zaitchik(Johns Hopkins University), Teppei J Yasunari(Arctic Research Center, Hokkaido University)

[U22-P01] Learning from the war against the Corona epidemic to ensure the availability of drinking water

*SHUBHAM TIWARI[1] (1.Indian Institute of Technology Roorkee)

[U22-P02] Integrate NASA Remote Sensing Data into your COVID-19 Research with our new Data Pathfinder

*Cynthia Hall[1], Kevin Ward[2] (1.NASA Goddard Space Flight Center, 2.NASA Earth Science Data Systems)

[U22-P03] Is the impact of COVID-19 modulated by well-water arsenic in rural Bangladesh? Setting a baseline.

*Alexander van Geen[1], Prabhat Barnwal[2], Yiqian Wang[2], Nishat Jui[3], Shabib Raihan[3], Ashraful Haque[3] (1.Columbia University of New York, 2.Michigan State University, 3.Innovations for Poverty Action, Bangladesh)

[U22-P04] The Spatial Pattern of Coronavirus Disease 2019 in China over Four Periods

*ZILAI ZHENG[1] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba)

[U22-P05] Consequences of modeling assumptions and scope of analysis on connections between meteorology and COVID-19

*Gaige Hunter Kerr[1], Hamada Badr[2], Lauren Gardner[3], Javier Perez-Saez[4], Benjamin F Zaitchik[2] (1.George Washington University, 2.Department of Earth and Planetary Sciences, Johns Hopkins University, 3.Department of Civil and Systems Engineering, Johns Hopkins University, 4.Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health)

[U22-P06] Limited Regional Aerosol Changes Despite Unprecedented NO2 Decline During the February Coronavirus Shutdown in China

*Michael S S Diamond[1], Robert Wood[1] (1.University of Washington Seattle)

[U22-P07] Will the pandemic of COVID-19 change climate?: tests using MIROC-ES2L earth system model

*Rumi Ohgaito[1], Michio Kawamiya[1], Tomohiro Hajima[1], Ken'ichi Matsumoto[1,2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Nagasaki University)

[U22-P08] Using mathematical models to assess the number of total deaths and deaths per 10000 people from the COVID-19 epidemic

*Qingqing Sun[1], Chunyi Wang[2] (1.Tianjin University, 2.Mathematics Faculty, University of Waterloo)

[U22-P09] Global early warning system by Complex-Envelope (CE) Processing of Seismic Waves

*Rudolf Unger[1] (1.Delft University of Technology)

[U22-P10] **A possible role of environmental arsenic against COVID-19**

*Satadal Das[1], Milan Sengupta[2], Rathin Chakraborty[3] (1.peerless hospital and b. k. roy research centre, kolkata, india, 2.D. N. De H. Medical College, Kolkata, India., 3.Dr.Bholanath Chakravarty Integrated Medical Research & Treatment Centre, Howrah,West Bengal, India.)

[E] Poster | U (Union)：Union

[U-23] New challenges to diversity, equality and inclusion under COVID-19

convener:Chiaki T. Oguchi(Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University), Rie Hori, S.(Department of Earth Science, Faculty of Science, Ehime University), Claudia Jesus-Rydin(European Research Council), Hodaka Kawahata(Atmosphere Ocean Research Institute, the University of Tokyo)

[U23-P01] GEOLATINAS: embracing, empowering, and inspiring Latinas in Geoscience

*Angela Meneses-Gutierrez[1,2,3], Rocío Caballero-Gill[4,3], Adriana Crisóstomo-Figueroa[7,3], Clara Rodriguez[8,3], Carolina Villarraga Morales[3], Grisel Jiménez Soto[5,3], Natalia A. Cifuentes[6,3] (1.Institute for Advanced Research, Nagoya University, Japan, 2. Disaster Mitigation Research Center, Nagoya University, Japan, 3.GeoLatinas, 4.George Mason University, USA, 5.South East Asia Carbonate Research Laboratory, Universiti Teknologi PETRONAS, Malaysia , 6.Department of Geosciences and Environment, National University of Colombia (Medellin), Colombia, 7.University of Leeds, Leeds, UK, 8.Petronas, Mexico)

[U23-P02] **How the COVID-19 Response Opens Broader Viewpoints for Promoting Inclusive Conferences in the Earth and Space Sciences**

*Beverly Smith-Keiling[1], Andreas Keiking[2] (1.University of Minnesota Twin Cities, 2.University of California-Berkeley)

[U23-P03] How to empower diversity, equality and inclusion for risk management in the COVID-19 Era

*Megumi Sugimoto[1] (1.Kyushu University)

[U23-P04] The Effect of COVID-19 on AGU Journal Authors by Gender and Geographical Location

*Paige Rene Wooden[1], Brooks Hanson[1] (1.American Geophysical Union)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Kunio M. Sayanagi(Hampton University), Fuminori Tsuchiya(Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University), Steven Douglas Vance(NASA Jet Propulsion Laboratory, California Institute of Technology)

[PPS01-P01] Pluto's surface albedo distribution and its evolution due to sublimation and condensation of ices

Hisashi Matsui[1], *Jun Kimura[1] (1.Osaka University)

[PPS01-P02] A low-energy energetic neutral atom analyzer (PEP/JNA) for JUICE mission

*Kazushi Asamura[1], Manabu Shimoyama[2], Yoshifumi Futaana[2], Yoshizumi Miyoshi[3], Takeshi Sakanoi[4], Yoshifumi Saito[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2.Swedish Institute of Space Physics, 3.Nagoya University, 4.Tohoku University)

[PPS01-P03] The Ganymede Laser Altimeter (GALA) for the JUICE mission – overview and current status

*Enya Keigo[1], Masanori Kobayashi[2], Jun Kimura[3], Noriyuki Namiki[4], Hiroshi Araki[4], Hirotomo Noda[4], Shoko Oshigami[1], Shingo Kashima[4], Shin Utsunomiya[4], Ko Ishibashi[2], Masanobu Ozaki[1], Takahide Mizuno[1], Yoshifumi Saito[1], Kazuyuki Touhara[1], Shunichi Kamata[5], Koji Matsumoto[4], Kiyoshi Kuramoto[5], Sho Sasaki[3], Satoru Iwamura[6], Yoshiaki Matsumoto[7], Masayuki Fujii[8], Naofumi Fujishiro[9], Yuki Sato[10], Takeshi Yokozawa[10], Tsutomu Numata[10], Satoko mizumoto[10], Hiroyuki Mizuno[10], Akihiko Sawamura[10], Kazuo Tanimoto[10], Hisato Imai[11], Hiroyuki Nakagawa[11], Okiharu Kirino[11], Hussmann Hauke[12], Kay Lingenauber[12], Reinald Kallenbach[12], Christian Althaus[12], Simone DelTogno[12], Thomas Behnke[12], Christian Huettig [12] (1.ISAS, 2.CIT, 3.Osaka Univ., 4.NAOJ, 5.Hokkaido Univ., 6.MRJ, 7.PTIJ, 8.FAM Science, 9.Astro-Opt, 10.Meisei Electric, 11.Cristal Optics, 12.DLR)

[PPS01-P04] Tidally heated convection and the occurrence of melting in icy satellites: application to Europa

*Kenny Vilella[1], Gael Choblet[2], Wei-En Tsao[3], Frederic Deschamps[3] (1.Hokkaido University, 2.LPG Nantes, 3.Institute of Earth Sciences, Academia Sinica)

[PPS01-P05] Measurements of Saturn's Zonal Wind from Voyager Images using Modern Cloud-Tracking Method

*Justin Garland[1], Kunio M. Sayanagi[1], Jacob L. Gunnarson[1], John J. Blalock[2,1] (1.Hampton University, 2.USGS Astrogeology Science Center)

[PPS01-P06] Inhibition of moist convection in the atmospheres of Jovian planets: the case of NH4SH formation by chemical reaction of NH3 and H2S

*Ko-ichiro SUGIYAMA[1], Kensuke Nakajima[2], Kiyoshi Kuramoto[3], Yoshi-Yuki Hayashi[4] (1.National Institute of Technology, Matsue College, 2.Kyushu University, 3.Hokkaido University, 4.Kobe University)

[PPS01-P07] Detectability of water plumes on icy moons with Earth-orbiting UV telescope

*Ryoichi Koga[1], Fuminori Tsuchiya[1], Go Murakami[3], Kazuo Yoshioka[2], Masato Kagitani[1], Tomoki Kimura[1], Atsushi Yamazaki[3], Ichiro Yoshikawa[2], Hajime Kita[3], Masaki Kuwabara[3] (1.Tohoku University, 2.The University of Tokyo, 3.JAXA/ISAS)

[PPS01-P08] **Development of a radial diffusion model of Jovian inner magnetospheric plasma transportation for a comparison with HISAKI data**

*Kazuki Yamaguchi[1], Takeshi Sakanoi[1], Fuminori Tsuchiya[1], Masato Kagitani[1], Tomoki Kimura[2], Ryoichi Koga[1], Reina Hikida[3] (1.Tohoku university, 2.Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, 3.Department of Earth and Planetary Science, Graduate School of Science, Tokyo University)

[PPS01-P09] Light Curve of Jupiter's UV Aurora and Io Plasma Torus after 2016 Obtained from Hisaki EXCEED

*Hajime Kita[1], Tomoki Kimura[2], Fuminori Tsuchiya[2], Go Murakami[1], Atsushi Yamazaki[1], Ryoichi Koga[2], Reina Hikida[3], Kazuo Yoshioka[3], Ichiro Yoshikawa[3] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency , 2.Tohoku Univ., 3.The University of Tokyo)

[PPS01-P10] Laboratory demonstration of cryogenic-specific reddish coloration with cryoplasma

*Noritaka Sakakibara[1], Yu Yu Phua[1], Tsuyohito Ito[1], Kazuo Terashima[1] (1.The University of Tokyo)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

[P-PS02] Lunar Science and Exploration

convener:Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Masahiro KAYAMA(Department of General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo), Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Yusuke Nakauchi(Japan Aerospace Exploration Agency)

[PPS02-P01] Cause of boulder falls near a lobate scarp on the Moon: source estimate based on the attenuation relation of peak ground accelerations

*Ayame Ikeda[1], Hiroyuki Kumagai[1], Tomokatsu Morota[2] (1.Graduate School of Environmental Studies, Nagoya University, 2.Department of Earth and Planetary Science, The University of Tokyo)

[PPS02-P02] The lunar tidal dissipation energy by the Earth-moon tide

*Ryuichiro Tanaka[1], Satoshi Kaneshima[2] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University)

[PPS02-P03] The heterogeneity of lunar plasma environment and its influences on lunar surface hydration

*Huizi Wang[1], Jiang Zhang[1], Quanqi Shi[1,2], Yoshifumi Saito[3], Ying Ye[1] (1.Shandong Key Laboratory of Optical Astronomy and Solar-Terrestrial Environment, School of Space Science and Physics, Institute of Space Sciences, Shandong University, Weihai, Shandong, China., 2.State Key Laboratory of Space Weather, National Space Science Center (NSSC), Chinese Academy of Sciences, Beijing, China, 3.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Sagamihara, Japan.)

[PPS02-P04] **Phase boundary and kinetics of moganite-coesite phase transition at high-pressure and high-temperature: implications for an impact event and trace of water on the Moon**

*Shin Ozawa[1], Masahiro KAYAMA[1,2], Tatsuya Sakamaki[1], Tomonori Ohashi[1], Akio Suzuki[1] (1.Department of Earth Science, Graduate School of Science, Tohoku University, 2.Department of General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo)

[PPS02-P05] Evaluating the thickness and stratigraphy of ejecta materials at the Chang'e-4 landing site

*Luyuan Xu[1], Xunyu Zhang[1], Le Qiao[2] (1.State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology, 2.Shandong Provincial Key Laboratory of Optical Astronomy and Solar-Terrestrial Environment, Shandong University, Weihai)

[PPS02-P06] An explaination of the origin of Davy Crater Chain on the Moon other than impacts of fragments comprising a comet

Akiya Saito[1,2], *Junichi Haruyama[1], Wataru Miyake[2] (1.Japan Aerospace Exploration Agency, 2.Tokay University)

[PPS02-P07] UZUME: A Lunar Lava Tube Exploration of Japan

*Junichi Haruyama[1] (1.Japan Aerospace Exploration Agency)

[PPS02-P08] On magnetic field observation in and near a lunar pit for understanding magnetic history of the Moon

*Hisayoshi Shimizu[1] (1.Earthquake Research Institute, University of Tokyo)

[PPS02-P09] Radiation dose and protection by a lunar hole and lava tube

*Masayuki Naito[1], Nobuyuki Hasebe[2], Satoshi Kodaira[1], Yoshiharu Amano[2], Junichi Haruyama[3] (1.National Institutes for Quantum and Radiological Scinence and Technology, 2.Waseda University, 3.JAXA)

[PPS02-P10] Breadboard Model of Bionic Legged Robot for Lunar Lava Cave Exploration

*LIANG CHEN[1] (1.Ashikaga University)

[PPS02-P11] Study of lunar 3-D terrain mapping using both the camera and the LIDAR loaded on the rover

*Ryuhei Yamada[1], Yuichi Yaguch[1], Keitaro Naruse[1] (1.The University of Aizu, Department of Computer Science and Engineering)

[PPS02-P12] **Characterizing Sites for Landed Lunar Missions with NASA's Moon Trek Portal**

*Emily Law[1], Brian Hamilton Day[2] (1.Jet Propulsion Laboratory, 2.Ames Research Center)

[PPS02-P13] Development of a compact LIBS instrument for future lunar explorations: a feasibility study using lunar meteorites

*Akinojo Ogura[1], Yuichiro Cho[2], Naoki Yamamoto[1], Koki Yumoto[2], Takafumi Niihara[3], Shingo Kameda[4], Seiji Sugita[2], Takahide Mizuno[5] (1.Department of Earth and Planetary Physics, University of Tokyo, 2.Department of Earth and Planetary Science, University of Tokyo, 3.Department of Systems Innovation, University of Tokyo, 4.School of Science, Rikkyo University, 5.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PPS02-P14] **Preparation status of Multi-Band Camera onboard SLIM lander**

*Kazuto Saiki[1], Makiko Ohtake[2], Yusuke Nakauchi[2], Hiroaki Shiraishi[2], Chikatoshi Honda[3], Hiroyuki Sato[2], Yoshiaki Ishihara[4], Takao Maeda[5], Chihiro Yamanaka[1], Hiroshi Nagaoka[2] (1.Graduate School of Science, Osaka University, 2.Japan Aerospace Exploration Agency, 3.University of Aizu, 4.National Institute for Environmental Studies, 5.Chuo University)

[PPS02-P15] The search for whistler-mode chorus emissions related to the Moon using ARTEMIS

*Wataru Sawaguchi[1], Yuki Harada[1], Satoshi Kurita[2] (1.Graduate School of Science, Kyoto University, 2.RISH, Kyoto University)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

[P-PS03] High-pressure phases in shocked meteorites: key to understanding impact events on parent asteroids

convener:Kishan Tiwari(Indian Institute of Technology Kharagpur)

[PPS03-P01] Thermal infrared measurement of impact in laboratory experiment

*Tetsuya Fukuhara[1], Shinsuke Abe[2], Masahisa Yanagisawa, Ryota Fuse[2], Naoya Sakatani[3] (1.Rikkyo University, 2.Nihon University, 3.JAXA/ISAS)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

[P-PS04] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Universite Cote D Azur Observatoire De La Cote D Azur CNRS Laboratoire Lagrange), Kevin John Walsh(Southwest Research Institute Boulder)

[PPS04-P01] Laboratory penetration experiments conducted at low effective gravity II

*Akiko Nakamura[1], Junpei Nakahata[2], Yuuya Nagaashi[1] (1.Graduate School of Science, Kobe University, 2.Faculty of Science, Kobe University)

[PPS04-P02] Experimental study of high-velocity impacts into granular material in reduced gravity

*Masato Kiuchi[1], Takaya Okamoto[1], Sunao Hasegawa[1], Akiko Nakamura[2] (1.Japan aerospace exploration agency, Institute of space and astronautical science, 2.Graduate School of Science, Kobe University)

[PPS04-P03] A Tentative Numerical Study on the Effect of Aspect Ratio of Cylindrical Projectile on Crater Morphology using iSALE code

*Yuri Shimaki[1] (1.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PPS04-P05] Automated Identification of Particles in Rock Gravel of Small Bodies

*Yuta Shimizu[1], Hideaki Miyamoto[1] (1.University of Tokyo)

[PPS04-P06] Development of lunar regolith simulants based on previous lunar explorations

*Takemura Tomohiro[1], Takafumi Niihara[1], Hideaki Miyamoto[1] (1.The University of Tokyo)

[PPS04-P07] **Estimation of abrasion rates of regolith particles on Itokawa and the Moon based on abration experiments.**

*Akira Tsuchiyama[1], Hirotaka Yamaguchi[2], Akiko Nakamura[3] (1.Research Organization of Science and Technology, Ritsumeikan University, 2.Graduate School of Science, Kyoto University, 3.Graduate School of Science, Kobe University)

[E] Poster | P (Space and Planetary Sciences)：P-PS Planetary Sciences

[P-PS05] Planetary Seismic Exploration-From InSight and Apollo to Future Missions-

convener:Taichi Kawamura(Institut de Physique du Globe de Paris), Takeshi Tsuji(Department of Earth Resources Engineering, Kyushu University), Ralph Lorenz(Johns Hopkins University Applied Physics Laboratory), William Bruce Banerdt(Jet Propulsion Laboratory)

[PPS05-P01] Estimation of the lunar near-surface effects on Moonquake waves amplification.

*Mohamed Amrouche[1], Renee Weber[2] (1.Schlumberger., 2.NASA Marshall Space Flight Center.)

[PPS05-P02] Scattering properties near Apollo 12 landing site inferred from numerical simulation of seismic wave propagation

*Riku Nomiyama[1], Yoshizumi Miyoshi[2], Kohei Toyama[2], Yasunobu Ogawa[3], Keisuke Hosokawa[4], Terumasa Tokunaga[1] (1.Kyushu Institute of Technology, 2.Institute for Space-Earth Environmental Research, Nagoya University, 3.National Institute of Polar Research, 4.Department of Communication Engineering and Informatics, University of Electro-Communications)

[PEM19-P03] Estimation of precipitating electron energy of pulsating aurora by multiwavelength aurora optical observation

*Kohei Toyama[1], Yoshizumi Miyoshi[1], Satoshi Kurita[1], Keisuke Hosokawa[2], Yasunobu Ogawa[3], Shin-ichiro Oyama[1], Satonori Nozawa[1] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Department of Communication Engineering Informatics,Univarsity Electro-Communications, 3.National Institute of Polar Research)

[PEM19-P04] Observation plan of pulsating aurora by the multi-spectral auroral camera on the LAMP rocket

Naoshi Yagi[1], *Takeshi Sakanoi[1], Miki Kawamura[1], Kazushi Asamura[2], Yoshizumi Miyoshi[3], Keisuke Hosokawa[4], Sarah L Jones[5], Marc Lessard[6] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2.ISAS/JAXA, 3.ISEE, Nagoya University, 4.Graduate School of Informatics and Engineering, The University of Electro-Communications, 5.Goddard Space Flight Center, NASA, 6.University of New Hampshire)

[PEM19-P05] Statistical study of EMIC waves and energetic electron precipitation: ground-based magnetometer and subionospheric VLF/LF radio measurements at subauroral latitude

*Asuka Hirai[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Yasumasa Kasaba[1], Yuto Katoh[2], Hiroaki Misawa[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3], Satoshi Kurita[3], Chae-Woo Jun[3], Martin G Connors[4] (1.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku Univ. , 2.Department of Geophysics, Graduate School of Science, Tohoku University, 3.Institute for Space-Earth Environmental Research, Nagoya University, 4.Athabasca University)

[PEM19-P06] First simultaneous observation of the isolated proton aurora at subauroral latitudes by a highly sensitive all-sky camera and the Van Allen Probes satellite

*Kohki Nakamura[1], Kazuo Shiokawa[1], Yuichi Otsuka[1], Atsuki Shinbori[1], Martin G Connors[2], Geoff Reeves[4], Charles Smith[3] (1.Institute for Space-Earth Environmental Research, 2.Athabasca Univ., 3.New Hampshire Univ., 4.Los Alamos National Laboratory)

[PEM19-P07] Modulation of Pc1 wave ducting by equatorial plasma bubbles

*Hyangpyo Kim[1], Kazuo Shiokawa[1], Jaeheung Park[2,3], Yoshizumi Miyoshi[1], Junga Hwang[2,3], Akira Kadokura[4] (1.Institute for Space-Earth Environmental Research, Nagoya University, Nagoya, Japan, 2.Korea Astronomy and Space science Institute, Daejeon, South Korea, 3.Korea University of Science and Technology, Daejeon, South Korea, 4.Space and Upper Atmospheric Sciences, National Institute of Polar Research, Tokyo, Japan)

[PEM19-P08] Modulation of energetic electron distribution caused by toroidal mode ULF waves in association with periodic enhancement of chorus emissions

Atsuhiro Ono[1], *Yuto Katoh[1], Mariko Teramoto[2], Atsushi Kumamoto[1], Fuminori Tsuchiya[1], Yoshiya Kasahara[3], Shoya Matsuda[4], Ayako Matsuoka[4], Satoshi Kasahara[5], Shoichiro Yokota[7], Kunihiro Keika[5], Takefumi Mitani[4], Tomoaki Hori[6], Yoshizumi Miyoshi[6], Iku Shinohara[4] (1.Department of Geophysics, Graduate School of Science, Tohoku University, 2.Kyutech, 3.Kanazawa University, 4.ISAS/JAXA, 5.The University of Tokyo, 6.Nagoya University, 7.Osaka Univ.)

[PEM19-P10] **Comparative study of magnetic field and ion flux variations in inner magnetosphere during magnetic storms using Arase observations and RAM-SCB simulations**

*Sandeep Kumar[1], Yoshizumi Miyoshi[1], Vania Jordanova[2], Ayako Matsuoka[3], Kazushi Asamura[3], Shoichiro Yokota[4], Satoshi Kasahara[5], Kunihiro Keika[5], Tomoaki Hori[1], Iku Shinohara[3] (1.ISEE, Nagoya University, Japan, 2.Los Alamos National Laboratory, USA, 3.ISAS/JAXA, Japan, 4.Osaka University, Japan, 5.University of Tokyo, Japan)

[PEM19-P11] **Observational study on mass and charge dependence of plasma energization in the inner magnetosphere and near-Earth magnetotail**

*Kunihiro Keika[1], Satoshi Kasahara[1], Shoichiro Yokota[2], Masahiro Hoshino[1], Kanako Seki[1], Takanobu Amano[1], Lynn M Kistler[3], Masahito Nose[4], Yoshizumi Miyoshi[4], Tomoaki Hori[4], Iku Shinohara[5] (1.Graduate School of Science, The University of Tokyo , 2.Graduate School of Science, Osaka University, 3.University of New Hampshire, 4.Institute for Space-Earth Environmental Research, Nagoya University, 5.Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

[PEM19-P12] Improvement of detector response matrices of the high-energy electron experiments (HEP) onboard the Arase satellite

*Takefumi Mitani[1], PARK INCHUN[2], Tomoaki Hori[2], Takeshi Takashima[1], Satoshi Kasahara[3], Satoshi Kurita[2], Mariko Teramoto[4], Nana Higashio[1], Yoshizumi Miyoshi[2], Iku Shinohara[1] (1.Japan Aerospace Exploration Agency, 2.Nagoya University, 3.The University of Tokyo, 4.Kyushu Institute of Technology)

[PEM19-P13] Inter-channel normalization and energy spectrum correction of the high-energy electron experiments (HEP) onboard the Arase satellite

*Tomoaki Hori[1], Takefumi Mitani[2], Takeshi Takashima[2], InChun Park[1], Satoshi Kurita[1], Mariko Teramoto[3], Nana Higashio[4], Satoshi Kasahara[5], Shoichiro Yokota[6], Yoshizumi Miyoshi[1], Iku Shinohara[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.JAXA/ISAS, 3.Kyushu Inst. of Tech., 4.JAXA, 5.The Univ. of Tokyo, 6.Osaka Univ.)

[PEM19-P14] Evaluation of response characteristics of the XEP onboard the Arase spacecraft

*Kohei Ueda[1], Takefumi Mitani[2], Nana Higashio[3], Shoichiro Yokota[1], Takeshi Takashima[2], Yoshizumi Miyoshi[4], Iku Shinohara[2], Kentaro Terada[1] (1.Osaka University, 2.Japan Aerospace Exploration Agency/Institute of Space and Astronautical Science, 3. Japan Aerospace Exploration Agency, 4.Nagoya University/Institute for Space-Earth Environment Research)

[PEM19-P15] The observational study for high energy particles below L=2.1 using Hisaki

*Kazuo Yoshioka[1], Ichiro Yoshikawa[1], Atsushi Yamazaki[2], Go Murakami[2], Hajime Kita[2], Fuminori Tsuchiya[3], Tomoki Kimura[4], Yoshizumi Miyoshi[5], Satoshi Kurita[5], Mariko Teramoto[6] (1.Graduate School of frontier Science, The University of Tokyo, 2.Institute of Space and Astronautical Science / Japan Aerospace Exploration Agency, 3.Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 4.Tohoku University, 5.Institute for Space-Earth Environmental Research, Nagoya University, 6.Kyushu Institute of Technology)

[PEM19-P16] Calibration of waveform data measured by the electric sensors on board the Arase satellite

*Yoshiya Kasahara[1], Hiroyuki Nishizawa[1], Shoya Matsuda[2], Hirotsugu Kojima[3], Fuminori Tsuchiya[4], Atsushi Kumamoto[4], Yasumasa Kasaba[4], Ayako Matsuoka[2] (1.Kanazawa University, 2.ISAS/JAXA, 3.Kyoto University, 4.Tohoku University)

[PEM19-P17] Machine learning classification of low frequency waves observed by Arase satellite

*Shun Amano[1], Taketoshi Miyake[1], Yoshiya Kasahara[2] (1.Toyama prefectural university , 2.Kanazawa university)

[PEM19-P18] Evaluation of Automatic Determined UHR Frequencies by a Convolutional Neural Network

*Shoya Matsuda[1], Tatsuhito Hasegawa[2], Atsushi Kumamoto[3], Fuminori Tsuchiya[3], Yoshiya Kasahara[4], Yoshizumi Miyoshi[5], Yasumasa Kasaba[3], Ayako Matsuoka[1], Iku Shinohara[1] (1.Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 2.University of Fukui, 3.Tohoku University, 4.Kanazawa University, 5.Nagoya University)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

[P-EM20] Recent Advances in Ionosphere Observation and Modeling through New Observation Opportunities

convener:CHIYEN LIN(Center for Astronautical Physics and Engineering, National Central University, TAIWAN), Yen-Jung Wu(Space Sciences Laboratory, University of California, Berkeley), Yang-Yi Sun(China University of Geosciences), Charles Lin(Department of Earth Sciences, National Cheng Kung University)

[PEM20-P01] Compact Ionospheric Probe for CubeSat-based Science Missions

*Chi-Kuang Chao[1,2] (1.Graduate Institute of Space Science, National Central University, 2.Center for Astronautical Physics and Engineering, National Central University)

[PEM20-P02] Global Ion Density Distributions Observed by Advanced Ionospheric Probe Onboard FORMOSAT-5 Satellite

Pei-Cii Hong[1], *Chi-Kuang Chao[1,2] (1.Graduate Institute of Space Science and Engineering, National Central University, 2.Center for Astronautical Physics and Engineering, National Central University)

[PEM20-P03] **Ionospheric responses on the 21 August 2017 solar eclipse by using three-dimensional GNSS tomography**

*Chia-Hung Chen[1], Charles Lin[1], Akinori Saito[2], Mamoru Yamamoto[3], Susumu Saito[4] (1.Department of Earth Sciences, National Cheng Kung University, 2.Department of Geophysics, Graduate School of Science, Kyoto University, 3.Research Institute for Sustainable Humanosphere, Kyoto University, 4.Electronic Navigation Research Institute, National Institute of Maritime, Port, and Aviation Technology)

[PEM20-P04] **Traveling Ionospheric Disturbances Triggered by Typhoon Hagibis (2019)**

*Yu-Chen Cheng[1], Charles Lin[1], Shih-Ping Chen[1], Min-Yang Chou[2] (1.Department of Earth Science, National Cheng Kung University, Tainan, Taiwan, 2.COSMIC Program Office, University Corporation for Atmospheric Research Boulder, CO, USA)

[PEM20-P05] Study of Medium-Scale Traveling Ionospheric Disturbances in Low-Latitude Ionosphere Using an Automatic Algorithm

*Pin-Hsuan Cheng[1], Charles Lin[1], Hanli Liu[2] (1.Department of Earth Sciences, National Cheng Kung University, 2.University Corporation For Atmospheric Research)

[PEM20-P06] Short-term Variabilities of Wave-3 and 4 Structures in the Low-latitude Ionosphere

*Jia-Ting Lin[1], Charles Lin[1], CHIYEN LIN[2,3], P. K. Pedatella[1], Nicholas M Pedatella[4,5] (1.Department of Earth Sciences, National Cheng Kung University, Taiwan, 2.Center for Astronautical Physics and Engineering, National Central University, Taoyuan, Taiwan, 3.Graduate Institute of Space Science, National Central University, Taoyuan, Taiwan, 4.High Altitude Observatory, National Center for Atmospheric Research, Boulder, CO, USA, 5.COSMIC Program Office, University Corporation for Atmospheric Research, Boulder, CO, USA)

[PEM20-P07] Taiwan Radio Occultation Process System (TROPS) : Preliminary results of ionospheric products

*Wen-Hao Yeh[1], Cheng-Yung Huang[1], Kun-Lin Chen[1], Tzu-Pang Tseng[2], Hsu-Hui Ho[3], Jing-Mei Wu[4], Jyun-Ying Huang[3], Hsiu-Wen Li[4], Ching-Chieh Lin[3] (1.National Space Organization, National Applied Research Laboratories, Taiwan, 2.Geoscience Australia, Australia, 3.Taiwan Analysis Center for COSMIC, Central Weather Bureau, Taiwan, 4.GPS Science and Application Research Center, National Central University, Taiwan)

[PEM20-P08] GNSS observation of ionospheric variation due to perturbations near the Earth’s surface

*Yang-Yi Sun[1] (1.China University of Geosciences (Wuhan))

[PEM20-P09] A multi-directional particle detector on HXMT

*Hong Guo Shen

[PEM20-P10] New observations of the total electron content over Ho Chi Minh City

*Tam Dao[1,2], Minh Huy Le[3], Brett A Carter[1], Que Le[2] (1.SPACE Research Centre, School of Science, RMIT University, Australia, 2.Department of Physics, International University, Vietnam, 3.Institute of Geophysics, Vietnam Academy of Science and Technology (VAST), Vietnam)

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

[P-EM21] Surprises from the Subauroral Zone: Synthesizing Ground and Space-Based Observations and Theory

convener:Connors Martin G(Athabasca University), Kazuo Shiokawa(Institute for Space-Earth Environmental Research, Nagoya University)

[PEM21-P01] Subauroral-zone surprises obtained from the PWING project

*Kazuo Shiokawa[1], Martin G Connors[2] (1.Institute for Space-Earth Environmental Research, Nagoya University, 2.Athabasca University)

[PEM21-P02] The pulsating aurora of January 27, 2017 as observed by e-POP, NOAA spacecraft, and ground assets

*Martin G Connors[1], Andrew W Yau[2], Kazuo Shiokawa[3], Claudia Martinez Calderon[3], Xinlin Li[4] (1.Athabasca University, 2.University of Calgary, 3.Nagoya University, 4.University of Colorado)

[PEM21-P03] SAR arc at 68^{o} geomagnetic (71^{o} geographic) North for Kp = 0+

*Shin-ichiro Oyama[1,2,3], Atsuki Shinbori[1], Anita Aikio[2], Heikki Vanhamaki[2], Yasunobu Ogawa[3], Mirjam Kellinsalmi[4], Tero Raita[2], Mike Rietveld[5], Kazuo Shiokawa[1], Ilkka Virtanen[2], Lei Cai[6], Abiyot Workayehu[2], Marcus Pedersen[2], Kirsti Kauristie[4], Boris Kozelov[7], Andrei Demekhov[7] (1.Institute for Space-Earth Environmental Research, Nagoya University, Japan, 2.Space Physics and Astronomy Research Unit, University of Oulu, Finland, 3.National Institute of Polar Research, Japan, 4.Finnish Meteorological Institute, Finland, 5.EISCAT, Norway, 6.KTH Royal Institute of Technology, Sweden, 7.Polar Geophysical Institute, Russia)

[PEM21-P04] Simultaneous observation of detachment of a bright Stable Auroral Red (SAR) arc by a ground-based camera and the Arase satellite on 4 November 2019

*Yudai Inaba[1], Kazuo Shiokawa[1], Shin-ichiro Oyama[1,9,10], Yuichi Otsuka[1], Atsuki Shinbori[1], Yoshizumi Miyoshi[1], Yoichi Kazama[2], Shiang-Yu Wang[2], Sunny W.T. [E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

[A-HW33] Prediction of water and sediment dynamics from small to large scales

convener:Yoshiyuki Yokoo(Fukushima University), Yuko Asano(The University of Tokyo)

[AHW33-P01] Quantitative evaluation of sediment dynamics caused by extreme rainfall events in August 2016 in the Pankenushi River, Hokkaido, northern Japan

*Hiromi Akita[1], Shigeru Mizugaki[1], Yasuhiro Murakami[1] (1.Civil Engineering Research Institute for Cold Region)

[AHW33-P02] Evaluation of suspended sediment sources at the basin scale: a case study of coastal basin, Hokkaido, northern Japan

*Shigeru Mizugaki[1], Junichi Ohtsuka[1], Yasuhiro Murakami[1], Hiromi Akita[1], Atsushi Tanise[1], Masa-aki Murayama[1] (1.Civil Engineering Research Institute for Cold Region, PWRI)

[AHW33-P03] Dependency of watershed-scale rainwater storage on watershed-area at the occurrence times of slope failures: a preliminary investigation in Japan

*Hikaru Satou[1], Yoshiyuki Yokoo[2], Chris Leong[2] (1.Graduate School of Symbiotic Systems Science, Fukushima University, 2.Faculty of Symbiotic Systems Science, Fukushima University)

[AHW33-P04] Sediment dynamics after the 1973 landslide event in mountain watersheds of Hokkaido, Japan

*Takashi Koi[1], Yasutaka Tanaka[1] (1.Center for Natural Hazards Research, Hokkaido University)

[AHW33-P05] Factors controlling concentration of dissolved ^{90}Sr and ^{137}Cs in river water in the Chernobyl exclusion zone.

*Matsushita Koki[1], Yasunori Igarashi[2], Yuichi Onda[1], Yoshifumi Wakiyama[2], Alexei Konoplev[2], Gennady Laptev[3], Sergii Obrizan[4], Volodymyr Demianovych[4], Mark Zheleznyak[2] (1.Tsukuba University, 2.Institute of Environmental Radioactivity at Fukushima University, 3.Ukrainian Hydrometeorological Institute, 4.Chernobyl Ecocentre, State Agency of Ukraine on Exclusion Zone Management)

[AHW33-P06] Explication the effect of thinning on suspended sediment runoff in a cypress and cedar plantation forest by end-member mixing analysis using Fukushima-derived Cs-137, Cs-134 and Pb-210ex

*Motosuke Kinoshita[1], Yuichi Onda[2], Soo Youn Nam[3], Hiroaki Kato[2], Takashi Gomi[3], Chen-wei Chiu[3], Keisuke Taniguchi[4] (1.University of Tsukuba, 2.Center for Research in Isotopes and Environmental Dynamics, University of TSUKUBA, 3.Tokyo University of Agriculture and Technology Institute of Agriculture Division of International Environmental and Agricultural Science, 4.Fukushima Prefectural Centre for Environmental Creation)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-HW Hydrology & Water Environment

[A-HW37] Interdisciplinary approach to support climate change adaptation measures in regional scale

convener:TEBAKARI TAICHI(Toyama Prefectural University), Yadu Pokhrel(Michigan State University), Masashi Kiguchi(University of Tokyo), Sompratana Ritphring(Kasetsart University)

[AHW37-P01] **International Interdisciplinary Collaboration Essential to Linking the Changing Antarctic Ice Sheets with Global Coastlines**

*Robin Elizabeth Bell[1] (1.Lamont Doherty Earth Observatory of Columbia University)

[AHW37-P02] Development of climate change-related data accumulation system in Thailand

*Masashi Kiguchi[1], Chaiporn Jaikaeo[2], Eiji Ikoma[1] (1.The University of Tokyo, 2.Kasetsart University)

[AHW37-P03] Development of future climate scenario based on multi GCMs of CMIP5 and rain gridded data observed by multi-agencies in Thailand

*Masashi Kiguchi[1], Ruthaikarn BUAPHEAN[2], Aphantree YUTTAPHAN[2], Boonlert ARCHEVARAHUPROK[2], Eiji IKOMA[1], Taikan OKI[1,3] (1.The University of Tokyo, 2.Thai Meteorological Department, 3.United Nation University)

[AHW37-P04] Interannual variability of timing of monsoon-onset in South East Asia

*Ryosuke Kato[1], Tomohito Yamada[2] (1.Hokkaido university graduate school of engineering, 2.Hokkaido university faculty of engineering)

[AHW37-P05] Deep learning for seasonal to sub-seasonal rainfall prediction in Chaophraya river basin

*Kiyoharu Hasegawa[1], Shinjiro Kanae[1] (1.Toyko Institute of Technology)

[AHW37-P06] Seasonal precipitation forecast model in wet and dry seasons using global monthly surface temperature by deep learning

*Shingo Zenkoji[1], Taichi Tebakari[1], Kazutoshi Sakakibara[1] (1.Toyama Prefecural University)

[AHW37-P07] Using weather pattern recognition to classify and predict summertime heavy rainfall occurrence over the Upper Nan river basin, northwestern Thailand

*Ryosuke Kato[1], Dzung Nguyen-Le[2], Tomohito Yamada[2] (1.Hokkaido university graduate school of engineering, 2.Hokkaido university faculty of engineering)

[AHW37-P08] Impact of Rainfall on Urban Traffic Flow based on Probe Vehicle Data in Bangkok

*Tsuyoshi Takano[1], Hiroyoshi Morita[1], Shinichiro Nakamura[2], Miyazaki Hiroyuki[3], Wasan Pattara-atikom[4], Napaporn Piamsa-nga[5] (1.Nippon Engineering Consultants Co., Ltd, 2.Nagoya Univ., 3.Asian Institute of Technology, 4.National Electronics and Computer Technology Center, 5.Kasetsart Univ.)

[AHW37-P09] Investigation of Extreme Flood Changes in the Mekong River Basin Using +4K Climate Simulation

*Sophal Try[1], Shigenobu Tanaka[1], Kenji Tanaka[1], Takahiro Sayama[1], Chantha Oeurng[2] (1.Kyoto University, 2.Institute of Technology of Cambodia)

[AHW37-P10] Climate change and land use change impact assessment on flood and inundation in a river basin in Sumatra island in Indonesia

*Kodai Yamamoto[1], Takahiro Sayama[2], Apip Apip[3] (1.Graduate School of Engineering, Kyoto University, 2.Disaster Prevention Research Institute, 3.Research Center of Limnology, Indonesian Institute of Sciences)

[AHW37-P11] AN ASSESSMENT OF RESERVOIR OPERATION POTENTIAL FOR FLOW REGULATION IN THE CHAO PHRAYA RIVER BASIN

*SARITHA PADIYEDATH GOPALAN[1], Naota Hanasaki[1] (1.National Institute for Environmental Studies)

[AHW37-P12] Regional climate change impact on water quality in the lower Chao Phraya River, Thailand

Taichi Tebakari[1], Sanit Wongsa[2], *Horiuchi Yusuke[1] (1.Toyama Prefectural University, 2.King Mongkut's University)

[AHW37-P13] Research on the current thermal energy budget of land surface by continuous observation of near-surface ground temperature in Kanto Plain, Japan

*Osamu Matsubayashi[1], Hideki Hamamoto[2], Sachio Ehara[3] (1.National Institute of Advanced Industrial Science and Technology, 2.Center for Environmental Science in Saitama, 3.Institute for Geothermal Information)

[AHW37-P14] **Good Practices for Climate Change Adaptation in Agricultural Sector, Thailand**

*KOSHI YOSHIDA[1] (1.Ibaraki University)

[AHW37-P15] **Evaluation of salinity effects on rice production in farmers' fields in Ban Phai, Khon Kaen, Thailand**

*YI YANG[1], Rongling Ye[1], Thanyaluck Nontasri[2], Mallika Srisutham[2], Supranee Sritumboon[3], Masayasu Maki[4], KOSHI YOSHIDA[5], Kazuo Oki[6], Koki Homma[1] (1.tohoku university, 2.Khon Kaen Univ., Thailand, 3.LDD, Thailand, 4.Fukushima Univ., 5.Ibaraki Univ., 6.Univ. Tokyo)

[AHW37-P16] Calibration of cultivar parameters of SIMRIW-RS (rice simulation model for remote sensing) for the rice growth monitoring in Thailand

*Koki Homma[1], Mongkol Raksapatcharawong[2], Watcharee Veerakachen[2], Peerapon Prompitakporn[2], Masayasu Maki[3], Kazuo Oki[4] (1.Tohoku University, 2.Kasesart University, 3.Fukushima University, 4.The University of Tokyo)

[AHW37-P18] Farmers' perception of climate change induced drought in the Northeast Thailand

*Miki Nodera[1], Keigo Noda[1], Koshi Yoshida[2], Mallika Srisutham[3] (1.Gifu University, 2.Ibaraki University, 3.Khon Kaen University)

[AHW37-P19] **Research on farmers' awareness of adaptation to climate change and its information collection and sharing in rural area in Thailand**

*Kyoko Matsumoto[1], Mallika Srisutham[2], Supranee Sritumboon[3], Sompratana Ritphring[4], Masashi Kiguchi[1], Taikan Oki[5] (1.Institute of Industrial Science, The University of Tokyo, 2.Facutly of Agriculture, Khonkaen University, 3.Land Development Department, 4.Faculty of Engineering, Kasetsart University, 5.Institute for Future Initiatives, The University of Tokyo)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CC Cryospheric Sciences & Cold District Environment

[A-CC38] Ice cores and paleoenvironmental modeling

convener:Ayako Abe-Ouchi(Atmosphere and Ocean Research Institute, The University of Tokyo), Ryu Uemura(Nagoya University), Kenji Kawamura(National Institute of Polar Research, Research Organization of Information and Systems), Nozomu Takeuchi(Chiba University)

[ACC38-P02] **Compositions of dust and sea salts in the Dome C and Dome Fuji ice cores from Last Glacial Maximum to early Holocene based on ice-sublimation and single-particle measurements**

*Ikumi Oyabu[1], Yoshinori Iizuka[2], Kenji Kawamura[1,3,4], Eric Wolff[5], Mirko Severi[6], Rumi Ohgaito[4], Ayako Abe-Ouchi[7,1,4], Margareta Hansson[8] (1.National Institute of Polar Research, Research Organization of Information and Systems, 2.Institute of Low Temperature Science, Hokkaido University, 3.Department of Polar Science, The Graduate University of Advanced Studies (SOKENDAI), 4.Japan Agency for Marine Science and Technology (JAMSTEC), 5.Department of Earth Sciences, University of Cambridge, 6.Department of Chemistry “Ugo Schiff”, University of Florence, 7.Atmosphere Ocean Research Institte, University of Tokyo, 8.Department of Physical Geography, Stockholm University)

[ACC38-P03] Evolution in geometry of firn in ice sheets detected by dielectric anisotropy

*Shuji Fujita[1,2], Kotaro FUKUI[3], Mikihiro Hirabayashi[1], Iizuka Yoshinori[4], Sumito Matoba[4], Atsushi Miyamoto[5], Takeshi Saito[4], Hideaki Motoyama[1,2], Toshitaka Suzuki[6] (1.National Institute of Polar Research, Research Organization of Information and Systems(ROIS), 2.SOKENDAI, Japan, 3.Tateyama Caldera Sabo Museum, Japan, 4.ILTS, Hokkaido Univ., Japan, 5.Hokkaido Univ., Japan, 6.Yamagata Univ., Japan)

[ACC38-P04] Dielectric anisotropy measurement of Dome Fuji ice core and implications for crystal orientation fabric development

*Tomotaka Saruya[1], Shuji Fujita[1,2] (1.National Institute of Polar Research, 2.The Graduate University for Advanced Studies)

[ACC38-P05] Development of a numerical ice-sheet model for simulation of summit dynamics

*Fuyuki SAITO[1], Ayako Abe-Ouchi[2,1], Takashi Obase[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Atmosphere Ocean Research Institute, Univ. of Tokyo)

[ACC38-P06] Layering, densification and bubble close-off of firn at a new site near Dome Fuji, East Antarctica

*Ryo Inoue[1], Shuji Fujita[2,1], Kenji Kawamura[2,1,3], Fumio Nakazawa[2,1], Ikumi Oyabu[2] (1.The Graduate University for Advanced Studies, SOKENDAI, 2.National Institute of Polar Research, 3.JAMSTEC)

[ACC38-P08] PMIP4/CMIP6 Last Interglacial simulations using different versions of MIROC, with and without vegetation feedback

*Ryouta O'ishi[1], Wing-Le Chan[1], Ayako Abe-Ouchi[1,2,3], Sam Sherriff-Tadano[1], Rumi Ohgaito[3] (1.Atmosphere and Ocean Research Institute, the Universitoy of Tokyo, 2.National Institute of Polar Research, 3.Japan Agency for Marine-Earth Science and Technology)

[ACC38-P09] Response of convective systems to changes in orbital forcing of the last interglacial

*Minoru Chikira[1], Yohei Yamada[2], Ayako Abe-Ouchi[1], Masaki Satoh[1] (1.The University of Tokyo, Atmosphere and Ocean Research Institute, 2.Japan Agency for Marine-Earth Science and Technology)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

[A-GE40] Subsurface Mass Transport and Environmental Assessment

convener:Hirotaka Saito(Department of Ecoregion Science, Tokyo University of Agriculture and Technology), Shoichiro Hamamoto(Department of Biological and Environmental Engineering, The University of Tokyo), Yuki Kojima(Department of Civil Engineering, Gifu University), Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University)

[AGE40-P01] Environmental Impact Assessment of Open Loop Geothermal Heat Pump System in Gifu City, Central Japan

★Invited Papers

*Randa Permanda[1], Tomoyuki Ohtani[1] (1.Gifu University)

[AGE40-P02] Estimation of correlation between soil organic matter and soil components using neural network

*Masaki Kiyohiro[1], Yasushi Mori[1], Yutaro Yamamoto[1] (1.Okayama University Graduate school of Environmental and Life Science)

[AGE40-P03] Fracture domain of granite based on orientation analysis and its relation to water conducting fractures: an example from the “-500m access/research gallery-North” of the Mizunami Underground Research Laboratory

*Koji Shimada[1], Masakazu Niwa[1], Ryuji Takeuchi[1], Kenji Amano[1] (1.Japan Atomic Energy Agency)

[AGE40-P04] Effects of Moisture Content on Soil Water and Ion Movements in the Vicinity of Soybean Roots

*Rui Nakasone[1], Shoichiro Hamamoto[1], Naoto Nihei[2], Taku Nishimura[1] (1.Graduate School of Agricultural and Life Sciences, the University of Tokyo, 2.Fukusima University)

[AGE40-P05] The effect of gas emission from organic matter on the stability of rice terraces structure

*Yasushi Mori[1], Mayuka Kashi[1], Tomoyo Kurozumi[1], Hiroaki Somura[1], Milagros Ong How[2] (1.Graduate School of Environmental and Life Science, Okayama University, 2.Global Harvester)

[AGE40-P06] **Effects of Macropore Structures on Agricultural Soil’s Greenhouse Gases Emission**

*Thanh Long Bui[1], Yasushi Mori[1] (1.Graduate School of Environmental and Life Science, Okayama University)

[AGE40-P07] **Interaction between Nano-Bubbles and Colloidal Particles in Saturated Porous Media under Flowing Condition**

Takuya Sugimoto[1], *Shoichiro Hamamoto[1], Taku Nishimura[1] (1.Department of Biological and Environmental Engineering, The University of Tokyo)

[AGE40-P08] Numerical Analysis of the Effects of Capillary Barrier under Subsurface Drip Irrigation to Improve Water-use Efficiency

*Koichi Noguchi[1], Hirotaka Saito[1] (1.Tokyo University of Agriculture and Technology)

[AGE40-P09] Deformation analysis of fill dams due to level 2 earthquakes using PIV

*Mai Masutani[1], Tomotaka Sato[2], Hirotaka Saito[3], Yuji Kohgo[2] (1.Graduate School of Agriculture, Tokyo University of Agriculture and Technology, 2.United Graduate School of Agricultural Science, Tokyo University of Agriculture and Technology, 3.Department of Ecoregion Science, Tokyo University of Agriculture and Technology)

[AGE40-P10] **An observation of swelling behavior and microstructural change for granulated bentonite mixtures under controlled relative humidity**

*Mazhar Nazir[1], Akihiro Matsuno[1], Takeshi Saito[1], Ken Kawamoto[1] (1.Graduate School of Science and Engineering, Saitama University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

[A-GE41] Energy-Environment-Water Nexus and Sustainable Development

convener:Ming Zhang(Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST), Yonghong Hao(Tianjin Normal University), Jet-Chau Wen(National Yunlin University of Science and Technology), Ken Kawamoto(Graduate School of Science and Engineering, Saitama University)

[AGE41-P01] **Season Effect of the Operation of IPCC Reactor on Solar Photocatalysis of Phenol Wastewater**

*Wen-Shiuh Kuo[1], An-Chi Chen[1] (1.National United University, Taiwan)

[AGE41-P02] Solar photocatalysis of MeO wastewater with metal@TiO_2 film

*Ting-Yu Zeng[1], Ling-Syuan Tzeng[1], Wen-Shiuh Kuo[1] (1.National United University, Taiwan.)

[AGE41-P03] **Effects of fine content on mechanical properties of recycled concrete aggregates for unbound road base materials in Vietnam**

*Thai Hong Nam[1], Akira Kato[1], Takeshi Saito[1], Ken Kawamoto[1] (1.Graduate School of Science and Engineering, Saitama University)

[AGE41-P04] Development of filtering materials for removing heavy metals utilizing industrial by-products

*Akito Ujiie[1], Buddhika Bandara[1], Akihiro Matsuno[1], Takeshi Saitou[1], Ken Kawamoto[1] (1.Saitama university)

[AGE41-P05] Effects of Silicic Acid on Arsenite Leaching from Spent Calcium-Based Arsenic Adsorbents

*Hajime Sugita[1], Terumi Oguma[1], Ming Zhang[1], Junko Hara[1], Yoshishige Kawabe[1] (1.National Institute of Advanced Industrial Science and Technology)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

[A-GE42] Interactions between Earth Critical Zone Hydrogeological Processes and Ecosystem

convener:Wang Wenke(Chang'an University), Yaqian Zhao(Xian University of Technology), Jet-Chau Wen(National Yunlin University of Science and Technology), Ming Zhang(Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST)

[AGE42-P01] **The Impact of LSTM Network Structure on Flood Process Simulation and Forecast Period: A Case Study of the Middle Yellow River**

★Invited Papers

*Caihong Hu[1] (1.school of water conservancy science and engineering, zhengzhou university, Zhengzhou city, Henan Province, P.R.China, 450001)

[AGE42-P02] **CHARACTERIZATION OF WATER RETENTION AND HYDRAULIC CONDUCTIVITY PROPERTIES FOR GRADED RECYCLED AGGREGATES BLENDED WITH AUTOCLAVED AERATED CONCRETE GRAINS IN VIETNAM**

*Nam Pham Van[1], Akira KATO[1], Akihiro MATSUNO[1], Hoang Giang NGUYEN[2], Van Tuan NGUYEN[2], Takeshi SAITO[1], Ken KAWAMOTO[1,2] (1.Graduate School of Science and Engineering, Saitama University, Japan, 2.National University of Civil Engineering, Vietnam)

[AGE42-P03] **UTILIZATION OF CONSTRUCTION aND DEMOLITION WASTE (CDW) AND INDUSTRIAL BY-PRODUCTS(IBPS) AS LOW-COST LIMING AGENTS FOR NEUTRALIZATION OF SOIL ACIDITY**

*Isiri Upeksha Nagasinghe[1], Takeshi Saito[1], Akihiro Matsuno[1], Akira Kato[1], Ken Kawamoto[1] (1.Department of Civil and Environmental Engineering, Graduate School of Science and Engineering, Saitama University, Japan)

[AGE42-P04] Estimation of Coastal Aquifer Properties Using Multiple-Frequency Ocean Tides

*Ming Zhang[1], Ling Yang[2], Yonghong Hao[2], Zhixue Zhao[2], Tongke Wang[2] (1.Institute for Geo-Resources and Environment, Geological Survey of Japan, AIST, 2.Tianjin Normal University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-GE Geological & Soil Environment

[A-GE43] Extending Hydropedology- -in memory of Professor Henry Lin

convener:Kosuke Noborio(Meiji University), Yasushi Mori(Graduate School of Environmental and Life Science, Okayama University)

[AGE43-P01] History of Hydropedology and perspectives

*Kosuke Noborio[1] (1.Meiji University)

[AGE43-P02] Simulation of Water Harvesting with a Sand Ditch using WASH_2D

*Haruyuki Fujimaki[1], Majed Abu-Zreig[1] (1.Arid Land Research Center, Tottori University)

[AGE43-P03] Hydraulic properties of clay loam paddy soils in Japan.

*Taku Nishimura[1], Shoichiro Hamamoto[1] (1.Deptartment of Biological and Environmental Engineering, Graduate School of Agricultural and Life Sciences, University of Tokyo)

[AGE43-P04] **Cosmic-Ray Neutron Sensing for Measuring Soil Water Content at Area Wide Scale: Case Study at IAEA and Future Collaboration**

★Invited Papers

*Ammar Wahbi[1], Trenton Franz[2], Hami Said Ahmed[3], Lee Kheng Heng[3], Peter Strauss[4], Hisashi Tsujimoto[1], Haruyuki Fujimaki[1] (1.Arid Land Research Center, Tottori Univeristy, Tottori, Japan, 2.School of Natural Resources, University of Nebraska-Lincoln, Nebraska, USA, 3.Soil and Water Management & Crop Nutrition Subprogramme, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, International Atomic Energy Agency, Vienna, Austria, 4.Institute for Land and Water Management Research, Federal Agency for Water Management Austria, 3252 Petzenkirchen, Austria)

[AGE43-P05] Relationship between GPS signal and soil volume moisture content / electrical conductivity

*Natsumi Naganuma[1], Shinsuke Aoki[2], Tetsushi Ikegami[3], Kosuke Noborio[4] (1.Graduate School of Agriculture, Meiji University, 2.Institute of Soil, Water, and Environmental SciencesAgricultural Research, The Volcani Center, 3.School of Science and Technology, Meiji University, 4.School of Agriculture, Meiji University)

[AGE43-P06] Reviewing the EC Temperature Calibration Equations and Tracing Two Dimensional Distribution of Soil Nutrients.

*Yuki Sunakawa[1], Satoko Fujita[2], Yuki Ito[3], Shinsuke Aoki[4], Kosuke Noborio[2] (1.Graduate School of Agriculture, Meiji University , 2.School of Agriculture, Meiji University, 3.Gilat Research Center, Agricultural Research Organization, Israel, 4.Institute of Soil, Water, and Environmental Sciences Agricultural Research, The Volcani Center, Israel)

[AGE43-P07] Case study of current status and issues of new entrant apple farmers in Nagano Prefecture

*Takamitsu Kai[1] (1.Meiji University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG44] Extratropical oceans and atmosphere

convener:Youichi Kamae(Faculty of Life and Environmental Sciences, University of Tsukuba), Toyama Katsuya(Meteorological Research Institute), Hyodae Seo(Woods Hole Oceanographic Institution), Yoshi N(Hokkaido University)

[ACG44-P01] Seasonality and Regional Characteristics of Sea-Surface Wind Responses to Mesoscale SST Features assessed by Transfer Functions

*Ryusuke Masunaga[1], Niklas Schneider[1] (1.International Pacific Research Center, University of Hawaii)

[ACG44-P02] Ocean warming patterns and heavy rainfall over East Asia associated with atmospheric rivers

*Youichi Kamae[1], Wei Mei[2] (1.Faculty of Life and Environmental Sciences, University of Tsukuba, 2.University of North Carolina at Chapel Hill)

[ACG44-P03] Predictability of 2019 stratospheric sudden warming in the Southern Hemisphere and its impact of surface weather

*Hiroaki Naoe[1], Chiaki Kobayashi[1], Yayoi Harada[1], Yukiko Imada[1], Shuhei Maeda[1], Toshihiko Hirooka[2] (1.Meteorological Research Institute, 2.Kyusyu University)

[ACG44-P04] Interaction between a typhoon moving westward in western Japan and a cold vortex

*Mine Taisei[1], Yoshihiro Tachibana[1] (1.Faculty of Bioresources, Mie University)

[ACG44-P05] On the maintenance mechanisms for the wintertime subtropical high over the South Indian Ocean

*Ayumu Miyamoto[1], Hisashi Nakamura[1], Takafumi Miyasaka[1,2], Yu Kosaka[1], Bunmei Taguchi[3], Kazuaki Nishii[4] (1.Research Center for Advanced Science and Technology, The University of Tokyo, 2.Japan Meteorological Business Support Center, 3.School of Sustainable Design, University of Toyama, 4.Graduate School of Bioresources, Mie University)

[ACG44-P06] Surface velocity variation of the Kuroshio-Kuroshio Extension system -its relations with local monsoon winds-

*YUXIANG QIAO[1], Hirohiko Nakamura[2], Kako Shinichiro[3], Ayako Nishina[2] (1.The United Graduate School of Agricultural Sciences, Kagoshima University, 2.Faculty of Fisheries, Kagoshima University, 3.Graduate School of Science and Engineering, Kagoshima University)

[ACG44-P07] The potential impact of the 2014-2016 marine heat wave over the North Pacific on the atmosphere

*Kazuaki Nishii[1], Bunmei Taguchi[2], Hisashi Nakamura[3] (1.Graduate School of Bioresources, Mie University, 2. Faculty of Sustainable Design, University of Toyama, 3.Research Center for Advanced Science and Technology, The University of Tokyo)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG45] Multi-scale ocean-atmosphere interaction in the tropical Indo-Pacific region

convener:Yu Kosaka(Research Center for Advanced Science and Technology, University of Tokyo), Sang-Wook Yeh(Hanyang University), Takanori Horii(Research and Development Center for Global Change (RCGC), Strategic Research and Development Area, Japan Agency for Marine-Earth Science and Technology (JAMSTEC)), Hiroki Tokinaga(Disaster Prevention Research Institute, Kyoto University)

[ACG45-P01] Diurnal cycles of precipitation and lightning in the tropics observed by TRMM3G68, GSMaP, LIS, and WWLLN

★Invited Papers

*Shoshiro Minobe[1], Jun Hyock Park[1], Katrina S. Virts[2] (1.Graduate School of Science, Hokkaido University, 2.The University of Alabama in Huntsville)

[ACG45-P02] Intermodel diversity in the impact of tropical volcanic eruptions on ENSO

*Masamichi Ohba[1] (1.Central Research Institute of Electric Power Industry)

[ACG45-P03] Revisiting the ENSO impact on the Indian Ocean SST based on the combined linear regression

*Lianyi Zhang[1,2,3], Yan DU[1,2], Tomoki Tozuka[3], Shoichiro Kido[3] (1.South China Sea Institute of Oceanology, Chinese Academy of Sciences, 2.University of Chinese Academy of Sciences, Chinese Academy of Sciences, 3.The University of Tokyo)

[ACG45-P04] Assessments of salinity impacts on SST using a linear inverse model

★Invited Papers

*Shoichiro Kido[1], Tomoki Tozuka[1] (1.Graduate School of Science, The University of Tokyo)

[ACG45-P05] The relationship between the boreal summer intraseasonal oscillation and the Pacific-Japan pattern

*Ayako Seiki[1], Yu Kosaka[2], Satoru Yokoi[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Research Center for Advanced Science and Technology, The university of Tokyo)

[ACG45-P06] The Impact of IOD on rainfall over Spain

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG46] Atmospheric deposition impact on Terrestrial and marine Ecosystems

convener:Eyal Rahav(Israel Oceanographicand Limnological Research), Adina Paytan(University of California Santa Cruz)

[ACG46-P01] The hitchhike's guide to bacterial transport: the role of viable dust-borne microbes deposition into marine environments

*Eyal Rahav[1], Barak Herut[1], Adina Paytan[2] (1.Israel Oceanographic and Limnological Research, Haifa 31080, Israel, 2.Institute of Marine Science, University of California, Santa Cruz, CA, 95064, USA)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG47] Global Carbon Cycle Observation and Analysis

convener:Kazuhito Ichii(Chiba University), Prabir Patra(Research Institute for Global Change, JAMSTEC), Forrest M. Hoffman(Oak Ridge National Laboratory), Makoto Saito(National Institute of Environmental Studies)

[ACG47-P02] Preliminary results for GOSAT-2 Level 4 global surface fluxes

*Makoto Saito[1], Yosuke Niwa[1], Tazu Saeki[1], Kazutaka Murakami[1], Richao Cong[1], Tatsuya Miyauchi[1], Hisashi Yashiro[1], Tomohiro Shiraishi[1], Ryuichi Hirata[1], Yukio Yoshida[1], Isamu Morino[1], Hibiki M Noda[1], Hirofumi Ohyama[1], Akihide Kamei[1], Tsuneo Matsunaga[1] (1.National Institute of Environmental Studies)

[ACG47-P03] Toward a long-term global inversion of atmospheric CO_2 for elucidating seasonal and interannual variations of natural carbon fluxes

*Yosuke Niwa[1] (1.National Institute for Environmental Studies)

[ACG47-P04] INVERSION ESTIMATES OF METHANE EMISSION IN EAST, SOUTH AND SOUTHEAST ASIA IN 2010-2017 USING GOSAT AND GROUND-BASED OBSERVATIONS

*Fenjuan Wang[1,2], Shamil S Maksyutov[1], Rajesh Janardanan[1], Aki Tsuruta[3], Akihiko Ito[1], Isamu Morino[1], Yukio Yoshida[1], Johannes W. Kaiser[4], Greet Janssens Maenhout[5], Ed Dlugokencky[6], Ivan Mammarella[7], Jost V. Lavric[8], Tsuneo Matsunaga[1] (1.NIES National Institute of Environmental Studies, 2.Department of Climate Change, National Climate Center, 3.Finnish Meteorological Institute, 4.Deutscher Wetterdienst, 5.European Commission Joint Research Centre, 6.Earth System Research Laboratory, NOAA, 7.University of Helsinki, 8.Max Planck Institute for Biogeochemistry)

[ACG47-P05] Refinement of a diagnostic terrestrial ecosystem model using AsiaFlux network data toward GCOM-C SGLI GPP/NPP product

*LI JIAWEI[1], Kazuhito Ichii[1], Hideki Kobayashi[2], Wei Yang[1] (1.Chiba University, 2.Japan Agency for Marine-Earch Science and Technology)

[ACG47-P06] In-situ observation of greenhouse-gas flux at proglacial grounds of a glacier – preliminary result for Gulkana Glacier, Alaska-

*Keiko Konya[1], Go Iwahana[3,2], Tetsuo Sueyoshi[4], Tomoaki Morishita[5] (1.Japan Agency for Marine-Earth Science and Technology, 2.Universitry of Alaska, Fairbanks, 3.Hokkaido university, 4.Ninational Institute of Polar Research, 5.Forestry and Forest Products Research Institute)

[ACG47-P07] Testing machine-learning methods toward improvement of terrestrial CO2 flux estimations

*Zhiyan Liu[1], Kazuhito Ichii[1] (1.Center for Environmental Remote Sensing Chiba University, Chiba University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG48] Projection and detection of global environmental change

convener:Michio Kawamiya(Japan Agency for Marine-Earth Science and Technology), Kaoru Tachiiri(Japan Agency for Marine-Earth Science and Technology), Hiroaki Tatebe(Japan Agency for Marine-Earth Science and Technology), V Ramaswamy(NOAA GFDL)

[ACG48-P01] Methodology of probabilistic climate projections for the assessment of climate change mitigation pathways

*Junichi Tsutsui[1] (1.Central Research Institute of Electric Power Industry)

[ACG48-P02] Improvement in runoff reproducibility of a land surface model and its implications for the energy-water balances on land

*Kumiko TAKATA[1], Naota Hanasaki[1] (1.Center for Climate Change Adaptation, National Institute for Environmental Studies)

[ACG48-P03] **Impact of volcanic eruption on surface climate in VolMIP experiments by MIROC-ES2L**

*Manabu Abe[1], Tomohiro Hajima[1] (1.Japan Agency for Marine-Earth Science and Technology)

[ACG48-P04] Effect on the Earth system of realizing a 1.5 °C warming climate target after overshooting to the 2 °C level

*Kaoru Tachiiri[1], Diego Silva Herran[2], Xuanming Su[1], Michio Kawamiya[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Institute for Environmental Studies)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG49] Greenhouse Gas Monitoring from Space: Current Capabilities, Challenges, and Future Needs

convener:kurosu thomas p(Jet Propulsion Laboratory, California Institute of Technology), Annmarie Eldering(Jet Propulsion Laboratory), Akihiko Kuze(Japan Aerospace Exploration Agency), Tsuneo Matsunaga(Center for Global Environmental Research and Satellite Observation Center, National Institute for Environmental Studies)

[ACG49-P01] A high-resolution CO_2 inverse modeling using observations from the global ground-based monitoring network and the GOSAT satellite

*Shamil Maksyutov[1], Rajesh Janardanan[1], Tomohiro Oda[2], Makoto Saito[1], Yukio Yoshida[1], Johannes W Kaiser[3], Vinu Valsala[4], Edward Dlugokencky[5], Tsuneo Matsunaga[1] (1.National Institute for Environmental Studies, Tsukuba, Japan, 2.USRA/NASA GSFC, Greenbelt, USA, 3.DWD, Offenbach, Germany, 4.Indian Institute for Tropical Meteorology, Pune, India, 5.Global Monitoring Division, NOAA, Boulder, USA)

[ACG49-P02] GOSAT series product validation with TCCON, Sky radiometer and lidar data

*TRIEU THI NGOC TRAN[1], Isamu Morino[1], Osamu Uchino[1], Yukitomo Tsutsumi[1], Tetsu Sakai[2], Tomohiro Nagai[2], Akihiro Yamazaki[2], Hiroshi Okumura[3], Kouhei Arai[3], Ben Liley[4] (1.National Institute for Environmental Studies (NIES), Tsukuba, Japan, 2.Meteorological Research Institute, Japan Meteorological Agency, Tsukuba, Japan, 3.Graduate school of Science and Engineering, Saga University, Saga, Japan, 4.National Institute of Water and Atmospheric Research, Lauder, New Zealand)

[ACG49-P03] Observations of the Tropical Land Biosphere response to the 2015-2016 El Niño with the Orbiting Carbon Observatory-2 (OCO-2) and Greenhouse gases Observing SATellite (GOSAT)

*David Crisp[1] (1.Jet Propulsion Laboratory, California Institute of Technology)

[ACG49-P04] Global and local flux estimation of carbon dioxide and methane by GOSAT satellites

*Akihiko Kuze[1], Nobuhiro Kikuchi[1], Hiroshi Suto[1], Kei Shiomi[1], Fumie Kataoka[2] (1.Japan Aerospace Exploration Agency, 2.Remote Sensing Technology Center of Japan)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG50] Earth & Environmental Sciences and Artificial Intelligence

convener:Tomohiko Tomita(Faculty of Advanced Science and Technology, Kumamoto University), Shigeki Hosoda(Japan Marine-Earth Science and Technology), Ken-ichi Fukui(Osaka University), Satoshi Ono(Kagoshima University)

[ACG50-P01] A precipitation prediction using an artificial neural network model based on observation time series data

He Zhang[1], Naoki Matsumoto[1], *Tomohiko Tomita[2] (1.Graduate School of Science and Technology, Kumamoto University, 2.Faculty of Advanced Science and Technology, Kumamoto University)

[ACG50-P02] Climate Prediction by Using Periodic Convolutional Recurrent Network

*Ekasit Phermphoonphiphat[1], Tomohiko Tomita[2], Masayuki Numao[1], Ken-ichi Fukui[1] (1.Osaka University, 2.Kumamoto University)

[ACG50-P03] K-means clustering of Argo profiles for identifying circulation patterns

*Nozomi Sugiura[1] (1.Japan Agency of Marine-Earth Science and Technology)

[ACG50-P04] A Preliminary Study on Algo Float Trajectory Prediction using Multimodal Convolutional LSTM

*Serina Higashi[1], Takahiro Kinoshita[1], Shigeki Hosoda[3], Ken-ichi Fukui[2], Satoshi Ono[1] (1.Kagoshima University, 2.Osaka University, 3.Japan Marine-Earth Science and Technology)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG51] Satellite Earth Environment Observation

convener:Riko Oki(Japan Aerospace Exploration Agency), Yoshiaki HONDA(Center for Environmental Remote Sensing, Chiba University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo), Tsuneo Matsunaga(Center for Global Environmental Research and Satellite Observation Center, National Institute for Environmental Studies)

[ACG51-P01] Australian bushfire captured by AHI/Himawari-8 and SGLI/GCOM-C

*Yukio Kurihara[1], Kazuhisa Tanada[1], Hiroshi Murakami[1], Misako Kachi[1] (1.Japan Aerospace Exploration Agency / Earth Observation Research Center)

[ACG51-P02] Detecting the Kuroshio-induced island vortices observed from GCOM-C and Himawari-8 data

*Po-Chun Hsu[1], Chung-Ru Ho[1] (1.Department of Marine Environmental Informatics , National Taiwan Ocean University)

[ACG51-P03] **Variability of groundwater storage in Northern India using the GRACE**

*Amit K Singh[1], M Saravanan[2], Swetabh Patel[3] (1.School of Environmental Sciences, Jawaharlal Nehru University,New Delhi, 2.College of Health Science,Mekelle University, Ethiopia, 3.Department of Agronomy,Iowa State University USA)

[ACG51-P04] The characteristics of precipitation and anvil cloud detected by GPM/DPR

*Koichi Toyoshima[1], Hitoshi Hirose[2], Atsushi Higuchi[1] (1.Center for Environmental Remote Sensing, Chiba University, 2.JAXA EORC)

[ACG51-P05] Improvement for infrared rainfall estimation algorithm of GSMaP using machine learning

*Hitoshi Hirose[1], Takuji Kubota[1], Atsushi Higuchi[2], Koichi Toyoshima[2], Shoichi Shige[3], Tomoo Ushio[4], Tomoaki Mega[4] (1.Japan Aerospace Exploration Agency, 2.Center for Environmental Remote Sensing, Chiba university, 3.Department of Science, Kyoto University, 4.Department of Engineering, Osaka University)

[ACG51-P06] Sensitivity experiment of aerosol models in aerosol retrieval algorithm and comparison with ground-based observation using GOSAT/CAI and GOSAT-2/CAI-2 data

*Makiko Hashimoto[1], Hideaki Takenaka[1], Chong Shi[1], Teruyuki Nakajima[1] (1.Japan Aerospace Explortion Agency)

[ACG51-P07] High resolution Motion Vector for the GSMaP MVK

*Tomoaki Mega[1], Tomoo Ushio[1] (1.Osaka Univ.)

[ACG51-P08] Validation of GSMaP toward practical hydrological use over Vietnam: basin-scale validation and estimation of accuracy with time lapse from microwave observation

*Masato I. Nodzu[1], Jun Matsumoto[1,2], Thanh Ngo-Duc[3], Long Trinh-Tuan[3], Tri Truong-Duc[4] (1.Tokyo Metropolitan University, 2.Japan Agency for Marine-Earth Science and Technology, 3.University of Science and Technology of Hanoi, Vietnam Academy of Science and Technology, 4.Ministry of Natural Resources and Environment, Vietnam)

[ACG51-P09] Cloud and aerosol discrimination algorithm for EarthCARE/ATLID lidar

*Eiji Oikawa[1], Hajime Okamoto[1], Tomoaki Nishizawa[2], Kaori Sato[1], Rei Kudo[3] (1.Research Institute for Applied Mechanics, Kyushu University, 2.National Institute for Environmental Studies, 3.Meteorological Research Institute, Japan Meteorological Agency)

[ACG51-P10] **Climate and air pollution impact on wheat crop over Eastern Indo Gangetic Plains of India**

*geetika sonkar[1] (1.Banaras Hindu University)

[ACG51-P11] Orverview of Earth Clouds, Aerosols and Radiation Explorer (EarthCARE) projects

*Takahashi Chikako[1], Riko Oki[1], Takuji Kubota[1], Maki Kikuchi[1], Yuichiro Hagihara[1], Mayumi YOSHIDA[1] (1.Japan Aerospace Exploration Agency)

[ACG51-P12] Sources of countercurrent in northeastern Taiwan

*Chen-Chen Ho[1], Po-Chun Hsu[1], Ching-Yuan Lu[1], Chung-Ru Ho[1] (1.Department of Marine Environmental Informatics, National Taiwan Ocean University)

[ACG51-P13] **An improved procedure for estimation of propagation distance of tweek atmospherics**

*Masafumi Kanno[1], Hiroyo Ohya[2], Kazuo Shiokawa[3], Hiroyuki Nakata[2], Toshiaki Takano[2] (1. Graduate School of Science and Engineering, Chiba University, 2.Graduate School of Engineering, Chiba University, 3.Institute for Space-Earth Environmental Research, Nagoya University)

[ACG51-P14] Current status of the calibration for the GPM DPR

*Takeshi Masaki[1], Toshio Iguchi[2], Kaya Kanemaru[3], Kinji Furukawa[4], Naofumi Yoshida[1], Takuji Kubota[5], Riko Oki[5] (1.Remote Sensing Technology Center of Japan , 2.Earth System Science Interdisciplinary Center, University of Maryland, 3.National Institute of Information and Communications Technology, 4.Satellite Applications and Operations Center, Japan Aerospace Exploration Agency, 5.Earth Observation Research Center, Japan Aerospace Exploration Agency)

[ACG51-P15] Observing Simulation System Experiment for Future Small Precipitation Radar Constellation: Impact on GSMaP Accuracy

*Yamaji Moeka[1], Takuji Kubota[1] (1.Japan Aerospace Exploration Agency (JAXA))

[ACG51-P17] **Calibration of INSAT-3D meteorological satellite imager visible channel using Moon**

*Shailesh Parihar[1], A.K. Mitra, R. Bhatla[1] (1.Banaras Hindu University, Varanasi, India)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG52] Large Ensemble Modeling Approaches as Tools for Climate and Impacts Research

convener:Rodgers Keith Bradley(IBS Center for Climate Physics), Shoshiro Minobe(Graduate School of Science, Hokkaido University), Hideo Shiogama(Center for Global Environmental Research, National Institute for Environmental Studies), Ryo Mizuta(Meteorological Research Institute)

[ACG52-P01] Increase in Rain-on-Snow events in Japan as projected by large ensemble of regional climate simulations

*Masamichi Ohba[1], Hiroaki Kawase[2] (1.Central Research Institute of Electric Power Industry, 2.Meteorological Research Institute)

[ACG52-P02] Projected changes in extreme precipitation in a 60-km AGCM large ensemble and their dependence on return periods

*Ryo Mizuta[1], Hirokazu Endo[1] (1.Meteorological Research Institute)

[ACG52-P03] Detection and Analysis of Tropical Cyclones in the d4pdf Mega-ensemble Projection

*Adrean Webb[1], Tomoya Shimura[1], Nobuhito Mori[1] (1.Kyoto University, Disaster Prevention Research Institute, Coastal Disaster Research)

[ACG52-P04] ESM-projected global change in the indices of extreme weather using the TR3S method of bias-correction

*Martin Gomez-Garcia[1], Akiko Matsumura[1], Daikichi Ogawada[1] (1.Nippon Koei Co., Ltd. Research and Development Center)

[ACG52-P05] **Droughts, fires and fire emissions of CO_2 and $PM_{2.5}$ in equatorial Asia due to historical and future climate changes**

*Hideo Shiogama[1] (1.Center for Global Environmental Research, National Institute for Environmental Studies)

[ACG52-P06] Future change in phytoplankton phenology simulated by large ensemble experiment

*Ryohei Yamaguchi[1], Keith Rodgers[1,2], Karl J Stein[1,2], Axel Timmermann[1,2], John P Dunne[3], Richard D Slater[4], Sarah Schlunegger[4] (1.IBS Center for Climate Physics, 2.Pusan National University, 3.NOAA Geophysical Fluid Dynamics Laboratory, 4.Princeton University)

[ACG52-P07] Seasonality Constraints on the rate of Pteropod Habitat Compression under 21st Century Climate Change

*Keith Bradley Rodgers[1,2], Sarah Schlunegger[3], Richard Slater[3], Burke Hales[4] (1.IBS Center for Climate Physics, 2.Pusan National University, 3.AOS Program, Princeton University, 4.Oregon State University)

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-CG Complex & General

[A-CG53] Terrestrial monitoring using new-generation geostationary satellites

convener:Yuhei Yamamoto(Center for Environmental Remote Sensing, Chiba University), Yunyue Yu(NOAA National Environmental Satellite, Data, and Information Service), Tomoaki Miura(Univ Hawaii), Kazuhito Ichii(Chiba University)

[ACG53-P01] Evaluation of Estimated precipitation product by machine learning method using Himawari 8

*Koichi Toyoshima[1], Hitoshi Hirose[2], Atsushi Higuchi[1] (1.Center for Environmental Remote Sensing, Chiba University, 2.JAXA EORC)

[ACG53-P02] Development and application of land surface products using Himawari-8 AHI

*Kazuhito Ichii[1], Yuhei Yamamoto[1], Kodai Hayashi[1] (1.Chiba University)

[ACG53-P03] Monitoring seasonal variations in vegetation activities over Southeast Asia using Himawari-8

*Kodai Hayashi[1], Kazuhito Ichii[1], Yuhei Yamamoto[1] (1.Chiba University)

[ACG53-P04] Analysis of the spatial variations in the phenology of deciduous broadleaf forests in Japan with Himawari-8 NDVI hyper-temporal signatures

*Tomoaki Miura[1], Shin Nagai[2] (1.University of Hawaii at Manoa, 2.JAMSTEC)

[E] Poster | H (Human Geosciences)：H-GM Geomorphology

[H-GM02] Geomorphology

convener:Tsuyoshi Hattanji(Faculty of Life and Environmental Sciences, University of Tsukuba), Masayuki Seto(Fukushima Future Center for Regional Revitalization, Fukushima University)

[HGM02-P01] Bank erosion owing to tidal currents and its impact on village distribution in the Sittaung River estuary, Myanmar

*Naoko Nagumo[1], Daisuke Harada[1], Tanjir Saif Ahmed[1,2], Shinji Egashira[1] (1.International Centre for Water Hazard and Risk Management, Public Works Research Institute, 2.National Graduate Institute for Policy Studies)

[HGM02-P02] Grain size and OSL dating of river bank dune deposits: an example from the Kiso River, central Japan

*Kazuaki Hori[1], Kohei Ohata[1], Yuji Ishii[2,3] (1.Nagoya Univ., 2.JSPS, 3.AIST)

[HGM02-P03] Topographic development process of bedrock river: model experiment

*Yuta Takase[1], Noritaka Endo[1] (1.Kanazawa University)

[HGM02-P04] Patterns of slopes and geological structure in the Atsuma River catchment, Hokkaido

*Takahisa Furuichi[1,2], Seiji Yanai[3], Tomoya Hayakawa[4] (1.Miyagi University of Education, 2.University of the Sunshine Coast, 3.Ishikawa Prefectural University, 4.Nippon Koei, Co. Ltd.)

[HGM02-P05] Radiocarbon-based Chronology of Valley Head Deposits: A Case Study of Landslide Scars in Hofu, Yamaguchi Prefecture

Takatoshi Kawano[1], *Tsuyoshi Hattanji[2], Takahisa Furuichi[3], Shoji Doshida[4], Yasushi Tanaka[5] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Faculty of Life and Environmental Sciences, University of Tsukuba, 3.Miyagi University of Education, 4.National Research Institute of Fire and Disaster, 5.Komazawa University)

[HGM02-P06] Impact of Understory Coverage and Tree Height on Sediment Transport Activity in Tenryu Artificial Forest, Japan

*Kautsar Qurratul Aini Binti Mahyudin[1], Fumitoshi Imaizumi[1] (1.Shizuoka University)

[E] Poster | H (Human Geosciences)：H-QR Quaternary research

[H-QR04] Innovative Applications of Trapped-Charge Dating to Quaternary Geochronology

convener:Toru Tamura(Institute of Geology and Geoinformation Geological Survey of Japan, AIST), Shin Toyoda(Department of Applied Physics, Faculty of Science, Okayama University of Science), Yuji Ishii(National Institute of Advanced Industrial Science and Technology), Sumiko Tsukamoto(Leibniz Institute for Applied Geophysics)

[HQR04-P01] Optically stimulated luminescence (OSL) dating using quartz extracted from loess as archeo-sediments of Paleolithic site

*Yorinao Shitaoka[1] (1.Department of Environment System, Faculty of Geo-environmental Science, Rissho University)

[HQR04-P02] Luminescence dating and age correction of marine terrace deposits in Kamikita Coastal Plain and Shimokita Peninsula, northeastern Japan

*Kazumi Ito[1], Toru Tamura[1] (1.Geological Survey of Japan, AIST)

[HQR04-P03] Comparison of luminescence readers using post-Infrared Infrared stimulated luminescence of K-feldspar from last interglacial marine terrace deposits

*Hayashizaki Ryo[1], Eiji Nakata[1] (1.Central Research Institute of Electric Power Industry)

[HQR04-P04] **Late Quaternary loess accumulation at the Rudak section in Uzbekistan, central Asia: Chronology and palaeoclimate implications**

★Invited Papers

*Jingran Zhang[1], Xinying Zhou[2], Hao Long[3] (1.Nanjing Normal Univ., 2.IVPP, CAS, 3.NIGLAS)

[HQR04-P05] Dating of hydrothermal silicified sediments by thermoluminescence

*Naoya Obata[3,1], Takashi Goto[4,1], Chitaro Gouzu[1], Jun-ichiro Ishibashi[2], Shin Toyoda[3] (1.Hiruzen Institute for Geology and Chronology Co., Ltd., 2.Kyushu University, 3.Okayama University of Science, 4.Fuji Geological Institute)

[HQR04-P06] Applications of trapped-charge dating techniques to hydrothermal mineral deposits collected from active seafloor hydrothermal fields

*Jun-ichiro Ishibashi[1], Naru Tsukamoto[1], Yusuke Okazaki[1], Taisei Fujiwara[2], Naoya Obata[2], Takashi Goto[2], Chitaro Gouzu[2], Shin Toyoda[3] (1.Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 2.Hiruzen Institute for Geology and Chronology, 3.Okayama University of Science)

[HQR04-P07] **Luminescence dating of the late Quaternary terrestrial-marine interaction sedimentary history of the north Jiangsu coastal plain and the Yangtze River delta in China**

*Lei Gao[1], Hao Long[1], Toru Tamura[2] (1.Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, 2.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[HQR04-P08] Composite chronology of Paleolithic sites in Jebel Qalkha revealed by pIRIR dating

Risako Kida[1], *Toru Tamura[2], Seiji Kadowaki[1] (1.Nagoya University Museum, Nagoya University, 2.Institute of Geology and Geoinformation Geological Survey of Japan, AIST)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

[H-DS08] Tsunami and tsunami forecast

convener:Hiroaki Tsushima(Meteorological Research Institute, Japan Meteorological Agency), Tatsuya Kubota(National Research Institute for Earth Science and Disaster Resilience)

[HDS08-P01] Probabilistic Hazard Assessment of Tsunami due to Large Earthquakes along the Nankai Trough

*Kazuhiro Ichijo[1], Yutaka Hayashi[1], Yasuyuki Kawazoe[2], Fumihiko Imamura[3], Hisashi Suito[1] (1.Ministry of Education, Culture, Sports, Science and Technology, 2.Japan Meteorological Agency, 3.International Research Institute of Disaster Science, Tohoku University)

[HDS08-P02] Characterized earthquake fault models along the Nankai Trough for probabilistic tsunami hazard assessment

*Kenji Hirata[1], Tadashi Kito[2], Nobuhiko Toyama[2], Hiroyuki Fujiwara[1], Hiromitsu Nakamura[1], Nobuyuki Morikawa[1], DOHI YUJI[1], Hisanori Matsuyama[2], Kenshi Ohshima[2], Yasuhiro Murata[3], Ryu Saito[3], Mariko Korenaga[4], Yuta Abe[4] (1.National Research Institue for Earth Science and Diaster Prevention, 2.OYO corporation, 3.KKC, 4.CTC)

[HDS08-P03] Tsunami simulations for probabilistic tsunami hazard assessment in the Nankai Trough

*Ryu Saito[1], Kenshi Ohshima[2], Tadashi Kito[2], Yasuhiro Murata[1], Tomoyuki Shibuki[1], Mariko Korenaga[3], Yuji Dohi[4], Hiromitsu Nakamura[4], Kenji Hirata[4], Hiroyuki Fujiwara[4] (1.KOKUSAI KOGYO CO., LTD, 2.OYO Corporation, 3.CTC (ITOCHU Techno-Solutions Corporation), 4.NIED (National Research Institute for Earth Science and Disaster Resilience))

[HDS08-P04] Probabilistic Tsunami Hazard Assessment for Nankai Trough:Weight Ratio and Results of PTHA

*Yuta Abe[1], Mariko Korenaga[1], Shinichi Akiyama[1], Teppei Ono[1], Hiroyuki Fujiwara[2], Kenji Hirata[2], Hiromitsu Nakamura[2], Tadashi Kito[3], Yasuhiro Murata[4] (1.ITOCHU Techno-Solutions Corporation, 2.National Research Institute for Earth Science and Disaster Resilience, 3.OYO Corporation, 4.Kokusai Kogyo Co., Ltd.)

[HDS08-P05] Consideration of tsunami source generated in the Hyuga-nada region in 1662

*Kei Ioki[1], Yusuke Yamashita[2], Yoshihiro Kase[3] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology, 2.Disaster Prevention Research Institute, Kyoto University, 3.Geological Survey of Hokkaido, Hokkaido Research Organization)

[HDS08-P06] Source of the 1923 great Kanto earthquake explaining observed tsunami waveforms

*Yumi Nakadai[1], Yuichiro Tanioka[1] (1.Hokkaido University)

[HDS08-P07] Volcanic tsunami earthquakes repeating at submarine calderas (2): Kinematic source modeling of the 2015 Torishima earthquake

*Osamu Sandanbata[1], Shingo Watada[1], Kenji Satake[1], Hiroo Kanamori[2], Luis Rivera[3], Zhongwen Zhan[2] (1.Earthquake Research Institute, the University of Tokyo, 2.California Institute of Technology, 3.Université de Strasbourg, CNRS, IPGS UMR 7516, F-67000 Strasbourg)

[HDS08-P08] Sliding direction of the landslide that caused the 1998 Papua New Guinea tsunami

*Akio Katsumata[1], Yasuhiro Yoshida[2], Kenji Nakata[1], Kenichi Fujita[3], Masayuki Tanaka[1], Koji Tamaribuchi[1], Takahito Nishimiya[1], Akio Kobayashi[1] (1.Meteorological Research Institute, Japan Meteorological Agency, 2.Meteorological College, Japan Meteorological Agency, 3.Geospatial Information Authority of Japan)

[HDS08-P09] Simulation of reflected tsunami wave caused by the three cases of earthquake off Fukushima prefecture

*Kenji Nakata[1], Takeyasu Yamamoto[1] (1.Meteorological Research Institute, Japan Meteorological Agency)

[HDS08-P10] Real-Time Tsunami Detection Based on Ensemble Empirical Mode Decomposition

*Yuchen Wang[1], Kenji Satake[1], Takuto Maeda[2], Masanao Shinohara[1], Shin'ichi Sakai[1] (1.Earthquake Research Institute, University of Tokyo, 2.Graduate School of Science and Technology, Hirosaki University)

[HDS08-P11] Early estimation of tsunami height from near-fault ocean bottom pressure records: Comparison of DONET and S-net data

*Ayumu Mizutani[1], Kiyoshi Yomogida[1] (1.Graduate School of Science, Hokkaido University)

[HDS08-P13] Analytic solutions of seismic tsunamis' initial waveforms: a mathematical study

*Chi-Min Liu[1] (1.Department of Civil Engineering, Chienkuo Technology University)

[HDS08-P14] Predictions of tsunamis caused by possible outer-rise earthquakes in the Japan Trench

*Toshitaka Baba[1], Naotaka YAMAMOTO CHIKASADA[2], Yasuyuki Nakamura[3], Gou Fujie[3], Koichiro Obana[3], Seiichi Miura[3], Shuichi Kodaira[3] (1.Graduate School of Social Science and Technology, Tokushima University, 2.NIED, 3.JAMSTEC)

[HDS08-P15] Influence of coastal structures on probabilistic tsunami inundation assessments

*Toru Takeda[1], Toshitaka Baba[2], Tsuneo Ohsumi[3], Hiroyuki Fujiwara[4] (1.Graduate School of Advanced Science and Technology Education Department of Intelligent Mechanical Systems Engineering Construction Creative System Engineering Course, Tokushima University, 2.Graduate School of Science and Technology, Tokushima University, 3.National Research Institute for Earth Science and Disaster Prevention , 4.National Research Institute for Earth Science and Disaster Prevention)

[HDS08-P16] Simulations of sediment movement for tsunami deposits in Kamoda Pond along the Nankai Trough

*Takuya Saito[1], Toru Takeda[1], Kei Yamashita[2], Toshitaka Baba[3] (1.Graduate School of Advanced Science and Technology Education Department of Intelligent Mechanical Systems Engineering Construction Creative System Engineering Course, Tokushima University, 2.International Research Institute of Disaster Science, 3.Graduate School of Science and Technology, Tokushima University)

[E] Poster | H (Human Geosciences)：H-DS Disaster geosciences

[H-DS09] Landslides and related phenomena

convener:Masahiro Chigira(Disaster Prevention Research Institute, Kyoto University), Fumitoshi Imaizumi(Faculty of Agriculture, Shizuoka University), Gonghui Wang(Disaster Prevention Research Institute, Kyoto University)

[HDS09-P01] A new method for landslide extraction using optical and SAR images

*Yuga Kumagai[1], Masaru Fujita[2], Yasukuni Okubo[2], Kiichiro Kawamura[1] (1.Yamaguchi University, 2.Japan Space Systems)

[HDS09-P02] Landslides caused by the 2018 Hokkaido Iburi-tobu earthquake - Shallow slides of tephra deposits and deep-sheeted bedrock slides -

*Makoto Kaneko[1], Norio Oyagi[1], Hiroshi, P. Sato[2], Yusuke Muramiya[1] (1.Fukada Geological Institute, 2.College of Humanities and Sciences, Nihon University)

[HDS09-P03] **The geomorphic characteristics of landslides induced by The 2018 Eastern Iburi earthquake, Hokkaido**

★Invited Papers

*Rasis Putra Ritonga[1], Takashi Gomi[2,4], Hefryan Sukma Kharismalatri[2], Rozaqqa Noviandi[3], Yoshiharu Ishikawa[4] (1.United Graduate School of Agricultural Science, Tokyo University of Agriculture and Technology, 2.Institute of Global Innovation Research, Tokyo University of Agriculture and Technology, 3.International Environmental and Agricultural Science, Tokyo University of Agriculture and Technology, 4.Graduate School of Agriculture, Tokyo University of Agriculture and Technology)

[HDS09-P04] Relationship between the subsurface structure and the deformation area accompanied with the 2018 Hokkaido Eastern Iburi earthquake in a fill in Atsuma town, Hokkaido

*Issei Doi[1], Ryokei Azuma[2], Yuki Maenaka[2], Toshitaka Kamai[1] (1.Disaster Prevention Research Institute, 2.Faculty of Technology, Osaka Institute of Technology)

[HDS09-P05] Seismic site response of tephra slope: a case study for the landslides triggered by the 2018 Hokkaido Eastern Iburi Earthquake

[SSS04-P01] Toward to construction of strong-motion database for seismic hazard assessment in Japan

*Nobuyuki Morikawa[1], Hiroyuki Fujiwara[1], Asako Iwaki[1], Takahiro Maeda[1], Hisahiko Kubo[1], Shin Aoi[1], Kenichi Kato[2], Yusuke Tomozawa[2], Fumino Suzuki[2], Toshiaki Sato[3], Toru Ishii[3], Naomi Shimazu[3], Jun'ichi Miyakoshi[3], Atsuko Oana[3], Hongjun Si[4], Toshihiko Hayakawa[5], Takayuki Hayashi[6], Natsuki Kishida[6], Saburoh Midorikawa[7] (1.National Research Institute for Earth Science and Disaster Resilience, 2.Kobori Research Complex Inc., 3.Ohsaki Research Institute Inc., 4.Seismological Research Institute Inc., 5.Mitsubishi Space Software Co., Ltd., 6.Tokio Marine & Nichido Risk Consulting Co., Ltd., 7.Tokyo Institute of Technology)

[SSS04-P02] **Tilt and rotational motions during the strong shaking**

*Toshimi Satoh[1] (1.Shimizu Corporation)

[SSS04-P03] Analysis of pulse-like waves observed in the eastern part of Fukushima Prefecture during the 2011 Tohoku earthquake

*Tomiichi Uetake[1], Kazuhito Hikima[1], Akihito Shimmura[1], Masatoshi Fujioka[1], Ryosuke Sugimoto[1] (1.Tokyo Electric Power Company Holdings)

[SSS04-P04] **Ground Motion Estimation from the Initial P Wave of the Great Earthquake**

*Zijun WANG[1], Boming ZHAO[1], Takao KAGAWA[2], Masanori HORIKE[3] (1.Beijing Jiaotong University, 2.Tottori University , 3.Hanshin Consultants Co., Ltd.)

[SSS04-P05] **Damage Hazard Caused by the Great Earthquake Ground Motion**

*Boming ZHAO[1], Zijun WANG[1], Takao KAGAWA[2], Masanori HORIKE[3] (1.Beijing Jiaotong University, 2.Tottori University, 3.Hanshin Consultants Co., Ltd.)

[SSS04-P06] Disaster mainly of stone torii by the Yamagata Offshore Earthquake in 2019

*Takayuki Kawabe[1] (1.Ex. Faculty of Education, Arts and Sciences, Yamagata University)

[SSS04-P07] Source inversion using empirical Green's functions for the 2019 Off Yamagata earthquake (Mj 6.7)

*Yoshiaki Shiba[1] (1.Central Research Institute of Electric Power Industry)

[SSS04-P08] Source rupture process and strong motion generation areas for the 2018 Hokkaido Eastern Iburi earthquake

*Kazuhiro Somei[1], Ken Miyakoshi[1], Yujia Guo[1] (1.Geo-Research Institute)

[SSS04-P09] Conjugate fault model of the 2018 Anchorage, Alaska, intraplate earthquake (M_W 7.1) based on strong-motion waveform inversion

*Yujia Guo[1], Ken Miyakoshi[1], Masato Tsurugi[1] (1.Geo-Research Institute)

[SSS04-P11] An idea to extract effective fault size from a slip distribution estimated by inversion analysis

*Kazuhito Hikima[1], Akihiro Shimmura[1] (1.Tokyo Electric Power Company Holdings, Inc.)

[SSS04-P12] Estimation of subsurface structure based on microtremor and gravity observation in Shigaku area, Mt. Sanbe, Shimane Prefecture, Japan

*Tatsuya Noguchi[1], Yutaro Itohara[1], Mayuko Kuya[1], Isamu Nishimura[2], Takao Kagawa[1] (1.Faculty of Engineering, Tottori University, 2.Graduate School of Engineering, Tottori University)

[SSS04-P13] Estimation of Subsurface Structure and Ground Motion Characteristics in the Damaged Areas of the 2016 Central Tottori Prefecture Earthquake

*Isamu Nishimura[1], Tatsuya Noguchi[2], Takao Kagawa[2] (1.Tottori Univercity Graduate School of Engineering, Department of Management of Social Systems and Civil Engineering, Civil Engineering Course, 2.Tottori Univercity Graduate School of Engineering)

[SSS04-P14] CMP-SPAC and SPAC microtremor array surveys around Tegano active fault, Gifu, Japan

*Masayuki Yoshimi[1], Haruhiko Suzuki[2] (1.Geological Survey of Japan, AIST, 2.Oyo Corporation)

[SSS04-P15] Improvement of Accuracy to Estimate Phase Velocity using Arbitrary Shape Arrays with Extra Observation Sites

*Huan Zhang[1], Kahori Iiyama[1], Hitoshi Morikawa[1] (1.Tokyo Institute of Technology)

[SSS04-P16] Site Classification Method in Microtremor Array Exploration Using a Supervised Machine Learning

*Takumi Hayashida[1] (1.International Institute of Seismology and Earthquake Engineering, Building Research Institute)

[SSS04-P17] **Verification for the Deep Sedimentary Velocity Structure in the Kathmandu Valley using Receiver Function Analysis**

*Michiko Shigefuji[1], Nobuo Takai[2], Subeg Bijukchhen[3] (1.Kyushu University, 2.Hokkaido University, 3.Khwopa Engineering College, Nepal)

[SSS04-P18] Detect of Underground Velocity Discontinuity by Autocorrelation of Strong Motion Data in the Osaka and Kyoto Basins

*Shuta Fukutome[1], Kimiyuki Asano[1], Tomotaka Iwata[1] (1.Disaster Prevention Research Institute, Kyoto University)

[SSS04-P19] **CONSTRUCTION OF SHALLOW AND DEEP LAYERS COMBINED MODEL IN THE KANTO REGION, JAPAN**

*Hiroaki Yamanaka[1], Yoko Tono[2], Shigeki Senna[3], Masahiro Ohbuchi[4], Hiroyuki Fujiwara[3] (1.Interdisciplinary Graduate School of Science and Engineering,Tokyo institute of Technology, 2. Earthquake Research Institute, University of Tokyo, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Ministry of Education, Culture, Sports, Science and Technology)

[SSS04-P20] Estimation of earthquake ground motions at MeSO-net stations

*Atsushi Wakai[1], Shigeki Senna[1], Atsushi Shimizu[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SSS04-P21] Modeling of subsurface velocity structure from seismic bedrock to ground surface based on array microtremor observation in Aso area

*Shigeki Senna[1], Atsushi Wakai[1], Atsushi Yatagai[2], Yoshiaki Inagaki[2], Hisanori Matsuyama[2], Hiroyuki Fujiwara[1] (1.National Research Institute for Earth Science and Disaster Resilience, 2.OYO Corp)

[SSS04-P22] The examination of liquafaction damage rate by recent earthquakes

*Shigeki Senna[1], Kyoko Ozawa[1] (1.National Research Institute for Earth Science and Disaster Resilience)

[SSS04-P23] **Ground Motion Estimation by using Microtremor H/V Spectral Ratio**

*Guan-Yu Chen[1], Che-Min Lin[2], Kuo-Liang Wen[1] (1.Department of Earth Science, National Central University, Taoyuan, Taiwan, 2.National Center for Research on Earthquake Engineering, Taipei, Taiwan)

[SSS04-P24] ISNL- - an new parameter of soil nonlinearity used for Taiwan and New Zealand earthquake

*Kao Ching[1], Huang Jyun-Yan[2], Wen Kuo-Liang [2] (1.National Central University, 2.National Center for Research on Earthquake Engineering)

[SSS04-P25] Assessment of the liquefaction risk at Re-liquefied site

*CHIH-SHENG KU[1], Yun-Ling Hsieh[1], Po-Wei Cheng[1] (1.I-SHOU University)

[SSS04-P26] Experimental Study on Dynamic Shear Modulus of Cohesive Soil in Beijing Plain

*Yi Fang, Guoxing Chen, Yanju Peng, Yuejun Lyu

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

[S-SS05] Innovative data analysis methods for characterization of seismicity

convener:Francesco Grigoli(ETH Zurich Swiss Federal Institute of Technology Zurich), Bogdan Enescu(Department of Geophysics, Kyoto University), Aitaro Kato(Earthquake Research Institute, the University of Tokyo), Yosuke Aoki(Earthquake Research Institute, University of Tokyo)

[SSS05-P01] **Erecting and Observation Data of Broadband Seismic Array in Haiyuan- Liupanshan Fault Zone, Ningxia, China**

*Guofu luo[1], Heqin - Ma[1] (1.Earthquake Administration of Ningxia Hui Autonomous Region)

[SSS05-P02] Energy release patterns and shaking effects of earthquakes in the Japan Trench: A Hilbert-Huang Transform approach

*Swapnil Mache[1], Kusala Rajendran[1] (1.Indian Institute of Science, Bangalore)

[SSS05-P03] The 2019 September 15th Stigliano natural seismic sequence revealed by a local network designed for induced seismicity monitoring

*Chiara Cocorullo[1], Giancarlo Graci[2], Stefano Limonta[1], Alexander Garcia[3], Thomas Braun[3], Francesco Grigoli[4] (1.SolGeo srl, 2.TOTAL E&P ITALIA, 3.INGV, 4.ETH-Zurich, Swiss Seismological Service)

[SSS05-P04] The systematic spatial bias pattern of earthquakes related to tectonic heterogeneity

*Yijun Zhang[1] (1.Southwest JiaoTong University)

[SSS05-P05] Location of seismic events with a single station using Distance Geometry Solvers

*Francesco Grigoli[1], William L Ellsworth[2], Miao Zhang[3], Simone Cesca[4], Claudio Satriano[5], Mostafa Mousavi[2], Gregory C Beroza[2], Stefan Wiemer[1] (1.ETH-Zurich, Switzerland, 2.Stanford University, United States, 3.Dalhousie University, Halifax, Canada, 4.GFZ-Potsdam, Germany, 5.IPGP-Paris, France)

[SSS05-P06] Evaluation of deep-neural-network-based seismic arrival-time picking method for S-net data

*Rintaroh Suzuki[1], Naoki Uchida[1], Weiqiang Zhu[2], Gregory C Beroza[2] (1.Research Center for Prediction of Earthquakes and Volcanic Eruptions Graduate School of Science, Tohoku University, 2.Department of Geophysics, Stanford University)

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

[S-SS06] Active faults and Paleoseismology

convener:Hisao Kondo(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology), Mamoru Koarai(Earth Science course, College of Science, Ibaraki University), Takashi OGAMI(National Institute of Advanced Industrial Science and Technology), Yoshiki Sato(Advanced Industrial Science and Technology, Geological Survey of Japan)

[SSS06-P01] Active tectonics of the northern Banda Arc, eastern Indonesia: a preliminary geomorphic mapping

*Adi Patria[1,3], Hiroyuki Tsutsumi[2], Danny Hilman Natawidjaja[3] (1.Graduate School of Science and Engineering, Doshisha University, 2.Department of Environmental Systems Science, Doshisha University, 3.RC for Geotechnology, Indonesian Institute of Sciences (LIPI))

[SSS06-P02] Paleoseismological studies along the un-ruptured southern segment of Yokote Basin Fault Zone, northeast Japan

*SHREYA Arora[1], Hisao Kondo[1] (1.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[SSS06-P03] Parametric study on ground surface deformation forming pull-apart basin

*Hidetaka Saomoto[1] (1.National Institute of Advanced Industrial Science and Technology)

[SSS06-P04] S wave seismic reflection survey on the Shikano fault appeared in the 1943 Tottori earthquake

*Takao Kagawa[1], Tatsuya Noguchi[1], Koji Yamada[2], Tetsuya Takemoto[2] (1.Tottori University Graduate School of Engineering, 2.Hanshin Consultants Co., Ltd.)

[SSS06-P05] Offset streams across active faults in Chugoku region in the southwestern Japan

*Takashi Azuma[1] (1.National Institute of Advanced Industrial Science and Technology)

[SSS06-P06] Change in stress with seismic cycles in coherent and mélange units in the Cretaceous Shimanto Belt, SW Japan

*Makoto Hashiguchi[1], Yoshitaka Hashimoto[1] (1.Kochi University)

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

[S-SS07] Earthquake prediction and forecast+pre-earthquake geoscientific changes(TBD)

convener:Masayuki Obayashi(Japan Agency for Marine-Earth Science and Technology), Toshitaka Baba(Graduate School of Science and Technology, Tokushima University), Chi-Yu King(Retired)

[SSS07-P01] Long-term level and temperature changes in groundwater at the frontier land zone for impending great earthquakes at the Nankai trough, southwest Japan
- Recent anomalous changes, possible great earthquake precursors -

*Tameshige Tsukuda[1] (1.none)

[SSS07-P02] **Application of different statistical tools to investigate radon time-series data for earthquake precursory studies in Taiwan**

*Vivek Walia[1], Arvind Kumar[1], Ching-Chou Fu[2], Shih-Jung Lin[1], Cheng-Horng Lin[1,2] (1.National Center for Research on Earthquake Engineering, NARL, Taipei, Taiwan , 2.Institute of Earth Sciences, Academia Sinica, Taiwan)

[SSS07-P03] Correlations of earthquake properties with geomagnetic ULF precursor characteristics over multiple events

*Muhammad Khairul Adib Muhammad Yusof[1], Mardina Abdullah[1,2], Nurul Shazana Abdul Hamid[1,3], Suaidi Ahadi[4], Akimasa Yoshikawa[5] (1.Space Science Center, Institute of Climate Change, Universiti Kebangsaan Malaysia, Malaysia, 2.Department of Electrical, Electronic and Systems Engineering, Faculty of Engineering and Built Environment, Universiti Kebangsaan Malaysia, Malaysia, 3.Department of Applied Physics, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Malaysia, 4.Department of Geophysics, Indonesian Agency for Meteorology, Climatology and Geophysics, Jakarta, Indonesia, 5.International Center for Space Weather Science and Education, Kyushu University, Fukuoka 812-8581)

[SSS07-P04] Recent Advances in Earthquakes Relocation and Probabilistic Seismic Hazard Assessment for Risk Mitigation and Planning in West Africa

*Umar Afegbua Kadiri[1], Tahir Abubakar Yakubu[1], Friday Ezomo, Brassnavy Manzunzu (1.Centre for Geodesy and Geodynamics Toro)

[SSS07-P05] Ionosphere Magnetic Field Precursor Anomalies Extraction Associated with 2016 Ecuador Earthquake using NMF

*Mengxuan Fan[1], Kaiguang Zhu[1], Xiaodan He[1], Kaiyan Li[1], Dedalo Marchetti[2], Chengquan Chi[1], ZINING YU[1] (1.Jilin University, 2.National Institute of Geophysics and Volcanology)

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

[S-SS08] Statistical seismology and underlying physical processes

convener:Yasuhiro Yoshida(Meteorological College, Japan Meteorological Agency)

[SSS08-P01] Stress induced from large earthquakes since 1900 and temporal b value change in Nankai trough

Junhyung Lee[1], Ilgoo Kim[1], *Tae-Kyung Hong[1] (1.Department of Earth System Sciences, Yonsei University)

[SSS08-P02] Microseismicity distribution and inferred fault geometry beneath the western Marmara Sea, Turkey, deduced from long-term ocean bottom seismographic observations

*Yojiro Yamamoto[1], Dogan Kalafat[2], Ali Pinar[2], Narumi Takahashi[3,1], Zeynep Coskun[2], Remzi Polat[2], Haluk Ozener[2], Yoshiyuki Kaneda[4,1] (1.Japan Agency for Marine-Earth Science and Technology, 2.KOERI, Bogaziti University, 3.National Research Institute for Earth Science and Disaster Resilience, 4.Kagawa University)

[SSS08-P03] Spatio-temporal characteristics of seismicity in the source region of the 2011 Tohoku earthquake

*MEITONG DUAN[1], Takuji Yamada[1], Jun Kawahara[1] (1.IBRAKI University)

[E] Poster | S (Solid Earth Sciences)：S-SS Seismology

[S-SS09] INDUCED AND TRIGGERED SEISMICITY: CASE STUDIES, MONITORING AND MODELING TECHNIQUES

convener:Luca Urpi, Yusuke Mukuhira(Institute of Fluid Science, Tohoku University), Bogdan Enescu(Department of Geophysics, Kyoto University), Francesco Grigoli(ETH Zurich Swiss Federal Institute of Technology Zurich)

[SSS09-P01] **Investigation of the physical link between the injection induced seismicity and information from borehole logging**

*Yusuke Mukuhira[1], Martin Ziegler[2], Takatoshi Ito[1], Hiroshi Asanuma[3], Markus O Häring[4] (1.Institute of Fluid Science, Tohoku University, 2.Department of Earth Sciences, Engineering Geology, ETH Zurich, 3.AIST, 4.Häring GeoProject)

[SSS09-P03] **Estimation of focal mechanisms of large number of induced seismicity to understand fracture system in the geothermal reservoir**

*Kangnan Yan[1,2], Yusuke Mukuhira[1], Takatoshi Ito[1], Yinhui Zuo[2], Hiroshi Asanuma[3], Markus O Häring[4] (1.Institute of Fluid Science, Tohoku University, 2.State Key Laboratory of Oil and Gas Geology and Exploitation, Chengdu University of Technology, 3.Fukushima Renewable Energy Institute (FREA), National Institute of Advanced Industrial Science and Technology (AIST), 4.Häring GeoProject)

[SCG60-P03] Earthquake detection based on deep learning

Junyu Yu[1,2], *Takahiko Uchide[2], Yuji Yagi[1] (1.Graduate School of Life and Environmental Sciences, University of Tsukuba, 2.Geological Survey of Japan, AIST)

[SCG60-P04] Large-scale matched-filter analysis with similarity search

*Naoto Mizuno[1], Satoshi Ide[1] (1.Department of Earth and Planetary Science, The University of Tokyo)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

[S-CG61] The Japan Trench: Learning from the 2011 M=9 Tohoku-Oki earthquake, a decade later

convener:Takeshi Iinuma(National Research and Development Agency Japan Agency for Marine-Earth Science and Technology), Asuka Yamaguchi(Atomosphere and Ocean Research Institute, The University of Tokyo), Aitaro Kato(Earthquake Research Institute, the University of Tokyo), Tianhaozhe Sun(Pacific Geoscience Centre, Geological Survey of Canada)

[SCG61-P01] Vertical deformation style along the Sanriku coast inferred from coastal geology examined after the Tohoku earthquake

*Yuichi Niwa[1], Toshihiko Sugai[2] (1.Faculty of Science and Engineering, Chuo University, 2.Department of Natural Environmental Studies, Graduate School of Frontier Sciences, The University of Tokyo)

[SCG61-P02] Trial of the crustal deformation detection accompanied with the tremor activities in Fukushima-Oki deduced from the ocean bottom pressure gauge data

*Hideto Otsuka[1], Yusaku Ohta[1], Ryota Hino[1], Kazuaki Ohta[2] (1.Research Center for Prediction Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 2.National Research Institute for Earth Science and Disaster Resilience)

[SCG61-P03] Seafloor Displacement along the Japan Trench Caused by the 2011 Tohoku-Oki Earthquake Examined by Repeated Bathymetric Surveys

★Invited Papers

*Toshiya Fujiwara[1,9], Shuichi Kodaira[1], Gou Fujie[1], Yuka Kaiho[1], Toshiya Kanamatsu[1], Takafumi Kasaya[2], Yasuyuki Nakamura[1], Tetsuo No[1], Tsutomu Takahashi[1], Takeshi Sato[3], Narumi Takahashi[4,1], Yoshiyuki Kaneda[5,1], Katharina Bachmann[6], Christian dos Santos Ferreira[6], Gerold Wefer[6], Michael Strasser[7], Tianhaozhe Sun[8] (1.Research Institute for Marine Geodynamics, Japan Agency for Marine-Earth Science and Technology, 2.Research Institute for Marine Resources Utilization, Japan Agency for Marine-Earth Science and Technology, 3.Sapporo Regional Headquarters, Japan Meteorological Agency, 4.National Research Institute for Earth Science and Disaster Resilience, 5.Kagawa University, 6.MARUM, University of Bremen, 7.Institute of Geology, University of Innsbruck, 8.Pacific Geoscience Centre, Geological Survey of Canada, 9.Kochi University)

[SCG61-P04] Modelling of spontaneous and periodic slow slip in the northern part of the Japan Trench

*Ryoko Nakata[1,2], Takane Hori[1], Ryota Hino[2] (1.Japan Agency for Marine-Earth Science and Technology, 2.Graduate School of Science, Tohoku University)

[SCG61-P05] Structural-morphological and sedimentary features of forearc slope off Miyagi, NE Japan: implications for development of forearc basins and plumbing systems

*Jih-Hsin Chang[1], Jin-Oh Park[2], Tzu-Ting Chen[3], Asuka Yamaguchi[2], Tetsuro Tsuru[4], Yuji Sano[2], Ho-Han Hsu[3], Kotaro Shirai[2], Takanori Kagoshima[2], Kentaro Tanaka[2], Chiori Tamura[2] (1.Geological Survey of Japan, National Institute of Advanced Industrial and Science Technology., 2.Atmosphere and Ocean Research Institute, The University of Tokyo., 3.Institute of Oceanography, National Taiwan University., 4.Tokyo University of Marine Science and Technology.)

[SCG61-P06] Structural variation in the shallowest part of the Japan Trench subduction zone and its correlation with shallow megathrust slip and tsunamigenesis

*Yasuyuki Nakamura[1], Toshiya Fujiwara[1], Shuichi Kodaira[1], Seiichi Miura[1], Koichiro Obana[1] (1.Japan Agency for Marine Earth Science and Technology)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

[S-CG62] Investigation of inputs to subduction zones: Influence of tectonic processes on the incoming plate

convener:Makoto Yamano(Earthquake Research Institute, the University of Tokyo), Tomoaki Morishita(School of Geoscience and Civil Engineering, College of Science and Technology, Kanazawa University), Gou Fujie(Japan Agency for Marine-Earth Science and Technology)

[SCG62-P01] Incoming Plate Faulting at the Outer Slope of the Middle America Trench offshore Mexico

*Emmanuel Soliman M Garcia[1], Yoshihiro Ito[1] (1.Disaster Prevention Research Institute, Kyoto University)

[SCG62-P02] Analysis of the variations in topographic features around the outer-rise of Japan trench

*Tomoko Hanyu[1], Jin-Oh Park[2], YUE SUN[2], Ehsan Jamali Hondori[2], Yukari Kido[3] (1.Kobe Ocean-Bottom Exploration Center, Kobe University, 2.Atmosphere and Ocean Research Institute, The University of Tokyo, 3.Japan Agency for Marine-Earth Science and Technology)

[SCG62-P03] Drift sediments recording bottom current history in NW Pacific

*Kiichiro Kawamura[1], Tomoka Adachi[1], Maki Suzukawa[1] (1.Yamaguchi University)

[SCG62-P04] Effects of lithology on the mechanical properties of the input materials at the Hikurangi margin

*Alexi Kristina Allen[1], Hiroko Kitajima[1] (1.Texas A and M University)

[SCG62-P05] Subduction initiation at active spreading mid-ocean ridge indicated by ultrahigh temperature slab melting

*Chiou-ting Lin[1], Kuei-Chih Feng[2], Masaki Enami[3], Hou-Chun Liu[4], Ji-Hao Zhu[6], Ron Harris[5], Wei-Dong Sun[1] (1.Center of Deep Sea Research, Institute of Oceanology, Chinese Academy of Sciences, 2.Department of Mechanical Engineering, Ming Chi University of Technology, 3.Institute for Space–Earth Environmental Research, Nagoya University, 4.Department of Earth Science, National Cheng Kung University, 5.Department of Geology, Brigham Young University, 6.State Oceanic Administration, Second Institute of Oceanography, Ministry of Natural Resources)

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

[S-CG63] Dynamics in mobile belts

convener:Yukitoshi Fukahata(Disaster Prevention Research Institute, Kyoto University), Ray Y Chuang(Department of Geography, National Taiwan University), Toru Takeshita(Department of Natural History Sciences, Graduate School of Science, Hokkaido University), Hikaru Iwamori(Earthquake Research Institute, The University of Tokyo)

[SCG63-P01] Seismic potential along the Caribbean subduction zone northwestern Colombia revealed by GPS data

*Sindy Carolina Lizarazo[1], Takeshi Sagiya[2], Hector Mora-Paez[3] (1.Graduate School of Environmental Studies - Nagoya University, 2.Disaster Mitigation Research Center - Nagoya Univesity, 3.Geological Survey of Colombia - GeoRED Project)

[SCG63-P02] New Megathrust Locking Model for the Southern Kurile Subduction Zone Incorporating Viscoelastic Relaxation and Non-uniform Compliance of Upper Plate

*Yuji ITOH[1], Takuya NISHIMURA[2], Kelin WANG[3], Jiangheng HE[3] (1.Graduate School of Science, Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University, 3.Pacific Geoscience Centre, Geological Survey of Canada)

[SCG63-P03] Occurrence of normal-type earthquakes and stress loading model under Boso Peninsula, Japan

*Akinori Hashima[1], Hiroshi Sato[1], Toshinori Sato[2] (1.Earthquake Research Institute, University of Tokyo, 2.Graduate School of Science, Chiba University)

[SCG63-P04] 3-D Numerical Simulation of Island Arc Deformation Due to Steady Plate Subduction

*Yutaro Mori[1], Yukitoshi Fukahata[2] (1.Graduate School of Science, Kyoto University, 2.Disaster Prevention Research Institute, Kyoto University)

[SCG63-P05] Cause of the horizontal deformation of the Philippine Sea plate subducting beneath southwestern Japan

*Kazuki Miyazaki[1], Junichi Nakajima[1] (1.Department of Earth and Planetary Sciences, Tokyo Institute of Technology)

[SCG63-P06] Modeling strain concentration zones in Kyushu Island considering heterogeneous rheological structure

*Bunichiro Shibazaki[1] (1.International Institute of Seismology and Earthquake Engineering, Building Research Institute)

[SCG63-P07] Estimation of inelastic strain rate in the lower crust based on GNSS and seismic data and its implication for dynamics in Kyushu, southwest Japan

*Yuhei Yuasa[1], Satoshi Matsumoto[2] (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Science, Kyushu University)

[SCG63-P08] Tectonic development along the Hinagu fault zone, Kumamoto Prefecture, Japan

*Kenta Kobayashi[1], Keiji Ogashiwa[1] (1.Department of Geology, Faculty of Science, Niigata University)

[SCG63-P09] Physical modeling of postseismic deformation following the 2008 Iwate-Miyagi Nairiku Earthquake

*Yoshiki Takei[1], Youichiro Takada[2], James Daniel Paul Moore[3], Mako Ohzono[4] (1.Department of Natural History Sciences, Hokkaido University, 2.Faculty of Science, Hokkaido University, 3.Earth Observatory of Singapore, Nanyang Technological University, 4.Institute of Seismology and Volcanology, Graduate School of Science, Hokkaido University)

[SCG63-P10] Spatial change of extension direction detected by paleostress analysis in the Miocene Tanabe Group, Southwest Japan

*Noriaki Abe[1], Katsushi Sato[1] (1.Division of Earth and Planetary Science, Graduate School of Science, Kyoto University)

[SCG63-P11] Non-double-couple earthquake in the focal area of the 2000 Western Tottori earthquake by “0.1 manten” hyperdense seismic observation and spatial distribution of non-double-couple components

*Yuto Hayashida[1], Takumi Motokoshi[1], Satoshi Matsumoto[2], Yoshihisa Iio[3], Shin'ichi Sakai[4], Aitaro Kato[4], Group for "0.1 manten" hyperdense seismic observation Group registration (1.Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2.Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University , 3.Disaster Prevention Research Institute, Kyoto University, 4.Earthquake Research Institute, University of Tokyo)

[SCG63-P12] **Driving stress of the 2013 M_W5.8 Awaji Island earthquake, Japan, inferred from well-constrained focal mechanisms and its seismotectonic implication**

*Kazutoshi Imanishi[1], Makiko Ohtani[2], Takahiko Uchide[1] (1.Geological Survey of Japan, AIST, 2.Earthquake Research Institute, The University of Tokyo)

[BCG06-P08] New morphotypes, cell-wall structures, and elemental distribution of the Gunflint microfossils

*Kouhei Sasaki[1], Akizumi Ishida[1], Naoto Takahata[2], Yuji Sano[2], Takeshi Kakegawa[1] (1.Department of Earth Science, Graduate school of Science, Tohoku University, 2.Atmosphere and Ocean Research Institute, The University of Tokyo)

[BCG06-P09] Modelling the behaviors of marine carbon isotopic composition after Neoproterozoic snowball Earth event

*Akari Miki[1], Eiichi Tajika[1], Kazumi Ozaki[2] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Toho University)

[BCG06-P10] Paleoecological variations reconstructed by organic matter derived from lichens and fungi across the Cenomanian/Turonian boundary in the Tomamae area, northern Hokkaido, Japan

*Masashi A. Ikeda[1], Ken Sawada[2], Takuto Ando[3], Hideto Nakamura[4], Reishi Takashima[5], Hiroshi Nishi[5] (1.Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 3.Estuary Research Center, Shimane University, 4.Faculty of Science, Osaka City University, 5.The Center for Academic Resources and Archives, The Tohoku University Museum, Tohoku University)

[BCG06-P11] Petrography of magnesite-orthopyroxene-olivine veins in the Ujaragssuit Nunât layered ultramafic body terrane, southern West Greenland

*Toma Takahashi[1], Tomoaki Morishita[1], Tomoyuki Mizukami[1], Akihiro Tamura[1], Keita Itano[1], Juan Miguel Guotana[1], Ikuya Nishio[1], Kanta Takahashi[1], Kristoffer Szilas[2] (1.Kanazawa university, 2.University of Copenhagen)

[BCG06-P12] Palynomorph assemblage in sedimentary rocks of the Mesoproterozoic Qaanaaq Formation from northwestern Greenland.

*Yuki Hara[1], Takuto Ando[3], Ken Sawada[2] (1.Graduate School of Science, Hokkaido University, 2.Department of Earth and Planetary Science, Faculty of Science, Hokkaido University, 3.Estuary Research Center, Shimane University)

[BCG06-P13] Pb-Pb chronology of Fe-Ti oxides

*Ito Kengo[1], Tsuyoshi Iizuka[1] (1.The University of Tokyo)

[E] Poster | B (Biogeosciences)：B-CG Complex & General

[B-CG07] Phanerozoic biodiversity change: radiation and extinction

convener:Yukio Isozaki(Department of Earth Science and Astronomy, Multi-disciplinary Sciences - General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo), Yusuke Sawaki(The University of Tokyo)

[BCG07-P01] Investigation on the internal texture of demospongiae fossil in meta-tuff from the Cambrian Akazawa Formation, Hitachi district

*Michio Tagiri[1], Katsutoshi Hanawa[2], Akira Oikawa[2], Noriaki Watanabe[3] (1.Hitachi City Museum, 2.Geonet Hitachi, 3.Graduate School of Environmental Studies, Tohoku Univ.)

[BCG07-P02] **Re-evaluating acid digestion for the analysis of organic carbon and nitrogen contents and stable isotope ratios in geological reference materials**

*Wataru Fujisaki[1], Yohei Matui[1] (1.Japan Agency for Marine-Earth Science and Technology)

[BCG07-P03] Taxonomy of Silurian conodonts from the Yokokurayama Group, Kurosegawa tectonic zone, distributed in Kochi Prefecture

*Akifumi Ito[1], Sachiko Agematsu[1], Yuichi Fukushima[1] (1.University of Tsukuba)

[BCG07-P04] **Devonian ostracods from the Fukuji area, Takayama City, Gifu Prefecture, central Japan**

*Mai Harashima[1], Sachiko Agematsu[1] (1.University of Tsukuba)

[E] Poster | G (General)：General

[G-01] Amazing technologies and capabilities that contribute to STEAM

convener:Day Brian Hamilton(NASA Ames Research Center), Emily Law(Jet Propulsion Laboratory), Go Murakami(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Kristen J Erickson(NASA Headquarters)

[G01-P01] Dagik Earth: 3-D digital globe for STEAM education in schools and museums

*Akinori Saito[1], Takuya Tsugawa[2], Takahito Kazama[1], Noriyuki Nishi[3], Yoshisuke Kumano[4] (1.Department of Geophysics, Graduate School of Science, Kyoto University, 2.National Institute of Information and Communications Technology, 3.Faculty of Science, Fukuoka Universtiy, 4.Graduate School of Science and Technology, Graduate School of Education, Shizuoka University)

[G01-P02] Increasing the understanding of abstract chemical concepts using VR programming

Garrison Penzo[1], Dante H Delgado[1], *Colleen M Knight[1] (1.College of Coastal Georgia)

[G01-P03] **STEAM Engagement with NASA's Solar System Treks**

*Brian Hamilton Day[1], Emily Law[2], NASA Solar System Treks Team -[2] (1.NASA Ames Research Center, 2.NASA Jet Propulsion Laboratory)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS01] Tsunami deposit

convener:Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University), Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Masaki Yamada(Department of Geology, Faculty of Science, Shinshu University), Takashi Ishizawa(International Research Institute of Disaster Science, Tohoku University)

[MIS01-P01] Distribution of tephra and tsunami deposits in Shikotan Island: Outline of the Japan-Russia joint research in 2019

*Yuichi Nishimura[1], Alexander Shishkin[2], Yasuhiro Takashimizu[3], Daisuke Sugawara[4], Takashi Ishizawa[5], Koichiro Tanigawa[6] (1.Graduate School of Science, Hokkaido University, 2.Institute of Marine Geology and Geophysics, Russian Academy of Sciences, 3.Faculty of Education, Niigata University, 4.Museum of Natural and Environmental History, Shizuoka, 5.International Research Institute of Disaster Science, Tohoku University, 6.The National Institute of Advanced Industrial Science and Technology)

[MIS01-P02] Facies description of 15 valley-filled tsunami deposits observed in Lake Tokachi-Chobushi for the past 2500 years and evaluation of their recurrence intervals

*Kiyoyuki Shigeno[1], Futoshi Nanayama[2,5], Kazuaki Watanabe[2], Masayuki Ishii[3], Keita Fukatsu[4] (1.Meiji consultant co.,Ltd., 2. Geological Survey of Japan, AIST, 3.Ishii Professional Engineer Office, 4.Notsuke Peninsula Nature Center, 5.CWMD,Kumamoto Univ.)

[MIS01-P03] Relationship between facies of tsunami deposits and paleo sedimentary environment which were reconstructed from plant macro fossils in peat

*Takashi Ishizawa[1], Yuichi Nishimura[2] (1.International Research Institute of Disaster Science, Tohoku University, 2.Institute of Seismology and Volcanology, Hokkaido University)

[MIS01-P04] Ages and distribution of paleo-tsunami deposits since 6 ka at Koyadori, Yamada Town, Iwate Prefecture, northeast Japan

*Daisuke Ishimura[1], Keitaro Yamada[2] (1.Department of Geography, Tokyo Metropolitan University, 2.Research Organization of Science and Technology, Ritsumeikan University)

[MIS01-P05] Machine-learning for correlation of tsunami deposits using geochemical proxy

*Kamiya Tomohisa[1], Kazuhisa Goto[2], Takashi Ishizawa[1], Hiroshi Tetsuka[1], Erick Velasco R.[1], Daisuke Ishimura[3], Kenta Satoh[1] (1.Tohoku University, 2.University of Tokyo, 3.Tokyo Metropolitan University)

[MIS01-P08] Numerical study of the formation process of sandy deposit formed by the 2011 Tohoku-oki tsunami

*wataru nakamura[1], Kazuhisa Goto[2], MASASHI WATANABE[3] (1.Tohoku University, 2.The University of Tokyo, 3.Chuo University)

[MIS01-P09] Reduction Effect of Tsunami Sediment Transport by Coastal Forest: Numerical Simulation of the 2011 Tohoku Tsunami on Sendai Plain, Japan

*Satoshi Kusumoto[1], Kentaro Imai[1], Aditya Gusman[2], Kenji Satake[3] (1.JAMSTEC, 2.GNS Science, 3.ERI, The University of Tokyo)

[MIS01-P10] Temporal change in sedimentological and geochemical characteristics of the 2011 Tohoku-oki tsunami deposits in the northeastern region of Fukushima Prefecture

*Kentaro Izumi[1], Ikuro Narayama[1], Tomoya Abe[2] (1.Faculty & Graduate School of Education, Chiba University, 2.Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

[MIS01-P11] Flow reflection of onshore tsunami and features of the deposits

*Yasuhiro Takashimizu[1], Hibiki Saito[1] (1.Niigata University)

[MIS01-P12] Numerical estimation of paleotsunami size at southern part of Japan Trench based on geological records

*Hokuto Higaki[1], Kazuhisa Goto[2], Hideaki Yanagisawa[3], Daisuke Sugawara[4] (1.Tohoku University, 2.Department of Earth and Planetary Science, The University of Tokyo, 3.Department of regional Management, Faculty of Liberal Arts, Tohoku Gakuin University, 4.Museum of Natural and Environmental History, Shizuoka)

[MIS01-P13] Detailed analysis of tsunami deposits made by large-scale laboratory experiments

*Takumi Yoshii[1], Shiro Tanaka[1], Masafumi Matsuyama[1] (1.Central Research Institute of Electric Power Industry)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS02] Environmental, socio-economic and climatic changes in Northern Eurasia

convener:Pavel Groisman(NC State University Research Scholar at NOAA National Centers for Environmental Information, Asheville, North Carolina, USA), Shamil Maksyutov(National Institute for Environmental Studies), Evgeny P Gordov(Institute of Monitoring of Climatic and Ecological Systems SB RAS), Akiyo Yatagai(Hirosaki University)

[MIS02-P01] BIOAVAILABILITY OF METALS DEPENDING ON THEIR SPECIATION IN NORTHERN LOW-SALINE WATER

*Tatyana I Moiseenko[1], Marina I Dinu[1] (1.Russian)

[MIS02-P02] Divergent responses of ecosystem water-use efficiency to extreme droughts over Northern Eurasia

*Mengtian Huang[1], Panmao Zhai[1] (1.Chinese Academy of Meteorological Science)

[MIS02-P03] Homogeneity analysis of air temperature and wind speed records of the Azov-Black sea region

*Natalia Alexandrovna Lemeshko[1], Vladislav P. Evstigneev[2,3], Maxim P. Evstigneev[2], Pavel Ya. Groisman[4] (1.SPBU, 2.IPTS, 3.SevSU, 4.IORAS)

[MIS02-P04] Soil response to sub centennial climate change

*Natalia Alexandrovna Lemeshko[1], Vladislav P. Evstigneev[2,3], Alexey V. Rusakov[1], Pavel Groisman[4] (1. SPBU , 2.IPTS , 3.SevSU, 4.IORAS)

[MIS02-P05] Climate change impacts on seed quality and distribution of light-needled *Pinus sylvestris* and *Larix* spp. in Northern Eurasia in a warming climate

*Nadezhda Tchebakova[1], Elena I. Parfenova[1], Elena V. Bazhina[1], Nina A. Kuzmina[1], Pavel Y. Groisman[2] (1.Institute of Forests, Siberian Branch, Russian Academy of Sciences, 2.NC State University Research Scholar)

[MIS02-P06] Northern Eurasia Future Initiative (NEFI), Update

*Pavel Groisman[1,2,3] (1.NC State University Research Scholar at NOAA National Centers for Environmental Information, Asheville, North Carolina, USA, 2.Shirshov Institute of Oceanology, Russian Academy of Sciences, Moscow, Russia , 3.Hydrology Science and Services Corporation, Asheville, North Carolina, USA)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS03] Structure and deformation in the overlying plate due to subduction and related feedbacks

convener:Hiroshi Sato(Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo), David A Okaya(University of Southern California), Eh Tan(Institute of Earth Sciences, Academia Sinica), Masahiro Ishikawa(Graduate School of Environment and Information Sciences Yokohama National University)

[MIS03-P01] Three-dimensional seismic velocity model of the Nankai Trough subduction zone considering marine seismic reflection and onshore seismic data

*Ayako Nakanishi[1], Minako Katsuyama[1], Narumi Takahashi[1,2], Hiromi Kamata[1], Katsuhiko Shiomi[2], Shuichi Kodaira[1], Yoshiyuki Kaneda[1,3] (1.Japan Agency for Marine-Earth Science and Technology, 2.National Research Institute for Earth Science and Disaster Resilience, 3.Kagawa University)

[MIS03-P02] Deformation of the seismogenic zone in the northeastern part of the Izu Peninsula, Japan, inferred from GNSS observations

*Ryosuke Doke[1], Ryou Honda[1], Masatake Harada[1], Kazuki Miyaoka[2], Teruyuki Kato[1], Mikio Satomura[3] (1.Hot Springs Research Institute of Kanagawa Prefecture, 2.Japan Meteorological Agency, 3.Shizuoka University)

[MIS03-P03] Shift in provenance composition of Cretaceous Japan arc: from Jurassic granitoids/accretionary complex to Cretaceous granitoids

*Ryo Hasegawa[1], Yukio Isozaki[1], Atsushi Yamamoto[3], Yukiyasu Tsutsumi[2] (1.The University of Tokyo, 2.National Museum of Nature and Science, 3.Kindai University)

[MIS03-P04] High-resolution seismic profiles in the Shonai plain and Yamagata basin, northern Honshu, Japan

*Naoko Kato[1], Tatsuya Ishiyama[1], Hiroshi Sato[1], Shin Koshiya[2], Taro Koike[3], Katsuya Noda[3] (1.Earthquake Research Institute,University of Tokyo, 2.Faculty of science and engineering, Iwate University, 3.Geosys, Inc.)

[MIS03-P05] Seismic transect across the central part of Northern Honshu, Japan

*Hiroshi Sato[1], Tatsuya Ishiyama[1], Hirokazu Ishige[2], Naoko Kato[1], Masanao Shinohara[1], Takaya Iwasaki[1,6], Eiji Kurashimo[1], Hidehiko Shimizu[2], Shinji Kawasaki[2], Susumu Abe[2], Makoto MATSUBARA[3], Shin Koshiya[4], Tetsuo No[5], Shuichi Kodaira[5], Naoshi Hirata[1] (1.Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo, 2.JGI, Inc., 3.National Research Institute for Earth Science and Disaster Resilience, 4.Iwate University, 5.Japan Agency for Marine-Earth Science and Technology, 6.Association for the Development of Earthquake Prediction)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS04] An asteroid impact in SE Asia at 0.8 Ma and its effect on the environment and biota

convener:Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo), Paul A Carling(University of Southampton), Wickanet Songtham(Nakhon Ratchasima Rajabhat University, Thailand), Kerry Sieh(Nanyang Technological University)

[MIS04-P01] Discovery of Australasian microtektites in the hemipelagic sediments of the Japan Sea: It's significance and implications

*Ryuji Tada[1,2,3], Toshihiro Tada[3], Jumpei Yoshioka[4] (1.Geo-Cosmology Center, Chiba Institute of Technology, 2.Research Center for Earth System Science, Yunnan University, 3.Department of Earth and Planetary Science, the Univeristy of Tokyo, 4.Atmospheric and Ocean Research Institute, the University of Tokyo)

[MIS04-P02] Ejection behavior after hypervelocity oblique impacts in an atmosphere

*Kosuke Kurosawa[1], Ryota Moriwaki[1], Kojiro Suzuki[2], Takafumi Matsui[1] (1.Planetary Exploration Research Center, Chiba Institute of Technology, 2.Department of Advanced Energy, Graduate School of Frontier Sciences, The University of Tokyo)

[MIS04-P03] Shock-induced vitrification affected on cathodoluminescence of quartz: possibility as a shock barometer and its potential application to natural impact samples

*Yu Chang[1], Masahiro KAYAMA[2], Eiichi Tajika[1], Yasuhito Sekine[3], Toshimori Sekine[4], Hirotsugu nishido[5], Takamichi Kobayashi[6] (1.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2.Department of General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo, 3.Earth-Life Science Insitute, Tokyo Institute of Technology, 4.Center for High Pressure Science and Technology Advanced Research, 5.Research Institute of Natural Science, Okayama University of Science, 6.National Institute for Materials Science)

[MIS04-P04] Evaluation of shock deformation of the basement sandstone around the probable impact site of Australasian Tektite Event using synchrotron X-ray diffraction analysis

★Invited Papers

*Toshihiro Tada[1], Masahiro KAYAMA[2], Yu Chang[1], Akira Miyake[3], Yohei Igami[4], Ryuji Tada[1,5,6], Paul A Carling[7], Wickanet Songtham[8], Eiichi Tajika[1] (1.Department of Earth and Planetary Science, The University of Tokyo , 2.Department of Multi-Disciplinary Sciences, The University of Tokyo , 3.Division of Earth and Planetary Sciences, Kyoto University , 4.Institute of Materials and Systems for Sustainability, Nagoya University, 5. Planetary Exploration Research Center, Chiba Institute of Technology, 6.Research Center for Earth System Science, Yunnan University, 7.Geography and Environmental Science, University of Southampton, 8. Northeastern Research Institute of Petrified Wood & Mineral Resources, Nakhon Ratchasima Rajabhat University)

[MIS04-P05] Quaternary stratigraphy and occurrence of the Australasian tektites in Thailand, Laos PDR, and Cambodia: implication of the impact location

*Wickanet Songtham[1], Ryuji Tada[2], Paul A Carling[3], Toshihiro Tada[2], Praphas Chansom[1] (1.Nakhon Ratchasima Rajabhat University, Thailand , 2.The University of Tokyo, Japan, 3.The University of Southampton, United Kingdom)

[MIS04-P06] Assessment for BPCA method as biomass burning proxies and their application to meteorite impact event

*Song Lu[1], Youhei Yamashita[2], Tomohisa Irino[2], Toshihiro Tada[3], Ryuji Tada[3] (1.Graduate School of Environmental Science, Hokkaido University , 2.Faculty of Environmental Earth Science, Hokkaido University, 3.Department of Earth and Planetary Science , Graduate School of Science, The University, of Tokyo)

[MIS04-P07] Converging lines of evidence for burial of the Australasian impact crater within the Bolaven volcanic field, Southern Laos

*Kerry Sieh[1], Jason Herrin[1], Dayana Schonwalder Angel[1], Vanpheng Sihavong[2], Brian Jicha[3], Brad Singer[3], Weerachat Wiwegwin[4], James Daniel Paul Moore[1], Paramesh Banerjee[1], Tawachai Chualaowanich[4], Punya Charusiri[5] (1.Earth Observatory of Singapore, Nanyang Technological University, 639798 Singapore, 2.Department of Geology and Mines, Ministry of Energy and Mines, Vientiane, Lao People's Democratic Republic, 3.Department of Geoscience, University of Wisconsin–Madison, Madison, WI 53706, 4.Department of Mineral Resources, Ministry of Natural Resources and Environment, Ratchatewi, 10400 Bangkok, Thailand, 5.Department of Geology, Chulalongkorn University, Khet Pathumwan, 10330 Bangkok, Thailand)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS05] Cenozoic Evolution of the Asian Monsoon and the Indo-Pacific Paleoclimates

convener:Masanobu Yamamoto(Faculty of Environmental Earth Science, Hokkaido University), Steven C Clemens(Brown University), Hongbo Zheng(Research Center for Earth System Science, Yunnan University), Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo)

[MIS05-P01] Isotope analysis of Neogene marine sediment from Maldives

*Yuka Tatera[1], Katsuyuki Yamashita[1], Tsuyoshi Ishikawa[2], Mayuri Inoue[1] (1.Okayama University, 2.Kochi Institute for Core Sample Research, JAMSTEC)

[MIS05-P02] Human activities during last 700 years as recorded in the concentrations of polycyclic aromatic hydrocarbons and pentacyclic triterpene methyl ethers in sediment cores from Lake Suigetsu

*Masaya Inagaki[1], Hideto Nakamura[2], Masanobu Yamamoto[1], Takeshi Nakagawa[3] (1.Graduate School of Environmental Science, Hokkaido University, 2.Faculty of Science, Osaka City University, 3.Research Center for Palaeoclimatorogy, Ritsumeikan University)

[MIS05-P03] Reconstruction of paleoclimate changes in the region where the Okhotsk culture flourished over the past 2,700 year

*Ryuichi Seto[1], Osamu Seki[2], Masanobu Yamamoto[3], Takuya Itaki[4] (1.Graduate School of Environmental Science, Hokkaido University, 2.Institute of Low Temperature Science, Hokkaido University, 3.Facility of Environmental Earth Science, Hokkaido University, 4.Geological Survey of Japan, AIST)

[MIS05-P04] Fluvio-sedimentary response to late Quaternary climate at the Himalayan frontal thrust, central Nepal

*Mari Hamahashi[1], Judith Hubbard[1], Samuel Haines[1], Rafael Almeida[2], Edgardo Latrubesse[1], Sanjita Mishra[3], Lewis Owen[4], Soma Nath Sapkota[3] (1.Earth Observatory of Singapore, Nanyang Technological University, 2.Yachay Technical University, Ecuador, 3.Department of Mines and Geology, National Seismological Center, Nepal, 4.North Carolina State University, USA)

[MIS05-P05] Tropical western Pacific hydrology during the last 6000 years based on charcoal records from Borneo

*Masanobu Yamamoto[1], Takafumi Kikuchi[1], Hiromichi Sakurai[1], Ryoma Hayashi[2], Osamu Seki[1], Takafumi Omori[3], Abdullah Sulaiman[4], Hasrizal Shaari[5], Lulie Melling[6] (1.Faculty of Environmental Earth Science, Hokkaido University, 2.Lake Biwa Museum, 3.The University of Tokyo, 4.Minerals and Geoscience Department Malaysia, 5.Universiti Malaysia Terengganu, 6.Tropical Peat Research Institute)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS06] Dust

convener:Ishizuka Masahide(Kagawa University), Yasunori Kurosaki(Arid Land Research Center, Tottori University), Thomas Sekiyama(Meteorological Research Institute), Kana Nagashima(Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change)

[MIS06-P01] Detection of aeolian dust in a sedimentary sequence at Tsujita Site

*Haranosono Daichi[1], Shin Toyoda[1], Kenji Nagai[2], Toshirou Naruse (1.Okayama Univesity of Science, 2.Aichi Gakuin University)

[MIS06-P02] Effect of stone on threshold friction velocity in Tsogt-Ovoo, Mongolia: Observation and Model simulation

*Batjargal Buyantogtokh[1], Yasunori Kurosaki[1], Masahide Ishizuka[3], Tsuyoshi T Sekimaya[2], Taichu Y Tanaka[2], Atsushi Tsunekawa[1], Mitsuru Tsubo[1] (1.Arid Land Research Center, Tottori University, 2.Japan Meteorological Agency, Meteorological Research Institute, 3.Faculty of Engineering and Design, Kagawa University, Japan)

[MIS06-P03] Monitoring dry-season vegetation mass at a dust hotspot (Tsogt-Ovoo) in the northern Gobi Desert

*Jing Wu[1], Yasunori Kurosaki[1], Ganatsetseg Batdelger[2], Adrian Chappell[3], Ishizuka Masahide[4], Batjargal Buyantogtokh[1] (1. Arid Land Research Center, Tottori University, 2.Information and Research Institute of Meteorology, Hydrology and Environment, Mongolia, 3.School of Earth and Ocean Science, Cardiff University, UK, 4.Faculty of Engineering and Design, Kagawa University)

[MIS06-P04] Wind tunnel experiment on sand saltation splash by using a high-speed camera

*Ishizuka Masahide[1], Yasunori Kurosaki[2], Hiroaki Hagino[3], Kazuki Nanko[4], Gantsetseg Batdelger[5], Yukio Yasuda[4], Satoru Suzuki[6] (1.Kagawa University, Faculty of Engineering and Design, 2.Tottori University, Arid land research center, 3.Forestry and Forest Products Research Institute, Tohoku Research Center, 4.Forestry and Forest Products Research Institute, Department of Disaster Prevention, Meteorology and Hydrology, 5.Information and Research Institute of Meteorology Hydrology and Environment, Mongolia, 6.Forestry and Forest Products Research Institute, Center for Forest Damage and Risk Management)

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS07] Aqua planetology

convener:Yasuhito Sekine(Earth-Life Science Insitute, Tokyo Institute of Technology), Hidenori Genda(Earth-Life Science Institute, Tokyo Institute of Technology), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University), Tomohiro Usui(Japan Aerospace Exploration Agency)

[MIS07-P01] Isotopic fractionation of methane gas with clathrate hydrate formation under the condition of ice crust / internal ocean boundary in icy satellite

*Kushi Kudo[1], Atsushi Tani[1], Keita Yamada[2], Naohiro Yoshida[2,3] (1.Department of Human Environmental Science, Graduate School of Human Development and Environment, Kobe University, 2.Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 3.Earth–Life Science Institute, Tokyo Institute of Technology)

[MIS07-P02] Observation of the interface between ice and water under high pressure with gas as a simulation of the bottom of ice crust in icy bodies

*Kenshiro Moriyama[1], Atsushi Tani[1] (1.Department of Human Environmental Science, Graduate School of Human Development and Environment, Kobe University)

[MIS07-P03] H_2-rich hydrothermal environment in the Enceladus' subsurface ocean

*Takazo Shibuya[1], Sota Numaho[1,2], Hisahiro Ueda[1], Sakiko Kikuchi[1], Yutaro Takaya[3], Takuya Saito[1], Mariko Abe[1], Masaru Tomita[2], Ken Takai[1] (1.Japan Agency for Marine-Earth Science and Technology, 2.Keio University, 3.Waseda University)

[MIS07-P04] Abiotic nitrate reduction in hydrothermal environments and nitrogen cycle in early earth

*Manabu Nishizawa[1], Takuya Saito[1], Akiko Makabe[1], Takazo Shibuya[1], Ken Takai[1] (1.Japan Agency for Marine-Earth Science and Technology)

[MIS07-P05] Experimental study of phosphorus dissolution from hydroxyapatite in liquid CO_2

*Kaito Seo[1,2,3], Takazo Shibuya[3], Fujishima Kosuke[4], Ken Takai[3], Masaru Tomita[1,2] (1.Graduate School of Media & Governance, Keio Univ., 2.Inst. Adv. Biosci., Keio Univ., 3.X-Star, JAMSTEC, 4.ELSI, Tokyo Tech)

[MIS07-P06] Effects of minerals on the formose reaction: implication for the potential ribose formation on ancient Mars

*Chinatsu Ono[1], Takeshi Kakegawa[1], Yoshihiro Furukawa[1] (1.Graduate School of Science, Tohoku University)

[MIS07-P07] **Hydrogen generation by water-rock reactions on the early Mars**

*Hisahiro Ueda[1], Takazo Shibuya[1] (1.JAMSTEC)

[MIS07-P08] Impact-generated hydrothermal systems that can promote organic synthesis: Implications for the origin of life

*Kazumu Kaneko[1], Yasuhito Sekine[2], Takazo Shibuya[3], Hisahiro Ueda[3], Natsumi Noda[2,4] (1.Department of Earth and Planetary sciences, School of science, Tokyo Institute of Technology, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Japan Agency foe Marine-Earth Science and Technology, 4.Department of Earth and Planetary science, Graduate School of science, The University of Tokyo)

[MIS07-P09] Clumped isotope signatures of abiotic methane formed via Fischer-Tropsch catalysis and their implications

*ZHANG NAIZHONG[1], YASUHITO SEKINE[1], MAYUKO NAKAGAWA[1], NAOHIRO YOSHIDA[1] (1.Earth-Life Science Institute, Tokyo Institute of Technology)

[MIS07-P10] **Development of novel characterization method for extraterrestrial clay mineral**

*Kosuke Inoue[1], Keisuke Fukushi[2], Koki Morida[3], Hiroki Suga[4], Yoshio Takahashi[4] (1.Kanazawa University , 2.Institute of Nature and Environmental Technology, 3.Graduate School of Science, The University of Kanazawa, 4.Graduate School of Science, The University of Tokyo)

[MIS07-P11] Evolution of aqueous environment on Early Mars inferred from reconstructed water chemistry at Gale

*Keisuke Fukushi[1], Yasuhito Sekine[2,1] (1.Institute of Nature & Environmental Technology, Kanazawa University, 2.Earth-Life Science Institute, Tokyo Institute of Technology)

[MIS07-P12] Effective formation of Al-rich surface clays through acidic water activity on early Mars

*Mitsuteru Sugiuchi[1], Yasuhito Sekine[2], Shuya Tan[2,3], Natsumi Noda[2,3], Yoshio Takahashi[3], Ramses M Ramirez[2] (1.Department of Earth and Planetary Science, School of Science, Tokyo Institute of Technology, 2.Earth-Life Science Institute, Tokyo Institute of Technology, 3.Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo)

[MIS07-P13] **The Preparation for Return Sample from Asteroid Ryugu by STXM at KEK-PF**

*Hiroki Suga[1,2], Sakiko Kikuchi[3], Shuya Tan[1,4], Shohei Yamashita[2], Yasuo Takeichi[2], Daisuke Wakabayashi[2], Masao Kimura[2], Yoshio Takahashi[1,2], Yasuhito Sekine[4] (1.Graduate School of Science, The University of Tokyo., 2.Institute of Materials Structure Science, High Energy Accelerator Research Organization (KEK)., 3.Institute for Extra-cutting-edge Science and Technology Avant-garde Research (X-star), Japan Agency for Marine-Earth Science and Technology (JAMSTEC)., 4.Earth-Life Science Institute (ELSI), Tokyo Institute of Technology.)

[MIS07-P14] Clustering analysis of Ryugu spectral data obtained by NIRS3 infrared spectrometer onboard Hayabusa2 spacecraft

*Moe Matsuoka[1], Hikaru Iwamori[2], Deborah Lolin Domingue[3], Tomohiro Usui[1], Kohei Kitazato[4], Takahiro Iwata[1] (1.ISAS/JAXA, 2.Earthquake Research Institute, the University of Tokyo, 3.Planetary Science Institute, 4.University of Aizu)

[MIS07-P15] Recognition and classification of Martian chaos terrains using imagery machine learning

*Hiroki Shozaki[1], Yasuhito Sekine[2], Nicholas Guttenberg[2,3] (1.Tokyo Institute of Technology, School of Science, Dept. of Earth and Planetary Sciences, 2.Earth-Life Science Insitute, Tokyo Institute of Technology, 3.Cross Compass Ltd.)

[MIS07-P16] Reactive iron supply control dominant sulfur species in the limestones of Ediacaran Doushantuo and Dengying Formations

*Fumihiro Matsuura[1], Ryoichi Nakada[2], Yuichiro Ueno[3,2], Yusuke Sawaki[4], Masafumi Saitoh[5], Kajitani Iori[4], Tomohiro Usui[1] (1.JAXA, 2.JAMSTEC, 3.Tokyo Tech, 4.The University of Tokyo, 5.University of Lausanne)

[MIS07-P17] New sulfur isotopes 1-D photochemical model for revealing early earth's atmosphere

*Yoshiaki Endo[1,2], Mark W. Claire[2], Chester E. Harman[2,3], Laura Crick[2] (1.Tokyo Institute of Technology, 2.University of St Andrews, 3.NASA Ames Research Center)

[MIS07-P18] Retrieval of vertical structure in the Martian atmosphere during 2007 global dust storm by OMEGA/MEx limb observation

*Risei Kogure[1], Arnaud Mahieux[2,3], Hiromu Nakagawa[1], Shohei Aoki[2], Yasumasa Kasaba[1], Nao Yoshida[1] (1.TOHOKU University, 2.Belgian Institute for Space Aeronomy (BIRA-IASB), 3.University of Texas at Austin, USA)

[MIS07-P19] Numerical experiments of climate of early Mars by the use of DCPAM

*Masaki Ishiwatari[1], Yoshiyuki O. Takahashi[2], George L. Hashimoto[3], Kiyoshi Kuramoto[1], Yoshi-Yuki Hayashi[2] (1.Department of Cosmosciences, Graduate school of Science, Hokkaido University, 2.Department of Planetology, Graduate School of Science, Kobe University, 3.Department of Earth Sciences, Faculty of Science, Okayama University)

[U-02] Assessment and Accountability of Scientific Knowledge Creation

convener:Michiyo SHIMAMURA(Japan Agency for Marine-Earth Science and Technology), Yasuhiro Yamanaka(Faculty of Environmental Earth Science, Hokkaido University), Kiyoshi Suyehiro(Japan Agency for Marine-Earth Science and Technology), Brooks Hanson(American Geophysical Union)

Scientific indices such as the number of citations or impact factor have been widely adopted in Japan and elsewhere to gauge scientific outputs without sufficient deliberations on their relationships to the true value of science and researchers' efforts or the harm and perverse incentives that result. If such disconnect exists, overreliance to these indices may lead to biases in research including in aiming for shorter-term goals. They are often requested by the solution-seeking stakeholders as well.

In the field of geoscience, a wide latitude of research styles exists and forms our community, from a focus on urgent societal needs to intellectual curiosity about our Earth. Such characteristics vary among fields making general comparisons across fields not straightforward. The adoption of simple evaluation indices as above may hinder the truly useful assessment of research. This trend influences gravely the research environment and thus the behavior of early-career researchers. What is the right direction for science and how should science be assessed?

In this session, we invite the members of the geoscience research community to discuss "ideal" science, recognize its diversity and identify the needs for changes. We welcome reports from different parts of the world and novel ideas to evaluate our own research activities that may lead to creating a culture that fulfills accountability to society. We envision this session to have infuse lively discussion and invite the audience to interactive exchanges.

[U02-P01] Let's start the discussion of the international tuning of research assessment in earth science to create a culture and indicators of “creation of knowledge”

*Yasuhiro Yamanaka[1], Michiyo SHIMAMURA[2], Kiyoshi Suyehiro[2] (1.Faculty of Environmental Earth Science, Hokkaido University, 2. Japan Agency for Marine-Earth Science and Technology)

Let's start the discussion of the international tuning of research assessment in earth science to create a culture and indicators of “creation of knowledge”

*Yasuhiro Yamanaka[1], Michiyo SHIMAMURA[2], Kiyoshi Suyehiro[2]

1. Faculty of Environmental Earth Science, Hokkaido University, 2. Japan Agency for Marine-Earth Science and Technology

We propose to the members of international Earth science communities a challenging attempt to create a culture in which the research community self-evaluates its research activities and fulfill its accountability to the public.

The Science Council of Japan amended the “Code of Conduct for Scientists-Revised Edition-” (2013), to include in “Research activities” that “Scientists should publish their research results in papers, etc.” and in “Dialogue with the public” that “Scientists will strive to provide scientific advice”. A proposal on open science recognizes that “data users can make research achievements with papers and patents, but data producers and data distributors cannot make research achievements with individual names”(Science Council of Japan, 2016). That is, the responsibilities of researchers (scientists) to entrustments by the society are becoming clearer.

However, the research community still implicitly believes that “research achievements = papers”. We think that this has led to the misuses of indicators such as citation counts and impact factors (IFs), to “*the worship of papers*” in organizations and researchers' performance evaluations, and the over-emphasis on research fields, such as science and technology, which excel at directly solving problems. These are distortions caused by easily adopting quantifiable items as evaluation indices without the ideals of science and researchers contributing to “creation of knowledge,” and it is strongly desired to review them from the ground up. Also, as the medieval university has died due to the spread of typographic printing (Yoshimi, 2011), the explosive development of the information infrastructure using the Internet with artificial intelligence has fundamentally shaken not only the presence of the university but also the value for “creation of knowledge”. Meanwhile, the society strongly expects the academia to contribute to the realization of a sustainable society, and the “Scientific and Technological Community” was designated as one of the nine “Major Groups” in the formulation of “2030 Agenda” well known as SDGs (United Nations, 2015).

We propose to get started with the following steps:

(A) as a grasp of research activities (Institutional Research, IR), we will clarify researchers’ perception of “creation of knowledge” and their actual state of research activities. We respect that the researchers have their own philosophies and values for "creation of knowledge," which may likely derived from their disciplinary roots. To clarify these, we aim to conduct interviews and questionnaires for JpGU ID holders (members and meeting participants).

(B) We would like to survey the recognition of “creation of knowledge” of the overseas researcher communities and stakeholders and the actual state of their research activities. To this end, we ask AGU, EGU, national science policy officials, funding agencies for information on advanced initiatives and the

©2020. Japan Geoscience Union. All Right Reserved.

code of conduct of researchers etc. in each country. We intend to make an international comparison of the value measures related to “creation of knowledge”.

(C) As we will hold this session at JpGU on the visualization of “creation of knowledge” and proposal of its indicators according to the progress of (A, B) surveys and syntheses, and will also start dialogues with the public as well as discussions in the researcher community. To this end, the emphasis is on the process of discussion and dialogue based on the concept of “tuning”, and mutual understanding and respect of individual "research style" is to be achieved in a multicultural symbiosis of the research community (securing academic diversity).

[U-03] Sustainable global groundwater management for human security

convener:Yoshihide Wada(International Institute for Applied Systems Analysis), Makoto Taniguchi(Research Institute for Humanity and Nature)

Sustainable management of water resources is an overwhelming task, when faced with a growing population that is increasing its demand for food, energy and water. Except frozen ice, groundwater is world's largest fresh water resource, but increasing over-exploitation of groundwater resources has been reported over intensely irrigated regions. Groundwater is the prime source for drinking water supply and irrigation, hence critical to global water, food and energy security contributing to human security. But also for sustaining low flow requirements and ecological values of groundwater dependent ecosystems, the contribution by groundwater flow is essential. Groundwater therefore needs to be managed wisely, protected and especially sustainably used. In itself this is a challenge, however under a changing environment including climate, land use, population growth, this task becomes a challenge especially in the light of limited data availability and consequential uncertainties. From arid over humid to arctic regions, in every type of climate changing environmental conditions become apparent and have very different effects. In this session we invite contributions, which report on research on the consequences of a changing environment for future management, protection, and sustainable use of groundwater. Methodologies, strategies, case studies as well as quantitative techniques for dealing with uncertainty and limited data availability are of interest for this session. We welcome studies describing how groundwater resources benefit from an Integrated Water Resources Management approach. Furthermore, contributions describing case studies and new techniques for active management and protection of groundwater resources such as artificial recharge and conjunctive use are welcome.

1. National Sun Yat Sen University, 2. Zhejiang University, 3. University of Toyama

Excess nutrients have been discharged into the oceans by rivers, making many coastal regions hypoxic or even anoxic. Most people do not realize that a substantial fraction of the freshwater on land also enters the oceans directly from the seabed, unseen by human eyes. This process is called submarine groundwater discharge (SGD) and it amounts to 0.2-10% of global river discharge. The SGD releases nutrients, alkalinity (TA), and dissolved inorganic carbon (DIC) into the oceans while reducing their dissolved oxygen (DO) content and pH but the results are largely unknown quantitatively. A case study indicates that the freshwater component of the SGD equals around 5.2% of the annual river discharge in Taiwan, where the over-pumping of groundwater has been a serious problem. Further, the SGD exports N, P, Si, TA, and DIC in amounts equivalent to 12.7, 0.9, 9.3, 21.1 and 19.6%, respectively, of those in riverine fluxes. Unfortunately, such results cannot be generalized to a region - let along to all coastal seas around the world - because the total area of Taiwan is too small. Whereas rivers have been extensively studied, only a handful of reports concerning nutrients, TA and DIC fluxes have focused on SGD. Worse, the relevant literature is mainly concerned with the flux per unit area of SGD discharge into oceans. Such data cannot be extrapolated to the global oceans as the discharge area is unknown. On the other hand, the yield, which is the flux per unit area of the river basin, can be extrapolated from readily available river basin data but to the best of our knowledge the yield has been reported for only three river basins. An accurate estimate of the SGD flux is essential to predicting coastal environments in an era of rapid global change but most - if not all - coastal biogeochemical models have no SGD component. Substantial errors may arise if SGD is ignored, especially in estuaries, bays, inland seas, deltas and salt marshes. Since the areas of thousands of river basins worldwide are known, with a knowledge of even a limited number of data on the yield the global amount of material flux by SGD may be reasonably estimated and its effect on the coastal biogeochemistry better evaluated.

Quantitative assessment of the impacts of sustainable irrigation on global bioenergy production

*Zhipin Ai[1], Naota Hanasaki[1]

1. National Institute for Environmental Studies, Japan

Bioenergy production plays a critical role in many stringent climate scenarios to achieve the 2-degree target at the end of this century. Earlier reports showed that unconstrained irrigation can substantially increase the global bioenergy production and therefore reduce land requirement for bioenergy production. However, the extent and consequences of water-resources-constrained irrigation has been poorly explored. We first developed a future bioenergy land use scenario with strict natural and food protection considerations. Next, we quantitatively investigated the effects of a new sustainable irrigation scheme on the global bioenergy production in 2090 under representative concentration pathway (RCP) 2.6 based on an enhanced global hydrological model. Finally, we investigated the possible uncertainties from different irrigation schemes, general circulation models, and social economic pathways and made explicit comparisons with previous studies. Under our scenario, although we can stay within the planetary boundary for freshwater, the global bioenergy production falls short of the requirement prescribed in IPCC-RCP2.6.

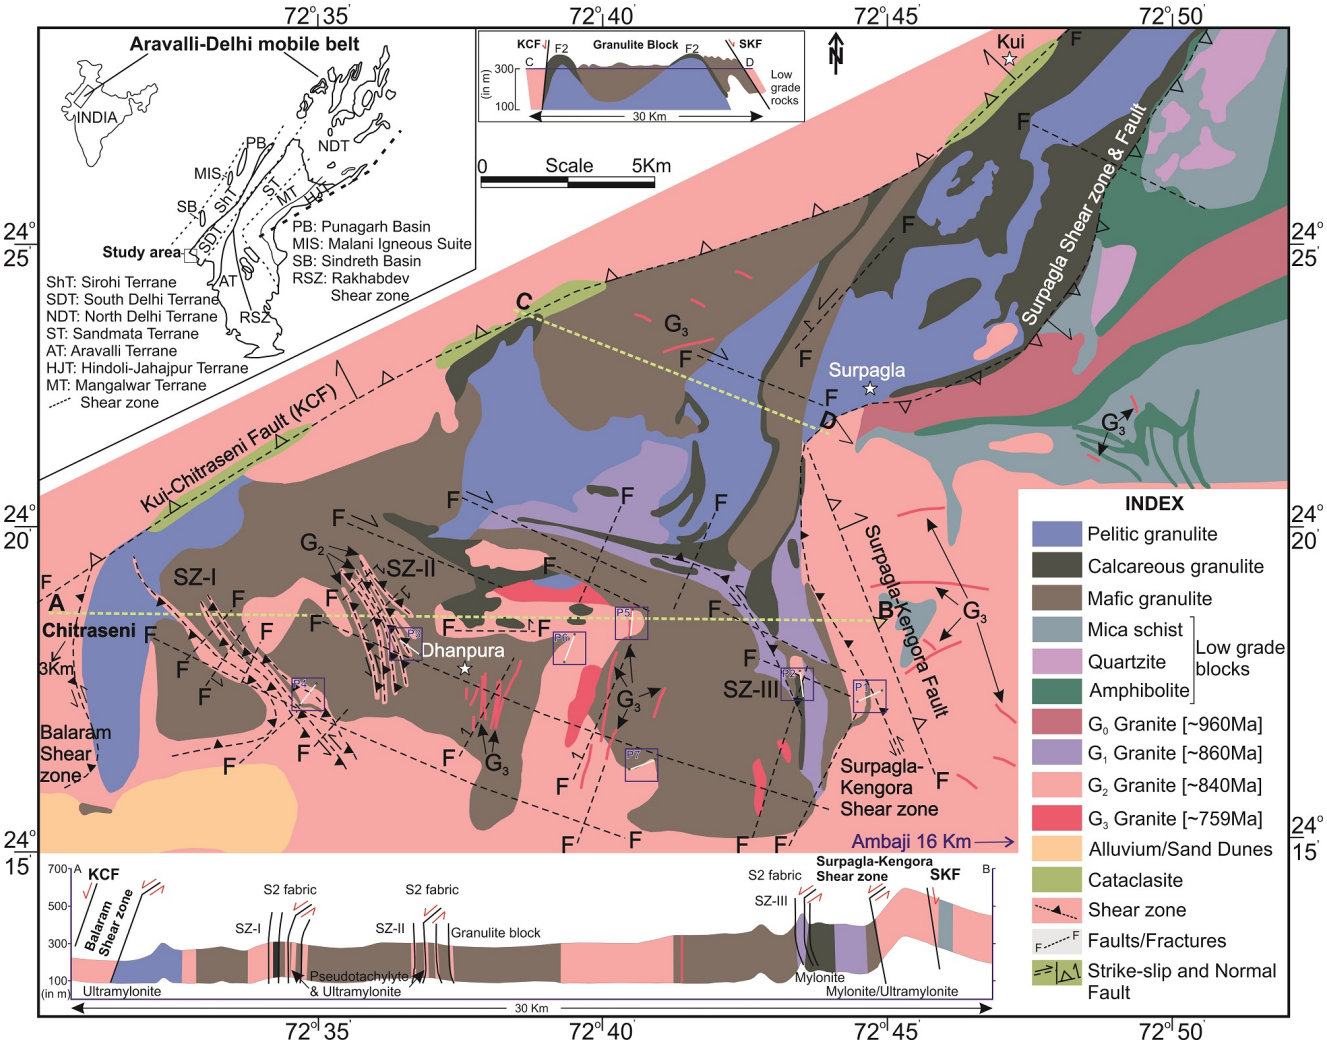
Integrated structural, geophysical and hydrogeological approaches for sustainable groundwater resources in Precambrian basement rock terranes, India



*Rudra Mohan Pradhan[1], Tapas Kumar Biswal[1]

1. Department of Earth Sciences, Indian Institute of Technology Bombay, India

The flow and occurrence of groundwater in Precambrian basement rock aquifers are mainly governed by various factors such as geologic structures, lithology, fault and fracture densities, and topography. The study attempts to investigate sustainable groundwater resources to meet the demand in semi-arid Precambrian basement terrane using integrated field-based structural, geophysical, and hydrogeological approaches. The study area is a part of the Aravalli Delhi Mobile Belt (ADMB) that comprises low to high-grade rocks. Structural features such as brittle and ductile shear zones have mapped in detail followed by subsurface resistivity tomography for mapping deep-seated aquifers. The paleostress results from the fault slip data show two prominent stress regimes i.e. NE-SW and NW-SE extensional regimes in the study area. Further, resistivity imaging data have been collected based on the structural features in 07 different locations and interpreted to obtain the resistivity parameters and to locate high yielding groundwater bearing zones. For a pilot study, a total of 06 boreholes (150 m depth) were drilled for pumping test analysis based on the acquired structural and geophysical data. The study reveals that the high yielding aquifers (Q=180-220 lpm) are confined to ductile shear zones than brittle shear zones. Thus, the hydrogeological importance of various factors related to movement and occurrence of groundwater presented here will provide a basis for future water supply development programs to meet the groundwater needs.

[U-04] International Efforts Supporting Global Navigation Satellite System-Enhanced Tsunami Early Warning

convener:Rundle John B(University of California Davis), Kazuyoshi Nanjo(University of Shizuoka), Eiichi Fukuyama(Kyoto University / National Research Institute for Earth Science and Disaster Resilience)

With little to no warning more than 230,000 lives were lost to the Great Indian Ocean Tsunami of December 26, 2004. This devastating loss of life focused the efforts of scientists, engineers and politicians to strengthen tsunami early warning systems beginning with an accurate and rapid estimate of tsunami potential. A combined network of seismic and geodetic sensors quickly emerged as an accurate, efficient, and cost effective enhancement to tsunami early warning systems for those at risk communities nearest the earthquake epicenter. In the months following the Great Indian Ocean Tsunami, geophysicists demonstrated that analysis the GPS network of the Global Geodetic Observing System could have provided warning within 15 minutes after the Sumatran earthquake if the network data were available in real time. On March 11, 2011, the Tohoku-oki earthquake and tsunami unleashed another terrible tragedy upon the Japanese people and posed great challenges to the Japanese government. The Tohoku-oki earthquake occurred off shore from the world's most advanced GPS network, the GEONET, designed and operated by The Geospatial Information Authority of Japan (GSI). The Tohoku-oki earthquake did underscore the potential and extraordinary societal value of Global Navigation Satellite Systems (GNSS) to tsunami warning systems. Several retrospective studies of the Tohoku-oki earthquake deformation captured by the GEONET demonstrated that accurate tsunami inundation predictions could be provided within 5 minutes of the earthquake occurrence.

In this session, we solicit papers on topics related to the realization of such a system, including instrumentation, data collection and availability, modeling, forecasting/nowcasting, and software development, as well as capacity building and linkages to international organizations, the Sendai Framework for Disaster Risk Reduction, and UN Sustainable Development Goals.

[U04-P01] GNSS total electron content for ionospheric tsunami early warning

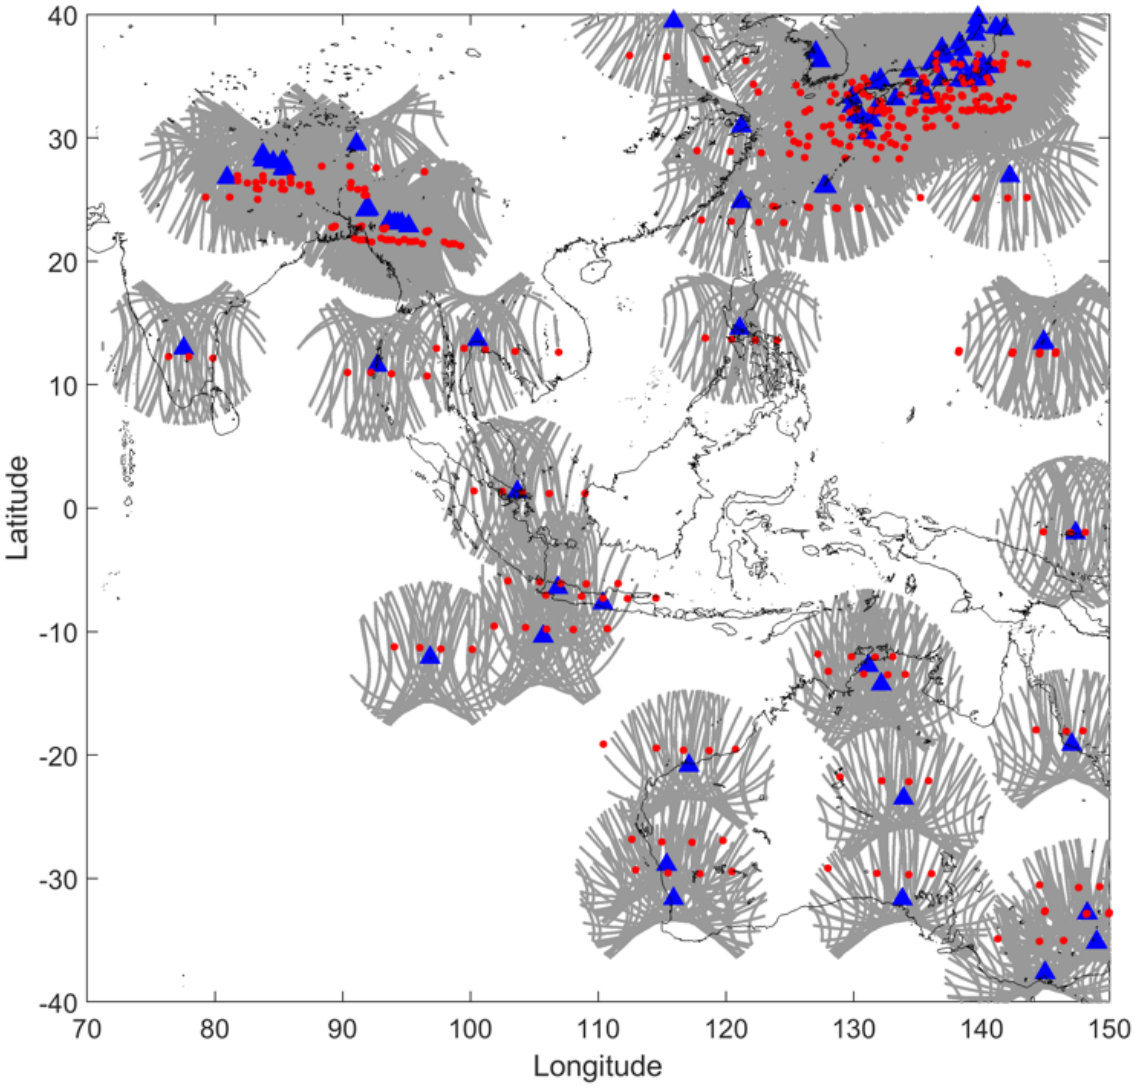
GNSS total electron content for ionospheric tsunami early warning



Tien-Chi Liu[1], Katsumi Hattori[2], *JANN-YENQ Liu[3,4,5], CHIYEN LIN[3,4], Yu-Lin Tsai[1], Tso-Ren Wu[1]

1. Graduate Institute of Hydrological and Oceanic Sciences, National Central University, Taiwan, 2. Graduate School of Science, Chiba University, Japan, 3. Center for Astronautical Physics and Engineering, National Central University, Taiwan, 4. Department of Space Science and Engineering, National Central University, Taiwan, 5. Center for Space and Remote Sensing Research, National Central University, Taiwan

Tsunami waves can induce Tsunami Traveling Ionospheric Disturbances (TTIDs) of the total electron content (TEC). In this study, we examine the TEC derived by ground-based receivers of the global positioning system (GPS) and identify TTIDs induced by 2004 Indian Ocean tsunami. Simulations of the COMCOT (Cornell Multi-grid Coupled Tsunami) model and analyses of the circle method, the ray-tracing technique, and the beam-forming technique are used to show that TTIDs can be quickly detected and confirmed after the tsunami occurrence. Finally, the ionospheric TEC derived by existing ground-based GNSS (global navigation satellite systems) receiving stations is demonstrated to be useful to support the tsunami early warning system.

[U-05] Advanced understanding of Quaternary and Anthropocene hydroclimate changes in East Asia

convener:Chuan-Chou Shen(High-Precision Mass Spectrometry and Environment Change Laboratory, Department of Geosciences, National Taiwan University), Yusuke Yokoyama(Atmosphere and Ocean Research Institute, University of Tokyo), Kaoru Kubota(Graduate School of Human Development and Environment, Kobe University), Li Lo(Department of Geosciences, National Taiwan University)

For the sustainability of biosphere and human society, it is crucial to in-depth understand Earth climate system changes on different timescales in Quaternary. Anthropogenic forcing is also strongly affecting different aspects of human living environments, natural ecological through physical and chemical climatic perturbations, especially in East Asia with swift economic takeoff in the recent decades. We welcome climate and environmental reconstructions based on natural archives, proxy data, numerical simulations especially on the topics of monsoon, precipitation belt shifting, typhoon, and drought histories in Quaternary and Anthropocene. Atmospheric and oceanic interactions, greenhouse gases radiative forcing and anthropogenic forcing impact from regional to global scale are also welcomed.

Precessionally Paced Foraminifera-bound Nitrogen Isotope Variations in the Solomon Sea Influenced by Eastern Equatorial Pacific Upwelling Intensity

*Haojia Abby Ren[1], Wei-Ning Fang[1], Yi-Chi Chen[1], Kuo-Yen Wei[1], Chuan-Chou Shen[1]

1. National Taiwan University

The surface water in the Western Equatorial Pacific (WEP), although is depleted with nitrate and other major nutrients, bears isotopic signature of partial nitrate assimilation in the nutrient-rich Eastern Equatorial Pacific (EEP). Driven by the easterlies, Equatorial Under Current upwells to the surface of the EEP, where biological uptake only partially consumes nitrate and leaves the remaining nitrate enriched in its nitrogen isotopic composition. Through multiple cycles of uptake and remineralization, the elevated nitrogen isotopic composition is recorded by organic matter and is spread out to regions away from the EEP, partly causing the WEP thermocline nitrate $\delta^{15}N$ to be much more elevated than the global mean. We then expect the $\delta^{15}N$ in the WEP to be sensitive to the expansion and shrinking of the EEP high nutrient region during past climatic cycles.

This study reports foraminifera-bound $\delta^{15}N$ (FB-$\delta^{15}N$) of two planktonic species –*Globigerinoides sacculifer* and *Globigerinoides ruber* –from a sediment core in the Solomon Sea over the last 158 ka. The FB-$\delta^{15}N$ values, similar between the two species, fall between 7‰ to 13‰. The core-top FB-$\delta^{15}N$ (9.2‰) is approximately equal to the modern subsurface nitrate $\delta^{15}N$ (9.4‰), the dominate nitrate source to the Solomon Sea surface. The FB-$\delta^{15}N$ values are significantly elevated during periods with high local summer/fall insolation with a strong precessional pacing. While without a clear glacial/interglacial difference, at both terminations, the FB-$\delta^{15}N$ hits lowest values (~8.3‰) before an abrupt increase.

The lack of clear glacial/interglacial change, yet a strong precessional pacing in the Solomon Sea FB-$\delta^{15}N$ record, implies a low latitude control and an insignificant influence from oxygen minimum zones in the eastern tropical Pacific. Supported by modern hydrologic data and modeling exercises, we argue that the variations in our FB-$\delta^{15}N$ record reflects changes in the EEP surface nutrient status, such that expansions of the high nitrate pool cause the observed high FB-$\delta^{15}N$ values. Together with reconstruction in the EEP paleoproductivity, our record strongly indicates enhanced EEP upwelling during periods with local insolation maximum, consistent with previous modelling studies showing a strong precessional control on ENSO evolution.

Annual record of boron isotopes of massive *Porites* coral skeleton from Chichijima Island in the western North Pacific

*Kaoru Kubota[1], Ryo Nakano[2], Masafumi MURAYAMA[2], Tsuyoshi Ishikawa[1], Yusuke Yokoyama[3], Atsushi Suzuki[4]

1. Kochi Institute for Core Sample Research, JAMSTEC, 2. Faculty of Agriculture and Marine Science, Graduate School of Integrated Arts and Sciences, Kochi University, 3. Atmosphere and Ocean Research Institute, The University of Tokyo, 4. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

Long-term pH record in the surface ocean is limited to the very recent period, for the last three decade, hampering our understanding of natural variability of surface seawater pH and recent anthropogenic decline due to surface ocean carbon dioxide concentration increase (ocean acidification). Boron isotope composition of skeleton of long-living massive Porites coral, a known seawater pH proxy, can potentially provide continuous, long-term record. Here we present result of boron isotope measurement for the century-long living massive *Porites* coral from Chichijima Island in the western North Pacific in annual time resolution. Boron isotope ratio was measured by using multi-collector ICPMS, Thermo Scientific *Neptune* installed at Kochi Core Center, in a precision of ±0.1 permil (2 standard deviation). A method of boron isotope measurement for the coral sample was modified from the previous application, namely anion exchange column was skipped to make the measurement simple and enhance the sample throughput. The new annually resolved boron isotope record shows good agreement with previously reported one from Guam Island, at least in decadal timescales.

Gauging Quaternary Sea Level Changes using various sea level indicators and GIA model

*Yusuke Yokoyama[1], Anthony Purcell[2], Takeshige Ishiwa[3]

1. Atmosphere and Ocean Research Institute, University of Tokyo, 2. Research School of Earth Sciences, The Australian National University, 3. National Institute of Polar Research

Past sea level indicators play a key role in tracking the history of global climate. Variations in global sea level are controlled mainly by growth and decay of continental glaciers and temperatures that are closely correlated with the mean global climate state (glacial and interglacial cycles). Our understanding of global climate and sea level has benefited significantly from improvements in ocean floor sampling as well as from the application of new analytical techniques and isotope mass spectrometry. This presentatin will overview of recent advances in paleo-sea level studies based on analysis of samples and data from deep-sea sediment cores and drowned coral reefs.

Sea-level change in Tongatapu, the Kingdom of Tonga for the last 3000 years based on local marine reservoir effect and geophysical modeling

*Naoto Fukuyo[1,2], Anthony Purcell[3], Geoffrey Clark[4], Phillip Parton[4], Yusuke Yokoyama[1,2]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Department of Earth and Planetary Sciences, Faculty of Science, The University of Tokyo, 3. Research School of Earth Sciences, The Australian National University, 4. College of Asia and the Pacific, Australian National University

Reconstructing the history of Holocene relative sea levels around Tonga provides essential constraints on the recent geological evolution of this region and paleoenvironmental context for archaeological studies. However, there are few sea-level records currently available from the region, and no quantitative paleoenvironmental studies using geochemical/physical methods have been reported. In this study, we reconstruct sea-level histories for Tongatapu island using radiocarbon measurements and glacio-hydro-isostatic adjustment (GIA). Our analyses suggest that changes in the average size of bivalves (Gafrarium tumidum) are synchronous with corresponding changes in the paleoenvironment. These changes also correspond to the timing of the increase of local marine reservoir effects (ΔR) from 219±78 to 376±69. Sea surface salinity (SSS) changes within Fanga ' Uta lagoon were also synchronous with these changes caused by a gradual decrease in the exchange of water in and out of the lagoon. Salinity seems to have been higher than present at approximately 2.6 cal kyr BP, suggesting an embayment that was relatively open to the ocean. Predicted mid-Holocene sea level height using GIA modeling indicates less than 1 m above sea level in Tongatapu, suggesting that previously reported observations of mid-Holocene high stand require additional factors other than GIA. Furthermore, present-day satellite-based observed (i.e., GPS) vertical uplift rate in Tongatapu is ten orders of magnitude higher than the long-term uplift rate obtained from Holocene sea-level data.

High-resolution Holocene records of a stalagmite from maritime Japan

*Shota Amekawa[1], Akihiro Kano[1], Kenji Kashiwagi[2], Taiki Mori[3], Fumito Shiraishi[4], Chuan-Chou Shen[5,6,7]

1. Graduate School of Science, The University of Tokyo, 2. Department of Environmental Biology and Chemistry, Faculty of Science, University of Toyama, 3. Graduate School of Integrated Sciences for Global Society, Kyushu University, 4. Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 5. High-precision Mass Spectrometry and Environment Change Laboratory (HISPEC), Department of Geosciences, National Taiwan University, 6. Global Change Research Center, National Taiwan University, 7. Research Center for Future Earth, National Taiwan University

In East Asia, the climatic factor for the lowered meteoric water $\delta^{18}O$ during mid-Holocene than the last glacial period is still controversial. Previous interpretations on stalagmite $\delta^{18}O$ were recently re-examined with new records from the maritime Japan, in eastern part of the Asian monsoon region beyond the influence from Indian summer monsoon (Mori et al. 2018). However, their stalagmite presented limited records in the Holocene section because of low growth rate. Here, we report another stalagmite from the same cave (Kiriana cave in Mie Prefecture), which provides high-resolution records of stable isotopes and trace element during Holocene.

The ages of the 34-cm-long stalagmite were determined at 17 horizons through Uranium-Thorium dating method at the National Taiwan University. Stable isotopes were measured at 0.2-mm intervals using an isotope ratio mass spectrometer (Thermo Finnigan DeltaPlus) connected with an on-line gas separation and introduction system (GASBENCH II) at the Kyushu University. Trace element analysis was performed with inductivity coupled plasma optical emission spectrometer (iCAP7200, Thermo Fisher Scientific) at the Hiroshima University.

The stalagmite $\delta^{18}O$ displays similar temporal patterns with the Chinese records but exhibits much smaller amplitude of $\delta^{18}O$ than the Chinese records. This result supports the idea of Mori et al. (2018) that the stalagmite $\delta^{18}O$ record from this cave is a superimposed signal of variations in air temperature and seawater $\delta^{18}O$, rather than the hydroclimatic control on meteoric water $\delta^{18}O$. On the other hand, $\delta^{13}C$ of the stalagmite has more than 2‰ shift from mid- to late-Holocene with ~1‰ excursions in millennial timescale. The variation synchronized with Mg/Ca suggests that the $\delta^{13}C$ change is largely affected by prior calcite precipitation (PCP) from the infiltrating water in the karst bedrock, which generally increases under a dry condition. Supposing that $\delta^{13}C$ record of this stalagmite reflects PCP induced by precipitation change, we propose that precipitation or EASM variability is recorded more clearly in $\delta^{13}C$ rather than $\delta^{18}O$ of stalagmite in maritime Japan.

Keywords: Stalagmite, Stable isotope, Trace element, East Asian summer monsoon, Holocene

Mg/Ca and stable oxygen isotopes of individual foraminifera in the tropics: Climate variability or ecology?

*Sze Ling Ho[1], Jeroen Groeneveld[2,3], Andreas Mackensen[4], Mahyar Mohtadi[3], Thomas Laepple[2]

1. Institute of Oceanography, National Taiwan University, 10617 Taipei, Taiwan, 2. Alfred Wegener Institute, Helmholtz Center for Polar and Marine Research, Telegrafenberg A45, D-14473 Potsdam, Germany, 3. MARUM-Center for Marine Environmental Sciences, University of Bremen, Klagenfurter Strasse 2-4, D-28359 Bremen, Germany, 4. Alfred Wegener Institute, Helmholtz Center for Polar and Marine Research, Am Alten Hafen 26, D-27568 Bremerhaven, Germany

Foraminifera are commonly used in paleoclimate reconstructions as they occur throughout the world's oceans and are often abundantly preserved in the sediments. Traditionally, foraminifera-based proxies like $d^{18}O$ and Mg/Ca are analyzed on pooled specimens of a single species. Analysis of single specimens of foraminifera allows reconstructing climate variability on timescales related to El Niño-Southern Oscillation (ENSO) or seasonality, thus has the potential to shed more light on the hydroclimate changes in regions such as East Asia. However, quantitative calibrations between the statistics of individual foraminiferal analyses (IFA) and climate variability are still missing. We performed Mg/Ca and $d^{18}O$ measurements on single specimens from surface sediments (modern to 300 years old) from different settings to better understand the signal recorded by individual foraminifera. We used three species of planktic foraminifera (*G. ruber* (s.s.), *T. sacculifer*, and *N. dutertrei*) from the Indo-Pacific Warm Pool (IPWP) and one species (*G. ruber* (pink)) from the Gulf of Mexico (GoM). The Mg/Ca-$d^{18}O$ relationships for different species agree well with published calibrations. IFA statistics (both mean and standard deviation) of Mg/Ca and $d^{18}O$ between the different sites show a strong relationship indicating that both proxies are influenced by a common factor, most likely temperature variations during calcification. This strongly supports the use of IFA to reconstruct climate variability. However, our combined IFA data for the different species only show a weak relationship to seasonal and interannual temperature changes, especially when seasonal variability increases at a location. This suggests that the season and depth habitat of the foraminifera strongly affect IFA variability, such that ecology needs to be considered when reconstructing past climate variability. Further studies on surface sediments and depth-stratified plankton tows would allow better characterization of IFA signal, and ultimately improve the robustness of IFA-based climate variability reconstructions.

Insight to Western Pacific circulation from coral skeletal radiocarbon

*Shoko Hirabayashi[1,2,3], Yusuke Yokoyama[2,3], Atsushi Suzuki[4], Tezer Esat[5], Yosuke Miyairi[2], Takahiro Aze[2], Fernando Siringan[6], Yasuo Maeda[7], Hironobu Kan[1]

1. Faculty of Social and Cultural Studies, Kyushu University, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 4. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST), 5. Research School of Earth Sciences, The Australian National University, 6. Marine Science Institute, University of the Philippines, 7. Institute of Natural and Environmental Sciences, University of Hyogo

Radiocarbon ($\Delta^{14}C$) in seawater is used as a reliable tracer of water mass advection and mixing in water bodies. The calcium carbonate (aragonite) skeletons of reef-building corals contain annual density bands that records the $\Delta^{14}C$ values of surface water at the time at which the coral skeletons took up dissolved inorganic carbon from ambient seawater. Thus, coral skeletal $\Delta^{14}C$ records can also be used as a sensitive proxy of water mass mixing. $\Delta^{14}C$ values for the pre-bomb period can be also used for estimation of local marine reservoir age (R) and their regional offset (ΔR), which varies not only spatially, but also temporally because of changes in ocean circulation associated with climatic changes. Compiling coral skeletal $\Delta^{14}C$ datasets in the western Pacific will contribute to our understanding of the oceanography of the region and can be used for discussion of its relationship to climate change such as El Nino-Southern Oscillation.

In this study, high-resolution coral skeletal $\Delta^{14}C$ dataset during the Anthropocene and Holocene are reported from the western Pacific. Our $\Delta^{14}C$ data indicates a significant increase in $\Delta^{14}C$ from 1946 to 1994 related to atmospheric nuclear bomb testing, with more rapid increase in the South China Sea (SCS) than in the Pacific. The unusual, rapid $\Delta^{14}C$ increase (early bomb-^{14}C spikes) in the 1950s related to the “close-in fallout” found in our SCS and Ryukyu corals. Although three early bomb-^{14}C spikes have been reported from Guam and from Ishigaki, only one such spike was clearly detected in the SCS. The amplitude of the bomb-^{14}C spike in the SCS was less than half that in Ishigaki, likely due to upwelling around Luzon Island and the Kuroshio intrusion into the SCS. We also calculated ΔR during the Holocene using paired analyses of $\Delta^{14}C$ and ^{230}Th on pristine corals. An abrupt ΔR shift occurred between 5.5 ka BP and 4.0 ka BP in the northwest Pacific. Compared with the previously reported data from the Tropical East Pacific and Great Barrier reef, the timing of the shift was different because the ^{14}C content of the northwestern Pacific was affected by not only the intensity of upwelling at the Peru-Chile coast, but also by the East Asian monsoon.

Surface productivity and potential terrestrial ecology system in the central Okhotsk Sea during the middle-early Pleistocene

*Li Lo[1], Lukas Smik[2], Simon T. Belt[2]

1. Department of Geosciences, National Taiwan University, 2. School of Geography, Earth and Environmental Sciences, University of Plymouth

Here we present the first multi sterol biomarkers results from the central Okhotsk Sea using Site MD01-2414 (53°11.77’ N, 149°34.80’ E, water depth 1123 m) during the past 1.2-1.5 million years ago (Ma). We measured brassicalsterol, campesterol, and beta-sitosterol. Results show that the brassicalsterol, campesterol and beta-sitosterol varied from 0-1200, 0-12 and 10-40 ng g^{-1} dried sediment, respectively. The brassicalsterol shows both significant 23- and 41-kyr cycles, where the campesterol and beta-sitosterol show only precession cycle. This is the first report of sterols variations in the central Okhosk Sea during the 41-kyr world. Brassicalsterol variations may be mixed with surface productivity changes and terrestrial organic matter input, meanwhile the potential use of campesterol and beta-sitosterol as regional terrestrial plant biota changes may need further geographical verification in the future.

Keywords: Okhotsk Sea, Pleistocene, Surface productivity, Terrestrial biota

Lake water distribution derived from surface water oxygen and hydrogen isotopes around Fuji Five Lakes

*Ota Kosuke[1,2], Yusuke Yokoyama[1,2], Yosuke Miyairi[2], Shinya Yamamoto[3], Toshihiro Miyajima[2]

1. University of Tokyo, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Mount Fuji Research Institute, Yamanashi Prefectural Government,

The process of water flowing into lakes through precipitation, groundwater, and river water varies depending on the region and season, and it is important to clarify the details in order to know the state of the lake in the future. In previous studies, oxygen and hydrogen isotope ratios have been widely used as effective tools for estimating the origin of precipitation and groundwater.
The results of oxygen and hydrogen isotope ratios in precipitation and groundwater have been reported around Mt. Fuji. However, it is difficult to estimate the groundwater catchment area in the northern part of Mt. Fuji where Fuji Five Lakes are located due to the lack of oxygen and hydrogen isotope data compared to the southern and eastern parts.Results of oxygen and hydrogen isotope ratios in precipitation and groundwater have been reported around Mt. Fuji. However, it is only reported that the oxygen isotope / hydrogen isotope ratio is lighter in the northern ridge of Mt. Fuji, where Fuji Five Lakes are located, than in the southern and eastern ridges.
For example, in Lake Motosu, continuous surveys of surface water vanadium concentration, water temperature and water quality surveys in summer and winter, and vertical surveys of water temperature and water quality throughout the year, show that precipitation accounts for a large part of the water balance. However, since the northern foot of Mt. Fuji was formed by a lava flow, it is difficult to identify the catchment area and was necessary to consider the groundwater flow between Lakes Motosu, Shoji, and Sai.
In the hydrological survey and lake bottom survey of Lake Kawaguchi, at the observation point about 100 m east of Unoshima located in the center of the lake, disturbances in the stratified structure of water temperature and electrical conductivity were observed, and from the bottom of the lake at a depth of about 8 m, the outflow of water with different water quality was newly confirmed.
As described above, continuous accumulation of data is small in the Fuji Five Lakes area, and since the surroundings of Fuji Five Lakes are complex topography with lava, estimation of the groundwater catchment area only from the results of oxygen and hydrogen isotope ratios was difficult.
In this study, the oxygen and hydrogen isotopes of the lake water of Fuji Five Lakes are continuously measured at monthly intervals. Therefore, the surface water of Fuji Five Lakes was collected periodically at monthly intervals from June 2018, and the oxygen and hydrogen isotope ratios of the lake water were measured. A wavelength scan cavity ring-down spectrometer of the Institute of Atmosphere and Ocean Research, The University of Tokyo was used for the measurement. In addition, the results of the groundwater measurement and the water balance study were combined to give a comprehensive discussion, and seasonal changes in the oxygen isotope ratio of Fuji Five Lakes and the groundwater catchment area of Fuji Five Lakes were estimated.
Lakes Kawaguchi, Sai and Yamanaka tended to have higher isotopic ratios during the summer. This result is consistent with the strong effect of evaporation in summer. On the other hand, isotope ratio in Lake Motosu became lighter in summer. Since Lake Motosu is located near the Pacific Ocean, there is a possibility that precipitation with different travel routes is supplied in summer.
In addition to the above results, the groundwater catchment area of Fuji Five Lakes is estimated by comprehensively considering the measurement results of groundwater around the lake and the results of water balance studies.

Carbon and oxygen isotopes and ^{14}C age of travertine and spring water in NW Iran

*Yubo Zhang[1], Yoshihiro Asahara[1], Masayo Minami[2], Masaki kaneko[1], Hadi Amin-Rasouli[3], Hossein Azizi[3]

1. Graduate School of Environmental Studies, Nagoya Univercity , 2. Institute for Space Earth Environmental Research, Nagoya University, 3. University of Kurdistan

Travertine is calcium carbonate precipitated from spring water, groundwater and so on and is widely distributed in northwest Iran. It is one of suitable samples which can reconstruct paleoenvironment on land with a high resolution because of its high deposition rate (1 –20 mm/yr) (Henning et al., 1983; Liu et al., 2003). In this study, we focus on one of the travertine hills in northwest Iran, and discuss the formation age and source of the travertine based on a series of data for ^{14}C, $\delta^{13}C$, $\delta^{18}O$ and major and trace elements.

More than 20 travertine rock samples were collected from the base to the top of a travertine hill in the Takab area, NW Iran. The elevation of the travertine hill is about 60 m. A fault is found near the base of the hill. Several water samples from springs of various sizes (10 cm to 100 m) were collected near the hill in October 2018 and May 2019 to compare the isotope and chemical compositions between the travertine and spring water.

Firstly, ^{14}C concentrations were measured for the travertine rocks and dissolved inorganic carbon (DIC) in the spring water samples by AMS, and $\delta^{13}C$ and $\delta^{18}O$ were determined by IR-MS. Then, major (Ca, Mg) and trace elements (As, Sr, REE, etc.) were analyzed by ICP-MS.

The ^{14}C ages for the travertines range from 42 kBP to 22 kBP. Above the fault, as the elevation increases, the ^{14}C age tends to get younger, but not monotonically. The ^{14}C age of the hill top is 25 kBP. DIC of large spring water has a younger ^{14}C age (18 kBP) than that of small spring water (31 kBP). When we assume that the travertine was precipitated from the small spring like water (31 kBP), we cannot calculate formation age ofn the hill top travertine. Therefore, the large spring water is assumed as the source spring water for the hilltop travertine at the hill top. Based on this assumption and the ^{14}C data, the formation age at the hill top can be estimated as 8–5 ka. In addition, one of the estimation on the growth rate is approximately 5 mm/yr.

The carbon stable isotope compositions ($\delta^{13}C$) is +7 to +12‰, indicating that the travertine is thermogene. Above the fault, the $\delta^{13}C$ value gradually decreases from the base to the top. The $\delta^{13}C$ value at the base (~+10‰) is higher than that at the hill top (~+7‰). So it is assumed that, during the formation of travertine, the travertine spring water type changed from the small spring type water to the large spring type water. In the presentation, we will also discuss data for $\delta^{18}O$ values and major and trace element compositions, possibly indicating paleoclimate and paleotemperature.

[U-10] Linking Education and Research Communities in Geosciences: Engaging the Public and Local Communities

convener:Vincent Tong(University College London), Takashi Oguchi(Center for Spatial Information Science, The University of Tokyo), Renee M Clary(Mississippi State University), Keiko Kuge(Department of Geophysics, Graduate School of Science, Kyoto University)

Developing links between research and education is important for maximizing the impact of Earth and Space Sciences and for nurturing a global geoliterate community. Initiatives involving research, education and public engagement abound, building communities that bring educators, researchers and those with dual interests together is, however, not always straightforward. While many researchers are engaged in activities at national and international levels, educators may focus on projects primarily shaped by institutional and national priorities. In this session, we investigate the challenges and opportunities of advancing research-education synergies in Earth and Space Sciences through engaging the general public and local communities. We focus on success stories showcasing educational and outreach initiatives that aim to bring researchers and educators together. Ways of fostering collaborations, evidencing impact and developing leadership will be highlighted. Projects that address the UN Sustainable Development Goals (SDGs) are particularly welcomed.

The Seismological Society of Japan (SSJ) started various outreaching activities following the 1995 Kobe earthquake. As a component of the activities, the Committee for School Education was formed aiming to communicate with educators for delivering updated knowledge in seismology and solid earth science through school education. The committee members consist of both researchers and school teachers.

The committee has been trying to build communication networks among researchers and school teachers so that they can provide and exchange information on earth science and science education. One of major activities is annual summer school for teachers and university students, which has been held since 1996 at various places visiting sites of geophysical/geological interest. In 2009, the committee also started to conduct teaching certificate renewal courses, lectures and practices which school teachers must take in order to renew their certificates every ten years. Courses are held at about ten sites in cooperation with SSJ members. In conjunction with the SSJ Fall Meeting, two kinds of classes on earthquakes have been given since 2014. One is for children to make simplified seismometers and the other is for school teachers to learn about teaching materials related to earthquakes.

Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

Since the occurrence of the 1995 Kobe earthquake, the Seismological Society of Japan (SSJ) has made significant efforts on education and outreach (EO) by setting several committees effective. Development of each committee, which has been supported by the participation of teachers and journalists, has made a wide range of contributions on EO. After the 2011 Tohoku earthquake, the SSJ decided to act in a more comprehensive way in order to promote the EO activities by starting a special committee in 2013 to exchange information of all EO activities in the associated committees and construct comprehensive plans as SSJ. This presentation shows the ongoing EO activities by the SSJ, which are listed below.

- Short courses for the renewal of teaching licenses (every year)
- Annual summer school for teachers
- Annual summer school for kids
- Short class of earthquakes for kids and teachers before/after the SSJ fall meeting
- Activities to support Geoparks (for example, tours in geoparks)
- Training courses concerning the prediction of strong ground motions
- Essays associated with strong ground motions
- Open seminars associated with strong ground motions
- Seminars in earthquake affected areas
- Quarterly magazines ‘Naifuru’ of earthquake topics for the public
- FAQs on earthquakes for the public on the SSJ website
- Mailing list linking between researchers and public
- Press conferences during the SSJ fall meeting and JpGU meeting every year

20th Children's Summer School on Seismology and Volcanology in the Tango Peninsula, Japan

*Yasuyuki Kano[1], Executive Committee for 20th School Children's Summer Course on Seismology and Volcanology

1. Earthquake Research Institute, The University of Tokyo

The 20th Children's Summer School on Seismology and Volcanology was held in the Tango peninsula, part of which is covered by the San’in Kaigan UNESCO Global Geopark, Japan. The main subject of the summer school is the shape of the tango peninsula and the 1927 Kita tango earthquake. The summer school was held on August 10 and 11. The students enjoyed a variety of lectures, experiments, and fieldworks. They also made discussion in small groups to present their summary of the summer school. The stops for the field trip and outdoor experiments includes: Miyazu History Hall, Amanohashidate Sightseeing Boat, Niizaki shrine, Tango Eco-Future Park, Amino station of Hi-net operated by NIED, Amino train station, two outcrops of Goumura fault which appeared at the time of the 1927 earthquake, and Kyotango City Local Museum.

The summer school is organized by the executive committee consists of members from the Seismological Society of Japan (SSJ), the Volcanological Society of Japan (VSJ), the Geological Society of Japan (JGS), and Earth Design School as local organization. The preparation begins in December 2017 by calling for venue of the summer school. The venue, Tango area, is officially announced in March 2018. The executive committee is organized in October 2018. Thirty members of the executive committee share the role of lecturer, facilitator for the entire school or separate group, public relation, logistics, safety officer and so on. The continuous effort to provide the summer school yields the rich knowledge of organizing summer school for school children.

The 21th Children's Summer School on Seismology and Volcanology will be held on August 18 and 19, 2020 at the area of Mt. Asama North Geopark, Japan.

Development of e-learning materials for GIS exercises in Japan and their outcomes

*Hiroyuki Yamauchi[1], Takashi Oguchi[2], Yuichi S. Hayakawa[3,2], Toshikazu Seto[2]

1. Department of Natural Environmental Studies, Graduate School of Frontier Sciences, The University of Tokyo, 2. Center for Spatial Information Science, The University of Tokyo, 3. Environmental Geography, Faculty of Environmental Earth Science, Hokkaido University

We have been conducting a project to develop GIS exercise materials for Japanese university students. In this project, we distribute the materials on the Internet via GitHub. The learning contents in the materials are divided into four sections according to the target of learning: 1) basic operations of GIS software, 2) equipment usage for field data collection, 3) utilization of Web GIS, and 4) GIS programming with Python. Explanation of GIS analyses in the materials consists of short text descriptions and screen-captured images showing data processing using free GIS software packages such as QGIS. We also provided sample data compiled from open data for the exercises. Users can learn GIS using the materials with free of charge. The online materials have been utilized in not only universities but also industries, governments, and groups of citizens in Japan. In this presentation, we introduce the construction and operation of the materials, and demonstrate how they worked in the community.

Enhancing the impact of sustainability research and education: Distributed leadership as a guiding model

*Vincent Tong[1]

1. University College London

United Nations Sustainable Development Goals (SDGs), which are presented as a set of highly connected objectives, provide a comprehensive framework for addressing a wide range of global challenges. Higher education institutions play a special role in advancing the SDGs. Here I present some key findings from case studies of Japanese academics working on sustainability research and education, ranging from natural sciences to social science and policy. The academics in this study are at different career stages and are from both research-intensive and teaching-focused institutions in Japan. Qualitative research methods including questionnaires, semi-structured interviews, document analysis were used. I discuss the significance of the research findings through the lens of leadership models and approaches to data in academic work. In particular, I will highlight the transformational potential of distributed leadership in research and education. Distributed leadership requires not only building new institutional structures but also questioning established academic identities and cultures. Informed by findings from this study, I will also argue that distributed leadership may serve as an effective guiding model for enhancing the impact of SDG research and education. In addition, I will also discuss how distributed leadership is implemented in other cultural contexts, including the new American Geophysical Union's Education Section and a UK consortium that aimed to bring research and education closer together.

[U-20] "Open Colloquium" Exploring the Earth's interior using cutting edge science and technology

convener:Hiroko Watanabe(Research Center for Neutrino Science, Tohoku University), William F McDonough(Department of Earth Science and Research Center for Neutrino Science, Tohoku University, Sendai, Miyagi 980-8578, Japan), Kenta Ueki(Japan Agency for Marine-Earth Science and Technology), Eiichiro Araki(Japan Agency for Marine-Earth Science and Technology)

New advances in technology are being used to explore the Earth. These include, but are not restricted to, neutrino geophysics, drilling the deep oceanic biosphere, and drilling to the Moho. Application of these new technologies to studies of the Earth provide critical new constraints and hopefully, new and unimagined insights. Recent technological advances, as well as advances in experimental and theoretical studies are revealing clues of how the Earth operates at a wide range of scales (microns to mega-meters). We seek to understand links from the core to atmosphere that connects the biosphere and geosphere through time. Near-future exploration of the Earth's interior with these new technologies will provide much-needed data on the internal structure of our planet and potentially its habitability. We anticipate presentations on recent advances in science and technologies that provide insights into physical, chemical, and biological processes and structures on and in the Earth. We welcome contributions from science and engineering.

[U20-P01] Study of Ocean Bottom Detector for observation of geo-neutrinos from mantle

Observation of geo-neutrinos originating from radioactive isotopes in the Earth (238U,232Th, etc.) can be converted to the amount of radioactive isotopes and the heat generated by their decays which governs the Earth dynamics.
KamLAND experiment achieved world's first observation of geo-neutrinos in 2005. Improvement of observation accuracy allowed us to reach the level where we can obtain geoscientific knowledge. However, it is hard to obtain information on the mantle because 70% of neutrinos observed by detector currently operating or planned are derived from the crust (Figure 1).
Given that the oceanic crust is thinner than the continental crust and has lower densities of U and Th, Ocean Bottom Detector (OBD) makes it sensitive to geo-neutrinos originating from Earth's mantle. OBD is expected to provide transformative insights into the deep Earth.Unique feature of OBD is separation from the reactors which are the main background sources of continental detectors. In addition, this movable detector can observe at multiple points in the ocean.
Scientists at the University of Hawaii started to discuss the idea of observing the geo-neutrinos on the sea floor 15 years ago as the detector called "Hanohano"(Figure 2). Unfortunately, the idea has not been realized yet.
In 2019 joint research between Tohoku University and JAMSTEC was started to lead the comprehensive research relating to understanding the Earth's deep interior and realize OBD. We are currently working on the design of 10-ton prototype detector for the ultimate goal of a 10-50kt detector.
The prototype detector will demonstrate necessary technological developments and measure the environment which will be references for future detector design.
In this presentation, we will present results of detector design based on Monte Carlo simulation.

Learning from the war against the Corona epidemic to ensure the availability of drinking water

*SHUBHAM TIWARI[1]

1. Indian Institute of Technology Roorkee

The solidarity and morale with which the world is fighting the Corona epidemic encourages citizens as a society to reimburse various basic needs. Today, the developing countries are fast moving towards reimbursement of the basic needs of its citizens (such as food to eat, clothes to wear and house to stay, etc.). On the other hand, the availability of water for drinking and agriculture need to pay attention and launch a comprehensive campaign. Long-term water security and access to clean water are essential for public health. We have to stand as an organized society and fight together to ensure the availability of water by learning from the war of the Corona epidemic. When the world is in the grip of an epidemic, it is difficult to draw attention to the global water crisis, one of the greatest environmental risks to mankind. Nevertheless, the coronavirus threat reminds us how important water is to our lives. This study highlights the strategies learnt from Corona epidemic for management of water resources.

Integrate NASA Remote Sensing Data into your COVID-19 Research with our new Data Pathfinder

*Cynthia Hall[1], Kevin Ward[2]

1. NASA Goddard Space Flight Center, 2. NASA Earth Science Data Systems

NASA and other Earth-observing agencies are using satellite and airborne data to assess regional and global environmental, economic, and societal impacts of the COVID-19 pandemic. Whether the goal is to discover the forces behind the virus' spread or to look at effects on the environment due to changes in human behavior, NASA's remote sensing data can provide baselines for comparison and show new trends over time.

NASA's Earth science data collections provide a wealth of information to aid in our understanding of Earth processes and the data are all freely and openly available at earthdata.nasa.gov. Choosing the right datasets and tools to answer a scientific question often requires expert knowledge and guidance. To help novice users access, explore, and use NASA Earth science data, we have developed a series of data pathfinders.

Data pathfinders provide direct links to commonly used datasets and data products across NASA's Earth science data collections. Pathfinders supplement Earthdata search capabilities by providing access to datasets through commonly used tools, providing different ways of visualizing the data, options for subsetting the data, and options for saving the data in different file formats.

The COVID-19 pathfinder is for users who are studying the environmental signals surrounding the novel severe acute respiratory syndrome (SARS) coronavirus, SARS-CoV-2. It provides links to datasets that can be used to research changing environmental impacts on air quality, water quality, land cover changes, and more, that are the result of modified human behavior
patterns. This pathfinder provides links to measurements of temperature, humidity, and ultraviolet (UV) irradiance, which offer an opportunity to assess the possibility of seasonal trends in virus transmission. It also provides links to datasets related to water availability, such as the amount and rate of precipitation, soil moisture, and groundwater resources. Water availability and possible drought conditions need to be continuously monitored to ensure uninterrupted water services for hospitals and other critical services during the pandemic.

Come see how you can easily find NASA data to enhance your research.

Is the impact of COVID-19 modulated by well-water arsenic in rural Bangladesh? Setting a baseline.

*Alexander van Geen[1], Prabhat Barnwal[2], Yiqian Wang[2], Nishat Jui[3], Shabib Raihan[3], Ashraful Haque[3]

1. Columbia University of New York, 2. Michigan State University, 3. Innovations for Poverty Action, Bangladesh

The first three known COVID-19 cases were reported in Bangladesh on March 7, 2020. Almost two months later, the official count exceeded 50,000 cases while the number of deaths attributed to COVID-19 was still below 1000. Even these numbers, widely held to be underestimates, show no sign that a plateau has been reached as of June 4, 2020. This contribution describes the launch of a series of phone-based surveys to gauge the impact of COVID-19 in rural Bangladesh. The new monitoring builds on a recently launched randomized-controlled trial across 135 villages of Bangladesh to compare the effectiveness of different ways of delivering well-water tests for arsenic in terms of triggering household responses that reduce exposure to arsenic. To set the stage for the trial, our field team visited during the middle two weeks of January 2020 a total of 16,000 households in person to conduct a census. Two cell phone numbers were recorded for each household at the time and these made it possible to start calling them during the two middle weeks of May. All households were asked if anyone had died in 2019 to establish the pre-COVID-19 mortality for this population of 75,000.
Household were also asked if anyone had died since the beginning of 2020. As of May, 2020, the number of deaths reported for 2019, corresponding to a crude mortality rate of 7.7 per 1000, was if anything higher than in 2020 after correcting for the portion of the year covered. There was no difference between 2019 and 2020 as of May 2020 either in the distribution among different causes of death, self-reported in broad categories, the distribution of ages at death, or the location of death. This could well have change dramatically by the time our second round of phone surveys is completed later this summer. When field activities resume, hopefully in September 2020, all 12,000 wells in the study village will be tested for arsenic and are anticipated to span a wide range of concentrations. By combining phone and field surveys, we will be uniquely positioned to ascertain if the documented impact of arsenic exposure on the immune system translated also into differential responses to COVID-19.

The Spatial Pattern of Coronavirus Disease 2019 in China over Four Periods

*ZILAI ZHENG[1]

1. Graduate School of Life and Environmental Sciences, University of Tsukuba

Coronavirus disease (COVID-19) broke out in Wuhan city and expanded rapidly throughout China. The government has taken a series of tough unprecedented interventions to prevent the spread of the disease. Now, COVID-19 in China has passed the peak and entered the last stage of the pandemic. The aim of this study is to identify the spatial distribution pattern of new confirmed cases in China, in order to understand how interventions affected the COVID-19 spread. First, four-time periods were categorized according to the proportion of new confirmed cases in Hubei. Then, spatial autocorrelation analyses were employed to explore geographic patterns in these four periods. Finally, outliers were analyzed by calculating an Anselin local Moran's I statistic. The results show that the spatial patterns of the COVID-19 in the first three periods spread are the high cluster and random in the fourth period. As the proportion of new confirmed cases in Hubei has dropped significantly, the spatial pattern of the epidemic also has a major transformation. Many economic and culturally developed cities became the focus in addition to Wuhan city.

Consequences of modeling assumptions and scope of analysis on connections between meteorology and COVID-19

*Gaige Hunter Kerr[1], Hamada Badr[2], Lauren Gardner[3], Javier Perez-Saez[4], Benjamin F Zaitchik[2]

1. George Washington University, 2. Department of Earth and Planetary Sciences, Johns Hopkins University, 3. Department of Civil and Systems Engineering, Johns Hopkins University, 4. Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health

Research on past influenza and coronavirus outbreaks demonstrates that the spatiotemporal evolution of transmission exhibits pronounced associations with meteorological variables, such ambient temperature and humidity. There are many open questions regarding the causal pathways that connect the ambient meteorology to the transmission of the novel coronavirus (COVID-19), but evaluating the statistical associations between COVID-19 and meteorology represents an important first step and presents potential challenges and opportunities for controlling the future spread of the virus.
Many recent refereed and non-refereed studies have examined the connection between meteorological variables and COVID-19; however, the landscape of the literature is constantly changing, and it is important to provide a synthesis to evaluate gaps. These studies yield contrasting results linking COVID-19 with meteorology both within and across regions. Differences likely stem from different focus regions and measuring periods, different methodologies (i.e., statistical methods, dependent variable(s), controls, etc.), or a combination of these two factors. To understand how methodology impacts key findings, we discuss how studies draw statistical associations between meteorology and COVID-19 and their intrinsic limitations and suggest ways that future research could improve the detection of associations.

Limited Regional Aerosol Changes Despite Unprecedented NO2 Decline During the February Coronavirus Shutdown in China

*Michael S S Diamond[1], Robert Wood[1]

1. University of Washington Seattle

Following the emergence of a novel coronavirus in Wuhan, the People’ s Republic of China instituted a number of strict lockdown and more general socio-economic shutdown measures throughout the country starting in late January and continuing into February 2020 in order to arrest the spread of the disease. This resulted in a sharp economic contraction unparalleled in recent Chinese history. Satellite remote sensing shows that nitrogen oxide pollution declined by an unprecedented amount (~50% regionally) from its expected unperturbed value, but regional-scale column aerosol loadings and cloud microphysical properties were not detectably affected. The disparate impact may be tied to differential economic impacts of the shutdown, in which the transportation sector, a disproportionate source of nitrogen oxide emissions, underwent drastic declines (~90% reductions in passenger traffic), whereas industry and power generation, responsible for >90% of particulate emissions, were relatively less affected (~10% reductions in electricity and thermal power generation). Meteorology (particularly warm temperatures) and non-linear chemical reactions also likely played a role in driving the disparity.

Will the pandemic of COVID-19 change climate?: tests using MIROC-ES2L earth system model

*Rumi Ohgaito[1], Michio Kawamiya[1], Tomohiro Hajima[1], Ken'ichi Matsumoto[1,2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Nagasaki University

The world is now being altered by the pandemic of COVID-19 that has limited economic activity in the first half of 2020 to protect human lives from the virus. This restriction on economic activity has resulted in lower emissions of anthropogenic greenhouse gases and aerosols (Le Quere et al. 2020). Will this reduction in emissions have an impact on the climate? Using an earth system model MIROC-ES2L (Hajima et al. 2020) used to project global warming in CMIP6, we conducted sensitivity experiments to reduce anthropogenic greenhouse gases, black carbon, and SO2 by 20% in 2020 and 2021, branching off from the global warming scenario experiments submitted to CMIP6 (the 20% reduction in greenhouse gas emissions is driven by an 18.6% reduction in per capita gross domestic product in 2020).

As a result, it was suggested that the Arctic region may have a warming effect. It is also suggested that this may modulate decade-scale climate change. Further analysis will be carried out and presented.

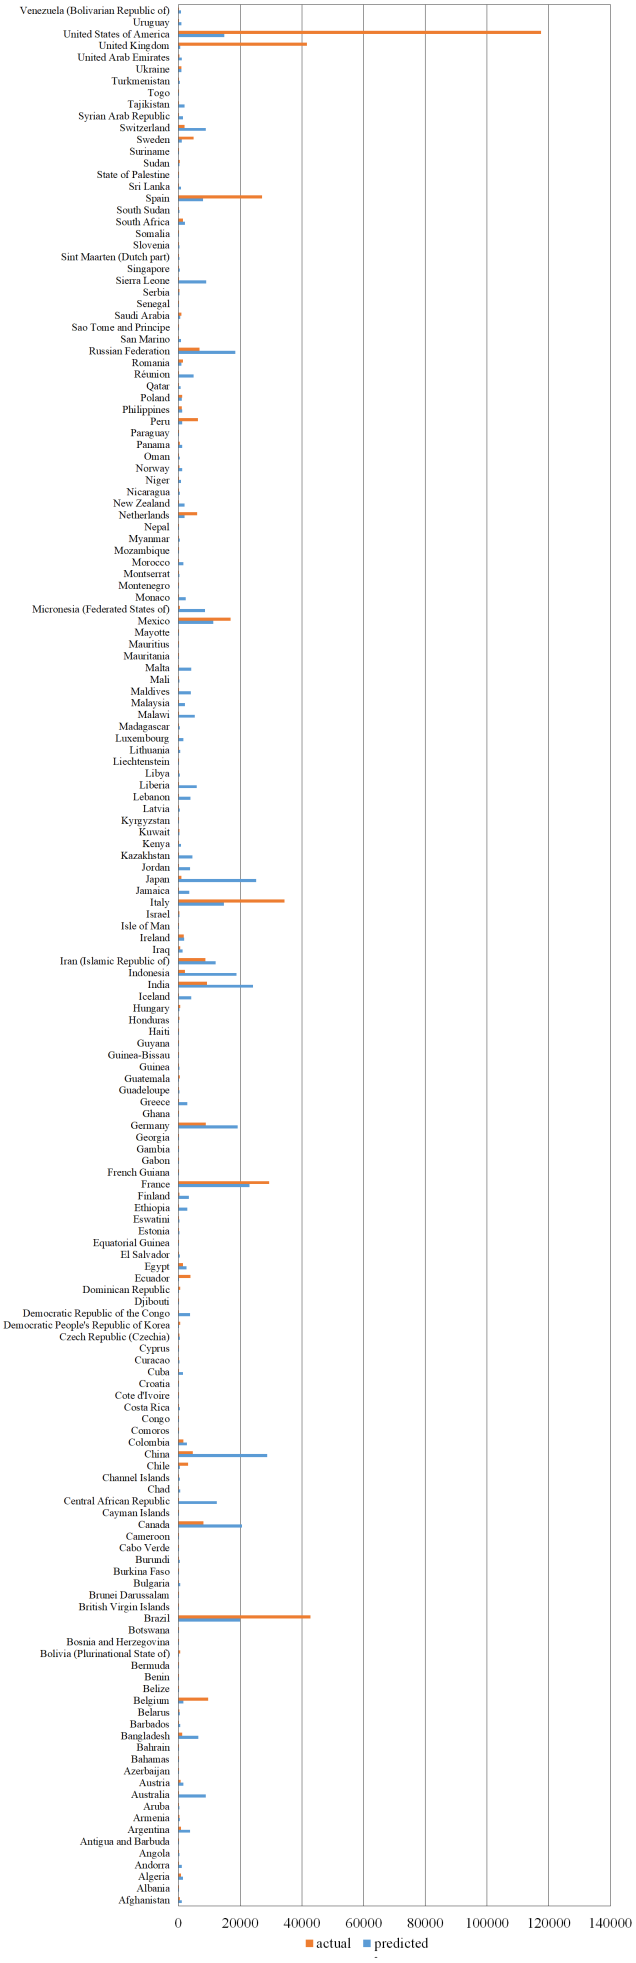
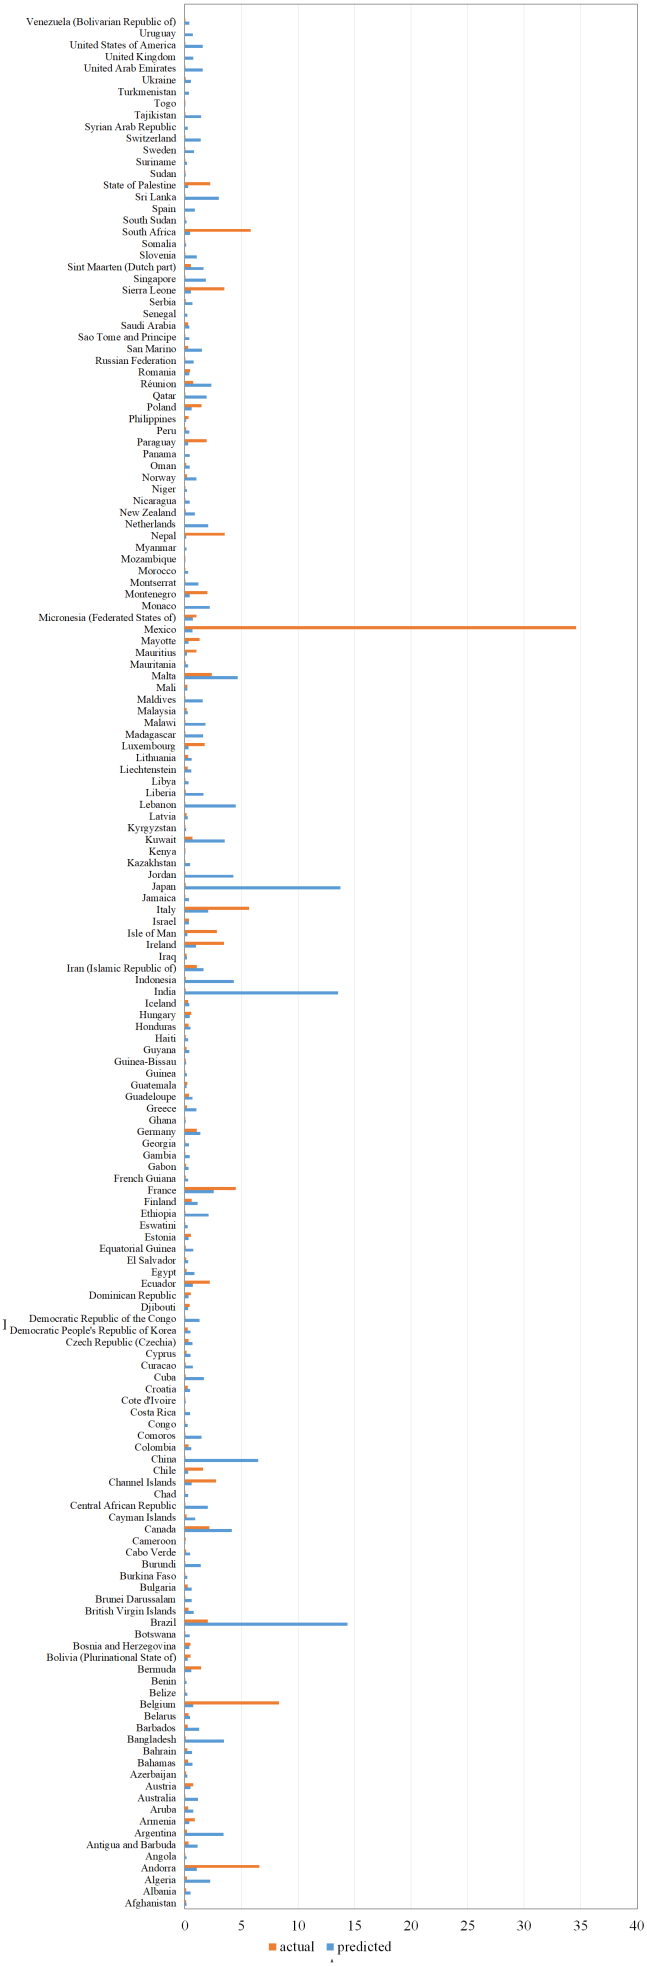
Using mathematical models to assess the number of total deaths and deaths per 10000 people from the COVID-19 epidemic



*Qingqing Sun[1], Chunyi Wang[2]



1. Tianjin University, 2. Mathematics Faculty, University of Waterloo

Death tolls and death tolls per 10000 people of 161 countries and regions as 13 June, 2020 were predicted by "random forest" (https://github.com/qingqingsun-code/covid-19-prediction). The reference indexes are (1) past and present flight routes, (2) change rate of population, world share, population density, net change population density, migrant density, land area, (3) fertility rate, density, median age, (4) urban population proportion, urban areas, urban population density, (5) 65+ older population density, proportion of 65+ older population, (6) numbers of hospital beds per 1,000 people, intensive care unit (ICU) beds per 10000 people, density of medical doctors (per 10000 population), density of nursing and midwifery personnel (per 10000 population), density of pharmacists (per 10000 population), (7) gross domestic product (GDP) Nominal ($) per people, GDP per chasing power parity (PPP) (Int. $) per people, (8) out of pocket expenditure as percentage of current health expenditure % (US$), direct financial plan on fighting COVID-19, current health expenditure (CHE) as percentage of gross domestic product (GDP)(%), CHE per capital (US$), domestic general government health expenditure (GGHED) as percentage of general government expenditure (GGE)(%), (9) average of international health regulation score capacity scores, universal health coverage (UHC) service coverage index. Based on the heatmap of correlations, the highest indexes were annual rate of population change, urban area, and GGHED as percentage of GGE. Predicted death tolls (441,692) were 4.64% high than the statistical death toll (422,090). Predicted mean death toll per 10,000 was 1.14, higher than the statistical one 0.78. Because patients with basic diseases are less resistant to COVID-19, there is a possible statistical bias in the number of deaths in some country and region. It is also not ruled out that some of the dead patients have not been diagnosed. Quarantine order is the main reason for the difference between simulated data and statistical data. As a global community, we need solidarity, disclosure information, cooperation in the development of vaccines, sound medical relief supplies to limit the spread of COVID-19.

Global early warning system by Complex-Envelope (CE) Processing of Seismic Waves

*Rudolf Unger[1]

1. Delft University of Technology

Given a pandemic situation such as C-19 or any other potential mutation, and an earthquake striking at some point during its development, how could science aid to confront two simultaneous disasters?

We answer from a) an anthropological/psychological point of view and b) a seismic technology perspective.

A) Strict isolation and a disaster such as earthquake or volcanic eruption imply antagonist forces and strategies which require original and dynamic disaster preparedness. Michael Levitt (Nobel 2013) has alerted on the dangers of strict confinement and has compared SARS-Cov-2 and its predecessor SARS-Cov (2003) and its effects on the lives of the populations (suicides, domestic violence, etc.) including worries which lower the immune system. Enhancing the immune system and implementing hygiene are important steps as is social physical distancing. Cognitive approach strengthens the mind through statistics and understanding of the process.

B) As we are learning again from C-19 the importance of early warnings and open global data sharing, we need to enhance the search for medical and natural disaster precursors, and to develop efficient global Big Data (BD) communicating precursor systems. To achieve this objective, we elaborate on a system for continuous Active Geophysical Monitoring (AGM, controlled-source high-resolution 3D time-lapse monitoring of Earth physics parameters and potential earthquake precursors), Geophysical Exploration (GE) resolution optimization and multiple-signal analysis by Complex-Envelope (CE) Processing of Seismic Waves.

CE = dual time series of Instantaneous Amplitude (IA) and Instantaneous Phase (IP), obtained through quadrature processing of (seismic) wave time series. We show significant CE contributions in Nuclear Test Ban Treaty (NTBT) earthquake vs. underground explosion verification and monitoring (automatic detection and classification), in AGM, and in GE.

Should two disasters happen simultaneously, technology provides precise (seismic) methods to accurately contribute to a better preparedness and stronger psychological stamina to face reality.

A possible role of environmental arsenic against COVID-19

*Satadal Das[1], Milan Sengupta[2], Rathin Chakraborty[3]

1. peerless hospital and b. k. roy research centre, kolkata, india, 2. D. N. De H. Medical College, Kolkata, India., 3. Dr.Bholanath Chakravarty Integrated Medical Research & Treatment Centre, Howrah,West Bengal, India.

Before 20th Century arsenic compounds were the first drug of choice in most of the diseases, however, as it is a known poison, it lost its status with the development of modern science, and at present they are only used in four important diseases - acute promyelocytic leukaemia, hepatocellular carcinoma, autoimmune diseases, and in African trypanosomiasis. In this study we first observed much less COVID-19 cases in some arsenic rich groundwater areas of West Bengal. Then we aimed to find out whether negative correlate between groundwater arsenic levels and COVID-19 incidence is present in different parts of the world. We presumed that in developed countries it would be extremely difficult as groundwater arsenic, even if it is present in a much higher level in some areas; it will not influence human beings due to polished modern water supply system. Even then after analysis we became totally convinced that there is a definite relationship and in areas where groundwater arsenic levels are high COVID-19 incidence is much less, and in many countries it is lowest, compared to all other areas in those countries. This finding may be an incidental one, however, we must look details into it.

The lack of representation of women in geoscience is a reality, and although recent efforts have been made towards closing the gender gap, we are far from achieving gender balance. Furthermore, this problem is amplified for women with mixed heredity or coming from developing countries, who rarely find themselves represented in leadership roles in academia and industry. To tackle this issue, GeoLatinas, an initiative to empower women of Latin-American ethnicity, started in 2018.

GeoLatinas is an inclusive, member-driven organization dedicated to promote, embrace and empower the work and research of Latinas, and inspire current and future generations of Latin Americans to pursue careers in Earth and Planetary Sciences. The organization relies on six interactive groups to increase its reach and potential: an Advisory Committee, a Board of Directors, Liaisons, Regional leaders (Ambassadors), a Leadership Council, and Local Teams. Aided by the development of remote communication and a strong Visibility and Social Media team, GeoLatinas has now more than 240 active members and volunteers across 27 countries.

In this presentation, we will discuss the GeoLatinas organization, its collective efforts, and use one of our initiatives as an example of how we catalyze inclusion, equity, and retention in Geoscience. We will specifically discuss the strategies undertaken by the Visibility and Social media committee that have helped increase the visibility of Latinas in Earth Sciences and the importance of social media as a tool for representation. Furthermore, we will share lessons learned from the GeoLatinas group journey towards diversity and gender equality, as well as future initiatives to continue supporting our community.

How the COVID-19 Response Opens Broader Viewpoints for Promoting Inclusive Conferences in the Earth and Space Sciences

*Beverly Smith-Keiling[1], Andreas Keiking[2]

1. University of Minnesota Twin Cities, 2. University of California-Berkeley

From the 1948 Universal Declaration of Human Rights to current diversity statements, science entities in the U.S. and globally promote and enhance diversity and equity. For example, AGU, EGU, and Europlanet aim to 'foster an inclusive environment where science and scientific careers can flourish,' 'improve equality of opportunity and diversity,' and 'build a diverse inclusive community,' 'respectively. Clarity from JpGU members' broader viewpoints on diversity and inclusion statements are needed for promoting inclusion. One area is in scientific conferences, not only in the participation in the conference but also engagement and representation at every level. With a goal to increase equitable participation in scientific conferences, engagement and representation at every level, we made initial observations and employed strategies while hosting (together with colleagues) four AGU Chapman conferences between 2011-2016. Within the Social Ecological Model Framework, individual and interpersonal inner-level determinants were our primary target leading us to seek broader viewpoints through an internationally distributed survey. Early observations from this survey and participation in a virtual EGU 2020 conference following the Covid-19 response highlighted the importance of two inclusive practices that were highly ranked in our survey by respondents prior to the outbreak: 1) Live streaming or conference chats for open access, and 2) Additional accommodations for disability (vision, hearing, etc.). These early survey results about what constitutes an inclusive conference apply to virtual delivery, and can help develop strategies to promote advocacy for policy changes and for additional measures that could be applied at conference initiation. This would target the outer level determinants at the policy level to promote inclusion. Yet, through an equity lens, virtual access does not solve all challenges.

How to empower diversity, equality and inclusion for risk management in the COVID-19 Era

*Megumi Sugimoto[1]

1. Kyushu University

Natural disasters happen, so it has been a situation where vulnerabilities and minorities are historically liable to be sacrificed as secondary disaster. For example, the 1906 San Francisco earthquake caused a large number of immigrants from China, whose English and geography were unknown, due to fires. The Great Kanto Earthquake in 1923 spread social unrest among people and spread the hoax that Koreans attacked, killing Koreans by vigilante band.

In the COVID-19 Era, violence and repulsion of people from China and Asians, which seem to be the source, occurred. Even in Indonesia, which is famous as a pro-Japanese nation, rumors spread that the first person was infected by a Japanese person, several attacks on Japanese were reported, and Japanese people were alerted as Japan embassy information. Minorities are week in foreign countries. A black man was killed by a police in US and demonstrations are taking place all over the world. In some areas, looting has occurred and social unrest is easily amplified. These have been repeatedly historically. It is extremely difficult to see if this secondary damage can be stopped by ethics, understanding of people, and harmony of races.

UN Secretary-General alarmed COVID-19 risk to women could harm us all. Pandemics economic impact likely to fall hard on females already facing burdens. This situation means excellent young scientist, especially females from developing countries face more difficulties to study in developed countries than before.
What kind of countermeasures can humans take in this situation? This paper specifically explains that diversity, equality and inclusion function for risk management.

The Effect of COVID-19 on AGU Journal Authors by Gender and Geographical Location

*Paige Rene Wooden[1], Brooks Hanson[1]

1. American Geophysical Union

AGU’ s commitment to building and supporting a diverse group of Earth and space scientists impels us to monitor the data we have on our constituents. When the COVID-19 pandemic forced institutions to close their physical spaces, many researchers and professors were forced to work from home. Media outlets and individuals wondered if women specifically would be shouldering the childcare and/or homeschooling responsibilities decreasing the time they had to for professional and research duties. AGU has been monitoring the effect that the stay-at-home orders have had on our journal authors by analyzing our monthly submission data. We focused specifically on gender, age, and geographical region of individuals submitting manuscripts (“corresponding author”). We found that there have been no statistically significant monthly fluctuations in the number of women across all age groups submitting articles in 2020 and compared to their monthly submissions of 2018 and 2019. We did see some decrease in submissions in February from certain countries but as of May 2020, most countries have returned to their normal submission rates. We do see that submissions of revised manuscripts, which may require access to physical spaces and/or equipment and collaboration with co-authors, decreased among both male and female corresponding authors from February through April. The relative stability of new submissions from various groups may indicate a few things: 1) that stay-at-home orders may afford some more time to submit an article while others less, 2) article submission itself is a relatively simple and straightforward task if the research, analysis, and writing is complete, and 3) we may see decreased submissions later in the year or next year if there is a sustained lack of access to research subjects/materials and analytical tools.

[P-PS01] Outer Solar System Exploration Today, and Tomorrow

convener:Jun Kimura(Osaka University), Kunio M. Sayanagi(Hampton University), Fuminori Tsuchiya(Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University), Steven Douglas Vance(NASA Jet Propulsion Laboratory, California Institute of Technology)

The giant planets provide many keys to understanding planetary processes. They play an important role in shaping our solar system, and the physical and chemical processes they harbor also provide a unique opportunity to study the phenomena relevant for studying Earth and other planets, including exoplanetary systems. In this session, we discuss a wide range of topics encompassing the giant planets and their moons, including their origins, interiors, atmospheres, compositions, surface features, and electromagnetic fields. To advocate for current and future outer planets exploration (Juno, New Horizons, JUICE, Europa Clipper, Dragonfly and beyond), we also call for discussions on future missions to explore giant planet systems, including how to develop better international cooperation. Discussion in this latter category will include progress in developing a solar sail mission concept for observing the Jupiter system and its trojan asteroids.

Pluto's surface albedo distribution and its evolution due to sublimation and condensation of ices

Hisashi Matsui[1], *Jun Kimura[1]

1. Osaka University

Flyby Observations of NASA's New Horizons spacecraft of Pluto in 2015 revealed that H_2O, N_2, CH_4, CO ices coexist on the surface of Pluto and that the surface has a strong difference of reflectivity in lalitudes, middle and high latitudes are bright and low latitudes are dark, which strongly suggests a different amount of ice. However, an origin of such bright and dark color distribution on the surface is still unclear. In previous researches about a temporal changing of albedo on the Jovian and Saturnian moons, it has been shown that sublimation of H_2O ice due to an insolation affects albedo changing on their surfaces. On Pluto, condensation of ice in the atmosphere also should affect Pluto's surface albedo because Pluto has an atmosphere with surface pressure of approximately 1 Pa. In this study, we model relationship between ice behavior such as sublimation and condensation and change of albedo, and consider quantitatively about N_2 and CH_4 that is main components of atmosphere with a numerical simulation for the purpose of investigating the origin of the albedo variation on Pluto.
In our model, we assume an initial surface state that bright ice and dark non-ice material exist uniformly mixed in depth by micrometeorite bombardment and that surface has uniform albedo which can be modeled by the volume ratio between ice and non-ice materials. Subsequently, entire surface of Pluto is divided into 12 latitudinal bands by 15 degrees, and we calculate the surface temperature with thermal inertia according to a change of insolation on each latitude considering orbit, rotation cycle and precession. When the temperature exceeds the sublimation point which depends on the surface atmospheric pressure, the ice sublimes and the non-ice material remain on the surface. Sublimed ice exists as the atmospheric gas, and the gas can be condensed on the surface when the temperature of atmosphere falls below the condensation point. Moreover, we calculate a cycle that time variation of the volume ratio of ice and non-ice material due to sublimation and condensation changes albedo, and nally we examine temporal change of the Pluto's surface albedo over millions of years.
As a result, we nd that insolation varies greatly for each latitude and seasons because Pluto has the large inclination of the obliquity, and thus sublimation and condensation amount of ice change greatly for each latitude and seasons. Amount of N_2 atmosphere formed by sublimation is consistent with observation, and this suggests that Pluto has a large N_2 circulation between surface and atmosphere. In addition, we nd a possibility to reach the overall trend of the albedo on current Pluto from initial globally uniform surface albedo through this process. Also, because the changes of albedo distribution depending on the thermal inertia and initial albedo, there is a possibility that thermal inertia depending on porosity and initial albedo affects albedo distribution on current Pluto.

A low-energy energetic neutral atom analyzer (PEP/JNA) for JUICE mission

*Kazushi Asamura[1], Manabu Shimoyama[2], Yoshifumi Futaana[2], Yoshizumi Miyoshi[3], Takeshi Sakanoi[4], Yoshifumi Saito[1]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. Swedish Institute of Space Physics, 3. Nagoya University, 4. Tohoku University

We are developping a low-energy (10eV-3keV) energetic neutral atom analyser (PEP/JNA) which is to be onboard European JUICE spacecraft. Ganymede has its own intrinsic magnetic moment. There is considered to be a magnetosphere around Ganymede because of interactions between plasma in the Jovian magnetosphere and Ganmede's magnetic field. However, its characteristics is different from the terrstrical one, since Alfven mach number of upstream plasma flow (corotational plasma flow around Jupiter) is less than 1 (sub-sonic). JNA (Jovian Neutral Analyzer) will reveal characteristics of the Ganymede's magnetosphere by measurement of scattered and sputtered particles generated by precipitation of plasma particles onto Ganymede's surface. Measurement of these particles will provide spatial distribution of plasmas in remote sense, since electric/magnetic field do not affect trajectories of neutral particles. For the instrument development, the flight model is under development. We will discuss current status of JNA.

The Ganymede Laser Altimeter (GALA) for the JUICE mission –overview and current status

*Enya Keigo[1], Masanori Kobayashi[2], Jun Kimura[3], Noriyuki Namiki[4], Hiroshi Araki[4], Hirotomo Noda[4], Shoko Oshigami[1], Shingo Kashima[4], Shin Utsunomiya[4], Ko Ishibashi[2], Masanobu Ozaki[1], Takahide Mizuno[1], Yoshifumi Saito[1], Kazuyuki Touhara[1], Shunichi Kamata[5], Koji Matsumoto[4], Kiyoshi Kuramoto[5], Sho Sasaki[3], Satoru Iwamura[6], Yoshiaki Matsumoto[7], Masayuki Fujii[8], Naofumi Fujishiro[9], Yuki Sato[10], Takeshi Yokozawa[10], Tsutomu Numata[10], Satoko mizumoto[10], Hiroyuki Mizuno[10], Akihiko Sawamura[10], Kazuo Tanimoto[10], Hisato Imai[11], Hiroyuki Nakagawa[11], Okiharu Kirino[11], Hussmann Hauke[12], Kay Lingenauber[12], Reinald Kallenbach[12], Christian Althaus[12], Simone DelTogno[12], Thomas Behnke[12], Christian Huettig [12]

1. ISAS, 2. CIT, 3. Osaka Univ., 4. NAOJ, 5. Hokkaido Univ., 6. MRJ, 7. PTIJ, 8. FAM Science, 9. Astro-Opt, 10. Meisei Electric, 11. Cristal Optics, 12. DLR

We present an introduction, current status, and role of the Japan team for the Ganymede Laser Altimeter (GALA) for the Jupiter Icy Moon Explorer (JUICE) mission. JUICE is a mission of ESA to be launched in 2022, and GALA is one of the payloads of JUICE.

Major objectives of GALA are to provide topographic data of Ganymede, the largest satellite of Jupiter, and to measure its tidal amplitudes. The latter is crucially important to detect and to characterize an underground ocean on Ganymede. Furthermore, GALA supports geological studies, e.g., identification of characterization of tectonic and cryo-volcanic regions, impact basins, and craters. GALA also provides information on surface roughness and the albedo.

For the laser altimetry, GALA emits and receives laser pulses at about 500 km altitude above Ganymede. Wavelength, energy, and repetition frequency of the laser plus are 1064 nm, 17 mJ, and 30 Hz, respectively. Reflected beam from the Ganymede surface is received by the receiver telescope with 25 cm diameter aperture, re-focused by the BEO including a narrow band-pass filter, and then detected by the APD detector.

Development of GALA is carried out in international collaboration by Germany, Japan, Switzerland, and Spain. GALA-Japan will develop the Backend Optics (BEO), the Focal Plane assembly (FPA) including an avalanche photo-diode (APD) detector, and the Analog Electronics module (AEM) in the receiver chain.

Tidally heated convection and the occurrence of melting in icy satellites: application to Europa

*Kenny Vilella[1], Gael Choblet[2], Wei-En Tsao[3], Frederic Deschamps[3]

1. Hokkaido University, 2. LPG Nantes, 3. Institute of Earth Sciences, Academia Sinica

Observations of icy satellites have revealed widespread marks of cryovolcanism. Because aqueous cryomagmas are negatively buoyant, two processes are required to explain these observations: one mechanism to generate melt close enough to the surface, and another one to transport this melt to the surface. Here, we investigate the generation of melting in a systematic way, using a set of 85 numerical simulations where we vary the viscosity contrast, Rayleigh number, and tidal heating rate. Applied to Europa, and considering a hydrosphere composed of pure water, our simulations suggest that isolated melt pockets can be generated close to the surface (≈5 km) as long as the ice layer thickness (d*) remains modest (15<d*<35 km). However, the generation of melting becomes increasingly difficult as the amount of anti-freeze compounds in the subsurface ocean increases. Furthermore, the proportion of melting increases very sharply with increasing tidal heating rate. In particular, when the tidal heating rate exceeds a threshold, an asymptotic regime is reached where the surface heat flux remains constant, i.e., the tidal heat generated above this threshold is only used for melting the ice shell. In that regime, we found a direct relationship between the surface heat flux and d*. Finally, we provide a new assessment of Europa's thermal state. Using available constraints, we propose that the ice shell thickness should exceed 25 km. However, d*≈25-35 km implies a tidal power (>3 TW) much larger than expected. An extrapolation of the trends suggested by our results indicates that a more reasonable tidal power (<1 TW) would involve d*≈ 80-100 km.

Measurements of Saturn's Zonal Wind from Voyager Images using Modern Cloud-Tracking Method

*Justin Garland[1], Kunio M. Sayanagi[1], Jacob L. Gunnarson[1], John J. Blalock[2,1]

1. Hampton University, 2. USGS Astrogeology Science Center

We present preliminary analysis of Saturn images captured by the Voyager mission investigating how the planet’s zonal wind speeds have evolved in time between 1980 and the Cassini era. Global zonal wind as a function of latitude during the Voyager flybys have been retrieved by previous studies; notably Sanchez-Lavega et al. 2000's measurements have been treated as the standard wind profile of Saturn. However, they employed manual tracking methods that returned only 2075 wind vectors, while newer analyses of Cassini data employ automated digital tracking algorithms. No study has systematically analyzed the wind speeds during the Voyager flybys and the Cassini era using a consistent method. We aim to make new wind measurements by first improving the navigation of the images of Saturn captured by the Voyager spacecraft’s Imaging Science Subsystem (ISS) camera, and then applying an automated 2D Correlation Imaging Velocimetry (CIV) technique. We also analyze Cassini Imaging Science Subsystem (Cassini ISS) images using the same methodology. This provides a long-baseline (more than a Saturnian year) analysis of global zonal winds over time for the planet. I hypothesize that new measurements of Saturn’s equatorial wind will address the longstanding discrepancy between results from Voyager and those from later observations. Sanchez-Lavega et al. 2000 reports a wind speed of approximately double that found by later studies using Hubble and Cassini. I expect that analyzing the Voyager datasets with modern, automated methods will help us better constrain previously published trends in wind profiles retrieved for the planet. I also aim to provide a stronger baseline Voyager wind profile for future studies than what is currently available in the literature.

Inhibition of moist convection in the atmospheres of Jovian planets: the case of NH4SH formation by chemical reaction of NH3 and H2S

*Ko-ichiro SUGIYAMA[1], Kensuke Nakajima[2], Kiyoshi Kuramoto[3], Yoshi-Yuki Hayashi[4]

1. National Institute of Technology, Matsue College, 2. Kyushu University, 3. Hokkaido University, 4. Kobe University

In the atmospheres of Jovian planets, condensation of heavy components, such as H2O, NH3, CH4, is thought to suppress vertical convection (Guillot, 1995). In addition to these clouds resulting from condensation of the above components, the formation of NH4SH by chemical reaction of NH3 and H2S is predicted as the important cloud formation processes. Because the chemical process consumes the components heavier than the lighter major components as condensation process does, it can be anticipated that the formation of NH4SH can also suppress convection. However, the degree of possible suppression, or whether it can inhibit convection, have not investigated yet.

Here we investigate the criterion of convection inhibition associated with the formation of NH4SH in thermochemical equilibrium framework. With the convection inhibition criteria obtained in the investigation, we also examine the structure of convection in parameters where convection inhibition by NH4SH formation is thought to emerge using cloud convection model (Sugiyama et al 2009; 2011; 2014).

Detectability of water plumes on icy moons with Earth-orbiting UV telescope

*Ryoichi Koga[1], Fuminori Tsuchiya[1], Go Murakami[3], Kazuo Yoshioka[2], Masato Kagitani[1], Tomoki Kimura[1], Atsushi Yamazaki[3], Ichiro Yoshikawa[2], Hajime Kita[3], Masaki Kuwabara[3]

1. Tohoku University, 2. The University of Tokyo, 3. JAXA/ISAS

In this study, we consider the mirror size of UV space telescope, which can detect OI and HI emissions emitted from plumes on icy moons. Hubble Space Telescope (HST) observed the enhancement of HI 121.6 nm and OI 130.4 nm emissions near the Europa South Pole (Roth et al., 2014). They considered the electron impact of H_2O in the plume yields HI and OI emissions. However, geological conditions of emitting gasses form Europa plumes are not known.

The EXCEED (Extreme Ultraviolet Spectroscope for Exospheric Dynamics) spectrometer onboard the Hisaki satellite has conducted long term monitoring of ultraviolet emissions (52.0-148.0 nm) from the Io plasma torus and Jupiter’s aurora since 2013. We also observed OI 130.4 nm around Jupiter moon Io’s orbit, and analyzed spatial distribution and temporal variations of oxygen atoms in Io torus. However, the spatial resolution of Hisaki/EXCEED is too rough (~17”) to resolve Io and Icy moon’s disk (for example, Europa’s diameter is ~1.0”). One of the main goal of post Hisaki UV satellite is to observe icy moon’s atmosphere continuously with high resolution and confine conditions under which plume eruptions occur.

We calculated the OI 130.4 nm and HI 121.6 nm counts of Europa plume (signal) and atmosphere, solar reflection, geocorona and interplanetary medium (noise), and estimated the mirror diameters, which can meet the demand that the signal to noise ratio is over 3 with integration time of 10 hours and spatial resolution of ~0.2 arcsec. Requested mirror diameters are ~140 cm when the altitude of the satellite is 1000 km, and ~100 cm when the altitude is 30,000 km.

Development of a radial diffusion model of Jovian inner magnetospheric plasma transportation for a comparison with HISAKI data

*Kazuki Yamaguchi[1], Takeshi Sakanoi[1], Fuminori Tsuchiya[1], Masato Kagitani[1], Tomoki Kimura[2], Ryoichi Koga[1], Reina Hikida[3]

1. Tohoku university, 2. Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, 3. Department of Earth and Planetary Science, Graduate School of Science, Tokyo University

We developed a time-dependent radial diffusion model to calculate chemical reactions and radial transport of ions and electron in the Jovian inner magnetosphere. We compared the model results with HISAKI observation, and found that the neutral source rate from Io to the magnetosphere is 5.0×10^{-4} ($/m^3/s$), the oxygen-sulfur ratio is 2.0, and the radial diffusion coefficient is 4.2×10^{-8} ($/R_J^2/s$) near Io.
Jovian first satellite Io has active volcanoes and releases the plasma of the volcanic gas origin to the magnetosphere. The 90% of total mass of the plasma is mainly supplied from Io (Hill, Dessler, and Goertz, 1983). The plasmas co-rotate with Jupiter and distribute in a donut shape called Io Plasma Torus (IPT). The plasma diffuses outward on the time scale of several tens of days while obtaining the rotation angular momentum of Jupiter. Revealing the mass and energy balance of plasmas is an important subject to understand the macroscopic physical phenomena in the Jovian inner magnetosphere. The radial distribution of Jovian magnetospheric plasma has been examined based on steady state models and observations of Voyage 1, 2 and Cassini spacecraft. However, the time dependent model and comparison of the model with continuous observations have not been reported yet.
The purpose of this study is to develop a model that has a capability to track the time variation of the radial plasma distribution and compare it with HISAKI observation.
In the model, we track mass and energy balances of major heavy ions of Io origin (O^+-O^{3+} and S^+-S^{4+}). The equation system is based on the mass and energy transport model of steady state magnetospheric plasma developed by Delamere et al. (2005). The time evolution of radial transport was solved with the Fokker-Planck equation and we used FTCS method for numerical computation. The radial diffusion coefficient is expressed as $D_{LL}=D_0(L/L_0)^m$, where L is the L-value, $L_0=5.9$, and D_0 is a free parameter of the model. We set a radial grid size (dL) as a function of exponentials of the radial distance so that radial dependence of the Courant number ($2D_{LL}dt/dL^2$, dt is a time step) becomes weak. For the inner and outer boundary conditions, we set the radial gradient of the density and temperature to 0 at the Io's orbit (5.9 R_J), and fixed them with extrapolated values of HISAKI observation at 30 R_J. We considered several chemical interactions: charge exchange, electron impact ionization, electron recombination, Coulomb interaction and radiation due to electron collision excitation based on Delamere & Bagenal (2003). Radiative and recombination rates are calculated from the CHIANTI atomic database. The initial values of temperature and density of each ions and thermal electrons were given from the HISAKI observations in November 2013 when Io's volcanic activity was quiet (Yoshioka et al. 2018). The density of neutral atoms (O, S) were also given by HISAKI observation (Koga et al. 2018b) as initial values, and their total source rates and the source composition ratio (O/S) are free parameters.
In order to verify the validity of the model, the steady state temperature and density of ions and electrons in the region of 6-10 R_J were compared with the HISAKI observation. We found that highly ionized ions have low density, and temperature of ions is almost stable around 100 eV except S^+ which has 200 eV. We obtained the parameters that best matched with HISAKI observation. As a result, the O/S is 2.0, the neutral source rate is 5.0×10^{-4} ($/m^3/s$), and D_{LL} is estimated to be 4.2×10^{-8} ($/R_J^2/s$) near Io. The source

characteristic is consistent with the main atmospheric composition of Io (SO_2) and DLL is found within a range of previous estimations. As a future work, we aim at quantitative verification by comparing with D_{LL} based on a numerical analysis.
In this presentation, we'll show the correspondence between the quantitative inspection results of each parameter and the observation results of HISAKI.

Light Curve of Jupiter's UV Aurora and Io Plasma Torus after 2016 Obtained from Hisaki EXCEED

*Hajime Kita[1], Tomoki Kimura[2], Fuminori Tsuchiya[2], Go Murakami[1], Atsushi Yamazaki[1], Ryoichi Koga[2], Reina Hikida[3], Kazuo Yoshioka[3], Ichiro Yoshikawa[3]

Hisaki is an Earth-orbiting satellite launched in 2013. The purpose of this mission is to observe UV emission from planetary atmospheres and magnetospheres by the spectrometer EXCEED (Extreme Ultraviolet Spectroscope for Exospheric Dynamics). Hisaki EXCEED began its monitoring of the Jovian system in December 2013 with a 140 arcsec −20 arcsec dumbbell slit which is designed to observe the Io plasma torus and Jovian aurora simultaneously. Hisaki EXCEED can continuously observe the Jovian system along the 106 min orbit for several months, which is a feature never available for large facilities such as Hubble Space Telescope.

The guide camera of Hisaki broke down around mid-2016. From 2016 to 2017, we tried to observe the aurora and torus simultaneously without the guide camera. The location of Jupiter was set to in the narrow slit region, however, sometimes aurora moved away from the narrow slit region. Therefore, we use two observing modes, “torus mode” and “aurora mode” since 2017. The Jovian disk is located in the wide-slit region for the aurora mode. Both north and south auroras are observed, and only one side of the torus can be seen. For the torus mode, we set the location of Jupiter to the narrow slit region, and the torus fit within the wide-slit region. We made a light curve of the aurora and torus over 900-1480A and 650-780A, respectively.
Although the light curves obtained after 2016 are missing some parts, we compare the light curves with HST and ground-based observation. A large HST campaign has been made since the arrival of Juno, and aurora brightenings were observed by both Hisaki and HST. The torus light curve shows minor enhancement of volcanic activity around the end of 2017, which is roughly consistent with the sodium observation. Therefore, we successfully corrected Jupiter’s position and the obtained aurora and torus light curve are consistent with other observations.

Laboratory demonstration of cryogenic-specific reddish coloration with cryoplasma

*Noritaka Sakakibara[1], Yu Yu Phua[1], Tsuyohito Ito[1], Kazuo Terashima[1]

1. The University of Tokyo

Reddish coloration and color diversity among icy bodies in the outer solar system are one of the important characteristics for understanding the environment and history of the solar system. Ultra-red objects only occur far from the Sun such as some Trans-Neptunian objects and Centaurs, whereas the reddish coloration is absent among cometary nuclei and dead comets closer to the Sun lack (Luu & Jewitt 1996; Sheppard 2010). The reddish color has been attributed to refractory tholin-type materials (Cruikshank et al. 2005). However, because the tholin-type materials are very stable even when warmed to room temperature, the origin of color distribution in the cryogenic world remains debatable (Dalle Ore et al. 2011). In this presentation, we will provide experimental demonstration of reddish coloration that is stable only at cryogenic temperatures.

The reddish coloration was produced on methanol- and water-containing ice irradiated with 3% nitrogen-containing helium cryoplasma at 85 K. Cryoplasma is non-equilibrium plasma source whose gas temperature can be controlled continuously at wide range of cryogenic temperatures below room temperature (Stauss et al. 2018), which enables coexistence of plasma with ice without melting (Sakakirbara & Terashima 2017; Sakakibara et al. 2019). The reddish color faded and disappeared at 120–150 K as the ice was heated. This behavior is distinct from well-known refractory organic tholins that are stable even when heated to room temperature. By temperature programmed desorption analysis and LC-MS/MS analysis of the residue at room temperature, the reddish material was suggested to be nitrogen-containing organic compounds.

The temperature dependence of reddish coloration under cryogenic conditions could add on a new explanation for the absence of ultra-red coloration closer to the Sun in the outer solar system; the cryogenic-specific reddish materials sublimate or convert to other colorless compounds at higher cryogenic temperatures, as an icy body travels from the Trans-Neptunian region to the inner solar system. Our result implies that a reddish material specific to cryogenic environments might be a promising clue for the investigation of color diversity and formation mechanism of the outer solar system. Moreover, cryoplasma was expected as a novel modern technology for accelerating the investigation of chemistry and materials science in cryogenic space environments including the outer solar system.

[P-PS02] Lunar Science and Exploration

convener:Masaki N Nishino(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science), Masahiro KAYAMA(Department of General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo), Hiroshi Nagaoka(Japan Aerospace Exploration Agency), Yusuke Nakauchi(Japan Aerospace Exploration Agency)

Scientific data sets acquired by Japanese lunar mission SELENE (Kaguya) have become the standard of the lunar sciences. Other missions such as Chandrayaan-1, LRO, GRAIL, LCROSS, LADEE, Artemis, and Chang'e series as well as ground observations are also providing new knowledges of the Moon. Apollo/Luna samples and lunar meteorite analyses are also being advanced. In concurrence with these studies, some countries including Japan are planning near-future lunar missions. In this session, we will discuss scientific results based on newly acquired lunar data, strategies for future missions, lunar sample analyses, and theoretical and experimental studies of lunar sciences.

Cause of boulder falls near a lobate scarp on the Moon: source estimate based on the attenuation relation of peak ground accelerations

*Ayame Ikeda[1], Hiroyuki Kumagai[1], Tomokatsu Morota[2]

1. Graduate School of Environmental Studies, Nagoya University, 2. Department of Earth and Planetary Science, The University of Tokyo

High-resolution images obtained by the Lunar Reconnaissance Orbiter Camera (LROC) show that lobate scarps were widely distributed on the whole Moon [Watters et al., 2010; 2015]. Kumar et al. [2016] suggested that boulder falls, that produced boulder trails on crater wall, might be triggered by moonquakes in the lobate scarps. However, they did not quantitatively estimate the magnitude of the moonquake and the relationship with landslide areas. In this study, to examine whether or not boulders falls were triggered by moonquakes in nearby lobate scarps, we evaluated the moonquake magnitude required for boulder falls on inner ring the Schrödinger Basin. We identified boulder trails using LROC images and measured the entire area of source region of boulder falls. The empirical relationship between the landslide area and the maximum acceleration of large-scale earthquakes ($M > 5$) on the Earth is approximated by a power-law [Tiwari and Ajmera, 2017]. We derived the relationship between the landslide area and the maximum acceleration under the lunar gravitational acceleration from the relationship for earthquakes. Based on the relationship, the maximum acceleration for moonquake was calculated from the surface area of source region of boulder falls. We used the attenuation equation for seismic wave [Kanno et al., 2006] to estimate the magnitude of the moonquake from the maximum acceleration. Since estimated land slide area was small, we extrapolated both the landslide relationship and the attenuation equation to apply to the Moon. Based on an assumption of the epicenter on the lobate scarp, the magnitude of the moonquake generating the boulder falls was estimated to be about 2, comparable to that for shallow moonquakes observed by Apollo’s seismometer. This result is compatible to the interpretation that the boulders falls were due to the moonquake along the lobate scarp.

The lunar tidal dissipation energy by the Earth-moon tide

*Ryuichiro Tanaka[1], Satoshi Kaneshima[2]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University

It is assumed that the magnetic field with the dynamo existed about 4 billion years ago in the moon. It seems that the tidal power is related to this. The moon is being distorted into an oval form by the tidal power, and besides, heating occurs in the lunar inside. The tidal power becomes strong so that the distance from the Earth to the moon is near. Because the distance was nearer than the present in the past, it is assumed that the tidal power is related to the lunar dynamo. In addition, it seems that there is a low viscosity layer in the mantle bottom of the moon from seismic wave observation. Heating by the tidal power grows big in such a layer and may affect the lunar core. In this study, I calculated the lunar tidal dissipation energy and examined the influence that the low viscosity layer gives around.

When the lunar tidal quality factor is 100, I calculated the tidal dissipation energy. I could get the result that the dissipation in the low viscosity layer accounted for 99% of the whole.

The heterogeneity of lunar plasma environment and its influences on lunar surface hydration

*Huizi Wang[1], Jiang Zhang[1], Quanqi Shi[1,2], Yoshifumi Saito[3], Ying Ye[1]

1. Shandong Key Laboratory of Optical Astronomy and Solar-Terrestrial Environment, School of Space Science and Physics, Institute of Space Sciences, Shandong University, Weihai, Shandong, China., 2. State Key Laboratory of Space Weather, National Space Science Center (NSSC), Chinese Academy of Sciences, Beijing, China, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Sagamihara, Japan.

The evidences for lunar water (e.g., polar ice and OH^-/H_2O) have been discovered in recent lunar missions. The dynamic lunar hydration/dehydration cycle over a lunar day and the suppression of lunar water within lunar magnetic anomalies indicated that solar wind proton should be an important source of lunar surface water. However, the Moon passes through its surrounding plasma environment comprised of solar wind, magnetosheath, and magnetotail. Therefore, the dependence of lunar water content on plasma parameter remains further deep investigations. In this study, we try to find the relevance between the variability of lunar water and lunar plasma environment based on the observations from the Kaguya MAP-PACE and Chandrayaan-1 M^3 spectrometer. We first study lunar hydration inside/outside the magnetosphere using the M^3 spectral data, from which it is unexpectedly found that the polar surficial OH/H_2O abundance remains the same level when in the solar wind and in the magnetosphere. We suggest that the particles from the magnetosphere (Earth wind, naturally different from solar wind) contribute to lunar hydration. And then we studied lunar hydration inside/outside the plasma sheet, in which the proton has a broad velocity distribution with a wide thermal spread. A case study shows that the water content at the same region on the Moon is different when in the plasma sheet and in the lobe of Earth’s magnetotail. Nevertheless, more work is needed to understand the physical mechanism.

Phase boundary and kinetics of moganite-coesite phase transition at high-pressure and high-temperature: implications for an impact event and trace of water on the Moon

*Shin Ozawa[1], Masahiro KAYAMA[1,2], Tatsuya Sakamaki[1], Tomonori Ohashi[1], Akio Suzuki[1]

1. Department of Earth Science, Graduate School of Science, Tohoku University, 2. Department of General Systems Studies, Graduate School of Arts and Sciences, The University of Tokyo

Moganite is a monoclinic SiO_2 mineral that forms by precipitation from alkaline fluid under high-pressure condition. Recently, moganite was first discovered in a lunar meteorite NWA 2727, supporting water activity on the surface of the Moon (Kayama et al., 2018). Moganite in NWA 2727 always coexists with coesite, a high-pressure polymorph of SiO_2. This fact suggests that a heavy impact event occurred on the host site of NWA 2727 on the Moon, resulting in high-pressure phase transition of moganite to coesite. On the other hand, other silica polymorphs such as quartz, tridymite and cristobalite in NWA 2727 have not been transformed into coesite. Although moganite seems to change into coesite more easily than other silica polymorphs, the phase boundary and kinetics of the moganite-coesite phase transition remain unknown. In this study, we performed high-pressure and high-temperature experiments on terrestrial moganite up to 8 GPa and 500 ˚C to determine the phase boundary and kinetics of the moganite-coesite phase transition.

In all experiments, natural terrestrial moganite (Gran Canaria, Spain) and synthetic quartz powders were loaded separately in two different sample rooms in a high-pressure cell and kept at the same pressure and temperature conditions. The samples were first compressed to the target press load at ambient temperature and then heated to the target temperature. The high-pressure and -temperature experiments and X-ray diffraction (XRD) measurements were conducted at the beamline AR-NE5C of the Photon Factory at the High Energy Accelerator Research Organization (KEK).

As a result of time-resolved XRD analysis, it was revealed that moganite transformed into coesite more rapidly than quartz under the conditions of ~5 GPa and 425 ˚C and ~8 GPa and 250 ˚C. The different kinetics between moganite and quartz would be due to a similar crystal structure between moganite and coesite with a common four-membered rings structure (Murashov and Svishchev 1998) and/or relatively high water content of moganite (1-5 wt% in general) compared with quartz, both of which reduce the activation energy of the phase transition from moganite into coesite. Our result demonstrated that the different phase transition kinetics of silica polymorphs to coesite can explain the contrasting coexistence relationship of silica minerals in NWA 2727: in a short duration of an impact event, only moganite was able to transform into coesite with a relatively high phase transition speed. In addition, this fact revealed here supports the possibility that moganite in NWA 2727 is indigenous to the Moon.

Evaluating the thickness and stratigraphy of ejecta materials at the Chang'e-4 landing site

*Luyuan Xu[1], Xunyu Zhang[1], Le Qiao[2]

1. State Key Laboratory of Lunar and Planetary Sciences, Macau University of Science and Technology, 2. Shandong Provincial Key Laboratory of Optical Astronomy and Solar-Terrestrial Environment, Shandong University, Weihai

On 3rd January 2019, China's Chang'e-4 (CE-4) lunar probe successfully landed on the Von Kármán crater on lunar far-side and deployed Yutu-2 rover. The Von Kármán crater is located in the highly-cratered terrain within the South Pole-Aitken (SPA), indicating the CE-4 landing site has experienced complex emplacement sequences of both near and distant ejecta materials. This complicates the interpretation of CE-4 surface *in-situ* measurements of the Visible and Near Infrared Spectrometer (VNIS) and Lunar Penetrating Radar (LPR) onboard Yutu-2 rover. In order to evaluate the sources and amounts of all considerable (> 10 cm in thickness) ejecta materials on the landing site of Chang'e-4, we thoroughly examine the ejecta delivered by all crater-forming events possibly occurred later than the formation of mare unit within Von Kármán crater in this study. We find a total of 20 craters throughout the Moon may deliver unneglectable ejecta (> 10 cm in thickness) superposed on the mare units of the landing site of Chang'e-4 and confirm that the ejecta from Finsen crater is the most dominant foreign materials, followed by the ejecta of Von Kármán L.

Keywords: Moon, Chang'e-4, impact ejecta

An explaination of the origin of Davy Crater Chain on the Moon other than impacts of fragments comprising a comet

Akiya Saito[1,2], *Junichi Haruyama[1], Wataru Miyake[2]

1. Japan Aerospace Exploration Agency, 2. Tokay University

The Lunar Davy crater chain (located at 11.0 ˚S , 6.3 ˚W on the Moon) is a line of about 20 craters, the averaged diameter of which is about a few km, and extends over a length of 45 km.
The origin of the formation of the Davy crater chain have not been clarified. One explanation is the collision of ejectors from a primary crater that should exist in the direction of the chain, Another one is those of the split nuclei of a comet. In both cases,however,difficulties have been pointed out.
We have studied it with high resolution ortho-image data and elevation data (Digital terrain model, DTM) obtained by the Terrain Camera onboard Japanese lunar orbiter SELENE and large area image data from LRO WAC, and found that the Davy crater chain is a group of young craters and forms an arc. We, furthermore,investigated the central direction of the arc of the Davy crater chain, and identified a young crater Lalande (4.4 ˚S, 8.6 ˚W) with about 22 km in diameter at 210 km north-northwest from the Davy crater chain.
We deduced relations for the physical parameters between a primary crater and its secondary craters and applied it to Crater Lalande and Davy crater chain for (1) the ratio of total mass released from the primary crater to mass per an ejector vs. the primary crater diameter, (2) the average of secondary crater diameters and the distance between the primary crater and (3) the secondary craters.between a primary crater and its secondary crater. The results were harmonious with the relations between other previously identified primary-secondary craters on the Moon.
We conclude that the Davy crater chain is a group of secondary craters forming an arc shape prospective from the Crater Lalande.
Furthermore, we found that Catena Aburfeda, also forming an arc, is a group of secondary craters from Crater Tycho, too.

UZUME: A Lunar Lava Tube Exploration of Japan

*Junichi Haruyama[1]

1. Japan Aerospace Exploration Agency

In this century, huge vertical holes with a diameter and depth of several tens of meters have been discovered on the Moon by the Japanese lunar explorer SELENE (Kaguya). From the US Lunar Reconnaissance Orbiter (LRO) high-resolution images revealed that the floors of the holes are not bowl-shaped like a normal craters.
It is reasonable to think that such a vertical hole formed when a meteorite collided with an underground space such as a lava tube. In fact, data from oblique observations by LRO showed that there are deep spaces at the bottom of the vertical holes. In addition, in the US gravity field observation satellite GRAIL data, large mass deficits were found along a rille (lava river) in the Marius Hills, at the middle of which a vertical hole exists. In addition, along the rille, specific underground echoes implying the existence of a lava tube were also identified in SELENE Lunar Radar Sounder data. The existence of lava tubes on the Moon becomes more certain.
Lava tubes will be effective shelters from meteorites and radiation on the Moon, making them the best lunar base construction sites. Exploration of lava tubes is therefore the most important topic of international space exploration programs. In the third edition of the Global Exploration Roadmap (GER) submitted by the International Space Exploration Coordination Group (ISECG), which aims to create an international space exploration framework led by national space agencies.
On the other hand, exploration of the lava tube on the moon provides various scientifically important information. We are examining a plan to explore lunar vertical holes and associated lava tubes, with naming it as "UZUME"(Unprecedented Zipangu Underworld of the Moon Exploration).
In this presentation, we will explain how the UZUME will contribute on planetary science, the main purposes of it are
(1) Increasing knowledge about how habitable regions that nurtured life formed, evolved and maintained and then life was born in the past,
(2) Increasing knowledge of the universe which is necessary for us humans to expand our habitable regions from the Earth to the space.

On magnetic field observation in and near a lunar pit for understanding magnetic history of the Moon

*Hisayoshi Shimizu[1]

1. Earthquake Research Institute, University of Tokyo

History of the Moon and lunar dynamo can be discussed using quantities related with magnetization near the lunar surface. For example, paleointensity studies of lunar rock samples showed that the Moon likely possessed strong intrinsic magnetic field until 3.56 Ga, and probably had weaker magnetic field up to around 1 Ga. Also, directions of isolated magnetizations estimated from magnetic field observations by Lunar Prospector and SELENE-Kaguya show possibility of reorientation of lunar pole in the past. However, it is not well understood what was the energy source to drive the lunar dynamo during the period, and also when the dynamo stopped generating the magnetic field.

Magnetic field observation at the lunar surface by Apollo project revealed existence of local-scale magnetic anomalies which cannot be detected by satellite magnetic field observations. The local-scale magnetic anomalies are likely due to the magnetization close to the surface of the Moon. Since this magnetization also contain information of the magnetic field at the time when the part of the crust was magnetized, it is worth pursuing further information of the magnetization by in-situ magnetic field observations.

A lunar pit can be a suitable place for magnetic field observation to estimate magnetization very close to the lunar surface. A reason is that a pit is a place where large magnetic field signal due to magnetization is expected, because it introduces inhomogeneity to the crustal magnetization. In addition, layered magnetization, which is caused by variation of lunar magnetic field, may be obtained by magnetic field observations along the pit wall.
A feasibility study on the use of magnetic field observation in and around a lunar pit to estimate local crustal magnetization was conducted. In this presentation, requirement to prove the magnetization and favorable configuration of observation are discussed by supposing location and size of the lunar pit.

Radiation dose and protection by a lunar hole and lava tube

*Masayuki Naito[1], Nobuyuki Hasebe[2], Satoshi Kodaira[1], Yoshiharu Amano[2], Junichi Haruyama[3]

1. National Institutes for Quantum and Radiological Scinence and Technology, 2. Waseda University, 3. JAXA

The lunar surface is directly exposed to high energetic particles such as Galactic Cosmic Ray (GCR) particles and Solar Energetic Particles (SEPs), which are shielded by thick atmosphere and geomagnetic field on the Earth. Long term manned missions to the Moon, Mars or deep space will occur more severe radiation exposure than that we have experienced, which may result serious health hazards of space crews. Then, strategic radiation protection is mandatory to guarantee health of crews by relieving radiation dose.

The Moon is the closest celestial body to the Earth and expected as a next body developed by humans in near future. Recently, cameras on SELENE have discovered vertical holes on the lunar surface, at Marius Hills, Mare Tranquillitatis and Mare Ingenii. It is considered that such lunar vertical holes are formed by meteorite impacts collapsing the roof on lava tubes. Therefore, entrances of lava tubes may open at the bottom of the vertical holes. Radar observation suggests a possible lava tube exists about 100m in depth at a subsurface near a vertical hole at Marius Hills. Vertical holes associating lava tubes reduce radiation dose of cosmic ray particles coming from the zenith. In this work, the radiation dose at the lunar surface was numerically evaluated, and its reduction in the lunar vertical hole was estimated. The GCR particles in solar minimum and maximum phases and large SEP events, called ground level enhancement (GLE) events observed on the Earth, are assumed as primary events.

The effective dose equivalent due to GCR particles reached up to 267.8 mSv/y in solar minimum phase, and that due to a GLE event observed at Jul. 2000 was 509 mSv/event at the lunar surface. It was found that the contribution of secondary particles to the total radiation dose was ~8% at most. This fact implies that the elemental composition of lunar surface, whether mare region or highland region for example, does not make any considerable difference in the total radiation dose. On the other hand, the radiation dose become ~10% at the center bottom of vertical hole expecting Marius Hills, 50 m in diameter and 43 m in depth. The radiation dose reduction is mainly due to the solid angle of primary particle. However, the contribution of secondary particles increased to ~20% at the bottom. This is also due to the solid angle subtended by the secondary particle sources, the wall and bottom of the hole. The effective dose equivalent reduced to 20 mSv/y at the edge bottom of the vertical hole. This value corresponds to the reference value of occupational exposure determined by ICRP. If there is over 25 m space, 50 m from the hole center, the effective dose equivalent becomes less than 1.0 mSv/y, the reference value of public exposure. Our results show that the vertical hole and lava tubes are promising sites for human long stay in future from the aspect of radiation protection. The detail results of numerical experiments and evaluation of space radiation protection will be presented and discussed.

Breadboard Model of Bionic Legged Robot for Lunar Lava Cave Exploration

*LIANG CHEN[1]

1. Ashikaga University

C. Liang and T. Arai

Ashikaga University, Tochigi, Japan (liangchen960809@gmail.com)

Recently, some large, deep vertical holes were discovered at Marius Hills, *Mare Tranquillitatis*, and *Mare Ingenii* on the lunar surface by Japanese spacecraft SELENE (Kaguya) using lunar surface image data acquired by the Terrain Camera (TC) (Haruyama et al., 2009; Robinson et al., 2012; Kaku et al., 2017). Lunar lava tubes can play an important role in both science and human exploration. They might be ideal sites for future lunar bases, because of their stable thermal conditions and potential to protect people and instruments from micrometeorites and cosmic ray radiation. Their stable and protected environment also makes them an enticing research target: original lava compositions, textures, and even magmatic volatiles are expected to be preserved in pristine condition within these lava tubes (Haruyama et al., 2012; Haruyama et al., 2016). Examining their interiors could provide unique insights concerning the evolutionary history of Moon. In the future, we will expand our search to other regions on Moon where additional subsurface lava tubes may be discovered. In this study, we have been developing the lunar exploration robot. We believe using a bionic mechanism with intelligence will be more stable for complex rocks than a wheel mechanism in the lunar environment. Our robot has individual motors for every single joint compared with other legged robots, hence it has higher flexibility. However, for the prototype to safely and efficiently explore lunar caves, certain conditions are required: 1. Stability of the survey instrument in space and cave environment 2. the optimum size of robot and onboard instruments, 3: Autonomous control under lunar cave. Currently, we have developed a reinforcement learning method for the robot. This presentation will introduce the current status and highlights of our bionic legged robot, including mobility, flexibility and agility. To test the function of the survey instrument, we are creating a simulated environment of lunar caves. We will also improve the balance system of the robot by testing it in the simulated environment, and ensure its functionality during a real exploration on the moon. The results of these experiments will be published at JpGU-AGU joint meeting 2020.

Study of lunar 3-D terrain mapping using both the camera and the LIDAR loaded on the rover

*Ryuhei Yamada[1], Yuichi Yaguch[1], Keitaro Naruse[1]

1. The University of Aizu, Department of Computer Science and Engineering

The lunar landing mission is next main topic for survey and utilization of the Moon. Many remote sensing observations by Kaguya, LRO, GRAIL, LADEE and Chang’ e programs have almost completed comprehensive knowledge of the lunar surface in recent 15 years. The landing exploration can provide details of local terrain, geology and chemical composition on a selected area. Then, deployment of the geophysical sensors such as seismometer, thermometer and magnetometer using a lunar lander and/or a rover should provide the new chances to investigate the lunar interior structure since Apollo-era. In this study, we target to construct the accurate 3-D terrain map around the landing site in range from several hundreds of m to a few km using both the camera and the 3-D LIDAR loaded on the lunar rover.

The accurate 3-D terrain map can provide the detailed frequency distribution of size of the boulder and its shape, geometries of the craters and relief of the surface around the site. This information helps us to investigate the formation process and age of the area. Then, we can utilize the map to select the scientific target with other sensor data and design the route of the rover to the target.

We have studied the method to construct the 3-D terrain map using the 3-D LIDAR point cloud data by the SLAM (Simultaneous Localization and Mapping) algorithm, and we can construct the 3-D map with accuracy of a few –about 10 cm [Yamada et al., 2019]. On the other hand, the 3-D map consisting of only the LIDAR data is usually sparse especially in far range. The camera image can be used to complement the space and provide color information in the map. We have also studied the calibration method to match the camera image and the LIDAR point cloud data to construct the accurate 3-D map with high resolution [Yamada et al., 2020]. In this presentation, we will introduce the methods of 3-D map construction and calibration. Then, we will perform the mapping test using the both the camera and the LIDAR loaded on the wagon and/or the small rover in outside area and indicate the result of the 3-D map. Finally, we will also discuss the application of the method to the lunar science and exploration, operation of the rover and the future vision using the lunar rover.

Characterizing Sites for Landed Lunar Missions with NASA's Moon Trek Portal

*Emily Law[1], Brian Hamilton Day[2]

1. Jet Propulsion Laboratory, 2. Ames Research Center

NASA's Moon Trek (https://trek.nasa.gov/moon/) is one of a growing number of interactive, browser-based, online portals for planetary data visualization and analysis produced by NASA's Solar System Treks Project (SSTP). Moon Trek continues to be enhanced with new data and new capabilities enabling it to facilitate the planning and conducting of upcoming lunar missions by NASA, its commercial partners, and its international partners.

Moon Trek is being used for growing number of mission planning, specifically for site characterization. Its baseline visualization and analysis tools allow users to measure the diameters, heights and depths of surface features. Users can plot Sun angles altitude and azimuth. More advanced account-level tools allow users to perform computationally-intensive analyses. These include ray-traced lighting analysis for user-specified areas over user-specified time/date ranges and time intervals. Lighting analyses also produce maps of watts per square meter for the area specified. Electric surface potential analyses can also be generated for user-specified areas and intervals. Machine learning-based hazard analyses include boulder detection and distribution, crater detection and distribution, and slope analysis. Large data products can be subsetted, allowing users to download regions of specific interest. The LRR/LLR Geometry Calculator allows researchers to find, visualize, and analyze images taken by the Lunar Reconnaissance Orbiter (LRO) that are applicable to Lunar Laser Retro-Reflector (LRR) and Lunar Laser Ranging (LLR) studies and planning.

Using an in-house stereo workflow, SSTP is able to produce new NAC-based high-resolution mosaics and DEMs. These are particularly useful in our work with Commercial Lunar Payload Services (CLPS) providers using Moon Trek in site characterization for landing and surface operations.

Important new tools are currently being integrated into Moon Trek. A Convolutional Neural Network (CNN) is being implemented, trained to automatically detect rockfalls in LRO NAC imagery, and integrated into Moon Trek. Such rockfalls are interesting because they enable remote analysis of tectonic activity, surface evolution, and mechanical surface properties. A new line-of-sight tool will support detailed studies of solar illumination, line-of-sight communications with the Earth, and communications with assets in lunar orbit.

This presentation for JpGU will highlight Moon Trek's tools that are useful in facilitating site characterization for future Lunar missions.

Development of a compact LIBS instrument for future lunar explorations: a feasibility study using lunar meteorites

*Akinojo Ogura[1], Yuichiro Cho[2], Naoki Yamamoto[1], Koki Yumoto[2], Takafumi Niihara[3], Shingo Kameda[4], Seiji Sugita[2], Takahide Mizuno[5]

1. Department of Earth and Planetary Physics, University of Tokyo, 2. Department of Earth and Planetary Science, University of Tokyo, 3. Department of Systems Innovation, University of Tokyo, 4. School of Science, Rikkyo University, 5. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The composition of lunar surface is a fundamental observable for understanding the geology of the Moon. For example, in situ measurements of Mg# on a mineral-by-mineral basis help us understand the differentiation process of the lunar magma ocean, adding information to the Mg# map obtained from the orbit [Ohtake et al., 2012]. Elemental analysis is also important for the future lunar polar missions because it provides possible water detection with its geologic context.

Laser-induced breakdown spectroscopy (LIBS) is a method that enables such spot-by-spot analyses. LIBS analyzes the emission spectra from laser-induced plasma that exhibits a number of emission lines characteristic to individual elements. The laser beam is focused on a sample to ~100 microns, allowing the analysis of individual minerals. In addition, LIBS analysis can be conducted from several meters away in a few minutes and the laser pulses can excavate the surface of a sample up to several millimeters. In fact, LIBS was/will be used on Mars for NASA’ s Curiosity and Mars 2020 rovers [Reess et al., 2018]. In contrast, no actual measurements have been made on the Moon yet. A previous study for a lunar LIBS revealed that major elements can be measured with the accuracy of several wt% [Lasue et al., 2012]. However, their laboratory study did not focus on the miniaturization of the instrument: they switched three spectrometers with different wavelength ranges; the laser in their research was about 1 m long.

In our study, the entire LIBS components were assembled in a package to be portable. Our LIBS instrument is 35 cm×30 cm×20 cm and ~8 kg including a laser, spectrometer, CCD camera, optics with an automatic focusing function, controllers, breadboard, and enclosure. The instrument has a simple electrical interface, namely 12, 15, and 24-28 VDC power lines and one USB hub for communication.

Using the LIBS package, we constructed a quantitative analysis model for major elements with a goal to achieve the precision sufficient to classify lunar crusts. We conducted a series of experiments as follows: 20 geological standard samples from National Institute of Advanced Industrial Science and Technology (AIST) and United States Geological Survey (USGS) were pressed and located in the vacuum chamber under 3×10-2 Pa, 1 m away from the LIBS components. Laser pulses from a Nd:YAG laser (~30 mJ at 1064 nm) were applied 100 times at 5 spots. Ninety spectra were averaged after correcting dark, continuum emission, and relative sensitivity of the optical system. The corrected data were used to build the models with univariate analysis (UVA) (i.e., calibration curves) and multivariate analysis (Partial Least Squares, PLS). The precision of the model was acquired by the leave-one-out cross validation. Then, the concentrations of major elements (Si, Fe, Al, Mg, Na, Ca, Ti, K) in the lunar mare meteorite NWA479 were predicted (phenocryst and groundmass separately) using the models.

Our quantitative analyses yielded the model prediction precisions better than 1 wt% (Na2O and TiO_2), 2 (CaO and K2O), 3 (FeO), and 8 wt% (SiO_2). We also found that elements with strong emission lines were better predicted by UVA than by PLS: as 6.29 wt% (PLS) vs 3.90 (UVA) wt% for MgO, 1.04 wt% (PLS) vs

©2020. Japan Geoscience Union. All Right Reserved.

0.69 wt% (UVA) for Na_2O. Also, the predicted concentrations of Mg, Al, and Ca in phenocryst (olivine) and groundmass (plagioclase and pyroxene) of the lunar meteorite were distinguished against each other, indicating the possibility of mineral-to-mineral measurements on the Moon. From the calibration activity, we also found that the geological samples with Fe_2O_3> 20 wt% and CaO > 16 wt% are necessary to improve the accuracy of Mg# and An# predictions, because lunar meteorites contain higher $Fe2O_3$ and CaO than typical igneous rocks on the Earth. In addition, we conducted a separate LIBS experiment with the engineering model of the Nd:YAG laser used for Hayabusa-2's LIDAR instrument. The obtained LIBS spectra exhibited a number of emission lines, indicating the feasibility of LIBS measurements with the flight-proven laser. The preliminary results from the lunar meteorite experiment using the compact LIBS instrument suggest the possibility to analyze the composition of minerals quantitatively on the lunar surface.

Preparation status of Multi-Band Camera onboard SLIM lander

*Kazuto Saiki[1], Makiko Ohtake[2], Yusuke Nakauchi[2], Hiroaki Shiraishi[2], Chikatoshi Honda[3], Hiroyuki Sato[2], Yoshiaki Ishihara[4], Takao Maeda[5], Chihiro Yamanaka[1], Hiroshi Nagaoka[2]

1. Graduate School of Science, Osaka University, 2. Japan Aerospace Exploration Agency, 3. University of Aizu, 4. National Institute for Environmental Studies, 5. Chuo University

Smart Lander for Investigating Moon (SLIM) project is on going at JAXA. It will be launched in fiscal year 2021 as Japan’ s lunar-landing mission. The main purpose of this project is to demonstrate various techniques for pinpoint landing within a hundred meters in radius on the moon. Demonstration of the SLIM landing technology will cause a paradigm shift from "exploring where it is easy to land" to "exploring where we want to land." After landing, the SLIM project plans to operate Multi-Band Camera (MBC) to observe around the landing site. We are now testing an engineering model of MBC.

As a landing site for SLIM mission, one of the small fresh craters just outside of the Theophilus crater is selected. This crater (diameter ~200 m) locates 13.3º S, 25.2º E outside the southwest rim of Theophilus and named “Shioli”. There is olivine-rich lithology, which is probably mantle (or the lower part of the crustal) origin excavated by the Nectaris basin forming impact as suggested by the global distribution of the olivine-rich sites (Yamamoto et al. , 2010) , well before the formation of the Theophlius. In order to identify this unknown lithology and estimate its origin, MBC has a spatial resolution (1.3 mm/pixel at 10 m) that distinguishes plutonic rock texture and a band combination (10 bands; 750, 920, 950, 970, 1000, 1050, 1100, 1250, 1550, 1650 (nm)) that identifies mineral species. And most importantly, MBC has plan to estimate Mg # (=Mg/(Mg+Fe) atomic ratio) of olivine.

In order to advance basic research on spectroscopic observation of lunar rocks, we have developed a line spectrometer using the same image sensor (Xenics, FPA0.9-1.7_640_4_TE1) as MBC. The range of observable wavelength is 850 - 1700 nm (can be expand to 750 - 1700 nm in the future) . Line Spectrometer can observe continuous spectra and also have one-dimensional spatial information. By observing various rock samples with this spectrometer, we would like to succeed in deriving the detailed mineralogy of the olivine-rich exposure in the lunar spectroscopic observation at the SLIM project. Preliminary observations show that olivine grains in rocks are more difficult to observe than powdered olivine, and the locations where absorption peaks can be observed are biased toward mineral grain boundaries.

This study is supported in part by JSPS Grants-in-Aid for Scientific Research: Grant Number 19H01953.

The search for whistler-mode chorus emissions related to the Moon using ARTEMIS

*Wataru Sawaguchi[1], Yuki Harada[1], Satoshi Kurita[2]

1. Graduate School of Science, Kyoto University, 2. RISH, Kyoto University

Whistler-mode chorus emissions are narrow band emissions observed mostly on the dawn and day side in the Earth’s inner magnetosphere [Burtis and Helliwell, 1969; Burtis and Helliwell, 1976]. Their frequency band is typically from 0.2 f_{ce} to 0.8 f_{ce}, where f_{ce} is the electron cyclotron frequency at the magnetic equator. They are also found in the magnetospheres of Jupiter [Coroniti et al, 1980], Saturn [Hospodarski et al, 2008] and Mars [Harada et al, 2016], but their presence has not been confirmed near unmagnetized bodies without dense atmospheres.

The generation of whistler-mode waves is based on the linear theory in which the free energy source of waves is provided by the temperature anisotropy of electrons with respect to the background magnetic field [e.g., Tsurutani et al., 1979]. However, it does not explain the characteristic chirping of chorus. Therefore, nonlinear theories were proposed and it was shown that whistler-mode waves in an inhomogeneous medium could effectively trap cyclotron-resonant electrons [Dysthe, 1971] and then resonant current could strongly amplify waves [Nunn, 1974; Omura et al,1991]. The incoherent waves occur first based on the linear theory, then the wave field traps cyclotron-resonant electrons, and eventually the amplitudes of the waves increase nonlinearly.

The Moon is an unmagnetized and airless body. Various kinds of plasma phenomena occur as a result of the interaction of solar wind and magnetospheric plasmas with the Moon’s exosphere, surface, and crustal magnetic field [Halekas et al,. 2012]. For example, electron anisotropy caused by the absorption on the lunar surface drives cyclotron resonance of waves traveling toward the Moon with electrons reflected from the lunar surface by magnetic mirroring, leading to generation of whistler-mode waves [Harada et al., 2014]. As the amplitudes of the whistler-mode waves are comparable to those of chorus emissions in the Earth’s inner magnetosphere, it may be expected that chorus-like waves are possibly present in the vicinity of the Moon.

We searched for and identified chorus-like events with discrete rising tone elements from the magnetic field data obtained by the ARTEMIS mission, and tested whether they are consistent with the nonlinear model by Omura et al. (2008) and whether they are Moon-related waves by two point measurements.

[P-PS03] High-pressure phases in shocked meteorites: key to understanding impact events on parent asteroids

convener:Kishan Tiwari(Indian Institute of Technology Kharagpur)

Shocked meteorites, which are the products of collisions in between their parent asteroids, contain shock melt veins, which are pervasive localized zones of very high pressure, temperature, and frictional melting. Minerals entrained in and around such SMVs being subjected to such extreme conditions are transformed to high-pressure polymorphs and thus such shocked meteorites serve as unique natural samples to study the mechanism of such polymorphic transformations. Based on shock metamorphic features observed in olivine and plagioclase, produced at different P-T conditions, a shock stage classification system has been developed with highest shock stage, S6 corresponds to 75-90 GPa. But the pressure stability range established by static high-pressure experiments for the high-pressure polymorphs reported in shocked meteorites is much lower than that indicated by their corresponding shock stage. Such a large difference is mainly because such polymorphic transformations depend on kinetics of the reaction and the actual P-T-t path experienced by the mineral grains during the shock. Computational modeling and microscopic studies of shock front behavior and shocked samples indicate that interaction of shock waves with mineral grain of different shock impedance may result in pressure heterogeneity and localized spikes in temperature. Compositional and textural analyses of matrix portions in shocked meteorites have revealed that they have crystallized directly from the chondritic melt at high pressure. Thus, phase relations and mineral stability at different P-T conditions derived from static high-pressure experiments can be used to infer the crystallization pressure and shock pressure. Estimated shock pressure can be used to calculate shock velocity, impact velocity, and parent body size by using the Rankine-Hugoniot equation. So apart from transformation mechanisms, shocked meteorites can provide us with information about collision dynamics on their parent asteroids.

[PPS03-P01] Thermal infrared measurement of impact in laboratory experiment

Ground based observations of Lunar impact flash with visible wavelength contributes progress of the impact physics. Meanwhile, the visible observations are restricted to the direct flash at the night side. When the thermal infrared emission from an impact is observed, coverage can be expanded not only to the nightside but also to the dayside. The thermal infrared observation also would detect residual hot spot after the impact event. When the temperature variation is derived from the continuous observation of the residual hot spot, thermal inertia, from which an energy budget correlated with size of the crater, would be obtained. Epoch of the impact and the temperature at that time may be estimated from the thermal relaxation profile even if the impact could not be directly detected. As a first step, we have measured artificial impact flashes using a thermal infrared camera in a laboratory experiment.

The impact experiment with 15 shots has been carried out in a vacuum chamber. SiO_2 sand with ~345 μm diameter was set inside, and an uncooled microbolometer array (UMBA) camera detecting the thermal infrared wavelengths at 10 μm (8 -14 μm) was configured outside of the chamber. Thermal infrared images were continuously obtained with 10 Hz via a thermal transmission window. When a polycarbonate impactor with a size of 2 mm struck the sand with a speed of 6.6 km/s, the temperature distribution and profile of the crater created on the sand surface was obtained from brightness temperature distribution in the UMBA images.
The temperature profile of the sand surface after the impact has been estimated in each pixel using images continuously obtained. The maximum temperatures were estimated to 1700-2600 K at the time of impacts. Notably, the result showed unexpected horizontal temperature distributions; the temperature of the crater limb was higher than that of the crater center at the time of impact. However, the limb temperature drastically decreased less than 1000 K, and the limb temperature became lower than center temperature after 0.5 seconds.

[P-PS04] Regolith Science

convener:Koji Wada(Planetary Exploration Research Center, Chiba Institute of Technology), Akiko Nakamura(Graduate School of Science, Kobe University), Patrick Michel(Universite Cote D Azur Observatoire De La Cote D Azur CNRS Laboratoire Lagrange), Kevin John Walsh(Southwest Research Institute Boulder)

Recent planetary explorations have revealed that almost all solid bodies in the solar system are covered with small particles, called regolith. The surface geology, especially regolith behavior on the surfaces of solid bodies, becomes increasingly more important as represented by Hayabusa mission and other on-going and planned sample-return missions such as Hayabusa2, OSIRIS-REx, and MMX.
For fully understanding the regolith science, it is required to know and compare the regolith conditions on various celestial bodies, from asteroids to planets, with various methods.
Therefore, this session welcomes broad topics related to regolith on various celestial bodies, such as asteroids, comets, the Moon, the martian moons, Mars, etc. Papers on the formation, evolution, and alteration processes of regolith particles and regolith systems on the surface of planetary bodies, remote and in-situ observational results and techniques, analyses and results of returned samples, and laboratory, numerical, and theoretical studies on the fundamental physical and chemical processes are all welcome.
Note that what we call regolith is not just fine grains: all kinds of materials (more or less loose) that lie on the surface, from cobbles to finer grains, are our targets.

Laboratory penetration experiments conducted at low effective gravity II

*Akiko Nakamura[1], Junpei Nakahata[2], Yuuya Nagaashi[1]

1. Graduate School of Science, Kobe University, 2. Faculty of Science, Kobe University

Laboratory measurements of the penetration depth of an impactor with a velocity of m/s in a granular layer under Earth’ s gravity were compiled to give an empirical relationship between drop height and penetration depth that is applicable for various granular materials (Uehara et al., 2013). There are limited data on the penetration depth under low gravity. In low-velocity (2–40 cm/s) impact experiments with a quartz sand target under low effective gravities (~0.2–1 m/s^2), the penetration depth was independent of the effective gravity (Murdoch et al., 2016).

To investigate the penetration of an impactor into granular material as an analogue of planetary regolith, we examined the low-velocity impact of a sphere into a granular layer at low effective gravity in the laboratory experiments. The target granular material was packed in a bucket. The bucket was fixed with two electromagnets; when the electromagnets were switched off, it dropped vertically downward, reducing the effective gravity, which was monitored by an accelerometer. In our previous set-up we used constant-force springs to hang the bucket and the effective gravity averaged 2.5 m/s^2 (Nakamura et al., 2019JpGU). In our new study, we used two linear shafts to guide the bucket. The impactor was a 16. 7-mm-diameter glass sphere. A plastic straw with horizontal lines drawn on it was glued to the glass sphere. The penetration process of the glass sphere with the straw was imaged at 960 fps by a camera attached to the bucket. We used 1-mm-diameter glass spheres and 0.7-1 mm peach seed fragments as targets.

In this study, the effective gravity was lower than 0.09 m/s^2. The glass sphere collided with the granular target at a relative velocity of between 3 and 4.5 m/s. The final depth of the impactor roughly matched the expected value given by an analytic penetration model (Katsuragi and Durian, 2013).

Experimental study of high-velocity impacts into granular material in reduced gravity

*Masato Kiuchi[1], Takaya Okamoto[1], Sunao Hasegawa[1], Akiko Nakamura[2]

1. Japan aerospace exploration agency, Institute of space and astronautical science, 2. Graduate School of Science, Kobe University

The surfaces of small bodies are in a microgravity environment. Therefore, it is important to understand how gravity affects crater size to estimate physical properties of the surface. Several studies have investigated the effect of gravity on crater size for low-velocity to high-velocity (1 m s^{-1} to 6.6 km s^{-1}) impacts: the gravitational dependence of crater size was obtained in the low- and high-gravity range (Gault & Wedekind, 1977; Schmidt & Housen, 1987; Cintala et al., 1989; Takagi et al., 2007; Kiuchi et al., 2019). It was shown that the crater diameter was proportional to -0.165 ~ -0.19 power of the gravitational acceleration except for the one conducted using drop tower and showed that the crater diameter formed under microgravity was not different from the one formed under 1 G (Takagi et al., 2007) . The difference in the results of previous studies is not understood because the number of available laboratory data is limited. On the other hand, collisions between planetary bodies generally occur at high-velocities ranging from several kilometers per second to several tens of kilometers per second. However, there are few experimental examples in high-velocity regions over several kilometers per second in reduced gravities. A drop tower or a parabolic flight are generally used for microgravity experiments, however, it is difficult to conduct impact experiments at a velocity of several kilometers per second in these experimental facility.
In this study, we developed a drop system to conduct high-velocity impact experiments in reduced gravity. By assembling a simple drop tower in the vacuum chamber of a two-stage light-gas gun at the Japan Aerospace Exploration Agency (JAXA), low gravity experiments at the impact velocity of several kilometers per second can be realized. The drop system is consists of ball bearings and two rails for dropping a target container smoothly. The top of the container was fixed near the ceiling of a chamber with a height of 2 m by electromagnets, and the container is dropped by turning off electromagnets. The acceleration values are measured by an accelerometer placed at the bottom of the container. When the container filled with 12 kg of sand was dropped under vacuum condition, simulated gravity on the container was obtained in the range of 0.06 - 0.07 G. The falling time of the container was about 0.4 s in these condition.
In addition, we conducted high-velocity impact experiments. The ambient pressure was 100 Pa. While the container was falling, a projectile was fired by the two-stage light-gas gun. The crater formation process was observed with a high-speed video camera installed outside the vacuum chamber. We used quarts sand of representative diameter 425 μm as the target material, and used a polycarbonate sphere of diameter 4.76 mm as the projectile. A polycarbonate sphere is 1.2 g cm^{-3} in density. The target material was loosely filled in a stainless steel container with a diameter of 30 cm and a height of 10 cm. A projectile was impacted at a velocity of 1.2 km s^{-1}. As a result, the diameters of craters formed at 0.06± 0.03 G was about 1.8 times larger than the one formed at 1 G. Gravitational dependence of the crater diameter was clearly observed. We organized the results using pi-scaling (e.g., Holsapple, 1994) and found that our results in reduced gravity agreed well with the crater size scaling law for the sand targets (Housen and Holsapple, 2011). Note that diameters of craters formed in reduced gravity shows the lower limit of the final crater diameter because the crater formation may not have been completed before the container dropped. In the presentation, we will discuss the crater formation time and introduce the additional impact experimental results.

A Tentative Numerical Study on the Effect of Aspect Ratio of Cylindrical Projectile on Crater Morphology using iSALE code

*Yuri Shimaki[1]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The small carry-on impactor (SCI) onboard the Hayabusa2 spacecraft successfully detonated on April 5, 2019, and created an artificial crater on the surface of asteroid Ryugu. Besides the main copper liner, the SCI produces irregular-shaped forward debris composed of copper or SUS that form concentric features on the target surface. These concentric features, including sub-crater candidates, were also observed on the surface of Ryugu. However, it is not obvious whether irregular-shaped debris produces typical bowl-shaped craters, although the effect of SCI-like hollow-shaped projectile has been investigated numerically (Kurosawa et al., 2015). In this study, I report a tentative numerical study on the effect of the aspect ratio of a cylindrical projectile on the crater morphology.

In this work, I use the iSALE shock physics code (Amsden et al., 1980; Collins et al., 2004; Wünnemann et al., 2006). A cylinder with an aspect ratio (height/width) and a uniform sand layer was used as the projectile and the target. The impact velocity was set to 2 km/s. The Tillotson EOS for iron and quartz were used. The aspect ratio was varied from 0.36 (disk) to 8.0 (rod), while the volume was almost constant. A gravity of 9.8 m/s^2 was included in the calculation. After the calculations, the depth and diameter of the crater were measured.

With the increase of the aspect ratio of the projectile, the depth of the crater increased, while its diameter was almost unchanged. In this poster, the detailed analysis of the crater morphologies will be described.

Acknowledgments: I appreciate the developers of iSALE, including G. Collins, K. W ünnemann, B. Ivanov, J. Melosh, and D. Elbeshausen. Numerical computations were carried out on PC cluster at Center for Computational Astrophysics (CfCA), National Astronomical Observatory of Japan. I am grateful for the iSALE users group in Japan, including K. Kurosawa, Y. Kanada, R. Suetsugu, and S. Wakita, and the LOC of iSALE workshop 2019 at CfCA.

Automated Identification of Particles in Rock Gravel of Small Bodies

*Yuta Shimizu[1], Hideaki Miyamoto[1]

1. University of Tokyo

Numerous boulders and fine particles are commonly distributed over the surface of small bodies, as revealed by the recent space exploration missions [e.g. 1]. Their mechanical properties, such as the shape and size distribution, are considered to be critical for the understanding of the geological surface processes [2], and for the landing safety of the landing/touchdown missions [3]. However, precise identification of the outlines of such particles is challenging due to irregular particle shapes, overlapping particles, image resolution limits. Here, we present a computational approach for the automated identification of particles based on the image feature extraction algorithm utilizing the convolutional neural networks (CNNs). We prepare images of the imitated surface of small bodies by using simulated material (simulant) of the regolith of small bodies [4], and then carefully identified thousands of particles manually. With the data of profiles, the model is trained, enabling nearly 80 % of profiles of particles of simulant to be correctly traced without the aid of manual analysis. Moreover, particles on the global surface of asteroid Itokawa are automatically identified by using tens of images taken in the Hayabusa mission, and identified profiles are mapped on the shape model. We measure the sizes of particles, revealing the cumulative size-frequency distribution (CSFD) of particles on the global surface of Itokawa to have the power-law index of -3.48±0.08, which is consistent with the CSFD calculated in the previous research [5]. The approach of this study can rapidly identify numerous particles, which can be a promising tool for analyzing countless images of the surface of small bodies taken in current and near future space exploration missions.

Development of lunar regolith simulants based on previous lunar explorations

*Takemura Tomohiro[1], Takafumi Niihara[1], Hideaki Miyamoto[1]

1. The University of Tokyo

Several countries and agencies plan lunar missions to lunar polar regions in the 2020s (e.g., NASA's Lunar Flashlight, Chinese Chang'E 6, NASA's VIPER, Japanese SELENE-R) to investigate the existence (abundance) of water ice, with the aim to establish lunar bases as gateways to deep space explorations including a manned mission. For the assessment of lunar surface environment (e.g., surface temperatures, regolith properties) and its interaction to lunar lander/rover, as well as the planning of observations and in-situ analyses on surface compositions, subsurface structures, and water ice, a vast amount of lunar regolith simulants, which should be as realistic as possible, are necessary to produce. Previous lunar regolith simulants were developed based on Apollo samples, so that they approximate compositions of materials on the lunar nearside only, which is insufficient for the modeling of the surface of lunar farside and polar regions. Therefore, the objective of this study is to compile remote-sensing data (several chemical composition maps) (Elphic et al., 1998; Lawrence et al., 1998; Lawrence et al., 2007; Lucey et al., 2000; Lucey et al., 1995; Ohtake et al., 2009) and Apollo sample data, and to establish a procedure of the development of simulants of the far-side and polar region as well as the nearside.

In this study, we collected several types of igneous rock and test the accuracy of rock type and texture to use for simulants. Then we revisited Apollo sample data and decided the most favorable ranges of particle size distribution, chemical composition, mineral assemblage, particle shape and texture of our simulant, and established manufacturing procedure.

We finally developed four different types of lunar simulants: mare simulant of the lunar near side, highland simulant of the lunar near side, the South Pole Aitken (SPA) basin simulant, and highland simulants of lunar far-side were prepared by the above procedure using an analysis technique such as XRF. Unlike the existing simulants (e.g., JSC-1), the simulant produced in this study are within the constraints of elemental/chemical compositions of Apollo samples and remote-sensing data, and they show a wide range of validity for modeling the surface of each site, in terms of particle size-frequency distribution, mineral abundance and the chemical composition, which would lead to precise estimates of the surface conditions of future landing sites.

Estimation of abrasion rates of regolith particles on Itokawa and the Moon based on abration experiments.

*Akira Tsuchiyama[1], Hirotaka Yamaguchi[2], Akiko Nakamura[3]

1. Research Organization of Science and Technology, Ritsumeikan University, 2. Graduate School of Science, Kyoto University, 3. Graduate School of Science, Kobe University

External 3D shapes and surface morphologies of Itokawa and lunar regolith particles examined by X-ray nanotomography and SEM showed that some particles have rounded edges, which should be formed by mechanical abrasion [1-3]. Seismic shaking by micrometeoroid impacts on the Itokawa surface was proposed for the abrasion [1]. In order to understand abrasion processes and evolution of regolith particles on the airless bodies, abrasion experiments have been made [4,5]. In this study, we have performed additional abrasion experiments together with SEM observation of abraded grains in order to examine abrasion process and obtaine a general equation for the abrasion rate and the results were applied to abrasion of Itokawa and lunar particles.

The samples used were quartz, olivine ($Fo_{\sim 90}$) and basalt. They were crushed and grains 1~2 mm in size were selected except for some to examine grain size effect (0.5~1 mm and 2~4 mm). These grains (~6.5g) were put into a vessel (10 mL) of agate, dunnite or basalt with ~50% fraction. Then the vessel was shaken with vertically-vibrational motion in a mill (Multi-beads-shocker: YASUIKIKAI Co.). Powder with the size less than 1/6 of the grain size (e.g., <250 mm for 1~2 mm grains) produced by abrasion was removed by sieving. The amount of abrasion, P, was defined as the difference between the grain masses before and after the abrasion, which was normalized by the initial grain mass.

For quartz grains, P increases with abrasion duration, t, (20 sec to 360 min) with the power of ~0.25 irrespective of vibration rate, Ω(100 to 2500 rpm). The amount of abrasion in the first 1 min, P_1, increases with Ω(100 to 3000 rpm) for quartz, olivine and basalt. The powers of P_1 - Ωrelation, m_i, at Ω< ~700 rpm (m = 0.1~0.4) are smaller than those at Ω> ~700 rpm (m_i = 1.2~2). P_1 increases with the grain size, d, at Ω = 2000 rpm for quartz and the power value is temporally ~1.6. If we assume that the power relation between P and t is applicable to different sample materials and that between P_1 and d to different sample materials and Ω, we can obtain the following equation; $P = A_i \times \Omega^{mi} \times d^{1.6} \times t^{0.25}$ (Eq.1), where A_i is the proportionality and the suffix i denote the sample materials. SEM observation together with the P–t relation showed that the abrasion advances by chipping grain corners (chipping) for P < ~1% while grain corners and edges become rounded (wearing) for P > ~1%.

The maximum accelerations by impact on Itokawa and the Moon can be estimated to be ~1 and ~100 m/s^2 based on the impact experiments [6], which correspond to $\Omega$of ~100 and ~700 rpm, respectively. This gives A_i' s in Eq.1 with d = 1.5 mm and t = 1 min are ~0.2 % (olivine) on Itokawa and ~0.5 % (basalt) on the Moon. If typical grain convection time by impact of ~180 s on Itokawa [7] is adopted as the maximum value of t, P is estimated to be ~0.003 and ~0.1 % for d = 100 μm and 1 mm, respectively. As the Itokawa grains have rounded edges (wearing), >~4×10^9 and >~3000 times of impact are required, respectively, for P > 1 %. If the impact frequency on Itokawa [7] is considered, these numbers of impact required for wearing are too large, suggesting that grain abrasion on Itokawa is not expected and impact on the larger parent body (>~20 km) [8] should be necessary. In contrast, on the Moon, A_i ~ 0.5% suggests possible abrasion because of longer residence time in a regolith layer than Itokawa.

[P-PS05] Planetary Seismic Exploration-From InSight and Apollo to Future Missions-

convener:Taichi Kawamura(Institut de Physique du Globe de Paris), Takeshi Tsuji(Department of Earth Resources Engineering, Kyushu University), Ralph Lorenz(Johns Hopkins University Applied Physics Laboratory), William Bruce Banerdt(Jet Propulsion Laboratory)

Given that seismic exploration is one of the most successful approach to study the internal structure of planetary bodies, it has been proposed to various planetary missions. Starting from Passive Seismic Experiment on Apollo missions, various seismic experiments were proposed over the next 50 years. Recently, several such proposals have been approved and thus we are entering a new active era of planetary seismology. In early 2019, the NASA InSight Lander successfully deployed the first seismometer on the surface of Mars and detected the first Marsquakes. In addition, recent global interest in lunar exploration has rekindled interest in a new seismic network on the Moon. In-situ resource utilization is being intensively discussed and seismic exploration has been investigated as an approach to search for subsurface water/ice. Finally, the Dragonfly mission was selected as NASA's next New Frontiers mission and a set of short period seismometers is being considered for its payload. With such a diversity of on-going and future missions, the next decade should see significant advances planetary seismology. The aim of this session will be to discuss the latest planetary seismology discoveries and possible future exploration and developments in this field. In terms of recent discoveries, the focus will be on analyses of InSight seismic data from Mars as well as results from other missions. The session will also include discussion on future missions, both selected and proposed. These include the active seismic experiment on the Japanese Lunar Resource Prospector mission and the seismic experiment on NASA's Dragonfly. Though planetary seismology has a long history dating back to the Apollo era, the associated research community is relatively immature due to the nearly 50-years gap in new data. We propose this session to provide opportunity to bring together scientist working on related topics and encourage discussion and collaboration for future development of this theme.

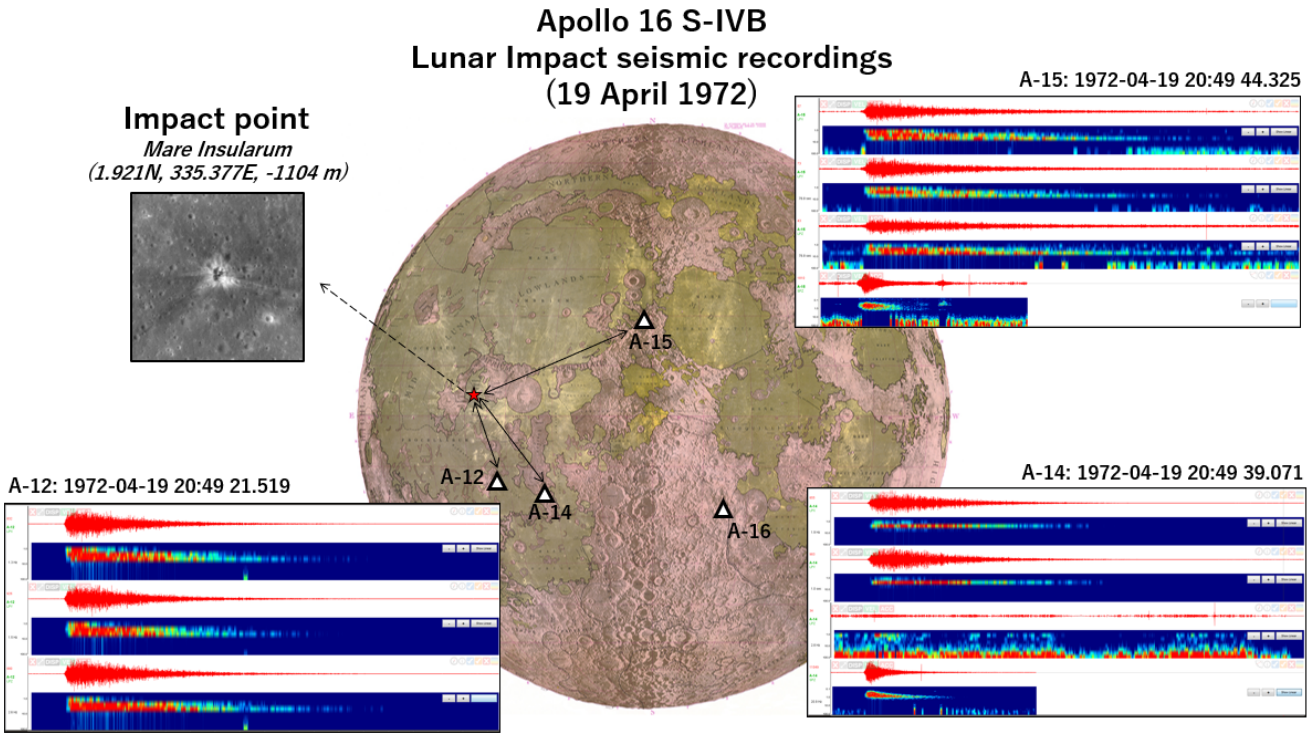
Estimation of the lunar near-surface effects on Moonquake waves amplification.

*Mohamed Amrouche[1], Renee Weber[2]



1. Schlumberger., 2. NASA Marshall Space Flight Center.

Ever since the Apollo days, pioneering works on lunar seismology have mainly focused on understanding the deep structure of the Moon. Over the last decades we have witnessed a significant leap in high-resolution mapping of the surface of the Moon and lunar surface geology and topography became well known. However, the effects of the lunar surface geological features on moonquakes amplification remain poorly described in the lunar seismology literature. Meanwhile, studies of the terrestrial near-surface geology and topography effects on earthquake wave-amplification evolved and led to the establishment of a whole new branch of seismology, referred to as ‘Near-surface seismology’. It became a scientific fact today that the near-surface geology and the complexity of the topography play significant roles as far as earthquake wave amplification is concerned.

The aim of this study is to attempt an initial near-surface seismology analysis of the lunar seismic data recorded at the different Apollo Lunar Surface Experiments Packages (ALSEP) sites deployed by NASA during the different Apollo missions. We propose to adapt and apply modern seismic site effect estimation techniques, such as the seismic spectral ratio and the reference site response to the surface lunar meteorite and artificial impacts, as well as the shallow moonquakes cataloged by ALSEP. Results from this study will provide a new perception of the near-surface wave behavior in a lunar environment, and help the estimation of the lunar regolith effects on moonquake wave amplification. The understanding of the lunar near-surface geological and topographical effects on the moonquakes behavior will provides key elements for the future Lunar Geophysical Network deployment site selection, by avoiding the potentially high amplification sites based on the surrounding topography and local geology.

Scattering properties near Apollo 12 landing site inferred from numerical simulation of seismic wave propagation

*Keisuke Onodera[1,2], Taichi Kawamura[1], Satoshi Tanaka[3], Yoshiaki Ishihara[4], Takuto Maeda[5]

1. University of Paris/Institut de Physique du Globe de Paris, 2. The Graduate University for Advanced Studies (SOKENDAI), 3. Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 4. National Institute for Environmental Studies, 5. Hirosaki University

Abstract

As demonstrated on the Earth, seismological investigation is a well-established way to constrain the planetary interior, and it has been applied to extraterrestrial bodies, such as the Moon [1] and Mars [2]. Basically, the uncertainty of an inner structure model highly depend on how precisely seismic phases can be read. However, in the case of the Moon, the scattering coda in the data is so intense that it is difficult to determine the phase arrivals, resulting in a large uncertainty in the resulting structure model.

This intense scattering is considered to be caused by the subsurface fractured layers called regolith or megaregolith and local topographies. The previous studies mainly investigated the scattering properties of regolith and megaregolith (e.g. quality factor Q, thickness of the layer) by analyzing the Apollo seismic data (e.g. [3][4][5][6]). Yet, there are several different models, and the lunar scattering property is still under discussion [7]. As for the scattering effect by the lunar topography, few studies looked into this although its influence on scattering-coda development has been discussed [5].

This study conducted numerical simulations of seismic wave propagation in order to constrain the scattering properties around the Apollo 12 and 14 landing sites. Because we introduced both scattering media and topographical models (surface and Moho), the output waveforms include both scattering effects. As reference seismic events, the Apollo artificial impacts were selected because their origin times, impact locations and impact parameters are well-constrained (e.g. [8][9]). The velocity structure consists of 4 layers (scattering layer 1, scattering layer 2, crust, mantle) whose parameters were referred from VPREMOON [10]. In the top 2 layers, 2 different random media based on the results by Blanchette-Guertin et al. [5] and Onodera et al. [11] were inserted. As for the source condition, we assumed isotropic radiation of P-wave as an analogue of an impact [12] and Kupper wavelet as source time function with excitation time of 0.65 s. In the simulations, we performed parameter studies on V_p/V_s ratio and thickness for the top 2 scattering layers. By comparing each simulated wave with the Apollo data in terms of rise time and seismic energy, we evaluated what kind of model is preferable to explain the data.

As a result, one of the coda envelopes for the Apollo S-IVB impact events was well reproduced from the simulations, leading to the constraint on the scattering properties of Mare Cognitum region. Our results indicate that the scattering layer in this region can be modeled with 2 different scattering layers. The first 7.5 km layer consists of 200 m scale heterogeneity with 28% velocity fluctuation while the second layer exists up to 10 km depth including 600 m scale scatterers with 14% fluctuation. As for velocity structure, we obtained the smaller V_p/V_s ratio (1.2-1.4) compared to the previous studies (> 1.7 [13]). Since the P and S-wave velocity ratio becomes smaller as the sample gets drier, our results are consistent with our understandings that the Moon has much drier environment than the Earth.

Seismologist are used to handle seismometer dataless in addition to the raw data generated by the instruments, and for classical seismometer, the dataless is fixed and provided with the instrument. No change in the sampling rate is also made.

As Insight Seismometer evolve in a very demanding environment, both the sampling rate and instrument configuration might change, especially due to possible limitation in the transmission bandwidth. The instrument configuration varies also on several level. Primary acquisition may vary, according to the operational needs of scientist or the engineering team. According to the external environment used fir filters may be changed, especially during HP3 hammering sessions and calibrations. Each time, we need the to set a specific FIR filter on the acquisition electronics and return back to a classical one just after the hammering or calibration session ends. The datalogger processing varies depending on the way some channels combination has to be made. Insight dataless provides also the possibility to detect a variation of the instrument transfer function during the mission and set it on a established date and time.

Insight dataless has to take into account all the configuration changes and report it into the dataless which may required to be updated for every telemetry.

Data processing is based on flight software configuration files which describes the data flow from the acquisition electronics to the continuous telemetry waveform, including used FIR filters or channels combination if needed. This also determines the continuous data sampling rate.

The link between the channel and its environment is described in CFCT files containing the channel starting and ending date and the used software configuration file during this period. This period determines the fir filters used by the acquisition electronics, or transfer function if they change.

All these needs have been satisfied using a python based program which fetches in arborescent directories whom names are related to the utilisation date and time and contain the needed information and its expiration date for the acquisition electronics part for the first part of the channels dataless. This program also reads the flight software configuration files to provide the second part of the dataless until the continuous or the event waveform.

All the above process is checked every week by the team, which also check for gaps and any off-nominal operations. Gaps, mostly due to transmission issues, can be later filled by specific event request, in addition to those associated to Mars Quake Service detected events At the end, all SEIS data, including their datales, are available through requests made to the Mars SEIS data service (https://www.seis-insight.eu/en/science/science-summary), IRIS-DMC and PDS.

Comparison of attenuation and scattering of Lunar and Martian structures

A limited number of seismic investigations have been performed on other planets and satellites. The only extraterrestrial seismic data available were those collected by the Apollo missions on the Moon and the InSight mission (Interior exploration using Seismic Investigations, Geodesy and Heat Transport) on Mars. Lunar and Martian seismograms appear to be extremely different from terrestrial ones. The seismic signals are characterized by a gradual beginning, a broad maximum and a very long decay lasting up to 20 minutes and 1 hour for Mars and the Moon respectively, compared to a few minutes on Earth. This unexpected long coda results from the low attenuation and intense scattering of highly porous and fractured regolith and megaregolith layers. This intense multiple scattering generates long ringing coda waves and makes difficult to identify direct arrivals of seismic waves such as P and S-waves. However, radiative transfer is well suited to model this process, and it can be approximated by the diffusion equation. Based on the envelope records of Mars and Moon events, the coda has been quantified by two parameters: the time arrival of the maximum of energy (t_{max}) and the decay rate of the energy, named the coda quality factor (Q_c). t_{max} quantifies the diffusion and Q_c is sensitive to attenuation. The data analysis of event 128a revealed that t_{max} and Q_c of Mars differ from those of Moon or Earth. In fact, Q_c of Mars is significantly smaller than that of the Moon and closer to the value of the Earth. This first result may imply that Mars contains more volatiles than the Moon and less than the Earth. To confirm this hypothesis, we need to separate the attenuation from the scattering by using more data which is in process.

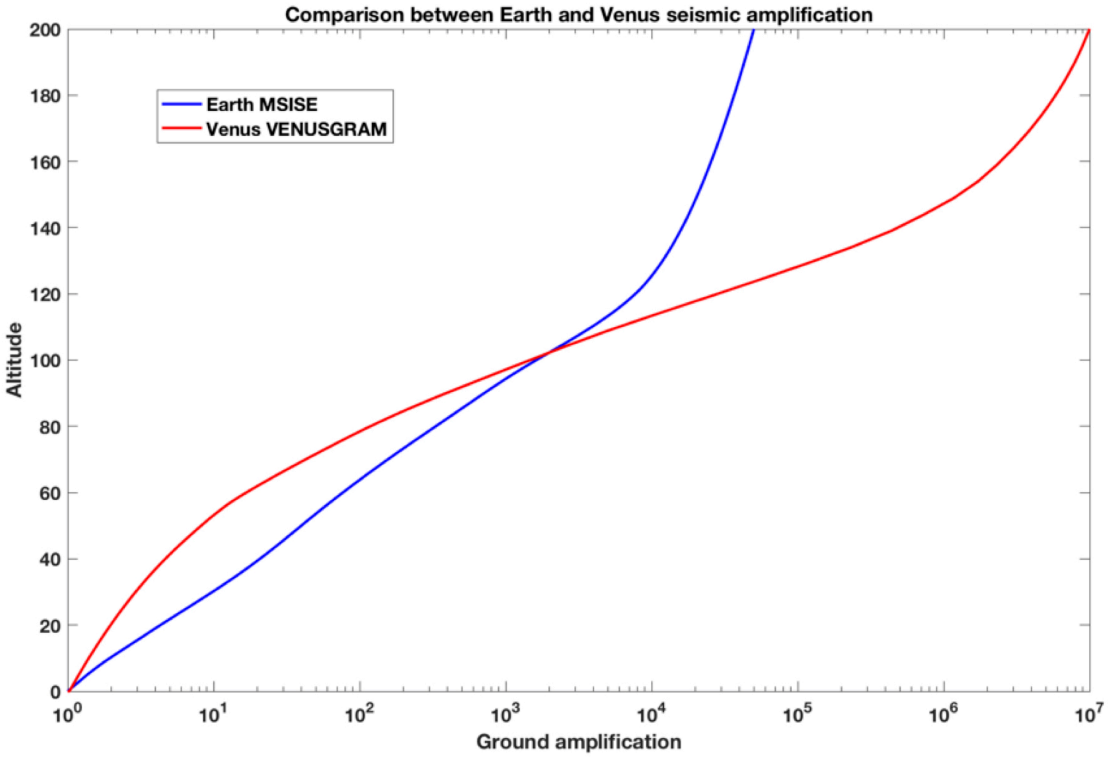
Orbital Remote sensing seismology on Venus: the VAMOS concept.

*Philippe Henri Lognonné[1], Attila Komjathy[2], Siddharth Krishnamoorthy[2], Raphael F. Garcia[3], Balthasar Kenda[1], Brian M. Sutin[2]

1. Université de Paris, Institut de physique du globe de Paris, CNRS, 2. Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA 91109, USA, 3. Institut Supérieur de l'Aéronautique et de l'Espace SUPAERO, 10 Avenue Edouard Belin, 31400 Toulouse, France

Due to the adverse surface conditions on Venus with its extremely high temperature and pressure, it is infeasible, even using flagship mission resources, to place seismometers on the surface for an extended period of time. Performing remote atmospheric seismic monitoring from an orbiting platform could provide a breakthrough in the detection of seismicity on Venus and the monitoring of seismic wave propagation in the Venus ionosphere.

Venus is surrounded by the brightest naturally occurring airglow layer known in the Solar System. Airglow is a result of various atoms, molecules, and ions that get photoionized by ultraviolet radiation from the Sun and then release energy as visible and infrared light when they recombine and return to their normal state. Perturbations in the neutral atmosphere caused by seismicity on Venus leave an imprint in this airglow layer, spanning altitudes from 90-110 km.



We propose to use remote optical observations of this layer to study these perturbations, allowing us to infer the currently unknown seismicity of the solid planet below. Two specific airglow emissions are investigated, one occurring at 1.27 μm (visible on the night-side) and the other at 4.3 μm (visible on the day-side).

The seismic signal in the Venus atmosphere will be related to the amplification generated by the decay of the density with altitude. This is provided on Figure 1 and compared to Earth. An amplification comparable to Earth is obtained at 100 km, the height of the 1.27 microns on Venus. We get a factor 30 of additional amplification at the height of the 4.3 micron emission (135 km) and even more at higher altitude/
We will summarize here the principal findings of the VAMOS concept study, for which we performed an in-depth analysis and modeling both for the 1.27 μm nightglow and the dayside 4.28 μm non-local thermodynamics equilibrium (non-LTE) signals associated with the waves. The results show that the detection threshold for the proposed imager is expected to be Ms=6 for 1.27 μm and Ms=5 for 4.28 μm.

Figure1: Comparison of the amplification of surface waves for Earth and Venus. Earth model is MSISE while Venus model is VENUSGRAM. See Lognonné et al (*J. Acoust. Soc. Am.*, doi: 10.1121/1.4960788, 2016) for models properties and references.

[P-PS06] Science of Venus: Venus Express, Akatsuki, and beyond

convener:Takehiko Satoh(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Kevin McGouldrick(University of Colorado Boulder), Hideo Sagawa(Kyoto Sangyo University), Thomas Widemann(Observatoire De Paris)

In this century, our knowledge about the earth's twin sister, Venus, has greatly been advanced through two latest missions, ESA's Venus Express and JAXA's Akatsuki. The latter, in Venus orbit since December 2015, is providing high-quality data that allow studies of atmospheric dynamics in particular. Successful missions are the trigger of ideas of new missions (Russian Venera-D and Indian Shukrayaan-1 under development, European EnVision, and some US proposals). This session invites papers of the new results from data (spacecraft and ground-based), latest results of theoretical and numerical works, and descriptions of new missions as well.

Polarimetry of Venus upper atmosphere with a new single-shot type polarimeter

*Takehiko Satoh[1,2], Masato Kagitani[3], Takeshi Sakanoi[3], Takao M. Sato[4], James O'Donoghue[1]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. Department of Space and Astronautical Science, The Graduate University for Advanced Studies, SOKENDAI, 3. Faculty of Science, Tohoku University, 4. Space Information Center, Hokkaido Information University

Polarimetry is a powerful mean of sensing aerosol properties in the upper atmosphere of Venus as demonstrated by Hansen and Hovenier (1974). They analyzed the ground-based linear polarization data of Venus (disk integrated) and found that the data were consistent with a uniform cover of sulfuric acid droplets of which effective radius and variance are 1.05 um and 0.07, respectively. In 1980’s, OCPP onboard Pioneer Venus Orbiter performed spatially-resolved imaging polarimetry, and studied in detail characteristics of aerosols and their variability (Kawabata et al. 1980; Knibbe et al. 1998; Braak et al. 2002).

Our team carried out polarimetric observations of Venus in 2012, 2014, and 2015 at Kyoto University’s Hida Observatory, by attaching HOPS (Hida Optical Polarimetry System) to the 65-cm refracting telescope. The 930-nm data revealed rapid decrease of the polar haze from 2012 to 2014, while 435-nm data indicated change in cloud-top altitude in polar regions (Enomoto et al., in revision). HOPS is a traditional two-beam type polarimeter and thus requires a set of 4 images with the half-wave retarder plate rotated every 22.5 degrees to obtain the linear polarization vectors. From the ground, variable seeing condition during these 4 exposures is unavoidable and is major source of error when obtaining linear polarization.

A single-shot type polarimeter should therefore be advantageous for observations of planets as required exposure time is usually short and small spatial scale (~arcsecond order) matters. We are developing such a polarimeter by utilizing a “Wedged Double Wollastone (WeDoWo)” (Oliva, 1997) device as an analyzer. The device is composed of 6 precision-shaped calcite blocks: the first two (wedges) separate the incident light into two beams, and beams are subsequently separated to four beams of different polarization state ($I \pm Q$, and $I \pm U$). This allows us to obtain linear polarization vectors just in one shot. We plan to use this instrument during BepiColombo’s flyby to Venus (closest approach on 15 October 2020). There will be 4 instruments (UVI and LIR onboard Akatsuki, plus PHEBUS and MERTIS onboard BepiColombo/MPO) to observe the upper atmosphere of Venus but none has the polarimetric capability. Therefore, our observations with a new single-shot type polarimeter will complement observations from the space.

Venus's Atmospheric Features in UV as Viewed from Ground-Based Observations

*Ryan M. McCabe[1], Kunio M. Sayanagi[1], John J. Blalock[1], Jacob L. Gunnarson[1], Javier Peralta[2], Candace L. Gray[4], Kevin McGouldrick[5], Takeshi Imamura[2], Shigeto Watanabe[3], Yeon Joo Lee[6]

1. Hampton University, 2. Institute of Space and Astronautical Sciences, JAXA, 3. Department of Earth and Planetary Sciences, Hokkaido Univ., Japan, 4. Apache Point Observatory , Sunspot, NM, 5. LASP, Univ. of Colorado Boulder, 6. Technical University of Berlin, Germany

We are currently investigating the dynamics of Venus's atmosphere to understand the link between variability of atmospheric superrotation to the existence and occurrences of the Y-feature. The atmospheric superrotation, in which the equatorial atmosphere rotates with a period of approximately 4-5 days (~60 times faster than the solid planet), has forcing and maintenance mechanisms that remain to be explained. Temporal evolution of the zonal wind could reveal the transport of energy and momentum in or out of the equatorial region, and eventually shed light on mechanisms that maintain the Venusian superrotation. We postulate that the Y-feature is a manifestation of equatorial waves (either Kelvin, Rossby, or a combination of the two in nature) that may play a role in such energy transport that could affect Venus's superrotation. To understand the connection between the Y-feature and the superrotation, we must determine the frequency of the Y-feature's existence, the variability of the atmospheric wind field, and analyze the connection between the two to determine to what extent the Y-feature plays a role in Venus's superrotation.

We characterize the existence of the Y-feature's occurrence and phase speed between 2006 and 2017. It is observed in ultraviolet images captured by the Venus Monitoring Camera on board the ESA Venus Express (VEX) spacecraft which observed Venus's southern hemisphere as well as the Ultraviolet Imager on the Akatsuki spacecraft which viewed pole to pole latitudes. We also extend our analysis to ground-based observations between 2016 and 2019. This includes data captured with the 3.5 m Astrophysical Research Consortium telescope at the Apache Point Observatory (APO) in Sunspot, NM and small 10-inch scale telescopes at Hampton University in Hampton, VA. Images we have captured demonstrate that, even under unfavorable illumination, it is possible to see large features that could be used to supplement gaps in dayside UV data during Akatsuki.

The method for observing and analysis of atmospheric features seen in UV from ground-based observations is discussed. Preliminary Akasuki wind measurements made using a 2D Correlation Image Velocimetry method developed at Hampton University are also presented.

Our work has been supported by NASA MUREP NNX15AQ03A and NASA PATM NNX14AK07G.

3-D Thermal Structure of the Venus Atmosphere Obtained by Akatsuki/LIR

*Masahiro Akiba[1], Makoto Taguchi[2], Tetsuya Fukuhara[2], Takeshi Imamura[3], Toru Kouyama[4], Takao M. Sato[5]

To maintain the fast circulation of the Venus atmosphere, thermal tides have been considered a very important candidate of a driving engine, because they can transfer eastward momentum from the accelerating region of the upper atmosphere to the ground [Kouyama et al., 2019]. We investigated the vertical structure of brightness temperature distribution above the cloud-tops based on the emission angle dependence of the sensing altitude of LIR onboard Akatsuki. We used LIR data obtained when Akatsuki was in the altitude range from 60,000 to 100,000 km during the period from October 19, 2016 to October 2, 2018. Each brightness temperature image with 328x248 pixels was divided into 3280x2480 sub-pixels, and 32 successive images were accumulated after precise adjustment of the Venus disk position. Emission angles are converted to sensing altitudes by a radiative transfer calculation with nominal temperature and cloud particle distributions [Sato et al., 2014]. Thus, we derived a local time-altitude cross section of the brightness temperature deviation above the cloud-tops in the latitude ranges of 0-30, 40-50, 55-65, 70-80, and 80-90. Sensing altitudes change slightly with latitude but range vertically about 7 km depending on the emission angles. A Fourier analysis shows the vertical distribution of temperature in the equator region is dominated by a semidiurnal tide with a tilt of the phase with increasing altitude. The maximum positive temperature deviation appears around 10 and 21 LT at the bottom of the sensing altitudes. It is suggested that the thermal tide is generated deep in the cloud deck by solar heating and propagates upward. On the other hand, a diurnal tide dominates in the higher latitudes. Latitudinal dependence of the observed amplitudes, phases and their tilt angles of diurnal and semidiurnal tides will be discussed by comparing with those from a numerical simulation.

An uppermost haze layer above 100 km found over Venus by the SOIR onboard Venus Express

*Seiko Takagi[1], Arnaud Mahieux[2], Valérie Wilquet[2], Séverine Robert[2], Ann Carine Vandaele[2], Naomoto Iwagami

1. Hokkaido University, Graduate School of Science, 2. Belgian Institute for Space Aeronomy

The Venus cloud consists of a main cloud deck at 47 –70 km, with thinner hazes above and below.The upper haze on Venus lies above the main cloud surrounding the planet, ranging from the cloud top (70 km) up to as high as 90 km.
The Solar Occultation in the InfraRed (SOIR) instrument onboard Venus Express (ESA) was designed to measure the Venusian atmospheric transmission at high altitudes (65 –220 km) in the infrared wavelength range (2.2 –4.3 μm) with a high spectral resolution. We investigate the optical properties of Venus’ s haze layer above 90 km using SOIR observations. Vertical and latitudinal profiles of the extinction coefficient, optical thickness, and mixing ratio of aerosols are retrieved. One of the most remarkable results is that the aerosol mixing ratio tends to increase with altitude above 90 km at both high and low latitude. It is speculated that sources of haze are transported upward from under altitude 90 km and haze is produced at high altitude. In this presentation, we will report the results and speculate how aerosols could be produced at such high altitudes.

Variations in the activities of planetary-scale waves at the Venusian cloud top observed by Akatsuki UVI

*Masataka Imai[1], Toru Kouyama[1], Atsushi Yamazaki[2], Shigeto Watanabe[3], Manabu Yamada[4], Shin-ya Murakami[2], Takeshi Imamura[5], Takehiko Satoh[2], Masato Nakamura[2], Kazunori Ogohara[6], Takeshi Horinouchi[7]

Planetary-scale waves at the Venusian cloud-top cause periodic variations in both ultraviolet (UV) albedo patterns and winds. Since planetary-scale waves are considered to play crucial roles in the momentum and material transports in the Venusian atmosphere, investigating these periodicities and its temporal change could provide a better picture of how these waves get involved in the atmospheric dynamics on Venus. In this study, we analyzed the periodicities in the UV albedo and the cloud-tracking wind variations (Horinouchi et al., 2017) derived from both 283-nm and 365-nm UVI channels observed in the OP2016 (October 2016 -- April 2017), OP2017 (June -- October 2017), OP2018A (January -- June 2018), and OP2018B (August -- December 2018). We used the successive time blocks having a time range of ±15 days extracted from the original time series and conducted Time-Shifting Lomb-Scargle (TSLS) periodogram analysis [Imai et al., 2019].

Our previous study revealed the temporal evolution of prominent 5-day waves in OP2017 for the first time, and we could find corresponding temporal changes in planetary-scale UV features. Since the reconstructed horizontal wind field had planetary-scale vortices, which was nearly equatorially symmetric and centered at ~35° latitude in both hemispheres, the observed 5-day wave can be interpreted as the equatorial symmetric Rossby wave. The amplitude of wind variation associated with the observed Rossby wave was amplified gradually over ~20 days and attenuated over ~50 days. An ~3.8-day periodic signals were observed in the zonal wind and brightness variations in the equatorial region before the Rossby wave amplification. Although the amplitude and significance of the 3.8-day mode were relatively low in the observation season, this feature is consistent with a Kelvin wave. In this observation season, there was only a small difference in the periodicities and wind field between 283-nm and 365-nm channels.

In OP2018B, we also found ~4-day and ~5-day periodicity in winds. However, the reconstructed horizontal wind field showed southwest and northeast elongated oscitation in the southern hemisphere rather than the vortices, and latitudinal asymmetry in the amplitude of wind variation was prominent. In contrast to the OP2017, ~4-day wave had relatively large amplitude to the ~5-day wave, and ~4-day wave seems gradually degraded through the observation season. While the difference in the sensing altitude of both 283-nm and 365-nm still unclear, wave signals were much clear in 283-nm channel, and these findings might indicate OP2018 was the active season for the wave excitation and the wave source was closer to the 283-nm observation altitude. In the Akatsuki observation era since the end of 2015, OP2017 and OP2018B are the representative season for investigating the evolution of planetary-scale waves. In this presentation, we will show the summary of how these two observation seasons are different and what kind of mechanisms are related to the prominence of ~4-day wave and ~5-day wave.

The global variation of Venus cloud investigated from AKATSUKI 1-μm camera

*Seiko Takagi[1], Naomoto Iwagami

1. Hokkaido University, Graduate School of Science

Venus is our nearest neighbor, and has a size very similar to the Earth’ s. However, previous observations discovered an extremely dense (90 bar at the surface) and CO_2-rich atmosphere, with H_2SO_4 thick clouds. The Venus cloud consists of H_2SO_4 main cloud deck at 40 −70 km, with thinner hazes above and below.The upper haze on Venus lies above the main cloud surrounding the planet, ranging from the top of the cloud (70 km) up to as high as 90 km.
Near infrared (0.986 μm) dayside image of Venus has taken by solid state imaging (SSI) of the Galileo spacecraft (NASA). It appears almost flat, there are some small scale features with a contrast of 3 % [Belton et al., 1991]. In Takagi and Iwagami. (2011), it may be calculated that the source of the contrast of the order of 3 % in near infrared Venus dayside image is due to variation in the cloud optical thickness.
On December 7, 2015, AKATSUKI (JAXA) approached Venus and the Venus orbit insertion was successful. After the Venus orbit insertion, many 0.90 μm Venus dayside images were taken by the 1 μm near infrared camera (IR1) onboard AKATSUKI.
In this study, Venus cloud variations are investigated from 0.90 μm Venus dayside images taken by IR1 cameraglobally. Further, meteorological some changes that contribute to cloud variation are examined with radiative transfer calculation including high-altitude cloud model [Takagi et al., 2019]. Furthermore, I will introduce Venus observation plan using the 1.6 m Pirka telescope and Multi-Spectral Imager (MSI) [Watanabe et al., 2012] mounted on the Cassegrain focus of the telescope at the Nayoro Observatory of Hokkaido University.

Cosmic rays and high energetic particles at Venus: Analysis of triggered pulse events detected by Akatsuki/LAC

*Masataka Imai[1], Yukihiro Takahashi[2], Ralph Lorenz[3], Mitsuteru Sato[2]

1. National Institute of Advanced Industrial Science and Technology, 2. Hokkaido University, 3. Johns Hopkins University Applied Physics Laboratory

Cosmic rays and high energetic particles from astrophysical sources outside the solar system are an important contributor to planetary radiation environments. On Venus, cosmic rays cause ionization in the atmosphere, and this effect is considered as a dominant ionization source. We have known that some bodies within the solar system shine to X-rays, and in the case of Venus, charge exchange interactions between highly charged ions in the solar wind and the Venusian atmosphere would be one of the X-ray sources. However, our understanding of the environment of the high energetic particles around the Venus orbit is quite limited. Therefore, the detection of cosmic rays by the instrument onboard Venus orbiter provides us precious information.

Lightning and Airglow Camera (LAC), which is one of the onboard instruments of Akatsuki, is a new type of lightning detector equipping 8×8 pixels (16×16 mm) APD (avalanche photodiode) detector and enables detecting optical lightning flash with 30 kHz sampling rate. LAC adopts the pre-trigger sampling method to record pulsed signals by using half of 64 pixels. Despite no detection of flashes attributable to lightning, LAC recorded over 500 cosmic ray events during the 49 observation sessions of LAC from August 2016 to January 2020. The estimated average event rate of LAC was 0.44 events min^{-1}. Considering the director size, the previous detection report of Pioneer Venus star sensor [Burucki et al., 1981; 1991] was 38 (or 12 during quiet sun) events min^{-1}, and this low event rate might be caused by the LAC shielding is less susceptible to cosmic ray triggers. The output peak values of the pulsed signals have covered almost from 6 digits to 80 digits, and intense events having large peak value (>80 digits) seem to be randomly recorded. Since the energy of cosmic rays is high enough to excite photoelectron inside the detector, this wide range of the peak values can be caused by the incidence angle of cosmic rays to the face of the APD detector. Under this assumption, the possibility of the incidence angle (θi) is proportional to sin2 θi when we expect the isotropic cosmic ray incidence, where θi is the angle measured from the normal vector of the sensor plane. We conducted a statistical analysis with 501 recorded cosmic ray events and found that detected events roughly follow the assumed isotropic incidence relation. However, there was minor disagreement, and one of the possible explanations is that we should consider the energy distribution of cosmic rays and/or the complex structure of LAC shielding. On the other hand, we could find the event rate has some dependence on Venus–Spacecraft distance, and our result indicates a slightly higher rate of around 6000 km and almost monotonical increase of event rate from 9000 to 12000 km from the Venus surface. If they are some high energetic particles from the sun, then these observation distances correspond to the refraction angle of ~30° and 24°–19°. Hoever, we currently do not have any plausible explanation for this.

Ground-based Observation of planetary lightning flashes by using Photomultiplier tube

*Tatsuharu Ono[1], Yukihiro Takahashi[1], Mitsuteru Sato[1], Shigeto Watanabe[1], Seiko Takagi[1], Masataka Imai[2]

1. Department of Cosmosciences, Graduate School of Science, Hokkaido University, 2. National Institute of Advanced Industrial Science and Technology

The lightning flashes observation is useful as a way to understand the atmospheric large structure and the chemical reaction constituting the atmosphere. The lightning flashes have been observed in the Earth and Jupiter. It is suggested that there is a relationship between the zonal jet and the cumulonimbus with lightning in Jupiter (Gierasch et al.,2000, Ingersol et al., 2000). It is difficult to know the vertical convection covered by the dense clouds by using multi-wavelength observation. However, the lightning flashes observation can use for monitoring the atmosphere dynamics like the vertical convection covered by dense clouds. And one hypothesis suggests that some components of the Jovian atmosphere are created by lightning flashes. It is important to know the lightning to understand the formation mechanism of the atmosphere. In Venus, it is considered that there are lightning generated by the charge separation by the ice particle like the Earth or cloud particles of sulfuric acid. The existence of Venusian lightning is controversial for over 20 years. In the previous study, there are radio wave observations and optical observations by CCD. There is no robust evidence of existence the lightning because it is difficult to distinguish between the lightning signal and the electrical noise or other plasma waves, the observation area is limited, and the CCD's sensitivity is not enough for lightning flashes. If we can confirm the existence of Venusian lightning like the Jovian, it leads to an understanding of the Venusian atmosphere dynamics and atmospheric components.

Our study’s purpose is to reveal the relationship between lightning and atmospheric dynamics. For this purpose, we develop the instrument to equip for the Pirka telescope. By using it, we observe Venus more than tens of hours to obtain the lightning’s light curve, occurrence frequency, and distribution. We reveal the relationship between lightning and atmosphere dynamics by comparing the lightning data and wind velocity and cloud distribution.

The Planetary Lightning Detector (PLD) we developed is designed for Venusian and Jovian lightning flashes' observation. From the previous study, the dominant wavelength of the lightning flashes could be 777 nm in Venus (Borucki et al.,1996). PLD equips narrowband filter (FWHM = 1nm) of 777 nm. PLD observes the light by using a Photomultiplier tube. The minimum exposure time is 50 microseconds. The maximum time resolution is about $2x10^4$ points/s. PLD’s FOV can be changed to 5”, 10”, 30”, 60” pinhole and 2”x11” slit by using field stops. Slit and Pinhole are used for Venus’s night-side observation. To obtain the lightning’s light curve, we operate the bandpass filter to remove noise and large time scale variation by the atmosphere. And then, we search the large count value over 3-sigma. We have observed Venus by using PLD. For Venus’s data, we have obtained a few events whose count value is over the 3-sigma. These energies are estimated. The energy is about 10^9 to 10^{10} J. However, the light curves are too short less than 2 milliseconds and similar to the cosmic ray’s light curves obtained on different days. From this result, it’s considered we only observed the cosmic ray in this observation time. The observation time is not enough to reveal the lightning occurrence frequency for Venus. In the future, we increase the total observation time by using shorter exposure time.

Observation of the Venusian Lower Atmosphere in the 1.7 μm Band by Near-infrared Echelle Spectrometer onboard PIRKA Telescope in Nayoro Observatory

Daiki Tsukiyama[1], *Hiroyuki Maezawa[1], Atsushi Nishimura[1], Masataka Imai[4], Hidenori Takahashi[2], Masuo Tanaka[2], Yukihiro Takahashi[3], Mitsuteru Sato[3], Seiko Takagi[3], Shin-ichiro Okumura[5], Yeon Joo Lee[6]

1. Department of Physical Science Osaka Prefecture University, 2. Institute of Astronomy, School of Science, The University of Tokyo, 3. Hokkaido University, Graduate School of Science, 4. The National Institute of Advanced Industrial Science and Technology, 5. Japan Spaceguard Association, 6. Technical University of Berlin

Over the past 20 years, various exoplanets have been discovered, and observations of habitable Earth-like planets have been actively promoted. Venus, which is surrounded by the CO2 atmosphere, is one of the important observation targets for understanding the fundamental atmospheric properties of planets. The surface of Venus has the higher atmospheric temperature and pressure than those of the Earth. However, the temperature and pressure in the cloud region of Vebus are similar to those at the Earth’ s troposphere. Recently based on the ultraviolet band absorption features toward the cloud region of Venus, the possibility that microbes such as bacteria may remain in this region has been discussed. Therefore, a more detailed understanding of how the lower and upper layers of the atmosphere circulate through these cloud regions, and how the physical and chemical environments of the atmosphere are balanced between them is expected.

The 10 m radio telescope at the Nobeyama Radio Observatory (Nagano Prefecture) of the National Astronomical Observatory of Japan has been monitoring of the millimeter-wave band spectral lines of carbon monoxide in the Venusian middle atmosphere since 2011. CO at an altitude of around 80 km shows long-term changes in the time-scale of the solar activity cycle and shorter-term ones. For a detailed understanding of these changes, it is important to promote systematic simultaneous observations of trace molecular species toward the upper and lower atmospheres by the milli/submillimeter-wave band and the near-infrared band spectroscopies, respectively.

In August 2018, a test observation of the Venusian lower atmosphere was performed at Nayoro Observatory using a near-infrared echelle spectrometer (NICE) (University of Tokyo) mounted on the PIRKA telescope (Hokkaido University). Although there were many days when the atmospheric condition was unstable due to the influence of typhoons, on 8/22, we succeeded in detecting the spectrum from the night side lower atmosphere of Venus in the 1.7 μm band. The resolution of the spectrometer was $\lambda / \delta \lambda = 5600$, the slit size was 1 "×6.7", and HIP 69701 was observed as the standard star for the intensity calibration. The seeing (1 sigma) was 2.5”. The profile of the obtained spectrum was well consistent with the atmospheric radiative transfer model (Y.-J, Lee et al.) of Venus using the HITEMP database.

The University of Tokyo Atacama Observatory (TAO) Project is promoted by Institute of Astronomy (IoA), the University of Tokyo with many collaborators. In 2021, NICE is scheduled to be installed on the infrared band TAO telescope with a 6.5m diameter aperture on the summit of Cerro Chajnantor at Atacama in Cile (alt. 5640 m). Near the TAO site, Atacama large millimeter-wave submillimeter-wave interferometers are operated. Therefore, it is expected that simultaneous observations toward the Venusian upper and lower atmospheres on the same day will be possible. We will report the results of the

observation with NICE and the installation plan of NICE onto TAO.

A sensitivity study of the radiative-convective equilibrium temperature profile in Venus atmosphere

*Miho Sekiguchi[1], Masahiro Takagi[2], Hideo Sagawa[2], Yoshihisa Matsuda[3]

1. Tokyo University of Marine Science and Technology, 2. Kyoto Sangyo University, 3. Tokyo Gakugei University

Venus has a dense atmosphere entirely covered by a thick cloud layer (ranging over 50 –70 km altitude). Due to the high opacity of the atmosphere, there is almost no remote-observational access to the lower atmosphere below the cloud. Past (only a few, though) in-situ measurements suggest that the atmosphere is stable below the cloud down to 32 km, and then a convective layer appears down to 18 km. The lower atmosphere below 18 km seems to be stable again. The nature of such a thermal structure is still not understood clearly.

To better knowledge on the thermal structure (radiative transfer of the thermal flux), we calculated the radiative-convective equilibrium temperature profile of Venus atmosphere using a newly developed 1-D radiative transfer model “MSTRN-Venus”. The absorption coefficients of the molecular gases in the Venus atmosphere (CO_2, H_2O, CO, SO_2, HF, HCl, and OCS) are calculated in each 0.025cm^{-1} wavenumber and correlated k-distribution are calculated and applied. The spectroscopic parameters such as the transition position and line strength are taken from the recent compilations of HITRAN, HITEMP, and UCL08 catalogs. In addition, the collision-induced absorption of CO_2 is also included. We prepared the absorption coefficients under several pressure and temperature conditions within the ranges of 0.01 - 100 bar and 100 - 800 K, respectively. The results are kept in a look-up table of (p, T) domain so that we can interpolate the absorption coefficient for any pressure and temperature condition without repeating a burden computation. The upward and downward flux density is calculated for a given atmospheric profile using the MSTRN code. This code has been successfully applied in several studies of our terrestrial atmosphere, and also adopted as the radiation calculation module of several general atmospheric circulation models.

The presentation will discuss the sensitivity of the radiative-convective temperature profile concerning the abundance of minor species, incoming solar heating, and cloud opacities.

Meridional distribution of CO on Venus

*Shinya Kuwayama[1], George HASHIMOTO[1]

1. Okayama University

We constructed a model which calculates the meridional distribution of some minor chemical species such as CO, H_2O, and H_2SO_4 in the Venus' atmosphere. Our model consists of chemical reactions, advection, diffusion, condensation/evaporation, and sedimentation of cloud particles. The atmospheric temperature and density profiles are fixed, and a steady one-cell structure of the meridional circulation in each hemisphere is assumed. A steady state distribution is numerically solved by using time-marching.

Trials toward first Venus analysis product by data assimilation of Akatsuki observation

*Yukiko Fujisawa[1], Shin-ya Murakami[2], Norihiko Sugimoto[1], Masahiro Takagi[3], Takeshi Imamura[4], Takeshi Horinouchi[5], George HASHIMOTO[6], Masaki Ishiwatari[5], Takeshi Enomoto[7], Takemasa Miyoshi[8], Yoshi-Yuki Hayashi[9]

Observations of the Venus Orbiter "Akatsuki" provide us horizontal distributions of the horizontal wind derived from cloud tracking of the UVI camera images and of temperature observed by the LIR camera. However, these observations are very limited with respect to altitude, local time (day or night side), and frequency. It is difficult to elucidate general circulation including with various temporal and spatial scales only from observations. In this study, we aim to produce a Venus objective analysis that has high temporal and spatial resolutions by assimilating the Akatsuki observations into a general circulation model.

The model used in this study is a Venusian GCM (AFES-Venus) and the Venus AFES LETKF Data Assimilation System (ALEDAS-V) based on the Local Ensemble Transform Kalman Filter (LETKF) that has been developed for the first time[1]. Using ALEDAS-V, we have examined impact of data assimilation on thermal tides for the Venus Express wind observations[2]. In addition, we have examined the reproducibility of a unique atmospheric structure so-called “cold collar”, a cold latitudinal band encircling the warm polar vortex at about 60–70 km altitudes, in order to elucidate the effects of fixed temperature observations by multiple small satellites[3].

In this presentation, we will introduce results obtained for idealized data assimilation. One is for vertical profiles of temperature assuming radio occultation observation with realistic trajectory (Related to Hosono et al.[4]). The other is for distributions of horizontal wind assuming camera observation (Related to Fujisawa et al.[5]). These are necessary attempts before assimilating actual observation data. Furthermore, we will also introduce the results of assimilating actual Akatsuki observation data.

Dynamics of Decadal Sulfur Dioxide Variability in Venus' Atmosphere with a Simple Model

*Pushkar Kopparla[1], Ashwin Seshadri[2], Takeshi Imamura[1], Yeon Joo Lee[3], Javier Peralta[4]

1. University of Tokyo, 2. Indian Institute of Science, 3. Technical University of Berlin, 4. ISAS JAXA

Water and sulfur dioxide are important trace gases in the atmosphere of Venus. The photolysis of sulfur dioxide in the upper clouds produces sulfuric acid, which forms the thick cloud decks characteristic of the planet's atmosphere. Sulfur dioxide concentrations at the cloud top of Venus have been observed to oscillate on decadal timescales, characterized by sharp spikes and gradual declines. The variation is suspected to occur due to dynamical variability in the deep atmosphere of Venus but the exact mechanism has remained a mystery. Using a simple one dimensional box model where water and sulfur dioxide are cycled between the cloud tops and the deep atmosphere, we explore the dynamics of the sulfur dioxide oscillations. We find that the periodicity of the oscillation is dependent on vertical transport and thermal decomposition timescales in the deep atmosphere, while the shape of the oscillation depends on the transport timescale in the cloud layer.

[P-PS07] Solar System Small Bodies: Explorations of Ryugu, Bennu, and the Solar System at Large

convener:Taishi Nakamoto(Tokyo Institute of Technology), Tatsuaki Okada(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Dante S Lauretta(University of Arizona), Masateru Ishiguro(Department of Physics and Astronomy, Seoul National University)

Small Solar System bodies, including asteroids, comets, satellites, and inter-planetary dust particles, are interesting and provide lots of information on the origin and evolution of our Solar System. They can be remotely sensed by telescopes, be visited by spacecraft and studied at high resolution in a variety of wavelengths from IR to visible, UV, X-rays, and gamma rays, and even with neutrons. In addition, recently spacecrafts have been sent to return samples. In this session, all the contributions on the small solar system bodies are welcome. But this year, we especially welcome contributions on recent advances on the study of Ryugu and Bennu whether obtained by rendezvous spacecraft, remote sensing, or other methods.

Hayabusa2 spacecraft had accomplished the 1st and 2nd touchdown sampling onto C-type near-Earth asteroid Ryugu in Feb. and Jul. 2019 [1]. The spacecraft left the asteroid in last Nov. to return its reentry capsule including recovered asteroidal samples in this Dec. We have been preparing for receiving the samples and performing their initial description at the Extraterrestrial Sample Curation Center (ESCuC) of Japan Aerospace Exploration Agency (JAXA). The recovered samples will be the first C-type asteroid samples never experienced terrestrial atmosphere. Thus we have developed clean chambers for handling the Hayabusa2-returned samples without exposing to terrestrial air and installed them into the newly developed clean room in the ESCuC [2]. The clean chambers consist of five components; CC3-1 and CC3-2 for vacuum procedures, CC3-3 for changing environment from vacuum to nitrogen condition, CC4-1 and CC4-2 for procedures in nitrogen condition.

The procedures after the recovery of reentry capsule at the landing site will be mainly done by Hayabusa2 Sampler developing team, securing the capsule, removing support frame to extract the sample container, cleaning its surface and setting it into the gas sampling system to recover gaseous sample inside the sample container. Then the condition inside the container will be kept in vacuum to be enclosed into its transportation box in which will be sealed in nitrogen condition and sent back to Japan by air. After it will arrive to Japan, it will be instantly transported to ESCuC in the JAXA Sagamihara campus, to be introduced into the class 10,000 clean room for further procedures. Subsequently, procedures for the sample container after then are planned as follows; (1) opening the transportation box to extract the container, (2) removing the heat shield using the milling machine, (3) cleaning the outer surface of the container and checking its cleanliness, (4) fixing the container into the container opening system and removing parts of container which must not be introduced to the clean chamber, (5) introducing the container to the CC3-1, (6) evacuating the CC3-1 to reach high vacuum condition, (7) opening the container, (8) extracting a sample catcher from the container, (9) transferring the catcher to the CC3-2, (10) removing the cover of the chamber A of the catcher, (11) recovering small amount of samples from the chamber A under the vacuum condition, (12) setting a temporal cover to the chamber A of the catcher, (13) transferring the catcher to the CC3-3, (14) changing the environment of the CC3-3 from vacuum to purified nitrogen condition, (15) setting the handling jig to the catcher, (16) transferring the catcher to CC4-2 via CC4-1, (17) measuring bulk weight of the samples including the catcher and the jigs and observing the interior of the chamber A of the catcher, (18) transferring the catcher to CC4-1, (19) dismantling the catcher, (20) recovering samples inside each of the chambers of the catcher, (21) transferring the samples to CC4-2, (22) measuring the weight of the samples from of the chambers of the catcher and observing them with the optical microscope, (23) picking up individual samples, (24) performing their weight measurements, optical observations, FT-IR analyses and MicrOmega analyses, and (25) enclosing them into their containers for transportation or preservation.

So far, we have done rehearsals for the procedures (4) and (9) to (14) two times for each, and will continue tests and rehearsals for each of the procedures as those necessary for them will be ready to use

until this Sep. Then we will refresh the clean chambers, instruments, jigs and tools for the procedures to be ready for receiving samples returned by Hayabusa2 in this Dec.

Introduction: Ryugu is a C-type asteroid possessing a low-albedo surface with low abundance hydrous minerals [1], which is similar characteristics observed for carbonaceous meteorites. Therefore, the asteroid material is expected to contain many types of organic matters including amino acids. The occurrence of organic compounds in Ryugu will provide clues to the evolution of prebiotic molecules, redox and thermal condition as well as aqueous alteration of the asteroids in the solar system. We have organized an international analytical team for the soluble organic matter (SOM) of the Hayabusa2-returned samples. Because the total sampling amount is expected to be small (~100 mg) [2], and because meteoritic SOM usually occurs as a complex mixture consisting of various types of organic compounds with very small concentrations at each compound, we have been developing high-sensitive and high-resolution analytical techniques [3]. The first rehearsal analysis is conducted using small amounts of carbonaceous chondrites.

Samples and Methods: The powdered samples (~50 mg) of CM carbonaceous chondrites and baked serpentine (as a blank) were extracted sequentially with non-polar to polar solvents in a clean room. The solvent extracts were analyzed using: 1) High-resolution mass spectroscopy (HRMS) using Fourier Transform-Ion Cyclotron Resonance/Mass Spectrometry (FT-ICR/MS) [4], 2) HRMS with nano-liquid chromatography (nanoLC) with Orbitrap MS [5],3) Chiral amino acid analysis using multi-dimensional (2D or 3D) high-performance liquid chromatography (HPLC) with high-sensitive fluorescence detection (FD) coupled with HRMS [6, 7]. 4) Compound-specific isotope analysis using gas chromatography (GC)/Orbitrap MS and GC/combustion/isotope ratio mass spectrometry (GC/C/IRMS), 5) *In situ*organic compound analysis and molecular imaging using desorption electrospray ionization (DESI) equipped with Orbitrap MS [8, 9]. 6) Spatial resolution imaging of organic compounds using time of flight-secondary ion mass spectrometry (ToF-SIMS) [10], and 7) Bulk chemical and isotopic compositions of organic matter (C and N) using nanoEA-IRMS [11].

Results and Discussion: The 3D-HPLC/FD analysis clarified some chiral amino acid distribution using ~mg of the Murchison meteorite, in which non-proteinogenic amino acids were present as racemic mixtures. The FT-ICR/MSanalysis of Murchison revealed significantly diverse molecular compositions with the homologous series using both positive and negative ions, being consistent with the previous studies [4]. The various structural isomers (the same molecular composition but different chemical structures) were identified using nanoLC/nanoESI/Orbitrap MS. The nanoLC coupled with nanoESI could enhance the sensitivity of detection by three magnitudes compared to that of conventional HPLC with ESI. The chromatographic HRMS data was deconvoluted by a hand-made software, in which the CHN compounds were predominant, being similar results as the previous study [5]. The heterogeneous distribution of the CHN compounds was revealed usingDESI/HRMS. These results indicate that the current analytical methods can be available to reveal organic molecular characteristics of the Ryugu samples, if the returned samples contain SOM similar to the Murchison SOM. We further plan to conduct the second rehearsal

analysis using less samples (~10 mg) of various carbonaceous meteorites.

Asteroid explorer Hayabusa2 observed Cb-type asteroid 162173 Ryugu between June 2018 and November 2019 at a distance below 20km. The Telescopic Optical Navigation Camera (ONC-T) [1–4] onboard Hayabusa2 observed Ryugu with 7 broadband filters ranging in wavelength from 0.40–0.95 μm. On 8 January 2019, ONC-T observed the asteroid in the opposition geometry from ~20 km distance, through one rotation period (7.6 hr) in 7-band. The local solar phase angle of each pixel ranges from 0.0° to ~1.7°. This data set is well suited to derive the normal albedo, defined as the radiance factor (I/F) at phase angle 0° [5]. We present the normal albedo map from this observation.

The data number of the raw image pixels are converted [4] to I/F. The observation geometry of each pixel is calculated using the Ryugu shape model [6] produced by the Hayabusa2 shape model team. We fit a linear function to the phase function plot within the phase angle range 0.2–1.7°. Using this phase function, each pixel's I/F was extrapolated to normal albedo. Finally, we create a mosaic map of normal albedo for each band.

Since the observed brightness at the opposition condition is less affected by shadows or topographic undulation than other geometries, the derived map successfully shows the albedo distribution under minimal noise conditions. The color study [e.g. 1, 6, 7, 8] of Ryugu reported that the spectral slope from b-band (0.48 μm) to x-band (0.86 μm) exhibits the greatest regional variation on Ryugu. We found that the normal albedo is well correlated with the b-x spectral slope. Further study is necessary to interpret this relationship.

Acknowledgment: We thank the entire Hayabusa2 team to achieve the observation and analysis. Change in boulder surface spectra on asteroid Ryugu induced by touchdown operations of Hayabusa2

*Yudai Takai[1], Seiji Sugita[1], Rie Honda[2], Tomokatsu Morota[1], Shingo Kameda[3], ERI TATSUMI[4], Yuichiro Cho[1], Kazuo Yoshioka[1], Hirotaka Sawada[5], yokota yasuhiro[5], Naoya Sakatani[5], Masahiko Hayakawa[5], Moe Matsuoka[5], Manabu Yamada[6], Toru Kouyama[7], Hidehiko Suzuki[8], Chikatoshi Honda[9], Kazunori Ogawa[5]

The Hayabusa2 spacecraft arrived at the asteroid Ryugu in June 2018, and various static observations have revealed a large number of boulders on Ryugu's surface and its low bulk density of 1190 kg/m^3, suggesting its "rubble-pile" structure (Watanabe et al., 2019). Sugita et al. (2019) reported two main types of boulders on Ryugu: a type 1 boulder is dark and rugged and a type 2 boulder is brighter and has smooth surfaces. The variety of boulders might be the results of sampling from different lithologies in its parent body.
On 21 February 2019, Hayabusa2 successfully touched down for the first time. During the touchdown operation, the optical navigation cameras (ONCs) onboard Hayabusa2 obtained high-resolution images. These imagesshow that boulder's surfaces swept by the sampling projectile impact and thruster gas jets apparently changed in brightness. In this study, using the high-resolution image data we investigated quantitatively the brightness and spectra of the boulders before and after the touchdown to understand the intrinsic optical characteristics of the boulders.
We analyzed 43 continuous images taken by ONCs when the spacecraft gradually descended from an altitude of 10 meters and touched down on Ryugu's surface and then the thruster made it lifted up. Multiple images show that the existence of a variety of boulders even in a few cm scale. The thruster gas jets during the touchdown produced a large amount of debris from Ryugu's surface, and the entire field of view was darkened. Finally, the surface of area near the touchdown site was covered by the dark debris.
We focused on a boulder nicknamed "Turtle Rock", which is classified as type 1. The boulder seems to become brighter immediately after the touchdown. We measured its relative brightness to a boulder that was defined as a reference of brightness because it wasn't covered by the debris through the touchdown. The result shows that the relative brightness of "Turtle Rock" increased by 5~20% compared with before the touchdown and became as bright as type 2 boulders. In addition, a comparison of its spectra before and after touchdown shows that the boulder became bluer after the touchdown. The results are summarized as follows. "Turtle Rock", which is dark and redder and is classified as type1, became brighter and bluer after the touchdown. These results suggest that spectral characteristics of the boulders changed from "type1" to "type2" by sweeping of the dark debris from the boulder surface, suggesting that the variations in boulder surface spectra might be caused by geologic processes on Ryugu such as space weathering and thermal metamorphism not by processes on the parent body.

The Surface Roughness of (162173) Ryugu based on the Topography from HAYABUSA2 Laser Altimeter (LIDAR)

*Shinsuke Abe[1], Noriyuki Namiki[2], Koji Matsumoto[2], Hirotomo Noda[2], Hiroki Senshu[3], Naru Hirata[4], Hirohide Demura[4]

1. Department of Aerospace Engineering, College of Science and Technology, Nihon University, 2. National Astronomical Observatory of Japan, 3. Planetary Exploration Research Center, Chiba Institute of Technology, 4. The University of Aizu

Introduction: The Japanese asteroid explorer Hayabusa2 spacecraft explored the near-Earth asteroid (162173) Ryugu between June 2018 and November 2019. During this period, the laser altimeter (LIght Detection And Ranging, LIDAR) onboard Hayabusa2 collected over 7 million measurements of the spacecraft range to the asteroid surface [8]. The surface roughness and global surface roughness maps for Ryugu were carried out using the LIDAR topography data. The surface roughness which is defined as RMS deviation over different horizontal scales enables to give a new insight into an origin and geologic processes of a small body. The roughness is also related to the self-affine nature of planetary surfaces through a value called the Hurst exponent, H (0 In this study, we investigated the correlations between the surface roughness and the geological features on Ryugu compared with those on Itokawa and Eros. Comparing Hurst exponent of Ryugu with other bodies, the surface evolution of rubble-pile small bodies will be discussed.

Results and Discussion: Deviograms provide a quantitative way to compare the surfaces of different bodies to one another [2-7]. The deviogram of Ryugu appears to have shallower slopes over all baselines than Eros and Moon. On the other hand, comparing the deviogram with Itokawa, it looks like a straight line that increases with increasing baseline. The Hurst exponent of Ryugu is 0.69 at L=8~60m (0.74, L=8~30m). The deviograms of Eros and Moon showed self-affine (straight-line in the deviogram) nature [4], and have a similar Hurst exponent (0.97, L=4~200m) compared to Mercury [3]. On the other hand, the Hurst exponent of Itokawa is 0.51 (L=8~32m). According to [4], Higher Hurst exponent (~1) might be indicative of the surfaces dominated by impact cratering. Several craters on Ryugu have topographically distinctive raised rims while those on Itokawa do not. Unlike Eros (which is believed to be a Fractured Monolith), Ryugu is thought to have a rubble-pile structure [9]. Therefore, due to lack of the ability to support large-scale topography, it is assumed that the Hurst exponent of Ryugu is higher than Itokawa but lower than Eros, Moon and Mercury. It is indicated that the Hurst exponent of Ryugu showed well-correlation to the surfaces topography which is dominated by impact cratering [3-5]. The surface roughness change by a collision will be examined by using the SCI (Small Carry-on Impactor) event.

The Hayabusa2 project is a sample return mission that aims to bring back samples from the C-type asteroid "Ryugu".The Hayabusa2 spacecraft successfully touched down on Ryugu on February 22, 2019. Previous observations suggest thatRyugu has a relatively high porosity of >50% and many largesurface boulders.These characteristics indicate that Ryugu has a rubble pile structure. Estimation of the macroporosity requires the bulk density of the constituent blocks of Ryugu, which is currently unknown. At present, the estimated porosity is calculated using the grain density values of two carbonaceous meteorites withsimilar spectrato Ryugu. The grain densities are 2.42±0.06 g/cc(CI) and 2.74-3.26 g/cc(CM)respectively. The total porosity is estimated using these values of 51±1% and 57-63%, respectively.On February 22, when the Hayabusa2 spacecraft touched down, the optical navigation camera, ONC-W1, observed the state of the landing. In this study, we analyzed the images from ONC-W1 and estimated the bulk density of the boulders on Ryugu's surface.

East-west asymmetric crater ejecta on Ryugu

*Naoyuki Hirata[1], Noriyuki Namiki[2]

1. Kobe University, 2. National Astronomical Observatory of Japan

Asteroid 162173 Ryugu is a top-shaped body formed by a prior period of rapid spin. Major craters on Ryugu appears an east–west asymmetric profile of crater rims; their western crater rims are sharp and tall, while their eastern crater rims are rounded and low. Although there are various possible explanations, we theoretically assess the effect of rotation as a possible origin of this east-west asymmetry. It is known that the trajectories and fates of ejecta are affected by the effect of rotation, especially the Coriolis force and the inertial speed of the rotating surface. As a result, we found that east-west asymmetric crater rim can be explained by the effect of a rotation, only if the inertial speed of the rotating surface is nearly equal to the first cosmic velocity of the body. In particular, Urashima, Cendrillon, and Kolobok craters might be formed, when Ryugu was fast rotator with a rotation period of ~3.6 hours. Brabo crater may be relatively younger.

Hayabusa 2 spacecraft revealed that a small carbonaceous asteroid (162173) Ryugu is a rubble pile with overall density 1.19 x 10^3kg/m^3 [1].
The surface of Ryugu is covered with various sizes of boulders. On Ryugu, the relative abundance of large boulders (>20m) is about twice as that of Itokawa or Bennu [2,3]. On the surface of Itokawa, several cracked boulders are observed and compared with cracked fragments from impact experiments [4]; impacts on Itokawa or its parent body would form boulder cracks.

Thermal fatigue is advocated for the disintegration process of surface rocks [5], where diurnal / annual thermal cycle may promote crack growth in the rocks on regolith over various spatial and temporal scales [6]. Growth of crack is rapid enough to fracture a few 10 cm size rock [7].

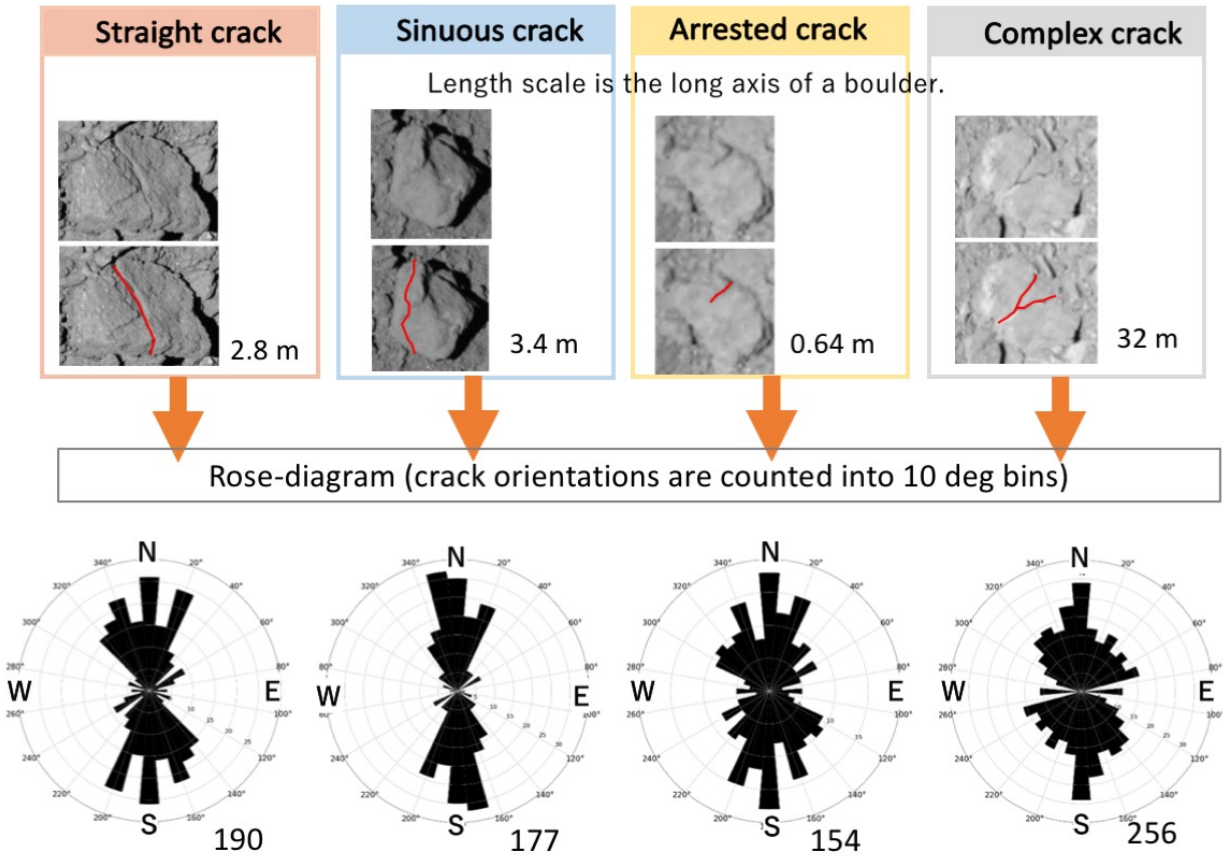
In preliminary analysis, we noticed that cracks on Ryugu boulders have preferred meridional orientation [8]. Desert rocks of the Earth and Mars have preferred orientation of cracks [9,10]. Here in this study, we analyzed more than 500 cracks on Ryugu boulders and checked their orientations. We analyzed 101 images (taken from 29-4083m height at proximity operation phase by Hayabusa-2 ONC-T. Image resolution is 3mm/pixel at best. We confirm the image position and resolution from shape model matching (SPC) and/or altimetry data by LIDAR. Hayabusa 2 usually observes the surface from the direction of the sun, which provide low phase angle data with short shadow width. We carefully check images so that we do not pick up the shadowed surface structure as a crack. Some cracks are confirmed using the image with different (larger) solar phase angle.

To check if a rock has a crack or not, 15-20 pixels are necessary. At the highest resolution, we may check a rock as small as 20cm. Assuming the same range size, about 2-5% of boulders have cracks. So far, we do not observe changes of the abundance ratio of cracked rocks on the Ryugu surface.

We classified cracks into four styles (as shown in the Figure):

(a) Straight cracks: Some cracks are running linearly without bending or kinking. (b) Sinuous cracks: Some

©2020. Japan Geoscience Union. All Right Reserved.



cracks have bowing, bending, and wavy structure. (c) Arrested cracks: We observed many rocks have a crack which does not go through. (d) Complex (typically branched) cracks.

We separated the strike of cracks into 18 directions with 10deg bin. We analyzed 538 boulders and found 60% of their cracks have the meridional direction (+-15deg from N-S) except complex type. This trend is common among crack types as well as rock size.

If boulder cracks on Ryugu are formed by impact processes, whether impacts occur before or after Ryugu formation, the direction of cracks should distribute more randomly. So far, solar-induced thermal stress on a surface boulder by diurnal rotation and annual revolution of Ryugu might be a possible process for the growth of boulder cracks in the meridional direction.

C-type asteroids are considered to be parent bodies of carbonaceous chondrites and formed from fragments of undifferentiated celestial bodies. The carbonaceous chondrites are enriched in volatile species such as carbon, organics, and water thus thought to be the most primitive chondrites. The elemental abundance of the carbonaceous chondrites is consistent with that of the sun. The asteroid explorer Hayabusa2 has been accomplished its asteroid proximity phase operations, unraveling poorly known connections between the C-type asteroids and the carbonaceous chondrites.

The purpose of the Hayabusa2 mission is not only to obtain samples of the C-type asteroid 162173 Ryugu but also to acquire lots of information about Ryugu [1]. After arrival at Ryugu, the Hayabusa2 has performed a variety of science observations using remote sensing instruments such as Optical Navigation Camera (ONC), Near-Infrared Spectrometer (NIRS3), and Light Detection and Ranging (LIDAR) to characterize Ryugu. The observations by the Thermal Infrared Imager (TIR) [2], a mid-infrared thermographic camera mounted on Hayabusa2, allow us to analyze the digital thermal images which indicate the thermal radiation from Ryugu in order to determine the physical state of the asteroid surface.

TIR has a field of view (FOV) of 16.7˚×12.7˚ and the effective pixels of the detector of 328×248, resulting in the spatial resolution about 0.051˚ per pixel [2]. A temperature range that TIR can cover is 150 to 460 K and the well-calibrated temperature range is 230 to 420 K.

Global thermal images of Ryugu indicate low thermal inertia, suggesting a highly porous physical state of the surface relative to typical carbonaceous chondrites, even for large boulders [3]. Close-up thermal images taken during the descent operations show that most of the surface is also covered with highly porous boulders, but some boulders are obviously more consolidated like typical carbonaceous chondrites.

In this study, we investigated temperature variations of boulders and their physical state in the specific regions. We used the high-resolution thermal images taken below the altitude of 500 m during the descent operations for the release of MINERVA rovers on 21st September 2018, the release of MASCOT lander on 3rd October 2018, the touchdown rehearsals (TD1-R1A on 15th October 2018 and TD1-R3 on 25th October 2018), the first touchdown (TD1) on 21st February 2019, and the close-up observations around the second touchdown candidate region (DO-S01) on 8th March 2019. We measured the temperatures of individual boulders on these areas using the TIR images. We will report and discuss the details of the results of the temperature variations of surface boulders of these above regions on asteroid Ryugu.

Evaluation of Surface Temperature Variation on Asteroid Ryugu caused by Space Weathering

*Takehiko Arai[1], Tatsuaki Okada[2], Satoshi Tanaka[2], Tetsuya Fukuhara[3], Hirohide Demura[4], Naoya Sakatani[2], Toru Kouyama[5], Yuri Shimaki[2], Hiroki Senshu[6], Tomohiko Sekiguchi[7], Jun Takita[8]

Recently, space weathering is known as the phenomenon that causes spectral differences between meteorites and asteroids by ground observations (Clark et al., 2002). A result of analysis for a returned sample of Hayabusa spacecraft revealed surface modification on the asteroid Itokawa occurred due to space weathering (Noguchi et al., 2011). An inverse correlation was found in the observed parameters of the surface albedo and the characteristic peak of infrared spectra, known as the Christiansen feature, on the lunar surface (Lucey et al., 2017). These results imply that spectral shape in the thermal infrared range of asteroids may be changed due to space weathering. This study evaluates the effect of space weathering that occurred on the surface of the asteroid 162173 Ryugu by numerical calculation and compares that with the observed temperature by the Thermal Infrared Imager (TIR) onboard Hayabusa2 observation (Okada et al., 2017). TIR observed surface temperature of Ryugu with a spatial resolution of 0.051 degrees from June 27, 2018, to November 13, 2019 (Watanabe et al., 2019). TIR reveals the evolutional history of Ryugu, such as the physical properties of the coalesced bodies, and the thermal changes of the surface and inner materials. Thermal inertia is the main target, and surface roughness (Groussin et al., 2013) is also an important parameter that caused by surface shadows of light, and multiple radiations apparently change the local temperature of the surface. Both thermal inertia and surface roughness affects the peak shift of diurnal time on the surface temperature of Ryugu and probably cause the orbital changes as studied as the Yarkovsky effect (Bottke et al., 2002). The space weathering will be minor effects for the temperature change of Ryugu. In this study, we compare the anticipated temperature on Ryugu due to space weathering and the observed temperature with TIR. We assumed the solar spectral irradiance at the orbit of Ryugu and the surface composition of carbonaceous chondrites similar to the asteroid Ryugu. The amount of space weathering is assumed in dissociation energy as energetic erosion due to ion radiation of <10^6 years (Kracher and Sears, 2005). The result of the spectral change in an anticipated flux was a few W/m^2 in the spectral range of 8-12 micrometers. Therefore, TIR is not able to resolve such a faint difference in radiation. However, space weathering also changes in the whole range of spectra, and that will cause the darkening and reddening on the surface material (Thompson et al., 2019). These effects will decrease the bond albedo and increase the surface emissivity. The space weathering may cause an increase in temperature of the inner material, as well as the uppermost surface. Thus, the observed brightness temperature may be increased. We calculated the variation of radiation temperature with the reflection of solar flux, which is depended on the value of the bond albedo using the thermal model code of TIR (Takita et al., 2017). The result of this calculation indicated that variation of the surface temperature due to space weathering is a few Kelvin. Therefore, TIR is potentially able to detect the temperature variation due to space weathering, as well as surface thermal properties, depended on the thermal inertia and the surface roughness.

The effects of porosity of surface materials on the reflectance spectra of C-type asteroids

*Eiichi Kagawa[1], Tomoki Nakamura[1], Kana Amano[1], Lucie Riu[2], Moe Matauoka[2], Osamu Sasaki[3]

1. Department of Earth and Planetary Materials Sciences, Faculty of Science, Tohoku University, 2. Institute of Space and Astronautial Siences/Japan Aerospace Exploration Agency, 3. The Tohoku University Museum

C-type asteroids are classified into several subtypes based on their reflectance spectra. Compositional and physical properties (e.g., mineral composition, surface roughness, and alteration and weathering degrees) are responsible for the diversity of the reflectance spectra of C-type asteroids. Some previous studies (e.g., Cloutis et al. 2018) have investigated how these properties impact the reflectance spectra of carbonaceous chondrites (CCs) whose parent bodies are C-type asteroids. In this study, we have carried out compaction experiments of Murchison CM chondrite powder ($< 155\ \mu$m) in order to understand quantitively the porosity dependence on the reflectance spectra.

The Murchison powder sample was put in a sample holder, compacted by manual tapping of the holder, and further compressed by a SUS plate to make six different porosity levels of the sample. The initial, uncompacted sample was prepared by leveling the surface (and designated as tap-0 sample). To reduce the surface porosity, the sample holder was tapped 10 times (tap-10 sample), 20 times (tap-20 sample) and 40 times (tap-40 sample). After the sample holder were tapped 40 times, the sample holder was pressed with the SUS plate by hand (hand-press sample) and by 500 kg (500kg-press sample). The reflectance spectra and the porosity of all samples were then measured by FT-IR and micro-tomography CT, respectively, at Tohoku University.

The porosity of the sample powder decreases as the sample were compacted from the tap-0 to 500kg-press sample. In addition, we found that the porosity decreases from the surface to the bottom of the sample powder and thus it is essential to obtain the surface porosity (not bulk porosity) to understand the porosity dependence on the spectra. We define the surface porosity as the porosity between the surface to the depth to which light comes in from vertical direction: light can penetrate through spaces between small grains and stop at a depth at which it is absorbed.

The measurement of the reflectance spectra showed that decreasing the surface porosity of the powder sample with tapping 0 to 40 times results in an increase in reflectance at 550nm wavelength with a small change of the slope of spectra. On the other hand, decreasing the surface porosity by pressing (hand-press and 500kg-press samples) results in brightening at shorter wavelengths and bluer-sloped spectra. The bluing of the spectra is probably due to an increase of the surface flatness by pressing using the flat surface of the SUS plate.

Our results indicate that the surface porosity and the spectral features are correlated: as the surface porosity decreases, the reflectance increases with a slight reddening of the slope of spectra. Small changes of the slope indicate small changes of the roughness of the surface by tapping. On the other hand, pressing with the flat SUS plate changed the roughness of the surface making it flatter surface, which results in bluing of the spectra. Therefore, the changes of spectral properties of the hand-press and 500kg-press samples are resulting from mixed effects of decreasing surface porosity and flattening of the surface. Our results provide a quantitative relationship between grain-size, porosity, and spectral features of C-type asteroids. Further studies with the same experimental procedures using different grain size of

©2020. Japan Geoscience Union. All Right Reserved.

the powder sample are required to distinguish between porosity and grain-size effects and to isolate only porosity effect on the spectra of C-type asteroids.

Evidence of Boulder Mass Movement in the Northern Latitudes of Asteroid Bennu and Implications for its Surface Evolution

*Yuhui Tang[1], Dante S Lauretta[1], Ronald Ballouz[1], Daniella DellaGiustina[1], Carina Bennet[1]

1. University of Arizona

The OSIRIS-REx spacecraft has returned data from the mission's Detailed Survey of the boulder-dominated surface of asteroid (101955) Bennu, which has allowed the creation of a global basemap at a pixel scale of 5 cm (Bennett et al. 2020). With only small (<20-m diameter) patches of smooth regolith, Bennu's surface evolution is likely dominated by boulder mobility. Here, we perform a focused investigation of a region between 295° and 340° longitude, and 15° and 80° N latitude, where a large concentration of boulders is distributed in a pattern indicating a possible mass flow.

We used the Small Body Mapping Tool (SBMT; Ernst et al. 2018) to measure and count boulders, utilizing the 5-cm global basemap projected on the Bennu shape model (Barnouin et al. 2019), with additional images supplemented to view shadowed areas. Using this mosaic, we delineated the hypothesized mass flow region. Within the resulting boundary, there is a large elevation change (50 m), relative to the geoid, in the north-south direction and a minimal elevation change (5 m) in the east-west direction. Within this region, we characterized boulders larger than 1.5 m, using an ellipse to capture their overall shape, size, and orientation in order to provide quantitative information regarding their spatial distribution and physical properties.

The results of the boulder count are combined with gravitational and elevation data from the 80-cm (facet size) shape model. Our preliminary results reveal a relationship between the elevation of the site and the density of boulders present, where a higher density of larger boulders sit at lower elevation in the east-west direction. This implies that mass movement in the east-west direction resulted in the migration of these boulders into their current lower-elevation position. Analysis of boulder orientations, however, shows a preferential alignment with the north-south direction, hinting at sliding movement in that direction. The nature of the flow, such as its origins and history, therefore, are still being investigated.

The method developed here will be further used to model similar flow features that may be present in other regions of Bennu. Such studies could help elucidate the processes that formed the Bennu surface that we see today, both globally and locally (for example, changes following cratering events).

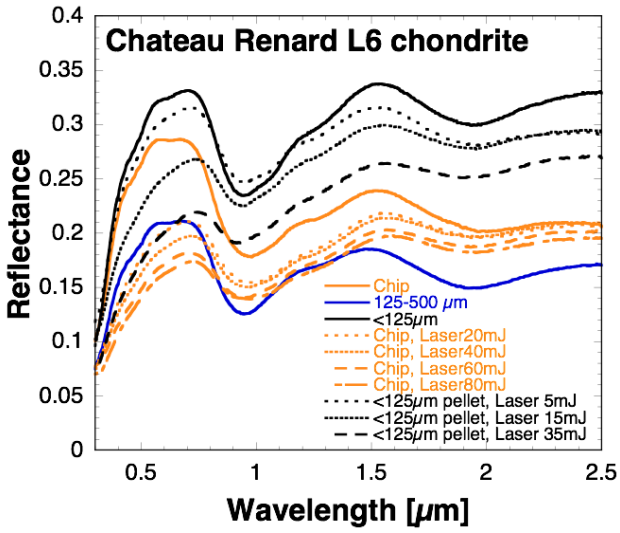
Q-type asteroids: possibility of having non-fresh weathered surfaces without fine particles



*Sunao Hasegawa[1], Takahiro Hiroi[2], Katsuhito Ohtsuka[3], Masateru Ishiguro[4], Daisuke Kuroda[5], Takashi Ito[6], Sho Sasaki[7]

1. Japan Aerospace Exploration Agency, 2. Brown University, 3. Tokyo Meteor Network, 4. Seoul National University, 5. Kyoto University, 6. National Astronomical Observatory of Japan, 7. Osaka University

Itokawa particles not only put an end to the S-complex asteroid problem, but also brought the new mystery that space weathering time scale three orders of magnitude shorter than previously thought mechanisms.
The orbital evolution caluculation in this study (Hasegawa *et al.* 2019, *PASJ* **71**, 103) reveals that the mechanism of refreshing the surface by the close encounter of the planet can be applied to maximally about halves of currently known Q-type asteroids, but not to the remaining about halves.
The results of laboratory experiments on space weathering show that the spectrum of Q-type asteroids in the case of asteroid surface without less than 100 micron particles even when space weathered can be explained.
Solar radiation pressure and electrostatic force can be considered as a mechanism to release particles smaller than 100 micron and it has been found that they can be applied to Q-type asteroids less than 0.5 km in diameter with very small perihelion or less than 0.3 km in diameter.

Three-dimensional tracking of various sized glass beads ejected from crater formed by high-velocity impact

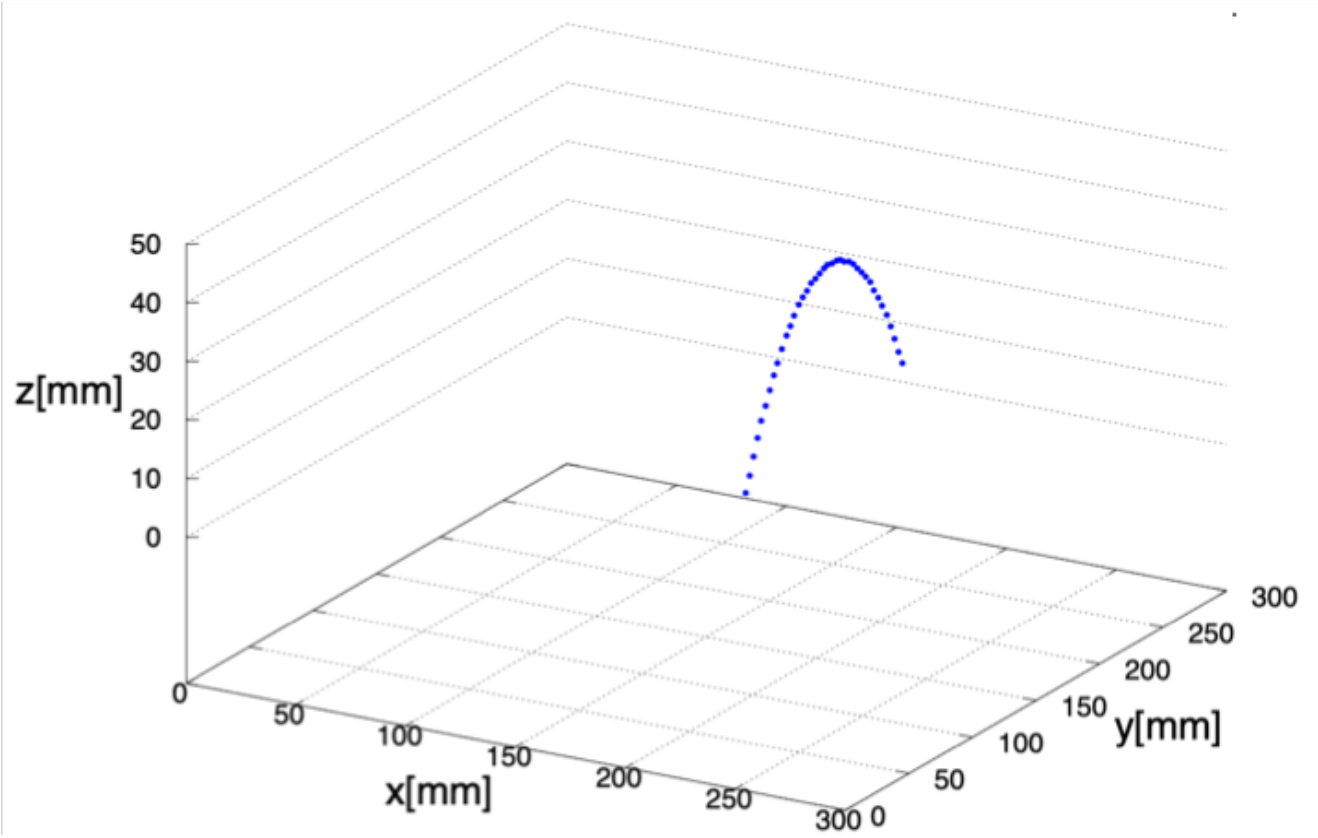
*Hatsune Okawa[1], Minami Yasui[1], Masahiko Arakawa[1], Sunao Hasegawa[2], Yusaku Yokota[1], Yuya Yamamoto[1]

1. Graduate School of Science, Kobe University, 2. Japan Aerospase Exploration Agency, Institute of Space and Astronautical Science

Impact cratering has been recognized to be a general phenomenon occurring during the formation and evolution of solar system bodies. During crater formation, impact ejecta deposits on the surface around the crater, so it is important to consider the resurfacing process of solid bodies. Many researchers studied the velocity distribution of impact ejecta and the velocity distribution is well described by the π-scaling theory [1]. We can apply this scaling law for homogeneous targets, but recent asteroid explorations revealed that the boulders on the asteroid surface had a wide size frequency distribution [2][3], so this size frequency distribution might affect the scaling laws. Previous cratering experiments using a uniform-sized granular targets showed that an axisymmetric cone-like ejecta curtains were observed. On the other hand, Kadono et al. [4] observed non-axisymmetric and non-uniform ejecta curtain for targets with non-uniform particle sizes. They proposed that the formation mechanism of a non-uniform ejecta curtain might be related to the ejecta velocity distribution depending on the particle size. In this study, we carried out impact cratering experiments using granular targets with a particle size distribution, and established a three-dimensional particle tracking method for various sized ejected particles in order to examine the effects of the particle size on the ejecta velocity distribution.

Impact experiments were conducted by using a one-stage vertical gas gun at Kobe Univ., and a two-stage vertical gas gun at ISAS. Targets were glass beads with the size of 0.1, 1, 3, and 10 mm; they mixed evenly with an equal mass. We used 3-mm-sized spherical projectiles made of nylon, glass, alumina, titanium, zirconia, and iron at Kobe. The impact velocity ranged from 129 to 208 m/s. At ISAS, we used 1-mm-sized spherical projectiles made of aluminum, titanium, iron, and copper. The impact velocity ranged from 1.2 to 4.4 km/s. We used two synchronized high-speed cameras with a framing rate of 2000 to 10000 fps in order to obtain the three-dimensional trajectory of ejected beads.

The observational procedure is described as follows. First, we recorded a rectangular parallelepiped reference (30 cm ×30 cm ×40 cm) by two cameras to determine the spatial coordinate of the bead in the chamber. Next, we conducted impact experiment without a reference and recorded the ejecta curtain by synchronized two cameras. In order to identify each bead on their images, 6-8 colored glass beads (3, 5, 10, 18mm in the diameter) were set on the target surface near an impact point before the shot. Finally, we tracked the colored beads on each image, then obtained each bead position in the three-dimensional coordinate system based on the reference.



In this study, non-axisymmetric and non-uniform ejecta curtain was observed for all shots. And we succeeded to obtain three-dimensional trajectories of ejected beads by using the above method. The analyzed beads moved at a constant velocity in the horizontal direction, while they were accelerated in a vertical direction by the earth's gravity (~10 m/s^2), showing a parabola trajectory. Our data was scattered slightly, but they could be approximate by the π-scaling theory. The ejection velocity distributions were divided into two trends which the one was twice larger than the other at same initial position. We should clarify this cause in the future. Besides, we did not observe the effects of bead size on the velocity

©2020. Japan Geoscience Union. All Right Reserved.

distribution. Most beads were ejected radially from the impact point regardless of bead size while a part of them were ejected in different directions. This large angle deviation might be caused by the collision with larger beads before or after being ejected from the target surface.

Effects of surface topography on ejecta growth and crater formation process

*Yusaku Yokota[1], Masahiko Arakawa[1], Minami Yasui[1], Yuya Yamamoto[1], Hatsune Okawa[1], Sunao Hasegawa[2]

1. Graduate School of Science, Kobe University, 2. Japan Aerospace Exploration Agency

Impact craters are a typical geological feature found on solid bodies such as asteroids and satellites. The crater shape was observed to change depending on an impact angle and surface topographies. The crater formed on a plane surface usually looks like a circle except for craters formed by an oblique impact. Then, most impact craters are observed to be circular, but the crater found on a slope is usually elliptical. In addition, recent spacecrafts such as Hayabusa2 and OSIRIS-REx have revealed that Ryugu and Bennu have a bulge terrain at the equatorial region and large impact craters with a unique shape are found on the bulge. However, the effects of the bulge topography on the crater formation process have not been well understood. In this study, we performed crater formation experiments on targets simulating a bulge and a ridge made of regolith and investigated the effects of the topography on crater shape, ejecta growth and its sedimentation process.

We have prepared a mountain range and a cone shape target in order to simulate a bulge and a ridge. The target is composed of quartz sand with a diameter of 100 mm and the angle of repose for quartz sand is about 30 degrees. The slope was controlled to be 20 degrees and 30 degrees for the mountain range type and 30 degrees for the cone shape type. The impact experiments were conducted by using a vertical gas gun, and the mountain range target was set in a glass container to observe the crater formation from the side. The cone type target was set in a stainless container, and was placed in a vacuum chamber. The chamber was evacuated below 1000 Pa or less. The projectile was an alumina sphere with the diameter of 3 mm and an aluminum sphere with the dimeter of 2 mm, and it was impacted on the target surface vertically at the speed from 69 m/s to 202 m/s for the mountain range type target and from 1.19 km/s to 4.19 km/s for the cone type target. For the mountain range type target, the horizontal distance from the summit to the impact point, d, was changed from 1 mm to 19 mm, and for the cone type target, the width of the cone shape was changed from 85 mm to 280 mm.

As a result, the crater shape was found to strongly depend on d in the mountain range type target, and the craters formed near the summit were observed to be elliptical. The major axis of the ellipse appeared to be along the ridge direction, and the minor axis appeared to be along the slope direction. The aspect ratio of the major axis to the minor axis decreased with the increase of d, and at the same d, it increased with increasing the impact velocity. In the cone type target, the depth-to-diameter ratio was always smaller than that of the crater formed on the plane surface, and it was found that the ratio became smaller as the impact velocity increased. Furthermore, the smaller the width of the cone shape is, the greater the excavation efficiency is. In addition, it was found that the ejecta curtain formed on the slope had a smaller curtain angle on the side of the impact point, and that the asymmetry of the ejecta curtain increased when the d was smaller (figure).

Heating effects on the structures and elemental ratios of IOM in Jbilet Winselwan and Y 793321 CM chondrites

*Ryota Ichimura[1], Yoshihiro Furukawa[1], Tomoki Nakamura[1], Megumi Matsumoto[1], Mariko Ando

1. Department of Earth and Planetary Materials Sciences, Faculty of Science, Tohoku University

Organic compounds in carbonaceous chondrites record heating and mechanical modifications induced by parent-body and nebular processes. In particular, insoluble Organic Matter (IOM) has been modified by thermal and aqueous processes and its irreversible carbonization has proceeded during alteration. Using solid-state ^{13}C nuclear magnetic resonance (NMR) spectroscopy, Raman spectroscopy, light elemental composition analyses, and electron microscopy, we investigated chemical structure of carbon, C, H, N elemental abundance, and morphology of IOM. The IOM extracted from two CM2 chondrites, Jbilet Winselwan and Y 793321, which may be a good analog for C-type asteroid Ryugu of the Hayabusa2 sample-return mission. These meteorites are classified to heating stage- II in the mineralogical classification scheme based on Nakamura (2005) and experienced a similar degree of aqueous alteration. However, it was suggested that they might have undergone a different thermal history: Jbilet Winselwan was subjected to long-term internal heating by short-lived radionuclide ^{26}Al (Fujiya et al., 2019), while Y 793321 was subjected to short-term impact-induced heating (Nakamura, 2006).

The results of Raman analysis of both IOMs show negligible difference from IOMs in other unheated and heated CM chondrites. The solid-state ^{13}C NMR spectra indicate that low molar ratios of aliphatic carbon to aromatic carbon (~0.14) for both IOM. These ratios are clearly lower than that ratio of lower heating stage-I samples (~0.5) (Yabuta et al. 2005). This indicates that the loss of aliphatic component or the increase of aromatic component of IOMs during heating of the meteorites in asteroids. Elemental analysis shows low H/C ratios (~0.40) in the two meteorites. These ratios are lower compared with stage-I samples (~0.70) (Yabuta et al. 2005). Therefore, the structural and elemental properties of IOMs in both two CM chondrites are similar and consistent with heating stage-II samples.

The results of Raman analysis of IOMs in the two meteorites show no difference from heating stage-I samples in contrast to the NMR and elemental analysis results. The difference suggest that the stage II heating transformed most organic carbon into aromatic but did not transform the carbon to graphitic. The results suggest that incipient structural changes by low-temperature heating of IOMs can be better characterized by NMR and elemental analysis, and further graphitization at high temperature can be well detected by Raman spectroscopy (e.g., Busemann et al. 2007).

Survival of organic materials during atmospheric entry of micrometeorites

*Masayuki Uesugi[1], Motoo Ito[2], Naotaka Tomioka[2], Yu Kodama[3], Takuji Ohigashi[4], Hayato Yuzawa[4], Kentaro Uesugi[1], Akira Yamaguchi[5], Naoya Imae[5], Naoki Shirai[6], Yuzuru Karouji[7], Aiko Nakato[7], Kasumi Yogata[7], Kaori Hirahara[8], Ikuya Sakurai[9], Toru Yada[7], Masanao Abe[7]

National institute of Polar Research, 6. Tokyo metropolitan university, 7. Japan aerospace exploration agency, 8. Osaka University, 9. Nagoya University

Organic compounds in extraterrestrial materials are thought to be one of the important components for the building block of Earth, especially for the origin of life. It is considered that those organic materials would be transported to the Earth by micrometeorites, because previous studies suggested that the flux of micrometeorite to the Earth is much larger than that of meteorites (5.38 x 10^4 kg/y for meteorites and 4 x 10^7 kg/yr for micrometeorites) [1-2]. In addition, micrometeorites show distinct feature that their composition is rather similar to carbonaceous chondrites than ordinary chondrites [3]. Thus, micrometeorites should be an important carrier for the organic materials from interplanetary space to the earth. It is well known that the micrometeorites heated up to 2000 degree Celsius during the atmospheric entry, due to frictional heating. During such intense heating under the oxidized condition, organic compound would be modified and/or destructed. It is important to evaluate the effect of heating of organic compounds during the atmospheric entry, to investigate origin and evolution of terrestrial organics.

In April of 2019, the Hayabusa2 spacecraft succeeded in the sampling of regolith materials from surface of the asteroid Ryugu, which is classified to C type asteroid and considered to be a parent body of carbonaceous chondrites. The sample would contain organic materials those free from the effect of heating during atmospheric entry and even free from terrestrial contamination or weathering. The Phase2 curation team Kochi started the rehearsal analysis of the Hayabusa2 returned samples, using Antarctic micrometeorites (AMMs)[4-5], and found that amount of organic nano-globules survived in the AMMs larger than 150 μm, those would have experienced intense heating during atmospheric entry due to large moment of inertia. Numerical calculations showed that such AMMs would have heated higher than 1000 degree Celsius, and also showed that ram pressure during the heating is almost equivalent to 1 atm.

In order to investigate the possibility of survival of organic matters in intense heating, we conducted heating experiment of carbonaceous meteorites at 1 atm, and evaluate the effect on the organic materials using scanning transmission x-ray microscopy and near edge x-ray absorption fine structure (STXM-NEXAFS) analysis. Results of the experiments show that organic materials are easily destructed in oxidized condition even by short-term heating, and are robust against heating for reduced environment.

We can examine the conditions of atmospheric entry of the micrometeorites by comparing the structural features of organic materials in extraterrestrial materials (e.g. the Hayabusa2 returned samples and AMMs), with experimental products, and would give important constraints on the evolution of organic matters in early Earth or primitive terrestrial environment.

Near-Earth Asteroid Survey with Tomo-e Gozen

*Ryou Ohsawa[1], Jin Beniyama[1], Shigeyuki Sako[1], Seitaro Urakawa[2], Shin-ichiro Okumura[2], Jun-ichi Watanabe[3], Makoto Yoshikawa[4], Tomoki Morokuma[1], Tomo-e Gozen collaboration

1. Institute of Astronomy, Graduate School of Science, The University of Tokyo, 2. Japan Spaceguard Association, 3. National Astronomical Observatory of Japan, 4. JAXA Institute of Space and Astronautical Science

Advances in astronomical observation has rapidly increased the number of solar system small bodies. Up to now, more than 930,000 objects have been discovered. Large part of newly discovered objects are near-earth asteroids, whose perihelion distances are less than 1.3 au. About 2,000 near-earth asteroids are newly discovered annually. Only a small fraction of near-earth asteroids smaller than about 140 m have, however, been discovered so far. Surveys of such small near-earth asteroids are important in the contexts of the evolution of solar system small bodies as well as the planetary defense. Small asteroids become sufficiently bright to be detected only when they are in the vicinity of the Earth. The closer asteroids are, the faster their apparent motion become. Such a fast apparent motion causes significant sensitivity loss by trailing in observations with standard observation systems with CCD cameras.

We have developed a wide-field mosaic CMOS camera, Tomo-e Gozen, mounted on the 105-cm Schmidt Telescope in Kiso Observatory, the University of Tokyo. Tomo-e Gozen is equipped with 84 CMOS sensors and monitors the sky of about 20 sq-degrees at 2 Hz. The total amount of the data obtained in a night is as much as 20 TB. An unique feature of Tomo-e Gozen is a continuous, video-like observation. Tomo-e Gozen is designed to detect every transient phenomena with timescale of about 1 second. The specifications of Tomoe Gozen, a high sensitivity, large field-of-view, and high frame rate, are ideal to detect fast moving objects, such as near-earth asteroids close to the Earth.

A wide-field survey with Tomo-e Gozen have started in October, 2019. A number of transient phenomena, near-earth asteroids, and space debris have been detected by dedicated data reduction pipelines. A near-earth asteroid pipeline detects every linear motion in the video data. Objects moving at 1–50"/s are successfully extracted even in crowded fields. In the operation in 2019, 6 near-earth asteroids are newly discovered. All the absolute magnitudes of the detected asteroids are fainter than 25 mag, corresponding to about 40 m in diameter assuming that the geometric albedo is 0.1. The survey with Tomo-e Gozen successfully detected small near-earth asteroids. In this presentation, the specifications of Tomo-e Gozen and the survey design are presented, as well as the algorithm to detect moving object in huge data, as much as 20 TB per day. Then, future prospects of the Tomo-e Gozen survey are discussed

The Tomo-e Gozen project conducts optical wide-field survey programs with a wide-field CMOS camera, Tomo-e Gozen, attached on the 105-cm Schmidt telescope at the Kiso Observatory, the University of Tokyo. Tomo-e Gozen is the world's first wide-field CMOS camera which covers 20 square degrees with 84 chips of 35 mm full HD CMOS image sensors. A wide-field and high-cadence survey in the optical wavelengths began in 2018 with the Tomo-e Gozen (hereafter referred to as the Tomo-e Gozen transient survey). The main purpose of this survey is to detect young supernovae. However, the survey simultaneously detects a large number of moving objects in their images. As one of the by-products of the survey, here we show our preliminary result about production of phase curves (solar phase angles versus absolute magnitude) of more than 20,000 small solar system bodies including main-belt asteroids, near-Earth asteroids, Jupiter Trojans, Centaurs, and Transneptunian objects. Combining the moving object catalogue derived from the survey and the output ephemeris that the Horizons/JPL system provides, we are now able to obtain phase curves of these objects almost automatically. As the Kiso moving object catalogue is updated and being expanded on a daily basis, the number of the objects (small bodies) that we deal with goes up as well. Our result, when completed, will make a fair complement as well as a significant keystone to what is already published such as from the Pan-STARRS systematic survey on the knowledge of the surface characteristics of the small solar system bodies.

Size distribution of Jupiter's Trojan asteroids in the L5 swarm obtained by the Subaru/Hyper Suprime-Cam

Kotomi Uehata[1], *Tsuyoshi Terai[2], Keiji Ohtsuki[1], Fumi Yoshida[3]

1. Graduate School of Science, Kobe University, 2. Subaru Telescope, National Astronomical Observatory of Japan, National Institutes of Natural Sciences, 3. Planetary Exploration Research Center, Chiba Institute of Technology

We obtained the size distribution of asteroids in Jupiter's L5 Trojan swarm using the Hyper Suprime-Cam (HSC) attached to the Subaru Telescope. Observation was carried out on January 9, 2016 (UT). The survey covered about 18 square degrees of sky area near the opposition and around the ecliptic plane with 240-sec exposure with the *r*-band filter. We detected 189 L5 Jupiter Trojans (JTs) with the detection limit of $m_r = 25.6$ mag. Out of these detected objects, 90 objects with absolute magnitude $H_r < 17.08$ mag and heliocentric distance $R < 5.5$ au were selected as our unbiased sample to derive the size distribution. Assuming a geometric albedo of 0.07, which is a mean albedo of JTs, the size range of our unbiased sample corresponds to 2–20 km in diameter. We fit a single-slope power law to the cumulative distribution for the absolute magnitude H (i.e., $dN/dH \propto 10^{\alpha H}$) and found the best-fit index α to be 0.37 ± 0.01. This value agrees well with the one for L4 JTs obtained by Yoshida & Terai (2017) also through a survey with the Subaru/HSC. Combining the cataloged magnitude distribution for larger objects, we obtained a magnitude distribution of L5 JTs for $8 < H_V < 17$, and found that the obtained broken power-law distribution agrees well with the one obtained by Yoshida & Terai for the L4 swarm in the same size range. This suggests that the L4 and L5 populations have the same origin. On the other hand, according to Fraser et al. (2014), comparison of the size distributions of still larger objects (diameter larger than about 100 km) showed that the distributions of JTs and hot TNOs are indistinguishable, which supports the model that JTs were captured from scattered TNOs. Our results are consistent with the model that both L4 and L5 JTs were originated from the scattered TNOs.

Measurement of Size Distribution of Cold Classical Trans-Neptunian Objects

*Tsuyoshi Terai[1], Fumi Yoshida[2], Keiji Ohtsuki[3]

1. Subaru Telescope, National Astronomical Observatory of Japan, National Institutes of Natural Sciences, 2. Planetary Exploration Research Center, Chiba Institute of Technology, 3. Graduate School of Science, Kobe University

Trans-Neptunian objects (TNOs), a small-body population beyond Neptune's orbit, are generally divided into several dynamical subpopulations. One of them, so-called "cold classical" (CC) population, consists of non-resonant objects with dynamically cold orbits, i.e., low inclinations and eccentricities. Since they have been free from significant gravitational perturbation from Neptune and thus are likely to maintain the primordial orbits since the formation, the CC population is a key for understanding the formation and evolution of the planetesimal disk in the outer solar system. In particular, the size distribution of CC population provides essential clues to unveil their nature and history of the primordial planetesimal disk. The shape of its size distribution reflects the results from the planetesimal accretion and mutual collision processes, which is useful information to explore the environment of planetesimal disk and the dynamical/collisional evolutions.

Our study is to measure the luminosity function (corresponding to the size distribution) of CCs down to a diameter of 100 km or less. Since TNOs are so far/faint, their sky number density with the same detection limit is very low compared with other small-body populations. Therefore, a combination of a large aperture telescope and a wide-field imaging instrument is required to obtain sufficient data for deriving the luminosity function with high accuracy. We performed an optical survey observation for TNOs using the 8.2-m Subaru Telescope and Hyper Suprime-Cam, a gigantic mosaic CCD camera with a wide field-of-view of 1.5 deg in diameter, around the ecliptic sky area of 14 deg^2 with two (*g*- and *r*-band) filters on January 26, 2015 UT. Few have ever reported the absolute magnitude distribution of the CC population around 100 km in diameter from a single survey. Our homogeneous survey data acquired with the same instrument, at the same field, and by the same technique allows us to obtain a precise statistical sample.

We detected 173 TNOs from our survey data. The 50%-completeness detection limit is 25.0 mag in *r* band, corresponding to 80 km in diameter at heliocentric distance of 45 au assuming a geometric albedo of 0.1. We extracted a debiased sample containing 47 of the CC candidates based on their sky motion, brightness, and color. The absolute magnitude distribution derived from our CC sample are well fitted by a broken power law as pointed out by previous studies, but the bright-end slope looks shallower than those of the previous studies. We will discuss the similarity and difference between the obtained size distribution and that of other small-body populations such as Jupiter Trojans and Neptune Trojans.

Comparison of original orbits of Oort Cloud new comets given in various catalogues

*Takashi Ito[1], Arika Higuchi[1]

1. National Astronomical Observatory of Japan, National Institutes of Natural Science

Nearly isotropic comets with very long orbital period are supposed to come from the Oort Cloud. Recent observational and theoretical studies have greatly revealed the dynamical nature of this cloud and its evolutionary history. However, many issues are yet to be known. Our goal is to understand current structure of this cloud as well as its dynamical origin. For estimating the current structure of the Oort Cloud, key information lies in the original orbit of the Oort Cloud new comets (OCNCs) that are defined at a distance where these objects do not receive gravitational perturbation from major planets (such as at rg = 250 au from the Sun before comets enter into the planetary region). There have been several attempts to obtain OCNC's original orbits, but it never has been an easy task. This requires numerical orbit propagation of the observed comets with high accuracy including perturbation from major disturbing bodies. In addition, non-gravitational forces often play significant roles here. First and foremost, the orbit determination of OCNC includes substantially large uncertainty because of limited number of observational arcs and very large eccentricity of the comets (~1). Here we show our preliminary result of comparison of various catalogues of OCNCs' original orbital elements at rg = 250 au: So-called the Warsaw catalogues by Krolikowska, the ephemeris given by MPC (Minor Planet Center), that given by Horizons/JPL, and others calculated by a few individuals (Marsden, Kinoshita, and Nakano). The resulting orbits that these catalogues yield are overall similar, but sometimes they are starkly different by reasons yet to be known. Through a series of plots with a help of our own orbit propagation using numerical and analytic methods, we give considerations on which catalogue yields the information that is the most significant (or the most fundamental) for understanding structure, origin, and evolution of the Oort Cloud.

Observational campaigns of (3200) Phaethon in 2017-2019

*Fumi Yoshida[1], Tomoko Arai[1], Ko Ishibashi[1], Peng Hong[1], Ryo Ishimaru[1], Takaya Okamoto[2], Jun-ichi Watanabe[3], DESTINY+ collaborators

1. Planetary Exploration Research Center, Chiba Institute of Technology, 2. Institute of Space and Astronautical Science, 3. National Astronomical Observatory of Japan

The asteroid (3200) Phaethon is the flyby target of the DESTINY+ mission. Generally flyby missions requires a detail investigation of the flyby targets for the mission planning and instrument design. Thus, ground-based observations for the flyby targets have important roles for leading the mission success.

We have investigated (3200) Phaethon and related objects by ground based observations from 2017 to 2019. We organized observation campaigns every year : for Phaethon in 2017, for (155140) 2005UD, which is a possible fragment from Phaethon, in 2018, and again for Phaethon to determine the size by occultation observations in 2019.
Our presentation will show the observational results of Phaethon and 2005UD, which were updated every year, and also the observation plan next several years.

Flyby Observation of Asteroid (3200) Phaethon to Be Conducted by Cameras onboard DESTINY$^+$ Spacecraft

*Ko Ishibashi[1], Peng Hong[1], Takaya Okamoto[2], Takahiro Ishimaru[2], Shunsuke Sato[2], Manabu Yamada[1], Osamu Okudaira[1], Tomoko Arai[1], Fumi Yoshida[1], Shingo Kameda[3], Masato Kagitani[4], Takahiro Iwata[2], Tatsuaki Okada[2], Takeshi Takashima[2]

1. Chiba Institute of Technology, 2. Japan Aerospace Exploration Agency, 3. Rikkyo University, 4. Tohoku Universtiy

DESTINY$^+$ (Demonstration and Experiment of Space Technology for INterplanetary voYage, Phaethon fLy-by and dUst Science) is a mission proposed for JAXA/ISAS Epsilon class small program, currently in the pre-project phase (Phase-A). DESTINY$^+$ is a joint mission of technology demonstration and scientific observation. The near-Earth asteroid (3200) Phaethon, the flyby target, is known as a parent body of the Geminid meteor shower, the size of which is approximately 5 to 6 km in diameter.

In this mission, spatially resolved images of Phaethon will be taken by two onboard cameras, the Telescopic CAmera for Phaethon (TCAP) and the Multiband CAmera for Phaethon (MCAP) during the flyby, in order to understand the nature of a meteor shower's parent body, which is one of the sources of interplanetary dust particles that are thought to be an important transport medium of organic matter to the Earth. The spacecraft flybys Phaethon with relative speeds of 30 to 40 km/s. Despite such a high flyby speed, the cameras are required to take unblurred images of Phaethon.

The main purposes of the DESTINY$^+$ flyby observation of Phaethon is to understand the geology of a parent body of a meteor shower, and in particular constrain the dust ejection mechanisms from active (i.e., dust-ejecting) asteroids. The specific objectives of the camera observation are taking images for (1) obtaining the global shape of Phaethon, (2) obtaining the semi-global features of Phaethon such as large impact craters and an evidence of surface disruption, (3) observing the local features of Phaethon such as topography related to dust ejection, and (4) observing the material distribution on Phaethon. The observations (1) to (3) will be conducted by TCAP, and (4) by MCAP.

TCAP is a telescopic panchromatic camera for high spatial resolution imaging of the surface of Phaethon and have a rotational mirror for automatic asteroid tracking during flyby. The rotational mirror can change the direction of the boresight from 0 to 180 deg. This enables to observe Phaethon throughout the flyby with wide solar phase angles, which is extremely important to image and understand the surfaces of planetary bodies because the solar phase angle affects significantly the appearance of geological features in taken images.

MCAP is a multiband camera, the wavelengths of which are 400, 480, 550, 700, 850, and 950 nm (700 and 950 nm are optional bands) and has multiple optical systems and sensors in order to take all band images simultaneously. This is because there is not enough time to take each band image in turn with changing bandpass filters using such as a filter wheel in this high-speed flyby mission. MCAP does not have a tracking mirror due to the weight limitation. Instead, the boresight of MCAP is fixed to the spacecraft with 40 deg off the relative velocity vector of the spacecraft and, Phaethon will be imaged while it is in the relatively wide field of view of MCAP.

We will explain the flyby imaging sequence of DESTINY$^+$, and show the conceptual designs of TCAP and MCAP.

Imaging experiment simulating DESTINY$^+$ flyby exploration

*Peng Hong[1], Ko Ishibashi[1], Takaya Okamoto[2], Osamu Okudaira[1]

1. Planetary Exploration Research Center, Chiba Institute of Technology, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

DESTINY$^+$ (Demonstration and Experiment of Space Technology for INterplanetary voYage, Phaethon fLyby and dUst Science) mission plans to conduct high-resolution imaging during close flyby of asteroid (3200) Phaethon, which is considered as a parent body of Geminid meteor shower. During the high-speed flyby, the asteroid tracking mirror of Telescopic Camera for Phaethon (TCAP) will rotate to obtain unblurred high-resolution images with a spatial resolution up to 3.5 m/pixel at closes approach. Because of the nature of flyby mission which has limited duration of spatially-resolved imaging by TCAP, it is very important to design imaging sequence in order to maximize scientific achievements. Currently TCAP plans to observe the surface of Phaethon with a spatial resolution less than 120 m/pixel for about 9 minutes with an imaging rate of about 1 frame per second, which results in about 50 images with spatial resolutions less than 10 m/pixel. We have conducted ground-based experiment simulating the imaging sequence of TCAP during the flyby to understand how much scientific achievements, especially for creating 3D shape models, would be obtained with the current mission design. Also, the optimization of the imaging conditions during the flyby would be possible based on the results of the experiment, We used a CMOS camera using a candidate sensor for TCAP and a downscaled telescopic lens in order to realize the actual TCAP imaging sequence in a 20m-wide dark room. Asteroid models made by a 3D printer were irradiated with a collimated light source simulating the sunlight. We slid the camera mounted on an optical rail and took images of the asteroid models simulating the observation sequence of TCAP from 151 seconds to 0 seconds before the closest approach. We will report 3D shape models produced from the obtained images and discuss potential scientific results achieved by the current mission design and implication for optimizing the TCAP imaging conditions during the flyby.

Modeling of an Ejecta Cloud in the Vicinity of Asteroid (3200) Phaethon: A Predicton for the Detection of Ejecta Dust by the DESTINY+ Dust Analyzer (DDA)

*Hiroshi Kimura[1], Masanori Kobayashi[1], Koji Wada[1], Tomoko Arai[1], Hiroki Senshu[1], Ko Ishibashi[1], Takayuki Hirai[1], Fumi Yoshida[1], Peng Hong[1]

1. PERC/Chitec

We report on the detectability of an ejecta cloud around Asteroid (3200) Phaethon by the DESTINY+ Dust Analyzer (DDA), based on a model of dust dynamics in the cloud for a collection of spherical dust particles of blackbody with a power-law mass distribution. We demonstrate that solar radiation pressure plays a vital role in shaping the spatial distribution of dust particles in the ejecta cloud of Phaethon by expelling small particles from the sunward direction. We find that the DDA onboard the DESTINY+ spacecraft will have an opportunity of detecting dust particles in the ejecta cloud of Phaethon if the closest approach to the asteroid is confined within 500 km at 1 au from the Sun. Increased opportunities are seen if the Phaethon flyby takes place at a closer distance of 250 km and a smaller heliocentric distance of 0.8 au, and if the surface of Phaethon is porous and the initial velocity of ejecta exceeds 20 m/s. It turns out that impacts of 100 μm-sized ejecta particles scarcely happen to make tiny holes on the surface of the spacecraft during a flyby and that the spacecraft does not seem to suffer a serious damage nor encounter a centimeter-sized particle that causes catastrophic destruction of the spacecraft.

Development and ground calibration strategy of DESTINY$^+$ Dust Analyzer

*Takayuki Hirai[1], Masanori Kobayashi[1], Tomoko Arai[1], Hiroshi Kimura[1], Ralf Srama[2], Harald Krueger[3], Hikaru Yabuta[5], Motoo Ito[6], Mario Trieloff[4], Sho Sasaki[7], Tomoki Nakamura[8], Hajime Yano[9]

1. Chiba Institute of Technology, Planetary Exploration Research Center, 2. University of Stuttgart, 3. Max Planck Institute for Solar System Research, 4. Heidelberg University, 5. Hiroshima University, 6. Japan Agency for Marine-Earth Science and Technology, 7. Osaka University, 8. Tohoku University, 9. Japan Aerospace Exploration Agency

DESTINY$^+$ mission aims to perform fast flyby observation of an active asteroid, 3200 Phaethon, dust observation during the interplanetary cruising and Phaethon flyby phases. DESTINY$^+$ Dust Analyzer (DDA) for the dust observation is the successor to the Cosmic Dust Analyser (CDA) onboard the Cassini spaceprobe, using impact ionization time-of-flight mass spectrometry. The develpment of DDA has been led by University of Stuttgart, Germany, while the interface adjustment between the spacecraft and DDA, the ground calibration, and so on are conducted in coordination between Japanese and German research team. In this presentation, the latest instrument design reflected the restriction of mass resource and the strategy of ground calibration utilizing secondary ion mass spectrometry (SIMS) will be reported.

Keywords: Cosmic dust, 3200 Phaethon, Dust mass analyzer, SIMS

Visualization and Analysis of Data from Small-Body Missions with NASA's Solar System Treks Portals

*Brian Hamilton Day[1], Emily Law[2], NASA Solar System Treks Team -[2]

1. NASA Ames Research Center, 2. NASA Jet Propulsion Laboratory

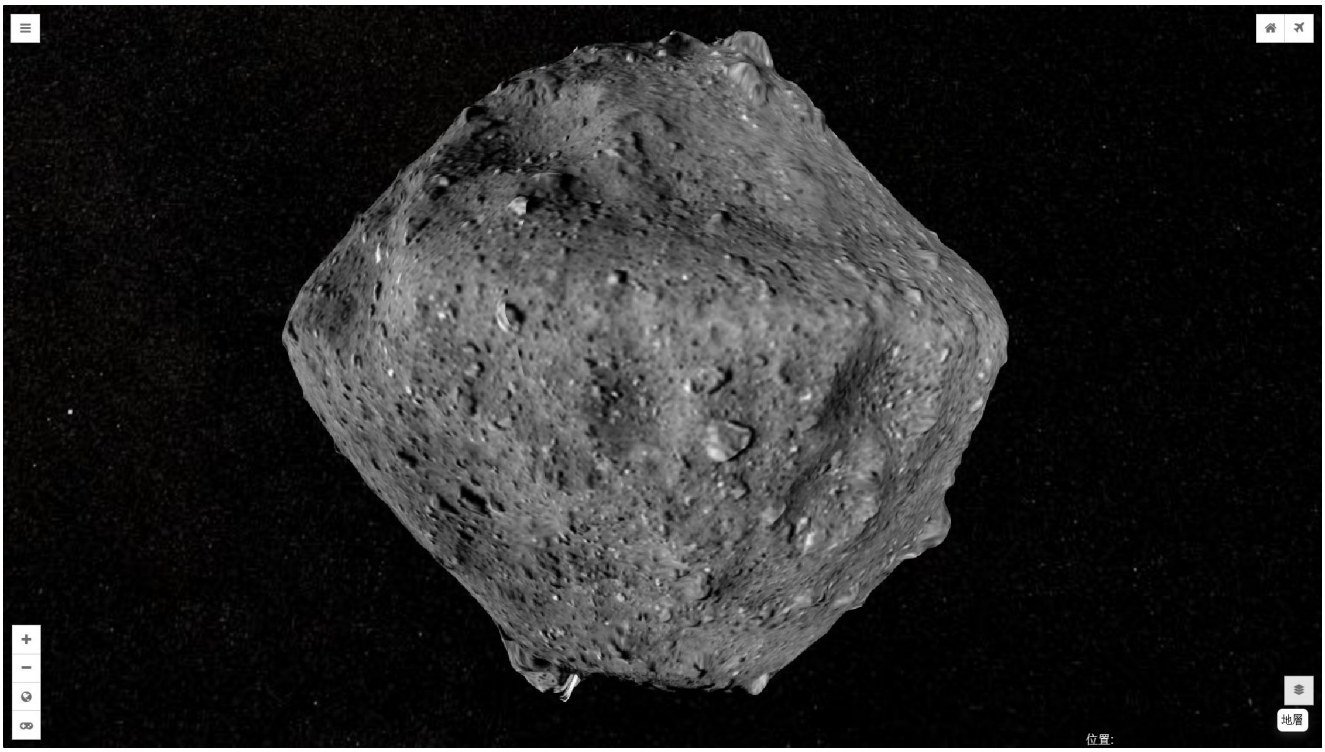
This presentation provides an overview of portals within NASA's Solar System Treks Project (SSTP) that specifically target small bodies within our Solar System.

These portals each allow for visualization of different data products in 2D maps with various projections. They also allow users to conduct interactive 3D flyovers. The VR tool allows users to generate their own virtual reality flyovers for any user-defined paths along the bodies' surfaces. Other tools let users measure distances, generate elevation plots, and create 3D print files for user-defined regions or the entire body.

JAXA's Hayabusa 2 mission recently completed a campaign of reconnaissance, sample collection, and rover deployment at the near-Earth asteroid (162173) Ryugu. JAXA is providing mission data to SSTP, which is incorporating it into the new Ryugu Trek portal (https://trek.nasa.gov/ryugu). The internationalized user interface features controls in both English and Japanese. The portal's bookmarks feature takes users to particular areas of interest for more detailed looks at specific landforms and sites. On Ryugu, we focus on the surface sample site, impactor and sub-surface sample site, as well as landing sites and traverse paths for the HIBOU, OWL, and MASCOT rovers.

While Hayabusa2 was exploring Ryugu, NASA's OSIRIS-REx mission began conducting a detailed examination of the asteroid (101955) Bennu, another near-Earth object. At the request of NASA's Planetary Science Division and the OSIRIS-REx mission, SSTP began implementation a new portal for the asteroid Bennu, featuring data that is being returned from OSIRIS-REx. The Bennu Trek portal (https://trek.nasa.gov/bennu) reveals Bennu's top-like shape, a fascinating commonality with Ryugu. It also reveals details of Bennu's intensely boulder covered terrain. Bookmarked features include Nightingale, Sandpiper, Osprey, and Kingfisher, the top four candidates for sample collection.

In its investigations of Vesta and Ceres, NASA's Dawn mission has returned spectacular data of the surfaces of these two prominent small bodies within the asteroid belt. This presentation will showcase the use of the Ceres Trek (https://trek.nasa.gov/ceres) and Vesta Trek (https://trek.nasa.gov/vesta) portals and demonstrate how they can be used to visualize and analyze particularly interesting landforms such as the pitted terrain on Vesta and relic cryovolcanoes on Ceres.



Under development at this time is a new portal for Mars' larger Moon, Phobos. This portal will make extensive use of data from ESA's Mars Express. It is being designed in collaboration with JAXA to support Japan's upcoming Martian Moons eXploration (MMX) mission. This presentation will provide a preview of a prototype for Phobos Trek.

Other Near-Earth asteroids being considered as candidates for future portals include (433) Eros utilizing data gathered by the NEAR Shoemaker mission, and (25143) Itokawa using data from JAXA's Hayabusa mission. Together, a growing collection of small body Trek portals would enhance capabilities for comparative planetology among this fascinating class of objects.

©2020. Japan Geoscience Union. All Right Reserved.

All of these products are efforts in the NASA Solar System Treks Project, available at https://trek.nasa.gov. NASA's Solar System Trek online portals provide web-based suites of interactive data visualization and analysis tools to enable mission planners, planetary scientists, students, and the general public to access mapped data products from past and current missions for a growing number of planetary bodies. These portals are being used for site selection and analysis by NASA and its international partners, supporting upcoming missions. In addition to demonstrating the capabilities of selected portals in this presentation, we will solicit input from the community for ideas for future enhancements to the portals.

Comet Interceptor mission: an overview and an expected contribution from Japan

*Satoshi Kasahara[1], Shingo Kameda[2], Kazuo Yoshioka[1], Ayako Matsuoka[3], Hideyo Kawakita[4], Shinnaka Yoshiharu[4], Jun-ichi Watanabe[5], Yoshifumi Saito[6], Ryu Funase[1,6], Ozaki Naoya[6]

1. The university of Tokyo, 2. Rikkyo University, 3. Kyoto University, 4. Kyoto Sangyo University, 5. National Astronomical Observatory of Japan, 6. Institute of Space and Astronautical Science

Comets are pristine small bodies and thus provide key information about the solar system evolution. Remote observations by ground observatories have characterized various comets, while in-situ observations by spacecraft have brought much more detailed information on several comets. However, the direct observations by spacecraft fly-by or rendezvous have been limited to the short-period comets, which neared the sun many times in the past and thus lost some of primitive characteristics. The Comet Interceptor mission, led by ESA, aims at a long period comet or an interstellar object. We, Japanese team, will provide an ultra-small daughter spacecraft, whose closest approach will be less than 1,000 km, allowing the first-ever multi-spacecraft fly-by observations of a comet.

Thermal Infrared Multi-band Imager for the Hera Mission

*Tatsuaki Okada[1,2], Tetsuya Fukuhara[3], Satoshi Tanaka[1], Takehiko Arai[4], Naoya Sakatani[1], Yuri Shimaki[1], Hiroki Senshu[5], Hirohide Demura[6], Toru Kouyama[7], Tomohiko Sekiguchi[8], Sunao Hasegawa[1], Makoto Yoshikawa[1]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. University of Tokyo, 3. Rikkyo University, 4. Ashikaga University, 5. Chiba Institute of Technology, 6. University of Aizu, 7. National Institute of Advanced Industrial Science and Technology, 8. Hokkaido University of Education

Introduction: Thermal infrared multi-band imager TIRI is now under study to investigate thermophysical properties and materials of the surface of S-type binary asteroid Didymos in the ESA Hera mission.

Hera Mission: Hera is the ESA's asteroid mission to explore the S-type binary asteroids Didymos (780 m in diameter, 2.26 hours in rotation, 2.1 kg m^{-3}) and its moon (160 m in diameter, 11.9 hours in 1.2 km orbit), and a part of the first international planetary defense mission AIDA (Asteroid Impact and Deflection Assessment) with the NASA DART (Double-Asteroid Redirection Test) mission [2]. DART will be launched in 2021 and perform an impact to Didymoon in 2022. Impact phenomena like impact flash and the moon's orbit change will be observed by ground observations, but the dimension of impact crater, the possible alteration of materials, and the detailed orbit and nutation will be observed by Hera. Hera will be launched in 2024 and arrive at the binary asteroid in 2027.

Hera Operations: Early Phase will start at 30 to 20 km altitude, followed by observations at the altitude of 20 to 10 km. CubeSats will be deployed, followed by observations at 20 to 10 km, then at 10 to 5 km. Finally, Extended Phase will start for closer flyby or orbiting the Didymos.

TIRI Instrument: TIRI is a one-box instrument, consisting of the sensor unit BOL and the electronics unit SHU, with the targeted specification of the total mass < 5 kg, the power < 30 W, and the envelope area < 300 x 150 x 200 mm. Power of unregulated 28 V and 2 channel survival heaters are supplied from the Hera spacecraft. A basic design is from UNIFORM2 [3].

BOL: BOL is based on an uncooled micro-bolometer array of 1024 x 768 pixels, reads at 60 Hz, covers 8 to 14 μm wavelength, and has the FOV of 10° x 7.5°. The detector is pre-calibrated before launch to convert to brightness temperatures. Detector temperature should be controlled using a Peltier during operation. BOL has a capability of multi-band thermal imaging using an 8-point filter wheel, 3 narrow bands for Christensen Features (CF) at 8-10 μm, the other 3 bands for Reststrahlen Features (RF) around 11-13 μm, another one wide band for 8 to 14 μm or no filter for thermal imaging, and the rest for blank as a shutter. BOL possibly has a mechanical shutter outside of the 100 mm-diameter aperture, for on-board temperature calibration and direct insolation avoidance.

SHU: SHU has the functions of data readout from BOL, an on-board data processing, a HK collection, a packet production, a command and telemetry control via Spacewire, a power supply control, a filter wheel control, and a shutter control. SHU captures the raw thermal images of 1024 x 768 pixels at 14 bit depth at 30 or 60 Hz. Image integration and bit-shifts are performed to produce high-S/N 15-bit images. Dark frame subtraction is performed with shutter-close or deep sky images before lossless image compression and CCS-DS packetization. The packets are stored into telemetry queue buffers, to be sent to the spacecraft OBC via Spacewire. The concept is inherited from TIR [4].

©2020. Japan Geoscience Union. All Right Reserved.

Contribution to Hera by Japan: In addition to remote sensing of surface physical state of the binary asteroid by TIRI, just lilke the TIR on Hayabusa2 [5], Japanese contribution to Hera is strongly desired for its advanced experiences in Hayabusa2 mission: impact experiment and simulations, shape modeling, thermal mapping, operations at asteroid approach and proximity, and ground observations.

Acknowledgments: This work is partly supported by ISAS/JAXA Research Fund for International Collaborative Missions in FY2019.

Janus is a NASA SIMPLEx mission currently in Phase B. The SIMPLEx program is designed around the idea of using secondary launch opportunities to explore interplanetary destinations. The Janus mission concept plans to take advantage of the NASA Psyche launch to send two spacecraft to fly by Near Earth Objects of interest. A specific point design has been developed that sends two spacecraft to two binary asteroid systems, (175706) 1996 FG3 and (35107) 1991 VH, both of which have been observed repeatedly with photometry, spectrometry and radar (see Figure 1).

The Janus mission sends light-weight, low-cost spacecraft built by Lockheed Martin to encounter these high-science value small body targets. The science instruments are a visible and IR imager, from Malin Space Science Systems. The spacecraft will perform a rigorous remote sensing campaign when the object is a point source, and when resolved. The spacecraft will track the binary asteroid systems through closest approach, allowing for a combination of absolute surface resolution, relative resolution across the target asteroids and phase angle coverage unparalleled in previous asteroid flyby missions.

Janus science will combine flyby observations of the target binary asteroids with ground-based observations, enabling the high resolution imaging and thermal data to be placed into a global context and leveraging all available data to construct an accurate topographical and morphological model of these bodies. Based on these measurements, the formation and evolutionary implications for small rubble pile asteroids will be studied.

The science team members all have experience on asteroid missions or have made extensive ground based observations of NEAs. The industry team has extensive experience in the design, fabrication and operation of interplanetary spacecraft and instrumentation.

Acknowledgements: The Janus mission is supported by NASA under a contract from the SIMPLEx Program Office. Part of this research was conducted at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with NASA.

Time evolution of the Jacobi integral of the elliptic restricted three-body problem

*Arika Higuchi[1]

1. National Astronomical Observatory in Japan

In our previous studies, we investigated the conditions for the temporary capture of asteroids around a planet. For permanent capture of asteroids as stable satellites, so-called irregular satellites, energy dissipation is required. Interactions of temporarily captured asteroids with a hypothetical gas disk or atmosphere around Mars, the tidal force from the host planet, and the split-up of binary asteroids have been considered as the mechanism of energy dissipation. For all these mechanisms require fine-tuning of parameters for reasonable results. As new research, I investigate the effect of the eccentricity of the host planet on energy dissipation in the framework of the elliptic restricted three-body problem. Jacobi integral, which is a well-known conservational quantity in the circular restricted three-body problem, is no longer conserved in the elliptic restricted three-body problem. However, the behavior of the non-conserved part could tell us the behavior of the asteroids temporarily captured. In the presentation, I will analiticaly and numericaly show if the region on the orbital parameter space exists, where the Jacobi integral keeps changing toward a value that is suitable for satellites.

Planetesimal Formation by Collisional Growth of Dust Aggregates in Disk Formation Phase

Ryohei Ozaki[1], *Taishi Nakamoto[1]

1. Tokyo Institute of Technology

Introduction: Planets are thought to be formed from planetesimals, though the formation process of planetesmals has not been understood well. Some proposed mechanisms include the gravitational instability of the dust layer, the streaming instability, and the successive collisional growth of dust aggregates. It is not clear if required conditions for these mechanisms are met in real protoplanetary disks or in the early solar nebula.

Recent astronomical observations of protoplanetary disks suggest that planets start to form in the class 0 phase, i.e., the disk formation phase, in which the mass accretion from a parental molecular cloud core to the disk continues [1]. If this is the case, planetesimals should be formed in the disk formation phase, too. Theoretically, however, it was suggested that the planetesimal formation seems difficult in the disk formation phase [2], mainly because the disk temperature in the class 0 phase is so high that dust aggregates are likely to drift into the central star due to the gas drag.

In the previous study [2], the disk was assumed to be a viscous accretion disk in which turbulence and viscous energy dissipation are present in the whole disk. This disk tends to have a higher temperature structure. On the other hand, it is known that when the ionization degree of the disk is low enough, the region becomes “dead” and neither turbulence nor dissipation takes place. In the disk with the dead zone, the temperature becomes lower than that of the “active” disk. Then, it is expected that the radial drift of dust aggregates is suppressed. In this study, we examine the temperature structure of the disk in the class 0 phase with the dead zone, and see if dust aggregates can grow to planetesimals or not.

Dust Growth in Dead Zone: We theoretically modeled and obtained the temperature structure of the disk with the dead zone and examined if the dust aggregates can grow to planetesimals with some physical parameters such as the mass accretion rate in the disk and the distance from the central star. We found that with a typical parameter range, it is hard for dust aggregates to grow to planetesimals. However, when the mass accretion rate in the disk is as low as 10^{-7} M_{sun} yr^{-1} or lower, planetesimal may be formed through collisional growth. Those parameter sets may be realized in a quiescent phase of the FU Ori phenomenon.

[P-PS08] Mars and Mars system: results from a broad spectrum of Mars studies and aspects for future missions

convener:Hideaki Miyamoto(University of Tokyo), Tomohiro Usui(Japan Aerospace Exploration Agency), Yuki Harada(Kyoto University), Sushil K Atreya(University of Michigan Ann Arbor)

A wealth of new data from the US, European, Russian, and the Asian exploration missions are contributing to improved understanding of geologic and climate evolution and the habitability of Mars. Eight spacecraft are currently operating at Mars, with six in orbit (Odyssey, MRO, MAVEN, Mars Express, Mangalyaan and TGO) and two on the surface (MSL-Curiosity and InSight), the largest number ever at any given time. In addition, Mars 2020, ExoMars and the Emirates Mars Mission are all scheduled to be launched in 2020. JAXA's MMX mission to explore Phobos, Deimos, and Mars is scheduled for a 2024 launch. This shows that the scientific community, international space agencies and the general public are committed to the exploration of the fascinating world of Mars. Synergistic investigations of ongoing or already completed missions together with modeling studies and earth-based observations are gradually revealing the nature of Earth's most closely resembling planet, which took a different evolutionary track than the other terrestrial planets. Seasonally, temporally and episodically variable phenomena seen on the surface and the atmosphere indicate that Mars is presently active. Thus, this session is planned to discuss recent results from a broad spectrum of Mars studies encompassing the interior, surface, atmosphere, plasma environment, and the Mars system including its two satellites. Abstracts on instrumentation and future mission plans are also encouraged for this session, as both the presenters and the audience would greatly benefit from ensuing discussions and feedbacks.

Experimental study on thermal properties of high porosity particles for understanding physical properties of Phobos surface

*Amiko Takano[1], Naoya Sakatani[1], Hideaki Miyamoto[2], Tomohiro Usui[1], Takafumi Niihara[2], Bernadett Pál[3], Takahiro Iwata[1]

1. Japan Aerospace Exploration Agency, 2. University of Tokyo, 3. Hungarian Academy of Sciences

Origin of Martian satellites; Phobos and Deimos is important in clarify the history of Mars system. Martian Moons eXploration (MMX) has been selected for JAXA's next sample return mission. Observation of the physical properties of the target bodies' surfaces are expected to lead to obtaining geological information on the surface, which could constraint their origin and evolution. It is also important for developing technology for the sample return mission.

In this study, we focus on thermal inertia which is the main factor that determines the surface temperature and one of the important parameters for understanding the surface properties (ex. density and particle size) of planetary surface. The average thermal inertia of Phobos was estimated at ~70 J $m^{-2}K^{-1}s^{-½}$ from infrared observations by Mars Global Surveyor (MGS) [1].

Spectral observation data suggests that Phobos may be a primitive D-type asteroid [2]. Thermal infrared observation of a primitive C-type asteroid Ryugu by Hayabusa2 spacecraft and a primitive B-type asteroid Bennu by OSIRIS-REx spacecraft revealed that the surface of these primitive asteroids are covered with high porosity boulders and pebbles [3, 4, 5]. These observation results suggest that the materials on primitive body are highly porous. Therefore, the particles themselves on Phobos also may have a high porosity. However, experimental research on thermophysical properties for such materials is lacked. Thus, it is essential to understand the thermal properties of the high porosity particles of the Phobos surface layer.

In this study, we will conduct an experimental study on the thermal conductivity of the high porosity particles, understand the heat transport mechanism of porous particle system, and constrain the surface physical properties of primitive small bodies from thermal inertia data. This study will not only deepen the understanding of the geological background of the Phobos surface, but also provide future exploration methods such as MMX landing site selection.

In this presentation, we report the results of thermal conductivity measurements in vacuum using Phobos regolith simulant (UTPS, [6, 7]) and glass beads. UTPS is an artificially generated sample that has been used as a reference simulant of the Phobos surface for the MMX mission, and has many voids inside the grains. Therefore, UTPS was used to understand the surface condition of Phobos, which may have high voids. Based on the experimental results on the thermal conductivity of UTPS and glass beads, we will discuss about the effect of micro-porosity within grains on thermal conductivity.

Near-infrared Hyperspectral Imager MacrOmega on MMX to Observe Martian System: Its Observation Plans and Development

*Takahiro Iwata[1], Hiromu Nakagawa[2], Tomoki Nakamura[2], Jean-Pierre Bibring [3], Cedric Pilorget [3], Vincent Hamm[3], Fuminori Tsuchiya[2], Lucie Riu[1], Moe Matsuoka[1], Hiroyuki Kurokawa[4]

1. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 2. Tohoku University, 3. Institut d'Astrophysique Spatiale, Université Paris-Sud, 4. Tokyo Institute of Technology

The Martian Moons Exploration (MMX) is a probe which will be launched by the Japanese launch vehicle H-III and will navigate the quasi satellite orbit of Phobos and will make a fly-by of Deimos. MacrOmega is a hyperspectral imager in the wavelength range of 0.9 to 3.6 micrometers which is under development to be installed on the MMX spacecraft. It is based on MicrOmega on the ExoMars Rover and Hayabusa2 MASCOT and modified as a hyper-spectral imager with spectroscopic function provided by an Acousto-Optic Tunable Filter (AOTF).

MMX aims to elucidate the evolution of our solar system by investigating the migration process of primitive materials in the early stage. NIRS4/MacrOmega will observe hydroxide or hydrated mineral absorptions on Phobos and Deimos in the wavelength of 2.7-3.2 micrometers. By analyzing the shape of the spectra, we will distinguish between water in hydrous silicate minerals, water molecules, and water ice particles. MacrOmega will also try to detect the absorption by organic matter in the wavelength range of 3.3-3.5 micrometers. These results will support efforts to answer the question of the origin of the Martian satellites and identify whether they are satellites formed by a giant impact or asteroids captured by Mars. MacrOmega will observe Phobos to survey the sampling site before sampling, to investigate the sampling site precisely at the touch-down mode, and to make global mapping. Global mapping of Phobos to select prior areas and landing sites will be performed on the quasi satellite orbit. Precise mapping for candidate landing sites will be followed on the lower altitude. In the touch down phase, we will observe toward sampling site at full wavelength in the descending and landing processes. Observations for Deimos will be basically executed from the fly-by orbit, and they are examined to be made at the near circular orbit. It will also monitor the global distributions and dynamics of the Martian atmosphere. We will report and discuss on the observation plans and the development status of the instruments.

The JAXA-led Martian Moons Exploration (MMX) mission is scheduled for launch in 2024 to reveal the origin of two moons: Phobos and Deimos. MMX spacecraft will be inserted into quasi-satellite orbit (QSO) to observe Phobos, which will contribute to improving our geodetic knowledge such as shape, rotation, and gravity field of the satellite. Although it is not straightforward to relate internal properties to the origin, these geodetic observations are precious to infer internal structure (Le Maistre et al., 2019). A shape model, one of the geodetic products, is also of importance for interpreting remote sensing observation as well as selecting landing site to sample surface materials. This paper describes current strategy for MMX shape modeling.

In contrast to the current situation of limited number of Phobos images with inhomogeneous spatial resolution (Karachevtseva et al., 2014), MMX will provide number of images with more homogenous quality and resolution. The initial base shape model will be constructed from telescopic camera images to be acquired during terminal rendezvous phase from a few thousand kilometers distance, with Phobos being framed within the field of view of the camera. More detailed topography will be reconstructed from images taken from QSO with higher spatial resolution. The size of QSO are roughly divided into three levels, i.e., high (QSO-H, 100x200 km), mid (QSO-M, 50x100 km), and low (QSO-L < 50 km). For QSO-H configuration, the apparent orbital period in Phobos-centered inertial frame is about 35 days and we will be able to observe dayside of Phobos for about two weeks. In order to provide a shape model in early stage of investigation, we will make use of the first QSO-H period with spatial resolution better than 2 m and with scan observation covering at least ±30 deg latitudinal band.

Stereophotoclinometry (SPC), the same technique as used for Hayabusa2 (Watanabe et al., 2019), is also one of the candidates to be applied to MMX. In order to make the shape modeling effective, based on a planned QSO-H trajectory, we investigated the optimal timings of observations with illumination conditions that are preferable for SPC. The LIDAR data, that will be available at least around regions with the lowest altitude, give the scale of the shape model. Preliminary study shows that the necessary observations will be completed within the first dayside observation chance, even if we consider realistic bus operation time during which Phobos cannot be observed, when certain speed of spacecraft attitude scan is realized.

Restoration of highest-resolution images of Phobos observed by the High-Resolution Stereo Camera (HRSC) onboard Mars Express

*Ryodo Hemmi[1], Hiroshi Kikuchi[2]

1. The Universit Museum, The University of Tokyo, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

Spacecraft camera images generally contain imaging artifacts (e.g., distortions, blurs, and noises) which can substantially affect the accuracy of image-based measurements (e.g., crater counting) and their higher-level products (e.g., a global image mosaic). On 23 July 2008 (orbit 5851) and 9 January 2011 (orbit 8974), the Mars Express spacecraft acquired highest-resolution (~0.9 m/pixel) images of Phobos surface by the Super Resolution Channel (SRC [1]) of the High-Resolution Stereo Camera (HRSC [2]). Despite their high spatial resolution, previous studies have not investigated these SRC images because they contain severe pepper noises (“blemish” pixels [1]) and motion smears. However, the surface of Phobos is covered by a number of small craters, roughly circular or oval in outline, which enables us to estimate a point spread function (PSF). Thus, the objective of this study is to characterize and reduce these artifacts with the estimated PSF and to restore high-quality SRC images.
We selected ten raw datasets of highest-resolution SRC images, removed pepper noises from them by using a boxcar filter, and tested several deconvolution techniques (e.g., blind deconvolution, Wiener filter, iterative Lucy-Richardson method) assuming a linear PSF, which we found by try-and-error. Here, we report the results from the deconvolution of the SRC images and discuss the advantages of our method.

Re-impacts from the craters residing at the deepest location generating the blue units on Phobos

*Hiroshi Kikuchi[1]

1. Japan Aerospace Exploration Agency

Re-impact sites from the deepest crater on a body in space preserve much of original information. The surface of the Martian satellite Phobos is spectrally divided into red and blue units [1]. The former are globally distributed, while the blue units have been observed inside and outside the Stickney crater—the largest and deepest crater on Phobos. Outside the crater, the blue units are concentrated in the region from the south to the west (south-west blue units) and in the region east of the crater (east blue units). Several models can explain the east blue units [e.g., 2, 3]. However, the mode of formation of the south-west blue units is still unknown, despite its vast area. We propose that the combination of ejecta from Stickney and Limtoc (a crater located on the floor of Stickney) contributes to the formation of the blue units. We test the model using ballistic simulations incorporating an updated shape model with randomly generated ejecta velocities, different values of orbital radii to Mars, and various launching velocities to track the emplacements of the ejecta particles. The results show the distribution of global blue units are recreated when the combined re-impact sites of ejecta from Stickney and Limtoc have orbital radius (X_{Ph}) values of $X_{Ph} > 3.34\ R_M$ and $X_{Ph} < 3.04\ R_M$, respectively. This suggests that the blue material is concentrated deep underneath the surface, and the age of Stickney crater may be sufficiently old to be estimated from the crater densities [4].

Mars and Earth - distinct inner Solar System products

*Takashi Yoshizaki[1], William F McDonough[1,2]

1. Tohoku University, 2. University of Maryland, College Park

Terrestrial planets provide Solar System insights into the evolution of accretion, core-mantle and crust-mantle differentiation, and surface processes. Similarities and differences between the Earth and Mars made the former habitable and the other inhospitable to uninhabitable. Here we com-pare compositional models for Mars and the Earth to reveal their shared and distinctive properties. Terrestrial planets accreted more high-temperature materials and are depleted in the moderately volatile elements as compared to chondritic asteroids, with the Earth being more depleted than Mars. These compositional properties resulted from nebular chemical fractionation processes, not post-accretionary losses of moderately volatile elements. In agreement with Wänke and Dreibus (1988), Mars' accretion occurred under nearly uniform oxidizing conditions in the presence of a nebular disk, whereas Earth's accretion likely initially occurred under reducing conditions followed by additions of more oxidizing materials. Growth of the Earth occurred during and post-nebular disk's lifetime. Mars' lower Mg# in the mantle reflects a more oxidizing core formation condition than that of the Earth's, leading to Mars' smaller core size and an absence of nominally lithophile elements (e.g., V, Cr and Mn) in its core. Early loss of its dynamo is consistent with Mars having quickly spent its primordial heat (i.e., heat of accretion and core formation), leading to a low sur-face heat flow and a planetary engine driven by its radioactive elements (planetary Urey number ~0.9). These observations may also explains the absence of plate tectonics on Mars even in the presence of surface water early in its history.

Examination of the similarity between crack patterns due to dry fracture on the ground and heat-shrink polygons on Mars

*Chihiro Uemura[1], Takahiro Iwata[1,2], Akio Nakahara[3], Tomohiro Usui[2], Yosuke Matsuo[3], Rina Noguchi[2]

1. SOKENDAI, 2. ISAS/JAXA, 3. Nihion Univ.

Polygons of several tens of meters formed by thermal contraction have been found in the middle and high latitudes of Mars. These polygons may limit the past and present Mars environmental conditions, and research is ongoing. (e.g., Levy et al., J. Geophys. Res. (2009))
Shape, size, and direction of the polygon are determined by various environmental conditions around the polygons. In particular, the shape of polygons found in the crater tends to have anisotropy according to the angle of the slope. It is reported that the shape is close to a rectangle parallel to the slope direction in the steep region, but it becomes random in the gentle slope region at the bottom of the crater bottom(e.g., Ulrich et al., Geomorphology (2011)). A conventional theory suggested that the anisotropy of the shape depends on the slope angle.
On the other hand, it was reported that a similar anisotropic crack pattern appeared in an analog experiment on the ground. When the shear stress induced by vibration exceeds the yield stress of the paste, it can remember the memory of vibration and, when it dries, the direction of crack propagation depends on the memory of such motion(memory effect of paste; Nakahara and Matsuo, PRE (2006)). The dry crack pattern usually takes a random shape. Since the paste is easily broken in the flowing direction, when the paste is flowed along the slope, a dry crack pattern close to a rectangle parallel to the slope is formed. This phenomenon is attributable to that a cluster structure of particles extending parallel to the flowing direction is formed microscopically, and this structure is maintained because of its plasticity. The point is that not only the external force but also the rheology (plasticity, etc.) of the fluid affects the shape of the dry crack pattern. This phenomenon is close to the thermal contraction polygon on Mars, and anisotropic shapes may be formed due to factors other than the slope angle. In that case, it is expected that not only the slope angle but also the properties of the soil in the past are factors that determine the anisotropy of the polygon shape. By testing this hypothesis, it may be possible to constrain the properties of the soil in the past (such as plasticity, rheology and then water content).
In this study, we used the image data of HiRISE, a high resolution camera mounted on MRO(NASA). We quantify the anisotropy by measuring the angle of the polygon shape and find the threshold of the slope angle where the anisotropy appears. We further check a range of the threshold values in different types of polygons and evaluate the validity of slope angle as a controlling factor of the polygon anisotropy.

Search of shallow subsurface reflectors in Chryse and Acidalia Planitiae on Mars

*Aina Oura[1], Yasumasa Kasaba[1], Atsushi Kumamoto[1], Rina Noguchi[2], Ken Ishiyama[3], Fuminori Tsuchiya[1], Tomohiro Usui[2], Chihiro Uemura[4]

Recurring slope lineae (RSL), one of recent major discoveries on Mars, are surface features which may be linked to current icy processes. These are characterized by narrow dark features which incrementally lengthen down steep slopes, fade in colder seasons, and recur annually. Candidate and confirmed RSL sites are mainly distributed in four regions, (1) southern mid-latitudes (SML), (2) Valles Marineris (VM), (3) equatorial highlands, and (4) northern Chryse Planitia and southwestern Acidalia Planitia (CAP). The RSLs in (2) VM and (4) CAP are more densely located than others, and it may indicate the existence of cryosphere in both regions. For the VM area, Noguchi et al. (submitted) investigated from this point of view. In this paper, we investigated subsurface structures of the other region, CAP, by the subsurface radar data taken by Mars SHAllow RADar sounder (SHARAD) onboard the Mars Reconnaissance Orbiter (MRO). For the geological information, we also used the Java Mission-planning and Analysis for Remote Sensing (JMARS, https://jmars.asu.edu/).

The RADAR frequency of SHARAD is 15-25 MHz with the bandwidth of 10 MHz which corresponds to the depth resolution of 15 m in vacuum. The spatial resolution is 0.3 to 1 km along the track direction and 3 to 7 km along cross-track direction. For the comparison with the SHARAD radargrams, we created virtual radargrams emulating the surface and clutter echoes by the Kirchhoff approximation with the topographic altitude maps from MGS/MOLA data. These emulated radargrams were used for the identification of nadir signals not from subsurface reflectors. We also investigated digital terrain models (DTMs) created on MarsSI (https://marssi.univ-lyon1.fr/MarsSI/) to sample the elevation (or thickness) of crater walls close to the candidates of subsurface reflectors. We produced the stratigraphic columns which were divided into fine, coarse and very coarse layers from each DTM, and then identified their depth in the plane around craters. Those procedures are common with the ones which were adopted in Noguchi et al.

We surveyed over 200 orbits in the CAP region. The confirmed detection of subsurface reflectors were in 10 orbits, and the candidates were in more than 50 orbits. Using geologic map, we try to discuss the subsurface structure and identify what kind of layers they are. For example, one radargram (data ID: 03814501) showed a subsurface reflector at mean depth of 125 m in vacuum (2-way delay time: 831 ns). Another radargram (data ID: 04923501) showed a different reflector at mean depth of 55 m in vacuum (2-way delay time: 367 ns). On the other hand, 2 DTMs near these orbits indicated that the boundary of fine and coarse layers was at the depth of about 50 m. We have not precisely calculated the plausible dielectric constant yet, but it ranges from almost 1 to nearly 8 if the reflection happens at that boundary (e.g. pure water ice: 3.15 [Matsuoka et al., 1997], basalt with no voids: 14.9 [Rust et al., 1999]). It will be tough and difficult to conclude the permittivity in the lack of DTMs.

Our statistical result suggested that the distribution of subsurface reflectors was not correlated with RSL sites, but those reflectors were distributed in close to the boundary of geological unit. Furthermore, these subsurface reflectors located shallower than previous study in other regions (e.g. Arcadia Planitia [Bramson et al., 2015]). Although we do not expect that there is abundant subsurface ice, the characteristics of these reflectors should be deeply studied.

Development of subsurface radar for future Mars, the Moon, and asteroid explorations

*Atsushi Kumamoto[1], Hideaki Miyamoto[2], Toshiyuki Nishibori[3], Fuminori Tsuchiya[1], Ken Ishiyama[4]

1. Department of Geophysics, Graduate School of Science, Tohoku University, 2. University of Tokyo, 3. JAXA, 4. Tsuruoka College, National Institute of Technology

Specification and design of radar for subsurface structure measurements in future Mars, the Moon, and asteroid exploration missions have been investigated. In Mars Aqueous-environment and space Climate Orbiter (MACO), measurements of mars subsurface ices in mars low and mid-latitude region (suggested by recurring slope lineae (RSL)) by subsurface radar sounder are planned in order to clarify the contribution of subsurface water cycle to mars climate. This observation also enables us to select out candidate sites for future landing explorations. In JAXA's lunar ice prospector mission by an international collaboration between Japan and India in early 2020s, measurements of three-dimensional distribution of ice below the lunar surface by ground penetrating radar (GPR) installed on the rover are proposed. Design of this GPR could be a baseline of designs of future space-born GPR. Based on the observations of bulk density and boulder size on the surface by Hayabusa, 25143 Itokawa is suggested to be a rubble-pile asteroid. If the size and shape of the rocks inside the asteroid are determined by radar sounder, we can discuss the formation process of the asteroid based on them.

For MACO mission, we are proposing a radar sounder installed on the orbiter transmitting chirp pulse in a frequency range of 50-150 MHz with a peak power of 10 W in order to detect ice within a depth of several 100 meters at a vertical resolution of 1.5 m. For JAXA's lunar ice prospector mission, we are proposing a ground penetrating radar installed on the rover transmitting chirp pulse in a frequency range of 0.5-3 GHz with a peak power of 15 dBm in order to detect ice within a depth of several meters at a vertical resolution of 6 cm. For exploration of asteroid internal structures, the radar sounder for MACO will be applicable also. If we can plan bistatic radar sounding by using radar, transponder, and reflector installed on another orbiter or lander in addition, we can determine not only the subsurface structure of permittivity contrast but also the absolute value of permittivity for discussion of porosity and composition of the internal rock lumps.

In design of the radars for space missions, we can not select parts freely. We have to use limited rad-hard semiconductor parts. In 50-150 MHz, there are selectable D/A converter (DAC) and A/D converter (ADC). So we can select the method using DAC and ADC: Transmitting and reference signals are generated by DAC, and receiver output is sampled by ADC. On the other hand, in 0.5-3 GHz, there are not selectable DAC and ADC. So, we are planning to use VCO for generation of transmitting and reference signals. We are now developing BBM of transmitter and receiver considering parts selection and design for space-born instruments. In late 2020, we are planning performance tests with BBM by measuring soil simulant.

Acknowledgment: This study was supported by JSPS KAKENHI Grant Number 19K21891.

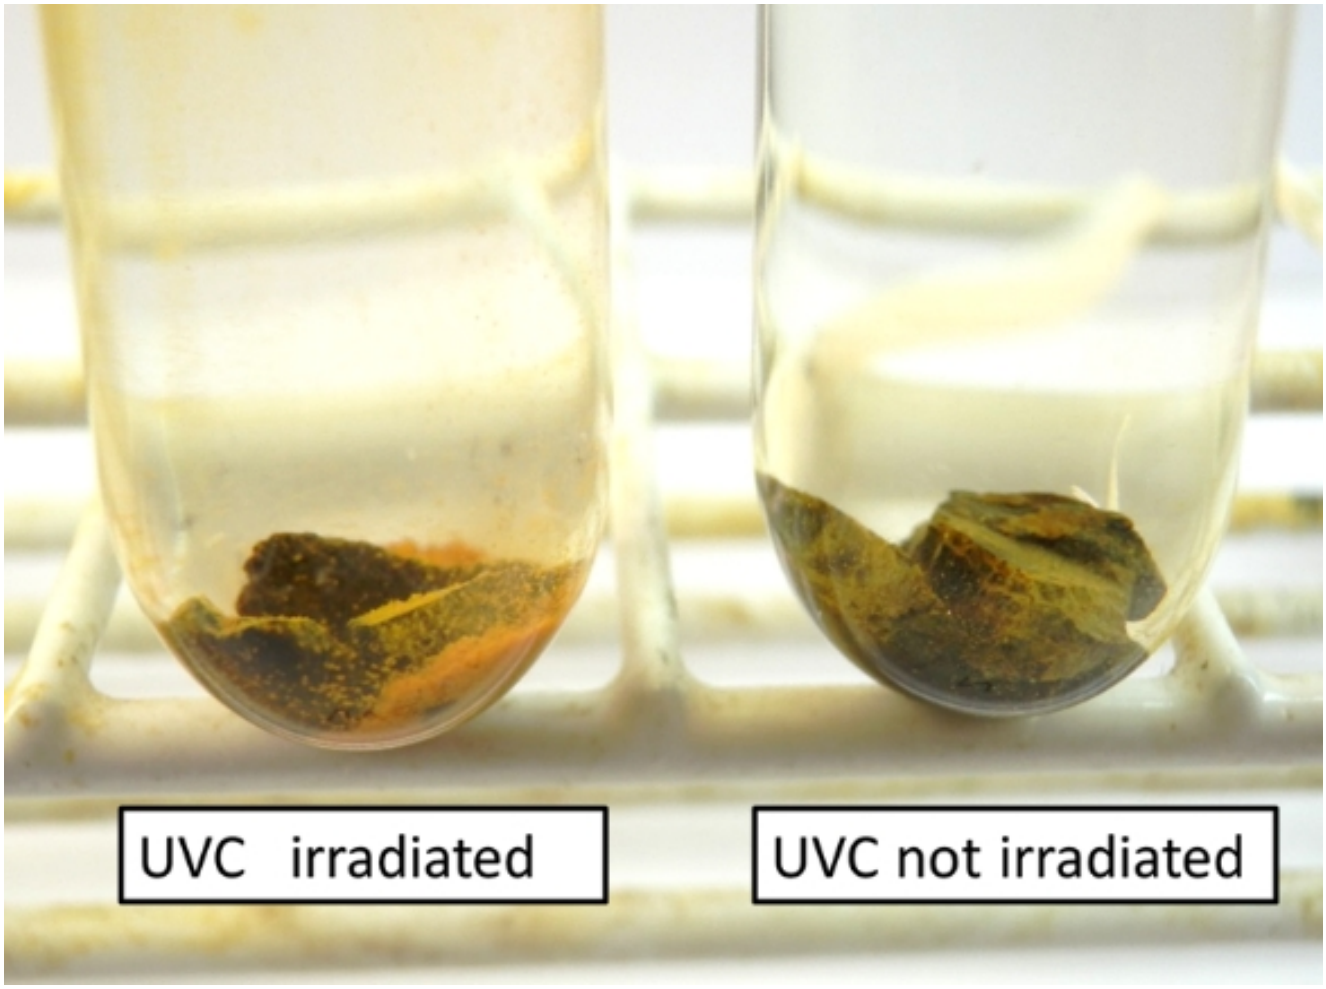
Increase in trivalent iron elution amount and iron compounds from fayalite by ultraviolet C



*Nobuo Komori[1]

1. The United Graduate School of Education Tokyo Gakugei University

In order to explain one of the causes of the large amount of iron oxide on the surface of Mars, the following experiment was conducted by a science club at my junior high school.Ultraviolet rays C was applied to fayalite in hydrochloric acid and sulfuric acid which had been degassed to pH2 as much as possible. Fayalite we used is from Kawamata-machi, Fukushima Prefecture. We selected similarly shaped fayalite and weighted ones at a weight of 1g.These fayalite samples were immersed in acidic aqueous solution in test tubes.Then, ultraviolet rays were irradiated for 200 hours or longer. Every few days, the concentration of total iron ions and trivalent iron ions in the aqueous solution were measured using a digital pack test.Ultraviolet rays C are generated by a germicidal lamp.This peak wavelength is 245 nm and the ultraviolet intensity is about 20 W / m^2.
The results of the this experiment showed that , the concentration of trivalent iron ions in the acidic aqueous solution was significantly increased more than the ones that were not irradiated by ultraviolet rays. Also, the ratio of the trivalent iron ion concentration to the total iron ion concentration was larger when it was radiated by ultraviolet rays.We conducted this experiment three times and the results came to be the same for all three experimet. Also,after the experiment, more brown fine powder was generated in the test tube irradiated with ultraviolet rays than not irradiated. According to the result of X-rays diffraction,,this brown powder seemed to be mostly made from non-crystallized in brown fine powder. Furthermore in the case of hydrochloric acid, it turned out that this brown powder contained Lawrenceite and goethite. Similarly , in the case of sulfuric acid, we found out that metahohmannite and alum were contained.
For the results mentioned above, we can say that ultraviolet rays C increases the concentration of trivalent iron ions eluted from rocks immersed in an aqueous solution and increases the amount of iron compounds.Iron oxide and sulfate minerals have been found on Mars. It is presumed that ultraviolet rays C from the sun promoted the production of these minerals in the past when the Martian sea dried up.

Introduction of the highest resolution image to the Mars Web-GIS “RedAce” to study the local and detailed surface environment

*Hiroshi Sakai[1], Hayashi Yohei[2], Hironori Fukuchi[1], Yuya Matsubara[3], Yoshiko Ogawa[1]

1. The University of Aizu, 2. National Observatory of Japan, 3. The University of Aizu(Now NTTDocomo Inc.)

Water is thought to be an important element in terraforming. There is certain evidence of water on Mars. Therefore, many probes have been launched to Mars. A lot of observation data have been accumulated about Mars. To understand the surface environment of Mars consistently, it is essential to examine these diverse and large amounts of observational data. In such a situation, Geographic Information System (GIS) is very useful. GIS is good at visualizing, integrating and analyzing multiple kinds of information. Web-GIS is a tool which can handle a wide variety of observational data on the web. Among the various kinds of Mars observation data, spectral data are important to identify the types and distributions of hydrous minerals on Mars. Hydrous minerals are important keys to understand the water on Mars.

We have developed a Web-GIS “Red Ace” [1] focusing on the visualization of spectral data from multiple instruments: THEMIS data and CRISM data.

The Web-GIS "RedAce" shows some kinds of image data, too: DEM data from MOLA, band ratio images from THEMIS data, and thumbnail images of CRISM. Those image data are all installed in the system and displayed to the users. However, these images are viewed from a wide angle and it is difficult to perform local analysis.

In this study, we introduce high quality image to the Web-GIS “Red Ace”. The objective is to extend the system so that user can visually and intuitively grasp the features of the Mars surface topography in detail and conduct integrated analysis combining image data and spectral data.
Image data of Mars have been collected from many cameras. We select HiRISE to install in the system. HiRISE is one of the six devices in the Mars Reconnaissance Orbiter (MRO) that can capture the highest quality images (up to 25cm/pix). About 1.8 million pieces of data exist. There are mainly Experimental Data Record (EDR), Reduced Data Record (RDR), and Digital Terrain Model (DTM) types of data. RDR is processed from the EDR and is provided and published in the format of JP 2000. We use RDR data which are calibrated image data. Currently, image data installed in Web-GIS "RedAce" are formatted as CUB data.

Estimation of dust optical depth observed by MGS/TES from visible images observed by MGS/MOC using a convolutional neural network

*Karin miyabe[1], Kazunori Ogohara[1]

1. Graduate school of the University of Shiga Prefecture

For understanding cause and movement of dust haze, we need the atmospheric dust distribution ranging from O(10) to O(100) km in order to understand the initiation and development of dust haze. Although visible image data have been observed by several orbiters, dust optical depth (DOD) cannot be derived from them. And we cannot distinguish thin dust haze from water ice clouds. Therefore, DOD measured by a infrared spectrometer is useful. However, FOV of the spectrometer is generally so narrow that it cannot resolve the development of fine structures of dust haze.

For that reason, we develop a method for estimating DOD of each pixel in images observed by MGS/MOC from the local patterns of the visible images themselves by using the Convolutional Neural Network (CNN), where the ground truth is given by DOD observed by MGS/TES.

Because most of DOD data was much smaller than 1. Such imbalance in the data volume between large and small DODs tends to results in poor estimation of DOD. Therefore, we extracted the same number of DOD data from each regularly divided bin. And trained the CNN model using the data. Validation loss was 0.148. However, it was turned out that predicted DOD highly depended on local brightness in MGS/MOC images. Hence we tried to improve CNN model by normalizing the input data. Consequently, the validation loss increased from 0.148 to 0.181, which means degradation of the model. This degradation is not a serious problem but pave the way to improve the performance of the estimation because dependency of the DOD estimation on local brightness has been reduced.

At my presentation, we will report results of improvement of the CNN model by data augmentation or complication of the model structure.

Survey of dayside reconnection signatures at Mars with MAVEN

*Yuki Harada[1], Jasper S. Halekas[2], Gina A. DiBraccio[3], Shaosui Xu[4], Suranga Ruhunusiri[2], Takuya Hara[4], Jared Espley[3], James P McFadden[4], David L Mitchell[4], Christian Mazelle[5]

1. Graduate School of Science, Kyoto University, 2. Department of Physics and Astronomy, University of Iowa, 3. NASA Goddard Space Flight Center, 4. Space Sciences Laboratory, University of California, Berkeley, 5. IRAP, University of Toulouse, CNRS, UPS, CNES

We present a preliminary survey of magnetic reconnection signatures observed in the upper ionosphere of Mars. A variety of recent measurements from MAVEN suggested that magnetic reconnection likely takes place on both dayside and nightside of Mars. For nightside reconnection signatures in the Mars' magnetotail, a statistical analysis revealed notable asymmetry in their spatial distributions with respect to the motional electric field in the upstream solar wind (Harada et al., 2017), demonstrating that these statistical properties could provide valuable information on the driving mechanisms of magnetic reconnection processes at Mars. In contrast to the relatively well-studied nightside counterpart, the dayside reconnection at Mars has been examined only for very limited cases (Halekas et al., 2009; Harada et al., 2018), and its statistical properties remain unclear. Such information would have important implications for global dynamics of the Martian magnetosphere because it is proposed that the dayside reconnection plays a major role in changing magnetic topology and morphology not only in the dayside upper ionosphere but also in the nightside magnetotail, thereby globally modifying pathways of escaping ionospheric ions. Here we conduct a systematic survey of dayside current sheet crossings and reconnection signatures embedded therein in a similar manner to the previous nightside survey. We will discuss the occurrence rate, spatial distributions, and upstream driver control of the reconnection signatures detected in the dayside upper ionosphere of Mars.

Seasonal variation of neutral and ion compositions in the Martian upper atmosphere observed by MAVEN/NGIMS

*Nao Yoshida[1], Naoki Terada[1], Hiromu Nakagawa[1], Dave A Brain[2]

1. Dep. Geophysics Graduate School of Science Tohoku University, 2. LASP, University of Colorado

The Martian thermosphere, exosphere, and ionosphere are intermediate atmospheric regions strongly impacted by coupling from below with the lower-middle atmosphere and coupling from above with external forces, such as solar EUV and solar wind. Atmospheric reservoir in these regions is believed to determine the composition of species that escape to space. Jakosky et al. (2017) and Slipski et al. (2018) recently showed substantial variations in the altitude of a compositional boundary, called the homopause, below which gases are well-mixed by eddy diffusion (homosphere) and above which gases are diffusively separated according to their own scale heights by molecular diffusion (heterosphere). Yoshida et al. (submitted) showed that N_2/CO_2ratio in the lower thermosphere varies seasonally and latitudinally owing to the variation of the homopause altitude. However, the variation of the ionospheric composition, which can escape to space, responding to the lower thermospheric variation has not been well understood.

The variation of the ionospheric composition is observed by Neutral Gas and Ion Mass Spectrometer (NGIMS) aboard Mars Atmosphere and Volatile EvolutioN (MAVEN). The variation of CO_2^+density at 200 km altitude in the ionosphere resembles that of CO_2density at 140 km altitude at the top of the lower thermosphere. Higher CO_2^+density appears near perihelion and lower CO_2^+density near aphelion. Additionally, the observed sinusoidal trend of CO_2^+density suggests that ionospheric density is relatively controlled by the seasonal variation of the neutral upper atmosphere than the long-term variation of solar EUV flux. On the other hand, N^+density shows the opposite trend with CO_2^+density, which could be explained by the fact that the photochemical loss of $N^+$is caused by the reaction with CO_2. We also have investigated the vertical structures of CO_2^+, O_2^+. $O^+$and N^+densities between 150 and 400 km altitude. The closer relationship between the neutral upper atmosphere and ionosphere is also confirmed below 250 km altitude. The scale height of the major ion species is almost two times larger than that of neutral species. We find that CO_2^+density has a largest variation, by a factor of ~7 at 200 km altitude. Meanwhile, the slopes of ion densities in the photodynamical region between 300 and 380 km altitudes increase compared with those in the diffusion region between 180 and 230 km altitudes in MY34 L_s= 59˚ - 63˚, MY33 L_s= 70˚ - 73˚, and MY33 L_s= 148˚ -154˚, except for in MY33 L_s= 342˚- 346˚. This fact implies that effects from external forces, such as upward flow and local heating induced by the solar wind interaction, may change the slopes of ion densities in the photodynamical region. Additionally, mixing ratio of CO_2^+/O_2^+can vary along the season in the range of ~0.017 to ~0.097, by a factor of ~6, around 370 km altitude. However, mixing ratios of $O^+/O_2^+$and $N^+/O_2^+$are almost constant and their seasonal variations are unclear. The larger variation of the observed CO_2^+/O_2^+than that of O^+/O_2^+might suggest that CO_2^+escape rate can change by up to a factor of ~6 due to the ionospheric composition, however, the observed CO_2^+/O_2^+ cannot fully explain the reported ratio of heavy ion escape rates (e.g., Lundin et al., 2009; Carlsson et al., 2006). It may imply that additional mechanisms to change CO_2^+/O_2^+might exist above our observation range.

In this study, we will classify the NGIMS dataset in terms of (1) the intensity of solar wind pressure and (2) the intensity and direction of interplanetary magnetic field to understand the increase of the slopes of ion densities observed in the photodynamical region. Additionally, we will discuss the possibility of local heating by low-frequency waves (e.g., Fowler et al., 2018; Harada et al., 2019). Thus, we can evaluate the connection between the lower thermospheric composition and the ionospheric composition that can

[P-EM11] Heliosphere and Interplanetary Space

convener:Kazumasa Iwai(Institute for Space–Earth Environmental Research (ISEE), Nagoya University), Yasuhiro Nariyuki(Faculty of Education, University of Toyama), Ken Tsubouchi(University of Electro-Communications), Masaki N(Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science)

This session aims to secure comprehensive insights into physical processes of plasmas and fields in the heliosphere. Presentations of the recent studies from any approaches (integrated observation/theoretical modeling/massive numerical simulation) are welcomed. Topics are not restricted to any specific issues: phenomenological studies on solar flares/CME/solar wind, and related fundamental physics problems such as shocks/waves/turbulence/particle transport and acceleration can be the main target, including heliospheric high-energy phenomena and their impact on the Earth's environment.

Dispersion measures(DMs) derived from pulsar observations provide an integral of the plasma density on the line-of-sight (LOS) from the pulsar to the observer. The purpose of this research is to estimate the solar wind (SW) plasma density in this cycle from the rise in DM value when the LOS of pulsar approaches the sun. The solar activity of this cycle is very low and the SW plasma density decreases. Pulsar observation is useful for examining this change because they cover a wide range of distances and latitude. We used the Crab pulsar in this research. Crab pulsar is a neutron star that emits pulsed radiation over a wide frequency range, and radiation is observed at intervals of about 33 milliseconds. This radiation is affected by plasma, such as interstellar medium (ISM) and SW, causing signal propagation delays. This delay depends on frequency; i.e. DM. The LOS of Crab pulsar approaches a distance of ~$5R_s$(R_s: solar radius) in mid-June every year. Previous observations showed an excessive rise in DM when the LOS of Crab pulsar approached the sun. We observed the Crab pulsar for the period from September 2018 to June 2019 using a 327MHz radio telescope (SWIFT) for IPS observation in Toyokawa. The observation time for a given day was 6 minutes, and 8 minutes for June 2019. Focusing on strong pulses (SNR > 15) during observation, we determine the optimal DM so that the pulses have the highest intensity. Observations from January to March 2018, relatively many pulses were observed. DM data with little influence of SW is obtained from this observation data and this DM data represents the effect of ISM. We analyze the DM value of June 2019 to investigate the SW plasma density at ~$5R_s$. We will present the results of this analysis at the JpGU 2020.

Occurrence dependence on solar activity cycle for type III radio bursts based on the automatic detection analyses

*Yuichiro Seki[1], Hiroaki Misawa[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Tatsuya Fujimoto[1]

1. Tohoku University

Type III solar radio bursts are one of intense radio wave emissions that appear with the solar flares. They appear in the wide frequency range from the GHz to kHz band, and show a large negative frequency drift. A generation process of type III bursts is thought that high energy electrons originally generated with magnetic reconnections during a flare event excite Langmuir waves in the solar corona and/or interplanetary space, then the Langmuir waves are converted into electromagnetic waves observed as type III bursts. It is therefore generally assumed that the frequency of type III bursts reflects the plasma density in the solar corona and/or interplanetary space where the radio waves are generated, and their frequency drift reflect the plasma density distribution and the velocity of high-energy electrons.

It is well known that density distributions of the solar plasma differ depending on the activity of solar surface area (ex. Aschwanden and Acton, 2000). This implies that the plasma density distribution roughly varies with the solar activity cycle and therefore the frequency drift rates of type III bursts might show solar cycle dependence since the drift rate should reflect plasma density distributions along the paths of high energy electrons and also their energies. Although the occurrence rates of type III bursts are known to show a positive correlation with solar activity, our knowledge for solar cycle dependence of the drift rates has been still limited (ex. Zhang et al., 2018).

In this study, we have investigated statistical occurrence features of type III bursts, especially drift rate, flux density and their mutual relations, to clarify their solar cycle dependence. For this purpose, we have tried to make statistical analyses of type III bursts using a database of solar radio spectra observed with the Nancay Decameter Array (NDA) in France since 1977. We have analyzed the low-resolution data (175 kHz frequency resolution, 1 second time resolution) of the Nancay Decameter Array (NDA) in Paris, France. Although the observation frequency range of NDA is 10MHz-80MHz, we have used the spectra for 30-80MHz to avoid hard artificial radio noises below 30MHz.

In this analysis, an automatic burst detection system was newly developed to make the statistical analyses. At first, the spectrum data were divided every few minutes and reduced the thermal radiation level of the sun which temporally changes with the altitude of the sun due to atmospheric extinctions. Next, candidates of solar radio bursts were picked up as the ones whose radio flux exceeded some threshold level. Then, more plausible candidates as type III bursts were sorted out automatically as the bursts appearing continuity in the frequency and time domains at some extents and also with the negative frequency drift. Finally, we identified type III bursts through a visual check.

Using the developed automatic detection system, analyses for the NDA data observed in the solar cycle 24 have been performed. A preliminary result shows that the number of detected type III bursts in 2018 (near the solar minimum) was reduced to about 1/55 compared to that in 2013 (around the solar maximum). In the presentation, we will introduce the automatic type III bursts detection system and show solar cycle dependence for the occurrence characteristics of type III bursts with the discussion of their background processes.

The characteristics of type III solar radio bursts in ^{3}He-rich impulsive solar energetic particle phenomena

*Tatsuya Fujimoto[1], Hiroaki Misawa[1], Fuminori Tsuchiya[1], Takahiro Obara[1]

1. Tohoku University

Solar Energetic Particles (SEPs) are protons, electrons, and heavy ions of 10 keV to several tens GeV generated with flares and coronal mass emissions (CMEs), which are explosive phenomena near the solar surface. SEPs are classified into two types; i.e., impulsive and gradual types, based on the elemental abundances and the time profile of ion flux variations. Also, it has been reported that a phenomenon called type III radio bursts, which are suddenly appearing emissions caused by flares, are often observed in the tens to hundreds of MHz band when impulsive SEPs occur [Cane et al., 1986; McDowell, 2003]. Type III bursts are thought to be generated by energetic electrons accelerated by magnetic reconnections during flares, which propagate along the open magnetic field lines. That is, an injection of the energetic electrons into the solar corona leads to the generation of Langmuir plasma waves, and the waves are converted into radio waves as Type III bursts where the radio wave frequency is as same as the local plasma frequency. Type III bursts appear in the frequency range from GHz to kHz, and show rapid negative frequency drifts. The spectral structure is considered to reflect the motion of accelerated electron beams.
Impulsive SEPs, also known as electron-based events, show higher ratios of ^{3}He/^{4}He and Fe/O than general composition of the solar corona. Temerin and Roth [1992] proposed that the electromagnetic ion cyclotron (EMIC) waves would exist in the accelerating region of the electron beams that generate type III bursts in the solar corona by a similar physical process of the electron beam generation to that in the Earth’ s auroral region. In this idea, EMIC waves are thought to play a resonator which selectively increases flux of ions, such as ^{3}He and Fe. According to this idea, it is expected that both the flux of impulsive SEPs and the spectral structure of type III bursts include some features related to particle accelerations. However, there are few reports comparing characteristics of SEPs and spectrum structures of type III bursts from such a viewpoint, and the relationship between both of them has not been clarified. In this study, we have tried to make a detailed comparative analysis for impulsive SEP phenomena and type III bursts to elucidate relationship between both of them. We have analyzed energy and flux time profiles of SEPs using solar particle data observed with the ACE, WIND, and SOHO satellites staying around the L1 point. On the other hand, we have analyzed spectra of type III bursts such as frequency drift rates and micro structures using solar radio wave data observed with the WIND satellite, and ground-based solar radio telescopes AMATERAS of Tohoku University and the other domestic and overseas radio telescopes. In the presentation, we will report the results of the comparison studies for the characteristics of ion and electron fluxes of impulsive SEPs and those of the spectra of the type III bursts, and discuss the relationship both of them including generation processes of impulsive SEPs.

Acknowledgments: Solar energetic particle data are provided by the ACE Science Center, NASA, and the Turku University Space Research Laboratory. We thank the operation groups of the ACE, WIND, and SOHO projects.

Relationship between solar energetic particles and spectral fine structures of metric type II radio bursts

*Hiroaki Misawa[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Tatsuya Fujimoto[1]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University

It is well known that a type II burst is one of sporadic and intense solar non-thermal radio phenomena, which shows gradual negative frequency drift in the metric to kilometric wavelength ranges and is generated with a coronal mass ejection (CME) event. As a plausible generation process of type II bursts, it is proposed that electro-static plasma waves originated from energetic electrons are effectively converted to electro-magnetic waves (type II bursts) at the region where the local plasma frequency is equal to wave frequency. A type II burst often occurs with energetic protons and ions with the energy of more than the MeV grade, and such an energetic phenomena is called a solar energetic particle (SEP) event. The coincident occurrence of type II bursts and SEPs strongly suggests that both energetic electrons and protons/ions would be the same origin initiated by a CME event. The occurrence characteristics of type II radio bursts and also SEPs have important information on the origins and generation processes of energetic particles and have been of course investigated well individually, however their relationships have been not well known except a recent research for the kilometric to hectometric type II bursts (Iwai et al., 2020).

We have investigated the relationship between SPEs and metric type II bursts from a view point of the clarification of characteristics of SEPs from the occurrence characteristics of type II bursts. We have especially paid attention to spectral fine structures of type II bursts identified in the metric wavelength by our group (Kashiwagi et al., 2016). At the first stage of this study, we have reanalyzed drift rates of fundamental elements of type II bursts using the radio data observed with the AMATERAS system, Tohoku University for three type II burst events observed in 2011 –2013 with weak to extinct SEP natures. In our presentation, we will introduce purpose of this study including a viewpoint of space-weather and preliminary results of the relationship between SEPs and spectral fine structures of type II bursts.

Spectral Structures of Type II Solar Radio Bursts and Solar Energetic Particles

*Kazumasa Iwai[1], Seiji Yashiro[2], Nariaki Nitta[3], Yuki Kubo[4]

1. Institute for Space–Earth Environmental Research (ISEE), Nagoya University, 2. The Catholic University of America/NASA GSFC, 3. Lockheed Martin Advanced Technology Center, 4. National Institute of Information and Communications Technology

We investigated the relationship between the spectral structures of type II solar radio bursts in the hectometric and kilometric wavelength ranges and solar energetic particles (SEPs). To examine the statistical relationship between type II bursts and SEPs, we selected 26 coronal mass ejection (CME) events with similar characteristics (e.g., initial speed, angular width, and location) observed by the Large Angle and Spectrometric Coronagraph (LASCO), regardless of the characteristics of the corresponding type II bursts and the SEP flux. Then, we compared associated type II bursts observed by the Radio and Plasma Wave Experiment (WAVES) onboard the Wind spacecraft and the SEP flux observed by the Geostationary Operational Environmental Satellite (GOES) orbiting around the Earth. We found that the bandwidth of the hectometric type II bursts and the peak flux of the SEPs has a positive correlation (with a correlation coefficient of 0.64). This result supports the idea that the nonthermal electrons of type II bursts and the nonthermal ions of SEPs are generated by the same shock and suggests that more SEPs may be generated for a wider or stronger CME shock with a longer duration. Our result also suggests that considering the spectral structures of type II bursts can improve the forecasting accuracy for the peak flux of gradual SEPs. This study is based on the results obtained from the Coordinated Data Analysis Workshop for SEPs organized by PSTEP on 2017 (PSTEP-SEP-CDAW).

Stellar flare of a close binary system during the NICER-Hisaki Observing Campaign 2018-2019

*Tomoki Kimura[1], Wataru Iwakiri[2], Atsushi Yamazaki[3], Go Murakami[3], Fuminori Tsuchiya[4], Kazuo Yoshioka[5], Hajime Kita[3], Masaki Kuwabara[3], Shin Toriumi[3]

Department of Complexity Science and Engineering, University of Tokyo, Kashiwa, Japan

Dynamics of stellar flare is still not well understood compared to the sun because of lack of continuous monitoring of distant stars at multiple wavelengths. Here we present a flare event at a close binary system, UX Arietis, monitored with the planetary extreme ultraviolet (EUV) space telescope Hisaki and the NICER X-ray Telescope from late 2018 to early 2019. Time variabilities in the EUV and X-ray spectra of the binary were successfully monitored from the beginning to the end of flare. Emission power at the Hisaki EUV wavelengths peaked at 6e+24 W, which is comparable with that measured in the NICER X-ray wavelength at 0.4-8 keV. The EUV spectrum was indicative of carbon, nitrogen, oxygen, and silicon ion emission lines. Electron temperature and density, emission measure, and ion balance were reduced from the emission lines by the spectral diagnostics. The spectral diagnostic indicates that EUV emission region with density and temperature comparable to the solar chromosphere expanded to spatial scale of a stellar radius (1-4e+6 km) during the flare. We interpret the EUV emission region is a flare ribbon expanding in the chromosphere. The X-ray spectrum was also diagnosed in a similar manner with the EUV spectrum with a collisional plasma emission model implemented in the XSPEC tool. Derived parameters are indicative of a compact flare loop on a spatial scale of stellar radius heated up simultaneously with the flare ribbon expansion. The derived flare spatial scale clearly contradicts the previous implication that the flare loop bridges between the two stars of binary system separated by 1.6 AU (2.4e+8 km) (Simon et al., 1980). At the flare rising time, the total mass of flare loop 3e+18 kg was significantly supplied from the chromosphere by the evaporation upflow with a speed of ~500km/s. The total energy of 1e+30 W was dissipated in the flare, which leads the magnetic flux of the flare loop to be more than 55G. These results are the first ever constraints on the mass and energy transfer processes between the flare loop and chromosphere at the stars.

Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 5. Graduate School of Science, Tohoku University, 6. Planetary Plasma and Atmospheric Research Center, Tohoku University, 7. The University of Tokyo

The Hisaki (SPRINT-A) satellite has main scientific objectives of the planetary magnetospheric physics and atmospheric evolution by long-term observations, but also carried out an observation of helium atom resonance scattering in interplanetary space. A material in the interstellar medium (ISM) travels into the heliosphere over the heliopause due to the relative velocity between the heliosphere and interstellar gases. The helium atoms move into the neighboring from the sun without ionizing because of its high ionization energy. The helium atoms are bent by sun gravity along the Keplerian orbit and forms a high density region on the down wind side, which is called helium cone. The distribution of helium atoms in the helium cone can estimate the speed and direction of the interstellar wind, and the density and the temperature of the helium atom in interstellar gases. This study has been carried out from the 1970s, but the interplanetary helium atoms observation is one of powerful tools to recognize the interstellar medium from inside the heliosphere. The Hisaki satellite carried out the observation of the resonance scattering in the helium cone during November and December from 2015 to 2019 five times. The interstellar wind direction derived from the comparison between the observation and the model simulation coincide the results of the other satellite observation. It means that the interstellar wind is stable in these years.

Group movement by magnetic coupling of high-speed protons running side by side in the chromosphere of the Sun

*Shinji Karasawa[1]

1. Miyagi National College of Technology Professor emeritus

There are a lot of spicules in the chromosphere at the surface of the Sun. The proton (H^+) rises at high speed from the bottom of the chromosphere to the top increasing the speed by the magnetic effect. When H^+ reaches the corona region, the mean free path becomes longer and does not occur the ionization. In the surface layer of the Sun, the movement of electrons is changed by the motion of H^+, but the movement of H^+ does not change by electromagnetic waves and the momentum of electrons.
The magnetic field that moves with H^+ generates an electric field vertically, and electrons accompany with the field. The high-speed H^+ that runs side by side is magnetically coupled, and the electron rarely re-combine with H^+ by the repulsive magnetic force. The distance d_{eq} that brings the force of magnetic equal to the force of the coulomb is obtained by using the relationship $\mu_0(qv)^2/(2\pi d_{eq}) = (q)^2/(d_{eq})^2$. In case that the speed of H^+ is 100km/sec, d_{eq} is 0.5 mm.
There is a cusp structure at the top of the plasma loop. There is an Electromagnetic Fluid Dynamic theory that the soft X-rays are generated by magnetic reconnection. However, when H^+ is bundled together by magnetic effects, a cross point becomes a cusp structure and it releases soft X-rays. When the subsequent plasma develops larger than the preceding plasma, it becomes faster and flare is generated.
The momentum of H^+ groups causes the superrotation of west side wider on the mid-day hemisphere on Venus by accelerating the west side and slowing down the east side. The solar wind has significant effects on the solar system [1].

[P-EM12] Coupling Processes in the Atmosphere-Ionosphere System

convener:Huixin Liu(Earth and Planetary Science Division, Kyushu University SERC, Kyushu University), Yuichi Otsuka(Institute for Space-Earth Environmental Research, Nagoya University), Yue Deng(University of Texas at Arlington), Loren Chang(Institute of Space Science, National Central University)

The Atmosphere-Ionosphere (A-I) system forms the so-called near-Earth space. Recent rapidly expanding use of satellite constellations in Low-Earth Orbit (LEO) drives a high demand for better understanding and accurate forecast of the global A-I system for scientific and operational purposes. This session aims to provide a forum for research advances and frontiers related to these aspects, and we invite presentations on global A-I coupling at all temporal and spatial scales. This includes but is not limited to: A-I coupling via atmospheric waves (tides, gravity waves, planetary waves) and trace gases (CO2, O3, H2O), A-I response to Space Weather events (solar flares, CMEs, CIRs), polar-equatorial or inter-hemispheric coupling via TADs/TIDs/disturbance dynamo/penetration electric field, ionospheric plasma irregularities, ionospheric currents, etc. Observations, theoretical studies, model simulations, data assimilation, instruments development are all highly welcome.

Center for Chemical Physics of Atmosphere, Moscow 119991, Russian Federation

One of the fundamental problems of remote sensing is to establish the nature of the source of decimeter microwave radiation, taking into account the dependence of its intensity on the current state of the atmosphere and to determine the interfering factors of radiation propagation (charged aerosol layers, their hydration, etc.). This leads to uncontrolled behavior of the measured intensity and to difficulties in calibrating the receiving equipment.

It was previously assumed that this source has a cosmic origin and corresponds to the radiation of a hydrogen radio line observed at radio telescopes with a wavelength of 21 cm and a transition frequency of 1.4204 GHz. The estimates show that the power of the flux of cosmic radiation arriving at the radiometer is several orders of magnitude lower than the flux density of its own incoherent microwave radiation D and E of the layers of the ionosphere in the decimeter range. Therefore, incoherent super background decimeter radiation, which is formed at an altitude of 80–110 km due to the population of Rydberg states, is the main source.
Since the source is located below the orbiting satellites, a fundamentally new method for making the necessary measurements is proposed.

Relationship between Na layer and CNA variations observed over Syowa, Antarctic

*Takuo T. Tsuda[1], Ryo Tozu[1], Kyogo Takizawa[1], Yoshimasa Tanaka[2], Takuya Kawahara[3], Mitsumu K. Ejiri[2], Takanori Nishiyama[2], Takuji Nakamura[2]

Metallic layers, such as Na, Fe, Mg, K, and Ca layers, exist in the mesosphere and lower thermosphere, that correspond to the height range of the ionospheric D and E regions. In the polar region, energetic particles precipitating from the magnetosphere can often penetrate into the E region and even into the D region. Therefore, the influence of energetic particles on the metallic layers is of interest regarding changes in atmospheric composition accompanied by auroral activity or geomagnetic activity.

In this study, we have performed a statistical data analysis on Na layer responses to geomagnetic activity using Na density data, together with simultaneous cosmic noise absorption (CNA) data, obtained at Syowa, Antarctic (69.0ºS, 39.6ºE) in 2000-2002. It is found that the Na densities around the topside of Na layers tended to decrease during geomagnetic active days, but in contrast the CNA tended to increase. The amounts of Na density responses, i.e., Na density decrease or Na loss, were increasing with magnetic local time (MLT) from dusk hours to dawn hours, and those of CNA responses, i.e., CNA increase, were also increasing with MLT. Thus, there were clear negative correlations between the Na density and the CNA variations. These results indicate that the the Na loss around the topside of Na layer was induced by the energetic particle precipitation during geomagnetic active days.

Occurrence feature of plasma bubble observed in mid-latitudes during geomagnetic storms using GNSS-TEC data

*Sori Takuya[1], Yuichi Otsuka[1], Atsuki Shinbori[1], Takuya Tsugawa[2], Michi Nishioka[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. National Institute of Information and Communications Technology

Plasma bubbles, which have a significantly sharp depletion of plasma density, are one of the ionospheric irregularities in the low-latitude and equatorial regions. Within the plasma bubbles, plasma density irregularities with different spatial scales exist. They are generated in the bottomside F region of the nighttime equatorial ionosphere after sunset by Rayleigh-Taylor instability (RTI) mechanism [e.g., Farley et al., 1970; Kelley, 2009]. The growth rate of RTI increases with increasing eastward electric fields and increasing ionospheric altitude. During large geomagnetic storms, plasma bubbles are sometimes observed at mid-latitudes because they extend to higher altitudes and latitudes by larger upward $\mathbf{E} \times \mathbf{B}$ drifts [e.g., Ma and Maruyama, 2006; Aa et al., 2018]. In this study, we analyzed total electron content (TEC) and rate of TEC index (ROTI) [Pi et al., 1997] data obtained from global navigation satellite system (GNSS) receivers over the world after 2000 to clarify causes of storm-time plasma bubbles which reach mid-latitudes. We regard plasma bubbles extending the mid-latitude of more than 30° during geomagnetic storms as mid-latitude plasma bubbles. Two-dimensional GNSS-TEC and ROTI data with spatial and temporal resolutions of 0.5°×0.5° in longitude and latitude and 5 minutes, respectively are used. In order to find storm-time mid-latitude plasma bubble events, we create geomagnetic latitude-time plots of ROTI at 20 h (local time) for 1 year. We defined the SYM-H variations with the minimum value of less than -40 nT as geomagnetic storm events, and identified 49 events during 2000. For each storm event, we investigated the relationship between temporal and spatial variations of ROTI and other parameters (solar wind and geomagnetic indexes) in these events. As a result, we have found that the plasma bubbles in 6 of 49 storm events extended to mid-latitudes associated with geomagnetic storms. These plasma bubbles are caused during the main phase of large geomagnetic storms having the minimum SYM-H values of less than -150 nT and the steep gradient of SYM-H values (more than -40 nT/h). The dawn-to-dusk (Ey) component of interplanetary electric field, derived from solar wind speed (Vx) and the north-south (Bz) component of interplanetary magnetic field (IMF) ($Ey = -(Vx \times Bz)$), shows larger value, compared with other geomagnetic storms. This suggests that the dawn-to-dusk convection electric field in the polar ionosphere is significantly enhanced by solar wind-magnetosphere interaction under the southward IMF condition. The electric field imposed on the polar ionosphere propagates instantaneously to the equatorial ionosphere [Kikuchi et al., 1996]. The eastward electric field induced by the southward-turning of IMF Bz could enhance of the eastward electric field at the dusk sector, causing the mid-latitude plasma bubbles by RTI. In the presentation, we will show statistical characteristics of storm-time mid-latitude plasma bubbles by analyzing ROTI data in other storm events after 2001.

Three-dimensional ionospheric simulation of the Es layer: Physical mechanism of the sporadic appearance

*Satoshi Andoh[1], Akinori Saito[1], Hiroyuki Shinagawa[2], Mitsumu K. Ejiri[3], Shinichi Miyazaki[1]

1. Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology, 3. National Institute of Polar Research

Physical mechanism of sporadic appearance of the mid-latitude sporadic E layer (Es layer) was studied by using a three-dimensional high precision numerical model. Es layer is a thin layer of metallic ion plasma appearing in the ionospheric E region. When the layer is observed from a point, it shows sporadic appearances. While it is widely accepted that the vertical wind-shear of the diurnal/semi-diurnal tide is responsible for the generation of the Es layer, the sporadic appearance of the Es layer cannot be explained by this tide-windshear theory. Recently, the self-consistent atmosphere-ionosphere model GAIA (Ground-to-topside model of Atmosphere and Ionosphere for Aeronomy) has reproduced three-dimensional neutral wind fields containing both tidal and gravity waves. Consequently, it has become that the effect of tidal and gravity waves on structures of Es layer can be investigated at the same time.

We have developed a three-dimensional ionospheric numerical model. Three-dimensional neutral winds of the GAIA were used as an input in every 10 minutes for given day. The ionospheric model successfully reproduced the day-to-day variability of the Es layers that was observed by a Ca-ion lidar. Structures of Es layer reproduced in the neutral winds containing both tidal and gravity waves were circular or belt-like, and their scales were about 100-1000 km. As a result, we found that the structure of the Es layer was horizontally transported by the neutral wind, causing sporadic appearance of the Es layer.

Time and height variability of Fe-layer in the Mesosphere and the Lower Thermosphere region at Syowa Station, Antarctica (69.0˚S, 39.6˚E) based on a resonance scattering lidar measurements in two winter seasons

*Takanori Nishiyama[1,2], Mitsumu K. Ejiri[1,2], Takuo T. Tsuda[3], Katsuhiko Tsuno[4], Toru Takahashi[5], Makoto Abo[6], Takuya Kawahara[7], Takayo Ogawa[4], Satoshi Wada[4], Takuji Nakamura[1,2]

1. National Institute of Polar Research, 2. The Graduate University for Advanced Studies, SOKENDAI, 3. The University of Electro- Communications, 4. RIKEN, 5. University of Oslo, 6. Tokyo Metropolitan University, 7. Shinshu University

The National Institute of Polar Research (NIPR) is leading a prioritized project of the Antarctic research observations. One of the sub-projects is entitled the global environmental change revealed through the Antarctic middle and upper atmosphere. Profiling dynamical parameters such as temperature and wind, as well as minor constituents is the key component of observations in this project, together with a long-term observation using existent various instruments at Syowa, Antarctica (69.0˚S, 39.6˚E). As a part of the sub-project, we developed a new resonance lidar system with multiple wavelengths. The lidar transmitter is based on injection-seeded, pulsed alexandrite laser for 768-788 nm (fundamental wavelengths) and a second- harmonic generation (SHG) unit for 384-394 nm (second harmonic wavelengths). The laser wavelengths can be tuned into the resonance wavelengths by a wavemeter that is calibrated and validated using a wavelength- stabilized He-Ne laser and a potassium vapor cell for doppler-free spectroscopy.

This lidar has capabilities to measure density variations of minor constituents such as atomic iron (Fe, 386 nm), atomic potassium (K, 770 nm), calcium ion (Ca^+, 393 nm), and nitrogen molecular ion (N_2^+, 390, 391 nm) and temperature profiles in the mesosphere and lower thermosphere (MLT) region. It can also estimate temperature profiles from the upper Stratosphere to the lower mesosphere using signals of Rayleigh scattering. The lidar system installed at the Syowa Station by the 58th Japan Antarctic Research Expedition (JARE 58) in January 2017, and then its observation has been continued by October 2018.

In this presentation, we are going to report initial results focusing on Fe atom and temperature variability in MLT region. In the two seasons, Fe measurements have been carried out for a total of 59 nights (653 hours). Preliminary analysis demonstrated that the seasonal variability of Fe atom abundance from February to October, which has a peak and a secondary peak at May and September respectively, is well agreed to those in preceding studies. In addition to seasonal variations, Fe atom response to energetic particles forcing due to magnetic storms and substorms will be analyzed in detail and discussed. Since Syowa station is located under aurora oval in the southern hemisphere, chemical reactions and electromagnetic dynamics are important for understanding of short-term variations on Fe density as well as wave forcing driven by atmospheric gravity waves.

Analysis of VLF Band Waves near the Sq Current System observed by S-310-44 Sounding Rocket

*Taketoshi Miyake[1], Ryuichiro Nakamura[1], Keigo Ishisaka[1], Takumi Abe[2], Atsushi Kumamoto[3], Makoto Tanaka[4]

1. Department of Electrical and Computer Engineering, Faculty of Engineering, Toyama Prefectural University, 2. Japan Aerospace Exploration Agency Institute of Space and Astronautical Science Department of Solar System Sciences, 3. Department of Geophysics, Graduate School of Science, Tohoku University, 4. Tokai University, ICT Education Center

The Sq current system is one of the ring current which occurs in the lower ionosphere in the winter daytime. It is caused the specific plasma phenomena such as electron heating and strong electron density disturbance. S-310-44 sounding rocket experiment was carried out to investigate the special phenomena near the Sq current focus, at 12:00 JST on January 15th, 2016. The rocket passed through the Sq current focus, and all the scientific instruments onboard the rocket worked successfully. In this experiment, the Electric Field Detector (EFD) observed the VLF band AC electric fields up to 6.4kHz in the altitude from 100km to 160km. We made the altitude profile of the electric field spectra, and found clear VLF band waves with the frequencies from 2kHz to 3kHz at the altitude about 100km. These VLF band waves are observed during only the rocket ascent. The Fast Langmuir Probe (FLP) observed that the electron temperature increase about 150K larger than the background in this region, and the frequency variation of the VLF band waves shows good correlation with the electron temperature as shown in Figure 1. According to the polarization analyses, the electric fields of the VLF band waves are oblique, not parallel to the magnetic field. The frequency range of this VLF band waves is consistent with the ion cyclotron frequency. These results suggest that the VLF band waves observed in this experiment are one of the ion cyclotron harmonic waves whose frequencies vary with the temperature ratio of the electron and the ion (Te/Ti). We are going to investigate further the VLF waves observed by the rocket experiment, and clarify the heating mechanism of the electrons near the Sq current focus.

Monte Carlo simulation of solar EUV scattering by oxygen ions

*Shin ya Nakano[1], Yuta Hozumi[2], Akinori Saito[3]

1. The Institute of Statistical Mathematics, 2. University of Electro-Communications, 3. Department of Geophysics, Graduate School of Science, Kyoto University

It has been reported that the Extreme ultraviolet (EUV) at 83.4 nm, which is scattered by oxygen ions (O+), was observed by an imager of ISS-IMAP in the umbra of the Earth. However, the single scattering of solar radiation in the upper atmosphere would not well explain the observation. This study modeled the EUV scattering by a Monte Carlo method. This method allows us to consider multiple scattering. The result suggests the EUV at 83.4 nm is observable even in the umbra. However, the feature of the observation by ISS-IMAP is not necessarily reproduced. Possible reasons of the discrepancy between the simulation and the observation will be discussed.

Automatic detection of Spread-F on ionogram using Machine Learning

*Shimizu Junji[1], Hiroyuki Nakata[1], Hiroyo Ohya[1], Toshiaki Takano

1. Graduate School of Engineering, Chiba University

Ionospheric irregularities referred to as equatorial spread-F are very important phenomena in terms of radio wave propagation because their spatial scales are from centimeters to tens of kilometer and they affect wide-band radio waves. Therefore, they interfere the reliability of satellite-ground communications, navigation systems and so on. The ionozonde is one of the useful observation systems of spread-F. If spread-F in the ionogram, which shows the reflection height of HF radio waves versus carrier frequency, is detected automatically by a machine learning system, real time detection of spread-F could be replaced by the automatic detection system using the machine learning system. In this study, therefore, we have developed an automatic detection of spread-F in the ionogram using machine learning.

In order to construct the classifer, the ionograms observed at 4 observatories (Wakkanai, Kokubunji, Yamagawa, Okinawa) utilized by National Institute of Information and Communications Technology were prepared. As for learning data, we used 400 ionograms with spread-F observed at each stations in 2018. HOG (Histogram of Oriented Gradients) feature extraction is used in obtaining the feature quantity.

Using the classifier to detect spread-F in the ionograms observed at Okinawa in May 2019, a detection rate reached about 90%. This classifier is also enable to detect the spread-F in the ionograms obtained at Kokubunji and Yamagawa with the detection rate of 90%. However, the detection rate of the spread-F in the ionograms observed at Wakkannai is very low (about 60%). In the presentation, we will present the comparison with another observation point at the same period.

Examination of the ionospheric perturbations propagation associated with H-IIA rocket launchings

*Junpei Yamazaki[1], Hiroyuki Nakata[2], Hiroyo Ohya[2], Toshiaki Takano[2], Keisuke Hosokawa[3]

1. Graduate School of Science and Engineering, Chiba University, 2. Graduate School of Engineering, Chiba University, 3. Department of Communication Engineering and Information, University of Electro-Communications

It is reported that passage and exhaust plumes associated with rocket launches generate TEC perturbations observed by GEONET data (e.g. Furuya and Heki, 2008; Lin et al, 2014, 2017). On the other hand, there are few studies about ionospheric perturbations associated with rocket launches away from rockets' trajectories. Becouse the disturbances due to exhaust plumes do not apper in the distance from the trajectories, we can extract the disturbances only affected by the atmospheric wave. Using HF Doppler sounding, therefore, we analyzed ionospheric perturbations associated with H-IIA (Flight.25 and 26) whose trajectories are relatively far from the Japanese Islands. The Doppler sounding system is utilized by the University of Electro-Communications. In this system, the radio waves of 5.006 MHz and 8.006 MHz are transmitted from Chofu campus of University of Electro-Communications and those of 6.055 MHz and 9.595 MHz are from Nagara transmitter Radio NIKKEI. In this study, the Doppler shifts data observed at Sugadaira, Oarai, Kakioka, and Fujisawa were used. In those data, the perturbations of Doppler frequency associated with H-IIA (Flight.25 and 26) were observed about 35 minutes after the launches. It is confirmed that this delay corresponds to the propagation time of the infrasound wave from the rocket to observation points once reflected on the ground. In both events, the periods of the disturbance of Doppler shift were 100~200 s (5~10 mHz). The Doppler frequency perturbations appered when the infrasound wave reached the obserbations point after reflection on the ground as compared to the case where the infrasound wave reached the observation point directly. The Doppler frequency perturbation consist of two packets, the first half (packet A) and the second half (packet B). In case of packet A, the arrival time of the perturbations at high altitude were faster than that of at low altitude. Therefore, it denoted that infrasound wave propagated from high altitude to low altitude. In case packet of B, the arrival time of the perturbations at both high and low altitude were simultaneously observed. This result indicates that the infrasound wave propagate almost horizontally.

Spatial and temporal distributions of atmospheric gravity wave potential energy evaluated using ERA-5 temperature data over the equatorial latitudes

*Shih-Sian Yang[1], Chen-Jeih Pan[1], Uma Das[2], Chian-Chiau Lin[3]

1. National Central University, Jhongli, Taoyuan 32001, Taiwan, 2. Department of Physics, Indian Institute of Information Technology, India, 3. Environmental Research and Information Center, Chang Jung Christian University, Taiwan

In this study, we used the temperature profiles retrieved from ERA5, the newest atmospheric reanalysis dataset issued by the European Centre for Medium-Range Weather Forecasts (ECMWF), to evaluate the potential energy (E_P) in the atmosphere from the near ground surface to ~80 km altitude over the equatorial latitudes of ±10°. E_P is calculated from the fluctuation of temperature, which is considered to be generated by atmospheric gravity waves (AGWs), and we have constructed the spatial and temporal distributions of E_P over the equatorial latitudes using the high-resolution data from ERA5. In this study, we will present the variations of E_P in time, altitude, and longitude. Overall, E_P is controlled by the zonal flow of the background atmosphere. Especially the time-varied descending structures of high E_P value coincide with the westerly shear of zero-wind in the stratosphere, which implies the Kelvin wave-mean flow interactions in the stratospheric altitudes. Besides, the longitudinal analysis shows that E_P is higher in the eastern Pacific at all altitudes except around the tropopause. In addition, we checked the E_P values during different atmospheric and oceanic conditions, to examine the possible relationship between El Niño/La Niña and atmospheric gravity waves. With regards to the E_P distribution caused by Kelvin waves in the stratosphere, we will also compare the results with the Kelvin wave amplitudes obtained by the two-dimensional fast Fourier transform (2D-FFT) method in this presentation.

Atmospheric wave propagation observed by GNSS-TEC: Fireball explosion and atmospheric mode

*Ai Matsushita[1], Kosuke Heki[1]

1. Hokkaido University Graduate School of Science

The electron distribution in the ionosphere is often disturbed by various phenomena in the atmosphere. They are observed as changes in TEC (Total Electron Content) along line-of-sight connecting GNSS (Global Navigation Satellite System) satellites and receivers. For example, large meteorites entering the Earth’ s atmosphere often explode and are recognized as fireballs. Sound waves and internal gravity waves excited by them propagate through the atmosphere, reach the ionospheric F region, and change TEC. A fireball appeared near Chelyabinsk, Russia, on February 15, 2013, one of the largest fireball events in the observation history, made significant disturbance signals in TEC observed with multiple GPS satellites and ground receivers. In our study, we first confirm the TEC signals in the 2013 Chelyabinsk event, and then look for the TEC disturbance signals following the emergence of a large-scale fireball over the Bering Sea in December 2018 using data from nearby GNSS stations. We found temporary positive TEC changes and continuous TEC fluctuations shortly after the fireball event. Although the numbers of satellites and stations were not sufficient, these signals are considered to have originated from this fireball event.

Next we obtained continuous TEC records in 2019 using the QZSS (Quasi-Zenith Satellite System) geostationary satellite (PRN07), which enables long-term stable TEC observations in and around Japan. We performed preliminary investigations to detect various kinds of TEC disturbances. First, we conducted spectral analysis of the QZSS-TEC time series with various time windows. As a result, we identified peaks such as the diurnal changes and its harmonics, and the rotation period of the sun. Ground observations of gravimeters and broadband seismometers revealed incessant excitation of the Earth's free oscillations. It was also found that the two components having periods close to the atmospheric modes with periods of 3- 4 minutes have significantly larger amplitudes than other components. This suggests the coupling between the solid earth and the atmosphere. It is possible that there are same frequency components in TEC variations, but it has not yet been confirmed. In this study, we examine if we can detect weak atmospheric modes by using continuous QZSS-TEC data.

Keywords: TEC, GPS, QZSS

Investigation of the climatology and long-term variations of the stratospheric Kelvin waves using ERA-Interim

*Chen-Jeih Pan[1], Shih-Sian Yang[1], Uma Das[2], Wei-Sheng Chen[1]

1. Institute of Space Science, National Central University, Taiwan, 2. Department of Physics, Indian Institute of Information Technology, India

In this study, we proposed a new aspect, based on the temporal evolution of the stratospheric zonal wind, investigating the properties of Kelvin waves during different temporal stages of quasi-biennial oscillation (QBO) in the stratosphere. 16 cycles of the stratospheric QBO were found during the period of 1979–2018 using the zonal wind profiles over the equatorial region (±10˚), which was retrieved from ERA-Interim, a long-term reanalysis dataset produced by the European Centre for Medium-Range Weather Forecasts (ECMWF). The duration of each QBO cycle varies from 23 to 42 months among the 16 cycles, and this variability causing the investigations regarding Kelvin waves and QBO are unexpectedly arduous. Therefore, we tried to standardize the elapsed time during each QBO cycle to 0–1, to study the climatological connections between the QBO phase and the amplitudes of wavenumber 1 as well as wavenumber 2 Kelvin waves. Another reanalyzed atmospheric parameter of temperature were retrieved from the same ERA-Interim dataset, and the Kelvin wave amplitudes at 6–24 days periods were analyzed using the method of two-dimensional fast Fourier transform (2D-FFT). The results of the present study show the dominant wave period varies from shorter to longer periods as the time elapses in a QBO cycle. Fast Kelvin waves are more evident in the upper stratosphere, but slow Kelvin waves are further apparent in the lower stratosphere. Besides, we also found the Kelvin wave activities have significantly increased in the 21st century. The present study is the first attempt to investigate the long-term (40 years) morphology of Kelvin waves using the ERA-Interim reanalysis dataset. Conclusions regarding the climatological variations of Kelvin waves lend us further understanding of the Wave-mean flow interactions in the stratosphere over the equatorial region.

Statistical study of seasonal dependence of MSTID occurrence and propagation velocity using the SuperDARN Hokkaido East HF radar

*Wataru Hazeyama[1], Nozomu Nishitani[1], Tomoaki Hori[1]

1. Institute for Space-Earth Environmental Reseach

We present the results of the statistical study of medium-scale traveling ionospheric disturbances (MSTIDs) using the SuperDARN Hokkaido East (43.53˚N, 143.61˚E) high-frequency (HF) radar data from 2009 to 2018. We applied a three-dimensional fast Fourier transform method developed by Matsuda et al. (2014) to the dataset and analyzed the diurnal and seasonal dependences of the propagation direction and horizontal phase velocity of MSTIDs. Southwestward propagating MSTIDs are common during winter in the nighttime and southward propagating MSTIDs are common during winter and equinoxes in the daytime. Although rare in comparison with the southwestward propagating MSTIDs, certain number of northward propagating MSTID events are found. We also found a clear negative correlation between the yearly power spectral density of nighttime MSTIDs and F10.7 solar flux index. This negative correlation can be explained in terms of the linear growth rate of the Perkins instability.

Keywords: MSTID, SuperDARN radar

First simultaneous observation of nighttime medium-scale traveling ionospheric disturbance (MSTID) by a ground airglow imager and the Arase satellite in the inner magnetosphere

*Kouki Kawai[1], Kazuo Shiokawa[1], Yuichi Otsuka[1], Yoshiya Kasahara[2], Fuminori Tsuchiya[3], Ayako Matsuoka[4], Yasumasa Kasaba[3], Kazushi Asamura[4], Satoshi Kasahara[6], Yoshizumi Miyoshi[1], Shin-ichiro Oyama[1,7,8], Yoichi Kazama[5]

1. Institute for Space-Earth Environmental Research, Nagoya Univ, Japan, 2. Kanazawa Univ, Japan, 3. Tohoku Univ, Japan, 4. Japan Aerospace Exploration Agency, 5. Academia Sinica, 6. Tokyo Univ, Japan, 7. Oulu Univ, Finland, 8. National Institute od polar Research

Medium Scale Traveling Ionospheric Disturbance (MSTID) is the propagation of the electron density fluctuation in the ionospheric F-layer. The mechanism of MSTID generation is based on the theories of atmospheric gravity waves from the ground and ionospheric E-F coupling and Perkins instability. It is known by simultaneous observation of airglow imagers in both hemispheres that the MSTID has a mirror image structure at the magnetic conjugate hemisphere. If the MSTID is generated by the E-F coupling and Perkins instabilities and grow up with **E**×**B** drift, the polarization electric field associated with the growth of the MSTID should propagate along the magnetic field lines. So, we are expected to observe the electric field variations by the Arase satellite flying in the inner magnetosphere. This observation has never been reported. Therefore, in this study, we have analyzed the MSTID observed at 06:00:00-06:30:00 UT on November 3, 2018, in detail by the airglow camera at Gakona (62.39 N, 214.78 E), Alaska, and the Arase satellite in the inner magnetosphere. The purpose of this study is to understand the correspondence between the MSTID structure in the ionosphere and the electromagnetic field and plasma in the conjugate inner magnetosphere. The electric field observed by the electric field detector (EFD) and the electron density observed by the high frequency analyzer (HFA) of plasma wave experiment (PWE) on board the Arase satellite fluctuated associated with the structure of the MSTID, when the satellite footprint in the ionosphere crossed almost perpendicularly to the phase surface of the MSTID. We projected the electric field variations observed by the satellite onto the ionosphere. We found that the electric field variations were nearly perpendicular to the phase surface of the MSTID. This variation indicates the polarization field that causes the MSTID through **E**×**B** drift. We also inferred the direction of the possible Pedersen current and the background electric field from the observed direction of the propagation and the electric field variations in the ionosphere, though we could not obtain direct evidences of these current and electric field from the current observation. We discuss these observation results in relation to the generation and growth mechanisms of MSTIDs.

Study of variations in the D-region ionosphere after the 2016 Kumamoto earthquakes using VLF/LF transmitter signals

*Tekkan Akashi[1], Hiroyo Ohya[2], Hiroyuki Nakata[2], Fuminori Tsuchiya[3]

1. Graduate School of Science and Engineering, Chiba University, 2. Graduate School of Engineering, Chiba University, 3. Graduate School of Science, Tohoku University

There have been many reports for the variations in the F-region ionosphere associated with earthquakes based on GPS-TEC (total electron content), ionosondes, SuperDARN(Super Dual Auroral Radar Network) Hokkaido HF (high frequency, 3-30 MHz) radars, and HF Doppler observations [e.g., Tsugawa et al., 2011].In the D-region ionosphere, oscillations of LF (low frequency, 30-300 kHz) transmitter signals with a period of 100 s were reported about five minutes after mainshock of the 2011 Tohoku Earthquakes [Ohya et al., JGR, 2018]. The reflection height of the LF waves was 67 km, and the LF oscillations were caused by acoustic waves excited by seismic Rayleigh waves based on simulation of neutral atmosphere. However, the D-region response after earthquakes was reported only in above case study, and more investigation is required. In this study, we investigate the lower ionospheric variations associated with the 2016 Kumamoto earthquake using VLF(very low frequency, 3-30 kHz)/LF transmitter signals. The foreshock (Mw 6.2) and mainshock (Mw 7.0) of the 2016 Kumamoto earthquakes occurred at 12:26:34 UT on April 14, and at 16:25:05 UT on April 15, 2016, respectively. The propagation paths were BPC(68.5 kHz, China)-SGR (Sasaguri, Japan), JJY60kHz(Saga, Japan)-SGR, and JJY40kHz(Fukushima, Japan)-SGR, and JJI(22.2 kHz, Miyazaki, Japan). In addition, we used vertical velocity data of seismometers of the F-net (Full range ,,,network) provided by the Data and Disaster Prevention Research Institute, Japan. As for the mainshock, variations in the LF intensity had a period of 100 s about five minutes after the maishock based on wavelet analysis. The duration of the LF variations was about six minutes. The onset of the LF variations was agreement with arrival time of acoustic waves excited by the Rayleigh waves below the LF path. The coherence between the JJY40kHz-SGR intensity and seismic velocity at SBR (Seburi, Japan) close to the JJY40kHz-SGR path (the distance: 35 km) was high to be 0.73 for the period of 128 s. It suggests that acoustic waves that propagated vertically from the location of the LF path caused the LF variations. In the session, we will also show the results of the foreshock, and discuss the cause of the VLF/LF variations in addition with the mainshock.

Analysis of source and generation mechanism of atmospheric gravity waves and MSITDs observed in airglow images in Hawaii

*Hideto Naito[1], Kazuo Shiokawa[1], Yuichi Otsuka[1], Takeshi Sakanoi[2], Akinori Saito[3], Takuji Nakamura[4]

1. Nagoya University, 2. Tohoku University, 3. Kyoto University, 4. National Institute of Polar Research

Atmospheric gravity waves (AGWs) and medium-scale traveling ionospheric disturbances (MSTIDs) are important wave phenomena in the upper atmosphere, since they can control global dynamics of the atmosphere and affect GNSS positioning. Matsuda et al. [JGR, 2014] proposed a method of deriving the horizontal phase velocity and propagation direction of the power spectral density of waves found in images using three-dimensional Fast Fourier transform. However, there has been few report to apply this method to airglow images obtained near the equator except for Perwitasari et al. (AnnGeo, 2018) in Indonesia. In this study, we applied the analysis method of Matsuda et al. [2014] to airglow images obtained at wavelengths of 557.7 nm and 630.0 nm during the three years from 2013 to 2016 at Haleakala (20.7°N, 203.7°E) in Hawaii. We clarified the statistical features of AGWs and MSTIDs over Hawaii, and compared them with features seen in Japan reported by Takeo et al. [JGR, 2017] and Tsuchiya et al. [JGR, 2018], where the latitude, longitude and orography are greatly different those of Hawaii.

The three-year averages of the phase velocity spectra of AGWs observed in airglow images at a wavelength of 557.7 nm show that there was no difference in the zonal propagation between summer and winter. In Japan, however, it is known that the propagation direction is eastward in summer and westward in winter. We reported this result in JpGU2019 and discussed this difference due to latitudinal variation of mesospheric jet wind which controls AGW propagation through wind filtering effect. In the presentation we will discuss the source of atmospheric gravity waves from the tropospheric upward flow and jet using reanalysis data in the troposphere. As a result, the upward flow in the troposphere was not strongly observed in the area where the wave source was expected. This is probably due to the averaging, so we will analyze each observation day.

The MSTIDs observed in airglow images at a wavelength of 630.0 nm show that the power spectral density (PSD) was strongest and the waves propagate mainly in the east-west direction in winter. We reported this result in SGEPSS2019 and discussed a mechanism for generating MSTIDs due to atmospheric gravity waves. We will discuss the source of atmospheric gravity waves related to this mechanism from the tropospheric upward flow and jet using reanalysis data. As a result, the upward flow in the troposphere was not strongly observed in the east-west direction where the wave source is expected. This is probably due to the averaging, so we will analyze each observation day. Regarding the east-west propagation of MSTIDs in winter, we made detailed event study using zonal keogram and wave number spectrum, and compared with MSTIDs observed in Japan.

Solar flare effects of the D-region ionosphere using daytime tweek atmospherics and VLF/LF standard radio waves

*Kodai Yamanobe[1], Hiroyo Ohya[1], Hiroyuki Nakata[1], Kazuo Shiokawa[2], Fuminori Tsuchiya[3], Kozo Yamashita[4], Yukihiro Takahashi[5]

1. Chiba Univ., 2. Nagoya Univ., 3. Tohoku Univ., 4. Ashikaga Univ., 5. Hokkaido Univ.

It has been known that intensity and phase of very low frequency (VLF, 3-30 kHz)/low frequency (LF, 30-300 kHz) transmitter signals significantly change due to intense ionization by solar flares [e.g., Mitra, 1974; Thomson et al., 2005]. The duration of the D-region enhancements due to X-ray is easier to be estimated using the VLF/LF waves, because the relaxation time for recombination in the D-region ionosphere is short to be within ~100 s [e.g., Ohya et al., 2015]. Santolik and Kolmasova [2017] showed daytime tweek atmospherics (1.5-10.0 kHz) did not become observable for two hours at least just after a solar flare of M2.2 class, which suggests large absorption due to the solar flare. In this study, we investigate solar flare effects on the D-region ionosphere using tweek atmospherics and VLF/LF transmitter signals. We analyzed the daytime tweek atmospherics observed at Moshiri (44.37N, 142.27E), Japan, during several M-class flares occurred in 2015. The sampling frequency was 20 kHz, and the wideband VLF data were recorded for each two minute at 20-22 and 50-52 minutes every hour. The transmitters used in this study were NWC (21.817S, 114.167E, 19.8 kHz), JJI (32.05N, 130.82E, 22.2 kHz), JJY40kHz (37.37N, 140.85E), JJY60kHz (33.47N, 130.18E), and BPC (34.63N, 115.83E, 68.5 kHz).The receivers were PTK (Pontianak, Indonesia, 0.003N, 109.367E), and SGR (Sasaguri, Japan, 33.632N, 130.505E). The occurrence rate of the tweeks after the M-class solar flares was smaller than that before the flares except for a M2.0-class flare. When the distance between the sub-solar point and the middle point of the VLF/LF paths decreased, amplitude of the variations in the VLF/LF phase and time difference between onsets of variations in X-ray flux and the VLF/LF intensity increased for a few M-class solar flares. It suggests that the D-region ionization near the sub-solar point was more intense than that located away from the sub-solar point. In the session, we will show the results in detail and discuss the solar flare effects on the D-region ionosphere.

The spatial structures and seasonal variations of the polar mesospheric clouds seen from the meteorological satellite Himawari-8

*Yuta Hozumi[1], Takuo T. Tsuda[1], Kento Kawaura[1], Yoshiaki Ando[1], Keisuke Hosokawa[1], Hidehiko Suzuki[2], Takuji Nakamura[3], Ken T. Murata[4]

1. University of Electro-Communications, 2. Meiji University, 3. National Institute of Polar Research, 4. National Institute of Information and Communications Technology

Polar mesospheric clouds (PMCs) consist of water-ice particles, and have been observed near the summer polar mesopause region. Production and disruption of PMC are sensitive to the background mesospheric state, such as the temperature and water vapor conditions. Its distribution is strongly affected by the background wind. Hence, PMC is a good proxy for the thermal structure and dynamics in the high latitude summer mesosphere.

Observations of PMC have been widely performed by various methods from the ground as well as from Low-Earth-Orbit (Leo) satellites. However, these methods have some limitations, especially in local time coverage or observational continuity to monitor the long-term PMC activity. While a large number of studies have been done with the LEO satellites data, there are only a few studies of PMC observations from Geostationary Earth Orbit (GEO) satellites, which include Meteosat First Generation (MFG) and Meteosat Second Generation (MSG). The GEO satellites provide full-disk images of the Earth including the polar mesosphere on the Earth's limb, which would give valuable opportunities for PMC observations.

Recently, our group found that the PMC signal can be observed by the Advanced Himawari Imager (AHI) onboard Himawari-8, the Japanese Geostationary-Earth-Orbit meteorological satellite (Tsuda et al., 2018). In the presentation, we will show the PMC detection method for application to Himawari-8 AHI images. To evaluate the PMC signal correctly, the background emissions from atmospheric scattering (i.e., Rayleigh scattering) should be removed. We present how we remove the background emissions and evaluate the PMC signal. The detection capability, especially the limit of sensitivity, of AHI on the PMC observations will be discussed. Based on the detection method, The PMC spatial structures and its temporal variations will be presented.

Fireball-associated variations in the D-region ionosphere observed using VLF/LF transmitter signals

*Takeru Suzuki[1], Hiroyo Ohya[2], Fuminori Tsuchiya[3], Kazuo Shiokawa[4], Hiroyuki Nakata[2]

1. Graduate School of Science and Engineering, Chiba University, 2. Graduate School of Engineering, Chiba University, 3. Graduate School of Science, Tohoku University, 4. Institute for Space-Earth Environmental Research, Nagoya University

Meteors and fireballs are known to ionize the D-region and lower E-region ionospheres at 80-120 km heights [Davies, 1966]. The fireballs are meteors that the magnitude of brightness is larger than -4 based on the IAU (International Astronomy Union) definition. TID (traveling ionospheric disturbance) associated with the Chelyabinsk meteoroid in Russia was reported based on GPS-TEC (total electron content) observations [Perevalova et al., 2015]. The amplitude of the TEC variations was 0.07-0.5 TECU, and the period was 10 minutes. The epicenter of the TID was airburst point at 20-30 km heights of the meteoroid, and the velocities were 250-660 m/s. However, few quantitative studies for the lower ionosphere associated with meteors and fireballs have been reported. In this study, we investigate the variation in the lower ionosphere during a fireball occurred in Hokkaido, using VLF (very low frequency, 3-30 kHz) / LF (low frequency, 30-300 kHz) transmitter signals. The VLF/LF transmitter signals are reflected in the lower ionosphere and are sensitive for variations in electron density in the lower ionosphere. The transmitters used in this study were JJY40kHz (Fukushima, Japan, 37.37˚N, 140.85˚E), JJY60kHz (Saga, Japan, 33.47˚N, 130.18˚E), and JJI (Miyazaki, Japan, 22.2 kHz, 32.05˚N, 130.82˚E). The receiver was located at RKB (Rikubetsu, Japan, 43.45˚N, 143.77˚E). Periodic variations of 100-200 s were identified by a wavelet transformation of the signal intensities for the JJY40kHz-RKB, JJY60kHz-RKB, and JJI-RKB paths at about five minutes (12:01 UT) after the fireball. The phases of the JJY40kHz-RKB and JJY60kHz-RKB paths had similar periods of 100-200 s at that time. We consider that these variations of intensity and phase are caused by the D-region variations due to acoustic waves in the atmosphere excited by the fireball. If the acoustic waves were excited at the luminous point (118 km altitude), the VLF/LF reflection point (90 km altitude) or vanishing point (25 km altitude) of the fireball, the propagation times of the acoustic waves from the exited point to the LF reflection point at 90 km height over RKB were calculated to be 138 s, 126 s, or 311 s, respectively. The arrival time (311 s) of the acoustic waves excited from the vanishing point at the 25-km altitude agrees with the onset timing of the VLF/LF variations (~5 minutes), suggesting that the acoustic waves excited from the fireball caused the variations in electron density in the D-region ionosphere. We will also show results with another fireball event over Nagano, Japan, at 13:00 UT on 12 November, 2019, and discuss the fireball effects on the lower ionosphere.

Layers of metal ions in the mesosphere and lower-thermosphere (MLT) are produced by meteoric ablation. The meteoric metal ions have relatively long chemical life time in the MLT region and behave as plasma affected by neutral atmosphere dynamics. In the mid-latitude, the meteoric metal ions in the MLT region are generally accepted as key species for generation of sporadic E (E_s) layer in the wind shear theory. The close link between the E_s layer and metal ion layer has been also clearly by radar and lidar observations [Raizada et al., 2012; Ejiri et al., 2019]. On the other hand, the latitudinal differences in behaviors of the metal ion are still unknown. Recently, the Whole Atmosphere Community Climate Model incorporated a large database of neutral and ion–molecule reaction kinetics of calcium (Ca) species (WACCM-Ca) simulated the seasonal Ca^+ layer globally [Plane et al., 2018]. However, the results cannot be vilified well because observation lacks except at the mid-latitude in the northern hemisphere.

A new resonance scattering lidar system with frequency-tunable alexandrite laser was developed by the National Institute of Polar Research (NIPR) and installed at Syowa Station (69˚S, 40˚E) by the 58th Japan Antarctic Research Expedition (JARE 58). Density profiles of Ca^+ in the MLT region over Antarctic were successfully observed 6 nights in total in 2017 and 2018. In this presentation, we will show temporal variation of the Ca^+ layer in Antarctic for all events and discuss its characteristics.

Generation and movement of equatorial plasma bubbles: Roles of vertical plasma drifts, seeding perturbations, and geomagnetic storms

*Chaosong Huang[1]

1. Air Force Research Laboratory Albuquerque

We study the characteristics and generation mechanism of equatorial plasma bubbles measured with the Communication/Navigation Outage Forecasting System satellite. It is found that the global distribution of the prereversal enhancement (PRE) of the postsunset equatorial vertical ion drift is very similar to that of the bubble occurrence. Ion density perturbations in different local time sectors are analyzed, and there is no obvious correlation between the afternoon ion density disturbances and the evening bubble occurrence. The results indicate that the PRE is the primary factor that controls the generation of plasma bubbles and that seeding perturbations may always exist in the equatorial region. Effects of geomagnetic storms on the PRE are examined. Penetration electric fields during the storm main phase cause enhancements of the PRE, increasing the occurrence of plasma bubbles, and disturbance dynamo electric fields during the storm recovery phase cause the PRE to decrease, suppressing the occurrence of plasma bubbles. Furthermore, geomagnetic storms cause strong westward plasma drifts in the nighttime equatorial ionosphere, which can reverse the normal eastward drifts of plasma bubbles to westward. The relationship among plasma bubble occurrence, postsunset vertical plasma drift, seeding perturbations, and geomagnetic storms will be addressed.

Variations of the Earth's magnetic field during fall of the Tunguska and Chelyabinsk bolides: analogies and differences

*Ravil Rakhmatulin[1]

1. Institute of Solar-Terrestrial Physics, SB RAS

A superbolide with an estimated mass of 13,000 tonnes exploded at an altitude of 22 km over the city of Chelyabinsk (Russia) at 03 hours 20 min. 33 sec. UTC on February 15, 2013. It is now known as the Chelyabinsk meteorite. Over the past 100 years after the fall of the Tunguska meteorite on June 30, 1908, this event was an entry of the second largest object from outer space into the Earth’s atmosphere. In the literature describing the occurrence of magnetic effects during the fall and explosion of the Tunguska meteorite in the magnetosphere and atmosphere of the Earth on June 30, 1908, some researchers mentioned a change in variations in the Earth's magnetic field 80 minutes before the explosion itself [Kucherov, 2008]. Similar features of the magnetic field components observed by the Irkutsk Magnetic Observatory are identified by the comparative analysis of the magnetic field variations during the falls of the Tunguska and Chelyabinsk space bodies through the magnetosphere.

Acknowledgments

The reported study was funded by RFBR, Russian-Taiwanese joint research project number 18-55-52006 MHT_a. Experimental data recorded by the magnetometric complex of Center for Common Use «Angara» (http://ckp-rf.ru/ckp/3056/) obtained with budgetary funding of Basic Research program II.16 were used.

Atmospheric oscillations in the Sq-EEJ current system using MAGDAS (Global Geomagnetic Observation Network) magnetic field data were analyzed for a comprehensive understanding of the three-dimensional coupled atmosphere-ionosphere-magnetosphere system. In this study, we focus on the 6-day oscillation phenomenon (Q6DO) excited in the troposphere and report its globality, its seasonal dependence of its excitation characteristics, and its solar activity dependence respectively.

It is known that, the quasi-6-day wave (Q6DW), one of the atmospheric waves, is caused by atmospheric heating by moist air in the tropical troposphere [Miyoshi and Hirooka1999] and has a seasonal dependence that strongly develops in the spring and autumn equinoxes [H.-L. Liu et al. 2004]. It has been suggested that the equatorial electrojet (EEJ) has a very high "variability" that fluctuates under the influence of various forcing mechanisms including atmospheric waves from the lower layer. Q6DO in Sq-EEJ current system was verified with CHAMP satellite, Swarm satellite, EEJ intensity data and EEJM (EEJ empirical model) and geopotential height of MLS measurement [Yamazaki et al., 2018]. In addition, the distribution of it near the equator was clarified using the total electron content (TEC) from GPS data and the geopotential height of Aura satellite / MLS measurements. A nearly one-to-one correspondence is found between Q6DW activities in the ionosphere and lower thermosphere [Yamazaki et al., 2019]. However, understanding of wave components in the atmosphere, which is expected to appear in the ground magnetic field fluctuation data excited by the Sq-EEJ current system, is not advanced.

In this study, we analyzed the globality of the 6-day oscillation phenomena in EEJ, the seasonal dependence of its excitation characteristics, and solar activity dependence using magnetic field data of MAGDAS.

For the analysis, we use EE-index, a proprietary index developed by Kyushu University to capture in real time the EEJ, a phenomenon of the ionosphere on the magnetic equator [T. Uozumi et al. 2008] and [T. Ueno et al. 2008]. EE-index is composed of three elements: EDst, EU and EL. EDst represents the global symmetric variation of the magnetic field above the magnetic equator, and EU ·EL represents the variation component of the magnetic field due to EEJ and CEJ, respectively. In this study, we extracted Q6DO in EEJ using the EUEL data from January 1, 2005 to February 25, 2019. The main analysis procedure is as follows.

(1) For the daytime peak of EUEL data (1h value) of each observation point, the quasi-6-day fluctuation component was extracted by a bandpass filter for 5-7 days.

(2) Compare the results of three observation points with more than 60% of the annual data and verify if it is a global phenomenon.

(3) Verification of solar activity dependence by comparison with solar activity index F10.7.

(4) Verification of seasonal dependence.

©2020. Japan Geoscience Union. All Right Reserved.

As a result, it was revealed that Q6DO in the Sq-EEJ current system is a global phenomenon that develops at about the same time regardless of magnetic longitude and latitude and is dependent on solar activity. It was also found that Q6DO has similar seasonal dependence to Q6DW in the atmosphere. Details of the analysis will be introduced in the lecture.

As a future work, it is necessary to look at mid-latitude observation points in order to see a wider range of global distribution. Also, between stations with similar magnetic latitudes such as ANC and DAV, there is a difference in the amplitude of Q6DO, therefore it is necessary to grasp and verify the annual fluctuation trends of each station.

Henveforth, how Q6DO originating from thermal convection in the atmosphere will be affected before reaching the ionosphere and excite EEJ fluctuations

That will be displayed using the GAIA model (the numerical model integrated with the atmospheric model that covers the whole atmospheric region and the ionospheric model) This study will be carried out as a part of the joint research of the Kyushu University-GFZ group.

Investigating of cusp heating process by using chemical releases of Ba/Sr: Initial result of CHI rocket experiment

*Taro Watanabe[1], Yoshihiro Kakinami[2], Masa-yuki Yamamoto[1], Miguel Larsen[3], Mark Conde[4], Takao M. Sato[2], Yuuichi Kaga[2], Takako Kaga[2]

1. Kochi University of Technology, 2. Hokkaido Information University, 3. Clemson University, 4. University of Alaska Fairbanks

In the thermosphere of the cusp region, there are atmospheric heating phenomena that mechanisms are unexplained so far. Lühr et al. [2004] showed atmospheric density enhancements accompanied by the very intense small-scale field-aligned currents (FAC) filaments in the cusp region observed by the CHAMP satellite. They concluded that the Joule heating in the E region of ionosphere caused an up-welling of neutral atmosphere and it led to a density enhancement at 400 km and above. And they also concluded that the small-scale electric field associated with the closure currents of small-scale FACs causing Joule heating may play an important role in the enhancement. In order to obtain the evidence of the Joule heating, more quantitative measurements, especially electric field measurements with high-resolution are required. We observed neutral wind and ion drift with chemical release experiments of Ba/Sr. In November 2014, the sounding rocket experiment named the Cusp Region Experiment 1 (C-REX-1) was launched from Andøya Space Center. C-REX-1 was aimed at measuring the up-welling in the cusp region causing the neutral density enhancements. However, no signatures of the up-welling and small-scale electric field were observed.
We newly developed band-pass filters for ionized Ba (Ba^+, 614.2 nm) and Sr (460.7 nm) with 6 nm bandwidth. The wavelengths of 614.2 nm / 460.7 nm corresponding to the resonance scattering emission of Ba^+/Sr, respectively. We calibrated absolute sensitivity of our system with the filters to determine exposure and ISO speed for Ba/Sr chemical release experiment.
In December 2019, two rocket experiments named C-REX-2 and the Cusp Heating Investigation (CHI) were planned. CHI was launched, but C-REX-2 was postponed due to the low magnetospheric activity and weather conditions. CHI was launched from Svalbard Rocket Range at 09:30 UT, 10 December 2019. And Ba/Sr gases successfully released between the altitude of about 350 km and 180 km (planned nominal) from all of 8 canisters. The resonance scattering emission of Ba^+/Sr gases was optically observed from two ground observation sites of Longyearbyen and Ny-Ålesund in Svalbard, where are about 120 km apart from each other, to determine the velocity of ion drift and neutral wind by triangulation. At each site, we installed two cameras with the filters for Ba^+/Sr. And we successfully obtained the image of Ba^+/Sr drifting. In this paper, we report the initial results of CHI.

Characterization of counter electrojet current according to specific time frame in Southeast Asian sector

*Nur Izzati Mohd Rosli[1], Nurul Shazana Abdul Hamid[1], Mardina Abdullah[1], Akimasa Yoshikawa[2], Teiji Uozumi[2]

1. Universiti Kebangsaan Malaysia, 2. Kyushu University

Counter electrojet, CEJ current refers to the sudden reversal of equatorial electrojet, EEJ current towards the opposite direction (westward) that is usually happen at dip-equatorial region. In this study, the CEJ occurrence at Southeast Asia region is identified using EUEL index during solar cycle 24. The EUEL index is selected as it is a local index that define EEJ at particular location without global magnetospheric disturbance. The CEJ current can be categorized into a few types depending on its occurrence: morning CEJ (0500-1100), afternoon CEJ (1300-1700), evening CEJ (1800-2200) and night CEJ (2300-0400). The continuous 1-minute data has been utilized to describe CEJ behaviour in each time frame. This behaviour is including the amplitude and duration of the current itself, as well as its dependence toward local time and seasons.

Characterizing ionospheric irregularities with GEONET

*Guanyi Ma[1], Qi Li[1], Takashi Maruyama[2,1], Jinghua Li[1], Qingtao Wan[1], Xiaolan Wang[1], Jiangtao Fan[1], Jie Zhang[1]

1. National Astronomical Observatories, Chinese Academy of Sciences, 2. National Institute of Information and Communications Technology

Ionospheric irregularities disrupt the propagation of radio waves in the frequency range below a few GHz, a band used by navigation and communication systems such as Global Navigation Satellite System (GNSS). Detailed understanding of the irregularity characteristics is helpful to estimate potential degradation of the performance of radio systems. Dense GNSS network can work as two-dimensional array to provide the spatial structure of the irregularities. With high spatial resolution vertical total electron content (VTEC), we propose a spatial fluctuation of total electron content (TEC), SFT parameter, to identify and analyze ionospheric irregularities by using the world’s densest GNSS Earth Observation Network (GEONET) of Japan. The data used in this study are carrier phase of the dual frequency GNSS signals from more than 1300 GNSS receivers of GEONET. VTEC is derived by assuming that it is identical in a grid of 0.1˚× 0.1˚ in longitude and latitude, and removing a quantity of inter-frequency hardware bias mixed with integer ambiguity. SFT is defined as the spatial dispersion of TEC within a specific area at a given time. The size of the specific area for SFT calculation is chosen as 0.8˚× 0.8˚ in longitude and latitude, which corresponds to approximately 77 km×95 km at 400 km height 35˚N of Japan. An SFT map is generated by sliding window to show the spatial variation of the ionospheric irregularities in two dimensions. The map can be used to obtain the size, shape, orientation and intensity distribution of the irregularity structures. Case studies are carried out for three strong irregularity events on 12 February 2000, 20 March 2001 and 10 November 2004. The irregularities are found to be anisotropic branching structures, which elongate in north-south direction when first seen at lower latitudes. The structures can move and deviate from their previous orientations, and eventually drift perpendicular to their orientations. Such analyses of SFT maps with GEONET observation successfully provide a new perspective of irregularity morphology and evolution.

Program of the Antarctic Syowa MST/IS Radar (PANSY radar) is a large atmospheric and VHF-band radar located at the Antarctic Syowa Station. This radar has the capability of a MST radar which observes mesosphere, stratosphere, and troposphere, furthermore it is capable of observing plasma quantities in an altitudinal range from 100km to 500km using the ionospheric incoherent scatter (IS). In 2015, the PANSY radar performed the first ionospheric IS observation in the Antarctica. PANSY radar has a frequency of 47MHz, so it is capable of observing the echoes of field aligned irregularities (FAI) in E region. If FAI has a space scale of half wavelength of radio waves they are coherently backscattered, so PANSY radar observes the coherent echoes from 3-m-scale FAI. Signal processing using adaptive beamforming has been developed, because IS observation of PANSY radar is affected by the FAI echoes. PANSY radar has the FAI array of 24 antennas in addition to the main array of 1045 antennas. FAI array comprises of a pair of peripheral linear arrays of 12 antennas, and it can separate the signal from various angles using the directionally-constrained minimization of power (DCMP) algorithm. In fact, by this algorithm, we can observe not only electron density in the background but also FAI and its motion. In the presentation, we will show the temporal variation of FAI by the imaging observation using the PANSY radar, and figure out a physical process of FAI generation, development, and vanish, by comparing with the data of geomagnetic field or aurora at Antarctic Syowa Station.

Vertical profile of ionospheric disturbances associated with Tohoku Earthquake using GPS occultation observation

*Hiroyuki Nakata[1], Yuto Imae[2], Toshiaki Takano[1], Hiroyo Ohya[1]

1. Graduate School of Engineering, Chiba University, 2. Department of Electrical and Electronics Engineering, Faculty of Engineering, Chiba University

Many studies have reported that ionospheric disturbances occur after giant earthquakes. One of the causes is the infrasound wave excited by ground motions and/or tsunami. The horizontal propagation of the ionospheric disturbances after large earthquake have been examined in detail by using a network of ground-based GPS receivers. On the other hand, the vertical propagation of coseismic ionospheric disturbances especially is rarely reported. In this study, to examine the vertical propagation of the ionospheric disturbances excited by tsunami, we have examined electron density profiles observed by GPS radio occultation measurements of FORMOSAT-3/COSMIC satellites. We analyzed the ionospheric disturbances caused by Tohoku Earthquake (M9.0) occurred at 5:46:18UT on 11 March 2011. Density profiles observed within 3 hours after the passage of tsunami were analyzed. In extracting disturbed components from observed density profiles using Chapman model, short wavelength fluctuations were recognized over altitude 300~500 km. Wavelength spectrums of these fluctuations were calculated using wavelet transform. It is confirmed that the spectrum intensity for the wavelength of 10~64 km were enhanced. Maruyama and Shinagawa (2014) showed that acoustic waves generated by ground motions of seismic wave excite ionospheric disturbances with the wavelength of several tens kilometers. The present results is consistent with these previous studies.

Statistical study of the growth rates of medium-scale traveling ionospheric disturbances observed with GNSS-TEC

*Takafumi Ikeda[1], Akinori Saito[1], Takuya Tsugawa[2]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology

Medium scale traveling ionospheric disturbance is one of phenomenon in ionosphere and has been studied after 1960th [Hines, 1960].We think two mechanisms, E-F coupling and Perkins Instability, will relate to growth for MSTID at night in mid-latitude [Tsunoda and Cosgrove, 2001 ; Perkins, 1973].Perkins instability can explain propagating direction,but not for generation. Maximum linear growth rate of perturbation intensity of Pedersen conductivity expected from E-F coupling is less than 5 minutes [Yokoyama et al., 2009], which is far shorter than one expected from Perkins Instability [Fukao and Kelley, 1991 ; Miller et al., 1997 ; Shiokawa et al., 2003]. However, Es layer's spatial and temporal scale is less than 100km and 15min [Maeda et al., 2013 ; S.Saito et al., 2007],which is different from E-F coupling model's ones [Yokoyama, 2009]. And also they are different from MSTID’s ones, which are 200-400 km and around 2hours [Otsuka et al., 2011].
So we can't explain MSTID's saturating process only by E-F coupling and we have not observed the rletaion between that process and two mechanisms about growth rate. Therefore, to decide which instability is responsible for growth of nighttime MSTID after generating frontal structure, the growth rate of MSTID was observationally determined with ground-based GNSS network data.
We statistically investigated the growth rate of nighttime-MSTID in Japan in 2014 observed with GNSS-TEC. We applied twospace and time spectral analysis to calculate MSTID’s growth rates. We compared growth rate observed with linear growth rate of Perkins Instability for two method. We calculated latter using by ion temperature, neutral wind velocity, electric field and O mass density of GAIA model [Jin et al., 2008] and magnetic field of IGRF model.
The growth rate of nighttime -MSTID observed was 1.0 - 6.0 ×10-4 s-1 during 1800LT-2400LT in summer.Linear growth rate of Perkins instability in summer was 1.0 - 6.0 ×10-4 s-1 during 1800LT - 2400LT, so they were less than one of the E-F coupling instability.And we observed Es layer by Ionozonde at Kokubunji in 2014 and compared with LT distribution of growth rates in summer. At the result, the peak time of Es layer after midnight was consistent with that of growth rates.However, seasonal distribution of linear growth rates was different from observed growth rates, because we didn't considered about the effect about southern hemisphere for linear growth rates.
In presentation, we talk the detail about the relation between growth rates and two mechanisms, also relation between north and sourthern hemishphere about
nighttime MSTID's generation.

Retrieval of the Mesosphere and Lower Thermosphere (MLT) physical and chemical properties with the proposed Superconducting Submillimeter-Wave Limb-Emission Sounder 2 (SMILES-2)

*Philippe Baron[1], Satoshi Ochiai[1], Hideo Sagawa[2], Akinori Saito[3], Takatoshi Sakazaki[3], Masato Shiotani[3], Makoto Suzuki[4]

1. National Institute of Information and Communications Technology, 2. Kyoto Sangyo University, 3. Kyoto University, 4. Japan Aerospace Exploration Agency

Submillimeter-Wave Limb-Emission Sounder 2 (SMILES-2) is a satellite mission proposed in Japan to probe the middle and upper atmosphere (20–160 km) [1,2]. The main instrument is composed of 4K cooled radiometers operating near 0.7 and 2 THz. The geophysical information would be retrieved from the molecular lines contained in the spectral bands. The diurnal changes of the horizontal wind above 30 km, temperature above 20 km, ground-state atomic oxygen above 90 km, as well as abundance of about 15 chemical species, could be retrieved. In this study we discuss the sounding of the mesosphere and lower thermosphere (60–160 km). Unlike [3] that only considered the radiometer at 763 GHz, a special focus will be put on the complementarity of the 3 spectral bands for retrieving the physical parameters (wind, temperature and density) as well as the composition (O, O_3, H_2O, NO, CO, HO_2 and OH). The presentation will also include a discussion on the retrieval of the 3 components of the geomagnetic fields using the Zeeman effect on the molecular and atomic oxygen lines at 773 GHz and 2.05 THz. The measurement performance will be discribed as the retrieval precision assessed with simulations.

Formation of a Ring-Like Region of Increased Electron Temperature in the Subauroral Ionosphere in Winter

Innokentiy Alexeevich Golikov[1], Artem Yurevich Gololobov[2], *Ilia Ilyich Varlamov[1,2]

1. Yu.G.Shafer Institute of Cosmophysical Research and Aeronomy (IKFIA), Siberian Branch of the Russian Academy of Sciences, 2. M. K. Ammosov Northeastern Federal University (NEFU),

The results of numerical simulations of the electron temperature (Te) are compared with measurement data provided by the CHAMP satellite to show the possibility of the formation of a ring-like region of temperature increase in the subauroral ionosphere surrounding the auroral oval in the range of 04–07 h (UT) when the high-latitude ionosphere is on the night (shaded) side.
Brace et al. (1982) and Kofman (1984) used experimental data to reveal the effects of an increase in the electron temperature in the subauroral ionosphere— “hot spots.” Numerical modeling of the thermal regime of the high-latitude ionosphere was addressed in a number of studies (Schunk et al., 1986; Klimenko et al., 1991; Mingalev and Mingaleva, 2002; Prölss, 2006; David et al., 2011) analyzing the sources of hot spots. The hot spots were shown to be associated with descending heat fluxes, electric fields, and decreased electron densities ne in the region of the main ionospheric trough (MIT). These results were obtained mainly for equinox conditions, and they allow a good description of the spots as structural features of the spatial distribution of Te. We compare the results of numerical simulations and measurements obtained by the CHAMP satellite to study specific features of the spatial distribution of the electron temperature in the F region of the high-latitude ionosphere for winter conditions

Keywords: subauroral ionosphere, electron temperature, heat flux, ring current

Magnetic Field Measurement in the Ionosphere by using 2U-size CubeSat

*Kentarou Kitamura[1], Kazumasa Imai[2], Taku Takada[2], Manabu Shinohara[3], Makoto Wakabayashi[4], Masahiro Tokumitsu[5]

1. NIT, Tokuyama College, 2. NIT, Kochi College, 3. NIT, Kagoshima College, 4. NIT, Niihama College, 5. NIT, Yonago College

We started a development of CubeSat with the dimension of 20*10*10 cm under collaboration with 10 colleges to observe the small perturbation of the geomagnetic field at the LEO. Focus of the observation is to understand the global distribution of the Sq (Solar quiet) currents flowing in the dayside ionosphere, and to try an in-situ observation of the InterHemispheric Field Aligned Current (IHFAC). In particular, the IHFAC was theoretically predicted by Maeda [1974] and Fukushima [1979, 1991] to interpret the north-south asymmetry in the potential pattern. However, the fine structures and natures of IHFAC have not been well understood, although there are several observations of IHFAC from the ground magnetic observation and satellite observations (e.g. Yamashita and Iyemori, 2002, and Park et al., 2002).

In this study, the fluxgate magnetometer is installed in the CubeSat to observe the 3D fine structures of Sq current system. The thermal vacuum test was conducted for the fluxgate magnetometer to confirm the temperature drift of the sensor. As a result, the temperature drift of the magnetic sensor is less than 1nT/degree which is satisfy the requirement of the specification for observations of the Sq current. In addition, the fundamental feasibility studies depending on the electric power budget, orbital life time, the communication capacity, and specification of the magnetometer show that the observation of the Sq current by CubeSat is well feasible with a short duration of the development and quite low-cost.

Keywords: CubeSat, Sq current system, Fluxgate magnetometer

Observations of night time Sporadic-E layer by HF Doppler sounder network: association with Medium-Scale Traveling Ionospheric Disturbance (MSTID)

*Ryo Matsushima [1], Keisuke Hosokawa[1], Jun Sakai[1], Mitsumu K Ejiri[2], Michi Nishioka[3], Takuya Tsugawa[3]

1. The University of Electro-Communications, 2. National Institute of Polar Research, 3. National Institute of Information and Communications Technology

Sporadic-E (Es) is a thin layer in the E-region ionosphere (~100 km) composed of dense metallic ions and electrons. Es is known to appear in the mid-latitude region during summer months. Extremely high electron density within Es sometimes reflects radio waves in VHF frequency range, especially above 100 MHz. Such a Es-related reflection of radio waves causes anomalous long- distance propagation of waves leading to radio interferences of commercial/navigation signals. Thus, Es is one of the important ionospheric phenomena which should be studied in the framework of space weather applications. Recent theoretical studies and numerical simulations have suggested that Es plays an important role in generating wave-like structures at F-region altitudes in summer nighttime, which are known as Medium-Scale Traveling Ionospheric Disturbances (MSTIDs). However, there have been only a few studies investigating the simultaneous observations Es and MSTIDs appearing in the E and F regions, respectively. Such a situation is primarily due to the lack of instruments that can directly observe Es in summer night time. To overcome this limitation, we employed data from HF Doppler (HFD) sounder network in Japan to detect Es in summer night time and tried to evaluate the E-F coupling, i.e., Es in the E-region and MSTIDs in the F-region. The HFD system is composed of a transmitting station in Chofu, Tokyo (35.7˚N, 139.5˚E) and receiving stations at ~10 places in Japan. Based on such multi-point observations, we can derive the dynamical characteristics of Es layer, for example, its moving speed and direction.
In this paper, we show an Es event on August 22, 2014 (00:00 to 02:00 JST). This Es event was analyzed in detail by Ejiri et al. (2019) who used a Lidar system to detect Es above Tokyo. The HFD system also detected the same Es feature near the Tokyo area. We made use of Es reflection data from the HFD receivers in Sugito, Saitama (36.0˚N, 139.7˚E), Fujisawa, Kanagawa (35.3˚N, 139.5˚E) and Sugadaira, Nagano (36.4˚N, 138.3˚E). By using this triangle observation, we succeeded in deriving the horizontal speed and direction of the motion of Es. In addition, we estimated the phase velocity of MSTIDs seen in the maps of Total Electron Content (TEC) from GPS receivers of GEONET. The Es layer propagated with a horizontal speed of 68.9 m/s in the azimuthal direction of - 113.0˚ from the geographic pole (approximately SWW). The phase speed of the simultaneously observed MSTIDs was estimated to be 68.1 m/s and the propagation direction was -110.1˚. This striking correspondence of the dynamical characteristics of Es and MSTIDs implies that the E-F coupling is actually working in the generation process of summer night time MSTIDs and MSTIDs are moving in tandem with Es.

Keywords: Sporadic-E (Es), MSTIDs

SMILES-2, satellite mission for observation of the stratosphere, mesosphere, and lower thermosphere with THz receivers

*Satoshi Ochiai[1], Philippe Baron[1], Yoshihisa Irimajiri[1], Akira Kawakami[1], Toshiyuki Nishibori[2], Makoto Suzuki[2], Yoshinori Uzawa[3], Yasunori Fujii[3], Hiroyuki Maezawa[4], Akinori Saito[5], Takatoshi Sakazaki[5], Masato Shiotani[5]

1. National Institute of Information and Communications Technology, 2. Japan Aerospace Exploration Agency, 3. National Astronomical Observatory of Japan, 4. Osaka Prefecture University, 5. Kyoto University

The Satellite Observation of the Whole Atmosphere - Superconducting Submillimeter-Wave Limb-Emission Sounder (SMILES-2) is a satellite mission for observation of the stratosphere, mesosphere, and lower stratosphere with submillimeter-wave receivers at frequencies of 638 GHz, 763 GHz, and 2 THz. SMILES-2 will measure submillimeter-wave limb emission spectra from atmospheric molecules and atom, that is molecular oxygen, atomic oxygen, water vapor, ozone, and many chemical species. Atmospheric temperature and horizontal wind can be retrieved from the limb spectra as well as the concentrations of those species. The SMILES-2 satellite is planned to have an orbit at an altitude of 550 km and an inclination of 66 degree. with which the latitude coverage of limb observation reaches 80 degree. Since the non-sunsynchronous orbit precesses at a rate of one round per 119 days, SMILES-2 can observe diurnal cycles in 1.5 or 3 month. Height profiles will be measured with a horizontal interval of 690 km along the satellite subtrack. By measuring the same atmosphere two times at an interval of 8 min., horizontal wind vector can be retrieved from two measurements in different looking directions. Superconducting heterodyne receivers will be used to receive the submillimeter-wave limb emission. Receiver configuration is basically same with that of JEM/SMILES, which is a predecessor of SMILES-2 and was operated on the International Space Station in 2009. Unlike JEM/SMILES, SMILES-2 has three frequencies, two antennas, and digital spectrometers. The precision and altitude range for temperature and wind are improved in SMILES-2 comparing with JEM/SMILES. The estimated precisions of temperature and wind measurements would be 0.2 K and 3 m/s in the stratosphere, and 40 K and 20 m/s in the lower thermosphere, respectively, when the vertical resolution is 2.5 km. Those measurement precisions can be achieved only with superconducting receivers. If we use Schottky mixers for submillimeter-wave receivers, we will get 10 times worse noise level and cannot get enough data for latitude-altitude section even with 1 day mean.

Mission part of SMILES-2 is being designed to have 3 year lifetime, using a mechanical 4-K cryocooler that is demonstrated 4 year life in a ground test. The design of the cryostat, which contains superconducting mixers to be cooled, follows that of JEM/SMILES, so that a risk of the development is largely mitigated. Superconducting mixer (HEB mixer) for the 2 THz receiver us developed at NICT and also at Osaka Prefecture University.

We estimated the resource requirement of the SMILES-2 mission to study feasibility of SMILES-2 on a JAXA M-class mission. The power resource is very limited in an M-class satellite comparing with the case of JEM/SMILES. The power consumption of the cryocooler, which is the largest power consuming component, is estimated to be about 159 W after three year operation on orbit. The estimation is made on the assumption that the cooling power required receiver components is less than that of JEM/SMILES and that a recent efficient compressors are used. The total power consumption of the mission system can be balanced with the satellite bus power provision, which will be 323 W for the mission system when the satellite is at the status of a maximum sun-shade ratio of 37 % for the SMILES-2 orbit. Another issue is to keep the development cost low. We studied measures to reduce the cost on the condition that we use superconducting receivers for the mission and that the satellite takes non-sunsynchronous orbit. The cost

estimated is within the scale of M-class mission if we suppose that some receiver components are developed in collaboration with outside-funded partners.
The SMILES-2 proposal was submitted to the competitive M-class missions announced by JAXA/ISAS.

Numerical study of the internal mesh structure for ion drift velocity analyzer on sounding rocket

*Ryuto Hashiba[1], Takumi Abe[2]

1. Graduate School of Science, Hokkaido University, 2. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

In the upper atmosphere (above 80 km), the neutral atmosphere and plasma coexist. The momentum transfer between the neutral atmosphere and plasma is the important process in elucidating phenomena such as ionospheric dynamo and ionospheric plasma density disturbance. However, there are very few reports on simultaneous and in-situ observation of the key parameters. Especially in the lower ionosphere where this process plays an important role, observation data is limited because satellites cannot fly for long periods of time. Therefore, in order to understand the interaction between the neutral atmosphere and plasma in the ionosphere, it is necessary to develop an analyzer that can observe the ion drift velocity.

To measure the ionospheric plasma, we are developing the ion drift velocity analyzer for sounding rocket. The analyzer is composed of a combination of RPA (Retarding Potential Analyzer) and IDM (Ion Drift Meter), which have been used for ionospheric ion observation. RPA enables ion energy analysis by applying voltage to metal mesh. In addition, the normal component of the drift velocity and the ion density and temperature can be estimated.

In the analyzer under development, the RPA section is composed of six mesh grids. The ions are accelerated or decelerated by the voltage applied to the mesh grid. Inside the RPA, it is desirable that the potential distribution between the meshes is uniform in the tangential direction. However, it is expected that this condition is not satisfied. In the case of non-uniform potential distribution, the magnitude of acceleration or deceleration differs depending on the ion trajectory, which may affect the velocity estimation error. Further, the mesh spacing and the wire diameter are directly connected to the transmittance, and the potential distribution may be non-uniform in the plane if the mesh is too coarse.

In this study, the potential distribution near the mesh grid was examined using SIMION, a software that calculates the trajectory of charged particles in the space where electromagnetic fields exist. By estimating the potential distribution, problems relating to the design of the mesh configuration can be sorted out, and the type and structure of the metal mesh suitable for the measurement can be determined. In this presentation, we will present the simulation results, the current status of mesh grid electrode design, and future work.

Using a Software Defined Radio to Receive the FORMOSAT-7 RF Beacon and Derive the Total Electron Content

*Tsai-Ju Yu[1], Loren C. Chang[1], Jann-Yenq Liu[1], Tung-Yuan Hsiao[2]

1. Graduate Institute of Space Science and Engineering, National Central University, Taoyuan City, Taiwan, 2. Accelerator Laboratory, Nuclear Science and Technology Development Center, National Tsing Hua University, Hsinchu, Taiwan

FORMOSAT-7/COSMIC-2 is a joint US-Taiwan six satellite constellation launched in 2019 focused on atmospheric and space weather. One of the payloads is a radio frequency (RF) beacon that transmits at 400 MHz, 965 MHz and 2200 MHz. By receiving two of these frequencies and calculating the phase difference, the ionospheric total electron content (TEC) can be derived. For this purpose, a simple RF beacon receiver was set up using the GNU Radio, a free and open-source signal processing software, and a Universal Software Radio Peripheral (USRP) software defined radio (SDR). We compare the results with the data obtained by existing ground based GNSS receivers to determine if the results are consistent.

Keywords: GNU Radio, FORMOSAT-7, USRP, beacon, total electron content (TEC)

Neutral and ion dynamics seen in GAIA with variable high-latitude input

*Chihiro Tao[1], Hidekatsu Jin[1], Hiroyuki Shinagawa[1], Yasunobu Miyoshi[2], Hitoshi Fujiwara[3]

1. National Institute of Information and Communications Technology, 2. Department of Earth and Planetary Sciences, Kyushu University, 3. Faculty of Science and Technology, Seikei University

Upper atmosphere shows variations reflecting complex interactions under inputs from lower and upper regions. These interactions have been an important target of the upper atmosphere physics and space weather purpose. GAIA, Ground-to-Topside Model of Atmosphere and Ionosphere for Aeronomy, is the whole atmosphere model including interaction with ionized plasma under solar EUV variation and a various waves input using a meteorological reanalysis data. We input magnetospheric variation into GAIA via electric field deposition at polar region and auroral electron precipitation using empirical models. We input polar electric potential map based on Weimer model driven by solar wind and interplanetary magnetic field with saturation effect of cross-polar-cap potential for large potential case. Variable auroral precipitation driven by Kp index is considered. Enhancement of total electron content upto mid-to-low latitude during the magnetospheric storm event is produced due to the consideration of penetration electric field. We will discuss application to neutral density variation and ionospheric storms in this presentation.

Keywords: GAIA, atmosphere-ionosphere coupling, high latitude variation

Time-dependent responses of the neutral mass density to magnetospheric energy inputs into the cusp region in the thermosphere

*Tomokazu Oigawa[1], Hiroyuki Shinagawa[2], Satoshi Taguchi[1]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institute of Information and Communications Technology

Recent satellite observations have shown that the neutral mass density around 400 km altitude in the cusp is significantly larger than that of ambient regions. The mass density enhancement is 33 % on average, and can be over 100 % during geomagnetic storms. It is considered that soft electron precipitation and local heating in the F region play significant roles in generating the mass density anomaly. However, we still have not understood how such processes contribute to the mass density anomaly in detail. Previous modeling studies are partially successful in reproducing the mass density anomaly under geomagnetically disturbed conditions, whereas previous studies have difficulties reproducing sufficient mass density enhancements under quiet conditions. In the cusp ionosphere-thermosphere system, various processes, such as ion-neutral drag, Joule heating, heating and ionization by particle precipitation, chemical processes, and diffusion, are strongly coupled. Furthermore, the mass density anomaly has small scale features, such as kilometer-scale field-aligned currents and strong vertical dependence of heating. In order to study the mesoscale density anomaly in the cusp, we employ a new high-resolution numerical model including various physical and chemical processes. In the high-latitude ionosphere, the ion density, temperature and velocity are highly variable and affect to the neutral dynamics significantly. Thus, precise calculations of spatially-dependent and time-dependent profiles of ions are crucial to study such ionosphere-thermosphere dynamics. Therefore, we also include time-dependent processes of ions in our model. At first, Joule heating rate is maximized immediately by ionization. However, ion-neutral drag, chemical processes, and diffusion all act to decrease the Joule heating rate significantly. Modeled mass density enhancements are smaller than the observations, indicating that additional energy sources, such as Alfvén waves propagating from the magnetosphere, are needed.

2-dimentional FDTD simulation about spatial structure change of sporadic E layer

*takuto tawaki[1], Taketoshi Miyake[1]

1. Toyama prefectural university

Sporadic E layer occurred in the E region of the ionosphere at the altitude of 90km to 140km causes unexpected propagation characteristics of the MF radio waves. Es layers with spatial structure are found in recent observations. In order to confirm the influence of spatial structures of the sporadic E layer on the MF radio waves propagation, we performed a series of 2-dimensional FDTD simulations using different Es layer models. In these simulations, we observed the spatial profiles of the magnetic field and the altitude profiles of the magnetic field along the assumed trajectory of the sounding rocket.

Simulation results indicate that spatial structure of Es layer affect the propagation characteristics of MF radio waves. These influences are shown especially on propagation characteristics of MF radio waves above the altitude of the Es layer. Therefore, spatial structure of Es layer can be estimated by analyzing the altitude profile of the magnetic field.

Keywords: sporadic E layer, ionosphere

Atmospheric density variations observed by GOCE

*Nakayama Sayuka [1], Liu Huixin[1]

1. Earth and planetary science division,Kyushu university,Japan

Using observations from the GOCE satellite, we examined the dependence of the thermospheric density with solar flux level at different local times. The results show that at dawn there is positive correlation. The coefficient of correlation is 0.6279. At dusk positive correlation can be found. The coefficient of correlation is 0.5390. Seasonal variation of density shows maximum in spring and fall, and it shows minimum in summer. We further examined the ratio between dawn and dusk. The results show an increasing in the ratio from 2010 to 2013, however, there is only a very weak dependence on solar flux is found. We further compare these results with those obtained by CHAMP, and found the ratio between dawn-dusk, day-night thermospheric densities is a relatively stable value than is not much influentially by solar flux levels. This feature can serve as a constrain parameter for thermosphere models.

Keywords: thermospheric density, ratio

revision and data assimilation of a whole atmosphere-ionoshere model GAIA

*Hidekatsu Jin[1], Yasunobu Miyoshi[2], Chihiro Tao[1], Hiroyuki Shinagawa[1], Hitoshi Fujiwara[3]

1. National Institude of Information and Communications Technology, 2. Kyushu university, 3. Seikei university

Temporal and spatial variations in the ionospheric electron density and thermospheric mass density can have significant impacts
on radio communications between ground and space, GNSS navigations, satellites' orbit and attitude and so on. In order to nowcast
and forecast upper atmospheric variations and disturbances, a whole atmospheric model, GAIA, has been developed, Since 2011, when the initial version of GAIA was developed, we have revised it several times so that it can better reproduce upper atmospheric states. Recent updates include more rigorous treatments of ion and electron energetics, ion compositions and chemical reactions, solar radiation effects, and so on. Those updates lead to smaller RMSEs by up to several tens of percents for climatological ionospheric parameters. Data assimilation technique is also being implemented into the model using global ionospheric observations. We will show results from these revisions and assimilation of GAIA, and discuss future directions.

Keywords: ionosphere, thermosphere, space weather, assimilation, simulation, model

Overview of Vertical Incidence Pulsed Ionospheric Radar 2 (VIPIR2) observation in Japan

*Michi Nishioka[1], Hideo MAENO[1], Hiroyuki YAMAKAWA[1], Takumi Kondo[1], Takuya Tsugawa[1], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology

National Institute of Information and Communications Technology (NICT) has been observing ionosphere by ionosondes for over 70 years in Japan. In 2017, we replaced the previous ionosondes with Vertical Incidence Pulsed Ionospheric Radar 2 (VIPIR2) ionosondes, which is mainly developed in NOAA. VIPIR2s are automatically operated at four stations at Wakkanai (Sarobetsu), Kokubunji, Yamagawa, Okinawa (Ogimi). In the presentation, we give an overview of our system and introduce some recent topics on our observation: 1. Estimation of arrival directions of received echo, and 2. Improvement of automatic scaling method. For estimation of arrival directions, two methods of Fourie imaging and Capon method are tried. These methods are confirmed by using data of oblique sounding. For the improvement of automatic scaling, we apply one of machine learning techniques and construct a model for scaling. The accuracy of some parameters is improved.

Keywords: VIPIR2, ionosonde, ionosphere, arraival angle, manual scaling, machine learning

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

[P-EM13] Dynamics of Magnetosphere and Ionosphere

convener:Aoi Nakamizo(Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University), Akiko Fujimoto(Kyushu Institute of Technology), Yuka Sato(Nippon Institute of Technology)

This session provides an opportunity to present recent results from satellite and ground-based observations and theoretical and simulation studies on the magnetosphere, ionosphere, and their coupling processes. We invite talks and posters discussing various phenomena related to the magnetosphere-ionosphere system: solar wind-magnetosphere interaction, magnetosphere-ionosphere convection, field-aligned current, magnetic storms/substorms, neutral-plasma interaction, ionospheric ion inflow and outflow, aurora phenomena, and so forth. Discussions on planetary and satellite ionospheres and magnetospheres, future missions and instrument developments are also welcome.

Overview of electron number density and plasma wave observations by SS-520-3 NEI/PWM

*Atsushi Kumamoto[1], Yuto Katoh[1], Hirotsugu Kojima[2], Keigo Ishisaka[3]

1. Department of Geophysics, Graduate School of Science, Tohoku University, 2. Research Institute for Sustainable Humanosphere, Kyoto University, 3. Toyama Prefectural University

Preparations and preparative studies for electron number density and plasma wave observations in the earth' cusp region by impedance probe and plasma wave monitor (NEI/PWM) onboard the SS-520-3 sounding rocket are overviewed. The main objective of SS-520-3 is to observe acceleration processes of escaping ions from ionosphere in the cusp region. It was originally scheduled to launch from Svalbard in 2017. However, due to failure of the rocket avionics found in the integration test in Japan, the launch was postponed. The development and unit test of SS-520-3 NEI/PWM were already finished before the integration test in 2017. So, we were performing some preparative studies.

The observations of accurate electron number density in a range from 10^3 to 5 x 10^6 /cc and plasma wave spectrum in a wide frequency range from 300 Hz to 20 MHz will be performed by SS-520-3 NEI/PWM. The electron number density is determined from measured capacitance of impedance probe (NEI-S) extended into the ionospheric plasma. Plasma waves are detected by antenna and preamplifier of Low Frequency Analyzer System (LFAS). NEI/PWM obtains plasma wave spectrum from the signal from LFAS. Electron number density is an essential parameter to discuss resonance conditions between plasma waves and particles in their interactions. SS-520-3 NEI/PWM is designed to perform monopole measurements of plasma waves in order to clarify the distribution of the wake-induced plasma waves around the rocket [Endo et al., 2015]. Detection of lower hybrid resonance (LHR) by wideband impedance probe operated in a frequency range from 1 to 10 kHz will be tried first in the ionosphere by SS-520-3 NEI/PWM. It provides information of ion density including cold components and ion composition. The wideband impedance probe is planned to be used also in S-520 sounding rocket experiment in 2022.

We performed preparative analyses on relations between broadband extremely low frequency waves (BBELF) and ion heating by using Akebono data. The results suggest that not only the Alfvenic component of plasma waves around O+ cyclotron frequency but also electrostatic component around lower hybrid resonance (LHR) frequency contribute to the ion heating [Ishigaya, 2019].

Acknowledgement: The SS-520-3 rocket observation will be conducted by the Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency (ISAS/JAXA). NEI/PWM was manufactured by System Keisoku Co.Ltd. Antenna and preamplifier of LFAS, which provides signals to PWM, was developed by H. Kojima of Kyoto University, and manufactured by Sakase Adtech Co.,Ltd., and Meiwa System Co. Ltd., respectively. Preflight environmental tests of NEI/PWM were performed using the facilities of the Industrial Technology Institute of the Miyagi Prefectural Government (ITIM), and Space Chamber Laboratory, ISAS/JAXA.

Geomagnetic N+/O+ variation in the Ring Current Observed by the Arase (ERG) Satellite

*Koichiro Tsuda[1], Shoichiro Yokota[1], Satoshi Kasahara[2], Kunihiro Keika[3], Tomoaki Hori[4], Yoshizumi Miyoshi[4], Iku Shinohara[5], Kentaro Terada[1]

1. Department of Earth and Space Science, Graduate School of Science, Osaka University, 2. The University of Tokyo, 3. Department of Earth and Planetary science, Guraduate School of Science, The University of Tokyo, 4. Institute for Space-Earth Environment Research, Nagoya University, 5. Japan Aerospace Exploration Agency/Institute of Space and Astronautical Science

O+ and N+ are important ring current ions in magnetic storms and they can be a tracers of ion outflows from the deep ionosphere. Much Many researches haves been devoted to the escape of O+, but N+ has not been studied much, possibly because its mass per charge ratio is similar to that of O+ and separating the two is difficult.
We investigated the statistical properties of O+ and N+ in the ring current based on ion composition measurements (~10-180keV/q) by medium-energy particle experiments-ion mass analyzer (MEP-i) on board the Arase (Exploration of energization and Radiation in Geospace, ERG) satellite. By applying a fitting function to the TOF spectrum, we can separated N+ and O+ in the data obtained during geomagnetic storm on 16 July 2017. From the results of fitting we obtained the ratio of N+/O+. As a result the ratio of N+/O+ during geomagnetic storm and during geomagnetic quiet times is found to be about 0.2~0.4 and <0.2 respectively. In this presentation we will discuss ion outflow from the deep ionosphere.

Precipitation Loss of Radiation Belt Electrons by Two-band Plasmaspheric Hiss Waves

*Zhaoguo He[1]

1. Sun Yat-sen University

A two-band plasmaspheric hiss consisting of an upper band (frequency up to 10 kHz) and a lower band (frequency below 1 kHz) was observed by the Van Allen Probes. The electron scattering effect driven by this two-band plasmaspheric hiss is evaluated by the quasilinear diffusion theory for the first time. The calculated pitch angle diffusion rates of the lower-band hiss exist a "gap" with minimum magnitude at around α=70deg, a condition not conductive to the transport of large pitch angle electrons toward the loss cone. However, the diffusion rates of the upper-band hiss have peak values at ~ α=70deg, making up for the "gap" of the lower-band hiss diffusion rates. The wave data-driven quasilinear diffusion simulations demonstrate that the collaborated effect of the lower and upper band hiss can cause significant precipitation loss of energetic electrons of tens to several hundred keV within 1 day.

We have found that energetic electron bursts up to (sometimes, up to 1 MeV) 300 keV appear at the plasma sheet boundary at substorm onsets. The purpose of this study is to address where do the energetic electron bursts at higher latitude come from and what is the contribution of magnetotail reconnection and its associated acceleration process to the generation of the energetic electron bursts. The electron bursts show uni- and bi-directional components (possibly generated by near-Earth reconnection) in the lower energy part (E < 200 keV), while lack of parallel and anti-parallel components are observed in the higher energy part. The magnetic field line model indicates that the Arase satellite was located in the transition region between dipole-like and tail-like fields. Interestingly, the higher energy component of bursts shows signatures of the drift echo. In order to explain these observational features of the electron bursts at the plasma sheet boundary, we have performed test particle simulations traced from magnetotail. At this moment, a possible interpretation of the higher energy electron burst is a signature of substorm injections in the high latitude. We will discuss the origin of MeV electrons at the plasma sheet boundary based on the particle dynamics as well as comparing the distribution functions with those observed in the magnetotail.

PARM-HEP Observation of Microburst Precipitation over Pulsating Aurora

*Taku Namekawa[1,2], Takefumi Mitani[1], Kazushi Asamura[1], Yoshizumi Miyoshi[3], Keisuke Hosokawa[4], Yasunobu Ogawa[5], Shinji Saito[6], Yoshifumi Saito[1]

1. Japan Aerospace Exploration Agency, 2. The University of Tokyo, 3. Nagoya University, 4. The University of Electro-Communications, 5. National Institute of Polar Research, 6. National Institute of Information and Communications Technology

The phenomenon called microburst that radiation belt particles precipitate to the Earth’s atmosphere is thought to be largely related to the dissipation of high energy electrons in radiation belt. It is suggested that this phenomenon is caused by pitch angle scattering of the magnetospheric particles by plasma waves, which is a mechanism similar to the cause of the pulsating aurora observed in the Earth’s polar region. There is a possibility that the origin of microburst can be clarified by proving simultaneous occurrence of microburst and pulsating aurora, but observational verification has not been made yet. For that purpose, we have developed a high-energy electron detector (HEP) for the observation of sub-relativistic - relativistic energy electrons that make up the microburst. This instrument is installed as one of the core instruments of the PARM instrument package developed for the simultaneous observation of the pulsating aurora and microburst by the international student sounding rocket experiment RockSat-XN and LAMP (Loss through Auroral Microburst Pulsation) sounding rocket experiment. We have succeeded in obtaining the flight data on 13 January 2019 from RockSat-XN sounding rocket experiment. Since the rocket was unfortunately launched on the dayside under quiet condition, simultaneous observation with pulsating aurora was impossible and the significant microbursts cannot be detected, but we detect quasi-relativistic energy electrons that can be explained by pitch angle scattering by weak chorus waves in the quiet dayside magnetosphere. On the other hand, LAMP rocket experiments are prepared for launch in winter 2020. We load an anti-coincidence counter on HEP mounted on LAMP to eliminate the effects of penetrating particles such as galactic cosmic rays. In this presentation, we will show the outline and observation results of HEP as well as the current status of the preparation for the launch of LAMP.

We observed ~20 Hz intensity modulation of pulsating aurora at Syowa Station by high-speed camera pointing at magnetic zenith for a few min time interval, 30 min after the aurora breakup occurred on September 22, 2018. The footprints of the Arase satellite was located within the all-sky field of view at that time, and ~20 Hz intensity modulation was observed in the intensity of the lower band chorus waves. We present the possible correlations between the plasma waves and pulsating aurora in more detail, and examine the resonant energy quantitatively.

Relationship between ECH waves, ionospheric F-region ionization and pulsating aurora based on ground-based optical, EISCAT and Arase satellite observations

*Mizuki Fukizawa[1], Takeshi Sakanoi[1], Yasunobu Ogawa[2], Keisuke Hosokawa[3], Yoshiya Kasahara[4], Shoya Matsuda[5], Ayako Matsuoka[6]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. National Institute of Polar Research, 3. Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 6. Research Division for Space Plasma, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

When a substorm occurs, various plasma waves are excited near the magnetic equator of the inner magnetosphere. In particular, there are chorus waves and electrostatic electron cyclotron harmonic (ECH) waves from midnight to morning. These waves can scatter a pitch angle of electrons by cyclotron resonance and the electrons scattered in a loss cone precipitate into the Earth’s atmosphere, causing diffuse auroral emission. Since the resonance energy of chorus waves is a few keV to tens of keV and that of ECH waves is a few hundred eV to a few keV, chorus waves contribute to the auroral emission in the ionospheric D–E region and ECH waves contribute to that in the ionospheric F region (Fukizawa et al., 2018, GRL). The relationship between chorus waves and pulsating aurora and ionization in the D–E region has been clarified by previous studies (e.g., Kasahara et al., 2018, Nature; Miyoshi et al., 2015, JGR: Space Phys.; Nishimura et al., 2010, Science). However, the relationship between ECH waves and pulsating aurora and ionization in the F region is not well understood. In this study, based on ground-based optical, incoherent scatter radar, and satellite-based observations, we investigated the relationship between ECH waves, pulsating aurora and ionization in the F region.

First, we analyzed the observation data of an all-sky imager and European Incoherent Scatter (EISCAT) radar from September 2016 to December 2019. The proportion of events where ionization was observed in the F region by EISCAT radar was 50 % of the events where pulsating aurora was observed at the magnetic zenith by the all-sky imager (filter transmission wavelength: 560 nm ±5 nm) installed in Tromsø (69˚35’ N, 19˚14’ E, invariant latitude: 66˚12’ N), Norway. When a pulsating aurora with a wavelength of 557.7 nm is generated, there are chorus waves as a driving source near the magnetic equator. It has been confirmed by statistical analysis of satellite observation data that the probability that ECH waves are also excited in the magnetic equator when chorus waves are excited is high (Meredith et al., 2009, JGR: Space Phys.). Therefore, ECH waves may be the driving source of the F-region ionization detected by our analysis.

Secondaly, we investigated a simultaneous EISCAT-Arase event obtained from 01:40 to 03:00 UT on September 26, 2019. Although the ionospheric footprint of the Arase satellite was located within the filed of view of the all-sky imager, the weather in Tromsø was cloudy and no pulsating aurora was detected by the all-sky imager. However, chorus and ECH waves were observed by the Arase satellite and ionization in the D–E and F regions was observed by EISCAT radar. The chorus wave and ECH wave observed by the Arase satellite are partially observed exclusively, and the D–E region ionization and the F region ionization observed by the EISCAT radar show similar characteristics. Although the footprint of the Arase satellite at an altitude of 110 km derived from the IGRF magnetic field model was located about 170 km south of the EISCAT radar observation point, these results suggest that there is a relationship between chorus wave

©2020. Japan Geoscience Union. All Right Reserved.

and ionization in the D–E region and that between ECH wave and ionization in the F region.

In the future works, we will analyze spectroscopic data with a wavelength of 427.8 nm that emits in the D–E region and those with a wavelength of 844.6 nm that mainly emits in the F region to investigate whether the time change of each emission has characteristics similar to that of chorus waves or ECH waves.

Simultaneous ground-satellite observation of dayside pulsating aurora

*Shumpei Abe[1], Keisuke Hosokawa[1], Yasunobu Ogawa[2]

1. The University of Electro-Communications, 2. National Institute of Polar Research

Pulsating aurora (PsA) is a type of diffuse aurora which shows quasi-periodic modulation of luminosity. It has been known that PsA is usually observed during the late recovery phase of substorms in a magnetic local time (MLT) sector extending from the post-midnight to dawn. Previous studies indicated that PsA originates from quasi-periodic precipitation of electrons, which are scattered by whistler mode chorus waves near the equatorial plane of the magnetosphere. Most of the previous studies of PsA are focused on observations on the nightside and dawnside. However, recent studies, for example Han et al. (2015), indicated that PsA is observed even on the dayside (from the morning to the noon sector) at high-latitudes slightly below the cusp region. Those studies presented the MLT distributions of such Dayside-PsA (D-PsA) events, but detailed characteristics of D-PsA, such as its pulsating period and the origin of its temporal variation, have not yet been clarified. To reveal such properties of D-PsA, we have used optical data obtained from the all-sky WATEC imagers (AWIs, Ogawa et al., 2019) in Longyearbyen, Norway (78.1N˚,16.04˚E), whose temporal resolution is 1 Hz for the green-line (557.7 nm) observations. In addition, to observe chorus waves in the magnetospheric counter part of the DPsA region, we made use of wave data from the THEMIS satellite located near the equatorial plane of the magnetosphere. To verify the association between chorus wave and D-PsA, we investigated a D-PsA event in 25 minutes from 0720 to 0745 UT on December 10, 2018. This D-PsA event was observed by AWI and THEMIS simultaneously. Through direct comparison of the auroral luminosity from AWI with the chorus intensity from THEMIS, and additional cross-correlation analyses, we confirmed that there is a one-to-one correspondence between the brightness variation of D-PsA and the intensity modulation of chorus wave, which is very similar to the situation of PsA on the nightside and dawnside. To highlight the difference between PsAs on the nightside and dayside, we derived the distribution of pulsating period of D-PsA by applying the Stockwell transform to 6 events of D-PsA seen in Longyearbyen. From this statistical analysis, we found that the typical period of D-PsA is relatively longer (the peak was located at 35 sec) than that of nightside PsA. According to these results, we suggest that the driver of electron precipitation causing D-PsA is again whistler mode chorus waves in magnetosphere; thus, the mechanisms is similar to that of the nightside PsA. However, the prominent difference in the pulsating period of D-PsA means that the property of dayside chorus wave differs from that on the nightside to dawn side.

Characteristics of periodicity of the dayside pulsating aurora and its response to solar wind obtained by multi-wavelength all-sky cameras at South Pole Station

*Miki Kawamura[1], Takeshi Sakanoi[1], Mizuki Fukizawa[1], Naoshi Yagi[1], Yusuke Ebihara[2], Tetsuo Motoba[3], Akira Kadokura[4], Yasunobu Ogawa[4]

1. Tohoku University, 2. Research Institute for Sustainable Humanosphere, Kyouto University, 3. Nagoya University, 4. National Institute of Polar Research

We report the event analysis on the characteristics of dayside pulsating aurora obtained with ground-based imagers, and its solar wind response. Pulsating aurora is a diffuse aurora that shows time variation with a period from a few to several tens s. It l usually seen from the midnight to the morning sectors (0-6MLT).Recent studies showed that pulsating aurora is caused cyclotron resonance between chorus waves and electrons near the magnetospheric equator [e.g., Kasahara et al., 2018]. Electrostatic electron cyclotron harmonics (ECH) play additional role to cause the pulsating aurora. Considering the dayside pulsating aurora, changes of solar wind dynamic pressure would affect the resonance conditions in the dayside magnetosphere [Engebretson et al., 1994, Vorobjev et al., 1999, Motoba et al., 2017]. However, it is difficult to observe dayside pulsating aurora because of sunlit conditions, and detailed characteristics, and generation mechanisms of pulsating aurora are not understood well.
It is important to examine the similarity and discrepancy between dayside pulsating aurora and morning side pulsating aurora, and its solar wind response to understand these issues,We examined the multi-spectral all-sky image data taken at the South Pole Station (geomagnetic latitude 74.4 ˚) to clarify the characteristics of the dayside pulsating aurora. The South Pole Station is a suitable for dayside auroral observations which provide continuous auroral images for 24 hours from May to August. From the data obtained with a panchromatic Watec all-sky camera (time resolution 0.5 s) and ASI-1 (time resolution 64 s, wavelength 557.7 nm and 630 nm) , we found dayside pulsating auroral events in the two nights of June 24 and 25, 2014. The main pulsation period was in the range of 10-50 s on the both cases on June 24 and 25, which is consistent with previous studies of dayside pulsating aurora, and similar to that seen in the morning-side pulsating aurora. We also found that the pulsating aurora on June 25 moved toward the higher magnetic latitudes greater than 74.5 deg. Compared the pulsating aurora with geomagnetic activity, solar wind dynamic pressure, and auroral intensity ration of 630nm and 557.7 nm emission, we see that the magnetic activities were quiet (AE˜50-100, IMPBz˜0-+6[nT]) on the both cases of June 24 and 25, 557.7 nm aurora was more intense than 630 nm aurora which indicates that the source region is the magnetospheric plasma sheet. Interestingly, the solar wind dynamic pressure increased from P = 1.0 [nPa] (8MLT) to P = 5.5 [nPa] (11MLT) only for the case on June 25. These results suggest that the source region of pulsating aurora in the dayside magnetosphere expanded toward higher latitudes caused by significant enhancement of solar wind dynamic pressure. The expansion of the source region of pulsating aurora is probably related with the minimum B pockets [Tsurutani and Edward, 1977] which is a weak magnetic field region at high-latitudes distorted by strong solar wind dynamic pressure. The increase of chorus wave growth rate may contribute to electron pitch angle scattering in this region.

Latitudinal distributions of magnetic variations in the near-earth magnetosphere during substorm

*Shun Imajo[1], Masahito Nose[1], Mari Aida[2], Nana Higashio[2], Haruhisa Matsumoto[2], Kiyokazu Koga[2], Akimasa Yoshikawa[3], Yoshizumi Miyoshi[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Japan Aerospace eXploration Agency, 3. ICSWSE, Kyushu University

We examine the latitudinal distributions of magnetic variations in the near-earth magnetosphere during substorms by simultaneous magnetic observations of the first Quasi-Zenith Satellite (QZS-1) and the Engineering Test Satellite VIII (ETS-VIII). QZS-1, which has a unique orbit of quasi-zenith orbit with an inclination of 41º, an apogee of 7.1 Re radial distance, and an orbital period of 24 h, can stay for a long time in the near-earth magnetosphere away from the magnetic equator. ETS-VIII is a geosynchronous satellite located at the E146º longitude, which is within the QZS-1 longitude range. We selected 356 dipolarization events at ETS-VIII when the difference of magnetic local time between QZS-1 and ETS-VIII was less than 1 h.
Typical magnetic variations are classified into 5 types roughly depending on the magnetic latitude of QZS-1 (MLAT) as below:
(Type 1) In |MLAT|<~ 20º, QZS-1 naturally observed magnetic variations similar to those at ETS-VIII with a small delay (1–2 minutes).
(Type 2) In ~20º<|MLAT|<~30º, the onset of large magnetic excursions at QZS-1 was several tens of minutes delayed by the dipolarization onset at ETS-VIII. The excursions were not similar to those at ETS-VIII and were polarized in the azimuthal direction with large-amplitude oscillations.
(Type 3) In ~30º<|MLAT|<~50º, QZS-1 observed small magnetic excursions without oscillations. Surprisingly, the time delay between QZS-1 and ETS-VIII was only within 1–2 minutes.
(Type 4) In ~40º<|MLAT|<~50º, QZS-1 sometimes did not observe any variations.
(Type 2+3) Some events had both features of Type 2 and Type 3.

The large-magnetic excursion of type 2 events can be considered to be a direct crossing of the field-aligned currents (FACs). The large delay time corresponds to the poleward expanding time of the substorm currents system. The oscillations with the excursion may be caused by a small-scale structure of FACs. On the other hand, the small magnetic excursion of type 3 events can be considered to be a magnetic effect outside (polar side) the FACs. This is similar to the magnetic bay on the low-latitude ground, which is the magnetic effect inside (equator side) the FACs. We call the magnetic variation that we found “magnetospheric polar side bay”. If the intensity of the FAC is small or QZS-1 is far away from the FACs, any magnetic variations may not be observed at QZS-1, so the event was classified into type 4. The latitudinal distribution of polarization, amplitude, and delay time will be quantitively examined. Also, we will further investigate the relation among the magnetic variation away from the magnetic equator, plasma particles, and aurora, using the Arase satellite, which has a large inclination of 32º.

If Pi2 is onset indicator of substorms, what triggers Pi2s?

*Osuke Saka[1]

1. Office Geophysik

Close analyses of substorm onset using data from all-sky imagers, ground magnetometers, and plasma and magnetic field measurements at geosynchronous orbit obtained in the Global Aurora Dynamics Campaign (1985-1995) revealed that equatorial Pi2s can pick up in statistical base as well as for case studies the onset of individual field line dipolarization of substorms [Saka et al., 2010; Saka and Hayashi, 2017]. The analyses also show that field-aligned flows towards the equatorial plane (inflow) intensified radial inhomogeneity of plasma pressure in the pre-onset intervals, which initiated slow magnetoacoustic wave through Ballooning instability. The excited slow magnetoacoustic wave would smooth out the radial inhomogeneity by the associated azimuthal expansion of the flux tubes. The smoothing of the radial inhomogeneity is consisted of oscillating transition of flux tubes (at Pi2 periodicity) from one stable geometry with smaller curvature radius to the other of larger curvature radius of geomagnetic field lines, which will be referred to as field line dipolarization [Saka, 2019b].
The analyses also showed that flux tubes linked to negative and positive bays at higher and lower latitudes, respectively, oscillated coherently at Pi2 periods [Saka et al., 2012; Saka, 2019b]. Oscillating flux tubes associated with positive bay may trigger cavity/waveguide mode in low latitudes [Allan et al., 1996; Li et al., 1998], while flux tubes for negative bay yields convection surge in the midnight magnetosphere [Saka, 2019b]. Electromotive force generated in the auroral ionosphere by the convection surge produced field-aligned currents in it [Saka, 2019a].

In the dip-equator, a singular latitude of the cavity/waveguide mode [Allan et al., 1996], only isotropic mode can be excited. This leads us to suppose that a very large propagation velocity (or large wavelength exceeding whole circle of the Earth) of Pi2s in the nightside sector [Kitamura et al., 1988] would be caused by the dawn-dusk asymmetry of non-propagating compressions. This contrasts with the high-latitude Pi2s that propagated typically at 20km/s eastward and westward in the sector east and west of the substorm center, respectively [Samson and Harrold, 1985].

Time evolution of aurora structures associated with inverted-V electron distributions

*Morio Tanaka[1], Satoshi Taguchi[1], Keisuke Hosokawa[2]

1. Department of Geophysics, Graduate school of science, Kyoto University, 2. Department of Communication Engineering and Informatics, University of Electro-Communications

The inverted-V is an energetic electron precipitation event, which can be seen as a V-shape structure in electron flux spectrograms, and causes intense auroral arcs. Previous satellite observations have suggested that the inverted-V structure would be stable for 5 min at least, but the detailed characteristics of its time evolution are still unclear. Aurora image data (557.7 nm and 630 nm) from an all-sky imager at Longyearbyen, Svalbard, and precipitating electron and magnetic field data from the DMSP spacecraft (F16, F17, F18, F19) are used to identify the aurora structures associated with inverted-V, and track their time evolution. The result of the analysis indicates that the auroral structures associated with inverted-V electron distributions tend to have longer durations than previously reported from the satellite observations. Some periodic features of the auroral structures are also seen. Key parameters for the stability of the inverted-V, i.e., parallel electric field are discussed in terms of phases of a substorm.

Automatic Classification of Auroral videos based on 3D-CNN

*Toru Mikuriya[1], Akiko Fujimoto[1], Yoshizumi Miyoshi[2], Yasunobu Ogawa[3], Keisuke Hosokawa[4]

1. Kyushu Institute of Technology, 2. Nagoya University, 3. National Institute of Polar Research, 4. The University of Electro-Communications

There are several approaches for classifying all-sky images of aurora with handcrafted methods. The recent enhanced on the fields of computer vison and machine learning research resulted from growing the environment of information processing allows to easily develop the automatic classification of aurora images into some labeled groups. The previous researchers have proposed handcrafted classification models of snapshot aurora images with aurora shapes, color features and aurora velocity (motional differences between two aurora images), etc. They work well for the type of discrete aurora, since they have fine structure of aurora shape. Now we attempt the non-handcrafted and automatic distinction of diffuse aurora such as pulsating aurora with the supervised 3D-Convolutional Neural Network (3D-CNN) technique. We use 605 aurora all-sky imager videos (each movie has 60 frames with 1 second time resolution) to extract the feature of quasi-periodic pulsation aurora motion which is the main characteristic of pulsating aurora. The supervised learning data has two categories, 1) pulsating aurora and 2) no pulsating aurora, and we divide all videos into 8:2 for learning /evaluation processes and test process, respectively. The k-Cross Validation (k=5) resulted in higher accuracy of our model (larger than 90 %). We found the classification accuracy depends on the number of 3D-CNN filter in time direction, and our model works well on the lower number than the typical frequency of pulsating aurora.

Spectral investigations on short-wavelength infrared aurora and airglow (0.9-1.6 μm): Ground-based observations in the both polar regions and developments of 2-D imaging spectrograph with high resolutions

*Takanori Nishiyama[1,2], Makoto Taguchi[3], Masato Kagitani[4], Yasunobu Ogawa[1,2], Hidehiko Suzuki[5], Takeshi Sakanoi[4], Fuminori Tsuchiya[4], Peter Dalin[6], Urban Brändström[6]

1. National Institute of Polar Research, 2. The Graduate University for Advanced Studies, SOKENDAI, 3. Rikkyo University, 4. Tohoku University, 5. Meiji University, 6. Swedish Institute of Space Physics

Dayside aurora, polar patch, and airglow are the key phenomena for the understanding of the dayside magnetosphere, ionosphere, and neutral atmosphere coupling process. Those phenomena have been mainly monitored by active/passive radio remote sensing such as HF/VHF/UHF radar, GPS/GNSS and LF wave receiver, and riometer, but spatial and temporal resolutions by those measurements are basically not so good in comparison to optical measurements. Short-wavelength infrared (SWIR) wavelength is crucially important because lower sky irradiation by Rayleigh scattering may allow us to conduct ground-based optical observations even on the dayside. In order to make spectral investigations on the dayside and a feasibility study for the future dayside optical measurements, we operated a Czerny-Turner type 1-D imaging spectrograph at Syowa station (69.0˚S, 39.6˚E, from March to October in 2018) and Kiruna (67.8˚N, 20.4˚E, from late August in 2019).

The spectrograph with two selectable gratings (150 lpmm and 600 lpmm), whose spectral ranges and those per pixel are 510 nm and 119 nm, and 0.50 nm/pixel and 0.11 nm/pixel, respectively, focuses on continuous measurements of SWIR aurora (N_2 1st Positive band and N_2^+ Meinel band) and SWIR airglow (mainly, OH 3-1 band). We presented two events on 6 and 8 May 2018 in which strong intensifications of SWIR aurora emissions are found synchronized with auroral breakup at Syowa station. This is the first study that show absolute intensity of N_2^+ Meinel band (1-0 and 0-0) and N_2 1st Positive band (0-0, 1-2, and 0-1) in the unit of Rayleigh and temporal evolutions of the emissions with high temporal and wavelength resolutions less than 30 seconds and 1.0 nm respectively so far. With regard to airglow, $P_1(2)$ and $P_1(4)$ emissions in OH 3-1 band allow us to estimate OH rotational temperature near the mesopause with errors less than 8 K for data of signal-to-noise (S/N) ratio greater than 2, which show good correlations to neutral temperature measured simultaneously by co-located Fe resonance scattering lidar. The continuous measurements of OH rotational temperature make it possible to study a variability of atmospheric waves and temperature changes due to energetic particle forcing in polar regions.

In addition, we are currently developing a 2-D imaging spectrograph with a fast optical system and a wide field-of-view (FOV). This spectrograph is designed for SWIR wavelength ranging from 1.09 to 1.25 microns that covers strong auroral emissions in N_2^+ Meinel band (0-0) and N_2 1st Positive band (1-2, and 0-1). FOV and angular resolution are 55 degrees and 0.11 degrees per pixel, respectively. If a 30-microns slit is used, wavelength resolutions are 2230 and 5070, with two different gratings (950 lpmm and 1500 lpmm). The S/N ratio for 1 kR emissions can be expected to be larger than 1.0 in a few seconds exposure time. Therefore, we can investigate temporal variability of dayside reconnection and pulsating auroras with sufficient sampling rates of a few seconds. This spectrograph will be installed at The Kjell Henriksen Observatory/The University Centre in Svalbard, Longyearbyen (78.2˚N, 15.6˚E). Taking advantage of its location, 24-hours continuous observations can be expected (solar zenith angle larger than 96 degrees)

©2020. Japan Geoscience Union. All Right Reserved.

near the winter solstice. Additionally, collaborative studies with active/passive radio remote sensing such as EISCAT Svalbard radar and LF radio receiver will be done in the near future to evaluate spatial and temporal characteristics of dayside aurora.

“Great Wall” seen in the omega band: full-color digital camera observation from the International Space Station

*Sota Nanjo[1], Natsuo Sato[2], Yuta Hozumi[1], Keisuke Hosokawa[1], Ryuho Kataoka[2,3], Yoshizumi Miyoshi[4], Shin-ichiro Oyama[2,4,5], Mitsunori Ozaki[6], Kazuo Shiokawa[4], Satoshi Kurita[4]

Department of Polar Science, School of Multidisciplinary Sciences, SOKENDAI, The Graduate University for Advanced Studies, 4. Institute for Space-Earth Environmental Research, Nagoya University, 5. Ionospheric Physics Research Unit, University of Oulu, 6. Graduate School of Natural Science and Technology, Kanazawa University

Astronauts have been taking a large number of sequential auroral photographs from the International Space Station (ISS) using digital single lens reflex cameras. These images have been published online (Gateway to Astronaut Photography of Earth). We have introduced that a method for projecting such images on the horizontal surface at the altitude of aurora by using city lights as markers [Nanjo et al., 2020, submitted]. This method could also be used for estimating the height structure of aurora. Since ISS orbits the Earth with a period of about 90 min, it is possible to observe large-scale structures of aurora in the MLT direction of 4-5 hours as a snapshot. As one example of such large-scale structures, we investigate omega bands which are wave-like structures in the morning sector. Various terrestrial/satellite observations of aurora from below/above have indicated that the western (night) side of the omega structure tend to be brighter than the eastern (morning) side [e.g. Opgenoorth et al., 1994; Amm et al., 2005]. However, since these observations have captured the omega structure as a two-dimensional image, the vertical structure of omega bands has not yet been revealed. The rim direction observations from ISS enable us to see the aurora obliquely; thus, its vertical structure (i.e., height profile) can be captured.

During several cases of omega bands, we found that there are thin wall-like discrete auroras (“Great Wall”) showing a few hundreds of km height. Great Walls are observed in the borderlines of the western flank of the torch structures and the dark part, and extends in 300-600 km mainly in the north-south direction. As shown in the figure, Great Wall is greenish at the bottom and reddish at the topside. It is also confirmed that the existence of Great Wall in the western side of torch is common in both the hemispheres. The simultaneous appearance of reddish and greenish lights extending in the magnetic field direction infers precipitation of electrons in a broadband energy range. This result is somewhat different from the earlier UV observation by Amm et al (2005) who reported the energy of precipitating electrons in a range of 2-5 keV in the omega structures. This could be because the spatio-temporal resolution of the UVI imager was insufficient and the Great Wall could not be extracted. In addition, active pulsating aurora are seen inside the omega structure. Owing to simultaneous observation of chorus waves at the conjugate area in the magnetosphere with the THEMIS satellite, they are typical pulsating aurora caused by the wave particle interaction. In the presentation, we will show the energy range of electron precipitation in the region of Great Wall estimated from the ISS measurement and discuss the origin of the Wall in the context of current closure in the magnetosphere-ionosphere coupling system.

A tool to diagnose magnetosphere under northward IMF conditions: Simultaneous detections of TPA and omega-band aurora

*Motoharu Nowada[1]

1. Shandong Provincial Key Laboratory of Optical Astronomy and Solar-Terrestrial Environment, Institute of Space Sciences, Shandong University, Weihai

In this study, we try to explore the feasibility on whether or not the magnetospheric processes under northward Interplanetary Magnetic Field (IMF) conditions can be diagnosed using two different auroral phenomena; transpolar arc (TPA) and omega-band aurora. Both TPA and omega-band aurora can occur during the northward IMF intervals, and their appearances are closely related with the nightside magnetospheric processes. TPA can be formed and grown by the field-aligned currents induced by the plasma flow shear or the plasm vortex structures between the fast plasma flows generated by magnetotail magnetic reconnection and slower background magnetospheric flows, and the convection of the reconnection-formed closed magnetic fluxes, which cause in the nightside plasma sheet. On the other hand, the omega-band aurora can be attributed to the Kelvin-Helmholtz instabilities triggered by the flow shear between the plasma flows of the nightside magnetospheric boundary layer such as low-latitude boundary layer (LLBL) and background magnetospheric (plasma sheet) flows. If both auroral phenomena can simultaneously be observed, we might remotely investigate (diagnose) how the plasma and its energy are transported in the nightside magnetosphere and at the magnetospheric boundary region under northward IMF conditions. We will discuss the feasibility of this magnetospheric diagnosis, giving the observational example(s) of simultaneous observations of two different auroral phenomena, that is, TPA and omega-band aurora, and in-situ magnetospheric observation(s).

Transient and localized field-aligned current in the cusp region associated with the Sudden Commencement

*Shigeru Fujita[1]

1. Meteorological College, Japan Meteorological Agency/ Nationa Institute of Polar Research

The Preliminary Impulse (PI) and the Main Impulse (MI) are the characteristic geomagnetic variations in the high-latitude region associated with the Sudden Commencement (SC) [Araki, 1994]. These geomagnetic variations appear mainly in the region below the auroral latitudes. This is because the field-aligned currents (FACs) causing these variations appear there [Fujita et al., 2003a,b]. Thus, many studies have been treating the behavior of SC in the region below the auroral latitudes. However, there are few studies about the SC-associated plasma and geomagnetic variations in the cusp region and the polar cap region.

We will report the transient and localized FAC in the cusp region associated with the SC. This FAC is found in the numerical results by REPPU (the global MHD simulation). This current appears in the northward IMF condition with a non-zero IMFBy component. The transient FAC in the cusp region is upward for the positive SC in the pre-noon sector when IMFBy is eastward. The upward FAC in the afternoon sector appears in the negative SI case under the same IMF condition. This transient FAC does not seem to appear in the southward IMF condition. We note that the FAC is too small to make a significant ground magnetic signature.

We will explain the mechanism of the transient FAC associated with the SC. Before the SC, there exists the magnetospheric convection corresponding to the round cell convection in the ionosphere for the north IMF condition. The simulation reveals that the sudden compression of the magnetosphere deforms the pattern of this magnetospheric convection to create a small-scale clockwise vortex transiently in the pre-noon sector. Deformation of the magnetospheric convection and formation of the vortex causes the transient FAC from the NBz current system. In the negative SI case, the clockwise vortex appears in the afternoon sector. When the IMF is southward, such transient vortex does not seem to appear in the two-cell pattern of the magnetospheric convection.

Existence of the Region1 field-aligned current system for zero interplanetary magnetic field

*Tsubasa Hashimoto[1], Masakazu Watanabe[2], Ryuho Kataoka[3], Shigeru Fujita[4], Takashi Tanaka[5]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2. Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University, 3. National Institute of Polar Research, 4. Meteorological College, Japan Meteorological Agency/ National Institute of Polar Research, 5. International Center for Space Weather Science and Education

The interaction between the solar wind and the magnetosphere for southward interplanetary magnetic field (IMF) is manifested in the development of the region 1 field-aligned current system and equivalently in the formation of ionospheric two-cell convection. Recent research indicates that the energy source of the region 1 current system is the high-pressure plasma in the magnetospheric cusp. Thus, understanding the cusp formation process is one critical issue in magnetospheric physics. On the other hand, solar activity has been modulating anomalously since solar cycle 23. In particular, a prolongation of the minimum period and a decrease of the maximum have been reported. If this trend continues, the IMF intensity is expected to become very small in the future. Therefore, investigating the cusp for infinitesimal IMF (for which reconnection effects are minimal) in comparison with the ‘normal’ cusp for southward IMF, contributes significantly not only to better understanding of the solar wind-magnetosphere interaction but also to future prediction of the global environment. For this purpose, we reproduced the magnetosphere under very small IMF using the Reproduce Plasma Universe (REPPU) code [Tanaka, 2015]. In the simulation, a quasi-steady state magnetosphere was produced under the solar wind and IMF conditions of density = 5cm^{-3}, Vx = -370km/s, Bx = 0.0nT, By = -0.05nT, Bz = 0.086nT (total intensity B = 0.1nT and clock angle $\theta = 30^{\circ}$), and temperature = 340,000K. The simulation reproduced the observed field-aligned current system for small IMF(-0.5nT < Bz < 1.5nT,|By| < 1.5nT) [Watanabe et al,1998]. There exists a clear difference between the cusp for infinitesimal IMF and the cusp for southward IMF. Normally, the cusp consists of the equatorward “load” in which electromagnetic energy is converted to thermal energy and the poleward "dynamo" in which thermal energy is converted to electromagnetic energy. The dynamo on the high latitude side is the energy source for the region 1 current system. Although this structure does not change even for infinitesimal IMF, a salient feature for infinitesimal IMF is the imbalance between the load and the dynamo. In the normal cusp, the load and the dynamo are almost balanced. However, in the cusp for infinitesimal IMF, the load is much smaller than the dynamo. This imbalance implies the existence of more than one energy supply route to the cusp dynamo, with one of them emerging solely for infinitesimal IMF. In the presentation, we report the detailed analysis of the simulation data and discuss the role of the cusp from the point of view of the functional aspect in the solar wind-magnetosphere interaction.

A Modified Magnetosphere-Ionosphere Coupling Model by Including the Hall Effects due to Thinning of the Near-Earth Plasma Sheet

*Pai-Sheng Wang[1], Ling-Hsiao Lyu[1]

1. Institute of Space Science and Engineering, National Central University, Taoyuan, Taiwan

Thinning of the near-Earth plasma sheet is commonly observed during the growth phase of a substorm. If the thickness of the near-Earth plasma sheet is between the ion’ s gyro radius and the electron’ s gyro radius, the unmagnetized ions and the magnetized electrons will move in different directions and result in a Hall effect in the near-Earth plasma sheet. This situation is similar to the collisional ions and the collisionless electrons in the E-region ionosphere. Kan et al. (1988) have proposed a Magnetosphere-Ionosphere coupling model to simulate the field-aligned current distributions in the ionosphere before the onset of a substorm. We modify the 1988 M-I coupling model by adding the Hall effect in the near-Earth plasma sheet during the growth phase of a substorm. We find that the Hall effect in the tail can enhance the field-aligned current and change the spatial distribution of the field-aligned current. As a result, both the intensity of the field-aligned currents and the spatial distribution of the upward field-aligned currents obtained in our simulations are in good agreement with the observed field-aligned currents at the onset of a substorm.

Alfvénic disturbances generated by the ionospheric polarization and the convection reversal in the magnetosphere

*Aoi Nakamizo[1], Akimasa Yoshikawa[2], Shinichi Ohtani[3], Takashi Tanaka[2]

1. Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology, 2. Faculty of Science, Kyushu University, 3. The Johns Hopkins University Applied Physics Laboratory

The ionospheric polarization due to conductance non-uniformities largely deforms the global ionospheric convection pattern [*Nakamizo and Yoshikawa*, 2019]. Then it is supposed that the ionospheric polarization should act as the internal driver of the magnetosphere and our succeeding study using global MHD model shows that the ionospheric polarization actually and largely affects the magnetosphere; When the ionospheric Hall conductance is distributed non-uniformly, regardless of IMF-By=0 condition, the whole magnetosphere shows dawn-dusk asymmetry and a kink-type structure appears in the near-earth convection field. The structure resembles the magnetospheric Harang Reversal reported by preceding model studies. It is also confirmed that the magnetosphere remains symmetric between the dawn and dusk sides and the near-earth convection field shows no kink-type structure for the uniform ionospheric Hall conductance (no Hall polarization field). The result for the near-earth region suggests that the Hall polarization is necessary not only for the ionospheric Harang Reversal but also for the magnetospheric one.

The process by which the ionospheric polarization affects the magnetosphere in the simulation space should be as follows: The ionospheric potential deformed by the ionospheric polarization is mapped back to the inner boundary (I.B) of simulation space. The bulk velocity is updated there, and the perturbation propagates in the magnetosphere, modifying the momentum and energy balance. The FAC is determined in the magnetosphere updated in this way and is inputted to the ionospheric solver, where the ionospheric potential mapped back again to the magnetosphere is calculated. The M-I system develops with the succession of this cycle [*Yoshikawa et al.*, 2010], in which the ionospheric polarization effect is accumulatively included.

In order to confirm[visualize] this process and understand how the ionospheric driven component modifies the magnetosphere, we implemented the parallel/anti-parallel Alfvén mode separation method proposed by *Yoshikawa et al.* [2011] in the global simulation. When this method is applied to satellite observational data, it enables us to separate Alfvénic disturbances into components propagating parallel and anti-parallel to the ambient magnetic field, that is, components propagating from/to the ionosphere to/from the magnetosphere. We apply the separation to the 3-D simulation data.

In this study, we focus on the Harang Reversal and corresponding region in the magnetosphere. In the case of the uniform Hall conductance distribution, the Alfvénic disturbance from the I.B. propagates to the magnetosphere symmetrically between the dawn and dusk sides with opposite signs, corresponding to the dawn-dusk symmetric 2-cell ionospheric convection pattern. Both the ionospheric and magnetospheric convection pattern stay symmetric, never showing reversal structures no matter how the M-I system is activated by the external driver (solar wind and IMF). In the case of the non-uniform Hall conductance distribution, the Alfvénic disturbances from the I.B. propagates to the magnetosphere asymmetrically between the dawn and dusk sides because of the ionospheric potential deformed by Hall polarization. The magnetospheric convection gradually shows a meandering. As the time proceed, the kink-type structure is formed corresponding to the Harang Reversal in the ionosphere. The result indicates

©2020. Japan Geoscience Union. All Right Reserved.

that the cause of magnetospheric Harang structure is, at least in the global model, the ionospheric Hall polarization.

Near-earth plasma environment and injection simulated by global magnetosphere model with precession of magnetic axis

*Aoi Nakamizo[1], Yasubumi Kubota[1], Tsutomu Nagatsuma[1], Takashi Tanaka[2]

1. Applied Electromagnetic Research Institute, National Institute of Information and Communications Technology, 2. Faculty of Science, Kyushu University

The plasma distribution from the inner plasma sheet to the geosynchronous orbit is the important information not only as the plasma supply for the inner magnetosphere but also as the environment for artificial satellites. Besides, disturbances such as the plasma bubble intrusion and/or plasma injection associated with tail dynamics and substorms are superposed on the background population in that region.

Global MHD simulation is one of the powerful ways to complement observations and to know deductively what is going on in that region. However, there has been much room for improvement in our model toward the realistic simulation. In this paper, we report our recent model improvements and the performances. The improvement targeting on the magnetosphere-ionosphere coupling process is reported separately.

In order to accurately calculate the magnetic field configuration, we introduced the inclination of the magnetic axis (tilt). Besides, we introduce the precession between the magnetic axis and the rotation axis. Although the precession may appear to be less effective, it is considered to be effective because it alters the ionospheric conductance distribution, which largely modify the magnetospheric convection and dynamics (and therefore the plasma environment in the near-earth region) through the M-I coupling processes as shown by *Nakamizo and Yoshikawa* [2019]. Actually, background plasma distribution and intrusion from the plasma sheet are quite different between simulations with and without precession. We will show the results for equinoxes and solstices.

Automatic identification of FLR events in VLOS data of multiple SuperDARN radars

*Hideaki Kawano[1,2], Akira Sessai Yukimatu[3,4], Nozomu Nishitani[5], Yoshimasa Tanaka[3,4], Satoko Saita[6], Tomoaki Hori[5]

1. Department of Earth and Planetary Sciences, Kyushu University, 2. ICSWSE, Kyushu University, 3. National Institute of Polar Research, 4. SOKENDAI, 5. ISEE, Nagoya University, 6. Kitakyushu College

The FLR (field-line resonance) can take place where the frequency of waves coming into the magnetosphere matches the eigenfrequency of a geomagnetic field line, which runs through the ground, the ionosphere, and the magnetosphere. The FLR causes field-line eigen-oscillations having the maximum in power and the largest changing rate in phase (as functions of L or the latitude) at the resonance point. From the FLR frequency one can estimate the density along the corresponding magnetic field line, because, in a simplified expression, 'heavier' field line oscillates more slowly.
Since the FLR oscillates the ionospheric plasma, too, the SuperDARN radars could monitor the two-dimensional (2D) instantaneous distribution of the FLR frequency, from which one could estimate the 2D plasma-density distribution on the magnetospheric equatorial plane, including the location of the plasmapause. However, visual identification of the FLR in the SuperDARN VLOS (Velocity along the Line of Sight) data is time-consuming, and the visual identification could miss FLR events superposed by non-FLR oscillations of VLOS (which could be called 'hidden' FLR events). In addition, there are lots of VLOS data to be analyzed.
Thus, we have been developing a computer code to automatically identify the FLR by using the Gradient method (a general name referring to both the amplitude-ratio and the cross-phase methods). This method cancels out the superposed perturbations by dividing the data from a Range Gate (RG) by the data from a nearby RG along the same beam, since the FLR frequency tends to depend on the latitude more strongly than the superposed perturbations. Another advantage of applying the Gradient method to the SuperDARN VLOS data is that we can choose any pair of RGs (along the same beam) with different distances, and thus can identify what distance is the best to identify the FLR. This distance reflects the resonance width, which is an important quantity reflecting the diffusion and dissipation of the FLR energy.
We have been developing a computer code to do the above. So far we have developed a subroutine to be applied to one beam, and tested it: We have applied the subroutine to the VLOS data of a few tens of beams of a few radars, and compared the results with the results of visual identifications we had independently made by examining the raw amplitude and phase distribution along the beams.
As a result, the subroutine has identified all the visually identified FLR events at the right location. The subroutine has also identified FLR events which were missed by the visual identification. In addition, the subroutine has identified possible 'hidden' FLR events.
We are now developing a code to automatically apply the subroutine to all the beam-aligned RG pairs (with all the RG-RG distances) of all the beams of a SuperDARN radar. By using the code we expect to identify much more FLR events than by visual identification; the automatically identified FLR events would include events simultaneously observed at several locations by several radars, enabling to monitor the 2D distributions of the plasma density.

Statistical study of SAPS occurrence characteristics using the SuperDARN HOkkaido Pair of (HOP) HF Radars

*Kento Oya[1], Nozomu Nishitani[1], Tomoaki Hori[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

We investigate the occurrence characteristics of Sub-Auroral Polarization Streams (SAPS), using the Super Dual Auroral Radar Network (SuperDARN) Hokkaido pair of (HOP) radars. The goal is to clarify the longitudinal dependence of SAPS occurrence characteristics. In this study, we studied the occurrence rate of the flow that can be considered as SAPS, vs MLT and MLAT by using the beam swinging technique (*Ruohoniemi et al.,* 1989) and ovation technique (*Kunduri et al.,* 2017). Finally, we could catch the true occurrence characteristics of SAPS. We set criteria for the SAPS event, i.e., the flow speed should exceed 150 m/s and should have mainly westward component. We obtained the overall characteristics of SAPS, i.e., equatorward shift of high occurrence rate region with increasing MLT and geomagnetic activity. Some of the characteristics are different from previous studies (e.g., Kunduri et al., 2017). The SAPS regions seem to be located at higher latitudes than the previous studies and the SAPS occurrence peak regions are located at later MLT. These differences might be due to the difference in geographic longitude, as well as the relative values between geographic and geomagnetic latitudes (Far-East Siberia to Pacific vs North American region). We also found new feature, i.e, westward flows from midnight to morning at relatively low geomagnetic latitudes, that could not be caught in the previous studies probably due to the limitation of radars fields of view, especially lower latitude boundary.

Ion precipitation in the cusp for stably northward IMF: Seasonal dependence

*Haruto Koike[1], Satoshi Taguchi[1]

1. Department of Geophysics, Graduate School of Science, Kyoto University

Plasmas are injected into the cusp through lobe reconnection when IMF is northward. Previous studies have shown that the flux of the cusp ion precipitation at the ionospheric heights tends to increase as the solar wind dynamic pressure increases. In order to quantify the solar wind control of the flux of the cusp ion precipitation and understand other key parameters for the ion precipitation for northward IMF, we examined ion precipitation data obtained by DMSP F16, F17, and F18 during three years. Our automated detection of the cusp ion precipitation took more than 500 events that occurred at higher latitudes than 78 MLAT during stably northward IMF. The result of the statistical analysis shows that the seasonal dependence of the cusp ion flux exists in addition to the solar wind parameter dependence. We discuss the result in terms of the dipole tilt angle effect and/or the effect of the solar illumination of the ionosphere.

Keywords: Cusp, ion precipitaion, solar wind, northward IMF

Hemispheric Asymmetry of the Vertical Ion Drifts at Dawn Observed by DMSP

*Mohan Liu[1], Xiao-Xin Zhang[1], Fei He[2], Wenbin Wang[3]

1. National Satellite Meteorological Center, 2. Institute of Geology and Geophysics, Chinese Academy of Sciences, 3. High Altitude Observatory, National Center for Atmospheric Research

Based on the measurements from Defense Meteorological Satellite Program (DMSP) F12, F13, and F15 satellites in 1995–2014, we report significant hemispheric asymmetries in vertical ion drift velocity (Vz) at dawn (0500–0700 solar local time) in geomagnetic and geographic coordinates. Vz is distributed in 0300–0900 magnetic local time sector in both the northern (NH) and southern (SH) hemispheres. The north-south asymmetries are persistent no matter under what kind of seasonal, solar activity, and IMF conditions. In the polar cap, downward Vz is stronger in the SH. Such difference shows clear IMF BY dependence and is more significant in the local winter and/or under low solar activity conditions. In the geomagnetic coordinates, the auroral zone is dominated by upward Vz in the NH but by downward Vz in the SH statistically. In the geographic coordinates, the geographic longitudinal variation of Vz is more pronounced in the SH. The seasonal variations of high-latitude Vz are different in the NH and SH. The average asymmetric feature of Vz largely depends on the occurrence and magnitude of ion upflow/outflow, which are modulated by the combined effects of the asymmetric magnetic field configuration between the two hemispheres, and the dynamic processes in the tightly coupled ionosphere-thermosphere system, and their (probably nonlinear) interactions with each other.

Ground-based observations of MF/HF auroral radio emissions at three stations

*Yuka Sato[1,2], Atsushi Kumamoto[2], Yuto Katoh[2], Yasunobu Ogawa[3], Akira Kadokura[3], Atsuki Shinbori[4]

1. Nippon Institute of Technology, 2. Graduate school of Science, Tohoku University, 3. National Institute of Polar Research, 4. Institute for Space-Earth Environmental Research, Nagoya University

We launched ground-based observations of MF/HF auroral radio emissions more than a decade ago at two stations (The Husafell Station, Iceland, September 2005; The Kjell Henriksen Observatory, Svalbard, September 2008) and found multiple unknown properties of MF/HF auroral radio emissions, e.g. polarization features [*Sato et al.*, 2008, 2015] and existence of a higher frequency component [*Sato et al.*, 2012]. To make a next siginificant step for a futher understanding of MF/HF auroral radio emissions, we installed a new dedicated instrumentation at the KAIRA (Kilpisjärvi Atmospheric Imaging Receiver Array) site in Kilpisjärvi, Finland (Latitude: 60.07 N, Longitude: 20.76 E) in the summer of 2018. It is a passive receiving system designed to realize a high-resolution spectral, interferometric and polarization measurements using 4 loop antennas and a software-defined radio (SDR) receiver. This SDR receiver can implement high-speed, flexible digital signal processing of RF signals and obtain high-resolution spectra pauselessly throughout the night in a wide frequency range up to 6 MHz. In addition, we plan to upgrade the receiving system in Iceland to utilize a similar SDR receiver this summer. One of the main research subjects of this project is radio emission spontaneously emitted from aurora. There are long-known three types of MF/HF auroral radio emissions identified at ground level: auroral hiss, medium frequency burst (MFB), and auroral roar. Investigation into the generation of these emissions not only offers a tool of great promise for remote sensing of ionospheric plasma processes and parameters but also gives the foundation for understanding various radiation mechanisms that occur in planetary magnetospheres and plasma in space. In combination with the long-term continuous observations in Iceland and Svalbard and future EISCAT_3D experiments, observation with this new instrumentation will provide a first-time opportunity to reveal spatiotemporal variations of macro and fine structures of MF/HF auroral radio emissions associated with substorm evolution. In this presentation, we show detailed specification of the new instrumentations and some initial results.

Keywords: radio emissions, auroral phenomena, wave-particle interactions

Application of Magneto-Impedance Sensor to Geomagnetic Field Measurements for Constructing Distributed Arrays of Small Instruments (DASI)

*Nomura Hiroshi[1], Masahito Nosé[1], Hitoshi Aoyama[2], Takeshi Kawano[2], Masafumi Hirahara[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Aichi Steel Corporation

Magneto-impedance (MI) effect was discovered about 25 years ago and micro-size magnetic sensors that utilizes this effect become commercially available. We made some modifications to the commercially available MI sensors as they can cover the range of the geomagnetic field. For the period of March 30 to April 27, 2018, we conducted experimental observations of geomagnetic field variations with the MI sensors at Mineyama observation site, which is located about 100 km north-west of Kyoto. Data obtained with the MI sensors were compared with those from the fluxgate magnetometer that has been working at the site. Results showed that the MI sensor recorded geomagnetic variations with amplitudes of ~1 nT that were also detected with the fluxgate magnetometer. This suggests that MI sensors are useful for researches in geomagnetism or space physics. Furthermore, MI sensors are much less expensive than fluxgate magnetometers.
We are developing a low-cost system to measure the geomagnetic field using the MI sensor. This system includes a Raspberry Pi, a commercially available AD converter, and power supply circuits for generating a stable power supply voltage. In presentation, we will show observation data from this system and discuss the possibility of using this system in Distributed Arrays of Small Instrument (DASI).

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

[P-EM14] Frontiers in solar physics

convener:Shinsuke Imada(Institute for Space-Earth Environmental Research, Nagoya University), Alphonse Sterling(NASA/MSFC), Takaaki Yokoyama(School of Science, University of Tokyo), Toshifumi Shimizu(Institute of Space and Astronautical Science, JAXA)

Over recent decades, Sun-observing satellite missions have told us much about the dynamic solar atmosphere. These satellites can observe magnetic activity in the solar corona at wavelengths inaccessible from ground-based telescopes, such as X-rays and EUV. Additionally, the seeing-free conditions of space allow for consistent, high-spatial resolution at visible wavelengths; e.g. the HInode satellite can observe solar surface magnetic field elements down to ~0.2 arcsec. From observations such as these, we have identified three important points regarding what is required form future space-based solar missions to solve fundamental solar problems, such as how the corona is heated and what drives solar eruptions: (1) seamless observation over all temperature regimes of the solar atmosphere, from the chromosphere to the corona, at the same time; (2) high spatial and temporal resolution to resolve elemental structures of the solar atmosphere, and to track their evolution; and (3) plasma diagnostic capability to quantify the dynamics of elementary process taking place in the solar atmosphere. To meet these requirements, recently the solar physics community in Japan proposed the Solar-C_EUVST mission, which will be launched in the mid-2020s. Furthermore, additional top-rate solar observatories, such as the Parker Solar Probe (PSP), Solar Orbiter, and the Daniel K. Inouye Solar Telescope (DKIST), will be operating in the years leading up to Solar-C_EUVST. In this session we will discuss what solar physics observational and numerical-simulation studies are required prior to the mid-2020s, to prepare most efficiently for the new observational era. We welcome contributions dealing with remote-sensing space-based observations (e.g. from Hinode and SDO), in-situ observations from near- and deep-space (e.g., PSP, Pioneer), ground-based observations, and numerical studies.

Prediction of sunspot number and latitude distribution using machine learning

*Kento Michiwaki[1], Shinsuke Imada[1], Yoshizumi Miyoshi[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

For space weather study, it is important to estimate the solar activity in near future. Recently, it is believed that the polar magnetic field at the solar minimum is one of the indicators for the next solar activity. Therefore, many studies try to estimate the solar polar magnetic field for the cycle prediction. The temporal variation of the polar magnetic field can be reproduced by using the surface magnetic flux transport calculation model (SFT model). The SFT model consists of advection term due to differential rotation and meridional circulation, magnetic diffusion term, and flux emergence term. The advection and the diffusion coefficients are estimated by modern observations. On the other hand, estimation of future flux emergence is still very difficult. Therefore, estimating when and where the sunspots will be emerge is crucial for cycle prediction study.
In this study, we predicted the sunspot number using RNN (Recurrent Neural Network), which is one of the machine learning technique. Also, the latitude distribution (batterfly diagram) was predicted using CNN (Convolutional Neural Network). As a result, for the prediction of the number of sunspots, by using the sunspot number of former half of the cycle as the input data, we succeeded to predict the sunspot number of latter half of the cycle. For the prediction of the appearance latitude, the transition and the periodicity of the appearance of the sunspot from the middle latitude to the low latitude were able to be reproduced.

Solar activity varies periodically in 11 years. Because the solar activity is one of the main origins of the variability of the solar-terrestrial environment, it is important to predict the solar activity especially in the category of space weather study. It is known that the polar magnetic field at the solar minimum is closely correlated with the solar activity at the next solar activity. This correlation was confirmed by observing the current sun precisely. On the other hand, it is not clear whether there was a similar correlation in the past sun. Therefore, the aim of this study is to analyze the past sunspot drawing images to verify whether the polar field value at the solar minimum is also good correlation with the next solar activity. Especially, we focused on the Dalton minimum when sunspots were little in the early 1800s. We extracted latitude and longitude of sunspot from drawings in the early 1800 's. Furthermore, we generated magnetograms from sunspot drawings by using cGAN(Conditional Generative Adversarial Nets), one of the popular machine learning methods, and will discuss the validity of these magnetograms. In future, we will calculate the polar magnetic field in the Dalton minimum from these generated magnetograms by surface magnetic flux transport model and compare it with the correlation.

Solar surface flow around the cycle 24 minimum

*Kengo Matoba[1], Shinsuke Imada[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

Solar flares have significant impacts on the Earth’s environment. Flares are now believed to be associated with sunspot’s activities. Therefore the 11-year variability in sunspot numbers is one of the major origins of the decadal variability in the solar environment. Predicting sunspot number in next solar cycle is very important for space weather. Building the next solar cycle prediction scheme is the key to long-term space weather research. Recently, it is believed that the polar magnetic field during the minimum period is one of the good indicator for the next solar cycle activity. Surface flux transport (SFT) models are often used to estimate polar magnetic fields. On the other hand, the SFT model requires several parameters, such as meridional circulation, rotational difference, and turbulent diffusion. These parameters are not fully understood, and especially their temporal variation is still unclear.

In this study, we focused on two typical solar surface flows, differential rotation and meridional circulation. We apply a magnetic element tracking (MET) module to SDO/HMI magnetic field data to obtain solar surface velocities. Because HMI has been available since 2010, we calculated solar surface flow using ten years data. We can capture more than 5,000,000 elements and average for each latitude. As a result, we obtain the latitudinal profile of the meridional flow and differential rotation speed. We also studied the temporal variations of the meridional flow and differential rotation speed in cycle 24. We find that the differential rotation/meridional flow speed is faster/slower at the latitude where the sunspots frequently emerge, respectively.

Impact of morphological asymmetry in a sunspot group on the solar cycle prediction

*Haruhisa Iijima[1], Hideyuki Hotta[2], Shinsuke Imada[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Faculty of Science, Chiba University

The spatial structure of leading sunspots is more coherent than that of following sunspots. This well-known characteristic of sunspots produces significant impact on the formation of polar magnetic field and cycle prediction. Using the surface flux transport model, we quantified the effect of this morphological asymmetry of sunspots on the polar field formation for the first time. We find that (1) the morphological asymmetry prevents the build-up of the polar magnetic field by orders of magnitude and (2) the model with the asymmetry shows better agreement in the temporal profile of the observed axial dipole strength. Considering the clear relation between the polar magnetic field and the cycle amplitude, our results suggest a strong impact of the morphological asymmetry on the solar cycle prediction.

Thermal non-equilibrium plasma during a solar flare

*Shinsuke Imada[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

Plasma in the solar corona is believed to be in thermal equilibrium because of the occurrence of weak Coulomb collisions. To date, many studies have discussed the plasma dynamics in the solar corona assuming thermal equilibrium. Most phenomena observed in the solar corona can be explained under this assumption because the available temporal resolution is not sufficient to resolve non-equilibrium conditions. After Hinode was launched, a very high temporal resolution became available, especially for spectroscopic observation. Now, we can discuss plasma heating or acceleration in the solar corona using extreme-ultraviolet (EUV) spectroscopic observations with high time resolution. Further, we can also observe the solar corona at multiple wavelengths with high spectral resolution. Owing to Hinode observations, we can now discuss plasma dynamics under thermal non-equilibrium conditions, such as non-equilibrium ionization. In this talk we will discuss Thermal non-equilibrium plasma during a solar flare oberved by Hinode.

Hall MHD calculation of magnetic reconnection assuming coronal heating

*Kyohei Murakami[1], Shinsuke Imada[1], Haruhisa Iijima[1], Yoshizumi Miyoshi[1]

1. Nagoya University Institute for Space-Earth Environmental

The solar corona is hotter than the solar surface, and its heating mechanism is not clear. Coronal heating can be explained by dissipating even 1% of the convective energy on the solar surface. One of the models that explain coronal heating is energy dissipation by nanoflares, which are thought to be small magnetic reconnections. Fast magnetic reconnection can occur by the Hall effect when the current layer scale is comparable to the ion inertia length. If the magnetic field lines twisted inside the sun rise to the corona, the density around the current layer will decrease sharply, and the ion inertia length will increase. This plasma condition might cause Hall reconnection during flux emergence. The purpose of this study is to create a model for magnetic reconnection when flux emergence occurs using Hall MHD. Gravity was added horizontally along the current sheet to simulate flux emergence. This gravity represents the gravity along the loop when the magnetic field emerges. Simulating gravitational stratification in the direction along the loop reproduced the situation where the density in the emerging magnetic field decreases in the corona. No reconnection occurs in the ideal MHD, but reconnection occurs when gravity is applied. This is because the density of the current layer was reduced by gravity, and the current layer was thinned and numerically dissipated. We added the Hall effect to the simulation and discuss the effect in the current sheet considering the gravitational stratification.

Statistical investigation of magnetic and temperature properties of white-light flares

*Kyoko Watanabe[1], Kosuke Tsuruda[1], Satoshi Masuda[2], Sam Krucker[2,3,4]

1. National Defense Academy of Japan, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. University of Applied Sciences Northwestern Switzerland, 4. UC Berkeley

White-light flare is a phenomenon in which has enhancement of visible continuum in a solar flare, and is mainly associated with a large flare. Although the emission mechanism of white-light flares has not been well understood yet, previous studies have suggested that their origin is accelerated non-thermal electrons and that a relatively strong magnetic field exists in the acceleration site (e.g. Watanabe et al., 2017).

So, we tried to estimate the coronal magnetic field strength by using the turn-over frequency of gyro-synchrotron emission in microwaves (Dulk 1985). We used the Nobeyama Radio Polarimeters (NoRP) for >M3 class flares during the period from January 2011 to December 2017. We found 29 events which were simultaneously observed with white-light (SDO/HMI continuum) and microwave (NoRP) which had loop-top microwave source in the image observed with Nobeyama Radioheliograph. However, we couldn't find any difference in turn-over frequencies with or without white-light emission. In order to investigate the relationship between white-light emission and coronal magnetic field, this method might be too simple because the turn-over frequency is determined by not only the magnetic field strength but also the electron density and so on (Dulk 1985).

To overcome this problem, next, we tried to compare field strength and temperature of white-light emission region. The former/latter can be derived from SDO/HMI magnetogram/three continuum bands of Hinode/SOT. We performed a statistical analysis for 35 Hinode white-light events and then found the field strength of white-light emission region were correlated with the maximum brightness of the white-light emission. Assuming that the magnetic field strength at the acceleration site in the corona is somehow proportional to the photospheric magnetic field strength at the white-light emitting region, this result suggested the strong acceleration process which produces WLFs takes place at the strong magnetic field region in the corona. Moreover, we also found that the amount of the white-light enhancement was approximately proportional to the fourth power of the radiation temperature. From this result, it is considered that the white-light enhancement is black body radiation. From the above results, it is considered that in the white-light flare, large number of electrons accelerated by strong magnetic fields penetrate to the foot-points near the photosphere, and as a result, black body radiation emits as white-light emission at the heated region.

Validation of EUV dynamic spectra and their impact on the ionosphere

*Shohei Nishimoto[1], Kyoko Watanabe[1], Shinsuke Imada[2], Toshiki Kawai[2], Tomoko Kawate[3], Hidekatsu Jin[5], Kyoung-Sun Lee[4]

1. National Defense Academy, 2. Institune for Space-Earth Environmental Research, Nagoya University, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Center for Space Plasma and Aeronomic Research, University of Alabama in Huntsville, 5. National Institute of Information and Communications Technology

Solar flares suddenly emit strong multi-wavelength electromagnetic emissions. Among these emissions, soft X-ray and extreme ultraviolet (EUV) emissions cause the sudden ionospheric disturbance (SID) and effect on radio communication (Dellinger 1937). We need soft X-ray and EUV flare spectra for predicting SID, however, EUV flare spectra observation with high spectral and temporal resolution are very limited, the numerical model for predicting EUV emissions is needed. One of them is the Flare Irradiance Spectral Model (FISM; Chamberlin et al., 2008). Although FISM is the most widely used model now, this model has some problems such as uncertain physical processes due to empirical model.

Hence, we are trying to construct new prediction model of flare EUV dynamic spectra which can explain simple physical models in flare loop (Imada et al., 2015; Kawai et al., under review). In this model, we use the hydrodynamic simulation of the solar flare model given in the CANS (Coordinated Astronomical Numerical Software) 1D package and the CHIANTI atomic database (Del Zanna et al., 2015). First, by using CANS1D, we calculate the time evolution of density and temperature of a single flare loop whose loop length is estimated from observed flare ribbon distance. Then we obtain the flare (X-ray and EUV) spectra of the simulated coronal loop by using the CHIANTI atomic database. Using this model, we reproduced EUV dynamic spectra for some flare events, and compared with observed EUV spectra by SDO/EVE. As a result, we found that our calculation results clearly reproduced most of the EUV lines on short wavelength during flare. Moreover, we found that our model well reproduce the total EUV flare energy especially at wavelengths shorter than 14 nm.

Furthermore, in order to examine the effect of flare EUV emission on the Earth’ s ionosphere, we input our calculated flare EUV spectra to the Earth's atmospheric model GAIA (Ground-to-Topside Model of Atmosphere and Ionosphere for Aeronomy; Jin et al., 2011), and reproduced the ionospheric response.

In this presentation, we will discuss the physical parameters that affect flare EUV spectra and the effects of flare emissions on the Earth’ s ionosphere.

Recent and Upcoming Studies of Solar Coronal Jets

*Alphonse Sterling[1], Ronald Moore[2,1], Navdeep Panesar[3,4]

1. NASA/MSFC, 2. U of Alabama Huntsville, 3. LMSAL, 4. Baeri

Solar jets occur throughout the solar atmosphere, including in coronal holes, quiet regions, and active regions. Observations at X-ray and EUV wavelengths show that frequently jets are made by eruptions of small-scale filaments, called “minifilaments.” Recent studies indicate that many of, or even the majority of, these jet-producing minifilament eruptions occur at locations where opposite-polarity photosphere magnetic fluxes merge and cancel. These observations support the idea that flux cancelation builds a magnetic flux rope along which cool minifilament material gathers, and that the flux rope subsequently erupts to form the jet through a sequence of magnetic reconnections. In this presentation we will update our recent investigations into jets, and discuss expectations and needs for jet studies with new Sun-observing instruments.

Perspective of simulation studies for the Solar-C_EUVST science

*Takaaki Yokoyama[1], Shinsuke Imada[2], Haruhisa Iijima[2], Shin Toriumi[3]

1. School of Science, The University of Tokyo, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. Institute of Space and Aeronautical Science, JAXA

The proposed science objectives of the Solar-C_EUVST are I. formation of the solar atmosphere and the solar wind and II. driving mechanisms of solar flares and eruptions. For the understanding of the complicated observational data, the complementary supports of the numerical MHD simulations are absolutely essential. In this presentation, we are going to summarise the current status of the simulation studies in the viewpoint as supporting tools for the Solar-C_EUVST data interpretations, and attempt to make a prospect for further development.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

[P-EM15] Plasma Theory and Simulation

convener:Seiji Zenitani(Kobe University), Fan Guo(Los Alamos National Laboratory), Takayuki Umeda(Institute for Space-Earth Environmental Research, Nagoya University), Takanobu Amano(Department of Earth and Planetary Science, University of Tokyo), Yasuhiro Nariyuki(Faculty of Education, University of Toyama)

This session invites contributions in plasma theories and simulations. Theoretical and/or numerical results on plasma processes (magnetic reconnection, collisionless shocks, wave-particle interactions, and boundary problems) and their applications in space, solar, astrophysical, and laboratory environments are welcome. Results in computational techniques for simulations and for data analysis are also welcome, including applications of Machine Learning. The session will be held in English.

Full particle-in-cell simulation of the interaction between two plasmas for laboratory experiments on the generation of magnetized collisionless shocks with high-power lasers

*Takayuki Umeda[1], Ryo Yamazaki[2], Yutaka Ohira[3]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Aoyama Gakuin University, 3. The University of Tokyo

A preliminary numerical experiment is conducted for laboratory experiments on the generation of magnetized collisionless shocks with high-power lasers by using one-dimensional particle-in-cell simulation. The present study deals with the interaction between a moving aluminum plasma and a nitrogen plasma at rest. In the numerical experiment, the nitrogen plasma is unmagnetized or magnetized by a weak external magnetic field. Since the previous study suggested the generation of a spontaneous magnetic field in the piston (aluminum) plasma due to the Biermann battery, the effect of the magnetic field is of interest. Sharp jumps of the electron density and magnetic field are observed around the interface between the two plasmas as long as one of the two plasmas is magnetized, which indicates the formation of tangential electron-magneto-hydro-dynamic discontinuity. When the aluminum plasma is magnetized, strong compression of both the density and the magnetic field takes place in the pure aluminum plasma during the gyration of nitrogen ions in the aluminum plasma region. The formation of a shock downstream is obtained from the shock jump condition. The results suggest that the spontaneous magnetic field in the piston (aluminum) plasma plays an essential role in the formation of a perpendicular collisionless shock.

PIC simulation on non-linear development of lower hybrid waves instabilities driven by energetic ions with a ring-like velocity distribution: the comparison of initial value problems and energetic-ion injection models.

*Tsubasa Kotani[1], Mieko Toida[2], Toseo Moritaka[2], Satoshi Taguchi[1]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. National Institute for Fusion Science

Instabilities driven by energetic ions are important issues both for space plasma and magnetically confined plasma aimed for fusion energy. In the auroral region of the Earth’ s magnetosphere, waves near the lower hybrid resonance frequency, ω_{LH}, driven by energetic ions can contribute ion energization. Here, ω_{LH} is estimated as $\omega_{LH} \sim \sqrt{\Omega_i \Omega_e}$ where Ω_i is the ion cyclotron frequency and Ω_e is the electron cyclotron frequency. These waves, namely lower hybrid waves (LHWs) driven by energetic ions are also observed in the Large Helical Device (LHD) for fusion plasma. In the LHD, energetic ions are generated by the perpendicular neutral beam injection (NBI) for plasma heating.

One-dimensional, electromagnetic, particle-in-cell (PIC) simulations are used to investigate the non-linear evolution of lower hybrid waves instabilities driven by energetic ions with a non-Maxwell velocity distribution. These instabilities can excite LHWs. Energetic ions have a ring-like velocity distribution perpendicular to the magnetic field. Here two models with and without the continuous injection of energetic ions into plasma are examined in detail. The speed of the energetic ions is smaller than the Alfvé n speed, and the density ratio of the energetic ions to the bulk ions is several percent. The following results are obtained in the injection model. LHWs keep the larger amplitudes after the saturation. The clear wavenumber shift is found due to the change of the velocity distribution function. Furthermore, the electric field resulting from the instabilities gives energy to the bulk ions. On the other hand, in the value problem, LHWs get damped immediately after the saturation and the clear wavenumber shift is not observed. Other simulations varying the width of the ring-like velocity distribution are also performed.

A comparison of relativistic particle integrators in a fast magnetized flow (2)

*Seiji Zenitani[1], Tsunehiko Kato[2]

1. Kobe University, 2. National Astronomical Observatory of Japan

The particle-in-cell (PIC) method is one of the most important tools to study kinetic processes in space and in astrophysical sites. Basic frameworks and numerical schemes for PIC simulation have long been established. For example, the Boris (1970) integrator to advance particles has long been used in PIC simulation, as it is introduced by several textbooks. Recently, there is a renewed attention to numerical schemes for PIC simulation, in particular in particle integrators, because the classical schemes are incapable of the situations in astrophysics. For example, Vay (2008) and Higuera & Cary (2017) have proposed numerical schemes to preserve the force-free condition, E + V x B = 0, which is ideal to study a magnetized relativistic flow.
In this contribution, we will present a comparison of various particle integrators for PIC simulation in a relativistic plasma flow. Carrying out 80,000 long-term test-particle simulations, we have evaluated particle motions in the electromagnetic field. It is found that many numerical schemes fail to advance particles at the correct speed, because they are unable to satisfy the force-free condition. As a consequence, we observe numerical acceleration/deceleration of particles, whose amplitude is proportional to (delta t)**2. We have developed a second-order theory to predict the numerical acceleration/deceleration. We extend our earlier results in the SGEPSS 2019 meeting, and then we will present a general theory to deal with non-zero parallel velocity.

Particle Simulation of Triggered Emissions from Large Amplitude Whistler-mode Waves

*Takeshi Nogi[1], Satoko Nakamura[1,2], Yoshiharu Omura[1]

1. Reserch Institute for Sustainable Humanosphere, Kyoto University, 2. Institute for Space-Earth Environmental Research, Nagoya University

We perform one-dimensional electromagnetic particle simulations to study basic processes of whistler-mode wave radiation from an antenna locatd at the magnetic equator and its nonlinear interaction with energetic electrons. Approximating the dipole magnetic field by a parabolic magnetic field, we assume a cylindrical geometry for particle dynamics with a parabolic magnetic field taken along the axis of the cylinder, while we solve Maxwell's equations including Poisson's equation on the axis by the FDTD method. We put an antenna perpendicular to the background magnetic field, and oscillate the antenna current at fixed frequencies with different durations to change the length of the triggering pulse. We observe falling-tone emissions triggered from a short pulse at a frequency close to half the electron cyclotron frequency. Through the process of falling tone emissions, we find trapped particles generates the resonant current parallel to the wave magnetic field, which decreases the frequency of the seed waves near the equator. By changing the wave frequency and the length of the triggering wave packet, we can control the occurrence of rising and falling tone emissions.

Electromagnetic particle simulation of whistler mode triggered emissions in the equatorial magnetosphere

*Yuya Fujiwara[1], Yoshiharu Omura[1], Takeshi Nogi[1], Yikai Hsieh[1], Satoko Nakamura[1,2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Institute for Space-Earth Environmental Research, Nagoya University

We performed a one-dimensional electromagnetic particle simulation with a uniform magnetic field. We studied electromagnetic waves radiating from two orthogonally aligned antennas in a transverse plane. To find generation of whistler mode waves, we drove anntenas by currents oscillating with frequencies below the electron cyclotron frequency. We confirmed the mode of radiated waves in 3 cases: right-hand polarized external currents, left-hand polarized external currents, and the linearly polarized external current. We found that we can generate propagating waves without evanescent waves by right-hand polarized external currents and we applied this setting of external currents in the simulation. We injected energetic electrons during the propagation of the triggering wave and found some triggered emissions after electrons injection. We analyzed the dependency of the triggering wave amplitude and the number of injected energetic electrons in the simulation. By changing the frequency of the driving currents temporally, we simulated propogation of rising or falling tone emissions and analyzed interactions between triggering waves and injected energetic electrons on the basis of the nonlinear wave growth theory [1].

Study of the Pitch Angle Scattering of Small Pitch Angle Electrons by Coherent Whistler-Mode Waves

*Genki Ishizawa[1], Yuto Katoh[1], Masahiro Kitahara[1], Atsushi Kumamoto[1], Tomoki Kimura[1,2], Yohei Kawazura[1,2]

1. Department of Geophysics Graduated School of Science Tohoku university , 2. Frontier Research Institute for Interdisciplinary Sciences Tohoku University

Previous studies indicated that whistler mode chorus emissions scatter the pitch angle of energetic electrons, contributing diffuse and pulsating aurora, and reported a high correlation of observed wave amplitude to both auroral luminosity [Nishimura et al, 2010] and electron flux in loss-cone [Kasahara et al, 2018]. However, detailed processes scattering electrons into the loss cone are still unclear. Conventionally, the pitch angle scattering of energetic electrons has been considered as a diffusion process based on the quasi-linear theory. On the other hand, recently Kitahara and Katoh (2019) theoretically and numerically revealed that coherent whistler-mode waves effectively trap small pitch angle electrons and change their pitch angle away from the loss cone. Further investigation for the detailed process of the pitch angle scattering by chorus emissions has been required.

In the present study, we have updated the test particle code of Kitahara and Katoh (2019) in order to treat a large number of electrons at a massively parallelized supercomputer system. By using the developed code, we compute the motion of energetic electrons moving along a field line under the presence of a packet of monochromatic whistler-mode waves generated at the magnetic equator. We assume both the wave amplitude and frequency of whistler-mode waves by referring to the typical parameters observed in the magnetosphere; we assume the wave frequency 0.3 times of the electron gyrofrequency at the magnetic equator, and change the wave amplitude from 0.01 to 0.1% of the background magnetic field intensity at the equator. We also change the duration of the wave packet as well as the amplitude modulation in time, corresponding to the sub-packet structure of the waveform of chorus elements; the duration time of main wave packet and sub-packet at the magnetic equator are assumed to be 97.2 ms and 14.6 ms, respectively. Our simulation results show that most of resonant electrons are trapped by the waves and scattered in the pitch angle range away from the loss cone in the case of waves without amplitude modulation, as reported by Kitahara and Katoh (2019). When the amplitude modulation is present, we find electrons scattered into the loss cone and evaluate the ratio of the number of electrons inside/outside the loss cone quantitatively.

Furthermore, since previous studies revealed that whistler mode waves propagating toward the equator also contribute nonlinear trapping of resonant electrons (e.g., Omura and Summers, 2006), we consider the effects of the location of whistler-mode wave's source region by changing the wave generation region in the simulation system from the magnetic equator to the off-equatorial region. Simulations with initial conditions based on the observed pitch angle distribution in the inner magnetosphere are also performed to compare with the Arase satellite observation. Based on the simulation results, we discuss the favorable condition and roles of nonlinear trapping in the pitch angle scattering of energetic electrons.

Development of numerical code of the electron transport equation with spectral method

*Takuma Katou[1], Takanobu Amano[1]

1. The University of Tokyo

An acceleration process of non-thermal particles is one of the fundamental subjects of space physics. The standard theory of cosmic ray electrons is the diffusive shock acceleration (DSA). However, DSA cannot explain an acceleration of non-relativistic electrons. Although the alternative acceleration process is needed to generate higher energy electrons, it has still been unclear.

We proposed the stochastic shock drift acceleration model (SSDA, Katou and Amano 2019) as this acceleration process. In the previous study, we calculated the energy dependence of electron function under the assumption of the spatial dependence and isotropic pitch-angle distribution. The result is consistent with observations of Earth's bow shock by the MMS spacecraft (Amano et al. submitted). Comparing with observations more precisely, we need to solve the electron transport equation, and derive both the spatial and pitch-angle dependence of distribution function. However, it is not easy to calculate analytically, then we must calculate numerically.

We developed the numerical code to derive spatial, energy, and pitch-angle dependence of the electron distribution function by solving the electron transport equation. We used a 5th order finite-difference method with MP5 for spatial and energy dependence, and 3rd order Runge-Kutta method for calculating time dependence. On the other hand, we used the pseud-spectral method for determining pitch-angle dependence by expanding into Legendre polynomials. It makes the calculation of the pitch-angle scattering process simpler. We calculated the energy and spatial distribution of electrons under DSA by our code and compared with analytical solutions. In this presentation, we report the result of this test.

Vlasov solver using rational Chebyshev function

*Taiki Jikei[1], Takanobu Amano[1]

1. The University of Tokyo

Vlasov simulation solves the Vlasov equation using a mesh in phase space. Compared to popular Particle-In-Cell method, it gives higher accuracy in general because of the noiseless property. However, it requires a lot more computational resource because of the use of additional mesh in velocity space. Velocity space essentially has an infinite interval, so the procedure of discretizing it is not obvious. A solver which is both accurate and efficient at the same time is needed.

In this study, a new Vlasov-Poisson solver using spectral method has been developed. The Vlasov equation is splitted into advection in x and v directions, both are calculated by a semi-Lagrangian method. Interpolation is done by approximating the distribution function by Fourier series expansion in x direction and rational Chebyshev series, which is Chebyshev polynomial transformed to cover infinite interval, expansion in v direction. One has to choose a "map parameter" which determines how far the grid points are spread out. This expansion should have the accuracy advantage of spectral method as well as being able to treat the distribution function as a truly unbounded function in v direction. Expansion of both x and v directions can be done using FFT.

Comparison against other methods for application to standard test problems in 1D such as linear and nonlinear Landau dampings and two stream instability will be presented. The optimum choice of “map parameter” L will also be discussed.

A Multistate Low-dissipation Advection Upstream Splitting Method for Ideal Magnetohydrodynamics

*Takashi Minoshima[1], Keiichi Kitamura[2], Takahiro Miyoshi[3]

1. Center for Mathematical Science and Advanced Technology, Japan Agency for Marine-Earth Science and Technology, 2. Yokohama National University, 3. Hiroshima University

The magnetohydrodynamic (MHD) simulation is an indispensable way to study nonlinear dynamics in space and astrophysical plasmas. To capture high speed flows, discontinuities, and shocks that are frequently observed in these environments, many modern MHD simulation codes are built based on upwind schemes such as the Flux Vector Splitting method and the Flux Difference Splitting method. In particular, the HLLD approximate Riemann solver developed by Miyoshi and Kusano (2005) has an advantage of shock capturing capability with sufficient accuracy and robustness, and thus it becomes a de fact standard method for computational plasma physics.

The upwind schemes sometimes encounter severe numerical difficulties in stringent condition. The scheme tends to suffer from the numerical shock instability when a high Mach number multidimensional shock is well aligned to the grid spacing, and it causes a catastrophic solution such as the odd-even decoupling and “Carbuncle” phenomena. The mechanism of the instability has not been fully understood yet. On the other hand, the scheme is inherently hard to obtain a correct solution of very low Mach number (~0.01) flows, owing to excessive numerical diffusion. We need a novel numerical scheme to tackle a situation including both incompressible and hypersonic flows.

The Advection Upstream Splitting Method (AUSM; Liou et al.1993) and its variants (e.g., Liou 1996) have been widely adopted in computational aerodynamics. The AUSM-family schemes are alternative to other upwind schemes (FVS, FDS, HLL-type) in order to improve accuracy, robustness, and computational efficiency, and some of them are known to be robust against the numerical shock instability. Furthermore, recent AUSM-family schemes are extended to “all-speed” regime, in which a compressible simulation can get accurate solutions in low Mach number limit (Liou 2006, Shima and Kitamura 2011, Kitamura and Shima 2013). Although these advantages are quite attractive to MHD simulations as well, the extension of the scheme has been quite limited thus far (Han+09, Shen+12, Xisto+14, Kitamura+18).

Consequently, we propose a new AUSM-family scheme for MHD simulations. Following the AUSM methodology, we split the flux in MHD equations into the mass flux, pressure flux, and magnetic tension flux. The mass and pressure fluxes are designed to improve the robustness against the numerical shock instability and the accuracy of low Mach number MHD flows. The magnetic tension flux is built to be consistent with the HLLD solver so as to capture MHD discontinuities. The resulting scheme, terms Multistate Low-dissipation AUSM, is expected to overcome numerical difficulties inherent in familiar upwind schemes. We present several benchmark tests including typical shock tube problems, nearly incompressible Kelvin-Helmholtz instability, and Richtmyer-Meshkov instability to verify the expected capability. Hence, the scheme must be a promising tool to tackle the solar-terrestrial system that includes low speed flows (e.g., solar interior and surface) as well as high speed flows (e.g., solar wind and CMEs).

On the rate of electron injection at collisionless shocks

*Takanobu Amano[1]

1. Department of Earth and Planetary Science, University of Tokyo

The acceleration of charged particles at a collisionless shock is conventionally understood in terms of the first-order Fermi acceleration, also known as the diffusive shock acceleration (DSA) mechanism. The nonthermal emission spectrum from relativistic electrons accelerated at strong astrophysical shocks is roughly consistent with the standard mechanism. However, it is well known that the DSA can not efficiently accelerate non-relativistic electrons because of the lack of scattering agents. There must be a mechanism that extracts a fraction of particles in the thermal pool and inject them into the relativistic energy range. Such a mechanism appears to be inactive at shocks of modest strength in the heliosphere, where relativistic electrons are usually not observed. The observations imply that the injection process must operate efficiently at strong astrophysical shocks, which should, however, be suppressed at weak and moderate shock strength.

Recent theoretical development and observational verification of the stochastic shock drift acceleration (SSDA) model [Katou & Amano 2019, Amano et al. 2020] have cast light on the electron injection problem. The model predicts that the injection into the relativistic energy range is possible only at high-speed and highly-oblique shocks. Therefore, it discriminates fast astrophysical shocks (such as young supernova remnant shocks with > a few thousand km/s) from heliospheric shocks (with typical speeds of a few to several hundred km/s). Such a success in explaining existing observations naturally raises the question of how many particles are then finally injected into the population of cosmic-ray electrons. We here make an attempt at a quantitative estimation of the electron injection rate within the framework of the SSDA model.

The SSDA theory at this moment is not sophisticated enough to predict the amount of the injected electrons by itself. We thus take a phenomenological approach using the information available from in-situ observations of the Earth's bow shocks reported in the past. The electron velocity distribution function (VDF) measured at the bow shock often exhibits the so-called flat-top VDF, which is nearly constant at low velocities up to some threshold and then decreases in a power-law from beyond that. There have been observational indications that the threshold velocity corresponds to the energy of the quasi-static cross-shock electrostatic potential in the de Hoffmann-Teller frame. Since the potential may be estimated from the flow kinetic energy of the shock, we can estimate the transition velocity between the flat and power-law parts. We adopt the flat-top VDF and assume that the power-law index is given by the SSDA theory. Under these assumptions, we have constructed a model that can estimate the injection rate as a function of macroscopic parameters of the shock (such as the shock speed).

The model shows that the electron injection rate naturally possesses a strong dependence on the shock speed, a tend independent of the shock obliquity. The higher shock speeds lead to much more efficient rates of electron injection. The shock obliquity may potentially strengthen the shock speed dependence even more. We find that a reasonable amount of electron injection rate may be reached with parameters relevant for young supernova remnant shocks. The validity of the model may, in principle, be tested using available in-situ spacecraft observations at planetary bow shocks.

A Study of Evolutions of Growth Rates and the Most Unstable Modes in the Events of Sub-magnetosonic Kelvin-Helmholtz Instabilities in an MHD plasma

*Chun-Yen Hsu[1], Ling-Hsiao Lyu[1]

1. Institute of Space Science and Engineering, National Central University, Taoyuan, Taiwan

The growth rates of the sub-magnetosonic Kelvin-Helmholtz (K-H) instability in an unbounded magnetohydrodynamic (MHD) plasma are studied theoretically based on the new shooting method we proposed in Refs. [1] and [2]. Traditionally, the eigenfunction of the unstable mode in the K-H instability is obtained by integrating the governing equations from a given perturbation boundary. In the new shooting method, the eigenfunction of the unstable mode in the K-H instability is obtained by integrating the governing equations from the center of the velocity shear layer. We found that the location of the perturbation boundary varies with tangential wavelength, the growth rate, and the Mach numbers of the surface waves. To verify our theoretical results, we have carried out a higher-order MHD simulation. Our simulation results indicate that when the locations of the perturbation boundaries expand away from the center of the velocity shear layer, the growth rate decreases, and the tangential wavelength of the most unstable mode increases. Both the amplitude distributions and the phase distributions of the eigenfunctions obtained in our simulations are in good agreement with those obtained in our theoretical studies.

Structure formation in chiral magnetohydrodynamics: Effect of background magnetic field

*Takahiro Miyoshi[1]

1. Hiroshima University

Anomalous transports due to quantum anomalies have been theoretically predicted. In a system with a chirally imbalanced medium and a magnetic field, the so-called chiral magnetic effect (CME) that induces a current along the magnetic field is expected to appear, such as in electroweak plasmas in the early Universe and in quark-gluon plasmas in heavy-ion collisions. The macroscopic dynamics of a charged medium, on the other hand, is controlled by magnetohydrodynamics (MHD). In order to investigate the linkage between microscopic CME and macroscopic motion of the charged and chirally imbalanced medium, chiral MHD has recently been proposed [Yamamoto, 2016; Rogachevskii, et al., 2017]. Its properties, however, are not fully clarified though several theoretical and simulation studies have been carried out so far. In this study, we investigate the effect of the background magnetic field on the chiral plasma instability (CPI) driven by the chiral term in the induction equation using two-dimensional chiral MHD simulations. The results show that finer magnetic structures than those in CPI without the background magnetic field are formed.

Synchrotron maser emission and associated particle acceleration in relativistic shocks

*Masanori Iwamoto[1], Takanobu Amano[2], Masahiro Hoshino[2], Yosuke Matsumoto[3]

1. Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 2. Graduate School of Science, The University of Tokyo, 3. Graduate School of Science, Chiba University

Relativistic shocks are ubiquitous in the universe, in which synchrotron maser instability produces intense electromagnetic precursor waves. Recent one-dimensional simulations show that longitudinal electrostatic waves, which are called wakefields, are induced in the wake of the large-amplitude electromagnetic waves and that nonthermal particles are generated during the nonlinear collapse of the wakefields (Lyubarsky 2006; Hoshino 2008). This particle acceleration may explain the origin of ultra-high-energy cosmic rays (Chen et al. 2002).
Although the synchrotron maser instability in the context of relativistic shocks are important for the cosmic ray acceleration, it has so far been discussed solely with one-dimensional simulations (e.g., Langdon et al. 1988) and it is not well known whether the same mechanism can operate in more realistic multidimensional systems. However, our high-resolution two-dimensional (2D) PIC simulations (Iwamoto et al. 2017, 2018) showed that the wave emission continues with substantial amplitude for the first time. We confirmed that the large-amplitude electromagnetic precursor waves continue to persist and that the wakefields are indeed excited by the intense electromagnetic waves (Iwamoto et al. 2019). The wakefields collapse during the nonlinear process of the parametric decay instability in the near-upstream region, where both ions and electrons are accelerated by the motional electric field in the upstream and produce clear nonthermal tails in the particle energy spectra measured in the upstream rest frame. In this talk, we discuss this particle acceleration and wave-plasma interaction for more details.

[P-EM16] Magnetospheric Multi Scale (MMS) mission: Accomplishments and Future Plans

convener:Yoshifumi Saito(Solar System Science Division, Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), James L Burch(Southwest Research Institute), Barbara L Giles(NASA Goddard Space Flight Center), Hiroshi Hasegawa(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency)

NASA's Magnetospheric Multiscale (MMS) formation flying satellites have been making unprecedentedly high time resolution measurements of collisionless plasmas in and around Earth's magnetosphere since it was launched in 2015. After completing its nominal mission in 2018, MMS has continued its observations including targeting the magnetic reconnection in the Earth's magnetotail.
The major purpose of this session is to summarize the new world of electron physics that MMS has so far revealed and also to consider a future observation plan recently submitted by the mission team for the extended mission of MMS especially during the coming several years.
The collaboration with multiple missions including Geotail, Cluster II, THEMIS, Arase and other solar terrestrial probes while MMS focuses into electron scale is the key to understanding multiscale phenomena in the Earth's magnetosphere.
We solicit contributions from satellite observations, numerical simulations, laboratory observations, and theories that relate MMS observations. Contributions to the possible future observation plans are especially welcome.
This is a joint session with American Geophysical Union (AGU).
We hope this session will promote further international collaboration among Japan, United States and space physicists all over the world.

Magnetic reconnection controls the transport of solar wind mass and energy into Earth's magnetosphere and is the key to explosive energy release in the magnetotail during magnetospheric substorms. A simplest form of magnetic reconnection in space occurs in the magnetotail where the magnetic fields are nearly antiparallel, no significant jumps in plasma parameters exist across the current sheet, and no significant turbulence is seen in the inflow (lobe) regions. The Magnetospheric Multiscale (MMS) spacecraft, however, have revealed complex features such as a displacement of the stagnation point relative to the X point in the outflow jet direction even for magnetotail reconnection. Here, using in situ observations from MMS in the magnetotail, we present evidence of secondary magnetic island formation in a reconnecting electron-scale current sheet in the magnetotail detected by MMS. The electron diffusion region (EDR) of the event, first reported by Zhou et al. (ApJ, 2019), was recovered by two reconstruction techniques. One is based on electron magnetohydrodynamics equations (Sonnerup et al., JGR, 2016), and the other on polynomial expansion of the magnetic field using instantaneous measurements by the four spacecraft of the magnetic field and particle current density (Denton et al., JGR, 2020). The results from both reconstructions show that a small-scale magnetic island was growing in a reconnecting current sheet with a thickness of about one electron inertial length, consistent with fully kinetic simulations of antiparallel reconnection (Daughton et al., PoP, 2006). It suggests that secondary island formation is an intrinsic process in the EDR of antiparallel reconnection, and reconnection may drive turbulence energy cascade at sub-ion scales by creating sub-ion-scale islands in electron-scale current sheets.

The near-Earth plasma sheet becomes cold and dense under northward interplanetary magnetic field (IMF) condition, which suggests entry of solar wind plasma into the magnetosphere across the magnetopause. The cold and dense trend of the plasma sheet is more apparent in the magnetotail flank regions that are interface between cold solar wind plasma and hot magnetospheric plasma. Several physical mechanisms have been proposed to explain the solar wind plasma entry across the magnetopause and resultant formation of the cold-dense plasma sheet in the tail flank regions. However, cold-dense plasma is occasionally found in the midnight magnetotail as well, and plasma transport from the magnetopause deeper into the magnetosphere has not been understood yet. Here we report that cold-dense plasma is simultaneously detected in a wide region of the near-Earth plasma sheet, including the inner magnetosphere, under the prolonged northward IMF and relatively high dynamic pressure conditions, by using data from Geotail, MMS, ERG, and Cluster. In one event, the ion distribution functions on the duskside both in the outer magnetosphere and in the inner magnetosphere show two distinct populations in low- and high-energy ranges, which implies that the low-energy (cold) population of solar wind origin may enter the magnetosphere by a common process. On the other hand, energies of the cold component and the magnetic field strengths suggest that the cold component in the inner magnetosphere may not have its origin in the magnetotail. We also note that no southward turning of the IMF took place for the period of our interest and thus no injection from the magnetotail into the inner magnetosphere was expected. The entry location(s) of the cold-dense plasma found deep inside the magnetosphere and its transport mechanism remain to be studied.

Uncertainties on Fields Gradients and Propagation Velocities Estimated From Multi-Spacecraft Missions

*Gerard Marcel CHANTEUR[1]

1. CNRS & Sorbonne Université, Laboratoire de Physique des Plasma

Multi-spacecraft missions involving at least four spacecraft with identical instruments allow to estimate :
i/ three-dimensional spatial gradients of fields simultaneously measured by the different spacecraft
The estimation of the spatial gradient of a physical field relies generally upon the hypothesis of linear spatial variations of this field throughout the volume of the cluster of measurement points. Within this approximation the estimated gradient is unique whatever is the weighting of the different points of the cluster. However uncertainties affecting the estimated gradient depend upon the adopted weighting. Case studies will be discussed and simulated uncertainties will be compared with respect to weighting.
ii/ three-dimensional propagation velocities of waves or discontinuities
Propagation velocities of waves or discontinuities can be estimated by timing methods. Usually a reference spacecraft is chosen and only three pairs of non coplanar spacecraft are used, nevertheless results can be improved by considering all pairs of spacecraft and looking for the optimal weighting of all time delays. The optimal approach will be presented and applied to reanalyze some Bow-Shock crossings by CLUSTER.

PIC simulation of electron acceleration at quasi-perpendicular collisionless shock: Application to Earth's bow shock

*Fumiko Otsuka[1], Shuichi Matsukiyo[2], Mitsuo Oka[3]

1. NIT, Kurume College, 2. ESST, Kyushu Univ., 3. UC Berkeley

At Earth's quasi-perpendicular bow shock, non-thermal electrons are observed in-situ measurements. The electrons are thought to be accelerated at the shock through the scatterings by electromagnetic waves upstream and downstream of the shock. Oka et al. (2017, 2019) reported in situ evidences of pitch-angle scattering of non-thermal electrons by whistler waves at the Earth's bow shock, by using data provided by the Magnetospheric Multiscale (MMS) mission. However, the detail electron acceleration process remains unclear.

In this study we perform a self-consistent one-dimensional full particle-in-cell (PIC) simulation of a quasi-perpendicular shock to model the Earth's bow shock. The simulation parameters are the Alfven Mach number 7.1, the shock angle 70 degree, plasma beta 0.3, the ion to electron mass ratio 625, and the ratio of electron plasma to cyclotron frequency 10. In the simulation power-law energy distribution of the electron is formed at the shock transition region, and the anisotropic pitch-angle distribution is found in the upstream region of the shock. We investigate the upstream wave properties and the non-thermal electron trajectories to reveal the electron acceleration and scattering processes in detail. The result will be compared with the MMS data at the Earth's quasi-perpendicular bow shock.

Preparedness for extreme space weather events

*Mamoru Ishii[1], Daikou Shiota[1], Chihiro Tao[1]

1. National Institute of Information and Communications Technology

Space weather is phenomenon in near-Earth space which can impact on human society. It is important to estimate the quantitative influence of space weather for social activities, however, it has not been discussed the relation between the space weather activity and it's impact on each social utility. One of the reasons is discommunications between space weather researchers and users in the society. We have been discussing with space weather information users to make clear the quantitative impact of space weather on the social activity, in addition to discuss plausible maximum level of space weather event in Japan. This study has been executed in the framework of PSTEP since 2015, and we prepare a document to show our results. In this presentation, we show the present results of our discussion.

Value of forecast: forecast verification in user's perspective

*Yuki Kubo[1]

1. National Institute of Information and Communications Technology

Recently, forecast verification and model validation have become popular topic in space weather research, especially, in operational space weather forecast. These verification studies focus on assessing a forecast skill in viewpoint of forecast providers. These are useful for forecasters or model developers to improve the forecast systems or models. On the other hand, the optimal forecast for a forecast provider is not always the optimal forecast for forecast users. Also, the forecast which is the optimal for certain user is not always the optimal for all users, that is, value of forecast depends on each user. Therefore, an assessment of value of forecast is important for forecast users.

In this study, we perform forecast verification in user's perspective. The decision-theoretic approach is employed to evaluate value of forecast. This method is not new, and already well-known in terrestrial weather forecasting community. However, it is not widely used in space weather forecasting community. We show some examples of value of forecast for a deterministic and probabilistic forecast. We will discuss the strength point of probabilistic forecast.

Keywords: Forecast verification, User's perspective, Deterministic forecast, Probabilistic forecast

Statistical analysis of short-wave fadeout toward extreme event estimation for space weather hazardous map of Japan

*Chihiro Tao[1], Michi Nishioka[1], Takuya Tsugawa[1], Daikou Shiota[1], Susumu Saito[2], Kyoko Watanabe[3], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology, 2. Electronic Navigation Research Institute, 3. National Defense Academy

Solar flares trigger enhancements of ionospheric plasma density including D-region which causes absorption of radio waves especially at high-frequency (HF) ranges. This phenomena is called short wave fadeout (SWF) or Dellinger effect. This SWF interrupts trans-ionospheric radio communication system including ground-to-ground radio communications, satellite communication system, and disaster prevention radio system. SWF is one of important topics of space-weather hazardous-map for Japan society. In order to understand SWF statistical characteristics and behaviour, we analyse long-term (~20 years) ionosonde data observed by NICT and estimate extreme case based on the results.

We analyse manually scaled parameters with 15 min. resolution from ionosonde observation in Tokyo over 1997 to 2016. We use minimum reflection frequency, fmin, for detection of Dellinger effect. Since fmin varies with local time (LT) and season, we refer to dfmin, fmin subtracted by its 27-day running average at the same LT. SWF is detected by (i) dfmin>2.5 MHz, (ii) dfmin>3.5 MHz, and (iii) blackout criteria, occurred daytime associated with any flare(s) greater than C-class in this study. We refer to GOES flare list for the flare size.

As a result, SWF occurrence maximizes at local noon and decreases with the solar zenith angle. We confirm that the dfmin value and SWF duration increase with the flare size. We estimate the absorption strength and compare it with an empirical relationship derived from long-distance circuits by Maeda and Inuki [1972]. The absorption strength of ionosonde is almost ~1/3 of that of the long-distance circuits, which would be affected by elongation of ionospheric pass due to oblique propagation. From our analysis and extension of the empirical relationship, we estimate the duration of extreme events, i.e., once per 10-year, 100-year, and 1000-year occurrence events, to be 1-2.2 hour, 2.3-5 hour, and 4.6-11 hour, respectively. We also discuss probable longest duration of originating solar flare.

Effect of equatorial plasma bubbles on midlatitude region

*Tatsuhiro Yokoyama[1], Hiroyuki Shinagawa[2], Yuichi Otsuka[3]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. National Institute of Information and Communications Technology, 3. Institute for Space-Earth Environmental Research, Nagoya University

Equatorial plasma bubble (EPB) is a well-known phenomenon in the equatorial ionospheric F region. As it causes severe scintillation in the amplitude and phase of radio signals, it is important to understand and forecast the occurrence of EPB from a space weather point of view. In order to simulate the instability in the equatorial ionosphere, a 3D High-Resolution Bubble (HIRB) model has been developed. It provides a unique opportunity to study the development of EPBs under various conditions. During a severe space weather event, intense penetration electric fields are expected even in the equatorial ionosphere. If the penetration electric fields enhance the pre-reversal enhancement of the eastward electric field in the dusk sector, the growth rate of the Rayleigh--Taylor instability is greatly intensified to force EPBs to reach very high apex altitude. Such EPBs can reach midlatitude regions along the flux tubes with very high apex altitude and cause communicaton/navigation outage in midlatitude. We will expand the simulation domain of the HIRB model to cover the midlatitude region, for example the latitude of Tokyo area, and estimate the background conditions under which EPBs can reach and affect the midlatitude ionosphere. Previous observations of such extreme events will be compared with the simulation results.

Calculation of the ray paths and propagation times of HF radio waves in the simulator of HF-START project.

*Ryo Nakao[1], Hiroyuki Nakata[2], Kornyanat Hozumi[3], Takuya Tsugawa[3], Susumu Saito[4], Hiroyo Ohya[2], Toshiaki Takano[2], Mamoru Ishii[3]

1. Graduate School of Engineerings, Chiba University, 2. Graduate School of Engineering, Chiba University, 3. National Institute of Information and Communications Technology, 4. Electronic Navigation Research Institute

HF simulator Targeting for All user's Regional Telecommunications (HF-STRAT) is a collaborative project with NICT, ENRI and Chiba University to provide the information of nowcast of radio propagation. In this project, propagation of HF radio waves is calculated by ray-tracing. Using the results of ray-tracing, we have determined whether HF radio wave travels between any two points. To verify the results of ray-tracing, we have compared the differences of the propagation time determined by the ray-tracing with the observation of the HF radio waves transmitted from Nagara transmitter, RadioNIKKEI (35.46˚N, 140.20˚E). HF receivers are located at Chiba University (Chiba, 35.62˚N, 140.10˚E), Sarobetu (Hokkaido, 45.16˚N, 141.74˚E), Yamagawa (Kagoshima, 31.20˚N, 130.61˚E), Ogimi (Okinawa, 26.68˚N, 128.15˚E). In comparing the propagation time between Chiba and the other receivers, it is found that there was a difference of the propagation time between the ray-tracing results and the observations. This is because it is assumed that ground waves are propagated from Nagara to Chiba. By calculating the loss of electric field strength between Nagara and Chiba, we found that the loss of sky wave that is reflected by ionosphere was almost comparable to that of ground wave. Thus, it is possible that the radio wave propagation between Nagara and Chiba is not ground wave but sky wave that is reflected by ionosphere or both ground wave and sky wave signals are received simultaneously by receiver at Chiba. In addition, the comparison between observation of propagation time differences using distant receivers except Chiba and propagation times derived from ray-tracing calculation is in progress to validate results of simulator. In the simulator, we also plan to provide users with options to choose three types of electron density models (IRI, GNSS tomography, GAIA). For these options, we will use the electron density distributions determined by each model in the ray-tracing calculation and analyze the differences between the ray-tracing results statistically.

Characteristics of F-region irregularities near a northern anomaly crest during the rising half of solar cycle 23

Hsin-Hua Wu[1], Pei-Yu Chen[1], *Chien-Chih Lee[1]

1. Department of Applied Geomatics, Chien Hsin University of Science and Technology

In this work, we study the F-region irregularities near the northern crest of equatorial ionization anomaly (EIA) in the west Pacific sector. During 1996-2000, the F-region irregularities are observed by the Chungli ionosonde (24.9˚N, 121.2˚E), YMSM GPS receiver (25˚N, 121.6˚E), and DMSP satellites. It is noted that the 23rd solar cycle began in 1996 and had a maximum in 2000. The data of F-region irregularities are spread F of ionosonde, GPS phase fluctuations of GPS, and plasma bubbles of DMSP satellites. The seasonal and nighttime variations in occurrence probabilities for spread-F, GPS phase fluctuations, and plasma bubbles are calculated. In general, the seasonal variations in occurrence probabilities are different each year. In any year, the seasonal variations of three instruments are different from one another. In the nighttime variations in occurrence probabilities, the variations of spread-F are not the same as that of GPS phase fluctuations. And, the effects of solar activity on the nighttime variations are different each season. These results indicate that the characteristics and mechanisms of F-region irregularities would vary with seasons and/or solar activities.

Variations of thermospheric mass density probed from satellite orbit change

*Wataru Miyake[1]

1. Tokai University

The kinetic energy of LEO satellites is generally decreased by atmospheric drag in the thermosphere. The drag is dependent on atmospheric mass density especially near the perigee. The mass density has been investigated through the decrease of kinetic energy of LEO satellites. The mass density in the thermosphere is controlled by the temperature, and solar EUV radiation and geomagnetic activity cause large variation of the temperature. This leads to variation of satellite drag with progress of 11 year cycle of sun spots. In the last solar minimum, record-low thermospheric density was reported, which may not be simply attributted to low solar activity. Increased concentration of CO2 in the lower thermosphere is expected to produce a cooler, more contracted thermosphere. It is, therefore, of interest how low the thermospheric density is in the current solar minimum. The Geospace Exploration Satellite Arase launched on December 20, 2016. The initial apogee and perigee are 32,000 km and 440 km, respectively. Its low perigee enables us to investigate the mass density in the thermosphere. We have so far found long-term decrease of the kinetic energy of the satellite, which can be interpreted in terms of the atmospheric drag. From the change in the satellite orbit, we will discuss how the atmospheric density of the thermosphere changes in the current solar minimum.

Influence of the solar wind on El Nino

*Kazuyoshi Yamashita[1]

1. Yokohama National University, Graduate School of Env. & Inf. Sciences

Although it is certain that the sun magnetic activity affects the global environment, the details are not clear.In this presentation, we analyze the influence of the solar wind on global environment on the basis of our previous studies [1, 2].The AE index and total ozone data were used to detect the influence of the solar wind on El Nino.In the analysis, we considered that the influence of the energetic particle fluxes(EPP)-NOx on ozone at low latitudes may be comparable to the effects of solar UV radiation [Callis et al., 2000, 2001; Langematz et al., 2005; Rozanov et al., 2005].
We found that the change of the total amount of ozone in the region at low latitudes affects atmospheric stability and a monsoon, and thus, it may become the harbinger of the El Nino.

Development of Space Environment Customized Risk Estimation for Satellite (SECURES)

*Tsutomu Nagatsuma[1], Haruhisa Matsumoto[2], Kiyokazu Koga[2], Masao Nakamura[3], Aoi Nakamizo[1], Yasubumi Kubota[1], Yoshizumi Miyoshi[4]

1. National Institute of Information and Communications Technology, 2. Japan Aerospace Exploration Agency, 3. Osaka Prefecture University, 4. Nagoya Unibersity

Variations of space environment in geospace driven by the solar activity is one of the factors that cause satellite anomaly. When a failure occurs in a satellite, it is important to understand the current condition of the space environment around the satellite in order to identify the cause and take proper action quickly.
However, risk of satellite anomaly due to space environment is not the same as each satellite, because the risk depends not only on the space environment but also on the design and materials of individual satellite.
Based on this idea, we have developed SECURES (Space Environment Customized Risk Estimation for Satellite) by combining space environment models and spacecraft charging models. In SECURES, we are focusing on the risk of spacecraft charging (surface/internal) for geosynchronous satellites. For estimating surface charging, we have combined the global MHD simulation model with the satellite surface charging models. And for internal charging, we have combined the radiation belt models with the satellite internal charging models. We have also developed the test product based on the SECURES. The current status and future directions of SECURES will be reported in this presentation.

Spacecraft surface charging and discharging risk estimation method around geosynchronous altitude

*Masao Nakamura[1], Hirotaka Maeda[1], Tsutomu Nagatsuma[2], Mamoru Ishii[2]

1. Osaka Prefecture University, 2. NICT

Spacecraft surface charging often induces spacecraft anomalies by electrostatic discharging (ESD) around the geosynchronous altitude. We are developing a real-time spacecraft surface charging risk estimation system for the Space Environment Customized Risk Estimation for Spacecraft (SECURES) of the space weather forecast Project for Solar-Terrestrial Environment Prediction (PSTEP). For the surface charging analysis, we make charging analysis models of target satellites and simulate their surface charging potentials by using the Spacecraft Plasma Interaction Software (SPIS). Since it takes hours or days to calculate the surface potentials for a given plasma environment, we develop a real-time estimation method using empirical functions based on the pre-calculated results. The method can quickly estimate the equilibrium floating potentials of the spacecraft surfaces for the predicted on-orbit plasma environments, e.g., by a global MHD simulation. The differential potentials between the spacecraft surfaces are important to evaluate the ESD risk assessment. We study the time scale of the differential potential development to evaluate the frequency of recurrent ESD for severe plasma environments.

Study of IMF By dependence of plasma injection position using real-time magnetosphere simulation data

*Yasubumi Kubota[1], Aoi Nakamizo[1], Kaori Sakaguchi[1], Tsutomu Nagatsuma[1], Mitsue Den[1], Yuki Kubo[1], Takashi Tanaka[1,2]

1. National Institute of Information and Communications Technology, 2. Kyushu University

Surface charging of artificial satellite is one of the risks caused by dynamical variations of space environment. It often occurs when a satellite is exposed by electrons of ~10 keV injected from the tail plasma sheet during substorms. Magnetosphere-ionosphere coupling global MHD simulation is one of the powerful ways to predict the timing and location of plasma injection.
Now we are developing a real-time numerical simulator for space weather forecast using magnetosphere-ionosphere coupling global MHD simulation called REPPU (REProduce Plasma Universe) code. The feature of the simulation code is high robustness for extreme solar wind parameters; the unstructured grid system enables us to calculate the whole region with the uniform accuracy. The spatial resolution is 30722 grids in the spherical planes and 240 grids in the radial direction. The simulator is driven by the real-time solar wind data obtained by the DSCOVR spacecraft.
We investigate the IMF By dependence of plasma injection position using real-time simulation data. We found that injection position tends to distribute in the dusk side (dawn side) when the IMF By is positive (negative). Comparison of the simulation results with the CPCP, AE index, and plasma variations observed by geostationary orbiting satellites will also be reported.

Multi point measurements of geomagnetically induced currents in the Chugoku region

*Kumiko K. Hashimoto[1], Kentarou Kitamura[2], Takashi Kikuchi[3], Yusuke Ebihara[4]

1. Kibi International University, 2. National Institute of Technology, Tokuyama College, 3. Nagoya University, 4. Kyoto University

With cooperation from Yamaguchi power management office of the Chugoku Power Electric Co., we installed instruments of the geomagnetically induced current (GIC) measurement in Higashi-Yamaguchi and Shin-Yamaguchi electric power substations on March 2018 and March 2019, respectively. We analyzed correlations between the GIC from the two substations and magnetometer data for Space weather events, such as magnetic sudden commencements, magnetic pulsations, substorm positive bay etc. Our results show that the GIC at Higashi-Yamaguchi and Shin-Yamaguchi substations mainly correlates with east-west component of magnetic field or north-south component of the induced electric field. On the other hands, intensities of the GIC at Shin-Yamaguchi substation are 2-4 times larger than that at Higashi-Yamaguchi. The Chugoku region is characterized by power lines parallel to coasts extending east and west. Shin-Yamaguchi substation is located at the west end of the two trunk power lines from the Sanyo- and Sanin-region, whereas Higashi-Yamaguchi substation is in the middle of the power line network. The geometric feature may be a main cause to amplify the GIC at Shin-Yamaguchi.

SuperDARN future plan in terms of Planning of phase X 6-year project of Japanese Antarctic Research Expedition and beyond

*Akira Sessai Yukimatu[1,2]

1. National Institute of Polar Research, 2. SOKENDAI

Planning of phase X 6-year project of Japanese Antarctic Research Expedition (JARE 64-69, 2022-2028) has been actively discused. We here try to discuss and summarise SuperDARN future plan at Antarctic Syowa station in terms of Phase X JARE project and beyond.
NIPR in Japan has joined the SuperDARN (Super Dual Auroral Radar Network) project since its establishment in 1995 and run 2 SENSU SuperDARN radars, Syowa South and Syowa East radars (SENSU stands for “Syowa South & East HF Radars of NIPR for SuperDARN”) in Japanese Antarctic Syowa station (69.00 S, 39.58 E) in polar auroral zone. Both radars have substantially contributed to the SuperDARN project and scientific researches, for example, studies on various types of auroral phenomena, geomagnetic pulsations, substorms, reconnection, precise neutral wind observation around mesopause region using meteor echoes, studies on polar mesospheric summer echoes (PMSEs), magnetosphere-ionosphere-neutral atmosphere vertical coupling, studies on influence of low solar activity or grand minimum on geospace space weather. We here summarise our important achievements so far including during current phase IX JARE project period and will discuss on issues remaining unresolved and ways forward and the future perspective of the scientific direction of our SENSU SuperDARN research towards phase X JARE period and beyond as one of the comprehensive observations at Syowa station and as one of the most important basic, long-term and cutting-edge geospace scientific tools especially in terms of space weather and space climate.

Study of dependence of solar flare induced SuperDARN Doppler velocity on X-ray intensity, SZA and season

*Tomoya Takada[1], Nozomu Nishitani[1], Tomoaki Hori[1]

1. Institute for Space-Earth Environmental Research

Solar flares cause various ionospheric disturbances. Short wave fadeout (SWF) is one typical example, and has been studied for several years using several kinds of instruments. Doppler flash, which is a sudden increase in Doppler speed of ground scatter echoes observed by SuperDARN radars, has been recently reported, but has not been studied comprehensively yet. Watanabe and Nishitani (2013) investigated the dependence of Doppler speed on radar slant range and elevation angle, and they found that the effect of the D-region ionosphere change plays a dominant role in generating Doppler flash effect. In this study, we examined the dependence of X-ray flux, Solar Zenith Angle (SZA) and season. We analyzed 70 solar flare events from Feb 2011 to Sep 2017. Doppler speed is positively correlation with instantaneous X-ray flux. On the contrary, we cannot find the clear relationship between the Doppler speed and SZA / season. Possible reasons for such poor correlation will be discussed..

Keywords: SuperDARN, Solar flare, Doppler flash

Summary of the five-year extended observations of Nobeyama Radioheliograph

*Satoshi Masuda[1]

1. Institute for Space-Earth Environmental Research, Nagoya University

Nobeyama Radioheliograph (NoRH) had been operated by the International Consortium for the Continued Operation of Nobeyama Radioheliograph (ICCON) since April 2015. However, the operation of NoRH finished at the end of March in 2020. Nagoya University collected the operational costs from international/domestic partners was unique and operated NoRH as a representative of ICCON. This style was very unique in the Japanese solar telescopes. The daily check of the instruments/computers/data were done by international/domestic collaborators. Finally, for five years, 33 researchers in nine countries (Belgium, China, Germany, Japan, South Korea, Russia, Switzerland, U.K., U.S.A.) did this task as a chief observer. Thanks to their contributions, scientific data were taken for almost the whole period except the following two periods, from late January 2018 to early April 2018, and from early May 2019 to early June 2019.

The original scientific targets were ‘particle acceleration in solar flares’ and ‘long-term solar activity variation’ for this extension. Unfortunately, since the solar flare activity was very low since April 2015, only 38 solar flares (max ~ M6.7 class) were detected during this extension period. Before the extension, about 900 flares were observed. So the increment of solar flare data was not so large. As for the latter topic, we could derive the data of the polar brightening in this solar cycle in addition to the previous two cycles. Then, Gopalswamy et al. (2018) predicted the peak sunspot number of the next solar cycle from the polar brightness at 17 GHz and Fujiki et al. (2019) found the very good correlation between the solar wind speed and the polar brightness at 17 GHz.

One of the most outstanding outcomes is the growth of the international collaboration in this field. Based on this activity, now we are considering the next framework of the international collaboration with the Chinese new solar radio telescope, so-called MUSER.

Keywords: solar radio, solar flare, solar activity

Phesant tail aurora: The oldest record of astronomical phenomenon in Japan

*Ryuho Kataoka[1], Kazuaki Yamamoto[2], Yasunori Fujiwara[1], Kozue Shiomi[1], Nobuo Kokubun[1]

1. National Institute of Polar Research, 2. National Institute of Japanese Literature

The oldest record of an astronomical phenomenon in Japan was recorded in the Nihon-shoki as follows: "On December 30 in 620, a red sign appeared in heaven. The length was more than 1 jo (10 degrees). The shape was similar to a pheasant tail (Suiko-Tennou, 28)". The appearance of a red sign has been recognized as an expression of a bad omen in literature, while it has been interpreted as the northern lights in geophysics. We introduce the latest scientific findings that the northern lights show a fan-shaped appearance with a red background when appearing over Japan (Kataoka et al., 2019). After showing that the fan-shape is similar to a pheasant tail, also pointing out the low possibility of comets, we conclude that the oldest record of the red sign is consistent with the appearance of the northern lights over Japan.

Plasma waves causing relativistic electron precipitation events at International Space Station

*Ryuho Kataoka[1], CALET Collaboration, Arase Collaboration

1. National Institute of Polar Research

We introduce the latest paper (Kataoka et al., 2020) showing three different types of relativistic electron precipitation (REP) events observed at International Space Station (ISS), associated with electromagnetic ion cyclotron (EMIC) waves or whistler mode waves as observed by the Arase satellite at conjugate locations near the magnetic equator. Three different detectors installed on the ISS were complementarily used; CALET/CHD as the detector of precipitating MeV electrons, MAXI/RBM as the detector of sub-MeV electrons from horizontal and vertical directions, and SEDA-AP/SDOM to quantitatively measure the energy spectrum. The REP event on Aug 21, 2017 shows a quasi-periodic intensity variation at ~1 Hz which corresponds to variations of the EMIC waves at the Arase altitudes. The REP event on April 24, 2017 shows rapid and irregular intensity variation which corresponds to the amplitude variation of chorus waves, while the REP events on October 26, 2017 shows a smooth quasi-periodic time variation at ~0.2 Hz which corresponds to the amplitude variation of “electrostatic” whistler mode waves. This study clearly demonstrates that the time variation of REP events at ISS are caused by various types of plasma waves near the magnetic equator.

Investigation of the Relation Between Magnetospheric Activity and Solar Wind Parameters Based on Potential Learning

*Ryozo Kitajima[1], Motoharu Nowada[2], Ryotaro Kamimura[3]

1. Dept. Engineering, Tokyo Polytechnic University, Kanagawa, Japan, 2. Shandong Provincial Key Laboratory of Optical Astronomy and Solar-Terrestrial Environment, Institute of Space Sciences, Shandong University, Weihai, P. R. China, 3. IT Education Center, Tokai University, Kanagawa, Japan

Nowadays, it is so important in saving our economic activity and evading the disasters caused by terrestrial electromagnetic effects to predict both temporal and spatial scales of the geomagnetic disturbances based on in-situ solar wind observations. Recently, Neural Network (NN) is one of the notable techniques for the predictions of the magnetospheric activities. However, NN has a problem referred to as ‘black box’, which is difficult to extract which solar wind parameters are the most important for prediction. In this study, we examine a significant relationship between K_p index, which represents the magnetospheric activity, and the solar wind conditions based on an interpretable neural network: ‘Potential Learning (PL)’. A feature of the PL is to make a network that can understand the input variables by learning the “input potentialities”, which are indices calculated using the variances of the solar wind parameters as input variables.
In this study, we investigate the magnetospheric activity profile when the Interplanetary Magnetic Field (IMF) oriented southward ($B_z < 0$). As the input solar wind data, we utilize the two components of the magnetic field (B_x, B_y) in GSE, and solar wind flow speed, and number density during 20 years between 1999 and 2018. Furthermore, we divide the associated values of K_p into two groups (targets): ‘K_p = 6- to 9 (positive target)’ and ‘K_p = 0 to 1+ (negative target)’. Because the data number of positive target was smaller than that of negative target, the negative target samples are randomly selected so that the data numbers of both targets become equal. Based on the PL neural network, we obtain two important results; 1) the solar wind plasma flow speed might have the most influential in the increase of the K_p index, and 2) as the secondary influential parameter for the K_p increase, the solar wind proton density is considered. In the presentation, we will discuss feasibility of the application to the prediction of the magnetospheric activity based on the solar wind parameters.

Cosmic Ray Intensity Increase Associated with Slow Coronal Mass Ejection

*Wataru Kihara[1], Chihiro Kato[1], Kazuoki Munakata[1], Yukino Ko[1], Ryuho Kataoka[2], Akira Kadokura[2], the GMDN collaborations -

1. Department of Physics, Shinshu University, 2. National Institute of Polar Research

Shinshu University installed a cosmic ray detectors at Syowa Station in the Antarctic, in cooperation with the National Institute of Polar Research, and started muon and neutron observations at the same point in February 2018. As a result we observed cosmic ray fluctuations due to coronal mass ejection on 2018 August 25. This event caused a large geomagnetic storm with a Dst index of -174nT despite of a miner coronal mass ejection that occurred during the solar minimum. Furthermore, satellite observations showed that the coronal mass ejection was slow and the high-speed solar wind from the corona hole was catching up. From these perspectives, this event is a very interesting. In this study, we analyzed this coronal mass ejection event by using the global muon detector network and neutron monitors installed around the world and Syowa Station in the Antarctic. As a result, it was found that the cosmic ray density increased in the latter half of the period when this coronal mass ejection event was observed. We discuss the cause of the increase in cosmic ray intensity.

Study on the global occurrence characteristics of Pc2 pulsation with the 10Hz data of the MAGDAS9 system

*Taisei Kabasawa[1], Akimasa Yoshikawa[2], Teiji Uozumi[3], Akiko Fujimoto[4], Shuji Abe[3]

1. Kyushu University, 2. Department of Earth and Planetary Science, Kyushu University, 3. International center for space weather science and education, Kyushu university, 4. Department of information technology, Kyushu Institute of Technology

Geomagnetic field disturbance observed on the ground is affected by the space weather phenomena such as magnetic storms and auroral substorms. Recent research shows that the Pc2 pulsation of which frequency range 5-10 seconds is observed at the inner magnetosphere as EMIC wave that is associated with the high-energy process activated O^+ during magnetic disturbance.
By using 10Hz sampling MAGDAS data, we found that the Pc2 type pulsation are simultaneously observed from high to middle-and-low latitudinal region during a magnetic storm time substorm. Also, we found that such global Pc2 pulsations have the local time distribution peaked at 6LT and during 11-15LT local noon time and the mainly enhanced at March-July. This occurrence characteristics is different from that of Pc1 pulsation that previous research reports.
In this presentation, we will report the preliminary results of observational analysis of Pc2 pulsation by using MAGDAS network. We also discuss the comprehensive approach for understanding global coupling process among inner magnetosphere and high-middle-low latitude to the equatorial region by using FM-CW radar data, PWING induction magnetometer data, and the geo-space environment data from the ERG satellite.

Keywords: Pc2 pulsation, EMIC waves, global coupling

Data assimilation of radiation belt electrons using the DREAM code and multiple spacecraft data of Arase, Himawari, and GPS

*Kaori Sakaguchi[1], Andrew Walker[2], Sophie Graf[2], Reinhard Friedel[2], Takefumi Mitani[3], Nana Higashio[3], Takeshi Takashima[3], Tsutomu Nagatsuma[1], Mamoru Ishii[1]

1. National Institute of Information and Communications Technology, 2. Los Alamos National Laboratory, 3. Japan Aerospace Exploration Agency

We report data assimilation results of multi radiation belt electron data into Dynamic Radiation Environment Assimilation Model (DREAM). DREAM is a data assimilation software that can calculate radiation belt electron flux for arbitrary spacecraft positions using 1-D radial diffusion equation based on the ensemble Kalman filtering method. In this study, observation data from three spacecrafts with different orbits; Arase (high elliptical orbit with inclination 31 degrees), Himawari-8 (geosynchronous), and seven GPS (semi-geosynchronous) were fed into DREAM, and energetic electron fluxes along Van Allen Probe in the high elliptical orbit with inclination 10 degrees were sampled for the evaluation. Data assimilation were performed for one month of August 2018 which includes a geomagnetic storm event of Dst=-188 nT on 26 Aug. The observed flux variations of ~700 keV and ~1 MeV electrons were almost perfectly reproduced by DREAM both for quiet and storm times along the orbit of Van Allen Probe A. We found that the performance of prediction highly depended on energy range, L shell, and quality fed data set. The results suggest that DREAM can be a powerful tool for prediction of radiation belt electron flux along arbitrary orbits with high accuracy if it is fed appropriate data set.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

[P-EM18] Study of coupling processes in solar-terrestrial system

convener:Mamoru Yamamoto(Research Institute for Sustainable Humanosphere, Kyoto University), Yasunobu Ogawa(National Institute of Polar Research), Satonori Nozawa(Institute for Space-Earth Environmental Research, Nagoya University), Akimasa Yoshikawa(Department of Earth and Planetary Sciences, Kyushu University)

The Earth accepts vast input of energy and material from the Sun. The Earth's environment is maintained by the balance between their inputs and outputs. It is therefore important to study energy and mass transport on the Earth. This is an international session that discusses studies of the coupling processes in the Sun-Earth system based on the project "Study of coupling processes in solar-terrestrial system" that was approved by the Master Plan 2014/2017 of Science Council of Japan. We continue proposing the project to the Master Plan 2020. The facilities and networks included are Equatorial MU Radar (EMU) in Indonesia to study the whole equatorial atmosphere, the EISCAT_3D radar system in northern Scandinavia to study detailed structures and elementary processes of the magnetosphere-ionosphere coupling in the polar region, and global networks of various ground-based instruments and observation data. We will show the current status of the project and discuss sciences by soliciting variety papers. This session is open to the world, and we strongly encourage submission of papers related to other facilities and projects, i.e., atmospheric or incoherent scatter radars, observation networks, satellites, and simulation or theoretical studies, etc.

Development of Software-Defined Multichannel Receiver for Equatorial Atmosphere Radar (EAR)

*Hiroyuki Hashiguchi[1], Nor Azlan Bin Mohd Aris -[1], Mamoru Yamamoto[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

Equatorial Atmosphere Radar (EAR) is a very high frequency (VHF) Doppler radar operated with an active phased-array antenna system at 47 MHz. It had originally been equipped with a single receiving channel system since its establishment in 2001 at the equator in Kototabang, West Sumatra, Indonesia (0.20S, 100.32E). We have developed a multichannel receiver system for the EAR using a combination of the Universal Software Radio Peripheral X300 (USRP X300) and GNU Radio software. There are a number of advantages to have multichannel receiver systems such as to enable spaced-antenna method and spatial domain interferometry.

Two USRP X300 devices, corresponding to four receiving channels, were synchronized using 10 MHz reference clock and a pulse per second (1 PPS) signal. The standard observation system of the EAR is retained by splitting the received echo signals through directional couplers which enabled simultaneous observation of the two different techniques, spaced-antenna and Doppler beam swinging. The signal <gwmw class="ginger-module-highlighter-mistake-type-3" id="gwmw-15814652745326432130038">for</gwmw> spaced-antenna application is fed to the USRP X300s for digital conversion, and then stored on a Hard Disk Drive (HDD). The <gwmw class="ginger-module-highlighter-mistake-type-2" id="gwmw-15814652881083188773963">ranging</gwmw> of the data is carried out by taking advantage of the leaked transmitted pulse, before demodulated and coherently integrated.

Performance analysis using multiple receiving <gwmw class="ginger-module-highlighter-mistake-type-3" id="gwmw-15814652985556454852304">antennas</gwmw> orientation for the application of spaced-antenna methods on the EAR has been carried out through multiple experiments over the duration between April 2019 and September 2019. Phase correction is applied to all channels for a single spectrum in the real time signal processing for improving the phase synchronization. The initial results show the existence of noticeable fluctuations in the estimated horizontal wind. Then, a comparison of the EAR spaced-antenna (SA) performance with five different orientations taking into consideration the size of receiving antenna and its separation distance has been presented, where the horizontal wind profiles using Full Correlation Analysis (FCA) were estimated and compared with the standard EAR data. Based on the results, the configuration with the largest aperture shows slight advantages over the other four configurations but with limited improvement.

We can apply the achievement of this study to the Equatorial MU radar (EMU), which is proposed to be constructed at West Sumatera, Indonesia. The EMU system is the similar to the MU radar, but its antenna consists of 1045 Yagi antennas with 55 groups and it has 64 receiver channels.

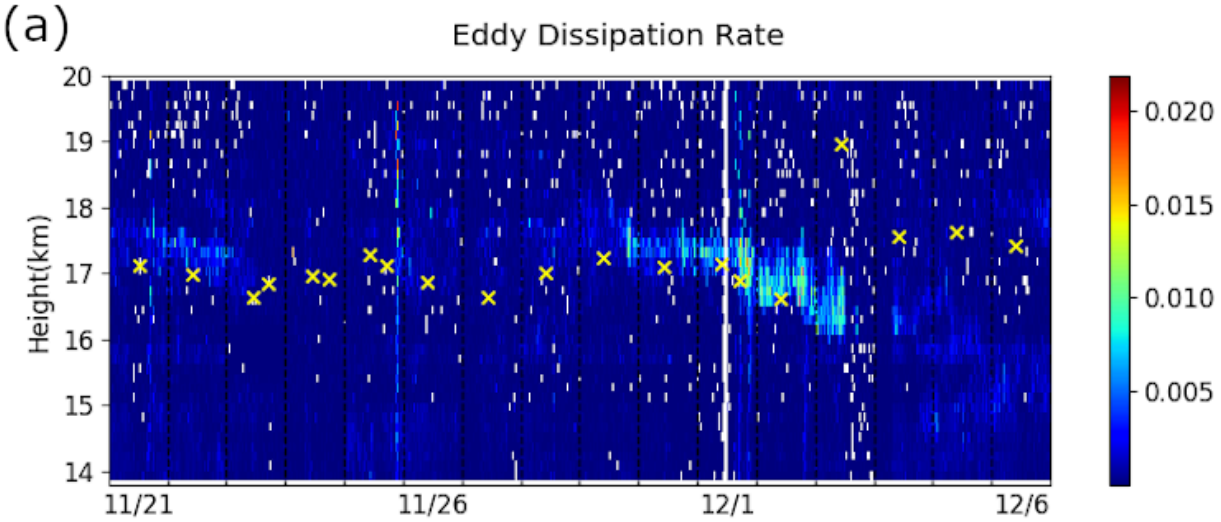
Observation of ozone vertical mixing due to KH instability in tropical tropopause layer

*Momoko Hashino[1], Hiroyuki Hashiguchi[1], Richard Wilson[2], Shin-Ya Ogino[3], Junko Suzuki[3]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. LATMOS/IPSL, Sorbonne Université, 3. Japan Agency for Marine-Earth Science and Technology

The tropical tropopause layer (TTL) is a transition region between the troposphere and the stratosphere peculiar to the tropical zone. Physical and chemical processes in the TTL are important because they affect Stratosphere-Troposphere Exchange (STE). However, there have been few direct observations of TTL, and most previous researches have focused on large-scale waves, so the details of smaller processes related to TTL and STE are still unknown. In this study, we analyzed small-scale turbulence near the TTL region and the associated transport using the data of observation campaign conducted in collaboration with STRATEOLE-2 (TTL / lower stratospheric observation project using super pressure long duration balloons). In particular, we investigated whether the Kelvin-Helmholtz instability, which was shown to occur in TTL in previous studies, affects the vertical distribution of ozone.



We use the data obtained by ozone and GPS sondes released from the Equatorial Atmospheric Observatory in West Sumatra, Indonesia from November 21 to December 6, 2019, and the data observed with the Equatorial Atmospheric Radar (EAR) during the same period.

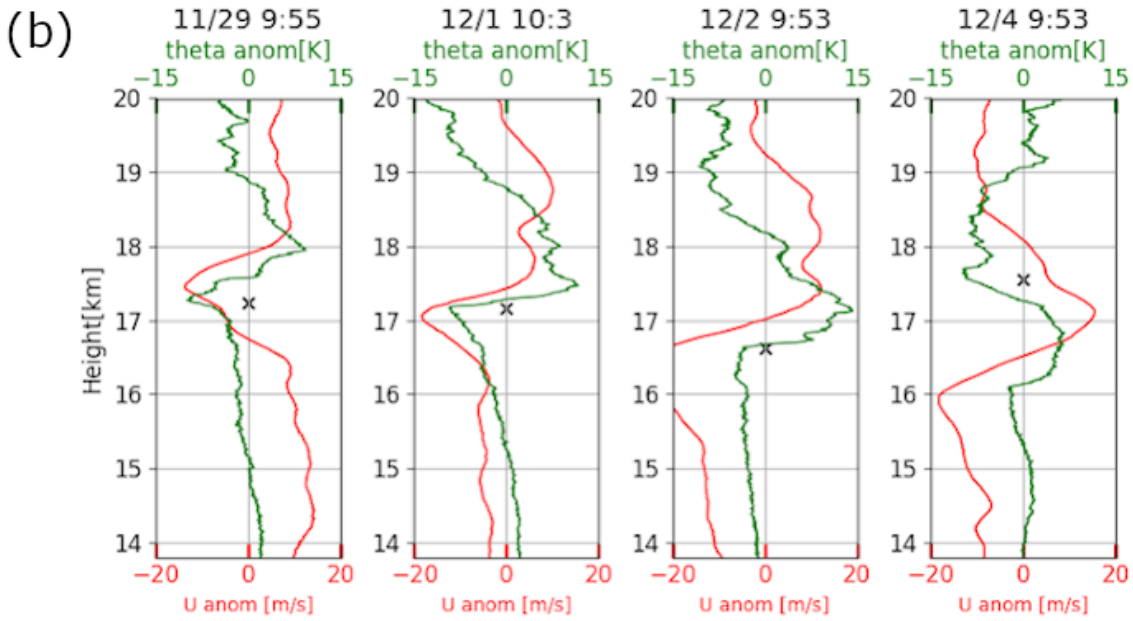


Figure (a) shows the turbulence intensity calculated from the EAR spectral width data, and the crosses indicate the tropopause defined as the lowest temperature (Cold Point Tropopause; CPT). The feature of CPT jump and strong turbulence observed on December 2-3 is similar to previous observations, suggesting the breaking of equatorial Kelvin waves. Figures (b) and (c) are the profiles of four sonde observations before and after the CPT jump. Figure (b) shows the deviation from the mean of the zonal wind (red) and the potential temperature (green), and (c) shows the vertical wind shear (red), deviation of ozone mixing ratio (green), and Richardson number (blue) (blue vertical line indicates Ri = 0.25). The phase shift between the zonal wind field and the temperature field shown in (b) is similar to that of the equatorial Kelvin wave, and propagates downward with increasing amplitude. The vertical wind shear shown in (c) is large in the altitude regions where the zonal wind anomaly shown in (b) suddenly changes from negative to positive and the amplitude is large (17.5-18 km altitude on November 29, moving downward with time). In this altitude regions, although the Richardson number does not always satisfy the condition in which KH instability occurs (Ri <0.25), the features of wind shear and Brunt-Väisälä frequency (not shown) are consistent with previous studies, suggesting the existence of KH billows. In the same altitude regions, the amount of ozone increases with altitude.

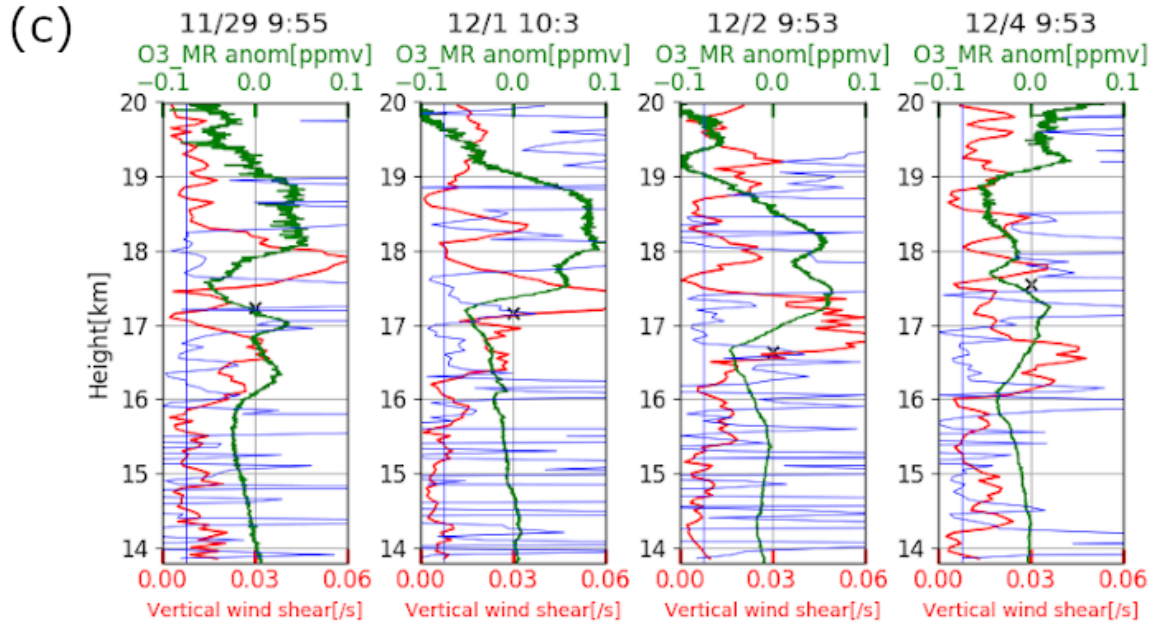

We have conducted direct observations of TTL and have shown that KH billows caused by strong vertical shear due to the increase in the amplitude of the zonal wind before and after the equatorial Kelvin wave breaking may cause vertical mixing of ozone. As a future work, we will investigate whether other factors than atmospheric mixing are related to the fluctuation of ozone amount.

Study of daily and seasonal variation of the equatorial ionization anomaly in Asia based on satellite-ground beacon experiment

*Mamoru Yamamoto[1], Yuki Sakamoto[1], Kornyanat Hozumi[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. National Institute of Information and Communications Technology

Studies of ionospheric structures by the satellite-ground beacon experiment have been conducted in Southeast Asia. We have deployed a meridional chain of five beacon receivers from 0.2S to 18.2N along 100E meridian and investigated the meridional distribution of total electron content (TEC) of the ionosphere. Although there were preceding studies of time and spatial variabilities of the equatorial ionization anomaly (EIA), the data analysis was limited in the short period. It was because the estimation of bias values was not easy and time-consuming. In this study, we developed a method to automate the bias estimation. As a result, we obtained absolute TEC distribution from a large amount of data and created the TEC database. Using this database, we analyzed latitudinal TEC distribution in a wide area, from Thailand to Indonesia in 2012-2015.
EIA is characterized by two crests in latitudinal TEC distribution that are generated by the plasma fountain effect. We defined EIA by representing the TEC latitudinal structure by a fourth-order polynomial function. By investigating the occurrence ratio of EIA at each hour, we found that EIA grows in the period from 9 to 12 LT, showed its maximum at around 13 LT, and decays in the period after 13 until 23 LT. We further investigated the EIA hemispheric asymmetry at different local timings. In the period from 13 to 23 LT, while EIA is already generated and gradually decays in time, the northern crest tends to exceed the southern crest in summer. In winter, the hemispheric asymmetry is reversed. By comparing this result with the wind model, we found that the hemispheric asymmetry in the period is affected by the meridional winds. In the period from 9 to 12 LT, while EIA is growing, the trend of hemispheric asymmetry was opposite; the southern crest is larger in summer, and the northern crest is larger in winter. By comparing this result with O/N2 distribution model, we found the possibility that, during the growing phase of EIA, the hemispheric asymmetry is affected by the composition of atoms and molecules in the atmosphere.

Development of transmitter and antenna on board of sounding rocket for the TEC measurement

*Koki Kurokawa[1], Mamoru Yamamoto[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

A sounding rocket experiment is planned by JAXA in 2021/2022 period for the study of medium-scale traveling ionospheric disturbance (MS-TID). By transmitting two radio beacon with a frequency ratio of 3 : 8 from the rocket and measuring the phase difference between the two signals on the ground, the total electron content (TEC) on the radio wave path from the rocket to the ground can be measured. To realize this observation, we are now developing the observation equipment onboard of this rocket. The instruments are a dual-band beacon transmitter of 150MHz and 400MHz and a set of antennas that are installed on the rocket skin. The transmitter needs to output two phase-coherent radio waves at the same time. As the signal source, we selected Si5338 which is a high-performance, low-jitter clock generator capable of synthesizing at most four signals with different frequencies. The antenna system consists of four elements that can transmit both frequencies. The elements must fit the harsh environment (high temperature, intense vibration, etc.) that is expected at the outside of the sounding rocket at launch. As we transmit a relatively low frequency of 150 MHz / 400 MHz signals, we selected the dual-band Planar Inverted-F Antenna (PIFA) that is useful to reduce the size of the antenna. Selection of high dielectric-constant material is another important issue for antenna-size reduction. This antenna is designed by using electromagnetic-field simulation software called CST. This software can be linked with other antenna design software. With this software, we tried to find the optimized antenna shape by simulating electromagnetic response of the antenna with variety of parameter settings.In the presentation, we report the current status of the transmitter and antenna for the sounding rocket experiment.

Ionospheric observations by Equatorial Atmosphere Radar during annular eclipse in December 2019

*Rieko Takagi[1], Tatsuhiro Yokoyama[1], Mamoru Yamamoto[1], Kornyanat Hozumi[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. National Institute of Information and Communications Technology

The area of the Earth's atmosphere above an altitude of about 80 km is called the ionosphere, where molecules and atoms are partially ionized. Since the electron density varies depending on altitude, time, and location, radio waves passing through the ionosphere are delayed or refracted, which cause satellite communication failures and decrease GPS positioning accuracy. There is a need to accurately measure and predict the electron density distribution. It is known that a solar eclipse reduces the amount of sunlight when the moon passes in front of the sun in the daytime and affects the electron density distribution. In this study, during the annular solar eclipse near Southeast Asia on December 26, 2019, we observed the ionospheric E region with the Equatorial Atmosphere Radar (EAR) near the equator in West Sumatra, Indonesia, and analyzed the observation data. We also compared the results with ionosonde observations in Southeast Asia. Although clear 150-km echoes were observed with the EAR in the days before and after the eclipse, the 150-km echoes were not detected on the eclipse day. On the other hand, the E-region echoes showed significant variation in the distribution of echo power and Doppler velocity, which is thought to be affected by the solar eclipse.

Upgrade of equatorial plasma bubble simulation toward coupling with GAIA model

*Taichi Komoto[1], Tatsuhiro Yokoyama[1], Hiroyuki Shinagawa[2]

1. Research Institute for Sustainable Humanosphere, 2. National Institute of Information and Communications Technology

As space development progresses rapidly, stable use of satellite communication and navigation is strongly demanded, and a highly accurate and reliable positioning system using GPS is required. One of the causes of the GPS error is a physical phenomenon that occurs in the equatorial ionosphere called plasma bubble. A plasma bubble is a phenomenon in which the density stratification in the lower ionosphere becomes unstable and the low-density region rises like a bubble, and the inside of the bubble has a very unstable and irregular structure. Therefore, it has a great influence on radio wave propagation, but it is almost impossible at present to predict the occurrence of plasma bubbles. The purpose of this study is to develop a numerical model that combines a global ionospheric numerical model and a local ionospheric numerical model to predict the occurrence of plasma bubbles self-consistently, and to clarify the conditions of their generation. The global atmosphere-ionosphere coupled model GAIA has a grid spacing of about several hundred kilometers and cannot reproduce local structures such as plasma bubbles. On the other hand, the local ionosphere model can represent the fine internal structure of plasma bubbles because the grid spacing is less than 1 km, but it is limited to a narrow simulation domain and also applies periodic boundary conditions. Therefore, it is not possible to simply expand the simulation domain. Thus, by combining the global model and the local model hierarchically, we aim to develop a model that can reproduce the generation of plasma bubbles consistently with retaining their original advantages. Toward the coupling of the two models, we expand the simulation domain of the local model to cover the whole longitude under natural boundary conditions including diurnal plasma density variations. We will report the current status and initial results of the model development.

Long-term statistical analysis of the ionospheric observation with the MU radar

*Tatsuhiro Yokoyama[1], Masanori Ueno[1], Mamoru Yamamoto[1]

1. Research Institute for Sustainable Humanosphere, Kyoto University

An incoherent scatter radar (ISR) is a powerful tool to observe various ionospheric parameters. The ISR enables us to estimate various physical quantities in the ionosphere from the spectrum of the radar backscatters. The MU radar located in Shigaraki, Japan has regularly been operated as the ISR since the beginning of the MU radar operation in 1986. Electron and ion temperatures, ion drift, and echo power are observed and released in a public database. We have conducted a long-term statistical analysis of the IS observation with the MU radar from 1986 to 2019. The results are mostly consistent with the past results and IRI model outputs. The results during the deep solar minimum in the previous solar cycle show a large discrepancy between the observation and IRI model.

Space weather modelling of the dayside polar ionosphere and thermosphere

*Hitoshi Fujiwara[1], Yasunobu Miyoshi[2], Satonori Nozawa[3], Yasunobu Ogawa[4], Hidekatsu Jin[5], Chihiro Tao[5], Hiroyuki Shinagawa[5]

1. Faculty of Science and Technology, Seikei University, 2. Department of Earth and Planetary Sciences, Kyushu University, Japan, 3. Institute for Space-Earth Environmental Research, Nagoya University, Japan, 4. National Institute of Polar Research, Japan, 5. National Institute of Communication Technology, Japan

From the European Incoherent Scatter (EISCAT) radar observations, we have shown some features of the ionospheric disturbances in the dayside polar cap region where ionospheric and thermospheric observations are not enough to understand the space weather effects. For example, some ionospheric disturbances have been observed in the northward of Longyearbyen (> 80° latitude) even during geomagnetically quiet periods, while disturbances are generated in the auroral region (at Tromsø) during the geomagnetically disturbed periods. CME-induced disturbances and ionization due to high energy particle precipitation have been also observed in the dayside polar ionosphere.
In order to understand and predict the phenomena in the dayside polar ionosphere and thermosphere, we have also made modelling/simulation studies. In particular, we focus on modelling the effects of precipitating particles on the dayside polar ionosphere and thermosphere in the context of the Japanese Space Weather projects. In the present study, we will show some observational and simulation results: for example, the dayside ionospheric disturbances observed with the EISCAT radar system and simulations with a GCM. In addition, we will introduce our attempt to estimate productions of ions, NOx, and HOx in the altitude of 50-500 km due to precipitating particles.

Network observations of aurora and airglow with low-cost multi-wavelength imager system

*Yasunobu Ogawa[1], Akira Kadokura[1], Yoshimasa Tanaka[1]

1. National Institute of Polar Research

This paper introduces a new system that can monitor aurora and atmospheric airglow using a low-cost Watec monochromatic imager (WMI) equipped with a sensitive camera, a filter with high transmittance, and the non-telecentric optics. It is demonstrated that the WMI system is capable of detecting 428-nm, 486-nm, 558-nm, and 630-nm auroral intensities properly, through comparison with those measured with a collocated imager system with narrower band-pass filter. Since 2013 a set of multi-wavelength WMIs has been operating in northern Scandinavia, Svalbard, and Antarctica. The WMI system is currently used to obtain (1) 428-nm auroral data at multipoint sites (located in the horizontal range of about 50-100 km) for research on three-dimensional structure of aurora using the auroral tomography method, and (2) multipoint data with a wavelength of 630-nm (in the horizontal range of about a few 1000 km) for study of large scale phenomena such as dynamic variation of the auroral oval and drift motion of polar patches. Most of the current WMI databases are open to the public via the web page (http://pc115.seg20.nipr.ac.jp/www/opt/index.html). Future development of the low-cost WMI system is expected to provide a great opportunity for constructing a global network for multi-wavelength aurora and airglow monitoring.

A pulsating aurora event observed by an optical spectrograph at Tromsø, Norway

*Takuo T. Tsuda[1], Chengyu Li[1], Keisuke Hosokawa[1], Satonori Nozawa[2], Tetsuya Kawabata[2], Akira Mizuno[2], Shin-ichiro Oyama[2], Junichi Kurihara[3]

1. University of Electro-Communications, 2. Nagoya University, 3. Hokkaido University

Pulsating auroras are a diffuse-type aurora, and are characterized by a repetition of brighter (on-phase) and darker (off-phase) auroral emissions with periods of a few to a few tens of seconds. Optical observations for pulsating auroras have been widely performed for many years. Recent major activities in the optical imaging observation would be, for example, high-speed observations for faster modulations (3-Hz or higher) in the emission intensity during on-phases of pulsating auroras, and ground network observations in association with satellites in the magnetosphere for source regions of pulsating auroras. While such imaging observations equipped with bandpass or cutoff filters are useful for observing several auroral emission lines and bands of specific atoms and molecules, there is relatively less information on optical spectra of pulsating auroras.

We have been investigating optical spectra of pulsating auroras observed by an optical spectrograph at Tromsø, Norway (69.6ºN, 19.2ºE). Our spectrograph is capable of measuring optical emission intensity in mainly visible range from 480 to 880 nm with a resolution of 1.6 nm. The aperture, i.e. F-number, is 4. The field-of-view (FOV) is 0.03ºx2º, which is pointed at magnetic field-aligned direction. The time resolution is 1 second, and thus it can observe pulsating auroras, which have periods from a few to a few tens of seconds.

In this presentation, we show a pulsating aurora event occurred in morning hours on 6 March 2017. The event was a relatively long-lasting event over the FOV of spectrograph, and it allowed us to make more data integrations to enhance signal-to-noise ratios. According to a time-series of observed auroral emission data, we integrated spectral data for on- and off-phases separately. After such data integrations, auroral emission lines, such as OI 557.7 nm, OI 630.0 nm, and OI 844.6 nm, as well as emission bands, such as N2 1PG, were clearly found in both integrated-optical spectra of on- and off-phases. Then, we calculated a difference spectrum between the optical spectra of on- and off-phases. In the difference spectrum, clear line-like shapes were found for the emission lines of OI 557.7 nm and OI 844.6 nm. On the other hand, a shape of the difference spectrum around 630 nm does not seem to be a line-like shape due to OI 630.0 nm, and it seems to be a part of band-like shape of the emission band of N2 1PG. These results would suggest an importance of spectral observations of pulsating auroras, in addition to imaging observations.

Study of atmospheric stability in the polar upper mesosphere and lower thermosphere above Tromsø by using sodium LIDAR data

*Sakiho Maeda[1], Satonori Nozawa[1], Takuya Kawahara[2], Norihito Saito[3], Takuo T. Tsuda[4], Satoshi Wada[3], Toru Takahashi[5], Tetsuya Kawabata[1], Chris Hall[6]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Faculty of Engineering, Shinshu University, 3. RIKEN Center for Advanced Photonics, RIKEN, 4. The University of Electro-Communications, 5. Department of Physics, University of Olso, 6. UiT The Arctic University of Norway

We will report atmospheric stability in the polar upper Mesosphere and Lower Thermosphere (MLT) region (80-105 km) above Tromsø, Norway (69.6˚N, 19.2˚E) based on 2500 hours of sodium LIDAR data.

We have analyzed temperature and velocity data (6 min and 0.5 km resolutions) obtained over 8 seasons from October 2012 to March 2019 (about 2500 hour measurements of 237 nights). We have evaluated both static (convective) instability and dynamic (shear) instability using the square of Brunt–Väisälä frequency (N^2) and Richardson number (R_i), respectively. Furthermore, we have calculated the instability probability defined as the percentage of an occurrence rate of unstable regions over the time interval. The probabilities of static instability and dynamic instability are shown as P($N^2 < 0$) and P($0 < R_i < 1/4$), respectively. The temperature data and wind data are used to calculate N and wind shear (dv/dz), respectively.

We have found that P($N^2 < 0$) varies from a maximum of 20.6 % to a minimum of 0.5 %, and P($0 < R_i < 1/4$) varies from a maximum of 14 % to a minimum of 1.6% in the altitude region between 85 km to 95 km. P($N^2 < 0$) tends to be larger than P($0 < R_i < 1/4$). These probabilities do not show any obvious monthly variations from October to March, rather day-to-day variabilities are prominent. As shown in Figure 1, over the entire period, P($N^2 < 0$) at around 90 km altitude tends to be lower than those at around 80 km and 100 km: the static instability was less likely to occur at around 90 km. There is a weak correlation between P($0 < R_i < 1/4$) and the semidiurnal tidal amplitude, but no correlation between P($N^2 < 0$) and the semidiurnal tidal amplitude is found.

Based on these observational results, we will present the characteristics of the atmospheric stabilities in the polar winter MLT region above Tromsø. Furthermore, the results will be compared with those in mid-latitude.

Observational evaluation of temperature/wind perturbations associated with small-scale AGWs : Parameterisation and validation of wave structures

*Shin Suzuki[1], Satonori Nozawa[2]

1. Faculty of Regional Policy, Aichi University, 2. ISEE, Nagoya University

The Tromsoe Na lidar operated by the Institute for Space-Earth Environmental Research, Nagoya University has monitored wind and temperature structures associated with auroral activity in the high latitude upper atmosphere since 2010. Although the observations are limited during the winter night, the lidar detected atmospheric wave signatures with period of a few hours and temperature change related to the wave propagation with high precision (less than 1K). Furthermore, this lidar started five-direction observation from 2012: horizontal distance between the beam positions are 58 km or 22 km at a height of 100 km and the observational setup can detect smaller-scale perturbations.

In this study, we tried to identify small-scale (less than 100 km) and short-period (less than 1 h) gravity waves by using the Tromsoe Na lidar. Gravity waves contribute significantly to the wind field and thermal balance in the mesosphere and lower thermosphere (MLT) region because they vertically transport horizontal momentum from the lower atmosphere. It is also pointed that, in particular, smaller-scale and shorter-period waves tend to transport larger momentum. Small-scale gravity waves in the MLT region are mainly studied with airglow imaging measurements. The airglow measurements, however, cannot observe temperature and wind perturbations directly, which are necessary for the estimation of wave’s momentum flux. Based on temperature and wind perturbations with the five-direction lidar, we evaluate dynamical effect of small-scale gravity waves propagating in the upper atmosphere quantitatively.

In this presentation, we will report some initial results derived from simultaneous measurements of the lidar and airglow imaging in 2013-2016.

Development of SDR-based scintillation detector system integrated with MAGDAS project

*Akiko Fujimoto[1], Shuji Abe[2], Akimasa Yoshikawa[2]

1. Kyushu Institute of Technology, 2. Kyushu University

Radio communications and radio navigation (GPS: global positioning system, GNSS: Global Navigation Satellite System) are used in worldwide and widely deployed in a variety of fields, for example, tracking, automated vehicle, clock synchronization or sport analysis. The ionosphere, where is a part of Earth's upper atmosphere between 80 and about 600 km in altitude, plays an important role in the radio/telecommunication and navigation. The ionosphere is characterized by the high density of free electrons produced by the energetic photo-ionization of ultraviolet (UV) and X-rays from the Sun. The structure of ionosphere is not stable and variable in the time of day, season, latitude and solar activity, because of the differences of the energetic photo-ionization process. The irregularities and disturbances in the ionosphere cause various severe problems, for example, lower accuracy of the radio navigation due to GPS/GNSS scintillation, disruption in High Frequency (HF) radio wave bands or interference due to anomalous propagation, etc. Especially, more robust correction models for ionospheric GPS/GNSS delay errors are required to enhance the utility value of GPS/GNSS clock synchronization for the fifth generation (5G) wireless technology. Also, the real-time alert for interference on HF radio waves is necessary for the safety navigation.
We have developed the SDR (Software-Defined Radio) -based scintillation detector system integrated with MAGDAS (http://data.icswse.kyushu-u.ac.jp) project. This system will be installed at the observatory where operates the FMCW radar to measure ionograms. Thus, our new system allows to investigate and monitor simultaneously the magnetic field variation recorded by MAGDAS magnetometer, the ionosphere plasma density profile in altitude with high time resolution and GPS scintillation level. We will present our initial development status.

Recent and future activities of ICSWSE and MAGDAS project

*Shuji Abe[1], Akiko Fujimoto[2], Teiji Uozumi[1], Akimasa Yoshikawa[1,3]

1. International Center for Space Weather Science and Education, Japan, 2. Kyushu Institute of Technology, Japan, 3. Department of Earth and Planetary Sciences, Kyushu University, Japan

International Center for Space Weather Science and Education (ICSWSE), Kyushu University is the research institute for conducting research and education in space weather. We are operating world-wide magnetometer array named as "MAGDAS/CPMN (MAGnetic Data Acquisition System/Circum-pan Pacific Magnetometer Network)" (Principal Investigator: Dr. A. Yoshikawa) for these. It consists of over seventy fluxgate magnetometers, one induction magnetometer, and four FM-CW (Frequency Modulated Continuous Wave) radars. One of our recent research topics is Equatorial Electrojet (EEJ). To accelerate the understanding of EEJ structure, we are constructing dense instrument array across the magnetic equator at Peru and Malaysia in recent year. The latest magnetometer is installed at Penang, Malaysia last September. On last March, we maintained the latest FM-CW radar at Sicaya, Peru. We calculate EE-index (Uozumi et al, 2008; Fujimoto et al., 2016) for space weather nowcast/forecast using realtime magnetometer data along the magnetic equator, and publish it at each hour on the web. We provide our observational information and data including old project via our website, and via IUGONET (Inter-university Upper Atmosphere Observation NETwork) web service and data analysis software. We believe MAGDAS data will help any researchers for their research under proper rule.

Day-to-day Variability of Field-Aligned Irregularities Occurrence in Nighttime F-region Ionosphere over Equatorial Atmosphere Radar : A Combinatorics Analysis

*Dyah Rahayu Martiningrum[1], Mamoru Yamamoto[2], Rezy Pradipta[3]

1. National Institute of Aeronautics and Space - LAPAN, Indonesia, 2. Research Institute for Sustainable Humanosphere (RISH), Kyoto University, Japan, 3. Institute for Scientific Research, Boston College, Chestnut Hill, MA, United States

This paper presents a statistical analysis to investigate day to day variability of field-aligned irregularities (FAI) occurrence in nighttime F-region ionosphere over the Equatorial Atmosphere Radar (EAR), West Sumatra, Indonesia. FAI echoes were identified based on signal intensity of backscatter radar observations. We analyzed nighttime F-region FAI during 3 years starting in January 2011 to December 2013. For the first time, a combinatoric analysis was applied to examined the statistical likehood of various day-to-day FAI occurrence patterns. The empirical day-to-day combinatorics analysis was performed based on binary classification of EAR observation data into either FAI occurrence (+) or FAI absence (-) for each calendar data. We gathered all possible permutations of various day-to-day FAI occurrence patterns, from 1-day to 6-day patterns, and compile them into histogram. The combinatorics analysis was performed in 4 separate time interval to account for seasonal variation : two equinoxes (March and September) and two solstices (June and December). EAR data show that FAI occurrence probability is maximum for the two equinoxes, and that it is minimum for the two solstices. The combinatorics analysis shows that certain day-to-day patterns are more likely to occur than others, and such “combinatorics fingerprints” also depend on season. During the solstices, persistent absence of FAI over several consecutive days far outweighed persistent FAI occurrence over an equivalent grouping of days with the same length. Meanwhile, during equinoxes, we found a generally more equitable distributions between persistent day-to-day FAI occurrence and persistent day-to-day FAI absence. This findings may open new ways to help forecast FAI occurrence on a regional basis.

[E] Poster | P (Space and Planetary Sciences)：P-EM Solar-Terrestrial Sciences, Space Electromagnetism & Space Environment

[P-EM19] Dynamics of the Inner Magnetospheric System

convener:Kunihiro Keika(Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo), Aleksandr Y Ukhorskiy(Johns Hopkins University Applied Physics Laboratory), Yoshizumi Miyoshi(Institute for Space-Earth Environmental Research, Nagoya University), Lynn M Kistler(University of New Hampshire Main Campus)

The inner magnetosphere is highly variable because dynamical
variations of incoming energy from the solar wind, magnetospheric tail,
and the ionosphere. Cross-regional/cross-scale/cross-energy couplings
are key processes to understand this dynamical system, and coordinated
observations by multi-satellites and ground-based observations are
very essential to reveal these processes. In the 24th solar cycle,
a number of satellites such as Van Allen Probes, MMS, THEMIS, DSX and
Arase, coordinated ground-based observations (THEMIS-GBO, SuperDARN,
EISCAT, magnetometers, riometer, etc), and numerical simulations
(global kinetic model, MHD model, micro PIC, hybrid simulations) have
successfully investigated the inner magnetosphere system. Papers on recent results
on the inner magnetosphere and/or its coupling with the other regions,
including the ionosphere and the outer magnetosphere are invited. And
presentations on new projects for the inner magnetosphere are also
welcome.

Numerical simulation on energetic electron precipitations by chorus waves

*Yoshiki Ito[1], Shinji Saito[2], Yoshizumi Miyoshi[1]

1. Nagoya University, ISEE, 2. National Institute of Information ans Communications Technology

Whistler mode chorus waves cause scattering and acceleration of energetic electrons in the inner magnetosphere. The interaction processes have been modeled as a diffusive process. The pitch angle diffusion coefficients of the pitch angle scattering depend on the power of chorus waves so that the scattering rate also depends on the wave amplitude. On the other hand, several previous studies indicated that the Lorentz force by the wave magnetic field is larger than the mirror force if the wave amplitudes increase and the electron trajectories in the velocity space are different from the diffusive distributions. In this study, we investigate the chorus wave amplitude dependence of electron scattering using the GEMSIS-RBW simulation code. The RBW simulation demonstrates the generation of periodical rising-tone chorus waves propagating along a magnetic field line to higher latitudes and local pitch angle scattering by the imposed waves on the field line.
As the wave amplitude increases, the pitch angle of the electrons is scattered by the non-resonant interaction due to the influence of the wave magnetic field. We discriminate of resonant and non-resonant electron population, and investigate the amplitude dependence of precipitating electron counts for two populations. A positive correlation was found between the wave intensity and precipitating counts of resonant electron when the wave amplitudes are smaller than 10^-4 of the ambient magnetic fields..
When the wave intensity becomes large, precipitating counts of resonant electrons decrease. The parameter ρ (e.g., Saito et al., 2016) has used as a proxy to discriminate different interaction processes among diffusion, phase trapping and dislocation. Note that a positive correlation between the wave intensity and precipitating counts of resonant electrons are violated despite of small ρ (<1), i.e., diffusive interactions. Simultaneously, precipitating counts of non-resonant electrons increases, indicating that non-resonant interactions contribute to precipitation of electrons.

A pipeline for comprehensive tracking of pulsating patches in All-Sky Imager data

*Riku Nomiyama[1], Yoshizumi Miyoshi[2], Kohei Toyama[2], Yasunobu Ogawa[3], Keisuke Hosokawa[4], Terumasa Tokunaga[1]

1. Kyushu Institute of Technology, 2. Institute for Space-Earth Environmental Research, Nagoya University, 3. National Institute of Polar Research, 4. Department of Communication Engineering and Informatics, University of Electro-Communications

Pulsating aurora is a type of diffuse aurora with quasi-periodic variations in intensity. It is characterized as multiple on-off switching patches with a typical horizontal size from 10 to 200 km. The pulsating aurora is caused by intermittent precipitations of a few –tens keV electrons. With the development of auroral optical observations based on All-Sky Imager (ASI) system, it is expected to elucidate long-term variations, detailed spatiotemporal properties of pulsating aurora, including size evolutions, dominant frequencies, drift velocities, life times.

However, quantifications of comprehensive spatiotemporal properties of pulsating aurora are formidable task due to increasing amount of ASI data. In addition, an existence of non-pulsating background diffuse auroras often makes it difficult to identify individual patches. Hence, it is important to establish a fundamental technique for tracking multiple pulsating patches in ASI data undisturbed background arcs.

In this study, we built a new pipeline for comprehensive tracking of multiple pulsating patches over video sequences of the ASI. The process consists of three distinct steps: (i) extraction of pulsating patches to distinguish them from non-pulsating background arcs, (ii) segmentation individual patches over spatiotemporal domain and (iii) linking segmented regions lined up in time direction. The extraction step is carried out by a spatiotemporal filtering called Eulerian Video Magnification. This technique amplifies periodic color variations in a given temporal frequency band of interest. Since pulsating patches periodically switches in a characteristic frequency, we can successfully amplify them by selecting an appropriate frequency band. In the segmentation step, we apply a simple thresholding image binarization technique for each sequence over time. Then, we link identical patches by applying Hough transformation for identifying lines from a 3D point-cloud which describes centroid positions of segments in a spatiotemporal domain. This step is done under the assumption that an identical pulsating patch drifts roughly in a same direction affected by the global magnetospheric convection.

We examined the performances of our tracking pipeline using the WATEC ASI data obtained at Tromso, Norway. The exposure time of the WATEC ASI is second. In a visual inspection, our method successfully tracked noticeable pulsating patches in spite of the existence of background arcs. In the presentation, we demonstrate the tracking results showing trajectories of pulsating patches. Further, we will discuss some technical issues to be overcome for comprehensive tracking of pulsating patches. Moreover, we will discuss the MLT and geomagnetic activity dependence of the derived patch motions of the pulsating aurora.

Estimation of precipitating electron energy of pulsating aurora by multiwavelength aurora optical observation

*Kohei Toyama[1], Yoshizumi Miyoshi[1], Satoshi Kurita[1], Keisuke Hosokawa[2], Yasunobu Ogawa[3], Shin-ichiro Oyama[1], Satonori Nozawa[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Department of Communication Engineering Informatics,Univarsity Electro-Communications, 3. National Institute of Polar Research

Pulsating aurora (PsA) is a type of diffuse aurora that is mainly observed from post-midnight to the morning sectors during the recovery phase of substorms. PsA is characterized by quasi-periodic intensity modulation with ~2 -20 s intervals as a main modulation. The main modulation includes an internal modulation of about 1.5 to 3 Hz called an internal modulation.Mainly Electrostatic Cyclotron Harmonic (ECH) waves and whistler-mode waves cause the pitch angle scattering of energetic electrons in the magnetosphere, and PsA is generated by the precipitating electrons with high energy of several to 100 keV. In particular, the whistler-mode chorus waves play the role. The lower-band chorus (LBC) causes an electron precipitation of more than several keV, and the upper-band chorus causes steady precipitation of less than 1 keV. Estimations of the precipitating electron energy of the pulsating aurora from the ground-based observations have been performed. Ono et al.[1993] observed the emission intensities of a nitrogen molecule ion at 427.8 nm emission line and an oxygen atom at 844.6 nm emission line using a photometer, and estimated the energy of the precipitating electron by combining the ratio of the two emission intensities and the model calculation. However, Ono et al.[1993] conducted observations using narrow-field instrument, and the energy estimation by observation using an all-sky camera has not been performed. In Tromso, Norway, several high-sensitivity EMCCD cameras have been installed, which have been simultaneously observing the all-sky image of the emission intensity of sky image of the emission intensity of the 427.8 nm emission line and the 844.6 nm emission line at a sampling frequency of 10 Hz. In addition, a five-wavelength photometer that can observe the emission intensity of the emission lines at 427.8 nm and 844.6 nm in the magnetic zenith direction is also operated. In this study, we compared the data of the photometer and the EMCCD cameras installed in Tromso, and evaluated the sensitivity of the cameras. In addition, we estimated the precipitating electron energy of the pulsating aurora by compering emission intensity ratio of the two emission lines using the all-sky image reflecting the sensitivity evaluation results and the emission intensity calculation results obtained by the GLOW model[Solomon, 2017]. In this presentation, we report the results of the two-dimensional spatial distribution of the estimated precipitating electron energy. Moreover, we discuss the possible errors of the estimated energy.

Observation plan of pulsating aurora by the multi-spectral auroral camera on the LAMP rocket

Naoshi Yagi[1], *Takeshi Sakanoi[1], Miki Kawamura[1], Kazushi Asamura[2], Yoshizumi Miyoshi[3], Keisuke Hosokawa[4], Sarah L Jones[5], Marc Lessard[6]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. ISAS/JAXA, 3. ISEE, Nagoya University, 4. Graduate School of Informatics and Engineering, The University of Electro-Communications, 5. Goddard Space Flight Center, NASA, 6. University of New Hampshire

We are developing the multi-spectral auroral imager (AIC2) installed on the LAMP rocket. We report the current status of development and future plan of AIC2. Chorus waves generated in the magnetospheric equatorial region are thought to cause the pitch angle scattering of electrons in a wide energy range (several keV –1 MeV or more). Therefore, a correlation between pulsating aurora and microbursts is expected. However, there is no simultaneous observation between them. The LAMP rocket aims to carry out simultaneous observation of pulsating aurora and microbursts with comprehensive instrument of plasma particles, magnetic fields, and optical imaging to reveal the mechanism. This rocket is scheduled to be launched at Poker Flat Research Range in December 2020. The project PI is Dr. Sarah L, Jones of NASA/GSFC, and instruments measuring thermal electrons, low energy electrons, intermediate energy electrons and magnetic field are provided from institutes in US, and the instrumental package called PARM2 (Pulsating AuRora and Microburst 2) is proved by the Japanese team.
AIC2 consists of two CMOS detectors AIC-S1 and S2 and an electrics AIC-E, and will perform simultaneous auroral imaging at two wavelengths. We adopted the consumer CMOS camera ZWO ASI183MM for detector. Compared with the detector of AIC on the Rocksat-XN rocket launched last year, we improved 5 times lower noise (3.6 e-RMS) and 16 times wider dynamic range (12 bit A/D) in sampling at the detector. AIC-S1 targets the E region N2 aurora with an interference filter (Andover, CW 670 nm, FWHM 20 nm) and an objective lens (SpaceCom JF17095M, f = 17 mm, F/0.95, field of view 29 deg x 29 deg). AIC-S2 is designed for F-regin O 844.6 nm aurora with an interference filter (Andover, CW 846.1 nm, FWHM 4.4 nm) and an objective lens (SpaceCom HF3.5M-2, f = 3.5mm, F/1.6, field of view 106 deg x 106 deg). To gain S/N and reduce data size, binning is performed for original 3660 pix x 3600 pix image, and a 60 bin x 60 bin image is produced for each frame. AIC2 is mounted on a despun platform to cancel a rocket spin. Combining the despun platform with rocket attitude control, AIC-S1 will point to the magnetic footprint to perform simultaneous observation between fine structure of pulsating aurora and precipitating electrons. AIC-S2 will point west and cover the wide area from the rim of the earth to nadir, and obtain the height profile of O 844.6 nm emission as well as the pulsating auroral distribution in the wide range. The time resolution is 10 frame/s. At the apex altitude (~ 450km), the spatial resolution at nadir is 3.0 km x 3.0 km for AIC-S1 (E-region), and 6.3 km x 6.3 km for AIC-S2 (F-region). The AIC-E consists of two NanoPi M4 board computers, custom FPGA, power supply, and signal processing electronics to handle a large amount of image data generated from two cameras. We also newly developed a heat pipe to cool the heat generated at two CPUs of NanoPi M4.
On the development of AIC2, we carried out the electrical interface test between AIC-S1, S2 and AIC-E from September 2019 to this February, and confirmed the data acquisition with 10 frame/s, image binning and data communication. We also made the calibration test with the integrated sphere in NIPR in June and August 2019, and estimated the dynamic ranges of AIC-S1 and S2 to be 0.27-3100 kR and 2.2-27000 kR, with the resolutions of 48 R/bit and 410 R/bit, respectively, in the case with a gain of 450. In addition, we conducted a data communication test using a despun table with slip ling connector that is almost similar to the flight model in March 2019. We confirmed that that the data communication via the

©2020. Japan Geoscience Union. All Right Reserved.

slip ring works as expected if we use a differential signal interface, and shielded and twist-pair cables. By July 2020, we will perform environmental tests, such as vacuum, temperature and vibration tests, in Japan, and interface test with the flight model despun table is planned at the University of New Hampshire.

Statistical study of EMIC waves and energetic electron precipitation: ground-based magnetometer and subionospheric VLF/LF radio measurements at subauroral latitude

*Asuka Hirai[1], Fuminori Tsuchiya[1], Takahiro Obara[1], Yasumasa Kasaba[1], Yuto Katoh[2], Hiroaki Misawa[1], Kazuo Shiokawa[3], Yoshizumi Miyoshi[3], Satoshi Kurita[3], Chae-Woo Jun[3], Martin G Connors[4]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku Univ. , 2. Department of Geophysics, Graduate School of Science, Tohoku University, 3. Institute for Space-Earth Environmental Research, Nagoya University, 4. Athabasca University

Electromagnetic ion cyclotron (EMIC) waves are observed as Pc1-2 pulsations in the Earth’s magnetosphere. These waves are excited due to the temperature anisotropy of ring current ions near the magnetic equator, and scatter the pitch angle of relativistic electrons through cyclotron resonance. This process causes the precipitation of high-energy electrons into the atmosphere, and is considered as one of the mechanisms to cause the loss of the outer radiation belt. There are two major questions left in this scenario. One is the amount of the contribution from the EMIC waves to the overall loss of radiation belt electrons. Another one is the conditions favorable to pitch angle scattering.
We performed a statistical study of EMIC waves associated with electron precipitations from November 2016 to December 2018. EMIC waves were observed by ground-based magnetometers installed at Athabasca, Canada (54.6˚N, 246.7˚E, L=4.3), which are operated by the PWING (‘study of dynamical variation of Particles and Waves in the INner magnetosphere using Ground-based network observations’) project. We used an automatic detection algorithm based on Bortnik et al. (2007) to identify EMIC wave events. Electron precipitation events were identified from the VLF radio waves propagating from transmitters at NDK, US (25.2kHz, 46.37˚N, 261.47˚E) and NLK (24.8kHz, 48.20˚N, 238.08˚E) to the receiver installed at Athabasca. Since these transmitted VLF waves are sensitive to ionization changes in the lower ionosphere, they are modulated when electrons with energies of > 100 keV precipitate above the propagation paths of VLF radio waves. In order to detect the electron precipitation events caused by EMIC waves, we identified the decreases in the amplitude of VLF signals temporally corresponding with the appearance of EMIC waves by visual inspection. In the period of analysis, we identified 999 EMIC wave events, and found 23 events clearly associated with electron precipitations. While total EMIC waves had higher occurrence rates in the dawn sector than in the dusk sector, most of the EMIC waves accompanied by electron precipitation occurred in the dusk sector during substorms. Theoretical study suggests that resonance energies of electrons interacting with EMIC waves decrease in the region of high plasma density (e.g. Summers and Thorne, 2003). Inside the plasmasphere, the resonant energy becomes down to several hundred keV. From statistical analysis and theoretical considerations, we suggestthat the ring current protons are injected inside the duskside plasmapause during substorms and excite EMIC waves in the high plasma density regions. These EMIC waves are likely to scatter relativistic electrons with energies from several hundred keV to a few MeV.

First simultaneous observation of the isolated proton aurora at subauroral latitudes by a highly sensitive all-sky camera and the Van Allen Probes satellite

*Kohki Nakamura[1], Kazuo Shiokawa[1], Yuichi Otsuka[1], Atsuki Shinbori[1], Martin G Connors[2], Geoff Reeves[4], Charles Smith[3]

1. Institute for Space-Earth Environmental Research, 2. Athabasca Univ., 3. New Hampshire Univ., 4. Los Alamos National Laboratory

Isolated Proton Aurora (IPA) is the spotted aurora extending east and west at subauroral latitudes produced by energetic proton precipitation. Proton auroras are produced by energetic protons precipitating from the magnetosphere through charge-exchange collisions with atmospheric particles in the ionosphere. From previous studies, IPA has been considered to be generated by electromagnetic ion cyclotron (EMIC) waves which can scatter the pitch angle of energetic protons into the loss cone. However, simultaneous observation of IPA and its source plasma and electromagnetic fields in the magnetosphere has never been done before. Because EMIC waves are a key component contributing to the rapid loss of radiation-belt particles into the atmosphere, it is important to understand the mechanisms of EMIC wave-particle interaction. In the present study, we studied simultaneous observation events of EMIC-associated IPAs by ground all-sky camera at Athabasca and plasma and electromagnetic fields in the magnetosphere by the Van Allen Probes satellite. The EMIC waves were observed by the Van Allen Probes satellite at ~5:30 UT when the footprint of the satellite passed over an IPA on March 16, 2015. Proton flux from 5 eV to 20 keV observed by HOPE onboard the satellite increased rapidly at the time when satellite crossed the IPA. Electron flux at energies of ~500 eV also increased. The proton temperature anisotropy was 1.5-2.5 during the arc crossing. In addition, electron density observed by EMFISIS decreased from 4:20 UT to 6:20 UT, indicating that the IPA crossing was near the plasmapause. Electric field observed by EFW had no characteristic fluctuation associated with the IPA crossing. We will discuss these observations in relation to the possible IPA generation mechanisms.

Modulation of Pc1 wave ducting by equatorial plasma bubbles

*Hyangpyo Kim[1], Kazuo Shiokawa[1], Jaeheung Park[2,3], Yoshizumi Miyoshi[1], Junga Hwang[2,3], Akira Kadokura[4]

1. Institute for Space-Earth Environmental Research, Nagoya University, Nagoya, Japan, 2. Korea Astronomy and Space science Institute, Daejeon, South Korea, 3. Korea University of Science and Technology, Daejeon, South Korea, 4. Space and Upper Atmospheric Sciences, National Institute of Polar Research, Tokyo, Japan

Pc1 waves generally propagate along the ambient magnetic field in the magnetosphere, but turn to oblique or perpendicular directions when they reach the ionosphere. If the waves are continuously observed over a wide latitudinal range, they can be considered as ducting waves. Ducting Pc1 waves can be attenuated by various physical processes such as absorption, scattering, and leakage as they propagate away from the injection region, and the sustainability of wave ducting depends on the ionospheric condition such as conductivity and plasma density. An earlier study from Kim et al. (2018) from the Swarm observations suggested that plasma density variations can affect Pc1 wave propagation within the ionosphere, i.e., wave attenuation can be controlled by electron density structure of the ionosphere. This finding, however, is not yet sufficient to fully elucidate density dependence of wave propagation, because they did not consider wave source variations, and did not discuss in detail possible inter-satellite differences of the wave intensity and electron density observed by the Swarm-A and Swarm-C, which fly in a tight formation.

In this study, we present remarkable relationship between ducting Pc1 wave and electron density based on the Swarm satellites. We show two ducting Pc1 events propagating across equatorial plasma bubbles (EPBs) that occurred on 7 April 2016 and on 27 September 2017. From the observations, we found that the EPBs modulate the Pc1 wave propagation by setting up boundaries and holes in the ionospheric waveguide, which can cause wave reflection and leakage. We also found that changes of Pc1 wave intensities generally follow the electron density variation, and that the intensity is stronger at high-density region than relatively low-density region. From the comparison between Swarm-A and Swarm-C observations, we conclude that ionospheric plasma plays a vital role in Pc1 waveguide even though their density becomes significantly low in EPBs.

Modulation of energetic electron distribution caused by toroidal mode ULF waves in association with periodic enhancement of chorus emissions

Atsuhiro Ono[1], *Yuto Katoh[1], Mariko Teramoto[2], Atsushi Kumamoto[1], Fuminori Tsuchiya[1], Yoshiya Kasahara[3], Shoya Matsuda[4], Ayako Matsuoka[4], Satoshi Kasahara[5], Shoichiro Yokota[7], Kunihiro Keika[5], Takefumi Mitani[4], Tomoaki Hori[6], Yoshizumi Miyoshi[6], Iku Shinohara[4]

Whistler-mode chorus emissions play significant roles in the acceleration and the loss of energetic electrons in the terrestrial magnetosphere. Previous studies revealed that chorus emissions satisfy the cyclotron resonance condition with electrons in the wide ranges of the kinetic energy and pitch angle and cause the periodic precipitations of energetic electrons into the atmosphere through wave-particle interactions, contributing to diffuse and pulsating auroras [e.g. Nishimura et al., 2010, S. Kasahara et al., 2018a]. While the mechanism controlling the periodicity of the chorus wave generation is one of essential problems unsolved in the magnetospheric physics, the roles of ULF waves have been discussed in several decades. In the present study, we analyze substorm-related toroidal mode ULF waves, chorus emissions, and energetic electrons simultaneously observed by the ERG satellite, and propose a model explaining how toroidal mode waves modulate energetic electrons. We focus on the event observed from 21:30 UT to 22:00 UT on March 27, 2017, the recovery phase of the CIR-driven storm. The ERG satellite traversed in the dawn sector of the ring current region, where the range of L-value was from 6.3 to 5.9, the magnetic local time from 04:00 to 04:12, and the magnetic latitude from -12.7 to -7.4 degrees during the analyzed event. From the observations of the Onboard Frequency Analyzer (OFA) of the Plasma Wave Experiment (PWE), the Magnetic Field Experiment (MGF), the Medium-energy particle experiments - electron analyzer (MEP-e) and the High-energy electron experiments (HEP), we find one-to-one correspondence among chorus emissions, toroidal mode ULF waves, and energetic electrons in the energy range 35-60 keV. We estimate the resonant energy to be about 30-300 keV, considering the first-order cyclotron resonance condition under the parameters determined based on the observations of the High Frequency Analyzer (HFA) and the OFA of the PWE and the MGF. Based on the results of analysis, we suggest that the intensity variations of chorus emissions are caused by the modulations of energetic electrons. The intensity of chorus emissions enhances at the timings when the toroidal component of the wave magnetic field has a peak in the westward direction as well as the enhancement of the flux and the temperature anisotropy of energetic electrons. From the observed phase relationship between the wave magnetic field of the ULF waves and the modulations of energetic electrons, it is expected that the locations corresponding to the wave phases when the flux enhancement (depletion) are expected to be the dense (sparse) region due to the concentration (divergence) of the E×B drift velocity between the wave electric field of the ULF waves and the ambient magnetic field. The azimuthal wave number and the wavelength of the observed ULF waves are estimated to be about 49-120 and 2000-4900 km, respectively, assuming that modulated energetic electrons satisfy the drift resonance condition with the ULF waves. The estimated m-numbers correspond to those reported as Transient Toroidal Waves [e.g. Takahashi et al., 1996], rather than the typical values of externally generated toroidal mode ULF waves observed in the inner magnetosphere.

Comparative study of magnetic field and ion flux variations in inner magnetosphere during magnetic storms using Arase observations and RAM-SCB simulations

*Sandeep Kumar[1], Yoshizumi Miyoshi[1], Vania Jordanova[2], Ayako Matsuoka[3], Kazushi Asamura[3], Shoichiro Yokota[4], Satoshi Kasahara[5], Kunihiro Keika[5], Tomoaki Hori[1], Iku Shinohara[3]

1. ISEE, Nagoya University, Japan, 2. Los Alamos National Laboratory, USA, 3. ISAS/JAXA, Japan, 4. Osaka University, Japan, 5. University of Tokyo, Japan

Understanding the physical processes that control the dynamics of energetic particles in the inner magnetosphere is important for both space-borne and ground-based assets essential to the modern society. The storm time distribution of ring current ions in the inner magnetosphere depend strongly on their transport in evolutions of electric and magnetic fields along with acceleration and loss. In this study, we compare the magnetic field and ion flux (H^+, He^+, and O^+) variations during geomagnetic storms using Arase observations with the self-consistent inner magnetosphere model: **R**ing current **A**tmosphere interactions **M**odel with **S**elf **C**onsistent magnetic field (RAM-SCB). We investigate evolutions of ambient magnetic field taken from Arase MGF observations and RAM-SCB simulation during different phases of geomagnetic storms. Moreover, we compare pressure distributions of H^+, He^+ and O^+ from both the Arase LEPi/MEPi measurements and the RAM-SCB simulation to investigate which ions contribute the magnetic field deformation.

Observational study on mass and charge dependence of plasma energization in the inner magnetosphere and near-Earth magnetotail

*Kunihiro Keika[1], Satoshi Kasahara[1], Shoichiro Yokota[2], Masahiro Hoshino[1], Kanako Seki[1], Takanobu Amano[1], Lynn M Kistler[3], Masahito Nose[4], Yoshizumi Miyoshi[4], Tomoaki Hori[4], Iku Shinohara[5]

1. Graduate School of Science, The University of Tokyo , 2. Graduate School of Science, Osaka University, 3. University of New Hampshire, 4. Institute for Space-Earth Environmental Research, Nagoya University, 5. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

The ion pressure in the Earth's inner magnetosphere is generally dominated by a few to a few 100s keV protons. Oxygen ions of ionospheric origin, O^+, can make a significant contribution to the ion pressure during geomagnetically active periods. Our previous study showedclear oxygen-proton differences in energy spectra in the outer part (L>5) of the ring current region. The results indicate the occurrence of mass-dependent or selective acceleration in the inner magnetosphere and/or near-Earth magnetotail. The present study extends analysis toward ions with different mass and/or charge states. We primarily use data from the MEP-i (Medium-Energy Particle experiments - ion mass analyzer) on board the Arase spacecraft, particularly when the Arase apogee was positioned on the night side during magnetic storms. MEP-i measures ions with energies of ~10 to 180 keV/q and distinguishes between different ion species.

Energy spectra of singly-charged ions (H^+, He^+, O^+) show mass dependence, with He^+ and O^+ having harder spectra than H^+. The spectral slope of doubly-charged ions (He^{++}, O^{++}) is steeper for H^{++} than O^{++}. For ions with the same mass, singly-charged ions show harder spectra than doubly-charged ones. The results indicate that energization processes in the near-Earth magnetotail are more dependent on mass than charge. This suggests that the ion energy gain in the magnetotail is not determined by a complete displacement across the global electric field potential only. An important factor is likely the limited spatial scale of the electric field associated with narrow flow channels during magnetic field reconfiguration (dipolarization), which has been reported comparable to gyro-radii of heavy ions.

Improvement of detector response matrices of the high-energy electron experiments (HEP) onboard the Arase satellite

*Takefumi Mitani[1], PARK INCHUN[2], Tomoaki Hori[2], Takeshi Takashima[1], Satoshi Kasahara[3], Satoshi Kurita[2], Mariko Teramoto[4], Nana Higashio[1], Yoshizumi Miyoshi[2], Iku Shinohara[1]

1. Japan Aerospace Exploration Agency, 2. Nagoya University, 3. The University of Tokyo, 4. Kyushu Institute of Technology

The high-energy electron experiments (HEP) onboard the Arase satellite detects 70 keV-2 MeV electrons and generates three-dimensional velocity distribution data for these electrons in every period of the satellite's rotation. Electrons are detected by two instruments, HEP-L and HEP-H, which differ in their geometric factor (G-factor) and energy range they cover. HEP-L detects 70 keV–1 MeV electrons with the G-factor of 9.3 $\times 10^{-4}$ cm^2 sr at maximum, while HEP-H observes 0.7 MeV–2 MeV electrons with the G-factor of 9.3 $\times 10^{-3}$ cm^2 sr at maximum. The instruments utilize silicon strip detectors and application-specific integrated circuits to read out incident charge signals from each strip.

In order to deduce the distribution of incident electrons from the direction and energy detections in orbit, we have developed a detector simulator using the Geant4 toolkit. Using the simulator, we calculate response matrices of the detectors and derive incident fluxes from the detected counts. The derived fluxes of electrons at around 100 keV are consistent with those observed by the medium-energy particle experiments - electron analyzer (MEP-e), which utilizes an electrostatic analyzer.

Recently, we have evaluated effects on detection efficiency caused by on-board signal processing. We found that the detection efficiency for higher energy electrons affected by parameters such as an energy threshold and readout noise, which are used to determine whether to read out the signal from the detector. We have updated the response matrices taking those parameters into account. In this presentation, we will present our calibration methods and their evaluation status. Especially, we will show a comparison before and after updating the matrices.

Inter-channel normalization and energy spectrum correction of the high-energy electron experiments (HEP) onboard the Arase satellite

*Tomoaki Hori[1], Takefumi Mitani[2], Takeshi Takashima[2], InChun Park[1], Satoshi Kurita[1], Mariko Teramoto[3], Nana Higashio[4], Satoshi Kasahara[5], Shoichiro Yokota[6], Yoshizumi Miyoshi[1], Iku Shinohara[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. JAXA/ISAS, 3. Kyushu Inst. of Tech., 4. JAXA, 5. The Univ. of Tokyo, 6. Osaka Univ.

Detailed evaluation of the relative efficiency of azimuthal channels and their dependence on the energy of incident electrons has been conducted for the high-energy electron experiments (HEP) onboard the Arase satellite since the start of the satellite operation. Recently the simulation model of the instrument response has been improved to consider a realistic threshold and noise level of the onboard electronics for triggering an event of electron incidence in the detector system. The updated simulation model brings out new response properties of the instrument which could significantly modify the incident energy dependence as well as the relative efficiency among azimuthal channels, particularly at high energy. Accordingly, science data products such as Level-2 electron differential flux data are also to be updated on the basis of newly deduced calibration parameters. We show how the new electron flux data and their angular distribution are compared to the previous versions. Comparison with flux data of the other electron instruments onboard shows the same level of consistency in flux value for the lower energy part, while there still remains some discrepancy in the MeV range.

Evaluation of response characteristics of the XEP onboard the Arase spacecraft

*Kohei Ueda[1], Takefumi Mitani[2], Nana Higashio[3], Shoichiro Yokota[1], Takeshi Takashima[2], Yoshizumi Miyoshi[4], Iku Shinohara[2], Kentaro Terada[1]

1. Osaka University, 2. Japan Aerospace Exploration Agency/Institute of Space and Astronautical Science, 3. Japan Aerospace Exploration Agency, 4. Nagoya University/Institute for Space-Earth Environment Research

The extremely high-energy experiment (XEP) onboard the Arase spacecraft was designed to measure 0.4-20MeV electrons. Electrons are detected by five solid-state silicon detectors (SSDs) and a single-crystal inorganic scintillator of cerium-doped gadolinium orthosilicate (GSO). The SSDs detect 0.4-5.4MeV electrons and the GSO detects 6-20MeV electrons. While the XEP plays an important role in observing the main components of the radiation belt, its energy response has not been fully examined. In this study, we reproduced XEP geometry which is almost the same as the flight model and conducted an irradiation test using the Geant4 toolkit to examine its energy response in detail. The simulation results show how high energy electrons affect low energy bins. We have found that when high-energy electrons (about 5 MeV or more) are incident, the SSD detection area detects most of them as about 1.8-2.8 MeV. We have also performed a more accurate calibration of the observed data using the response function matrix obtained from the simulation. We will present pre- and post- calibration comparisons of observed data.

The observational study for high energy particles below L=2.1 using Hisaki

*Kazuo Yoshioka[1], Ichiro Yoshikawa[1], Atsushi Yamazaki[2], Go Murakami[2], Hajime Kita[2], Fuminori Tsuchiya[3], Tomoki Kimura[4], Yoshizumi Miyoshi[5], Satoshi Kurita[5], Mariko Teramoto[6]

1. Graduate School of frontier Science, The University of Tokyo, 2. Institute of Space and Astronautical Science / Japan Aerospace Exploration Agency, 3. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 4. Tohoku University, 5. Institute for Space-Earth Environmental Research, Nagoya University, 6. Kyushu Institute of Technology

Hisaki is a low-altitude satellite with an orbital altitude of about 1000 km and an inclination of 30 degrees which is equivalent to 1.2-2.1 in L-value. Hisaki has been designed as an EUV spectroscope for observing Jupiter and other planets, but its photon-detector is also sensitive to radiation such as protons and electrons. In particular, electrons of more than 5 MeV and protons of more than 50 MeV can penetrate the shield of the instrument and reach the detector. Therefore, Hisaki can be used as a radiation monitor in the low altitude area (low L-value).

The Hisaki launched in November 2013 has been observing planets for more than 6 years. We have summarized the count rates caused by radiation and clarified that the trend is dependent on solar activity in orbital regions with L-values greater than 1.8. In addition, it was confirmed that the count increased several times with a timescale of several hours in response to solar activity like SEP. These phenomena were also captured by radiation monitors onboard the ISS in the orbital region of higher L-values (L>3) and were recognized as SEP particle injection. However, no clear observational evidence has been obtained for the behavior near L-value 2.

In this presentation, we will discuss the behavior of high-energy particle at various time constants in the low-altitude region around Earth.

Calibration of waveform data measured by the electric sensors on board the Arase satellite

*Yoshiya Kasahara[1], Hiroyuki Nishizawa[1], Shoya Matsuda[2], Hirotsugu Kojima[3], Fuminori Tsuchiya[4], Atsushi Kumamoto[4], Yasumasa Kasaba[4], Ayako Matsuoka[2]

1. Kanazawa University, 2. ISAS/JAXA, 3. Kyoto University, 4. Tohoku University

The Plasma Wave Experiment (PWE) on board the Arase satellite measures electric field from DC to 10 MHz, and magnetic field from a few Hz to 100 kHz. The waveform capture (WFC) is one of subsystems of the PWE and is dedicated to measuring waveform for the two electric components and three magnetic field components. The WFC aims at detailed measurements of plasma waves in the VLF range such as chorus, hiss and lightning whistler, but it is necessary to be corrected for gain and phase according to the frequency responses of sensors and receivers. In particular, the electric field data needs to be corrected in consideration of the antenna impedance of the electric field sensor. The characteristics of the impedance strongly depend on the electron density and temperature at the observation point. We have been operating the onboard calibration system regularly, and the frequency response is statistically derived as a function of electron density. In the present study, we evaluated the frequency response by deriving the refractive indices of lightning whistlers or chorus emissions in two different ways; one from E/B ratio of the waveform data measured by the WFC and the other from dispersion relation of whistler mode wave.
First, we select the events when wave normal directions of chorus or lightning whistlers were almost parallel (< 30 degrees) against the ambient magnetic field. Second, we derive refractive indices by calculating the E/B ratio from the waveform data. On the other hand, we also derive the refractive indices theoretically by the dispersion relation of whistler mode wave using in situ cyclotron frequency, plasma frequency and wave normal direction. These refractive indices shall essentially match when the electric field is appropriately calibrated. In other words, we estimate the quantitative error of frequency response of electric sensor comparing the difference between them. In the present study, we report the current status of the calibration process and show the reliability of the waveform data in electric field after calibration.

Machine learning classification of low frequency waves observed by Arase satellite

*Shun Amano[1], Taketoshi Miyake[1], Yoshiya Kasahara[2]

1. Toyama prefectural university , 2. Kanazawa university

Various types of low frequency waves are observed by Electric Field Detector (EFD) onboard Arase satellite. In this study, we are going to detect these low frequency waves from EFD data, and classify these waves into several types by using machine learning.Various types of low frequency waves are observed by Electric Field Detector (EFD) onboard Arase satellite. In this study, we are going to detect these low frequency waves from EFD data, and classify these waves into several types by using machine learning.
At first, we use SVM method to detect low frequency waves from 24 hour plots of EFD spectrum data. We tested several parameters of SVM, and detected low frequency waves with more than 96% accuracy ratio. We applied this SVM method to EFD spectrum data from 2017 to 2019, and succeeded in detecting 806 low frequency waves.
Next, we try to classify these detected low frequency waves into several types by clustering. We apply K-means method and hierarchical clustering method to the image data of EFD spectrum plot and the numerical data which are the duration time and the center frequency of the low frequency waves, respectively. Therefore, we found 5 types of low frequency waves with different characteristics.

Evaluation of Automatic Determined UHR Frequencies by a Convolutional Neural Network

*Shoya Matsuda[1], Tatsuhito Hasegawa[2], Atsushi Kumamoto[3], Fuminori Tsuchiya[3], Yoshiya Kasahara[4], Yoshizumi Miyoshi[5], Yasumasa Kasaba[3], Ayako Matsuoka[1], Iku Shinohara[1]

1. Institute of Space and Astronautical Science/Japan Aerospace Exploration Agency, 2. University of Fukui, 3. Tohoku University, 4. Kanazawa University, 5. Nagoya University

The ambient electron density is one of the important properties of space plasma. Typical regions in the geospace is characterized by the different electron density profile (e.g., plasmasphere, plasma trough and plasma plume.) The most popular way to determine the quantitative electron density is observing the upper hybrid resonance (UHR) emission. The High Frequency Analyzer (HFA) and the Onboard Frequency Analyzer (OFA) is subsystems of Plasma Wave Experiment (PWE) aboard Arase [Miyoshi et al. (2018), Kasahara et al. (2018), Kumamoto et al. (2018), Matsuda et al. (2018)]. The HFA measures wide frequency range (0.1-10 MHz) electric power spectra with a time resolution of 1, 8 or 60 s. This covers a typical frequency range of UHR frequency in the inner magnetosphere. The OFA measures the electric field from DC to 20 kHz with a time resolution of 1 s and a good frequency resolution compared with the HFA.

A neural-network-based approach for the automatic detection of UHR frequencies is proposed by Zhelavskaya et al. (2016), using the local electron cyclotron frequency f_{ce}, orbital parameters (L and MLT), geomagnetic index (Kp), and observed electric field spectra. Recently, Hasegawa et al. (2019) proposed a technique for the automatic UHR frequency determination using convolutional neural network (CNN). They reported that the mean absolute error of the predicted UHR frequencies by the ResNet model was 3.664 bins when excluding additional inputs except for the observed electric field spectra observed by the Arase/PWE and labeled UHR frequency data. They also pointed out that additional features (orbital parameters and geomagnetic index) had almost no impact for the accuracy on the UHR frequency determined by CNN. In this study, we perform the further evaluations of the CNN-based UHR frequency determination from the point of view of science. We found that the error rate of the predicted UHR frequencies from the HFA spectra is less than 0.07 (7% of wave frequency) above 30 kHz. However, the error rate derived from the HFA spectra becomes worse when the wave frequency is below 10 kHz. We considered that this worsening shows a detection limit of UHR emissions due to the increasing of the noise level of the HFA receiver. On the other hand, the noise level in the overlapped frequency range (1-20 kHz) is smaller than the noise level of the HFA. We found that the error rate derived by the OFA spectra is better than the error rate derived from the HFA spectra in this frequency range. The best error rate was 0.07 at 8.41 kHz, while the error rate from HFA spectra was 27.7%.

[P-EM20] Recent Advances in Ionosphere Observation and Modeling through New Observation Opportunities

convener:CHIYEN LIN(Center for Astronautical Physics and Engineering, National Central University, TAIWAN), Yen-Jung Wu(Space Sciences Laboratory, University of California, Berkeley), Yang-Yi Sun(China University of Geosciences), Charles Lin(Department of Earth Sciences, National Cheng Kung University)

Rapid developments in space technology are advancing our understanding of ionospheric space weather by increasing a great number of ground- and space-based observations over the recent decades. In the ground segment, the dense ground-based GNSS networks, radars, and airglow instruments have greatly extended the observational coverages. In the space segment, the extraordinary satellite missions, such as FORMOSAT-7/COSMIC-2, ESA-SWARM NASA-ICON and -GOLD, providing a variety of observations all over the world such as airglow, temperature, neutral winds, current, ion drifts, plasma density that contribute to the understanding of middle and upper atmospheric dynamics. Increasing ground based observations are also important for coordinations with these satellite missions.
With the large amount and diversity of datasets, theoretical and empirical models can be validated, and implemented for inclusion of new thermosphere and ionosphere phenomena. Furthermore, remarkable breakthrough of data assimilation techniques advances the ionosphere monitoring and forecast.
The purpose of this session is to solicit studies providing observations, theoretical and empirical modeling and data assimilation on the multiple scales of ionospheric phenomena, from global morphology to small-scale irregularities and traveling ionospheric disturbances. Studies from magnetically quiescent to storm conditions as well as influences from lower atmosphere will also be solicited.

Compact Ionospheric Probe for CubeSat-based Science Missions

*Chi-Kuang Chao[1,2]

1. Graduate Institute of Space Science, National Central University, 2. Center for Astronautical Physics and Engineering, National Central University

Compact Ionospheric Probe (CIP) is an all-in-one ion sensor that can measure ion concentrations, velocity, or temperature in a time-sharing way. It is also capable of in-situ measuring ionospheric plasma density irregularities up to 1,024 Hz over a wide range of spatial scales. CIP is developed by National Central University (NCU) to occupy in a 0.7U form factor for CubeSat science missions. Currently NCU has completed all CIP design reviews and started production for sounding rocket and CubeSat missions. It is expected to be placed on a hybrid sounding rocket for a preliminary flight test at the middle of 2020 and then will be installed on INSPIRESat-1 and IDEASSat CubeSats for launch at the end of 2020. In this poster, CIP specifications will be outlined and some observations done by its predecessor, Advanced Ionospheric Probe onboard FORMOSAT-5 satellite, will also be presented.

Global Ion Density Distributions Observed by Advanced Ionospheric Probe Onboard FORMOSAT-5 Satellite

Pei-Cii Hong[1], *Chi-Kuang Chao[1,2]

1. Graduate Institute of Space Science and Engineering, National Central University, 2. Center for Astronautical Physics and Engineering, National Central University

A FORMOSAT-5 satellite has been launched on 25 August 2017 CST into a 98.28° inclination sun-synchronous circular orbit at 720 km altitude along the 1030/2230 local time sectors. The orbital coverage provides a great opportunity to survey terrestrial ionosphere from equatorial to polar region every two days. Advanced Ionospheric Probe (AIP) is a piggyback science payload developed by National Central University for the FORMOSAT-5 satellite to measure ionospheric plasma concentrations, velocities, and temperatures. It is also capable of measuring ionospheric plasma density irregularities at a sample rate up to 8,192 Hz over a wide range of spatial scales. In this poster, global ion density distributions observed by FORMOSAT-5/AIP in the pre-midnight sector can be averaged monthly and seasonally from in-situ measurement since November 2017. Wave-3 and wave-4 patterns are clearly detected from the distributions and varied with season and solar cycle. It is adversely indicated that FORMOSAT-5/AIP can provide high quality data to identify long-term ionospheric ion density variations.

Ionospheric responses on the 21 August 2017 solar eclipse by using three-dimensional GNSS tomography

*Chia-Hung Chen[1], Charles Lin[1], Akinori Saito[2], Mamoru Yamamoto[3], Susumu Saito[4]

1. Department of Earth Sciences, National Cheng Kung University, 2. Department of Geophysics, Graduate School of Science, Kyoto University, 3. Research Institute for Sustainable Humanosphere, Kyoto University, 4. Electronic Navigation Research Institute, National Institute of Maritime, Port, and Aviation Technology

In this study, we study the ionospheric responses on the August 2017 solar eclipse event by using a three-dimensional tomography algorithm with the ground-based GNSS (global navigation satellite system) total electron content observations around the Northern America. This three-dimensional ionospheric electron density structure from the tomography can provide us more information regarding to how the density variations and propagations are. Results show that the ionospheric electron density depletion triggered by the solar eclipse is distributed to all the altitudes. The most electron density depletion is around 40% compared with the previous day of solar eclipse. We further conduct a procedure of Fourier analyses to derive the vertical phase and group velocities of the electron density propagations. Results show that the opposite directions of the vertical phase and group velocities around 300 km altitude imply the energy source by the solar eclipse.

Traveling Ionospheric Disturbances Triggered by Typhoon Hagibis (2019)

*Yu-Chen Cheng[1], Charles Lin[1], Shih-Ping Chen[1], Min-Yang Chou[2]

1. Department of Earth Science, National Cheng Kung University, Tainan, Taiwan, 2. COSMIC Program Office, University Corporation for Atmospheric Research Boulder, CO, USA

The tropospheric severe weather system could affect the ionospheric plasma structure through triggering vertical propagating gravity wave disturbances. By analyzing receiving signals from Global Position System (GPS), we calculate the total electron content (TEC) to observe the corresponding ionosphere variations triggered by the severe weather events. On 11 October 2019, a series of traveling ionospheric disturbances (TIDs) generated by a strong typhoon Hagibis was observed in the ionosphere over Japan region. Over the central Japan, concentric TIDs (CTIDs) signature with periods 10-25 min, phase velocity 277.8m/s characters were observed. Over the Hokkaido area, north of the typhoon, another TIDs with the south-westward propagation was also observed. It has the concentric gravity wave characteristics of 10-25 min period and 500 km radius at 200 km altitude traveling for 103 minutes. Although the TIDs at the north has the characteristics of concentric gravity wave, it also has the property of medium scale TIDs (MSTIDs).

Study of Medium-Scale Traveling Ionospheric Disturbances in Low-Latitude Ionosphere Using an Automatic Algorithm

*Pin-Hsuan Cheng[1], Charles Lin[1], Hanli Liu[2]

1. Department of Earth Sciences, National Cheng Kung University, 2. University Corporation For Atmospheric Research

This study investigates the medium–scale traveling ionospheric disturbances (MSTIDs) and plasma bubbles statistically at the low–latitude equatorial ionization anomaly (EIA) region. To distinguish and categorize the MSTID and plasma bubble features, we apply both the three–dimensional fast Fourier transform (3D–FFT) and support vector machine. Statistical results together with COSMIC–1 RO data and the high–resolution Whole Atmosphere Community Climate Model (WACCM) indicate the following characteristics. First, the southward (equatorward) MSTIDs are observed almost every evening and morning during spring and winter. On the contrary, southward MSTIDs are more discernible at midnight in summer, majorly propagate from Japan, but least observed in autumn. Second, northward (poleward) MSTIDs are detected more frequently from noon to midnight in spring and summer with secondary occurrence rate peak in spring likely caused by atmospheric gravity waves (AGWs). Third, the occurrence rates of equatorial plasma bubbles in descending order are Spring, Fall, Summer, and Winter.

Short-term Variabilities of Wave-3 and 4 Structures in the Low-latitude Ionosphere

*Jia-Ting Lin[1], Charles Lin[1], CHIYEN LIN[2,3], P. K. Pedatella[1], Nicholas M Pedatella[4,5]

1. Department of Earth Sciences, National Cheng Kung University, Taiwan, 2. Center for Astronautical Physics and Engineering, National Central University, Taoyuan, Taiwan, 3. Graduate Institute of Space Science, National Central University, Taoyuan, Taiwan, 4. High Altitude Observatory, National Center for Atmospheric Research, Boulder, CO, USA, 5. COSMIC Program Office, University Corporation for Atmospheric Research, Boulder, CO, USA

In this study, the day-to-day variabilities of wavenumber-3 and 4 longitudinal structures in the ionosphere after the launch of FORMOSAT-7/COSMIC-2 (F7/C2) in July 2019 is investigated using the Global Ionosphere Specification (GIS). The GIS is based on implementation of assimilating 1500-1800 F7/C2 radio occultations (ROs) per day, in conjunction with ground-based global positioning system (GPS) TEC measurements with international reference ionosphere providing background electron density information. The most prominent components of wavenumber-3 and 4, the eastward propagating nonmigrating diurnal tide with zonal wavenumber 3 (DE3), diurnal eastward propagating nonmigrating tide with zonal wavenumber 2 (DE2), and stationary planetary wave 3 and 4 are examined. The results reveal that wave-3 and 4 tidal amplitudes change of 2-4 TECu (represent ~15-25% in background TEC value) regularly occur on very short timescales (~1–2 days) at the equatorial ionosphere anomaly (EIA) crests, it could be considered as the modulation of the E region dynamo. The strong asymmetries of wavenumber 4 occur around the maxium amplitude of the whole period in October, which implies the in-situ effects due largely to meridional neutral winds. Further, to investigate their relationship to the tidal wind field of this hypothesis, these results are compared to the Whole Atmosphere Community Climate Model (WACCM) using the Data Assimilation Research Testbed (DART).

Keywords: longitudinal structure in ionosphere, wavenumber-3 and 4, short-term variabilities of tides

Taiwan Radio Occultation Process System (TROPS) : Preliminary results of ionospheric products

*Wen-Hao Yeh[1], Cheng-Yung Huang[1], Kun-Lin Chen[1], Tzu-Pang Tseng[2], Hsu-Hui Ho[3], Jing-Mei Wu[4], Jyun-Ying Huang[3], Hsiu-Wen Li[4], Ching-Chieh Lin[3]

1. National Space Organization, National Applied Research Laboratories, Taiwan, 2. Geoscience Australia, Australia, 3. Taiwan Analysis Center for COSMIC, Central Weather Bureau, Taiwan, 4. GPS Science and Application Research Center, National Central University, Taiwan

Taiwan Radio Occultation Process System (TROPS) is a Taiwan-built data process system has developed by National Space Organization (NSPO), Taiwan Analysis Center for COSMIC (TACC), and GPS Science and Application Research Center (GPSARC). Presently, TROPS is used for data processing of FORMOSAT-7/COSMIC-2 (F-7/C-2) mission, which contains six low Earth orbit (LEO) satellites and launched in late June, 2019. F-7/C-2 is the follow on mission of FORMOSAT-3/COSMIC (F-3/C) mission, which also contains six LEO satellites to receive GPS signal for RO observation. F-3/C mission can provide around 1000 electron density profiles of ionosphere. F-7/C-2 mission can provide around 2000 electron density profiles of ionosphere due to F-7/C-2 satellites not only receive GPS signal but also GLONASS signal. In this study, the data performance and the validation results of preliminary ionospheric retrieve results of TROPS for F-7/C-2 will be presented.

GNSS observation of ionospheric variation due to perturbations near the Earth’s surface

*Yang-Yi Sun[1]

1. China University of Geosciences (Wuhan)

Both solar activity (e.g. solar flare, coronal mass ejection, and moon shadow) and perturbations from the lower atmosphere (e.g. cyclone, walker circulation, and El Niño - Southern Oscillation) and ground (e.g. earthquake, tsunami, and volcanic eruption) change the ionospheric structure. The ground- and space-based Global Navigation Satellite System (GNSS) is a powerful technique for capturing atmospheric variabilities in both horizontal and vertical directions at various altitudes, that help us to seek a deeper understanding of the solar-terrestrial environment. Other than the impact of solar activities, numerous ionospheric phenomena that result from perturbations from lower atmosphere and ground remain unexplained. This study first shows the effect of longitudinal distribution of convection, such as El Niño - Southern Oscillation (ENSO), on the quasi-biennial oscillation (QBO) from the stratosphere (U30 index) to ionosphere at low latitude. The ENSO signals in the QBOs at various altitudes are observed by the FORMOSAT-3/COSMIC radio occultation (RO) sounding profiles of temperature and electron density. The RO technique records ENSO signals which are pertinent to the ongoing study attempting to establish the long-term change in the troposphere connection to the upper atmosphere. Moreover, surface perturbations due to a large earthquake and tsunami can also significantly perturb the ionosphere. The horizontal movement of seismo-traveling atmospheric disturbance (STAD) in the ionosphere have been comprehensively observed by dense ground-based GNSS networks. However, evidence for the vertical component of STAD is rare. This study shows that the 2010 Mw8.8 Chile, 2011 Mw9.0 Tohoku, and 2015 Mw7.8 Nepal earthquake/tsunami can perturb the vertical structure of not only the ionosphere but also the stratosphere. The detection of STAD in the lower atmosphere and a more comprehensive understanding of STAD propagation in the whole atmosphere benefit to earthquake/tsunami early warning system.

Keywords: GNSS, ionospheric weather, surface perturbation

A multi-directional particle detector on HXMT

*Hong Guo Shen

The hard X-ray Modulation Telescope(HXMT) lunched on June 15, 2017 is the first special space science experiment project in China. HXMT operates in a low earth orbit with an altitude of 550km and an inclination of 43 degrees. The radiation of high-energy charged particles is an important environmental factor threatening the satellite and on-board payloads. Among them the background of the main detector (high energy detector which energy spectrum is 20~250keV) that the high-energy proton interacts with its material and the satellite material may affect the observation sensitivity of the telescope, and a large number of electrons and the secondary effects of electrons can also affect the working state of the main detector. The complex spatial distribution and dynamic changes of high energy charged particles are revealed by the results of the radiation environment detection of space charged particles carried out by low orbit satellites such as SAMPEX, NOAA and FY-1 in China. As the first orbit to carry out scientific exploration, HXMT satellite has not yet measured charged particle observation data.
As one of the payloads of the satellite, the newly developed multi-directional particle detector carries out the wide energy spectrum detection of high-energy electrons(0.2MeV~1.5MeV) and protons(3MeV~150MeV) in orbit space and the particle flux measurement from 16 directions covering 180 degrees. These observation data will provide more accurate dynamic data of orbital space particle radiation environment for the safe operation of HXMT satellite in orbit and the realization of scientific objectives, and also provide detailed data for future space environment modeling and in-depth space environment research.

New observations of the total electron content over Ho Chi Minh City

*Tam Dao[1,2], Minh Huy Le[3], Brett A Carter[1], Que Le[2]

1. SPACE Research Centre, School of Science, RMIT University, Australia, 2. Department of Physics, International University, Vietnam, 3. Institute of Geophysics, Vietnam Academy of Science and Technology (VAST), Vietnam

In January 2018, a Trimble NetR9 GNSS receiver was installed at Ho Chi Minh City International University (HCMIU), Vietnam National University, which is located at 10˚52' N, 106˚48' E in the geomagnetic equatorial region. This GNSS receiver continuously records data every 1s and 30 s every day over Ho Chi Minh City. From the obtained data, we estimated the total electron content (TEC) using the carrier-phase method which is a combination of code and phase measurements. The results present some features for the diurnal and seasonal TEC variations using this GNSS receiver during 2018 - 2019. The changes of TEC observed at HCMIU as well as other nearby stations and the same longitude region in the latest moderate geomagnetic storm G3 on August 2018 were investigated. Furthermore, we calculate the rate of change TEC index (ROTI) concerning time from the satellite signal phases. The distributions of ROTI over these two years of solar minimum show significant occurrences of scintillation, which are caused by small-scale ionospheric irregularities in the equatorial region during equinox months after sunset. The results presented indicate that the GNSS data recorded at HCMIU is a worthy reference dataset near the geomagnetic equator for further research about ionospheric monitoring.

[P-EM21] Surprises from the Subauroral Zone: Synthesizing Ground and Space-Based Observations and Theory

convener:Connors Martin G(Athabasca University), Kazuo Shiokawa(Institute for Space-Earth Environmental Research, Nagoya University)

Recent studies, including some facilitated by citizen science, have shown the subauroral ionosphere to be more active than previously suspected. Unusual emissions, from SAR arcs to STEVE, indicate previously little studied physical processes in this region. Some arise from conjugacy to the radiation belts, while others have origins which remain unclear. This session attempts to stimulate synthesis of observations from different domains to address phenomena which appear difficult to explain when examined from only one of the many new sources of information about the subauroral zone. Optical observations have expanded to include those with the very high resolution of amateur DSLR cameras, yet this sporadic source is well complemented by continuous observation from the few comprehensive subauroral observatories. As ever, conjugacy with spacecraft plays an important role in assessing possible sources of precipitation or waves that may stimulate the subauroral ionosphere, and there are indeed now many space assets (RBSP, Arase, THEMIS, MMS) with footprints at least sometimes in that region. Various polar-orbiting low-altitude satellites traverse it regularly. The installation of low-latitude poleward-looking incoherent scatter radars, with large fields of view in the subauroral zone, also provides context and the ability to extract physical parameters continuously. The sometimes-extreme conditions now known to exist in the subauroral region have stimulated theory to expand the parameter range needed to explain ionospheric phenomena. We welcome contributions integrating multiple sources of observation and theoretical approaches to hopefully transform what is initially surprising into a new view of an unsuspectedly active region.

Additional Coauthor: PWING Team (http://www.isee.nagoya-u.ac.jp/dimr/PWING/en/)

The PWING stands for “study of dynamical variation of Particles and Waves in the INner magnetosphere using Ground-based network observations”. This project is a 5-year project (2016-2020) by the Grant-in-Aid for Specially Promoted Research of the Japan Society for the Promotion of Science (JSPS) (16H06286). This project deploys all-sky imagers, induction magnetometers, VLF receivers, and broad-beam riometers at 8 stations at subauroral latitudes around the north-pole to cover longitudinal variation of aurora and electromagnetic disturbances in the inner magnetosphere. Details of the PWING project can be seen at http://www.isee.nagoya-u.ac.jp/dimr/PWING/PWING_web_e.htm. In this presentation, we review recent new results obtained by the PWING project at subauroral latitudes, particularly at Athabasca (ATH), Canada, (55°N, 247°E, magnetic latitude: 61.7N).

The pulsating aurora of January 27, 2017 as observed by e-POP, NOAA spacecraft, and ground assets

*Martin G Connors[1], Andrew W Yau[2], Kazuo Shiokawa[3], Claudia Martinez Calderon[3], Xinlin Li[4]

1. Athabasca University, 2. University of Calgary, 3. Nagoya University, 4. University of Colorado

The Cassiope/e-POP (now also known as Swarm-E) Canadian scientific satellite`s Fast Auroral Imager observed pulsating aurora with its infrared camera in two passes over North America on January 27, 2017. On one of these passes the Radio Receiver Instrument was also operating. The ground path of NOAA-19 was nearly coincident geographically with that of e-POP, although offset slightly in time. The most relevant ground instrumentation was the THEMIS ASI array which showed the pulsating aurora with 3 second cadence, and VLF receivers at Athabasca and Kapuskasing of the PWING project led by Nagoya University, and University of Calgary`s ABOVE VLF array. Both FAI and ground cameras show a distinct poleward border to the pulsating aurora, which lay between magnetic latitudes of approximately 64º and 68º. The MEPED instrument on NOAA-19 showed broad maxima in electron precipitation in the 40 and 130 keV channels, with distinct peaks in the loss cone electrons at several latitudes within the pulsating aurora zone. Chorus emissions were also observed in the VLF during the event. The footpoints of THEMIS A,D, and E were slightly poleward of the pulsating aurora when it was most active. A lack of wave activity there suggests that the mechanisms generating pulsating aurora were tightly confined to the region within about 10 Re of the Earth, which is consistent with where filled loss cones were observed by NOAA-19.

Stable Auroral Red (SAR) arc has been studied for more than half century since its academic discovery in Southern France in 1958 as one of the typical optical features occasionally seen at subauroral latitudes. Generation mechanism of the SAR arc is related to storm-time interactions at the overlapped region between the plasmasphere and the ring current. Thus most events have been found out of the auroral oval such as ~60 deg in geomagnetic latitude. In this study, however, we will present a SAR arc event at 68 deg geomagnetic (71 deg geographic) north in the Scandinavian sector during period of geomagnetically quiet condition of Kp = 0+. The SAR arc, which was captured with cameras (630 nm) at Abisko and Kirpisjärvi, appeared coinciding with a pseudo substorm onset at 71-72 deg geomag. N and rapid equatorward expansion of the polar cap potential estimated with the SuperDARN. However, the SAR arc disappeared in about 7 minutes along with a sudden shrinking of the polar cap potential. Conjunction measurement with the Swarm A/C suggests that the SAR arc was located at poleward slope of the ionospheric trough or slightly its outside. These experimental evidences suggest that, in the early stage of this SAR arc generation, the magnetosphere compressed the ring current region inward, resulting in a contact of the ring current region to the plasmasphere but expansion of the polar cap potential was too short to coalescent the ring-current hot ions and plasmaspheric electrons at the plasmapause, which corresponds to the trough minimum in the ionosphere.

National Institute of Polar Research

Stable auroral red (SAR) arc is an aurora with dominant 630.0-nm emission of oxygen atoms generated at subauroral latitudes slightly lower than the aurora oval. SAR arcs were first reported in southern France [Barbier, 1958] and have long been investigated since then. Precipitating electrons (or heat flux) of ~several electronvolts (eV) have been considered as the source of SAR-arc emissions. Kozyra et al. [1997] noted that there were three possible mechanisms to generate these low energy electrons. The first hypothesis is the Coulomb collision between plasmaspheric electrons (energies less than 1 eV) and ring current ions (several tens of keV) [e.g., Rees and Roble, 1975; Kozyra et al., 1987]. The energy is transported into the ionosphere via heat conduction or as a low energy electron flux [e.g., Cole, 1965; Prolss, 2006]. The second hypothesis is that the Landau damping of electromagnetic ion cyclotron (EMIC) waves causes heated electrons and their pitch angle scattering and precipitation into the ionosphere [Cornwall et al., 1971]. The third is that the kinetic Alfven wave with the parallel electric field to the magnetic field accelerates plasmaspheric electrons to the ionosphere. In our previous study, we reported the first conjugate observation of a SAR arc on March 28, 2017 using an all-sky imager and the Arase satellite [Inaba et al., JpGU (PEM13-P14), 2019; Inaba et al., SGEPSS (R006-27), 2019]. We confirmed that EMIC or kinetic Alfven waves associated with the SAR arc were not observed by the Arase satellite and concluded that Coulomb collisions between ring-currrent protons and plasmaspheric electrons are the main cause of SAR arc generation. In this presentation, we show a new conjunction event of a bright Stable Auroral Red (SAR) arc observed by a ground-based camera and the Arase satellite on 4 November 2019. The conjunction was obtained at the time when the arc was detached equatorward from the main auroral oval. Similar to the previous event, the Arase satellite was near the plasmapause and in ring current at the crossing of the detaching SAR arc. However, Arase observed both electron and proton flux enhancements at energies below 1 keV near the magnetic equator over the bright detaching SAR arc (~1 kR). On the basis of these facts, we discuss the difference of particle and field characteristics between the newly-detached, bright arc on 4 November 2019 and the somewhat stable, faint arc on 28 March 2017.

Spatial-temporal variations of the SAPS structure with recurrent period of a few minutes observed by the SuperDARN HOP radars

*Nozomu Nishitani[1], Tomoaki Hori[1], Mariko Teramoto[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Kyushu Institute of Technology

Super Dual Auroral Radar Network (SuperDARN) is a powerful tool for monitoring ionospheric plasma convection not only at high latitudes, but also at sub-auroral and mid- latitudes. The SuperDARN Hokkaido Pair (HOP) of radars are 2 mid-latitude SuperDARN radars, located at the lowest geomagnetic latitude (36.9 degrees) at present. In this paper, the SuperDARN Hokkaido Pair (HOP) of radars data with special operation modes are used to study the spatial-temporal structure of the wavy variations of plasma flow with recurrent period of a few minutes embedded in larger-scale, fast flow structures at subauroral latitudes (SAPS). We focus mainly on the events on Sep 08, 2017 and Aug. 26, 2018, both of which occurred near the peak of large geomagnetic storm (minimum Dst: -124 nT and -174 nT). These events were recorded by the SuperDARN radars with higher temporal resolution (3 and 12 seconds respectively) camping beams. Using both camping beam data and 2-dimensional data (with 1 to 2 min temporal resolution) enable us to examine the period, wavelength and propagation speed of these wave structures. In addition, using the data with the new fitting algorithm (fitacf Ver. 3) we have more extended coverage of the echo regions. The wave structures have limited spatial extent in magnetic local time. On the other hand, there are several differences between these events such as period, propagation speed and geomagnetic latitude. Their possible generation mechanisms will be discussed.

Keywords: SuperDARN, SAPS, wave variations

New curiosities observed from ground-based data: KHF-VLF Emissions

*Claudia Martinez Calderon[1], Jyrki Manninen[2], Tauno Turunen[2]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Sodankylä Geophysical Observatory, University of Oulu, Sodankylä

Thanks to the implementation of sferics filtering above f = 4 kHz, a previously unknown strange spectral world of differently structured high-frequency waves has been observed on the ground station of Kannuslehto (KAN, MLAT=64.4˚N, L=5.46). These type of signals were first reported reported by Manninen et al. 2016 using using 1-hour spectrogram, where they often resembled 'sticks' or 'wands'. However, looking more closely they seem to be mostly composed of hiss bursts with durations of a few seconds. An example of two observations made by KAN is shown in Figure 1. These high frequency VLF emissions have been named KHF-VLF, standing for Kannuslehto High-Frequency VLF.

During campaigns where KAN was active between 2006 and 2015, they KHF-VLFs were observed during 60 to 90% of all campaign days. KHF-VLFs were often detected during the winter campaigns in the period between 2016 and 2019. We noted that when solar activity was high KHF-VLFs were observed very regularly. For example, during the winter 2014-2015 campaign, they were observed on 52 days out of 59, and in winter 2015-2016 on 75 days out of 91.

While these type of emissions are clearly observed quite often, currently there are no statistical studies on the occurrence and properties of these waves. Here, we will present the main characteristics of KHF-VLF emissions, their latest observational results from KAN data, as well as discussing observations at other VLF ground-stations and/or satellites in the inner magnetosphere.

[E] Poster | P (Space and Planetary Sciences)：P-AE Astronomy & Extrasolar Bodies

[P-AE22] Exoplanets

convener:Masahiro Ikoma(Department of Earth and Planetary Science, The University of Tokyo), Norio Narita(The University of Tokyo), Yuka Fujii(National Astronomical Observatory of Japan)

Exoplanetary science, which began with the discovery of a hot Jupiter in 1995, reached a significant turning point by the detection of countless super-Earths by the Kepler space telescope. In 2018, the new space telescope TESS was launched to conduct an extensive survey of exoplanets orbiting nearby bright stars, opening a new era of characterization of exoplanet atmospheres. Moreover, recent observations have identified a growing number of terrestrial planets in the so-called habitable zone. While exoplanets have been targeted mainly for astronomy until recently, it would be fair to say that Earth and planetary science is finally becoming a research field to make a central contribution. This session aims at allowing participants to share their research results and new ideas regarding exoplanets and also inform the current status of their projects. Exoplanet science is a growing, interdisciplinary research field. We welcome participants from various fields.

Climate for land planets

*Takanori Kodama[1]

1. University of Bordeaux

Most of the studies for habitable planets focus on the boundary of the habitable zone in which a planet can maintain liquid water on its surface for a long term. Previous studies assumed a planet with a large amount of water on its surface. However, exoplanets should have various amounts of water on their surface.

Kodama et al. (2019) showed the relationship between the insolation at the inner edge of the habitable zone and the water distribution on a planetary surface. A land planet that has a small amount of water on its surface can maintain liquid water when it receives stronger insolation than that at the inner edge of the habitable zone for a planet with a large amount of water.

In this presentation, we summarize the climate for a land planet and show the results for TRAPPIST-1 d as a land planet.

The Numerical Simulation for Detecting Atmospheric Oxygen on Exoplanets Around M and K Stars.

*Toru Muraoka[1], Osada Naoya[1], Shingo Kameda[1], Go Murakami[2], Norio Narita[3], Masahiro Ikoma[4], Hitoshi Fujiwara[5]

1. Rikkyo University, 2. Institute of Astronomical Science, Japan Aeronomy Exploration Agency, 3. National Astronomical Observatory of Japan, 4. Tokyo University, 5. Seikei University

To date, more than 4000 exoplanets have been detected. In recent years, thanks to the activities of probes such as Kepler and TESS, study on terrestrial planets in the habitable zone (HZ) around M-type and K-type low-mass, low-temperature stars has been advanced. Characterization of such a habitable exoplanet requires Transit spectroscopy and the detection of a planet's atmospheric elements. However, in general, the detection of planetary atmospheric elements other than hydrogen is difficult owing to their small distribution compared to the size of the planet. M and K stars are relatively active and emit strong UV radiation. An oxygen-rich, carbon dioxide-poor (i.e., Earth-like) atmosphere of a planet located in such a star's HZ would get heated by ionization and dissociation and expand to significant size compared to the planetary radius [Kulikov et al., 2007, Tian et al., 2008b]. The World Space Observatory-UV (WSO-UV) is a multi-national space telescope project, led by Russia, to be launched in 2025. The key scientific objective would involve studying extrasolar planetary atmospheres in the presence of strong UV radiation fields. In this study, we simulated Earth’ s atmosphere by considering that the Earth was placed in the HZ of M and K stars. Furthermore, we estimated the possibility of detecting oxygen by means of simulated transit spectroscopic observations.

Prevalence and extent of magma oceans in rocky bodies

Diogo Lourenço[1,2], *Matthieu Laneuville[1]

1. Earth-Life Science Institute, Tokyo Institute of Technology, 2. University of Califorinia, Berkeley

It is well accepted that the Earth and most rocky bodies in the Solar System went over a magma ocean stage during and immediately after their accretion (e.g., Tonks and Melosh, JGR 1993; Elkins-Tanton, Annu. Rev. Earth Planet. Sci. 2012). Based on this, it is generally assumed that magma oceans are common and widespread throughout the Universe, and that they exist throughout all the accretion stage of different bodies. Another common assumption made is that magma oceans extend deep inside the bodies and cover their entire surface. However, how frequent magma oceans are, and how deep do they extend, is not well constrained. In this work, we aim to understand the factors that control the formation duration of magma oceans, and the conditions that lead to deep ones. Understanding these questions is of extreme importance, as a magma ocean sets up the conditions for future mantle dynamics and tectonic activity, the composition of the atmosphere, and the possibility for the existence of oceans, and life.

We present a model that computes the extent of melting in a planet by taking into account the input of energy from impacts during accretion, and output of energy from radiative cooling of a magma ocean. We test two ways of taking into account the energy input due to impacts: (1) a parameterized distribution of impactors' distribution and energy, following Shibaike et al., (Icarus, 2016) and (2) using frequency and intensity of impacts extracted from N-body simulations (e.g., de Vries et al., PEPS 2016). Furthermore, we will show how the results are affected by: (1) how opaque the atmosphere is, (2) different impacts histories and accretion times, and (3) how the energy of a single impact is distributed in the interior of the body, i.e, does the melt generated spread out evenly across the globe as assumed by, for example, de Vries et al. (PEPS 2016), or the magma ocean generated has different depths at different locations around the planet as predicted by Reese and Solomatov (Icarus, 2006) for higher solid mantle viscosities.

Exploring Super-Earth Surfaces: Albedo of Near-Airless Magma Ocean Planets and Topography

*Yuichi Ito[1], Darius Modirrousta-Galian[2,3], Giuseppina Micela[2]

1. University College London, 2. INAF - Osservatorio Astronomico di Palermo, 3. University of Palermo

We propose an analytic function for the bond albedo of an airless or near-airless magma ocean planet (AMOP). We generated multiple 1D fractal surfaces with varying compositions unto which we individually bombarded 10,000 light rays. Using an approximate form of the Fresnel equations we measured how much of the incident light was reflected. Having repeated this algorithm on varying surface roughnesses we find the albedo as a function of the Hurst exponent, the geochemical composition of the magma, and the wavelength. As a proof of concept, we used our model on Kepler-10 b to demonstrate the applicability of our approach. We present the albedos of different lava compositions and multiple tests that can be applied to observational data in order to determine their characteristics. Currently, there is a strong degeneracy in the surface composition of AMOPS due to the large uncertainties in their measured albedos. In spite of this, when applied to Kepler-10 b we show that the high albedo could be caused by a moderately wavy ocean that is rich in oxidised metallic species such as FeO, Fe2O3, Fe3O4. This would imply that Kepler-10 b is a coreless or near-coreless body.

How does the nodal precession affect observations of hot Jupiters around A-type stars?

*Noriharu Watanabe[1], Norio Narita[2]

1. The Graduate University for Advanced Studies, SOKENDAI, 2. Astrobiology Center

More than 4,000 exoplanets have been found. Even though most of these discovered exoplanets are orbiting around Solar-type (F/G/K type) stars, there are also a small number (~20) of exoplanets, most of them are hot Jupiters, around hot (B/A type) stars. Despite the small number, we have known that they tend to have a wide range of projected spin-orbit obliquities, the apparent angle between the stellar spin axis and the planetary orbital axis. Because hot stars are rapidly rotating in general, they make themselves more oblate. When a planetary system satisfied these two conditions, the misaligned orbit and the flatten host star, its orbital nodal precession occurs. The nodal precessions of two planets have been reported so far: Kepler-13Ab (Szabó et al. 2012) and WASP-33b (Johnson et al. 2015), both of which are orbiting around A-type stars. Especially, Watanabe et al. (2020) found that the nodal precession period of WASP-33b is ~840 years and this hot Jupiter transits in front of the host star for only ~20% of the whole precession period. In this research, we focused that how the nodal precession affects observations of hot Jupiters around A-type stars by theoretical models.

Zhou et al. (2019) estimated the occurrence rate of hot Jupiters around A-type stars 0.26±0.11% from the TESS sample, which is a little lower than rates of F/G type stars (F-type star: 0.43±0.15%, G-type star 0.71±0.31%). However, this previous study did not consider orbital nodal precession around A-type stars. Thus, we have calculated how the occurrence rate of hot Jupiters around A-type stars changes when the precession is applied. First, we formulated the ratio between the period for transiting in front of a host star and the orbital nodal precession period (ε). Then, we simulated 100,000 models of planetary systems of a hot Jupiter and an A-type star. In this simulation, we set values of essential parameters randomly based on the detected values of hot Jupiters around A-type stars. In general, the possibility of planetary transit almost equals to the ratio of the sum of the ratio of the stellar radius to the semi-major axis to the number of samples, but the possibility should be calculated by the sum of ε when the orbits are precessing. However, we derived that the possibility of planetary transit of hot Jupiters is 17.8% whether we consider the nodal precession or not. Therefore, the nodal precession does not affect the occurrence rate of hot Jupiters around A-type stars.

We also calculated how many orbits of hot Jupiters enter and leave in front of hot stars for ten years. First, we derive we computed the precession speeds of 100,000 models using equations from Barners et al. (2013) and Iorio (2010). Then, we simulated the ten-year-changes of impact parameters of all simulated models. As a result, ~2,500 models begin to transit their host stars as viewed from the Earth, other ~2,500 models finish transiting, and ~120 planetary orbits pass through their stellar disks for ten years. We have also found that there are a few hot Jupiters whose trajectories will depart from their stellar disks even though their impact parameters are almost zero. This simulation shows that the transit possibility is stable but perhaps a part of detected hot Jupiters will be disappeared after ten years later. Consequently, we should observe a hot Jupiter around a hot star continuous by Doppler tomography, a method to measure projected spin-orbit obliquity and impact parameter, and estimate how its transit trajectory is shifting and when it will end to transit.

WASP-76 b: A Tale of Two Spectra

*Billy Nelson Edwards[1], Quentin Changeat[1], Robin Baeyens[2], Angelos Tsiaras[1], Ingo Waldmann[1]

1. University College London , 2. Instituut voor Sterrenkunde, KU-Leuven

The Hubble Space Telescope’ s Wide Field Camera 3 (WFC3) has been widely used for transmission and emission spectroscopy of exoplanet atmospheres, identifying the main molecular constituents, detecting the presence of clouds and probing their thermal structure. Hubble observations of the emission spectra of a number of ultra-hot Jupiters have led to somewhat surprising results. Initially, these very hot planets were predicted to have inverted temperature pressure profiles due to strong optical absorption by TiO/VO in the upper atmospheres. However, observations of their emission spectra have been inconclusive on their thermal structure and composition. While some datasets show rich spectral features, others can be fit with simple blackbody models.

I will present the analysis of the Hubble transmission and emission spectra of WASP-76 b, an ultra-hot Jupiter with a day-side temperature of ~2500 K. The data was reduced and fitted using the open-source codes Iraclis and TauREx3. Previous studies of the WFC3 transmission spectra of WASP-76 b found hints of TiO and VO or non-grey clouds. Accounting for a fainter stellar companion to WASP-76, we reanalyse this data and show that removing the effects of this background star changes the slope of the spectrum, resulting in these visible absorbers no longer being detected, removing the need for a non-grey cloud model to adequately fit the data but maintaining the strong water feature previously seen. However, our analysis of the emission spectrum suggests the presence of vanadium oxide (VO) and an atmospheric thermal inversion, with tentative evidence for titanium oxide (TiO) and a muted water (H_2O) feature.

A feasibility study on the detection of molecular species in exoplanet atmospheres by high-resolution transmission spectroscopy with SPICA/SMI

*Kawauchi Kiyoe[1], Yui Kawashima[2], Teruyuki Hirano[3], Yuka Fujii[4], Taro Matsuo[5], Kazumasa Ohno[3], Ayaka Okuya[3]

1. University of Tokyo, 2. SRON - Netherlands Institute for Space Research, 3. Tokyo Institute of technology, 4. Earth-Life Science Institute, Tokyo Institute of technology, 5. Nagoya University

Spectroscopic observations during planetary transits allow us to probe atmospheres of exoplanets (so-called "transmission spectroscopy").
In particular, high-resolution spectroscopy (R>20,000) has been proved to be one of the most powerful tools to directly investigate specific atoms/molecules in exoplanet atmospheres.
At optical wavelengths, alkali metals (i.e., Na and K) and Hα lines have been traditionally studied by ground-based telescopes (e.g., Casasayas-Barris et al. 2018, Gibson et al. 2018). In more recent studies, atoms and molecules, such as He and CO, were also detected by near-infrared high-resolution spectroscopy (e.g., Salz et al. 2018, Brogi et al. 2016), but more molecules in exoplanet atmospheres are still awaiting detections by current and future instruments.
Rich features and absorption bands of many molecules, which are important to understand the planet formation and evolution, are also located in the mid-infrared region (>5 micron); for instance, disequilibrium species such as HCN and C2H2 are crucial in the context of testing scenarios of UV irradiation and atmospheric mixing on exoplanets. However, detections of those molecules in the mid-infrared are unfeasible with observations from the ground, due to strong background emissions. Those molecules are expected to be detected by future observations from the space, such as by the JWST and SPICA missions.
In order to conduct a feasibility study on the detections of those molecules by future space missions, we performed a series of numerical simulations for high-resolution spectroscopy in the mid-infrared, taking into account the expected instrumental properties and background noises.
We specifically focused on SPICA/SMI observations, which provide us a unique opportunity to perform mid-infrared high-resolution spectroscopy. In this presentation, we will report on the results of our simulations and discuss the prospect to study exoplanet atmospheres using mid-infrared spectroscopy.

Characterizing exoplanets with low-frequency radio observations

*Yuka Fujii[1], Keitaro Takahashi[2], Tomoki Kimura[3], Jun Hashimoto[4], Yuhiko Aoyama[5], Yuta Shiohira[2], Yuka Terada[6], Hajime Kita[7], Fuminori Tsuchiya[3], SKA-JP planet team

1. Earth-Life Science Institute, Tokyo Institute of Technology, 2. Kumamoto University, 3. Tohoku University, 4. National Astronomical Observatory of Japan, 5. Tsinghua University, 6. University of Tokyo, 7. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

While characterization of individual exoplanets is often performed in the ultraviolet, optical, and infrared domains where the main observables are the atmospheric properties, low-frequency radio observations would serve as a complementary approach to characterize certain aspects of planets, mainly associated with the magnetospheric and ionospheric properties. With the Square Meter Array (SKA; around 0.1-10 GHz) being built, we explore the potential of SKA observations for characterizing various types of exoplanets as a part of SKA-JP science working group.

One of the recognized scientific goals of SKA is to search for the auroral emissions from exoplanets, which can constrain the planetary magnetic field strengths (e.g., Zarka 1997). A number of observations have been conducted so far, but no clear evidence has been obtained yet (e.g., Grießmeier et al., 2017 and references therein). We discuss the synergies with transit observations (due to the anisotropy of emission), direct imaging observations of young massive planets (for constraining the internal structure or the magnetic scaling laws by, e.g., Christensen et al., 2009), and gravitational microlensing observations (with the characteristic magnification curves; Shiohira et al., submitted). We also discuss the auroral radio generation by the pair of a close-in rocky planet and the host star via a mechanism similar to Io-Jupiter system as a probe of the planetary ionospheres.

A radio source observed through an exoplanet atmosphere (i.e., transmission observations in the radio domain) would be another opportunity to study the planetary magnetic fields as well as the surrounding plasmas, through the Faraday rotation and the time delay (Withers & Vogt 2017). This can be tested with Jovian magnetosphere passing in front of distant pulsars. We find that such events occur about 0.5 times/year on average, and SKA will have a sufficient sensitivity to detect the effects of Jovian magnetosphere.

Lastly, we argue that the gas-accreting proto-planets being formed in the protoplanetary disks emit the radio recombination lines (RRL) that are detectable with SKA, as estimated based on Aoyama et al., (2018). Compared with the tracers of the accretion processes at the shorter wavelengths (e.g., Hα; Haffert et al. 2019), RRL will be more sensitive to the (proto-)planets in young, optically thick disks, due to the reduced extinction efficiency. Detecting RRL would be critical to identify the very birthplace of the gaseous planets as well as to constrain the geometry and the rate of the planetary gas accretion at the early phase.

The evolution outcome of the planetary systems predicted from the observed protoplanetary disk of HL Tau

*Shijie Wang[1], Kazuhiro Kanagawa[1], Toshinori Hayashi[1], Yasushi Suto[1]

1. University of Tokyo

The ring/gap substructure of HL Tau has been intensively studied. Conventionally, it is interpreted as a result of unseen massive planets located inside the gaps. Motivated by this interpretation, we carried out N-body simulations to evolve the HL Tau planetary system from the current configuration to eventually 10 Gyrs after the disk dispersal. At the disk phase, we implement both planetary migration and mass growth effects coupled with the evolution of the disk profile. By varying the disk parameters, we produced a variety of widely-separated planetary systems consisting of three super-Jupiters at the end of the disk dispersal. We showed how the final configuration and planetary mass depend on disk parameters. We found no planet-pair has a period ratio less than 2.1 due to convergent migration. We continue integrating the orbits up to 10 Gyrs after the disk dispersal using pure gravitational N-body simulations. Most of the systems are found to be stable for at least 10 Gyr in only marginal resonance state. We discuss implications of our results in terms of the observed widely-separated planetary systems HR 8799 and PDS 70.

Stability of resonant trapping of planetesimals during the migration of a giant planet

*Sho Shibata[1], Masahiro Ikoma[1]

1. Graduate School of Science, The University of Tokyo

Recently revealed close-in exo-gas-giants contain much heavy elements. Standard planetary formation theory cannot explain the origin of their heavy elements, however, the capture of planetesimals via planetary migration might be a source of those heavy elements. We focus on the resonant trapping, which has an important role for the accretion of planetesimals. The stability of resonant trapping, which means how strongly the resonance keep trapping planetesimals under perturbations, like collisions and gravitational interactions between planetesimals, is still not clear. In this study, we investigate the stability of resonant trapping using numerical integration of planetesimals. We expands an analytical equations for resonant trapping obtained by Malhotra 1993. We discuss the relation between the stability of resonant trapping and heavy elements contained in close-in gas giants. Our results would be important for discussing other problems related with resonances, like satellite formation or asteroid distribution in our solar system.

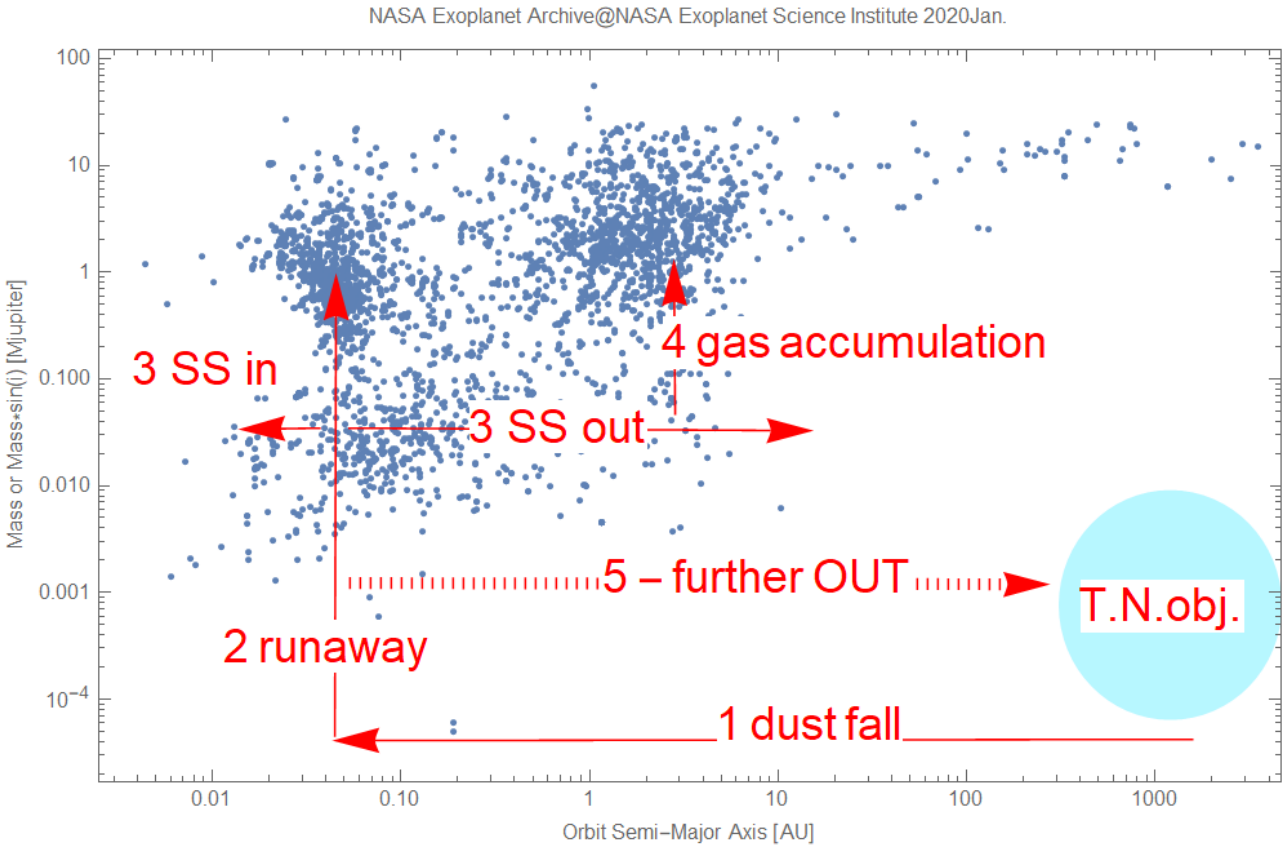
Variety of Planets from the Outer Edge of the Inner Hole

*Masahiro Morikawa[1], Suzuka Amaya[1]

1. Department of Physics, Ochanomizu University

Planets are very common objects in the Universe. This is already evident from recent discoveries of thousands of exoplanets. However, the standard theory of their formation encounters many notorious difficulties, such as the dust/planet fall and the disk lifetime problems. We do not try to avoid each problem but accept and use all of them positively to find a natural scenario that all these problems indicate.

All the falling problems indicate that dust falls, by the dissipation with gas, toward the central star. All the time scale problems indicate that the relevant processes of planet formation should be rapid. Therefore, **there must be a void of gas very inside**, say at radius 0.04 AU, and the falling dust must stop there at the outer edge of this inner hole. This is our first assumption, without specifying any Physical processes such as MRI, co-rotation instability, photoevaporation, or whatever. Then the following processes, 1 to 5, take place in the sequence, which naturally yields the variety of planets we observe today(Fig.1).



Dust and dust clusters fall toward the center but stops at the edge of the inner hole and accumulate there. We analytically estimate the size-dependent falling time scales. They may be very short such as several hundred years. Turbulence and frequent destructive collision, with dissipation, on the common Kepler orbit, promote their coalescence. **The dense and coherent motion of dust at the edge of the inner hole induces the runaway growth of several huge planets of size Jupiter.** This species is the Hot-Jupiters. This orbit is too close to the center and Hot-Jupiters may not be stable. However, this runaway time scale is short and several hundred years based on the standard disk model parameters. **These massive planets at the outer edge slingshot dust clusters inward and outward.** This stage of evolution is essential to yield a variety of planet species. Small dust clusters of size less than 10 Earth-mass are shot in and out, but cannot effectively accrete gas, and the size of them cannot grow. This species is the Rockey-Planets. They can be shot widely to 0.01AU to 1000 AU. On the other hand, dust clusters of size more than 10 Earth-mass can be shot up to 0.4AU by one Jupiter (pure three-body system) and 1 to 100 AU by two Jupiters (pure four-body system). These shot planets would migrate toward the center but shot again outward; the migration problem does not arise since the planets are always dynamical objects regulated by the outer edge of the inner hole. **Large dust clusters of size more than 10 Earth-mass shut outside can effectively accrete gas**, and the size of them can grow while the gas exists there. In this process, their initially large eccentricity dramatically reduces by acquiring the angular momentum of the gas. This species is the Cold-Gas-Giants or Ice-Giants, depending on the distance blown. They form gap and spiral structures on the planetary disk. **Much smaller dust clusters can be shot very far and become the seeds of `Trans-Neptunian Objects`,** including `Kuiper Best` of exoplanet systems. The dust cluster of 10^{12}Kg, for example, can be shot 100 to 1000AU within a time scale of 5000 years. Their orbital inclination can easily exceed 30 degrees. Furthermore, the eccentricity of them sometimes exceeds one. Therefore, a vast number of stray objects in the interstellar space can be produced.

We verify our model based on the basic predictions of the model.
a) All the cores of the planets, as well as small diffuse objects, are made from a common ratio of materials. This is because all the planet cores are formed at the outer edge of the inner hole as a mixture of falling

©2020. Japan Geoscience Union. All Right Reserved.

dust.
b) These core materials had experienced a thermal metamorphosis in the past. This is because all the planet cores are formed at the outer edge of the inner hole near to the central star. The temperature can easily rise to 2000 K there, which is enough to yield thermal metamorphosis.
These properties also apply to the `Trans-Neptunian Objects`. The study on comets and meteorites of our solar system may provide some information for our model.

Orbital evolution of close-in super-Earths via atmospheric escape

*Naho Fujita[1], Yasunori Hori[2], Takanori Sasaki[1]

1. Department of Astronomy, Kyoto University, 2. Astrobiology Center, National Institutes of Natural Sciences

Recently, a lot of super-Earths close to their host stars have been discovered especially around M dwarfs. Orbital distributions of planets in multiple close-in super-Earth systems are different each other. The mass-radius relationship of the super-Earths indicates that some of them have a substantial atmosphere, while others have almost no atmosphere. The origin of these differences remains unclear.

Close-in super-Earths would undergo atmospheric escape via the energy-limited hydrodynamic escape driven by stellar X-ray and UV irradiations. Considering the angular momentum exchange of a system, the super-Earths those experience atmospheric escape and lose their mass must move outward. However, little attention has been given to the orbital evolution of the planets due to the mass loss by hydrodynamic escape of their atmosphere.

In this study, we aim to gain a better understanding of the origin of multiple close-in super-Earth systems by calculating the atmospheric mass loss and the orbital evolution of the planets. We also aim to make theoretical predictions for the future observations of super-Earths around M dwarfs.

Keywords: super-Earth, atmospheric escape, orbital evolution

Bayesian inference of occurrence rates of super-Earths in systems with cold-Jupiters around low-mass stars

*Masahiro Ogihara[1], Hiroki Harakawa[2]

1. National Astronomical Observatory of Japan, 2. Subaru Telescope

Transit observations of exoplanets with space telescopes (e.g., Kepler) have revealed an abundant class of close-in super-Earths (SEs). The occurrence rate of giant planets in wide orbits (also known as cold Jupiters or CJs) can be studied using the data obtained via radial velocity (RV) observations, which have been conducted for more than 20 years. As the occurrence rates of SEs and CJs are estimated, the correlation between SEs and CJs can also be discussed. According previous studies, it is likely that CJs coexist with SEs, and this is expressed by a high conditional probability P(SE|CJ) of about 90%.

Recently, observations of super-Earths around low-mass stars have attracted increasing attention. In fact, several new RV surveys of M dwarfs have been initiated; these operations include IRD-SSP with the Subaru telescope and CARMENES. We are interested in whether the conditional probability of P(SE|CJ) is also high around M dwarfs.

In this study, we present an estimate of the conditional probability of P(SE|CJ) around M dwarfs using Bayes' inference. We find that the conditional probability of the existing SEs under the existence of CJs is quite high even around M dwarfs. We also discuss whether the existence of CJs enhances the growth of SEs. It is likely that the high conditional probability of P(SE|CJ) is simply a reflection of the high amount of solids available for planet formation. For a more robust discussion, more RV observation data are needed. In addition, dynamical simulations that include the effects of CJs on SEs are also required.

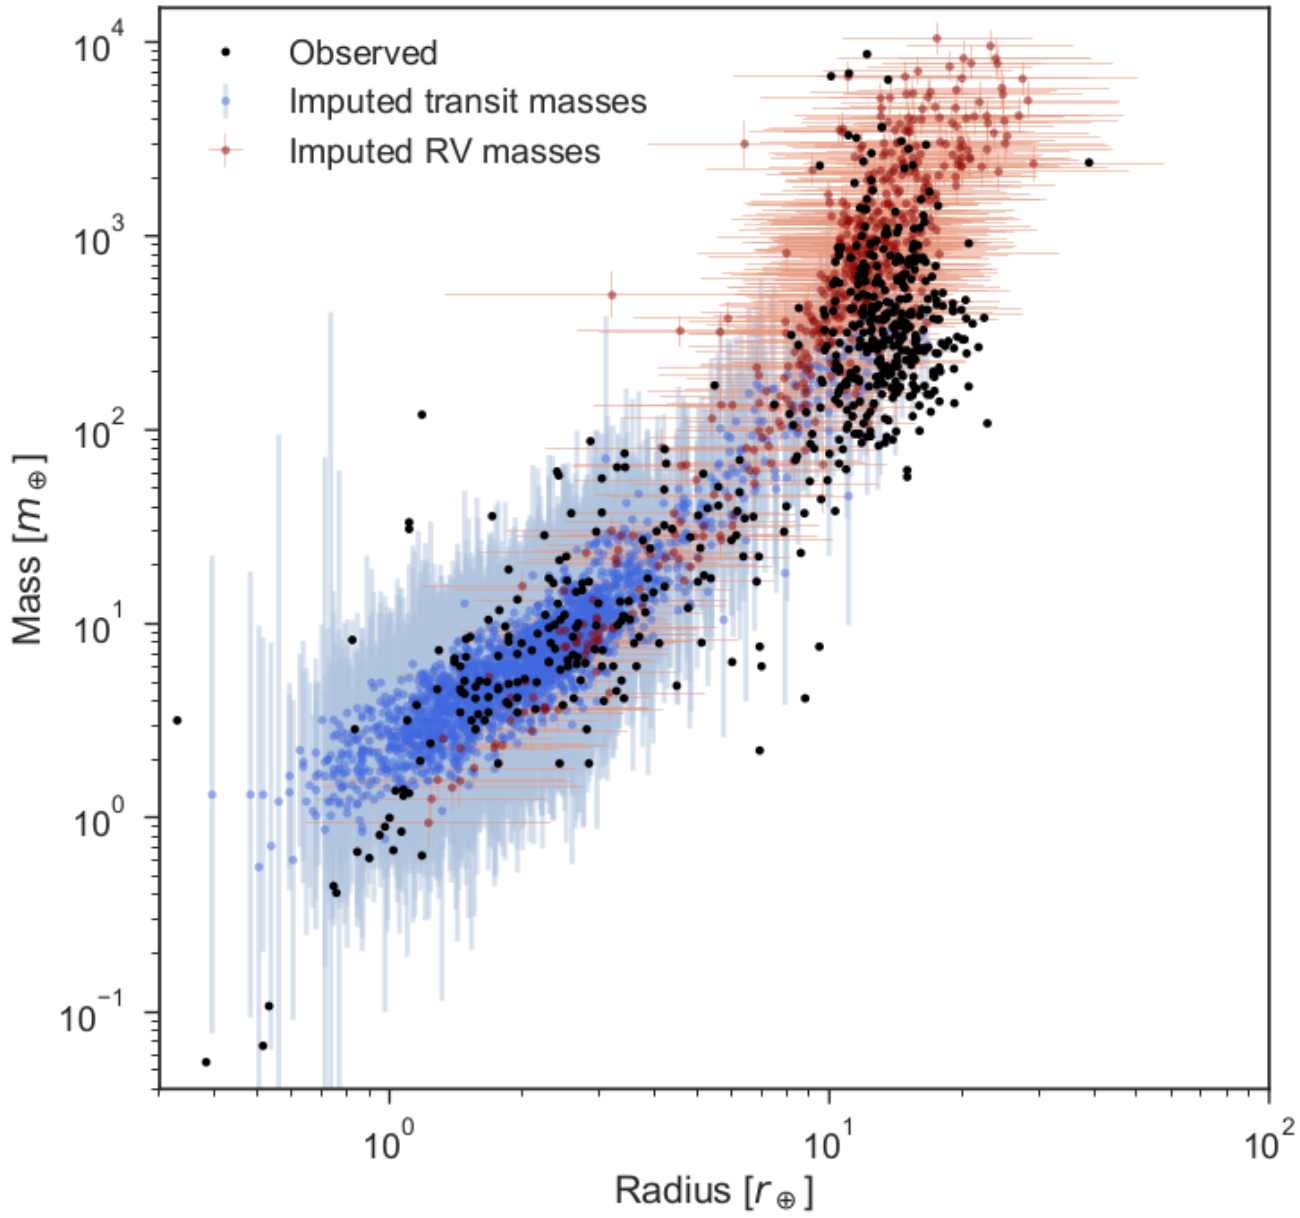
Filling in the gaps: imputing the missing properties of exoplanets with machine learning

*Elizabeth Tasker[1], Matthieu Laneuville[2], Nicholas Guttenberg[2]



1. Institute of Space and Astronautical Science (ISAS), JAXA, 2. Earth-Life Science Institute (ELSI), Tokyo Institute of Technology

Understanding planet formation requires a large statistical sample. However, while the total number of extrasolar planets discovered is large, the known properties of individual worlds remains sparse. This issue cannot be resolved by more observations alone. Measurable planet properties depend on detection technique, but multiple detections are frequently impossible: a situation likely to degrade still further as we probe smaller worlds on longer orbits. One solution is to impute missing properties based on the current known distribution. In this talk, I will present one method for such an interpolation using a neural network.

Neural networks are strong at identifying complex trends within data that has a high number of dimensions, making this technique well suited to mining the maximum information from the exoplanet archive. The results focus on imputing planetary mass; a particularly tricky measurement as neither of the two main techniques for exoplanet detection --radial velocity and transit methods-- can estimate this value alone. However, the principal could be applied to other planetary properties and used to explore both formation theories or target selection schemes for future instruments.

[P-CG23] Shock responses of planetary materials elucidated from meteorites and laboratory experiments

convener:Takuo Okuchi(Institute for Planetary Materials, Okayama University), Toshimori Sekine(Center for High Pressure Science and Technology Advanced Research), Naotaka Tomioka(Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology)

Impact phenomena have been recognized to play essential roles in the processes of planetary evolution. Recent progresses in nanoscale analysis of meteorites, asteroid explorations, as well as laboratory experiments for simulating shock dynamics on planetary materials are collaboratively revealing complex effects of shock-induced processes in planetary evolution. Recently, several new metastable high-pressure phases have been identified in strongly shocked meteorites. Their occurrences indicate that the shock-induced physical states are far from thermodynamic equilibrium and contain very complicated processes. On the other hand, laboratory experiments including laser-driven shock techniques have recently been making remarkable progresses. They successfully simulate a variety of fast non-equilibrium processes at transient high-pressure conditions reaching tens to a few hundreds of gigapascals, that uniquely affect the physical and chemical properties of planetary materials upon impacts. Here we discuss how planetary materials are compressed, fractured, transformed, melted, and quenched during impact events by referring these recent studies. We welcome presentations from interdisciplinary research fields related to shock responses of planetary materials.

Research Center for Inland Seas, Kobe University, Kobe, Japan

The research focuses on the paradox between the low shock stage of carbonaceous chondrites and the marks of hypervelocity impacts, indicated by magnetic parameters which shows the mark of significant alteration triggered by impact induced shock.

Solving the paradox above a theory about the role of multiple impact produced structures instead of one energetic hypervelocity impact has been already introduced. Based on this theory, we propose a hypothesis and test of nanoscale fragmentation as evidence for multiple low-intensity impacts by nanoscale mineral components. Nano-scale minerals may be created and re-aligned by the physical weathering of coarser grains triggered by the shock of multiple impacts. Our goal is to support or decline the hypothesis by performing magnetic fabric studies, which are capable of separating the ultra-fine grain components, i.e., the possible indicator of nanofragments and their character.

Scanning electron microscope, rock magnetic and magnetic fabric studies were conducted on three carbonaceous chondrites: Allende, Jbilet Winselwan (Jbilet) and Murchison. FeNi alloys, iron sulphides (pyrrhotite) and magnetite were the main magnetic minerals contributing to the magnetic fabric. The fabric was foliated, and the susceptibility ellipsoid was oblate, thus indicating that impacts are an important process in the development of the fabric; this finding is consistent with previous studies. Significant differences were revealed between the studied meteorites by comparison of the anisotropy of the magnetic susceptibility and the frequency dependence of the anisotropy of magnetic susceptibility parameters (a sensitive indicator of the alignment of nano-size magnetic grains).

Comparison of the three studied meteorites suggested a complex ‘impact history’. The foliated well-aligned directions in the fabric of the studied meteorites and homogenized (non-scattering fabric parameters) may suggest the influence of a hypervelocity impact, which probably influenced the fabric of the (parent body of the) meteorite at the regional level. In contrast to the influence of the hypervelocity impact, which caused the fracturing and dislocation of the grains in the entire fabric, the repeating low-velocity impact potentially induced 1.) the weakening of the foliation (e.g., Allende, Murchison) in general and 2.) the formation and dispersed distribution of nanofragments (e.g. Allende and Jbilet) by e.g. physical erosion of the coarser grains or their re-alignment (e.g., Murchison). This phenomenon might appear differently in various parts of the meteorite, in which heterogeneity (in the magnetic parameters –scattering data) might indicate the limitation in spreading of the effect of multiple low-intensity impacts.

In-situ observations of shock-induced dehydration of goethite

*Tsubasa Tobase[1], Huijeong Hwang[2], Yongjae Lee[2], Takuo Okuchi[3], Toshimori Sekine[1,4]

1. Center for High Pressure Science and Technology Advanced Research, 2. Department of Earth System Sciences, Yonsei University, 3. Institute of Planetary Materials, Okayama University, 4. Graduate School of Engineering, Osaka University

Hydrous minerals play a role as water carrier because of their high temperature stabilities and shock resistance. Water is present as a major component of the atmospheres, surfaces, and interiors of planets, and it is important to investigate the dehydration reactions in hydrous minerals by impact processes to understand the formation and evolution of planets and the origin of life. We presented the shock recovery experimental results on goethite last year. At that time, powdered samples were capsuled in steel containers although the containers were not completely closed and there was a small gap space for dehydrated water to escape freely. The results indicated partial dehydration and produced hematite. However, it remains an open question when the dehydration occurred and what effects are expected at the partial water pressure. This time we carry out direct observation of the dehydration reaction by *in-situ* x-ray diffraction using an x-ray free electron laser (XFEL) to confirm the dehydration of goethite.

We tried to prepared sintered bodies of goethite at high pressures but failed to have thin plates. Instead we prepared thin films of goethite powders glued by manicure (~200 mm thick). We used XFEL at Pohang with a flat panel x-ray detector to observe the diffractions and an optical laser to drive shock wave. The XFEL beam is 25 fs at 12 keV and focused ~20 mm diameter and optical laser beam with 150 ps FWHM, 800 nm wavelength, and ~1 mJ energy focused ~40 mm diameter. The samples were free standing and subject to vertical XFEL beam and 5 degree off optical laser beam from the normal.

We obtained a series of diffraction images as a function of delay time for optical laser irradiation. All the diffractions consisted of those from the starting goethite without manicure, detailed analyses for the strong peaks of hematite as the dehydration product revealed that the shoulders of goethite peaks contains part of hematite peaks at late delay times. This can confirm *in-situ* formation of hematite by the shock-induced dehydration of goethite. The nucleation and growth of hematite during shock compression are extreme fast, and can be explained to be quenchable from the previous shock recovery experiments. We did not measure the pressure directly, and we can evaluate the threshold pressure from the diffraction peak shit of the hematite. These results suggest dehydration of goethite at relatively low shock pressures. The usage of manicure glue will help powdered sample preparation for XFEL that requires thin enough samples and we will develop further to apply not only hydrous minerals but also silicates by the help of manicure for XFEL experiments.

We thank the PAL-XFEL team for their help. This research was partially supported by the National Natural Science Foundation of China (NSFC No. 41974099).

Gekko XII experiment on magnetized collisionless shock

*Shuichi Matsukiyo[1], Takumi Higuchi[2], Hiroo Murakami[2], Youichi Sakawa[3], Taichi Morita[1], Kentaro Tomita[1], Ryo Yamazaki[4], Takayoshi Sano[3], Yasuhiro Kuramitsu[5], Shuta J Tanaka[4], Natsuki Ishizaka[4], Shin Kakuchi[4], Shuto Sei[4], Kei Sugiyama[4], Masato Ota[3], Shunsuke Egashira[3], Tomohiro Izumi[3], Kentaro Sakai[5], Takumi Minami[5], Hiroki Nishioka[2], Mariko Takagi[2], Takuto Kojima[2], Kento Aihara[4], Shota Kanbayashi[4], Sara Tomita[4], Yoshiharu Nakagawa[3], Takahiro Nishimoto[5], Masaki Takano[5]

1. Faculty of Engineering Sciences, Kyushu University, 2. Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, 3. Institute of Laser Engineering, Osaka University, 4. Department of Physics and Mathematics, Aoyama Gakuin University, 5. Graduate School of Engineering, Osaka University

Collisionless shocks often play important roles in various high energy phenomena in space. Shock reformation is a periodic collapse and formation process of the shock front occurring even when the upstream plasma is completely uniform and steady, and contributes to the generation of large amplitude waves and to particle acceleration. It is a phenomenon unique to a collisionless system. The structure called a foot, ramp, and overshoot repeats formation and collapse with gyro motion of the ions reflected at a shock. It was theoretically predicted in the 1980s by using computer simulation, but has not been proven yet. In this research we aim at the demonstration of shock reformation, which is not realized by the in-situ observation in space, by using the Gekko XII high power laser experiment at Institute of Laser Engineering (ILE), Osaka University. An aluminum plate target surrounded by nitrogen gas, to which an external magnetic field is applied, is irradiated by the Gekko XII laser (700 J * 4 beam, a wavelength of 1053 nm, a Gaussian long pulse (1.3 ns)). The target plasma sweeps the magnetized gas plasma which is produced by the strong radiation due to laser-target interaction. As a result, a shock wave is generated in the magnetized gas plasma. In the experiment in 2019 we could successfully apply 3.8T ambient magnetic field in the experimental system for the first time. The observed shock clearly contains inner structures not seen in our previous experiments without ambient magnetic field. We identified the so-called overshoot and foot in the shock transition region. In addition, a precursor of a shock modified by the ambient magnetic field is also identified in the early stage after the main laser shot.

Laser-driven shock compression experiments of synthetic wadsleyite and ringwoodite crystals

*Takuo Okuchi[1], Narangoo Purevjav[1], Norimasa Ozaki[2], Takayoshi Sano[3], Yuhei Umeda[2], Ryosuke Kodama[2,3]

1. Institute for Planetary Materials, Okayama University, 2. Graduate School of Engineering, Osaka University, 3. Institute of Laser Engineering, Osaka University

Dense mineral polymorphs of Mg_2SiO_4 (β-phase as wadsleyite, γ-phase as ringwoodite, and ε-phase as poirierite [1,2]) are possible major constituents of mantles of terrestrial planets, as well as of extrasolar super-Earths. Physical properties of these polymorphs at high pressure and temperature conditions are essential for understanding the past evolution history and current status of these rocky planets. Laser-shock Hugoniot measurements of α-Mg_2SiO_4 forsterite with the lowest initial denstiy, previously conducted at GEKKO-XII high-power laser system at Osaka University, had provided significant evidences on its incongruent melting and crystallization phenomena at ~ 300 GPa and ~ 10^4 K [3], which has stimulated discussion on physical and chemical processes of Mg_2SiO_4 system during the growth histories of the large-sized rocky planets. On the other hand, Hugoniot equation of states of the other polymorphs of Mg_2SiO_4, as represented by those of wadsleyite with ~ 8 % larger density and of ringwoodite with ~14 % larger density than forsterite, were not yet systematically studied; these will provide independent evidences on the relevant properties of Mg_2SiO_4, such as the existences of inhomogenious liquids generated by incongruent melting at wide pressure and temperature regimes.

We are therefore conducting systematic measurements on the Hugoniot states of these polymorphs by using GEKKO-XII laser system [5], which includes the regimes of their melting. The target sample crystals of dense minerals were synthesized using our pre-established slow-cooling method at static high pressure and temperature conditions [4]. These sample crystals are physically homogeneous and optically perfectly transparent, which give very high quality datasets of velocity interferometer system coupled with the high-power laser. The current results and technical developments will be presented and discussed.

1. Introduction

Baddeleyite (ZrO_2), commonly found in mafic igneous rock, can be applied as a shock pressure barometer and a geochronometer in meteorites. It can offer essential information on the timing and intensity of a meteorites impact, which help us to understand the planetary formation and evolution. Previous researches on natural shocked-baddeleyite in the earth’s rock and meteorites have observed grain refinement and the orthogonally related crystallographic orientations of the baddeleyite grains, which may infer the occurrence of phase transition. Although the phase transition behavior of baddeleyite at high pressures has been intensively investigated under hydrostatic conditions, there is little information on dynamic response of the phase transition under shock loading conditions. Therefore, it is required to clarify the phase transition behavior of baddeleyite under shock compression in order to utilized as a shock barometer.

Here, we performed *in situ* X-ray diffraction measurements on shock-loaded baddeleyite on nanosecond time scale using shock-driving laser and synchrotron X-ray.

2. Methods

We performed the experiments at NW14A beamline at PF-AR (Photon Factory Advanced Ring), High Energy Accelerator Research Organization (KEK), Japan. Baddeleyite samples were in form of square-shaped plates with dimensions 5 ×5 and a thickness of 0.06 mm. A 25 μm PET film ablator with Al coating was attached on the sample surface. The crystal structure of the sample was determined by XRD to be monoclinic (space group $P2_1/c$) with lattice parameter of a = 5.156(2) Å, b = 5.199(2) Å, c = 5.310(2) Å, β = 99.23(3)°, and V = 140.54(6) Å^3. Nd:glass laser with the wavelength of 1064 nm, pulse energy of 16 J, pulse width of 12 ns at the beamline was used for shock-driving source. The laser beam was focused by optical lens to a diameter of 500 μm on the sample surface. The velocity data was obtained by VISAR (velocity interferometer system for any reflector) measurement. For TR-XRD experiments, the synchrotron X-ray pulse of PF-AR was used as a probe source. The energy, the pulse width, and the size on the sample surface were 15.57 keV, about 100 ps, and 450 μm (H) ×250 μm (W), respectively. The XRD data at the timing within 40 ns after shock compression and that beyond 1000 ns were collected. For each XRD data, lattice parameters were refined by Rietveld method.

3. Results

The free surface velocity reached 0.914 km/s. From the velocity, the peak shock pressure determined by the U_s–u_p Hugoniots (U_s = 4.38 + 1.37 u_p km/s) (Mashimo et al., 1983) was 13.4 GPa.

The phase transition from monoclinic phase to orthorhombic-I ZrO_2 phase (the first high-pressure phase) was observed at 6.5 ns (compression state). The phase transition boundary under shock compression was determined to be 3.3 GPa, which is slightly lower than that observed in the previous static compression experiments. The compression of orthorhombic-I ZrO_2 reached to V/V_0 = 0.956, corresponding to the pressure of 14.0 GPa. Although the peak pressure in the study was beyond the phase transition boundary between orthorhombic-I and orthorhombic-II ZrO_2 (the second high-pressure phase) in phase diagram, orthorhombic-II ZrO_2 did not appear. During release state, orthorhombic-I ZrO_2 returned to monoclinic

©2020. Japan Geoscience Union. All Right Reserved.

phase, and finally orthorhombic-I ZrO_2 disappeared completely. Our direct observation revealed that the displacive-type phase transition between monoclinic and orthorhombic-I ZrO_2 can occur regardless of strain rate, but the reconstructive-type phase transition between orthorhombic-I and orthorhombic-II ZrO_2 depends on the time scale of compression.

No EOS models over 100 GPa, which corresponds to planetary impacts conditions, has been investigated by the experimental approach although calcite is a common mineral in chodritic meteorites and surface materials of rocky planets. In this study, calcite single crystals were shock compressed to pressures between 200 and 1000 GPa using the laser driven decaying shock method. Our temperature profiles by decaying shock experiments indicated the large difference from the theoretical model (SESAME 7331) with increasing pressure, and a melting of shocked calcite occurred between 140 and 270 GPa along the Hugoniot. The residual temperature of released calcite was estimated to be approximately 3300 K at the shock pressure of 200 GPa (at shock temperature of 6000 K).

[P-CG24] Future missions and instrumentation for space and planetary science

convener:Kazuo Yoshioka(Graduate School of frontier Science, The University of Tokyo), Satoshi Kasahara(The university of Tokyo), Kazunori Ogawa(Japan Aerospace Exploration Agency), Mitsunori Ozaki(Faculty of Electrical and Computer Engineering, Institute of Science and Engineering, Kanazawa University)

Not only national space agencies but some universities and even companies in the world are now leading a number of space science and exploration missions and also energetically initiating new research activities for satellite and rocket developments and international collaborations in these days because the Earth observations from the space and the space explorations could be achieved much easier than a few decades ago (e.g. ultra-small satellite). The deployment to the space, which itself is not purely a scientific purpose but one of methods for better sciences, is vigorously motivating the technical innovation and the educational development. For successful space missions, it is also crucial to research and develop aim-oriented on-board instruments, and the fundamental research and development of observational instrumentation with future perspectives could totally lead space missions in some case. Detailed investigation and evaluation on various on-board instruments are needed during their proposals, selections, and fabrications in order to promote the missions, and inevitably we have to make multi-sided arrangements and evolution at every process and aspect of any type of space missions, independently of their mission sizes. In this session, we focus on these comprehensive research activities in the space and astronomy missions, including the mission integrations and the individual instrumental developments, and we also call many presentations showing the uniqueness and renovation regarding the mission strategy and methodology, and the status and latest results in the related state-of-the-art researches and developments, which would provide all of researchers and developers with invaluable opportunities for active discussion, information sharing, and collaboration toward the realization of more missions for more fruitful space sciences and explorations in nearer future.

The Martian Moons eXploration (MMX) is planned to survey two Martian moons, Phobos and Deimos, and return samples from Phobos. MMX will be launched in 2024 and carries several scientific instruments. The OROCHI (Optical RadiOmeter composed of Chromatic Imagers) is wide-angle multiband camera which consists of 7 cameras with bandpass filter in specific visible wavelength (e.g., 730nm; Phyllosilicate feature). The specification is 12.22 mm/F4, 3296(H) x 2472(V) pix, 73(H) x 58(V) deg, 20 m/pix@20km, MTF@Nyquist>0.3. The OROCHI is aimed to constrain the global surface composition and physical structure of Phobos. In our scientific goals, Signal-to-Noise ratio of the OROCHI needs to be S/N > 100 in order to detect faint absorption clearly. Origins of the noise are mainly electrical noise from a CCD sensor and stray light from a optical system, and we focused on the latter. Stray light is generated by reflected lights at sensor, filter, and lens surfaces, therefore, the S/N ratio depends on these reflectance. We designed a similar optical system of the OROCHI in software and performed stray light analysis by measuring the reflectance of a sensor candidate and assuming that of filter and lens. Then, we estimated the S/N ratio. Although the S/N did not reach 100 at the beginning of analysis, we could achieve finally over 100 by following approaches; decreasing the reflectance of the filter and lens, keeping the filter away from the sensor, and reducing the number of lenses. In this study, we propose the OROCHI’s optical design, results of stray light analysis, and the improvement method.

The Martian Moons Exploration (MMX) mission has been planned to launch a Martian moons probe in 2024 as one of next planetary exploration missions in Japan. In this mission, the spacecraft reaches on quasi-satellite orbits around Phobos and makes remote-sensing observations. The spacecraft then carries out two times of landing and samples material of the Phobos surface. The spacecraft finally comes back to the Earth to bring the collected samples back. The MMX program shifted to the Phase-B in the beginning of February 2020 and basic design of the spacecraft and instruments have been started. In this presentation, we introduce the science-side organizational framework of MMX including science teams and scientific instrument teams we have constructed so far in the entire organization of MMX.

MMX has a new concept of organized science teams and this concept is a new attempt in the Japanese planetary exploration missions to enhance scientific results. As the largest science team Science Working Team (SWT) is defined to have all scientific researchers in MMX and achieve the science objectives of MMX. The SWT consists of Science Board (SB), Sub-Science Teams (SSTs), and a part of Instrument Teams (ITs) and Working Teams (WTs). SB is in charge of making decisions as recommendation to the project from scientific point of view, and manages and controls all teams in SWT. The SSTs are organized to fulfill the MMX's science objectives by using all available observation and analysis data taken from remote sensing observation, rover observation, and return sample analysis. For this purpose, the SSTs are responsible to making science and data analysis strategy, consider requirements for the instruments, check instrument performances, and actually analyze observation data to make science results. MMX has currently the following five SSTs: Origin of Phobos and Deimos, Early Solar System Evolution, Surface Science and Geology, Mars Science, and Geodesy. Most science objectives of MMX require multi-instrument data analyses and they will be effectively conducted in these SSTs.

MMX has a large number of instruments for observations and sampling, including non-scientific instruments which are possibly used also for science studies. These are: Circum-Martian Dust Monitor (CMDM), Light Detection and Ranging (LIDAR), Macroscopique Observatoire pour la Minéralogie, l'Eau, le Glaces et l'Activité (Near-Infrared Spectrometer, MacrOmega), Mars-Moon Exploration with Gamma-Rays and Neutrons (MEGANE), Mass Spectrum Analyzer (MSA), Rover developed by CNES-DLR, Telescopic Nadir Imager for Geomorphology (TENGOO), Optical Radiometer Composed of Chromatic Imagers (OROCHI), Interplanetary Radiation Environment Monitor (IREM), Super High Vision Camera (SHV), Coring Sampler (CSMP), Pneumatic Sampler (PSMP), Sample Return Capsule (SRC), etc. The ITs develop these

Design of Small Ion Mass Spectorometer for Comet Interceptor Mission

*Rurie Mizuno[1], Satoshi Kasahara[1]

1. The university of Tokyo

Time-of-flight mass spectrometers have measured dynamics and compositions of space plasmas. In particular, linear-electric-field time-of-flight analyzers have high mass resolution and are useful for in-situ measurement. Comet interceptor mission which is planned by ESA and JAXA will also use this type of mass spectrometer.

Comet interceptorInterceptor, currently studied in ESA and JAXA, is a mission to observe a dynamically new comet by flyby multi-spacecraft flyby. The mission goal is to characterize a dynamically new comet, which is relatively pristine compared to returning comets explored so far, to obtain a unique view along the evolutionary path of comets from their formation to migration into the inner solar system. One of the key measurements to achieve this goal is the ion measurement, which provides information on nucleus/coma composition as well as the solar wind-coma plasma interaction. Major molecules in a cometary coma, such as H_2O, CO_2, CO, NH_3, and hydrocarbons, consist of volatiles H, C, N, and O. Therefore, in this mission we have to divide the component of coma: C^+, N^+, O^+. To distinguish these atomic ions, the ion mass spectrometer needs relatively high to meet the constraint of the mass resolution, $m/\Delta m > 50$. There is also a constraint of on the size: volume (< 4U), to be accommodated on a relatively small (~24U) Japanese sub-spacecraft for this mission.

However, there has been no ion mass spectrometers meeting satisfying this resolution and size constraint simultaneously. Here we designed a small and high mass resolution ion mass spectrometer for the Comet Interceptor mission. For the high mass resolution, we adopt a linear-electric-field time-of-flight technique. To reduce the size of linear-electric-field time-of-flight the analyzer, we optimized the sensor optics by using a software keeping their high mass resolution. We simulated the design with through SIMION 3D calculation.
Changing the electrode’ s forms and voltages, we obtained a high mass resolution $m/\Delta m$>50~130 at full width at half maximum, with under the following condition: the sensor radius was 50 mm and height was 70mm.

An international multi-point space exploration mission for intergrated observations in the space-Earth coupling system

*Masafumi Hirahara[1], Masatoshi Yamauchi[2], Yoshifumi Saito[3], Hirotsugu Kojima[4], Kazushi Asamura[3], Takeshi Sakanoi[6], Yoshizumi Miyoshi[1], Naritoshi Kitamura[5]

1. Institute of Space-Earth Environmental Research, Nagoya University, 2. Swedish Institute of Space Physics, 3. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 4. Research Institute for Sustainable Humanosphere, Kyoto University, 5. Graduate School of Science, The University of Tokyo, 6. Graduate School of Science, Tohoku University

We report the current status and plan of a multi-point space plasma exploration mission for intergrated in-situ and remote-sensing satellite observations in the space-Earth coupling system. This mission is based on the international collaboration by Japanese FACTORS mission consisting of two identical compact satellites and the Swedisn InnoSat program of a micro satellite in order to realize the first Japanese formation flight configuration in the space and upper atmosphere, whose scientific goal of the most significance is the demonstrative and quantitative investigations on the plasma acceleration/transport mechanisms and the electromagnetic coupling processes emerging in the terrestrial polar magnetosphere and ionosphere. Beyond any previous space plasma exploration in our Japanese research community and the other overseas, we are proposing serveral cutting-edge measurement methodologies using high-time/spatial resolution techniques and direct evaluations for the energy transports between the plasma waves and particles as well as the simultaneous multi-point observations by the adjacent satellites with their controllable separation distances of 1-50 km. In this presentation, we focus particularly on the importance and strategy of the multi-point simultaneous observations carried out by these three compact/micro satellites of FACTORS and InnoSat.

Auroral imaging at visible and far-ultra-violet wavelengths for the future polar orbiting satellite mission FACTORS

*Takeshi Sakanoi[1], Masafumi Hirahara[2], Yoshizumi Miyoshi[2], Kazushi Asamura[3], Keisuke Hosokawa[4], Yoshifumi Saito[3], Hirotsugu Kojima[5], Naritoshi Kitamura[7], Mizuki Fukizawa[1], Shin-ichiro Oyama[2], Takuo T. Tsuda[4], Akinori Saito[6], Harald Frey[8], Nick Shneider[9]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. ISEE, Nagoya University, 3. ISAS/JAXA, 4. School of Informatics and Engineering, The University of Electro-Communications, 5. RISH, Kyoto University, 6. Graduate Shool of Science, Kyoto University, 7. Graduate Shool of Science, The University of Tokyo, 8. SSL, University of California, Berkeley, 9. LASP, University of Colorado Boulder

We report the science objectives, feasible design of instruments, and current status of the future polar orbiting satellite mission FACTORS, mainly focusing on the auroral imaging. FACTORS stands for Frontiers of Formation, Acceleration, Coupling, and Transport Mechanisms Observed by the Outer Space Research System, which is going to be proposed as a next-generation multi-satellite formation flight mission. Major scientific targets are: 1) energy transport in the magnetosphere-ionosphere (MI) coupling system and their relationship to small-scale auroral phenomena, 2) particle transport in the MI system by ion outflow, and 3) neutral-ion coupling in the auroral thermosphere. Observation of small-scale plasma parameters and simultaneous auroral imaging data obtained with multi-satellite measurements in the altitude range from ~300 km to 4000 km enable us to understand dynamical spatial and time variations in the MI coupling system, such as an Alfvenic wave acceleration and small-scale discrete aurora. Field-aligned current, particle distribution function, and Poynting flux obtained with FACTORS are the key parameters to reveal small-scale aurora.

We are making the design and development of visible and far-ultra-violet (FUV) imagers for this mission. To observe dynamical morphology of small-scale aurora, both visible and FUV images are required to have high-spatial and high-time resolution capability. Therefore, we set the instrumental requirement for visible imager to measure small-scale faint aurora with a spatial resolution of ~1km x 1km at apogee (~4000km altitude), a time resolution of ~10 frame/sec and sufficient sensitivity for auroral intensity of ~1 kR. Target auroral emission should be permitted lines, and N2+ 1NG (391 or 428nm) or N2 1PG (670nm) are candidates. We have established high-spatial and high-time resolution auroral imaging measurement with Reimei/MAC, and the similar objective lens (F/1.6, f =50 mm) made of fused silica, which has radiation hard capability, can be used. For the visible detector, we are discussing CCD or space-qualified sCMOS which has low-noise and radiation-hard performances.

Concerning the FUV imager, it was originally designed to measure a wide area (a few thousand km range) to monitor medium scale auroral phenomena, such as westward travelling surge and omega band. However, from recent discussion, the satellite will not be in the noon-midnight meridian sun-synchronous orbit, but in an orbit with a lower inclination angle. In this case, the period of satellite sunlit conditions increases where the visible camera cannot operate due to the scattering of sunlight and earth’ s dayside reflection. On the other hand, the intensity of sunlight is relatively lower in the FUV range, and we can obtain auroral FUV images during sunlit conditions. Thus, the FUV imager now plays a more important role to achieve the scientific objectives of FACTORS. Here, we require the high-time and high-spatial resolution capabilities with a few km x a few km, several frame/sec, and sufficient sensitivity for auroral emission at ~1 kR. We examined the FUV detector and objective system so far. Recent progress in FUV detector technology enables us to use a space-qualified FUV 2D array detector without high-voltage image intensifier. We investigated the performance of CCD and sCMOS detectors for the FUV imager. We set the field-of-view (FOV) of the FUV imager to be ~10 deg x 10 deg. According to this relatively narrow

©2020. Japan Geoscience Union. All Right Reserved.

FOV requirement, and thanks to the latest lens polishing technology, we designed the objective system made of CaF2 aspherical lenses with a F-number of 2.5 and focal length of 50 mm. The candidate auroral emission is OI 135.6 nm, and/or N2 LBH band (140-180 nm), and the wavelength is selected by a space-qualified FUV bandpass interference filter. We present estimations of counts detected by the preliminary designed FUV imager.

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, 8. Education Center on Computational Science and Engineering, Kobe University

Transverse ion acceleration (TIA) in the terrestrial polar magnetosphere is one of science targets in the future mission FACTORS. Although plausible mechanisms of the TIA have been discussed in a lot of studies, they are still unclear. Since the TIA is believed to be a source for escaping ions in the polar region, understanding the TIA process is crucial in studying scenarios of time evolution in the earth’s atmosphere. There is a strong view that the energy source for the TIA is plasma waves. Since there are various plasma waves as candidates for the energy source including both of electrostatic and electromagnetic modes, measurements of electric field components of plasma waves are significant in the FACTORS mission. However, there are some issues to be fixed for precisely measuring electric fields by the satellites. For example, three axial measurements of electric fields are essential even though we don’t have experiences installing three axial electric field sensors on former satellites. To meet the scientific objectives of the FACTORS mission, we design a new measurement system of electric field components of plasma waves considering the following points: (1) development of three axial electric field sensors, (2) implementation of an interferometry mode for identifying phase velocities of observed plasma waves with short wavelengths, and (3) computer simulations for precise calibrations of electric fields. The development of three axial electric field sensors is very new because we have been using long wire antennas that are deployed using satellite spins. We need to develop new antennas deployed by their own mechanisms for the FACTORS mission. Since 6 units of electric field sensors in number are installed on the satellite, their mass resource should be reduced drastically. As for the interferometry mode, knowing phase velocities of observed plasma waves allows us to interpret plasma wave modes consulting plasma wave dispersions. Since the interferometry mode uses electric field sensors as monopoles, it requires a lot of resources in receivers and telemetries. The design considering the use of the interferometry mode is inevitable. Three axial electric field sensors and the interferometry mode provide us with unique observation data of electric field components. To achieve quantitative and precise observations, precise calibrations of electric fields picked up by sensors are crucial. Electric field sensors on board satellites show complicated characteristics in space plasmas. In particular, their characteristics for plasma waves with short wavelengths are more complicated. We evaluate the characteristics of electric field sensors in space plasmas with help from computer simulations. In the present paper, we introduce the current design of the electric field measurement system in the FACTORS mission and discuss crucial aspects to be considered for measuring electric fields in the FACTORS mission.

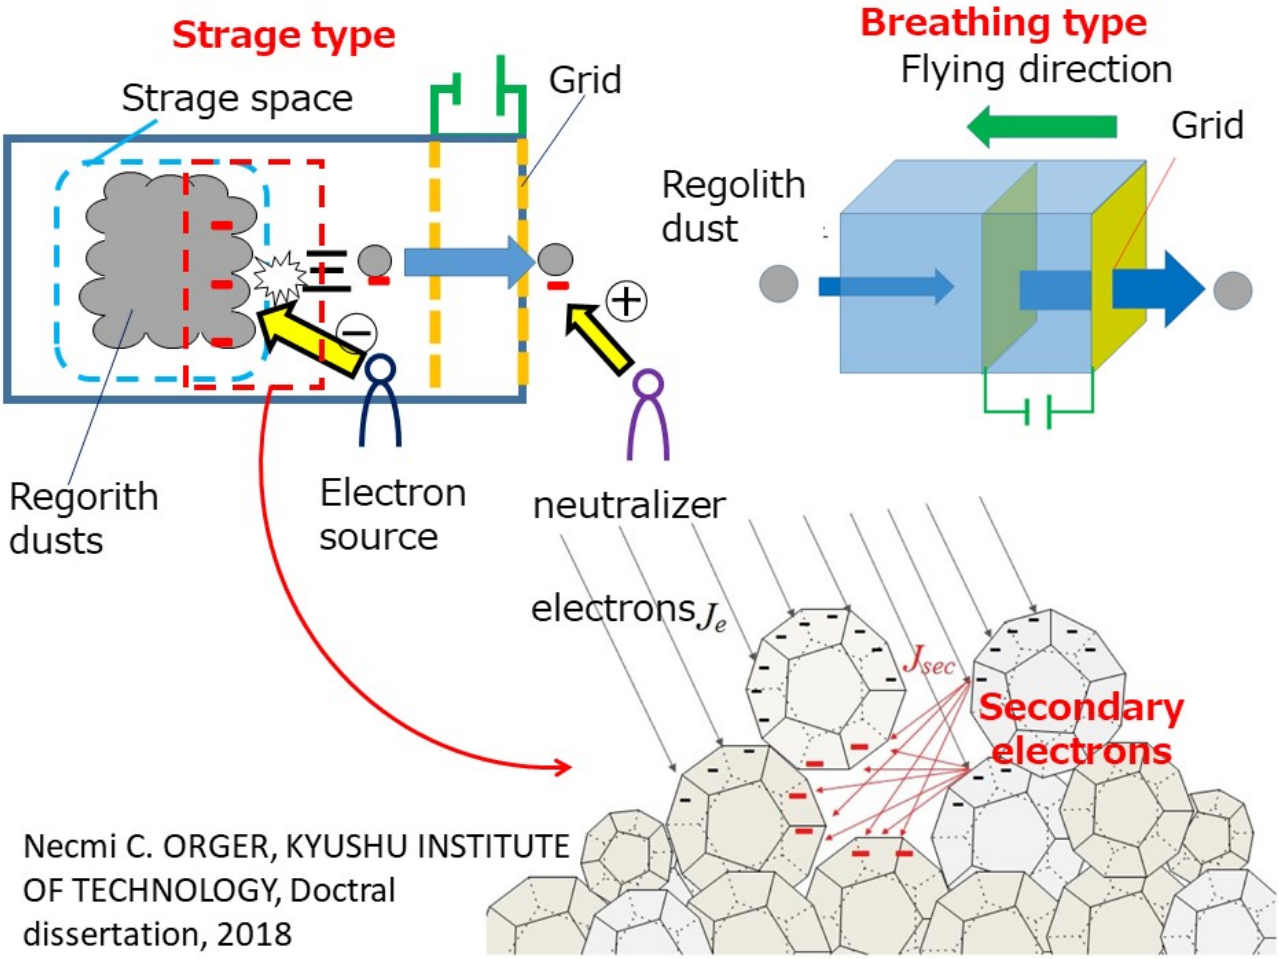
Investigation of requirements for regolith thrusters

*Noruji MUTO[1], Necmi Cihan ORGER[1], Jose Rodrigo CORDOVA-ALARCON[1], Kazuhiro Toyoda[1], Mengu Cho[1]

1. Kyushu Institute of Technology

A problem in lunar-orbit missions is the short orbital life of low-orbit spacecraft due to the moon's irregular gravity field. To sustain the orbit, much propellant is required to be loaded, whereby the mission would be costly. In recent years, electric propulsion devises have been applied to small satellites, which are growing in demand because of their short time required for development and the low risk of mission failure. We here suggest the "Regolith thruster", a new electric propulsion system which collects propellant material during the lunar-orbit flight. The Moon surface is covered with clastic materials derived from the weathered surface rocks called regolith, and its dust particles are of micro-meters in diameter. The dust particles are suspended above the moon surface, as observed by American lunar explorers.



Two types of regolith thruster have been considered. The "breathing type" captures lofted dust particles in orbit and accelerates them directly with a voltage applied grid. Our theoretical studies suggest that a grid of several-tens-of-square-meters class will be necessary to obtain sufficient thrust with this type. The “storage type” thruster uses electron source to generate secondary electrons to release the dust particles by micro-cavity charging. Dust particles are released by electrification in micro cavities (microcavities) formed by each other. This is due to the very small size of the microcavities on the lunar surface, so that the patched surface charge causes a strong repulsion against adjacent dust particles, which moves to the grid and is accelerated. When using a regolith simulant with a particle radius of 45 μm or less, only a small thrust of about 10^{-9} N can be obtained with the storage type. The volume required for the “particle storage space” of a storage-type regolith propulsion system, assuming that particles of each size fill the storage space, exponentially increases as the particle radius increases. If the particle radius is 5μm or less, each side can be made to fit into a cube of 10×10×10 cm (= 1U size small satellite).

Assuming that the regolith thruster obtains the velocity increment ΔV used in the previous studies, the required propulsion and satellite specifications can be investigated: the weight ratio of propellant and regolith thruster increases as the particle radius increases. This tendency is significant with a large value of ΔV. The propulsion device gains thrust because it shoots mass from the fuselage and propels by reaction. Once the weight ratio required to obtain the ΔV of the launched object (and propellant) and the spacecraft is obtained, the weight ratio will increase as the particle radius increases. The particles are desired to be of 1.0μm or less in radius so that the weight ratio can be easily achieved for a small satellite.

The minimum required number of orbits per month to obtain a specific ΔV is 10^8, and it has been found that filling the particle storage in orbit takes a considerable amount of time. If a method other than loading regolith dust directly on lunar surface is wanted, it is necessary to consider collecting particles using tethers, etc. While regolith dust is being used in the lunar orbiter, it continues to fill the storage units with new regolith dust.

Attitude Control System for Kanazawa-SAT3 Microsatellite

*Yuki Yasuda[1], Kohei Fujiki[1], Takuya Nakashima[1], Tomohiko Imachi[1], Satoshi Yagitani[1], Yoshiya Kasahara[1], Daisuke Yonetoku[1], Tatsuya Sawano[1], Makoto Arimoto[1]

1. Kanazawa University

Kanazawa University has been developing a micro satellite, Kanazawa-SAT^3. This satellite is equipped with a device to observe celestial bodies emitting gravitational waves with X rays, and aims to elucidate the mechanism of black hole formation by estimating the time of arrival and direction of arrival of gravitational waves.

In this research, we studied algorithm for attitude control of the satellite. We plan to spread SAP (Solar Panel) after the satellite is separated from the rocket, and stop rotation of the satellite by attitude control called de-tumbling. After that, we plan to judge if the current location sunshine or shady by using STT (Star Tracker) and solar sensors. If it is sunshine, we plan to capture the sun. If it is shady, we plan to decide attitude of the satellite by using STT, and wait until it is sunshine. We plan to turn SAP to the sun and turn mission devices to the deep space direction.

We studied attitude control used GAS (Geomagnetic Aspect Sensor) and MTQ (Magnetic Torque), and implemented the control system. We constructed the environment for unit test of RW (Reaction Wheel) used for attitude control of the satellite. We measured errors of GYR (Gyro Sensor) used for detecting angular velocity of the satellite, and corrected the errors.

MTQ is a device that controls the attitude of the satellite by generating torque by interference with the geomagnetism by applying a voltage to flow an electric current to the magnetic coil. GAS is a device for detecting the direction of the geomagnetic vector. MTQ and GAS are controlled by OBC (On Board Computer) and MC (Media Convertor). We can get maximum torque when MTQ generates torque is orthogonal to the geomagnetism. Because the torque generated by MTQ influence on the detection value of GAS, we have to wait after stopping to input voltage to MTQ to be stabilize output voltage of GAS. This waiting time is revealed to be more than 200 msec by our measurement. And we implemented de-tumbling-mode used to stop rotation of the satellite, unloading-mode used to unload when the rotation per minutes of RW is saturated, and manual-mode used to assign directly the effective voltage to input MTQ as attitude control using MTQ.

RW is a device to generate a control torque from the reaction of a rotor which is accelerated by a motor and is controlled by transmitting commands from the OBC by serial communication under RS-422 standard. The unit test has already been carried out by substituting OBC for PC, however the cable has a bad influence on the operation because RW is a rotating object. Therefore, we studied and constructed a system for wirelessly connecting the RW and PC by making the RS-422 communication wireless. Specifically, commands from the PC are wirelessly transmitted to Arduino by XBee, and the RW is controlled via the RS-422 transceiver. We use air-bearing for the operation test to reduce friction.

GYR have characteristics that fluctuate the bias voltage is fluctuated in a stationary state and it is also changed by temperature change. To reduce the fluctuation, we multiply the bias voltage by the average used the program implemented on microcomputer in a stationary state. We calculated the correction function basis on the measurement result of the GYR’ s bias voltage by temperature change.

©2020. Japan Geoscience Union. All Right Reserved.

In the future, we plan to evaluate de-tumbling-mode and unloading-mode implemented to MC, evaluate RW by performing the operation test using the wireless RS-422 communication system, make circuit board for satellite to mount GYR.

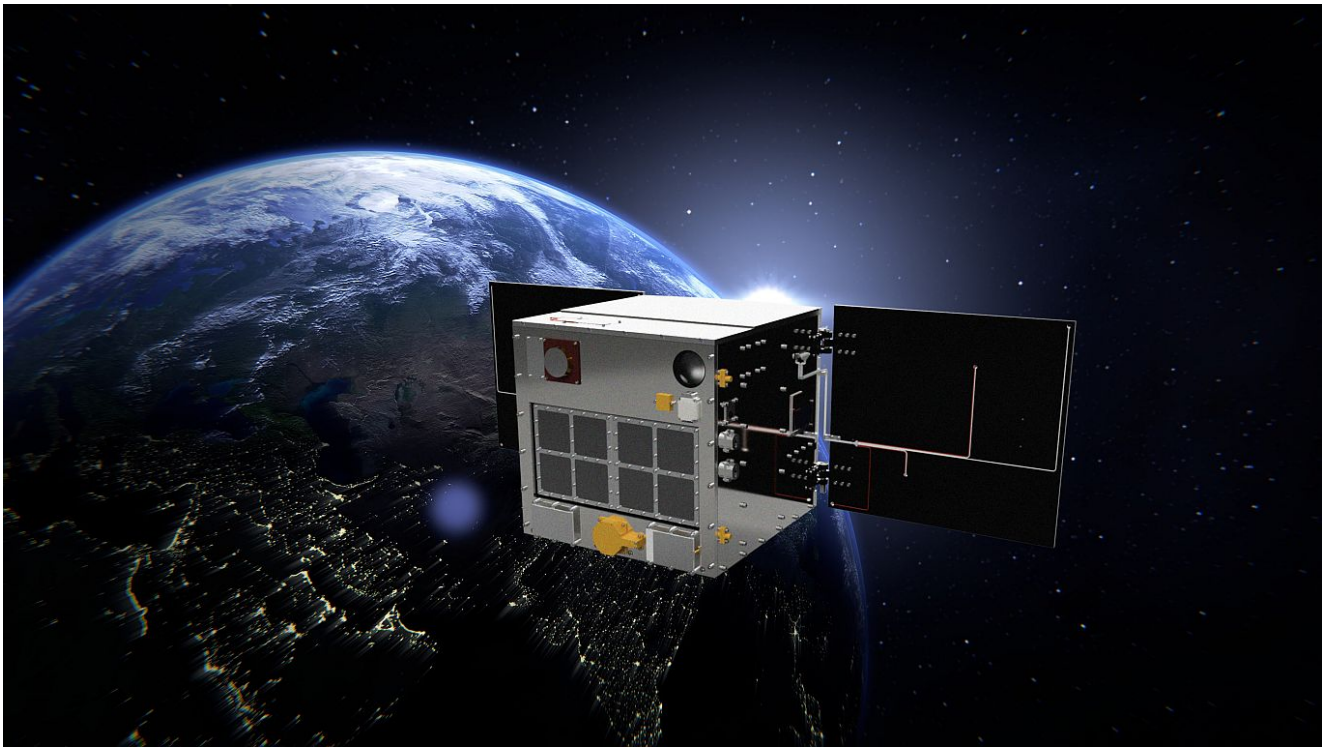
Microsatellite Development and Education of Space Science and Technology at Kanazawa University



*Tomohiko Imachi[1], Satoshi Yagitani[1], Daisuke Yonetoku[1], Yoshiya Kasahara[1], Tatsuya Sawano[1], Makoto Arimoto[1], Kei Sano[1], Yoshitaka Goto[1], Mitsunori Ozaki[1], Ryuichi Fujimoto[1]

1. Kanazawa University

At Kanazawa University, Advanced Research Center for Space Science and Technology (ARC-SAT) has been established on July 1, 2019. ARC-SAT has 3 research divisions: Satellite Development Division, Astronomy & Astrophysics Division and Solar-Terrestrial Science Division. ARC-SAT is concluding “Kanazawa University Satellite Project (Kanazawa-SAT^3: Study and Training in Space Science and Technology for Kanazawa Cube-Satellites)”. In this project, a space science and engineering course has been established in the Graduate School of Natural Sciences in April 2018. This course is based on the 'satellite development by students', and students are actually involved in the design, fabrication, ground tests, and operation of scientific satellites, aiming to train personnel who are familiar with space science and space engineering, with satellite-development skills.
As an activity of ARC-SAT and Kanazawa-SAT^3 project, a microsatellite is being developed by staff and students of Kanazawa University. It is a scientific satellite which will contribute to the elucidation of the mechanism of gravitational wave generation by identifying the source of gravitational wave by detecting the arrival direction of gamma rays and X rays radiated at the same time when a gravitational waves are generated by collision of astronomical objects. It is a microsatellite with a total weight of 50 kg or less, and its size is cubic with a side of 50 cm, and will be inserted into a solar synchronous orbit at about 660 km altitude. The satellite is on the stage of flight model assembly. And for the ground station, we have installed a paraboric antenna (2.4 m is diamiter) and a crossed Yagi antenna (14 elements) in Kanazawa university.
In the presentation, we will report the details of ARC-SAT and Kanazawa-SAT^3 project, and the development status of our satellite.

S Band and UHF Band Communication Systems for Kanazawa-SAT3 Microsatellite

*Koyo Ina[1], Mayuko Tachiya[1], Teruya Minamoto[1], Tomohiko Imachi[1], Satoshi Yagitani[1], Yoshitaka Goto[1], Daisuke Yonetoku[1], Yoshiya Kasahara[1], Tatsuya Sawano[1], Makoto Arimoto[1]

1. Kanazawa University

Kanazawa University is developing the first Kanazawa University's microsatellite, named as Kanazawa-SAT3(Study and Training in Space and Technology for Kanazawa Cube-Satellite). Kanazawa University satellite's mission object is to identify the source of gravitational waves by detecting the occurrence time and arrival direction of X-rays and gamma rays observed simultaneously with gravitational waves.

In this research, we are developing communication system for Kanazawa University satellite. Kanazawa University satellite has three communication systems, S band communication, UHF band communication and Iridium communication. There systems is composed of each antennas and transceivers. We summarize S band communication system and UHF communication system in detail as the following.

About the S band communication system, Kanazawa University satellite are equipped with two types of antennas: S band patch antennas and S beacon antennas. On the satellite side, the S band patch antennas for both transmission and reception are mounted on the front panel and the rear panel of the satellite. The S beacon antennas are also mounted on the front panel and the rear panel of the satellite. On the ground station side, we use a parabolic antenna of 2.4 m in diameter at Kanazawa University. S band system is a main communication system between the satellite and the ground station, and plays a role of high speed data communication and beacon transmission. We tested transceivers to be mounted on the satellite and communicator for the ground station by wired connection. And we developed satellite tracking system for the S band antenna. We evaluated the tracking system by performing tracking experiments for a satellite which passes over Kanazawa and receiving the S band signal. As a result of tracking experiments using the satellite tracking system, we confirmed that we could continuously receive signals from the satellite. As future work, we have to test communication system using the S band antenna. And also, it is necessary to develop the communication software for transceiver.

About the UHF communication system, Kanazawa University satellite are equipped with antennas we are developing. On the satellite side, the antennas are mounted for receiving and transmitting independently on the front panel and the rear panel of the satellite. On the ground station side, we use the Yagi antenna with 14 crossed elements at Kanazawa University. This system plays a role of transmitting commands from the ground station to the satellite and transmitting telemetry information from the satellite to the ground station. We adopt PIFA(planar inverted-F antenna) as UHF band antennas on the satellite. In this antenna, a dielectric is inserted into the gap between the patch plane and the ground plane to shorten the wavelength and miniaturization. This antenna body is made of aluminum, and the dielectric is made of polycarbonate. We measured the developed antenna and compared it with the simulation results to evaluate the characteristics. Also, like S band communication system, we developed satellite tracking system for the UHF band. As future work, we have to test transceiver to be mounted on the satellite and communicator for the ground station by wired connection. After that, we test communication system using the PIFA. Also, it is necessary to develop the communication software for transceiver.

Development of ASIC for energetic electron detector for future planetary explorations

*Shin Sugo[1], Satoshi Kasahara[1], Hirokazu Ikeda[2], Hirotsugu Kojima[3], Takahiro Zushi[4], Motoyuki Kikukawa[3], Kazushi Asamura[2]

1. The University of Tokyo, 2. Institute of Space and Astronautical Science, 3. Research institute for sustainable humanosphere, Kyoto University, 4. National Institute of Technology, Nara College

The origins of electrons in our solar system are the solar wind and the ionized atmosphere of planets and satellites, and their energy is typically less than 1 eV, at most 1 keV. Nevertheless, energetic electrons of more than tens of keV have been observed in all planetary magnetospheres. Some fraction of these electrons precipitate into the atmosphere and deposit their energy. However, it is difficult to quantitatively evaluate the effects of energetic electrons on the atmospheric dynamics and chemistry of outer planets and their satellites, due to the lack of detailed measurements. For such future observations, it is important to cover the large solid angle, since the energetic electron flux is not necessarily isotropic. Keeping this in mind, we develop an energetic (10 - 100 keV) electron detector which has hemispherical field of view without the spacecraft spin. For planetary explorations, which place stringent limitation on payload mass, we aim to miniaturize the sensor by applying the ASIC (Application Specific Integrated Circuit) technology to analog signal processing circuits. It is composed of preamplifiers, shaping amplifiers, peak holders, comparators, and Analog-to-digital converters. We designed an ASIC so that its dynamic range and the wave form peaking time to be 10^6 e^- and ~1 us, respectively, in consideration of the gain and the high capacitance of the assumed detector (Avalanche Photodiode, APD). The performance was confirmed in the simulation. Furthermore, we designed the layout of the ASIC circuit optimized for APD and estimated that it could be mounted on a 5 mm square chip. This size is about 100 times smaller than the size of the analog circuit board (70 mm x 30 mm) before applying ASIC technology and it is estimated to reduce the weight of the energetic electron detector by half (about 1.5 kg).

Development and Integration of the High-Speed Current Detection Circuits in Particle Sensors Dedicated to Wave-Particle Interaction Analyzer

*Motoyuki Kikukawa[1], Hirotsugu Kojima[1], Kazushi Asamura[2], Yoshifumi Saito[2]

1. Research Institute for Sustainable Humanosphere, Kyoto University, 2. Institute of Space and Astronautical Science

In the terrestrial inner magnetosphere, there is a population of particles whose energies are in ~MeV range and much higher than those of the solar wind. The magnetosphere is so tenuous that particle to particle binary collisions rarely occur. Therefore, particles exchange their energies through plasma waves. However, especially for high-frequency waves, it is not easy to observe a direct clue of the energy transfer from the particles to waves and vice versa.

A conventional observation method of wave-particle interaction has a problem that phase difference information of the plasma wave vector and the particle velocity vector is lost. For this reason, it is difficult to calculate the amount of energy transfer quantitatively. However, WPIA (Wave-Particle Interaction Analyzer) is recently introduced for observation of the wave-particle energy transfer [1]. It calculates inner product of plasma wave vectors and particle velocity vectors for each particle detection event on a satellite and determines the amount of energy conversion directly. The high relative time precision for detecting vectors of plasma waves and particles is essential in WPIA. This requires a synchronous measurement of plasma wave receivers and particle detectors. We introduce a system that feeds feeble current pulses generated by particle detectors into plasma wave receivers to achieve the synchronization. The developing system is a chip consists of two stages based on an ASIC (application specific integration circuit) technology. The first stage is the current-voltage conversion circuit. It picks up a current pulse and converts into a voltage signal with enough amplitude to drive the second stage. The second stage contains a comparator and a peak-hold circuit. They ensure picking up the real signals with availability of threshold settings. Because of the ASIC technology, our system is highly compact in size and weight compared to conventional circuits which are made of discrete electronic components. When our system is onboard micro-satellites, simultaneous multipoint observation of wave-particle interactions can be realized at low cost.
In this study, we develop the circuit which can output detection signals within 30ns after the arrival of particles. These signals can be reset within 12ns from the reset command. The size of one channel of the developed circuit is 210μm×570μm. Since the conventional circuit was several centimeters in size, we have reduced the area of this circuit by more than one tenth.

In this session, we show the details of the chip designed for the particle detection circuits including experimental results.

Development of the wideband analog integrated circuit for plasma wave receivers

*Shoya Nakao[1], Takahiro Zushi[1], Hirotsugu Kojima[2]

1. National Institute of Technology, Nara College, 2. Kyoto University

Plasma waves are the important observation target for scientific missions investigating space plasma phenomena, and many scientific satellites observe plasma waves using onboard plasma wave instruments. Plasma wave receivers are composed of electromagnetic sensors and a plasma wave receiver which processes signals picked up by sensors. The plasma wave receiver requires high-performance electronic circuits, and it causes an increase in mass and volume. On the other hand, the miniaturization of observation instruments is highly demanded. Part of its reasons is the expanding usage of microsatellites and the increasing onboard instruments of satellites. To resolve this problem, we use the Application-Specific Integrated Circuits (ASIC) technology which enables to miniaturize electronic circuits. We already realized miniaturized waveform and spectrum types of plasma wave receiver by developing ASIC; however, frequency coverages of the developed receivers are up to 100 kHz, and wideband receiver is required.

In this study, we improve analog ASIC to become wideband. In previous analog ASIC, upper limit of the frequency coverage is determined by the frequency coverage of the anti-aliasing filter. The anti-aliasing filter is realized by using switched capacitor filter, and it requires high frequency clock signal. Thus, the operational amplifiers which compose switched capacitor filter requires wider frequency coverage then the receiver’ s frequency coverage, and it is the biggest issue in broadening the previous ASIC. In this study, we develop the operational amplifier specialized for switched capacitor filter. In the presentation, we describe detailed design of the developed operational amplifier and switched capacitor filter.

Basic study on search coil magnetometer for improving magnetic sensitivity

*Yohei Yamaka[1], Yuya Tokunaga[1], Mitsunori Ozaki[1], Satoshi Yagitani[1]

1. Kanazawa University

In order to safely operate satellite services, we have been investigating the plasma waves from 1 Hz to 10 kHz. To probe the magnetic field vectors of plasma waves, we use search coil magnetometers along with preamplifiers. The magnetic sensitivity are important profiles to determine the electrical performance of search coil. The lower value of magnetic sensitivity is better for probing the weaker plasma waves. In this study, we propose two methods for improving the magnetic sensitivity of previous search coils. The noise components characterized by the search coil impedance are dominant of the magnetic sensitivity in the frequency range from 100 Hz to 10 kHz, so decreasing the inductance values of search coils is necessary to achieve the better magnetic sensitivity. By using two search coils connected in parallel, the first method decreases a total inductance. The decreased inductance improves the magnetic sensitivity from 100 Hz to 10 kHz. In the second method, we use an adder circuit to synthesize the outputs of three search coils each having preamplifiers. The magnetic sensitivity from 1 to 10 kHz is better than the previous search coil because of decreasing the inductance of each search coil. We evaluated the magnetic sensitivity for two methods of the search coils. From the measurement results, the magnetic sensitivities at 2.5 kHz of first and second methods improve by 5.37 dB and 4.19 dB compared with that of the previous search coil, respectively. The magnetic sensitivity of first method is better than that of the second one, but the first method is impractical for scientific satellites due to having the mass and volume with 2 times larger than those of the previous search coil. On the other hand, the search coil by the second method increases the total power consumption depending on the number of preamplifiers, but it can be practical because of suppressing power consumption using application specific integrated circuit technology.
In this presentation, we will present the basic study on the search coil magnetometers for improving the magnetic sensitivity in detail.

Development of an instrument to measure ion drift velocity and density in the ionosphere

*Takumi Abe[1], Shigeto Watanabe[2], Akinori Saito[3], Ryuto Hashiba[4]

1. Japan Aerospace Exploration Agency, Institute of Space and Astronautical Science Department of Solar System Sciences, 2. Hokkaido Information University, 3. Kyoto University, Graduate School of Science, 4. Hokkaido Universiity

The lower ionosphere is known as a unique region where charged particles and neutral particles co-exist. The charged particles tend to move in a direction different from neutral particles, because of a difference in those behaviors against the electromagnetic force. Characteristic phenomena such as dynamo current and polarization electric field existing in this region are attributed to such peculiarity in this region. The momentum transfer between the charged and neutral particles plays an important role in generating these phenomena. It is desirable to make a direct measurement of charged and neutral particles by using instrument on the sounding rocket to further understand such unresolved phenomena.

In 2018, we started developing an ion drift velocity analyzer which enables us to estimate the ion drift velocity and density in the lower ionosphere. It is well known that Ion Drift Meter (IDM) and Retarding Potential Analyzer (RPA) had been installed on low-altitude satellite, such as Dynamic Explorer-2 and Atmospheric Explorer series. Our instrument will be required to have the functions that these two have.

As the first step of the instrument development, a numerical simulation was carried out to design the internal structure, and thereby we determined a basic structure of the instrument which consists of RPA section in the front and multiple sector anodes of IDM section in the end. In the first half of 2019, the prototype model was developed after we obtained the design outlook that the instrument provides the ion density and velocity in a good accuracy. The IDM section has a total of 72 small sector electrodes so that an estimation of the drift velocity vector can be made with enough accuracy. The electrodes are arranged in the hemispheric inner surface which receives the incident ions passing through the RPA section.

Then, we put the prototype instrument in the vacuum chamber to evaluate its performance on the ionospheric plasma condition. The main results from our evaluation are summarized as follows:
1) Individual electrode in the IDM section can measure significant level of current due to thermal ions which pass through the RPA section.
2) The electrode can independently detect incident current even though the space between adjacent electrodes is small.
3) The ion current distribution represented by the 72 electrodes seems reasonable as expected from a velocity of the incident ions.
4) The current collected by the electrodes has a decreasing trend as expected as an RPA function, and it significantly changes depending on the DC bias applied to the RPA voltage.

In the next step, we are going to develop a low-energy ion source which can generate drifting ions whose energy is several eV. Through the experiment using the ion source, a function to estimate the bulk energy of the ions will be evaluated. The latest status of our instrument development will be explained in the presentation.

Satellite-to-satellite radio occultation for the exploration of planetary atmospheres

*Takeshi Imamura[1], Hiroki Ando[2], Norihiko Sugimoto[4], Hideo Sagawa[2], Masahiro Takagi[2], Katsuyuki Noguchi[8], Kazunori Ogohara[7], Atsushi Yamazaki[9], Takahiro Iwata[9], Tomotaka Yamamoto[3], Satoshi Ikari[3], Yosuke Kawabata[3], Shoko Sano[3], Yukiko Fujisawa[4], Ryu Funase[3], Mutsuko Morimoto[4], Mirai Abe[6], Asako Hosono[5]

Department of Physics, Keio University, 5. Toshimagaoka Women High School, 6. Faculty of Law, Keio University, 7. School of Engineering, The University of Shiga Prefecture, 8. Department of Information and Computer Sciences, Nara Women's University, 9. Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency

In order to understand the climate system of planets, it is necessary to reveal the three-dimensional circulation of energy and atmospheric compounds. Methods of observing planetary atmospheres that have made significant achievements to date can be broadly classified into direct measurements by landers and optical remote sensing by orbiters and ground telescopes. Although the former can accurately measure various physical quantities, it cannot capture physical and/or chemical processes involving large spatial changes. The latter enables global observations; however, the vertical resolution is typically limited to a scale height (several kilometers), and thus layered structures characteristic of planetary atmospheres cannot be well resolved. Moreover, the pressure field, which is critical for understanding atmospheric dynamics, cannot be measured. Because of these limitations, for example, the three-dimensional structures of water and dust transport on Mars have not yet been identified, and the three-dimensional structure of the angular momentum transport in Venus’ s atmosphere that sustains the high-speed atmospheric circulation has not yet been identified.

We consider satellite-to-satellite radio occultation can make a breakthrough in the sciences of planetary atmospheres. In conventional radio occultation observations, the planetary atmosphere is observed by using radio waves transmitted from the spacecraft and received at a ground station when the spacecraft is hidden behind the planet as seen from the ground station. This method can measure the temperature, the pressure and absorbing materials at high vertical resolutions of several hundred meters; however, it has a disadvantage that it cannot capture the spatial structure because the observation points are limited by the positional relationship among the spacecraft, the planet and the earth. Based on this recognition, we are studying the possibility of radio occultation observation between a mother spacecraft and small satellites from the viewpoint of both science and engineering. By this method, the altitude distributions of physical quantities can be acquired with high vertical resolution globally at dozens of observation points every day. Such a method has already been used for the earth’ s atmosphere.

Satellite-to-satellite radio occultation, when applied to Mars, would enable to (1) derive the three-dimensional wind structure from the temperature and pressure distributions using data assimilation, (2) understand the atmosphere-crustal water exchange and water transport using three-dimensional data of water vapor and atmospheric dynamics including the boundary layer, and (3) expand the observation points, which have been limited to the morning and evening regions in the conventional radio occultation, to all local time to understand the diurnal cycle. Such measurements also serve as basic information for the analysis of observational data taken by other methods in the same period. For Venus, satellite-to-satellite occultation can retrieve three-dimensional atmospheric motions in broad altitude

regions including inside and below the sulfuric acid cloud that is difficult to observe optically. It will also reveal the three-dimensional circulation of sulfuric acid, which is the cloud forming material, leading to the understanding of climate control by cloud processes. In addition to the observations of the neutral atmospheres, three-dimensional tomography of the ionospheres by electron density measurements is also possible. In this presentation we will discuss scientific values of the measurements and introduce preliminary results of engineering studies.

Though surface of Mars is cold and dry, Mars had harboured a large amount of liquid water on the surface in early stage of the history. Several billion years ago, Mars was similar to the early Earth from which life arose, and life would have also emerged on Mars. Although the Viking mission in 1976, which explored life on Mars, did not find evidence for life [1], many findings supporting the habitability on Mars have been discovered since the Viking mission: past and present aqueous environments, organic compounds, methane and reduced compounds supporting microorganism as energy sources, and so on [2] [3]. These findings tend to suggest that microorganisms might still exist on Mars surface.

For searching extant microorganisms, a microscopic instrument is a powerful tool, which directly images life forms and identify their shapes, sizes, and other morphological and biochemical characteristics. However, it has not been used in space missions yet. For *in situ* imaging of particles and microbial cells, we have proposed the Life-signature Detection fluorescence Microscope (LDM) which visualizes organic compounds by staining the samples with fluorescent pigments [4]. The LDM scans a volume of 1 mm^3 and detects organic compounds including cells and other biological materials in high sensitivity ($<10^4$ cells per gram clay). The fluorescent pigments have been selected to identify the fundamental features of cells by differentiating organic compounds surrounded by membranes or those show enzyme activity. The LDM is also equipped with a high-resolution imaging system (1 μm/pixel) which visualizes detailed life forms as well as regolith and dust particles [5]. Our investigation goals are the followings. 1) High-resolution characterization of regolith and dust particles. 2) Search for organic compounds in Mars surface samples. The compounds include cells, other biological materials, and abiotic polycyclic aromatic hydrocarbon (PAH). 3) Identify cell-like structure in which organic compounds are enveloped by membrane, which may represent Martian life.

In this presentation we will report the current status of the development of LDM and potential application to planetary explorations.

Development of a near-infrared high-resolution Echelle spectrograph ESPRIT for planetary atmospheric observations

*Ayumu Kambara[1], Takeshi Sakanoi[1], Masato Kagitani[1], Yasumasa Kasaba[1], Aya Otomo[1], Yasuhiro Hirahara[2]

1. Planetary Plasma and Atmospheric Research Center, Graduate School of Science, Tohoku University, 2. Graduate School of Environmental Studies, Nagoya University

We report the latest status of development of near-infrared spectrograph, ESPRIT (Echelle Spectrograph for Planetary Research In Tohoku university). This spectrograph is designed to be optimized for observations of near-infrared emission and absorption from planetary atmospheres and satellites. The emission and absorption in the infrared wavelength range have information of physical phenomena, such as the composition and density of the molecular species of the atmosphere, temperature and wind speed. Because of the high-resolution spectroscopic capability of ESPRIT, we can obtain the atmospheric velocity from the Doppler shift of the emission lines and the temperature from the intensity ratio of multiple emission lines. To understand the time and spatial variations in the various ranges, it is necessary to carry out long-term and flexible observations of planetary atmosphere with ground-based telescopes and planetary probes. Since an infrared high-resolution spectrograph is big and heavy, in most cases they are installed on medium- and large-class ground telescopes, and opportunities were limited with proposal-based operations. We will install ESPRIT on our 60 cm telescope (T60) at the summit of Haleakala (3040m), and achieve the monitoring measurement. Our main observation target is the infrared emissions in Jovian thermospheric H_3^+/H_2 aurora and airglow, and ESPRIT will be provided to wider users in observations of various targets including the lower cloud layer (around 2.3 um) and airglow (1.27 um) in Venus and H_2O and CO_2 atmosphere in Mars. We plan to install ESPRIT on T60 first, and in the future, we will install it on the 1.8 m off-axis telescope PLANETS.

ESPRIT can change an imaging mode and spectral mode with a long slit (length 50 arcsec). A slit viewer will be installed to monitor the position of slit on a planetary disk. We adopt the Raytheon InSb 256x256 array of which wavelength range is in the range of 1-4 um. The plate scale at the detector is 0.3 arcsec/pixel (field of view 76 arcsec) in the case of F12 incident light. The whole optical system is cooled down to 90 K with the radiation shield by using the He refrigerator, and the detector unit is cooled down to 35 K. For the spectral mode, the echelle grating (31.6 gr/mm, blaze angle 71 degrees, 29mmW x 136mmL x 20mmT) is used. This was selected so that the diffraction efficiency is greater than 0.8 at the wavelengths of Jovian H_3^+ emission (3.95 um), and H_2 emission (2.12 and 2.30 um). The resolution of spectrograph is R~20,000. The mechanism is used to change the grating angle from 62 to 80 degrees, and we can observe the 1.27, 2.12, 2.30, 3.41, and 3.95 um wavelength bands (wavelength coverage $1.0\times10^{-3}\lambda$) by this mechanism. with an angle stability of 1 arcsec/5min (corresponding to a Doppler velocity of 0.5 km/s in Jovian auroral emission). This stability was verified by previous tests. When ESPRIT is installed to T60 and we set the slit the polar aurora emissions in the east-west direction, we estimate that this data can be obtained for every 3 min (SNR~15), and the intensity distribution in Jovian polar region with 5-10 frames can be acquired in about 1 hour. This time resolution would be sufficient to clarify the time variations of disturbances in the magnetosphere and ionosphere, as well as the coupling processes between ions and neutral winds in Jovian thermosphere.

In the present situation, we almost completed the fabrication of mechanical and optical systems, such as the echelle grating mechanism, filter turret, slit-imaging change mechanism, collimating and camera mirrors, grating and other components. We will manufacture the heat path and the cooling box for the detector. Further, we will perform the electrical tests of the detector using the driving and read-out

©2020. Japan Geoscience Union. All Right Reserved.

electronics and software under vacuum and cooling conditions. We plan to install the detector unit to ESPRIT by this June, and start the integration test of ESPRIT from July.

Development of the absorption cell filters for remote D/H observation

*Masaki Kuwabara[1], Kazuo Yoshioka[2], Makoto Taguchi[3], Takuya Kawahara[4], Shingo Kameda[3]

1. JAXA, 2. The Univ. of Tokyo, 3. Rikkyo Univ., 4. Shinshu Univ.

The hydrogen atoms in the planetary exosphere scatter the solar Lyman-alpha radiation and produce a faint glow surrounding the planet. The brightest emission among the planetary coronas is hydrogen Lyman-alpha. Absorption cell technique is an efficient tool for remote sensing of the planetary coronas and allows us to measure not only an intensity distribution of the Lyman-alpha emission but also a temperature distribution in the planetary exosphere. These distributions are quite important to quantitatively estimate of the escape rate of the present planetary atmosphere. Since the absorption cell technique can be used as a light-weight ultra-high resolution filter, it will be crucial for realizing an imaging instrument for observation of planetary coronas with small spacecraft. Absorption performance of the cell strongly depends on parameters such as filament shape, filament temperature, applied power to the filament, filled gas pressure, optical path length, and position of the beam path. The hydrogen absorption cells have been developed to optimize the above parameters and evaluated using an ultra-high spectral resolution Fourier transform spectrometer installed at the DESIRS beamline of Synchrotron SOLEIL in France. In this presentation, the summary of the development and the remaining issues are presented. The basic design of an absorption cell imager and the application of it for future space missions are also presented.

[P-CG25] Planetary Magnetosphere, Ionosphere, and Atmosphere

convener:Kanako Seki(Graduate School of Science, University of Tokyo), Takeshi Imamura(Graduate School of Frontier Sciences, The University of Tokyo), Hiroyuki Maezawa(Department of Physical Science Osaka Prefecture University), Naoki Terada(Graduate School of Science, Tohoku University)

Exploration of Moon, Venus, Mars, Mercury, Jupiter, Saturn, and beyond together with rapid developments of numerical simulations provides us new view of planetary environment. This session collects general contributions of new findings about planetary magnetosphere, ionosphere, and atmosphere. New methodology and technology development studies for future explorations are also welcome. In order to put the common knowledge at different planets into perspective, this session aims to facilitate discussions on comparative planetary environments.

A storm more than 4,000 km in diameter occurs occasionally in Neptune. In previous study, Voyager 2 observed Neptune on May 24, 1989 and discovered a storm of 13,000 km in diameter called Great Dark Spot (GDS). GDS was located in southern hemisphere like Great Red Spot of Jupiter. But GDS became extinct when Hubble Space Telescope observed it in 1994. It is unknown whether it is a sudden thing or storms such as GDS always occur in Neptune. In addition, a huge storm of 9,000 km was observed on July 2 and June 26, 2017 by Keck observatory. It’s considered that storms of Neptune occurs at mid latitude in the north and south that an ascending air occurs. However, this huge storm occurred near the equator. A rotation axis of Neptune is 29.6 degrees, and the storm possibly occurred near the equator because of seasonal change. Neptune is observed by large telescopes such as Keck observatory and the Hubble Space Telescope, but it is difficult to always use those telescopes for Neptune observation. Therefore Neptune is not observed for long term on a short time scale. We developed the technique to estimate the drift rate and intensity of storms by observing a whole spectrum of Neptune in this study. When seeing is bad, it’s possible to observe and acquire the observation data of Neptune for a long term on a short time scale. The purpose is to deepen the understanding of the atmosphere convection structure of Neptune by chasing the detailed change of storms. In this study, we observed Neptune by using 1.6 m Pirka telescope that Hokkaido University owned. The observation time is from August 7, 2017 to January 17, 2018 and from October 22, 2018 to November 26 2018. The wavelength is 650-1050 nm in 2017, and 890, 855 nm in 2018. In this study, we used methane absorption 890 nm. Storms look brighter at 890 nm because the altitude of storms is higher than that of other areas. In addition, the appearance size of storms from the observation point changes by the rotation of Neptune, so an 890 nm flux changes by the rotation. We took the ratio of an 890 nm flux and an 855 nm flux to correct the effect of the earth atmosphere and calculated the theoretical values of the relative intensity by the rotation. We assumed storm's area and fit the observed values with the theoretical values in the least squares method to estimate the drift rate and 890 nm reflectance of the storms. We estimated that the drift rate and the 890 nm reflectance are 47.5˚/day, 0.252 in 2017, 24.9˚/day, 0.054 in 2018, respectively. In 2019, we assumed that there are three storms and estimated that the drift rate and 890 nm reflectance of the first storm are 22.8˚/day, 0.128, those of the second one are 39.6˚/day, 0.081, those of the third one are 51.9˚/day, 0.149, respectively. Molter et al., (2019) study shows that 2017 storm is located at 2˚N and the drift rate is 237.4±0.2 m/s or 47.78±0.04˚/day. This drift rate is consistent with the drift rate estimated in my study. We will compare the results of 2018 and 2019 with observations of other reseacher and amateur, and then discuss in the future.

Multi spectral observation of changes in Uranus' cloud obtained by Pirka telescope

*Haruki Sugiyama[1], Yukihiro Takahashi[1], Mitsuteru Sato[1], Seiko Takagi[1], Yuuki Sato[1], Tatsuharu Ono[1], Shuntaro Yokota[1]

1. Hokkaido University

Uranus was first observed to be free of severe weather changes like Jupiter. However, recent observations (Voyager 2, Hubble Space Telescope, Keck telescope) have revealed that Uranus has a long-time scale phenomenon of several decades and a short-time scale phenomenon of several days or weeks. Hammel and Lockwood (2007) reported a change in brightness on a time scale of about 20 years, which is half the orbital period of Uranus. Irwin et al. (2010) and Peter et al. (2015) showed that some bright clouds fluctuate in a few days. However, there are few observations of short-time scale cloud changes, and the time scale of these cloud phenomena is uncleared. Most observations have been performed once or twice a year, often for several days. This is because it is difficult to have observation time for large telescopes and space telescopes with high spatial resolution. The purpose of this study is to elucidate the time scale of cloud changes. In this study, we used a 1.6 m Pirka telescope and Multi Spectral Imager (MSI)(Watanabe et al., 2012) mounted at Cassegrain focus of Pirka telescope. This is a ground telescope located at Nayoro observatory of Hokkaido University, Japan, and mainly used for planetary observation. MSI enables to take images that cover a 3.3'x3.3' field of view with 0.389" pixel resolution at several visible to near infrared wavelength in a short time. Because this instrument has a liquid crystal tunable filters (LCTFs) that can change the transmission wavelength from 400 nm to 1100 nm, in about 150 ms. We made imaging observations at several wavelengthes from 650 nm to 900 nm for a total of 6 months from September 2019 to February 2020. However, the seeing of Nayoro is about 3 arcsec, which is almost the same size of Uranus. Therefore, in order to confirm the existence of clouds, I use a method of comparing the reflection flux at a methane absorption wavelength ($F_{methane}$) and the reflection flux at a non-absorption wavelength (F_{normal}). If there is a cloud, the incident light will be reflected by the cloud, so the absorption by methane will be weaker than without the cloud, and $F_{methane}$ / F_{normal} will be larger than without the cloud. Using this, it is possible to estimate the change in clouds by comparing the theoretical value of changes in $F_{methane}$ / F_{normal} due to the presence of clouds with actual observations. In this presentation, we will introduce the initial results of the data acquired from September to November 2019.

Parameter experiments of climates of various planets by the use of a general circulation model

*Yoshi-Yuki Hayashi[1], Yoshiyuki O. Takahashi[1], Masaki Ishiwatari[2], Kensuke Nakajima[3], George HASHIMOTO[4]

1. Department of Planetology/CPS, Graduate School of Science, Kobe University, 2. Department of Cosmosciences, Graduate school of Science, Hokkaido University, 3. Department of Earth and Planetary Sciences,Flculty of Sciences,Kyushu University, 4. Department of Earth Sciences, Faculty of Science, Okayama University

One of the interesting quests on exoplanets is to investigate the variety of thier possible surface environments and circulation structures of their atmospheres. For the propose of accumulating knowledge on those questions, we have been developing a general circulation model and have been performing parameter experiments on possible climates of exoplanets by the use of a general circulation model.

The model used in this study is DCPAM (http://www.gfd-dennou.org/library/dcpam/), which has been developed in our group. The model is composed of a dynamics of the primitive equation system and a number of parameterizations, such as radiation, turbulent mixing, and so on. In this study, we focus on the atmospheres whose composition is the same as that of the Earth. The parameters on which we consider dependence of the atmospheres are obliquity, rotation period, and radius of the planets. The values of obliquity we adopt for our parameter experiments are 0, 23.4, 60, 90 degrees, those of rotation periods are 1, 3, 10, 30 Earth days, and those of radius are 6371, 4247, 3186 km. We have to note we have not completed all of the sets given by the arbitrary combinations of them; the values of the parameters are extended from those of the present Earth's parameters.

A several interesting features are observed in the results of those experiments. One of those is the morphological change of mean meridional circulation. The latitudinal width of Hadley cell becomes larger with the increase of rotational period. As a result, Ferrel cells disappear in the experiments with rotation periods of 10 and 30 Earth days. In the presentation, additional features of parameter dependence will be also presented.

The influence of carbon escape on the evolution of the Martian atmosphere

Ryosuke Yagi[1], *Naoki Terada[1], Shungo Koyama[1], Takeshi Kuroda[1], Hiromu Nakagawa[1], Isao Murata[1], Yasumasa Kasaba[1]

1. Graduate School of Science, Tohoku University

The purpose of this study is to investigate the evolution of atmospheric composition in the early Martian atmosphere. Not only hydrogen and oxygen escapes but also carbon escape to space is considered in this study for two reasons. The first reason is that thermal escape of atomic carbon could be stronger than atomic oxygen on early Mars. The early Martian atmosphere was exposed to stronger Sun’s EUV and FUV radiations than today. The escape parameter, defined as the ratio of the gravitational potential to kinetic energy at the exobase level, could have been small enough to allow massive escapes of these species under such strong radiations. For example, the escape parameter of atomic carbon in the Martian atmosphere was estimated 0.75 times smaller than that of atomic oxygen, and because of an efficient dissociation of CO_2 the densities of these species at the exobase level were comparable at 4.1 billion years ago [Tian et al., 2009]. Hence, we consider that on early Mars, thermal escape of atomic carbon could have been stronger than atomic oxygen. The second reason is the discovery of the concentration of Mn in Gale Crater by Curiosity, which suggests that the early Martian atmosphere could have several mbar or more of O_2 partial pressure in the Hesperian [Noda et al., 2019]. Previous 1-dimensional photochemical models that considered hydrogen and oxygen escapes on current Mars suggested that the O_2 partial pressure could increase only up to 10^{-5} bar [e.g., Chaffin et al., 2017]. This is because the atmosphere self-regulates the loss of hydrogen and oxygen to 2:1 [McElroy and Donahue, 1972], which limits the imbalance between the hydrogen and oxygen escapes and hence prevents a massive oxygen buildup in the atmosphere. In this study, we consider atomic carbon escape as an agent to accumulate O_2 in the atmosphere.

We investigated the effect of carbon escape on the accumulation of O_2 in the atmosphere using two models. The first is a 1-box model that considers only the supply and loss of atmosphere from the atmospheric boundaries. This model was used to get an overview of the atmospheric evolution. The second is a 1-dimensional photochemical model. This model investigated the evolution of atmospheric composition taking into account atmospheric photochemistry in addition to the supply and loss from the atmospheric boundaries. This model was applied during periods when the atmosphere was expected to regenerate to be an O_2-dominated atmosphere after a massive loss of the atmosphere. The results of our 1-box model suggested that an O_2-dominated atmosphere was formed during times when oxygen thermal escape was diminished and carbon thermal escape was still strong. Applying the 1-dimensional photochemical model in the same period, i.e., early in Noachian, ~1 mbar of O_2-dominated atmosphere was formed in about 10^4 years. However, the period of the O_2-dominated atmosphere formation is inconsistent with the Curiosity measurement.

Therefore, we invoked the uncertainly in the evolution of stellar EUV flux due to the difference in the initial rotational speed of the star. When the star's initial rotation speed is fast, the period when the stellar EUV is strong lasts longer. Hence, the period during which the atmosphere cannot be maintained due to massive escape would be longer. This effect shifts the period when the O_2-dominated atmosphere is formed, so that it is in the Hesperian period. Our study suggests that ~1 mbar O_2-dominated atmosphere may be formed during the Hesperian period by taking into account carbon escape, if the stellar evolution

©2020. Japan Geoscience Union. All Right Reserved.

is the type of the fast rotator. This is consistent with the results of the Curiosity measurement.

Radiative Transport Simulations for 0.4 - 1.9 THz Band Heterodyne Spectroscopy of Martian Atmospheric Trace Gases

*Yuki Hamaguchi[1], Hiroyuki Maezawa[1], Hideo Sagawa[2]

1. Osaka Prefecture University, 2. Kyoto Sangyo University

Radiative transport simulations and line surveys for 0.4 -1.9 THz band heterodyne spectroscopy of the Martian atmospheric trace gases were performed assuming nadir and limb-sounding observations with an orbiter. Heterodyne spectroscopy with frequency high resolution is a useful tool to observe the vertical distributions of the temperature, trace molecules (CO, ^{13}CO, C^{18}O, C^{17}O, H_2O, HDO, $H_2{}^{18}O$, $H_2{}^{17}O$, ^{18}OCO, H_2O_2, HO_2, O_3, O_2, etc.), and their isotopes from the surface layer of the Martian atmosphere to an altitude of approximately 100 km. In particular, since a background emission source such as the sun is not required, observations can be carried out at any local time such as day/night, morning/evening, etc. In addition, this wavelength range is less affected by dust absorption and scattering so that this tool allows us to observe the lower atmosphere near the surface of Mars even during dust storms. It is also possible to measure the velocity fields of the atmosphere by utilizing the Doppler shift effect. These strengths will provide us the important information for understanding of the atmospheric oxidation processes and photochemical reaction networks in the Martian atmosphere, the three-dimensional information of the material and water circulations driven by seasonal and diurnal changes from the surface layer to the upper layer, the dissipation history of water vapor into space, the resources for terraforming and future manned Mars missions, and so on.

At present, a working group on the Mars Aqueous Environment and Space Climate Orbiter (MACO) project, with an eye to a future small or medium size Mars orbiter satellite, has been formed in Japan. In this study, we also investigated the optimum frequency bands for the THz-band heterodyne spectrometer, which is an optional instrument in this mission plan. The diameter of the antenna is assumed to be 35 cm. The heterodyne detector and spectrometer are assumed to be a Schottky barrier diode (SBD) mixer operated at room temperature and an autocorrelation type digital spectrometer with a bandwidth of 8 GHz and a resolution of 1 MHz, respectively. The shot noise of the SBD mixer detector was taken into account for the spectrum calculations. For example, in 0.9 THz band the emission lines of ^{13}CO, C^{18}O, C^{17}O, H_2O, HDO, ^{18}OCO, H_2O_2, HO_2, and O_3 can be observed simultaneously by optimizing the frequency setting in double-sideband mode. An altitudinal resolution of better than 6 km will be achieved. When observing high-rise H_2O up to around 100 km, it is possible to respond by switching to a dedicated frequency. How limb-sounding data is processed and compressed on board and downlinked is an important future issue.

In this conference, we will present the results of these simulations.

[A-AS01] High performance computing for next generation weather, climate, and environmental sciences

convener:Hiromu Seko(Meteorological Research Institute), Takemasa Miyoshi(RIKEN), Chihiro Kodama(Japan Agency for Marine-Earth Science and Technology), Masayuki Takigawa(Japan Agency for Marine-Earth Science and Technology)

A lot of advanced simulation studies are being conducted by high performance supercomputers, such as K computer and Earth Simulator, in various fields including meteorology. The high performance supercomputers enable us to conduct numerical simulations and data assimilation of observation big-data (huge high-density and high-frequency data) with a few orders of magnitude higher resolutions and ensemble numbers than those with the previous supercomputers. In addition, the post-K computer, Fugaku will be available as a successor of K, and studies for the Fugaku computer are in progress. At this session, we comprehensively pick up the topics in the Atmospheric and Hydrospheric Sciences Sessions of the 2020 Union Meeting that comprise the atmospheric, oceanic and land sciences. This session aims to promote recent studies related to the issues on high performance computing in weather, climate, and environmental studies using the K computer and other supercomputers, study plans using the Fugaku computer, and to enhance discussions on future directions of numerical simulations in meteorology.

本研究は数値気象モデルの要素（解像度と境界層スキーム（PBL））が豪雨のシミュレーションに与える影響を調べた。対象事例は2014年8月広島での豪雨である。モデルの解像度は5km, 2 km,と500m, 250 mであり、PBLスキームには、Mellor-Yamada-Nakanishi-Niino level3とDeardorffを用いた。

高解像度モデル（500mと250m解像度）は、低解像度モデル（5kmと2km解像度）よりも降水帯の位置や強度を正確に再現した。本事例ではPBLスキームの影響は小さかった。本研究では対流コア（CC s）のモデル解像度依存性についても調査を行った。モデルの解像度に対する対流コアの数の変化率は解像度500ｍで低くなる事がわかった。この結果は対流コアの数は解像度500mより高くすると収束する可能性を示した。これらの結果より本研究では高い解像度のモデル（解像度500m以下）の有用性について示した。

The Assimilation of Dual Phased Array Weather Radar Observations to Short-range Convective Forecasts

*James David Taylor[1], Guo-Yuan Lien[3], Shinsuke Satoh[2], Takemasa Miyoshi[1]

1. RIKEN Research center for computational science, 2. NICT National Institute of Information and Communications Technology, 3. Central Weather Bureau

The assimilation of Doppler velocity and reflectivity observations from phased array weather radar (PAWR) has been widely studied for the use of short-range numerical weather prediction (NWP) and have been found to have positive impact on analyses and forecasts of convective scale weather systems (Maejima et al 2017). However, these studies only assimilated observations from a single PAWR and the use of multiple PAWR observations for NWP has not yet been explored. With the recent development of PAWR located at sites in Osaka University and Kobe a common observation region has been established providing dual radar observations over a large area of the Kobe region, where sudden convective storms can develop and bring intense rain, causing hazardous conditions.

In this study we investigate the impact of utilizing dual PAWR observations for the prediction of a localized convective weather system. We employ the use of the SCALE-LETKF system (Lien et al, 2017), which couples the Local Ensemble Transform Kalman Filter (LETKF) with the Scalable Computing for Advanced Library and Environment (SCALE)-Regional Model (RM), to perform data assimilation experiments with 30-second-update of PAWR observations within a high-1km resolution mesh in order to capture the rapid development of convective activity. The dual reflectivity observations are initially used to identify and remove remaining false echoes from observations, including range sidelobes which are a common radar artifact, thereby improving upon existing quality control measures. Next, we introduce a process of combining reflectivity observations from both radars to reduce the loss of information from rain attenuation, which is a major problem for X-band radars. The results show that implementing these new data assimilation methods lead to improvements in both rainfall intensity and distribution in short range forecasts.

In recent years, a dense and frequent lightning observation system named “BOLT” was developed (e.g. Yoshida et al. 2014), observing every 10^{-6} seconds 3-dimensional lightning locations at 100-m resolution. The original data has a 70-km range in the horizontal and a 20-km range in the vertical. To assimilate the lightning location data with a regional numerical weather prediction model “SCALE” (Nishizawa et al. 2015), an observation operator to convert the model variables to lightning data is needed. In general, lightning is triggered by large electric charge originated from graupel collisions with strong updraft. Therefore, we investigated a relationship between the lightning observation data and the model graupel data. First, we performed a 30-seceond-update, 100-m-mesh SCALE-LETKF (Miyoshi et al. 2016, Lien et al. 2017) experiment with every 30-second Phased Array Weather Radar at Osaka University (Ushio et al. 2014), and we created every 30-second model data. For the lightning data, we calculated every 30-second lightning frequency per model grid. We investigated a scatter plot of the lightning frequency and the model graupel mixing ratio.

Using all lightning and graupel data, we could not find a clear relationship. However, by applying a criterion on lightning generation (Takahashi 1978), we found a high correlation between the lightning frequency and the graupel mixing ratio. Based on the result, we will develop an observation operator and try to contribute to a severe local rainfall forecast.

1. RIKEN

River water often plays an important role in fog formation in the coastal ocean. Fresh and light water input from rivers makes a thin layer over the ocean around the river mouth. Even if the thin layer is cooled in a cold season, water column can keep stratification. As a result, near surface atmosphere becomes colder than the surrounding area, and an inversion layer tends to occur in the lower atmosphere. This condition leads to generate and maintain fog near the river mouth.

It is important to predict the occurrence and duration of fog for air- and sea-port operations near the coast. For example, Haneda Airport is closed about once a year due to heavy fog events. In particular, a heavy fog event on March 8, 2016 would be related to the river inflow.

This study aims to simulate the coastal fog using a coupled atmosphere-ocean-river model and to enhance our forecasting capabilities. We conducted offline coupled experiments with atmospheric and ocean models for the heavy fog event on March 8, 2016. To generate the bottom boundary condition with fine resolution for the atmospheric model over Tokyo Bay, we used the Regional Ocean Modeling System (ROMS). We performed two experiments: the RIV/CTL experiments with/without the effect of the river input, respectively. The grid spacing was chosen to be 500 m, and the atmospheric forcing was taken from the operational numerical weather prediction data of the Japan Meteorological Agency (JMA) Meso-scale Model (MSM). The obtained sea-surface temperatures (SSTs) were merged with those of the National Centers for Environmental Prediction-Final Operational Global Analysis data (NCEP FNL). By using the merged data as the lateral and bottom boundary conditions, we calculated the atmospheric states by a regional atmospheric model SCALE with three nested domains: the grid spacing in the innermost domain was chosen to be 500 m.

The results showed that relative humidity north of the Haneda Airport in the RIV experiment was larger by 2-3% than that in the CTL experiment from the night of March 7 to the morning of March 8. This feature was found over a cold SST region in the RIV experiment extended from the mouths of the Arakawa-river and the Sumida-river. The cold SST was generated by an above-normal fresh water inputs from both rivers due to precipitation in the morning of March 7. Over the cold SST region, the atmospheric inversion layer was maintained for a longer time than the surrounding regions. South-westward near-surface wind at that time potentially contributed to generate the fog over the airport by bringing the humid air.

The ensemble Kalman inversion and its application into estimating parameters of a distributed rainfall-runoff model

*Le Duc[1,2]

1. JMBSC, 2. MRI

In data assimilation, the ensemble Kalman filter (EnKF) is a technique that based on sampling in estimating any system states given observations. Thus, uncertainties of the system state are represented by an ensemble of points which is propagated through time by a model and adjusted whenever observations are available. Compared with the variational methods, EnKF has two advantages: (1) the computation of EnKF is inherently parallel, and (2) the tangent linear model and its adjoint are not needed.

If we run a data assimilation scheme many times for the same observations, the system state would tend to overfit the observations. This simple fact shows that we can turn any data assimilation method to an optimization method. Now it becomes clear that for nonlinear optimization problems which have complicated nonlinear operators as complex models, EnKF suggests a viable derivative-free optimization method since we do not need to compute the derivatives of such nonlinear operators. The EnKF when applied in such problems is called the ensemble Kalman inversion (EKI) which inherits the two aforementioned advantages of EnKF. In this study we introduce and demonstrate the work of EKI by applying it into estimating parameters for a distributed rainfall-runoff model.

Retrieval of hygroscopic growth factor of uniformly mixed aerosol particles based on immune evolution algorithm

*Zhicha Zhang[1,2], Changjian Ni[1,2]

1. Chengdu University of Information Technology, 2. Plateau Atmospheres and Environment Key Laboratory of Sichuan Province

Based on decomposition of atmospheric extinction coefficient and Mie scattering theory, the objective function, which has the sole variable of the hygroscopic growth factor of uniformly mixed aerosol particles, was established. Furthermore, immune evolution algorithm was further used to optimize the objective function, and a feasible method was proposed to retrieve hygroscopic growth factor of uniformly mixed aerosol particles. The performance of the method was evaluated by utilizing the hourly ground observation data from nephelometer, aethalometer and GRIMM180 environment particle monitor in Chengdu from October 2017 to December 2017, as well as the coincidental environmental and meteorological data, which includes atmospheric visibility, relative humidity (RH) and NO_2 mass concentration. The results suggest that the retrieval algorithm is characterized by fast convergence, robustness and precision for all tested samples. hygroscopic growth model of uniformly mixed aerosol particles was established during autumn and winter in Chengdu. Note that this model could significantly improve the simulation accuracy of aerosol scattering coefficient in ambient conditions. The advantage of this model is that the average relative error between the simulated and the measured is only 12.7%. The universal algorithm is beneficial for subsequent study on the aerosol hygroscopic properties and its radiative forcing impacts.

A scale-aware PBL scheme: for the unified simulation in mesoscale and global circulation models

*Wei Wei[1]

1. Chinese Academy of Meteorological Sciences

With the development of high performance supercomputers, kilometer- or sub-kilometer-scale numerical simulations have been realized. In the past, turbulence is well resolved by three-dimensional (3D) large-eddy simulation (LES) at very fine grid sizes (10~100 m) and for grid sizes greater than 2 km, one-dimensional (1D) planetary boundary layer (PBL) parameterizations represent sub-grid turbulence in the PBL. When it comes to kilometer- to sub-kilometer-scale grid sizes, neither 3D LES nor 1D PBL parameterization perform appropriately, called the “Gray zone”. This study readapted the turbulence mixing length in the UW PBL parameterization by adding a partition function which is related to the horizontal resolution and PBL height. The developed UW parameterization (UWnew) and several other 1D PBL schemes were applied to the simulation of an ideal convective boundary layer at “Gray zone” scales using WRF model.

The results show that, in terms of the profiles of the area mean values and sub-grid heat/momentum flux, scale-aware UWnew and ShinHong schemes perform the best at “Gray zone” scales among all the schemes (including UWnew, UW, ShinHong, MYNN2.5, YSU, BouLac). And UWnew scheme shows more rational results in the PBL simulation compared with UW scheme. To specify the performance of UWnew scheme in the simulation at “Gray zone” scales, four simulations with different horizontal resolutions were launched using UWnew and UW schemes. In the case of “Gray zone” scales, the profiles of sub-grid heat/momentum flux from the UWnew simulation is smaller than that of the UW scheme. This is mainly resulted from the reduced turbulent heat/momentum exchange coefficient values in the PBL. The weakened vertical flux confirms that the UWnew scheme improves the simulation of the physical process at “Gray zone” scales in which the process is partly resolved and partly parameterized.

A near-real time weather forecast system based on a data assimilation system of Local Ensemble Transform Kalman Filter for the Nonhydrostatic ICosahedral Atmospheric Model (NICAM-LETKF Terasaki and Miyoshi 2017, Kotsuki et al., 2017) called NEXRA (NICAM-LETKF JAXA Research Analysis) has been developed by the collaboration of JAXA, RIKEN, and the University of Tokyo. The operational system, which is operated at JAXA’ s super computer (JSS2), provides 5-day weather forecast every 6-hour initialized by the ensemble mean of 100 members of the NICAM-LETKF data assimilation system. The assimilated observations are GSMaP (precipitation), AMSU-A (temperature), and PREPBUFR. At current stage, the 5-day forecast data with horizontal resolution at 112 km are available on the website (https://www.eorc.jaxa.jp/theme/NEXRA/index_j.htm). We introduce two resent progress toward the next generation NEXRA in this presentation. One is the development of the 5-day forecast system with finer horizontal resolution at 28/14 km, and the other one is a new NICAM-LETKF system assimilated observation data obtained from mhs (humidity) and atms (temperature and humidity), in addition with GSMaP, AMSU-A, and PREPBUFR. The new forecast system is initialized with 28/14 km data linear interpolated from 112 km initial states obtained from the current NICAM-LETKF system and the cloud microphysics scheme NSW6 (Tomita 2008) is used. To validate the new forecast system, we show the forecast experiment for the typhoon KROSA in August 2019 which hit SHIKOKU Island of Japan. Results show that the forecasted typhoon structure and the rain pattern of KROSA showing good agreements with observations. To validate the new system, we compare assimilation performance between the current and new NICAM-LETKF system.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

[A-AS02] Abnormal weathers and disasters in urban environments in East Asia related to climate change

convener:Masaru Inatsu(Faculty of Science, Hokkaido University), Yukari Takayabu(Atmosphere and Ocean Research Institute, the University of Tokyo)

Global climate change possibly increases weather disasters such as heatwave, gale, torrential rain, and heavy snowfall. Abnormal global-to-synoptic scale phenomena at least lay behind the frequent occurrence of local-scale extremes. The relation between large-scale pattern and local-scale abnormal weathers has recently been scrutinized by statistical analysis of high-resolution data derived from artificial-satellite observation and numerical simulations. Moreover, impact assessment of climate change to various sectors like water resource management, agriculture, energy control should be reduced to adaptation policies for industries and local governments including urban areas. This reduction generally requires close communication between scientists and stakeholders, with an aid of storyline approach to represent uncertain information on climate change. Therefore, studies on climate change, if limited to East Asia, range from global to urban scales and are interdisciplinary from fundamental to applications. This session calls for research topics in a various related field, and the participants can share possible future extensions of climate change studies.

Frequent occurrences of extraordinary weather events in recent years have disclosed the vulnerability of our society to unexperienced kinds of extreme events. Increase of such extreme weather events are attributed to the global warming. Since we expect to face even further increases of extreme events in future, it is necessary to help policy makers for making adequate adaptation plans. To this end, an essential point is to estimate the range of uncertainty for future changes of phenomena, and to adequately convey such information to the policy makers.

In this talk, we will introduce our project supported by the Environment Research and Technology Development Fund (2-1904). In this research, we employ the Storyline method, which is introduced to make physical explanations why and how extraordinary weather phenomena are affected by the global climate change. We especially focus on local phenomena around Japan, such as extreme rainfall, extreme droughts, heat waves, etc.

In our project, we study how extraordinary weather phenomena are linked to large-scale dynamics. We also discuss how to choose climate models from the CMIP5 and CMIP6 model ensembles, in order to represent a wide range of uncertainty in future change. Finally, we aim to extract small numbers of climate storylines which represent the possible range in future changes of extreme weather phenomena around Japan and their connections to changes in large-scale atmospheric condition.

A gusty wind by typhoons is one of the major natural hazards and has been the most threatening windstorm in urban districts. In Osaka City, the recorded highest instantaneous wind speed reached up to 60 m/s. The recent intense tropical cyclone, Typhoon Jebi, which landed the central part of Japan in September 2018 with the lifetime minimum central pressure of 915 hPa and the maximum wind speed of 48 m/s, exhibited a similar track compared to past disastrous typhoons: Typhoon Nancy (1961) and Muroto Typhoon (1934). Urban surface roughnesses, e.g. building obstacles, exert significant influences on the magnitude of wind gustiness. With the growing urbanization globally, quantification of turbulent winds in densely-built, urban districts is important to the assessment and prediction of risks of wind damages and the understanding of the underlying physical mechanisms. The influlences of densely built urban environments on the occurrence of wind gusts in urban districts of Osaka and Kyoto City during the landfall of Typhoon Jebi are studied by merging mesoscale meteorological and building-resolving large-eddy simulations (LES), which allows an explicit representation of the complicated building structures while retaining the strong mesoscale perturbations from the typhoon. With the successful reproduction of the track and intensity of the typhoon in meteorological simulations, the simulated winds at the boundary-layer top of the LES model are used to quantify the wind gusts in the urban district. The maximum wind gust in the analysis area of Osaka is around 60-70 m/s, which is comparable to the wind speed at the height of about 300 m. Such wind gusts are generated by the instantaneous downward momentum transfer in areas, where buildings with a high variability in the height are clustered. The instantaneous wind gusts are found to be the strongest when the building packing density is moderate. The results suggest that the risks of wind damages are mostly likely to be maximized in urban districts where the building height is highly variable and the packing density is moderate.

近年の相次ぐ極端な気象を経験することで、変動する気候に備えていくことの重要性が社会により理解されるようになってきた。この備えにはハード対策とソフト対策があり、その双方に領域再解析が重要な役割を果たすことができる。

領域再解析は全球再解析の枠組みのもとで、過去の観測データを用いて領域の４次元データ同化システムを回すことで実行することができる。この領域再解析にはかなりの計算資源や人的資源が必要であり、領域再解析が私たちの社会にどの程度のベネフィットをもたらすのかを考えることが必要である。

すでに気候モデルの専門家たちはd4PDF (Mizuta et al. 2017)など巨大アンサンブルによる将来予測実験を通じて、河川堤防や防潮堤などのハード対策の計画に貢献しつつある。気候変動への適応策が進められる中、d4PDFの結果は農業、水文、リスク管理など、様々な分野にも使われている。気候モデルの利用者たちは、シミュレーション結果を将来計画の意思決定に活用しつつある。ハード対策では、予算規模の大きさや長期間にわたる整備が必要であることから、情報の信頼度をしっかり確認しつつ進めていく必要がある。気候シミュレーションの信頼性を確認する一つの選択肢は、シミュレーション結果と自然変動の観測結果を比較することである。地域での適応策に肝要な地域の気候変動においては、全球の再解析よりも領域の再解析がこの比較において重要な役割を果たす。

領域再解析は気候変動の把握だけでなく、リスク管理やレジリエンスの強化にも重要な役割を持つ。領域再解析は、過去の顕著な現象について事実に基づいたシナリオを提供する。また、再解析は領域モデルによる予報の初期条件も提供し、これによる過去の予報は再予報と呼ばれる。特定の地域から見ると、気象による災害の頻度は一般に稀である。例えば、市町村単位で極端な現象への備えをするためには、長期間の再解析や再予報を用いて過去の極端現象から学ぶ必要がある。過去現象の再現に最新の数値予報システムを用いると、過去の事例を通じて得られた知見が今後の極端現象について数値予報で予測された時の行動判断に生かされることになる。というのは、極端現象に対する予報の信頼性についての知見を利用者が持つことができるからである。気象予測には大なり小なり誤差が必ず伴うことから、気象分野以外の様々な分野の専門家や利用者が意思決定をする際に、予報の信頼性を彼らが理解していることが極めて重要である。

このように、領域再解析には２つの重要な役割があることがわかる。一つは実際に起きている気候変動を把握し、確認すること、もう一つは過去の極端現象の知見を今後の極端現象への対応に活かすことである。前者の役割では、Fukui et al. (2018)のような手法を選択することが良いだろうし、後者については現業で使われている数値予報システムに近いもので衛星観測などの観測データも活用したものを使う手法を選択したい。防災対応分野や再生可能エネルギー分野が領域再解析・再予報の主要な利用者になるものと考える。

領域再解析の社会へのベネフィットをさらに高めるためには、海洋学、水文学・雪氷学、エネルギー部門、大気化学など様々な分野の専門家やデータ利用者たちとの連携の活性化が重要である。そのためには、d4PDFの活動を通じて発展してきた関係分野、利用者との連携を活用することが鍵となる。

最後に、国際連携の重要性も指摘しておきたい。第一段階としては、過去の観測データを近隣国で交換、共有化することが、各国での領域再解析の活動に貢献することになる。さらには再解析結果を共通する領域で比較することがこれらの国々にとって有益であろう。

Impacts of climate change on heavy wet snowfall in Japan: differences among wether patterns

*大庭 雅道[1]、杉本 聡一郎[1]
*Masamichi Ohba[1], Soichiro Sugimoto[1]

1. 電力中央研究所
1. Central Research Institute of Electric Power Industry

Wet snow is a primary cause of atmospheric icing, which can lead to severe damage to power towers and lines, resulting in electrical breakdowns and blackouts. This study investigated the influence of climate change on heavy wet snowfall events during the winter season in Japan. Self-organizing maps (SOMs) were used to explore the weather patterns (WPs) associated with changes in heavy wet snowfall. This study used climate projections obtained from the database for Policy Decision-making for Future climate change (d4PDF) to investigate the impacts of climate change on wet snowfall in Japan. The SOM technique was applied using the surface atmospheric circulation to determine the dominant heavy wet snowfall WP. The SOMs showed that some WPs had a significant effect on the magnitude, frequency, and location of heavy wet snowfall in Japan. The projected changes in the amount of heavy wet snowfall showed a nonuniform spatial distribution. Additionally, the impact of climate forcing on WPs associated with heavy wet snowfall was evaluated to understand the spatially heterogeneous changes in wet snowfall. The SOM analysis results suggest that the future changes in spatially heterogeneous extreme wet snowfall can be attributed to differences in WP responses to climate change. These differences can be attributed to the future variations in the region of the atmospheric layer at temperatures near 0 ˚C (rain-snow transition layer) among WPs, which can alter the spatial distribution and frequency of heavy wet snowfall. The findings can help inform structural design requirements to withstand regional climate change.

An application of the detection method for atmospheric fronts to a large ensemble climate data

*宮本 真希[1]、山田 朋人[1]
*Maki Miyamoto[1], Tomohito Tomohito[1]

1. 北海道大学
1. Hokkaido University

In recent years, heavy rainfall disasters attributed to atmospheric fronts often occur in Japan, such as the heavy rain event of July 2018 in western Japan and 2017 in northern Kyushu. A forecasting of the fronts as well as rainfall associated with them make impacts on society in disaster prevention such as risk avoidance due to heavy rainfall. To give an example, a weather forecast for short-term within 1 week, is useful to take refuge and for yearly long term is helpful to determine an evacuation plan.

A previous study made normalized parameter of thermal and dynamical variables, horizontal temperature gradient and isobaric relative vorticity. There is an atmospheric front at isobaric surface of 900hPa where the parameter is over threshold value. Around an atmospheric front, horizontal temperature gradient is larger than other regions. The wind converges in the boundary between warm air mass and cold air mass with rotation. Therefore, horizontal wind fields of the fronts have positive relative vorticity compared to others. This diagnostic detected the front accompanying passing of extratropical cyclone across the North Atlantic.

In this study, a thermal variable of the parameter used by the diagnostic is equivalent potential temperature and the objective diagnostic is specialized for the climate of north-western Pacific Ocean region around Japan. The equivalent potential temperature means the temperature and quantity of water vapor. Thus, the new diagnostic would detect the boundary between air masses which has the difference in quantity of water vapor as fronts. It called as water vapor front. It appears on East China Sea at south side of Baiu front. In the case of the heavy rain from June 28th to July 8th, 2018, nine o’ clock (Japan standard time) each day, the diagnostic detected a part of Baiu front in four days and all part of it in seven days. In addition, it detected water vapor fronts in the term of heavy rain in 2018. In other cases, it detected cold fronts, warm fronts, occluded fronts embedded with an extratropical depression. The parameter value increases with improvement of the depression.

This diagnostic would be used to detect the fronts in future climate. The used data is d4PDF, a database composed of the results from model experiments for 3,000 years in past climate and 5,400 years in future climate. We apply the method to the data for climate of the past and future. These application results would be compared and used to examine the variation of the frontal distribution with climate change.

Diurnal Variability of Urban Heat Island Intensity in Metro Manila, Philippines: An Initial Investigation

*John Asaula Manalo[1,2], Jun Matsumoto[1,3]

1. Department of Geography, Graduate School of Urban Environmental Sciences, Tokyo Metropolitan University, 2. Climatology and Agrometeorology Division, Philippine Atmospheric Geophysical and Astronomical Services Administration, Quezon City, Philippines, 3. Department of Coupled Ocean-Atmosphere-Land Processes Research, JAMSTEC, Yokosuka, Japan

Studies have shown that the Urban Heat Island (UHI) Effect driven by urbanization and industrialization is one of the major problems in the 21st century. In this study, the diurnal variability of urban heat island (UHI) intensity in the four stations located in populated cities in Metro Manila was investigated using the AWS measurements retrieved from the Philippine Atmospheric Geophysical and Astronomical Services Administration (PAGASA) of the Department of Science and Technology (DOST) from 2014 to 2018. Highest UHI intensity occurred at 20:00 PST was observed in the City of Manila (Port Area station, 4.03˚ C), at 21:00 PST in Pasig City (Pasig City Hall station, 2.95˚C), and at 19:00 PST and 21:00 PST in Quezon city (Science Garden station, 3.02˚C; La Mesa station, 4.28˚C, respectively). The maximum UHI intensity was observed generally during night time and lowest UHI intensity was observed during day time for all the stations. The results of this study will enable further research to better understand and mitigate the challenges brought by urbanization.

Land suitability evaluation for agricultural cropland in the Dornod province, Mongolia using Remote Sensing and GIS tools

*Tsolmon Renchin[1], Bayanjargal Darkhijav[1], Davaajargal Jargalsaikhan[2], Enkhjargal Natsagdorj[3], Batbayar Ganchudur[1]

1. National University of Mongolia, Mongolia, 2. Institute of Mathematics and Digital technology Mongolian Academy of Sciences, Mongolia , 3. Dept. of Geography, Ghent University, Ghent, Belgium

The purpose of this study is to create an estimation of cropland suitability map in the study area Dornod province, which belong to the Gobi and steppe region of Mongolia. The soil of the study area is suitable for agriculture, which is one of the main sectors of our economy. However, the pasturing livestock and the crop production are very vulnerable to climate change in the study area. Dry land expansion and pasture land degradation cause to agriculture land vulnerability. It is important to evaluate the impacts of climate change affecting to effectiveness of agriculture and implement the adaptation methods.

We used MODIS data over 2003-2018 to study how the soil moisture content and long term data have changed in the past and what trend is in the future. Multivariable regression analysis using satellite images for Normalized Vegetation Index (NDVI) and Land surface Temperature (LST) from MODIS and DEM Elevation soil and climate data were applied for the potential for crop production in the study area. Multivariable regression analysis provides an opportunity for understanding and analyzing the nature of other factors affecting the factors. In particular, we would propose some models for cropland suitability, which depends on many factors such as surface temperature, elevation, slope, orientation and other soil parameters in the Gobi and steppe regions of Mongolia. The result shows that output map created accurate result and reasonable for cropland suitability. The approach can be an advantageous indicator for carrying out agricultural management decisions and advise for decision-makers in the Gobi and steppe regions of Mongolia.

[A-AS03] Atmospheric Chemistry in Highly Polluted Environments

convener:Hongliang Zhang(Fudan University), Jianlin Hu(NUIST Nanjing University of Information Science and Technology), Jia Xing(Tsinghua University), Siyu Chen(Lanzhou University)

Due to the rapid growth of economy and fossil fuel consumption and lack of emission controls, Many Asian regions have experienced substantially elevated concentrations of air pollutants, such as China, India, and Southeast Asia. High concentrations of air pollutants have significant impacts on public health and also play an important role in the climate system. Understanding the emissions, fate, and impact of high air pollution in these regions is essential for designing effective control strategies.
In the many highly polluted regions, large amount of anthropogenic emissions from industrial and/or residential activities are mixed with biogenic emissions, wind-blown dust, and biomass burning, then undergo complex atmospheric chemistry processes and form secondary pollutants such as ozone and particulate matter. Many studies suggested that high pollution formation is much faster in these regions and cannot be completely explained by knowing atmospheric chemistry, indicating additional chemistry processes in highly polluted environments, which are likely associated with the complex emission sources, unique climate and topography. Progress has been made in several aspects, such as additional sources and formation pathways of atmospheric radicals, heterogeneous reactions on particle surface for sulfate and organic aerosol formation.
Studying atmospheric chemistry in highly polluted environments involves field measurements, lab experiments, and numeric modeling. It will advance our scientific understanding of the formation processes, improve our knowledge in sources of air pollutants, help develop air pollution control strategies for protecting public health and climate in these regions.

Significant contributions of upwind sources to ground-level ozone in the North China Plain

*Hongliang Zhang[1,2], Kaiyu Chen[2], Pengfei Wang[2], Siyu Wang[1], Peng Wang[3], Qi Ying[4], Jianlin Hu[5]

1. Fudan Univ., 2. LSU, 3. HKPU, 4. TAMU, 5. NUIST

With its adverse impacts on air quality, human health and ecosystem and increasing concentrations, ground-level ozone (O_3) is receiving increasing attention in China. Emissions of O_3 precursors, nitrogen oxides (NOx) and volatile organic compounds (VOCs), vary significantly spatiotemporally. Background and long transport of O_3 and its precursors have been shown to be important for O3 concentrations in the North China Plain (NCP). However, there is no study quantifying the contributions for designing effective controlling measures. This study uses a source-oriented version of the Community Multi-scale Air Quality (CMAQ) model with updated mechanisms to estimating contributions of different source regions to O3 in the NCP in summer 2017. Anthropogenic emissions are generated by an improved Emissions Database for Global Atmospheric Research (EDGAR+) and biogenic emissions are from the Model for Emission of Gas and Nature (MEGAN). Emissions from open burning are based on the Fire Inventory from NCAR (FINN). This study provides evidences the importance of considering regional transport to understanding O_3 formation, O_3-related human health risk and economic loss and helps policy makers in making control strategies.

How much do emissions from China affect Northeast Asia?

*Hongliang Zhang[1,2], Pengfei Wang[2], Chun Cheng[3], Yele Sun[3]

1. Fudan Univ., 2. LSU, 3. IAP, CAS

Air pollution in Asian countries is attracting local and international concerns and a common debate is that emissions from larger countries like China are likely to affect surrounding areas. Although this case is true at special meteorological conditions from observation analysis, it is very important to quantify the transport of pollution among different countries over long period. In this study, a source-oriented version of Community Multi-scale Air Quality (CMAQ) model was applied to quantify the contributions of nine source regions (North Korea, South Korea, Japan, Northeast China, Jing-Jin-Ji area, Shandong, Jiangsu and Shanghai (YRD) 1, Anhui and Zhejing and rest areas in China) to $PM_{2.5}$ and its primary PM (PPM) and secondary inorganic aerosol (SIA) in East Asia in 2019. Anthropogenic emissions were generated from a combination of the Multi-resolution Emission Inventory (MEIC) (for China area) and the MIX Asian emission inventory (for all other areas).

Keywords: Transport, Northeast Asia, PM2.5

Modeling analysis of the spatiotemporal distribution characteristics of the atmospheric ultrafine particle in North China Plain and Yangtze River Delta of China in 2016

Yanhong Zhu[1], *Jianlin Hu[1]

1. NUIST Nanjing University of Information Science and Technology

Epidemiological studies identify the strongest health associations with particles that have diameters <2.5 μm ($PM_{2.5}$) but toxicology studies suggest that particle with diameters <0.1 μm ($PM_{0.1}$) maybe even more dangerous. And $PM_{0.1}$ can be used as cloud condensation nuclei (CCN) to influence cloud processes. At present, there is no conventional observation of $PM_{0.1}$ in China, so its spatiotemporal distribution characteristics are not clear.

Model simulation is another effective method for the study of air pollution. Chemical transport model (CTM) is often used to reproduce the past pollution event, test the new air pollution mechanism, predict future air quality and provide high time-and-space resolution data for the epidemiological study. Until now there have been many CTMs analyzing the air pollution events in China, and the Community Multiscale Air Quality model (CMAQ) is one of the most commonly used CTM in China. In the numerical simulation of particulate matter by the CMAQ model, except for one level of nanometer of nucleation, simulation of particulate matter less than 2.5 μm is often used without smaller particle size bins. Therefore, the domestic model simulation study of $PM_{0.1}$ is rare.

The University of California, Davis/California Institute of Technology (UCD/CIT) regional reactive chemical transport model is a third-generation air quality model developed by the UC Davis team based on the 1980s California Institute of Technology (CIT). The composition, mass and number concentrations of the particle with the diameter between 0.01 and 10 μm are showed in 15 size bins. The first 5 size bins of the UCD/CIT model are for $PM_{0.1}$, so it can simulate $PM_{0.1}$. At present, the UCD/CIT model has been applied in the simulation of $PM_{0.1}$ in America. In this paper, for the first time, we use the UCD/CIT model to simulate the pollution of gas and particulate matter in China, compare the model performance of UCD/CIT with CMAQ and analyze the spatiotemporal distribution characteristics of $PM_{0.1}$ in China.

Impact of land-use changes on biogenic emissions and formation of ozone and secondary organic aerosols in China from 2013 to 2017

*JinLong Ma[1], Yu Wang[1], Peng Wang[2], hongliang Zhang[1]

1. Fudan University, 2. The Hong Kong Polytechnic University

Biogenic volatile organic compounds (BVOCs) emissions are the major source of secondary organic aerosol (SOA) and ground-level ozone (O_3), and are harmful to human health, especially in urban areas. However, with the rapid growth of urbanizations, changes in land-use in China will result in inaccuracies in the understanding of regional BVOCs emissions. In this study, the Model of Emissions of Gases and Aerosols from Nature version 2.1 (MEGAN2.1) module embedded within the Community Multi-scale Air Quality (CMAQ), coupled with the land-use dataset derived from Moderate Resolution Imaging Spectroradiometer (MODIS), was used to estimate the changes in emissions of BVOCs and their impacts on O_3 and SOA in China from 2013 to 2017. The results would highlight the importance of considering land-use changes due to urbanization in predicting O_3 and SOA.

Keywords: biogenic emissions, land-use, ground-level ozone, secondary organic aerosol, MEGAN2.1

Long term trends in air pollution in China

*Shengqiang Zhu[1], Siyu Wang[1], Zhihao Shi[2], Fei Ye[2], Jianlin Hu[2], Hongliang Zhang[1]

1. Fudan University, 2. Nanjing University of Information Science & Technology

With the rapid growth of industries and population in China over the past 30 years, the air pollutants emissions have increased and resulted in high pollution levels than past. This study predicts ozone and particulate matter (PM) in China over the past 30 years from 1990 to 2019 using the Community Multi-scale Air Quality (CMAQ) model. The meteorology in China over the past 30 years has been acquired by using Weather Research and Forecasting (WRF) model version 4.1.2. The past 30 years' anthropogenic emissions were generated based on the Emissions Database for Global Atmospheric Research (EDGAR). The emissions after 2012 were adjusted based on factors reflecting control measures. And the biogenic emission was from the Model for Emissions of Gases and Aerosols from Nature (MEGAN) version 2.1. The open burning emissions was from National Center for Atmospheric Research (NCAR) while the dust and sea salt emissions were generated in line CMAQ. The long term trends of emissions and ambient concentrations with spatial and temporal variations of air pollutants from 1990 to 2019 will be investigated after model validation against available measurements in China and around countries/regions.

Improving ozone simulation and understanding its adverse effects in India

*Mengyuan Zhang[1], Siyu Wang[1], Kaiyu Chen, Xue Qiao, Sri Harsha Kota, Hongliang Zhang[1]

1. Fudan University

In India, large anthropogenic emissions and relatively high solar intensity provide the most favorable conditions for the formation of ozone (O_3), which has significant adverse effects to human health and ecosystems. However, there are very limited sites with O_3, and assessments of O_3 effects are hindered. This study aims to simulate regional O_3 concentrations in India from 2012 to 2015 using the Community Multi-scale Air Quality (CMAQ) model at the resolution of 36 ×36 km^2. The meteorological fields are generated by the Weather Research and Forecasting (WRF) model. The anthropogenic emissions are generated from Emissions Database for Global Atmospheric Research (EDGAR) and the MIX Asian emission inventory. Emissions are adjusted to simulation years with different adjustment coefficients for different sectors and states. Biogenic and wildfire emissions are also provided to CMAQ. After the model results are validation, the levels, health and ecosystem effects are analyzed. The study reveals the importance of controlling O_3 in India and indicates more studies are needed for designing effective control strategies.

Comparison of the SAPRC18 and SAPRC11 photochemical mechanisms for ozone simulation in China

*Yu Wang[1], JinLong Ma[1], Peng Wang[2], Hongliang Zhang[1]

1. Fudan University, 2. The Hong Kong Polytechnic University

The latest SAPRC photochemical mechanism SAPRC18 (S18), an update from SAPRC11 (S11), is implemented into the Community Multi-scale Air Quality (CMAQ) model and applied to simulate ozone formation during the China Air Quality Study 2017. Compared to S11, S18 can better simulate NO_x recycling processes and formation of SOA precursors. The results from the S11 mechanism are compared with those from the S18 mechanism. The photolysis rates of new model species added to the mechanism by S11 are much lower than those of S18.

Keywords: S18, S11, CMAQ, photolysis rates

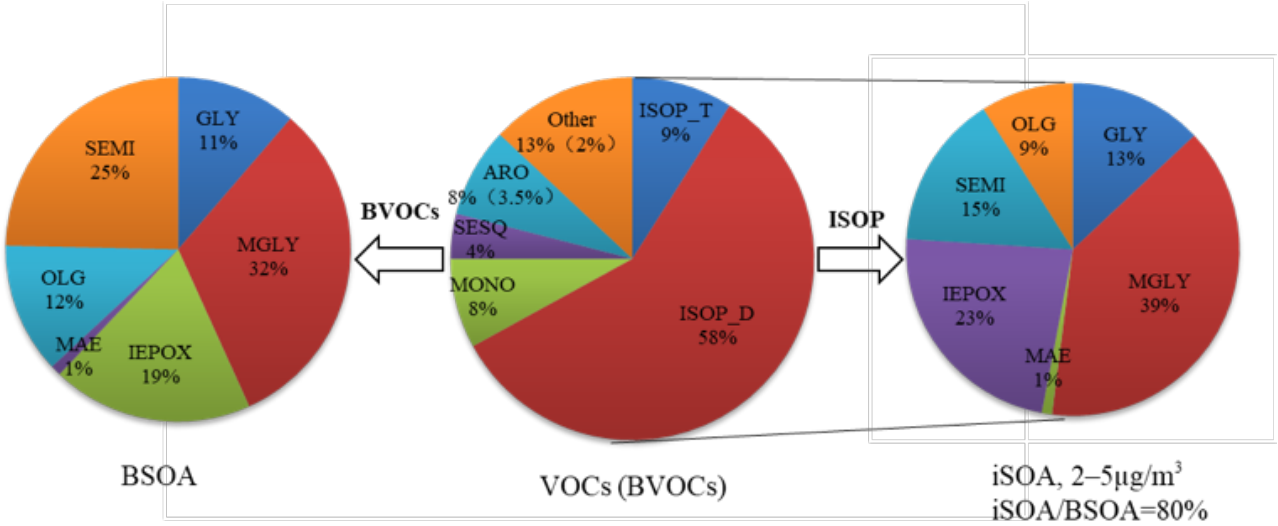
Contribution of biogenic sources to secondary organic aerosol in summertime in Shaanxi, China

*Yong Xu[1], Hongliang Zhang[2], Dexiang Wang[3]



1. Yangzhou University, 2. Fudan University, 3. Northwest A&F University

Abstract:A revised Community Multi-scale Air Quality (CMAQ) model with updated secondary organic aerosol (SOA) yields and a more detailed description of SOA formation from isoprene (ISOP) oxidation was applied to study the spatial distribution of SOA, its components and precursors in Shaanxi in July of 2013.

The emissions of biogenic volatile organic compounds (BVOCs) as the CMAQ input were generated using Model of Emissions of Gases and Aerosols from Nature (MEGAN). Emissions of ISOP and monoterpene (MONO) mostly were the highest with 1.73×10^{9}mol and 1.82×10^{8}mol in July in total, respectively. The spatial distribution of BVOCs emission was significantly correlated with the vegetation coverage distribution in Shaanxi. ISOP and its intermediate semi–volatile gases were the highest among BVOCs in the ambient with highest concentrations of about 7.0 and 1.4 ppb, respectively, and formaldehyde from biogenic sources was up to ~3 ppb in South Shaanxi.

Predicted SOA was generally 2–6 $\mu g/m^3$, of which biogenic SOA (BSOA) from biogenic source in the study region accounted for as high as 84% in average in Shaanxi. Three main BVOCs Precursors included ISOP (58%) and MONO (8%) emit in the studied domain, and ISOP transported from south China (9%). The Guanzhong Plain had the highest BSOA concentrations of 3–5 $\mu g/m^3$, and the North Shaanxi had the lowest of 2–3 $\mu g/m^3$. More than half of BSOA was due to reactive surface uptake of ISOP epoxide (IEPOX) (0.2–0.7 $\mu g/m^3$, ~19%), glyoxal (GLY) (0.2–0.5 $\mu g/m^3$, ~11%) and methylglyoxal (MGLY) (0.4–1.4 $\mu g/m^3$, ~32%), while the remaining was due to the traditional equilibrium partitioning of semi-volatile components (SEMI) (0.1–1.2 $\mu g/m^3$, ~25%) and oligomerization (0.2–0.4 $\mu g/m^3$, ~12%). Overall, SOA formed from ISOP (iSOA) contributed 1–3 $\mu g/m^3$ (~80%) to BSOA, of which GLY and MGLY accounted for 13% and 39%, respectively.

Keywords: CMAQ, MEGAN, precursors, isoprene, BSOA

Preliminary study on physical and chemical properties of dust

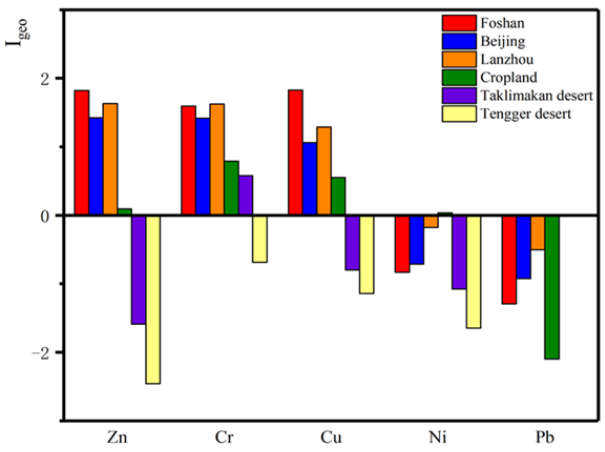
*Yuan Luo[1], Siyu Chen[1]

1. Lanzhou university

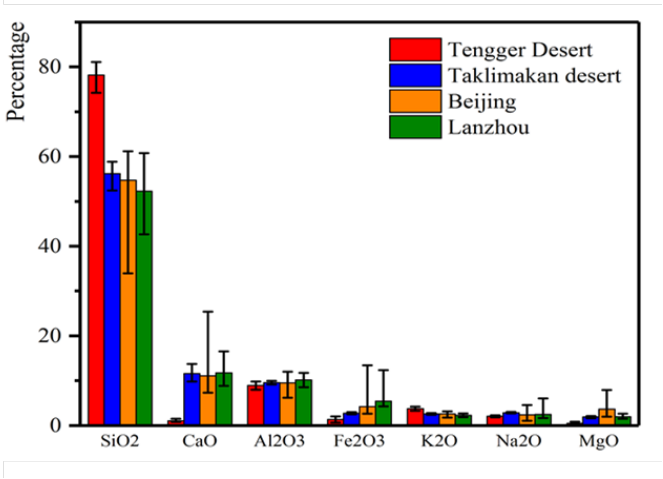
Dust aerosol is an important part of atmospheric aerosol, which affects the climate system through direct, indirect and semi-direct effects. The aerosol of dust can be divided into natural dust and man-made dust according to the source. Natural dust mainly comes from the desert, gobi desert and other bare surface. Anthropogenic dust is the part of dust that is directly or indirectly brought into the atmosphere by human activities.

The size of dust particles is an important factor that determines the suspension, transfer, deposition and life of particles. At the same time, the dust particles are easy to absorb bacteria, heavy metal pollutants, sulfate and organic pollutants during the transmission process, which are harmful to human health. In this study, we collected 400 samples from a variety of surfaces to further study the effects of different land cover and human activities on the properties of sand dust, and to provide a research basis for the differences between man-made sand dust and natural sand dust and the impact of such differences on man-made sand dust.

Particle size analysis the Malvern Mastersizer 2000 laser particle size analyzer was used for experimental related operations. The measuring range of the machine is 0.02~2000 μm, and the related operations such as testing, basic analysis, cleaning and so on can be well completed by using the Mastersizer 2000 software accompanying the machine. Element and mineral analysis was performed using an X-ray fluorescence spectrometer, Magic PW2403, and sample preprocessing was performed using a grinder and press.



The mean value of median particle size was shown as urban (151.25 μm) > desert (121.91 μm) > farmland (21.07 μm). The peak of grain size distribution curve is also shown as urban > desert > farmland, among which the bimodal distribution of urban road dust reflects the multi-source of road dust. On the one hand, human activities such as industry, transportation and agriculture produce large amounts of man-made dust. On the other hand, natural dust is transported over long distances to densely populated urban areas with high anthropogenic pollution emissions, and new anthropogenic dust is generated by mixing with local materials. According to the movement characteristics of different particle sizes of surface particles under the action of wind and their influence on human health, road dust particle sizes were classified according to the classification standards of atmospheric particles. The most concerned inhalable particles with particle size less than 10 m had the highest content in the farmland samples (31%), followed by the urban road samples (9%) and the desert samples (3%).



The study on the mineral composition of dust shows that natural dust is more different from manmade dust in SiO_2, CaO and Fe_2O_3. Compared with Taklimakan desert, Beijing and Lanzhou, the content of SiO_2 and CaO in Tengger desert is higher and CaO content is lower. The content of SiO_2 in natural dust is higher, while the content of Fe_2O_3 in man-made dust is higher. In terms of heavy metal analysis, Lanzhou is more polluted than Beijing, and Zn, Cr and Cu are more polluted.

In conclusion, particle size is shown as urban > desert > farmland. The content of SiO2 in natural dust is high, and the pollution of manmade dust by heavy metal is obvious.

Associations of fine particulate matter and health burdens in Handan city

*aifang gao[1,2,3,4,5,6], junyi wang[1], jianfei luo[1], aiguo li[1], jingyi li[4,5,6], Hongliang Zhang

1. School of Water Resources and Environment, Hebei GEO University, 2. Hebei Province Collaborative Innovation Center for Sustainable Utilization of Water Resources and Optimization of Industrial Structure , 3. Hebei Province Key Laboratory of Sustained Utilization and Development of Water Resources, 4. Jiangsu Key Laboratory of Atmospheric Environment Monitoring and Pollution Control, 5. Collaborative Innovation Center of Atmospheric Environment and Equipment Technology, 6. Nanjing University of Information Science & Technology

The North China Plain (NCP) has been experiencing severe air pollution in recent decades and high levels of fine particulate matter ($PM_{2.5}$) are related to different diseases. However, it is not clear the relationship between very high $PM_{2.5}$ and human health outcomes as most studies are conducted in developed countries with lower concentrations. At the present study, the integrated exposure-response (IER) model was applied to estimate the health effects of exposure to fine particulate matter ($PM_{2.5}$) in Handan city, China. The premature mortality(ΔMort), years of life lost (YLL), and mortality benefits due to $PM_{2.5}$ reductions were quantified in 2015-2017. According to YLL per 1000 person, the males had higher health risks than females. Decreasing $PM_{2.5}$ concentrations would lead to a significant reduction of premature mortality and YLL. This indicates that a more stringent measure adopted by Handan government would be needed to reduce fine particulate matter pollution and enhance the health benefits.

Data assimilation of lidar-derived aerosol extinction coefficients and its application in China

*Zengliang Zang[1], Xiaobin Pan[1], Yanfei Liang[1], Wei You[1], Yiwen Hu[1]

1. National University of Defense Technology

A three-dimensional variational (3DVAR) assimilation system for lidar-derived aerosol extinction coefficient profiles is developed, with the observational operator for aerosol extinction coefficients based on IMPROVE (The Interagency Monitoring of Protected Visual Environments) equation. Using the 3DVAR system, three experiments are performed by assimilating hourly lidar-derived aerosol extinction coefficient profiles and hourly mass concentrations of PM2.5 of air quality monitoring stations over China. Then, the subsequent 24h forecasts are carried out by using WRF-Chem (Weather Research and Forecasting model coupled to Chemistry) model. The results show that the data assimilation of lidar profiles can improve the skill score of aerosol following forecast with higher correlation coefficient and lower RMSE.

The effectiveness of the Air Pollution Prevention and Control Action Plan on the air quality and human health during 2013-2017 in China

Dian Ding[1], *Jia Xing[1], Shuxiao Wang[1]

1. Tsinghua University

In 2013, China released the “Air Pollution Prevention and Control Action Plan”, which set the roadmap for national air pollution control actions for the period of 2013-2017. A decrease in the PM2.5 concentration may lead to a substantial benefit for human health. This study aims to quantify the relative contributions four factors: emission reductions, changed meteorology, population growth, and a change in baseline mortality rates to the reduced PM2.5-related mortality (PM2.5-mortality) during the 2013-2017 period and evaluate the importance of emission controls for human health protection in China. We used the chemical transport model (i.e., WRF-CMAQ) as well as an integrated scientific assessment system (i.e., ABaCAS) in this study. The estimated total PM2.5-mortality in China was 1,389,000 (95% CI, 1,005,000-1,631,000) in 2013 but was substantially reduced to 1,102,000 (95% CI, 755,000-1,337,000) in 2017. Emission controls contributed 88.7% to this reduction in PM2.5-mortality, while changed meteorology, the change in baseline mortality rates, and population growth during 2013-2017 contributed 9.6%, 3.8% and -2.2%, respectively. The implementation of the Action Plan has significantly reduced the PM2.5 concentration in regions of China where population density is high, dominating the decline in PM2.5-mortality during 2013-2017. However, the health burden of PM2.5 pollution in China is still extremely high compared to that in other developed countries. An aggressive air pollution control strategy should be implemented in densely populated areas to further reduce the health burden.

Modeling the source-receptor relationships in highly polluted regions

*Jia Xing[1], Dian Ding[1], Shuxiao Wang[1], Jim Kelly[2], Carey Jang[2], Yun Zhu[3]

1. Tsinghua University, 2. U.S. Environmental Protection Agency, 3. South China University of Technology

Efficient prediction of air pollution responses to precursor emissions is a prerequisite for an integrated assessment system in developing effective control policies. Representing the nonlinear response of air pollutants to emissions control with accuracy remains a major challenge for policymakers and modelers. Here, we propose a novel method by applying the deep-learning approach in atmospheric chemical transport model (CTM), and employ the Extended Response Surface Modeling (ERSM) technique to develop response surfaces of PM2.5 and O3 concentrations as a function of pollutant emissions. The proposed method significantly enhances the computational efficiency and practicality by requiring CTM simulations with mean and 95th maximal normalized errors within 5% and 10% across all grid cells. With the newly developed method, we systematically investigate the nonlinear response of PM2.5 and O3 to emissions of multiple pollutants from different sources in three highly polluted regions in China including the Northern China Plain (NCP), Fen-Wei Plain (FWP), and Chuan Yu region (CYR). We found that the effectiveness of NO*x* controls for reducing $PM_{2.5}$ and O_3 are largely influenced by the ambient levels of NH_3 and VOC, exhibiting strong nonlinearities characterized as NH_3-limited/-poor and NO*x*-/VOC-limited conditions, respectively. The contribution from regional sources becomes larger during more polluted episodes, suggesting the importance of joint controls on regional sources for reducing the heavy air pollution.

Opposite Role of H_2SO_4 Formation Pathway on Secondary Organic Aerosol Formation Derived from Ethyl Ethacrylate Ozonolysis

*Peng Zhang[1]

1. Rcees

Stressed plants and polymer production can emit many unsaturated volatile organic esters (UVOEs). However, few studies attempt to explore secondary organic aerosol (SOA) formation of unsaturated esters under complex ambient conditions. In this study, we employed ethyl methacrylate (EM) as a UVOEs proxy to investigate SOA formation resulting from EM ozonolysis with or without seed particles in the presence of SO_2. Results showed that, in the absence of seed particles, a substantial increase in homogeneous formation of H_2SO_4 particles and enhanced acid-catalyzed oligomerization of carbonyl species promoted the increase of SOA with increasing SO_2. In contrast, increased particle acidity enhanced EM uptake and the chemical conversion of SOA but reduced SOA formation in the presence of seed particles. This was mainly ascribed to the fact that the ozonolysis of more adsorbed EM was hampered due to the formation of surface H_2SO_4 with increasing particle acidity. This study demonstrated that the opposite roles of SO_2 and seed particle addition on SOA formation and composition were closely related to the H_2SO_4 formation pathway. This research will not only help to advance our understanding of the complex chemical processes involved in UVOE-derived SOA but also of the complicated role of H_2SO_4 in SOA formation.

Investigating the performance of satellite-based models in estimating the surface $PM_{2.5}$ over China

*Siwei Li[1], Lechao Dong[1], Jie Yang[1], Wenxuan Shi[1]

1. Wuhan University

Accurate estimation of atmospheric particulate matter with particle diameter less than 2.5 μm ($PM_{2.5}$) concentration is important because of its adverse impacts on public health. Due to the limited spatial coverage of ground monitoring stations, satellite products are often used to estimate surface $PM_{2.5}$ concentration by constructing a comprehensive relationship between satellite-retrieved aerosol optical depth (AOD) and ground-based in-situ measured $PM_{2.5}$ concentration. The accuracy of the satellite-based models in estimating $PM_{2.5}$ concentration is critical for its usage in health assessment, however, the performance of satellite-based models has not been well evaluated yet. In this study, we propose a new method to validate and evaluate the accuracy and performance of two popular machine learning models Random Forest (RF) and the BP Neural Network (BPNN) in estimating $PM_{2.5}$ concentration over China. The two models were trained and tested based on a whole year of satellite-retrieved hourly AOD from HIMAWARI, ground-based in-situ measured $PM_{2.5}$ from China National Environmental Monitoring Center, ERA5 meteorological conditions and other auxiliary variables in 2017. It is found that the traditional validation method may overestimate the performance of the models in estimating the $PM_{2.5}$ at the area with sparse in-situ measurements. Moreover, the spatial distribution of the training data will largely affect the performance of the models. A variable parameter retrieval algorithm based on RF model shows a better overall performance than the fixed parameter RF model. The R^2 is greater than 0.83 when the distance of the test station to the nearest training station is smaller than 100 km, but reduces to 0.51 when the distance is larger than 500 km . Such results suggest that the performance of satellite-based model in estimating the surface $PM_{2.5}$ need carefully examined, and still exhibits considerable uncertainties to be further improved.

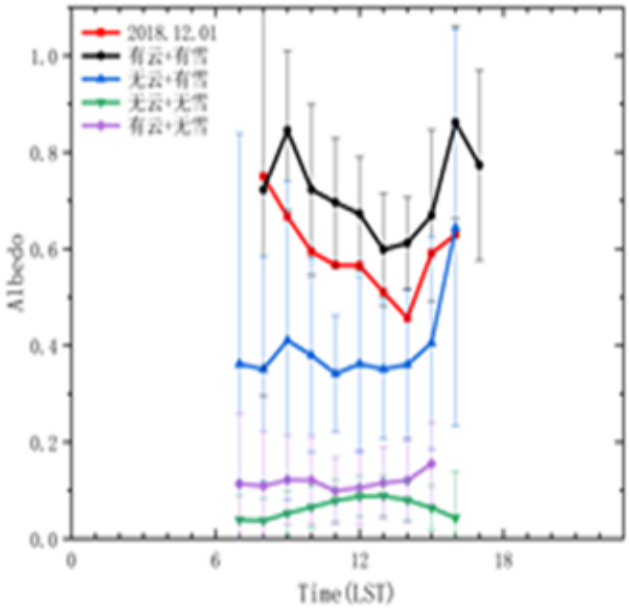
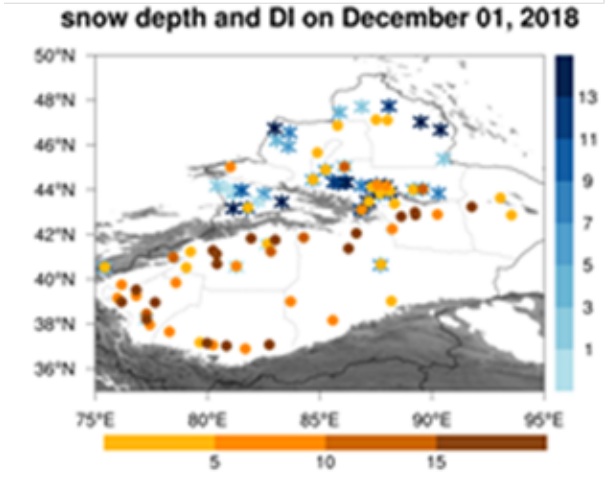
Tiramisu snow and the weakening of surface albedo

Siyu Chen[1], *Hongru Bi[1]



1. Lanzhou University



Since 1850, Earth's cryosphere has shown a global shrinking trend. The retreat of snow and ice had strongly impact on the hydrological cycle and the energy balance of the Earth system. And the melting of snow and ice attributed to the variation in snow albedo caused by LAIs deposited on the snow surface. These LAIs absorbed solar radiation, accelerated snow aging process, reduced albedo of the snow surface, and enhanced the melting of snow. However, the uncertainty of the emission of LAIs and the differences in research methods and regions, as well as the lack of observation data, resulted in the surface radiation forcing caused by LAIs, especially dust, still very uncertain. Dust is as a key factor in controlling albedo and subsequent glacier melting within the global warming perspective. Thus, quantitative studies on reduction of dust on snow surface albedo from synoptic scale are very important. On December 1, 2018, a rare weather event occurred in Urumqi, China, where snow accumulating on the land surface was covered with a layer of yellow dust. This rare weather event provided an excellent natural experiment for quantifying the effect of dust in snow on surface albedo. Based on ground observation data and reanalysis data such as MERRA-2 and ERA5, it was found that the dust snow was mainly caused by the large-scale strong cold caused by the Siberian trough and the southeast transport of dust-storms particles under the influence of the westerly jet. The generation dust particles reduced reflected radiation 20 W m^{-2} approximately. Compared with the changes of solar radiation under similar historical conditions, it was found that the cloud cover resulted in the surface albedo increase by about 0.23, when snow lead to counterpart increase about 0.28. But dust particles in the snow significantly reduced the surface albedo. Compared to historical conditions with the same snow depth and cloud cover, snow albedo caused by dust in snow decreased by approximately 28% and up to 34%.

Diurnal variations and source apportionment of ozone at the summit of Mount Huang, a rural site in Eastern China

*Jinhui Gao[1]

1. Southern university for science and technology

Comprehensive measurements were conducted at the summit of Mount (Mt.) Huang, a rural site located in eastern China during the summer of 2011. They observed that ozone showed pronounced diurnal variations with high concentrations at night and low values during daytime. The Weather Research and Forecasting with Chemistry (WRF-Chem) model was applied to simulate the ozone concentrations at Mt. Huang in June 2011. With processes analysis and online ozone tagging method we coupled into the model system, the causes of this diurnal pattern and the contributions from different source regions were investigated. Our results showed that boundary layer diurnal cycle played an important role in driving the ozone diurnal variation. Further analysis showed that the negative contribution of vertical mixing was significant, resulting in the ozone decrease during the daytime. In contrast, ozone increased at night owing to the significant positive contribution of advection. This shifting of major factor between vertical mixing and advection formed this diurnal variation. Ozone source apportionment results indicated that approximately half was provided by inflow effect of ozone from outside the model domain ($O_{3\text{-}INFLOW}$) and the other half was formed by ozone precursors ($O_{3\text{-}PBL}$) emitted in eastern, central, and southern China. In the $O_{3\text{-}PBL}$, 3.0% of the ozone was from Mt. Huang reflecting the small local contribution ($O_{3\text{-}LOC}$) and the non-local contributions ($O_{3\text{-}NLOC}$) accounted for 41.6%, in which ozone from the southerly regions contributed significantly, for example, 9.9% of the ozone originating from Jiangxi, representing the highest geographical contributor. Because the origin and variation of $O_{3\text{-}NLOC}$ was highly related to the diurnal movements in boundary layer, the similar diurnal patterns between $O_{3\text{-}NLOC}$ and total ozone both indicated the direct influence of $O_{3\text{-}NLOC}$ and the importance of boundary layer diurnal variations in the formation of such distinct diurnal ozone variations at Mt. Huang.

Optical Properties and Molecular Compositions of Atmospheric Brown Carbon in Nanjing, East China

*Junjun Deng[1], Xinfeng Wang[2], Wei Hu[1], Libin Wu[1], Pingqing Fu[1]

1. Institute of Surface-Earth System Science, Tianjin University, 2. Environment Research Institute, Shandong University, Jinan 250100, China

Brown Carbon (BrC) shows solar absorption behavior in ultraviolet and near-infrared region, and plays a significant role in atmospheric radiative forcing and regional/global climate. In present study, light absorption properties of water- and methanol-soluble BrC in ambient $PM_{2.5}$ in Nanjing in Western Yangtze River Delta in China during 2014-2015 were investigated. Besides, typical molecular compositions of BrC (nitrophenol compounds) with their light absorption contributions to BrC were also identified with ultra-performance liquid chromatography-triple quadrupole tandem mass spectrometry. The average concentration of water-soluble organic carbon (WSOC) was 6.1±3.0 $\mu g/m^3$, contributing to 61% of total organic carbon (OC). Larger WSOC concentrations in autumn and winter were related to the intense emissions from biomass burning. Light absorption coefficient (Abs), mass absorption efficiency (MAE) and absorption Angstrom exponent (AAE) of WSOC (methanol-soluble OC (MSOC)) were 5.8 Mm^{-1} (11.9 Mm^{-1}), 0.92 m^2g^{-1} (1.15 m^2g^{-1}) and 5.36 (4.97), respectively. Strong positive correlation (R^2=0.93) was found between light absorption of WSOC and MSOC. Both light absorption of WSOC and MSOC showed distinct seasonal variations, with larger Abs values in winter and autumn. The average concentration of the detected nitrophenol compounds was 9.1±7.9 ng m^{-3}. Among the detected nitrophenol compounds, nitrocatechols (NCs), which can be used as tracers of biomass burning, increased significantly in winter (8.6 ng m^{-3}) and autumn (5.6 ng m^{-3}). While nitrosalicylic acids (NSAs), which were mainly generated by secondary reactions, accounted for larger proportions in summer (52.4%) and spring (40.9%). Nitrophenols contributed 0.32±0.13% to total light absorption of MSOC. Light absorption contributions of nitrophenol varied in different seasons in the order of winter (0.43%) > autumn (0.32%) > spring (0.27%) > summer (0.21%). NCs are the most important light-absorbing components among all the nitrophenol compounds, with the light absorption contribution of 64.7%. These findings will help to better understand optical properties and climatic effects of light-absorbing organic aerosols.

Quantification of household emissions in non-attainment cities of Punjab, India

Arpit Katiyar[1], Jagriti Suneja[1], Mukesh Khare[1], Arvind K Nema[1], *Sri Harsha Kota[1]

1. Indian Institute of Technology Delhi

Air pollution has become a grave problem in recent times throughout the world, especially in north India. Studies have shown that household emissions is one of the major contributors to $PM_{2.5}$ in north India. In this study, a bottom-up emission inventory for household emissions from non-attainment cities in Punjab is developed. Emissions from household fuels such as wood, brushwood, straw, grass, coal, coal briquette, charcoal, dung, natural gas, LPG (Liquified Petroleum Gas), biogas and electricity have been quantified. The conclusions from this emission inventory is used to modify the European Union's EDGAR emission inventory. With this modified emission inventory, the contribution of $PM_{2.5}$ due to household emissions in Punjab is predicted using Weather Research and Forecasting model coupled with Chemistry (WRF-Chem). Results indicate significant contribution from household emissions calling for an urgent action to control $PM_{2.5}$ in this region.

Regional Source Apportionment of Summertime Ozone and Its Precursors in the Megacities of Beijing and Shanghai using a Source-Oriented Chemical Transport Model

*Peng Wang[1], Tao Wang[1], Qi Ying[2]

1. the Hong Kong Polytechnic University, 2. Texas A&M University

The Community Multiscale Air Quality (CMAQ) model with a source-oriented SAPRC-11 photochemical mechanism is developed in this study to quantify the source region contributions to surface O_3 in Beijing and Shanghai in August 2013. Non-background O_3 attributed to NO_x (O_3_NO_x) and VOCs (O_3_VOC) emitted from different source regions are determined using a three-regime approach that correctly attributes O_3 to NO_x and VOC precursors throughout the entire range of NOx-VOC-O_3 formation sensitivity. Averaged over the entire month and all grid cells, local emissions (51%) and emissions from Hebei (31%) are the two major contributors to non-background daily maximum 8-hour (DM8H) O_3 in Beijing. In Shanghai, local, Zhejiang and Jiangsu emissions account for 53%, 19% and 14% of the non-background DM8H O_3. Significant variations in local emission contributions are predicted among different model grid cells for both cities (Beijing, 6-80%; Shanghai, 3-76%). On high O_3 days in Beijing, the wind is persistently from the south with high wind speed (~5 m s^{-1}) in the evening and night. This leads to significant regional contributions of O_3 from Hebei, along with regional transport of VOCs and NO_x. In Shanghai, high O_3 days are associated with southwesterly/westerly wind in the morning, rotating to southeast in the early afternoon in a counter-clockwise direction. The surface wind then gradually turns back to southwest in the afternoon until the next morning, along with reduced wind speed. In Shanghai, daytime O_3 at the urban center is almost entirely due to local emissions. Low wind speed in the evening and night time allows local NO_x emissions to efficiently titrate regional O_3. In both cities, NO_x emissions are not transported regionally as efficiently as VOCs. Source region contribution analysis of the concentration weighted maximum incremental reactivity (CWMIR) shows that VOCs from other regions are less reactive than locally emitted VOCs. HCHO and acetaldehyde (CCHO) generated from the oxidation of other VOCs are important contributors to regionally transported reactive VOCs. In both regions, the overall CWMIR in both cities is quite similar (~4 moles O_3 per mole of VOC^{-1}).

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

[A-AS04] Formation of Air Pollution and Its Interactions with Weather/Climate

convener:Yang Yang(Nanjing University of Information Science & Technology), Meng Gao(State Key Laboratory of Environmental and Biological Analysis), Guangxing Lin(Pacific Northwest National Laboratory)

Air pollutants, such as aerosols and ozone, have significantly affected environment, human health, ecosystem, and climate. Anthropogenic emissions of air pollutants in major economic regions of the world, which have changed rapidly over the past few decades owing to economic development and environmental measures, will continue to change in the near future. Air pollution from the changing sources not only degrades local and remote air quality, but also modifies energy balance, cloud, precipitation and circulation patterns, leading to regional and global environmental and weather/climate change. Climate change and variabilities in the changing world can in turn affect the emission, chemistry, transport and removal of air pollutants at different scales. To better understand the formation of air pollution, and air pollution-weather/climate interactions, advances are needed in theoretical, observational and modeling studies.
Relevant topics include but are not limited to:
(1) formation mechanism of air pollution, both physical and chemical;
(2) source attribution of air pollutants in the past and future;
(3) impact of air pollution on weather (boundary layer, cloud, precipitation, etc.), modes of variability and climate change;
(4) influence of historical climate variability on air pollution (ENSO, PDO, AO, etc.);
(5) predictability of future climate change associated with projected emission changes and feedback on air pollution.

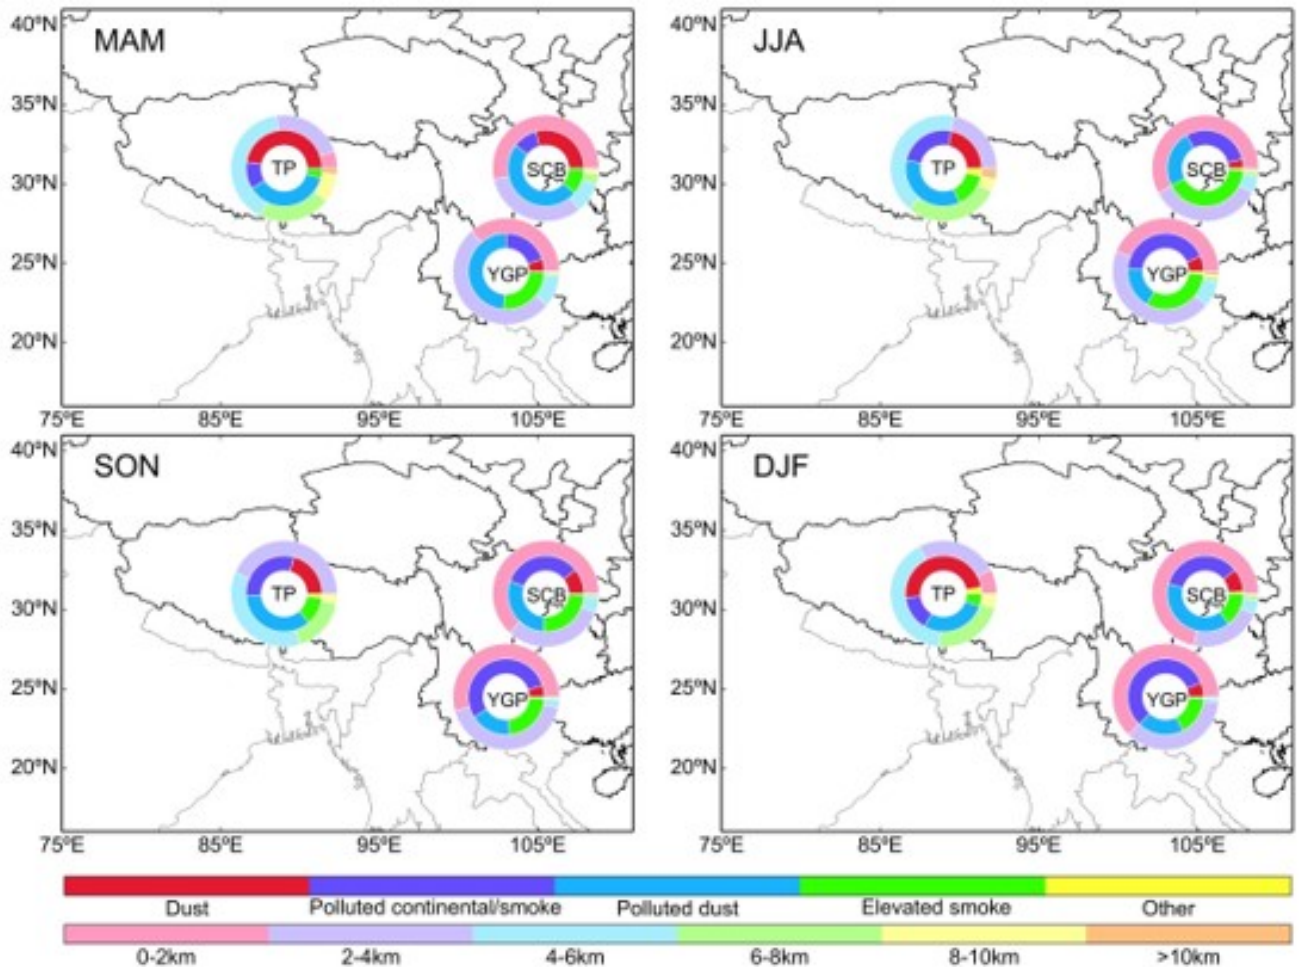
Seasonal distribution and vertical structure of different types of aerosols in southwest China observed from CALIPSO



*Tingting Liao[1], Zhengwu Ouyang[1], Bihan Wang[1], Ke Gui[2]

1. Chengdu University of Information Technology, 2. Key Laboratory of Atmospheric Chemistry (LAC), Chinese Academy of Meteorological Sciences

Aerosols significantly influence global and regional atmospheric systems. Different types of aerosols play different roles in atmosphere according to their radiation characteristics and existing height. Southwest China is recognized as a region with very complex terrain, consisted of three absolutely different geomorphic units (Sichuan Basin (SCB), Yungui Plateau (YGP) and Tibetan Plateau (TP)) with distinct characteristic in air quality and climate. However, a comprehensive understanding of the regions and three-dimensional (3D) characteristics of aerosol distribution and evolutions over Southwest China is yet to be achieved. Here, the seasonal distribution and vertical structure four types of aerosols including dust, polluted continental/smoke, polluted dust and elevated smoke was studied by using CALIPSO Level 2 nighttime aerosol profile product from 2007 to 2016. It is observed that the extinction coefficient of total aerosols over SCB is highest, among which, the type of polluted continental/smoke and polluted dust, related to anthropogenic sources, made the most contributions. Whereas we can also find these two types of aerosols declined since 2013, which might due to the strict supervision measures on industry emissions and biomass burning in agriculture in recent years. The elevated smoke aerosols over YGP in the altitude of 3km in spring were significantly higher than other seasons which might related to the biomass burning transported from South Asia, while the polluted continental/smoke aerosols in the altitude of 1-2 km were higher in autumn and winter, which is considered to be contributed by local biomass burning. The aerosol extinction coefficient over TP is nearly one magnitude lower than other two regions. However, either the dust and polluted continental/smoke from the Qaidam Basin, or smoke elevated from the Indo-Gangetic Basin, could be transported to the layer as high as 6km over TP, which might make profound impact on the climate system in Southwest China, event in Asia. The vertical structure and evolution of aerosols of different radiation properties over the complex terrain is supposed to provide reliable research foundation to the further study on the aerosols transport and the bifunctional feedback between aerosols, especial the absorptive aerosols, and the climate change.

Estimation of biogenic VOC emissions and their corresponding impact on ozone and secondary organic aerosol formation in China

*Xianyu Yang[1]

1. Chengdu university of information technology

Biogenic volatile organic compounds (BVOC) play an important role in global environmental chemistry and climate. In the present work, biogenic emissions from China in 2017 were estimated based on the Model of Emissions of Gases and Aerosols from Nature (MEGAN). The effects of BVOC emissions on ozone and secondary organic aerosol (SOA) formation were investigated using the WRF-CMAQ modeling system. Three parallel scenarios were developed to assess the impact of BVOC emissions on China's ozone and SOA formation in July 2017. Biogenic emissions were estimated at 23.54 Tg/yr, with a peak in the summer and decreasing from southern to northern China. The high BVOC emissions across eastern and southwestern China increased the surface ozone levels, particularly in the BTH (Beijing-Tianjin-Hebei), SCB (Sichuan Basin), YRD (Yangtze River Delta) and central PRD (Pearl River Delta) regions, with increases of up to 47 μgm−3 due to the sensitivity of VOC-limited urban areas. In summer, most SOA concentrations formed over China are from biogenic sources (national average of 70%). And SOA concentrations in YRD and SCB regions are generally higher than other regions. Excluding anthropogenic emissions while keeping biogenic emissions unchanged results that SOA concentrations reduce by 60% over China, which indicates that anthropogenic emissions can interact with biogenic emissions then facilitate biogenic SOA formation. It is suggested that controlling anthropogenic emissions would result in reduction of both anthropogenic and biogenic SOA.

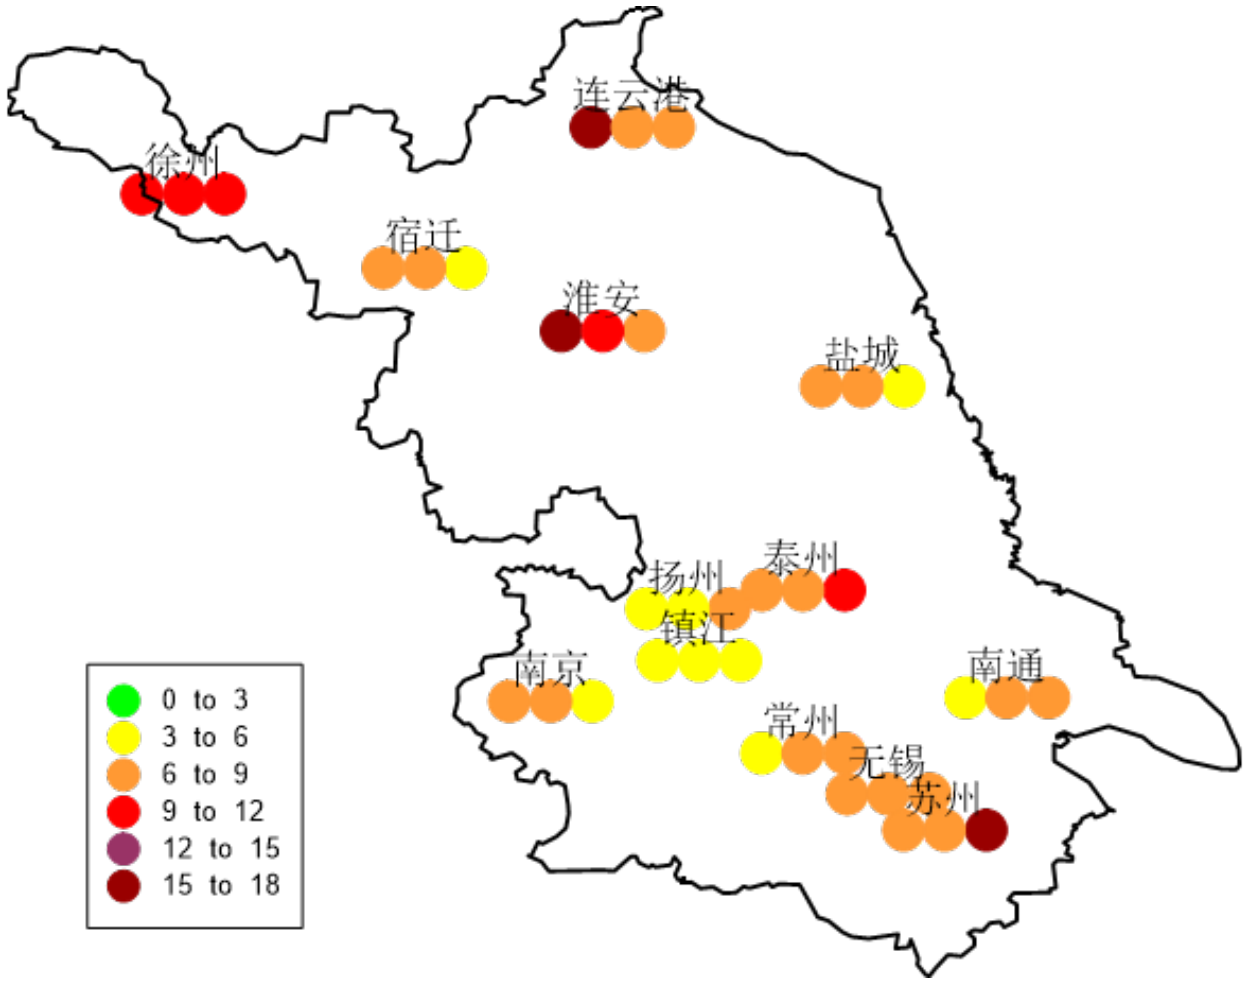
Characteristics of Severe Air Pollution in Jiangsu Province and its Relationship with Meteorological Conditions under Cold Air



*Lu Cao[1,2], Duanyang Liu[1,2], Peng Zhou[3], Wenlian Yan[2], Chen Hao[2]

1. Key Laboratory of Transportation Meteorology, 2. Jiangsu Meteorological Observatory, 3. Nanjing Meteorological Bureau

By analyzing the severe air pollution cases in Jiangsu Province during 2013-2018, we investigated the characteristics of meteorological conditions during those polluted episodes in this study. The results showed that in Jiangsu Province, the level of air pollution happened under cold air was mostly in Level 5. There were only 14% of all events in Level 6, which mostly took place when the cold air was from central pathway, and rarely cases were from easterly pathway. Generally, the air pollution episodes under central and western pathway were regional and continuous, with primary pollutant of $PM_{2.5}$, followed by O_3; while those under eastern pathway were local and short, frequently with primary pollutant of O_3. During severe pollution episodes, at high altitude, the cold air was mainly at north side of Jiangsu Province; at mid and low altitude, there was northwest airflow in front of ridge or weak shear; on the surface, Jiangsu was in the front of cold air. The stratification was stable with the mixing layer height less than 1.2 km, and there were vertical temperature inverse happened of more than 50% events. At the day and the day before the severe pollution episode, the wind speed was generally less than 4 m/s, and there was no or weak precipitation (<1.0mm/day). Compared to the easterly pathways, more air pollutants were transported from central or westerly pathway. The heavy pollution might be intensified under stable weather conditions with negative transportation upstream, very strong inverse and weak wind. In the circulation beneficial to the severe pollution, the maximum elevate of the 24-h mean concentration in Nanjing was less than 150 $\mu g/m^3$ from central-pathway cold air and less than 100 $\mu g/m^3$ from westerly and easterly pathway cold air. Overall, the severe air pollution in Jiangsu province was attributed to the combined contributions from local emission, regional transportation and unfavorable weather conditions.

Spatiotemporal variations of recent NO_2 concentrations and anthropogenic and meteorological drivers over typical urban agglomerations in China

*Yang Shen[1], Fei Jiang[1]

1. Nanjing University

Nitrogen dioxide (NO_2) is an important pollution gas that can affect air quality and human health. In this study, spatiotemporal distribution of NO_2 concentrations throughout China, and specifically in twelve typical urban agglomerations, were statistically analyzed with ground−based NO_2 observations from June 2014 to May 2019. The WRF−CMAQ model were also applied to separate and quantify the emission−related and meteorology−related NO_2 variations. NO_2 concentration in Beijing−Tianjin−Hebei (BTH) urban agglomeration showed an upward trend in 2014−2015, and a downward trend after 2016, while NO_2 in Yangtze River Delta (YRD), Yangtze River Middle−Reach (YRMR) and Cheng−Yu (CY) urban agglomerations continued to decline until 2017. High NO_2 values were predominantly concentrated in urban agglomerations with high NOx emissions like BTH, Shandong Peninsula (SP), Central Plain (CP), Central Shaanxi (CS) and YRD urban agglomeration. The number of sites with NO_2 decreasing in 2018 accounts for 67.37% compared to 2015, especially in BTH and CP, with the decrease of more than 20 $\mu g \cdot m^{-3}$. High−high concentration centers of NO_2 pollution were observed in high NO_2 areas, while low−low aggregations were observed in the South and southwest of China. In general, anthropogenic emissions contributed dominantly to NO_2 variations, and the contribution in winter was greater than in summer. The reduction of emissions in the winter of 2018 led to emission−related NO_2 variations in YRD, YRMR, CY, and Pearl River Delta (PRD) urban agglomeration reaching −7.41, −9.15, −9.57, and −15.09 $\mu g \cdot m^{-3}$, respectively. While in the winter of BTH, meteorological influence on NO_2 was more obvious than that of other regions, leading variations of 4.42, 4.09, −9.77, and 5.99 $\mu g \cdot m^{-3}$, respectively between 2014 and 2018 in adjacent years. This study makes it possible to look into the differences in NO_2 concentrations among typical urban agglomerations and provide a more complete understanding of NO_2 exposures in China.

Sub-seasonal seesaw of PM2.5 over the North China Plain in autumn and early winter

*Lian Xue[1]

1. Nanjing University

Severe PM2.5 pollution often strikes the North China Plain in autumn and winter in recent years. Due to its high impacts on society and human health, the prediction of pollution level at the end of the year is crucial to policymakers. Despite emission control policies, natural climatic variability is remarkably important in air quality prediction by modulating circulation and chemical production. Traditional analyses are mostly based on the seasonal averaged. While recent studies revealed a significant sub-seasonal variation of circulation which could mediate the air quality over the NCP on a higher frequency. In this study, a seesaw phenomenon on sub-seasonal timescale is reported, providing a new aspect to conduct sub-seasonal air quality prediction. Possible links to sub-seasonal atmospheric oscillation are also discussed.

Transport of Ozone Pollution Over the East China Sea and the Yellow Sea: a Case Study in Coastal Cities in Eastern China

*Yanhua Zheng[1], Fei Jiang[1], Shuzhuang Feng[1], Zhe Cai[2]

1. Nanjing Univ., 2. Nanjing CLIMBLUE Technology co.LTD

During August 28 and September 5, 2017, a large-scale ozone pollution occurred in the eastern coastal of China.According to the characteristics of the observed ozone, there are three different pollution stages(with slight differences among cities). In the Stage 1, there were significant overall pattern of diurnal high and nocturnal low in O_3 named "single peak pattern". In the Stage 2, the diurnal ozone decreased slightly compared with the Stage 1 while the nighttime ozone increased. The daily minimum O_3 was basically above 20ppb, and the diurnal variation was weakened. In the Stage 3, the nighttime ozone decreased significantly, which restored the "single peak pattern". Using WRF-CMAQ model to simulate the contamination and combining the ozone distribution with weather situation,results are as follows.In the Stage 2,compared with other stages,the eastern coastal regions are controlled by high pressure, lower temperature made the daytime photochemical reaction abate, the bigger northeaster made the air mass above the yellow sea and East China Sea carrying high ozone to coastal regions, so ozone was lower in the day but higher at night.Analyzing the ozone contribution of the main physicochemical processes, it was found that the contribution of horizontal transport in the Stage 2 was significantly higher than that in other stages especially at night.Based on the above analysis, the contribution of transport over the yellow sea and East China Sea to ozone pollution is confirmed.The particle diffusion analysis showed that the air mass had passed over the Beijing-Tianjin-Hebei, the three northeast provinces, Japan-Korea and sea before affecting China's eastern coastal.Using the ISAM source apportionment to further determine the pollutant source, the results showed that pollutant emissions of Japan-Korea and the Beijing-Tianjin-Hebei had obvious contribution to eastern coastal ozone and the contribution of the former than the latter, larger scope and more widely.

[A-AS05] Large-scale moisture and organized cloud systems

convener:Hiroaki Miura(The University of Tokyo), Atsushi Hamada(University of Toyama), Satoru Yokoi(Japan Agency for Marine-Earth Science and Technology), Masaki Satoh(Atmosphere and Ocean Research Institute, The University of Tokyo)

Water vapor plays a significant role in regulating the global atmospheric circulation, especially in the troposphere. The overturning circulation is directly driven by the longwave radiative cooling of water vapor and the latent heating/cooling through microphysical processes to balance it. This global circulation is composed of diverse atmospheric phenomena with various spatial and temporal scales. Developments of some significant turbulent motions such as 3D isotropic turbulence in clouds, stratocumulus and cumulus convection, squall lines and tropical cyclones, and the Madden-Julian oscillation, are essentially associated with moisture anomaly in each scale. Moisture is accumulated relatively slowly in larger horizontal scales, but is consumed relatively quickly in smaller ones. This significant scale gaps between the accumulation and consumption may be one of the causes of the long-lasting difficulty in developing the theory of the moist atmosphere. The aim of this session is to share the recent researches about the relationships between moisture and organized cloud systems in wider spatial and temporal scales to enhance collaborations between modeling, observational, and theoretical approaches in tackling this challenging task. Research results relating to the Years of the Maritime Continent (YMC), Radiative-Convective Equilibrium Model Intercomparison Project (RCEMIP), and mesoscale simulations of severe weather are welcome.

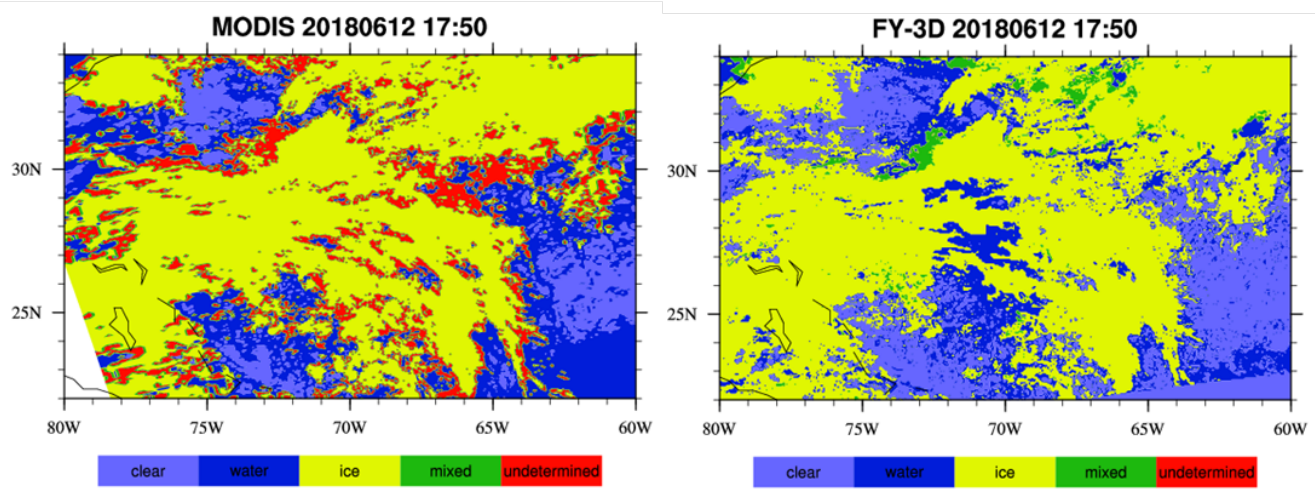
Inversion and Preliminary Validation for Global Cloud Classification and Cloud Phase Products of Fengyun-3D in CMA-NSMC

*Bo Li[1,2], Ruixia Liu[1,2]



1. China Meteorological Administration, 2. National Satellite Meteorological Center

FY-3 is the second generation polar orbiting meteorological satellite in China. The visible (0.58-0.68 μm), near infrared (1.55-1.64, 3.55-3.93 μm) and two long-wave infrared channels (10.3-11.3 μm and 11.5-12.5 μm) of the FY-3D MERSI (Medium Resolution Spectral Imager) instrument can be used to retrieve cloud classification and cloud phase (hereinafter referred to as CTY and CPH) products.

CPH and CTY products of FY-3D are retrieved based on the MERIS L1 data and cloud mask product. By using the spectral and texture characteristics of visible, infrared and near infrared channels data of L1 as well as the surface type classification data, threshold method is used to identify cloud phases of cloudy pixels, and 1 km resolution CPH is obtained. Then, combined with the results of thin cirrus cloud and broken cloud identification results, high, medium and low cloudy pixels are identified by threshold method, and a CTY product with 1 km resolution is obtained.

The precision of CPH is higher for simple-structured clouds, and POD (probability of detection) as well as CR (Consistency rate) is slightly lower for complex clouds. In general, FY-3D has a better performance on identification of water clouds and a slightly lower accuracy for the identification of ice phase. Compared with MODIS, the algorithm of FY-3D MERSI can recognize more than 90% CPH of the total cloud pixels. It should be noted that due to the different algorithm, the methods and criteria for identifying mixed and uncertain phases are different, which results in some differences between FY -3D and MODIS CPH outputs.

An Initiation Process of TD-type Disturbances under an Influence of Upper-Level Troughs

*Yuya Hamaguchi[1,2], Yukari Takayabu[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Department of Earth and Planetary Science, The University of Tokyo

In this study, the initiation process of the summertime tropical depression-type disturbances (hereafter, TDDs) in the western and central Pacific is investigated. TDDs are widely known as westward-travelling synoptic-scale disturbances over the western Pacific (Takayabu and Nitta 1993). As Ritchie and Holland (1999) reported, roughly 50% of western Pacific tropical cyclones form in association with TDDs. In spite of their social importance in terms of tropical cyclogeneses over the western Pacific, their initiation process has not been fully understood.
At the same time, though TDDs are thought to be originated from lower-tropospheric eddies in association with convection in principle, several studies have indicated that some of TDDs are initiated by upper-tropospheric forcing (*e.g.* Tam and Li, 2006; Heta, 1991). Despite the plausibility of the upper-level contribution on the initiation of TDDs, little research has been conducted on the statistical properties of TDDs induced by upper-level activities.
From these perspectives, using CLAUS brightness temperature and JRA-55 products, we statistically analyzed the relationship between TDDs' occurrences and the upper-level perturbations to understand the mechanism of the initiation process of TDDs.
As a result, it is revealed that about 30% of TDDs are generated under an influence of upper-level troughs (so called Mid-Pacific Trough), especially in the off-equatorial region near the date line. The initiation of such trough-related TDDs is associated with a preceding dynamical updraft at the back of the upper-level troughs. It enables convections to become deeper, which results in the development of low-level disturbances via the moisture-convection feedback. Furthermore, according to the composite figures on the trough-related TDDs, it is shown that their environments are much drier than those of other TDDs, which indicates that the upper-level troughs play important roles at the initial stage of their occurrence, especially in relatively drier conditions.

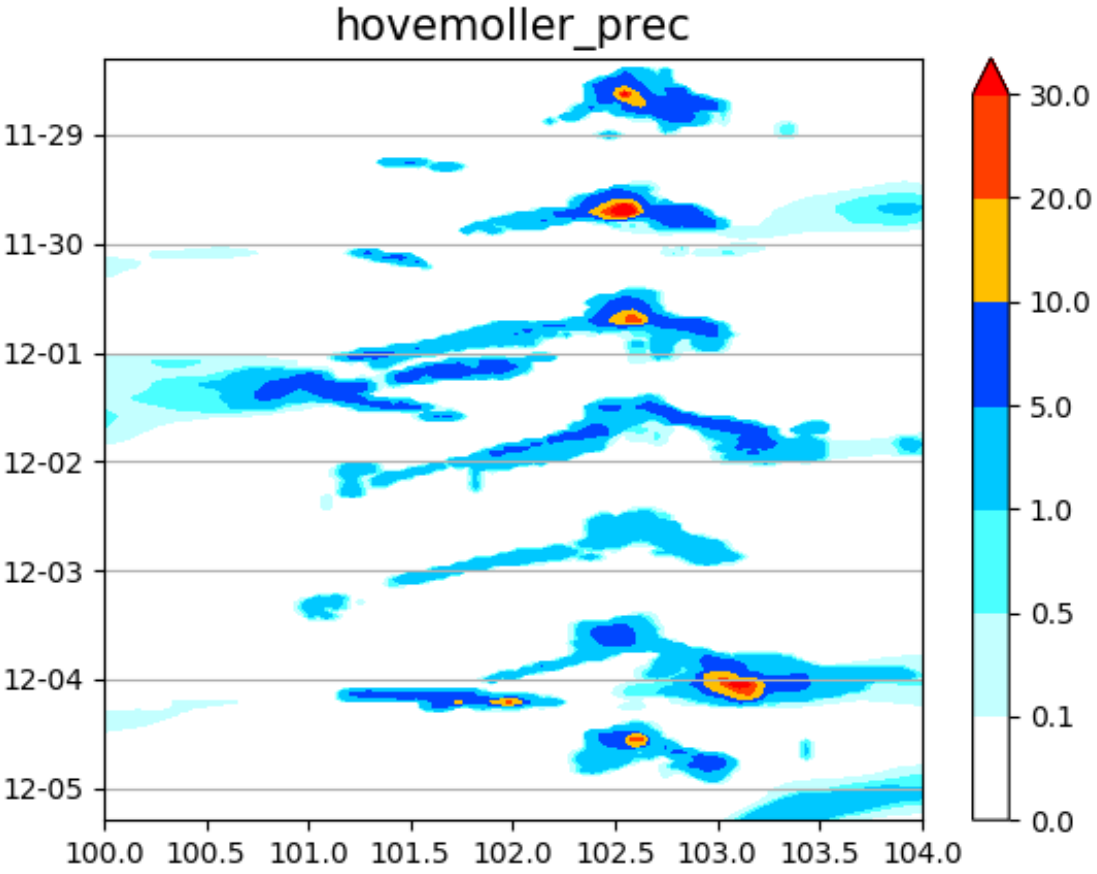
Numerical Study on the Diurnal Cycle of Precipitation Observed near the West Coast of Sumatra Island



*Mamiko Terada[1], Hiroaki Miura[1]

1. The University of Tokyo

Diurnal cycles of precipitation events are often observed around the Indonesian maritime continents region. Around the western coast of Sumatra, a diurnal cycle has a feature that a precipitation system develops over land in the afternoon, and then, moves offshore from evening through nighttime. Several mechanisms has been proposed about this precipitation movement but has not been sufficiently evaluated yet. Recently, two intensive observation campaigns named as the Pre Years of the Maritime Continent (Pre-YMC) and the Years of the Maritime Continent (YMC) have been operated near the west coast of Sumatra by the Japan Agency for Marine-Earth Science and Technology (JAMSTEC) to observe diurnal cycles and their interactions with larger-scale features. In this study, we simulate atmospheric phenomena in the Pre-YMC period using the Scalable Computing for Advanced Library and Environment –Regional model (SCALE-RM) and examine the mechanism of the precipitation migration.
At first, we perfomed a one week simulation initialized at 00 UTC on November 28, 2015 with a cumulus parameterization. In this simulation, the movements of the precipitation systems were reproduced every day at least marginally. Comparisons of the SCALE-RM simulation with the Pre-YMC radiosonde data confirms that the zonal wind and the specific humidity were quite similar. Then, another simulation was performed by setting the initial time at 00 UTC on November 23, 2015. This calculation was performed without any cumulus parameterization. Precipitation was reproduced everyday over land but its migration toward offshore did not happen except for one day. We are planning to examine the reason for this difference possibly due to with or without the cumulus parameterization.

A statistical study on precipitation characteristics coupled with equatorial Kelvin waves and equatorial Rossby waves.

*Yuhi Nakamura[1], Yukari Takayabu[1]

1. Department of Earth and Planetary Science, School of Science / Division of Climate System Research, Atmosphere and Ocean Research Institute, The University of Tokyo

Coupling structures between convection and equatorial waves are investigated using space-borne precipitation radar observation. Recent theoretical studies suggest that different equatorial wave modes can have different coupling mechanisms. However, observational studies on their precipitation characteristics are yet not enough. In order to tackle this issue, we quantitatively characterize precipitation coupled with equatorial Rossby waves (ERW) and equatorial Kelvin waves (EKW).
Based on wave phases determined with brightness temperature observed from the Geostationary Meteorological Satellites, composite analyses are conducted. TRMM 2A25 and 2H25 products are used to analyze precipitation characteristics. We prepare rainfall-area dataset by identifying areas of consecutive precipitating pixels. ERA-interim is used to obtain synoptic scale wave structures.
In the ERW, organized convective systems dominate directly following a shallow convection stage, without a developed convection stage. On the other hand, in the EKW, precipitation shows a tri-modal evolution: shallow convection, developed convection and organized convection stages. We also find a contrast in column water vapor (CWV) anomaly structures. With ERW, positive and negative CWV anomalies have similar amplitudes, while negative CWV anomaly in EKW is not clear.
As for the vertical structures, ERW has an upright structure, while EKW has a vertical tilt. The evolution of moisture field driven by wave disturbances may cause the contrast of the CWV anomaly.
These contrasts of convective evolution and moisture field suggest that these two equatorial waves have different unstable modes. ERW well correspond to ‘moisture mode’, which is driven by CWV anomaly. On the other hand, EKW well correspond to ‘gravity mode’, which is driven by buoyancy perturbation.
In order to clarify interaction between precipitation and wave disturbances in details, we further investigate energy and moisture budget.

Gravity wave response to convective heating and its importance to understanding the weak temperature gradient approximation and its limitation

*Ching-Shu Hung[1], Hiroaki Miura[1]

1. The University of Tokyo

Convection is a key process in tropical weather and climate. Its buoyant energy generation and turbulent mixing directly change the temperature and moisture distribution in the small area around clouds, while the secondary compensative circulations driven by its strong latent heating indirectly modulate the environment outside convective regions. Internal gravity waves generated by convection are considered as the key mechanism that communicates the imposed localized perturbation to the surrounding atmosphere. As these gravity waves propagating outward from heating centers, compensating subsidence is induced to balance the strong upward mass fluxes within clouds. The resulting adiabatic warming spreads the localized latent heating over a much wider domain that didn't experience convection. Through its propagation, convective-generated gravity wave quickly homogenizes the buoyancy perturbation, leading to the weak temperature gradient (WTG) feature widely observed in the tropic.

The analytical solutions of the gravity wave response to an isolated heat source were first derived in a two-dimensional hydrostatic Boussinesq fluid by Bretherton and Smolarkiewicz (1989). Their solution suggests that the adjustment time scale and range of gravity wave on temperature field depend on its propagation speed, which is simply controlled by background stratification and vertical structure of imposed heating. Dissipation, rotation, stratosphere, and cylindrically symmetry was further added into this highly idealized model. The modified solutions showed that both the extension to full dimensions and the inclusion of the stratosphere damped the wave signals in the troposphere as they propagated away from the heating source, trapping the response within a confined distance like dissipation and rotation. The combination of these damping scales could help identify the suitable time and space scales for the WTG approximation.

A regional model named SCALE-RM (Scalable Computing for Advanced Library and Environment) is utilized to justify the behavior of gravity wave response predicted by theoretical solutions and to further identify the damping scales in our cloud-resolving model. Several idealized experiments were carried out in a high-resolution configuration that is capable to resolve convective-generated gravity waves. The features in the numerical simulation are generally consistent with that in theory; however, for real convection, the situation becomes much more complicated as the strength and heating structure change along with the cloud's life cycle. Non-linear interaction might be another reason that deviates simulation from the linearized solution.

[A-AS06] Advances in Tropical Cyclone Research: Past, Present, and Future

convener:Yoshiaki Miyamoto(Faculty of Environment and Information Studies, Keio University), Sachie Kanada(Nagoya University), Akiyoshi Wada(Department of Typhoon and Severe Weather Research, Meteorological Research Institute), Kosuke Ito(University of the Ryukyus)

Tropical cyclones (TC) cause severe disasters in many countries by torrential rainfall and destructive winds. Strong TCs caused severe damages in many areas of Japan in this couple years; a record-breaking heavy rainfall occurred in western Japan due partly to Typhoon Prapirooon (2018), Kansai airport was forced to be closed by Typhoon Trami (2018), and Typhoon Faxai (2019) caused a long-term shut-down in Chiba prefecture. As the surface temperature of ocean, - the energy source of TC -, increases with global warming, TCs are expected to intensify in the future. Therefore, it is an urgent problem to obtain deeper understanding of mechanisms on TC intensity, structure, and motion, more accurate mid- to long-term projections of the TC parameters, and better forecast of TC. The TC researches are important for disaster prevention as well as the academic development, and hence do contribute to the future progress of earth and planetary science. In this session, we welcome papers on various aspects of TC studies. We hope that the session will provide a new direction for future TC researches.

Guangxi Weather Service Center, Nanning, China

ABSTRACT: Severe landfall typhoons (SLTYs) are defined as those with maximum sustained wind speed ≧ 41.5 m s^{-1} at landfalls, which strongly affect the coastal regions of China and cause grave losses of life and property. In this study, we analyze the SLTYs in China in peak summer (July-September) during the period 1973-2017, which are separated into three periods: period-I (1973–1987), period-II (1988–2003), and period-III (2004–2017). Results show that the SLTYs in China have abruptly increased since 2004, characterized by the count of about 65.9% (72.7%) of the SLTYs in China (South China) in period-III only. This phenomenon is partly attributed to the significantly-increased severe typhoon frequency and the longer duration of severe typhoon stage over the western North Pacific. The most potential factors can be summarized as follows. First, the abnormal easterly steering flow over the western North Pacific in period-III is beneficial for typhoons to march westward. Second, typhoons continue to strengthen before landfall in South China, which may be attributed to warming in the northern South China Sea and enhanced warm moist southerly monsoon flow. About 9.7% of typhoons with landfall in South China experienced a rapid intensification process in 24 h before landfalls in period-III. However, the percentage is only 1.6% and 3.1% for period-I and period-II, respectively. Third, intensified typhoons have been attracted to the warming land surface over South China since 2004, which is generally a result of air-land-sea interaction, and the conditions of air, land and sea are increasingly beneficial for SLTYs in China.

Abstract: Increasing intense landfalling typhoons (LFTYs) are of great coastal threatens to southern China. However, changes in genesis location and landfalling frequency of western North Pacific (WNP) LFTY dedicated to southern China remain unclear. Here we identified such LFTYs during peak summer and found that most LFTYs formed south of 20˚N and the LFTY genesis locations over southern WNP have also experienced a sharp interdecadal shift since 1998, which are mainly attributed to the large-scale environment changes induced by the Mega-La Niña-like climate shift. However, LFTY frequency (= “landfalling frequency of southern China typhoon”) shows a slight increasing trend but without significant interdecadal variation. Variations of LFTY frequency are mainly affected by the easterly steering flows near 20˚N over the South China Sea and the Philippine Sea, which are closely linked to the WNP subtropical high activity. Our results provide a new perspective on the LFTY activities dedicated to southern China.

Analysis of Multi-scale Circulation Characteristics Affecting the Multiple Tropical Cyclogenesis in Midsummer of 2018

*JIANYUN GAO[1], LIJUN YOU[2]

1. Fujian Institute of Meteorological Sciences, 2. Fujian Climate center

This study investigates the impact of multi-scale circulations (including large-scale circulation, intra-seasonal oscillation (ISO) and tropical waves) on the multiple tropical cyclogenesis (MTC) and discusses the deviation of vertical disturbance field of the whole atmosphere in the MTC active and inactive phases by taking a typical MTC in midsummer of 2018 as an example. The results are as follows. (1) The Western North Pacific (WNP) undergoes a 16-days MTC active phase with eight tropical cyclones (TCs) generated in sequence and a 19-days MTC inactive phase with only one TC generated in midsummer of 2018. (2) During the MTC active phase, the cross-equatorial airflow strengthens and monsoon trough extends eastward. The atmospheric circulation configuration of the low-level convergence and the upper level divergence in South China Sea (SCS) and WNP is conducive to TC formation. (3) The northward propagation of Eastern Asia and WNP ISO in summer has a significant modulation effect on the MTC sub-seasonal changes. The SCS and WNP are just in a northward wet (dry) phase of a strong ISO during the MTC active (inactive) phase. (4) The generation of the eight TCs in the MTC active phase is all related to tropical fluctuation, five of which are affected by two kinds of tropical waves at the same time. Tropical fluctuation provides the trigger conditions for the TC generation by changing local thermal and dynamic conditions. (5) The common influence of multi-scale circulation eventually leads to significant differences in the vertical structure characteristics of temperature-pressure disturbance field configuration, vertical motion disturbance and specific humidity disturbance in the MTC active and inactive phase. The application of the disturbance analysis method provides a new idea for the extended range forecast.

Improvement of Prediction Accuracy of 3-second gust caused by Typhoon –FDDA and High Resolution SST -

*Woosik Jung[1]

1. INJE University, Department of Atmospheric Environment Information Engineering, Gimhae, Republic of Korea

As industrialization has progressed rapidly since the 1980s, global warming is steadily going on. According to a study by the IPCC(2015), as global warming progresses, SST increases, the number of typhoons occurs decreases and intensity becomes stronger. In fact, SST around the western Pacific and the Korean Peninsula have recently increased at a faster rate than the average global increase in SST, and the intensity of typhoons affecting the Korean Peninsula has become stronger. In order to reduce the damage caused by typhoons in Korea, Typhoon Pre-prevention Disaster Model is developed and operated to calculate 3-second gust(maximum instantaneous wind speed) and damage cost that could occur during the typhoon’ s effect. In studies related to Typhoon Pre-prevention Disaster Model, studies on the development process and the characteristics of the Korean Peninsula impact typhoon applied to Typhoon Pre-prevention Disaster Model were preceded mainly by studies that conducted basic analysis to develop Typhoon Pre-prevention Disaster Model. However, studies to improve the accuracy of the 3-second gust, the result of the Typhoon Pre-prevention Disaster Model, were not preceded. Therefore, in this study, we apply the High resolution SST and FDDA to the WRF model used to derive input informations from the typhoon pre-prevention model, and then analyse the improvement of predictive accuracy of 3-second gust calculated from the Typhoon Pre-prevention Disaster Model. A total of four experiments were performed with the default experiment(EXP1) with no application, the experiment with adding high resolution SST(EXP2), the experiment with adding FDDA(EXP3) and the experiment with applying high resolution SST and FDDA simultaneously(EXP4). As a result, 3-second gust was best simulated when the results of the experiment using both high resolution SST and meteorological data FDDA were used as input data for the Typhoon Pre-prevention Disaster Model.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

However, studies to improve the accuracy of the 3-second gust, the result of the Typhoon Pre-prevention Disaster Model, were not preceded. Therefore, in this study, we apply the High resolution SST and FDDA to the WRF model used to derive input informations from the typhoon pre-prevention model, and then analyse the improvement of predictive accuracy of 3-second gust calculated from the Typhoon Pre-prevention Disaster Model. A total of four experiments were performed with the default experiment(EXP1) with no application, the experiment with adding high resolution SST(EXP2), the experiment with adding FDDA(EXP3) and the experiment with applying high resolution SST and FDDA simultaneously(EXP4). As a result, 3-second gust was best simulated when the results of the experiment using both high resolution SST and meteorological data FDDA were used as input data for the Typhoon Pre-prevention Disaster Model.

Improvement of Prediction Accuracy of 3-second gust caused by Typhoon –Meteorological Input Data : GDAPS, RDAPS, GFS -

*Woosik Jung[1]

1. INJE University, Department of Atmospheric Environment Information Engineering, Gimhae, Republic of Korea

The damage caused by recent typhoons affecting the Korean Peninsula has been increasing rapidly. The top 10 records of maximum instantaneous wind speed caused by typhoons has shown by typhoons since the 2000s. Compared to the past, the frequency of typhoons is decreasing and the intensity of typhoons is getting stronger. In order to reduce damage from typhoons, a Typhoon Pre-prevention Disaster Model developed and operated to predict 3-second gust(maximum instantaneous wind speed) caused by typhoons and to calculate the possible damage. In order to improve the accuracy of Typhoon Pre-prevention Disaster Model, meteorological input data such as GDAPS(Global Data Assimilation Prediction System), RDAPS(Regional Data Assimilation System), and GFS(Global Forecast System) were applied to the Model. 3-second gust calculated using GDAPS as the meteorological input data showed the most similar results to the observed values for the RMSE, MB, and IOA values used as statistical indicators, followed by RDAPS and GFS.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152).

Improvement of Prediction Accuracy of 3-second gust caused by Typhoon –Soil Data : GDAPS SOIL, GFS SOIL -

*Woosik Jung[1]

1. INJE University, Department of Atmospheric Environment Information Engineering, Gimhae, Republic of Korea

In order to reduce the damage caused by the typhoon, 3-second gust, which is the maximum wind speed that can occur during the typhoon, is a very important factor in terms of disaster prevention. Therefore, this study conduct to improve the prediction accuracy of Typhoon Pre-prevention Disaster Model that calculates the 3-second gust. UM(Unified Model) data has a problem in being used as input data because the initial soil moisture and the soil temperature unit and depth are different. Therefore, soil data from GFS(Global Forecast System) and FNL(NCEP final analysis) are mainly used as a substitute. In this study, soil moisture and soil temperature of UM data were adjusted to Typhoon Pre-prevention Disaster Model, and experiments were conduct to use the GDAPS(Global Data Assimilation Prediction System) as meteorological input data, and soil data as the existing method. At the same time, a single model using GDAPS as the meteorological input data and GDAPS SOIL as the soil data is also conduct. The results of 3-second gust calculated using Typhoon Pre-prevention Disaster Model were compared with 'GUST wind speed' in the buoy and 'Maximum instantaneous wind speed' on the beacon. The results of the analysis showed that the experiments using the results of a model using a GDAPS SOIL (Single Model) as input data for Typhoon Pre-prevention Disaster Model was more similar to the observed values and more consistent with the trend than the experiment applying soil data to GDAPS meteorological input data using GFS SOIL. In conclusion, if a single model is used as WRF soil data, which is input data, it is deemed possible to determine the optimal results when performing Typhoon Pre-prevention Disaster Model.

Autumn Typhoon on the Korean Peninsula - Comparison of Past and Present

*Woosik Jung[1], Hana Na[1]

1. INJE University, Department of Atmospheric Environment Information Engineering, Gimhae, Republic of Korea

Recently, the characteristics of typhoons affecting the Korean Peninsula are rapidly changing. As the typhoon affects the Korean Peninsula, and the SST in the Northwest Pacific, including the growing Korean Peninsula, increases at a faster rate than the global average SST, the intensity of the typhoon affecting the Korean Peninsula is increasing. In particular, the frequency and intensity of typhoons affecting the Korean Peninsula in September and October, called “Autumn Typhoon,” are increasing. In 2019, there were seven typhoons in the Korean Peninsula, of which three typhoons occurred in September, causing significant damage to the Korean Peninsula. Although the frequency and intensity of autumn typhoons are increasing, but previous studies on autumn typhoons are very insufficient. Therefore, this study compared and analyzed the change in overall characteristics including frequency, intensity, maximum instantaneous wind speed, and track for autumn typhoon. The analysis of maximum instantaneous wind speed and distribution during the typhoon period was carried out using the Typhoon Pre-prevention Disaster Model. The analysis showed that the proportion of autumn typhoons affecting the Korean Peninsula was increasing sharply in the 2011-2019 period compared to 2002-2010, and that the maximum instantaneous wind speed that occurs during the period of the fall typhoon was also increasing. In recent years, as the frequency and intensity of autumn typhoons increase simultaneously, the damage caused by autumn typhoons is gradually increasing. Therefore, in terms of disaster prevention, further research on autumn typhoon should be conducted later.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152).

Water vapor transport associated with remote precipitation caused by typhoon in autumn season

*Shinichi Kodama[1], Masaki Satoh[1]

1. Atmosphere and Ocean Research Institute, Univ. of Tokyo

In the autumn season of Japan, typhoon located far away from Japan increases the supply of water vapor to the rain front and causes significant precipitation. This phenomenon is called remote precipitation due to the indirect effects of typhoon, and in Japan there are only a few case studies. On the other hand, precipitation by the indirect effects of tropical cyclone on the North American continent is called the predecessor rain event (PRE), and many cases or statistical studies have been conducted. In this study, in order to clarify the mechanism of remote precipitation in Japan, I focused on the water vapor transport associated with remote precipitation caused by typhoon in autumn season and analyzed it.

The analysis period is from September 2004 to 2018 for 15 years, covering strong typhoons that developed below 950 hPa. When I checked the course of typhoons obtained, it was found that they were roughly classified into two courses: a course approaching while recurving to Japan and a course proceeding westward. Moreover, when I checked the water vapor transport by course, it was confirmed that a course approaching while recurving to Japan had large impact on Japan. Therefore, the analysis was limited to only typhoons on course that approaching while recurving to Japan.

In order to classify all 12 recurving typhoons into those with and without remote precipitation, I determined the definition of remote precipitation in Japan. As a result, 5 cases were judged as Japanese version of PRE and 7 cases as Not PRE (N-PRE). Moreover, as a result of a composite analysis of PRE cases with the typhoon center aligned with latitude lines, it was confirmed that PRE occurs around Japan on the day the typhoon center is located at 22.5 degrees north latitude. Furthermore, I defined the day as the reference day of day0 and compared the environmental fields before remote precipitation occurred from the composite analysis of PRE cases and N-PRE cases for 1 day before (day-1) and 2 days before (day-2). When I compared the extending changes of the subtropical high, PRE cases showed a weakening tendency from day-2 to day0, and N-PRE cases showed an increasing tendency. As a result, in PRE cases, the water vapor carried by the typhoon is blocked by the downward flow of the subtropical high in front, and there is no route to escape to the north or west, and the high water vapor situation is maintained mainly on the east side of the typhoon. Subsequently, the extending of the subtropical high will weaken, causing water vapor transport northward to Japan, which will lead to the occurring of PRE.

The impact of lower stratospheric temperature change on Typhoon

*Kenta Kobayashi[1], Nawo Eguchi[1], Kosuke Ito[2]

1. Interdisciplinary Graduate School of Engineering Science, Kyushu University , 2. Faculty of Science, University of the Ryukyus

In recent years, it is statistically clarified that the stratospheric dynamical change, such as sudden stratospheric warming (SSW) and quasi-biennial oscillation (QBC), affects on the cumulus convective activity in tropical zone. For example, the study examining the effect of stratospheric conditions during SSW has found that the activity of cumulus convection becomes deeper due to descending the unstable region from the lower stratosphere [e.g., Eguchi et al., 2015; Kodera et al., 2015]. For this reason, the importance of a quantitative understand of stratospheric effects on the troposphere has been recognized internationally [e.g., SATIO-TCS (Stratospheric And Tropospheric Influences On Tropical Convective Systems) on SPARC]. Although there are a few previous studies, it is not clear the relationship between the stratosphere and typhoons, yet. Therefore, we researched the effects of temperature changes at the lower stratosphere on typhoons by using the two-dimensional axial symmetry model (Rouunno and Emanuel, 1987). We changed temperature profile at the lower stratosphere and checked the changes in typhoon’s wind speed, height, etc. As a result, it was found that the upper troposphere becomes unstable, and the upper, lower, radial, tangential wind velocity increases due to deep convection when the temperature in the stratosphere is lower than the control simulation. At the presentation, we will show the effect of temperature change at the lower stratosphere on the typhoon activity in detail.

Sensitivity Experiments of Relative Humidity Assimilation on Typhoon Lan (2017)

Jaedeok Lee[1], *Kosuke Ito[1], Chun-Chieh Wu[2]

1. University of the Ryukyus, 2. National Taiwan University

Typhoon Lan (2017) caused tremendous flooding while passing through mainland Japan. A day before making landfall, Lan had robust eyewall and eye structures. During this period, valuable in-situ data were obtained through the Observing System Research and Predictability Experiment Pacific Asian Regional Campaign Ⅱ (T-PARC Ⅱ). The present study has constructed the three-dimensional relative humidity of Lan by performing statistical analyses between in-situ data obtained by T-PARC Ⅱ and the IRWVln produced by the Himawari-based technique. To assimilate this three-dimensional relative humidity, the initial conditions of Lan have been improved by using the dynamical initialization. The results of the sensitivity experiments show that as the magnitude of the innovation scale increases, the simulated precipitation structures seen by the outgoing longwave radiation or radar fields tend to well account for actual characteristics compared to satellite images or radar images. However, the influence of relative humidity correction appears to have little impact on track and intensity forecasts.

Role of VHTs and Helical flow organization in the formation of Tropical Cyclogenesis over North Indian Ocean

*EMMANUEL RONGMIE[1,4], Medha Deshpande[2], Mano Kranthi Ganadhi[1], Sopan Tukaram Ingle[3], Phani Murali krishna[2]

1. Research Scholar in Indian Institute of Tropical Meteorology Pune, 2. Scientist D in Indian Institute of Tropical Meteorology Pune, 3. Professor and Director in K.B.C. North Maharashtra University, Jalgaon, 4. North Maharashtra University, Jalgaon

Tropical Cyclogenesis (TCs) remains one of the most complex enigmas of dynamic meteorology. Many environmental factors contribute to the genesis of TCs. The main objective of this study is to understand ‘why’ and ‘how’ Mesoscale convective vortices (MCVs) cluster and the role of Vortical Hot towers (VHTs) in the Tropical Cyclones (TC). Reanalysis and satellite data for various cases of TC shows that the Mesoscale convective system (MCS) interaction in the presence of a large Scale. Multiple waves interact and modulate different requisite parameters compared to the presence of individual waves. To understand the interaction of MCVs and VHTs in the Pregenesis period, a numerical simulation experiment is carried out using ‘Model for Prediction across Scales (MPAS)’ focused over the Indian. Linkage of the primary and secondary circulation in the developing and non-developing TCs, the total kinetic terms and scalar quantity, total helicity are examined. Role of different component of horizontal and vertical helicity is examined. The importance of the study is to investigate the validity of helicity as an indication of large scale vortex instability.

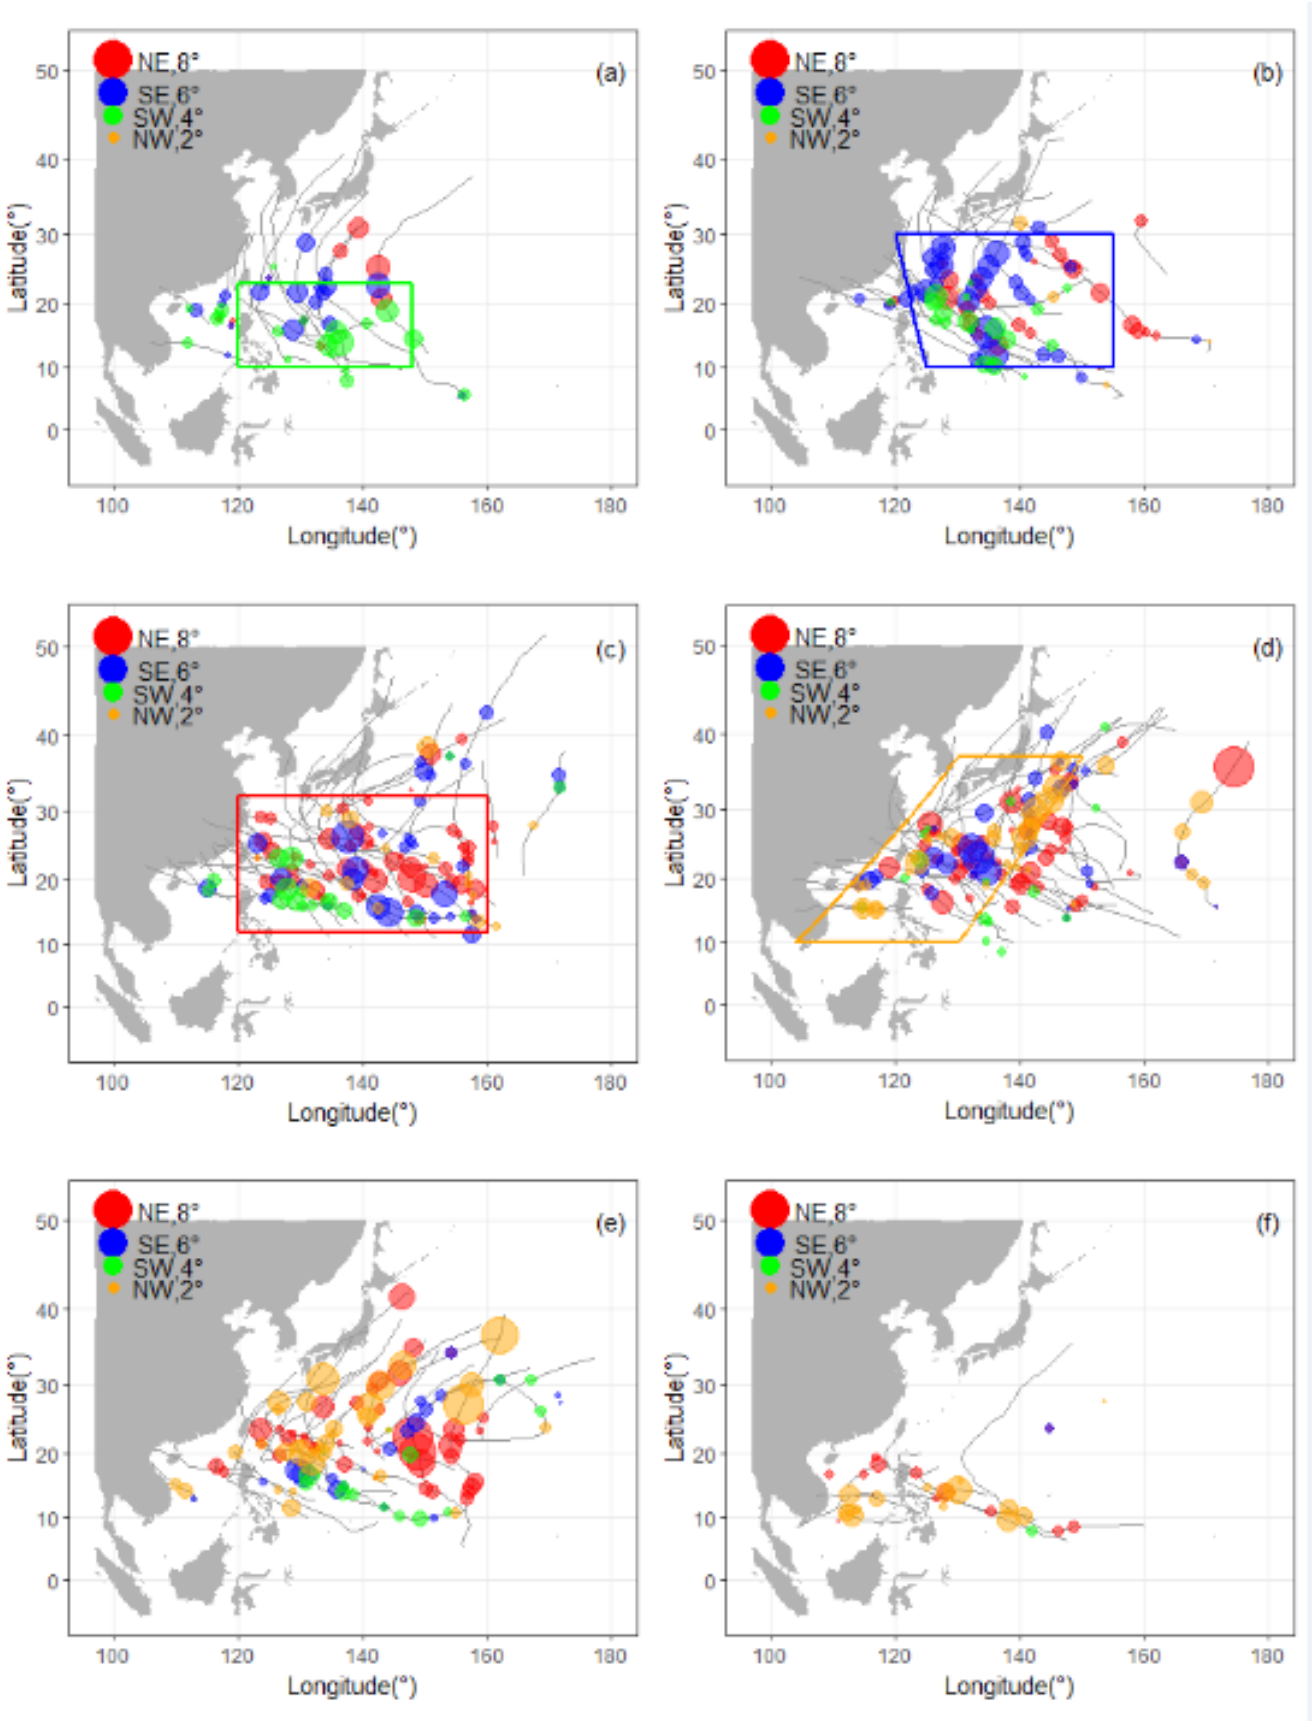
Monthly Variation and Spatial Distribution of Quadrant Tropical Cyclone Size in the Western North Pacific



*Tonghua Su[4], Wei Hong[1], Yulan Zheng[2], Bin Chen[3], Xiaoqing Ke[5]

1. Fujian Meteorological Observatory of of China Meteorological Administration, 2. Fujian Meteorological Information Center of China Meteorological Administration, 3. Electric Power Research Institute of State Grid Fujian Electric Power Company, 4. Fujian Climate Center of China Meteorological Administration, 5. Fujian Meteorological Service Center of China Meteorological Administration

With the tropical cyclone (TC) size parameter defined as the radius of 17-m·s^{-1} oceanic surface wind, 225 TC cases were recorded in the western North Pacific during 2000–2009 based on the QuikSCAT near-surface wind vector database and the best-track dataset. In accordance with the symmetry index (the ratio of minimum and maximum quadrant sizes), the TCs were classified into symmetric and asymmetric structures. The asymmetric TCs were divided into four types: the northeast, southeast, southwest, and northwest. The spatio-temporal characteristics of these TC types were further investigated. The monthly variation and the spatial distribution of maximum quadrant TC size exhibited significant differences among the four types. By contrast, the quadrant size of the symmetric TCs from June to November showed few changes (2.6˚–2.7˚ latitude). It was found that the TC lifetime is an important factor affecting the quadrant TC size because of its close relationship with the activities of the western Pacific subtropical high. In addition, the climatological mean circulation also has a notable influence on the quadrant TC size through superposition of prominent background wind. Symmetric TCs are more likely to occur in the oceanic region where the background low-level wind is the weakest.

Keywords: tropical cyclone, size, quadrant, lifetime, circulation, symmetry

Top-down estimation of terrestrial CO_2 flux in Northern Eurasia

*Tomoko Shirai[1], Misa Ishizawa[2], Motoki Sasakawa[1], Akihiko Ito[1], Toshinobu Machida[1], Shamil Maksyutov[1]

1. National Institute for Environmental Studies, 2. Environment and Climate Change Canada

We present a multi-year trend of terrestrial CO_2 flux from northern Eurasia, estimated by atmospheric inversion using a coupled model GELCA (Global Eulerian-Lagrangian Coupled Atmospheric model). Global monthly CO_2 flux distributions were estimated for the period 2002-2015 for 42 land and 22 ocean regions using the Observation Package data products (ObsPack GLOBALVIEWplus) which includes data from various types of atmospheric CO_2 direct measurements provided by large numbers of laboratories in the world. In this study, we added 9 tower observations from JR-STATION (Japan-Russia Siberian Tall Tower Inland Observation Network) to better constrain the area of interest.

In order to examine the impact of additional observational constraints in Siberia, we compared the inversion results with and without JR-STATION data. For the entire period, estimated global land fluxes agreed well with each other regardless of JR-STATION data. At regional scales, estimated fluxes showed significant difference mostly in Siberia and northeastern Europe. When focusing on the mean seasonal variations, summer uptake increased in western Siberia and northeastern Europe whereas it decreased in northeastern Siberia by adding JR-STATION data.

In terms of the long-term trend, the terrestrial sink was increasing both in Siberia and in Europe. Terrestrial CO_2 fluxes estimated for Siberia using JR-STATION data is -0.88 ±0.55 $GtCyr^{-1}$ and -1.36 ±0.42 $GtCyr^{-1}$ over the period 2002-2009 and 2010-2015, respectively. Those for Europe is -0.19 ±0.43 $GtCyr^{-1}$ and -0.42 ±0.30 $GtCyr^{-1}$, respectively. The increasing trend of the carbon sink in northern boreal areas can be explained by the combination of warming climate and the fertilization effect . Time series of these fluxes also reflect the effect of ENSO and extreme weather conditions. The interpretation of the multi-year variation of estimated fluxes in northern Eurasia will be presented.

Recent stagnation of CH_4 emission growth from East Asia based on the analysis of synoptic variations of atmospheric CH_4 and CO_2 observed at Hateruma Island

*Yasunori Tohjima[1], Jiye Zeng[1], Akihiko Ito[1], Naveen Chandra[2], Yosuke Niwa[1], Hitoshi Mukai[1], Tomoko Shirai[1], Motoki Sasakawa[1], Prabir Patra[2], Toshinobu Machida[1]

1. National Institute for Environmental Studies, 2. Japan Agency for Marine-Earth Science and Technology

Atmospheric mixing ratios of greenhouse gases including CO_2 and CH_4 have been monitored at Hateruma Island, Japan (HAT; lat. 24.1˚N, long. 123.8˚E) for more than 20 years by the National Institute of Environmental Studies (NIES). The observed CO_2 and CH_4 show secular increasing trends and seasonal variations, typical of a regional background sites, and consist of synoptic variations (ΔCO_2 and ΔCH_4) with duration ranging from several hours to several days. These synoptic variations were contain signals arising from the regional emissions from the continental East Asia, especially China, and were observed more often during late fall to early spring because of the suppression of the continental emissions signal during the East Asian monsoon in summer. Since the observed ΔCO_2 and ΔCH_4 in wintertime generally showed fairly good correlations, the variation ratio ($\Delta CH_4/\Delta CO_2$ ratio) can be used to constrain the regional emission ratio. In previous study (Tohjima et al., 2014), based on the fact that the fossil fuel CO_2 emissions were relatively well determined, we obtained the increasing rate of the CH_4 emission from China (about 1 Tg-CH_4 yr^{-2}) in 2000s from the comparison of the $\Delta CH_4/\Delta CO_2$ ratios between the observation and simulation. In this study, we revisited the temporal change in $\Delta CH_4/\Delta CO_2$ ratio at HAT and investigate the recent change in the CH_4 emissions from China. The observed $\Delta CH_4/\Delta CO_2$ ratio showed decrease for the entire period (1997-2019) from about 13 ppb/ppm to 8 ppb/ppm while its decreasing rate showed a gradual slowdown and appeared to reach bottom after 2010. Such change in the decreasing rate is mostly attributed to the slowdown of the increase in the fossil fuel CO_2 emissions from China. We calculated ΔCO_2 and ΔCH_4 by using a Lagrangian Particle Dispersion Model (LPDM) and several CH_4 and CO_2 flux maps based on bottom-up and top-down approaches. Then we scaled the CH_4 emissions from China so as to match the calculated $\Delta CH_4/\Delta CO_2$ ratio with the observation. The results suggested that the linear increasing trend of the CH_4 emissions from China for 2010s is significantly reduced in comparison with that for the 2000s.

Spatio-temporal variations of atmospheric methane concentrations over Japan: Data analysis of governmental monitoring and TROPOMI satellite from air pollution research viewpoint

*Yugo Kanaya[1]

1. Research Institute for Global Change, Japan Agency for Marine-Earth Science and Technology

As being an important greenhouse gas as well as a short-lived climate forcer, sources of atmospheric methane need to be understood well toward effective mitigation of climate change. Our best practice is to build bottom-up emission inventories by compiling available socio-economic data and emission-relevant information to optimize control measures; however, the uncertainty in the inventories is large and thus independent information is required for their evaluation and improvement. Ground-based and satellite observations will serve for the purpose. In this study, we analyzed long-term methane measurement data contained in the governmental monitoring to elucidate features of spatio-temporal variations. Here, the measured methane concentration levels are generally only used to be subtracted from the total hydrocarbon concentrations to yield non-methane hydrocarbon levels, important to ozone chemistry - and thus the data set has seldom been analyzed. Among the available data at several hundreds of sites during FY2009-2016, data at 39 non-roadside sites were selected, where annual average concentrations ranked within top 20 at least once. The data during 6-9 LT were monthly averaged and their normalized seasonal patterns were analyzed. From cluster analysis, three distinct patterns were found: First pattern was with large increases in summer/autumn. Two sites (Toasa in Hokkaido and Narashino-Saginuma in Chiba) with very high monthly-averaged concentrations (>2.5 ppm) were categorized to this cluster, where very strong local emissions were suspected. Second pattern was with wintertime increases, to which 20 sites normally within Tokyo/Osaka metropolitan areas were categorized. The pattern was understood as general air pollution behavior in terms of dilution/diffusion, suggesting influence from urban sources. The third pattern was with summertime increases, particularly during June-August. The categorized 17 sites are mostly from rural regions and emissions from rice paddy fields were implied. We will show more results on correlations with wind and other pollutants (e.g., NOx, CO). Features from TROPOMI satellite observations of methane over Japan are also to be discussed together with the analysis of the ground-based observations.

Variations of surface ocean pCO_2 and air-sea CO_2 fluxes in the Western Pacific Ocean

*Wataru Konarita[1], Shinji Morimoto[1], Shuji Aoki[1]

1. Center for Atmospheric and Oceanic Studies, Graduate School of Science, Tohoku University

Temporal and spatial variations of CO_2 partial pressure in surface sea water ($pCO_{2,sea}$) observed in the western Pacific were analyzed in terms of physics and chemistry of the ocean and the CO_2 fluxes between the atmosphere and ocean were also evaluatedand the CO_2 flux between the atmosphere and ocean . The $pCO_{2,sea}$ has been observed continuously on-board a cargo ship “Trans Future 5” on her round-trip between Japan and Australia. Systematic observations for the atmospheric pCO_2 ($pCO_{2,air}$) were have been also conducted in the western Pacific by a grab-sampling method using container ships sailing almost similar route.

In the equatorial region, interannual variabilities of $pCO_{2,sea}$ were clearly observed, and were highly correlated with the El Niño Southern Ocsillation (ENSO). Higher $pCO_{2,sea}$ observed in 2008 and 2012, coincident with La Nina, could be caused by transport of high salinity, low temperature and high dissolved inorganic carbon water upwelled off the coast of Peru to the observation line at the western Pacific Ocean. When large and strong El Nino occurred from 2015 to 2016, significant increase of $pCO_{2,sea}$ was observed between 25˚N and 25˚S. The $pCO_{2,sea}$ increase could be associated with remarkable decrease of the precipitation observed in the western Pacific region.

The CO_2 flux between the atmosphere and the ocean was calculated by using the air-sea pCO_2 difference in pCO_2 ($DpCO_2$) between the atmosphere and the surface ocean, sea surface temperature and wind speed at 10m height. In the western Pacific Ocean, the largest CO_2 absorption was found at 20˚S (−13.0 gC m^{-2} yr^{-1}), and the net CO_2 outgassing at equatorial area (1.2 gC m^{-2} yr^{-1}) were found.

The increase in $pCO_{2,sea}$ associated with the strong El Niño event in 2015 and 2016 may have caused a decrease in the oceanic CO_2 absorption throughout the western Pacific.

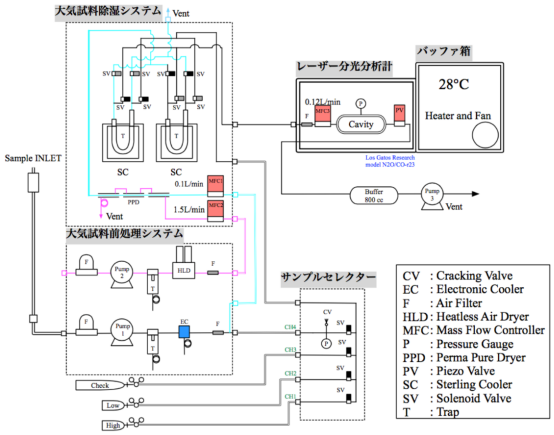
In-situ and continuous observation of atmospheric N_2O and CO concentrations at Syowa Station, Antarctica.

*Shogo Akai[1], Shinji Morimoto[1], Wei Li[1], Daisuke Goto[2], Shuji Aoki[1]

1. Graduate School of Science, Tohoku University, 2. National Institute of Polar Research

Nitrous oxide (N_2O) is one of the most important anthropogenic greenhouse gases and its infrared absorption efficiency is 200 times more than that of carbon dioxide (CO_2). In addition, since N_2O catalytically decomposes stratospheric ozone (O_3), N_2O is concerned to be a major factor for the destruction of the stratospheric ozone after the concentrations of atmospheric chlorofluorocarbons decreases in near future. Carbon monoxide (CO) is not considered as greenhouse gas generally, but atmospheric CO is closely related to the atmospheric CH_4 concentration through OH radicals, which are important reactant both with CH_4 and CO. Furthermore, CO is also a useful tracer for biomass burning and has an important role in the atmospheric chemistry. Therefore, it is important to reveal the temporal and spatial variations the atmospheric N_2O and CO concentration and to understand the cause of their variations quantitatively.



In this study, we developed a new continuous observation system for atmospheric N_2O and CO concentrations based on an OA-ICOS (Off-Axis Integrated Cavity Output Spectroscopy) laser spectrometer (Los Gatos Research, model N2O/CO r23) (Fig.1). Repeatability for the analysis of N_2O and CO concentrations by the system is estimated to be 0.14 ppb and 0.09 ppb (one standard deviation), respectively. The system was installed at Syowa Station, Antarctica, and continuous observation started in January 2019.

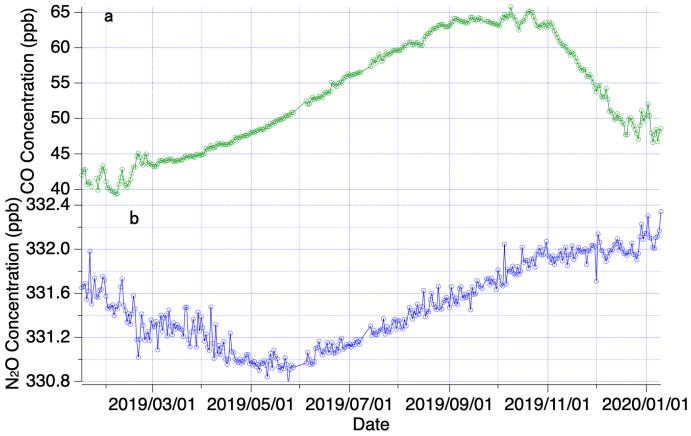


Figure 2 shows the temporal variations of the N_2O and CO concentrations observed by our system at Syowa Station since January, 2019. As shown in the figure, characteristic variations of N_2O and CO are found in each season. In the austral summer, in-phase and out-of-phase fluctuations of N_2O and CO were observed several times. These fluctuations could be caused by the transport of high N_2O and CO air mass affected by outgassing from the Southern Ocean and downward transport of stratospheric air into Syowa Station. In austoral spring, high CO event was captured at Syowa Station. It had been affected by serious biomass burning in Amazon and Australia.

In this presentation, we will introduce the observation system, thus developed, and show the temporal variations in the N_2O and CO concentration observed at Syowa Station in more detail.

Seasonal variations in the atmospheric Ar/N_2 ratio observed at ground-based stations in Japan and Antarctica and its application to an evaluation of the air-sea heat flux

*Shigeyuki Ishidoya[1], Kentaro Ishijima[2], Satoshi Sugawara[3], Yosuke Niwa[4], Yasunori Tohjima[4], Daisuke Goto[5], Kazuhiro Tsuboi[2], Shohei Murayama[1], Nobuyuki Aoki[1], Takashi Maki[2], Taichu Y Tanaka[2], Takashi Nakamura[6]

1. National Instutite of Advanced Industrial Science and Technology (AIST), 2. Meteorological Research Institute, 3. Miyagi University of Education, 4. National Institute for Environmental Studies, 5. National Institute of Polar Research, 6. Japan Meteorological Agency

Variations of the atmospheric Ar/N_2 ratio at the ground surface are driven principally by air-sea Ar and N_2 fluxes due to changes in solubility in seawater (e.g. Keeling et al., 2004). Recently, we expanded our model study for the gravitational separation to Ar/N_2 ratio, and found that temporal variations of gravitational separation in the middle atmosphere could also modify the long-term trend of the surface Ar/N_2 ratio (Ishidoya et al., in preparation). Therefore, the surface Ar/N_2 ratio is a unique tracer of the spatiotemporally-integrated air-sea heat flux and the circulation in the middle atmosphere. We have continued systematic observations of the Ar/N_2 ratio by using a mass spectrometer at Cape Ochiishi (43˚N, 146˚E), Tsukuba (36˚N, 140˚E), Takayama (36˚N, 137˚E), Hateruma Island (24˚N, 124˚E) and Minamitorishima (24˚N, 154˚E), Japan and Syowa station (69˚S, 40˚E), Antarctica since 2012. Clear seasonal Ar/N_2 ratio cycles with summertime maxima have been observed at the middle to high latitudinal stations, and the peak-to-peak amplitudes of the average seasonal cycles at Ochiishi, Tsukuba, Hateruma and Syowa were found to be 21, 11, 5 and 32 per meg, respectively. To evaluate the seasonal air-sea heat flux based on seasonal cycles of Ar/N_2 ratio in the atmosphere, we carried out simulations of the Ar/N_2 ratio using an atmospheric transport model (GSAM-TM) that incorporated the Ar (N_2) flux derived from an equation of the relationship between the air-sea Ar (N_2) flux and the air-sea heat flux (Keeling et al., 1993; Weiss, 1970). We use the air-sea heat flux components, which mainly drive spatiotemporal variations of the air-sea Ar (N_2) fluxes, and sea surface temperature (SST) from the ERA5 (Hersbach et al., 2019). Thus simulated seasonal cycles of Ar/N_2 ratio agreed well with those observed. On the other hand, the amplitudes of the seasonal cycles of Ar/N_2 ratio simulated by using the TransCom seasonal air-sea N_2 flux (Garcia and Keeling, 2001), widely used in the simulation of the atmospheric O_2/N_2 ratio and based on the past ECMWF seasonal air-sea heat flux, underestimate the observed seasonal cycles significantly. These facts suggest that the air-sea heat fluxes and SST from the ERA5 is reasonable to reproduce the atmospheric Ar/N_2 variations on the seasonal time scale.

Acknowledgements

We thank staff of Global Environmental Forum (GEF), the Science Program of the Japan Antarctic Research Expedition (JARE) and Japan Meteorological Agency (JMA) for their works to collect the air samples at Hateruma and Ochiishi stations (GEF), Syowa station (JARE) and Minamitorishima (JMA), respectively. This study was partly supported by the JSPS KAKENHI Grant Number 15H02814 and 18K01129, and the Global Environment Research Coordination System from the Ministry of the Environment.

Development of a new ISEE Chemical Lagrangian Model to elucidate the atmospheric composition changes in the mesosphere

*Tomoo Nagahama[1], Shingo Nakanishi[2], Fujita Ken[2], Tac Nakajima[1], Akira Mizuno[1]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Graduate School of Science, Nagoya University

Chemical composition in the mesosphere fluctuates significantly due to factors such as temperature, solar UV radiation and energetic particle precipitation from the space. In order to elucidate these mechanisms and evaluate their impacts, we have newly developed a chemical Lagrangian model that can handle from the troposphere to the mesosphere (e.g. Nakanishi et al., JpGU meeting, 2019). In the model, the trajectory of the particle box is calculated by a Lagrangian particle dispersion model which works with meteorological input data, and the chemical reactions in the particle box are also calculated by using a box model simultaneously. As the Lagrangian particle dispersion model, we used the FLEXible PARTicle (FLEXPART) model, which is extended so that the MERRA-2 reanalysis data can be used as input. As a result, we can calculate the trajectory up to an altitude of about 80 km from the surface. The position of the particle box is calculated every 15 minutes. As a box chemistry model, neutral molecule reactions consisting of 156 chemical reactions involving 58 chemical species and ion reactions of 263 reactions involving 77 species are calculated, respectively, using chemical reaction calculation software Kinetic Preprocessor (KPP). The concentration of each molecule in the box is calculated every 10 and 0.1 seconds, respectively. To validate the model calculations, 324 airmass boxes were released from the point at the altitude of 70 km in the polar and mid-latitude regions, and the two-day change in the concentration of ozone and ozone related substances was calculated. As a result, the diurnal variation of mesospheric ozone was qualitatively reproduced, although the value was about half of the value observed with Aura/MLS. In addition, we find that the difference in the ozone concentration in the Arctic region depends on the temperature on the transport route of the airmass. In the presentation, we will report on the details of the developed model, the characteristics of the time variation of the substances in the mesosphere as well as the results of comparison with observations.

Analysis of the mesospheric ozone enhancement event in the Arctic winter with a new ISEE Chemical Lagrangian Model

*Fujita Ken[1], Tomoo Nagahama[2], Shingo Nakanishi[1]

1. Graduate School of Science, Nagoya University, 2. Institute for Space-Earth Environmental Research, Nagoya University

Mesospheric chemical composition largely varies caused by environmental changes from the earth inside and outside. Environmental changes are, for example, temperature changes, solar UV, a large event of energetic particle precipitation. To understand the atmospheric composition changes caused by natural phenomena, we have installed millimeter-wave spectrometers in Rikubetsu (Japan), Syowastation (Antarctic), Atacama (Chile), Rio Gallegos (Argentine), and Tromso (Norway), and have been observing atmospheric minor molecules such as ozone, NO_x, HO_x, and ozone-depleting substances in the stratosphere and mesosphere. In addition to these observations, we need to analyze model simulation results to understand the impact of these changes on the global. For this purpose, ISEE has developed a new chemical transport model which is a combination of two models, FLEXPART and KPP. FLEXPART is a Lagrangian transport and dispersion model that is extended so that the MERRA2 reanalysis data can be used as input. Also, a chemical reaction software KPP (Kinetic Preprocessor) can calculate chemical changes simultaneously with the transport model. In order to validate the model calculation results, we compared the model output with mesospheric ozone dataset measured with JEM-SMILES from December 2009 to January 2010. During this period, a sudden increase in the ozone concentration (1 to 5 ppmv) in the Arctic mesosphere occurred. The analysis of the trajectories and ozone distribution in the mesosphere revealed that the ozone increase over Alaska region was caused by the effect of the air mass passing through the low temperature region. On other hand, the air mass passing through a region where the temperature was high contains with low ozone concentration. Therefore, it was found that the ozone concentration in the mesosphere depends on the temperature on the transport route. In this presentation, we will present the results of the comparison between the simulation and the JEM-SMILES dataset as well as the analysis results of the event which mesospheric ozone suddenly increases in the Arctic winter in 2009/2010 season.

Short-term variations of HCl and HF trends observed with FTIR at Tsukuba

*Isao Murata[1], Yoshihiro Tomikawa[2,3], Isamu Morino[4], Hideaki Nakajima[4], Hideharu Akiyoshi[4]

1. Graduate School of Environmental Studies, Tohoku University, 2. National Institute of Polar Research, 3. The Graduate University for Advanced Studies, SOKENDAI , 4. National Institute for Environmental Studies

HCl is a main chlorine reservoir species in the stratosphere. The amount of HCl is a good indicator of the potential for ozone depletion. Observed total column of HCl was decreasing in the 2000s after CFC regulations were introduced but showed increase from 2007 to 2011. Mahieu et al. [2014] investigated that this increase is due to interannual dynamical variability in the northern stratosphere from Fourier Transform Infrared spectrometer (FTIR) observations at 8 sites including Tsukuba and 3D-chemical transport model simulations.
In this study we extended the analysis of HCl total column observed with FTIR at Tsukuba to 2018 and HF total column was also anlyzed. HF is a good tracer of atmospheric transport. The temporal variation of HCl and HF total columns showed decrease again from 2011 to 2014 then increase from 2015 to 2018. Mass stream function was calculated from ERA-Interim meteorological data to confirm that these temporal variations are also due to stratospheric circulation change. The difference of the mass stream function between the average of 2003 - 2006 and the average of 2007 - 2010 shows negative values in the northern lower stratosphere. This means the deceleration of circulation and it is consistent with the result of Mahieu et al. [2014]. The difference between the average of 2007 - 2010 and the average of 2011 - 2014 shows positive values in the northern lower stratosphere that means the acceleration of circulation. These changes correspond to the HCl and HF temporal variation. Thus we confirm that the temporal variation of HCl and HF is basically due to stratospheric circulation change.
The situation is somewhat different for the period after 2015. The difference of mass stream function between the average of 2011 - 2014 and the average of 2015 - 2018 shows negative values in the northern lower stratosphere again and this is also consistent with the increase of HCl and HF total columns after 2015. However, MIROC3.2 Chemistry-Climate Model (CCM) results show that the decrease rates of HCl and HF became lower but continue to decrease after 2015. This means that the circulation change after 2015 isn't enough to explain the trend reversal and there are some possibility that the emission change in CFC-11 affects the increase of HCl and HF after 2015.

Impact of HFCs on stratospheric ozone and temperature as simulated by chemistry-climate models

*Hideharu Akiyoshi[1], Eric Dupuy[1], Yousuke Yamashita[2,1]

1. National Institute for Environmental Studies, 2. Japan Agency for Marine-Earth Science and Technology

Hydrofluorocarbons (HFCs) are anthropogenic compounds used as substitutes for ozone-depleting substances (ODSs). While they do not chemically interact with ozone (O_3), as greenhouse gases (GHGs) they substantially affect stratospheric temperature and circulation patterns, thus indirectly influencing O_3 concentrations. Steps have been taken to curb production of HFCs (Kigali Amendment to the Montreal Protocol, 2016). Assuming global compliance, HFC emissions should, therefore, reach their peak around 2040. Until then, however, their atmospheric abundance will keep increasing [1]. We present ensemble model simulations designed to assess the response of O_3, temperature and atmospheric circulation to increasing levels of HFCs. We analyze this response for climate conditions of 2095, following the Representative Concentration Pathway (RCP) 2.6 [2]. In this scenario, uncontrolled HFC emissions would induce a radiative forcing comparable to that of carbon dioxide, methane and nitrous oxide combined.

We simulate the effect of varying HFC concentrations in a 2095 climate, using the CCSRNIES-MIROC3.2 and CCSRNIES-MIROC5.0 three-dimensional (3D) chemistry-climate models [3,4]. These models use the same chemical module, but their physical modules are partly different. For each model, three ensemble simulations (“experiments”) are performed with different amounts of HFCs: no HFCs (control run), and two or three times (“2xHFC”, “3xHFC”) the HFC concentrations of Hurwitz et al. (2015) [5]. These correspond to abundance estimates for 2050, in the case of unregulated HFC emissions. Each experiment is an ensemble of 100 independent, year-long simulations. Background atmospheric levels of GHGs follow the RCP2.6 scenario for 2095. Estimated abundances of ODSs assume full compliance with the Montreal Protocol.

For each model version, results for the “2xHFC” and “3xHFC” cases are qualitatively similar. Therefore, we focus our analysis on the “3xHFC” experiment and illustrate ensemble-mean results for total column O_3, as well as for latitude/pressure cross-sections of O_3, temperature and zonal mean zonal wind.

At tropical and subtropical latitudes, we obtain ozone responses to increasing HFC concentrations which are roughly consistent with those from the zonal-mean two-dimensional (2D) model of Hurwitz et al. (2015) [5]. In addition, at these latitudes, the O_3 responses of the MIROC3.2 and MIROC5.0 models are consistent. For O_3, this robust response is a decrease around 50 hPa and an increase above and below. The temperature response to HFC increases is a warming of the stratosphere below 20 hPa. The resulting total ozone response is very small, because the positive and negative O_3 anomalies cancel each other vertically. When considering the high latitudes, however, the calculated O_3 responses are quite different, not only between the 2D model and both 3D MIROC models, but also between MIROC3.2 and MIROC5.0.

©2020. Japan Geoscience Union. All Right Reserved.

Such discrepancies in the high-latitude responses may be due to differences of planetary wave activity in the models, and of their interaction with stratospheric HFCs and O_3.

ODS and GHG dependence of total ozone at mid- and high latitudes indicated by multi-ensemble simulations using MIROC3.2 and MIROC5 chemistry-climate models

*Hideharu Akiyoshi[1], Masanao Kadowaki[2], Yousuke Yamashita[3,1], Eric Dupuy[1], Toshiharu Nagatomo[1]

1. National Institute for Environmental Studies, 2. Japan Atomic Energy Agency, 3. Japan Agency for Marine-Earth Science and Technology

Total ozone in the Arctic shows large interannual variations. The total ozone amount during Arctic spring is larger when the meridional circulation in the wintertime is stronger, thus when the Arctic polar vortex is weaker, and vice-versa. These variations mask the dependence of ozone concentration on ozone depleting substances (ODSs) and greenhouse gases (GHGs). Therefore, it is difficult to evaluate and isolate the effects of ODS regulations and GHG emissions from natural atmospheric variability, although ODSs and GHGs may influence the interannual variation of the atmosphere.

We conducted multi-ensemble simulations using two chemistry-climate models (CCMs). We considered the variability of interannual ozone variations to be a statistical variance. We investigated the ODS and GHG dependence of total ozone for extreme values of the variance, as well as for the mean of all ensemble members. In these simulations, the ODS and GHG concentrations were fixed at observed or projected values for specific years in the past and future (e.g., for the years 1960, 2000, 2050). Each simulation or experiment is uniquely defined by ODS and GHG levels corresponding to a specific year (for example, observed ODS levels of 1980 and projected GHG levels for 2050). For one experiment, the ozone variability among the ensemble members is then considered to be the interannual variation. We examined the ODS and GHG dependence of total ozone (i.e., as a function of the experiment), based on the minimum value found for each ensemble member at latitudes 45-90˚N (‘polar cap’) during Northern spring (March –May). From the single-member minimum values, we then calculated the multi-ensemble mean, the mean for the 5 ensemble members with largest minimum value (hereafter “highest 5 members”), and for the 5 ensemble members with the smallest minima (hereafter “lowest 5 members”). The results show that the ODS and GHG dependence is large for the lowest 5 ensemble members and small for the highest 5 ensemble members. For the lowest 5 members, ozone levels should be smaller in a high-ODS atmosphere and larger in a high-GHG atmosphere. Furthermore, the zonal-mean zonal wind is stronger than for the multi-ensemble mean, while the corresponding polar cap temperature in the lower stratosphere is lower than the mean. This indicates that the Arctic polar vortex is comparatively stronger in the lowest 5 members.

The dependence of total ozone between 45-90˚S in September –November (Southern spring) was also investigated. We found much smaller GHG dependence and much larger ODS dependence than for the Northern Hemisphere. The differences in the ODS and GHG dependence were much smaller among the multi-ensemble mean, the highest 5 members, and the lowest 5 members. This is consistent with much smaller interannual variations in the Southern Hemisphere and, hence, more influence of atmospheric chemistry on the ozone variations.

We conducted these analyses for MIROC3.2-CCM and MIROC5-CCM and compared the results of the two models. The difference in the ODS and GHG dependence of total ozone between these two models is

A modeling study on the roles of cloud distribution in global tropospheric chemistry: detailed evaluation of clouds in a chemistry climate model (MIROC-CHASER)

*Ryoki Matsuda[1], Kengo Sudo[1,2]

1. Graduate School of Environmental Studies, Nagoya University , 2. Japan Marine-Earth Science and Technology

Chemical reactions in the atmosphere directly affect the formation and loss of ozone, methane, nitrogen oxides, sulfur oxides, and aerosols, and have a great influence on the atmospheric environment and climate change. Since these reactions are driven by photodissociation of ozone and related species caused by ultraviolet radiation, they can be largely modulated by the distribution of clouds. This study quantitatively investigates the photolytic impacts of clouds on atmospheric chemistry by using a global chemical transport model (chemical climate model, CHASER), observational (satellite and aircraft) data, and reanalysis data.
For cloud fields, CHASER reproduced generally well the global distribution of total cloud amount as observed in the satellite (ISCCP D2) and reanalysis data (JRA-55). This model, however, tends to underestimate low-level clouds in the tropics with an overestimate in the high latitudes. Further verification for the other cloud parameters like optical thickness and radiative forcing is now in progress and will be discussed in the presentation.
Our sensitivity experiments with respect to the impacts of clouds on photolytic processes show that clouds reduce OH radical concentrations by 10-20% near the surface and increase by 10-20% in the upper troposphere, basically as a result of scattering and reflection of UV radiation by low-middle level clouds. Our simulations also suggest that the global mean OH concentration, proxy of the oxidizing capacity of the atmosphere, increases by about 14% due to clouds. Also, tropospheric ozone (O_3) concentrations decreaced by about 3% near the surface and increased by about 4% in the upper troposphere reflecting changes in NO_x concentration. These clouds' impacts on the atmospheric chemistry were verified by using aircraft observation data (NASA ATom-1, 2, 3). The result shows that the observed OH and O_3 concentrations are reproduced more accurately when clouds are properly considered in the model.
These results indicate that clouds have significant influences on the global atmospheric chemistry (especially on the OH concentration field). Since OH determines the concentrations of chemical species such as methane, carbon monoxide (CO), fluorocarbons (CFCs), etc. which are important for climate and stratospheric ozone, this study suggests that the variation and trends in the clouds can largely affect the chemical species, which may give an additional influence on climate and atmospheric environment.

Impacts of tropospheric bromine and iodine on global tropospheric ozone: a modeling study using CHASER

*Takashi Sekiya[1], Yugo Kanaya[1], Kengo Sudo[2,1], Fumikazu Taketani[1], Maki Noguchi Aita[1], Akitomo Yamamoto[1], Yoko Iwamoto[3], Katsuhiro Kawamoto[4]

1. Japan Agency for Marine-Earth Science and Technology, 2. Graduate School of Environmental Studies, Nagoya University, 3. Graduate School of Integrated Sciences for Life, Hiroshima University, 4. Graduate School of Maritime Sciences, Kobe University

Bromine and iodine catalytic cycles are recognized as additional and important sinks of tropospheric ozone, though most of global climate transport models do not consider processes relevant to tropospheric bromine and iodine compounds (Young et al., 2018). A few global models have been used to evaluate impacts of tropospheric bromine and iodine on global tropospheric ozone (e.g., Saiz-Lopez et al., 2014; Sherwen et al., 2016), while large uncertainties in emission model process representation and emission estimation still remain. We newly implement iodine chemistry process, short-lived halocarbon emission, and ozone-mediated inorganic iodine release from the ocean (Chang et al., 2004; Carpenter et al., 2013) in the CHASER chemical transport model (Sudo et al., 2002; Sekiya et al., 2018) and evaluated impacts of tropospheric bromine and iodine on global tropospheric ozone. Incorporating these processes reduced surface ozone concentration by 20% on the annual and global average over the ocean. The model which incorporates these processes showed better agreements with ship-borne in-situ observations on the R/V Mirai and Hakuho-maru (Kanaya et al., 2019) during 2014-2018 (mean bias = 0.04 ppbv, $r = 0.82$) than the standard model (mean bias = 2.36 ppbv, $r = 0.73$). We evaluated impacts of tropospheric bromine on global tropospheric ozone loss using different three oceanic emission estimates of short-lived brominated halocarbons ($CHBr_3$, CH_2Br_2, CH_2BrCl, $CHBr_2Cl$, and $CHBrCl_2$): a bottom-up estimate based on SeaWIFS satellite observations of chlorophyll-a (Ordóñez et al., 2012), a bottom-up estimate for $CHBr_3$ and CH_2Br_2 using ship-borne observations (Ziska et al., 2013), and a top-down estimate for $CHBr_3$, CH_2Br_2, $CHBr_2Cl$, and $CHBrCl_2$ derived from the ATOM aircraft-campaign observations (Wofsy et al., 2018) using the Bayesian inversion technique. When using these three emissions, the global tropospheric ozone loss owing to bromine were estimated to be 284, 72, and 211 Tg O_3/yr, respectively, which suggested that bromine-catalyzed loss highly depends on short-lived halocarbon emissions. For tropospheric iodine sources, oceanic iodine release (as HOI and I_2) triggered by heterogeneous ozone loss at the sea surface was dominant over iodinated halocarbons (CH_3I, CH_2ICl, CH_2IBr, and CH_2I_2). The global tropospheric ozone loss owing to atmospheric iodine chemistry was estimated to be 643 Tg O_3/yr, which was comparable to the values reported by previous studies. Furthermore, model results suggested that the initial heterogeneous ozone loss at the sea surface (192 Tg O_3/yr) was an important sink of global tropospheric ozone which has not been evaluated explicitly in the previous studies. These results demonstrated the importance of the processes related to tropospheric bromine and iodine on global tropospheric ozone. In future studies, it is necessary to get a better understanding of tropospheric bromine and iodine compounds' emission processes and to reduce their uncertainties.

The weekday/weekend ozone differences induced by the emissions change in Guangzhou megacity of China

*Yu Zou[1]

1. Institute of Tropical and Marine Meteorology, CMA,Guangzhou,China

Guangzhou, one of China’ s megacities, is beset with frequent occurrence of atmospheric photochemistry events in summer and autumn. In this study, weekday/weekend mixing ratios of ozone (O_3) and the O_3 precursors of non-methane hydrocarbons (NMHCs) and nitrogen oxides (NOx) were recorded at Guangzhou Panyu Atmospheric Composition (GPACS), a comprehensive site in Guangzhou, during the summer (June, July, and August) and autumn (September, October and November) of 2011. In both summer and autumn, weekday/weekend O_3 differences in the morning and at midday largely depend on how much the O_3 precursors are affected by anthropogenic emissions. In the mornings (6:00–9:00 LT), pollutants (i.e. NOx and NMHCs) were more strongly influenced by vehicular emissions in autumn than in summer. In autumn, O_3 titration and lower NOx on weekends in NMHCs-limited regimes lead to more rapid O_3 production, which resulted in the O_3 weekend effect during autumn morning. No O_3 weekend effect occurred on summer mornings because O_3 formation was in a NOx-limited regime, although O_3 titration still existed. At midday (10:00–16:00 LT), the increase of biogenic NMHCs emissions reversed the sensitivity of O_3 production from NMHCs-to NOx-sensitive. The weekday/weekend diurnal pattern of vehicular sources was the same at midday, more intense other human industrial activities in autumn not only gave rise to the higher mixing ratios of high-reactive anthropogenic NMHCs (e.g. aromatics) on weekdays, but also could affected the temperature in the city, leading to higher isoprene mixing ratio on weekdays. All these factors are likely to contribute to the O_3 weekday effect in autumn. Meanwhile no weekday O_3 effect occurred in summer due to the low-intensity industrial anthropogenic activities. Our results show that high-reactive NMHCs and NOx control can be effective for reducing peak O_3 mixing ratios in Guangzhou. Further investigation based on numerical models is required to reach more robust conclusions.

A Study on the Optimization of 3D Expressions for the Analysis of Local Scale Meteorological and Air Quality Information

*Woosik Jung[1], Gunwoo Kim[1]

1. INJE University, Department of Atmospheric Environment Information Engineering, Gimhae, Republic of Korea

In the last 10 years (2007 ~ 2016), 162 people have been killed and about 6.3 trillion won in property damage in Korea alone, the report showed. This is due to the increase of severe weather on the local scale as climate change progresses due to global warming. This study developed the 3D expression system specialized for the local scale. We used one of the commercial engines, Unreal Engine 4 and C++ language, to express meteorological and air quality information in 3D. As input data, the result of WRF and CMAQ modeling were used. Using high-resolution DEM data, 3D terrain was created, and wind vector field was implemented to indicate wind. And we have implemented isolines that indicate temperature and precipitation. In addition, by studying a new expression method to represent the wind, we implemented a stream vector and stream line, which is a vector and streamline moving along the wind flow. And the 3D volume rendering method using Raymarching algorithm is applied to express 3D data, cloud and air pollutant density.

For the analysis of local scale 3D expression cases, the day when the land and sea breeze was blown off the west coast including Seoul and Incheon was selected. And we analyzed a typhoon case of mesoscale. To show that air quality information can also be analyzed, the density of air pollutants such as fine dust and carbon monoxide was expressed and analyzed in 3D volume rendering. As a result of the case analysis, the modeling results were well reflected and the changes in meteorological and air quality information over time were easily identified. And the 3D volume rendering expression allowed us to analyze the vertical structure and distribution of clouds and air pollutants density in a new perspective.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2017R1D1A3B03036152)

Validation of tropospheric NO_2 column density data observed by TROPOMI: Comparison with 4AZ-MAXDOAS

*Hikaru Saito[1], Hitoshi Irie[1]

1. University of Chiba

TROPOspheric Monitoring Instrument (TROPOMI) aboard the Sentinel-5 Precursor satellite has an unprecedented fine horizontal resolution of 7 km×3.5 km (at nadir) for tropospheric nitrogen dioxide (NO_2) column observations and is expected to improve estimation of emissions, including localized kilometer-scale emissions. However, previous studies reported that underestimation could occur in tropospheric NO_2 column data from satellite observations, although its causes are still under discussion. The present study attempts to validate TROPOMI tropospheric NO_2 column data to confirm that the underestimate occurs and clarify the causes. For this purpose, we used ground-based 4-different-azimuth-viewing Multi-Axis Differential Optical Absorption Spectroscopy (4AZ-MAXDOAS) installed at Chiba, Japan (35.63ºN, 140.10ºE, 21 m asl). The 4AZ-MAXDOAS observed tropospheric NO_2 simultaneously in 4 different azimuth directions, enabling the evaluation of spatial inhomogeneity of NO_2, which has been considered to be the major cause of the underestimate. From 4AZ-MAXDOAS data, we found that differences in tropospheric NO_2 column data among 4 different azimuth directions reached up to 40%, indicating the existence of significant horizontal spatial inhomogeneity in NO_2 around the observation site. Then, we compared 4AZ-MAXDOAS data with coincident TROPOMI data. TROPOMI data showed an underestimation by up to about 50% compared to 4AZ-MAXDOAS data, confirming the underestimate in TROPOMI data. However, the correlation was not clear between the magnitude of the underestimate and the coefficient of variance in 4-azimuth data from 4AZ-MAXDOAS observations. This suggests that the observed underestimate cannot be explained only by the effect of the NO_2 spatial inhomogeneity. Instead, the underestimate should be attributed more significantly to the assumption made in the air mass factor calculation.

Chemical composition of atmospheric aerosols over Jakarta megacity

*Masahide Nishihashi[1], Hitoshi Mukai[1], Yukio Terao[1], Shigeru Hashimoto[1], Rizaldi Boer[2], Muhammad Ardiansyah[2], Bregas Budianto[2], Adi Rakhman[2], Gito Sugih Immanuel[2], Rudi Nugroho [3], Nawa Suwedi[3], Anies Marufatin[3], Muhammad Agus Salim[3], Dodo Gunawan[4], Eka Suharguniyawan[4], Asep Firman Ilahi[4], Muharam Syam Nugraha[4], Ronald Christian Wattimena[4], Bayu Feriaji[4], Qoriana Maulani[4]

1. National Institute for Environmental Studies, 2. IPB University, Indonesia, 3. Agency for the Assessment and Application of Technology (BPPT), Indonesia, 4. Meteorological, Climatological, and Geophysical Agency (BMKG), Indonesia

We have implemented a comprehensive observation of air pollutants and greenhouse gases around Jakarta megacity in Indonesia since 2016 to quantify anthropogenic emissions from the city and characterize them in terms of socioeconomic activities in the city.

In addition to the continuous monitoring systems of NO_x, SO_2, O_3, CO, CO_2, CH_4, and meteorological parameters, we installed three continuous dichotomous aerosol chemical speciation analyzers (ACSA-14, Kimoto) at Bogor (center of Bogor city) in 2016, Cibeureum (mountainous area, background-like site) in 2017, and Serpong (Jakarta suburb) in 2019. The ACSA-14 can automatically measure not only the mass concentrations of $PM_{2.5}$ and $PM_{10-2.5}$ and optically measured black carbon (OBC), but also the chemical composition of $PM_{2.5}$ and $PM_{10-2.5}$ (nitrate ion (NO_3^-), sulfate ion (SO_4^{2-}), water soluble organic compounds (WSOC), ammonium ion (NH_4^+)), simultaneously. The measurement interval is 3 hours to extend the replacement interval of filter tapes and chemical reagents for the chemical composition analysis of $PM_{2.5}$ and $PM_{10-2.5}$.

The averages of $PM_{2.5}$ from November 2017 to October 2019 are 23.9 $\mu g/m^3$ at Bogor and 18.3 $\mu g/m^3$ at Cibeureum. The seasonal averages of $PM_{2.5}$ observed at Bogor and Cibeureum in the dry season (May to October in 2018/2019) are 34.2 and 28.0 $\mu g/m^3$, which are 2.4 and 3.2 times higher than those of rainy season (November 2017/2018 to April 2018/2019), respectively. While the long-term trends of $PM_{2.5}$ observed at Bogor are similar to Cibeureum, the averaged $PM_{2.5}$ concentrations at Bogor in the dry and rainy seasons are 1.2 and 1.6 times larger than Cibeureum, respectively.

We compared the chemical composition of $PM_{2.5}$ observed at three sites in February 2020. The amount of SO_4^{2-} (20.9%) is almost same as WSOC (20.8%) at Bogor. The dominant components at Cibeureum are SO_4^{2-} (27.4%) and WSOC (13.4%). While the most dominant component at Serpong is WSOC (22%), the percentage of NO_3^- (13.2%) at Serpong is larger than Bogor (11.8%) and Cibeureum (8.7%). The NO_3^-/SO_4^{2-} ratio at Serpong (1.76) is higher than Bogor (0.82) and Cibeureum (0.43). These results suggest that the urban pollution caused by NO_x in automobile exhausts is significant at Serpong compared to Bogor and Cibeureum.
In our presentation, we will also present the result of $PM_{10-2.5}$, OBC, and the other species.

Seasonal Variation of Wet Deposition of Black Carbon in Arctic Alaska

*Tatsuhiro Mori[1], Yutaka Kondo[2], Sho Ohata[3,4], Yongjing Zhao[5], Puna Ram Sinha[6], Naga Oshima[7], Hitoshi MATSUI[8], Nobuhiro Moteki[9], Makoto Koike[9]

Institute for Advanced Research, Nagoya University, 5. Air Quality Research Center, University of California-Davis, 6. Department of Earth and Space Sciences, Indian Institute of Space Science and Technology, 7. Meteorological Research Institute, 8. Graduate School of Environmental Studies, Nagoya University, 9. Graduate School of Science, The University of Tokyo

Black carbon (BC) aerosol deposited in and onto Arctic snow increases the snow's absorption of sunlight and accelerates snowmelt. Wet removal of BC from the atmosphere plays a key role in determining its abundance in the Arctic atmosphere and in Arctic snow. However, this process is poorly understood, mainly due to the scarcity of relevant measurements. To reveal characteristic features of the wet deposition of BC, we made highly accurate measurements of mass concentrations of BC in snow and rain (C_{MBC}) and mass concentrations of BC in surface air (M_{BC}) at the Barrow Atmospheric Baseline Observatory, Alaska, from July 2013 to August 2017 and analyzed them along with routinely measured meteorological parameters from Barrow. Monthly mean M_{BC} and C_{MBC} were poorly correlated from midwinter to early spring, when C_{MBC} was close to the annual median while M_{BC} was at its annual peak. Seasonal variations in the altitude distribution of ambient BC concentration may lead to these differences in seasonal variation of M_{BC} and C_{MBC}, as may microphysical processes in mixed phase clouds. About 50% of the annual wet deposition of BC occurred in the three months of summer, associated with high values of total precipitation and BC originating from biomass burning. Size distributions of BC in snow and rain were stable throughout the year, suggesting that the size distribution of BC in the lower troposphere is similarly stable. These observations improve our understanding of the loss processes and hence the BC budget in the Arctic.

Investigation of wet removal rate of black carbon in East Asia: A perspective from airmass pathways

*Yongjoo Choi[1], Yugo Kanaya[1], Masayuki Takigawa[1], Chunmao Zhu[1], Seung-Myung Park[2], Atsushi Matsuki[3], Yasuhiro Sadanaga[4], Sang-Woo Kim[5], Xiaole PAN[6]

1. Japan Agency for Marine-Earth Science and Technology, Japan, 2. National Institute of Environmental Research, Korea, 3. Kanazawa University, Japan, 4. Osaka Prefecture University, Japan, 5. Seoul National University, Korea, 6. Chinese Academy of Sciences, China

Using long-term and harmonized measurements of black carbon (BC) and carbon monoxide (CO) from three representative background sites in East Asia (Baengnyeong and Gosan in South Korea, and Noto in Japan), the regional and seasonal differences in wet removal rates were investigated according to airmass transport pathways and meteorological conditions. To identify the airmass origin and accumulated precipitation along with trajectories (APT), backward trajectories at 500 m during 72 hours were calculated by the Hybrid Single Particle Lagrangian Integrated Trajectory 4 model. The European Center for Medium-Range Weather Forecasts (ECMWF) ERA5 hourly pressure and surface level meteorological data (0.25˚ ×0.25˚) were used as input data to obtain accurate and detailed information of each endpoint of trajectories. The wet removal rates were more efficient in South Korea and Japan among the region and in fall and winter among the season. These differences depending on the regional and seasonal division could be partially explained by the inherent difference in the coating thickness of BC particles, according to the dominant emission sectors. Because the industrial sector (thin coated) is dominant in East and North China, in contrast, the transportation sector (thick coated), mainly emitted from diesel vehicles, has a high portion in South Korea and Japan. By the same token, wet removal rates in winter and summer showed the highest and lowest depending on the dominant emission sectors, such as house heating (thick coated) and industry, respectively. Next, we calculated transport efficiency (TE) from FLEXible PARTicle (FLEXPART) Lagrangian transport model (version 10.4) to investigate the representativeness of wet removal rate of model. Overall median TE from FLEXPART was overestimated compared to measurement, implying underestimation of wet scavenging coefficients. The median of estimated below cloud scavenging coefficients showed slightly overestimation than that calculated from FLEXPART as a factor by 1.7. On the other hand, the median of calculated in-cloud removal coefficients including sub-grid effect was highly underestimated than that of estimation by a factor of 5.1. From the analysis of artificial neuron networks, the convective available potential energy (CAPE), which is well known as an indicator of vertical instability, should be considered in in-cloud scavenging process to improve the better representative regional difference in BC wet scavenging over East Asia.

Light absorption properties of organic aerosols at Fukue Island in 2018 spring

*Chunmao Zhu[1], Takuma Miyakawa[1], Hitoshi Irie[2], Fumikazu Taketani[1], Yugo Kanaya[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Chiba University

Light-absorbing organic aerosol, also termed as brown carbon (BrC) aerosol, is one of the most understudied aerosol components for its sources and effects on climate change. For a long time, organic aerosols had been deemed to cause cooling on the earth’ s surface. Recently model studies indicated that BrC is accounting for ~1/4 of warming effect by carbonaceous aerosols at the tropopause globally. However, observation about the light absorption properties of BrC aerosols, which are fundamental for climate change prediction, is very limited, especially in East Asia. The SKYNET observational data at Fukue Island were used to derive the Absorption Aerosol Optical Depth (AAOD) based on the aerosol optical depth and single scattering albedo. AAOD of BrC and AAE_{SKYNET}were then derived based on the light absorption characteristic differences among BrC, BC and dust. Teflon (PTFE) filter samples were also collected using the Continuous Particulate Monitor with X-ray Fluorescence (PX375, Horiba Inc.). BrC in the filters were extracted using methanol followed by syringe-filtration to remove black carbon and mineral particles. The light absorption coefficient and Absorption Angstrom Exponent (AAE_{filter}) of BrC were quantified based on measurement of light absorption spectra in the UV-visible light (300–800 nm). The extracts were filtered to remove dusts and black carbon and analyzed for light absorption. We found that AAE_{filter}were generally higher than AAE_{SKYNET}. Vertical profile of aerosol light absorption properties needs to be further studied in the future.

Can a global chemistry climate model reproduce interannual variabilities and trends of depositions of sulfate, nitrate, and ammonium preserved in the Southeastern Greenland Dome ice core?

*Kengo Sudo[1,2], Hinako Shiratsuchi[1], Yoshinori Iizuka[3]

1. Graduate School of Environmental Studies, Nagoya University, 2. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 3. Institute of Low Temperature Science, Hokaido University

Inorganic compounds like sulfur and nitrogen oxides (SOx/NOx) are mainly emitted from fossil fuel combustion or high-temperature air combustion associated with anthropogenic activities. Those components are chemically oxidized in the atmosphere to form sulfate and nitrate which cause air pollution and acid rain. Aerosols like sulfate and nitrate are also involved in the global climate change, inducing negative radiative forcing by scattering solar incident and changing clouds. For accurate evaluation and future projection of global changes in atmospheric environment and climate, it is vital to quantitatively validate a chemistry climate model that simulates global distributions of aerosols including sulfate and nitrate making maximal use of available observations. In this study, we evaluate global simulation by a chemistry climate model (CHASER) using a long-term (60 years) record of aerosol depositions preserved in the High-Accumulation Dome ice core in Southeast Greenland (SE-Dome) and investigate controlling factors of interannual variation and trends in inorganic ions of sulfate (SO_4^{2-}), nitrate (NO_3^-), and ammonium (NH_4^+).

It is found that our model simulation basically well captures both seasonal cycles and interannual variabilities in the flux of each component as seen in the ice core record for 1970s to 2010. The model calculations suggest that the long-term SO_4^{2-} trend seen in the ice core (-0.15 μmol L^{-1} d^{-1}) is mostly from SO_2 emission changes in the source areas like Europe, U.S. , and Asia over the decades. In contrast, long-term trends for NO_3^- and NH_4^+ (-0.06 and 0.01 μmol L^{-1} d^{-1}, respectively) appear to be affected largely by changes in natural sources and meteorological conditions in addition to the anthropogenic emissions of NOx and NH_3.

Interestingly the model simulation replicates the spiky peaks (positive anomalies) in concentrations (particularly for SO_4^{2-}) recorded in May 1992. The peaks were tentatively attributed to the 1991 eruption of Mt. Pinatubo in the previous studies. Our model simulation, however, nicely reproduces the concentration peaks even without any direct injection from the Mt. Pinatubo to the atmosphere, implying that anomalous changes in meteorological fields (most probably for transport and precipitation) are the dominant factors of the peaks in May 1992. Actually, the model simulation suggests that there were anomalously enhanced transport pathways from Europe and North America toward Greenland and the SE-Dome site for both of SOx, NOx, and NHx.

1. Center for Environmental Remote Sensing (CEReS), Chiba University

Aerosol optical thickness (AOT) at 380 and 670 nm retrieved from the Global Change Observation Mission-Climate (GCOM-C) observations from January to September 2019 was evaluated using the ground-based SKYNET sky radiometer measurements at Chiba (35.62˚ N, 140.10˚ E), Japan and Phimai (15.18˚ N, 102.56˚ E), central Thailand. Chiba and Phimai are urban and rural sites, respectively. AOT retrieved from the sky radiometer observations from were compared with the coincident multi-axis differential optical absorption spectroscopy (MAX-DOAS) AOT values. Under clear sky conditions, both the datasets show excellent agreement. The sky radiometer and GCOM-C AOT values show a good positive correlation (*R*) ~ 0.90 at 380 nm in both sites. At 670 nm, the *R*-values were 0.67 and 0.87 for Chiba and Phimai, respectively. Despite the low *R*-value at 670 nm over Chiba, the temporal variation of AOT was well reproduced by the satellite observations. Over both sites, the agreement between the datasets was mostly within ±0.2. Over Chiba, the higher differences in the AOT values were mostly related to cloud screening in the datasets. The mean bias error (MBE) (GCOM-C –Sky radiometer) for the Chiba site was ~ -0.08 and ~ -0.02 at 380 and 670 nm, respectively, for the coincidence criterion of 0.1˚ x 0.1˚. For the similar coincidence criterion, the MBE values were higher for the observations over the Phimai site. The potential reason was the influence of biomass burning in addition to the cloud influence. The spatial resolution of the satellite coincidence data had a significant impact on the MBE at 380 nm over the Chiba site. Overall, the retrieved AOT values of both datasets were generally consistent indicating the excellent potential of the GCOM-C observations of aerosol properties, especially in the ultra-violet region.

Atmospheric sulfate formation pathways over the past 60 years constrained by a global chemical transport model

*Shohei Hattori[1], Becky Alexander[2], Sakiko Ishino[3], Shuting Zhai[2]

1. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 2. Department of Atmospheric Sciences, University of Washington, Seattle WA 98195-1640, USA, 3. National Institute of Polar Research, Research Organization of Information and Systems, Tokyo 190-8518, Japan

Since the industrial revolution, the increase of sulfur dioxide (SO_2) had increased the SO_4^{2-} load. The period including the 1950s to 1970s had significant SO_2 emissions, but these emissions decreased after the 1980s across North America (NA) and Western Europe (WE), reducing atmospheric SO_4^{2-} burden. However, SO_4^{2-} aerosols decreased less rapidly than SO_2 reduction, suggesting the existence of chemical feedback processes.
In the atmosphere, SO_4^{2-} is produced from gas-phase SO_2 oxidation by hydroxyl radicals (•OH) and oxidation in aqueous-phase (i.e., in clouds). SO_2, dissolved in an aqueous-phase, forms S(IV) species (i.e., $SO_2{\cdot}H_2O$, HSO_3^-, and SO_3^{2-}) that react with hydrogen peroxide (H_2O_2), ozone (O_3), and molecular oxygen (O_2) to form SO_4^{2-}. Among these chemical processes, several studies have proposed several mechanisms causing the weakened response of SO_4^{2-} to SO_2 decreases.
To obtain quantitative information in sulfate formation pathways, we simulate global tropospheric sulfate chemistry using the version 12.5.0 of the GEOS-Chem chemical transport model. We performed the model simulations with anthropogenic emissions corresponding to the years 1960, 1973, 1986, 1999, and 2013, to investigate the past changes in atmospheric sulfate formation and its efficiency in response to the changes in anthropogenic emission.
Relative contributions of S(IV)+ O_3 and H_2O_2 were increased between 1973 and 2013 over the Eastern NA (ENA) and WE, and the proportional increases of S(IV) + O_3 pathway are consistent with our previous observation of triple oxygen isotopic composition of SO_4^{2-} in a Greenland ice core. The increase of S(IV) + O_3 pathway is best explained by an increase in the cloud water pH over the period, and not by O_3 concentration increase.
The promotion of S(IV) + O_3 pathway over the period caused higher SO_2 conversion efficiency for both summertime and wintertime in ENA and WE. On the basis of the GEOS-Chem model outputs, we found two regional characteristics: (i) gradual increase of SO_2 conversion efficiency in WE over the period, and (ii) a small increase of SO_2 conversion efficiency in ENA between 1960 and 1999 and an abrupt increase between 1999 and 2013.
In the presentation, we will discuss several implications including perspective for future sulfate formation by the worldwide reduction of SO_2 and the important role of acidity (defined as cloud pH) in the atmospheric chemistry.

High-temporal-resolution elemental characterization of fine-mode aerosols in springtime Asian outflow: Emission and removal characteristics, and comparison with model simulation

*Takuma Miyakawa[1], Akinori Ito[1], Chunmao Zhu[1], Yugo Kanaya[1]

1. Japan Agency for Marine-Earth Science and Technology

Trace metals in aerosol particles exhibit the various impacts on the ocean biogeochemistry (Mahowald et al., 2018). We conducted the semi-continuous measurements of elemental composition of fine mode ($PM_{2.5}$) aerosols using an automated X-ray fluorescence analyzer (PX-375, Horiba, Ltd., Asano et al., 2017) in a remote island, Fukue (32.75ºN, 128.68ºE), in Japan in the spring of 2018. Here we report the temporal variations of mass concentrations of geochemically important elements for this period, namely sulfur (S), lead (Pb), copper (Cu), manganese (Mn) and iron (Fe), and their relationships with some tracers, carbon monoxide (CO), black carbon (BC), and calcium (Ca). Positive correlation of Pb and Cu with CO and BC were found during the observation period, indicating the emission sources of these metals share the region where the large CO (and BC) emission sources are located. Further analyses of concentration-weighted trajectories also suggested the similar geographical characteristics of these elements and combustion tracers. We extracted the continental outflow air masses with minimized impacts of the (especially wet) removal during the transport to elucidate the emission ratio of Pb and Cu to CO, which were evaluated, for the first time in Asian outflow, to be 97.8 and 37.4 μg/g, respectively. The wet removal of Pb together with BC was also investigated based on the precipitation along the air mass transport. Impacts of Asian dust and anthropogenic (i.e., combustion) sources on Fe in $PM_{2.5}$ aerosols were diagnosed by using the measured BC concentration with the emission ratio of iron oxides to BC, and by comparing those simulated by the IMPACT model (Ito et al., 2019). Fraction of combustion-derived Fe for fine mode aerosols was evaluated to be less than 20% on average during the observation period.

Comparison of compositional characteristics of aerosol and rainwater samples collected in Nagoya

*Wei Chenran[1], Sonia Afsana[1], Qingcai Chen[2], Dhananjay Kumar Deshmukh[3], Kimitaka Kawamura[3], Michihiro Mochida[1,4]

Chubu Institute for Advanced Studies, Chubu University, Kasugai, Japan, 4. Institute for Space-Earth Environmental Research, Nagoya University, Nagoya, Japan

Organic aerosol is one of major components of atmospheric aerosol particles. Some volatile organic compounds (VOCs) react in the aqueous-phase of cloud droplets, and after the evaporation of liquid water, they form aerosol, which is called aqueous secondary organic aerosol (aqSOA). Further, organic aerosols may also change to aqSOA through aging in the aqueous phase. Although a number of laboratory experiments and model simulations have explored the mechanism of aqSOA formation, the mechanism in real atmospheric environments is still unclear. To find a clue to understand how aqSOA is formed in could droplets through aqueous-phase reactions, this study compares compositional characteristics of water-soluble components in aerosol and rainwater samples, as a means to compare the components of aerosols before and after the reactions in the real atmosphere.

Aerosol and rainwater samples were collected on campus of Nagoya University in Nagoya, Japan. The organics therein were fractionated into humic-like substances with a neutral nature (HULIS-n), humic-like substances with an acid nature (HULIS-a) and high-polar water-soluble organic matter (HP-WSOM). The optical properties of the samples were measured using a fluorescence spectrophotometer and an ultraviolet-visible spectrophotometer. Fourier transform infrared spectroscopy (FT-IR) was used to compare the chemical structural characteristics of aerosol and rainwater samples.

The analysis of the 3D fluorescence spectra shows that the HULIS-n-to-HULIS-a ratios based on the fluorescence intensity of two spectra regions (excitation wavelength from 240 to 260 nm and emission wavelength from 400 to 460 nm , and excitation wavelength from 320 to 360 nm and emission wavelength from 420 to 460 nm) from aerosol samples were in most cases larger than those of rainwater. A possible explanation is that some of the low-polar fluorescent substances (fluorescent substances in HULIS-n) were decomposed to non-fluorescent substances and that more-polar fluorescent substances (fluorescent substances in HULIS-a) were formed by aqueous-phase reactions. The FT-IR results present that HULIS-n and HULIS-a in aerosol samples show a smaller fraction of carboxyl group but a larger fraction of carbonyl group than those in rainwater samples, implying that the oxidation of carbonyl groups to carboxyl groups occured for HULIS-n and HULIS-a, and/or that aqSOA containing carboxyl group was formed from VOCs. Because the presence of water in the samples for the FT-IR analysis may have influenced on the quantification of functional groups, compositional characteristics of aerosol and rainwater samples should be further compared using other instruments such as an aerosol mass spectrometer.

Formation processes of dimers measured in α-pinene secondary organic aerosol particles

*Kei Sato[1], Sathiyamurthi Ramasamy[1], Satoshi Inomata[1], Shinichi Enami[1], Yu Morino[1]

1. National Institute for Environmental Studies

Formation of low-volatility compounds such as dimers detected in atmospheric aerosol particles will affect atmospheric organic aerosol level due to the influence from these dimers on volatility and viscosity of particles. In order to study formation mechanisms of dimers detected in forest particles,[1)] we used liquid chromatograph-mass spectrometry (LCMS) to analyze filter extracts of secondary organic aerosol (SOA) particles generated by chamber experiments on the oxidation of α-pinene. We determined the ratios of dimer to SOA mass for those with molecular weights (MWs) of 344, 358, and 368 as a function of experimental conditions including the oxidant of VOC, initial VOC concentration, the acidity of seed particles, and the temperature of chamber. We used 6 m^3 NIES smog chamber and temperature-controllable 0.7 m^3 Teflon bag chamber for generation of SOA particles. The dimer/SOA ratios measured for the reactions of O_3 with α-pinene were higher than those measured for the reactions of OH and NO_3 radicals with α-pinene. Formation of dimers barely occurred during reactions with OH and NO_3 radicals although the reactions of OH and NO_3 radicals with α-pinene forms carbonyl compounds, which could form dimers through acid catalyzed heterogeneous reactions, and organic peroxy radicals, which could form dimers through gas-phase association reactions. Furthermore, the concentrations of dimers with MWs of 344 and 358 in sample solutions showed linear correlations with the product from multiplication of the concentrations of corresponding monomers. Dimers with MW 358 could be successfully separated with a LC column from the chromatographic peaks of presumed monomers, pinic acid and terpenylic acid; suggesting that signals of dimers with MW 358 are not instrument artifacts and result from stable dimers existing in solution or particle phases. Dimers with MW 358 are likely to be formed through the reactions of Criegee intermediates; however, as formation process for dimer with MW 358 we cannot exclude hydrogen bonding formation[2)] from monomers formed from the gas-phase reaction with O_3. This research has been supported by the Environmental Research and Technology Development Fund from Environmental Restoration and Conservation Agency (grant no.5-1801) and NIES Research Founding Type A.

Nitric acid gas captured in quasi-liquid layers on ice surfaces

*Ken Nagashima[1], Josée Maurais[2], Ken-ichiro Murata[1], Yoshinori Furukawa[1], Patrick Ayotte[2], Gen Sazaki[1]

1. The Institute of Low Temperature Science, Hokkaido University, 2. Université de Sherbrooke, Québec, Canada

Ice crystal surfaces act as “reaction fields” for heterogeneous chemical reactions that involve atmospheric acidic gases, thereby causing serious environmental issues such as the catalytic ozone depletion by hydrogen chloride gas and the generation of nitrogen oxide gases (NOx) from the photolysis of nitric acid/nitrates. These chemical reactions cannot be explained solely by homogeneous processes. In addition, the surfaces of ice crystals near the melting point are covered with thin liquid water layers, called quasi-liquid layers (QLLs), which may play crucial roles in various chemical reactions. In this study, we chose HNO_3 as a model atmospheric gas, and directly observed the QLLs on ice basal faces by advanced optical microscopy [1]. Because P_{HNO3} in the troposphere shows considerable variations (e.g., ranging from ~10^{-6} Pa in clean air to ~10^{-2} Pa in polluted urban air [2,3]), the observations in this study were performed under some P_{HNO3} conditions (0, 10^{-4} and 10−2 Pa).

Irrespective of the presence/absence of the HNO_3 gas, the pure-QLLs and HNO_3-QLLs appeared with increasing temperature and disappeared with decreasing temperature. The shape of pure-/HNO_3-QLLs showed spherical dome and the contact angle of them on the ice basal face was ~1˚. The appearance temperatures of the pure-/HNO_3-QLLs were not so different (-1.9 and -0.5 to -1.8 ˚C, respectively). Although the disappearance temperature of pure-QLLs (-2.2 ˚C) was almost same as the appearance temperature, the disappearance temperature of the HNO_3-QLLs (-6.4 ˚C) was significantly lower than the appearance temperature of them under high-P_{HNO3} condition (10^{-2} Pa). The large thermal hysteresis between the appearance and disappearance temperatures suggests that the disappearance mechanisms of the pure-/HNO_3-QLLs were different. We found that the HNO_3-QLLs are not composed of pure water, but rather of aqueous HNO_3 solutions, and also that the HNO_3-QLL and the ice crystal were in equilibrium. The evidence and the disappearance mechanism are showed as follows.

The size of the HNO_3-QLLs decreased immediately after we started reducing the temperature. We could not observe such changes in the sizes of pure-QLL with temperature in the absence of the HNO_3 gas. When we assumed that the mass of HNO_3 in the HNO_3-QLL was constant during the relatively short observation time period, the volume reduction of the HNO_3-QLLs with decreasing temperature meant increasing of HNO_3 concentration of the HNO_3-QLL. We calculated the volume reductions as a function of temperature by using the HNO_3-H2O phase diagram. The calculated volume reductions were in good agreement with the volume reductions determined experimentally.

One of the plausible causes for the disappearance of HNO_3-QLLs could be the evaporation of HNO_3 from the HNO_3-QLLs. We calculated the equilibrium HNO_3 partial vapor pressure, Pe(HNO_3), of the HNO_3 -QLLs. As temperature decreases, Pe(HNO_3) increases. It is very reasonable to expect that when Pe(HNO_3) exceeds P_{HNO3} in the observation chamber with decreasing temperature, HNO_3 evaporates from the HNO_3-QLLs, resulting in the disappearance of the HNO_3-QLLs.

Recently, we studied the effects of hydrogen chloride gas on the behavior of QLLs (HCl-QLLs) on ice basal faces [4,5]. We found that the HCl-QLLs were also aqueous hydrochloric acid solution, and that the temperature and HCl concentration of the HCl-QLLs were also very close to those of a liquidus line: these

results were similar to those found in this study. Therefore, ice crystal surfaces would capture large amount of acidic gas components in the acidic-QLLs.

Five-years seasonal variations of nitrogen and triple oxygen isotopic compositions of atmospheric nitrate at Noto Peninsula, Japan

*Kazuki Kamezaki[1], Shohei Hattori[1], Atsushi Matsuki[2], Naohiro Yoshida[1,3]

1. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 2. Institute of Nature and Environmental Technology, Kanazawa University, 3. Earth-Life Science Institute

Anthropogenic nitrogen oxides (NO_x) emission from land to the atmosphere have been accelerated in East Asia. By increase of the anthropogenic pollutants in the atmosphere, atmospheric oxidizing capacity can be changed in East Asia. Moreover, the biological cycle can be changed because the atmospheric nitrate deposition is a source of nitrogen. Thus, the understanding of sources and formation pathways of atmospheric nitrate is important.

The nitrogen and triple oxygen isotopic compositions ($\delta^{15}N$ and $\Delta^{17}O = \delta^{17}O - 0.52 \times \delta^{18}O$) of atmospheric nitrate can be a tracer of the sources and formation pathways of atmospheric nitrate. The $\delta^{15}N$ of atmospheric nitrate can be used to estimate the sources and sinks of atmospheric nitrate. The $\Delta^{17}O$ of atmospheric nitrate can be a tracer of the relative importance of mass-independent oxygen-bearing species (e.g. O_3, BrO; $\Delta^{17}O \neq 0$ ‰) and mass-dependent oxygen-bearing species (e.g. OH radical; $\Delta^{17}O \approx 0$ ‰) during the conversion of NO_x to atmospheric HNO_3. In this study, we present five-years data of $\delta^{15}N$ and $\Delta^{17}O$ values in atmospheric nitrate collected at NOTO Ground-based Research Observatory (NOTOGRO) (37.5˚N, 137.4˚E) located at the north coast of Noto Peninsula, Japan.

The atmospheric nitrate concentrations did not show a clear trend, while the $\delta^{15}N$ and $\Delta^{17}O$ showed a clear seasonal variation with summer minimum and winter maximum. The trend of $\Delta^{17}O$ is caused by the seasonal changes in the O_3 / HO_x ratios decreasing in summer by ozone destruction and HO_X production (e.g. OH, HO_2 radicals) via UV irradiance. Although the correlation between $\delta^{18}O$ and $\Delta^{17}O$ values was observed throughout the year, the slope between $\delta^{18}O$ and $\Delta^{17}O$ values for coarse particles for the winter-spring period is only different from other seasons and fine particles. We will discuss possible explanations of this different isotope pattern for the winter and spring periods.

Impacts of ship emissions on atmospheric particulate matter and gaseous components over the Seto Inland Sea areas

*Moe Tauchi[1], Katsuhiro Kawamoto[2], Kazuyo Yamaji[1], Ryohei Nakatsubo[3], Yoshie Oshita[3], Yasuyuki Itano[4]

1. Kobe University, 2. Takamatsu Local Meteorological office, 3. Hyogo Prefectural Institute of Environmental Sciences, 4. Osaka City Research Center of Environmental Science

Our interest issue is to be clear control factors of elevated atmospheric pollutants over the Seto Inland Sea (SIS) and surroundings, where $PM_{2.5}$ levels are still higher than the other regions in Japan (Nakatsubo et al., 2020). The SIS area is closed and congested with many people live along its coastal zones. Even now, it has been concerned that high sulfur emissions from vessels using heavy fuel oil with relatively high sulfur content effect on air quality.

From 1 January 2020, in such a situation, the sulfur contents in fuel oil used on board ships operating outside emission control areas have been reduced from 3.50% to 0.50% (the sulfur limits). The global sulfur limits will make significantly reductions of sulfur oxides emissions from ships, and that should have major health and environmental benefits for the world, especially for populations living close to ports and coasts. The reduced ship sulfur emissions are expected to affect not only ambient sulfur-containing substance concentrations but also the other atmospheric pollutant components.

To assess the impacts of the fuel sulfur changes on air quality of the SIS areas, we investigated concentrations of SO_2 and $PM_{2.5}$ substances in the atmosphere over both land and sea from March 2017 to March 2020 only for the duration of the research voyage. Automatic sampling data at ambient air pollution monitoring stations facing to SIS were used for analyzing the coastal-landmass pollutants. As regards the marine air mass, SO_2 and $PM_{2.5}$ were sampled over the SIS area on board Training-ship Fukaemaru owned by Kobe University.

From January 1 to March 31 in 2018, percentage of sulfate ion in $PM_{2.5}$ along the SIS area is about 24.1%. We are carefully watching the atmospheric particulate matter and gaseous components around the SIS after starting the sulfur limits. Continued observation research should contribute for improvement of air quality and formulating environmental policy in the future.

Spatiotemporal variations of NO_2 over Fukuoka Japan, observed by multiple MAX-DOAS and 3-D coherent Doppler lidar

*Hironobu Ueki[1], Hisahiro Takashima[2], Martina Michaela Friedrich[3]

1. Fukuoka university graduate school, 2. Fukuoka university, 3. Belgian Institute for Space Aeronomy

To clarify spatiotemporal variations and transport processes in nitrogen dioxide (NO_2) over Fukuoka, an urban area in Japan, continuous NO_2 profile observations using Multi Axis Differential Optical Absorption Spectroscopy (MAX-DOAS) with high temporal resolution of four minutes have been conducted since October 2018 at three observatories: Yakuin (33.580˚N, 130.396˚E), Sohara (33.580˚N, 130.356˚E) and Fukuoka University (33.550˚N, 130.364˚E).

We first performed case studies at particular days and observed enhanced NO_2 contents above the city center on some days. In the case of 29 November 2018, high NO_2 concentrations were observed near the ground in the morning (around 7:00–10:30 am). Higher contents of NO_2 appeared gradually at higher altitudes over the urban area, and disappeared at around 13:00–14:00 pm. We investigated a three-dimensional (3-D) wind field observed using a 3-D coherent Doppler lidar installed at Fukuoka University. The NO_2 variations were consistent with the wind variation: the airmass with high NO_2 concentration was transported upward from near the ground over an urban area; it advected southward (landward) because of a sea breeze in the afternoon.

We also validated the tropospheric NO_2 vertical column density (VCD) using the Sentinal-5P/TROPospheric Ozone Monitoring Instrument (TROPOMI) satellite with MAX-DOAS observations. Results showed that the satellite data are underestimates, as shown in earlier studies (e.g., Kanaya et al., 2014), but large variations exist from 34% to 154%. These results suggest that underestimation can be attributable not only to the shield effect by aerosols near the ground but also to inhomogeneity and transport processes of the NO_2 airmass over urban areas.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

[A-AS08] Stratosphere-troposphere interaction

convener:Takatoshi Sakazaki(Graduate School of Science, Kyoto University), Takenari Kinoshita(Japan Agency for Marine-Earth Science and Technology), Pu Lin(Princeton University/NOAA Geophysical Fluid Dynamics Laboratory), Peter Hitchcock(Cornell University)

The dynamical, radiative, and chemical processes involved in the interactions between the stratosphere and troposphere are essential for understanding the present and future climate. Both observed data and high-resolution models have now clearly demonstrated that stratospheric processes can affect various tropospheric phenomena. Recently, processes coupling the troposphere and stratosphere in the tropical region have become a new focus.
 It has also been shown that the accuracy of tropospheric sub-seasonal and seasonal scale forecasts can be improved by more accurate representations of the stratosphere. As a result, interest is increasing in the predictability and reproducibility of specific stratospheric phenomena, including the Quasi-Biennial Oscillation (QBO) and its recent disruption as well as Stratospheric Sudden Warmings (SSW).
 This session will highlight recent progress in our understanding of stratosphere-troposphere interaction. We welcome studies of these and related phenomena in the troposphere and stratosphere (and mesosphere) based on observation, models and theory. Further, this session builds upon the middle atmosphere session traditionally held at the JpGU annual meetings and aims to provide a platform for sharing recent findings and promoting international collaborations on this topic.

This paper reports on a project to compare the representation of the semiannual oscillation (SAO) in the equatorial stratosphere and lower mesosphere among six major global atmospheric reanalysis datasets and with recent satellite SABER and MLS observations. All reanalyses have a good representation of the quasi-biennial oscillation (QBO) in the equatorial lower and middle stratosphere and each displays a clear SAO centered near the stratopause. However, the differences among reanalyses are much more substantial in the SAO region than in the QBO dominated region. The degree of disagreement among the reanalyses is characterized by the standard deviation (SD) of the monthly-mean zonal wind and temperature; this depends on latitude, longitude, height, and time. The zonal wind SD displays a prominent equatorial maximum that increases with height, while the temperature SD is minimum near the equator and largest in the polar regions. Along the equator the zonal wind SD is smallest around the longitude of Singapore where consistently high-quality near-equatorial radiosonde observations are available. Interestingly the near-Singapore minimum in SD is evident to at least ~3 hPa, i.e. considerably higher than the usual ~10 hPa ceiling for *in situ* radiosonde observations. Our measurement of the agreement among the reanalyses shows systematic improvement over the period considered (1980–2016), up to near the stratopause. Characteristics of the SAO at 1 hPa, such as its detailed time variation and the displacement off the equator of the zonal wind SAO amplitude maximum, differ significantly among the reanalyses. Disagreement among the reanalyses becomes still greater above 1 hPa. One of the reanalyses in our study also has a version produced without assimilating satellite observations and a comparison of the SAO in these two versions demonstrates the very great importance of satellite derived temperatures in the realistic analysis of the tropical upper stratospheric circulation.

Laplace's Atmosphere: An Array of Ringing Modes Discovered in Global Reanalysis Data

*Takatoshi Sakazaki[1], Kevin Hamilton[2]

1. Graduate School of Science, Kyoto University, 2. International Pacific Research Center and Department of Atmospheric Sciences, University of Hawai’ i at Manoa

We used newly-available ERA-5 hourly global reanalyses to examine the variations of atmospheric circulation on global scales and high frequencies. The space-time spectra of surface pressure displays a typical red background spectrum but also a striking number of isolated peaks. Some peaks represent astronomically forced tides but we show that most peaks are manifestations of the ringing of randomly excited global scale resonant modes. A few such modes have been tentatively identified in earlier observational investigations, but we demonstrate the existence of the full array of normal mode oscillations with periods as short as 2 hours. This is a powerful and uniquely detailed confirmation of the predictions of the theory of global oscillations that has its roots in the work of Laplace two centuries ago.

Bias correction of satellite multi-sensor total column ozone datasets and their merged ozone dataset

*Hiroaki Naoe[1], Takanori Matsumoto[2], Keisuke Ueno[3], Takashi Maki[1], Makoto Deushi[1], Ayako Takeuchi[2,4]

1. Meteorological Research Institute, 2. Japan Meteorological Agency, 3. Japan Meteorological Agency, Aerological Observatory, 4. Ministry of Land, Infrastructure, Transport and Tourism

This study evaluates 20 level 2 total column ozone (TCO) datasets acquired covering the 40 years from 1978 to 2017, by comparing satellite overpass data coincident with ground-based Dobson and Brewer spectrophotometer measurements. These 20 individual TCO datasets and a merged TCO datasets are corrected for systematic mean biases and drift. Two bias correction methods are used: simple linear regression (SLR) fitting of the data as a function of time and multiple linear regression (MLR) fitting of the data as a function of time, solar zenith angle, and effective ozone temperature. All of the satellite datasets agree well, within ±1-2%, with the ground-based measurements, except for some degraded data from the Total Ozone Mapping Spectrometer (TOMS)/Earth Probe during a terminated period and from the Ozone Mapping and profiling Suite (OMPS) provided from NOAA at an early stage of measurements. The OMPS data provided from NASA do not show any significant bias or trend relative to the ground-based data. The Global Ozone Monitoring Experiment/MetOp-A and -B datasets show abrupt changes of up to 7-8 DU coincident with the introduction of a new retrieval algorithm. The root mean square error of uncorrected merged datasets, 8.6 DU, is reduced to 8.4 DU after correction by multiple linear regression. Further, the negative trend is seen in 1979-1996 in the uncorrected merged dataset is reduced by 2 DU per decade in the corrected dataset. The TCO trend during 2000-2017 does not differ between the uncorrected and corrected merged datasets.

Relationship between the Boreal Summer Intra-seasonal Oscillation and the Stratospheric Quasi-Biennial Oscillation

*Yayoi Harada[1]

1. Meteorological Research Institute

In the equatorial stratosphere, quasi-biennial oscillation (QBO) is the dominant mode. The previous studies have shown the influence of QBO on Madden Julian Oscillation (MJO) during the austral summer (Nshimoto and Yoden 2017; Son et al. 2017). On the other hand, Kikuchi et al. (2012) pointed out that boreal summer intra-seasonal oscillation (BSISO), in which active convective region migrate northward in the Indian Ocean and the western Pacific with a period of 30 –90 days, is the dominant mode compared to MJO during the boreal summer. In this study, statistical relationships between stratospheric BSISO and QBO are examined. BSISO index based on Kikuchi et al. (2012), the Japanese 55-year Reanalysis (JRA-55, Kobayashi et al. 2015), ERA-Interim (Dee et al. 2011), and cloud top pressure (Rossw and Schiffer 1999) provided by International Satellite Cloud Climatology Project (ISCCP, Schiffer and Rossw 1983) are used for composite analysis.

The results reveal that the amplitudes of BSISO tend to be extraordinarily large during the strong low-frequency easterly anomalies at around the 20-hPa level associated with QBO. we also found that the frequency of lower cloud top pressures (higher cloud top heights) tend to increase during the strong easterly phase of QBO in the BSISO region. Moreover, we analyze the vertical profile of the static stability around the tropopause. The results obtained from the two reanalyses show more unstable (stable) condition in the lower stratosphere in BSISO region during the strong and weak easterly phases (westerly phase) of QBO, although the vertical profiles of the static stability in the upper troposphere are different from each other.

A statistical analysis of the turbulent kinetic energy dissipation rate estimated from the PMWE spectral width in the Antarctic

*Masashi Kohma[1], Kaoru Sato[1], Koji Nishimura[2], Masaki Tsutsumi[2], Toru Sato[3]

1. Department of Earth and Planet Science, Graduate School of Science, The University of Tokyo, 2. National Institute of Polar Research and The Graduate University for Advanced Studies (SOKENDAI), Tokyo, Japan, 3. Institute for Liberal Arts and Sciences, Kyoto University, Kyoto, Japan

The radar volume reflectivity and turbulent kinetic energy dissipation rate in the Antarctic mesosphere have been estimated from the polar mesosphere winter echoes (PMWE) using a vertical beam of the PANSY radar, which is a Mesosphere-Stratosphere-Troposphere radar, at Syowa Station (69˚S, 40˚E) over four years. The radar volume reflectivity exhibits a lognormal distribution in the range of 2×10^{-18}–5×10^{-15} m^{-1} for a height region of 55–82 km. The turbulent energy dissipation rate estimated from the spectral width of the PMWE ranges from 3×10^{-5}–3×10^{-1} m^2s^{-3}. From monthly histograms of the turbulent energy dissipation rate for a fixed solar zenith angle and altitude, it is revealed that the summer-to-winter transition of the turbulent energy dissipation rate occurs in March, while the winter-to-summer transition occurs in September. This seasonal variation accords well with that of gravity wave activity, suggesting that the turbulence in the mesosphere is likely caused by the gravity wave breaking.

Influence of stratospheric dynamics on tropical convection and equatorial waves

*Nawo Eguchi[1], Tomoe Nasuno[2], Kunihiko Kodera[3]

1. Kyushu University, 2. Japan Agency for Marine-Earth Science and Technology, 3. Meteorological Research Institute

Previous studies based on satellite observational data and model simulation found an enhancement of tropical convection in association with an abrupt change in tropical circulation during a Stratospheric Sudden Warming (SSW) event. The principal process of the stratospheric impact on the tropospheric variability could be a decrease of the static stability in the Tropical Tropopause Layer (TTL) by intensified upwelling in ascending branch of the Brewer-Dobson circulation [Eguchi and Kodera, 2007; 2010; Kodera et al., 2011, 2015; Eguchi et al., 2015]. The present study focused on enhanced deep convection and tropical cyclones over the southwestern Indian Ocean and the southwestern Pacific Ocean during the SSW event in January 2010 simulated in a global nonhydrostatic model, NICAM (Nonhydrostatic ICosahedral Atmospheric Model) [Satoh, et al., 2014] which explicitly calculates moist physics at a cloud-system-resolving resolution.
The upwelling in the lower stratosphere associated with the SSW event started around 5 January 2010, and the deep convection was formed from 8 to 14 January along 10 south degree latitude in the whole tropics (except for South American sector in the simulation) due to the negative static stability at the upper layers at TTL. In particular, the precipitation was extended longitudinally over the Indian Ocean after 8 January, which developed over high SST region across the Indian Ocean. A tropical cyclone developed within this region on 11 January. It is noted that deep convection was enhanced over the equatorial Africa on 8 and 9 January before enhancement of the longitudinally extended precipitation over the Indian Ocean. Eastward propagation of a convective coupled Kelvin waves from the Africa to the Maritime continent, might excite the longitudinally extended precipitation through a reduction of the static stability in the TTL. The convection over the Maritime continent was enhanced around 15 January when the Kelvin wave arrived there. Difference in responses of convective activity over the equatorial Africa and that over the Maritime Continent could be arose from a difference in convective characteristic in two regions such as higher cloud top altitude over Africa than that over the Maritime Continent.

The impact of stratosphere to troposphere: raising model top from 5hPa to 0.1hPa of GRAPES_GFS (weather model)

*Yong Su[1]

1. Yong Su

Over the past 15 or so years, there has been an increasing recognition of the role of the stratosphere in modulating tropospheric processes, especially for the winter hemisphere. Forecast centers such as ECMWF, Met Office have moved their model tops to the middle mesosphere, 80km or 0.01hPa, the GEM of ECCC also move their model top to 0.1hPa.

The Global Regional Assimilation and PrEdiction System, Global Forecast System, GRAPES_GFS, independently developed by the Numerical Weather Prediction Center of China Meteorological Administration, main task is the operational application of 0 to 10 day weather forecast. At present, the horizontal resolution is 0.25 degree, in vertical direction, height based terrain following coordinate is adopted, 60 layers, the model top is about 5hpa, located in the middle of stratosphere.

For the GRAPES_GFS, the model top is to low compare to other centers. The problem is that, on the one hand, the weather model generally adopts rigid boundary conditions, the distribution of the real atmosphere cannot be correctly simulated near the model top, so the low model top will cause the prediction deviation of the troposphere to increase gradually in the long-term cycle integration; On the other hand, raising the model top can make more satellite data into the data assimilation system, and this can directly improve the prediction effect of the stratosphere.

Based on the experience of IFS and GEM, we increase the vertical level of GRAPES_GFS from 60 to 87, and the model top is increased from 5hpa to 0.1hpa. We redesigned the sponge layer of the model, mainly including the Rayleigh Friction scheme which is close to the monthly average state, the W implicit damping scheme which changes with the altitude and latitude; In the physical process, we introduced the New non orographic gravity wave scheme, debugged the orographic gravity wave drag scheme, and adjusted the equation of saturation specific humidity at low temperatures.

Through the 4Dvar cycle forecast, we tested the prediction ability of the new high top system, with more reasonable simulation of the stratosphere and mesosphere, the prediction ability in troposphere is improved.

Parametrization of tropical coastal nonstationary gravity waves robustizing QBO

*Manabu D. Yamanaka[1]

1. Research Institute for Humanity and Nature / Professor Emeritus of Kobe University

The most dominant mode of cloud-rainfall generation in the equatorial troposphere is the diurnal cycle, which is seen typically in the world's longest coastlines surrounding major islands of the Indonesian maritime continent (IMC). Under the linear theory the coastal diurnal-cycle (so-called sea-land breeze) circulation is given by a sum of wave solutions, of which the dispersion relation is a cubic equation for vertical wavenumber squared m^2. Near the surface with large eddy viscosity/diffusivity (m^6 term) balancing the buoyancy (m^0 term), the velocity field is almost similar to a steady horizontal-convection cell, of which the intensity and horizontal scale (inverse horizontal wavenumber k^{-1}) are governed by the land-sea temperature contrast $k\Delta T$. Above this cell, with decreasing the viscosity/diffusivity, the acceleration (m^2 term) balances the buoyancy, which gives a combination of up/down-ward propagating gravity waves. Because $k\Delta T$ is reversed between day and night (with frequency $\omega = 2\pi/1$ day), the horizontal phase velocity $c = \omega/k$ directs land- and sea-ward, respectively. They are observed actually along the coastline of a major island larger than k^{-1} of a few hundreds of kilometers. They are longer and slower ($c \simeq 1\text{–}3\times10^2$ km/10 h $\simeq$ 3–7 m/s) than waves excited with an individual cloud convection, but shorter than intraseasonal scales (Kelvin or mixed Rossby-gravity waves).

With increasing altitude, the upward-propagating component of gravity waves is amplified to compensate the density decrease. Because the coastline is a closed curve, there are waves with c of all directions. However, waves with c of meridional directions may be filtered out by the Hadley meridional circulation, except for a calm zone along the equator (the ITCZ). The intraseasonal variations (Madden-Julian oscillations) with zonal (Walker-like) circulations pare down usually before landing the IMC (and the two true continents of Africa and South America). Therefore, waves with c of zonal (both east- and west-ward) directions are transmitted upward beyond the tropopause along the equator, which resembles Plumb's (1977) model considering waves with two discrete (equal but opposite) zonal c. If the velocity amplitude $|u|$ (with c of either east- or west-ward) reaches the magnitude of intrinsic phase velocity $|c - U|$ in a mean wind U, the wave breaks and U is accelerated (east- or west-ward, dependent on c), as parameterized for the middle atmospheric circulation since Lindzen (1981). Both east- and west-ward gravity waves are emitted upward from the tropical coasts every day, and their interactions with the middle-atmospheric circulation may induce the robust features of the stratospheric QBO. The wave amplitude $|u|$ and resulting acceleration (periodicity and amplitude of the QBO) are dependent on $k\Delta T$, which may be varied also with interannual variations of sea-surface temperature and much longer time-scale variations of the land distribution.

Height-dependent expression for the energy flux of equatorial waves: exact and approximate versions for unified model diagnosis

*Hidenori AIKI[1,2], Fukutomi Yoshiki[1], Yuki Kanno[2], Tomomichi Ogata[2], Takahiro Toyoda[3], Hideyuki Nakano[3]

1. Nagoya University, 2. Japan Agency for Marine-Earth Science and Technology, 3. Meteorological Research Institute

Synoptic scale waves in the atmosphere and ocean play an important role in the teleconnection of tropical and subtropical regions. For mid-latitude Rossby waves in the atmosphere, the expression for the energy flux for use in a model diagnosis, and without relying on a Fourier analysis or a ray theory, has previously been derived using quasi-geostrophic equations and is singular at the equator. A recent analytical study has derived an exact universal expression for the energy flux which can indicate the direction of the group velocity at latitudes for linear shallow water waves (Aiki et al., 2017 PEPS, doi:10.1186/s40645-017-0121-1). This analytical result is extended in the present study to a height-dependent framework for zonally and vertically propagating equatorial waves in the atmosphere. This is achieved by investigating the classical analytical solution of equatorial inertia-gravity waves, Rossby waves, mixed Rossby-gravity waves, and Kelvin waves. Expressions for the horizontal component of the energy flux are similar to each other between the height-dependent framework given by the present study and the height-independent framework given by Aiki et al. (2017), both of which are linked to a scalar quantity associated with the inversion of Ertel’ s potential vorticity (EPV). This EPV- inverted scalar quantity reduces to geostrophic streamfunction for mid-latitude Rossby waves and vanishes for gravity waves, a novel aspect for considering the energy flux. The expression of the vertical component of the energy flux, as given by the present study, requires computation of another scalar quantity based on a three-dimensional Fourier analysis in the combination of a zonal-vertical section and time space. For ease of diagnosis from a model, an approximate version of the universal expression is explored and illustrated for the development of tropical synoptic-scale waves observed in the Indian Ocean–Maritime Continent region during Austral summer.

CCMI stratospheric trends in relation to the stratospheric shrinkage

*Michal Zak[1], Petr Pisoft[1], Petr Sacha[1,2]

1. Dept. of Atmospheric Physics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, 2. Inst. of Meteorology, University of Natural Resources and Life Sciences, Vienna, Austria

Warming of the troposphere is directly connected with a positive trend of geopotential heights of pressure levels. This trend reaches its maximum around the tropopause and results also in the tropopause upward shift. In the stratosphere, the geopotential height trends are affected by the stratospheric cooling –there is a gradual reduction of the upward shift and even its reversal at about 10 hPa. That leads to a decreasing trend of the stratospheric thickness - a so-called stratospheric shrinkage. In this study, we calculate CCMI inter-model correlations of shrinkage with trends of various variables to separate the possible shrinkage effect and to analyze influence of the shrinkage on other middle atmospheric trends detected in the CCMI simulations.

A study of wave activities and ozone fluctuations around the Maritime Continent during YMC-BSM 2018

*Takenari Kinoshita[1], Junko Suzuki[1], Shin-Ya Ogino[1], Ryuichi Shirooka[1]

1. Japan Agency for Marine-Earth Science and Technology

The Transformed-Eulerian Mean (TEM) equations proposed by Andrews and McIntyre are useful tools for diagnosing the relationship between wave activities and the mean state. The three-dimensional (3D) extension of TEM equations has been conducted since 1980s and the recent study uses the 3D wave activity flux for the analysis of special structure of Rossby wave activities during Stratospheric Sudden Warming. On the other hand, to investigate the material transport associated with wave activities, it is necessary to consider the mean geostrophic flow (balanced flow) and the phase structure of stationary waves, which are included in the horizontal component of the 3D residual flow. Then, a unified analysis method using the 3D residual flow has not been established.
Based on the above, the purpose of this study is to establish a method for diagnosing the 3D structure of material transport associated with wave activities. We report the results of investigation on wave activities and ozone fluctuation around the Maritime Continent during the YMC-BSM 2018 campaign.

Traveling Planetary Waves in the Northern Hemisphere Winter Middle Atmosphere

*Koki Iwao[1], Toshihiko Hirooka[2]

1. National Institute of Technology, Kumamoto College, 2. Kyushu University

It is a well-established overview that quasi-stationary planetary waves propagating upward from the troposphere dissipate in the stratosphere to drive the meridional circulation in the winter hemisphere, while the meridional circulation in the mesosphere is driven mainly by gravity waves. On the other hand, the importance of traveling planetary waves in the stratosphere and mesosphere has been underscored in recent studies to bring about significant impacts on mean flows through their generation and dissipation. However, observational studies are insufficient for this region, so that detailed features are still unclear. Hence, this study investigates contributions of planetary waves (PWs) to the mean flow in the stratosphere and mesosphere during the Northern Hemisphere winter when PW activities are strong, by analyzing satellite data from Sounding of the Atmosphere using Broadband Emission Radiometry (SABER). Our analyses suggest that there would be a cancellation mechanism between easterly acceleration by monthly mean stationary planetary waves (STPWs) and westerly acceleration by remaining travelling planetary waves (TRPWs) in the polar lower mesosphere. When easterly winds appear in the mesosphere, STPWs propagating from the troposphere would dissipate in the lower mesosphere to accelerate easterly winds because STPWs could not propagate in easterly regions, but TRPWs would be generated there due to barotropic and/or baroclinic instability caused by the easterly winds in the mesosphere and accelerate westerly winds. This cancellation would contribute to maintain the easterly wind in the mesosphere for more than 10 days in some cases. Further analyses reveal that the wave generated in the polar lower mesosphere would be a downward propagating TRPW with a zonal wave number 1 traveling eastward with a period ~20 days. Moreover, the easterly wind in the mesosphere is frequently triggered by the dissipation of TRPWs developed in the stratosphere in the recovery phase of sudden stratospheric warmings, in addition to the dissipation of STPW propagating from lower layers.

Impact of Satellite Observations on Forecasting Sudden Stratospheric Warmings

*Shunsuke Noguchi[1,2], Yuhji Kuroda[2,3], Hitoshi Mukougawa[4], Ryo Mizuta[2], Chiaki Kobayashi[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Meteorological Research Institute, 3. Meteorological College, 4. Kyoto University

The observational impacts of satellite data assimilation on extended-range forecasts of sudden stratospheric warmings (SSWs) are investigated by conducting ensemble forecast experiments. We use two Japanese novel reanalysis products: the Japanese 55-year reanalysis (JRA-55) and its subset that assimilates conventional observations only (JRA-55C). A comparative examination on the reproducibility for SSWs between the two ensemble forecasts reveals that the impact of satellite observations is significant for forecasts starting 5 days before the SSW onset, with 20% less accuracy in the JRA-55C forecasts. Moreover, some of forecasts of vortex-splitting SSWs show a sudden appearance of deep difference, which lasts over a few months in the lower stratosphere and significantly affects the surface climate. These results highlight an important role of mesospheric and upper stratospheric circulations on the onset and development of SSWs.

[E] Poster | A (Atmospheric and Hydrospheric Sciences)：A-AS Atmospheric Sciences, Meteorology & Atmospheric Environment

[A-AS09] Cloud-Resolving Model Simulations for Climate and Weather Studies

convener:Toshihisa Matsui(NASA Goddard Space Flight Center), Masaki Satoh(Atmosphere and Ocean Research Institute, The University of Tokyo), Wei-Kuo Tao(NASA Goddard Space Flight Center)

Cloud-resolving models (CRMs) employs nonhydrostatic dynamic core, explicit microphysics and radiation processes to provide physically-realistic simulations of cloud structures, optical properties, and latent heat release, without parameterizing deep convection in coarse-resolution weather and climate models. CRMs can be run at a few km down to sub-km of horizontal grid spacing depending on science application and focused cloud systems. Over the past few decades, CRMs have been utilized in a variety of weather and climate studies; such as 1) understanding cloud-precipitation processes and interactions with aerosols, surface, radiation, and lightning processes, 2) evaluating and developing microphysics and convection with various in-situ and remote sensing observations, and 3) addressing climate issues to develop or replace convective-cloud parametrizations for global or regional atmospheric models. The goal of this session is to showcase the current efforts for these studies in the atmospheric community.
