Metaharzburgite in the Naran massif is composed of primary olivine (P-Ol), S-Ol, antigorite, and Cr-Spinel. S-Ol mainly occurs as mm-scale aggregates. S-Ol aggregate is composed of 10-50 μm Mg-rich olivines, magnetite, and sub-parallel bands of antigorite (B-Atg). Our previous study revealed that these S-Ol+B-Atg formed by pseudomorphic replacement of Opx during hydration of mantle wedge although primary Opx was not preserved [4]. P-Ol, S-Ol and B-Atg, and antigorite in matrix (M-Atg) show contrasting CPOs, respectively. P-Ol CPO shows the strong concentration of the *b*- and *c*-axes normal to the foliation and parallel to the lineation. It suggests plastic deformation by dislocation creep under relatively low stress and high-water condition. CPOs of M-Atg and P-Ol reveal clear crystallographic relationships between Atg and P-Ol: the concentrations of the *a*-, *b*- and *c*-axes of M-Atg are sub-parallel to the *b*-, *c*- and *a*-axes of P-Ol, respectively (topotactiv growth of M-Atg after P-Ol). In contrast to P-Ol, S-Ol aggregate does not show a strong CPO in an entire thin section, but the weak CPOs are developed in individual S-Ol aggregates. This indicates that the S-Ol CPO was developed not by deformation processes but was affected by the orientation of pre-exisiting Opx grains. The distribution of B-Atg in S-Ol aggregates could represent the cleavage of P-Opx, and the (001) plane of B-Atg is oriented sub-normal to the P-Opx cleavage. Assuming that Atg bands present the cleavage of P-Opx, the *c*- and *b*-axes of Atg are likely to be sub-parallel and normal to the Opx cleavages, respectively. These features suggest that high-T hydration of mantle wedge of the Naran massif proceeded without intense deformation and anisotropy development during initial stage of subduction zone development.

Crustal fracturing and brecciation processes in middle crust associated with granitoid intrusions in Sør Rondane Mountains, East Antarctica

*Tatsuya Takemori[1], Masaoki Uno[1], SATISH KUMAR[2], Noriyoshi Tsuchiya[1], Atsushi Okamoto[1]

1. Tohoku University, 2. Niigata University

Recent geophysical observations, such as seismic tomography and magnetotellurics methods, have shown that there is a correlation between the distribution of magma, H_2O-CO_2 fluid and hypocenters (Asamori et al., 2010). On the other hand, the observations of magmatic/hydrothermal deposits have revealed that granitic magmas and carbonate mineral veins are closely related to crustal failures (Oliver et al., 2006). In order to clarify these relationships, understanding of the dynamic fracturing processes, such as flow velocity, fluid pressure, etc. is necessary. In this study, we clarify the crustal fracturing processes by elucidating the origin and velocity of fluid in crustal fracturing and brecciation associated with granitic magma.

The survey area is Balchenfjella, Sør Rondane Mountains, East Antarctica, located within the collision zone during the formation of the Gondwana continent, where the middle and lower crustal materials of the granulite facies are exposed (Ishikawa et al., 2012). The host rock granulite is intruded by breccia dyke with a matrix of carbonate rock (hereinafter, referred to as carbonate breccia dyke) and granitic dyke that are more than 100 m wide, which captures carbonate rock, granite, gneiss as tens of cm to tens of meters of clasts. For two dykes, we estimated the temperature and pressure conditions at the time of intrusion, the origin of the fluid forming two dykes, created a model of the fracturing processes, and finally, estimated the fluid velocity during fracturing.

The results indicate that, the temperature and pressure conditions at the time of intrusion were P = 200 (MPa) and T = 580 to 700 (° C), which is equivalent to pyroxene-hornfels facies, indicating a crustal fracturing in the middle crustal conditions. Based on the carbon-oxygen isotope ratio and trace element composition, the matrix of carbonate breccia dyke has originated from sedimentary carbonate rock (metalimestone) and reacted with the magmatic fluid. Based on the bulk composition, the granitic dyke is syn-collisional granite. The particle size distribution of the captured clasts is 8~102 (m) for carbonate dyke and 17~61 (m) for granitic dyke. By using the Ergun equation, the minimum fluidization rate was calculated to be 190 (km/h) and 40 (km/h), respectively.

This suggests that five stages of magma/fluid activity and two types of brecciation had occurred. In particular, regarding brecciation, as magmatic fluid flows into the metalimestone layer during the intrusion of granite, CO_2 is released due to the decarbonation, and the fluid pressure exceeds the lithostatic pressure, disrupts the crust, rises at a flow velocity of over c. 200 km/h, and forms carbonate breccia dyke. Subsequently, the granitic magma intruded at c.40 km/h, forming granitic dyke.

From these observations, it is clarified that the decarbonation of carbonate rock caused by the intrusion of granite causes explosive crustal destruction and can move through the crust at velocities exceeding 200 km/h.

Multiple timings of high-grade garnet-forming metamorphism from Sør Rondane Mountains, East Antarctica

*Fumiko Higashino[1], Tetsuo Kawakami[2], Shuhei Sakata[3], Takafumi Hirata[3]

1. Faculty of Science, Okayama University of Science, 2. Kyoto University, 3. The University of Tokyo

In high-grade metamorphic rocks, U-Pb geochronology of zircon is a powerful tool to understand metamorphic events. This is because zircon represents relatively high closure temperature of U-Pb system and its atomic structure remains stable over long periods of geological time. Since zircon could record various metamorphic stages of high-grade metamorphism (e.g., Harley et al., 2007), the appropriate interpretation of their ages is significant. The REE pattern of distribution coefficient between zircon and garnet ($D_{REE(z/g)}$) has been used as a useful tool to establish the link between zircon geochronology and timing of garnet formation. A considerable issue is that the REE patterns of $D_{REE(z/g)}$ have been reported to become positive with decreasing temperature, increasing pressure, or increasing X_{Ca} in garnet (e.g., Harley et al., 2001; Rubatto, 2002; Hokada and Harley, 2004; Buick et al., 2006; Rubatto and Hermann, 2007). In spite of these uncertainty, traditional REE patterns of $D_{REE(z/g)}$ have been used to understand whether the garnet was formed in equilibrium with zircon or not. The typical way that experimental D_{REE} data sets are used to evaluate empirical data, is to overlay them on natural data sets and gauge their similarity. The flat REE pattern of $D_{REE(z/g)}$ is often interpreted to represent equilibrium between these two phases.

In order to handle empirical data sets in a practical manner, Taylor et al. (2017) proposed to use array plot whose slope from $D_{Yb(z/g)}/D_{Gd(z/g)}$ is plotted against $D_{Yb(z/g)}$ values. An advantage of the new array plot is usages of two key parameters which together can represent the slope of the REE pattern and REE abundance of the traditional REE partitioning plot. It is noted that more than one garnet and zircon generation may be formed by recrystallization and a degree of chemical re-equilibration varies in terranes that have undergone polymetamorphism.

In the Sør Rondane Mountains (SRM), East Antarctica, Late Proterozoic to Cambrian granulites are widely exposed (e.g., Jacobs and Thomas, 2004; Shiraishi et al., 2008; Osanai et al., 2013; Kitano et al., 2016). In the SRM, each metamorphic event has been correlated to the different zircon age groups, mainly using Th/U ratio of the dated zircon domains (e.g., Shiraishi et al., 2008). Limited number of previous studies have investigated REE patterns of zircon and garnet in the SRM (e.g., Hokada et al., 2013). Therefore, in this study, *in situ* U-Pb dating of zircon included in garnet and the $D_{REE(z/g)}$ values are evaluated using the array plot, in order to determine the timing(s) of garnet-forming metamorphism in selected regions of the SRM.

In situ U-Pb dating of zircon and quantitative analysis of REE in garnet and zircon have been performed using LA-ICPMS on seven mafic and pelitic gneisses collected from Perlebandet, Brattnipene, Pilten, Mefjell, and Balchenfjella in the SRM. The rims of zircon inclusions in garnet from seven samples gave U-Pb ages of ~560 Ma (Pilten and Balchenfjella), ~580 Ma (Perlebandet and Mefjell) and ~610-620 Ma (Balchenfjella and Brattnipene). Each sample gave a single peak age distribution for the zircon rim dating. Using the traditional $D_{REE(z/g)}$ pattern plots and the array plot, five samples are evaluated to be in equilibrium between host garnet and the dated zircon domain. Zircon rims included in garnet from the other two samples, on the other hand, were not in equilibrium with the host garnet. In summary, the five equilibrium samples could reveal the multiple timing of garnet formation in different regions of the SRM; Perlebandet (~580 Ma), Brattnipene (~610-620 Ma), Pilten (~580 Ma), and Balchenfjella (~560 Ma and ~610 Ma). The details of garnet-forming metamorphism will be discussed.

Thermal modeling for "Hot-on-cold" thrusting: Thermal structure during orogenic movement at the western boundary of Eastern Ghats Belt, India

*Fumihiko Sato[1], Tomoeki Nakakuki[1], Kaushik Das[1]

1. Hiroshima University

The boundary areas between the orogenic belts and pre-existing cratons preserve important information regarding the growth and evolution of old continents. The boundary areas experienced multiple phases of metamorphism, deformation, activities of crustal fluids, these hold the important key to understand continental evolutions. Regarding the orogenesis and its thermal structure, it is important to validate the petrogenetic evidence from rock records by computer simulation.
The Eastern Ghats granulite Belt (EGB) is a Proterozoic orogenic belt that extends ~1000km in the northeast-southwest direction along the east coast of India. Archean Baster craton (BC) is located just west of it. From the detailed structural geological, petrological and geochronological works, it is understood that “Hot-on-cold” thrusting occurred between the deep crust of EGB and the shallow crust of BC.
The present study area is north-western EGB, i.e. between the Phulbani domain and 10 km away from the boundary thrust. Monazite U-Th-total Pb (EPMA) dating and petrological data on the corundum + spinel + garnet-bearing granulite of this domain revealed that this area had undergone peak ultra-high temperature metamorphism in the deep crust during 1000-900 Ma. Following that the youngest thermal event is documented at approximately 650-500 Ma from the felsic gneiss. This youngest age was found inside EGB only within a few kilometers on both sides of the boundary, but most prominent close to the boundary.
We consider this age and its geographic spread is related to the final “Hot-on-cold” thrusting during the final amalgamation of EGB crust with the Indian continent. This thermal overprinting was up to the amphibolite facies. In order to understand the cooling process of after peak, we set this age distribution on the present erosional surface as the boundary condition of the thermal structure model and considered computer simulation of thrusting.
In this study, we present the results of the 2D/3D numerical simulations of “Hot-on-cold” thrusting and comparing it with the metamorphic rock records. The numerical model is carried out by computer calculation using the temperature equation obtained by discretizing the thermal advection and convection equations by finite volume method with progress in time.

Fluid-rock interaction and formation of high-grade metamorphic rocks in the Trivandrum Block, southern India

*Nishi Ayumi[1]

1. Faculty of Life and Environmental Sciences, University of Tsukuba

Infiltration of supercritical fluids from external sources into lower crustal rocks probably plays an important role on the formation and the stability of various high-grade metamorphic rocks. Generally, introduction of high-H2O activity fluids (such as pure H2O fluid) in the lower crust will enhance hydration or partial melting, whereas low-H2O activity fluids (such as CO2-rich fluid) will give rise to dehydration reactions to form anhydrous mineral assemblages (such as orthopyroxene-bearing granulite-facies assemblages). As a case study in southern India, this study evaluates the petrogenesis of a white-colored (bleached) hydration vein and a dark-colored dehydration vein associated with granulites from Parakkani and Marthandam in the Trivandrum Block, southern India. The Trivandrum Block is a granulite block formed by a Neoproterozoic to Cambrian (ca. 600-510 Ma) high-grade metamorphism probably related to a series of collisional events during the assembly of Gondwana supercontinent. The bleached vein occurring parallel to the foliation of the matrix anhydrous charnockite body (orthopyroxene + quartz + plagioclase + K-feldspar + biotite) is characterized by a hydrous mineral assemblage of garnet + biotite + quartz + plagioclase + K-feldspar. In contrast, the dark-colored vein occurring perpendicular to the foliation of the matrix garnet-biotite gneiss (garnet + biotite + quartz + plagioclase + K-feldspar) has an anhydrous mineral assemblage of orthopyroxene + quartz + plagioclase + K-feldspar + biotite. The field occurrences and the mineral assemblages in the host-vein rocks indicate possible effects of fluid migration in the lower crust for the formation of the two types of vein. It is important to note that the two veins occur in the same area around Marthandam. The preliminary results of this study thus suggest complex fluid migration history during the formation of granulites in the Trivandrum Block.

Structural geology of Hidaka Metamorphic Belt in the Mt.Nozuka and Mt.Rakko area, Hokkaido,JAPAN -Growth process and mechanism of the Cenozoic continental crust-

*Moeko Kanno[1], Tsuyoshi Toyoshima[2], Hayato Ueda[2]

1. Graduate school of Science and Technology, Environmental Science and Technology,Earth science, 2. Niigata University, Faculty of Science,Department Geology

Hidaka metamorphic belt (HMB) of the southwestern part of Hidaka belt, Hokkaido, northern Japan, was regarded as an island¬−arc type crustal slab formed by prograde metamorphism up to granulite-facies and voluminous partial melting during early Eocene (e.g. Osanai et al., 1992). However, Shimura et al. (2015) and Takahashi et al. (2017, 2018) recently proposed that HMB consists of two different metamorphic belts formed during 40–30 and 19 Ma respectively and there is the former on the latter. Shimura et al. (2018) also showed 40–30 Ma metamorphic rocks suffered 19 Ma metamorphism. Moreover, Jahn et al. (2014) reported granites were generated during 45–46 and 37 Ma in the northern part of Hidaka belt. From these new zircon ages, the necessary of reconstruction of tectonics of HMB was drawn.

We carried out structural analysis and zircon U–Pb geochronology of the Hidaka metamorphic and plutonic rocks from the Niobetsu River and Menasyunbetsu River regions, in order to discuss tectonics of HMB.

In the study area, HMB consists mainly of S-Type tonalite (Grt tonalite and Grt-Bt tonalite), I-Type tonalite (Hbl-Bt tonalite), Niobetsu complex (Owada et al., 2004), amphibolite and pelitic and psammitic gneisses. Niobetsu complex, consists of gabbro and diorite. Metamorphic inclusions are observed in S-Type tonalite and Niobetsu complex. Metamorphic rocks in the study area are of zones III and IV (Osanai et al., 1992). Metamorphic inclusions are also of zones III and IV. Most of the rocks align along a NW–SE trend except for N–S trending Niobetsu complex.

Newly obtained zircon U-Pb ages reveal three magmatic stages, two in Eocene at about 45 Ma (S-type tonalite), and about 33 Ma (I-type tonalite), and one in Miocene at about 19 Ma (diorite of Niobetsu complex) in HMB of the study area. Because these plutonic rocks are accompanied by migmatites and metamorphic inclusions, it is possible that three stages of magmatism went with metamorphism and HMB was formed by three stages of metamorphism.

Asymmetrical magmatic flow structure like S-C-C' fabric of mylonite is observed in margins of Niobetsu complex, indicating a normal sense of shear. The asymmetrical structure suggests that Niobetsu complex intrusion and magmatic flow occurred under extensional conditions.

In the study area, three stages of mylonitization are recognized: Dm1, Dm2, and Dm3 stages. Dm1, Dm2, and Dm3 mylonitizations were caused by dextral to dextral-normal sense, dextral to dextral-reverse sense, and dextral−sense of shear respectively. Mineral lineation in Dm1 mylonite plunges gently toward the southeast. Dm3 mylonitization is concentrated in rocks near the Hidaka Main Thrust.

Dm1 mylonitization showing dextral to dextral-normal sense of shear occurred under dextral transtensional conditions. In the northern− central parts of HMB, mylonitization of basal−lower S-type tonalites occurred under dextral transpressional conditions (Toyoshima et al., 1997). Basal−lower S-type tonalites in the northern and central parts of HMB are the products of 19 Ma magmatism (Kemp et al., 2007), while S-type tonalites in the study area are the products of 45 Ma magmatism. Therefore, it is possible that the dextral transtension and dextral transpression occurred during different deformation stages. Another possibility is when the dextral transtension and dextral transpression occurred during the

©2020. Japan Geoscience Union. All Right Reserved.

same deformation stage (Dm1). In this possibility, Dm1-mylonitizaton caused pivotal movement, rotation of shear plane, and the difference in type of fault between the northern–central and southern parts.

Raman carbonaceous material thermometry applied to mapping the thermal structure of contact metamorphic domains in the Hongusan area, central Japan incorporating the effects of widespread detrital carbonaceous material

*Ken Yamaoka[1], Simon Richard Wallis[1], Akira Miyake[2], Yui Kouketsu[3]

1. The University of Tokyo, 2. Aichi University of Education, 3. Nagoya University

Raman carbonaceous material thermometry (RCMT) can be applied to a wide range of lithologies and over a wide temperature range of 150–655 ˚C. The utility of this method opens the possibility of determining the thermal structure of metamorphic domains with unprecedented spatial resolution. RCMT is based on averages of numerous measurements in a single sample and a potential complicating factor is the presence of detrital carbonaceous material that can bias the average values. Such detrital grains are commonly recognized as grains of highly crystalline CM (close to graphite) amongst grains of lower crystallinity. Recent studies in the Himalayas and Taiwan have shown that the material cycling process in convergent plate margins leads to the storage of highly crystalline CM in sediment because it is relatively resistant to weathering and erosion processes. The existence of detrital CM needs to be assessed to estimate appropriate temperatures and errors using the RCMT. However, there are few studies where the effects of detrital material have been quantitatively studied. Application of RCMT to relatively low-grade metamorphic rocks (< ~400 ˚C) can easily detect the presence of detrital CM because of a crystallinity gap between weathering-resistant high-grade CM and lower-grade metamorphic CM. However, it is unknown whether detrital and metamorphic CM can be clearly distinguished in higher-grade metamorphic domains. It is also not clear whether detrital grains of CM with crystallinity less than graphite can also be present. In the Hongusan area of Aichi Prefecture, two distinct types of thermal structures can be recognized: firstly one associated with the regional high-*T/P* type Ryoke metamorphism, and secondly later overprinting contact metamorphism recognized around two separate granitic intrusions. Application of the RCMT to 100 metamudstone samples in the study area reveals that several samples show multimodal crystallinity of CM which indicates the existence of a large amount of detrital CM grains including both fully crystallized graphite and lower crystallinity metamorphic CM grains. A new procedure was developed to filter out the effects of detrital CM and assist in determining the metamorphic thermal structure. The results clearly show the distinct thermal structures related to regional and contact metamorphism with a high spatial resolution that can be used to determine the extent of the contact metamorphism. The estimated temperatures show good agreement with a more limited data set obtained using silicate equilibria models. Spatial changes in the distributions of the metamorphic and detrital CM clearly show that as the maximum temperature increases, CM with low crystallinity progressively transforms to graphite and multiple crystallinity peaks gradually merge to one at a high grade. These results show RCMT can be used to derive detailed and reliable temperature estimates even if the original metasedimentary rock contains a significant amount of detrital CM. The recognition of detrital CM can be used to infer the grade of metamorphic rocks present in the hinterland that supplied the detritus of the Mino–Tanba belt. This approach can be added to the tools used in the provenance analysis of sedimentary rocks. The contact aureole around the Shinshiro tonalite in this area is remarkably thick and may reflect the tectonic setting during magma emplacement or the cooling process of magma. The formation process may be constrained by considering the thermal model and the obtained Raman CM temperature.

Raman parameters of carbonaceous material estimated from fully-automatic spectral fitting method and their relation to vitrinite reflectance

*Shunya Kaneki[1], Yoshihiro Nakamura[2], Yui Kouketsu[3], Hideki Mukoyoshi[4]

1. Disaster Prevention Research Institute, Kyoto University, 2. Geological Survey of Japan, National Institute of Advancecd Industrial Science and Technology, 3. Graduate School of Environmental Studies, Nagoya University, 4. Graduate School of Science and Engineering, Shimane University

Carbonaceous material (CM) is widely distributed in sedimentary and metamorphic rocks, and its thermal maturity and crystallinity have been used as an indicator of burial and metamorphic temperature history. The relationship between maturity and temperature history of CM has been documented by various analytical techniques, including X-ray diffraction measurements, vitrinite reflectance measurements, transmission electron microscopy, infrared spectroscopy, and Raman spectroscopy. Among these, Raman spectroscopy is increasingly being used because of its rapidness and usefulness, as well as it is normally non-destructive technique (Henry et al., 2019).

A typical Raman spectrum of CM exhibits two distinct peaks of D (around 1350 cm^{-1}) and G bands (around 1580 cm^{-1}) (Tuinstra & Koenig, 1970). Various spectral parameters, which is associated with the thermal maturity of CM, are reported; e.g., intensity ratio and full-width at half maximum (FWHM) of D and G bands. Importantly, there are mainly two types in these spectral parameters: (1) parameters calculated from raw data, or (2) parameters calculated by performing spectral fitting. One of the representative parameters of the latter was proposed by Beyssac et al. (2002). Because it is argued that their R2 ratio (area of G band / area of D1+D2+G bands) is closely related to the CM maturity, numerous studies adopted the R2 ratio as a representative parameter of Raman spectra of CM (e.g., Kouketsu et al., 2014). On the other hand, Henry et al. (2018) suggested that spectral fitting should not be performed because it leads to unnecessary errors, and recommended to focus on the parameters that can be calculated from the raw spectrum without spectral fitting.

In the light of these backgrounds, the final goal of this study is to investigate whether spectral fitting of Raman spectra of CM is useful to evaluate its thermal maturity. As a first step toward this purpose, we developed a Python script that automatically perform spectral fitting of Raman spectra of CM. Analytical procedures of the script mainly consist of 5 parts: (i) smoothing by Savitzky-Golay filtering method, (ii) background correction with 1^{st} or 3^{rd} order polynomial function, (iii) normalization, (iv) setting of initial spectral parameters, and (v) non-linear spectral fitting with pseudo-Voigt function. We analyze the published data of Raman spectra of CM by Kouketsu et al. (2014), Mukoyoshi et al. (2018), and Nakamura et al. (2019), and compared the calculated parameters with the reported values of vitrinite reflectance. We will show preliminary results of our attempts in this presentation.

Raman spectroscopy of quartz eclogite in the Sanbagawa metamorphic belt: Potential of Raman geobarometry using kyanite-quartz system

*Yuki Tomioka[1], Yui Kouketsu[1], Tomoki Taguchi[2]

1. Nagoya University, 2. Kyoto University

The pressure–temperature conditions of metamorphic rocks have been estimated by using thermodynamic models based on the chemical equilibrium between coexisting minerals. Recently, the development of a new method called “Raman geothermobarometer” has been progressing. It applies Raman spectroscopy and focuses on the residual pressure of the inclusion minerals. In particular, “garnet-quartz Raman barometer” using quartz inclusions in garnet has been proposed as a useful technique, which estimates residual pressure from peak shift of Raman spectrum and converts to metamorphic pressure (Enami et al., 2007_AM; Kouketsu et al., 2014_AM). On the other hand, the host garnet forms a solid solution, and each end member has different physical parameters. Therefore, theoretical errors occur between the actual measurement value and the numerical calculation assuming garnet as an end member. In this study, we verified a new Raman geobarometer using kyanite instead of garnet. Neither kyanite nor quartz forms a solid solution, and kyanite is stable under a wide pressure and temperature range. Hence, the kyanite-quartz system may be applicable to various high-pressure metamorphic rocks.

The samples used in this study are quartz eclogites from the Gongen region in the Sanbagawa metamorphic belt, central Shikoku, southwest Japan. The peak metamorphic pressure–temperature condition of the Gongen quartz eclogite was estimated to be 2.3–2.4 GPa/675–740 ℃, which is the highest pressure in the Sanbagawa metamorphic belt in central Shikoku (Miyamoto et al., 2007_JMPS). In this study, five quartz eclogite samples were collected from one location on the ridge of Mt. Gongen and two locations along the Tokonabedani valley. Two quartz eclogite samples described by Miyamoto et al. (2007) were also analyzed. For each sample, Raman spectroscopic analyses were performed on thick sections (about 100 μm thick) and only quartz inclusions completely encapsulated in kyanite were analyzed. All Raman spectra of 237 quartz inclusions in kyanite showed a peak shift toward higher wavenumber sides indicating compressive stress. residual pressure values calculated from the peak shift showed a wide range of 0.16–0.89 GPa. In order to evaluate the factor of the variation in residual pressure, the inclusion diameter was measured, but no significant correlation was found with the residual pressure. Raman mapping was performed to confirm the distribution of the residual pressure inside the inclusion, but it is homogeneous except grain boundary. Therefore, the following possibilities are considered as the factors of the variation in residual pressure: (1) quartz inclusions were trapped in kyanite at wide pressure–temperature range, (2) effect of healed crack in host kyanite during exhumation.The peak metamorphic condition was calculated based on the maximum residual pressure of 0.89 GPa using a numerical model, and the result shows in good agreement with previously estimated range by using the thermodynamic modeling (Miyamoto et al., 2007). This result suggests that kyanite had been growing during the Sanbagawa peak metamorphic condition. Additionally, calculations using the maximum values at each sampling locations also show good agreement with the metamorphic range reported by the previous study, and thus Gongen quartz eclogite is thought to have subducted extensively to the deepest depth of the Sanbagawa metamorphism.

©2020. Japan Geoscience Union. All Right Reserved.

This study indicates that kyanite can be used as a host mineral like garnet, and the kyanite-quartz system can estimate the peak pressure–temperature condition. However, some unverified points remain such as the effect of the elastic anisotropy of kyanite and quartz, and the possibility of underestimating the metamorphic conditions by selecting the highest value from the few measurement results. In the future, research will be conducted toward the development of a highly reliable geothermobarometer based on these improvements.

The R.G. Coleman Cazadero Collection: A preliminary sample description for systematic curation

*Oka Hiroki[1], Tatsuki Tsujimori[1]

1. Tohoku University

The Ward Creek near Cazadero is one of the most classic blueschist localities in California Coast Ranges. The area is also known as a difficult place to sample due to private property concerns. In 2019, one of the authors (T. Tsujimori) received a collection-donation from Professor Robert G. Coleman; the rock collection include various metamorphic rocks from Cazadero (e.g., Coleman et al. 1965) and other areas[DPG1] . The aim for the donation was not only reuse and re-investigate the precious samples but also to curate the collection for future generations.

The RGC Cazadero Collection includes up to 222 rock samples (~40 kg), seventy-seven mineral separates, 126 petrographic thin-sections, field notes, maps, and photos. All rock samples were collected by Professor Coleman from 1950’s to early 1990’s. Both rocks and thin-sections are labeled with two or three-digit numbers indicating samples, abbreviation of collector's name, and two-digit numbers representing the year collected (e.g., 102-RGC-58). The labeling allows us to correlate among samples, thin-sections, notes, and maps. Some labels in the collection correspond to samples described in classic articles; we confirmed five samples in Coleman and Lee (1962), twenty-five samples in Coleman and Lee (1963), four samples in Coleman et al. (1965), four samples in Coleman and Papike (1968), and one sample in Coleman and Lanphere (1971). Thus far, we have examined all 126 petrographic thin-sections. Based on the preliminary petrographic observations using optical microscope, the samples can be grouped as metabasalt, metachert, and meta-ironstone. Hundred-eighteen thin-sections contains glaucophanic amphibole, and further forty-six glaucophane-bearing samples are characterized by the glaucophane + garnet mineral assemblage, indicating higher-grade metamorphism. Furthermore, five garnet- and glaucophane-bearing samples are eclogitic, containing mainly of garnet and omphacite. Notably one eclogite, 62-RGC-58 in Coleman et al. (1965), contains porphyroblastic lawsonite. All glaucophane-bearing samples show textbook-quality, spectacular microtexture with various color. Meta-ironstones and mtacharts also exhibit spectacular microtextures of dark-blue riebeckitic amphibole with numerous garnet, stilpnomelane, and rare deerite.

For the systematic curation, we are also attempting 'digitally archiving' paper materials. In this poster presentation, we will introduce our preliminary descriptions of the RGC Cazadero Collection, and will show potential for future petrologic and geochemical studies.

The Microstructure and Composition of Picrolitic Antigorite Veins in Serpentinites from the High-P Metamorphic Yuli Belt in Eastern Taiwan

*Ilona Talvikki Sakaguchi[1], Yui Kouketsu[1], Chin-Ho Tsai[2], Dominikus Deka Dewangga [2], Katsuyoshi Michibayashi[1]

1. Nagoya University, 2. National Dong Hwa University

Fluid activity plays a key role in many subduction zone processes such as in melt formation and elemental cycling. Serpentinite is an important component of the subducting oceanic lithosphere as well as the mantle wedge and the hydration and dehydration reactions of serpentine minerals have a major impact on the hydrodynamics of the subduction zone. Recently, it has also been suggested that fluids released from serpentine minerals could be the cause for seismicity occurring in subduction zones at intermediate depths (~50-300 km).

In order to study the nature of fluid flow in the subduction zone, we collected and analyzed serpentinite samples from Yuli belt, which is a high pressure metamorphic belt in eastern Taiwan. Yuli belt is mainly composed of pelitic, psammitic and chloritic schists, but also contains various other lithologies including several occurrences of serpentinites and meta-mafic rocks. The samples presented in this study were collected from the Juisui area, which is known for hosting several occurrences of glaucophane-bearing rocks suggesting that these rocks represent a relatively deep section of the subduction zone with peak metamorphic pressures around 10–13 kbar. Based on field observations, such as intensive quartz veining in the pelitic schist and Na-metasomatism in the contact of the pelitic schist and the serpentinites, it appears that the rocks in the Juisui area have been subject to widespread fluid infiltration.

Our study focuses on describing the microstructure and composition antigorite veins, which occur in the serpentinite bodies. Because antigorite is a high temperature serpentinine mineral, we interpret that the veins represent fluid flow occurring in the deeper parts of the subduction zone. The picrolitic antigorite veins have a fibrous appearance but are in fact composed of elongated splintery antigorite. The thickness of the veins ranges from a few millimeters to several centimeters. Various vein structures have been observed, including syntaxial and crack-seal veining. We also discovered several generations of cross-cutting antigorite veins suggesting multiple pulses of fluid flow. Unlike the matrix, the veins do not contain any magnetite. However, dolomite is often associated with the picrolitic antigorite veins and cross-cutting relationships imply that the CO_2-rich fluid entered the serpentinite around the same time that the antigorite veins formed. We will discuss the composition of the antigorite veins and the possible nature of the fluids that created them further in this presentation.

Estimation of P-T history of amphibolite tectonic blocks in serpentinite mélange of Kamuikotan metamorphic rocks

*Yuto Kimura[1], Toru Takeshita[1]

1. Department of Natural History Sciences, Graduate School of Science, Hokkaido University

Serpentinite mélange is a geological body which contains fragments(these are called tectonic blocks)of metamorphosed oceanic crust and sedimentary rocks.The tectonic blocks in serpentinite mélange have experienced various pressure and temperature conditions in the subduction channel.Serpentinite mé lange of the Kamuikotan metamorphic belt which is distributed in the central part of Hokkaido.According to Ishizuka and Imaizumi(1983),the estimated P-T histories are such ones where prograde metamorphism at intermediate-pressure conditions occur first,which are followed by retrograde metamorphism at high-pressure conditions based on the compositional zoning of minerals.However,Okamoto(2016)and Ando(2018)reported that many types of amphibolites are distributed in the area and compositional zoning of these minerals were found to be varied.This presentation describes new findings about tectonics and thermal evolution in the subduction zonebased on the P-T histories of the amphibolite blocks.The study area,Dainuppu river is located at c.30km northwest of Asahikawa city.Many types of amphibolite blocks occur in this area.Garnet-epidote-amphibolite show the mineral assemblage,Grt+Ep+Ca-Amp+Na-Amp+Ttn+Rt±Chl±Ms± Op,epidote-amphibolite,Ep+Ca-Amp+Na-Amp+Ttn±Rt±Chl+Ms+Qtz±Op and Chlorite rich epidote amphibolie,Ep+Ca-Amp+Ttn+Chl+Ms+Qtz±Op.The protolith of these samples is thought to derive from mafic rocks.P-T history of these samples were estimated by compositional zoning of minerals.In particular,P-T conditions of garnet-epidote-amphibolites are estimated by THERIAK-DOMINO(de Capitani and Petrakakis, 2010).As a result of these analysis,garnets recorded incleasing temperature path as shown by decresing Mn content from core to rim.Peak metamorphism of garnet-epidote-amphibolites were predicted from THERIAK-DOMINO,T=650℃,P=9.5kbar.Pistacite content($Ps=Fe^{3+}/(Fe^{3+}+Al)\times 100$)indicates decreasing temperature path as shown by increasing the ratio from core to rim(Ps=9.5 to~ 30)for all of matrix epidote.In particular, pistacite content of garnet-epidote-amphibolites recorded greater decreasing temperature than other samples.Almost all amphiboles indicate retrograde metamorphism from core to rim.Except chlorite rich epidote amphibolite,the Na-amphiboles overgrew hornblende~barroisite,shown by the drastic increases of the $^{(B)}Na$(~0.5p.f.u in core to 1.5-2.0p.f.u in rim).On the other hand,$Al^{(IV)}$ decrease 1.8-1.0 p.f.u.This retrograde metamorphism can be divided into two stages:the first where $^{(B)}Na$ remains almost unchanged at 0.55p.f.u and $Al^{(IV)}$ gradually decreases from 1.9 to 1.0-1.5p.f.u from core to rim,second which is characterized by drastic decreasing $Al^{(IV)}$ and increasing $^{(B)}Na$ (0.4-0.6p.f.u to 1.4-1.8p.f.u)in outer rim.Garnet-epidote-amphibolites and epidote amphibolite recorded both of the retrograde stages.The tectonics infered from estimated P-T history from tectonic blocks in Dainuppu river area are summerized as followed(1)Garnet-epidote amphibolites subducted at relatively warmer geotherm about 25-30℃/km(2)Subducted garnet-epidote amphibolites and epidote amphibolite were stagnated and subduction channel cooled down at least 15℃/km(3)Garnet-epidote amphibolites and epidote amphibolite were inferred to further experience retrograde metamorphism leading to the overgrowth of Na-amphiboles.The scheme of P-T history can be explain by the model of Gerya(2002) that the tectonic blocks showing clock wise and counter clock wiseP-T path which subduct earlier and later respectively, are juxtaposed at a deeper part and exhumed together,which Okamoto(2016)observed for tectonic blocks in Kamuikotan metamorphic belt.Similar P-T histories of the tectonic schemehave been inferred in eclogite from western-Iratsu body in Sambagawa belt Endo et al,(2012) and amphibolite from Nagal ophiolite complex in India Bhowmik and Ao,(2016).

Datolite in the high-pressure marble from the Eastern Iratsu body of the Sanbagawa metamorphic belt

*Kenta Yoshida[1], Sota Niki[2], Hikaru Sawada[1,2], Ryosuke Oyanagi[1]

1. Japan Agency for Marine-earth Science and Technology, 2. Geochemical Research Center, The University of Tokyo

Datolite [$CaBSiO_4(OH)$] was newly found from an eclogite-facies marble collected from the Eastern Iratsu body, where the eclogite-facies metamorphism has been recognized (e.g., Takasu & Kohsaka, 1987), in the Sanbagawa metamorphic belt of central Shikoku. The investigated marble is composed of calcite-dominated matrix and quartz pool, the latter of which contains datolite as an inclusion mineral in garnet. The matrix mainly consists of calcite, diopside, and garnet. Weak foliation is defined by the elongation of coarse and deformed grains of calcite. Garnet in the matrix contains omphacite, epidote, quartz, phengite, and albite as inclusions. Quartz pool occurs concordantly with the main foliation and is composed of quartz, garnet, calcite, and diopside with trace amount of pyrite and titanite. Garnet in the quartz pool shows patchy texture with the almost pure grossular part ($Grs_{98}Adr_2$) occurring as dark cores in back-scattered electron images (BSI) and the surrounding andradite-rich part ($Grs_{90}Adr_{10}$) recognized as bright part in BSI, the latter of which contains datolite.

The formation conditions of the datolite-bearing bright part of the garnet were estimated using quartz-Raman barometry (Kouketsu et al., 2014a) and thermodynamic calculation. Quartz grains occurring in the bright part were carefully selected and measured by a Raman micro-spectrometer (RAMANtouch, NanoPhoton), yielding $\Delta\omega_1$ values of ~5. Based on the mineral assemblage, the following temperature-dependent reactions were considered in the system of CASH-CO_2 using Perple_X (Connolly, 2005). The lack of zoisite and wollastonite in the quartz pool indicates a temperature range of approximately 500-600 ºC under the assumption of X_{CO2} ~ 0.01:

zoisite + quartz + calcite = grossular + CO_2 + H_2O

calcite + quartz = wollastonite + CO_2

Consequently, the formation conditions of the datolite-bearing bright part of the garnet were estimated as ~550 ºC and 1.1-1.3 GPa, which coincide with the peak temperature conditions of surrounding non-eclogite unit of the Besshi district (Kouketsu et al., 2014b).

In the Sanbagawa metamorphic belt, the most common phase of borosilicate is tourmaline that is formed both in prograde stage and retrograde stage. Datolite is reported only as vein-filling minerals that is considered to be retrograde origin in the Sanbagawa belt (Kato et al., 1957; Minagawa and Nishio, 2002). Both datolite and tourmaline can be stable under the pressure-temperature conditions of the Sanbagawa metamorphic belt including prograde through peak to most of retrograde stage. However, datolite is generally stable under the alkaline conditions (Yang and Rosenberg, 1995) where tourmaline is not (Morgan and London, 1989). The finding of datolite instead of tourmaline indicates the strong alkaline conditions during the formation of quartz pool. Model calculations of Galvez et al. (2015) indicated that the aqueous fluids equilibrated with a metapelite under the expected P-T conditions would be alkaline conditions if carbon is not incorporated in the model. According their calculation, the alkalinity of the fluid equilibrated with the rock would decrease during the exhumation. Therefore, tourmalines recognized in the retrograde stages of the Sanbagawa metamorphic belt becomes stable due to such decrease of

alkalinity.

The occurrence of jadeite in the ultramafic body discovered in the Sanbagawa belt, Shibukawa region, central Japan

*Hikaru Shioya[1], Katsuyoshi Michibayashi[1], Yui Kouketsu[1], Masaki Enami[1]

1. Nagoya University

The Sanbagawa belt is a representative high-pressure metamorphic belt of southwestern Japan. Shibukawa region is located along the border of Aichi and Shizuoka prefectures and consists of the Sanbagawa crystalline schist group and the Mikabu greenstone group. The Sanbagawa group consists of pelitic, psammitic and siliceous schists and the Mikabu group consists dominantly of greenstones with hornblendite, metagabbro and ultramafic bodies. Both groups occur alternatively in the region. The blueschist phase indicators such as jadeite, glaucophane and lawsonite have been reported previously. In particular, jadeite occurs in metagabbroic rocks surrounded by ultramafic rocks or lawsonite-bearing schists(Seki, 1960; Seki et al., 1960). From our field observation, we discovered jadeite-bearing veinlet was discovered in a dunite block of the Shibukawa ultramafic body. The veinlet cut through the dunite block and occur ~5mm in width. The veinlet consists of diopside, grossular garnet, chlorite and relict olivine in addition to jadeite, and minor euhedral magnetite. Jadeite grains occur as anhedral patches in the grossular grains and their grain sizes are less than 100 μm. The major element compositions of jadeite are rich in Na and Al (Na_2O=14.7–15.4 wt.%; Al_2O_3=24.3–25.5 wt.%) and poor in Ca (CaO=0.4–1.3 wt.%). Jadeite values (=(Na-Fe^{3+})/(Na+Ca)x100) are 92–97%. In this study, we present the occurrence and chemical compositions of jadeite in detail and discuss how this high-pressure mineral has been taken place in the Shibukawa region.

Geochronology of the Yorii metamorphic rocks on the Kanto Mountains - Extension of the Abukuma metamorphic rocks to Southwest Japan.

Shota Matsunaga [2], *Atsushi MIYASHITA[1], Tatsuki Tsujimori[2], Kazumasa Aoki[3], Shogo Aoki[3]

1. Seikei University, 2. Tohoku University, 3. Okayama University of Science

In the Pacific type orogen, non-metamorphic accretionary complexes (AC) and high *P/T* metamorphic rocks as deeper facies of AC, often exist in pairs, for example as the Shimanto belt and Sanbagawa belt. Jurassic AC is widely distributed in Japan arc. On Northneast Japan, part of the deep facies of the Jurassic AC are thought to be the Abukuma metamorphic belt (Hiroi, 1998). On Southwest Japan, the Oshima metamorphic rocks in the Shikoku region and the Higo metamorphic rocks in the Kyushu region are corresponding to the Abukuma belt, but it's not distributed widely (Takagi and Arai, 2003).
Tiny metamorphic rock masses are distributed in the low angle faults of the base of Atogura Nap in the Yorii area, the Kanto Mountains. These metamorphic rocks are called the Yorii metamorphic rocks (Takagi, 1991). The Yorii metamorphic rocks have been pointed out to be similar to the Abukuma metamorphic rocks on the basis of the Sr isotope initial values of the accompanying granites, but the sedimentary age and the metamorphic age of the original rocks have not been clarified.
In this study, the zircons U-Pb ages in pelitic gneisses of the Yorii metamorphic rocks were determined by LA-ICPMS. These ages are close to the zircon U-Pb ages and fossil ages of the Abukuma Belt, and it's indicates that the Yorii metamorphic rocks are probably an extension of the Abukuma Belt to Southwest Japan.

Geology, deformation, and metamorphism of high-grade Shimanto accretionary complex in Kerama Islands, Okinawa, Ryukyu arc

*Ippei Yamamoto[1], Kenichiro Tani[2], Yui Kouketsu[3], Rina Fukuchi[1], Hiroaki Koge[4], Asuka Yamaguchi[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. National Museum of Nature and Science, 3. Nagoya University, 4. National Institute of Advanced Industrial Science and Technology

The along-arc distribution of accretionary complexes in the Japanese Islands is extended to the Ryukyu arc. Kerama Islands is located at the southwestern edge of the Cretaceous to Paleogene Shimanto belt, 30 km away from Naha, Okinawa. Geology of Kerama Islands was reported until 1980s (Kashima and Takahashi, 1978; Kizaki and Yamamoto, 1985). Previous study shows that mineral composition of greenstone (epidote + actinolite) suggests high-*T* metamorphic condition and geochemical features of greenstone correspond to N-MORB (Chinen *et al.*, 2004). However, neither depositional age nor deformation structures of Kerama Islands has not been analyzed yet. In this study, we report lithology, deformation structure, depositional and metamorphic age, and peak paleotemperature of Kerama Islands to reconstruct formation history of accretionary complex. Implication of tectonic background in this area will be presented in “New perspectives on the geodynamics of East Asia” (S-IT29) session of this meeting.

In agreement with previous studies (Kashima and Takahashi, 1978; Kizaki and Yamamoto, 1985), our new geological map shows that the bedrock of Kerama Islands is made up of a pile of three lithological units, greenstone, metasandstone, and pelitic schist in ascending order. Metasandstone unit is characterized by massive metasandstone including psammitic schist layers. Dynamically recrystallized quartz grains are commonly observed under a microscope. Pelitic schist unit, which often consists of alternation of pelitic and psammitic schist, shows well-defined schistosity and overlies metasandstone unit with conformity boundary. Detailed observation of the contact between the top of greenstone unit and the bottom of sedimentary rock layer shows that the boundary records intrusion of basaltic lava, the protolith of the greenstone. In contrast, bottom of the greenstone unit is characterized by “conglomerate mylonite” originated from gravel sandstone, which records evidence of ductile shear deformation along an estimated thrust forming duplication of greenstone and metasediments.

Foliation of green, pelitic, and psammitic schists is parallel to bedding plane and dips SW in general. Stretching lineations and fibers of layer-parallel quartz veins on the foliation exhibit NW-SE trend. Axes of asymmetric folds observed in pelitic schist unit show NE-SW trend, suggesting top-to-SE shear. The fold axes are perpendicular to stretching lineations. High-angle normal faults branching from low-angle normal fault are found in pelitic schist unit. These deformation features are classified into three deformation stages: D1 (underthrusting), D2 (underplating) and D3 (exhumation), respectively.

U-Pb ages of detrital zircon grains obtained from metasandstone in Kerama Islands were carried out using LA- ICP-MS installed at the National Museum of Nature and Science. The youngest age of zircon is 104-110 Ma (early Cretaceous) and no zircon grains with late Cretaceous age is obtained.

We examined peak metamorphic temperature of pelitic schist and conglomerate mylonite. Raman spectra of carbonaceous materials in thin section of the samples are obtained using a Raman spectrometer with a 532 nm Nd-YAG laser (system installed at Nagoya University). The result shows that the bedrock of

©2020. Japan Geoscience Union. All Right Reserved.

Kerama Islands suffered 470-525˚C, which is consistent with the temperature range of metamorphic facies proposed in the greenstone.

The depositional age of the protolith of Kerama metamorphic rock is ˜100 Ma, corresponds to that of the northern part of the Shimanto belt. However, metamorphic temperature of the metamorphic rock in Kerama Islands is definitely higher than any reported temperatures in the Shimanto belt. Based on protolith age and metamorphic condition, Kerama metamorphic rock would be correlated to Sanbagawa belt in SW Japan (Itaya *et al.*, 2011; Aoya and Endo, 2017), Nagasaki metamorphic rock (Kouchi *et al.*, 2011), or Tananao schist belt in Taiwan (Chen *et al.*, 2016).

[S-MP39] Oceanic and Continental Subduction Processes

convener:REHMAN Hafiz Ur(Department of Earth and Environmental Sciences, Graduate School of Science and Engineering, Kagoshima University), Tatsuki Tsujimori(Tohoku University), Kazuaki Okamoto(Faculty of Education, Saitama University)

This session aims at bringing earth scientists from Japan and overseas to present their research related to the processes of oceanic and continent subduction, continent-continent collisions, metamorphism of crustal rocks, formation of the oceanic/continental arcs, and accretion/ tectonic erosion of material along subduction boundaries.

Topics such as role of the fore- and back-arcs in the subduction zones, process of accretion of volcaniclastic and terrigenous sediments along the subduction/collision boundaries, deformation and metamorphism of subducted crust, and exhumation will be the main focus of the session.

Exchange of ideas among geoscientists applying different approaches on problems related to the theme of the session are most welcome.

Deeply subducted Jurassic ridge hydrothermal ore deposit -case study from the Sanbagawa eclogite-amphibolite-blueschist-

Yuki Wakabayashi[1], *Yukari Otsuka[1], Kazuaki Okamoto[1]

1. Saitama University

Subduction of cold oceanic plate transports water down to mantle although most amount of water is released by dehydration process. The dehydration reaction and fluid chemistry are fixed by P, T, and redox state. High P/T metamorphic rocks are exhumed from the paleo-subduction zone. Therefore, dehydration process was recorded in the high P/T rocks. The sanbagawa metamorphic rocks suffered high P/T metamorphism at Cretaceous. It is notice that the Besshi-type ore deposit (Volcanogenic massive sulfide) is included in the Sanbagawa metamorphic rocks. origin of the Besshi ore deposit was related to Jurassic global deep-sea hydrothermal activity. Presence of the Bessi-type ore deposit in subducting plate might have controlled the redox state of blueschist-eclogite transformation. Field observation and sample collection were done from eclogite, amphibolite and blueschist outcrops from the Besshi area. In the Besshi area, the metamorphic rocks dips northward in general. Therefore, from north to south, the structural succession is traceable. From the north, metabasite-metachert association overlies the Tonaru eclogite mass, and amphibolite-blueschist succession underlies. The origin of the metabasite-association is ascribed as MORB and deep-sea sediment. Protolith of the Tonaru eclogite is considered as subducted oceanic Island Arc (Aoki et al., 2019). Under the microscope observation these rocks never contain considerable amount of sulfides. Underlying amphibolite and blueschist have mine drifts in each lithologies with certain sulfides. Bulk chemistry suggests that the protoliths are MORB and OIB. It suggests that the Sanbagawa amphibolite-blueschist has brought the ridge hydrothermal material beneath the stacked oceanic Island arc material in deep subduction zone at Cretaceous. Thus, subducted Jurassic-deep-sea-hydrothermal material was stored beneath the stacked Oceanic Island Arc in Cretaceous mantle.

Metasomatic and metamorphic signature of the MORB in the Shimanto belt

*Yuka Mikami[1], Kazuaki Okamoto[1]

1. Saitama University

Subduction and accretion history of Pacific plate is well reconstructed in the orogenic belt in SW Japan (e.g. Maruyama et al.,1997). Shimanto belt is composed of accretion complex from Cretaceous to Tertiary (e.g. Kimura et al.,2013). It distributes from the Kanto to Kyushu area extending over 800 km. Protoliths of the Shimanto belt is mainly composed of terrigenous sandstone and pelitic rocks and minor amount of limestone, chert and basalt. Origin of the Cretaceous basalt has been considered as either in-situ MORB due to ridge-subduction or accreted MORB due to the ridge subduction (e.g. Onishi and Kimura.1995). Recently Nozaki et al. (2018) have shown that the ridge hydrothermal ore deposit is associated the MORB in the Shimanto belt. To testify the extent of the hydrothermal alteration, we investigated the outcrops from Gobo area, in western Kii district. and Makimine area, Nobeoka district. From the Gobo area, the MORB outcrop is included as pillowed basalt in the sandstone mélange. The pillow margin suffered cataclastic deformation with alteration. In the Makimine area, there is a porphyry granite intruding the sandstone, and suffered contact metamorphism. Surrounding layers also suffered mylonitic deformation with metamorphism. Presence of large ring-dike (Okureyama dike) and Miocene granite are considered as overriding accreted margin on the subducting ridge due to back-arc rifting at 15 Ma. Contribution of the melt and heating effect from the hanging wall side of the Nobeoka thrust (the out-of-sequence thrust) might be greater than fluid facilitation of the thrust movement.

New titanite U–Pb age of so-called 'Inishi-type' calcareous rock from the Hida Belt: Constraints on timing of the carbonate–silicate rock interaction during a collision

*Hironobu Harada[1], Tatsuki Tsujimori[1], Shogo Aoki[2], Kazumasa Aoki[2]

1. Tohoku Univesity, 2. Okayama Univerity of Science

Titanite ($CaTiSiO_5$) is a widespread accessory mineral in calcareous gneiss that can contain small amount of uranium in its lattice. Because of relatively high closure temperature of Pb in titanite (~600–700˚C), it has a potential for direct dating of titanite-forming metamorphic reaction using the U–Pb isotopic system. We conducted titanite LA-ICPMS U–Pb dating for so-called 'Inishi-type' calcareous rock from the Hida Belt. The calcareous rock has also known as clinopyroxene-bearing migmatite, which is characterized by the presence of coarse-grained diopside–hedenbergite series clinopyroxene and titanite. It has been thought that the 'Inishi-type' calcareous rock had formed by the interaction between marble and amphibolite that might have occurred at a period of anatexis of lower to middle crust accompanying regional deformation and felsic magma intrusion. The investigated sample is pegmatitic calcareous rock that contains the mineral assemblage plagioclase ($An_{>25}$) + orthoclase + quartz + clinopyroxene + titanite ±calcite. The abundant occurrence of orthoclase suggests an effect of mixing of anatectic melt with a syenitic composition.

LA-ICPMS analyses of coarse-grained titanites show highly variable $^{238}U/^{206}Pb$ ratio (15.0–24.0) and $^{207}Pb/^{206}Pb$ ratio (0.172–0.419). The scattered trend defines an isochron line with a lower intercept at 225.4 ±2 Ma. This age was also supported by U–Pb age (222 ±3 Ma) of metamorphic zircon formed in marble. Our new titanite age is slightly younger than the inferred timing of peak metamorphism of the Hida Belt (~240 Ma). However, the result clearly indicates that 'Inishi-type' calcareous rock was formed by the post-collisional event, possibly anatectic event accompanying intrusion of syenitic magma into the calcareous rock. The timing of these events consistent with the age of post-collisional migmatite and syenite from the Sulu–Dabie ultrahigh-pressure metamorphic belt. Although zircon geochronology is not simple in orthogneiss-dominant polymetamorphosed metamorphic complex like the Hida Belt, titanite U–Pb dating for reaction rock formed via carbonate–silicate rock interaction would be effective to interpret timing of specific event

Stable isotope study of carbonate associated with antigorite serpentinite: O–C isotope characterization of a textually zoned calcite rock from the Itoigawa–Omi area, Japan

*Toshiaki Komata[1], Tatsuki Tsujimori[1], Hideko Takayanagi[1], Yasufumi Iryu[1]

1. Tohoku University

In order to understand carbon behavior in forearc serpentinite, we investigated a textually zoned metasomatic calcite rock associated with antigorite serpentinite of the Non-eclogitic Unit of the Omi area, Japan (Tsujimori, 2004 [doi:10.5575/geosoc.110.591]; Yamada et al., 2019 [doi:10.2465/jmps.190726]). The investigated calcite rock (~ 10 cm in size) occurs in 'blackwall'-like outcrop of chlorite-tremolite rock containing decimeters-size blocks of amphibolite and partially-carbonated antigorite serpentinites. The presence of antigorite and feritchromite in serpentinites and the lack of glaucophanitic amphibole rim in the hornblende of amphibolite suggest that the calcite rock had formed at the amphibolite-facies condition. The calcite-rich rock shows a concentric zoning that subdivided into three layers based on mineral assemblages. In the core part, a pseudomorph consisting of microcrystalline calcites with polycrystalline fine-grained talc aggregates suggest the presence of precursor dolomite. The transition of the mineral assemblage calcite + talc + quartz at the core to the assemblage calcite + talc + tremolite + quartz in the middle layer can be explained by decreasing X_{CO2} and/or increasing temperature.

Despite the zoned texture and the different mineral assemblage, systematic stable carbon and oxygen isotope analyses using by micro-sampling technique found no clear core-to rim change. $\delta^{13}C$ (‰ VPDB) and $\delta^{18}O$ (‰ VSMOW) values are from −5.0 to −4.1‰ (average −4.4‰ [n = 34]) and +15.6 to +16.4‰ (average 16.1‰ [n = 34]), respectively. It is noteworthy that $\delta^{13}C$ of zoned calcite rock is significantly higher than the $\delta^{13}C$ values of graphite (−8.6 to −7.9‰) in jadeitite in the Omi area (Ogawara and Akai, 2014 [doi:10.2465/jmps.131125a]) and also dolomite nodule (−13.4 to −13.6‰; this study) associated with lizardite serpentinite in the Franciscan Complex. Although there are a few possible carbon sources for the calcite rock, the $\delta^{13}C$ close to −5‰ might have reflected a mantle-derived carbon. On the other hand, relatively high $\delta^{18}O$ values suggest that the calcite-rock-forming aqueous fluids were in equilibrium with metasedimentary rocks.

The Miocene Kaikomagatake granitoid pluton in the Izu collision zone, central Japan: its petrogenesis, emplacement depth and exhumation history

*Satoshi SAITO[1]

1. Graduate School of Science and Engineering, Ehime University

The Miocene Kaikomagatake pluton is one of the Neogene granitoid plutons exposed in the Izu collision zone, where the juvenile Izu-Bonin oceanic arc is colliding against the mature Honshu arc. The pluton intrudes discordantly into the Cretaceous to Paleogene Shimanto accretionary complex of the Honshu arc along the Itoigawa-Shizuoka Tectonic Line, which is the collisional boundary between the two arcs. The pluton consists mainly of hornblende–biotite-bearing granodiorites and biotite-bearing granite. Zircon U-Pb age of 13.8 –12.4 Ma were reported (Sueoka et al., 2017), interpreted as the crystallization age of the pluton.

The Kaikomagatake pluton has SiO_2 contents of 68–75 wt%. It has high-K series compositions and its incompatible element abundances are comparable to the average upper continental crust. Major and trace element compositions of the pluton show well defined chemical trends. The trends can be interpreted with a crystal fractionation model involving the removal of plagioclase, biotite, hornblende, quartz, apatite and zircon from a potential parent magma with a composition of ~68 wt% SiO_2. The Sr isotopic compositions, together with the partial melting modeling results, suggest that the parent magma is derived by ~53 % melting of a hybrid lower crustal source comprising ~70 % K-enriched basaltic rocks of the Izu-Bonin arc and ~30 % Shimanto metasedimentary rocks of the Honshu arc. The petrogenetic model of the Kaikomagatake pluton suggests that the contribution of the metasedimentary component is required to produce incompatible element-rich granitoid magma with compositions comparable to the average upper continental crust (Saito et al., 2012).

The emplacement depth of the Kaikomagatake pluton estimated by the Al-in-hornblende geobarometer is ~2.2 –2.4 kbar (Watanabe et al., under revision). Combined with low-temperature thermochronological data reported by Sueoka et al. (2017), the magma emplaced and solidified at the upper to middle crustal depth (~9 –8 km depth) at 14 –12 Ma and is situated at the depth for a period of ~10 million years, and then uplifts rapidly after ~3.3 Ma with the exhumation rate of ~4 mm/year. The early stage of the collision between the Izu-Bonin and the Honshu arcs contributed little to exhumation of the collision zone crust at the Kaikomagatake pluton area.

Whole-rock chemical composition of the granitoids in Ryoke belt, Takanawa Peninsula, northwest Shikoku, southwest Japan

*Kazuya Shimooka[1], Satoshi SAITO[1], Kenichiro Tani[2], Toshiro Takahashi[3]

1. Graduate School of Science and Engineering, Ehime University, 2. National Museum of Nature and Science, 3. Graduate School of Science and Technology, NiigataUniversity

Mesozoic to Early Cenozoic granitic rocks are widely distributed along the Circum-Pacific continental margins. The Cretaceous –Paleogene granitic rocks in southwest Japan are a part of huge igneous belts that developed along the continental margin of East Asia. The granitic rocks in southwest Japan have been divided into three arc-parallel provinces including the Ryoke, San-yo, and San-in Belts based on their lithologies and geochemical characteristics, associated ore deposits, and formation ages (Ishihara, 1971). The Ryoke Belt is the type locality for the low-P/high-T metamorphic facies series defined by Miyashiro (1961), and consists of metamorphic rocks and Cretaceous ‘I-type’ and ilmenite-series granitoids (Takahashi et al., 1980). It has been suggested that a transect from the San-yo to Ryoke Belt represents a crustal cross section of the Cretaceous Asian continental margin down to mid-crustal depths (12–14km), and the Ryoke Belt represents the deep crust (Nakajima, 1994, 1996). Therefore, understanding the petrological processes of granitoid formation in the Ryoke Belt would contribute to understanding deep crustal processes along the continental margin (e.g., Akasaki et al., 2015).

We carried out whole-rock and Sr-Nd isotope analysis of the Ryoke granitoids exposed in the Takanawa Peninsula to indicate their petrological characteristic. Takanawa Peninsula located in northwest Shikoku island, southwest Japan. Multiple granitoids are distributed on the Takanawa Peninsula. The granitoids are mainly comprised of tonalitic rocks, granodioritic rocks, and granitic rocks. These show different SiO_2 content : 61-68 wt% for tonalitic rocks, 67-76 wt% for granodioritic rocks, 70-80 wt% for granitic rocks. And these show multiple trends on Harker diagram. Sr-Nd isotope composition of granitoids shows equivalent contents between SrI: 0.70669-0.70793 and NdI: 0.51217-0.51234. The multiple trends on Harker diagram suggest this area’s granitoids were comprised multiple magma. Similar SrI and NdI contents in granitoids suggest the same source of granitoids. Kagami et al. (1985; 2000) and Kodama et al. (2019) showed mafic rocks around this area had similar SrI (0.70654-0.70657) and NdI (0.51173-0.51241) composition to granitoids. Our results suggest that mafic rocks are a source material of granitoids in Takanawa Peninsula.

Pressure-to-depth conversion models for metamorphic rocks: review and application

*Arthur Bauville[1], Philippe Yamato[2]

1. Center for Mathematical Science and Advanced Technology, JAMSTEC, 2. University of Rennes 1, France

Pressure estimated from metamorphic rocks is one of the main tools for geodynamic reconstructions. The pressure-temperature path of UHP metamorphic rocks typically shows a linear increase of P and T followed by a rapid drop of Pressure at near-constant temperature. The geological history can be reconstructed by using the metamorphic pressure as a proxy for depth. Researchers often base their geodynamic reconstruction on a simple linear mapping of pressure to depth, by considering that the pressure is the weight of the overlying column of rock or lithostatic pressure. In recent years, an increasing corpus of evidence demonstrates that rocks can experience pressures that deviate from the lithostatic state on the order of GPa. These deviations can be at the scale of the orogen (Petrelli and Podladchikov, 2002), the outcrop (Jamtveit et al., 2018; Luisier et al., 2019); or even at the grain-scale (Tajcmanova, 2015). Thus, these studies raise the concern that metamorphic pressures may not be reliable proxies for depth, and therefore could not be used for geodynamic reconstructions. The objective of this contribution (1) to review the various models proposed in the literature for metamorphic pressure, (2) to formulate analytical models with simple assumptions that can be used to convert metamorphic pressure to depth even in the case where pressure deviates significantly from the lithostatic pressure. We use our pressure-to-depth conversion models to estimate the depth of ~60 samples from various orogens worldwide. The prediction of the different models varies widely. Some models predict depth as deep as 160km for specific samples, while other models predict depth <75 km (i.e. deepest depth of the Moho) for all data points. We discuss the limits of applicability and the geodynamic implications of each model.

Late Paleozoic-early Mesozoic magmatism in Delgerkhaan region, Central Mongolia: constraints from the zircon U-Pb age and geochemistry

*Ariuntsetseg Ganbat[1], Tatsuki Tsujimori[1,2], Chimedtseren Anaad[3], Munkhtsengel Baatar[3], Inna Safonova[4,5]

1. Department of Earth Science, Graduate School of Science, Tohoku University, Sendai, Japan, 2. Center for Northeast Asian Studies, Tohoku University, Sendai, Japan, 3. Mongolian University of Science and Technology, Ulaanbaatar, Mongolia , 4. Novosibirsk State University, Novosibirsk, Russia, 5. Sobolev Institute of Geology and Mineralogy, SB RAS, Novosibirsk, Russia

Investigating geochemical characteristics and crystallization age of igneous rocks is necessary to understand their petrogenesis and relation of orogenic belts formed in place of former oceans. The Mongol-Okhotsk orogenic belt is the youngest segment of the world’ s largest Central Asian orogenic belt. It formed by the suturing of the Mongol-Okhotsk Ocean and subsequent collision of the Siberian and North China cratons in late Paleozoic to Mesozoic time. The general geology and numerous intrusions of mafic to felsic igneous rocks younging from west to east along the Mongol-Okhotsk suture suggest that the ocean closed in a scissor-like manner, from the late Carboniferous to the Permian in central Mongolia and/or until the Triassic–early Jurassic in southeastern Transbaikalia. However, the robust time of its closure remains debatable. There are numerous large volcano-plutonic fields of late Paleozoic to late Mesozoic ages distributed over a huge territory from Russian Transbaikalia to northern and central Mongolia. The volcano-plutonic belts host abundant granitoid intrusions, both small to medium size plutons and huge batholiths. We studied igneous rock complexes in the Delgerkhaan region of the Khangay-Khentey turbidite basin, Central Mongolia, in order to understand the tectonic evolution of the western Mongol-Okhotsk belt. The study area hosts several granitoid plutons of diorite, granodiorite, monzodiorite, monzogranite and alkaline granite distinguished as Avdrant, Delgerkhaan and Batkhaan granitoid complexes, which intrude Devonian-Carboniferous sediments of the Khangay-Khentey turbidite basin. The zircons separated from seven representative intrusions have euhedral-subhedral shapes, oscillatory magmatic zoning, and Th/U values of 0.38-1.3, indicating their magmatic origin. The zircons of Batkhaan granitoids (2 samples) yielded U-Pb ages of 274±1 Ma and 282±3 Ma (~ Early Permian). The U-Pb ages of zircons of Delgerkhaan and Avdrant granitoids (5 samples) show the time of their emplacement between 240±3 Ma and 220±1 Ma (~Late-Middle Triassic). Chemically, the Early Permian intrusions and coeval rhyolitic lavas show typical geochemical affinities to A-type granites, i.e. high silica, alkalis and high-field strength elements (HFSE), element (REE) spectra. In tectonic discrimination diagrams, their compositions all plot in the fields of A-type granites. On the contrary, the Late-Middle Triassic intrusions are characterized by a wider range of major oxides matching the normal and high-K subalkaline series and indicating their affinity to I-type granites. In addition, they are enriched in light REE and large ion lithophile elements, depleted in heavy REE and HFSE, and show no or minor negative Eu anomalies. The Late-Middle Triassic intrusions are compositionally similar to igneous rocks formed in an active continental margin setting. According to the previous studies, island arc magmatism and double-sided subduction of the oceanic crust of the Mongol-Okhotsk Ocean started in early Carboniferous time followed by the deposition of the turbidite basin. The A-type geochemical features of the Early Permian granites and rhyolites allow us to conclude that they formed by low-degree partial melting of a crustal source in an extensional setting, which was triggered by slab break-off during subduction of the Mongol-Okhotsk oceanic plate.

[S-MP40] Thermal structure of subduction zones: modeling and the rock record

convener:Simon Richard Wallis(The University of Tokyo), Takayoshi Nagaya(Graduate School of Science, The University of Tokyo), Shoichi Yoshioka(Research Center for Urban Safety and Security, Kobe University)

The thermal structure of subduction zones is key to understanding the origin of magma,
the cycling of rocks and volatiles and the distribution of earthquakes in these regions. In recent years there have been many recent advances in thermal modeling of subduction zones and most are in broad general agreement. However, different approaches and different assumptions about boundary conditions mean that significant differences remain. The rock record of subduction-type metamorphism has the potential to provide useful additional constraints on the conditions of otherwise inaccessible regions. However, with few exceptions this record has not been closely considered in developing models. Recent studies have highlighted differences between the range of subduction conditions preserved in the rock record and those predicted for modeling of modern subduction zones. However, the reasons for such differences are unclear. Key remaining questions are how to improve the consistency between the modeling and rock record, and the most effective use of the rock record to constrain the boundary conditions for modeling. We invite contributions from subduction zone modelers and researchers of subduction-type metamorphic rocks. The aim of this session is to explore how best to combine these two approaches to estimate conditions along subduction zones and to improve our understanding of these geologically important regions.

Brucite as a major phase in the shallow mantle wedge

*Takayoshi Nagaya[1], Simon Richard Wallis[1], Kazuhiro Kawahara[2], Shunsuke Endo[3], Hiroshi Mori[4], Yoshihiro Asahara[5]

1. Graduate School of Science, The University of Tokyo, 2. Japan Oil, Gas and Metals National Corporation, 3. Shimane University, 4. Shinshu University, 5. Nagoya University

The shallow part of the mantle wedge in convergent margins is relatively low temperature and influx of water from the subducting slab will cause peridotite mantle to become serpentinized. If this serpentinization affects olivine-rich mantle and proceeds under low SiO2 activity, brucite can be a major phase where temperatures are <450˚C. However, only very few natural examples have been documented mostly from blocks witin serpentinite diapirs associated with subduction along the Izu-Bonin arc and the proportion and distribution of this mineral in the mantle wedge is not well known. The formation of brucite is generally thought to be suppressed by the supply of silica in excess of that present in olivine, either by the break down of pyroxene or the inflow of SiO2 in aqueous solution. The presence of brucite causes a drastic lowering of the strength of serpentinite even at proportions of a few per cent and determining its distribution and proportion is a key issue in developing physical models for the shallow mantle wedge. The subduction-type Sanbagawa metamorphic belt contains a large number of units derived from the wedge mantle. One of the largest of these units is the Shiraga metaserpentinite body. Brucite is present in two types (brucite I and II) that can be distinguished by their chemical zonation and microstructure. Brucite I shows clear reaction microstructures with antigorite to form olivine. In contrast, brucite II shows no reaction relationships with antigorite and is interpreted as a retrograde product. The original amount of brucite I was estimated based on both thermodynamic modeling combined with bulk rock composition and point counting of constituent minerals combined with metamorphic reactions. The results of the two techniques show the original fully hydrated shallow parts of the Sanbagawa mantle wedge contained ~10–15 vol.% brucite before the onset of exhumation of the Shiraga body and before peak metamorphic conditions. A distinct zone of brucite-free essentially monomineralic antigorite serpentinite occurs limited to a 100-m thick marginal zone of the body. This indicates a limited degree of Si-metasomatism by slab-derived fluids in the shallow mantle wedge. The presence of brucite may strongly affect the H2O budget and mechanical properties of serpentinite, these should be taken into consideration when examining the behavior of the shallow mantle wedge.

Development of high fluid pressure at the base of the shallow mantle wedge due to presence of an antigorite shear zone

*Simon Richard Wallis[1], Mari Yokota[1,2]

1. The University of Tokyo, 2. Nagoya University

Deep slow earthquakes in subduction zones are concentrated at the base of the wedge mantle, but the reasons for this relationship are not well understood. High fluid pressures are thought to be an essential component of slow earthquakes, enabling slip at low shear stresses characteristic of slow earthquakes and compatible with recorded high vp/vs ratios. One of the prerequisites for high fluid pressure is the presence of a cap rock that can trap fluid in a limited region. Quartz precipitated from slab-derived fluids has been proposed as important component to forming cap rocks at the base of the overriding crust. However, quartz is not stable in the mantle wedge and in this region a different mechanism is required. In the cool mantle wedge, the addition of SiO2 through the influx of aqueous fluids will cause the development of serpentine and the presence of this serpentine may also affect the permeability. Experimental evidence shows foliated antigorite serpentinite has a strong permeability anisotropy with very slow flow perpendicular to the foliation. A laterally continuous layer of foliated antigorite serpentinite could act as a cap rock but its presence is not widely recognized. The subduction-type Sanbagawa metamorphic belt preserves numerous blocks of former mantle wedge and the boundary with the surrounding slab-derived schists represents the paleo subduction boundary. Units that formed at depths of ~35-45 km similar to that shown by deep slow earthquakes show a 100 m-wide strongly-foliated zone of antigorite schist followed by narrow zone of actinolite and talc-bearing lithologies along the boundary with slab-derived metapelite. A estimate of the amount of fluid flow can be derived by using the amount of added silica needed to make the serpentinite compared to the original mantle lithology and the solubility of SiO2 at the recorded metamorphic temperatures. These calculations show good agreement with estimates based on modelling of slab dehydration reactions. A comparison with experimentally determined fluid permeability suggests that the presence of an antigorite shear zone will cause high fluid pressures to develop at around 35-45 km depth. The presence of an antigorite shear zone along the base of the mantle wedge may control the depth of deep slow earthquakes.

Mineralogy and structure of the shallow mantle wedge: evidence from seismic anisotropy in the Ryukyu Arc and structural petrological studies

*Takayoshi Nagaya[1], Simon Richard Wallis[1], Andrew Walker[2], James Wookey[3], Kazuhiko Ishii[4], Michael Kendall[5]

1. Graduate School of Science, The University of Tokyo, 2. University of Leeds, 3. University of Bristol, 4. Osaka Prefecture University, 5. University of Oxford

The dynamics of hydrated mantle in subduction zones is a key part of understanding recycling of materials from the Earth’ s surface into the deep interior. Antigorite is the main hydrous phase in the forearc mantle and the amount, distribution and alignment of antigorite are essential to understanding anisotropy, strength and fluid transport in this region. Seismic velocities are commonly used to identify antigorite-rich domains. However, antigorite is highly-anisotropic and depending on the seismic ray path, its properties can be very difficult to distinguish from non-hydrated olivine-rich mantle. Here, we utilize this anisotropy and show how an analysis of seismic anisotropy that incorporates measured ray path geometries in the Ryukyu arc can constrain the distribution, orientation and amount of antigorite. The Ryukyu arc is associated with very large s-wave splitting of around 1 s for both local slab and teleseismic events. These observations show the main source of anisotropy is within the mantle wedge. The size of the mantle wedge is insufficient to account for the large delay times by olivine alone and several previous workers have suggested that presence of aligned antigorite is the main cause of the anisotropy. We show that to account for the large delay times requires the presence of foliated antigorite-rich domains with an alignment that changes from vertical to slab-parallel. This orientation change suggests the presence of convective flow in the hydrated forearc mantle, a new insight into this zone that is traditionally considered to rigid block. Our modelling also allows quantitative estimates of the amount and distribution of the antigorite in the forearc. These estimates incorporate various sources of uncertainty including: variations in strength of natural antigorite CPO patterns, the degree of anisotropy caused by the crust, differences due to the method used to estimate seismic anisotropy from rock texture, and the model used to estimate anisotropy from the recorded seismicity. We find more than 54 % of the wedge must consist of antigorite. In addition, shear wave splitting analysis in several other subduction zones indicates large-scale serpentinization and forearc mantle convection are likely to be more widespread than generally recognized.

Low-pressure type metamorphic rocks from No-jima Island, Yamaguchi Prefecture

*ZEJIN LU[1]

1. Graduate School of Science and Engineering for Innovation, Yamaguchi University

No-jima island is located in the Seto Inland Sea, Yamaguchi Prefecture. It is a region that underwent Cretaceous low-pressure type regional metamorphism (Ryoke metamorphism). No-jima island is underlain by crystalline schists and metabasalts. Metabasalts show the geochemical character similar to the within plate basalts, for instance the green stones in the Mino-Tamba belt. Moreover, the metamorphic grade of the schists corresponds to the biotite zone of the Yanai region of the Ryoke belt, but the petrological character of the rocks from No-jima island has been unclear. In addition, the geological correlation with the neighboring area, Kasado-jima island, the Oshima peninsula, and Ohtsu-jima island has not been understood yet. Therefore, the aim of this study, based on the mineral paragenesis of the pelitic schists, is to discuss the metamorphism of the rocks from No-jima island, and also to unravel the thermal structure of the low-pressure type metamorphism, the Ryoke belt, in this region.

The metabasalts are mainly exposed on the northeastern part of the island but occur rarely in the west coast of the island. They are included in the schists of sedimentary origin as blocks. The metamorphic rocks are composed mainly of the pelitic schist and metamorphosed chert with bedded structure (siliceous schist hereafter) with trace amounts of calc-silicate schist as thin layers or lenses. The pelitic and siliceous schists are intermittently distributed on the western and southeastern coast of the island. Fold structures such as close folds often develop in the southern part of the island. Granite dikes with 1–2 m width intrude the schists on the western coast.

The metabasalt is porous and has a prominent pillow structure and often shows the amygdaloidal texture. Phenocryst minerals of igneous origin are of clinopyoroxene and plagioclase with minor amounts of amphibole. It contains recrystallized fibrous amphiboles partially coexisting with biotite. Calcite locally fill the amygdules and occurs as veins. The pelitic and siliceous schists show the repidoblastic texture, and are composed of Bt+Ms+Pl+Qtz±Grt±Chl. The pelitic schist locally involves Crd. The calc-silicate schist is composed of Bt+Cal+Qtz. The mineral assemblage of the pelitic schists changes from north to south of the island; Bt+Ms+Chl+Pl+Qtz in the north and Bt+Ms+Grt+Pl+Chl+Qtz±Kfs in the south. On the other hand, the mineral assemblage of siliceous schist is mainly Ms+Bt+Grt+Pl+Qtz. The island can, therefore, be divided into the biotite zone in north and the garnet zone in south in terms of the mineral paragenesis of the pelitic schists.

The chemical compositions of garnet from the pelitic and siliceous schists show XFe > XMn and XFe < XMn, respectively. The XMg values of the pelitic and siliceous schists are less than 0.035. The XCa values of the pelitic and siliceous schists are of less than 0.05 and more than 0.1, respectively. The garnet of pelitic schist and siliceous schist shows a normal zoning with reduced spessartine toward the rim, probably formed during prograde metamorphism. The geothermobarometers for garnet-biotite (Ferry and Spear, 1978) and garnet-pagioclase-biotite-quartz (Hoish, 1990) are adapted to the pelitic schist. As a result, the peak metamorphic temperature and pressure conditions are estimated to be 480–530 ℃ and 180–300 MPa, respectively. According to the result, the thermal structures around the Seto Inland Sea region are discussed.

[S-VC41] Timescales of magmatism: from genesis to eruption

convener:Chamberlain Katy Jane(University of Derby), Iona McIntosh(Japan Agency for Marine-Earth Science and Technology), Kenichiro Tani(Department of Geology and Paleontology, National Museum of Nature and Science), Akihiko Tomiya(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology)

Magmatic processes are known to operate across a range of timescales: from thousands to millions of years' residence and evolution within a magmatic plumbing system, through to the hours to minutes prior to eruption. Understanding the timescales of these magmatic processes, including accumulation, ascent, eruption, and final cessation of activity is vital for interpreting and responding to future magmatic activity. Together with thorough dating of deposits that reveal timing and frequency of past eruptions, this knowledge provides the foundation for improved hazard management in volcanic regions. By using a range of petrological, geophysical, geochemical and geochronological tools, increasingly detailed timescale constraints can be placed on past eruptive episodes.

In this session we invite submissions that examine magmatism and volcanism across a variety of timescales; from residence and rejuvenation within the crustal column, to eruptive triggering mechanisms and syn-eruptive processes, and their relation to the long-term timing and frequency of repeated activity.

Ocean island volcanoes which erupt effusively and explosively, with magmatic compositions ranging from basalt to rhyolite present challenging environments for forecasting of future eruptive activity. Ascension Island, in the south Atlantic, is one of these ocean island volcanoes, with a ~1 million year history of subaerial eruptive activity [1], but with the most recent eruption occurring only ~500 years ago [2]. Studies of the range of compositions erupted from Ascension Island have highlighted the importance of relatively closed-system fractional crystallisation in generating the evolved melts erupted, with low magmatic fluxes assigned to being responsible for clear spatial separation of mafic and felsic magmas at the surface [3]. Yet, identification of a mingled eruption has potential to further understand the origins of felsic melts at Ascension Island, and to provide greater constraints both on crustal structure and ascent rates of magmas.

In this contribution we present field observations, whole rock geochemical data, in situ mineral and melt inclusions analyses and textural characterisation of this unique mingled fall deposit from Ascension Island. This data is used to test the importance of fractional crystallisation vs. anatexis in generating the rhyolitic end-member of the mingled fall deposit, given that high water concentrations in melt inclusions are suggestive of formation at or near the Moho. Petrological data are used to infer multiple magmatic origins for the crystals. Glass and crystal compositional data is combined with textural observations to infer relatively short mingling to eruption timescales, on the order of days. The location of magma storage regions, and potential unrest timescales are particularly important on the populated Ascension Island where the nearest inhabited land mass is 1600 km away.

The August 2019 Eruption of Volcano 0403-091: timescales of pumice raft formation and evolution during dispersal

*Iona McIntosh[1], Isobel Yeo[2], Scott Bryan[3], Matthew Dunbabin[3], Kenichiro Tani[4], Patrick Collins[5]

1. Japan Agency for Marine-Earth Science and Technology, 2. National Oceanography Centre Southampton, UK, 3. Queensland University of Technology, Australia, 4. National Museum of Nature and Science, Japan, 5. Queens University Belfast, UK

A new eruption of Volcano 0403-091 (30 km NW of Vava’u, northern Tonga) occurred without warning on the 7th August 2019 following 18 years of dormancy. The eruption produced a >200 km2 pumice raft that was intercepted by two boats, causing navigational problems and hull abrasion. Rafts pose a range of potential hazards for marine traffic and infrastructure, yet their formation processes and evolution during dispersal are poorly understood. The 7th August raft was imaged by satellites almost daily, so its source and path are well-constrained. This eruption therefore provides a unique opportunity to sample both rafted pumice with known float times and sunken pumice at the vent, as well as a rare chance to study vent structure, hydrothermal activity and marine life interactions immediately following an explosive, shallow marine eruption.

Here we present the first results from a rapid response survey of the submarine vent site, conducted 6 months after the eruption. The vent was investigated using a small Remotely Operated Vehicle (ROV), a small Autonomous Underwater Vehicle (AUV) and a surface glider, alongside a grab sampler and mini-dredge designed for operation from a small vessel. Video transects, bathymetry and sampling together enable characterisation of the seafloor eruption products, post-eruptive vent morphology, and the recovery of seafloor ecosystems 6 months after an explosive shallow submarine volcanic eruption.

In addition, we compare the proximal seafloor deposits with a suite of samples from the floating pumice raft that experienced different float times, enabling us to compare the change in physical characteristics of pumice during its lifetime in the raft. These samples include pumice collected by a boat that intersected the raft shortly after eruption (floated for 1 week), and pumice subsequently collected from the shores of some Fijian Islands (floated for > 1 month). Physical, geochemical and textural (including high resolution X-ray computed tomography) analyses of these different pumice types from a single well-constrained eruption will help to determine the controls on pumice raft formation and their potential hazards for marine shipping and infrastructure.

Magma plumbing system at Zao volcano, NE Japan: time scales of magmatic processes revealed by chemical zoning in orthopyroxene phenocrysts

*Motohiro Sato[1], Masao Ban[1]

1. Graduate School of Science and Technology, Yamagata University

[Introduction]

Understanding of magma plumbing system is fundamentally the most important issue for the volcanic disasters mitigation. The youngest activity of Zao volcano (NE Japan) repeated phreato-magmatic eruptions in "Okama crater" (ca. AD1200 to present) and precursory phenomena, such as volcanic tremors and earthquakes has been observed since 2013. Recent advance of volcanic petrology allows us to reveal the magma plumbing system more in detail. The detailed analysis of textures and chemical zoning of phenocrystic minerals can provide useful information of the magma pluming system. Moreover, using the elemental diffusion chronometry applied to compositionally zoned crystals, we can know the time scales of complex magma dynamics. Here, we present and discuss pre-eruptive processes of Okama crater eruption products (Okp) by using zoning profiles of orthopyroxene phenocrysts.

[Mineral compositions and end-member magmas]

Juvenile bomb samples are medium-K and calc-alkaline series basaltic andesite to andesite (56-57% SiO2), including plagioclase, orthopyroxene, clinopyroxene and magnetite as phenocryst. Plagioclase phenocrysts show wide range of compositions between $An_{60\text{-}92}$ and broad peaks were identified ($An_{65, 75, 88}$). Orthopyroxene compositions range between 56-76 Mg# with two peaks (66, 74 Mg#). Clinopyroxene compositions range between 63-77 Mg# with a single peak (68 Mg#). These various crystals are made by magma mixing between low-T end-member magma (L-magma) with low An and Mg#, and high-T end-member magma (H-magma) with high An and Mg#. Physicochemical conditions of end-member magmas were constrained by using the rhyolite-MELTS algorithm. The optimum conditions for each end-member magmas are as follows, H-magma: >76 Mg#, 52-53% SiO_2, >1040˚C, 200-250 MPa, 5.0% H_2O, and L-magma: 64-66 Mg#, 60% SiO_2, 950-970˚C, 200 MPa, 3.0% H_2O.

[Zoning profiles of orthopyroxene phenocrysts]

The opx phenocrysts can be divided low-(opx-A, 64-66 Mg#), high- (opx-B, >72 Mg#), and extremely low-(opx-A’, <63 Mg#) Mg types based on core composition. Based on compositional zoning of rim (inside from outermost rim), opx-A are subdivided into -A1 to -A4. A1 show no zoning, while A2 to A4 have Mg rich rims (>70 Mg#). In the Mg rich rim, Al is high, but Cr is low in A2, Al and Cr are high in A-3, and Al and Cr are low in A4. Type B is subdivided into B1, which has normal zoned rim, and B2, which shows skeletal texture. Core compositions of opx-A are equilibrium in L-magma, and reverse zoned rim compositions of opx-A3 and core compositions of opx-B1 and -B2 are in equilibrium with H-magma. Outermost rims (66-67 Mg#, almost high-Al content) are observed in many of the phenocrysts, which were formed in the mixed magma. The composition of the mixed magma is estimated to be similar to that of the groundmass.

[Mixing processes and the time scales]

Based on above zoning profiles of Mg#, Al, and Cr in orthopyroxene phenocrysts, low-T and modified high-T magmas mixing is recognized other than low- and high-T magmas mixing. The modified high-T magma (Mm magma) was formed by incorporation of the mixed magma into the high-T magma when the

©2020. Japan Geoscience Union. All Right Reserved.

latter injected into the former. We estimated the residence time of both cases of mixing by Fe-Mg diffusion modeling applied to the Mg# zoning of orthopyroxene phenocrysts. The estimated timescales are mostly a few decades for low- and high-T magma mixing and a few days to decades for low-T and the Mm magma mixing.

The pre-eruptive processes of the Okp are proceeded as follows. The injection of the high-T magma and mixed with the low-T magma (a few decades before the eruption), resulted in the formation of the mixed magma. The injection of the high-T magma into the mixed magma formed the Mm magma tentatively, that mixed with the L-magma (a few decades to a few days before the eruption).

Discovery of Quaternary volcanism in southern Sakhalin

*Kenichiro Tani[1], Hiroshi Kawabata[2], Osamu Ishizuka[3], Takashi Sano[1], Alexey Yu. Martynov[4]

1. National Museum of Nature and Science, 2. Kochi University, 3. Geological Survey of Japan/AIST, 4. Far East Geological Institute, Russian Academy of Sciences

Cenozoic tectono-magmatic processes in the western Pacific margins and their precise timings are critical in comprehending the behaviors of the Pacific Plate motion and associated back-arc basin formation, such as those in the Philippine Sea Plate and the Eurasia margin during formation of the Sea of Japan.

Compared to the other parts of the western Pacific region, records of magmatism in the northwestern Pacific margin, including those in Sakhalin and Kamchatka, Russian Far East, are still not well studied.

The southern part of Sakhalin sporadically exposes Oligocene (~30 Ma) to Miocene (~5 Ma) basaltic to andesitic lavas and dikes along the western coast (Okamura et al., 1998; Shimazu et al., 1992; Takeuchi, 1997). Geochemical studies have suggested a change in magma generation occurred from older Oligocene-Miocene arc magmatism to younger Mid-Late Miocene alkaline and subalkaline intraplate-magmatism (Okamura et al., 2005). The largest occurrence of volcanic rocks in Sakhalin is in the Lamanon area, where basaltic lava and volcanic breccia are exposed in a wide (~40 km E-W and ~60 km N-S) zone. Furthermore, the Lamanon area is characterized by the presence of more than ten conspicuous cones, varying in size from ~1 to ~5 km in diameter. Erokhoev and Shilov (1971) documented one of the cones, Mt. Ichara, located at the western end, to be a dacite lava dome. But due to their difficult accessibility, no further research has been conducted on these cones.

We conducted a reconnaissance survey of the Lamanon cones in 2017, visiting three of the cones, Mts. Ichara, Krutaya, and Krasnova. Our survey confirmed that all of the cones are mono-lithologic, dacite lava dome. A recovered sample yielded a Pleistocene (<1 Ma) Ar-Ar plateau age, indicating the occurrence of Quaternary volcanism in Sakhalin for the first time. Furthermore, the whole-rock compositions of the Lamanon dacites show elevated Sr/Y ratios, and enrichment in Mg and Ni, which are consistent with geochemical affinities similar to those of adakite.

Since the slab depth of the Pacific Plate beneath the Lamanon area is deeper than 600 km, it is unlikely that dacite magma generation was related to the subducting slab. Instead, given that the Lamanon area is located at the northeastern continuation of the rift system within the Sea of Japan, we propose that deep crustal melting associated with the rifting may have generated the dacite magma.

Timescales of magmatic processes related to the AD 2000 eruptions at Miyakejima, Japan

*Chris Conway[1], Nobuo Geshi[1], Yumiko Harigane[1], Genji Saito[1], Akihiko Tomiya[1]

1. Geological Survey of Japan

Integrating the petrological and geophysical records of magmatism is necessary to improve our understanding of the types and timescales of processes that precede volcanic eruptions. Studies of recent eruptions in Japan provide opportunities for this improvement, due to the high-resolution network of monitoring equipment installed for active volcanoes. We present results from a diffusion chronometry case study of pyroclasts from an explosive eruption at Miyakejima on 18 August, 2000. Previous petrological studies have shown that this eruptive event was preceded by magma mixing, which makes it a suitable candidate for testing whether the timescales determined from crystal zoning patterns can aid the interpretation of geophysical data.
Timescales for magma mixing were calculated by modelling diffusion profiles in normally zoned olivine crystals, which record a late-stage magma hybridization event. Mineral chemistry and orientation data were collected by electron probe microanalysis (EPMA) and electron backscatter diffraction (EBSD) techniques, respectively. Utilization of multiple elements and correction for diffusion anisotropy ensured that the calculated timescales incorporated recent methodology developments in this field. The new and existing petrological constraints were compared with the time series of monitoring data during the eruptive episode. These comparisons highlight the difficulty of definitively attributing geophysical signals to magma recharge events where complex volcano-magmatic processes occur.

Boninite ascent rates constrained using chromite crystal chemistry: Observations of experimental products applied to the extrusive sequence of the Troodos Ophiolite

*Daniel Coulthard[1], Georg F Zellmer[1], Sebastien Jego[2], Akihiko Tomiya[3]

1. Volcanic Risk Solutions, Massey University, Palmerston North, New Zealand, 2. Institut des Sciences de la Terre d'Orleans, Centre National de la Recherche Scientifique, Universite d'Orleans, Orleans, France, 3. Geological Survey of Japan, Advanced Institute of Science and Technology, Tsukuba, Japan

Boninites are rare high magnesium andesites that often contain trace chromites that form early. These melts continue to crystallize a significant volume of silicate minerals. Magmatic differentiation drives chromite out of equilibrium with the residual melt with respect to both divalent and trivalent cation proportions. To simulate this process, we have performed internally heated pressure vessel experiments, providing insights into the processes of crystal-melt re-equilibration through time. While Fe-Mg exchange equilibrates the tetrahedrally coordinated divalent cations in chromite in < 6 hours, equilibration of trivalent cations in octahedral coordination with residual melts is slow. Our experimental results show chromite Al concentrations are ubiquitously lower, and Fe^{2+}/Fe^{3+} values are ubiquitously higher than modelled equilibrium values, indicating that there was insufficient time for significant Al and Fe^{3+} incorporation to occur at the expense of Cr. Similar observations can be made for natural chromite compositions in the extrusive sequence of the Troodos ophiolite. Based on a simple model of diffusive equilibration, we estimate that the core of a microphenocrystic chromite 60 μm in diameter (size of natural microphenocrysts: 50-500 μm; Cameron, 1985) may take up to 500 years to equilibrate under conditions analogous to the physiochemical state of melt at the time of eruption. For the extrusive sequence, this implies an ascent rate of boninites greater than 16 m/year for disequilibrium textures and compositions to be preserved.

Novel approach for olivine-hosted melt inclusion corrections and its application to northern Japan tephras.

*Raimundo Brahm[1], Georg F Zellmer[1], Takeshi Kuritani[2], Naoya Sakamoto[3], Daniel Coulthard[1], Mitsuhiro Nakagawa[2], Eiichi Sato[4], Hisayoshi Yurimoto[3]

1. VRS, Massey Univ., 2. Grad. School of Sc., Hokkaido Univ., 3. IIL, CRI, Hokkaido Univ., 4. Hokkaido Univ. of Educ.

Olivine-hosted melt inclusions (MIs) are widely used as a tool to study the early stages of magmatic evolution. There are a series of processes after MI trapping that affect MI composition, including post-entrapment crystallization (PEC) of the host mineral at the MI boundaries, exsolution of volatile phases into a “shrinkage bubble” and diffusive exchange between the MI and his host. Classical correction schemes applied to olivine-hosted MIs include PEC correction through addition of olivine back to the melt until it reaches equilibrium with the host composition and “Fe-loss” correction for Fe-Mg diffusive exchange as described by Danyushevsky et al. (2000). These two corrections rely on the assumption that the original host composition is preserved. Usually, studies focus on high forsterite melt inclusion (>Fo80), where the degree of correction is small and the olivine host composition is assumed to be preserved.

In this study we develop a novel MI correction scheme that is applicable to more evolved (< Fo80) melt inclusions where the original host crystal composition has not been preserved. The new scheme allows correction of MI compositions from antecrystic hosts with long and varied temperature histories. The correction relies on fitting a set of MIs compositions to modelled liquid lines of descent (LLD) through fractional crystallization (FC). A Matlab® script iterates FC simulations using alphaMELTS (Asimow and Ghiorso, 1998; Ghiorso and Sack, 1995) starting from the most primitive MI composition of a set. A grid of initial conditions with variable P, H_2O, fO_2, olivine addition and MgO/FeO_t of the first MI are selected to simulate the possible magmatic conditions and the effects of PEC and Fe-Mg exchange on the first MI.

After the generation of the FC simulations, each MI is fitted to the modelled LLDs by addition of olivine to the MI composition. The best fit for each MI is obtained by minimizing the compositional distance between the corrected MI and the LLD. We use the definition of the Aitchison distance for a compositional space geometry (Aitchison, 1986) to quantitively compare similarity between two compositions. The combination of the minimum Aitchison distance of the set of melt inclusion to each LLD is a measure of “good of fitness” of each FC model to the corrected set of MI compositions. Statistical analysis of the models shows that the best fit results for basic MI compositions converges on a particular mineral proportion of the FC path (olivine:pyroxene:plagioclase).

Application of this methodology to MI sets provides estimations of original compositions and magmatic conditions during MI entrapment. Two sets of MIs hosted in olivine antecrysts (Fo76-78) from basaltic tephras from Hakkoda and Akita-Komagatake volcanoes were processed using this methodology. Hakkoda MIs are enriched in Fe compared to whole rock trends, caused by Fe-gain through diffusive equilibration during storage, whereas most MIs in the Akita sample loss suffered of Fe during storage. Using the new correction methodology, we estimate that crystallization of the host crystals in Hakkoda occurred at <1.5 kb and c. 1.5 H_2O wt%, whereas in Akita it occurred at <1.0 kb and c. 1.0 H_2O wt%.

[S-VC42] Dynamics of volcanic eruptions and their physical and chemical processes

convener:Atsuko Namiki(Graduate School of Integrated Arts and Sciences, Hiroshima University), Christian Huber(Brown University), Michael Manga(University of California Berkeley), Yujiro Suzuki(Earthquake Research Institute, The University of Tokyo)

A Volcanic eruption is a hazardous phenomenon that results from a sequence of coupled processes, including storage in the subsurface and ascent to the surface. The volcanic gas exsolving from the ascending magma generates bubbles, which influence both the potential energy of the magma (density) and its resistance to flow (viscosity). Bubbles can sometimes deform and/or fragment the surrounding magma, leading up to explosive eruptions that develop volcanic plumes and/or pyroclastic flows. A broad range of approaches is required to tackle these processes and better understand the factors that govern the physics of explosive eruptions. We welcome contributions from interdisciplinary approaches, including, geophysical observations of active/quiet volcanoes, geochemical measurements of eruptive products, theoretical approaches, and numerical simulations, and laboratory experiments designed to explore the fundamental processes underlying explosive volcanism.

A Model Experiment of Fracture Induced Long-Period Events: Injection of Pressurized Gas Into a Viscoelastic Rock Analog

*Atsuko Namiki[1], Makoto Takahashi[1], Ryo Tsutsui[1]

1. School of Integrated Arts and Sciences, Hiroshima University

Low-frequency seismic waves are frequently observed in volcanic areas. To understand the source mechanism of such low-frequency signals, we conducted model experiments simulating the volcanic gas injection into a rock. The rocks heated by the ascending magma and hydrothermal fluid may be very hot and damaged, such that their shear wave velocities are low. Similarly, solidifying magmas should have a low shear wave velocity. Our experiments show that the injection of pressurized air into such soft rocks creates multiple cracks and causes pulse-like seismic signals. When the rock analog is further softened, only high-frequency oscillation appears. These results suggest that the low-frequency component observed in the volcanic area before the initiation of eruptions may be the result of crack generation.

Multi-parameter observations at Shikabe geyser and unique changes in interval between eruptions

*Ayuta Tsuge[1], Hiroshi Aoyama[1], Masayoshi Ichiyanagi[1]

1. Institute of Seismology and Volcanology, Faculty of Science, Hokkaido University

Geyser is a hot spring characterized by periodical spouting of superheated water together with steams or non-condensed gases. Since the physical processes of eruption of steam and hot water are similar to those of volcanic eruption, geysers have been studied as an analogy of volcanic eruption.

One of the major features of geyser phenomena is Interval between eruptions (IBE). IBEs are different for each geyser and have a wide range from a few minutes to several hours. Furthermore, a geyser sometimes has more than one constant IBE. For example, El Cobreloa geyser in El Tatio, Chile, repeats several small eruptions approximately every 14 minutes and followed by large eruptions lasting about one hour with a repeating period of about four hours (Namiki et al., 2014), and some geysers in Yellowstone National Park, United States, have changed the IBEs for long periods, which seem to be influenced by precipitation and river discharge (Hurwitz et al., 2008). However, there are few quantitative studies focusing on the mechanism of such IBE changes.

The Shikabe geyser in southern Hokkaido was discovered through the development of hot springs in 1952. It is a large geyser erupting more than 10m and haves a relatively short IBE about 12 minutes After the field experiments conducted by Otani in 1961 (Otani, 1961), any physical observation had not been carried out to this day although the eruption characteristics, such as IBE, eruption height and discharge volume, might have changed since then. Therefore, in this study we started multi-parameter observations using some physical monitoring instruments at the Shikabe geyser in order to obtain new knowledge on the phenomena associated with the geyser eruption and to understand the mechanism of IBE change. Since IBE of the Shikabe geyser is about 12 minutes, we can collect a lot of field data of spouting events. Moreover, an iron pipe conduit of a known diameter might be an advantage to constrain the geyser’s geometry.

The monitoring contents are video camera, thermal infrared camera, micro-barometer, acoustic sensor, tiltmeter, seismometer, and thermometer. The acoustic sensor and micro-barometer were placed at the same position about 4m from the vent, and the seismometer and tiltmeter were placed at the same position about 6m from the vent. The thermometer has a sensor attached to the vent and measures the temperature of the water when the hot water overflows from the nozzle. Observation started on November 25, 2019, and continuous data recording were made on five instruments except video camera and thermal infrared camera.

©2020. Japan Geoscience Union. All Right Reserved.

We confirmed regular pattern of signals corresponding to eruption and quiescence in the observed data. Micro barogram and acoustic signal show high frequency waves associated with eruption. Temperature signal captured successfully the timing of overflow and recorded the maximum temperature of hot water higher than 100℃. The seismogram contains a quite high frequency component associated with eruption. However, since it greatly exceeds the frequency band widely reported in the observation of volcanoes and geysers, we must check the seismic data carefully. The ground tilt in the transverse direction indicates changes clearly that seem to correspond to inflation and deflation of the reservoir. However, no clear change was observed in the radial direction, which suggests that the aquifer may have a complex geometry.

Our data show that IBE of the Shikabe geyser was not always constant but rather showing characteristic change in time. The average of IBE is about 12 to 13 minutes. IBE sometimes becomes 2-3 minutes longer than the mean interval, and the next IBE is certainly about 1 minutes shorter than the average. Compering the long IBE event with short one, both the quiescence period and the discharge period in one eruption cycle were long in the long IBE event, while both were short in the short one. The occurrence frequency of this characteristic IBE change varies day by day. As a next step, we would like to discuss the cause of this IBE change quantitatively, taking its relationship with weather conditions into account.

A new model of buoyancy-driven bubble coalescence with deformation effect

*Takafumi Maruishi[1], Atsushi Toramaru[2]

1. Department of Earth and Planetary Sciences, Graduate School of Sciences, Kyushu University, 2. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University

In low viscosity magma like basalts, a buoyant force can no longer be ignored. Bubbles move upward by buoyant force and approach each other. They coalesce when approached sufficiently and become larger. The large bubbles move upward quickly and release their gas contents to the surface. It relates to episodic activities observed in Hawaiian and Strombolian eruptions.

Moving bubbles drive flow around them and make near bubbles deform. In Manga and Stone (1995), they reported that the deformed bubbles attract near bubbles due to their hydrodynamic interaction. The attracting effect significantly changes coalescence dynamics but there are no theoretical models to predict their behavior.

Firstly, we drive equations describing bubble trajectory based on the theory which deals with two-body interaction taking bubble deformation into account. The equations allow us to calculate the relative movement of two bubbles. We assume that the liquid surrounding bubbles is viscous fluid and the deformation of the bubbles is small enough.

Relative trajectory is controlled by two dimensionless parameters, bond number (the ratio of viscous force driven by buoyancy and surface tension) and the size ratio of the two bubbles. The viscosity of the liquid effect only changes the time scale but doesn’t change the coalescence behavior. The calculation by the equations can reproduce the two-bubble trajectories reported in Manga and Stone (1995). Almost the same equations have already been derived and solved in the same paper but contain some errors and failed to reproduce the experimental data.

Secondly, we determine the critical conditions whether two bubbles coalesce or not. We have the critical initial separation as a function of bond number and size ratio of two bubbles. Coalescence efficiency is directly calculated from the critical separation. We compare the results of our calculation with experimental data in which coalescence efficiency in terms of critical separation of as a function of size ratio (Kushner et al., 2001; Manga and Stone, 1995). Coalescence efficiency increases linearly with bond number and reaches a constant value. This is caused by effective deformation for the large bond number. Our results agree well with the experiments. For small bond number (small bubble size), the coalescence efficiency decreases with increasing the size contrast. For large bond number (large bubble size), the calculation gives larger efficiency than the experimental data. The discrepancy is because of a limit of the approximation. The coalescence efficiency nearly constants for the large bond number in the experiments. So, we can treat efficiency as a constant for large bond number.

Our simple model can reproduce such a complex attracting behavior reported in the previous experiments. With our new method, we can calculate the evolution of bubble size distribution including bubble coalescence driven by buoyancy. It is noteworthy that the bubble interaction with the deformation effect show quite different behavior from rigid spheres case. For instance, the coalescence efficiency for the larger bubbles (larger than 5mm in silicate melts) considerably 10 times larger than rigid spheres case.

Experimental validation of a two-layer model for pyroclastic density currents

*Hiroyuki A. Shimizu[1], Takehiro Koyaguchi[2], Yujiro J. Suzuki[2], Brosch Ermanno[3], Gert Lube[3]

1. National Research Institute for Earth Science and Disaster Resilience, 2. Earthquake Research Institute, The University of Tokyo, 3. Massey University

During explosive volcanic eruptions, a hot mixture of volcanic particles and gas is ejected from the volcanic vent and can flow along the ground surface as a pyroclastic density current (PDC). A PDC is generally characterized by a strong density stratification; it is composed of a dilute current (particle volume fractions $\Phi < 10^{-2}$) over a dense basal current ($\Phi \sim 10^{-1}$). The dynamics of such strongly stratified PDCs can be investigated by a two-layer depth-averaged model (Shimizu et al., 2019, J. Volcanol. Geotherm. Res., 381, 168-184). In this study, we have validated our two-layer model by comparison with two experiments: (1) the pyroclastic-flow eruption large-scale experiment (PELE; Lube et al., 2015, J. Geophys. Res., 120, 1487-1502) and (2) a granular-flow experiment (GFE; Girolami et al., 2008, J. Geophys. Res., 113, B02202).

In the PELE, an experimental current is generated by the controlled gravitational collapse of a hot aerated suspension of particles and air from an elevated hopper into an instrumented inclined channel. A well-defined dataset has been newly obtained from the PELE for the purpose of validation and benchmarking. In the experiment, a strongly stratified current (consisting of a dilute turbulent suspension flow and a basal bedload region) flowed into the inclined channel and the distal horizontal channel, and it produced the deposits by progressive aggradation of particles at the base during flowing. Numerical simulations using our two-layer model were conducted under the same condition of the experiment. The numerical results for the upper dilute current (e.g., front position and thickness) agree well with the experimental data for the dilute suspension flow. The numerical results for the dense basal current and the deposits also agree with the experimental data, when the volume fraction in the dense basal current (Φ_b) is set to the value observed in the experiments (the time-averaged value for the bedload at an upstream point; i.e., $\Phi_b = 0.02$) and the constant deposition speed at the base of the dense current (D) is tuned to 3.7×10^{-4} m/s.

In the GFE, a stationary fluidized mixture in the rectangular-lock domain was released at time $t = 0$, flowed into the horizontal channel, and produced the deposits by progressive aggradation during flowing. Numerical simulations using the basal-layer model in our two-layer model were conducted under the same condition of the experiment. The numerical results agree well with the experimental data for the flow-front position as a function of time and the final deposit distribution, when Φ_b is set to the initial value measured in the experiment (i.e., $\Phi_b = 0.42$) and D is tuned to 1.7×10^{-2} m/s.

The above two results ($D = 3.7 \times 10^{-4}$ m/s and $\Phi_b = 0.02$ for the PELE; $D = 1.7 \times 10^{-2}$ m/s and $\Phi_b = 0.42$ for the GFE) imply that the physics is different between the bedload region observed in the PELE and the granular flow observed in the GFE. The value of D for the GFE can be quantitatively explained by the hindered-settling model for $\Phi_b = 0.42$. That for the PELE, on the other hand, is substantially smaller than the value predicted by the hindered-settling model ($D \sim 10^{-2}$ m/s for $\Phi_b = 0.02$). The small deposition speed (i.e., $D = 3.7 \times 10^{-4}$ m/s) and the small particle volume fraction (i.e., $\Phi_b = 0.02$) in the PELE are consistent with the qualitative observation that saltating/rolling/sliding of particles occur in the bedload region owing to a complicated combination of deposition and erosion processes (i.e., some particles do

©2020. Japan Geoscience Union. All Right Reserved.

not simply settle to the bottom) in this experiment. These results indicate that the dynamics and sedimentation processes of the dense basal layer depend on the source condition and/or the presence of the slope. A sophisticated dynamical model considering the combination of deposition and erosion processes may reproduce the experimental data both for the bedload region in the PELE and the granular flow in the GFE.

Numerical simulation of ballistic trajectories based on wind tunnel experiments

*Kae Tsunematsu[1]

1. Yamagata University

Ballistic projectiles are large (>10 cm) pyroclasts, ejected from erupting volcanoes, that draw parabolic trajectories without being influenced by the flow of the gas and solid mixture (e.g. Taddeucci et al., 2017). Transport dynamics of ballistic projectiles are studied by observing real volcanic eruptions or numerical simulations. The largest unknown factor of ballistic transport is aerial drag, which is hard to estimate by observation.

There are many examples of drag measurements for artificial shapes such as cylinders and cubes, but only a few examples of drag measurements using real volcanic rocks. Therefore, wind tunnel experiments were implemented using a block obtained from Zao volcano, which erupted in 1895 (Kochibe, 1896). In order to clarify the size effect we used blocks of the same shape but different sizes. The results of these experiments were (1) the drag coefficient depends on the Reynolds number (when the block rotates more than three times per second) and the cross-sectional shape, (2) the lift coefficient of the block is very low compared to the drag coefficient when the block is rotating.

Numerical simulations were conducted using the drag and lift coefficients obtained from the wind tunnel experiments. Based on the numerical simulation results we show how the drag and lift coefficients affect the transport of ballistic blocks with and without rotation, and the condition of the blocks that travel furthest, by varying the block size, the ejection angle, and the rotation status.

Excitation of airwave by a bubble bursting in particle-bearing fluids : regime transitions and implications for basaltic volcanic eruptions

*Ikuro Sumita[1], Kana Hashimoto[2]

1. Geosciences and Civil Engineering, Institute of Science and Engineering, Kanazawa University, 2. Graduate School of Natural Science and Technology, Kanazawa University

Basaltic magma becomes more viscous, solid-like (i.e., elastic-like) and non-Newtonian (shear-thinning, possessing yield stress), as its crystal content increases. However their effects on bubble bursting and airwave excitation are poorly understood. Here we conduct laboratory experiments to investigate these effects by injecting a bubble with a volume V into a suspension consisting of non-Brownian particles (volumetric fraction phi) and a Newtonian liquid. We match the refractive indices of the particles and liquid, so that the subsurface bubble is visualized. We show that depending on phi and V, airwaves with diverse waveforms are excited, covering a broad frequency band of f of the order of 10-10^4 Hz. In a suspension of phi <= 0.3, the bubble bursts after forming a hemispherical cap at the surface and excites a high-frequency (HF) - wave (f = 1 - 2 x 10^4 Hz) having an irregular waveform. However in a suspension of phi = 0.4, when the bubble V is above critical, it bursts as soon as it protrudes above the surface and excites Helmholtz resonance with f of the order of 10^3 Hz. Superimposed on the waveform is a HF-wave component excited upon bursting, and a low frequency (f of the order of 10 Hz) air flow which vents out when the aperture grows. This transition of bubble bursting style and airwave excitation mechanism can be explained by bubble film being stretched above a critical strain rate such that the film rutpures by brittle failure. We also study the case where the fluid level is lowered such that an air column (length L) resonance is excited in addition to Helmholtz resonance. When L exceeds critical, air column resonance continues longer than the Helmholtz resonance, because the decay rate of the former becomes smaller than that of the latter. Our experiments indicate that whenever Helmholtz resonance is excited, we may use the frequency and decay rate to constrain the bubble volume and aperture radius, and also to infer the change of magma rheology.

Ash fall observation using 2D-Video Disdrometer

*Eiichi Sato[1], Masato Iguchi[2]

1. Meteorological Research Institute, 2. Kyoto Univ.

Meteorological Research Institute (MRI) conducts ash fall observation using two-dimensional video disdrometers (2DVDs) in Sakurajima, Kagoshima. 2DVD is a ground-based instrument that originally observes precipitation particles, and is used for verification of dual-polarization radar observation. 2DVD can obtain particle size distribution, three-dimensional shape, and fall velocity of the targets by using an optical method. It is expected that it enable us to observe ash fall precisely, however, there are some drawbacks. One of the drawbacks is lowness of the ashfall capture rate, because it performs an "in situ" observation at a fixed point. In addition, the instrument is so sensitive that frequent maintenance is required.
On October 14, 2019, ash fall was successfully captured using a 2DVD in Kurokami, Sakurajima. As a result, it was found that a group of small and flat particles existed in the volcanic ash. It is known that a polarimetric parameter called differential reflectivity increases after secession of large particles from volcanic ash plume, and the observation result using 2DVD can be the evidence of this parameter change. In this presentation, the outline of the observation method using 2DVD and some observation results will be shown.

An attempt at quantification of starting eruption cloud at Sakurajima volcano

*Taishi Yamada[1], Masato Iguchi[1], Eisuke Fujita[2]

1. Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University, 2. National Research Institute for Earth Science and Disaster Resilience

Behavior of eruption cloud has a variety corresponding each stage in a sequence of an eruption. An eruption cloud (or column) during continuous ash emission is often modeled as a steady flow (e.g., Woods, 1988). Contrary, behavior of an eruption column in its starting stage is characterized as expansion and ascending, because the eruption cloud ascends into atmosphere with entraining surrounding air (e.g., Woods and Kienle, 1994). Ishihara et al. (1983) revealed that starting eruption cloud emerges from the crater rim with vertical velocity of promotional to altitude to the power of -3. After the cloud reached certain height, the velocity turns to a constant value of 21-28 m/s. Such a sequence is often explained by transition of driving force of starting eruption cloud. Eruption cloud emerges from the vent with gas thrust. As the eruption column ascend, the cloud obtains alternative driving force of the buoyancy with entraining surrounding air (Patrick, 2007).
The starting stage of an eruption cloud is also accompanied with considerable geophysical signals, such as strain change (Iguchi, 2009), seismic (Tameguri et al., 2002), and infrasound (Yamada et al., 2017). These previous studies examined source process of each geophysical signals, but few study focus on the relationship between the source dynamics of starting eruption cloud and the signals. Our goal in here is to understand how the source process of each geophysical signals can be connected to the dynamics of starting eruption cloud, and propose a method to constrain the behavior of stating eruption cloud with geophysical data. In this poster, some characteristics of starting eruption cloud revealed by still images at Sakurajima volcano are presented.
We installed a visual camera of DFKZ12GX236 with a resolution of 1920x900 pixels and an interval of 4 fps at station KUR (Sakurajima Volcano Research Center, Disaster Prevention Research Institute, Kyoto University) where about 5 km away from active Minamidake vents of Sakurajima volcano. Each pixel location is converted vertical- horizontal plane crossing the vent following a method by Terada et al (2003). Following this conversion, observed still images cover apparent height of 2.5 km above the crater rim, where about 0.9 km above the sea level. The location of KUR does not provide direct view of crater bottom of the Minamidake vents, where is located at 250 m beneath the Source-West crater rim on October 2018 (MLIT, 2018). We also refer data of radial extensometer and vertical short period seismometer at Arimura observation tunnel, and an infrasound microphone at station HAR.
To understand fundamental characteristics of starting eruption cloud, we examined time history of the top height of eruption column as a representative eruption cloud velocity of 12 events since October 2018. Most (10) events have a constant ascending velocity of 5-20 m/s during its ascending stage. Contrary, two events emerge from the crater rim with faster ascending velocity of 50-100 m/s. Velocity decrease to 20-40 m/s following 20 seconds. Radial strain change and the maximum value of seismic and infrasound records of the latter two events (65-122 nano strain, 71-84 μm/s, 57.8-72.2 Pa) are greater than that of events having a constant ascending velocity (38-63 nano strain, 0.3-86 μm/s, <48.9 Pa). In case of an event having the maximum ascending velocity (December 24, 2018), the radial strain and volume change rate estimated with infrasound signal (e.g., Oshima and Maekawa, 2000) have time history that well correlated with that of ascending velocity.
Those characteristics suggest that certain relation can exist between the excitation of the geophysical signals and gas thrust region of eruption cloud. Hence, the behavior of staring eruption cloud can be

©2020. Japan Geoscience Union. All Right Reserved.

constrained with analyzing enough number of events.

Temperature dependence of titanomagnetite composition in a titanohematite-free silicic magma

*Naoki Araya[1], Michihiko Nakamura[1]

1. Department of Earth Science, Graduate School of Science, Tohoku University

Titanomagnetite ($Fe_{3-X}Ti_XO_4$, X=0–1) is a common mineral in volcanic rocks. Due to the fast elemental diffusion in this phase and the sensitivity of its composition to temperature and oxygen fugacity, titanomagnetite has been used to probe pre-eruptive magmatic processes. When titanomagnetite coexists with titanohematite ($Fe_{2-X}Ti_XO_3$, X=0–1), the temperature and oxygen fugacity dependence of titanomagnetite composition is well known, and solid solution composition of the Fe-Ti oxides can be used as a thermo-oxybarometer. However, titanohematite-free magmas are common for mafic to intermediate systems, and the effect of magmatic parameters such as temperature, pressure, oxygen fugacity, and melt composition on titanomagnetite composition in a titanohematite-free system is poorly understood. To expand the applicability of titanomagnetite composition to probe pre-eruptive magmatic processes, it is necessary to determine the titanomagnetite–melt partitioning as a function of the above parameters in a titanohematite-free system. Thus, we conduct high-pressure and high-temperature experiments at 925–1050 ˚C, 50–150 MPa, and an oxygen fugacity at the Re–ReO_2 buffer (~ΔNNO +1.8). Matrix glass of the pumices from the Sakurajima 1914 Plinian eruption (SiO_2 ~70 wt%) was used as a starting material, and crushed titanomagnetite phenocrysts from the same eruption (ulvöspinel content 36 mol%) or pure magnetite crystals from Lovers Hole (New York, USA) were added as seed crystals. Experimental charges reproduced both titanohematite-free and titanohematite-bearing systems. When oxygen fugacity is buffered, the ulvöspinel content of titanomagnetite in titanohematite-free charges decreases with increasing temperature. This change is described as an exchange reaction of the magnetite component and the ulvöspinel component between titanomagnetite and silicate melt. The correlation between temperature and ulvöspinel content of titanomagnetite in a titanohematite-free system is opposite to that in a titanohematite-bearing system.

STRATIGRAPHY AND CHARACTERISTICS OF CALDERA II DEPOSITS, BATUR VOLCANIC COMPLEX, BALI, INDONESIA

*Rahajeng Ardinni Noor[1], Atsushi Toramaru[1], Agung Harijoko[2,3], Haryo Edi Wibowo[2], Tomoharu Miyamoto[1], Mitsuru Okuno[4]

1. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University, 2. Department of Geological Engineering, Universitas Gadjah Mada, Indonesia, 3. Disaster Studies Center, Universitas Gadjah Mada, Indonesia, 4. Department of Earth System Science, Faculty of Science, Fukuoka University, Japan

Batur Volcanic Complex (BVC) consists of two overlaying calderas, namely Caldera I and Caldera II, with several post-caldera cones within the calderas. The previous study correlated the Caldera I and II to Ubud Ignimbrite (23 k.a) and Gunungkawi Ignimbrite (20 k.a), respectively. Those ignimbrites cropped out at Ubud area of about 20 km on the southern of BVC. More recent study reported the younger (5.2 k.a) thick deposit of caldera-forming eruption cropped out inside the rim of Caldera I and surrounding the BVC. The deposit consists of Penelokan pumice fall of plinian phase deposit and Batur Ignimbrite. These deposits interpreted as the youngest caldera-forming eruption product of Caldera II instead of Gunungkawi Ignimbrite. This study intended to describe and report the stratigraphy and characteristic of the deposits in order to interpret the dynamic of caldera-forming eruption of Caldera II.

The juvenile materials of the deposits are composed of white, grey, and banded pumices and/or scoria. Analyses done in a total of 13 bulk samples from Penelokan Fall and Batur Ignimbrite, including Grain Size Distribution (GSD) in the size range of phi -5 to 1, componentry analysis in the size of phi -2 to -4, density analysis in juveniles in the size of phi -3 to -4 around 100 grains in each sample, x-ray fluorescence (XRF), thin section, and scanning electron microscope (SEM).

GSD data show that the deposits of Plinian fall and matrix of PDC have unimodal distribution. In the proximal area, Plinian fall dominated by coarse materials (phi -3 and -4) of pumice and/or scoria, whereas, the PDC dominated by fine materials (phi >1). The coarse materials in PDC mostly composed of lithic. The bulk density of white pumice range from 0.5-0.8 gr/cm^3, grey pumice 0.5-1.1 gr/cm^3 and scoria 0.9-1.1 gr/cm^3. Based on petrographic and SEM analysis, the vesicularity of juvenile deposits are 47.40-58.09% and mostly phenocryst poor (0.47-2.88%). Phenocryst are composed of plagioclase, orthopyroxene, and clinopyroxene. The occurrence of phenocrysts and microlites in white pumice are rare, in contrast, common in grey pumice and abundance in scoria. The XRF data show that the deposits are grouped into trachy-andesite to trachyte, and classified as sub-alkaline series. The PDC deposits have a wider range in SiO_2 content (61.95-68.05 wt %). However, Plinian falls relatively narrow (61.98-63.67 wt %) with LOI number 1.28-3.33.

The eruption of Caldera II of the Batur Volcanic Complex occurs from the Plinian eruption produces the Plinian-fall, and the unsteady column produced intra-plinian PDC. On the other hand, the collapse of the column deposited the ignimbrite. Most of the sequence deposited within the Caldera I floor, however when the eruption intensity increase, the deposit could reach the distal area up to 17 km from the Caldera I rim. Lithic rich content and basal lag breccia are suggesting the vent opening process occurs. After several continuous eruptions, the proximal area started to collapse due to the emptying of the magma chamber. The variation of juveniles and range of density generate by variation in physical characteristics primarily for crystal and microlite content.

Factors affecting the sequence of the Plinian eruption inferred from rock texture and physical properties - an example of the 1783 eruption, Asama volcano, Japan

*Tatsuki Mizuno[1], Fukashi Maeno[1], ATSUSHI YASUDA[1]

1. Earthquake Research Institute, Department of Earth and Planetary Science, University of Tokyo

Plinian-style eruption is characterized by a large-scale column formed by an explosive magma rising. It often shows variation of eruptive style such as pyroclastic flows and lava flows, and the eruption styles change complicatedly in the same series of activity. Determining the factors controlling the eruptive style and its change is important for predicting the sequence of the eruption. In this study, we focus on the 1783 eruption of Asama volcano in order to understand the magma ascent process and factors controlling eruptive style through analysis of chemical composition and observation of rock texture. In the climactic phase of the 1783 eruption, a large column was established and pumice-fall deposits were formed at first, then the eruptive style changed to pyroclastic flows. Magma composition in the pyroclastic flow phase changed to be lower SiO_2. Pumice-fall deposits are divided into 16 layers. Upper half of the deposits were formed in climactic phase. In the middle level of deposits, there are some red ash layers which may have formed by pyroclastic flows before climactic phase. The main units of pyroclastic flow deposits include gray scoriaceous juvenile clasts. The bottom layer of pyroclastic flows contains juvenile pumice clasts, so the changes of chemical composition and eruptive style was not simultaneous.

Pumice clasts from fallout and pyroclastic flow deposits were chosen for measurement of density, microscopy, and chemical analyses. The apparent density ranges 0.6-0.9 g/cm^3 in fall deposits, 0.7-0.95 g/cm^3 in pumiceous pyroclastic flow deposits, and 0.7-1.2 g/cm^3 in scoriaceous pyroclastic flow deposits. The ratio of the connected vesicles ranges 87-96% in fall deposits, 83-98% in pumiceous pyroclastic flow deposits, and 91-95% in scoriaceous pyroclastic flow deposits. The ratio of connected vesicles ranges widely in pumiceous clasts, pyroclastic flow deposits have lower ratio than fall deposit. Scoriaceous clasts have higher ratio than pumiceous clasts. Phenocryst types are plagioclase, orthopyroxene, clinopyroxene, and Fe-Ti oxide, and olivine is rare. SiO_2 content of groundmass glass shows bimodal distribution around 67wt% and 72wt%. Pyroclastic flow deposits contain abundant low-SiO_2 clasts than pumice-fall deposits. Magma temperature and water content are estimated from chemical composition of plagioclase and matrix glass (Putirka, 2008; Waters and Lange, 2015), then SiO_2= 67 wt%, T=1060-1100℃, H_2O=0.8-1.0 wt% and SiO_2=72 wt%, T=1000-1015℃, H_2O=1.2-1.4 wt%. Vesicles in pyroclasts in the upper units are more connected and elongated. Clast types in pyroclastic flows are similar to the lower part of fallout units, but scoriaceous ones have thick bubble wall glass. We analyzed crystal and vesicle textures by using the shareware program ImageJ and CSD correction (Higgins, 2006). Crystallinity range 7-14% and poor in microlite. The average vesicularity of each layer ranges around 75% in pumice-fall deposit, excepting middle level, and 65-67% in middle level fall deposit and pyroclastic flow deposit. Bubble number density (BND) ranges 2.0-4.0×10^{13} m^{-3}, then the flow deposits show higher in BND than the fall deposits. Decompression rate for each layer can be estimated from BND, SiO_2 content, water content, and temperature (Toramaru, 2006). It was calculated at 3.2-4.7×10^7 (Pa/s) in fall deposits, 5.0×10^7 (Pa/s) in pumice flow deposit, and 1.0×10^8 (Pa/s) in scoriaceous flow deposit.

The change of the decompression rate has a correlation with changes of the eruptive style from column formation to pyroclastic flow generation. Fall deposits accompanied by red ash in the middle layer, which

indicates simultaneous generation of pyroclastic flows, show high decompression rate. Based on these results, it is suggested that the increase of magma decompression rate is densely related to generation of pyroclastic flows during the climactic phase of the 1783 eruption.

Thermal history of pyroclasts reflecting the structure of eruption clouds: Application of textural analysis of pyrrhotite oxidation

*Keiko Matsumoto[1]

1. Geological Survey of Japan, The National Institute of Advanced Industrial Science and Technology

Entrainment of air in eruption clouds causes rapid oxidation of pyroclasts due to an increase of oxygen fugacity at a high temperature. Oxidation texture of sulfide minerals (pyrrhotite) in pyroclasts can be an indicator for the process of air entrainment and temperature change in eruption clouds as it forms via interaction with air. To demonstrate the contrast of air entrainment and thermal disequilibrium processes of Plinian and Vulcanian eruption columns, oxidation texture of pyrrhotite in four andesitic pyroclastic eruptions of Asama and Sakurajima volcanoes was investigated. Although pyrrhotite and oxidized pyrrhotite crystals were commonly observed in the pumice clasts of these four eruptions, the component proportions and degree of oxidation of the pyrrhotite crystals were significantly different between Plinian and Vulcanian fall-deposits. Component proportions of oxidized pyrrhotite crystals were high for pumice deposits of the Asama 1783 and the Sakurajima 1914 Plinian eruptions than those of the Asama 2004 and the Sakurajima 2010 Vulcanian eruptions. These results indicate that the temperature of pumice clasts was kept above the closure temperature of pyrrhotite oxidation in the Plinian eruption clouds for a long time, while they dropped quickly in the Vulcanian one. The high temperature maintenance in Plinian clouds probably reflects (i) multiple mixing of an eruption cloud due to the continuous nature of Plinian flow and (ii) heat retainment in a pumice clast in the buoyant plume of the Plinian cloud. Thus, textural analysis of oxidized pyrrhotite can be a new approach for constraining the duration of high temperatures of an eruption cloud from fall-deposits, thereby reflecting the eruption dynamics.

Crystal cargoes transported by arc magmas upon eruption often consist of complexly zoned phenocrysts with diverse histories. While these crystals record the early stage of magma formation and evolution, they are not ideal recorders of ascent processes, which are the keys to useful constraints for adequate volcano monitoring. Conversely, microlites and micro-phenocrysts, frequently associated with decompression-induced degassing or cooling, are relevant recorders of late-stage ascent processes. Our study focusses on the active Tongariro Volcanic Centre (TgVC), located at the southern end of the Taupo Volcanic Zone; an active volcanic complex that has produced a wide range of explosive eruption styles fed by intermediate magmas. Scoriae from these volcanoes contain glassy and nearly-aphyric tephras, carrying microlites of plagioclase and pyroxene (mostly orthopyroxene). Major element analyses, combined with textural information, are used to assess equilibrium between the microlites/micro-phenocrysts and the groundmass glass. Chemical disequilibrium of some plagioclase and pyroxene crystals with the surrounding glass is common in most tephras. To investigate this further, we mapped plagioclase and pyroxene phenocrysts, micro-phenocrysts and microlites at submicron resolution for major and trace element distributions via chemical mapping and SIMS-SCAPS imaging. From a total of 105 images, six plagioclase textural patterns are noted: resorption and overgrowth, oscillatory zoning, single compositional jump, sieve textures, fractures, and strontium zonation; while in pyroxene microlites the following textures are found: resorption and overgrowth, calcium-rich rims, magnesian core and calcic rims, fractures, and aluminium zonation. Microlite textures are observed down to <30 μm in most tephras from TgVC, and interpreted in the context of an interplay of magmatic processes involving multiple events of magma recharge/mixing, pressure fluctuations, fracturing, and rapid cooling and crystal growth. Since TgVC is located in an extensional tectonic setting, we envision a vertically oriented magma plumbing system, where short-lived and nearly-aphyric magma pulses accommodate crustal extension through dyking. Explosive eruptions occur when a hot magma batch fractures through previous intrusions, recycling a variety of small crystals grown under diverse physico-chemical conditions and stored in rapidly cooled, previously intruded dykes. Thus, textures cryptic to conventional imaging indicate that a significant proportion of the microlitic and micro-phenocrystic mineral cargo is of antecrystic origin (i.e. hence referred as “micro-antecrysts”) and cannot be attributed to late-stage nucleation and growth at the onset of volcanic eruptions.

[S-VC43] Magma crystallization, fragmentation, and their roles on volcanic eruption

convener:Takahiro Miwa(National research institute for earth science and disaster prevention), Satoshi Okumura(Division of Earth and Planetary Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University), Pranabendu Moitra(University of Arizona)

Crystallization of magma during magma ascent in the conduit has a large impact on the dynamics of volcanic eruptions. Magma viscosity and brittleness increase with crystallization. This change of rheological properties may cause brittle fragmentation of low-viscosity basaltic magma during highly explosive subplinian and Plinian eruptions. On the other hand, crystallization may form rigid crystal frameworks, causing efficient outgassing through the interaction between the crystal frameworks and growing gas bubbles in ascending magma, resulting in effusive eruptions. This session aims to integrate information of elementary processes to develop physical models of multiphase magma ascent and eruption. In this view, we welcome innovative and multidisciplinary contributions from experimental volcanologists, numerical modelers, petrologists, and also geophysicists who develop and extend techniques to explore crystallization and bubble-crystal interactions, and their effects on fragmentation and outgassing of multiphase magma during effusive and explosive eruptions.

Estimating the parameter to determine bubble - crystal interaction styles

*Ikeda Kyoko[1], Atsushi Toramaru[1]

1. Kyushu University, Department of Earth and Planetary Science

In the magma, the interaction between suspended crystals and the rising bubble made by buoyancy is important because the interaction can be expected to control the chemical evolution of magma chamber and their stratification through the rheological properties and bulk densities. Beline et al (2010) showed that there are three interaction styles with changing bubble diameter and viscosity of the liquid by laboratory experiments using an analog material: a single plastic cube and a controlled single bubble in viscous liquid. However, the crystal - bubble interaction is still poorly understood since the factors to make a difference among the three interaction styles are not explained enough. In order to solve this problem, we give some constraint on the controlling parameters to determine three interaction styles by analogue experiments.
The experiments are performed in the tank filled with viscous liquid (analog material of silicate melt)and prepared three different viscosity(0.29 Pa・s, 6.46 Pa・s, 19.1 Pa・s). The plastic cube (analog material of crystal) with 10 mm is suspended in liquid by a rod. The bubble is injected into the liquid from 11cm below the plastic cube from a syringe connected to a motor controlled by the PC program by which we can change the initial bubble size. We examine the probability of occurrence of three styles of interaction: "stuck", "pass", and "split"; "stuck" in which a bubble stays under the solid cube, "pass" in which a bubble moves around the cube and "split" in which a bubble separated into two bubbles. To determine the probabilities, we did the repetition of 10 times for the same condition of initial bubble radii and viscosity.
In our experiments, we observed two styles of the interaction of "stuck" and "pass" and not "split". It is found that the smaller bubble tends to “stuck”, on the other hand, the probability of “pass” became higher as the bubble radii are larger. To reveal the boundary of “stuck” and “pass”, we use Bound number which is a dimensionless number representing the ratio of bubble relaxation time and the bubble rising time per their radius. From the results of the examination using the size ratio between solid cube and the final attached bubble, and Bond number, it is suggested that there are two regimes in the mechanism of interaction styles. These two different regimes are caused by Reynolds number which is the ratio of inertia force and viscous resistance. In low Reynolds number regime is controlled by the final maximum bubble diameter which resulted from mechanical interaction between bubble and cubes in the higher viscosity. For example, if the deformed bubble diameter is larger in the horizontal length than the cube width, the bubble path throws the cube. In high Reynolds number regime is controlled by inertia force. The probability of occurrence of “pass” is higher as the bubble radius becomes larger with inertia force.
Thus, we found that there are two regimes in the bubble-crystal interaction style; one is a static regime (low Re) controlled by the geometrical relation in the horizontal sizes including static deformation, another is a dynamic regime (high Re) controlled by the inertia of a rising bubble by buoyancy.

Effects of equilibrium crystallization on conduit flow dynamics during the 1986 eruption at Izu-Oshima volcano

*Tomofumi Kozono[1], Hidemi Ishibashi[2], Satoshi Okumura[3], Takahiro Miwa[4]

1. Department of Geophysics, Graduate School of Science, Tohoku University, 2. Department of Geoscience, Faculty of Science, Shizuoka University, 3. Department of Earth Science, Graduate School of Science, Tohoku University, 4. National Research Institute for Earth Science and Disaster Resilience

A diversity of eruption styles has been mainly studied in silicic volcanism, in which the competition between vesiculation of hydrous magma and gas escape from the magma in conduit flow is one of the main factors controlling eruption styles (explosive or effusive). In basaltic magmatism, diverse eruption styles are also been observed especially in island arc volcanoes with hydrous magma. In this study, we investigated the origin of the diverse eruption styles during the 1986 eruption of Izu-Oshima volcano, Japan, using a 1-D steady conduit flow model. Ishibashi and Oida (2018) proposed that a variety of equilibrium crystallization paths during magma ascent caused by a difference in magma temperature is a key factor controlling the eruption styles which range from lava flow to sub-Plinian eruptions. We assessed the effects of the equilibrium crystallization on conduit flow dynamics during the 1986 Izu-Oshima eruptions. In the conduit flow model, magmatic properties of the Izu-Oshima eruptions were properly set based on petrological observations and thermodynamic modeling. We also applied various models for magma fragmentation (expansion, shear-induced, and stress) and gas escape (permeable flow and bubble segregation) because information about these processes in basaltic magma is limited. We obtained two distinct patterns of conduit flow depending on equilibrium crystallization path and magma temperature as expected in the previous study: a low (or high) temperature and high (or low) crystallinity magma induces a flow with high (or low) magma viscosity. When a shear-induced or stress fragmentation is applied, the flow with high viscosity leads to fragmentation and explosive eruption, whereas that with low viscosity leads to effusive eruption without fragmentation. We also found that expansion fragmentation is promoted for the flow with high viscosity when gas escape due to bubble segregation is applied because the high viscosity prevents the bubble segregation. Our results revealed that due to the above relationship between the crystallinity or viscosity and the explosivity of basaltic eruptions, there exist the conduit flow solutions corresponding to the lava flow and sub-Plinian eruptions at Izu-Oshima volcano. Although crystallization kinetics has been recognized as an important process controlling the eruption dynamics, our results indicate that the equilibrium crystallization process is also strongly controlling the eruption styles in basaltic volcanism.

Experimental study on groundmass crystallization of the Izu-Oshima 1986 B basaltic andesite magma during conduit ascent

Ryoya Oida[2,3], *Hidemi Ishibashi[1], Akihiko Tomiya[3], Masashi Ushioda[3], Natsumi Hokanishi[4], Atsushi Yasuda[4]

1. Faculty of Science, Shizuoka University, 2. Graduate School of Integrated Science and Technology, Shizuoka University, 3. GSJ, AIST, 4. Univ. Tokyo, ERI

Melting and crystallization experiments were performed for H_2O-saturated basaltic andesite magma of the Izu-Oshima 1986 B eruption at 0.1-200 MPa pressure conditions, to constrain the pre-eruptive pressure condition and to simulate crystallization process during conduit ascent of the magma. The 1986 B eruption was sub-Plinian and erupted almost aphyric (<1 vol.% phenocrysts of plagioclase), microlite-rich basaltic andesite magma with bulk SiO_2 content of ~54.5 wt.%. Powdered samples of the basaltic andesite were used for the starting materials of our experiments. We performed high-temperature phase equilibrium experiments at 0.1 MPa and high-pressure conditions (1010-1200ºC and 20-200MPa), using the fO_2-controlled electric furnace and the internally heated pressure vessel (KOBELCO Dr. HIP) at GSJ, AIST, respectively. In both experiments, the samples were heated at experimental temperatures for 3 hours and then quenched. Redox conditions were controlled at Ni-NiO buffer during the experiments at 0.1 MPa, whereas the high-P experiments were performed under more oxidized conditions because fO_2 was not controlled. The quenched samples were processed to polished thin sections for microprobe analyses. BSE image observations and chemical analyses of microlites and glasses were done using FE-EPMA (JEOL JXA-8530FPlus) and EPMA (JEOL-8800R) at ERI, University of Tokyo, respectively.
First, H_2O-saturated liquidus of the basaltic andesite magma was experimentally constrained and formulated as a function of pressure as $10000/T = 8.5 + 0.0027P + 0.049P^{0.5}$. Assuming the magma was at 1070-1100 ºC (Fujii et al., 1988) and saturated with H_2O and plagioclase in its magma chamber, the pre-eruptive pressure is estimated to be ~70-115 MPa; the pressure corresponds to the depth of ~2.8-4.6 km, which is consistent with previous geophysical result (Ida, 1995).
Secondly, phase equilibrium experiments were performed at 1080 ºC, the eruptive temperature of the magma, and various pressure conditions from 75 MPa to 0.1 MPa, to simulate crystallization during conduit ascent of the magma. Plagioclase and Fe-Ti oxide are found in all samples, whereas pyroxene crystallized at pressure lower than 35 MPa. As pressure decreases, plagioclase content increases from 2.5 vol.% at 75 MPa to 42.5 vol.% at 0.1 MPa. At 20 MPa, plagioclase and total crystal contents are ~20 vol.% and ~40 vol.%, respectively, which are similar to those in the natural scoria samples. Considering the effects of fO_2 and crystallization kinetics on crystallinity, the results suggest that the pressure at which crystallization ended during conduit ascent of the magma was lower than 20MPa, corresponding to the depth < ~1km. We infer that fragmentation occurred at the depth because the crystallinity of >~40 vol.% corresponds to the critical crystallinity at which viscous-brittle transition occurs for melt-crystal-bubble system with bubble content of <30-50 vol.%.
Lastly, the effect of temperature on crystallinity was examined at 20MPa. As temperature increases from 1080 ºC to 1110 ºC, total crystal contents drastically decrease from ~40vol.% to ~5 vol.%. The result indicates that decreasing temperature facilitates viscous-brittle transition and fragmentation due to increase of crystallinity. Therefore, temperature is a critical factor controlling eruption style of mafic magma. We think that the difference of eruption styles between A and B magmas of the Izu-Oshima 1986 eruption was essentially caused by the difference of magmatic temperature.

Effect of superheating on decompression-induced crystallization of hydrous rhyodacite magma: An experimental study

*Kazuhisa Matsumoto[1], Satoshi Okumura[1], Akihiko Tomiya[2]

1. Division of Earth and Planetaly Materials Science, Department of Earth Science, Graduate School of Science, Tohoku University, 2. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

Decompression experiments have been applied to determine decompression rates during magma ascent to the surface (e.g., Hammer and Rutherford, 2002). The texture of crystals in pyroclasts also records the pressure at magma fragmentation level during explosive eruption (e.g., Okumura et al., 2019). Comparison between the texture of crystals in natural pyroclasts and that in experimental products enables us to estimate the decompression rate and magma fragmentation pressure. This is a powerful method to estimate the processes of magma ascent; however, it has been thought that an experimentally reproduced texture of crystals depends on superheating before decompression. Indeed, two decompression experiments performed at the similar experimental condition but different superheating (Brugger and Hammer, 2010; Riker et al., 2015) show large difference in the number density of crystals.

In this study, we carried out a series of decompression experiments to investigate the effect of superheating on the number density and size of crystals and total crystallinity. We used powdered pumice sample of the 1977 sub-Plinian eruption of Usu volcano, Japan as a starting material. The liquidus temperature of this magma was estimated to be ~920˚C (Ohnishi and Tomiya, 2018). For the decompression experiments, we prepared four types of starting materials synthesized (annealed) at the same pressure (130 MPa) and temperature (900˚C), corresponding to the magma chamber condition (Ohnishi and Tomiya, 2018), but preheated at temperatures of 900, 940, 970, and 1300˚C (different degree of superheating) using a cold seal pressure vessel (CSPV) at Tohoku Univ and internally heated pressure vessel at GSJ/AIST. The durations of preheating and annealing are 2 to 48 h and 48 to 138 h, respectively. In the synthesized samples, no plagioclase was found when the sample was preheated at 1300˚C, and the number density of plagioclase increases with the decrease in preheating temperature although total crystallinity is not different. Decompression experiments were isothermally conducted at a temperature of 900˚C using CSPV, with continuous decompression from 130 to 30 MPa and decompression rates of 100, 20 and 5 MPa h^{-1}. After decompression, the sample was rapidly quenched, and the number density and size of crystals and total crystallinity were investigated.

Our results clearly indicate that the degree of superheating influences the number density and size of crystal. The number densities of plagioclase in the products preheated at 1300 and 970˚C are much lower than those at 940 and 900˚C . Under high decompression rate (100 MPa h^{-1}), no plagioclase was found in the product preheated at 1300˚C. The size of plagioclase is large in the products preheated at 1300 and 970˚C under decompression rate of 20 and 5 MPa h^{-1}.

We also observed the dependence of the number density on the decompression rates. The maximum number density of plagioclase was found at 20 MPa h^{-1} in the products preheated at 940 and 900℃. On the other hand, the number density in the product preheated at 970˚C shows only small variation with decompression rate. This indicates that the number density depends on decompression rate when crystallization is dominated by nucleation rather than growth.

On the basis of these results, we conclude that the degree of superheating controls the number density

©2020. Japan Geoscience Union. All Right Reserved.

and size of crystal as well as decompression rate. This is probably because the superheating determines the number density of clusters smaller than the critical nuclei size (Sato, 1995). When the number density of the cluster is high, the nucleation controls the relaxation of effective undercooling, while the undercooling is relaxed by the growth process under low number density of the cluster. Therefore, the effect of superheating must be considered when the decompression experiment and the resultant number density is applied to determine decompression rate and fragmentation pressure.

Analog experiment on vesiculation by crystallization with H_2O-KCl-CO_2

*Shiho Fujimura[1], Atsushi Toramaru[1]

1. Kyushu University

Volatile components such as H_2O and CO_2 are dissolved in the magma chamber under the volcano. These volatile components cause the bubble formation in the magma leading to the volcano eruptions.

One type of bubble formation in the magma chamber is induced by cooling and crystallization (so called “second boiling”). Crystals formation due to cooling by the host rock reduces the melt volume, and the volatile components that cannot be dissolved in the crystals concentrate in the melt.

Yoshigai (2011) investigated this process by an analog system using carbonated water. The carbonated water was used as the analog material of the melt, and the CO_2 as the volatile component in the melt. When the solution was cooled below freezing point, the crystallization of ice, the bubble formation ,and the pressure increase were observed. However, since the ice has larger molar volume than the solution, it was unclear whether the pressure increase was due to the generation of bubbles or the formation of the ice.

Therefore, the purpose of this study was to reproduce the cooling crystallization and the bubble formation by analog experiments without pressure increase due to the ice formation. In order to do that, we use the system H_2O-KCl-CO_2, taking the advantage of the crystallization of KCl.

From the H_2O-KCl phase equilibrium diagram, assuming the room temperature of 20 ℃, the 25 wt% KCl solution is thought to be just saturated at 20 ℃. When the solution of that concentration is cooled, it can be expected that KCl crystals gradually crystallize and bubble formation occurs.

The acrylic cylindrical container(the diameter: 5 cm, the height: 5 cm) was used in the experiment. Only the lower bottom (aluminum plate) of the container was cooled by using a Peltier device throughout the experiment. During the experiment, the temperature was measured by thermo-couples(both K type) at the top and bottom in the container and the pressure inside the container was measured by the pressure-transduce(made by KISTLER). The video image was taken by GoPro (HERO 7 BLACK).

The experimental results above the eutectic point of H_2O-KCl binary system show that the crystallization of KCl was observed, but no CO_2 bubble was generated. This can be interpreted that the concentration rate of CO_2 by the KCl crystallization is smaller than the solubility increasing rate by cooling, from the calculation.

In the experiments below the eutectic point -10 ℃ the total volume of H_2O and KCl crystals is expected to increase until the totally crystallized and to change depending on the amount of heat loss compensating the release of latent heat. We also examine the effect of surrounding temperature by controlling the variable temperature of used incubator where the container of solutions and sensors are set.

In the experiments performed at 10 ℃ and 16 ℃ of surrounding temperature, KCl was crystallized first, and below the eutectic point, ice and KCl crystals formed, and bubbles formed only near the inner side wall of the cylindrical container. However, in the experiment kept at 3 ℃, no bubbles formed even after

©2020. Japan Geoscience Union. All Right Reserved.

the solution nearly totally crystallized.

Bubbles were generated only around the crystals. It is suggested that, the crystals were thick and the gap between the crystal and the container was large. When the experiment performed above the eutectic point, no bubble was observed. The reason is considered that in the initial concentration performed in this experiment, the amount of crystals generated during cooling is insufficient. The calculation for silicate systems shows that the concentration of H_2O by crystallization dominates or is similar to the solubility increase of H_2O by cooling. So, in the silicate system, the crystallization can induce the volatile concentration and lead to the bubble formation.

Deep Crystallization of Tholeiitic Melt: Insights from Manguao Basalt, Palawan, Philippines

*James Cesar Avisado Refran[1], Tsukasa Ohba[1], Carlo Arcilla, Takashi Hoshide[1], Ma. Ines Rosana Balangue-Tarriela

1. Akita University

Manguao Basalt is a basalt-basaltic andesite lava flow field found on the northeast end of Palawan Island, Philippines. The relatively-stable nature of the Palawan Continental Block seemingly contradicts the presence of the geomorphologically-young lava flow field. This study investigates the occurrence and origin of Manguao Basalt, and its relation to evolution of the Palawan microcontinent.

Good exposures of the Manguao Basalt lava flow field are found nearshore; with flow structures and features (i.e. levees, channels, and tumuli) still intact and observable in several locations. The lava flow is generally blocky and vesicular, with perceptible phenocrysts and chert xenoliths. Macroscopic observations of obtained samples show identifiable olivine and pyroxene phenocrysts. Petrographic observations show olivine dominance in phenocryst and plagioclase dominance in groundmass. Pyroxenes are found both in phenocryst and groundmass assemblages. Mineral textures observed from petrography shows precedence of pyroxene phenocrysts from olivine. Plagioclase laths in groundmass also show precedence from anhedral groundmass pyroxenes. Volcanic glass fills the interstices between plagioclase and pyroxene; forming intersertal textures. A general overview of the crystallization sequence (pyroxenes àolivine àplagioclase àgroundmass pyroxenes), from petrography, is presented.

Major element chemistry from bulk-rock compositions characterizes the Manguao Basalt as subalkaline and tholeiitic. Bivariate diagrams show fractionation in ferromagnesians (i.e. olivine and pyroxenes) but limited fractionation in later-formed minerals (i.e. plagioclase). Total iron over magnesium (FeOt/MgO) versus silica (SiO_2) plots (Miyashiro, 1974) of Manguao Basalt shows 'straddling' tholeiite and calc-alkaline character. AFM ternary plots show diagnostic early iron enrichment, reflecting a tholeiitic trend. Trace element chemistry confirms the early ferromagnesian fractionation from nickel, chromium, and cobalt trends. Tectonic discrimination diagrams of Manguao Basalt show resemblance with different basalts from other known tectonic settings (i.e. continental flood basalts, island-arc basalts, continental-arc basalts, and within-plate basalts). However, association of Manguao Basalt with ocean-island basalts (OIB) or mid-ocean ridge basalts (MORB) appears inconclusive; plotting outside MORB-OIB array defined by Pearce (2008). These inconsistencies that accompany trace element discrimination diagrams have been pointed out by Li et al. (2015). Nevertheless, their utility is in constraining possible tectonic processes that influence melt generation and evolution. Trace element patterns in MORB- and OIB-normalized spider diagrams show enriched melt character of Manguao Basalt (i.e. more enriched than any MORB, but depleted compared to OIB). Characteristic Nb-Ta depletion is absent for Manguao Basalt, indicating possible non-subduction influence. Positive anomalies in continent-derived trace elements (e.g. K, Th, and Ba) are observable and consistent in any spider diagram presented (MORB-, NMORB-, EMORB-, and OIB-normalized).

Mineral chemistry data (olivine, orthopyroxene, clinopyroxene, and plagioclase) confirm crystallization sequence inferred from petrography. The most magnesian mineral species are orthopyroxene and clinopyroxene phenocrysts (Mg# > 80). Calculations using orthopyroxene barometer shows highest pressure (~5 kbar) and thermometers (i.e. opx-liquid) show highest temperatures (~1260 ˚C). Obtained

pressure and temperature conditions were used as benchmarks for simulations of source melting and crystallization.

Simulations of melting of different mantle sources (e.g. fertile and depleted mantle) were done using the MELTS program. Equilibrium and fractional melting from depressurization (15 kbar à5 kbar) of any mantle source produce liquids that are saturated in pyroxene components. Subsequent crystallization of melt, while being at equilibrium with source and at elevated pressures (~5 kbar) produce orthopyroxenes with similar compositions to orthopyroxenes in Manguao Basalt. The formation of olivine and the rest of the groundmass requires significant evolution of melt prior to its removal; as both components show 'evolved' melt origin. The model for magmatic underplating is presented here as a possible setup for the origin of Manguao Basalt.

Relationship between the change of eruption style and the rock texture of ejecta during the Shinmoe-dake 2018 eruption, Kirishima, Japan

*Sayaka Shohata[1], Fukashi Maeno[2], Yuki Suzuki[3], ATSUSHI YASUDA[2], Natsumi Hokanishi[2]

1. Department of Earth and Planetary Science, School of Science, The University of Tokyo, 2. Earthquake Research Institute, The University of Tokyo, 3. Faculty of Education and Integrated Arts & Sciences, Waseda University

The amount of crystals and crystal size distributions (CSD) in the groundmass reflect the history of crystal nucleation and crystal growth responding to processes of magma decompression and cooling. Recent eruptive events are well observed directly in detail, so there is a possibility to advance understanding the main factor which decide eruptive style by analyzing groundmass texture. Shinmoe-dake volcano, Japan, erupted in 2011 and 2018. The 2011 eruption was characterized by three sub-plinians and lava dome effusion, but the 2018 was only lava dome effusion. This difference is important to understand the eruptive style branching factor. However, discussion based on the detail analysis of ejecta is not enough. The purpose of this study is to compare the texture of different types of rocks erupted from the 2018 eruption and reveal the magma process, and to compare with the 2011 eruption which has been already studied (Suzuki et al., 2018) and discuss the cause of different eruptive style. The samples of the 2018 products are classified into four groups. Pumice ejected from the early stage eruption (P1), pumice ejected from the latter eruption (P2), lava effused from the summit crater after the P1 eruption (L), and ballistic ejecta that the eruption date is unidentified but after P1 (B). The samples were analyzed with EPMA and FE-EPMA. Chemical composition data analyzed by EPMA were used to calculate the crystallinity of groundmass based on mass balance. High magnification photos and element mapping data were processed and used for quantitative textural analysis. In quantitative analysis, plagioclase microlite number density and CSD were calculated mainly using the method of Higgins (2000). According to the analyzed composition data, the magma is almost the same as the 2011. However, there were textural differences for each type and it reflects different effective undercooling. L has the highest groundmass crystallinity, followed by P1 and B, and P2 has the lowest. Plagioclase number density of P1 was the largest, L and B had almost the same value, and P2 was the smallest. The CSD peak value of P2 was the highest, P1 was the second and near to the P2, L was the third, and B was the lowest. These results suggest the condition which crystallization occurred. L showed smaller number density than P1 and P2, but the highest crystallinity, so I presumed it experienced crystal growth effectively. B showed the smallest number density and steep slope in CSD. This means nucleation rate was larger than L. P1 had highest number density and CSD peak, it was formed under the highest nucleation rate. P2 showed the steepest slope in CSD so that it was formed under the lowest growth rate. The relationship between nucleation/ crystal growth rate and effective undercooling shows a bell-shaped. According to the result this time and comparison with the 2011 eruption, it can be arranged in ascending order, L, B, P1, P2 in terms of effective undercooling. Effective undercooling has a positive correlation with magma ascending rate. It can be presumed to reflect the slowest and constant ascent rate for the lava dome. Ballistic product rose slowly as lava but ejected with high speed from shallower conduit. At the early phase, pumice ascended slowly above the lava-forming magma. In contrast, latter phase pumice ascended quickly. Additionally, CSD value is higher than 2011, the features of P2 and 2011 sub plinian pumice, B and 2011 ballistic ejecta were similar. This can be interpreted that the 2018 eruption had lower magma discharge rate than 2011, and changing during the eruption. It was presumed that lava dome grew at a constant rate from the data of time-sequence observation (NIED), but textural analysis results suggest the speed of lava effusion

Stratigraphy and Unit Determination of Ranau Tuff in Sumatra, Indonesia

*Rachmi Mustika Pertiwi Putri Gunawan[1], Atsushi Toramaru[1], Tomoharu Miyamoto[1]

1. Department of Earth and Planetary Sciences, Kyushu University, Fukuoka, Japan

Ranau Tuff is a thick massive ignimbrite produced by a large caldera-forming eruption at ±33 ky ago. The deposit covers about 70 km around its vicinity with an approximate bulk volume of 173 km^3. The remnant edifice of Ranau has an unusual shape of caldera, which is thought to be caused by the combination of pull-apart basin and caldera formation. Active tectonic setting and volcanism in the area affected the process in the magma chamber and influenced the products, especially pumice clast in ignimbrite. Although it has a huge deposit, there are only limited studies about Ranau Tuff. Therefore, this study tries to characterize the pumice by classifying them into several types and clarify the stratigraphy to obtain an insight into the magma chamber condition.

We clarified the stratigraphy of nine locations around Ranau Lake by fieldwork. For non-welded deposits, we did the grain size analysis for dried samples from each layer by sieving tools. We did the component analysis for the grains larger than 2 mm by grouping into pumice, lithic, and free-crystal with the hand-picking method. For pumice grains with the selected size range (4-8 mm and 8-16 mm), we conducted the 3D volume measurement using Medit Solutonix D700 3D scanner and read the files by Hira 3D viewer to determine the bulk density. To know the major and trace element compositions of the pumice samples, we used the X-Ray Florescence (XRF) method.

From the fieldwork, it is found that Ranau Tuff mostly shows massive and non-welded ignimbrite with no evidence of the precursory Plinian phase. We observed thin fall deposit layers (5-10 cm) within the non-welded ignimbrite layers in Location 2 (9.2 km NE from caldera rim). Component analysis and mineralogy observation for the thin sections show three dominant pumice types of the ignimbrites; type A (pyroxene-bearing), type B (quartz-bearing), and type C. The lithic components are similar in all samples. Otherwise, the free-crystal of quartz, feldspar, biotite, and quartz-biotite aggregate are found in all locations except that in location 6 (type A pumice) and less than 5% in the lower part of location 9 (type C pumice). Qualitatively, the size of vesicle and phenocryst in pumice type A and C is smaller than that in type B. Besides, bubble-bearing and hourglass melt inclusions identified only in quartz phenocryst of pumice B. Major and trace element variation diagrams also show distinct trends among these pumice types. Therefore, we call the unit with each dominant pumice type by unit A (pumice type A), unit B (pumice type B), and unit C (pumice type C). Most of the deposits we found around Ranau Lake are unit B, only location 6 (36 m NE from caldera rim) is unit A and lower part of location 9 (15.6 km NE from caldera rim) is unit C which deposited before unit B.

A different system of magma in each unit is represented by the relation between its chemical trend and the pumice occurrence. Unit A (pyroxene-bearing) has less silica and potassium content than unit B (quartz-bearing) and C. The alkali-silica diagram of unit B does not show a clear trend which possibly affected by potassium content from biotite crystal in the whole-rock samples. However, there is a clear gap among the units in the incompatible trace elements-silica variation diagram such as Zr, Ba, K, Nb and does not show a linear relationship. This fact suggests different magma batches system formed prior to Ranau caldera-forming eruption.

3D crystal size distributions of pyroxene nanolites based on nanoX-ray CT analyses

*Shota Okumura[1], Mayumi Mujin[2], Akira Tsuchiyama[3,4], Akira Miyake[1]

1. Department of Geology and Mineralogy, Graduate School of Science, Kyoto University, 2. Division of Earth and Planetary Materials Science, Department of Earth Science, Tohoku University, 3. Research Organization of Science and Technology, Ritsumeikan University, 4. Guangzhou Institute of Geochemistry, Chinese Academy of Sciences

Groundmass texture of pyroclasts, such as crystal shapes and population density, reflects physical condition during crystallization and thus is important to understand ascent conditions in conduits. For instance, Castro et al. (2003) have confirmed crystal elongation with decreasing size, which means a change of physical condition. Besides, crystal size distributions (CSDs), which are the numbers of crystals per volume per each size-range, are used to infer magma dynamics, such as mixing and syneruptive ascent (e.g., Marsh, 1998). However, most of these studies are based on 2D analyses (SEM observations): CSDs are acquired through stereological corrections from 2D to 3D (Higgins, 2000). On the other hand, some researches have aimed to acquire true 3D texture through serial sectioning, X-ray computed tomography with pixel size of 3–30 μm (Jerram et al., 2018), and optical transmission microscopy (e.g., Castro et al., 2003). However, few 3D observations for pyroclasts have spatial resolution of smaller than μm-scale necessary for analyses of groundmass crystals; that is, their 3D dataset is insufficient. It is necessary to present their true 3D data and test accuracy of the stereological corrections of 2D data for CSDs. We aimed to infer the ascent conditions based on the true 3D data.

Recent researches on extraterrestrial samples have used synchrotron radiation-based X-ray computed nanotomography (SR-nanoXCT) at BL 47XU of SPring-8, a synchrotron radiation facility in Japan, with effective spatial resolution of ~100 nm (e.g., Tsuchiyama et al., 2012; Matsumoto et al., 2019). We applied this SR-nanoXCT to pyroxene nanolites (< 1 μm in width; Mujin et al., 2017) in pumices and acquired their 3D data and directly measured CSDs (CT-CSDs). We analyzed two pumices from the 2011 eruption of Shinmoedake, the Kirishima volcano: one is from a sub-Plinian eruption and the other is from a Vulcanian explosion. Two equant specimens (ca. 25 μm on a side) for the SR-nanoXCT were extracted from each pumice using a focused ion beam system (Quanta 200 3DS, FEI). We also acquired CSDs of pyroxene crystals in 2D with a field-emission SEM (JSM-7001F, JEOL) (SEM-CSDs) in addition to the CT-CSDs.

We found that the shapes of pyroxene nanolites exhibit different features between the two pumice samples, although the degree of elongation varies greatly from crystal to crystal even in each specimen: elongate prisms with swallowtail ends in the sub-Plinian pumice, and slightly thicker prisms with flat ends in the Vulcanian pumice. In the sub-Plinian pumice, smaller nanolites tend to become more elongate. However, such a tendency is not found in the Vulcanian pumice. As for CSDs, the CT-CSDs and the SEM-CSDs correspond well with each other. They show a log-linear figure for the Vulcanian pumice. On the other hand, for the sub-Plinian pumice, the SEM-CSD exhibits a kink at 1 μm of crystal width and a steeper slope in the finer size-range, and the CT-CSD also exhibits such a steep slope.

Because crystals become elongated with large undercooling (Shea and Hammer, 2013), the difference in degree of crystal elongation indicates that the sub-Plinian magma batch has undergone larger undercooling than the Vulcanian one. Besides, this elongation can affect figures of CSDs. There are cases where elongated small crystals generate a falsely-high population density of the small crystals (e.g., Castro

©2020. Japan Geoscience Union. All Right Reserved.

et al., 2003). For the sub-Plinian pumice, however, this effect appears to be insignificant, although the small nanolites become elongated. The concave upward curvature of the CSD is interpreted as an accelerated increase in population density and nucleation rate of small crystals, which results from increasing undercooling. These results are considered to reflect a difference in ascent rate for the eruption styles: the sub-Plinian magma batch ascended acceleratedly but the Vulcanian one was in a steady condition in the shallow conduit.

Pre-eruptive Magma Condition of Tondano Caldera I: Domato Tuff, Minahasa, NE Sulawesi, Indonesia

*Tabegra Disando[1], Atsushi Toramaru[1]

1. Department of Earth and Planetary Sciences, Kyushu University, Fukuoka, Japan

Tondano Caldera Complex (TCC) marked an important historical record of volcanism in the NE Sulawesi region. Domato Tuff was produced from Tondano Caldera I, on 2.0±0.4 Ma ($^{40}Ar/^{39}Ar$ isotopes), by the first event in TCC, with the widest distribution of dacitic to rhyolitic ignimbrites (~17 km^3 DRE). Aim of this study is to characterize Domato deposit and reveal the pre-eruptive magma condition shortly before the caldera-forming eruption occurred.

We conducted sample description, weight sieving for Grain Size Distribution (GSD), component analysis of grain, and bulk density measurement. To know the pumice texture and ash morphology, we carried out image analysis by optical microscope, SEM-EDS TM3030 Plus, and FOAMS version 1.0.4. Measurement of mineral and glass composition is conducted by FE-EPMA JEOL-JXA-8530F.

We found several layers of pyroclastic deposits with light to light brown pumice, fine to medium bubble, and poor crystal. GSD Data indicated a different characteristic on each layer which is classified into a pyroclastic fall unit showing grain-supported characteristics and two pyroclastic flows unit showing matrix-supported characteristics. Fall product comprises <10% of volcanic lithic (altered rock abundance) whereas in each flow product has 5-25% and 25-70% of various types of volcanic lithics (all deposits have <5% banded pumice and <1% single crystal). All of pumice has 0.6-0.9 g/cm^3 (0.7-0.8 g/cm^3 of mode) of bulk density; 60-74% of vesicularity; 20-32% of glass; and consists of phenocryst plagioclase; pyroxene; hornblende; and opaque mineral which increases the content up to 10% on flow unit.

By combining fieldwork data and laboratory analyses, we identified three units deposit as Plinian fall (P1), Ignimbrites (P2), and Lithic-rich Ignimbrite (P3). P1 and P2 have An_{41}-An_{54} of plagioclase; 72-78% of SiO_2 glass and An_{41}-An_{58} of plagioclase; 76%-81% of SiO_2 in glass while on P3 has lower An content (An_{32}-An_{49}) of plagioclase; higher silica content 77-81% of glass. The common texture on plagioclase is found as oscillatory zoning, patchy zoning, and glomeroporphyritic.

After synthesizing deposits characters observed all locations, these three units correspond to three phases from the Plinian eruption (P1); PDC (P2); then Lithic-rich PDC (P3) during evacuating of the magma chamber. Presence of precursory Plinian (P1) suggests an internal magmatism-triggered caldera-forming eruption. Abundance of altered rock in P1 proposes a volcanic cone which exists before the caldera formation. Production on the same type of volcanic lithic in higher abundance in P2 and P3 are enhanced by higher eruption intensity accompanying conduit widening in the single vent. The dominant oscillatory zoning plagioclase suggests a convection perturbation at the melt-crystal interface during fractional crystallization. Moreover, evolved compositions of magmatic glass from P1, P2, to P3 with time might be related to the shift of eruption style during caldera-forming eruption.

Magma fracturing, oxidation and nanolite crystallization processes during silicic magma eruption: Implication from textural and chemical analyses on oxidized obsidian

*Kyohei Sano[1], Eiichi Sato[2]

1. Graduate School of Regional Resource Management, University of Hyogo, 2. Faculty of Liberal Arts and Sciences, Osaka Prefecture University

Silicic volcanism ranges from explosive to effusive. Understanding what controls in such activity is an important issue to explain the explosive-effusive transition. Especially, a recent study revealed that oxygen fugacity affects the melt viscosity (Genova et al., 2017). Thus, it is important to characterize the microlite and/or nanolite as the indicator of magma fracturing, crystallization and oxidation processes on silicic magma eruption. At the Akaishiyama obsidian lava on Shirataki, northern Hokkaido, Japan, we can observe the red-colored oxidized obsidian mingled with black-colored obsidian on the surface of lava. The mingled obsidian shows various contrasts and distributions on the hand specimen, and we can consider that such various oxidation and fracturing textures reflect the different mechanisms of fracturing, outgassing, and oxidation during the eruption. In this study, we performed textural and chemical analyses on oxidized obsidian by using Field Emission Electron Probe Micro Analyzer (FE-EPMA) at Osaka Prefecture University to describe the textural variation relating to the magma fracturing and oxidation. Our analyses using FE-EPMA revealed that microlite and nanolite crystalized on oxidized and fractured texture. On this texture, we could also observe the chemical heterogeneity of FeO and CaO on glass chemical compositions. In this presentation, we describe the relation between nanolite crystallization and magma fracturing, oxidation texture and finally discuss the formation process of heterogeneous magma fracturing, crystallization and oxidation textures during the eruption.

Redox state and nanolite crystallization of erupting magma during ash forming eruption at Bromo Volcano, Indonesia

*Takahiro Miwa[1], Hidemi Ishibashi[2], Masato Iguchi[3], Genji Saito[4], ATSUSHI YASUDA[5], Natsumi Hokanishi[5]

1. National research institute for earth science and disaster resilience, 2. Shizuoka University, 3. DPRI, Kyoto University, 4. AIST, 5. ERI, University of Tokyo

We discusses a vent-conduit process during ash forming eruption at Bromo volcano, Indonesia, based on the observation of microstructure and redox variation of volcanic glass. The volcanic ash particles were collected in 24th March 2011 by real-time sampling from ongoing activity. The activity was characterized by strombolian eruption and emission of gray-brown ash plume with shock wave, showing magma head ascended to near the ground surface. The volcanic glass of the ash forming eruption comprises brown and black glasses under the stereoscopic microscope. Although both of volcanic glasses exhibits glassy appearance and identical chemical composition, observation of microstructure by Field-Emission Electron Micro Probe Analyzer (FE-EPMA) showed that the black glass contains nanolites (Mujin and Nakamura, 2014) in its matrix glass. The Fe-K edge μ-XANES (micro X-ray Absorption Near Edge Structure) spectra demonstrate that brown glass ($Fe^{3+}/\Sigma Fe$ = 0.20-0.26) is more reduced than black glass ($Fe^{3+}/\Sigma Fe$ = 0.32-0.60). From combination of the glass composition, the measured $Fe^{3+}/\Sigma Fe$ ratio and 1060 degree C of temperature, the oxygen fugacities are estimated to be NNO which is similar with that of magmatic gas from Bromo (Aiuppa et al. 2015) for brown glass and NNO+4 for black glass. Moreover we found that the oxygen fugacity becomes higher in nanolite-developed region around the edge or vesicle wall in a single black glass. These suggest close relationship between oxidation and nanolite crystallization. Vigorous recycling of eruptive material from repetitive eruptions can cause oxidation of volcanic glass and nanolite crystallization.

[S-GC48] Volatiles in the Earth - from Surface to Deep Mantle

convener:Takeshi Hanyu(Japan Agency for Marine-Earth Science and Technology, Research Institute for Marine Geodynamics), Gray E Bebout(Lehigh University), Hirochika Sumino(Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo), Yuji Sano(Division of Ocean and Earth Systems, Atmosphere and Ocean Research Institute, University of Tokyo)

Volatiles play an important role in the dynamical and chemical processes in the Earth. The presence of volatiles drastically changes mineral stability and rheological behavior of the rocks. Chemical fractionation, such as partial melting, hydration, and dehydration are controlled by volatiles in the rocks. Volatiles enhance the production of magmas and drive their ascent and volcanic eruption. The atmosphere and hydrosphere have been generated by variety of degassing events from the mantle through volcanism. Some volatiles in the Earth's surface have been suggested to be recycled back into the mantle beyond subduction zones. Although the significance of volatiles in the Earth's evolution has been recognized, each of these processes is poorly constrained. We therefore welcome contributions from experimental, observational, and modeling studies that help shed light on the behavior, chemical/physical characteristic, and flux/budget of volatiles, such as hydrogen, carbon, nitrogen, noble gases, halogens, and sulfur. We encourage studies linking the behavior of multiple volatile elements and their isotopic compositions. Studies investigating the linkage between volatile and solid geochemical tracers, the phase equilibria of volatile-bearing mantle assemblages, and the effect of volatiles on the physical properties of the mantle are also welcome.

We report new noble gas signatures of groundwaters, hot springs, and bedrock samples from two major fault system that form the plate boundary suture between the Eurasian and the Philippines Sea Plates. In the south, the east-dipping Eurasian Plate is associated with a relatively simple plate boundary fault as suggested by a well-defined cluster of earthquakes related to the active, east-dipping Chihshang Fault zone, which is the main conduit for mantle helium. In the north, as the subduction direction flips from the east-dipping Eurasian Plate to the north-dipping Philippine Sea Plate, the plate boundary fault is represented by a more complex system of east and west dipping structures. Clear signals of mantle contamination, as evidenced in helium isotopes, are also reduced in this area. We propose that as the subduction direction flips from south to north along strike, the tortuosity of the fault-related conduits increases, reducing the flow and limiting the release of mantle-derived gases.

^{4}He/U-Th dating of pore waters from Quaternary sediments of the Swiss Midland

*Yama Tomonaga[1], Edith Horstmann[1], Gaudenz Deplazes[2], Rolf Kipfer[1]

1. Swiss Federal Institute of Aquatic Science and Technology (Eawag), 2. National Cooperative for the Disposal of Radioactive Waste (Nagra)

Dating based on the ^{4}He/U-Th method can be used to estimate the residence time of pore waters in very low-permeable rocks and consolidated sediments. The residence time is inferred from the time necessary to accumulate radiogenic ^{4}He measured in the pore water being produced by the decay of U and Th in the sediment matrix [1].

In the Jurassic Opalinus Clay, the pore water still contains the signature of the original marine formation water that was entrapped during sediment deposition. The pore water composition was altered only by diffusive processes [2,3]. The fact that even ~100-Ma-old water signatures can be preserved in their original pore space suggests that such preservation might also be possible in much younger dense glacial deposits. The ^{4}He concentrations measured in the pore waters of glacial tills were translated into mean residence times of 15-25 kyrs [4] that agree rather well with the expected depositional ages of 25-31 kyrs [5]. These observations, as well as evidence from lacustrine sediments [6,7], suggest that, if the solute transport in the pore space is sufficiently attenuated, even unconsolidated sediments can "store" and host "old" pore waters.

In the present work we investigate if the ^{4}He/U-Th dating of pore waters can be used as a novel tool to complement other dating tools (e.g., optically-stimulated luminescence) for unconsolidated Quaternary sediments. We applied the ^{4}He/U-Th method to date pore waters in the time range of 10 to 100 thousands of years which covers the age range of the sedimentary depositions targeted by the Quaternary drillings (QBO) managed by the National Cooperative for the Disposal of Radioactive Waste (Nagra) in Switzerland. In particular, we focus on fine-grained lacustrine sediment layers that might provide low-permeability conditions suitable for the preservation of radiogenic ^{4}He concentrations in the pore space.

We report the preliminary results of the ^{4}He/U-Th dating based on the measurements conducted in sediment samples from selected QBO, highlighting potential and challenges of the method with respect to the studied glaciofluvial sediments of the Swiss Midland.

Noble gas composition in hot spring gas in Shikine Island, Izu–Bonin volcanic arc, Japan

*Kotaro Toyama[1], Hirochika Sumino[1], Muga Yaguchi[2], Takeshi Ohba[3], Takashi Toyofuku[4], Shigeki Wada[5]

1. The University of Tokyo, 2. Meteorological Research Institute, 3. Tokai Univ., 4. JAMSTEC, 5. Shimoda Marine Research Center, University of Tsukuba

Shikine island is located on the rear-arc side of the northern part of the Izu–Bonin arc, and is a rhyolite-dominated volcano which erupted in ca. 8000 years ago. Recently, the CO_2-rich emission were found in coastal area of southern Shikine island (Agostini et al., 2015 RSMS). It is considered that its gas is volcanic gas.

Geochemical features of volcanic gas provide important information on both the current status of cooling magma batches intruding the upper crust and interaction processes taking place between rising fluids and hosting rocks. Especially, noble gases have great potential as tracers for mantle sources and fingerprinting of geothermal reservoirs (Pinti et al., 2013, JVGR), because the noble gases in the gas are derived from three potential sources: the crust, the mantle, and the atmosphere. We report noble gas composition of hot spring free gases collected from 2 sites (Mikawa-bay and Jinata-hot spring) in coastal area of southern Shikine island during 2016 to 2019.

The measured $^{3}He/^{4}He$ ratios were corrected for atmospheric contamination based on $^{4}He/^{20}Ne$ ratios. The air-corrected $^{3}He/^{4}He$ ratios ranged from 7.8 to 8.0 Ra, where 1 Ra denotes atmospheric $^{3}He/^{4}He$ ratio of 1.4×10^{-6} (Ozima and Podosek, 2002, Noble Gas Geochemistry). This value is similar to that (8±1 Ra) of the upper mantle estimated from mid-ocean ridge basalts (MORB). The $^{20}Ne/^{22}Ne$ and $^{21}Ne/^{22}Ne$ ratios of the samples ranged from 9.86 to 9.93 and from 0.0292 to 0.0294, respectively, which are totally similar to the atmospheric component (9.80 for $^{20}Ne/^{22}Ne$ and 0.0290 for $^{21}Ne/^{22}Ne$; Ozima and Podosek, 2002). The $^{38}Ar/^{36}Ar$ ratios or 0.187–0.189 were also atmospheric (0.188; Ozima and Podosek, 2002). In contrast, the $^{40}Ar/^{36}Ar$ ratios ranging from 297 to 300, were slightly higher than that of the atmosphere component (296.0; Nier, 1950, Physical Review), suggesting that they reflect the gas source. Noble gas relative abundances are given using the F-value notation (Ozima and Podosek, 2002) in which measured abundances are normalized to the air abundance with ^{36}Ar as the reference isotope, i.e., $F(i)=(i/^{36}Ar)_{sample} / (i/^{36}Ar)_{atmosphere}$. Some researchers suggested that the relative abundances in fumaroles and hot-spring gases in geothermal area reflect elemental fractionation during boiling and steam separation at hydrothermal temperatures (Pinti et al., 2013 JVGR). The condensation temperature in the present area is estimated as about 150˚C adopting the model of batch fractionation using an initial air saturated seawater end-member at 25˚C to the observed $F(^{20}Ne)$ and $F(^{132}Xe)$.

Helium and CO_2 fluxes in Wakamiko caldera

*Ma. Teresa Escobar[1], Naoto Takahata[1], Kotaro Shirai[1], Takanori Kagoshima[1], Kentaro Tanaka[1], Hajime Obata[1], Yuji Sano[1]

1. Atmosphere and Ocean Research Institute University of Tokyo

Wakamiko caldera is part of the active volcanic arc system situated in Kagoshima Bay. It is closely being monitored because it has the potential for a destructive eruption. In this study, we collected seawater and sediment pore water samples within Wakamiko caldera and nearby sites around Kagoshima Bay in 2015. Helium isotopes, which are good geochemical tracers for sources of fluids, were measured to know the composition and origin of the hydrothermal effluents. Gas composition, including carbon and nitrogen isotopes, was also analyzed to understand the provenance of the dissolved gases in the pore water. This is the first report on the dissolved gases in sediment pore water in Wakamiko caldera.

Helium isotopic ratios in both seawater and sediment pore water show a mixture of air saturated seawater (~1Ra) and magma source with ~7Ra. This means the origin of excess helium-3 in bottom water is same as that in sediment. This trend is similar to previous studies in 2010 and 2014, which indicate that hydrothermal activity is stable in this period. The ^3He and ^4He fluxes derived from this study are 13.7 - 18.4 atoms/cm^2s and 1.51 - 1.54 x10^6 atoms/cm^2s, respectively. These estimates reflect background diffusion of helium in the Wakamiko caldera. Measurement of gas composition showed that the pore waters are CO_2 rich and stable carbon isotope analysis revealed that the CO_2 in the system is a mixture of biogenic sources and magmatic volatiles similar to that of Mt. Sakurajima. Finally, the estimated average magmatic CO_2 flux from the submerged caldera is 1.41 x 10^5 mol/yr.

Noble gas isotope compositions of mafic phenocrysts in the Stage 3 lavas of Kusatsu-Shirane Volcano

*Nobuko Kametani[1,2], Hirochika Sumino[3], Kenta Ueki[4], Morihisa Hamada[4], Yasuo Ishizaki[5]

1. Graduate School of Science and Engineering, University of Toyama, 2. Mount Fuji Research Institute Yamanashi Prefectural Government, 3. Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo, 4. Research Institute for Marine Geodynamics, Japan Agency for Marine-Earth Science and Technology, 5. Faculty of Sustainable Design, University of Toyama

Kusatsu-Shirane Volcano is an active volcano, composed of two composite pyroclastic cones (Mt. Shirane and Mt. Motoshirane). Typical eruptions at Kusatsu-Shirane during the last 140 years were phreatic eruptions, and the first historic phreatic eruption at Mt. Motoshirane occurred on 23 January, 2018. The chemical and isotopic compositions of volcanic gases can be useful indicator of volcanic activity because it can be a geochemical tracer for the contributions of various components such as magma, crust and atmosphere, and the degree of magma degassing. The air-corrected $^{3}He/^{4}He$ ratio of Sessho-gawara fumarole, located on 2 km east of the 2018 phreatic vent, had been constant at 7.0-7.5 Ra during 2014 and 24 January 2018, and dropped to 6.5 Ra on 13 February 2018 [1]. Therefore, Toyama et al. [1] expected that the low $^{3}He/^{4}He$ ratios observed after the 2018 eruption may reflect relative increase of the contribution of gas supplied from the Mt. Motoshirane hydrothermal reservoir which may have low $^{3}He/^{4}$ He ratio. However, the relationship of noble gas isotopic compositions between possible end-member components such as volcanic gas and evolved crustal magma and mantle-derived mafic magma, which is the possible source of hydrothermal fluid, is poorly understood. In order to obtain information on the noble gas isotopic ratios of mafic and evolved crustal magmas, we analyzed mafic phenocrysts in lavas erupted during the Stage 3 (after 16 ka [2]).

We report the noble gas (He, Ne, Ar) isotopic ratios of mafic phenocrysts (ol, opx, cpx) in the andesitic lavas of Kusatsu-Shirane Volcano. The lavas analyzed in this study were Kagusa Lava erupted from Mt. Shirane, and Sessho Lava and Furikozawa Lava both erupted from Mt. Motoshirane. After fragmentation of these lavas using SELFRAG Lab (High-voltage pulsed power selective fragmentation system) installed at JAMSTEC, about 100 mg each phenocryst was separated by hand picking. Noble gas (He, Ne, Ar) isotope analysis was conducted using a mass spectrometer installed at the University of Tokyo. In-vacuo crushing method was used for extraction of noble gases [3].

The preliminary $^{3}He/^{4}He$ ratios were as follows: cpx in Furikozawa Lava was 6.0 ±0.9 Ra; ol in Furikozawa Lava was 11.0 ±2.6 Ra; and ol in Sessho Lava was 8.3 ±0.5 Ra. These values are similar to the $^{3}He/^{4}He$ ratio of volcanic gases such as Kitagawa fumaroles on the northern flank of Mt Shirane (average 7.6 Ra) and Sessho-gawara fumaroles (average 7.2 Ra) [1]. The $^{4}He/^{40}Ar^{*}$ ratios (Ar* denotes non-atmospheric ^{40} Ar) were as follows: ol and cpx in Furikozawa Lava were 0.14 and 0.62, respectively; opx in Kagusa Lava was 0.22; and ol in Sessho Lava was 0.65. In contrast, Kitagawa fumaroles were 9.4 and Sessho-gawara fumaroles were 3.9. Because He is more soluble than Ar within silicate melt, $^{4}He/^{40}Ar^{*}$ ratio of magma would increase as it degasses. Using $^{4}He/^{40}Ar^{*}$ ratios as the index for the degree of magma degassing, Sessho Lava was slightly more degassed than Furikozawa Lava and Kagusa Lava. In contrast, the values observed in current fumaroles suggest that volcanic gas is derived from magma that is significantly degassed compared to magmas that have crystallized mafic minerals. These results suggest that $^{4}He/^{40}$ Ar* ratio of volcanic gas has a potential to be a good indicator to monitor degassing stage of magma and/or replenishment of undegassed primitive magma to a shallow magma chamber. As the

The complex melt–fluid–rock interaction history of a dismembered cumulate dunite from eastern Singhbhum Craton, India

*Tushar Mouli Chakraborti[1], Arijit Ray[2], Gautam Kumar Deb[2]

1. Hiroshima Univ., 2. Presidency Univ.

Serpentinized Cr–spinel bearing dunite to cpx–dunite rocks are found as a dismembered N–S trending unit within multiply deformed metasedimentary rocks of Mid–Proterozoic belonging to the North Singhbhum Mobile Belt, in the eastern margin of Archaean Singhbhum Craton, India. The elongated, lenticular unit occurs close to the Bangriposi Shear Zone. The northern part of the unit is significantly more serpentinized than the southern part, where serpentinization is restricted to veins. The unusual mineral assemblages and reaction relationships observed in these rocks can be grouped into three types– Type 1 assemblage is made up of relict olivine + diopside + apatite ±clinochlore + ferrichromite + serpentine + magnetite ±metal sulphides–oxides and is from the southern part. Type II assemblage consists of diopside + hydrous augite + clinochlore + Ca–amphiboles + ferrichromite ±apatite + serpentine + magnetite ±metal sulphides–oxides, and Type III is hydrous augite + clinochlore + Ca–amphiboles + ferrichromite + serpentine + magnetite ±metal sulphides–oxides. Relict olivines from Type I are zoned (core– $Fo_{82–84}$ & rims– $Fo_{76–80}$) and have unusually high NiO and MnO. They display cumulus textures and are accompanied in places by inter–cumulus diopside (Mg no. 87–93) having very low Al_2O_3, TiO_2, Cr_2O_3 and Na_2O. Diopsides from Type II have similar compositions except lower Mg no. (76–80). Augites from Type II and III contain high OH with low TiO_2, Cr_2O_3, Na_2O and variable Al_2O_3. They occur as aggregates enveloping serpentine pseudomorphs accompanied by interstitial Fe–rich clinochlore (Mg no. 74–88). Ca–amphiboles (Edenite and pargasite) occur exclusively with hydrous augite. Serpentines from Type I have higher Mg no. than Type II and III. Fe–Ni sulphides and Mn–oxides occur as accessories, more frequently in Type II and III. Bulk–rock chemistry of these rocks shows high LOI and FeO. Also, a significant enrichment in LREE is observed. Apart from the effects of serpentinization (serpentine growth, magnetite formation and Cr–spinel recrystallization) there are additional textural and chemical evidences of prior fluid–melt–rock interactions. The NiO and MnO rich olivines from the relict areas suggest secondary enrichment via a metal–rich fluid phase, which could’ ve been responsible for the metal–rich accessory phases. Textural evidence suggests that clinochlore and hydrous augite formed simultaneously, and along with formation of Ca–amphiboles, indicates involvement of a hydrated melt–fluid. Bulk–rock LREE enrichment without conspicuous enrichment in LILEs also point towards an enriched melt–fluid phase. Interstitial apatite requires infiltration of a Ca–rich melt–fluid. Single clinopyroxene thermobarometry yields almost similar temperature but varying pressure ranges for the three assemblage types– Type I: 0.3–0.7 GPa & 1140–1240 ˚C, Type II: 1–1.2 GPa & 1275–1300 ˚C, and Type III: 0.6–1.1 GPa & 1270–1330 ˚C. Ca–amphiboles from Type II and III yield average P–T ranges of 0.9 GPa & 1000 ˚C. The discussed evidences paint a very complex history of melt–fluid–rock interaction of these rocks. However, some facts and constrains can be established– (i) The protolith was a cumulate dunite to cpx–dunite unit possibly from the lower crust, (ii) The rocks experienced high–T melt–fluid–rock interaction either in a single or multiple stage leading to formation of hydrous silicates, Ni and Mn enrichment of olivines and bulk–rock LREE enrichment, and (iii) Serpentinization was the final event to affect these rocks, possible during their transport and emplacement. Considering lower oceanic crustal heritage of these rocks, possible sources of the melt–fluid of the high–T event could’ ve been high–T hydrothermal fluids or melt–fluids from rising from the mantle. This study highlights the importance of deciphering the melt–fluid–rock interaction histories of Precambrian ultramafic rocks.

SIMS sensitivity factors of ^{2}H and $^{16}O^{2}H$ relative to ^{18}O in spinel-structured oxides

*Georg F Zellmer[1], Naoya Sakamoto[2], Minami Kuroda[3], Isao Sakaguchi[4], Hisayoshi Yurimoto[2,5]

1. Massey University, 2. Hokkaido University, 3. AIST, 4. National Institute of Material Sciences, 5. Japan Aerospace Exploration Agency

Spinel-structured oxides ("spinels") are a group of nominally anhydrous minerals characterized by a wide range of solid solution. To allow the analysis of hydrogen in spinels by ion microprobe, Relative Sensitivity Factors (RSFs), which are typically matrix-dependent, need to be determined. For this work, we have selected five natural spinels from the Mg-Al-Fe-Ti-Cr-Mn-Zn compositional space. We present an approach to estimate spinel density on basis of bulk chemical composition determined by electron microprobe. Densities in our samples range from 3.7 to 5.1 g cm^{-3}. Samples were implanted with a fixed dose of deuterium (1 x 10^{15} atoms cm^{-2}) using an ion energy of 40 keV. Subsequently, we performed depth profiling using a Cs^{+} primary beam on the Cameca ims-1270 ion microprobe at Hokkaido University, monitoring secondary ion counts of ^{2}H and ^{18}O, and at high mass-resolution $^{16}O^{2}H$, $^{17}O^{1}H$, and ^{18}O, until the implanted ion counts dropped below background levels. From the reduced data, we calculated the RSFs for secondary ions of atomic ^{2}H and molecular $^{16}O^{2}H$ relative to ^{18}O as matrix element. RSFs for ^{2}H are similar for all spinels at 1.11 ±0.32 (2 σ) x 10^{22} atoms cm^{-3}, indicating a small matrix effect for ^{2}H despite the large compositional range of spinels studied. In contrast, RSFs for $^{16}O^{2}H$ relative to ^{18}O decrease with spinel density from 2.65 ±0.36 (2 σ) x 10^{21} atoms cm^{-3} at 3.7 g cm^{-3} to 3.41 ±0.73 (2 σ) x 10^{20} atoms cm^{-3} at > 4.5 g cm^{-3}, indicating a strong matrix effect on secondary dimer production during processes of ion sputtering and secondary ionization. Our data imply that the analysis of water in natural spinels may be undertaken through measurement of H or OH, but that spinel densities must be well-determined in the case of OH measurement. Mineral density effects on RSF values will have to be evaluated prior to analysis of water in other nominally anhydrous solid solution minerals.

ALOS-2 and Sentinel-1, which have highly enhanced capacity compared to previous SAR satellites, were launched in 2014, and their utilization has been widely expanding as data have accumulated for approximately five years. Other long-operating SAR satellites like TerraSAR-X and Cosmo-SkyMed also contribute to expanding the SAR utilization. Now we are facing a new and abundant era of the satellite SAR, along with a worldwide trend to an open and free data policy of satellite data, under the situation of next-generation advanced and/or constellated SAR satellite plans by both public agencies (e.g. ALOS-4 and NISAR) and private sectors. In addition, SAR technologies with other platforms, such as ground-based SAR with high temporal resolution and UAV (Unmanned Aerial Vehicle) SAR with flexible operability, have also been developed and used for various targets. These facts indicate that the SAR utilization has become widespread in both basic researches (e.g., earth science) and diverse applications (e.g., disaster prevention and forest monitoring). In this session, we would like to invite various kinds of research and application results with regard to SAR, sharing our knowledge and having a discussion for the advancement of the SAR utilization.

Development of InSAR tropospheric phase delay correction system at MRI (4th report)

*Satoshi Okuyama[1], Shinobu Ando[1], Toshiki Shimbori[1]

1. Meteorological Research Institute

Introduction

SAR Interferometry is a technique which utilize the phase information of the SAR images to detect surface displacement which took place between two observations. However, its result contains the effect of medium between the antenna and the target such as tropospheric delay. To correct the tropospheric delay, method which utilizes numerical weather model has been proposed (Hobiger et al., 2008; Ozawa and Shimizu, 2010). We have been developing a tropospheric delay correction system since 2018 and obtained good result (Okuyama et al., 2019). This version, hereinafter called “version 1”, had problem in computation efficiency. We have improved the efficiency by replacing the coordinate system for calculation of the tropospheric delay.

Changes

Version 1 calculates tropospheric delay in ECEF coordinate system for the best accuracy. However, SAR interferograms is in geographic coordinate system, while numerical weather model we used, NuSDaS-format JMA-MA (Meso-Analysis), is a gridded data in Lambert conformal conic (LCC) projection. The difference of coordinate system of the input data forced us to calculate numerous times of coordinate transformation. Our new version, “Version 2” computes tropospheric delay in LCC projection. This reduce the number of coordinate transformation to just once per point. As a result, computation time reduced greatly, from 5 hours to 3 minutes. Calculation in LCC projection assumes flat Earth and may result in inaccurate estimation, however, the difference between Version 1 and 2 is around 1.5mm. This is small enough compared to the phase stability of the interferograms.

Future direction

Version 2 calculates tropospheric delay at the ground surface by extrapolating values from bottom 2 planes. We will introduce Land Surface data to eliminate extrapolation.

Acknowledgement

PALSAR-2 level 1.1 data are shared among PIXEL (PALSAR Interferometry Consortium to Study our Evolving Land surface) and provided from JAXA under a cooperative research contract with ERI, Univ, Tokyo. The ownership of PALSAR-2 data belongs to JAXA.

Progress for detecting surface displacement associated with 2018 Boso SSE by ALOS-2 ScanSAR interferometry

*Yohei Kinoshita[1]

1. University of Tsukuba

The slow slip event (SSE) is known to release accumulated strain energy with no or slight seismic wave radiation. The SSE is usually detected by highly accurate geophysical measurements such as the Global Navigation Satellite System (GNSS) and seismometers because of very small surface deformation on the order of millimeters to centimeters, and small ground oscillation (named as a tremor). Until now, several papers reported SSEs at Tokai area (e.g. Yamamoto et al. 2005, EPS; Ozawa et al. 2016, EPS), Cascadia (e.g. Dragert et al. 2004, EPS; Hawthorne and Bartlow 2018, JGR), and Nankai Trough (Kobayashi 2017, EPS; Ozawa 2017, EPS). The area around Boso Peninsla is also a location where SSEs have occuered with intervals of several years (Fukuda 2018, JGR). However, most of the reffered papers here used GNSS observations that have a limitation of low spatial resolution (Usually a few tens of kilometers between ground stations). In the previous presentation (Kinoshita et al., JpGU2019), we reported that the surface displacement of the 2018 Boso SSE could be detected by the stacking method of Sentinel-1 SLCs with an atmospheric delay correction based on the Japan Meteolorogical Agency Meso-Scale Model (MSM). In this study we performed the InSAR analysis using ALOS-2 ScanSAR data for the purpose of complementing the results derived from Sentinel-1 InSAR.
We performed the InSAR analysis using the RINC software version 0.41 to interfere 14 ScanSAR images. The ScanSAR data used here spans from January 2016 to September 2019. The path and frame are 17 and 2900, respectively. Topographic phase contributions were modeled and removed by the use of the SRTM4 30m DEM. All the interferograms were phase-unwrapped with the SNAPHU software. Since interferograms were to some extent contaminated by the phase noise due to ionospheric disturbances, we applied the Split Spectrum Method for all the interferograms to remove this.
Most of processed interferograms showed significant coherence to recover the SSE displacement, although the non-dispersive atmospheric delay signal was also significant. The ionospheric contribution that is the dispersive component of the atmospheric delay could be effectively removed by the Split Spectrum Method.
By the presentation, I will perform the time series analysis and the atmospheric delay correction to mitigate the non-dispersive atmospheric contribution and to detect the SSE signal. I will present the progress of this study in the presentation.

Interseismic crustal deformation along the Xianshuihe Fault System, Western China, detected by ALOS-2 ScanSAR interferometry

*XUEMEI WANG[1], Youichiro Takada[2]

1. Department of Natural History Sciences, Graduate School of Science, Hokkaido University, 2. Department of Earth and Planetary Sciences, Hokkaido University

The Xiansuihe fault system (XFS) is a large-scale strike slip fault running eastern part of the Tibetan plateau. Its western part lies high altitude and dry area, while eastern part runs mountainous area partly covered by vegetation. Although we know XSF hosts many historical earthquakes, it is difficult to grasp its current activity mainly because it is too large and too remote to be equally covered by ground based observations like GNSS. Therefore, Interferometric Synthetic Aperture Radar (InSAR) is suitable technique to make a detailed map of current fault activities. Wang et al. (2009) reported strain concentration at the western part of XSF using C-band satellites (ERS-1/2 and Envisat), which suffered from low coherence. Also, their study area is very limited (> 100 km). Zhang et al. (2019) also reported interseismic strain localization along XSF using Sentinel-1 interferograms. But their results include strong oscillation probably affected by tropospheric disturbances.
In this study, we use ALOS-2 ScanSAR images to grasp overall interseismic crustal deformation along XFS. All the interferograms are processed by GAMMA software suite (Wegmüller and Werner, 1997). The SAR images we used are acquired from descending orbit, which is more sensitive to the XSF motion than those taken from ascending orbit. We processed three interferometric pairs with temporal baseline ranging from 3 to 4 years. The coherence of those interferograms are high in summer along all the fault traces, while it decreases in winter only in eastern section. Almost all the interferograms are covered by strong long wave-length noise, possibly resulting from ionospheric and tropospheric perturbations. Assuming that GNSS data are correct, we estimated the InSAR error at each GNSS station, and interpolated the errors into all the pixels to remove the long-wavelength noise (Fukushima and Hooper, 2011; Takada et al., 2018). The GNSS velocity field used for correction has been estimated by Liang et al., (2013). The interferograms thus corrected indicate strain rate concentration along the whole trace of XSF, which is much wider than previous studies. We are currently applying the time-series analysis and the split spectrum method (Gomba et al., 2015; Furuya et al., 2017) to remove ionospheric effects before the GNSS correction.

Estimation of crustal deformation at Azumayama volcano during Aug. 2014 –Oct. 2019 by using InSAR in comparison with GNSS

*Takehiro Arai[1], Yoshiko Ogawa[1], Yasuhiro Hisada[1], Hirohide Demura[1], Taku Ozawa[2], Satoshi Miura[3]

1. The University of Aizu, 2. Graduate school of Science and Faculty of Science, Tohoku Univeristy, 3. National Research Institute for Earth Science and Disaster Resilience

Azumayama volcano is one of the active volcanoes in Fukushima prefecture. Azumayama had been issued the volcanic alert level 2 during winter 2014 - fall 2016 and fall 2018 - spring 2019. It is the most active volcano in the Fukushima Pref. We have been working on to clarify time-series of crustal deformation at Azumayama volcano [1].

In this study, InSAR (Interferometric Synthetic Aperture Radar) analysis was conducted using the data of Advanced Land Observing Satellite 2 (ALOS2) / Phased Allay type L-band Synthetic Aperture Radar 2 (PALSAR2). The crustal deformation was estimated around Azumayama volcanobased on the 12 analysis pairs of InSAR. The numerical weather model MSM (Meso Scale Model) [2] was used to correct atmospheric delay. Then new InSAR results and GNSS [3] data were compared for consistent understanding of crustal deformation in the time series.

As the results, atmospheric delays in InSAR were mitigated for most analysis pairs by introducing numerical weather model (MSM). On the other hand, MSM atmospheric correction often did not work well for the InSAR pairs where the weather condition of either of the 2 observation dates was changing rapidly, such as the approach of a cold front or a typhoon. Temporary uplift and subsidence were observed in the north of the Oana crater and a sharp uplift was observed in the west of the crater the period from fall 2018 to spring 2019. The center of crustal movement was considered to had moved to the west of Oana crater from 2014 to 2019.

Extraction of topographic changes associated with the 2018 eruption and tsunami of Krakatau volcano using time-series SAR

*Daiki Inano[1], Hodaka Okazaki[1], Masanobu Shimada[1]

1. Tokyo Denki University

Synthetic aperture radar (SAR) has the advantage of being able to observe over a wide area without being affected by the weather or day and night. Because SAR passes through clouds and smoke, changes in the island immediately after the eruption can be clearly seen even if the eruptions and volcanic ash erupt from the crater. Then, in order to classify land and sea from the images observed by SAR, consider the definition of land and sea. The land area is a place where the altitude is 0 m or more, and the scattered signal is generally larger than that of the sea area. On the other hand, the sea area is a zone where the altitude is 0 meters, and the reflected signal is generally small. Since the signal in the land area is larger than that in the sea area, it appears bright in the amplitude image.

In this study, we used the time-series SAR data to extract changes in island area for topographic changes associated with the eruption of Anak Krakatau Island in 2018. We analyzed the image data from January 22, 2018 to May 21, 2019, and calculated the area change by two methods for three scenes in which the terrain changed significantly.

The first is a histogram method. From the amplitude image, histograms of the land area and the sea area are created, and an optimum threshold at which both distribution functions intersect is determined. Then, the area where the backscattering coefficient was larger than the sea was defined as land, and the area was calculated by multiplying the number of pixels in the land area by the image cell size. This method works with high accuracy when the island is clearly brighter than the sea. However, when the sea surface is rough and the scattering coefficient is high as in this study, it may be difficult to make clear identification.

The second is a shoreline extraction method. The pixel value of the amplitude image is forcibly set to 0 based on the threshold value obtained by the histogram method. Then, the coastline displayed brightly is extracted (manual operation), and the inside of the extracted closed curve is included in the land area. Similar to the histogram method, the number of land pixels was multiplied by the image cell size. The shoreline extraction method is considered to be a method that can calculate the area with higher accuracy than the histogram method without being affected by backscatter on the sea.

As a result, the area of Anak Krakatau Island was 2.88 square kilometer before the eruption, 3.07 square kilometer after the eruption, and 3.06 square kilometer several months after the eruption. As for the amount of change, the island area increased by 0.18 square kilometer before and several months after the eruption. It is said that it is difficult to analyze an island surrounded by the sea on all sides using the interferometric SAR method. The method in this study is considered to be very effective in the area where the coastline is clear even in the analysis of such islands.

Land subsidence prediction in Beijing plain using machine learning methods

*Yuyi Wang[1], Yun Pan[1]

1. Capital normal university

Land subsidence is usually difficult to be predicted due to its complex regulating processes, especially in the metropolitan environment, such as Beijing, where both natural and anthropogenic factors exist. This study aims to investigate the potential and limitations of machine learning methods in predicting land subsidence of a metropolitan area with a case study in Beijing, where significant land subsidence has been reported since early 1950s. The SAR image data of Radarsat-2 was collected, and the SBAS-InSAR (Small Baseline InSAR) interferometry was used to monitor the spatial distribution of land subsidence in the Beijing Plain from 2012 to 2015, while five machine learning methods (random forest algorithm, decision tree algorithm, extra tree algorithm, Boosting algorithm, neural network algorithm) were used to establish the models for prediction, with a focus on the driving factors of precipitation, groundwater level changes (unconfined water level and confined water level), distance from the fault, elevation, compressible layer thickness, and land use. The results shown that: (1) the extra tree method had the best performance (94.03%), followed by the boosting algorithm (93.91%) and decision tree (90.50%), in contrast to a degraded performance by the neural network (79.8%) and boosting algorithm (67.4%). (2) based on data mining methods of machine learning algorithms, the factor contribution rate of diving factors to land subsidence in Beijing plain was obtained, which showed that precipitation has the highest influence, followed by compressible layer thickness, confined water level change, unconfined water level change, distance from fault zone, altitude, and land use; (3) future development of land subsidence was simulated with varying groundwater level rise scenarios. The results demonstrated a good potential of machine learning methods in predicting and understanding the land subsidence in the metropolitan area towards a sustainable groundwater resources management.

Estimation of velocity distribution of Shirase Glacier derived from SAR data obtained by ERS-1/2 tandem mission (2)

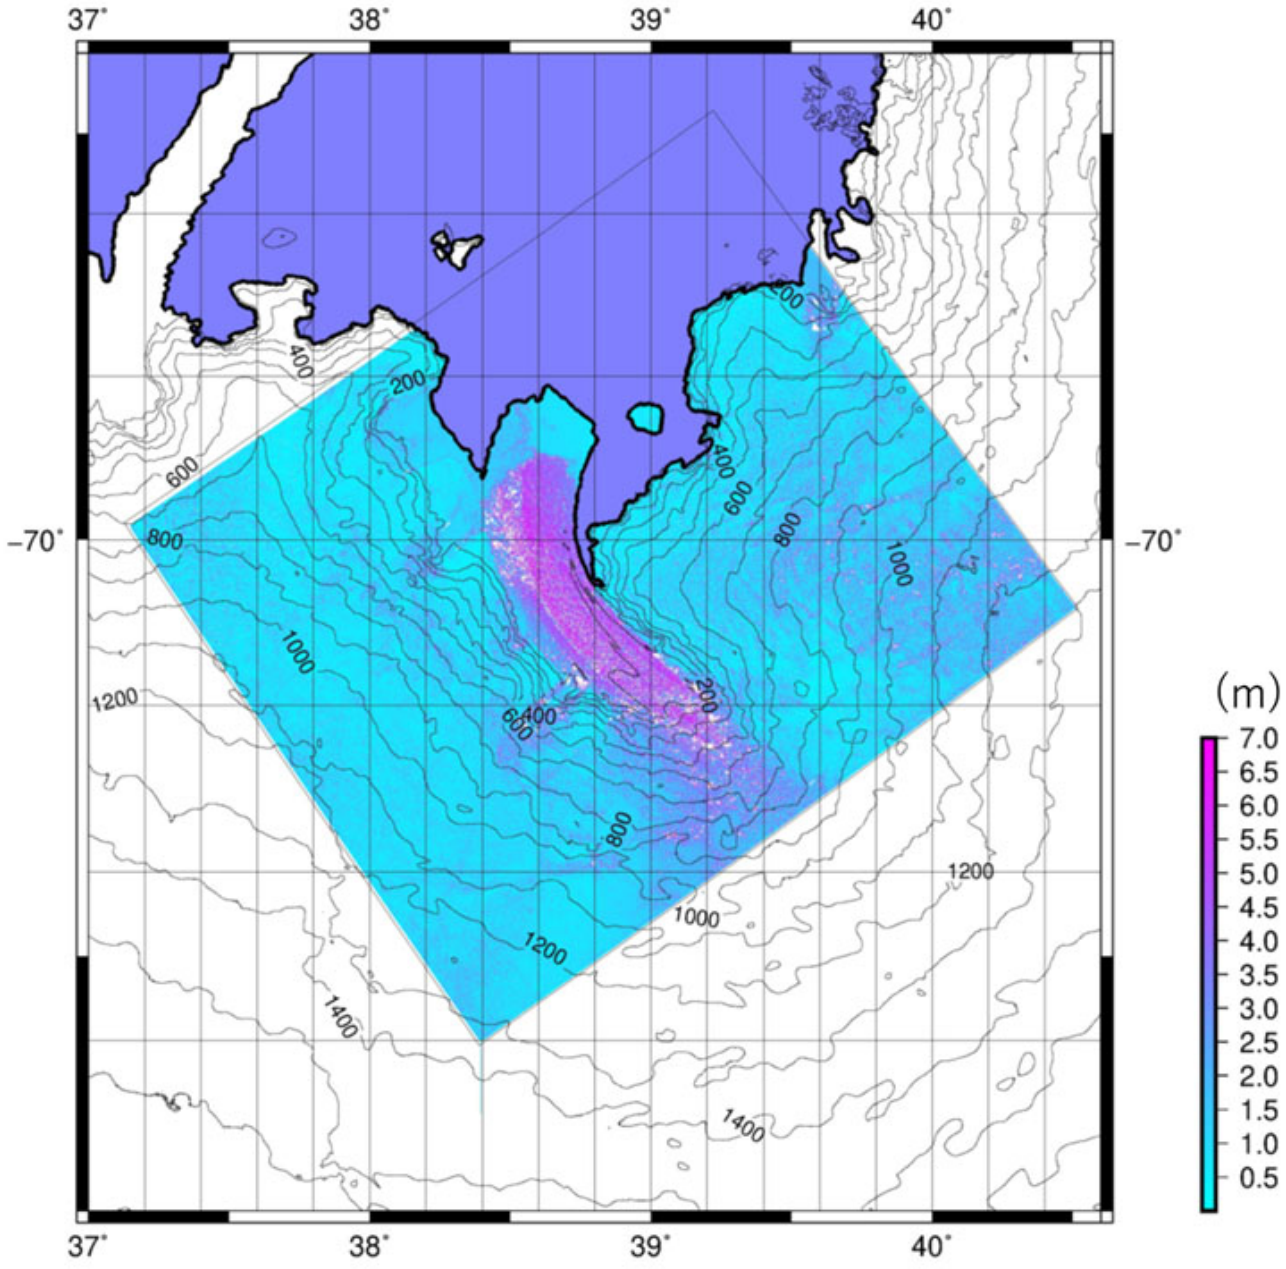
*Koichiro Doi[1,2], Yuichi Aoyama[1,2], Kazuki Nakamura[3], Tsutomu Yamanokuchi[4], Kazuo Shibuya[1]

1. National Institute of Polar Research, 2. The Graduate University for Advanced Studies, SOKENDAI, 3. College of Engineering, Nihon University, 4. Remote Sensing Technology Center

Shirase Glacier is one of the fastest flowing ice streams in Antarctica flowing into the southernmost of Lü tzow-Holm Bay in Dronning Maud Land, East Antarctica. It is important to clarify the spatial flow rate distribution with a high-resolution to investigate causes of the fast flow and the temporal flow rate changes. In order to make a high-resolution flow velocity map, we can apply a usual interferometric Synthetic Aperture Radar (InSAR) technique to an InSAR pair data. However, since flowing velocity of the ice stream is greater than 2 km/year (Nakamura et al., 2007, Aoyama et al., 2016), it is difficult to estimate the flow velocity by applying the InSAR technique to the ordinal repeat cycle SAR mission data.

Tandem mission by European Satellite of Remote sensing (ERS)-1/2 was conducted in 1996 and 1999. In this tandem mission, ERS-2 had flown after ERS-1 in the same orbit with an interval of one day, and many InSAR pairs with one day temporal baseline were obtained through the mission.

We successfully obtained three SAR interferograms over Shirase Glacier using this tandem mission InSAR pairs acquired at 1996/06/02-1996/06/03, 1999/11/14-1999/11/15 and 1999/12/19-1999/12/20. We estimated surface displacements along range direction (direction of radar illumination) by applying differential InSAR (DInSAR) with a TanDEM-X 90m DEM (Rizzoli et al., 2017) to remove topographic phase. We also estimated displacements along azimuth direction (direction perpendicular to range direction) by applying a split beam interferometry (SBI) (Bechor and Zebker, 2006) technique to the three InSAR pairs. By combining the range and azimuth displacements, spatial flow velocity distributions can be derived with a high-resolution. Since displacements obtained by the DInSAR and SBI techniques contain artificial displacements due to some interferometric phase trends, we estimated the artificial displacement trends from displacements over outcrop rock areas under an assumption that no crustal displacements occurred there for one day, and the trends were eliminated. We show an example of surface ice displacement over Shirase Glacier obtained from the pair 1999/11/14-1999/11/15 in the figure.



We can evaluate accuracies of the obtained ice surface displacements from the displacements over outcrop rock areas after the artificial trends for each pair. The averages standard deviations of the three pairs observed over the outcrop rock areas are 4 cm in range direction and 123 cm in azimuth direction.

We also compared the flow rates and directions with in-situ GNSS measurements situated on a downstream site in Shirase Glacier observed for three years from 2015 to 2017. We found mean differences between the two observations (DInSAR −GNSS) of -0.691 (m/day) in flow rate and 15.7 (deg.) in flow direction.

In the presentation, we will show two-dimensional flow velocity maps with a resolution of approximately 20 m at the three periods and discuss spatial and temporal velocity changes.

Evaluation of inundation area extraction method for the 2018 Western Japan heavy rainfall using PALSAR-2

*Hasatani Ryuta[1], Hiroto Nagai[2]

1. Waseda Univ School of Creative Science and Engineering, 2. Waseda Univ School of Education

In recent years, due to global warming, there are many opportunities to use SAR (Synthetic aperture rader) mounted on earth observation satellites for emergency observation of typhoons and heavy rains and for measuring damage over a wide area. Many methods for extracting the inundation areas from SAR have been proposed, but most of them are methods that perform threshold processing of the backscatter coefficient from the intensity information. However, a method of extracting the inundation area by combining the intensity information and the phase information has not been established yet, and there are few examples(Ohki et al., 2016).

In this study, PALSAR-2 satellite is used. From the intensity information, One is a normalized backscattering intensity change index image (NoBADI) (Nagai et al., 2017)is created. It is possible to display unusual inundation area using multiple images before inundation, And the other is a single image of the backscattering intensity was created. From the phase information, two types of images are created a pair immediately before and after the disaster: γ_{pre} (observation interval width: about 3 months) and a pair before and after the disaster: γ_{summer} (observation interval width: about 2 years). The verification area in this study is the inundation area of Kurashiki City and Soja City in Okayama validation prefecture, which was flooded by heavy rains on 2018, and the area 3 km around it. From the intensity information, Inundation areas were extracted by classifying land cover, paddy areas, upland areas, and building areas. From the topological information, Extract the inundation area in the building area. The κ coefficient was used as the index of inundation area extraction accuracy.

As a result of the inundation area extraction, it was found that the paddy field area and upland field area showed a higher value of κ coefficient when the backscattering intensity single image was used regardless of the presence of the speckle noise filter. It was confirmed that when the filter window size was enlarged, a high κ coefficient was shown. The urban area showed the highest value of the κ coefficient when the coherence image of the phase information was used. As for the κ coefficient of the phase information, γ pre: $\kappa = 0.397$ γ summer: $\kappa = 0.037$ was calculated.It is necessary to consider the observation period when creating interference pairs.

Next steps we will propose an optimal method for extracting the inundation area according to the geographical features, And Determine the optimal filter window size from the viewpoint of maintaining high resolution images.

Integration of ALOS PALSAR and Landsat-7 ETM+ data for buried lineaments extraction at the Farafra Oasis, Egypt

*Noha Ismail Medhat[1,2], M.-Y Yamamoto[1], K. Mansour[2], A.M Abbas[2], M. Abdel Zaher[2]

1. Kochi University of Technology, 185, Miyanokuchi, Tosayamada, Kami, Kochi, 782-8502, Japan, 2. National Research Institute of Astronomy and Geophysics, Helwan, Cairo 11421, Egypt

In the last few years, ALOS/PALSAR (L-band) (HH, HV, VH and VV) images have been widely used due to its ability to penetrate the surface in certain conditions for example of low moisture or dry friable sandy soil. Images from ALOS-1 sensor have been applied to delineate subsurface structures. Optical images such as Landsat-7 ETM+ data are used to discriminate between scatterings from earth surface and subsurface materials. Thus, Farafra desert is an optimal environment for L-band microwave penetration. Therefore, this research involves mapping and interpretation of lineaments, surface and subsurface structures. The interested four spots at Farafara sand sheets display many structures that not have been traced in the Egyptian official geological maps.

Speckle noise is found in radar images due to many reasons, for example, when an object strongly reflected between itself and the spacecraft causing noise. Refined LEE Filter (RLF) is applied for speckle noise reduction; speckle noise near strong edges is not strongly filtered, leaving the center of the pixel unfiltered, so, this procedure is an essential step in processing of polarimetric data to improve the accuracy of the data and enhance resolution. ALOS/PALSAR data are processed into circular polarization for providing the best viewing of morphological and subsurface lineaments. The ellipse shape governed by two axes; semi-major axis ‘a’ and semi-minor axis ‘b’. Orientation angle(ψ) is measured from positive horizontal axis X counter clockwise direction, orientation angle range from 0° to 180°. Ellipticity (χ) is a shape parameter defined by the degree of oval shape, defined by $\chi = arctan b/a$ and can take values between -45° to $+45^{\circ}$. As, the circular polarization yielded best outputs of subsurface structure in different trends, full polarimetric ALOS/PALSAR images (PLR) are transformed into circular polarization, by changing both angles into orientation angle $\psi = 0^{\circ}$ and elliptical angle $\chi = 45^{\circ}$. Full polarimetric images are represented in Pauli RGB. Landsat-7 ETM+ data are freely uploaded with the same date and location of ALOS/PALSAR images. Bands 1, 2, 3, 4, 5 and 7 are merged together, then bands (R:2, G:4, B:7) are changed to obtain best spatial resolution. Landsat-7 images have some gap areas, which is essentially be filled with Landsat-7 data acquired at the same time of the year by histogram matching technique to fill the missed pixels of the interested target scenes according to Landsat 7. The obtained rose diagram shows two trends of dominant and secondary; the most dominant direction is North West (NW 330˚), while the secondary trend is North (North 10°). This result is confirmed by the field survey. The dominant direction of lineaments extracted from ALOS/PALSAR images is well fitted with the secondary direction of the geological structure in the study area.

This work represents a stage of achievement in detecting buried lineaments covered by sand sheets by using ALOS/PALSAR and Landsat-7 ETM+. Surface and subsurface lineaments that can be extracted in Farafra formations. May be due to its geological nature and spatial resolution that well fit to ALOS/PALSAR radar wave. Extracted orientation of the lineaments; especially in sand sheets proved great correlation with the secondary trend of the geological structure at Farafra map. Ground penetrating radar can easily support confirmation of ALOS/PALSAR result at the traced interested spots; alternatively, consuming time and budget in exploring the whole area. In addition, parameter analysis of soil samples from field survey will be carried out, if possible.

Development of multi-type portable radar interferometer for volcano observation

Taku Ozawa[1], *Yuji Himematsu[1]

1. National Research Institute for Earth Science and Disaster Resilience

Recent advances in spaceborne SAR and its analysis techniques have enabled us to detect volcano deformation in a detailed. As a result, spaceborne SAR has been used as a useful tool in the evaluation of volcanic activity and the study of mechanisms. However, the frequency of spaceborne SAR observation is limited to the recurrence period satellite, and therefore, it is difficult to detect volcano deformation that its distribution changes greatly within a short time. Then, we are developing “multi-type portable radar interferometer” for detecting volcano deformation in the task B sub-theme 2 of the “Next Generation Volcano Research” project. It transmits radar wave from the ground, and then, can detect volcano deformation with high temporal resolution. By this sensor, we want to be able to observe a wide area as frequently as once a day by repeat observations. For this purpose, it is necessary to use a system that does not cause a decrease in coherence due to vegetation. Therefore, in this sensor, we adopted an L-band radar wave with high permeability to vegetation, and fabricated an experimental sensor. We carried out an experiment measurement within 1-hour by its sensor in the Asama-yama for 1 hour, and it was confirmed that high coherence was obtained. Furthermore, a phase change considered to be an atmospheric delay was detected (Ozawa and Himematsu, 2019).
Since it is necessary to carried out repeat observation in this system, it is necessary to confirm whether appropriate coherence can be obtained by the repeat path observation. Therefore, we carried out experiment measurements at the southwestern foot of the Tsukuba-san on October 16 and October 17, 2019. The slant distance to the summit is about 4 km. In this experiment, the rail was installed on the concrete part of the riverside of the Sakura-gawa, and the observation by the ground-based type was performed. Applying SAR interferometry to a data pair that observation interval was one day, a high coherence was obtained in the region where strong scattering intensity was obtained. At the summit, a phase change of about half a cycle is detected, which may be an atmospheric delay component. From this result, it was confirmed that the repeat path observation by the multi-type portable radar interferometer for volcano observation can be applied successfully. Furthermore, in order to investigate the continuity of coherence, a measurement experiment at the Tsukuba-san was performed every about once a month. High coherence was obtained in the result of data pair with an observation interval of one month. However, decorrelation became remarkable in the result of the data pair with the observation interval of 2 months, and in that with the observation interval of 3 months, the area where coherence was obtained was limited to around the summit where the vegetation was relatively sparse. From the above, it can be said that the continuity of coherence for the present version of experimental sensor is about two months. Tsukuba-san is covered by relatively dense vegetation, it may have caused such short continuity of coherence. However, its improvement is necessary, because longer continuity of coherence is preferable for volcano observation. Significant noise sometimes superimposes on the SAR image obtained from the current experimental sensor, and it may cause decorrelation. Now, we are improving hardware and software to solve this problem, and we will investigate whether these improvements can improve the continuity of coherence in the future.

An Open-Source InSAR Time Series Analysis Package LiCSBAS and Its Application

*Yu Morishita[1,2], Milan Lazecky [2], Tim J. Wright [2], Jonathan R. Weiss [3,2], Yasser Maghsoudi [2], John R. Elliott [2], Andy Hooper [2]

1. Geospatial Information Authority of Japan, 2. University of Leeds, 3. University of Potsdam

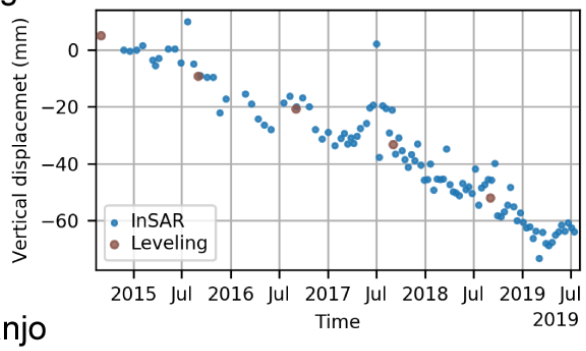
For the past five years, C-band Sentinel-1 and L-band ALOS-2 have provided abundant and useful Synthetic Aperture Radar (SAR) data, which have the potential to reveal global ground surface deformation at high spatial and temporal resolutions. However, for most users, fully exploiting the large amount of associated data is challenging, especially over wide areas. Whereas Geospatial Information Authority of Japan (GSI) has been monitoring surface deformations over Japan areas using ALOS-2 data, a sophisticated time series analysis technique has not been implemented for the nationwide scale.

To help address these challenges, we have developed LiCSBAS (https://github.com/yumorishita/LiCSBAS, https://doi.org/10.3390/rs12030424), an open-source SAR interferometry (InSAR) time series analysis package that integrates with the automated Sentinel-1 InSAR processor (LiCSAR). LiCSBAS utilizes freely available LiCSAR products, and users can save processing time and disk space while obtaining the results of InSAR time series analysis. In the LiCSBAS processing scheme, interferograms with many unwrapping errors are automatically identified by loop closure and removed. Reliable time series and velocities are derived with the aid of masking using several noise indices. The easy implementation of atmospheric corrections to reduce noise is achieved with the Generic Atmospheric Correction Online Service for InSAR (GACOS).

Using case studies in southern Tohoku and the Echigo Plain, Japan, we demonstrate that LiCSBAS applied to LiCSAR products can detect both large-scale (>100 km) and localized (~km) relative displacements with an accuracy of <1 cm/epoch and velocities of ~2 mm/yr with ~60 observations over 2 years. We detect displacements with different temporal characteristics, including linear, periodic, and episodic, in Niigata, Ojiya, and Sanjo City, respectively.

LiCSBAS and LiCSAR products facilitate greater exploitation of globally available and abundant SAR datasets and enhance their applications for scientific research and societal benefit.

Interferograms from satellites other than Sentinel-1 and generated using a variety of software packages can also be processed by LiCSBAS. The software will enable GSI to improve its monitoring capability and realize robust continuous nationwide monitoring of surface deformation exploiting ALOS-2 and coming ALOS-4 data.



We also present applications of LiCSBAS and LiCSAR products to all major urban areas in Japan and continental-scale Alpine Himalayan Belt in this presentation.

Acquisition and application of offshore W-VSP in deep gas field in East China Sea basin

*Shunli Gao[1], Senqing Hu[1], Jun Zhao[1]

1. China National Offshore Oil Corporation (CNOOC), China Limited-Shanghai

Offshore Walkaway &walkaround VSP(W-VSP) is one of the borehole seismic. Compared with towing cable seismic method, borehole seismic has less absorption and attenuation of high-frequency information because of less propagation paths, so it is an innovation attempt of seismic technology for deep gas fields in East China Sea.

Oil and Gas exploration in East China Sea basin reveals some special geological conditions: deep reservoir, complex structure and reservoir anisotropy which cause many problems in conventional streamer seismic acquisition and processing, such as multiple, low signal-to-noise ratio and low resolution.

The W-VSP test area is fully covered by 3D towing cable seismic data and the local structure is a small faulted anticline trap with nose structure background under the control of basement high. The main target layer is sand-shale interbedded deposited in the braided river delta of Eocene and the drilling shows that the trap is rich in gas in channel reservoir below 4000m.

After selecting the test well, making acquisition simulation design, optimizing the acquisition mode and parameters, W-VSP acquisition was conducted by placing geophone in the borehole and shooting around by seismic vessel. The 2D walkaway was conducted with the same survey line direction as the existing 3D survey to ensure the optimal data quality and matching with the existing data. Shot point range is 6000m for inline and crossline, and 3.0 km and 4.5 km for loop line. Shot interval is 25m. Time sampling rate is 1ms. Record length is 7000ms. The source is 4210in.cu^3 (single source) with 4 subarrays and 6m sinking depth.

Good results of field and processing data are obtained from W-VSP, which improves the interpretation accuracy of the structure and reservoir around the wellbore. In the deep layer below 4300m, band width of W-VSP data is 0-80 Hz, main frequency is 45 Hz, far higher than the 25 Hz of the streamer 3D seismic data.

By extracting suitable seismic processing parameters, such as attenuation factor and multiple models, well-driven streamer 3D processing is carried out, and we obtained high quality 3D seismic data with enhanced resolution and signal-to-noise ratio. The test shows that the seismic image can be effectively improved by this technology, which is good for sand tracing and gas reservoir description in offshore deep gas fields.

Well-driven 3D seismic processing mainly uses key technologies to obtain well-driven processing parameters from Z-VSP and W-VSP data, including: (1) true amplitude recovery factor TAR; (2) absorption attenuation factor Q; (3) corridor stack section; (4) anisotropic parameters; (5) time-depth relationship and velocity. Well-driven are mainly from the following aspects. Firstly, wavelet processing, ghost suppression technology and anti-Q filter technology and other offshore wide-band processing technologies are adopted to improve resolution and broaden the frequency band. Secondly, shallow

©2020. Japan Geoscience Union. All Right Reserved.

water multiple suppression, tau-p domain deconvolution, SRME, high-precision radon transform and other techniques are used to suppress various multiples step by step, focusing on the fidelity of de-noising process, to improve the signal-to-noise ratio. Finally, high precision velocity analysis, grid tomography modeling and pre-stack depth migration are applied to improve the imaging accuracy.
According to the analysis of well-driven 3D seismic processing results, due to the enhancement of deep energy and the effective removal of multiples, the results is improved in seismic events, having higher signal-to-noise ratio and better continuity. The sand distribution of the main gas reservoirs in deep layer are consistent with drilling results. Through tracking and interpretation of sand at 4600 m depth, the gas reservoir was revealed as a structural and lithological composite type, with the faulted anticline area of 0.54 km^2 at the high position. However, due to the lateral change of sand, the area of sand inclined stratigraphic trap is 0.38 km^2. The reserves calculated according to the fine description of this sand are consistent with the developed reserves of gas fields.

Study on the cause of the misalignment of the incidence azimuth of the air gun signal at the S-net station estimated from particle motion

*Ryoichi Iwase[1]

1. National Research and Development Agency, Japan Agency for Marine-Earth Science and Technology

The author estimated the orientation of the Ocean Bottom Seismometer (OBS) and seismic wave velocities in the sediment of seafloor surface at 12 stations of the large cabled observatory ” S-net” (Seafloor observation network for earthquakes and tsunamis along the Japan Trench), consisting of 150 stations in a vast area in the Pacific Ocean on the east coast of Japan from off Hokkaido to Boso Peninsula, which was installed by National Research Institute for Earth Science and Disaster Resilience (NIED). The result of the estimated orientation of the OBSs is consistent with Takagi et al. (2019). P-wave velocity is estimated to be around 1.8 km/s at most stations, and S-wave velocity is estimated to be less than 0.4 km/s at stations on landward slope and 0.3–0.7 km/s at those on the seaward slope of the trench.
However, the estimated incident azimuth of the air gun signal based on the particle motion does not always coincide with the actual azimuth of the air gun (ship azimuth) in time series, and misalignment is recognized. Some are caused by local seafloor topography such as a nearby seamount having a large relative height. On the other hand, however, misalignments are observed at some stations where such seafloor topography does not exist. Regarding the misalignment of the sound source azimuth, it was observed that in the sound source localization of an air gun using OBS off Kamaishi City in Iwate Prefecture the misalignment was up to approximately 9 degrees (Iwase, 2016).
The topographic feature common to the stations installed in the Japan Trench area is the slope. Therefore, the effect of the case where the fluid-solid interface is inclined was examined. However, the observed value cannot be explained by the inclination angle estimated from the 500 m mesh seafloor topographic data published by JODC of the Japan Coast Guard. Also, the slope estimated from the particle motion of the surface wave observed in the air gun signal is roughly equivalent to the seafloor topographic data.
When the relationship between the X-axis of the OBS and the azimuth misalignment was examined, the misalignment tends to be smaller in the azimuth of the X-axis of the OBS. This suggests the influence of the seismometer installation orientation and the coupling state with the seafloor.
I would like to thank and National Research Institute for Earth Science and Disaster Prevention (NIED), Earthquake Research Institute (ERI), The University of Tokyo, and Japan Oceanographic Data Center (JODC), Japan Coast Guard, for providing data.

Analysis of Seismic Waves from Continuous and Controlled Seismic Signal System in Kyushu Area

*Ryosuke Matsuura[1], Tatsunori Ikeda[2,3], Takeshi Tsuji[1,2,3], Koshun Yamaoka[4]

1. Cooperative Program for Resources Engineering, Kyushu University, 2. Department of Earth Resources Engineering, Kyushu University, 3. International Institute for Carbon-Neutral Energy Research (I2CNER), Kyushu University, 4. Earthquake and Volcano Research Center, Graduate School of Environmental Studies, Nagoya University

One of the methods to continuously monitor the underground is to use Accurately Controlled Routinely Operated Signal System (ACROSS). By mechanically spinning a weight, this apparatus continuously emits artificial seismic waves, which allows us to know the precise seismic velocity change between the ACROSS and seismometers. By monitoring the difference, underground movements such as earthquakes and volcanic activities can be linked to velocity change, which leads to prediction of such disasters. In this research, we focused on observing P-waves and S-waves which arrived the seismometers located around the ACROSS. Using weight stacking, we stacked maximum 119 days of data to distinguish ACROSS signal from random noises, weighing the signal according to the quantity of noise. By taking the motion of certain direction from the transfer function, different types of waves can be separated, making it easier to analyze in detail. We also investigated signal to noise ratio to clarify how far the signal travels. The result indicates that seismic waves from small-sized ACROSS in Kuju area can be observed 50-100 km far away, and seismic waves becomes clear enough to detect velocity change with 20 days of stacking in stations 10-30 km away. The results of ray tracing demonstrated that observed P-waves can be used to image and monitor the geothermal reservoir and the crustal seismic structure in Kyushu Island.

Development of seismic waveform monitor application by JAVA

*Masayoshi Ichiyanagi[1], Hiroaki Takahashi[1]

1. Institute of Seismology and Volcanology, Graduate School of Science, Hokkaido University

Aftershock activity, earthquake swarm and volcanic earthquakes occur continuously. Easy waveform monitoring system is required for real time monitoring everywhere during field work. We have developed an application system that can display continuous seismic waveforms in real time. This system was developed in JAVA language and does not depend on the operating system of computer system. It can run, therefore, on any laptop computers (Windows, Mac OS, etc.).
Waveform data recorded at seismic station are sent every second to data center at universityby WIN binary format (Urabe, 1994). Next, every minute binary data file is created using every second data packet. Finally, every minute binary data is converted to text format and stored to file server system. Our system can read simple text data because it can be applicable for any binary format.
By starting this system on the client personal computer, data is automatically downloaded from the file server and a continuous seismic waveform is displayed on screen.Data is updated automatically every minute by accessing to data file server. Waveforms of two stations can be displayed simultaneously on one JAVA window screen. Seismic station can be selected with the mouse from the selection screen. It is also possible to change the amplitude of the seismic waveform, and to display re-scaled waveform for the previous 30 minutes.
This system can also display long term data, e.g. crustal deformation data such as strain, tilt meter and tide gauges. Display time can be extended up to 48 hours. Simultaneous display of seismic and crustal deformation data on a screen is easily realized. In addition, any text format time series data can be applicable to this system.
Our new system provides easy real-time monitor tool in seismic activity, volcano activity, tsunami waveform, etc. Real-time earthquake monitoring is very important and necessary for risk management in the dangerous field work of earthquake and volcano observation. Our system is in operation stably in field observation and daily earthquake monitoring in Hokkaido University.

Yet another module for reading WIN format data in ObsPy

*Shigeki Nakagawa[1], Aitaro Kato[1]

1. Earthquake Research Institute, the University of Tokyo

The ObsPy (Beyreuther *et al*., 2010) is one of the common tools for processing seismic data. This tool can treat various formats of seismic data, of course including the WIN format. However, the original module for reading the WIN format data has some issues. The issues are: 1) bugs in decoding 0.5 bytes and 3 bytes compression data, 2) not treated properly with missing data and variable sampling rates, and 3) too slow. The third issue is a very serious problem reading large volume waveform datasets. For example, it takes 80 seconds to read a WIN format file containing 3000 channels data with one minute length. Major cause of these issues is that this original module was created by pure Python. Therefore, we have implemented yet another module for reading WIN format data. Features of our new module are: 1) reading the WIN format data and outputs the ObsPy Stream object, and 2) resolves above three issues in the original module. Calling shared libraries from Python is a typical technique to wrap the native libraries and improve execution times. Uehira *et al*. (2010) introduced shared libraries into the WIN system. The "libwinsystem.so" shared library provides various functions for reading or writing the WIN format data. Using this library for decoding the WIN compressed data in our module was effective in solving the first and third issues. To deal with second issue, when the gap of time stamps or sampling rates was found, our module separates waveform data properly. Reading a WIN format file using our module is about 8 times faster than the original module. We are planning to open our module to the public.

Calibration of broadband seismographs based on the teleseismic records

*Takeshi Kimura[1]

1. National Research Institute for Earth Science and Disaster Resilience

Broadband seismometer data are essential for the development of seismological studies such as those investigating earthquake sources and the Earth’ s structure. However, previous studies [e.g., Kimura eta l., 2015] have revealed that the metadata describing these data can possibly be contaminated by instrumentation response errors that are often difficult to recognize from visual waveform checks. Herein, we report on the development of a method to calibrate the instrumentation responses from recording ground motions in observation networks whose station intervals are smaller than 200 km.

The method is based on comparisons between teleseismic surface wave records at a target station and those at multiple surrounding reference stations, from which we estimate the corner period, damping factor and sensitivity in the instrumentation response at the target station. We applied the method to F-net broadband seismometers in Japan.

For STS-1 seismometer of vertical component at TMR station, we could not recognize obvious errors in the corner period and sensitivity. However, the damping factor had increased gradually since 2005 and reached about 2.0 in 2011. After the leveling of the seismometer in November 2011, the damping factor returned to about 0.7. For STS-2 seismometer of vertical component at SHR station, the sensitivity had been about half of the normal value from start of the observation to September 2012. After the replacement of the host-box, the sensitivity settled at normal value.

The estimated calibration values will be useful for the various research using the broadband seismometer data.

DEVELOPMENT OF CLOUD-TYPE MICROTREMOR OBSERVATION SYSTEM

*Shigeki Senna[1], Atsushi Wakai[1]

1. National Research Institute for Earth Science and Disaster Resilience

1. Introduction

In order to sophisticate seismic hazard maps, it is essential to construct highly accurate subsurface structure models. However, in addition that it costs immensely on boring surveys and seismic reflection surveys, it is very difficult to collect subsurface structure data in wide area although those efforts have ever been made. On the other hand, microtremor observations have been conducted in recent years, by which seismic period characteristics and subsurface velocity structure can be estimated in accuracy to some extent except earthquake observations. A microtremor observation is a greatly useful geophysical exploration method to construct subsurface structure models for earthquake ground motion prediction. For the purpose of obtaining dynamic characteristics on ground, it is necessary to make observations of microtremor, PS logging and surface wave. However, on especially PS loggings and surface wave surveys, it is not expectable to make a lot of observations due to a lot of costs, observers skills and difficulty of interpretation for analysis results. To get over these problems, we have ever developed an analysis method, equipment and a system with which we can make a great number of observations with quality of microtremor data kept.

2. Development of the Observation System

We made a system of a process from observation to analysis so that we can efficiently make use of the analysis methods described above. The system consists of ① a microtremor meter as an observation instrument, ② a mobile device, mainly a tablet device, which can transfer data from the spot to analysis system, ③ a cloud-type analysis system which can analyze data in real-time and can deliver analysis results, ④ a database and a data format which can manage data and analysis results etc.

3. Cloud-type Analysis System

Data registered in a database need to be automatically quality checked and analyzed, and then S wave velocity structure obtained from analysis results need to be delivered and checked with map information by using WEBGIS etc. Also, in order to confirm data quality check and analysis results on sites, it is necessary to analyze data transferred to a database in nearly real time and to make it possible to browse analysis results.

For realizing these requirements, it is our challenge to create an application for a smartphone and a &sbquocloud-type analysis system&sbquo which can rapidly conduct quality check and analysis of microtremor data. An application for a smartphone enables us to receive data in real time and to conduct quality check of data such as wave, spectra check and simple SN ratio management of microtremor, by using functions of &sbquoiBidou&sbquo. While, a cloud analysis system enables to conduct detailed analysis and quality check for received data, to estimate S wave velocity structure using the conventional analysis method almost automatically and to deliver analysis results within a few minutes. It is expected that this cloud system enables us to obtain analysis results from twenty to ten hundred times more rapidly than the normal system.

4. Conclusion

This system has a mechanism that human errors decrease on registration of location information, photos,

©2020. Japan Geoscience Union. All Right Reserved.

observation data, raw observed records and analyzed results because data registration and analysis etc. are completed on sites. By the mechanism, we can lend most of national institutes, which cannot conduct a research in spite of their willingness to observations due to expensive seismometers and beginners in the observation. In the future, increase of observer base, homogenization of data and acquisition of so many data can be the basis to create more accurate seismic hazard maps or earthquake susceptibility maps across the country.

Development of underground structure information analysis cloud system

*Shigeki Senna[1]

1. National Research Institute for Earth Science and Disaster Resilience

NIED has been constructing shallow and deep integrated ground models of 250m mesh units in 11 prefectures in the Kanto, Tokai and Kumamoto regions. Construction of a ground model requires a huge amount of data collection and model creation time, and it is difficult to create and verify a wide-area model without an efficient mechanism for modeling. In constructing this ground model, the following items are considered to be the most important items.

① Collection of basic ground data for building a ground model

② Standardization of ground data format and creation of database

③ Establishment of ground modeling method that can be automated and mechanism of automatic generation

④ Verification and correction of the created ground model

These four items do not function if they exist independently. By systematizing the four items as one system, it becomes possible to efficiently construct a ground model that can reproduce the same model no matter who models it. Also, it is difficult to model a wide area even if one of the above items is missing. In order to construct a nationwide ground model, NIED has constructed an underground structural information analysis cloud system that systematically organizes the above four items.

This cloud system uses a standard format of digital data related to the construction of ground models such as boring data, microtremor observation / analysis result data, ground models created based on local government earthquake damage assumptions, land use maps, seamless geological maps, and DEM data. It is possible to construct a ground model such as a 250m mesh or a 50m mesh based on the ground model construction method authorized by the earthquake headquarters. Modeling can also be verified from the constructed ground model and seismic and microtremor observation records (S-wave velocity and dominant period).
In the future, in order to further improve this system, we plan to promote the use of AI so that high-quality models can be constructed from a small amount of data.

[E] Poster | S (Solid Earth Sciences)：S-TT Technology & Techniques

[S-TT52] Seismic Big Data Analysis Based on the State-of-the-Art of Bayesian Statistics

convener:Hiromichi Nagao(Earthquake Research Institute, The University of Tokyo), Aitaro Kato(Earthquake Research Institute, the University of Tokyo), Keisuke Yano(The University of Tokyo, Graduate School of Information Science and Technology), Takahiro Shiina(Earthquake Research Institute, The University of Tokyo)

Recently, a big seismic database has been being constructed that collects data of vibrators implemented in such as buildings, lifelines and smartphones, in addition to seismic data of the conventional continuous/temporal dense seismic observation arrays. Development of methodologies and algorithms, which are inadequate at this moment, optimized to comprehensively analyze the seismic big data is essential in order to utilize the big database as much as possible for prevention/mitigation of earthquake disasters and clarification of earthquake phenomena. On the other hand, recent progress of Bayesian statistics is significant, which is the mathematical basis of various methodologies, such as machine learning, especially deep learning, to extract valuable information from big data. The state-of-the-art of Bayesian statistics is expected to substantially advance seismic big data analyses.
This session mainly accepts presentations that focus on analyses of seismic big data, especially related to analysis methods based on Bayesian statistics such as machine learning, sparse modeling and data assimilation, and their applications to real seismic data. Presentations related to mathematical or statistical theories beneficial to data analyses, feasibility studies of algorithms eventually applicable to real seismic data, and the current status of seismic observations and analysis results are also highly welcome.

Comprehensive analysis of deep low-frequency earthquakes in 52 regions all over Japan

*Ryo Kurihara[1], Kazushige Obara[1]

1. Earthquake Research Institute, The University of Tokyo

In the most volcanic regions all over Japan, deep low-frequency (DLF) earthquakes occur at depths of 10–50 km in which regular crustal earthquakes rarely occur. The dominant frequencies of DLF earthquakes are about 1–10 Hz, which is lower than those of regular earthquakes with similar magnitudes. DLF earthquakes near volcanoes are considered to be affected by fluid in the lower crust because they often occur in or around of low-velocity anomalies (e.g. Hasegawa et al., 2005). However, generating mechanism of DLF earthquakes and relationship with the surrounding structure are still unknown because hypocenters of DLF earthquakes do not have a good resolution due to their weak signals. Kurihara et al. (2019 SSJ) analyzed DLF earthquakes all over Japan based on relocation analysis using network correlation coefficient method (Ohta and Ide, 2011), classification using waveform correlation, and detection using matched filter technique. In results, for example in Hijiori, northeastern Japan, we showed that hypocenters of DLF earthquakes concentrate into some small isolated groups with separations of several kilometers in the vertical direction. Temporal activity patterns of DLF earthquakes are different in each group; in other words, there are both groups in which DLF earthquakes constantly occur and episodically occur. As like Hijiori, discrete distributions of groups of DLF earthquakes were also observed in many other volcanoes.

In this study, as for quantifying temporal activity patterns of DLF earthquakes, we defined an index “swarm ratio (SR)” for each group of all regions which show the ration of swarm DLF earthquakes and generally classified the activity patterns in 52 regions all over Japan. SR means the ratio of swarm DLF earthquakes out of all DLF earthquakes in the groups. Swarm DLF earthquakes were defined as the DLF earthquakes. Swarm DLF earthquakes are defined when 10 or more earthquakes occur with the shorter interval from the former earthquake than the expected interval time of the group.
In many regions especially in Tohoku district, only the groups of DLF earthquakes with SR lower than 0.7 in which DLF earthquakes constantly occur were observed. On the other hand, 12 regions, such as Yakedake and Ontake, included groups with high SR values over 0.7 that shows episodic occurrences of DLF earthquakes. In addition, magnitude-frequency distributions show that groups with episodic DLF earthquakes have high b-value in Gutenberg-Richter law compared to groups with constant DLF earthquakes. These results suggest that episodic DLF earthquakes may repeatedly occur in the concentrated same smaller-scale sources and constant DLF earthquakes may occur in some different sources.

An application of reversible-jump MCMC method for simultaneous determinations of 1-D velocity structures and hypocenters around a fault (I): Formulation

*Masayuki Kano[1], Takahiro Shiina[2]

1. Graduate school of science, Tohoku University, 2. Earthquake Research Institute, The University of Tokyo

Locations of earthquakes are one of the fundamental information in seismology. To determine hypocenters, a one-dimensional (1-D) velocity model, such as the JMA2001 1-D velocity model [Ueno et al., 2002], is routinely used. In the case of local seismic swarm activities, such as aftershocks of a large earthquake, a local 1-D velocity model is often constructed. Although a single 1-D velocity model was conventionally adopted for the source area of the swarm, it was reported that two or more 1-D velocity models can accurately estimate location of hypocenters when earthquakes occur at around a structural boundary [e.g., Sakai et al., 2004]; that is, seismic velocities change across the source area. Since such structural boundary often act as a slip plane of a large earthquake, preliminary understandings for the earthquake and monitoring of its aftershocks will improve by utilizing several local 1-D velocity models.

A 1-D velocity model is generally constructed based on seismological and/or geological knowledge [e.g., Sakai et al., 2004]. Three-dimensional analyses, i.e., tomographic inversion, would detect those heterogeneous structures if a large amount of seismological observations were obtained. In other words, with small dataset of seismic records, it is difficult to know a presence of structural boundary and velocity structures of each seismological/geological unit around a fault without obvious surface exposure of them. Therefore, in our series of presentation (this study and Shiina and Kano [this meeting]), we propose a Bayesian-based approach for simultaneous determination of hypocenters of earthquakes and 1-D velocity structures around a fault. Additionally, our approach assigns each station to a specific velocity model.

This study uses a reversible-jump Markov chain Monte Carlo (rj-MCMC) method to estimate 1-D velocity models and hypocenters of earthquakes. In an analysis of seismic velocity structure of Earth’s interior, the rj-MCMC method can change a number of discrete units, i.e., grid, block, or layer, and investigate P- and S-wave velocities of the discrete units. Bodin and Sambridge [2013] adopted this method to estimate a two-dimensional velocity structure. Based on their formulation, we developed the rj-MCMC approach; layered velocity structures and hypocenters are simultaneously determined when given a number of 1-D velocity models.

In this presentation, we will summarize formulations of the developed method in detailed. An application of this method for synthetic data sets will be summarized by Shiina and Kano [this meeting].

An application of reversible-jump MCMC method for simultaneous determinations of 1-D velocity structures and hypocenters around a fault (II): Synthetic analyses

*Takahiro Shiina[1], Masayuki Kano[2]

1. Earthquake Research Institute, The University of Tokyo, 2. Graduate School of Science, Tohoku University

Our series of presentation (this study and Kano and Shiina [this meeting]) proposes an approach that can simultaneously estimate one-dimensional (1-D) velocity models and hypocenters based on a reversible-jump Markov chain Monte Carlo (rj-MCMC) method. A location of earthquake is routinely determined by using locally optimized 1-D velocity model, such as the JMA2001 1-D velocity model [Ueno et al., 2002]. Meanwhile, two or more 1-D velocity model can improve estimation accuracy of hypocenters of which earthquakes occur at around structural boundary [e.g., Sakai et al., 2004].
As described in Kano and Shiina [this meeting], we developed the rj-MCMC method for determining hypocenters and structures when a number of 1-D velocity models is given. In this presentation, therefore, we evaluate the developed method by using synthesized data sets that derived from two 1-D velocity models. Since the rj-MCMC requires only travel times between an earthquake and a receiver, we employ fast-marching method [e.g., Sethian and Popovici, 1999; Rawlinson and Sambridge, 2004] for travel time calculations. Note that a rj-MCMC-based estimations of 1-D velocity model and hypocenters had been suggested [e.g., Ryberg and Haberland, 2019]. However, the previous studies for the 1-D case mainly handled earthquakes which widely distributed in the targeted area. We thus discuss advantages and shortenings of the rj-MCMC method to simultaneous determinations of hypocenter and single 1-D velocity model for concentrated hypocenters, i.e., seismic swarms and aftershocks of a large earthquake.

A Bayesian seismic tomography adapted to discontinuities

*Sumito Kurata[1], Naoya Takakura[1], Keisuke Yano[1], Fumiyasu Komaki[1]

1. Graduate School of Information Science and Technology, The University of Tokyo

Seismic tomography is an analysis method to estimate subsurface structures of the Earth using arrival times of earthquakes. In this study, we introduce two procedures to estimate velocity structures under western North America on the basis of arrival times of P-waves.
We divide subsurfaces into meshes with different seismic velocities. We consider associations among the meshes in the estimation of velocity parameters. Velocity structures are broadly continuous but change drastically along the discontinuity such as Moho and Conrad. In addition, they change largely along the boundary between land and sea. Therefore, we first adopt Bayesian estimation with the prior distribution accommodating such information.
We second introduce a regularization to estimate behavior of velocity structures around discontinuities more sharply. We apply a network Lasso-type regularization to estimate velocity parameters. We use the regularization term which penalizes difference of velocity parameters among adjacent meshes. With this effect, similar velocities will be smoothed, on the other hand, sharp changes of velocity will be emphasized.
The resulting velocity structure can capture change points of velocities more clearly. We compare our procedure with the existing tomography through numerical studies.

Multi-mode surface wave tomography with trans-dimensional hierarchical Bayesian inversion: application to Australia

*Kazunori Yoshizawa[1,2], Toru Taira[2]

1. Faculty of Science, Hokkaido University, 2. Graduate School of Science, Hokkaido University

Seismic surface waves are primary information sources for three-dimensional mapping of the crust and upper mantle. Most of the structural mapping for shear wave speed models in the crust and upper mantle has been based primarily on the linearized inversions of surface wave dispersion data. Such linearized inversions, however, involve intrinsic limitations, such as the influence of *a priori* constraints and the entrapment into local minima. With the increasing computational power, a fully nonlinear approach based on the model parameter search with the Markov chain Monte Carlo method is now feasible.

In this study, we employ the trans-dimensional hierarchical Bayesian (TDB) inversion to construct a new 3-D radially anisotropic S wave model in the Australian upper mantle, which requires almost no subjective *a priori* information. We use multi-mode phase speed maps in Australia by Yoshizawa (2014), and the local dispersion curves of multi-mode Love and Rayleigh waves are inverted for extracting the probability density functions of radially anisotropic S wave model. This process is repeated for all the grid points in our target region, which eventually produce a 3-D shear wave model.

The TDB approach requires significant computational power compared with the classical linearized inversions, i.e., several thousand times more CPU time is required in our case to evaluate more than a million models. Still, it enables us to flexibly parameterize the model parameters (i.e., the number of layers in this case, and data uncertainties can also be handled properly through the hierarchical Bayesian approach.

Through the comparisons of our new 3-D model from TDB approach with our earlier 3-D model from a conventional linearized inversion, we have found that the large-scale features are mostly consistent between these models. However, our new TDB model shows the enhanced strength of heterogeneity and well-resolved spatial distribution of seismic anisotropy, which well reflects the past and current tectonics of the continental upper mantle. In particular, the vertical change in shear wave speeds can be well constrained in the TDB model by the use of the trans-dimensional parameterization, and the data fit to dispersion curves are improved by the use of the hierarchical Bayes approach.

Twin Experiment of 4DVar Capable of Uncertainty Quantification Based on Seismic Wavefield Propagation

*Hiromichi Nagao[1,2], Shin-ichi Ito[1,2], Masayuki Kano[3], Mitsuru Matsumura[4]

1. Earthquake Research Institute, The University of Tokyo, 2. Graduate School of Information Science and Technology, The University of Tokyo, 3. Graduate School of Science, Tohoku University, 4. CJS Inc.

The four-dimensional variational method (4DVar) is a data assimilation technique widely used especially in the case of a massive numerical simulation model such as weather forecasting. The conventional 4DVar only optimizes parameters and initial conditions of time series but never evaluates their uncertainties. We proposed a new 4DVar that evaluated the uncertainties after obtaining the optima [Ito, Nagao et al., Phys. Rev. E, 2016]. The key technique in the new 4DVar is the second-order adjoint method, which obtains the product of a Hessian matrix and a given vector avoiding a direct computation of the Hessian matrix.

We verify this new 4DVar by applying it to an issue of seismic wave propagation in the two-dimensional field. The forward computation based on the wave equation is done by the finite volume method in space and the velocity Verlet method in time, which conserves the total energy during the time evolution. The periodic boundary conditions are assumed for the both horizontal boundaries of the computational domain, and the fixed boundaries are assumed for the top and bottom of the domain. The set of adjoint models is solved by a time integrator that enables an exact computation of Hessian-vector product without any discretization errors [Ito et al., 2019].

We report the result of this verification through a twin experiment that checks whether the new 4DVar properly estimates true values of parameters assumed in advance and quantifies their uncertainties.

On the Optimum Solutions of Bayesian Inversions

*Daisuke Sato[1], Yukitoshi Fukahata[1]

1. Disaster Prevention Research Institute, Kyoto University

Geophysical inversions are frequently built on the Bayesian inferences. Bayesian inferences provide the posterior probability distribution function (pdf) from 1) the observation equation to relate the data and model parameters and 2) the prior distribution of the model parameters, via Bayes' theorem. The more extended approach, called fully Bayesian inference, serves a joint posterior pdf in terms of model parameters and hyperparameters, by further considering the hyperprior distribution: the prior for the hyperparameters.

The posterior pdf requires criteria for informational reductions to obtain the most reliable (optimum) model parameters. The best way of reduction is nontrivial, and the criteria can be summarized into three groups. The first is the probability maximum of the posterior pdf (maximum a posteriori, MAP). This is the most intuitive way. Another is using the probability maximum in the marginalized posterior in terms of hyperparameters, by integrating the posterior pdf over the model parameters. The optimum model parameters are then evaluated as the ordinary weighted least squares given by the selected hyperparameters. This is exactly the Akaike Bayesian information criterion (ABIC), and has been adopted in the wide classes of geophysical inversions (Yabuki & Matsu'ura, 1996). The other is using the marginalized posterior pdf in terms of model parameters, by integrating the posterior over the hyperparameters. It contains, for example, the average, the median, and the most frequent values (the mode). The last group of indices has been common for the previous fully Bayesian inferences, such as Fukuda & Johnson (2008). Therefore, we call these as fully Bayesian inferences, in contrast to MAP and ABIC.

MAP, ABIC, and previous fully Bayesian inferences give similar results in most case (e.g., Fukuda & Johnson, 2008). However, we report a clear discrepancy between them for the case of large numbers of model parameters.

First, we derived the analytic expressions of the solutions for MAP and previous fully Bayesian inferences, as well as their uncertainty represented by covariances, in the problem where the observation equation is linear in terms of model parameters. The obtained solutions clarified that any kind of the previous fully Bayesian inferences (averages, modes, medians, and so on) almost surely gives the same estimate value as the MAP estimate in the asymptote of large numbers of model parameters, for wide classes of hyperprior like the uniform distribution. The solutions of MAP and the previous fully Bayesian inferences are further shown to be different from the solution of ABIC.

Next, we employed the synthetic test to clarify the difference between ABIC and other estimates, with using the small roughness as a prior (Yabuki & Matsu'ura, 1992). The numerical investigation clarified that distribution of MAP estimates (that is the posterior pdf itself) converged to the overfitted solution for given data and the prior is neglected unfairly, as we improve the resolution of models by increasing the number of model parameters. Meanwhile, the estimate of ABIC did not induce the aforementioned problem and provided the significantly closer estimates to the true solutions than MAP estimates with fine discretization.

©2020. Japan Geoscience Union. All Right Reserved.

These are counterintuitive from the standard view where ABIC is regarded as a tractable approximation to assess the joint posterior pdf in terms of model parameters and hyperparameters (Gelman et al., 2013). The accuracy deterioration due to the overfitting in the case of the higher resolution with fewer discretization errors can be a crucial problem in the inversions for real data, where the true parameters are intrinsically unknown. Our results suggest the way of improving the ordinary fully Bayesian inferences along the way of ABIC, and warn the potential risks hidden behind the MAP and previous fully Bayesian inferences.

Towards application of data-driven sparse sensor placement technique developed in fluid mechanics to seismology

*Takayuki Nagata[1], Keigo Yamada[1], Yuji Saito[1], Taku Nonomura[1], Keisuke Asai[1]

1. Tohoku University

Reduced-order modeling gathers a lot of attention in fluid mechanics for fluid analysis and flow control. Proper orthogonal decomposition (POD)[1] is one of the effective methods to decompose the high-dimensional fluid data into significant modes. The dimension of the flow field data can be reduced by reconstructing the data using several selected significant modes. In addition, if the data can be effectively expressed by a limited number of POD modes as shown in Fig. 1, the limited sensor placed at appropriate positions gives us the approximated full state information as follows[2]:

$\boldsymbol{y} = \boldsymbol{HUx}$, (1)

where $\boldsymbol{y} \in \mathbf{R}^p$, $\boldsymbol{H} \in \mathbf{R}^{p \times n}$, $\boldsymbol{U} \in \mathbf{R}^{n \times r}$, and $\boldsymbol{x} \in \mathbf{R}^r$ are the observation vector, the sparse sensor location matrix, the spatial POD modes, and the POD mode amplitude, respectively. Here, p, n, and r are the number of the sensor location, degree of freedom of the spatial POD modes, and the rank for truncated POD, respectively.

Schematic diagram of Eq. (1) is illustrated in Fig. 2. This problem is considered to be one of the sensor selection problems when the POD mode $\boldsymbol{U}$ and the strength x are assumed to be a sensor-candidate matrix and the latent state variables, respectively. Obtaining $\boldsymbol{H}$ matrix corresponds to the computation for the sensor selection, and the convex approximation method[3] and the QR-based greedy algorithm[2] have been used. In our group, data-driven sparse sensor selection algorithms for the data obtained in experimental fluid dynamics have been developed. The data in the fluid dynamics is noisy high-dimensional multi-component data so that a fast and robust sensor selection algorithm is necessary to realize a real-time on-line measurement and flow control. We proposed three algorithms recently.

Fast Greedy sensor selection algorithm for the scalar data

The computational cost is a critical problem for high-dimensional data analysis. We extended the previous QR-based greedy algorithm and reduced the computational cost. In our method, the objective function of the problem was redefined to be the maximization of the determinant of the matrix appearing in pseudo-inverse matrix operation. The procedure for the maximization of the determinant of the corresponding matrix is the same as that of the previous QR-based greedy method when the number of sensors less is less than or equal to that of state variables. When the number of sensors greater than that of state variables, new sensors are calculated by a proposed determinant-based greedy method which is accelerated by both determinant formula and matrix inversion lemma.

Fast Greedy sensor selection algorithm for the vector data

The multi-component data such as velocity distributions in x and y directions frequently appear in the fluid data. The sparse sensor selection using the convex approximation algorithm for the vector data was valid, but it requires long computational time to analyze high-dimensional data due to its expensive computational cost. Therefore, we extended our determinant-based greedy algorithm, which is a much lower computational cost compared to convex approximation, for vector data.

Fast greedy sensor selection in measurement with correlated noise

The noise-robust greedy sparse-sensor-selection method based on the determinant maximization was proposed. Optimization is conducted by maximizing the determinant of the matrix which corresponds to

the inverse matrix appearing in the Bayesian estimation operator. The computational cost is slightly larger than that of the previous methods, but the estimation accuracy is much improved. We will apply and improve these methods to seismic research with the seismic research group.

[S-TT53] Airborne surveys and monitoring of the Earth

convener:Shigekazu Kusumoto(Graduate School of Science and Engineering for Research, University of Toyama), Takao Koyama(Earthquake Research Institute, The University of Tokyo), Yuji Mitsuhata(AdvancedIndustrial Science and Technology), Shigeo Okuma(Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST))

Airborne surveys are useful to better understand the whole and/or the detailed structures of the Earth and their variations. They can be implemented from a traditional manned and newly-developed unmanned aircraft to efficiently map very large or remote areas with difficult access. We invite studies on theory, instrumentation, processing, modeling or inversion and applications of airborne surveys.

1. Earthquake Research Institute, The University of Tokyo, 2. Center for Environmental Remote Sensing, Chiba University

In Mt. Iwoyama, Kirishima, volcanic tremors have occurred since the end of 2013, and then some fumaroles are observed. A small phreatic eruption has occurred in the south of the edifice on 19th April 2018, in which the last eruption has occurred about 250 years ago. According to geodetic deformation measurements, inflation of the edifice was detected. The pressure source location is inferred at about 1km below the surface. Also, according to MT surveys, a clay layer is detected in the shallow area due to hydrothermal alteration. Therefore, the phreatic explosion may have happened due to vaporization of volcanic fluid through cracks of the clay layer (Tsukamoto et al., 2018). It is important to observe thermal change and gas emission at such a crack prior to explosions in order to understand the process of the phreatic explosion.

We have conducted high-resolution aeromagnetic survey by drone in Iwoyama in last May. In our survey, the DJI Matrice 600 Pro multicopter is used and Geometrics G-858 cesium optical pumping magnetometer is installed on it. The magnetic sensor is hung down at 5m from the drone. A GNSS receiver with barometric altimeter is also installed in order to correct the time and measure the position. It totally flew more than 15 km by 10 flights in a half of days. The flight courses were programmed prior to flights, and thus they can be reused again in the future surveys, and retrieve geomagnetic data along the same course.

We have carried out flights in 50 m and 100 m above the surface. In the west of survey area, geomagnetic total intensity anomaly by 750 nT at 50 m above and 500 nT at 100 m above were found. In the east, which is just above the Mt. Iwoyama, the anomalies are 400 nT at 50 m above and 100 m above. It indicates that demagnetization is occurred beneath the Mt. Iwoyama as inferred.

We conducted survey again in last December on the same flight courses which are programmed in a drone, in order to detect the temporal variation of magnetic intensity of the edifice. It, however, does not show significant changes, and it indicates that thermal condition beneath Iwoyama is not activated recently.

Droneborne survey has a potential to be a powerful tool to monitor a thermal condition beneath the volcano.

Utilization of Beta Angle for Detecting Edges in Potential Field Methods

*Tamer Mahmoud Ragab Farag[1,2], Remon Aziz[3,2], Hidiki Mizunaga[1]

1. Exploration Geophysics lab, Earth Resources Engineering Department, School of Engineering, Kyushu University, 2. Exploration Sector, Nuclear Materials Authority, 3. Center for Northeast Asian Studies, Tohoku University

Gravity and magnetic methods are potential field methods in exploration geophysics. Gravity method measure lateral variation in densities whereas magnetic method measures the lateral variation in magnetic susceptibility. One of the complications of interpretation of magnetic data is the displacement or skewness as a result that the geomagnetic field is not vertical in general. Depth, lateral variation of physical property, dipping angle, thickness and magnetic field inclination are important parameters affecting the shape and orientation of the anomalies. They make the qualitative interpretation specially for regional scale surveys (marine or airborne) very difficult. The magnetic anomaly over the causative body depends on latitude because of the dipolarity nature of the geomagnetic field in addition to the remnant magnetization of every magnetic source. Sources and edges detection is the first and one of the most important qualitative interpretation step of potential field methods in geophysics. A lot of methods were developed to delineate the edge of the subsurface bodies cause anomalies in gravity and magnetic based on the derivative in X, Y and Z directions. Total horizontal derivative, analytical signal and TDX revels the maximal of the source body edges. Whereas tilt angle and theta angle were developed to detect the maxima of the causative body. Beta angle has been developed to detect the source body and its edges depending on the derivatives in X, Y and Z directions. Beta angle is the angle between the analytical signal and the derivative in Z direction. It is narrower than tilt angle and marks the body edges sharper. Beta angle shows the magnetic anomalies with sharp edges. Beta angle has a range from $-\pi/2$ to $\pi/2$. Beta angle has been applied to airborne magnetic data and the result compared with THD, AS, Tilt angle, TDX and theta map. Beta angle map can delineate the different magnetic anomalies sources with sharp edges

Three Dimensional Geophysical Inversion of Airborne Magnetic Data from the Yellowstone National Park (YNP), Western North America

*Mohammad Shehata[1,2], Hideki Mizunaga[2]

1. Department of Geology, Faculty of Science, Port Said University, Egypt, 2. Department of Earth Resources Engineering, Faculty of Engineering, Kyushu University, Japan

Yellowstone National Park (YNP) displays numerous and extensive hydrothermal features. Airborne Total Magnetic Intensity (TMI) data of the area was acquired from the USGS. TMI data was processed and Reduce-to-Pole (RTP) map was produced. Analytic Signal (ASA) and Theta map filters were applied to the magnetic data to delineate the structural Lineaments of the magnetic sources. Three dimensional geophysical inversion was applied to the magnetic data using the algorithms of Li and Oldenburg (1996), the inversion reveals the 3-D distribution of the magnetic susceptibility for a depth of few kilometers which delineate the alteration zones of the geothermal system in the area. The inversion parameters were selected to fit both the resolution of subsurface model and calculation capacity of the running computer. The boundary of Yellowstone caldera was delineated efficiently from the ASA and Theta maps. Inversion results show that the hydrothermal zones coincide with magnetic lows observed in aeromagnetic surveys, which suggests a strong demagnetization of both the shallow and deep substratum within these areas associated with the removal of magnetic minerals by hydrothermal alteration processes over a thickness of a few hundred meters in hydrothermal areas at YNP, and that the maximum degree or maximum thickness of demagnetization correlates closely with the location of hydrothermal activity and mapped alteration.

Development of a multiband uncooled infrared cameras system for imaging volcanic sulfur dioxide (SO_2) gas

*Tetsuya Jitsufuchi[1]

1. National Research Institute for Earth Science and Disaster Resilience

National Research Institute for Earth Science and Disaster Resilience (NIED) launched the “Development of Remote Sensing Techniques for Surface Phenomena of Volcano” under the “Promotion Project for Next Generation Volcano Research Theme B subtheme 2 subtopic 2-2” in October 2016. The objective of this project is to develop a surface phenomenon imaging camera (SPIC), which combines the advantages of current airborne spectral imaging systems, visible-light cameras, and infrared cameras so that it can be used for both on-ground and oblique observations from helicopters. Under this project, we are planning to develop a new observation device called a surface phenomena imaging camera with uncooled infrared camera (SPIC-UC). In this study, we present first results of the development for SPIC-UC prototype. The SPIC-UC is planned to realize a highly cost-effective device used to measure the temperature and SO_2 gas concentration distributions by selecting an uncooled microbolometer focal plane array (FPA) to measure the long wave infrared regions (LWIR, 8000–14000 nm). To realize SPIC-UC, we prototyped a multiband uncooled infrared cameras system by adopting an uncooled VGA camera sensor (uncooled microbolometer) with built-in spectral filters. The prototyped cameras constitute a twin-lens camera system (capable of synchronous measurement) consisting of Camera 1 and Camera 2, with the following specifications: filters built in Camera 1 will have a transmission bandwidth for wavelengths of 9000 nm or more and those built in Camera 2 will have a transmission bandwidth for wavelengths between 8370 and 8920 nm, which much to the infrared light absorption region of SO_2 gas. The performance evaluations for the prototyped camera system revealed that it can achieve a NETD of approximately 0.6 K for blackbody temperatures of 0–81 ˚C in the ambient temperature range of -10 to 50 ˚C and that they can detect SO_2 gas concentration distributions of 1 to 2 ppmv or more at normal temperature in the background conditions of 50 ˚C or more. These results indicate that the proposed cameras can be a prototype SPIC-UC system.

Topographic changes in Kirishima Iwo-yama volcanic area obtained by UAV photogrammetry

*Yuichi Iwasa[1], Takeshi Matsushima[2]

1. department of earth and planetary sciences, graduate school of sciences, Kyushu University, 2. Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University

Aerial photogrammetry using UAV(Unmanned Aerial Vehicle) is a speedier, cheaper, and safer method than conventional topographic surveying methods, and has been spread rapidly in recent years. This can be utilized in active volcano observation, but there are still few examples.

In this study, We conducted mission flight by UAV in Kirishima Iwo-yama located Ebino city, Miyazaki prefecture before and after the phreatic eruption in April 2018. Then, the eruption area was three-dimensional modeled by aerial photogrammetry.

While the model before the eruption was successfully constructed, in the constructed model after eruption, a gap has occurred due to the effect of the fumarole. This is one of problems of UAV photogrammetry in active volcano. In this study, to resolve this problem, adding to the conventional nadir photography, the oblique photography from the low altitude was carried out again in November 2019. As a result, the model after the eruption could be constructed without the gap.

By comparing the model before and after the eruption, it was suggested that the local uplift detected by InSAR may be observed in the central part of survey area. In the erupted area, large topographic changes due to crater formation that could not be observed by InSAR were observed. From the measurement results, volume changes due to topographic changes before and after the eruption, which were not measured until now, could be estimated.

These results indicate that UAV photogrammetry is a simple and effective method for detecting topographic changes in active volcanic observation.

This work was partly supported by MEXT under Integrated Program for Next Generation Volcano Research and Human Resource Development, and under Earthquake and Volcano Hazards Observation and Research Program. Also it was supported by ERI, The University of Tokyo under Joint Usage Program.

[S-TT54] Creating future of solid Earth science with high performance computing (HPC)

convener:Takane Hori(R&D Center for Earthquake and Tsunami, Japan Agency for Marine-Earth Science and Technology), Yuji Yagi(Graduate School of Life and Environmental Sciences, University of Tsukuba, Tsukuba), Katsuhiko Shiomi(National Research Institute for Earth Science and Disaster Resilience)

Due to the development in computer science and computational science, large-scale or many times forward simulations and/or inversion analyses have become available recently. In solid Earth science, large-scale seismic wave propagation and crustal deformation with high fidelity models based on high resolution observation data have been demonstrated; uncertainty in crustal deformation caused by material properties and structures can be investigated based on many-time calculations for different material properties and structures; fault slip inversion analyses for non-Gaussian error distribution, etc. Thus, we will invite researchers who are applying HPC technology in forward simulations and inversion analyses and discuss how to improve more the collaboration between computer & computational sciences and solid Earth science not only in Japan but also from US and/or Europe. We are welcome submission by the researchers who are interested in this scope, especially students and young researchers.

Python based finite element code development for fluid geodynamics using JIT compiler and benchmark test

*Sangjin Park[1]

1. Kangwon National University

Python has very high productivity by supporting intuitive grammar and various libraries, but as an interpreted language, it is relatively slower than compiled languages such as c. Many attempts have been made to overcome working process of Python code which executes source code written by high-level language and translates to machine language simultaneously, including development of JIT (Just In Time) Compiler. Jit caches functions defined within the Python script by translating them into machine language. Since it omits the translation process to the machine language when reusing the cached function, Python using JIT compiler may show computational speed equal to the compiled language. We developed a Python-based finite element code for geodynamics equipped with JIT compiler, improving computational speed and keeping its good maintainability. Our code simulates the thermal convection within the coupled system between the time-dependent heat equation and the steady-state Stokes equation. It affords various simulations such as the boundaries between multiphase-fluid and large deformation of materials in Eulerian mesh with particle-in-cell method. In this study, we benchmarked various tests to assess the reliability of the code. Not only we successfully made simple mantle convection model but also we added a lot of geometries and sticky-air approach into test models using PIC (particle-in-cell) method.

Hybrid parallelization of Discrete Element Method (DEM): Toward a large-scale geotechnical HPC applications

*Mikito Furuichi[1]

1. Japan Agency for Marine-Earth Science and Technology

Discrete element method (DEM) is one of the standard simulation methods originally developed for granular physics and it has been recently extended to multi-physics simulations with advanced interaction models of visco-elasto-plastic rheologies and thermo-chemical reactions. Recently, DEM has been extensively utilized in various fields of studies such as geotechnics, geoscience, civil engineering, industry, and disaster prevention problems. This study presents the implementation and performance demonstration of parallel DEM simulation based on an iterative load balancer. The proposed techniques were verified by the reproducibility test. The numerical sandbox and slump tests with certain DEM particles demonstrated the efficiency of the large-scale DEM to capture the multi-scale events in the granular media. The visualization of the stress chains from the large-scale DEM simulation reveals the existence of arcuate stress structures that may control accretionary prism formation, which is an important scientific discovery

Elastic Green’s function library based on subduction zone models of high fidelity using the finite element method

*Takane Hori[1], Ryoichiro Agata[1], Tsuyoshi Ichimura[2], Kohei Fujita[2], Takuma Yamaguchi[2], Takeshi Iinuma[1]

1. Research Institute for Marine Geodynamics, Japan Agency for Marine-Earth Science and Technology, 2. ERI, The University of Tokyo

Green’s functions (GFs) for elastic deformation due to unit slip on the fault plane is an essential tool to estimate earthquake rupture processes and their preparation processes underground. Because these estimation results are often applied to creating socially important information such assessments of seismic and tsunami hazards, the dependence of these estimation results on the numerical models used for calculating GFs should be minimized to maintain the reproducibility of the estimations, which is essential to the reliability of the assessment. One solution is that the same GFs, which are calculated using numerical simulation models with high fidelity to a database of underground structures and the definitions of the coordinate systems to which many people agree, are used in various studies of estimating the underground processes. Here, we calculated an elastic Green’s function library based on subduction zone models of high fidelity using the finite element (FE) method, which is open to the public on a web server. We targeted two well-known subduction zones in Japan, the Nankai Trough and the Japan Trench subduction zones. The library was calculated based on the 3D heterogeneous elastic property of “Japan integrated velocity structure model version 1”, proposed for earthquake hazard assessments conducted by the Japanese government. In the FE meshes used for the calculation, the resolution of the layer boundaries in the underground structure is the same as that of the original database. The ellipsoidal shape of the earth, which is often approximated with a projected plane or a spherical shape, was also incorporated by faithfully following the definitions of the coordinate systems in Geodetic Reference System 1980 adopted by the International Union of Geodesy and Geophysics and the Japanese Geodetic Datum 2000. We expect the use of this library in estimating underground processes regarding earthquakes helps to minimize the variability of the estimation results depending on the settings of the numerical simulation model to calculate GFs, which should eventually contribute to the increase the reliability of seismic and tsunami hazard assessments. Furthermore, the library should also help researchers introduce a more realistic earth model in their analyses without laborious numerical model construction, numerical simulations and data processing.

The Higashi-Izu Monogenetic Volcano Field (HIMVF) comprises more than 70 subaerial monogenetic volcanoes on the eastern Izu Peninsula and 50 submarine volcanoes in the eastern offshore of the northern Izu-Bonin volcanic arc. Some of the volcanoes are arranged along a NW-SE trends, suggesting fissure eruptions. Petrological studies of the HIMVF have focused on the mafic volcanic rocks (e.g., Hamuro et al., 1983; Umino and Koyama, 1991; Takahashi et al., 2002; Nichols et al., 2012), whereas the felsic volcanic rocks have been investigated mainly to clarify the generation processes of felsic magmas (e.g., Miyajima, 1990; Suzuki et al., 2000; Kanai et al., 2013). In the present study, we investigated volcanic rocks from the Iwanoyama-Iyuzan chain, which represent the most recent subaerial eruptions (2.7 ka). These eruption products are bimodal in composition, comprising dacite and basaltic andesite. The dacites contain phenocrysts of orthopyroxene (Opx), plagioclase (Pl), and minor hornblende and clinopyroxene (Cpx), whereas the basaltic andesites and andesites contain Opx, Pl, Cpx, and olivine. Disequilibrium assemblages of phenocryst minerals and xenocrysts (quartz) are observed in the dacites and andesites.

Bimodal chemical compositions are apparent in Pl anorthite content (An mol. %) of An85-95 and An40-70, and in Opx Mg number (Mg#) of 76-80 and 68-72 in both the dacites and basaltic andesites. These bimodal compositions, as well as disequilibrium assemblages of phenocryst minerals and textures strongly suggest that both the mafic and felsic magmas underwent magma mixing and/or mingling. Whole rock major and trace element characteristic also show bimodality. Rare-earth element (REE) patterns differ between the felsic and mafic rocks; the dacites show enrichment in light REEs and concave down patterns of middle - heavy REEs, whereas the basaltic andesites display slightly inclined patterns from light to heavy REEs. $^{87}Sr/^{86}Sr$ ratios of the rocks show a small range (0.70328-0.70348), but differ slightly among volcanic units, indicating distinct sources for the parental magmas of each volcano.

The parental mafic magmas were probably basaltic andesite in composition, but with slight spatial variations in composition. The mafic magmas are inferred to have formed by mixing of lower crustal materials with primary basaltic magmas or by assimilation and fractional crystallization of the primary basaltic magmas. In contrast, the felsic magmas are interpreted to have been dacitic magmas, similar to the Iwanoyama and Ananoyama dacites. The parental magmas that formed these dacites may have been generated by partial melting of middle- to upper- crustal materials with some variations in $^{87}Sr/^{86}Sr$ ratios. The mafic and felsic magma types likely mixed and/or mingled to a degree and were then erupted in different locations along the fissure within a limited time interval.

Redox paths of granitic magma in Chiquicamata, northern Chile.

*Tetsuichi Takagi[1]

1. Research Institute for Geo-Resources and Environment, National Institute of Advanced Industrial Science and Technology

The western cordillera of South America is one of the largest-scale magnetite-series granitic terranes in the world. The granitoids consist mainly of granodiorite to quartz diorite in Cretaceous, and often contain copper porphyries that were mineralized under highly oxidized magmatic conditions. To investigate the redox paths of granitic magma of this terrane, petrography of granitic rocks in the Chiquicamata area of northern Chile has been conducted using the rock collection by Dr. Shunso Ishihara. The rock specimens 79CHU7 and 79CHU3 (Ishihara et al., 1984 Bull GSJ, 35, 503-536) were selected from the collection because they are the least hydrothermally altered. 79CHU7 is a bt-cpx-opx quartz monzodiorite with a magnetic susceptibility of 14.5 x 10^{-3} SI units. In the rock, maghemite occurs as subhedral grains without ilmenite lamellae, whereas magnetite or martite could not be found. Ilmenite occurs as composite grains with maghemite and discrete grains. The Fe-Ti oxides occur with/within pyroxenes, biotite, and as fine-grained inclusions in calcic plagioclase. The compositions of cpx-opx pairs yield 910 to 862 ˚C by two-px geothermometer (Putirka, 2008 RiMG, 69, 61-120). 79CHU3 is a bt-hbl granodiorite with a magnetic susceptibility of 13.5 x 10^{-3} SI units. Maghemite occurs as subhedral grains without ilmenite lamellae similarly to 79CHU7, whereas magnetite could not be found. Mn-rich ilmenite is found with maghemite, but is mostly replaced by rutile/hematite aggregates or titanite. The Fe-Ti oxides and titanite occur mostly with hornblende and biotite. Hornblende occurs as subhedral to euhedral and homogeneous grains, and shows the compositions of magnesiohornblende (Si= 7.2-7.4 apfu, O=23). The compositions of hbl-pl pairs yield 689 to 588 ˚C by hbl-pl geothermometer (Holland and Blundy, 1994 CMP, 116. 433-447). The petrography above mentioned indicates the following crystallization sequence: 1) magnetite crystallization began in the early magmatic stage, and continued to the late magmatic stage. 2) magnetite was oxidized to maghemite in the late magmatic to subsolidus stages under relatively dry conditions. In 79CHU3, ilmenite was decomposed by further oxidation. These phenomena are attributable to the Chiquicamata magma containing enough sulfuric gas to maintain fO_2 along the H_2S-SO_2 gas buffer (Takagi and Tsukimura, 1997 Econ Geol, 92, 81-86). Throughout the magmatic to subsolidus stages, the magma/rock were continuously oxidized by SO_2 during cooling.

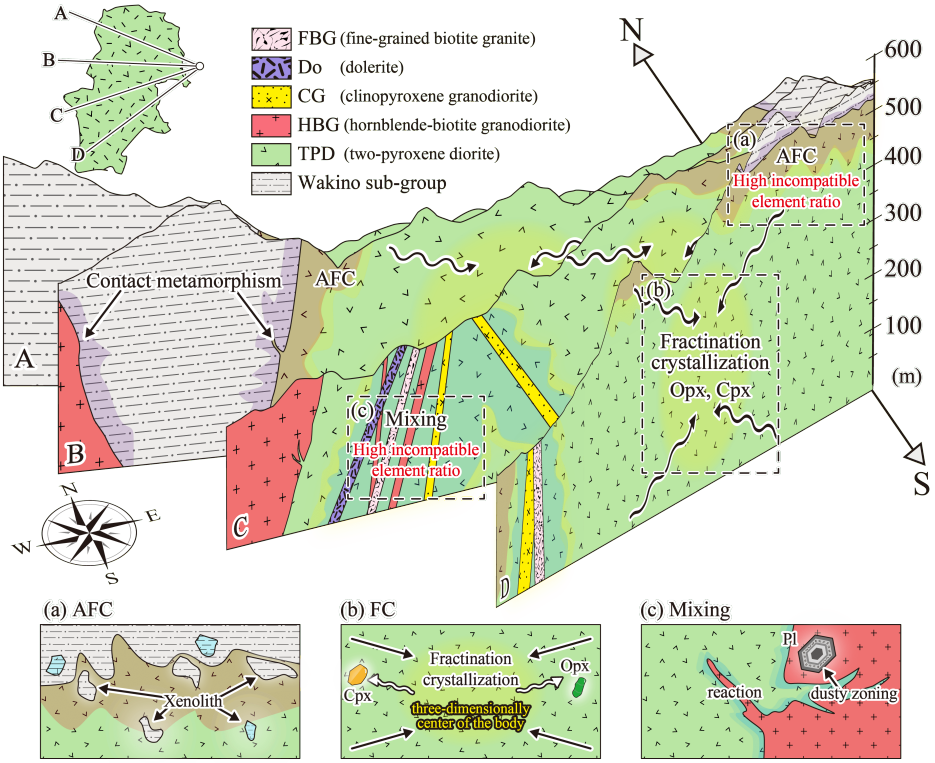
Anatomy of the Cretaceous Shaku-dake High-Mg diorite (HMD) intrusion, north Kyushu, SW Japan: Sheet on sheet model, and its genesis

*Keisuke Eshima[1], Masaaki Owada[1], Atsushi Kamei[2]



1. Yamaguchi University Graduate school of sciences and technology for innovation, 2. Shimane University Department of earth science, interdisciplinary faculty of science and engineering

The formation of plutons has fundamental implications for the geological linkage between volcanism and plutonism (e.g., Lipman, 2007; Macdonald et al., 2014), and ultimately for our understanding of the growth and evolution of the Earth’ s crust (e.g., Bachl et al., 2001; Annen, 2011; Menand et al., 2011). Much of the research on magmatic intrusions has focused on the mechanics and dynamics of dikes, which are the main agent for the vertical transport of magma through the crust (e.g., Lister and Kerr, 1991; Rubin, 1995; Menand and Tait, 2002). In comparison, that on sills has been discussed mainly on the mechanical and dynamical aspects of the propagation of sills, and on the deformation induced by sill intrusions (Pollard, 1973; Pollard and Holzhausen, 1979; Fialko et al., 2001; Malthe-Sørenssen et al., 2004). In recent years, however, the supply and emplacement mechanism of sills have been clarified from both of the detailed field research and experimental works using gelatin as natural analogs (Kavanagh, 2006; Menand, 2008, 2011). They stressed that such an emplacement mechanism gives an important role in the crustal evolution. Therefore, we performed the geological and petrological investigations and clarified a petrological character of magmatic processes, plumbing system, and growth process of the Shaku-dake high-Mg diorite (HMD) intrusion from the Cretaceous northern Kyushu batholith, Southwest Japan. It can contribute to the elucidation of large-scale igneous activity in northern Kyushu during the Cretaceous.

The granodiorites, the main constituent rock type of the Cretaceous batholiths from northern Kyushu, show the zircon U–Pb ages of 104 –102 Ma, and are accompanied coevally by fine-grained gabbro to diorite (e.g., Adachi et al., 2012; Tiepolo et al., 2012). Recently, the gabbro to diorite with the high-Mg andesite (HMA) compositions, referring to high-Mg diorite (HMD), has been reported (e.g., Kamei et al., 2004; Yuhara and Uto, 2007; Eshima and Owada, 2018; Eshima et al., 2019). The mantle-derived mafic magma is strongly involved in the origin of granitic magma as a parent magma and/or a heat source of crustal melting. The geology of Mt. Shaku-dake is composed of two-pyroxene diorite (TPD) and various dikes that intrude the Wakino sub-group as the host rock. The dikes are divided into five types; dolerite (Do), porphyritic fine-grained tonalite (PFT), clinopyroxene granodiorite (CG), hornblende-biotite granodiorite (HBG), and fine-grained biotite granite (FBG). In addition, the TPD intrudes into the host rock (Wakino sub-group) as the sheet converted from the vertical dike; thereby, suggesting the feeder dike. The TPD shows lithological variations on the metric and centimeter scales with different mineral mode and grain size. These field occurrences suggest that there were multiple injections of magma through the feeder dike before the TPD intrusion was fully consolidated. That is to say, the TPD intrusion is considered to be grown by the loading of sills and to bring to various compositional changes.

Formation process of pegmatitic pyroxenite in the western limb of Bushveld Igneous Complex, South Africa

Shuhei Yoshida[1], *Takuya Echigo[1], Yasushi Watanabe[1]

1. Graduate School of International Resource Sciences, Akita University

In the western limb of Bushveld Igneous Complex, South Africa, there are several discordant ultramafic intrusive rocks which cut the layered sequence of mafic-ultramafic plutonic rocks. We investigated the crystal growth process of the intrusive rock in Tweefontein area within southern part of the eastern Bushveld Igneous Complex. This intrusive rock is located in the upper critical zone in Rustenburg Layered Suite. The outcrop at Tweefontein is well-exposed and pegmatitic (grain size is greater than 2mm) pyroxenite intruded into the host rock, anorthosite. At the boundary between pyroxenite and anorthosite, grain size of the pyroxene is greater than the pyroxene at the core part of the intrusive rock. The pyroxenite consists of clinopyroxene (>80%), orthopyroxene (<10%) and other minor minerals such as plagioclase, hornblende, biotite and chlorite. It is notable that hornblende is present only in the course-grained clinopyroxene. SEM-EDS analysis showed that the end-member proportions of clinopyroxene are 46-47% wollastonite, 43-44% enstatite, and 9-10% ferrosilite and has no chemical zoning between their rim and core. Crystal size distributions (CSDs) of the clinopyroxenes showed linear trend and no local maximum. These trends reflect crystal growth process and absence of local maximum indicates that those clinopyroxenes grew by relatively simple process and neither Ostwald ripening nor annealing occurred. The CSD of coarse-grained pyroxenite has concave up curve and suggests that this trend resulted from crystal coarsening. Cawthorn et al. (2000) reported the ratios of Sr and O isotopes of this ultramafic intrusive rock at Tweefontein and concluded that there is no contribution of external fluid or assimilation of sedimentary rocks. These results suggest that hornblende in the course- grained pyroxenite crystallized as primary phase from the mafic-ultramafic magma which was enriched in water. The viscosity of hydrous silicate melt is much lower than anhydrous one and crystal growth of clinopyroxene can be promoted in the low viscosity magma.

Ilmenite-series granitoids of the Peninsular Ranges batholith of southern and Baja California and the inner zone batholith of southwestern Japan

*Mia Flores[1]

1. Stanford University

Belts of juxtaposed oxidized and reduced granitoids in continental margin batholiths around the circum-Pacific have been characterized primarily by striking differences in magnetic susceptibility. Oxidized belts display high magnetic susceptibility, which is proportional to magnetite content. The reduced rocks tend to be magnetite-poor and lack Fe-oxide minerals in general. Fundamentally, Fe-oxide mineralogy and abundance is a function of oxygen fugacity. The oxidized belts were termed “magnetite-series” and the reduced belts were termed “ilmenite-series” by Dr. Shunso Ishihara. The best examples of this juxtaposition are in the Peninsular Ranges batholith (PRB) of southern and Baja California as well as the inner zone batholith of southwestern Japan, in which 100s of km-long boundaries between magnetite-series and ilmenite-series granitoids exist. Specifically, the well-studied ilmenite-series granitoids of the Ryoke and San’yo belts of Japan act as comparisons to better understand the petrogenesis of the ilmenite-series La Posta belt of the PRB. Hornblende-biotite monzogranite of the San’yo belt were collected from quarries in Okayama prefecture. The Ushigaura tonalite and Ushigaura granite were sampled from exposures of the Ryoke belt on Shōdoshima Island. The Sierra San Pedro Martí r and Laguna Juarez plutons of the La Posta belt were sampled by previous researchers from San Diego State University. Both plutons are zoned from hornblende-biotite tonalite in the rim, to a zone of hornblende-biotite granodiorite, and to a two mica monzogranite in the core. Plutons of the La Posta belt commonly include titanite, unlike the San’yo and Ryoke belts, which may indicate relative differences in oxygen fugacity. Biotite and amphibole compositions, which are sensitive to pressure, temperature, water fugacity and oxygen fugacity, may provide more information about the conditions that ilmenite-series plutons cool under. Characterization of biotite and amphibole are a first step towards more detailed Tl isotope analyses as well as Fe3+/(Fe2++Fe3+) quantification.

Whole-rock chemical composition analysis of granitic rocks in the Goto Islands, southwestern Japan

*Kazuhiro Koga[1], Motohiro Tsuboi[1], Ryunosuke Ikeda[1], Misaki Kubo[1]

1. Kwansei Gakuin University

The Goto Islands in Nagasaki Prefecture are located on the western end of the Kyushu district, and on the southern end of the Sea of Japan. The Goto Islands consists of five main islands, Nakadori, Wakamatsu, Naru, Hisaka and Fukue islands from northeast to southwest. Some small islands distribute around main islands. Geology of the Goto islands consists of sedimentary rocks of the Goto group, tuffs, Goto granitic rocks, rhyolite and basalt (Kawada et al., 1994). Goto granitic rocks consist of granodiorite, granodiorite porphyry, and granophyre, and the ages of these rocks are reported c. 15 Ma (Ishikawa & Tagami, 1991). This age is related to the time of the opening of the Sea of Japan, and there is a possibility that the magmatism of these granitic rocks is related to the opening tectonics of the Sea of Japan. In this study, we analyzed whole-rock chemical composition of granitic rocks in the middle eastern part of Fukue Island, the northern part of Hisaka Island, and the northern part of Nakadori Island, and discuss their petrogenesis.

Granodiorite porphyry, granodiorite and granite occur in the middle eastern part of Fukue Island. The northern part of Hisaka Island is mainly composed of granodiorite and granite, and there are some outcrops where the leucocratic rocks and melanocratic rocks sharply border each other. Basic intrusive rocks are also identified. Granodiorite porphyry, granodiorite and granite with intermediate enclaves are identified in the northern part of Nakadori Island. There are also some outcrops where the melanocratic granitic rocks are included into the leucocratic granitic rocks. Granodiorite porphyry, granodiorite and granite from Fukue Island, granodiorite, granite and basic intrusive rocks from Hisaka Island, and granodiorite porphyry, granodiorite, granite and intermediate enclaves from Nakadori Island were sampled. The major elements and trace elements were analyzed with X-ray fluorescence spectrometry, and rare earth elements (REE) were analyzed with inductively coupled plasma mass spectrometry.

The content of SiO_2 ranges from 65.3 to 72.7 wt.% for granodiorite porphyry, from 62.4 to 75.9 wt.% for granodiorite and granite, 48.8 and 48.9 wt.% for basic intrusive rocks, and from 58.2 to 64.5 wt.% for intermediate enclaves. Onthe granodiorite porphyry, the content of Fe_2O_3, MnO, TiO_2 and P_2O_5 decreases, and K_2O and Al_2O_3 content increases with increasing SiO_2 content. On the granodiorite and granite, the content of Fe_2O_3, MnO, TiO_2, CaO, P_2O_5, Al_2O_3 and MgO decreases, and K_2O content increases with increasing SiO_2 content. On the SiO_2–FeO*/MgO diagram, the granodiorite porphyry shows calc-alkaline series composition. The other granitic rocks are divided into the high–FeO*/MgO group which shows extremely high FeO*/MgO ratio, and the low–FeO*/MgO group which shows tholeiitic series composition.

The geochemical discrimination diagram of trace elements (Pearce et al., 1984) shows that granodiorite porphyry and low-FeO*/MgO group granitic rocks have the characteristics of volcanic arc granite (VAG), and high-FeO*/MgO group granitic rocks have the characteristics of volcanic arc granite (VAG) to within-plate granite (WPG).

The REE patterns show that the samples are rich in light-REE and poor in heavy-REE. Both positive and negative Eu anomalies are observed in the REE patterns of the granitic rocks. Some samples show Ce

©2020. Japan Geoscience Union. All Right Reserved.

anomalies, probably due tothe weathering.

The chemical composition analysis reveals that the granitic rocks in the Goto Islands may have multiple origins.

Geochemical constraints on origin and formation of the Mikabu–Sorachi Plateau

*Naoto Kimura[1,2], Yuji Ichiyama[3], Takashi Miyazaki[2], Bogdan S. Vaglarov[2], Qing Chang[2], Takeshi Hanyu[2], Jun-Ichi Kimura[2]

1. Graduate School of Science and Engineering, Chiba University, 2. Japan Agency for Marine–Earth Science and Technology, 3. Graduate School of Science, Chiba University

It is generally accepted that mantle plume upwelling had been active in the Pacific Ocean during the Cretaceous period based on the thorough studies of Cretaceous oceanic plateaus (e.g., Larson, 1991; Coffin and Eldholm, 1994). The presence of the Izanagi–Farallon–Pacific triple junction in the Paleo–Pacific Ocean has been proposed based on the geometry of paleomagnetic anomalies (Sager et al., 1988, 1999; Nakanishi et al., 1989, 1999). An Early Cretaceous mantle plume arrival beneath the triple junction constructed the Shatsky Rise with its high degrees of melting (Sano et al., 2012). This plume also possibly formed several oceanic plateaus on the Izanagi and Farallon plates, and parts of them have been considered to be preserved as accreted fragments in continental margins (Sager et al., 1988; Larson, 1991; Kimura et al., 1994; Ichiyama et al., 2014).

The Mikabu and Sorachi–Yezo Belts are Cretaceous terrains distributed in Japan and contain voluminous greenstones as ophiolitic members, which are metamorphosed picrite, basalt, and gabbro. The Mikabu and Sorachi picrites have extremely magnesian olivine phenocrysts (up to $Fo_{93.5}$), and the mantle potential temperatures of more than 1600℃ are estimated (Ichiyama et al., 2012, 2014). The greenstones have been considered to be fragments of an oceanic plateau in the Jurassic–Cretaceous Pacific Ocean (Mikabu–Sorachi Plateau; MSP), and some scientists believe that this plateau was formed with the Shatsky Rise on the Izanagi–Pacific ridge (Kimura et al., 1994; Ozawa et al., 1999; Sakakibara et al., 1999; Ichiyama et al., 2012, 2014; Sawada et al., 2019). However, the zircon U–Pb dating of the Mikabu mafic rocks and sandstones shows igneous ages of ca. 155 Ma (Sawada et al., 2019; Endo and Yokoyama, 2019) and an accretion age of ca. 130 Ma (Endo and Wallis, 2017), respectively, implying that the MSP emerged on an intraplate (i.e., Izanagi plate) rather than on a plate boundary (i.e., Izanagi–Pacific ridge) because estimated travel time of the Izanagi plate would take ~80 Myr from the ridge to the trench (Müller et al., 2016).

Miyazaki et al. (2015) proposed that an isotopic boundary between the Indian and Pacific mantle types is present beneath the Pacific Ocean and has been stationary, at least, from Cretaceous to present. Recently, Aoki et al. (2019, 2020) suggested that metagabbro and mafic gneiss in the eclogite unit of the Sanbagawa Belt were formed in an island arc setting within the Pacific Ocean in 200–180 Ma. If this is a case, it would be expected that the Mikabu–Sorachi (ca. 155 Ma) greenstones record mantle isotopic heterogeneity beneath the Paleo–Pacific Ocean.

In this presentation, we will provide new geochemical and isotopic data of the Mikabu and Sorachi greenstones (picrite, gabbro, and alkali basalt). These data will enable us to constrain the source material and tectonic setting of the MSP in the Jurassic Pacific Ocean.

Gesis of vesiculation in basalt sills of the Shimokawa ophiolite in the northern Hidaka belt, Hokkaido with influence on basalt sill of the Ab-Kfs vein

*Kato Satomi[1], Sumio Miyashita[2]

1. Graduate school of science and technology, Niigata university, 2. Hokkaido Research Center of Geology

Vesiculation of magma depends on volatile components in the magma and the eruption depth. Basaltic rocks with N-MORB features from the Shimokawa ophiolite generally show poor vesiculation. However some of massive basalts are vesiculated up to 10 vol. %. Miyashita (1999) proposed that the high vesiculation is caused by an interaction between sediments and intruding magmas. We present new finding of Ab-Kfs veins, size distribution and bulk composition of the vesiculated massive basalt sills. We discuss how Ab-Kfs vein affects massive basalt sills.

The Shimokawa ophiolite is exposed in the northern part of central Hokkaido. Serpentinized harzburgite and gabbro occur at the lowest part. The lower part of the main body consists of alternation of dolerite and sediments, the upper part consists of pillow lava, and the middle part shows intermediate features between the upper and lower parts. (Miyashita and Watanabe, 1988). High vesicular massive basalt sills interlayered between sediments are found from three locations. The sediments are silicified along the contacts.

Massive basalt sill 1 about 22 m thick occurs at the lowest horizon in the vesiculated massive basalt sills. This sill contains many irregular shaped xenoliths of sediments, indicating that the sill intruded into unsolidified sediments.

The Shimokawa ophiolite shows typical N-MORB signatures (Zr/Nb>17). High vesicular basalts tend to be high LIL elements contents than poorly vesiculated basalts. REE ratios exhibits that there are two types in the Shimokawa ophiolite, about 0.8 La/Yb ratios with N-MORB patterns (sill 2, most of sill 3, most of pillow lava), and about 1.2 La/Yb ratio with T-MORB patterns (sill 1, some sill 3, some pillow lava). However, HFS elements that are immobile during alteration processes reveal N-MORB features. Therefore, LIL elements and light REE are probably modified from the primary compositions.

The Ab-Kfs veins are >2 mm width and thicker than later calcite veins. The border of the Ab-Kfs vein is not straight and waves. It is noted that the Ab-Kfs veins do not cut primary igneous crystals. We measured vesicularities of 22 samples from the massive basalt sill 1. The marginal part within 50 cm from the contact is not vesiculated. Vesicularities increase upward until about 18 m from the lower contact. But basalts containing Ab-Kfs veins show high vesicularity. Plagioclase number densities (PND) show a systematic variation. The margin shows a high value (40 number/mm^2) and inside shows low values (4-6 number/mm^2), implying that the margin is fine-grained and inside is coarse-grained. The PND of basalt containing the Ab-Kfs vein is higher than surrounding rocks (15 number/mm^2), indicating fine-grained than surrounding basalts. Cr_2O_3%(cpx) shows that inside of sill 1 is evolved (Cr_2O_3% (cpx) 0.25%), but surrounding Ab-Kfs vein is less evolved (Cr_2O_3% (cpx) 0.8%) as similar with those of the margin. Above facts suggest that the Ab-Kfs veins were formed before the solidification of the sills.

When magma intruded into thick unsolidified sediments, neighboring sediments are rapidly dehydrated

©2020. Japan Geoscience Union. All Right Reserved.

and solidified due to heating by magmas. Expelled hydrothermal fluids from the sediments could not escape from the sills because of sealing effects of overlying solidified sediments, leading mixing with magmas.

The Ab-Kfs veins were formed before the solidification of magma, as described above. Surrounding basalts of the Ab-Kfs veins are highly vesiculated and fine-grained. Furthermore pyroxene compositions of neighboring basalts are less evolved. Therefore, the Ab-Kfs veins affect cooling rate, volatile components and differentiation of injected magmas. Silicified sediments release H_2O, LIL elements such as K_2O and Rb, and CO_2 due to dissolution of organic carbon. The released elements are entrained in the intruding magma via the Ab-Kfs veins, resulting in high vascularity of magma.

Siliceous concretion in Miocene diatomaceous muddy rock, northeastern Noto Peninsula, central Japan

*Seika Oto[1], Kosei Komuro[1], Masaaki Shimizu[2], Hisatada Akahane

1. Toyama University, 2. Hokuriku Polytechnic College

Siliceous concretions called as "Koburi-ishi" are embedded in the diatomaceous muddy rocks from the Iizuka Formation of middle Miocene, the northeastern Noto Peninsula, central Japan. They have platy to ellipsoidal forms with 1-5 cm in diameter, are embedded in specific horizons or in association with faults, in the host diatomaceous muddy rocks which contain a large number of microfossils mainly of marine diatoms with radiolarians and sponge spicules. Here we describe the siliceous concretions mineralogically, and discuss their formative processes and environment.

Microscopic observation clarify that the siliceous concretions contain microfossils with hard matrices of siliceous phases and have concentric growth structure. This indicates that hard matrices phases were precipitated from interstitial solution. The XRD analysis for siliceous phases after the elimination of clay fraction indicates that both siliceous concretions and the host diatomaceous muddy rocks are composed of opal-A and opal-CT. The peak fitting assuming Gaussian distribution reveals that siliceous concretions contain more opal-CT than the host diatomaceous muddy rocks. The cristobalite in opal-CT from siliceous concretions has 4.121 ~ 4.137 Å, which is wider d-spacing of (101) than that from the host diatomaceous muddy rocks of 4.073 ~ 4.083 Å.

Original sediments of the host rocks from the Iizuka Formation were deposited under shallow marine environment. They were buried up to about 500 meters in depth of sedimentary sequences. Biogenic opal-A of diatoms in diatomaceous muddy sediments from the Iizuka Formation changed to opal-CT by the diagenetic phase transformation responsible for the burial depth. It is known that the sequences were uplifted repeatedly to the present location. The wider d-spacing of (101) of siliceous concretions suggests they were formed under shallower burial environment than host rocks. Considering that the solubility of silica in seawater is higher than that in meteoric water due to the contribution of Na-Si complex, the inflow of meteoric water by upheaval triggered the formation of the siliceous concretions. As the meteoric water invaded into a series of the sequences along permeable horizons or fault planes, mixing of interstitial seawater of the host diatomaceous muddy rocks and meteoric water took place at the permeable horizons or fault planes. As a result, dissolved silica in interstitial seawater was precipitated along the horizons or planes to form siliceous concretions.

Spectral Analysis of Cathodoluminescence of Barite

*Tomita Makiko[1], Shin Toyoda[1], Hirotsugu Nishido[1]

1. Okayama university of science

Cathodoluminescence (CL), luminescence following electron excitation, in minerals varies in emission color, intensity, and spectrum, gives information on impurity compositions and structural lattice defects. In the present study, CL of barite (BaSO4) was investigated, which had not been studied in detail. Although CL in many minerals has similarity with photoluminescence (PL), excited by UV, and radioluminescence (RL), excited by X-rays, it was found that barite is not the case.
Twenty-five natural barite samples, which show PL of various colors, were examined in the present study. SEM-CL analysis was conducted using an SEM (JEOL: JSM-5410) combined with a grating monochromator (Oxford: Mono CL2) in the range from 300 to 800 nm in 1 nm steps with a temperature-controlled stage from -190 to 25 ℃. The wavelength dependent photomultiplier response was corrected with a standard light source to have correct CL spectra. They were then converted to the ones according to photon energy in eV and then deconvoluted into Gaussian components with using OriginPro 9J.
Color CL images with blue emissions were obtained only from five samples while other samples show no CL, although most samples examined here exhibit various luminescent colors of blue, beige, yellow, white and magenta under a UV lamp.
As the result of the spectral analysis with deconvolution, the spectra with the strong and weak blue emissions have a broad band around 370 nm in UV-blue region, but no clear emission in red region. In previous studies, luminescence peaks were reported due to an intrinsic center of SO_4^{2-} and to an impurity center of Pb-ion or Eu-ion [1,2]. The peak position of the present result was found to be close to these previous studies.
With EPMA and LA-ICP-MS analysis, Pb contents were obtained in the samples. It was found that those with Pb content of 23.8 wt% or more show strong CL and that those with 500 ppm or less show weak CL, while those with no CL do not contain any impurity elements. The temperature-controlled CL measurements reveled that the peak position of blue CL of strong emission (hence larger Pb content) did not change with temperature, whereas the emission intensity of the sample, containing Pb of 0.5 wt% or less, increase with temperature.
Therefore, the blue CL emissions found in barite might be composed of an impurity center of Pb-ion activator or sensitizer, and the 3.28 eV component may be composed of SO_4^{2-}defect centers.

Mineralogical study on bur-shaped pyrite in SK050 volcanic ash in Uonuma Groupe, Niigata Prefecture

*Hiroaki Ohfuji[1], Akinori Matsuda[1], Takeshi Kakegawa[2]

1. Geodynamics Research Center, Ehime University, 2. Graduate School of Science, Tohoku University

Sedimentary pyrite shows a variety of morphologies and textures from euhedral crystals to framboidal, radiating and colloform aggregates depending on the formation environments. Here we report a very unique case of pyrite morphology, “bur-shaped” aggregate, found in microscopic pyrite occurring in SK050 volcanic ash, which is one of the many tephra layers intercalated in the Uonuma formation, Niigata Prefecture.

SK050 volcanic ash and the under- and overlying muddy sediment samples collected from the outcrop along the Shibanomata River in Oguni Town contain microscopic pyrite which can be divided into three types by morphology, (1) framboidal, (2) polyframboidal, and (3) bur-shaped aggregates. Framboidal and polyframboidal aggregates occur in all the sediment samples collected, while bur-shaped aggregates are found exclusively within the SK050 volcanic ash, where the relative proportion of framboidal aggregates is very low. Bur-shaped pyrite is characterized by spheroidal shape with a number of spines and shows a normal size distribution ranging from 20 to 60 μm in diameter, which is more or less larger than that of framboidal pyrite (10-50 μm). SEM observation on the cross-sections through the core prepared by FIB revealed that bur-shaped pyrite always has a framboidal pyrite in its core from which columnar pyrite crystals grew in a radiating manner. Each columnar crystal is terminated by a pyramidal apex, which corresponds to the spines observed on the outer surface of bur-shaped pyrite. These observations suggest that bur-shaped pyrite is a unique product of pyrite overgrowth around a framboidal pyrite core. Sulfur isotope analysis of the SK050 volcanic ash containing bur-shaped pyrite showed very heavy isotopic ratios ($\delta^{34}S$= ca. +20 ~ +25‰), which are clearly distinct from those of the under- and overlying sediments containing framboidal pyrite (ca. 0 ~ +15‰). It seems that bur-shaped pyrite formed as a result of an extensive overgrowth of pre-existing framboidal pyrite when a fluid highly saturated with pyrite penetrated into the SK050 volcanic ash layer which has a much higher permeability than the under- and overlying sediments.

Multi-photon luminescence measurement of natural and treated diamonds

*Shoko Odake[1], Hiroaki Ito[2], Hiroshi Takahashi[3], Shingo Ono[2]

1. GIA Tokyo Godokaisha, 2. Nagoya Institute of Technology, 3. Gemological Institute of America

Treatments are widely used to modify diamond’ s body color to improve it's value as a gem. Typical examples of treatments are annealing in high-temperature and high-pressure (HPHT) environment to remove brownish color from diamonds and irradiation with an electron beam to add bluish color. To distinguish between natural and treated diamonds, spectroscopic measurements are used. The spectroscopic measurements currently used are limited to the surface and the area near the surface of the diamond. In order to accurately and quickly distinguish between natural and treated diamonds, a method for evaluating the defect distribution inside the diamond is needed. In this study, distribution of defects in natural and treated diamonds were evaluated three-dimensionally by using multi-photon luminescence measurements.
The measurements were performed on natural untreated, HPHT treated (type I and type IIa), and electron beam irradiated diamonds. The measurement of multi-photon luminescence is widely used for biological research, and is a method capable of measuring three-dimensional defects inside a sample with nondestructive and high spatial resolution. A multi-photon laser-scanning microscope (Olympus, FV1200MPE) was used for the measurement. In a multi-photon laser-scanning microscope, excitation light from a femtosecond laser is reflected by a mirror and focused and irradiated to a sample using an objective lens. By using a galvanometer mirror, excitation light is moved in the XY direction, and the objective lens is moved in the optical axis direction, and scanning is performed in the Z direction, thereby enabling three-dimensional scanning. The multi-photon luminescence generated from the samples were collected using the objective lens, and the multi-photon luminescence intensity was measured using a photomultiplier tube. Band pass filters were used to isolate defects in specific wavelength ranges.
As a result, in natural diamonds the differences of the color center in different growth planes were visualized three-dimensionally. In treated diamonds, distribution of 1-micron size defects in HPHT were visualized. In irradiated diamonds, irradiation-related defects were observed only in the surface area. In this presentation, we will discuss details about differences between conventional methods and multi-photon luminescence measurements.

Study for development of geothermal exploration technique using thermoluminescence of feldspar

*Takahiro Sato[1], Nobuo Hirano[1], Noriyoshi Tsuchiya[1], Atsushi Okamoto[1]

1. Tohoku University

Japan has abundant geothermal resources, and geothermal development is important in energy strategies, but its development is not progressing. This is because geothermal power development costs are expensive, and lead times are long. As a solution to these problems, a simple geothermal exploration method using mineral thermoluminescence has been proposed. Thermoluminescence (TL) is a phenomenon in which energy is accumulated inside a mineral crystal by radiation, and this energy is released as luminescence by thermal stimulation. Light emission due to energy accumulated by natural radiation is called as natural thermoluminescence (NTL), and light emission due to energy accumulated by irradiation of artificial radiation is called as artificial thermoluminescence (ATL). Tsuchiya et al. (2000) and Saito et al. (2017) showed that Geothermal exploration using TL of quartz has effectiveness. Feldspar also emits TL like quartz, but few studies have been conducted on geothermal exploration methods using TL of feldspar. Feldspar is a ubiquitous mineral at the crust, if a geothermal exploration method using feldspar TL can be developed, TL geothermal exploration can be applied to areas without quartz. In addition, it is thought that the accuracy of the geothermal exploration method using the TL can be improved by using it in combination with the quartz TL. In this study, the basic properties of TL of feldspar were studied.

The geothermal exploration method using TL of quartz utilizes the difference in NTL intensity due to geothermal influence. This utilizes the property that accumulated energy is released by heat and utilizes the phenomenon that the intensity of light emission (NTL) decreases as it approaches the heat source, that is, as the geothermal temperature increases. An isothermal decay experiment was performed using K-feldspar in pegmatite to examine whether the same method can be applied to feldspar. As the heating environment conditions, three patterns were prepared: a sample only heated, a sample immersed in acidic water (Tamagawa hot spring water) and heated, and a sample immersed in neutral water (distilled water). These samples were reacted at temperature of 90, 125, 150, 200 and 250 ºC, and 24, 168 and 672 hours. The total number of samples is 45. To evaluate thermoluminescence, first observe the glow curve. Glow curve is obtained by subtracting background luminescence intensity (mainly infrared radiation from heater) from thermo luminescence intensity of mineral crystals. After that, integrate the glow curve from 50ºC to 350ºC and define that integrated value as the TL intensity. Regarding the relationship between the TL intensity and the heating temperature/time, the decay of TL intensity was observed as the heating temperature was higher and the heating time was longer. Regarding the relationship between the TL intensity and the heating environment, no change was observed in the tendency of the TL intensity decay even when the heating environment was changed. Therefore, it is considered that the decay of TL intensity depends more on the influence of temperature than on the influence of hydrothermal alteration. These results of the TL intensity decay were kinetically interpreted, and fitting was performed assuming a fifth-order reaction. As a result, the apparent activation energy was 1.25 eV. This value is in good agreement with the quartz results calculated in previous studies, indicating the possibility of geothermal exploration using NTL of feldspar.

In the poster presentation, feldspars collected from rocks such as tuff and granite will also be discussed.

Synthesis of highly dense and fine-grained crustal and mantle mineral aggregates by spark plasma sintering (SPS) technique

*Sanae Koizumi[1], Takehiko Hiraga[1]

1. Earthquake Research Institute,The University of Tokyo

We will present the synthesis of various types of the upper mantle and crustal mineral aggregates including mono-phase aggregates of Fe–free and Fe--bearing olivine, enstatite ($MgSiO_3$) and anorthite ($CaAl_2Si_2O_8$), two-phase composites of olivine + spinel, olivine + diopside ($CaMgSiO_6$), olivine + enstatite and anorthite + diopside and three-phase composites of olivine + enstatite + diopside. We prepared mineral powders through solid state reaction of source powders at high temperature (Koizumi et al. 2010). They are densified by spark plasma sintering, which results in obtaining highly dense and fine-grained aggregates. In SPS, it is essential to use proper starting powders and sintering conditions such as temperature, duration time and heating rate. At low temperature of 1130 - 1250˚C, short duration of 20 min and low heating rate of 10˚C/min, we could obtain aggregates with grain size of 0.2 μm in minimum.

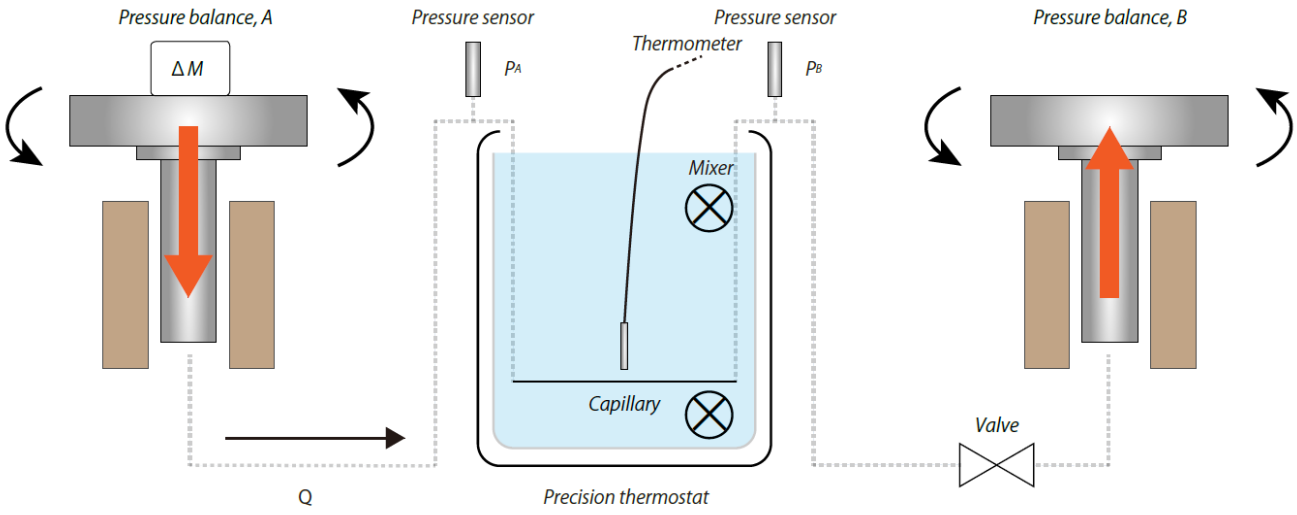
Development of simultaneous measurement system of viscosity and permeability for highly accurate evaluation of groundwater under high pressure and high temperature condition



*Tomoya Muramoto[1]

1. National Institute of Advanced Industrial Science and Technology

In predicting the flow behavior of groundwater, the viscosity of groundwater in the ground under high pressure and high temperature is very important. According to Darcy’s law, the volumetric flow rate of groundwater is determined by the balance between “Mobility” and “Driving Force”. Here, in order to determine “Mobility”, the viscosity of the fluid is required. From this, it can be said that the viscosity of the fluid is very important for accurately predicting the underfround flow field.

We developed a new method for the high-pressure viscosity measurement of a fluid using two pressure balances. In this method, the concept of a capillary method used in a viscosity measurement and cross-float technique are applied. We evaluated the pressure dependency of the viscosity of dioctyl sebacate. On comparing our results with the those in the literature, it was confirmed that the result showing the pressure dependence of viscosity was similar to that mentioned in literature. Thus, we confirmed that the measurement system developed in this study could accurately evaluate the pressure dependence of viscosity. In the future, focusing on the similarity between flow field descriptions based on Darcy’s law used for permeability measurements and Hagen-Poiseulle’s law used for highly accurate viscosity measurements by capillary method, we will develop simultaneous measurement system of viscosity and permeability at high temperature and high pressure. The measurement system to be developed in this study makes it possible to determine the permeability based on the national measurement standard, and to accurately evaluate of the permeability and mass transport characteristics of groundwater.

Evaluation of the influence of particle size on characteristics of particle shape using an automated particle image analysis

*AIKO HAYAUCHI[1], Daisuke Sasakura[1]

1. Malvern Panalytical division of Spectris Co., Ltd

1. Introduction

In many fields dealing with geology, the relation between particle morphology in the soils and various phenomena is widely studied. Particle morphology indicates particle size, particle shape and various other characteristics. In particular, size and shape are complementary relationship. As a previous research, we reported the results of particle shape evaluation of volcanic ash whose particle size was evaluated using a sieve, and clarified that particle size evaluation using a sieve is affected by the particle shape. [1]. Notable aspect of size and shape distribution matters are its having inversed relationship qualitatively. Typically, in soil, the finer particle are relatively more circular shape than the coarse particle. This is because, for example, finer particles are presumed to be provided by abrasion fracture when falling from a rock surface due to ground distortion and/or rising. Therefore, the simultaneously integrated investigation between size and shape is important.

The existing technology to investigate size and shape matter are the microscopic technics, sieving, sedimentation and laser diffraction analysis. Challenges of existing technologies on above are that it is each independent technic to investigate between size and shape. Especially, microscopic analysis is the near impossibility of measuring a statistically significant number of several ten thousand number of particles as recommended in ISO 13322-1,2 and quantitatively information. Recent advances in computer technology have allowed for a new automated particle image analysis (APIA) approach.

We reported and discuss about capability of APIA method was useful to resolve these issues on the model soil samples considerd fracture processes as one of realistic ground mechanics process.

2. Material and method

Sea sand, 300~600um(30~50mesh) (FUJIFILM Wako Pure Chemical Corporation) was used for this study. A part of the sample was milled with a ball mill (Mini Mill 2, FRITSCH).

As APIA system, Morphologi 4 (Malvern Instruments) was used for evaluation of particle size and shape. The observation mode was diascopic mode (Transmittance mode) and magnification was 125x in total magnification. The sample was dispersed with SDU (Sample Dispersion Unit) which attached Morphologi 4. Number of measured particles is over than 2,000 and parameter filter function on software was used based on shape and pixel number of particle image.

3. Result

Mean value of Circularity for original sea sand and 5 minutes milled sea sand is shown in Table 1. All particle circularity of original sea sand is smaller than all particle circularity of 5 minutes milled sea sand. For particles larger than 150um, circularity both original sea sand and 5 minutes milled sea sand are almost same. Particle of the same size as before milling, that is, particles of a large size, were simply particles that were not milled. Therefore, it is considered that these particles maintain their shape.

Focusing on the small particle size, it was confirmed that the trend was the same as the trend of all particle. In particular, the circularity of particles smaller than 20um was almost the same as the circularity of the whole particles. This is a simple result comes from the number ratio of particles smaller than 20um is highest (Percentage of particles by particle size is shown in Table 2).

These data will discuss in detail on that day.

©2020. Japan Geoscience Union. All Right Reserved.

4. Conclusions

It was confirmed that particle shape changes according to particle size with APIA method. The particle shape results from the shape of the particles in numerical majority. It is also revealed that it is necessary to use a number-based particle size distribution device to understand the number of particles by particle size.

Genesis of the low-Sr Granitoid in the northern Kyushu

*Yayoi Muraoka[1], Masaaki Owada[2], Teruyoshi Imaoka[2], Atsushi Kamei[3], Kazuhiro Miyazaki[1]

1. Advanced Industrial Science and Technology, 2. Yamaguchi Univ., 3. Shimane Univ.

The Cretaceous granitoids are widely exposed on the northern Kyushu, Southwest Japan. These granitoids were distinguished between the low-Sr and high-Sr granitoids by their Sr contents (Izawa et al., 1990). The boundary of these is the Kokura-Tagawa Tectonic Line (KTT). In the east side of KTT, the low-Sr granitoids are distributed. On the other hand, the high-Sr granitoids are exposed on the west side of KTT. The Hirao granodiorite and related granite dike are exposed on the east side of KTT. The Hirao granodiorite occurs as a stock with 16 km N-S and 4 km E-W, and has Sr contents of 213-291 ppm. In this study, the authors discussed the magmatic processes of the Hirao granodiorite and petrogenesis of the low-Sr granitoids by comparing the Ushikiri-yama granodiorite (high-Sr granitoid, details reported by Eshima et al., 2019).

The Hirao granodiorite and the granite dike have similar mineral assemblage, consisting mainly of plagioclase, quartz, K-feldspar, biotite and hornblende. In addition, the granodiorite and the granite dike geochemically resemble each other; for instance, their REE patterns and Sr-Nd isotopic values. The result of mass balance calculation reveals that the granite dike magma can be formed by subtraction of plagioclase and hornblende from the Hirao granodiorite magma.

The different Sr contents between the high- and low-Sr granitoids in this region can be explained by the following magmatic processes; magma mixing, assimilation of host rock, degree of fractional crystallization or partial melting, and composition of source materials. The magma mixing and assimilation of the host rocks were ruled out in terms of field occurrence. The geochemical study including trace elements and Sr-Nd isotopic compositions revealed that the Hirao granodiorite and the Ushikiri-yama granodiorite were shared with similarity source materials. Moreover, the magmatic processes of the both granodiorite were similar regarding the degree of fractionation and partial melting. Considering geochemical characteristics combined with melting experiments, the Hirao granodiorite representative of the low-Sr granitoid magma can be produced by relatively low-pressure melting rather than the high-Sr granitoid; thereby, leaving plagioclase as the residual phase at the source region.

[S-CG56] ICDP Oman Drilling Project: Oman to Oceanic Lithosphere to Island Arc Formation and Beyond

convener:Eiichi TAKAZAWA(Department of Geology, Faculty of Science, Niigata University), Katsuyoshi Michibayashi(Department of Earth and Planetary Sciences, Nagoya University), Sayantani Chatterjee(Niigata University, Department of Geology, Faculty of Science)

The on-going Oman Drilling Project has drilled numerous hard-rock cores of ancient oceanic lithosphere and the underlying subduction zone of the Samail ophiolite in Oman, with support from ICDP, IODP, the Sloan Foundation's Deep Carbon Observatory, and Japanese, US, and European research agencies. In this session, we invite presentations on the scientific results of Oman Drilling Project. We also invite related studies of on-land geological investigations of Oman ophiolites and experimental studies. The session is intended to be interdisciplinary, including the fields of geophysics, geochemistry, petrology, engineering, and biology.

Numerical prediction of effect of olivine content for proceeding of serpentinization

*Kazuki Yoshida[1], Atsushi Okamoto[1], Ryosuke Oyanagi[2], Hiroyuki Shimizu[3], Noriyoshi Tsuchiya[1], Oman Drilling Project Phase 2 Science Party

1. Tohoku university, 2. Japan Agency for Marine-Earth Science and Technology, 3. Kajima Corporation

The extent and progress of serpentinization within the oceanic lithosphere is a key to understanding global water circulation within the Earth's interior and seismicity at subduction zone. However, the mechanism to control the serpentinization rate of the oceanic lithosphere is still unclear. In this study, we reveals the importance of modal abundance of olivine grains on the feedback among fluid flow, fracturing and reaction based on the analyses of natural rocks and numerical modeling by distinct element method (DEM). The analyzed rocks are taken from Oman Drilling Project hole CM1A which through the crust-mantle transition zone. The analyzed rocks are olivine-gabbro, troctolite, dunite and wehrlite which show a large variation of the amounts of olivine. In troctolite and olivine gabbros, characteristic fracture patterns are observed: mesh-like texture within olivine grains and radial cracking around the olivine grains. Serpentine was observed along these fractures in olivine grains, it is suggesting that these fracture was a main fluid pathway during serpentinization. Moreover, a positive relationship was found between moral abundance of olivine and the extent of serpentinization.

The numerical simulation based on two-dimensional distinct element method (DEM) combining fluid advection and reaction (Shimizu and Okamoto., 2016) was conducted to examine the effect of amount of olivine grains to unreacted matrix. We consider a simple volume increasing hydration reaction (150% volume increase), and the rock model consist of reactive part (olivine) and unreactive part (plagioclase and pyroxene). We conducted five conditions varying distance between each olivine grains. As the result, the olivine grains made connected fracture network, which increase in permeability and reaction progress. However, when too low olivine content, it could not make enough fracture for reaction proceeding. In the other hands, when too much olivine amount condition, the permeability and bulk reaction progress become less because volume expansion caused fracture clogging which inhibited further fluid infiltration to fresh olivine grains.

These results suggest that (1) an increase of olivine amount results in development of fracture network to percolate fluids, but (2) too much olivine amounts prevent the fluid flow as volume-expansion close the fractures which obstruct fluid penetration. The discrepancy between natural observation and numerical modeling for dunite suggest the importance of other fluid pathways such as nano-scale pores in serpentine for complete serpentinization.

Serpentinization of the oceanic lithosphere provides significant impacts on biological activities at seafloors, as oxidation of Fe^{2+} in olivine results in a reduction of water to produce hydrogen and hydrocarbons. In serpentinized peridotites, Fe^{3+} is mostly contained in magnetite. However, the distribution of magnetite is not always uniform but commonly concentrated along veins. In addition, serpentine, which is the main constituent mineral of serpentinized peridotite, also can be a host phase for Fe^{3+}. Therefore, the behaviors of iron such as partitioning, mobility, and redox conditions, and their relation to hydrogen production during serpentinization are still poorly constrained. In this contribution, we report the preliminary results of micro- to nano-scale observation of magnetite and iron distribution within wehrlite and dunite at the crust-mantle boundary of the Samail ophiolite, recovered from the Oman Drilling Project hole CM1A. The synchrotron-based multi-scale X-ray CT images were taken by the beamline NW2A, PF-AR at KEK, Japan.

The wehrlite sample (CM1A-144Z-4-66-68) is partly serpentinized and olivine grains show mesh texture composed of mesh rim and veins. Mesh rim is composed of serpentine (Mg#~94) with minor brucite and magnetite. The vein in mesh texture is composed of serpentine (Mg#~95) + magnetite. Magnetite shows two types of occurrence: the first type of magnetite with a size of 1-2 μm occurs as planar aggregate at the center of the mesh veins. The second type of magnetite occurs in the mesh rim. The CT image reveals that the second type of magnetite accompanies pore with a size of ~0.5 μm, and seems to align. Within unreacted olivine mesh core, magnetite accompanying pore is also observed, which is similar to the second type of magnetite. Such occurrence suggests that the second type of magnetite was formed within fluid inclusions of olivine, and micro- to nano-scale pores were not collapsed during serpentinization although it essentially involves volume-increasing reactions.

In contrast to wehrlite, dunite (CM1A-90z) is completely serpentinized and cut by the later serpentine veins, which is a common feature of dunite samples from CM1A. In the matrix, magnetite uniformly occurs in size less than 5 μm, and does not show the evidence of mesh texture. The detailed observation revealed that later veins are composed of Fe-poor serpentine (Mg#~98) with reaction zones with plenty amount of magnetite. In the reaction zone, the euhedral magnetite with size in 10-30 μm was concentrated within the reaction zone. These occurrences suggest that magnetite was formed during serpentinization, iron could move by dissolution and precipitation processes in response to the infiltration of external fluids.

Department of Earth and Planetary Sciences, Nagoya University, 5. Géosciences Montpellier, CNRS, Université de Montpellier, 6. Lamont Doherty Earth Observatory, Columbia University

To assess pore geometry in the highly altered peridotites collected by the Oman Drilling Projects, we analyzed ultrasonic velocity of the serpentinized dunites and harzburgites from mantle sections at Holes BA1B, 3A, and 4A. First, we estimated serpentine fraction based on grain density to obtain the porosity-free reference velocity, suggesting a nearly complete serpentinization at shallow depth but decrease of hydration at deeper depth. We assumed that the difference between reference and measured velocity attributes to pores with spheroidal shape that are embedded in the samples. Application of effective medium theory to onboard P-wave and porosity data indicates that pore aspect ratio mostly lies between 0.1 and 0.01 and crack density is ranging from 0.58 to 0.02. We found a positive relationship between aspect ratio and serpentine fraction, suggesting a change in pore shape controlled mainly by the dissolution–precipitation processes during hydration, consistent with microstructural observations. The relatively high aspect ratio and hence high fluid flux at shallow depths also agree with the present-day hydration processes that are inferred from the borehole fluid chemistry. The inversion of ultrasonic data provides a series of elastic moduli, and we can estimate Poisson’ s ratio, which is a key physical property to interpret geophysical observations in the oceanic lithosphere.

Pore geometry in diabase collected by the Oman DP inferred from elastic wave velocity

*KUMPEI NAGASE[1], Ikuo Katayama[1], Kohei Hatakeyama[1], Yuya Akamatsu[1], Keishi Okazaki[2], Natsue Abe[3], Katsuyoshi Michibayashi[4]

1. Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University, 2. Japan Agency for Marine-Earth Science Technology, 3. Department of Earth and Planetary Sciences, Graduate School of Environmental Studies, Nagoya University

Geophysical survey observed anomalous low Vp/Vs ratio in oceanic upper crust (Spudich and Orcutt 1980). Although, it is previously explained by felsic rock such as trondhjemite is one of interpretation for such low Vp/Vs. Occurrence of trondhjemite is highly localized in ophiolite complexes (Christensen and Smewing 1981). Another possibly to explain is thick pore with large aspect ratio (shearer 1988). In this study, we measured physical properties of diabase collected from the Oman ophiolite, and we investigate pore aspect ratio from simultaneous measurement of velocity and porosity.
We developed simultaneous measurement system of elastic wave velocity and porosity under hydrostatic pressure, using Intra-vessel deformation and fluid flow apparatus at Hiroshima University. Elastic wave velocity and porosity were measured under confining pressure up to 200 MPa at fluid-saturated condition. Elastic wave velocity was measured by a pulse transmission method using both P- and S-wave piezoelectric transducers with a resonant frequency of 2 MHz. Porosity was calculated by initial porosity measured by pycnometer before compaction, and volume change of pore fluid after compaction using syringe pump. We used porous altered diabase with various porosity collected from the Oman Drilling project.
The experimental result shows that both P-wave and S-wave velocities increase with decreasing of porosity due to closing of pore. Sample with low porosity shows an increasing of Vp/Vs with increasing porosity whereas, sample with high porosity shows a decreasing of Vp/Vs with porosity. And then, we investigate pore aspect ratio from measured velocities and porosities based on application of effective medium theory by Kuster and Toksoz (1974). As a result, this implies that different aspect ratio in these samples, pore aspect ratio is more than an order of magnitude higher in the high porosity diabase. This implies that there is possibility that anomalous low Vp/Vs observed in the oceanic upper crust might be explained by the presence of pore with large aspect ratio.

Water Content in Nominally Anhydrous Mineral of Crust/Mantle Boundary Recovered by International Oman Drilling Project

*Muhamad Asyraf Aminuddin[1], Tomoaki Morishita[1,2], Juan Miguel Ramirez Guotana[1,2], Keita Itano[1], Kenji Shimizu[3], Takayuki Ushikubo[3]

The presence of water in the Earth’ s mantle has been to have a prominent role in the volatile cycle of Earth’ s mantle but measuring water flux into the mantle proved to be difficult and not fully constraint. Nevertheless, measuring water content in the mantle have its importance. It is known that some portion of water can be stored in nominally anhydrous mineral (NAM) like olivine and pyroxene which support the presence of water in the deep mantle. The significance of water retained in such minerals are that it can cause deformation to the minerals such as olivine which is the most abundant mineral in the mantle. Measuring water content in the oceanic plate specifically in the crust-mantle section is the most practical as water retained in the oceanic plate should be nearly zero due to the upwelling of the asthenosphere causing partial melting to occur extracting water into the melt. Therefore, the objective of this study is to measure water content in the oceanic crust specifically in the crust-mantle boundary.

As direct sample from the crust-mantle section is unattainable, ophiolite is used for this water content analysis as samples with the idea of measuring water content in oceanic plate as ophiolite is tectonically originated from mid-ocean ridge. However, some studies showed ophiolite might be affected by a later subduction zone tectonic setting (Lippard *et al.,* 1986) where second stage magmatism occurred at the subduction zone during obduction process. Thus, a high-water content could prove that ophiolite might be affected by subduction metasomatism. Ophiolite samples were from core samples recovered by International Oman Drilling Project in Samail Ophiolite, Oman. The core recovered reached about 400m depth and consists of layered gabbro (160 m), dunite (150 m) and harzburgite (75 m) with a compositionally gradational zone of 15m between dunite and harzburgite. Samples from each sequence (gabbro, dunite and harzburgite) of the core were used for water content analysis.

Secondary Ion Mass Spectrometry (SIMS) is used for water content analyses (Shimizu et al., 2017). SIMS have its disadvantage like high hydrogen background in low-concentration phases, but improved technique and procedure established by Hauri (Hauri et al., 2002; Koga et al., 2003: Shimizu et al., 2017) contributing for more reliable quantifications of low-level volatiles. Improved sample preparation technique and analytical sensitivity (Koga, 2003) are done like use of indium metal as embedment material instead of epoxy to limit the hydrogen background (Koga et al., 2003: Shimizu et al., 2017). IMS-1280HR of SIMS instrument is used which are installed in the Kochi Institute for Core Sample Research, JAMSTEC with 20 keV of Cs^+ ion beam bombarded to the sample surface with diameter 10-15 micrometer. Negative secondary ions of $^{12}C^-$, $^{16}OH^-$, $^{19}F^-$, $^{30}Si^-$, $^{32}S^-$ and ^{35}Cl signals will be collected from the center of analysis spot. The internally corrected data using ^{30} Si signal intensity were calibrated by the analyses of glass and olivine standard materials with known H2O concentrations.

Based on the result, $^{16}OH/^{30}Si$ signal intensities value on the layered gabbro sample are consistent with no significant changes of value on the rims and core of olivine. In contrast, $^{16}OH/^{30}Si$ signal intensities value on the dunite and harzburgite showed uncertainties where high hydrogen background occurred due to the presence of serpentine in the sample that prevent water to be completely removed during

©2020. Japan Geoscience Union. All Right Reserved.

degassing process prior analysis. Despite that, we can certain that the water content measured in gabbro sample is 34 ppm on average and the water content measured in dunite and harzburgite are on the range of 30-50 ppm. When comparing the value to the previous study of water content of olivine in natural peridotites obtained by Secondary Ion Mass Spectrometry (Kurosawa et. al., 1997, Warren & Hauri, 2014), the water content in olivine are significantly high. The explanation of high-water content of olivine is related to hydrous melting. Hydrous melting is where the presence of water in the mantle lower the solidus temperature allowing melts to be formed. The hydrous melting occurred in ophiolite support that subduction metasomatism might happened in ophiolite.

Microstructures, bulk and mineral chemistry of the gabbro cores of Holes GT1A and GT2A drilled in the Oman Drilling Project –Melt distribution in the subaxial lower crust

*Susumu Umino[1,3], Takahiro Fudai[1], Osamu Ishizuka[2], Yuki Kusano[2]

1. Kanazawa University, 2. Geological Survey of Japan, 3. JAMSTEC

The lower crustal section of the Oman Ophiolite was drilled in the Oman Drilling Project in 2016 to 2017 and recovered 400 m long cores each from Hole GT1A and GT2A in Wadi Gideah, north of Ibra. The purpose of this research is to correlate the microstructures and the amount of trapped melt of the gabbro samples and to understand the conditions of magmatic and hypersolidus deformation that operated in the lower crust beneath the Oman paleoridge axis.

Cored samples are predominantly olivine gabbros consisting of anhedral olivine, anhedral to subhedral clinopyroxene and subhedral to euhedral plagioclase. Deformed olivine aggregates and clinopyroxene with quarter structures are embedded in plagioclase with equilibrium granoblastic textures and large euhedral plagioclases with resorbed turbid cores. Considering these textures combined with the mechanical strength of the three constituent minerals, these gabbros suffered deformation under the presence of melt, which assisted complete recovery of strain through recrystallization of fine-grained plagioclase and overgrowth of euhedral rims around magmatic plagioclase cores. Poikilitic and ophitic clinopyroxene occur sporadically throughout the holes, which are commonly present in the upper gabbros. Hypersolidus deformation structures are present irrespective to depth.

The whole-rock Mg#s of gabbro core samples from stratigraphically lower and higher sections (Hole GT1A and GT2A) range in 72-83 and 68-79, respectively. The lowest Mg#s of 72-74 overlap those of the spreading-stage sheeted dikes. The whole-rock Al_2O_3 versus MgO plots indicate the whole-rock compositions are mainly controlled by accumulated plagioclase, olivine, clinopyroxene associated with a small amount of primitive melts. The whole-rock Mg# and incompatible elements (REEs and HFSEs) are lower and higher in GT2A, suggesting larger amounts of trapped melt at higher levels in the lower crust. Clinopyroxene preserve cores with higher Mg# than the rims and surrounding smaller clinopyroxenes. Lower Ti in the core and jumps in Ti concentration define the core-rim boundary of clinopyroxenes, through which Mg# gradually changes. In addition to this, olivine grains are almost homogeneous and consistently lower in Mg# than the clinopyroxenes with reversed rims in contact with olivines, indicating diffusive Fe-Mg exchange between olivine and clinopyroxene during cooling.

The amounts of trapped melt between cumulus phases were estimated by two ways. First one is to determine La and Ce concentrations in the core of clinopyroxenes with LA-ICP-MS. Second one assumes La and Ce concentrations of trapped melts to be equivalent to those of the sheeted dikes, and estimates the sheeted dike compositions by using an Fe-Mg partition coefficient of 0.275 (Putirka, 2003) between clinopyroxene and the melt. Mass balance calculations yield the amount of trapped melt in gabbros to be 5 to 10 mass% in general and 25 mass% at most.

Poorly developed modal layering, evidence of common hypersolidus deformation, ubiquitous presence of zoned cumulus minerals and common ophitic clinopyroxenes as well as the amount of trapped melt >5 mass% are all characteristics of foliated gabbros. In addition to this, field observations of the gabbros

©2020. Japan Geoscience Union. All Right Reserved.

along Wadi Gideah, including the Site GT1A and GT2A show that the gabbroic rocks poorly develop modal layering but foliation defined by shape-preferred orientation of clinopyroxenes in the most stratigraphic levels, including both GT1A and GT2A holes. Layered gabbros with well-developed modal layering are only present in the lowermost levels in the crust just above the Moho Transition Zone.

We concluded that both GT1A and GT2A sampled the thick foliated gabbros in Wadi Gideah section, which crystallized on the axial melt lens floor and were transported downward in the lower crust.

Trace element and Sr isotopic compositions of gabbros and peridotites at the CM1A drilling site of Wadi Tayin block in the Oman ophiolite

*Masako Yoshikawa[1], Tomoaki Morishita[2], Ryoko Senda[3], Tomoyuki Shibata[1]

Detailed petrological structure of the oceanic plate, which covers around 70% of the earth's surface, is still a debate due to difficulty in obtaining samples directly. Petrological section of the oceanic plate and its physical and chemical characteristics have been suggested from detailed observations of ophiolite, as ophiolites are believed to be fragments of the oceanic plate obducted to the surface by tectonic thrusting. However, it has been pointed out that geochemical signature of constituent rocks of ophiolite has often been affected by weathering and metamorphism during/after obduction which have severely changed their original elemental and isotopic compositions (e.g., Pearce & Cann, 1971).

The Oman ophiolite is one of the best preserved sections of oceanic plate (oceanic crust and upper mantle) worldwide, and consists of multiple blocks that lie along more than 400 km of the Arabian coast (eg, Nicolas et al., 1988). The Oman Drilling Project by the International Scientific Drilling Program was proceeded at multiple sites in the Oman ophiolite. We study samples of the CM1A site that penetrates the crustal-mantle boundary of the Wadi Tayin block in the southern Oman ophiolite.

The core sample is 404.15 m in length, composed mainly with olivine gabbro in the upper 160 m (Layered Gabbro sequence), with massive dunite from 160 m to 310 m (Crust-Mantle Transition sequence), and with deeper harzburgite (Mantle sequence)(Takazawa et al., 2019). Geochemical and isotopic compositions of these samples are expected to provide a continuous chemical composition of the oceanic plate, including the crustal-upper mantle boundary without chemical modification by surface weathering and metamorphism.

We analyzed trace element compositions of two gabbro samples and a dunite sample from Layered Gabbro sequence, three dunite samples from Crust-Mantle Transition sequence, and a harzburgite sample from Mantle sequence. Trace element concentrations generally decrease from the gabbros in Layered Gabbro sequence to the dunites in Crust-Mantle Transition sequence through the dunite in Layered Gabbro sequence and the harzburgite in the Mantle sequence. Multi-elemental patterns of samples, that is trace element concentrations normalized to mid-ocean ridge basalt, show following signatures; (1) the gabbros have gently convex shape at medium rare earth elements (REEs) with positive anomalies of Ba, Pb, Sr and Eu and negative anomalies of Th and U relative to neighboring REEs, (2) multi-element patterns of the dunite in Layered Gabbro sequence share depleted pattern from heavy REEs to medium REEs with positive anomalies of Sr and Eu of the harzburgite in Mantle sequences. The dunite, however, shows depleted pattern from middle REEs to light REEs, while the harzburgite shows enriched pattern with incompatible elements compared to middle REEs, and (3) the dunite samples in Crust-Mantle Transition sequence show U-shaped patterns, and extensive positive anomalies of Pb and Sr relative to surrounding elements.

We will report Sr isotopic compositions of these samples by comparing to the data from the Oman

The university of Tennessee, 7. National Taiwan University, 8. University of Montpellier, 9. Toulouse university, 10. Southampton University, 11. Columbia University

The transition from the crust to the mantle of Oman ophiolite was drilled at Holes CM1A and CM2B (Wadi Tayin Massif) during Phase 2 of the Oman Drilling Project (Nov. 2017-Jan. 2018). The 400m-long Hole CM1A core crosses from the lower crust, through the crust-mantle transition zone, into residual upper mantle peridotites. The 300m-long Hole CM2B core samples the crust-mantle transition zone and underlying residual mantle peridotites. The main logged lithological units are olivine gabbro, gabbro, dunite, harzburgite and wehrlite, associated with minor gabbronorite, troctolite, websterite, anorthosite, and chromitite. During Oman-DP Phase 2 Leg 3 (ChikyuOman; July-Aug. 2018), 95 and 67 samples of core from CM1A and CM2B, respectively, were analyzed for whole-rock major and minor elements (XRF) as well as CO_2 and H_2O concentrations (CHNS). XRD measurements were performed on the 69 onsite samples. Furthermore, whole-rock (pressed powder pellets) and mineral trace element contents were determined for selected samples onboard the D/V Chikyu, using the NewWave Research UP-213 Nd:YAG deep UV (213 nm) laser ablation system coupled with an Agilent 7500ce quadrupole ICP-MS.

Samples from holes CM1A and CM2B have a large petrological and chemical variability, mainly reflecting the different rock types, especially across the crust-mantle transition. CM1A and CM2B volatile element contents reflect extensive serpentinization linked to interaction with H_2O-rich fluids, and abundant carbonate veins downhole, suggesting an association between CO_2-rich fluids and serpentinization. Whole-rock and ortho- and clinopyroxene trace element abundances are similar to Oman ophiolite compositions described in previous studies. All gabbroic domains display nearly parallel REE patterns with a strong depletion in HFSE relative to REE. Dunites display variable trace element contents and REE patterns, negative or positive anomalies in Eu and commonly moderate to strong positive anomalies in U, Pb, Sr and Ti. The variation of REE concentrations and patterns observed in Oman dunites could be explained by melt-rock reactions leading to dunite formation, after the dissolution of orthopyroxene in harzburgite and interaction with interstitial melt.

Petrological study of the crust-mantle boundary using CM2B cores from the ICDP Oman Drilling Project.

*Natsuki Oyanagi[1], Eiichi TAKAZAWA[1,2], Sayantani Chatterjee[1], Oman Drilling Project Phase 2 Science Party

1. Faculty of Science, Niigata University, 2. VERC, IMG, JAMSTEC

In this study, a petrological and geochemical study was carried out on the origin of the crust-mantle boundary using the cores from Hole CM2B drilled by ICDP Oman Drilling Project in the Wadi Zeeb of the Wadi Tayin massif, southern Oman ophiolite. Many studies have been done on the origin of the crust-mantle transition zone (MTZ) in the Oman ophiolite, and various models have been proposed [1-9]. However, the process that created the boundary between the MTZ dunite and the mantle harzburgite has not been understood yet. This study aims to investigate the petrographic characteristics and mineral compositions of the cores from Hole CM2B, and to clarify the process forming the boundary between the MTZ and the mantle section.

Analytical results of mineral compositions revealed the presence of dunite with NiO content of olivine below the range of the olivine mantle array [10], indicating reactional fractional crystallization of olivine from a melt. There is also a dunite with a lower olivine Fo value than the range of olivine spinel mantle array (OSMA) [11], indicating the possibility of cumulus olivine crystallized from the melt. Furthermore, TiO_2 and Na_2O contents of clinopyroxene increased near the boundary between the MTZ dunite and the mantle harzburgite. Furthermore, clinopyroxenes in the dunites and harzburgites near the boundary between the MTZ and the mantle section are highly enriched in incompatible elements including rare earth elements (REEs).

We consider that the enrichment of incompatible elements at the boundary as a result of the zone melting of mantle harzburgite. The boundary between the MTZ and the mantle harzburgite is a kind of active reaction front where the dissolution of orthopyroxene (Opx) and precipitation of olivine continuously proceed to make dunitic MTZ thicker. For most of the incompatible elements the partition coefficients between Opx and melt are greater than those between olivine and melt. If the dissolution of Opx and precipitation of olivine continued for a long time to create a thick MTZ, the melt at the boundary becomes highly enriched in incompatible elements. This phenomenon is consistent with the presence of harzburgite, which has high spinel Cr# (=atomic Cr/[Cr + Al] ratio) and low olivine Fo value at the top of the mantle section.

On the other hand, the decrease in spinel Cr# in harzburgite at a depth of 260 m may be the result of a reaction with a melt flowing from the outside because of high Al_2O_3, TiO_2 and Na_2O contents and enrichment in REEs in the clinopyroxene at the corresponding depth compared to the surroundings.

Mantle-melt reaction recorded in the ICDP Oman Drilling Project Hole CM2B in Wadi Tayin massif of the Samail ophiolite

*Eiichi TAKAZAWA[1,2], Natsuki Oyanagi[1], Sayantani Chatterjee[1], Fatma Kourim[3], Katsuyoshi Michibayashi[4], Oman Drilling Project Phase 2 Science Party

1. Department of Geology, Faculty of Science, Niigata University, 2. VERC, IMG, JAMSTEC, 3. Institute of Earth Sciences, Academia Sinica, 4. Graduate School of Environmental Studies, Nagoya University

At the crust - mantle boundary of the Oman ophiolite, there is a dunite dominant layer of dozens to hundreds of meters in thickness called the crust-mantle transition zone (MTZ) [1]. The formation of MTZ dunite can be attributed to the accumulation of olivine crystallized from MORB melt [2] and the reaction of orthpyroxene-undersaturated MORB melt with harzburgite [3-6], and the involvement of fluid [7-10]. The ICDP Oman Drilling Project carried out onshore drilling of the crustal-mantle boundary of the Oman ophiolite in order to clarify the formation process of the MTZ and its relation to the oceanic Mohorovicic discontinuity.

The drilling site is located in the Wadi Zeeb of Wadi Tayin massif in the southern Oman ophiolite. Hole CM1A (UTM: 40Q 637000E, 2533870N) and Hole CM2B (UTM: 40Q 637000E, 2534270N) were drilled, and 404.15m and 300.00m cores were collected at 100% recovery rate, respectively. In the summer of 2018, the detailed core description was carried out on the deep-sea science drilling vessel "Chikyu", and measurements of chemical and physical properties of the cores were performed using various instruments.

In this study we report the downhole variations of whole rock major and trace element compositions in Hole CM2B with special attention to the boundary between MTZ dunite and mantle harzburgite. Across this boundary orthopyroxene (Opx) disappears in the MTZ dunite. Whole rock CaO wt% decreases from 0.7-0.9 wt% in the harzburgite to 0.3-0.6 wt% in the dunites of the lower part of MTZ to less than 0.2 wt% in the dunites of the upper part of MTZ. The existence of intermediate dunite in the lower part of MTZ, often with thin layers of gabbro and plagioclase wehrlite, may impose constraints on the origin of the MTZ dunite.

In the chondrite-normalized pattern of rare earth elements (REEs) in whole rock, most of the harzburgites show a spoon-shaped pattern depleted in middle rare earth elements, while the harzburgite at the contact to the MTZ dunite shows a convex upward pattern with enrichment in middle to heavy rare earth elements. A similar tendency is also observed in the clinopyroxenes in dunite and harzburgite. Clinopyroxenes in the harzburgites near the boundary between MTZ dunite and mantle harzburgite are most enriched in incompatible elements including REE.

The harzburgites and dunites at the boundary between MTZ dunite and mantle harzburgite are most strongly influenced by the reaction with the melt that formed MTZ dunite by the dissolution of opx and precipitation of olivine [3]. The top of the mantle harzburgite is thought to have been a reaction front where harzburgite reacts with the melt and converts it to dunite. It is considered that the MTZ became thicker as the reaction front moved deeper. In the process of dissolving Opx and crystallizing olivine, it is possible that a similar mechanism to zone melting was activated at the reaction front, causing the concentration of incompatible elements in the melt. The equilibrium with such a melt has made peridotites enriched in incompatible elements at the boundary.

High-Cr# (= atomic Cr/[Cr + Al]) chromite has been observed as the lining of inclusions within the host chromite, and has been proposed to have originated as early crystallizing microcrystals[1]. These high-Cr# chromite lining, however, cannot be explained by the host chromite–melt reactions, and consequently its origin remains controversial. Moreover, the genesis and the evolution of the inclusions are poorly understood. In this study, we used high resolution x-ray computed tomography (HRXCT) combined with scanning electron microscope (SEM) to obtain 3D and 2D images of inclusions within chromites from the Samail ophiolite to investigate the evolution of melt inclusions within chromite.

The 3D HRXCT and SEM images showed the spatial distributions of inclusions and the skeletal morphology of the host chromite. Under the rapid cooling, the host chromites grew skeletal crystals to trap melt inclusions [2]. After trapping melt inclusions, the host chromite continued to grow on the inner wall of the inclusions [3]. This overgrowth may be recognized as a high-Cr# chromite lining. Many previous studies of the inclusions in chromites have ignored the influence of the formation of lining [4]. The initial Cr content of the melt inclusions should have been much higher than previously estimated, suggesting that the parental melt for the chromitite may have been highly enriched in Cr, being supersaturated in chromite. Moreover, the 3D distribution of inclusions in host chromite with skeletal morphology implies that the formation of inclusions depended on the cooling rate of chromite-forming melt, implying that the parental melt of the chromitite was rapidly cooled in the Moho Transition Zone.

Silicate inclusions in dispersed chromites at the mantle-crust transition zone: the link between dunite and chromitite formations

Melt-rock reactions have a significant impact on the mineralogical and chemical composition of mantle peridotite. Observations in ophiolites and more patchy data from oceanic drilling show that below oceanic spreading centres, MORB-peridotite interaction at the transition between the mantle and the oceanic crust leads to the formation of a thick dunitic layer hosting chromitites ore bodies. Dunite and chromitite appear then to be two companion products of a common melt-peridotite reaction.

The petrological processes that originate the dunitic mantle-crust transition zone (DTZ) can be studied in the Maqsad area (Oman ophiolite) where is exposed a paleo-mantle diapir that fed the former spreading centre with MOR-like melts. The DTZ reaches more than 300 m in thickness atop the central part of the paleo-diapir. Interstitial melt suffered crystallization during its migration, comprising mainly plagioclase, clinopyroxene, but also orthopyroxene and pargasitic amphibole. The presence of such minerals witness migration of a hydrous melt that is restricted to this level and does not reach deeper levels in the mantle section. It was tentatively attributed to a parent melt hybrid between the MORB generated by the deep partial melting of the mantle and a hydrated fluid fraction coming from above, likely seawater in origin (Rospabé et al., 2017, *Geology*).

The presence of orthopyroxene and amphibole, together with mica, enclosed in chromite grains (scattered in dunites and in chromitites) strongly suggests that this hybrid melt was involved early in both the formation of dunite and the re-mobilization of chromium at the Maqsad mantle-crust transition zone (Borisova et al., 2012, *Journal of Petrology*; Rospabé et al., 2017, *Geology*). By the detailed and systematic study of the silicate inclusions enclosed in the chromite grains dispersed in the DTZ, we show they are an excellent target to make the link between the dunite and the chromitite ore bodies of higher grade. Our results suggest that the ore genesis processes involved in the formation of chromitites are not restricted to the ore bodies themselves but operated on the much larger scale of the whole DTZ. It leads to consider the entire DTZ as an ore deposit. In this spirit, the DTZ dunites may be regarded as low grade dispersed ore.

Long debate have been hold about the tectonic setting of the Oman ophiolite. Some researcher outlining the MORB affinity of most magmatic features in favour of a mid-ocean ridge setting and other insisting on the ultra-depleted nature of the mantle and the petrological and chemical characteristics of the metamorphic sole as support for a supra-subduction zone setting. Recent studies have suggested that the tectonic settings may have switched from an open ocean to a subduction zone, explaining most of the characteristics of the ophiolite as well as that of the metamorphic sole.

Magmatic dykes present within the mantle section show that several type of magma may have circulated in the Oman ophiolite: a MORB-like end-member melt and more a more depleted end-member melt, richer in Si with possible andesitic affinity. Only little mixing between these two end-members is observed in the mantle dykes and the geographical distribution is non random with MORB-like melts concentrating in the South-eastern massifs while andesitic melts are dominant in the north-western massifs. The same distribution can be observed for other ophiolitic features, like the chemistry of chromitite pods, the chemistry of chromian-spinels in pyroxenite dykes (richer in Ti and lower in Cr in the south-eastern massifs for both features), and the presence or absence of pyroxene-rich concordant layers in the mantle (abundant only in the north-western massifs).

In this study, we put an additional piece to this edifice by showing that the mantle chemistry, in particular its chromian spinel chemistry show basically the same type of variation. If the silicate chemistry was mostly buffered by mantle processes and do not show any significant difference all along the ophiolite, Cr# in Cr-pinels is on average 15% lower in the south-eastern massifs, in particular the Wadi Tayin massif, than in the north-western ones. This could suggest that the melting degree was significantly lower (about 4%) in the Wadi Tayin massif compared to the north-western part of the ophiolite, however the structure of the Wadi Tayin massif is in contradiction with this hypothesis. A partial melting degree about 4% lower would lead to a 10 to 20% decrease in the magma amount and then in a significantly thinner crustal section, which is not the case in the Oman ophiolite where all the massif a a similar crustal thickness.

On the other hand, Cr# in mantle Cr-spinel could be influenced by other processes than only partial melting and possibly reflects other petrographical properties. It is reasonable to think that the Wadi Tayin mantle melted at the same degree than in the other massifs of the Oman ophiolite. The lower Cr# can be explained in the frame of mantle heterogeneities and mantle sources variations. All well studied magmatic features showed that melts were richer in Al, Ti and lower in Cr, Si in the south-eastern massifs compared to the north-western part of the ophiolite. We conclude then that the mantle below the ophiolite presented large scale (70 to 150 km wide) heterogeneities and that mantle sources were basically different in the various part of the ophiolite. Crust and mantle dykes chemistry was strongly influenced by their mantle sources and cannot be interpreted only in the frame of tectonic settings. Our study cannot bring any definitive answer about the tectonics settings of the Oman ophiolite but show that the presence

of certain petrographical or chemical characteristics have to be considered with great caution.

Peridotites beneath the ophiolite: Petrology and chemistry of peridotite bodies located below the metamorphic sole of the Oman ophiolite

Main Tokinaga, Marie Python, Georges Ceuleneer, Tomoya Suzuki and Jean-Paul Breton

*Tokinaga Main[1]

1. Hokkaido University Department of Natural History Science Division of Earth and Planetary Systems Sciences

The Oman ophiolite is a large slab of Tethyan ocean floor obducted onto the Arabic peninsula. It comprises one of the largest pieces of exposed lithospheric peridotites and is a wonderful natural laboratory for mantle science. The emplacement of the ophiolite resulted from intraoceanic subduction in North-northeast direction followed by a period of continental subduction leading to the Oman margin burying. High pressure metamorphic rocks in the northern most Saih Hatat suggest a depth of about 40 km, lower grade metamorphism at the southern border of this massif as well as in Jebel Akhdar show that the subduction slope was rather steep (Breton et al., 2004).

The Oman ophiolite is the last of several nappes thrusted onto the autochtonous units (Saih Hatat and Jebel Akhdar), and then the highest in the general stratigraphic column of Oman (Béchennec, 1989). Although some melange do exist at the base of the ophiolite, with serpentine blocks interbedded within the Hawasina units, tectonic inversion was not observed in Oman up to now.

In this study, we describe the petrological characteristics of several relatively small peridotites bodies found in direct contact with the cretaceous limestones from the Arabic platform and located stratigraphically below the Hawasina units and the metamorphic sole. Those peridotite bodies are mostly located at the northern border of Jebel Akhdar, more rarely at the southern border of Saih Hatat. They crop out as a few meters to a few kilometers-wide massifs, most of the time highly serpentinised or carbonated and deformed. They are characterized by the absence of magmatic veins and dykes, their stratigraphic location below the amphibolite from the metamorphic sole, and when found as ophiolitic melange, by the inclusion of limestone blocks. In these 3 points, they differ from the ophiolite mantle main body, which is located above the Hawasina units and metamorphic sole, contains ubiquitously magmatic dykes and veins, and when observed as ophiolitic melange, contains blocks of amphibolite and/or pelagic sediment from the Hawasina nappes. One of the largest of these peridotites is located near a small village called Taww at the northeastern most border of Jebel Akhdar, so that by contrast to the ophiolite peridotites, we will call these peridotites the Taww peridotites. In order to understand the petrogenesis of the Taww peridotites, we sampled several peridotite bodies from both locations below and above the metamorphic sole and Hawasina units. Only one of our samples taken near Ibra had an unclear stratigraphic position (this sample is called “Ibra” in the present study).

The ophiolitic peridotites are all from the lowermost ophiolite, taken a few meters to a few tens of meter above the metamorphic sole. Their petrological characteristics are similar to what was described for basal peridotite by other researchers: they are mostly high depleted harzburgites containing 1 to 7% of Cpx with granular and porphyroclastic textures. The Taww peridotites seem to contain slightly less Cpx and more Opx but their textures are basically very similar to the usual ophiolite peridotites.

©2020. Japan Geoscience Union. All Right Reserved.

The mineral chemistry shows that the Taww peridotites as well as the ophiolite peridotites are residual harzburgites. However, the Taww peridotites, instead more depleted in Cpx than the ophiolite peridotites, show lower Cr-spinel Cr# and higher Al content in Opx, suggesting a possible lower melting degree than in the ophiolite but also a relatively Al-rich chemical environment. Cpx chemistry in Oman peridotites are difficult to interpret as refertilisation and melt trapping widely occurred during the magmatic history. In our study, Cpx in ophiolite lherzolites and Cpx-rich harzburgites (2 to 5% Cpx) show a Na and Ti-rich chemistry showing that they are mainly from trapped melts and refertilisation processes. By contrast, ophiolite harzburgites and the Taww peridotites, independently of their lithology, show a very depleted chemistry suggesting that they are mostly melting residue.

Evolution of Island Arc Volcanoes: Ankaramite-Andesite-Basalt (ANANBA) Model

*Yoshihiko Tamura[1], Tomoki Sato[1], Osamu Ishizuka[1], Yasuhiro Hirai[1], Takashi Miyazaki[1]

1. Research Institute for Marine Geodynamics, Japan Agency for Maine-Earth Science and Technology

Nishinoshima, a submarine andesitic volcano in the Ogasawara (Bonin) Arc, ~ 1 000 km south of Tokyo, Japan, suddenly erupted in November 2013, after 40 years of dormancy. Olivine-bearing phenocryst-poor andesites found in older submarine lavas from the flanks of the volcano have been used to develop a model for the genesis of andesitic lavas from Nishinoshima (Tamura et al., 2019). In this model, primary andesite magmas originate directly from the mantle as a result of shallow and hydrous melting of plagioclase peridotites. Andesites erupted from Nishinoshima that were produced in the recent history of the volcano have been generated by olivine fractionation of primary andesitic magmas.
Primary (high Mg#) andesite is produced only when the crust is thin, and consequently only in oceanic arcs. Active examples include boninites erupted in the northern Tonga arc and reararc (Cooper et al., 2010; Resing et al., 2011).
To further examine this hypothesis, we have dived Doyo Seamount by using manned submersible SHINKAI 6500 to sample primitive magmas from the volcano, which is located about 50 km north of Nishinoshima and is underlain by thinner curst (15 km) compared to Nishinoshima. Doyo Seamount is located approximately 900 km south of Tokyo at 27˚41’ N, 140˚48’ E in the Ogasawara Arc. There is a small satellite cone about 11 km east of the summit of Doyo Seamount at the depth of ~3,000 m. A ridge extends on the flank of the volcano from the summit in the ENE direction to the depth of ~2,400 m. Thus, we tried to sample this satellite cone and the deeper part of the ridge. Interestingly, 13 samples out of all 21 samples, which we have recovered during this dive 6K#1519, are olivine-clinopyroxene basalts containing 20-40 % of very coarse clinopyroxene phenocrysts, which could be called ankaramite. Ankaramites are strongly vesiculated and their blocks have rough and rugged surface, which are different from smooth surface of basaltic pillow lavas. Some of ankaramite magmas might have had explosive eruptions at the depth of 2,000~3,000 m, which have resulted in volcaniclastic cones or brecciated lava flows.
Similar primitive and phenocryst-rich ankaramitic basalts were recovered from the old submarine knolls near Nishinoshima (Tamura et al., 2019) and Kibblewhite volcano in the Kermadec arc (Hirai, PhD thesis 2020). We suggested that lithospheric mantle was thicker before the development of Nishinoshima volcano and other oceanic arcs. Primary basaltic magmas could have been generated at depth beneath the thicker lithospheric lid, and these magmas might have interacted with the lithospheric uppermost mantle during their ascent and have resulted in the unique ankaramite magmas. The temperature of the upper part of the mantle wedge increases with frequent passage of magmas through it, and continuous subduction beneath it will drench the whole mantle wedge, thus, the thickness of the lithosphere will decrease and approach the thickness of the curst in mature arcs. Doyo Seamount could represent the early stage of Nishinoshima volcano, and thus, ankaramite magma is deemed to be a precursor of andesitic magmas. We present here the evolution model of oceanic arc volcanoes, which start from ankaramites through andesites to basalts (ANANBA model).

[S-CG57] New perspectives of subduction zone earthquake dynamics through experiments across-scales

convener:Masataka Kinoshita(Earthquake Research Institute, University of Tokyo), Yoshio Kono(Geodynamics Research Center, Ehime University), Eiichiro Araki(Japan Agency for Marine-Earth Science and Technology), Hiroko Kitajima(Texas A&M University College Station)

Knowledge on subduction zone earthquake phenomena has considerably increased in the last decade. On the other hand, there are limits to seismological approach alone to comprehensively elucidate the earthquake mechanism in which phenomena that differ by 10 orders of magnitude in space and time, from earthquake nucleation/growth processes to its driving force. Steps to enable scientific earthquake forecasting should include; monitoring regional seismic/tectonic activity using networked observatories, sampling of and insitu measurement in seismogenic faults and plate materials through ultra-deep drilling, and reproduction/insitu-observation of fracture nucleation processes by high-pressure quantum-beam experiments. Through a close collaboration, we challenge a dynamic imaging of earthquake processes. Based on the proposal submitted as a Large Research Master Plan 2020 of the Science Council of Japan, we will deepen the interdisciplinary discussion on subduction-zone earthquakes and the state & property of lithosphere. We welcome, but not limited to, presentations from fields of ocean and land networks observation, seismogenic zone drilling, rock mechanical & quantum beam experiments, fracture process theory, etc.

Nankai Trough is one of the most active earthquake zones on the planet and has been focused for many years. Samples were collected from many drilling sites of the International Ocean Drilling Project drilled as a part of the Nankai Trough Seismogenic Zone Experiment project to explore the earthquake mechanisms within the Nankai Trough subduction zone system. We report the experimental results of frictional behavior for samples recovered at different locations in the Nankai subduction zone. Our findings will help to describe (1) the spatiotemporal variation in frictional behavior during the accretion process, (2) the potential for seismic activities along the décollement and splay faults, and (3) the evolution of the accretionary prism.

In this study, three drilling sites were selected which are located in sediments approaching subduction seaward of the trench (Site C0011), in young accreted sediments in the prism toe (Site C0006), and in older accreted sediments in the inner prism (Site C0002). We selected the samples based on the comparability of lithology and clay content. All samples from Site C0011 were Shikoku Basin sediments and samples from Site C0006 included both accreted trench deposits and accreted Shikoku Basin sediments. Laboratory shear experiments on intact samples were performed in a single-direct shear device at in-situ effective normal stresses, calculated assuming a hydrostatic pore fluid pressure, with samples saturated with 3.5% simulated salt water as pore fluid. Intact samples were trimmed from core samples into cylindrical shapes to fit the experimental cell (~20 mm height, ~25 mm diameter). Shear velocities were set to be 10 μm/s for a displacement of 5 mm as a “run-in” process before the velocity was stepped from 0.01 –0.03 –0.1 –0.3 –1 –3 –10 –30 μm/s for 700 μm displacement at each velocity. Friction data obtained from the measured shear stress normalized to the normal stress at each velocity step was fit to a rate- and state-dependent friction law to quantitatively investigate the potential for frictional instability.

Measured steady-state friction coefficients showed inverse correlations with clay content, but no clear relation with smectite content. Because this trend was observed at all three sites, frictional strengths could be primarily controlled by lithological composition: sandy trench deposits exhibit high friction coefficients whereas lower values are seen for clayey hemipelagic sediments. Samples from the prism toe generally showed higher friction coefficients than those from both other sites for the entire range of clay content. This could be because these currently overthrusted sediments at the prism toe may be highly overconsolidated due to lateral compression near the frontal thrust. Negative friction-velocity dependence, a prerequisite of unstable slip, was observed for the input and inner prism sediments even when the samples showed low friction coefficients. Prism toe material had both a negative and positive velocity dependence on friction.

Our measurements of friction velocity-dependence suggest that input sediment and old accreted sediment could be frictionally unstable and therefore favorable for seismic slip, whereas young accreted sediment may resist earthquake slip. Ongoing work on the sample from the deep part of old accreted

sediments is expected to provide further information on the slip partitioning between décollement and megasplay fault near the seismogenic zone, as well as fault activities and structural evolution within the Nankai accretionary prism.

Changes in frictional properties of mud gouge with depth in the Nankai Trough accretionary prism

*Kyuichi Kanagawa[1], Takuma Ogawa[2], Tomoya Funaki[2], Tomoya Nakanishi[3], Sayumi Sagano[3], Junya Fujimori[3], Michiyo Sawai[1]

1. School of Science, Chiba University, 2. Faculty of Science, Chiba University, 3. Graduate School of Science and Engineering, Chiba University

In order to investigate the changes in frictional properties of mud gouge with depth in the Nankai Trough accretionary prism, we conducted triaxial friction experiments on gouge of a mud sample cored from 2183.6 mbsf (meters below seafloor) at IODP Site C0002, at three conditions supposed at depths of 1000, 3000 and 5000 mbsf there. We conducted two series of friction experiments; slide-hold-slide experiments for static friction data and rate-stepping experiments for dynamic friction data. In the former series of friction experiments, sliding at an axial displacement rate of 1 μm/s was held for periods ranging from 10s to 10^4s, after which sliding was resumed at the same rate. In the latter series of friction experiments, axial displacement rate was changed stepwise among 0.1, 1 and 10 μm/s.

The slide-hold-slide experiments show that the coefficient of static friction μ_s decreases from 0.37–0.38 at the 1000 mbsf condition to 0.30–0.31 at the 3000 mbsf condition, while it increases to 0.33–0.36 at the 5000 mbsf condition. Healing $\Delta\mu$ (increase in friction coefficient upon resuming sliding after a holding time t_h) was not noticeable at $t_h \leqq 1000$s during the 3000 mbsf condition experiment, while $\Delta\mu$ was recognized at $t_h \geqq 100$s during the other experiments. $\Delta\mu$ increases logarithmically with t_h, which was more prominent at the 5000 mbsf condition. Dehydration of smectite at the 3000 mbsf condition where temperature was 100˚C possibly increased pore pressure in the impermeable gouge layer, which was responsible for the minimum μ_s and non-healing effect at $t_h \leqq 1000$s at this condition. While lithification of gouge particles by pressure solution was possibly responsible for increasing μ_s and $\Delta\mu$ with t_h at the 5000 mbsf condition where temperature was 150˚C.

The rate-stepping experiments show that the steady-state friction coefficient μ_{ss} also decreases from 0.32–0.35 at the 1000 mbsf condition to 0.29–0.31 at the 3000 mbsf condition, while it increases to 0.32–0.33 at the 5000 mbsf condition. The minimum μ_{ss} at the 3000 mbsf condition is also attributable to dehydration of smectite as in the case of μ_s. a–b value (rate dependence of μ_{ss}) decreases with depth from 0.0018–0.0062 at the 1000 mbsf condition to −0.0005–0.0017 at the 5000 mbsf condition, suggesting that a transition from aseismic faulting to seismic faulting occurs around the depth of 5000 mbsf at IODP Site C0002. Thus the megathrust supposed to be present at ≈5200 mbsf there is likely at a seismogenic condition. Dependence of a–b value not only on temperature but also on displacement rate suggests that thermally activated pressure solution is relevant to this change in frictional stability.

Frictional properties of greenstone: Effects of the seamount subduction on faulting at the subduction zone

*Michiyo Sawai[1], Junya Fukaumi[1], Miki Takahashi[2], Yasutaka Hayasaka[3], Kyuichi Kanagawa[1]

1. Chiba University, 2. Geological Survey of Japan, AIST, 3. Hiroshima University

Subducting seamounts are thought to generate large earthquakes by increasing the normal stress on the subduction interface and to act as asperities (e.g., Cloos, 1992). There is also a possibility that they act as barriers for rupture propagation due to the large resistance (e.g., Kodaira et al., 2000). On the other hand, since a seamount near the southern end of the Japan Trench has been mostly aseismic over the 80 years while many earthquakes have occurred in its adjacent areas, Mochizuki et al. (2008) suggested that the interplate coupling is weak there. In spite of many studies on subducting seamounts, frictional properties of seamount materials are still poorly understood. In this study, we conducted friction experiments to reveal the frictional strength of seamounts and investigate how the seamounts act at subduction zones.

We conducted friction experiments on gouges of a greenstone from the Akiyoshi terrane in Yamaguchi, where a huge seamount with Carboniferous to Permian limestone accreted during the Permian time (e.g., Sano, 2006). Thin layer of greenstone underlying the limestone is distributed over 10 km along a fault. Experiments were performed at slip velocities of 0.0013 to 1.3 m/s, normal stresses of 0.7 to 4.0 MPa, and wet but drained conditions, using a rotary-shear apparatus installed at AIST.
At a slip velocity of 1.3 m/s, typical slip-weakening behavior was observed; friction coefficient μ rapidly increased at the onset of sliding and then progressively decreased to ~0.1 with displacement. Steady-state friction coefficient μ_{ss} at this velocity clearly decreases with increasing normal stress. μ_{ss} is high up to ~0.7 at low velocities, and decreases to ~0.1 at a seismic slip velocity of 1.3 m/s. The sample deformed at this high velocity shows a clear localized shear zone, whereas the sample deformed at a low velocity does not. μ_{ss} of the Akiyoshi greenstone is higher than μ_{ss} of typical subduction zone materials especially at low velocities; μ_{ss} of sediments at the Tohoku subduction zone is <0.2 (Sawai et al., 2014) and μ_{ss} of those at the Nankai Trough is <0.4 (Tsutsumi et al., 2011). Hence a seamount possibly acts as a barrier for rupture propagation due to its high frictional strength.

Mechanical weakness of the Nankai accretionary prism: Insights from a correlation between Vp and strength of cuttings

*Manami Kitamura[1], Takehiro Hirose[2]

1. National Institute of Advanced Industrial Science and Technology , 2. Japan Agency for Marine-Earth Science and Technology, Kochi Instutute for Core Sample Research

The elastic wave velocity (Vp) and unconfined compressive strength (C0) of sedimentary rocks are key parameters needed to address the stress state at depth in subduction zones. However, a correlation between Vp and C0, particularly for active accretionary prism sediments, is unknow because samples from active offshore prisms have been limited to depths shallower than 1 km. We thus measure Vp on intact cuttings collected from 980 meters below seafloor (mbsf) to 3040 mbsf, the Nankai accretionary prism at Site C0002, Integrated Ocean Drilling Program (IODP) Expedition 348. Vp at room temperature and pressure gradually increases with depth from 2.2 - 2.5 km/s at 980 - 1180 mbsf to 2.5 - 3.2 km/s at 2910 - 3040 mbsf. Previous studies investigated that Vp for the Nankai accretionary prism sediments increases with increasing effective pressure, and provided the values of pressure correction of 0.02 –0.04 km/s per MPa (e.g., Raimbourg et al., 2010; Hashimoto et al., 2010; 2011). We thus use the value of pressure correction of 0.02 km/s per MPa to estimate the in-situ Vp. The in-situ Vp increases from 2.4 - 2.6 km/s at 980 - 1180 mbsf to3.2 - 3.8 km/s at 2910 - 3040 mbsf. Our estimated in-situ Vp are consistent with Vp measured on cores under in-situ pressure conditions by laboratory experiments (Raimbourg et al., 2010; Hashimoto et al., 2011) and Vp for logging while drilling (LWD) (Expedition 315 Scientists, 2009; Strasser et al., 2014; Tobin et al., 2015). Finally, we compare the relationship between our estimated Vp and C0 (reported by Kitamura et al., 2019) at the Nankai accretionary prism with the global empirical Vp-C0 relationships (e.g., Chang et al., 2006). The global empirical relationships are based on the data on onshore sedimentary rock samples all over the world. Our provided Vp-C0 relationship suggested that the Nankai accretionary prism sediments are weaker in strength (C0) than those of global trend at any given Vp.

Structural analyses of inner accretionary wedge in the Nankai trough based on borehole resistivity image

*Yohei Hamada[1], Takehiro Hirose[1], Yoshinori Sanada[2]

1. Japan Agency for Marine-Earth Science and Technology Kochi Institute for Core Sample Research, 2. Japan Agency for Marine-Earth Science and Technology Institute for Marine-Earth Expolaration and Engineering

The present geological structure of the inner accretionary wedge beneath forearc basin sediments records the history of the developing processes of the accretionary prism and the plate subduction zone. The macro scale structure of the inner wedge, however, is not well illustrated by seismic reflection due to poor contrast in acoustic impedance of the deep accretionary prism sediments. Consequently, the relationship between the development of the accretionary prism and its structural history is still unclear. We here analyze the logging data acquired in the IODP Nankai trough drilling project in order to clarify the geological structure of the inner wedge and to estimate the transition of strain direction of the Nankai trough.

In the Nankai Trough Drilling Project Exp. 314, 338 and 348, forearc basin and underlying accretionary prism were penetrated at site C0002 located in Kumano Basin. Continuous logging data are acquired from surface to approximately 3000 meter-below-seafloor (mbsf). Based on the collected resistivity image, gamma-ray, and sonic logs, we recognized and measured beddings and fractures and their strike and dip angles. Over 2000 beddings are found in the accretionary prism to be inclined in both NNW and SSE directions at high angles of 60-90˚. The fractures and faults are found at 300 locations. A fracture-concentrated zone was observed around 2600-2700 mbsf, however, the fracture and faults do not show any clear trends. Although these descriptions were approximately the same as the cruise reports and previous research (Boston et al. 2016), “eye spots” were newly identified on the resistivity image. This is considered to be a closed bedding around a fold axis, because the inclination direction of the formation changes significantly above and below the eye spot. The direction of the fold axis is considered to be given by the direction orthogonal to this eye spot and to be ENE–WSW.

The depth distribution of the fold was estimated based on the depth change of azimuth and dip of the bedding. The fold properties such as fold axis, axial plane, interlimb angle, and the wavelength are calculated from the beddings at inflexion points assuming that the fold can be regarded as a concentric fold. As a result, the folds are classified mainly as open-folds with large interlimb angle of 150˚ to 170˚, and the axis azimuths are ENE–WSW direction, which was consistent with the direction obtained from the eye spot. However, the plunges change greatly with 0-70 degrees, and it cannot be regarded as a single fold structure. These folding axes show a girdle distribution on a stereo plot suggesting that these folds were deformed secondarily by another folding having an axis in the NNW-SSE direction.

Our investigations revealed that the inner wedge of the Nankai accretionary prism consists of high-angle beddings and open-folds in two stages. Since the primal fold axes indicate the ENE-WSW direction with horizontal axial planes, it is considered that these primal folds were formed in outer wedge before tilting by accretion. During or after the tilting, the second folds have developed along the NNW-SSE direction. The direction of these primal- and second folds are consistent with the stress direction analysis using the borehole breakouts and the strike-slip fault movement in the vicinity of the giant branch fault (megasplay fault). The meso- and macro scale structure in the inner wedge, revealed in this research, can indicate the history of change in stress orientation during developing in accretionary prism.

Dynamic strain energy as new evaluation item of a seismogenic fault

*Arito Sakaguchi[1], Masato Ichiki[2], Kikka Takiguchi[1]

1. Yamaguchi Univ., 2. SANO TAISEIKISO ENGINEERING Co.Ltd

Since earthquake is stress response of the crust, the stress-strain record of the host rock around the fault tell us significant clue of the seismic mechanism. During inter-seismic period, host rock around the asperity deformed elastically to cause the earthquake. Immediately before the earthquake, a rupture propagates from deep nucleation point, and high stress must concentrate at tip of the fracture. This stress concentration causes elastic strain momentary in host rock of the fault, and high stress area moves with rupture propagation.

The strain energy of these event can be estimated from paleo-stress distribution around the fault. It is expected that the highest peak of stress must be appeared at fault center, and stress level will decrease with distance from the fault. The area under the stress decay curve in the stress-distance graph indicates strain energy of the host rock.

Paleo-stress of ancient fault rock can be estimated from elastic rebounded rock using calcite twin method (Sakaguchi et al., 2011).

The Okitsu Fault in Shimanto accretionary complex, southwest Japan is ancient seismogenic fault of plate subduction zone. This fault involves pseudotachylyte and can be observed more than 10 km along the strike of the fault. Higher stress than the background stress of regional Shimanto accretionary complex was found around the Okitsu Fault. This may be due to dynamic stress concentration during rupture propagation. The value of estimated dynamic strain energy is approximately 390 MJm^-2 at eastern tip of the Okitsu Fault. The strain energy along the strike of the fault decreases toward west and disappears at 2 km from the eastern tip. The strain energy along the fault increases again to several MJm^-2 at 9 km from the eastern tip. This strain energy variation may show existence of some locked asperities along the strike of the fault.

Depth dependent spatial variation of pore size distribution for sediments at Nankai accretionary prism

Kouku Inoue[2], *Wataru Tanikawa[1], Yoshitaka Hashimoto[2], Osamu Tadai[4], Manami Kitamura[5], Yohei Hamada[1], Takehiro Hirose[1], Weiren Lin[3]

1. Japan Agency for Marine-Earth Science and Technology, Kochi Instutute for Core Sample Research, 2. Kochi University, 3. Kyoto University, 4. Marine Works Japan LTD., 5. AIST

Sediment porosity at accretionary prism varies with burial depth mainly due to mechanical compaction. Elastic wave velocity and thermal conductivity that are primary governed by porosity thus increase with depth. On the other hand, influence of depth and compaction on pore size distribution is not well known. Permeability is related with not only porosity but also pore size distribution. Therefore depth variation of permeability can be estimated from that of pore size distribution by understanding the fundamental physical process that causes the depth variation. In this study, porosity and pore size distribution were measured on cuttings and core samples obtained by NantroSEIZE project, IODP Expedition 348 (Site C0002).

Sediment at site C0002 is mainly composed by silty sediment. 44 cuttings and 7 core samples were used in this study. At the beginning, samples were washed by sea water, then dried using vacuum pump. Then, porosity and grain density were measured by using a gas pycnometer. Finally, porosity and pore size distribution of the same samples used for the gas pycnometer measurements were measured by a mercury intrusion porosimeter. 3D X-ray microscope was used to visualize internal microstructures of samples, and XRD analysis was performed to evaluate mineral composition.

Our results show a porosity ranges from 20 to 55 % for the gas pycnometer method, and 15 to 50 % at 878-2825mbsf, and 2 to 5 % at 2830-3200mbsf for the mercury injection method. Both porosities deceased gradually with depth. However, at depth around 2200 mbsf, porosity was fluctuated at around 15 to 34%, which were deviated from depth reduction curve. On the whole, porosity measured by the gas pycnometer is relatively higher than that measured by the mercury porosimeter. Pore size distribution at depth shallower than 2000 mbsf show clear single peak, which represents model of pore size, and mode gradually decreased with depth. On the contrary, at depth greater than 2000 mbsf, pore size distribution shows broad and it is difficult to determine the mode.
3D X-ray microscopic images for samples at around 2200 mbsf show variation of amount of coarse grain particles and the fractures developed parallel to preferred orientation of sediment particles. XRD data shows variation of clay mineral compositions among samples. Therefore, fluctuation of porosity and pore size distribution around at 2200 mbsf is explained by the lithological variation and fracture formations. The average pore size decreases with depth, therefore, the permeability probably decreases with depth at Site C0002.

Reconstruction of splay fault activity based on integrated subsurface geological data of the slope basin on the Nankai accretionary prism off Muroto

*Yuichi Okuma[1,2], Asuka Yamaguchi[1], Rina Fukuchi[3], Hiroaki Koge[4], Juichiro Ashi[2,1]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. Department of Natural Environmental Studies, Graduate School of Frontier Science, the University of Tokyo, 3. DIA CONSALTANTS COMPANY LIMITED., 4. The National Institute of Advanced Industrial Science and Technology

Estimating activity of a splay fault is important to understand the long-term formation process of an accretionary prism as well as a pattern of coseismic slip propagation. Splay faulting causes local uplift in an accretionary prism, which would be recorded in a slope basin.
In this study, we conducted interpretation of subsurface structures of a slope basin located at the hanging wall of a splay fault to reconstruct activity of the splay fault on the off-Muroto area of the Nankai accretionary prism. 3-D seismic volume obtained during R/V *Ewing 9907/9908* cruise (Bangs et al., 2004) and high-resolution cross-section images obtained by deep towed subbottom profiler on the R/V Hakuho-maru KH-16-5 cruise were used in this study. This basin is located at 80 kilometers to the southwest of the Cape Muroto and a depth of 3000 m, and 8 kilometers long in northwest-southeast and 6.5 kilometers long in northeast-southwest forming an ellipse shape. Cores from Site 1175 and Site 1176 obtained by Ocean Drilling Program (ODP) Leg 190 were also reanalyzed to constrain lithology, structures and age.
As a result of seismic interpretation, three structural units and two splay faults were confirmed. They were named as Unit A, Unit B and Unit C from top to bottom, and landward and seaward splay faults as Splay Fault Y and Splay Fault Z, respectively. Unit A is characterized by tilted reflectors that getting steep with depth. The age of the bottom of this unit is estimated to be ~0.5 Ma, which means the tilting had started ~0.5 Ma due to the activity of Splay Fault Z. The high-resolution cross-section obtained by subbottom profiler (SBP) combined with tephra age results from Site 1175 core shows that activities of minor faults at the southern edge of slope basin, subsidiary formed by Splay Fault Z, decreased at ~105 ka, and stopped at ~28 ka. Considering these results, we constrained changes the activity of Splay fault Z: faulting started at ~0.5 Ma, gradually decreased at ~105 ka and stopped at ~28 ka.

Subduction of Kyushu-Palau Ridge can cause local thermal disturbance, as estimated from new heat flow data in the forearc in the eastern Kyushu, Japan

*Masataka Kinoshita[1], Rie Nakata[1], Yoshitaka Hashimoto[2]

1. Earthquake Research Institute, University of Tokyo, 2. Kochi University

In the Hyuga-nada forearc region off eastern Kyushu, weaker degree of plate coupling is inferred from frequent seismicity and the slow slips inferred from seafloor geodetic data. This exhibits a clear contrast against the strong coupling in the Nankai Trough region to the east. Based on 3D numerical simulation and the low heat flow values, Yoshioka (2007) suggested that the weaker coupling in Hyuga-nada is attributed to the lower temperature in the seaward side of the plate boundary. However, the tectonics around Hyuga-nada is much complicated from plate-scale to sub-km-scale, In a reginal scale, a colder and probably rough-surface crust (west Philippine Basin; ~60 Ma) is subducting with steeper dip angle at depth, in contrast to the young, smoother Shikoku Basin to the east. Along the old/young boundary, the Kyushu-Palau Ridge (KPR; trending N60W) is obliquely subducting toward N30W since several Ma B.P., possibly scraping off the overlying forearc block westward.

Here we present heat flow data including new ones obtained along JAMSTEC seismic lines to discuss how the heat flow is affected by these tectonic/morphological disturbances.

The heat flow marks a sharp boundary across KPR; it is 50-100mW/m2 to the east and 25-40mW/m2. The transition from high to low heat flow occurs in only 20 km across KPR. Higher heat flows of 100 mW/m2 to the east are located near the axis of Nankai Trough, similar to those reported off Muroto. It is attributed to the fluid discharge along decollement. The lack of such high heat flow to the west may simply the lack of measurement in the corresponding area.

We performed a simple 3D thermal modeling, considering the subduction of old and young crusts (age difference of 20 Ma) neighboring to each other. Both orthogonal and oblique azimuth of subduction are tested. Due to thermal exchange between the neighboring crusts the width of thermal transition becomes wider with time, but not much difference along subducting direction, probably because of rapid subduction. Calculated heat flow profile is generally in good agreement with the observed heat flow trend, consistent with Yoshioka (2007) results.

A closer inspection of heat flow and the morphological feature, however, reveals a coincidence between heat flow minimum and the location of subducted KPR (as supported by the magnetic anomaly) and the location of flow-frequency tremors. Seamount subduction is inferred to cause a local stress anomaly and an elevated pore pressure, which is associated to heat flow anomalies. We will discuss this local effect as well.

[S-CG58] Science of slow earthquakes: Toward unified understandings of whole earthquake process

convener:Satoshi Ide(Department of Earth an Planetary Science, University of Tokyo), Hitoshi Hirose(Research Center for Urban Safety and Security, Kobe University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Takahiro Hatano(Department of Earth and Space Science, Osaka University)

Accumulating observational studies on various types of slow deformation events, such as tectonic tremors, very low frequency events, and slow slip events, portrays some universal characteristics in generally complex behavior, including interaction among events and influence by various outer loadings. Some of these phenomena seem to have causal relation with the occurrence of very large earthquakes. A unified understanding of these slow and fast earthquake processes requires an approach integrating geophysics, seismology, geodesy, geology, and non-equilibrium statistical physics. We welcome presentations based on, but not limited to, geophysical observation, data analysis, analytical theory, numerical simulation, field study, and laboratory experiments.

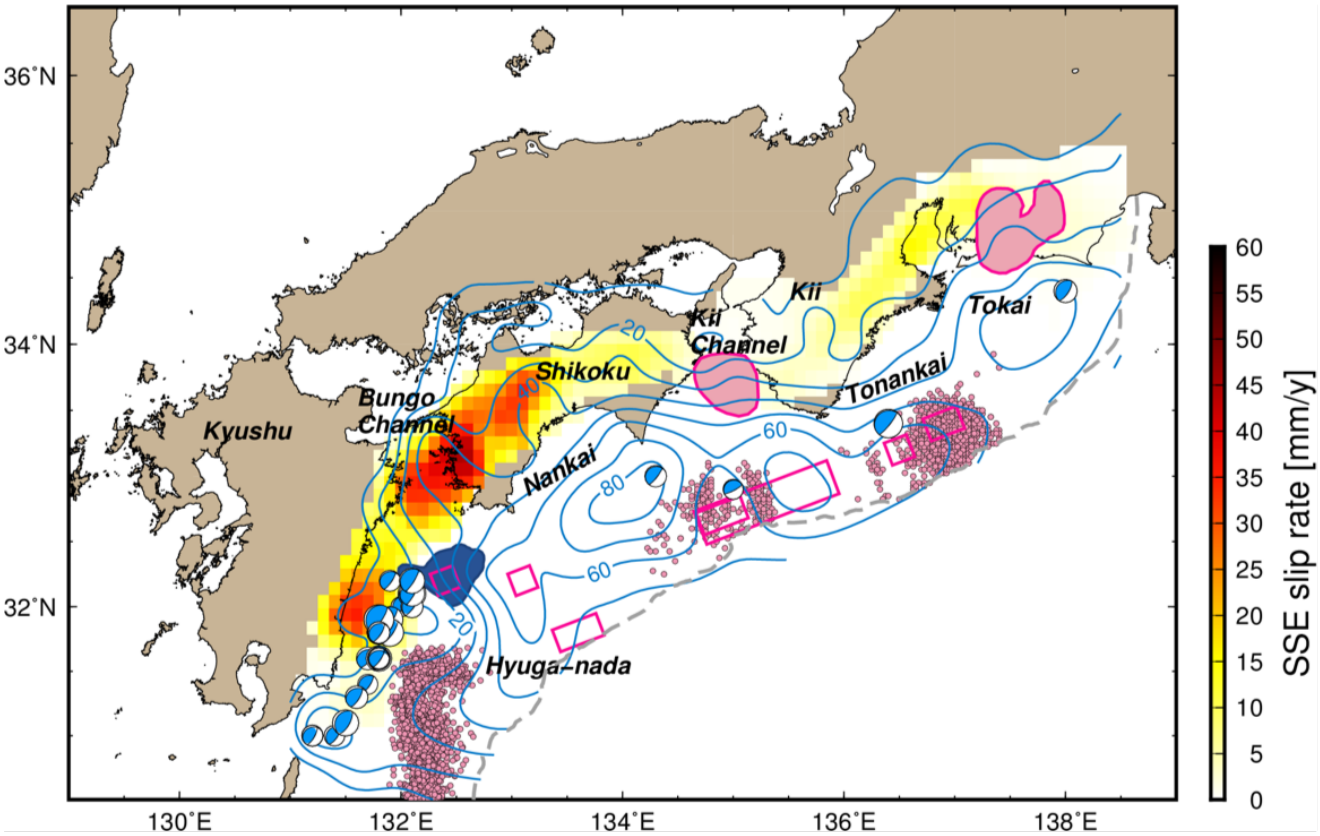
CMT inversion of offshore earthquakes along the Nankai Trough: Separated distributions of slow and regular earthquakes on the plate boundary

*Shunsuke Takemura[1], Ryo Okuwaki[2], Tatsuya Kubota[3], Katsuhiko Shiomi[3], Takeshi Kimura[3], Akemi Noda[3]

1. Earthquake Research Institute, the University of Tokyo, 2. University of Tsukuba, 3. National Research Institute for Earth Science and Disaster Resilience

Due to complex three-dimensional (3D) heterogeneous structures, conventional one-dimensional (1D) analysis techniques using onshore seismograms can yield incorrect estimation of earthquake source parameters, especially dip angles and centroid depths of offshore earthquakes. Indeed, detail analysis of 2016 southeast off the Kii Peninsula earthquake revealed that observed seismic and tsunami record could be explained by low-angle thrust faulting on the plate boundary (e.g., Kubota et al., 2018; Takemura et al., 2018; Wallace et al., 2016) but regional 1D moment tensor analysis showed high-angle reverse faulting mechanism.



Combining long-term onshore seismic observations and numerical simulations of seismic wave propagation in a 3D model, we conducted centroid moment tensor (CMT) inversions of earthquakes along the Nankai Trough. Green’s functions for CMT inversions of moderate earthquakes were evaluated via OpenSWPC (Maeda et al., 2017) using the Japan Integrated Velocity Structure Model (Koketsu et al., 2012). We re-analyzed moderate (*Mw* 4.3-6.5) earthquakes listed in the F-net catalog (Fukuyama et al., 1998; Kubo et al., 2002) that occurred from April 2004 to August 2019. By introducing the 3D structures of the low-velocity accretionary prism and the Philippine Sea Plate, our CMT inversion method provided better constraints of dip angles and centroid depths for offshore earthquakes. These two parameters are important for evaluating earthquake types in subduction zones.

Our 3D CMT catalog of offshore earthquakes and published slow earthquake catalogs (e.g., Kano et al., 2018) along the Nankai Trough depicted spatial distributions of slip behaviors on the plate boundary. The regular and slow interplate earthquakes were separately distributed, with these distributions reflecting the heterogeneous distribution of effective strengths on the plate boundary. By comparing the spatial distribution of seismic slip on the plate boundary with the slip-deficit rate distribution (Noda et al., 2018), regions with strong coupling were identified.

Acknowledgments
We used F-net waveform data and the F-net MT catalog (https://doi.org/10.17598/NIED.0005). Our CMT catalog and CMT results of assumed source grids for each earthquake are available from https://doi.org/10.5281/zenodo.3661116. The FDM simulations of seismic wave propagation were conducted on the computer system of the Earthquake and Volcano Information Center at the Earthquake Research Institute, the University of Tokyo. This study was supported by the Japan Society for the Promotion of Science (JSPS) KAKENHI Grant Numbers 17K14382 and 19H04626.

Understanding of temporal change in slow earthquake migration speed

*Keisuke Ariyoshi[1], Roland Burgmann[2], Jean-Paul Ampuero[3]

1. Japan Agency for Marine-Earth Science and Technology, 2. University of California, Berkeley, 3. Université Côte d'Azur

Recent observations show evidence of propagation of postseismic slip, which may contain information about the mechanical properties of faults. Ariyoshi et al. (2019) develop a new analytical relationship between the propagation speed of aseismic slip transients and fault frictional properties, modeled by a rate- and state-dependent friction law. In the paper, we identify systematic dependencies of afterslip propagation speed on effective normal stress σ and frictional properties (the coefficients a and a-b which quantify the instantaneous and the steady-state velocity-dependence of friction, respectively, and the characteristic slip distance L of fault state evolution). Lower values of the parameter $A=a\sigma$ cause faster propagation in areas where the passage of the postseismic slip front induces large shear stress changes $\Delta\tau$ compared to A, which are typically located near the mainshock rupture. In areas where $\Delta\tau/A$ is small, typically more distant from the mainshock, afterslip propagation speed is more sensitive to $(a\text{-}b)\sigma$. The propagation speed is proportional to initial slip velocity and, under the condition that loading span is significantly shorter than the passage of postseismic slip, inversely proportional to L. In this presentation, we extend our relationship to slow earthquake migration process by comparing our analytical solution with simulated results in previous model (Ariyoshi et al., 2012). The result can explain the reason why slow earthquake migration speed increases in the preseismic stage of megathrust earthquake because of increasing the initial slip velocity for small asperity ongoing chain reaction, which might be applicable to the observed slow earthquake activity in the preseismic stage of the 2011 Tohoku earthquake.

One-hour-duration SSEs found during a Short-term SSE in the Tokai region.

*Kazuki Miyaoka[1], Akio Katsumata[2], Satoshi Itaba[3]

1. Japan Meteorological Agency, 2. Meteorological Research Institute, 3. National Institute of Advanced Industrial Science and Technology

The Short-term Slow Slip Events (s-SSE) occur repeatedly several times per year in the deeper than the seismogenic zone of the Nankai Trough area southwestern Japan. These s-SSEs have moment magnitude equivalent to about 5.5 - 6.0 and duration of approximately a week.
Japan Meteorological Agency (JMA) operates borehole strain-meter network and analyses the s-SSE activities by using an hourly resampled data of them.
Recently, Katsumata et al, (2020) found a small change with extremely shorter duration than usual s-SSEs in time series data of laser extensometers installed in the Aichi and Shizuoka prefectures. We confirmed the existence of the small change in the one minute resampled strain-meter data in February 2019 Tokai s-SSE. Here, we report the analysis of the small rapid change.

A Mw6.0 s-SSE (hereafter parent-SSE) occurred from 3 to 11 February, 2019 in Aichi prefecture and evident changes of strain-meter data with intense tremor activity were observed.
In 5 February which is the most active period of the parent-SSE, smaller but faster changes were observed from 15:30 to 16:30 in the some stations around Aichi prefecture.
So, we performed analysis to infer the fault plane assuming a plate boundary slow slip. Result, a small slip equivalent to Mw5.0 with 1 hour duration was calculated.
Furthermore, two other similar changes were found in the parent-SSE with a careful data checking, Mw 4.8 small slip on the plate boundary with duration of 50 minutes and Mw4.8 one with 45 minutes were also calculated.
As well as the known s-SSE, these events were also accompanied with transient intense tremor activity.

We guessed them to be an unknown Slow Slip Event, faster than the known SSE occurred in the same tectonic mechanism on the plate boundary.

Ide et al. (2007) proposed a Moment-Duration scaling law for slow earthquakes and demonstrated that the various kind of slow earthquakes observed throughout the world are on the scaling law.
And Ide et al. (2007) pointed out a possibility of existence of Mw4-5 events with tens minutes to 1 hour in which no events have been observed. The new event presented in this work are exactly the predicted ones.

Activities of low frequency tremors in Sanriku-Oki before the 2011 Tohoku-Oki earthquake

*Hidenobu Takahashi[1], Ryota Hino[1], Naoki Uchida[1], Kazuaki Ohta[2], Masanao Shinohara[3], Ryosuke Azuma[1], Susumu Kawakubo[1]

1. Graduate school of Science Tohoku University , 2. National Research Institute for Earth Science and Disaster Resilience, 3. Earthquake Research Institute, the University of Tokyo

Recently, slow earthquakes have been discovered in Tohoku-oki by using the Seafloor Observation Network for Earthquakes and Tsunamis along the Japan Trench (S-net) (Tanaka et al., 2019). These activities differ from those in Nankai Trough (Obara and Kato, 2016), where sources of slow earthquakes and megathrust are clearly separated, and slow earthquakes are continuously distributed along the deeper and shallower side of the seismogenic zone, whereas those show complex spatial distribution along the Japan Trench (Nishikawa et al., 2019).

In northern Sanriku-Oki region between 39˚N and 40.7˚N, low frequency tremors (LFTs) frequently occur as well as very low frequency earthquakes (VLFEs) (Matsuzawa et al., 2015), but their activities are significantly lower in the southern Sanriku-Oki regions (~39˚N). Since the southern LFT cluster is located within the coseismic slip zone of the 2011 Tohoku-Oki earthquake (Iinuma et al., 2012), it is probable that the occurrence of the massive coseismic slip affects the LFT activities after the Tohoku-oki earthquake.

Here, we report the activities of LFTs in Sanriku-Oki before the 2011 Tohoku-Oki earthquake. We used 46 short-period ocean bottom seismograms (OBSs) deployed from Oct. 2007 to May 2008. The envelope correlation method (e.g. Obara, 2002, Ohta et al., 2019) is applied to the OBS seismograms, with almost the same parameter settings as the study by Nishikawa et al. (2019) using the S-net data. As a result, we detected 448 and 168 tremors in northern and southern Sanriku-Oki regions, respectively. In the northern region, LFTs show evident along-strike migration during multiple episodes, each of which has ~1 week duration. The migration speed is ~ 20 km/day, which is comparable to that observed in the deep LFTs in the western Shikoku of Nankai (Obara, 2002).

The S-net observation for two years after the 2011 Tohoku-Oki earthquake detected 2894 events in the northern region, while only 17 in the southern region. Our result using the OBS data in 2007 and 2008 suggests that the LFTs in the southern Sanriku-Oki was much more active before the Tohoku-Oki earthquake and the change in the LFT activity reflects the change of the behavior of the plate boundary caused by the massive interplate earthquake.

Detailed Spatial Slip Distribution for Short-term Slow Slip Events along the Nankai Subduction Zone, Southwest Japan

*Masayuki Kano[1], Aitaro Kato[2]

1. Graduate school of science, Tohoku University, 2. Earthquake research institute, The University of Tokyo

Short-term slow slip events (S-SSEs) with a duration of days to weeks have intensively occurred at the transition zone at depths of ~ 35 km along the Nankai subduction zone, southwest Japan. Because crustal deformation due to a single S-SSE is small, the source fault has been often represented as a single planar uniform slip model, resulting to little constraint on the spatial heterogeneity in amount of slip. Here, to comprehensively investigate the detailed cumulative spatial distribution of S-SSEs in the whole Nankai subduction, we adopted a stacking approach of GNSS data by referencing low-frequency earthquakes which are assumed to be accompanied by S-SSEs. We have successfully extracted cumulative displacements due to a series of S-SSEs occurred from 2004 to 2009, showing coherent signals that are almost opposite to the direction of plate subduction. Then, we inverted these surface displacements to fault slip along the plate interface. The estimated slip indicates significant slip patches laterally elongated along the transition zone at the depths of ~30–35 km, and small patches on the shallow portion of ~15 km depth in eastern Shikoku and Tokai as well as in western Shikoku inferred by Kano et al. (2019). The two shallow patches locate on the downdip edge of the coseismic slip area in 1946 Nankai earthquake, while the Tokai small slip is located on the shallower side of the anticipated source area of the magnitude 8 class earthquake. In addition, the large slip patches of S-SSEs are possibly complementary to the spatially dense low-frequency earthquake areas; the number of low-frequency earthquakes is low in major slow-slip areas. This spatial dependence of fault slip style even within the transition zone provides new insights of generation mechanism of slow earthquakes.

Fist detection of shallow tremor at the Guerrero gap, Mexico.

*Raymundo Omar Plata Martinez[5], Satoshi Ide[1], Naoto Mizuno[1], Masanao Shinohara[2], Tomoaki Yamada[3], Allen Husker[4], Jorge Real[4], Victor Cruz-Atienza[4], Yusuke Yamashita[5], Akiko Toh[1], Yoshihiro Ito[5]

1. Department of Earth an Planetary Science, University of Tokyo, 2. Earthquake Research Institute, University of Tokyo, 3. Japan Meteorological Agency, 4. Institute Geophysics, UNAM, 5. Disaster Prevention Research Institute, Kyoto University

The Guerrero gap, located at the Mexican subduction zone, is a seismic gap which has not had any significant earthquake (M>7) in almost 119 years. Furthermore, slow earthquakes like tectonic tremors and slow slip events are frequent in the down dip portion of the gap at approximately 40 km depth. Even when slow earthquakes in the Guerrero gap are well documented, until now there has been no confirmation of slow earthquake activity at the shallow portion of the gap close the trench. With no offshore instrumentation, it has been a difficult task to collect enough evidence to prove that tremors or slow slip take place near the trench. For this reason, a seven stations array of Ocean Bottom Seismometers (OBS) was deployed inside the Guerrero gap. One-year data was analyzed in search of shallow tremors using a modified envelope correlation method. Over 130 tremors were detected close to the trench. Tremors do not show any migration, but small burst of tremors show recurrence periods of approximately one and three months. Seismic signals of these tremors have duration between 10-100 sec, they show no clear arrivals both of P and S wave, are efficient at a frequency band between 2 and 8 Hz and are deficient at frequencies above 10 Hz, attenuating rapidly. More analysis is being done to understanding the nature of these tectonic tremors and their connection with seismicity. By comparing other seismic and geodetic data, such as ocean bottom pressure gauges, GPS/acoustic measurements and high-resolution bathymetry, we are now trying to explain tremor influence in the seismic hazard associated to the shallow portion of the GG.

Depth profile of frictional properties inferred from cuttings obtained at the Nankai trough C0002 drilling site

*Riho Fujioka[1], Ikuo Katayama[1], Takehiro Hirose[2], Manami Kitamura[3]

1. Hiroshima Univercity, 2. Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, 3. National Institute of Advanced Industrial Science and Technology

Nankai megathrust earthquakes has occurred repeatedly, and has caused great damage historically (e.g., Ando et al., 1975). To understand the process of Nankai megathrust earthquakes, Nankai Trough Seismogenic Zone Excavation Project (NanTroSEIZE) has been conducted as part of the IODP since 2007 to 2019. Friction experiments were performed using core samples collected at the Nankai Trough Seismogenic Zone Excavation Project (Ikari and Saffer, 2011 and Takahashi et al., 2014), however, depth variations were limited in these previous experiments because cores were retrieved from limited depth intervals. In order to make a continuous depth profile of frictional properties, we carried frictional experiments using cuttings samples collected at every 50 m over the interval from 860 to 3000 mbsf in the ultra-deep riser hole, Site C0002 .

Frictional tests were conducted by biaxial frictional machine at Hiroshima university under saturated conditions (brine,0.5 mol/L) at in-situ effective normal stress (σe = 9–34 MPa). The cuttings samples were ground and the grain size was adjusted to less than 106 μm. The gouge sample was sandwiched by gabbro blocks in double–direct configuration. After slip behavior reached a steady state at 3 μm/s, velocity was changed stepwise between 0.3, 3, and 33 μm/s. In this test, frictional coefficient at a steady state and the velocity dependence defined by the rate- and sate-dependent friction constitutive law were examined. All tests were conducted in water tank filled with brine. The relationship between friction properties and clay minerals were investigated by comparing the total clay mineral content and smectite content of cuttings samples reported by the IODP 348 Expedition data report.

Frictional coefficient at the drilling Site C0002N are ranging from 0.472 to 0.575. There is no relationship between depth and frictional coefficient. Frictional coefficient was slightly decrease with increasing smectite content, which is consistent with the pervious study (Takahashi et al., 2014). The smectite content of samples collected at a deeper depth decrease, and therefore we expect future increasing coefficient of friction of these samples in the future measurements of deeper samples. Velocity dependence of friction(a-b) were ranging from -0.009 to 0.020. In most cases, velocity strengthening was observed, but the neutral of velocity-dependence was characteristically appeared at depths around 1100–1800 mbsf. Although Takahashi et al. (2014) has reported velocity strengthening in all experiments at the Site C0002, velocity dependence might be influenced by effective normal stress. Since the occurrence of slow earthquake is possibility related to a neutral sate of velocity dependence (e.g., Ikari and Saffer, 2011), the observed neutral dependence might attribute to the shallow very low-frequency earthquakes observed in the Nankai accretionary prism.

Slip rate dependence of dynamic water permeability for low permeable fault and the role of fluid

*Wataru Tanikawa[1]

1. Japan Agency for Marine-Earth Science and Technology, Kochi Instutute for Core Sample Research

Evolution of fluid transport and mechanical properties of faults by frictional sliding is key to control slow earthquake and dynamic fault rupture. In this study, change of water permeability of simulated faults (granite and dolerite) by frictional sliding at slow (0.1 mm/s) to fast (1 m/s) slip rate with long slip displacements (~1 m) were investigated in laboratory experiments. Rotary shear apparatus was used in the laboratory tests at 2 MPa of normal stress. Elix pure water was used as pore fluid to measure permeability. Water permeability suddenly increased by sliding to achieve to steady state values. After slip stopped, permeability decreased gradually to initial permeability or below initial values in several ten minutes. Both dynamic permeability and friction coefficient show slip rate dependence that both permeability enhancement and reduction of friction is significant at high velocity sliding. Velocity step change tests confirmed the positive slip rate dependence of permeability. The slip rate dependence is explained by dilation of hydraulic aperture due to frictional heating because pore pressurization and thermal expansion of pore spaces on slip plane are effectively induced by thermal pressurization at high slip rate. The change of water viscosity by frictional heat in part explains the apparent permeability recovery after sliding. The lower dynamic permeability and lower friction of granite than those of dolerite is explained by rich in quartz minerals that polish slip surface strongly to reduce hydraulic apertures.
The laboratory results suggest the importance of permeability evolution on slow to fast earthquake processes; coseismic fault slip induces significant permeability enhancement that fail to occurrence of pore pressurization, whereas temporal small permeability change during slow slip suggests the difficulty in large pore pressure drop.

Keywords: permeability, friction coefficient, roughness, slow earthquake, thermal pressurization, slip rate dependence

Gouge friction on a meter-scale laboratory fault

*Futoshi Yamashita[1], Eiichi Fukuyama[2,1], Akihiro Shimoda[2], Shun Watanabe[3]

1. National Research Institute for Earth Science and Disaster Resilience, 2. Graduate School of Engineering, Kyoto University, 3. Faculty of Engineering, Kyoto University

National Research Institute for Earth Science and Disaster Resilience (NIED) has been conducting friction experiments with meter-scale rock specimens using a large-scale shaking table. We have presented a result that the work rate at which the meter-scale rock friction starts to decrease is one order of magnitude smaller work rate than that of the centimeter-scale one (Yamashita et al., 2015, Nature). Mechanical, visual and material observations suggested that the difference of frictional properties between centimeter and meter scale is caused by slip-evolved heterogeneous stress concentration on gouge bumps generated with the frictional slip. We confirmed that numerical simulation based on the observations is fully consistent with the experimental results. However, it should be noted that the natural fault zone generally involves gouge layer in it. Therefore, it is crucial to investigate which the scale dependence of frictional property can be seen or not under such a condition. To answer this question, we conducted meter-scale gouge friction experiments using the large-scale shaking table. We used metagabbro blocks from India as driver blocks. The contacting area was 1.5 m long and 0.1 m wide. As the simulated gouge, we ground metagabbro blocks by the jet mill, so that the average diameter of the gouge particle is approximately 10 μm and the maximum diameter of that is less than 200 μm. We roughened the fault surface by sandblasting after polishing the surface so that the fault surface can grip the gouge particles. We distributed the simulated gouge with a thickness of 3 mm on the fault and then sheared at a constant or step-change velocity after applying normal stress up to 6.7 MPa at maximum. We will present basic experimental results at the meeting.

Spatio-temporal correlations in tremor activity in south-west Japan

*Anca Opris[1], Takahiro Hatano[1]

1. Department of Science, Osaka University

Tremor activity is known to exhibit temporal episodic behaviour (burst-type activity followed by periods of inactivity), as well as spatial migration. Previous studies have investigated the temporal (Idehara et al., 2014) or the spatial clustering (Obara et al., 2010) of tremor activity in south-west Japan. We propose to investigate the correlations in tremors, based on the space-time combined correlation integral (Tosi et al., 2008). Thus, we are considering a simultaneous analysis of the interdistance among events in both space and time coordinates.
In previous studies, three distinct areas of tremor occurrence have been identified, with two seismicity gaps in between. Some explanations have been proposed for the phenomena, but no clear evidence can yet explain the presence of these seismically inactive regions. We aim to get some insight by modelling the spatial distribution and intermittent activation of the Shikoku, Kii and Tokai areas in respect to the Nankai and Tokai locked area. We analyse the local slope of time correlation dimension (d_t) as a function of time interval (σ) and hypocentral distance (r), using two different catalogues, retrieved from the World Tremor Database and a recently improved catalogue, respectively (Mizuno et al, 2019). We compare the obtained results for the two catalogues and discuss the overall implications on statistics of the different methods of detecting the tremor activity.

On 3-D resistivity structure in the SW part of Shikoku-Island, SW Japan, and sensitivity of the Network-MT responses to the structure

*Makoto Uyeshima[1], Ryoukei Yoshimura[2], Maki Hata[1], Hiroshi Ichihara[3], Koki Aizawa[4]

1. Earthquake Research Institute, The University of Tokyo, 2. Disaster Prevention Research Institute, Kyoto University, 3. Graduate School of Environmental Studies, Nagoya University, 4. Graduate School of Science, Kyushu University

In the Bungo channel region at the western margin of the Nankai megathrust rupture zones, the long-term slow slip events (SSE) repeatedly occurred about every 6 or 7 years and we are now having the most recent event. The SSE also activate deeper episodic tremors and slips (ETS) on the plate interface. In order to examine mechanism of the SSE and/or concurrent ETS activities, especially to clarify influence of interstitial fluids on occurrence of the events, or to detect movement of the fluids associating with the events, we have started the Network-MT survey in the western part of the Shikoku Island facing the Bungo channel since April, 2016.

We use metallic telephone line network of the Nippon Telegraph and Telephone Corp. to measure the electrical potential difference with long baselines of from several kilometers to 10 and several kilometers. We selected 17 areas in the western part of the Shikoku Island and installed 3 or 4 electrodes in the respective areas. The electrical potential differences measured in this way are known to be less affected by small scale near-surface lateral resistivity heterogeneities (e.g. Uyeshima, 2007). We also measure the geomagnetic field at two stations in the target region. With the aid of the BIRRP code (Chave and Thomson, 2004), we could estimate the frequency-domain response functions of good quality. After applying the 3-D DASOCC inversion code (Siripunvaraporn et al., 2004), which directly invert the Network-MT response between the voltage difference on each dipole and the magnetic field, we could obtain the 3-D resistivity structure in the target region. Data from Apr. to May, 2016 are used. Site (dipole) and period numbers are respectively 53 and 10 (from about 20 s to 10,000 s). Grid sizes of the model are 60 (NS), 57(EW) and 45 (vertical). We started from an initial model of uniformly 100 Ohm-m in land portion and sea water is fixed to be 0.3 Ohm-m. The initial RMS was 12. We got a model with RMS 2.42 on 5% error floor.

First, cross sections along lines in NNW-SSE with and without the slow slip events are examined. The most remarkable low resistivity anomalies are detected in the middle crust of the hanging wall of the subducting Philippine Sea slab in all the cross-sections. As was often pointed out in the previous studies (e.g. Hata et al., 2018; Ichihara et al., 2014), earthquakes also in this region tend to occur in the resistive area avoiding those low resistivity anomalies. Due to existence of this shallower crustal conductive anomalies, however, it was difficult to resolve resistivity distribution along the subducting slab. No remarkable conductive anomaly could be imaged in both of the areas with and without the slow slip events. In order to clarify the relationship between the resistivity structure and the slow slip area, plan view conductivity distributions parallel to the slab surface are examined and compared with the seismic Qp structures (Kita and Matsubara, 2016). Some positive correlation between both parameters can be detected. Mantle wedge above the slab with the slow slip event is relatively resistive and high Qp. On the other hand, mantle wedge above the slab without the slow slip event is relatively conductive and low Qp. The resistive and high Qp layer may indicate an impermeable layer which confine the fluids along the subducting slab. The confined fluids may cause slow slip events, although the fluids could not be explicitly imaged as the conductive anomaly. We also want to show temporal variation of the Network-MT responses.

As was written above, significant slow slip event occurred recently. Then, we want to show how the Network-MT responses are sensitive to temporal resistivity change along the slab. In a test model, 10 km

©2020. Japan Geoscience Union. All Right Reserved.

thick conductive layer is assigned just beneath the top surface of the slab. The resistivity is set to be 20 Ohm-m (thus 500 S anomaly). RMS of the best fit model was 2.42, whereas 3.65 for the test model. Decrease of the apparent resistivity and increase of the phase value in the relatively higher frequency range can be detected.

This study is supported by JSPS KAKENHI Grand Number JP16H06475 in Scientific Research on Innovative Areas "Science of Slow Earthquakes". It is also partly supported by the Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan, under its Earthquake and Volcano Hazards Observation and Research Program. We acknowledge staffs of the Nippon Telegraph and Telephone WEST Corporation and associated companies for their cordial support in the survey. We also thank H. Abe, A. Takeuchi and Y. Suwa in ERI for their help in preparing and installing instruments.

Variations of scaling relationships for shallow tremor; implications from the probabilistic cell automaton model

*Masaru Nakano[1], Suguru Yabe[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Geological Survey of Japan, AIST

Scaling relationships of seismic phenomena is one of keys to understand the source processes. In our previous study, the event size distribution of shallow tremor that occurred along the Nankai trough was well fitted by the tapered Gutenberg-Richter (TGR) (Kagan 2002 GJI) distribution (Nakano et al. 2019 GRL). In that study, the cutoff magnitude (Mc) of TGR, above which the event size distribution is well fitted by an exponential law, and the b-value (slope of the size distribution in logarithmic scales smaller than Mc) varied in each activity period. Detailed analysis showed that both Mc and the b-value temporally changed DURING activities in 2016 off Kumano and 2018 off Muroto (Nakano et al. 2019 JpGU). To clarify the factors that control the event size distribution may help our understandings of slow earthquake source mechanisms. In this study, we try to explain the observed changes in the event size distribution based on the 2D probabilistic cell automaton (PCA) model proposed by Ide and Yabe (2018 PAG), which well explains the statistical properties of the broadband slow earthquakes including event size distributions.

In the 2D PCA model, each cell has two states: “stop” and “slip”, which probabilistically alternates according to the states of neighboring cells. The controlling parameters of the 2D PCA model would be: the source size in x and y directions (Nx and Ny), the transition probability of the cell status (pb), ignition of fault slip (pl), and energy dissipation during slip (pv).

Our simulations show that the source size (Nx and Ny) and pb changes Mc without significantly affecting the b-value as already shown by Ide and Yabe (2018) (their Figure 4). On the other hand, increasing the excess stopping probability (pv) due to energy dissipation systematically reduces Mc while increases the b-value, namely smaller-size events predominate due to the suppression of event growth. The effects of ignition (pl), or loading, is small compared to pv, but further detailed studies are necessary because these parameters would affect the system in a similar way.

The observed changes in Mc and the b-value in the shallow tremor showed negative correlations in these parameters. In the 2016 off Kumano activity, Mc decreased in the end 5 days of the activity synchronized with the b-value increase and event number decrease. In the 2018 off Muroto activity, decreases in Mc was observed in the middle 30 days and end 30 days during 4 months activity, synchronized with the b-value increases and event number decreases. The observed changes in the size distributions can be explained by increase in the excess stopping probability (pv) during the lower activity periods.

In this study, we showed that the changes in pv systematically explains the observed temporal changes in the event size distributions of the shallow tremor, but its physical meaning is not clarified yet. Temporal changes in the stopping probability of cell movement in PCA may correspond to changes in the frictional properties along the causative fault. Further careful investigations based on experimental and/or theoretical studies to clarify materials that control the frictional properties on a fault, which changes could occur in a several to ten days, is necessary.

High Fluid Pressure Patch beneath the Décollement as a Potential Source of Slow Earthquakes at the Nankai Trough

*Takehiro Hirose[1], Yohei Hamada[1], Wataru Tanikawa[1], Nana Kamiya[2], Yuzuru Yamamoto[3], Takeshi Tsuji[4], Masataka Kinoshita[5]

Japan Agency for Marine-Earth Science and Technology, 4. Department of Earth Resources Engineering, Kyushu University, 5. Earthquake Research Institute, the University of Tokyo

Pore fluid pressure is important for understanding generation of both megathrust and slow earthquakes at subduction zones. However, its occurrence and quantitative constraints are quite limited. Here, we report the estimate of pore pressure by the analysis of transient upwelling flow from the borehole, that was observed while drilling the underthrust sediments in the Nankai Trough off Cape Muroto during IODP Expedition 370. In order to interpret the observed velocity and duration of the flow, we have solved a radial diffusion equation to estimate pore pressure before penetrating an aquifer. The calculation yields that the pore pressure exceeded ~3 MPa above hydrostatic and the size scale of the aquifer is several hundred meters, in case of an aquifer permeability of 10^{-13} m^2. Our result suggests that the underthrust sequence is currently composed of patchily-distributed high-pressure aquifers.

In the neighborhood of the drilling site, very low frequency (VLF) earthquakes have been reported (e.g., Obara and Kato, 2016). Seismic survey has suggested a possible linkage between high pore pressure zone and the distribution and generation of slow earthquakes (e.g., Kodaira et al., 2004). Furthermore, high temperature and pressure friction experiments by Sawai et al. (2016) suggested that a transition from stable to unstable slip behavior appears with increasing pore fluid pressure that is a prerequisite for the generation of slow earthquakes. Our result implies that the slow earthquakes at off Cape Muroto can be attributed with slip behaviors along not only décollement but also the patchily distributed high-pore-pressure aquifers in the underthrust sediments.

The November 11, 2018 long-period-monotonic big earthquake occuring near Mayotte island off East Africa and seismic activity observed by the Iranian broadband seismic stations

*Sadaomi Suzuki[1], Hossein Sadeghi[2]

1. Tono Research Institute of Earthquake Science, Association for the Development of Earthquake Prediction, 2. Department of Geology, Faculty of Science, Ferdowsi University of Mashhad, Iran

The 11 November 2018 Mayotte event (SEQ) was first introduced in the media by Maya Wei-Haas (2018) on National Geographic Magazine as a strange earthquake of which seismic waves were recorded by instruments around the world, but unusually nobody felt them. The Mayotte event in the absence of body waves caused long-duration, long-period surface waves traveling around the globe. Cesca et al. (2020) by analyzing regional and global seismic and deformation data suggested drainage of a deep magma reservoir. Tono Research Institute of Earthquake Science recorded the data with the broadband seismometer (STS-1) and gravimeter (gPhone) installed in Mizunami, Japan (Murakami et al., 2019). The records by Iranian broadband stations clearly showed the longperiod seismic signals around 10 (UTC) on November 11, 2018 (Figure 1). We studied records by 26 stations distributed throughout the country. The stations are operated by National Center of Broadband Seismic Network of Iran, International Institute of Earthquake Engineering and Seismology (IIEES). Since the frequency content of Fourier amplitude spectra appeared the signal of the surface waves as a peak around 0.06 Hz, we applied a bandpass filter of 0.05-0.07 Hz to the waveform data. To separate Rayleigh from love in surface waves, the filtered horizontal components were rotated to the radial and transverse components based on an assumed epicenter location at the latitude of 12.7S and longitude of 45.4E degrees. The stations considered as an array and the investigation was carried out in two ways. First, the position of each station was taken as the reference point of the array coordinate, and arrival delay times at the other stations relative to the reference were calculated. The phase velocity and the back-azimuth of each station were estimated through the least-square regression method. The estimated back azimuths were within 13 degrees from the back azimuths from the assumed epicenter. The average phase velocity for Rayleigh and Love phases are calculated as 2.97 and 3.31 km/sec, respectively. Second, we applied semblance analysis to six stations with the shortest spacing distances. However, the distance between the adjacent stations relative to the signal wavelength was not enough short to prevent spatial aliasing. Nevertheless, the interesting was that the semblance results were different for radial and transverse components. We calculated surface-wave magnitude (Ms) for the event and a number of recorded earthquakes occurring in the Mayotte area from May 13 to June 1, 2018. Linear regression was used to define relationships between the calculated Ms and the USGS body-wave magnitude (mb) and the local magnitude by BRGM catalog (Bertil et al. , 2019), and the moment magnitude (Mw) from the CMT solutions of HRVD and USGS.

Dense broadband seismic campaign for deep very low frequency earthquakes in Shikoku, Kii and Tokai regions in the Nankai subduction zone

*Akiko Takeo[1], Kazushige Obara[1]

1. Earthquake Research Institutute, the University of Tokyo

Very low frequency earthquake (VLFE) is one type of slow earthquakes observed by broadband seismometers at a period range around 20-50 s at the plate interfaces of subduction zones. The signal of deep VLFEs at the down-dip side of seismogenic zone tends to be small compared to that of shallow VLFEs at the up-dip side near the trench. To observe deep VLFEs, we have installed broadband seismometers in the Nankai subduction zone in three different stages.

In the first stage, we deployed three stations in the Shikoku island in 2015 by the earthquake and volcano hazards observation and research program. In the second stage, we deployed two stations in the Shikoku island and one station in the Kyushu island in 2017 as a part of “Science of Slow Earthquakes” project. The seismometers are either CMG-3T (120 s) of the Guralp or the Trillium QA/PA (120 s) of the Nanometrics. The recorders are LF-1100/2100 of the Hakusan. The data is in WIN format and is transferred to Earthquake Research Institute, the University of Tokyo in almost real time. These stations are called “BC series” because their target is the Bungo Channel region where various types of slow earthquakes have been observed. By analyzing these datasets, we have detected and determined centroid moment tensor and its uncertainty for 324 events from 2018 to early 2019.

In the third stage, in this study, we have installed 11 stations and will install 4 more stations from 2019 to 2020 as a part of “Science of Slow Earthquakes” project. The numbers of stations are 7 in the Shikoku, 4 in the Kii and 4 in the Tokai regions. We chose the locations in the Shikoku region near the active area of low frequency tremor but less active area of VLFEs to detect small events. The stations in the Kii and Tokai regions are located near the active area of VLFEs to analyze broadband (10-100 s) spectrum of each event. The seismometers are CMG-3T (120 and 100 s) tested in the Nokogiriyama observatory of Earthquake Research Insititute for one week. The recorder is RT130 of the Reftek. The data is in SEED-STEIM2 format and transferred to newly constructed virtual server on the Sakura VPS service by VPN connection (NXR mobile router and DTI SIM). We will continue monitoring these datasets and determine detailed source parameters of VLFEs to understand the dynamics of interplate slip in the future.

Fluid flow patterns in fluid injection into swelling gel particles

*Kojiro Otoguro[1], Yutaka Sumino[1]

1. Department of Applied Physics, Faculty of Science Division I, Tokyo University of Science

Frequency of slow slip events varies by pore-fluid pressure, and further, pore-fluid pressure varies by permeability change caused by silica dissolution [1]. It is important for comprehensive understanding of earthquake mechanism to understand not only how permeability change in various situations but also how fluid flows with such variation of permeability. For this purpose, we explore the fluid flow in varying permeability by an analogue injection experiment.

In this study, we tried to imitate a fluid flow in thin fracture. Thus, we used a thin 2-dimensiohnal cell made of two acrylic plates. The gap between the plates was set as 1 mm to imitate fracture. We initially filled the gap with samples, gel particle, made of sodium polyacrylate. This gel particle is so called ionic gel, and can swell to be 1000 times in its volume when pure water is added. Furthermore, we can tune the swelling rate, as well as final swelled volume by changing the salinity of water [2]. We used the gel particle whose typical radius 350 μm in dry condition. After we filled the cell with the sample, we tapped 10 times so as to have particle packed well [3]. We then injected an aqueous phase, an aqueous solution of sodium chloride, into the cell from the bottom of the 2-dimensional cell. As a control parameter, we have changed the concentration of sodium chloride Cs, and injection rate Q. The schematic illustration of experimental setup is shown in Fig. 1.

Fig.2 is the obtained phase diagram. In the diagram, particles are displaced by fluid flow in white areas, and fluid penetrates in deep black areas. At high Q and C_s, the gel particle did not swell significantly, and the injection front steadily expanded circularly without the interruption of fluid flow. On the other hand, at low Q and C_s, due to the swelling of gel particles, fluid flow was blocked, and the injection front branched. These behavior, the transition from branching to circular injection front, can be considered with a simple mathematical model.

Seismic reflection profiling across deep low-frequency tremor zone in western Shikoku, southwestern Japan

*Eiji Kurashimo[1], Kimihiro Mochizuki[1], Takashi Iidaka[1], Kazushige Obara[1]

1. Earthquake Research Institute, the University of Tokyo

The Nankai trough region, where the Philippine Sea Plate (PHS) subducts beneath SW Japan arc, is a well-known seismogenic zone of interplate earthquakes. In recent years, various slip motions with different time scales, including episodic tremors and very low-frequency earthquakes have been recognized in neighboring regions of the seismogenic zone (e.g., Obara and Kato, 2016). A narrow zone of nonvolcanic tremor has been found in SW Japan fore-arc, along strike of the arc (Obara, 2002). The spatial distribution of the tremor is not homogeneous in a narrow belt but concentrated forming clusters. Revealing structural factors that control the fault slip behavior is important to understand the subduction dynamics. The fluid pressure on a plate interface is one of the key factors to understand the fault slip behavior (e.g., Saffer and Tobin, 2011). Seismic reflection characteristics can provide important information on the fluid-related heterogeneity of structure around plate interface. A series of active seismic experiments were undertaken in 2008 and 2014 to obtain a structural image beneath the western part of Shikoku, southwestern Japan (Takeda et al., 2008, 2015). Takeda et al. (2015) provided the geometry of the subducting PHS. To investigate the lateral variation of reflection characteristics along tremor zone, we conducted active seismic experiment in the western part of Shikoku in November 2019. Our seismic experiment had two survey lines. One was carried out along a 80-km-long seismic line between Seiyo and Kumakogen (S-K line) in the east-west direction and the other was carried out along a 50-km-long seismic line between Ozu and Shimanto (O-S line) in the north-south direction. Six hundred seismic stations were deployed with about 200 m spacing for the S-K line and about 250 m spacing for the O-S line. Six explosive shots with charge size of 200 kg were fired on our survey lines. We obtained high signal-to-noise ratio explosion data along the entire length of the profile. The most remarkable feature of the record sections is that high amplitude reflections, probably from the top of the subducting PHS, are recognized. To obtain the detailed structure image, we applied the seismic reflection technique to explosion data. The stacked image shows several features of the deeper part of the hanging wall and the northward dipping plate boundary at 8-10 sec in two-way travel time.

Long-term Viscoerastic Relaxation and Spatially Inhomogeneous Viscosity Structure

*Yusaku Tanaka[1]

1. Earthquake Research Institute, University of Tokyo

Activities of very low-frequency earthquakes after mega-thrust earthquakes can be related to afterslips (e.g., Baba et al., 2020 JGR) but estimation of the spatiotemporal distribution of afterslip is difficult. For instance, GNSS observation can detect the signal of crustal deformation by afterslip + viscoelastic relaxation and their simultaneousness makes it hard to separate those signals.

One method for the separation is to use very long-term data. Time constant of afterslip is relatively short compared to that of viscoelastic relaxation, so the data obtained long after the earthquake do not include the signal of afterslip. By estimating viscoelastic relaxation based on those data and removing its contribution in the whole time series, we can gain the data mainly reflecting afterslip. This concept is very simple and today most of researches attempting to separate afterslip and viscoelastic relaxation are more or less related to it. However, it has one unignorable problem, namely, spatial inhomogeneousness of viscosity structure.

Suito (2017 EPS) suggested that three dimentional rheological heterogeneity is necessary for interpreting viscoelastic relaxation caused by the 2011 Tohoku-Oki earthquake based on GNSS data including ocean bottom stations and also showed that the viscosity of oceanic mantle can be higher than that of mantle wedge. However, it is still unclear if similar phenomena can be observed in different earthquakes and in different places.

In this presentation, I report that spatial inhomogenous viscosity structure is decisively important to interpret GNSS + satellite gravimetry observation results about post-seismic phenomena of the 2004 Sumatra-Andaman earthquake, the 2006-2007 doublet Kuril earthquakes, the 2009 Samoa-Tonga earthquake, the 2010 Maule earthquake, the 2011 Tohoku-Oki earthquake, and the 2012 Indian-Ocean earthquake. I also show the viscosity structure can possibly be even more complex than expected.

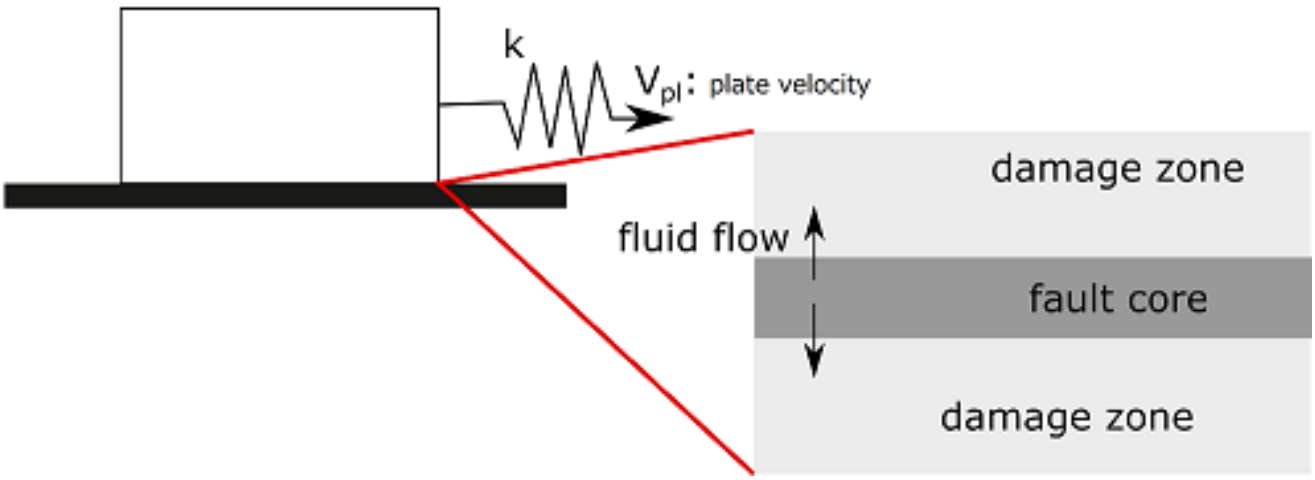
A physical model of tremor response to periodic external stresses in poroelastic medium



*Ryunosuke Sakamoto[1], Yoshiyuki Tanaka[1]

1. University of Tokyo Graduate School of Science

It is known that tectonic tremors are generated by the rupture of small rata-weakening asperities which is caused by slow slip on the surrounding plate interface. In most cases, tectonic tremors occur in areas where the pore fluid pressure is higher. Because high-pressure fluids reduce the effective normal stress significantly, tectonic tremors can be triggered by weak perturbing external stresses such as tidal stresses. Previous studies show that the rate for tremor occurrences exponentially changes [e.g., 1]. Other studies show that the peak of the tremor occurrence rate advances/delays relative to the peak of tidal stresses [2 & 3].So far, no model has been constructed that could explain all of the above observations with realistic fault parameters. Most of tidal response models did not take the presence of pore fluids into account. In this study, we reveal how the pore fluids behave under periodic external stresses by considering fluid pressure change due to dilatancy within fault core (fig) and show that this model could explain the observations reported above [1-3].In addition, we will discuss which kinds of material parameters affect the tidal sensitivity based on our model. Furthermore, we will investigate how the behavior of the system changes under multiple periodic perturbations.

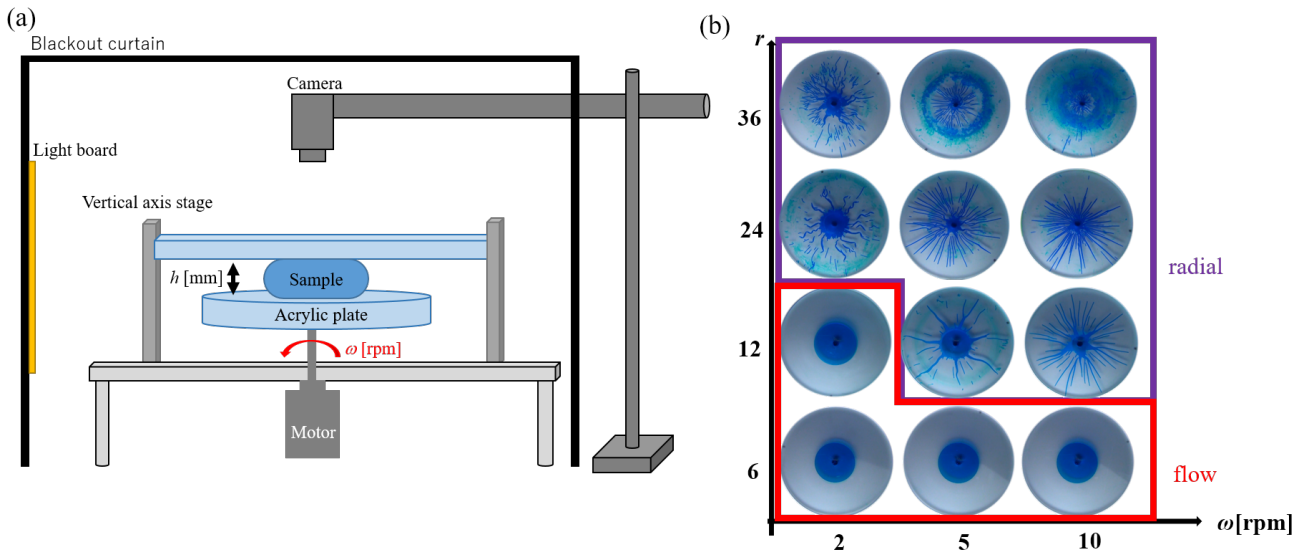
The radial pattern of brittle viscoelastic fluids between rotating parallel plates



*Tatsuya Nishikubo[1], Hiroki Ishikawa[1], Shoma Kato[1], Yutaka Sumino[1]

1. Department of Applied Physics, Faculty of Science Division I, Tokyo University of Science

Slow earthquake occurs at marginal region between seismogenic and steady sliding zones[1]. At the seismogenic zone, a subducting plate can be recognized as brittle elastic solid, whereas the plate can be recognized as ductile viscous liquids at the steady sliding zones. For this reason, we assume that the marginal material behavior, viscoelasticity, can be relevant to general slow earthquakes. Here we report the analogue experimental system with viscoelastic fluids under continuous shear with rotating plates.
As a viscoelastic fluids, we used a gel, which is mixture of micro emulsion with telechelic polymer, so called bridged emulsion. One reason for using this sample for the present experiment is that the gel is known to behave as an ideal Maxwell fluids with single relaxation time under linear oscillatory shear. Another reason for the choice of this gel is, in nonlinear rheological regime, the gel behaves as brittle solid with low fracturing energy at the shear rate higher than the inverse of the relaxation time. The gel is made from the mixture of cetylpyridinium chloride(CPCl), octanol, decane,0.2M NaCl aq, and poly (ethylene glycol) distearate as telechelic polymer, which has hydrophilic main chain with hydrophobic ends[2]. As a parameter, we changed the concentration of bridging telechelic polymer, which determined the shear modulus and relaxation time.
In order to observe long term behavior of sample under shear, we used rotating plates as an experimental geometry as shown in Fig. (a). A plate is rotated with fixed angular velocity on the other plate. The gap between the plates was kept as 1 mm. The angular velocity was used as the other parameter. The typical behavior of the sample is shown in Fig. (b). We found that the sample showed radial pattern when the angular velocity was large enough, whereas the radial pattern is absent for the small angular velocity. This transition of pattern was controlled by the characteristic shear rate which is determined by the relaxation time of the samples. Indeed, we observed the coexistence of flow and the radial patterns when the angular velocity was marginal. Such behavior can be understood due to the liquid and elastic nature of the sample depending on the shear rate.

Offshore surveys of seismic structures and seismicity of regular and low-frequency earthquakes around Amami islands

*Tsutomu Takahashi[1], Ayako Nakanishi[1], Yojiro Yamamoto[1], Yasushi Ishihara[1], Aki Ito[1], Ryuta Arai[1], Seiichi Miura[1], Shuichi Kodaira[1], Yoshiyuki Kaneda[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Kagawa Univ.

Ryukyu arc, southwestern Japan, shows high activities of various slow earthquakes such as slow slip events (e.g., Heki & Kataoka 2008; Nishimura 2014) and shallow low frequency tremors (e.g.,Yamashita et al. 2015). We conducted passive and active source surveys around Amami islands to elucidate detailed activities of regular and slow earthquakes and seismic structures. For the passive source survey, we deployed 30 short-period ocean bottom seismographs (OBSs) and 5 temporal onshore stations at 25~40 km interval. Deployed OBS recorded ground motion from Mar. 2019 to July or Aug. 2019. As a part of active source surveys, we conducted wide-angle OBS and multichannel seismic (MCS) reflection surveys along a survey line between Amami-Oshima and Tokunoshima islands by the R/V Kaimei of Japan Agency for Marine-Earth Science and Technology (JAMSTEC). This survey line is almost perpendicular to the Ryukyu trench. We laid out 30 OBSs at 6km interval along this survey line for the refraction survey.

Seismic data of the passive survey observed many regular earthquakes and several sequences of low frequency earthquakes (LFEs). We relocated a few hundred earthquakes (M>2) listed in the earthquake catalog by the Japan Meteorological Agency (JMA) by using OBS and onshore stations' data. We also estimated epicenters of about 200 LFEs by envelope correlation method. LFEs distribute between Amami islands and Ryukyu trench, and distance from the Ryukyu trench is about 20-80km. One of the LFE sequences locates at off west of the Amami plateau. Source area of this sequence shows relatively high activity of regular earthquakes. While, the source area of another LFE sequence off the southeast of Amami-Oshima island shows quite low activity of regular earthquakes. Our seismic section of active source survey crosses the latter LFE area. MCS reflection data shows strong reflection with negative polarity from the plate boundary beneath this LFE area. This spatial coincidence of reflective plate boundary and LFEs is similar with the southern Ryukyu arc (Arai et al. 2016). Power spectra and duration times of these LFEs are also resemble with those observed at southern Ryukyu arc. Bathymetry of the Philippine sea plate implies different geometrical properties of subducting plate between these two areas. Similarities of LFEs in these areas would become an important constraint for source and structure models at Ryukyu subduction zone.

Acknowledgement: This study is supported by "Research Project for Compound Disaster Mitigation on the Great Earthquakes and Tsunamis around the Nankai Trough Region" of the Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan. We are grateful for Amami-city, Tokunoshima-town, Amagi-town, China-town and Toshima-village for their kind corporation for onshore seismic observations.

Slip distributions of short-term slow slip events in the northern Kii Peninsula based on NIED Hi-net tilt measurements

*Chujo Naoya[1], Hitoshi Hirose[2,1,3], Takeshi Kimura[3]

1. Department of Planetology, Graduate School of Science, Kobe University, 2. Research Center for Urban Safety and Security, Kobe University, 3. National Research Institute for Earth Science and Disaster Resilience

In the southwest Japan subduction zone, short-term slow slip events (SSEs) with nonvolcanic tremor (Episodic Tremor and Slip: ETS, Rogers and Dragert, 2003) which last for several days to weeks occur repeatedly. Because the short-term SSEs occur at the downdip extension of a megathrust earthquake rupture zone, the SSEs are one of the key factors for stress buildup processes of the megathrust earthquakes (e.g., Obara and Kato, 2016)[h1] . Therefore, detailed slip distributions of short-term SSEs are important for understanding the strain accumulation and release at the ETS zone. In the northern Kii Peninsula, short-term SSEs have been detected by[h2] previous studies, but their fault motions have been modeled with uniform slip on a rectangular fault (e.g., Hirose and Obara, 2006).[h3] This may introduce a bias in the estimation of amount of slip.
Here we apply an inversion method which can express a spatial slip distribution to tilt step measurements in the northern Kii Peninsula and estimate detailed slip distributions of nine[h4] short-term SSEs from November 2004 to October 2009. We also discuss the classification of the short-term SSE source areas[h5] by analyzing multiple short-term SSEs in the northern Kii Peninsula.
We used time-series records of a high-sensitivity accelerometer (tiltmeter) installed at NIED Hi-net stations located in the Kii Peninsula and Tokai areas. We applied the BAYTAP-G (Tamura et al., 1991) program together with atmospheric pressure records observed at the Tsu Local Meteorological Observatory to the tilt records in order to remove tidal components and an atmospheric pressure response. We measured a tilt change (tilt step) due to an SSE after detrending. Although tilt steps of the analyzed SSEs have already been determined in previous studies (e.g., Hirose and Obara, 2006; Sekine et al, 2010), we redetermined them from the original tilt records to improve station coverage for an SSE and to obtain a more reliable tilt step dataset. We estimated a slip distribution that explains the tilt step dataset for an SSE by a conventional inversion method by Hirose and Kimura (submitted).
As a result, a spatial slip distribution for a short-term SSE in the northern Kii Peninsula is estimated based on tilt records for the first time. The estimated moment magnitudes of the nine SSEs range from 5.5 to 6.1. The obtained tilt steps, and main locations and magnitudes of the estimated slip are basically consistent with the previous studies (e.g., Hirose and Obara, 2006). A comparison of these slip distributions shows that the slip areas are roughly classified to two groups: one is that the center of a slip distribution is located mainly onshore (corresponding to the Shima Peninsula part of the tremor belt), and the other is that that is located offshore in the Ise Bay area (corresponding to the Ise Bay part of the tremor belt). This suggests that there are two “SSE patch” regions where SSEs of the similar size repeatedly occur on the plate interface.
Longer study period and more comprehensive detection of short-term SSEsmay improve our understandings of the relationship between recurrence intervals and magnitudes of SSEs, and the strain accumulation and release processes in the northern Kii Peninsula.

Trial detection of deep low frequency tremor using analog seismograms of Kanto-Tokai Observation Network in 1988-1990

*Takanori Matsuzawa[1], Tetsuya Takeda[1]

1. National Research Institute for Earth Science and Disaster Resilience

Slow earthquakes (i.e. low frequency tremor (LFT), very low frequency earthquakes and slow slip events (SSEs)) have been vigorously studied since the discovery of deep low frequency tremor (LFT) in the Nankai region (Obara, 2002). However, the past activity of LFT is not clear, as these events were not well known in 20th century and continuous seismic data in this period is rare due to the cost of data storage. Therefore, only analog seismograms are available source to reveal the LFT activity in such period. In terms of the crustal deformation, Kobayashi et al. (2006) revealed the activity of short-term SSEs in the Tokai region since 1984, using a strain meter of JMA. On the other hand, as the data volume of seismic data is much larger than that in geodetic observations, it is not easy to keep the recordings for a long time. Fortunately, NIED has stored the paper recordings of seismograms of the Kanto-Tokai Observation Network, which started since late 1970s. In our previous study, we have reported the tentative result of LFT detection in the Tokai region from 1980 to 1987, using this data (Matsuzawa and Takeda, 2019). In this study, we report the tentative result from 1988 to 1990, in which occurrence of a long-term SSE is reported (Kobayashi and Yoshida, 2004).

We visually examined waveforms at Shimoyama (SMY) seismograph in the Kanto-Tokai Observation Network by NIED, to detect active episodes of LFT, as in our previous study. The waveforms are identified as tremor-like signal lasts for several minutes and is repeatedly found within several days, even if a single station is used. When the number of low frequency signal is small within several hours, we discard the event, as it is not clear whether the signal is caused by a regular earthquake or a small LFT episode. This feature was also confirmed using simulated analog seismogram and current LFT catalog (Matsuzawa and Takeda, 2019). After visual inspection of the waveforms from 1988 to 1990, we found possible LFT episodes, for example, in Apr. 1988, Oct. 1988, Feb. 1989, Oct. 1989, Jun. 1990, and Sept. 1990. In addition, possible triggered tremor by a far field earthquake is found, for example, after an M7.7 earthquake in Philippines on Jul. 16, 1990.

In our studied period, six tremor episodes are detected, while short-term SSEs are reported in Apr. 1988, Oct. 1988, and Oct. 1989, which correspond to our detected episodes. In our previous study, we reported four tremor episodes in 1980-1985, and three episodes in 1986-1987. Combining our new result, our results suggests that tremor was active in 1986-1990. Tremor episode were active in 2003-2004 during a long-term SSE in 2000-2005. The activation of tremor in late 1980s is similar to the activation during a long-term SSE in 2000-2005. However, the active period of tremor precedes the period of the long-term SSE in this case. Therefore, the long-term SSE in late 1980s may start close to the deep LFT region and propagated to shallower part. Further study, including location of tremor episodes, might reveal the details and variety of slip process in long-term SSE events.

Estimation of the spatial distribution of Qs values beneath the Kii Peninsula, Japan by the twofold spectral ratio method

*Kodai Sagae[1], Hisashi Nakahara[1], Takeshi Nishimura[1], Kazutoshi Imanishi[2]

1. Solid Earth Physics Laboratory,Department of Geophysics,Graduate School of Science,Tohoku University, 2. National Institute of Advanced Industrial Science and Technology (AIST)

Evaluation of radiation energies of tremors is important to understand the generation mechanism. Previous studies estimated the radiation energy assuming a spatially uniform S-wave attenuation quality factor, Qs value, over the area of interest (e.g. Maeda and Obara, 2009). However, when we discuss a regionality of the tremor generation, the spatial changes of Qs values are important. The objective of this study is to estimate the spatial distribution of Qs values beneath the Kii Peninsula by using the twofold spectrum ratio method (e.g. Matsuzawa et al., 1989).

We use a dense seismic array (39 three-component velocity sensors, array aperture:1.5 km) installed by AIST at the Kii Peninsula. We also use seismograms recorded at a Hi-net station (N.HYSH) that is located close to the seismic array. We analyze the data for 2 years from July 2012 to July 2014, referring to the tremor catalog determined by Sagae et al. (2019 JpGU) in which 27,066 events are listed for the 2 years. For tremors recorded at the stations, we calculate velocity amplitude spectra and estimate their slopes at a frequency range of 2.0-4.0 Hz. Outliers are removed by setting a threshold of 4.4 times Median Absolute Deviation of the spectral slopes at each station. Totally, 18,330 events are selected for the following analysis.

We create horizontal blocks of 0.1×0.1˚ within a region of 136˚E to 137˚E and 34˚N to 35˚N. The twofold spectral ratio method is applied when the number of tremor events in a block is more than 100. We calculate twofold spectral ratios for two events locating in the block, when their separations are more than 5 km. Qs value is estimated by the twofold spectral ratio method. In this method, a logarithm of a twofold spectral ratio that is corrected for the geometrical spreading (log TSR) is linearly proportional to a twofold differential travel time (TDTT); The slopes is $-\pi f/Qs$, and an intercept is a term about the radiation pattern. However, the intercept is expected to be close to 0 when focal mechanisms of tremors occurring in a block are similar. At each narrow frequency band (2.0-4.0 Hz, 2.8-5.6 Hz, 4.0-8.0 Hz), we assume that Qs value of the structure along the ray paths from hypocenters to the seismic array and the Hi-net station is constant. Then, we estimate the slope ($-\pi/Qs$) and the intercept at each frequency band.

Estimated Qs values are summarized as follows; Qs values are in a range of 63-458, 58-896, and 66-2044 at 2.0-4.0 Hz, 2.8-5.6 Hz, and 4-8 Hz, respectively. Qs values estimated at the high frequency band tend to be larger. However, at the high frequency band, the number of blocks for which the Qs value is estimated to be a negative value increases. The intercepts are confirmed to be close to 0 (-0.03 ~ 0.008) in blocks for which Qs values are estimated to be a positive. This suggests that focal mechanisms of tremors occurring within the same block are similar.

3-D thermal modeling of generation mechanisms for short-term slow slip events and low-frequency earthquakes along the Ryukyu trench

*Nobuaki Suenaga[1], Shoichi Yoshioka[1,2]

1. Research Center for Urban Safety and Security, Kobe University, 2. Department of Planetology, Graduate School of Science, Kobe University

Interplate seismicity, such as short-term slow slip events (S-SSEs) and low-frequency earthquakes (LFEs), has been identified in the Ryukyu Trench, southwest Japan. As one of the specific characteristics of these events, the depths where S-SSEs take place at the plate interface beneath Okinawa Island are approximately 10 km shallower than those beneath the Yaeyama Islands. In this study, we constructed a three-dimensional parallelepiped thermal convection model associated with subduction of the Philippine Sea (PHS) plate beneath the Amurian (AM) plate at the Ryukyu subduction zone. We applied the subduction history of the PHS plate in the model region, referring to the plate rotation model and the trench motion model. Then, we performed a time-dependent numerical simulation for the last 15 Myr to elucidate the relationships among the calculated thermal structure, dehydration from the subducting plate, and interplate seismic events. To constrain the calculated thermal structure, we used observed heat flow data. As a result, the interplate temperatures where S-SSEs occur are estimated to range from 350℃ to 450℃ beneath both Okinawa Island and the Yaeyama Islands, although the latter are approximately 50-100℃ higher than the former. This temperature range corresponds well with that of the transition zone from unstable sliding to stable sliding. On the other hand, LFEs occur in a temperature range of 300 to 400℃ beneath both Okinawa Island and the Yaeyama Islands in our model, which is roughly within the temperature range of the transition zone, although it is approximately 50℃ lower than that in the region where S-SSEs occur. Using phase diagrams for hydrous minerals of the oceanic crust and the slab mantle, we estimated the water content distribution and dehydration gradient per unit distance in the subduction direction of the PHS plate. Near the S-SSE fault planes, a dehydration gradient of 0.05 wt%/km is identified beneath Okinawa Island associated with the phase transformation from blueschist to lawsonite blueschist within hydrous minerals of the oceanic crust. In contrast, dehydration gradients of 0.13 wt%/km and 0.12 wt%/km are identified beneath the Yaeyama Islands associated with the phase transformation from lawsonite blueschist to amphibole eclogite within the oceanic crust and from brucite to antigorite within the slab mantle, respectively. Further, there are no specific dehydration gradients in the LFE occurrence region beneath both Okinawa Island and the Yaeyama Islands in our model, although there is a possibility that dehydration fluid materials in the S-SSE occurrence region are transported to the LFE occurrence region, considering the migration feature of LFEs and the synchronicity of activity between S-SSEs and LFEs. Therefore, we conclude that both the interplate temperature and dehydration gradient play key roles in the occurrences of S-SSEs and LFEs and that the larger dehydration gradient beneath Yaeyama Island than beneath Okinawa Island is the main reason for the depth difference in S-SSEs.

Spatio-temporal evolution of long- and short-term slow slip events in the Tokai region, central Japan estimated from a very dense GNSS network, during 1997-2017

*Hiromu Sakaue[1], Takuya NISHIMURA[2], Jun'ichi Fukuda[3], Teruyuki Kato[4]

1. Graduate School of Science, Kyoto University, 2. Disaster Prevention Research Institute Kyoto University, 3. Earthquake Research Institute,The University of Tokyo, 4. Hot Springs Research Institute of Kanagawa Prefectural Government

We analyzed Global Navigation Satellite System (GNSS) data from 1997 to 2017 for the Tokai region of tne Nankai subduction zone, in order to investigate long- and short-term slow slip events (SSEs) on the subduction interface. The GIPSY-OASIS II software (version 6.1) was used to estimate daily coordinates of continuous GNSS stations operated by GSI and temporary GNSS stations operated by JUNCO (the Japanese University Consortium for GPS Research). It is well known that GNSS time series have many systematic signals and noises that do not result from SSEs. They include, for example, seasonal variations, co- and post-seismic deformation of the 2004 southeast off Kii Peninsula earthquakes (M_j 7.1/7.4), the 2008 Ibaraki-ken-oki earthquake (M_j 7.0), the 2008 Fukushima-ken-oki earthquake (M_j 6.9), the 2010 Fukushima-ken-oki earthquake (M_j 6.7), and the 2011 Tohoku-oki earthquake (M_w 9.0), and crustal deformation of volcanic activity on the northern Izu Islands in 2000. After removing them, we applied a modified Network Inversion Filter (NIF) [Fukuda et al., 2008] to estimate daily slip and slip rate on the subduction plate interface. Our results showed a long-term SSE from 2000 to 2005 involved two slip phases/subevents. The slip peak of the first phase was estimated at a depth of 20 km from the end of 2000 to the end of 2001. Another long-term slow slip with slower slip rates was estimated around this slip peak from 2013 to 2015. The slip peak of the second phase estimated at a depth of 30 km from the end of 2002 to the beginning of 2005. The slip area of the second phase was extended/migrated to the down-dip tremor area, and the recurrence period of tremor became short during this period. Our results show spatio-temporal distribution for not only those long-term SSEs in 2000-2005 and 2013-2015, but also short-term SSEs (M_w <6.1). The maximum estimated daily slip rates for short-term SSEs are an order of magnitude larger than those of the long-term SSE, and peak slip for short-term SSEs migrates along strike with LFTs synchronously.

Repeating activity of shallow low-frequency tremor in Hyuga-nada

*Yusuke Yamashita[1], Masanao Shinohara[2], Hiroko Sugioka[3], Aki Ito[4], Tsutomu Takahashi[4], Daisuke Suetsugu[4]

1. Disaster Prevention Research Institute, Kyoto University, 2. Earthquake Research Institute, the University of Tokyo, 3. Graduate School of Science, Kobe University, 4. Japan Agency for Marine-Earth Science and Technology

In the Hyuga-nada region, since the first observation of shallow tremor in 2013, ocean bottom seismological observations have been carried out in the focal area of the shallow tremor since 2014. From March 2017, ocean bottom seismological and geodetical observation have been conducted by the "Science of Slow Earthquakes", JSPS KAKENHI Grant-in-Aid for Scientific Research on Innovative Area, MEXT, Japan. During the first observation period, the ocean bottom seismometers (OBSs) were retrieved from January to February 2019, and good seismic records were obtained. From December 2017 to January 2018 during the observation period, shallow slow earthquake activity was documented from off east Tanegashima Island to Hyuga-nada, and shallow tremors and VLFE activity were recorded on the OBS network. The epicenter of shallow tremor was determined by almost same method as Yamashita *et al*. [2015]. The depth of the tremor source was fixed to the plate boundary model by Nakanishi *et al*. [2018], and the S-wave velocity structure was a uniform structure of Vs = 3.5km/s. For the analysis, the hypocenter was determined by a total of 18 OBSs, including 10 OBSs from another project (the research project for compound disaster mitigation on the great earthquakes and tsunami around the Nankai trough region, the MEXT of Japan) that had been conducting observations in the off east Tanegashima Island at the same time. As a result of the hypocenter determination, it was found that the epicenter distribution of shallow tremor almost coincided with the focal area up to the point where the epicenter distribution turned eastward in the area of the 2013 activity. This distribution is consistent with the first migration area of the two migrations seen in the 2013 activity. In the 2017-2018 activity, a clear migration from south to north direction was confirmed and the end point of the migration are almost the same as the first migration in the 2013 activity. The region where the migration has stopped is considered to be the region where the Kyushu Palau Ridge is subducted. According to the estimation results of the released seismic energy rate by Watanabe [2019], it is located in the region where the released seismic energy rate is relatively low. It is suggested that the heterogeneity of the structure around the plate boundary greatly affects the tremor activity region and the generation process of the shallow tremor. Our new result of the almost same hypocenter distribution and activity characteristics as in 2013, it has become clear for the first time that the shallow tremor activity occurs repeatedly in the same place and has similar activity characteristics in this region. Although no significant pressure change has been observed by ocean bottom pressure gauges at this moment and the expected short-term slow slip event has not been directly observed, its size was assumed to be not larger than Mw~6. The all equipment for second observation will be retrieved from spring to summer 2020.

Acknowledgments: This study is supported by the JSPS KAKENHI Grant Number JP16H06471, JP17K01328, and the research project for compound disaster mitigation on the great earthquakes and tsunami around the Nankai trough region, the MEXT of Japan.

Shallow low-frequency tremor in the Japan Trench subduction zone

*Sachiko Tanaka[1], Takanori Matsuzawa[1], Youichi Asano[1]

1. National Research Institute for Earth Science and Disaster Resilience

In the regions off Tokachi and Sanriku, we have identified shallow low-frequency tremor using the records from the Seafloor observation network for earthquakes and tsunamis along the Japan Trench, S-net (Tanaka et al., 2019). It occurs between the 10- and 25-km depth contours of the plate interface, and its characteristics including duration (half a day to a few weeks) and recurrence time (one month to one year) vary with location along the trench. In the present study, we extend our analysis to a wider offshore area from Hokkaido to Boso Peninsula. The data we used are the continuous three-component velocity seismograms recorded at 125 S-net stations (S1-S5) for the period from 2017 to 2019. We constructed root mean square (RMS) envelopes of the seismograms band-pass filtered between 2 and 10 Hz, and searched tremor sources every one minute using overlapping two-minute time windows by the method of Tanaka et al. (2019) based on an envelope correlation analysis (Obara, 2002) and an event clustering scheme (Frohlich and Davis, 1990). In addition to the regions off Tokachi and Sanriku, clusters of tremor were located in the regions off Fukushima and Ibaraki. These clusters also lie within a narrow zone between the 10- and 25-km depth contours of the plate interface. As is the case with the tremor off Tokachi and Sanriku, the tremor off Fukushima occurs at similar locations to the very low frequency (VLF) earthquakes detected using seismic data from onshore networks (Matsuzawa et al., 2015). About 20 episodes of tremor were observed in this region, and some were coincident with the VLF earthquakes. In the region off Ibaraki, tremor episodes were detected less frequently (six in the three years), with each lasting for half a day to a day, although these were located in a smaller area than previously reported by Nishikawa et al. (2019). On the other hand, no tremor was found in the large slip area of the 2011 Mw 9.0 Tohoku earthquake as was shown by Nishikawa et al. (2019). The locations of tremor and the variations of its properties show strong lateral heterogeneities of the slip behavior at the shallow plate interface in the Japan Trench subduction zone.

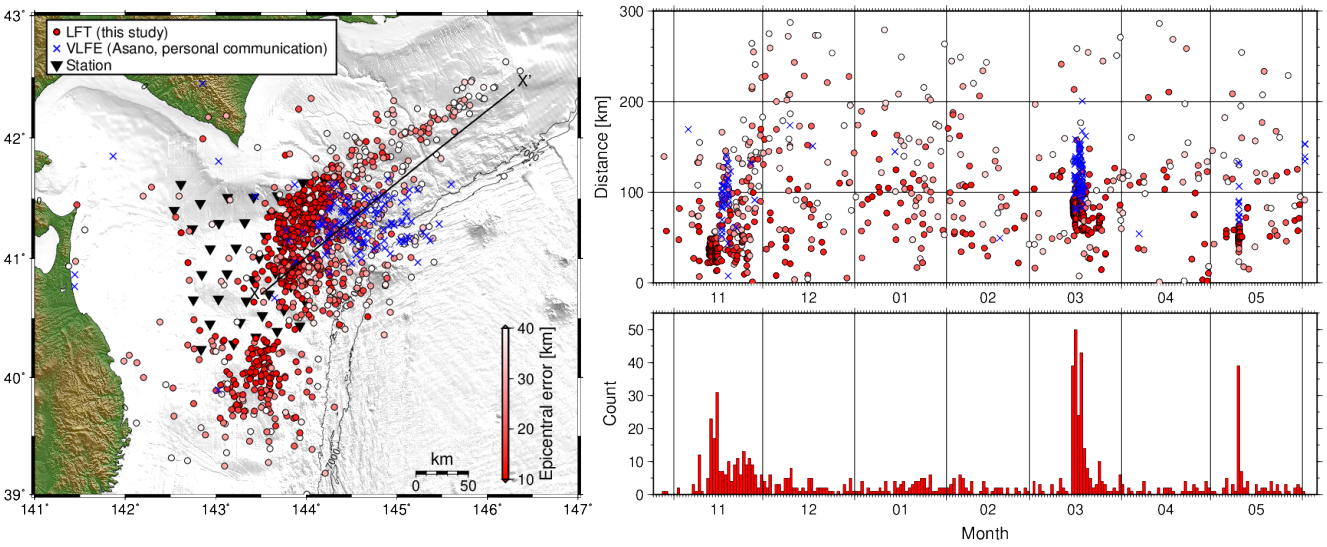
Shallow low-frequency tremor activity off Erimo, Hokkaido from 2006 to 2007 revealed from pop-up type ocean bottom seismometers

*Susumu Kawakubo[1], Ryosuke Azuma[1], Ryota Hino[1], Hidenobu Takahashi[1], Kazuaki Ohta[2], Masanao Shinohara[3]

1. Graduate School of Science, Tohoku University, 2. National Research Institute for Earth Science and Disaster Resilience, 3. Earthquake Research Institute, University of Tokyo

The shallow part of the plate boundary around the Kuril and Japan Trench junction, off Erimo, Hokkaido, is known as the place where slow earthquakes are comparatively active along the Japan island arc. In this region, VLFEs (Very Low Frequency Earthquakes) have been observed since the 2003 Tokachi-Oki Earthquake (Asano et al., 2008). On the other hand, LFTs (Low Frequency Tremors) were firstly discovered in 2016 based on the inspection of the seismograms obtained by the Seafloor observation network for earthquakes and tsunamis along Japan Trench (S-net) (Tanaka et al., 2019; Nishikawa et al., 2019). One of the important discoveries by the S-net is that the LFT activity off Erimo usually precede the VLFE activity by 0.5–4 days (Tanaka et al., 2019). The correlation between the LFTs and VLFEs persistence of the VLFEs activity before and after the 2011 Tohoku-oki Earthquake (Asano et al., 2008; Tanaka et al., 2019), it is expected that the LFT activity would exist before the S-net deployment and before the occurrence of the 2011 Tohoku-oki earthquake off Erimo region. This study aims to clarify the LFT activity in the region by analyzing the OBS records obtained in the development from 2006 to 2007.



In this study, we detect LFTs from the records of 42 pop-up type ocean bottom seismometers from October 25, 2006 to June 5, 2007. For detection of seismic events and determination of their hypocenters, we use the envelope correlation method (Ide, 2010). We defined an event as an earthquake if a maximum cross-correlation (CC) value exceeds 0.6 for more than 10 station-pairs. Then, we determined its hypocenter by using lag-times maximizing the CCs at the station pairs, as arrival time difference of S-waves from the source. For discrimination of LFTs from other type of events, we selected events with duration larger than 20 sec and of magnitude less than 3 as LFTs. After the first screening, we excluded the events having large epicenter errors and large time residuals. As a result, 989 LFTs were identified out of 10,445 events firstly detected. The detected LFTs were distributed at a certain distance from the trench axis and the LFTs with focal depth errors less than 10 km are distributed near the plate boundary.

During the analysis period, we found three major LFTs activities with VLFEs activities. During the first period (2006/11/12–19), the LFTs activity showed migration towards northeast by 16–23 km/day though detectivity of LFTs may be degraded by the pronounced aftershocks following the middle Kuril Trench earthquake on November 15, 2006. The LFTs during the second period (2007/3/15–19) also migrated but was directed towards southwest by 25–30 km/day. On the other hand, the last activity occurred in the narrower area than others and converged just one day on May 10, 2007, and the migration like previous periods was not recognized.

We found that every LFT swarm activity preceded the known VLFEs (Asano et al., 2008). The VLFEs detected 0.5–4.5 days after the onset of the LFTs swarm occasion. Similar relationship between the LFT and the VLFEs is reported for the current activities in the region (Tanaka et al., 2019). The locations of the swarm almost coincide with the LFT distribution located by the S-net data (Nishikawa et al., 2019). These common points between the LFT/VLFE activities at present and in 2006-2007 indicate that the shallow plate boundary off Erimo does not change in their behavior in terms of the slow-slip activity through the period containing the 2011 Tohoku-oki earthquake happened.

High-velocity frictional behavior of fault gouges in the presence of pore fluid

*Akito Tsutsumi[1]

1. Graduate School of Science, Kyoto University

Recent observations of slow earthquakes in the vicinity of high pore-fluid pressure suggest that variation in pore-fluid pressure plays a role in the underlying mechanism of the slow earthquakes. However, little is known of the frictional properties of subduction-zone materials in the presence of pore-fluids. To study the effect of pore-fluid on the seismic faulting process in subduction-zones, we performed friction experiments on the sediments entering to the Costa Rica subduction zone. Rotary-shear friction experiments were conducted on the input biogenic ooze material collected at reference sites U1381A during IODP Exp. 334 (Vannucchi et al., 2012) at normal stresses of 2.0–5.0 MPa and at various slip velocities V of 0.3–130 mm/s. The collected samples were oven dried at 60 degree Celsius for 24 hours, and gently disaggregated using a pestle to be used as the experimental gouges. We prepared two types of experimental conditions: impermeable and permeable conditions. Impermeable conditions consist of a pair of gabbro cylinders (25.0 mm in diameter) with an intervening thin layer of gouge (0.5 g). For permeable conditions we used a permeable sandstone (Berrea sandstone) instead of using gabbro for one side of the rock-cylinder pair. On both permeability conditions, distilled water (0.8–1.0 ml) was added to prepare pore-fluid saturated condition of the gouge initially. Under impermeable conditions, experiments performed at higher slip velocities (>3 mm/s) show a dramatic decrease in frictional coefficient values upon the initial shear loading. The value of the friction is as high as ~0.6 at the onset of sliding, following which it rapidly decreases to attain a value as low as ~0.1. The decreased friction value is constant at the lowered level for duration of slip as long as 100s, then it increases gradually to attain roughly steady-state value of ~0.6. Under permeable conditions, such a dramatic decrease and the following increase in frictional strength is not observed. The frictional behavior of the gouges under permeable conditions is similar to the behavior observed at the lowest slip velocity (0.3 mm/s) under impermeable conditions when friction is plotted against elapsed time. We suggest that the slip weakening and the following strengthening behavior observed at high velocity test under impermeable conditions is likely attributed to a transient change in fluid pressure inside of the fault zone during the shearing of the gouge. Magnitude of the pore-fluid pressure change should depend on the degree of pore-space change and the compressibility of the fluid filled gouge material. The experimental results suggest importance of studying how pore-fluid pressure evolves during faulting process to understand the frictional behavior of faults in subduction zones.

Detection of low-frequency aftershocks of the 2019 Ridgecrest earthquake sequence

*Ayako Tsuchiyama[1], Taka'aki Taira[2], Junichi Nakajima[1], Roland Bürgmann[3]

1. Earth and Planetary Sciences at Tokyo Institute of Technology, 2. Berkeley Seismological Laboratory, 3. Earth and Planetary Science, University of California, Berkeley

Low-frequency earthquakes generally have relatively stronger spectral components in the lower frequency range, compared to what is expected based on their magnitude. This type of earthquakes has been considered to be generated in some specific environments, such as volcanic regions and subduction zones that are also generating slow slip events and tremors. They usually occur in deeper regions below ~15km; however, some recent studies show that they can also be observed among aftershocks of large inland earthquakes in Japan (i.e., Niigata in 2004, Iwate-Miyagi in 2008, Kumamoto in 2016) with very shallow depth (~5km). Here, we attempt to detect such ‘low frequency aftershocks’ associated with a very recent earthquake sequence that occurred in Ridgecrest in California in 2019 on the source of waveform data from Plate Boundary Observatory Borehole Networks and nearby instruments archived at NCEDC, SCEDC and IRIS. We are considering The Frequency Index (FI) as a way to identify candidate events. FI is defined as: FI = log10(AH/AL), where AH and AL represent the mean spectral amplitude within the high-frequency band (e.g., 10-15 Hz) and low-frequency band (e.g., 2-5 Hz), respectively. We will discuss our results and the methods used to identify low frequency aftershocks from their spectra.

Structural characteristics of the Nankai trough subduction zone off Kii channel revealed from densely obtained seismic reflection profiles

*Yasuyuki Nakamura[1], Shuichi Kodaira[1], Tetsuo No[1], Yuka Kaiho[1], Kazuya Shiraishi[1], Gou Fujie[1], Seiichi Miura[1], Koichiro Obana[1]

1. Japan Agency for Marine Earth Science and Technology

Shallow very low frequency events (SVLFEs) activity has been recently investigated using offshore and onshore stations in the Nankai Trough. SVLFEs have been active off the Kumano basin, off Kii channel and Cape Muroto, but not active off the western Kii peninsula. To explore possible structural factors relevant to the SVLFE activity, we conducted seismic surveys in the Nankai trough between off Cape Shionomisaki and Cape Muroto. Two seismic reflection surveys were conducted in November –December 2018 and December 2019 –January 2020 using R/V Kaimei and R/V Kairei. In total, 44 seismic reflection profiles across the trough axis were acquired with 4km separation. In addition, eight profiles along the trough axis were obtained. Pre-stack time migrated profiles from the data collected in the 2018 survey and post-stack time migrated profiles from the data obtained in the 2019 –2020 survey were interpreted to map the structural features, e.g., top of the subducting oceanic crust, decollement, thrust faults. We observed the thickness of the sediments above the subducting oceanic crust is constant along the trough axis in the shallow most part of the Nankai subduction zone off the western Kii peninsula, where the SVLFE activity has been low. On the other hand, the thickness is variable off the Kii channel to Cape Muroto, where the SVLFE activity has been reported. The variation could be originated from the past subduction of the seamount and could be related to the local undulation of the subducting oceanic crust. Interpreted decollement in the shallow megathrust has positive polarity off the western Kii peninsula but shows negative off western Kii channel to Cape Muroto. We also recognized that the depth of the subducting oceanic crust could be greater in the landward portion of the survey area off the western Kii peninsula. Another local deep part of the subducting oceanic crust was detected around 32.7˚N, 135˚E where the SVLFE activity was reported to be lower.

Long-Term Activity Changes of Very Low Frequency Earthquakes in the Ryukyu Trench

*Mamoru Nakamura[1]

1. Faculty of Science, University of the Ryukyus

Very-low frequency earthquakes (VLFEs) have been occurring regularly along the Ryukyu Trench. Their activities are concentrated in the south of the Yaeyama Islands, off the south of Okinawa Island, and near Amami Island. The VLFEs occur every two to three months in each region. A single activity lasts about 1 to 3 days. Although there are several clusters of activities between Miyako Island and Okinawa Island, the activity of the VLFEs is low in this region. The long-term variation of the activity of VLFEs in the plate interface reflects the temporal variation of the degree of strain accumulation and strain release in the plate interface. Therefore, I investigated the long-term changes in the activity of VLFEs in each region. The data are based on the VLFEs catalog obtained by the method denoted by Nakamura and Sunagawa (2015). The arrival time of maximum amplitude of the VLFE was picked from the vertical waveform with a bandpass filter of 0.02-0.05 Hz, and the epicenter was determined using the arrival time of the maximum amplitude at each seismic station. The VLFEs whose magnitudes were 3.5 were used in the analysis. The used period is from 2002 to 2019.

As a result, the activity of the VLFE in the Yaeyama Islands has been gradually decreasing since 2002. In the Yaeyama Islands, a series of M_J 7.0 (March 26, 2002) and M_J 6.9 (March 31, 2002) inter-plate earthquakes occurred in 2002, and seismic activity with magnitudes of 6.0 or more temporarily increased in 2002. The changes in the regular earthquakes activity and VLFE activity would reflect the process in which the strain in the plate interface is temporarily partially released due to the change in the coupling rate at the plate interface in the southwestern part of the Ryukyu Trench.

On the other hand, in the vicinity of Okinawa Island, the activity of the VLFEs has been rapidly increasing since 2015. On the other hand, there was no increase in activities around Amami-Oshima Island during this period. During this period, earthquake swarms occurred in the subducting slab near the trench axis of the central Ryukyu Trench. This suggests that the change of the activity of the VLFEs and seismicity would reflect the release of the strain with the progress of the slow earthquake on the plate interface.

Seismic Velocity Mapping of the Plate Boundary Structures in the Slow Earthquake Gap Zone off Western Kii Peninsula, Nankai Trough

*Yanfang Qin[1], Gou Fujie[1], Shuichi Kodaira[1], Yasuyuki Nakamura[1], Yuka Kaiho[1], Tetsuo No[1], Koichiro Obana[1], Seiichi Miura[1]

1. JAMSTEC Japan Agency for Marine-Earth Science and Technology

Recently many slow earthquakes have been observed along the Nankai trough subduction zone, where the Philippine Sea plate underthrusts the Amur plate. These events show along strike variations, especially in the central part of the Nankai trough, they were observed off Kii channel and Shinomisaki, but not reported in the area between them, off western Kii peninsula. Slow earthquakes are considered to be the key to understand the nature of subducting plate boundary and its seismic coupling. In November and December 2018, an active source seismic survey was conducted by the Japan Agency for Marine-Earth Science and Technology (JAMSTEC) using R/V KAIMEI in Nankai subduction zone off Kii channel to Shonomisaki to investigate the structural features and its possible relationship to the slow events.

The cruise carried out 34 dense gridded multichannel seismic (MCS) reflection profiles to obtain a 3D overview of the fault distribution and deformation of the sediments. At the same time, a 2D refraction seismic survey was also implemented, with air gun shooting at the interval of 100 m, recorded by 96 high resolution ocean bottom seismometers (OBS) that were spaced 1 km apart, covered from the seaward side of the subduction trench to the accretionary prism. The data quality is good and we can trace first arrivals up to ~80 km, it allow us to reveal seismic velocity structure within the overlying plate and the crust of the subducting plate. We applied travel time tomography to the OBS data, the seismic velocity and seismic reflection image show the depth of décollement and the volume of materials between dé collement and the top of oceanic crust are diverse from Kumano area (e.g., Park et al, 2010; Kamei et al. 2013), where there are many slow earthquakes occurred. On the other hand, the toe of the accretionary prism is more homogeneous than that in the Kumano Basin, which could be due to the topography of the subducting oceanic crust, leading to different seismogenic structures.

Distribution of very low-frequency earthquakes in the Miyako Strait, central Ryukyu Trench

*Hiromu Furugen[1], Mamoru Nakamura[1]

1. Graduate School of Engineering and Sience, Univercity of the Ryukyus

Very low-frequency earthquake (VLFE) constantly occur in the Ryukyu Trench. This activity is low in the region where the mega-tsunami occurred in the past (Nakamura and Sunagawa, 2015), which suggests that the activity would correlate inversely to the occurrence of large earthquakes. The VLFEs also occur in the Miyako Strait, which is between Okinawa Island and Miyako Island. The VLFE activity in this region is low and their distribution is scattered. However, the detection ability of the VLFE in this region would be low because this area is far from the F-net stations of the NIED, and also the error of epicentral determination would be large. In this study, we conducted epicentral determination of the VLFEs including the data of temporary stations in order to reveal where the VLFEs occur in this region.

As a waveform of the broadband earthquake, we used the F-net stations of the NIED and the temporary stations (Hateruma, Tarama, Miyako, Kume, and Okinoerabu) which were set by Association for The Development of Earthquake Prediction (ADEP). The waveforms were band-pass filtered at the frequency range of 0.05–0.1Hz for seismogram of top and bottom, using the Seismic Analysis Code (SAC). Next, we searched the VLFE swarms which occurred between the Okinawa island to Miyako island from the VLFE catalog that is computed for the method of (Nakamura and Sunagawa, 2015), and we adopted the most remarkable events to the template. Next, we conducted the detection of the VLFE swarms which occurred in 5 October 2017 and epicentral determination.

Three VLFE events were detected and their hypocenters were determined during this period. The epicenters were located near 25.227N and 126.415E with a radius approximately 20 km. This position is almost the same as that obtained by Nakamura and Sunagawa (2015) and is distributed within a narrower area compared with the results of Nakamura and Sunagawa (2015). Although the accuracy of the location from the trench is poor because the seismic stations are parallel to the island arc, it indicates that the cluster of the VLFE in the region occur in a narrow area.

Spatiotemporal evolution of interplate slip in the Hyuganada and the Bungo Channel from 1996 to 2000 based on GNSS data

*Sawako Teshiba[1], Hitoshi Hirose[1,2]

1. Department of Planetology, Graduate School of Science, Kobe university, 2. Research Center for Urban Safety and Security, Kobe University

The Philippine Sea plate is subducting beneath the Amurian plate along the Nankai trough in southwestern Japan. In the western end of this area, the Bungo Channel and Hyuganada, it is known that afterslip and slow slip events (SSEs) occur on the plate interface. For example, in the Hyuganada region, afterslip follows two M 6.7 earthquakes in 1996 (e.g., Yagi et al., 2001) and repeating SSEs occur in the afterslip area (Yarai and Ozawa 2013), and SSEs repeatedly occur in the Bungo Channel (e.g., Hirose et al., 1999). Previous studies analyzed spatial and temporal slip history of a part of these events. For example, Yagi et al. (2001) showed the spatial slip distribution of the afterslip and Ozawa et al. (2007) studied the afterslip and an SSE around the Bungo Channel around 1997. However, few studies estimate the spatiotemporal slip history in the entire region between 1996 and 2000, the time period for which these slip events took place. Therefore, the purpose of this study is to estimate aseismic slip evolution in Hyuganada and the Bungo Channel , and to propose the occurrence of an SSE in 1998 in the afterslip area.

We use daily coordinates of GEONET GNSS stations processed by Geospatial Information Authority of Japan (GSI) (F3 solutions; Nakagawa et al., 2009). Coordinate time-series data at 47 stations in Kyusyu, Shikoku and Chugoku areas for the period between September 1, 1996, and June 1, 2000 are analyzed. We estimate a common-mode time-series that is calculated by 21 stations for the same period to remove noise of 47 stations. After remove common-mode, a secular liner component of these stations estimated by the period from October 1, 1998 to June 1, 2000, coseismic jumps and artificial steps caused by station maintenances are removed from these stations. We assume a geometry of the plate interface on the subducting Philippine Sea plate estimated by Shiomi et al. (2008) and Nakanishi et al. (2018), and the interface geometry is represented by 11 ×21 small square subfaults whose area is 13 ×13 *km2* for each. We apply a time-dependent inversion method (Hirose et al., 2014) to the preprocessed data to estimate a spatiotemporal slip evolution on the plate interface.

Three slip events are resolved. First event is a slip around Hyuganada started from around September 1996 and continued to October 1997. Second event is a slip around Bungo Channel continued from around January, 1997 to March, 1998. Third event is a slip around Hyuganada continued from around May in 1998 to March in 1999. First event corresponds to the afterslip of the two Hyuganada earthquakes. However, although the first earthquake in Hyuganada occurred on October 19, 1996, this event began from around September 1996. Probably, this is because the inversion contains temporal smoothness. Second event corresponds to the 1997 Bungo Channel SSE. We can divide the slip into three region spatially that are southwestern Shikoku, northeastern Bungo Channel and southwestern Bungo Cannel, because the slip distribution and the development of seismic moment show migrations of SSE two times. Seismic moment of the slip around southwestern Shikoku increased from around January to April in 1997, and the slip migrated to southwest after April. The slip around northeastern Bungo Channel started from around May in 1997 and seismic moment continued to increase until around November in 1997. The slip of this region expanded and migrated to southwest for the period of increasing seismic moment. Seismic moment of the slip around southwestern Bungo Cannel increased for

©2020. Japan Geoscience Union. All Right Reserved.

the period between around September and December in 1997. Third event is smaller area than the afterslip of Hyuganada in 1996 but almost same location. The slip of this event is about 10cm. Seismic moment of the slip is 6.0×10^{18} N/m (Mw=6.5). Yarai and Ozawa (2013) detected repeating SSEs in this region after 2005, hence the detected slip in 1998 is a likely predecessor of the Hyuganada SSEs.

We estimate the spatiotemporal evolution of aseismic slip in Hyuganada and the Bungo Channel, especially the afterslip of the two Hyuganada earthquakes and the Bungo Channel SSE in 1997 and an SSE in the afterslip area. We found that (1) slip migrations of the Bungo Channel SSE two times; and (2) an SSE occurrence in 1998, which is a predecessor of the reported Hyuganada SSEs after 2005 (Yarai and Ozawa, 2013).

An estimation of stress changes based on earthquake swarm seismicity accompanied by Boso slow slip events

*Tomoki Ukawa[1], Hitoshi Hirose[2,1]

1. Department of Planetology, Graduate School of Science, 2. Research Center for Urban Safety and Security, Kobe University

In off the coast of Boso peninsula, the occurrence of slow slip events (SSEs) are reported (e.g., Ozawa et al., 2003). SSE does not cause seismic motion and tsunami in itself, but in the northern part of the SSE area, earthquake swarm activity arises concurrently with SSE. A previous study stated that earthquake swarm were triggered by SSE (Hirose et al., 2014), so it is expected that an SSE affects a stress field in the area of earthquake swarm, but the quantitative relationship is poorly known. In this study, we estimate a stress change before and after each of the Boso SSEs by using the method of Dieterich et al. (2000) based on seismicity rate of the earthquake swarm.

We used JMA unified Hypocenter catalog from 1997/10/01 to 2015/12/31. And analysis domain in this study was approximately 60 km×60 km square and depth of 10 km~35 km. This domain contains almost entire areas of the earthquake swarm areas accompanied by the Boso SSEs. Because there was a possibility that detection ability of earthquakes have changed during the analysis periods, we assessed a completeness magnitude, and we selected earthquakes larger than or equal to M1.5.

To calculate the time series of stress changes, we applied seismicity rates to the equation (3) in Dieterich et al. (2000). The values of parameters required to the calculation are set as follows ;

A, a dimensionless fault constitutive parameter, is 0.005, that is the value used in Dieterich et al., 2000; normal stress is 340 MPa, that equals to the overburden pressure less hydrostatic pore-fluid pressure in a depth of 20 km; reference stressing rate is 0.05 MPa/yr . That was calculated under the assumption that the amount of one SSE’s stress drop (Hirose et al., 2012) was recovered in an average SSE’s recurrence interval. r , steady-state seismicity rate at the reference stressing rate, is 0.123 /day, we assume the seismicity is in steady-state from 2003/1/1 to 2006/12/31.

Consequently, stress changes in the SSEs, 2002SSE, 2007SSE, 2011SSE, and 2014SSE were +0.1 MPa, +0.5MPa, +0.5MPa, -0.7MPa, respectively. Their interval were changed 77mo.→58mo(2002SSE), 58mo.→50mo. (2007SSE), 50mo.→26mo.(2011SSE), and 26mo.→54mo. (2014SSE). That is the recurrence interval was shorten in cases with a positive stress change, and prolonged in negative stress change’s case. In the cases of 2002SSE and 2014SSE that the amount of stress increase was small or negative, the duration of the SSEs are about twice as long as other cases (Fukuda, 2018). This suggests that the duration and the complexity of a source process of an SSE may contribute to the stress change.

Spatial heterogeneity of shallow tremor activity near the Japan Trench

*Shukei Ohyanagi[1], Kazuaki Ohta[2], Yoshihiro Ito[3], Ryota Hino[4], Yusaku Ohta[4], Ryosuke Azuma[4], Masanao Shinohara[5], Kimihiro Mochizuki[5], Toshinori Sato[6], Yoshio Murai[7]

Tohoku University, 5. Tokyo University, Earthquake Research Institute, 6. Chiba University, 7. Hokkaido University

The Japan Trench subduction zone hosts various types of seismic activities, such as Mw 9.0 Tohoku Oki megathrust event, tectonic tremors, and VLFEs. Recent development of S-Net (cabled network of OBSs) and intense free-fall type OBS observations near the trench revealed very frequent activity of shallow tremor along the whole subduction margin [Nishikawa et al., 2019; Ohta et al., 2019; Tanaka et al., 2019]. The tremor identified in these studies have poor resolution in their depth, since they located the tremor with the envelope cross correlation method. From 2016 to 2017, we had deployed an array of 3 dense OBS arrays near the trench axis of offshore Fukushima region. Taking advantage of the array analysis, we have shown that the shallow tremor observed in the offshore Fukushima region is predominantly occurring at the plate interface [Ohyanagi et al., 2019 JpGU]. However, in this research, epicenter of the tremor is located solely based on arrival direction of tremor wave estimated at 3 arrays. Due to limitation of the method, tremor cannot be located in some area within the array of arrays network. Thus, distribution of tremor hypocenters has spatial gap which may caused by methodological issues.
Here, we updated hypocenters of ambient tremors and dynamically triggered tremors using the Multi Beam Back-Projection method [Ghosh et al., 2009; 2012] to verify if tremors are occurring at the spatial gap. Ghosh et al. (2009; 2012) does not evaluate uncertainty of located tremor explicitly. In our study, we evaluate uncertainty of located hypocenters following a method proposed in Arnadottir and Segall (1994). Succeeded in locating the tremors, we estimated their energy rate. The site amplification factor of each OBS is corrected between 2Hz –8Hz by the coda normalization method (e.g., Sato and Fehler, 1998). After the site amplification factor is corrected for each OBS, we evaluate seismic energy of the tremors at each array. At certain array, time delay is applied to waveforms of the tremors according to their slowness and arrival direction acquired through beamforming. The delayed traces are stacked to suppress ambient noise. The stacked traces at each array is then collected for geometrical spreading and intrinsic attenuation to estimate seismic energy at the source. At last, the estimated energy is divided by duration of the tremor to convert to the energy rate.
The updated location still shows spatial heterogeneity within a shallow tremorgenic region. The ambient tremor activity is more frequent in the up-dip part of the region, and less frequent in the down-dip part. Although spatial distribution of the energy rate of the tremors is more or less homogeneous within the whole region, some of the tremors occuring up-dip have about 2 order larger energy rate than others. The frequent and potential of high energy rate activity of the tremor in the up-dip part may be related to the crustal deformation observed near the trench axis in offshore Fukushima [Iinuma et al., 2016; Tomita et al., 2017].

Can crack-seal veins record recurrence intervals of slow earthquakes?

*Naoki Nishiyama[1], Kohtaro Ujiie[1], Masayuki Kano[2]

1. University of Tsukuba, 2. Tohoku University

The repeated slow earthquakes down-dip of the seismogenic zone may trigger megathrust earthquakes by transferring stress to the locked seismogenic zone. Recent geodetic study in the Nankai subduction zone suggested that recurrence interval of slow slip event has decreased from >5 years to ~1 year toward next megathrust earthquake. Repeated brittle thrusting near the downdip limit of the seismogenic zone was recorded in quartz-filled, crack-seal shear veins in the Makimine mélange of the Late Cretaceous Shimanto accretionary complex, southwest Japan. The crack-seal texture in the veins is defined by phyllosilicate inclusion bands subparallel or oblique to the vein margins. The geometry of inclusion bands in the veins indicates temporal order of crack-seal events. The measurement of the thickness of inclusion bands in shear veins show that there are three patterns of temporal change in inclusion band thickness: monotonous decrease or increase in band thickness or decrease and then increase in band thickness. We estimated the minimum time interval between crack-seal events by using a kinetic model of quartz precipitation. We assume fluid pressure drop from lithostatic to hydrostatic values at each crack-seal event, which is supported by large variations in fluid/vapor ratio of two-phase fluid inclusions between inclusion bands. The results show that the minimum time interval between crack-seal events decreased from 3–8 years to 0.2–0.5 years during 50–100 years, which is comparable to the temporal change in recurrence interval of slow slip toward next megathrust earthquake. If repeated brittle thrusting coincided with slow slip events (i.e., episodic tremor and slow slip), the crack-seal veins may be geological indicators for identifying past temporal change in slow slip recurrence interval. The progressive increase in recurrence interval of crack-seal events may reflect an increase in recurrence interval of slow slip after megathrust earthquake, while decreased and increased band thickness may represent the change in recurrence time of slow slip events before and after megathrust earthquake.

Complementary Distribution between Very Low Frequency Earthquakes and Interplatecoupling area in the southwestern Ryukyu Trench

*Ren Yakabu[1], Mamoru Nakamura[1]

1. University of the Ryukyus

No thrust earthquake of moment magnitude (Mw) > 8.0 has occurred in the past 300 years in the Ryukyu Trench, which is located in the northwestern boundary of the Philippine Sea Plate [Ando et al., 2009]. Thus, interplate coupling has been assumed to be low in the Ryukyu trench. However, a mega tsunami with the run-up height up to 30 m struck Ishigaki Island on April 24th , 1771. Very low frequency earthquakes (VLFEs) are very active along the Ryukyu Trench (Nakamura and Sunagawa, 2015). The clusters of the VLFE activities are distributed around Amami Island, Okinawa Island, and the Yaeyama Islands. In the Southwest Ryukyu trench, the locked zone is distributed to the west from 123 degrees (Hsu et al., 2012 GRL), and the source area of the 1771 Yaeyama tsunami is located around 125 degrees. The VLFE cluster near the Yaeyama Islands are complementary to the coupled area and tsunami source area. (Nakamura and Sunagawa, 2015). Nevertheless, since the hypocenter of the VLFEs was determined using the Fnet observation network, the accuracy of the hypocenter determination was poor at the western edge of the observation network, and it was difficult to determine the western extent of the VLFEs cluster areas. Then we analyzed the distribution of VLFEs in the southwestern edge of the Ryukyu Trench by integrating the data of Japan's Fnet observation network and Taiwan's broadband earthquake observation network (BATS). We used 3 F-net stations and 6 BATS stations from 2005 to 2018. The seismograms of the vertical component was 0.02-0.05 Hz band-pass filtered, and the waveforms at neighbor 2 or 3 stations were computed by the semblance analysis to determine the hypocenter. As a result, In the southwestern Ryukyu trench, the VLFEs was distributed to the east of the south-southwest offshore of Yonaguni Island. The cluster did not overlap with the coupled zone (Hsu et al. 2012) near Taiwan, indicating that the clusters of VLFEs and the coupled zones are distributed complemental.

Different deformation styles in the source regions of the 2019 Yamagata-oki earthquake and the 1964 Niigata earthquake

*Taku Ueda[1], Lina Yamaya[1], Yosihiko Ogata[2], Aitaro Kato[1]

1. Earthquake Research Institute, the University of Tokyo, 2. The Institute of Statistical Mathematics

On June 18, 2019, a Mj6.7 earthquake occurred at Yamagata-oki. The source region of this earthquake is adjacent to that of the Mj7.5 earthquake which occurred on June 16, 1964, and in this region, there are few aftershocks right after the 1964 earthquake, and the seismicity rate in recent years is extremely low (Earthquake Research Committee, 2019). This observation suggests that the source region of the 2019 Yamagata-oki earthquake was not ruptured by the Niigata earthquake, but the cause has not been revealed. In order to elucidate the relationship between these two areas, this study compared the characteristics of seismicity between the two areas.

We used the JMA catalog constructed by Japan Meteorological Agency (the Preliminary Determination of Epicenters). We applied HIST-ETAS (Hierarchical Space Time Epidemic Type Aftershock Sequence) model (e.g., Ogata, 2004) considering the spatial dependence of each parameter of the Space Time ETAS model (e.g., Ogata, 1998), to the hypocenter catalog (M1.8) from 1998 through 2019 in order to estimate the spatial distribution of background seismicity rate μ and number of aftershock occurrences K. As a result, we find that μ-value is higher and K-value is lower in the source region of Yamagata-oki earthquake than in that of Niigata earthquake.

In addition to these differences, we find that the b-value, which is one of the characteristics of the seismicity, is lower in the source region of Yamagata-oki earthquake than in that of Niigata earthquake. Moreover, comparing the seismic wave velocity structure obtained by Matsubara et al. (2019), the P wave velocity is lower in the source region of Yamagata-oki earthquake than in that of Niigata earthquake. The difference in seismic wave velocity and characteristics of seismicity between these two areas suggests that the macroscopic behavior in the source region of Yamagata-oki earthquake is more ductile than in that of Niigata earthquake. In more ductile area, microfracture is likely to proceed and it decreases seismic wave velocity. In addition, background seismicity rate (μ) decreases in more ductile area because of low brittleness. Moreover, the results of rock experiments and numerical simulation by Amitrano (2003) imply the increase in aftershock productivity (K) and the decrease in b-value in more ductile area. Focusing on the short-wavelength component of the linear strain rate distribution in the east-west direction (Meneses-Gutierrez and Sagiya , 2016), the different response for the 2011 off the pacific coast of Tohoku earthquake between the source regions of Yamagata-oki earthquake and Niigata earthquake is appeared. These differences may reflect different deformation styles between the two regions.

Uncovering complex characteristics of earthquake time series using complex network analysis

*Sumanta Kundu[1], Anca Opris[1], Takahiro Hatano[1]

1. Department of Earth and Space Science, Osaka University.

A detailed analysis has been performed by mapping the time series of seismic data into a complex network consisting of nodes and links. Each seismic event is considered as a node and the links are determined between pairs of nodes based on the criteria of visibility graph, which is found to be a useful tool in extracting the non-trivial characteristics of a time series. We have investigated both earthquake magnitude time series and inter-event time (IET) series for three different categories of earthquakes, namely, ordinary earthquakes, earthquake swarms, and tremors. Our analysis of the degree distribution of the associated network suggests that the magnitudes of the events for all types of earthquakes are statistically uncorrelated whereas, the inter-event time series show long-range correlations. In connection with the 1/f type noises, the IET series of tremors are found to have distinctly different behavior than the other two types of earthquakes. We also find that the associated networks for both the time series display small-world behavior, high clustering and hierarchical organization. Furthermore, our findings based on the assortativity coefficient reveal that the swarms are more intermittent in nature compared to the tremors.

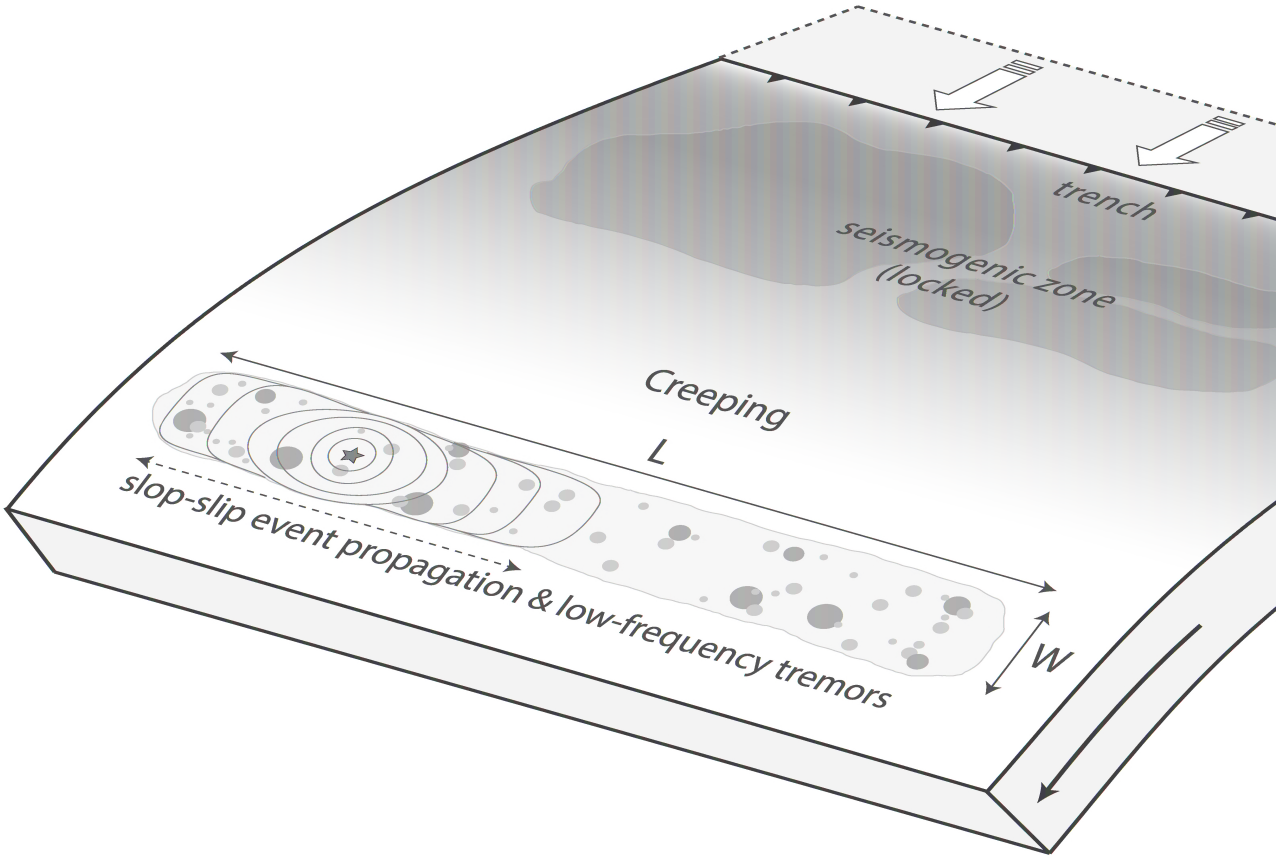
Exploring slow slip events and their scaling in 3D simulations of fault slip

*Luca Dal Zilio[1], Nadia Lapusta[1], Jean-Philippe Avouac[1]



1. Seismological Laboratory, California Institute of Technology, Pasadena, CA

Tectonic faults accommodate a wide spectrum of slip modes, ranging from earthquakes to slow slip events (SSEs). While regular earthquakes are events with rupture velocities governed by inertial stress transfer with elastic wave speeds, the physical mechanisms responsible for underlying slow fault slip phenomena are less understood. In particular, key questions remain about how SSEs nucleate and propagate and whether they follow different scaling laws from ordinary earthquakes. Observations have shed light on these issues. However, due to significant noise in the time series and uncertainties related to the relatively short observational timespan, there is no unique way to interpret observations and determine the underlying mechanism of such SSEs. To overcome this limitation and to investigate synthetic data of longer timescales, here we apply a rate-and-state friction law and dilatancy effects to a three dimensional model of a subduction megathrust. By testing a wide spectrum of frictional properties, we investigate under which conditions sliding instability develops into sustained slow slip events. In particular, we study the processes that control variations in slip velocity, propagation speed, stress drop, as well as the aspect ratio of individual uni- and bi-directional SSEs.

Our model explains the earthquake-like cubic moment-duration scaling of SSEs recently observed in Cascadia subduction zone. Our results suggest that regular earthquakes and SSEs are both the result of frictional stick-slip motion. The pulse-like propagation, along-strike segmentation, and frequency-magnitude distribution of our simulated SSEs are remarkably similar to those observed on the Cascadia subduction zone. However, in contrast to the traditional assumptions, the cubic moment-duration scaling of SSEs arises not because the average rupture velocity and the stress drop of SSEs are magnitude-invariant, but rather because they increase with the increasing SSE magnitude. These results not only illuminate the dynamics of SSEs but also demonstrate that the same scaling can arise for different underlying reasons. The traditional circular crack model with magnitude-invariant rupture velocities and stress drops, which is the standard explanation for the cubic moment-duration scaling, does not apply to SSEs. This finding raises the question whether this traditional model and its assumptions hold even for regular earthquakes.

Nature of the Lithosphere in Alternating Regions of Slow Earthquakes in South America

*POUSALI MUKHERJEE[1], Yoshihiro Ito[1], Takuo Shibutani[1], Emmanuel Soliman M Garcia[1], Raymundo Omar Plata Martinez[1]

1. Disaster Prevention Research Institute, Kyoto University

Subduction zones host some of the greatest megathrust earthquakes in the world. Slow earthquakes have been also discovered around the subduction zones of the Pacific rim very close to megathrust earthquakes in several subduction zones in Chile, Cascadia, Mexico, Alaska, and New Zealand (Obara and Kato, 2016). Investigating the lithosphere of the slow earthquake area versus non slow-earthquake areas in subduction zones is crucial in understanding the role of the internal structure to control slow earthquakes. Deep transient slow slip had been detected in the Atacama region in Chile (Klein et al., 2018). Socquet et al. (2017) suggested that aseismic slow slip is one of the potential precursors of the 2014 M_w8.1 2014 Iquique earthquake. In this study, we investigate the lithospheric structure beneath stations in and around the slow earthquake area in Atacama and Iqueque. We also study the non slow-earthquake areas in the South America subduction zone using receiver function analysis and inversion method using teleseismic earthquakes. Here we focus on, especially the Vp/Vs ratios from both the slow and non slow earthquake areas, because the Vp/Vs ratio is sensitive to the fluid distribution in the lithosphere; the fluid distribution possibly controls the potential occurrence of slow earthquakes. Additionally, the nature of the slab can also play a crucial factor. At the boundary of the slab, the Vp/Vs results show variation in the slow earthquake area, and far off from the slow earthquake area. The Vp/Vs ratio results across depth shows significantly higher value in the deeper oceanic slab region beneath the stations in the slow earthquake areas with higher contrast at the boundary. The stations very close to the slow earthquake areas also preserves high Vp/Vs contrast at the boundary of the slab. On the other hand, the Vp/Vs contrast at the slab boundary significantly reduces for the stations in the non slow earthquake area.

Keywords: Receiver function, Vp/Vs ratio, fluids, slow earthquake, slab, South America

[S-CG59] Evolution and movement of the crustal surface and application of geo- and thermochronology

convener:Noriko Hasebe(Institute of Nature and Environmental Technology, Kanazawa University), Shigeru Sueoka(Japan Atomic Energy Agency), Frederic Herman(University of Lausanne), Takahiro Tagami(Graduate School of Science, Kyoto University)

The terrestrial earth surface is the habitat of humans and undergoes drastic changes caused by endogenic and exogenic processes. Establishing the chronology of the past changes/episodes is a key to understanding ongoing processes and to predict future physical environments. This session aims at comprehensive understanding of dynamics of the earth's surface, including crustal movements, uplift-denudation processes, and subsequent landform development occurred in various spatio-temporal scales. In addition to the thermochronological approach, it welcomes interdisciplinary studies based on, e.g., tectonic geomorphology, structural geology, geodetic observation, cosmogenic nuclides, numerical calculations, and analogue experiments.

Northeast (NE) Japan is one of the best regions to study tectonics of island arc, because NE Japan has comparatively obvious island arc components of fore-arc, volcanic front, back-arc and back-arc basin. Therefore, there are many studies on the tectonic evolution of NE Japan (e.g. Amano and Sato, 1989; Sato, 1992; Nakajima, 2013). Ota (2010) says that the mountains in NE Japan are uplifted by compression across arc (i.e east-west compression). However, there are a few quantitative investigations of the mountain uplift and denudation histories which are important factors estimating island tectonics.

As a technique for measuring uplift or denudation rates, some are known (e.g. GPS survey, elevation of terraces, thermochronology etc.), but in regard to million-year-scale mountain uplift and denudation rates, it can be said that thermochronology is the most appropriate method. Thermochronology can reconstruct the time-temperature relationship of rock/mineral samples, based on radiometric ages and closure temperatures specific to the combination of radiometric dating methods and target minerals. Furthermore, some assumptions enable discussion of mountain uplift and denudation histories. At overseas massive orogenic zones thermochronology has been applied since 1970s (Hermam et al., 2013). At NE Japan there are, today, some studies that discuss differences of uplift/denudation history between fore-arc, Ou backbone range and back-arc using thermochronology (e.g. Sueoka et al., 2017; Fukuda et al., 2019; Fukuda et al., in review). However, in these preceding studies, it is not sufficient to discuss a respective and more particular thermal and denudation history about arc component units. Therefore, in this study, we focus on fore-arc side of NE Japan, Kitakami Mountains and Abukuma Mountains and then to estimate detail thermal and denudation history we apply thermochronology there.

We adopt apatite fission-track (AFT), apatite (U-Th-Sm)/He (AHe) analyses as thermochronological methods. AFT ages are 139.4-78.6 Ma at Kitakami, 61.0-40.5 Ma at Abukuma. AHe ages are 51.2-36.1 Ma at Kitakami, 75.9-60.1 Ma at Abukuma. With our results and ages which preceding studies provide we discuss age trend and denudation history respectively.

At Kitakami Mountains, AFT ages become younger gradually (140-80 Ma) from the most eastern locality to around 141.6 degrees longitude locality. On the other hand, all AHe ages are about 50-40 Ma except for the most western locality of which the AHe age is 90 Ma. However, at the most western locality the AHe age is older than the AFT age which usually indicates older ages because of the different closure temperature, so a local thermal event like hydrothermal activity possibly affect the ages of this locality.

At Abukuma Mountains, AFT age trend changes at Hatagawa fault zone (HFZ), which AFT ages tend to be younger in the west side of HFZ than in the east side. AHe age trend also seems to change at HFZ like AFT age trend, but considering the error bars it is not obvious. And at the most eastern locality the AFT age is comparatively young. Because the AFT age is younger than the AHe age at this locality, perhaps, there was a local thermal event like Kitakami Mountains.

©2020. Japan Geoscience Union. All Right Reserved.

Then we calculated the average denudation rate using the AFT ages. As the result of calculation, at every locality in Kitakami Mountains and Abukuma Mountains the average denudation rate is <0.10 mm/yr. Therefore, both mountains are stable at 10^{7-8} year time scale. However, this result does not suggest that the denudation rate is continuously <0.10 mm/yr, so to construct more detail denudation histories we have to apply new thermochronological method which is available at shorter time scale.

As future subjects, ①improvement of accuracy and precision by further analyzing ②increasing number of sampling localities and employing another thermochronological method (e.g. cosmogenic nuclides analysis) ③applying new thermochronological methods (e.g. thermal inverse modeling by AFT; Electron Spin Resonance thermochronometry) to estimate more detail thermal and denudation histories ④ discussion of geothermal gradient, uplift model and tectonics model at Kitakami Mountains and Abukuma Mountains.

AFT thermochronology of Cretaceous granites from the northern part of the NE Japan Arc: estimating thermal/denudation histories based on thermal inverse modeling

*Shoma Fukuda[1,2], Shigeru Sueoka[2], Noriko Hasebe[3], Akihiro Tamura[4], Tomoaki Morishita[4], Takahiro Tagami[1]

1. Graduate School of Science, Kyoto University , 2. Japan Atomic Energy Agency, 3. Institute of Nature and Environmental Technology, Kanazawa University, 4. Department of Earth Sciences, Kanazawa University

Northeast (NE) Japan Arc is located at the subduction zone on the Pacific plate, which is known as a typical island arc because of having the inland linear topographic alignments and the island arc units. The tectonic history of the NE Japan Arc has been investigated by geologic and geomorphic researches so far. In particular, the evolution of the NE Japan arc after the opening of the Sea of Japan since ca. 15 Ma was well-understood (e.g., Sato, 1992, Jour. Geophys. Res.; Nakajima, 2013, INTECH; Yoshida et al., 2013, Geol. Soc. Lond. Spec. Pub.). Recently, the multidisciplinary project entitled “Crustal Dynamics” has successfully discovered a lot of geoscientific implications based on geodesy, geomorphology, and geology (Iio et al., 2018, EPS). As one of the disciplines in this project, thermochronology aimed at reconstructing vertical movements of the shallow crust over long-term timescales (>10^6 yr) in the unit of an island arc, and has contributed to revealing thermal/denudation histories coeval with the intense E-W compressive stress field since the Quaternary.

Thermochronology is a discipline which generally uses radiometric ages obtained from radiometric dating methods, and closure temperatures specific to the combinations of applied dating methods and these targeting minerals (namely, thermochronometers). Thus, thermal histories of rock bodies can be revealed, and moreover, denudation histories of them can also be estimated under the assumption of geothermal structure. Low-temperature thermochronology is useful for understanding upper crustal mountain building processes, which includes (U-Th)/He and fission-track (He and FT, respectively) methods for apatite and zircon. However, thermochronometric approaches directly measure cooling processes of rock bodies. Therefore, it is noteworthy that uplift histories require some assumptions, such as appropriate geothermal gradients and dynamic equilibrium between denudation and uplift (see the principle and application of thermochronology in Sueoka et al., 2016, Geosci. Fron.; Sueoka and Tagami, 2019, Jour. Geogr.).

Research findings by thermochronology of the NE Japan Arc are introduced here. We collected the Cretaceous-Paleogene granitic samples across the southern part of the NE Japan Arc, which is called as the S-traverse, and applied apatite and zircon He (namely, AHe and ZHe) methods (Sueoka et al., 2017, EPS), and apatite FT (AFT) methods (Fukuda et al., 2019, JAES:X) into island arc provinces, i.e., the Abukuma mountains, the Ou Backbone Range (OBR), and the Iide and Asahi mountains. These studies uncovered the contrasts of thermal and denudation histories between each tectonic unit. In the latest research, we have applied He methods into the northern part of the NE Japan Arc, namely, the Kitakami mountains, the OBR, and the Shirakami and Taihe mountains as the N-traverse (Fukuda et al., in press, EPS). This study attempted to reveal the overall trend of thermal and denudation histories along the NE Japan Arc. Consequently, estimated the similar contrasts of them along the S-traverse, which quantitatively provided that the landform development of arc-along direction is probably controlled by the E-W compressive stress field. In this presentation, we report the results of AFT dating and thermal

inverse modeling along the N-traverse in order to improve the thermal/denudation histories obtained by He thermochronometers.

We obtained AFT ages ranging from 138.0–2.0 Ma, which were consistent with the age contrasts between island arc provinces based on the He methods. In addition, thermal inverse modeling using by HeFTy (Ketcham, 2005, RiMG) provided high-accuracy thermal/denudation histories. On the fore-arc side, slow cooling patterns were estimated since the Cretaceous-Paleogene, while in the OBR and on the back-arc side, rapid cooling patterns were inferred since few Ma as last cooling episodes. Such last cooling episodes perhaps reflected the intense compressive stress field after the Quaternary, which indicated comparable to Fukuda et al. (2019, JAES:X). These observations implied that the S- and N-traverses have probably similar trends of thermal and denudation histories based on AFT methods as well as He thermochronometers. For enhancing the spatial-temporal resolutions of data, some future works will involve applying the application of lower-temp. thermochronometers (e.g., ESR or OSL methods), and extending our study area by increasing the number of sampling localities. Now, we have been conducting ongoing researches around the Kitakami, Abukuma mountains, and the OBR. Further investigations are desirable.

Izu-Bonin arc collision and mountain formation of the South Fossa Magna region: New insights from low-temperature thermochronology

*Yumi Kobayashi[1], Shigeru Sueoka[2], Shoma Fukuda[1], Barry P. Kohn[3], Tatsunori Yokoyama[2], Noriko Hasebe[4], Akihiro Tamura[5], Tomoaki Morishita[5], Takahiro Tagami[1]

School of Earth Sciences, University of Melbourne, 4. Institute of Nature of Environmental Technology, Kanazawa University, 5. Department of Earth Science, Faculty of Science, Kanazawa University

The South Fossa Magna region is one of the unique regions in the world, being situated at an active arc-arc collision zone. It is thought that up to four crustal blocks of the Izu-Bonin arc have collided with this area since the middle Miocene, resulting in crustal modification of the Honshu arc side (e.g. Amano et al., 1999; Kano, 2002). However, the timing and effect of these blocks are still debatable.
Horizontal deformation such as the rotation of the collided blocks has been studied mainly by paleomagnetism. In this study, in order to reveal the vertical deformation, low-temperature thermochronometry was performed on basement granites. The uplift and denudation history were estimated and compared with the collision events.
Apatite fission track (AFT) ages obtained in this study were significantly younger than the granite formation ages and are consistent within an uncertainty of $\pm 2\sigma$ at all localities. The apatite (U-Th)/ He (AHe) ages were younger or consistent within an error than the AFT ages and previously reporter ages. Using this data inverse thermal history modeling using the HeFTy software (Ketcham, 2005) was carried out. Results indicate that the last cooling started at about 1 Ma in the northern and central parts of the Kofu granites in the Kanto Mountains, and at about 5 Ma in the southern part. Considering only the timing for the onset of the last cooling, these ages are in accord with the collision ages previously reported for the Izu block and the Tanzawa block, respectively.
The average denudation rates in the South Fossa Magna region were estimated from the age and temperature of the onset of the last cooling and these are consistent with average uplift rates over the last 0.1 Ma estimated from the elevation of fluvial terraces (Fujiwara et al., 2005). This suggests that vertical deformation such as uplift of the Honshu arc side has continued at a constant rate from the time of collision of the Izu block to the present.
In summary, our results suggest that collisions between the crustal blocks affected uplift of the mountains. However, considering that cooling rates in the Tanzawa Mountains, which are closest to the Izu block, did not increase due to the collision of the Izu block (Yamada and Tagami, 2008), the collision of the Izu block might not have directly influenced the uplift and denudation of the Tanzawa Mountains. For further discussion on the tectonic history of the crustal blocks, thermal inversion analysis at more localities in the Kanto Mountains and Misaka Mountains, which are located northwest of the Izu block, are required.

Analyses of Sag Pond Stratigraphy to Assess the Disaster History along Lembang Fault, West Java, Indonesia

Januar Ridwan[2], *Noriko Hasebe[1], Eko Yulianto[2], Nandang Supriatna[2], Amar Amar[2]

1. Institute of Nature and Environmental Technology, Kanazawa University, 2. Research Center for Geotechnology, Indonesian Institute of Science

Sag pond stratigraphy studies have a potential for the assessment of Lembang fault activity. Previous results have showen some indication of the earthquake-related process in the sag pond sedimentation record, but the level of confidence is uncertain especially for the events revealed by the recent Paleoseismological studies. This research conducted using the diatom analysis to see the fluctuation of sag pond water level and change in depositional environment, which is controlled by the Lembang fault movement. We analyzed Cihideung sag pond deposit from the playground in Graha Puspa Estate area, Lembang, Indonesia, which also used in the previous sag pond stratigraphy research. The diatom analysis was carried out combined with sediment characterizations, including water content, grain size measurement, organic matter, carbonate concentration, and biogenic silica analysis. We also provide radiocarbon ages to open the correlation with the estimated great earthquakes by present paleoseismology research of Lembang fault. We recognized the stratigraphy of ~5m core and classified into five sedimentary units which represent the sedimentation history of the Cihideung sag pond. We interpret sedimentation changes that could represent the earthquake-related process and classified based on the level of confidence. The event with highest level of confidence include three events that related to the humic sag pond formation and two great earthquake event in 15th Century and 1771-1537 BCE. However, this assessment still need improvement with better resolution and other additional analyses in the future to enhance the confidence in the reconstruction of paleoseismological events.

Dating marine terraces by terrestrial cosmogenic nuclides: applicability and limitations

*Yuki Matsushi[1], Tetsuya Komatsu[2], Shigeru Sueoka[2], Yusuke Yonaga[2], Yumi Ogawa[2], Natsuko Fujita[2], Yoko Saito-Kokubu[2]

1. Disaster Prevention Research Institute, Kyoto University, 2. Japan Atomic Energy Agency

This study overviews methodology for application of terrestrial cosmogenic nuclides for dating marine terraces. Accumulation of in-situ produced cosmogenic nuclides in near-surface bedrock reflects several factors such as exposure duration, sedimentation, and denudation of the landform. For cases of uplifted coastal surfaces, inheritance accumulated under pre-emergence erosional environment also affects the age accuracy, which can be inferred from the nuclide concentration of a representative modern wave-cut bench. We simulated evolution of subsurface depth profiles of cosmogenic ^{10}Be concentration in quartz in terrace bedrock emerged at marine isotope stages (MIS) 1, 5e, 7, 11, and 13 with different parameter settings. Applicability and limitation of this method were then tested by comparing those model curves to actual depth-concentration profiles measured using boring cores extracted at two uplifted marine terraces in Muroto Peninsula, southern-east Shikoku, Japan, elevated to ~160 m above the present sea level.

Constraining thermal/denudation histories in the last 0.1 Myr using multi-OSL-thermochronometry applied to samples from deep boreholes

*Manabu Ogata[1], Georgina King[2], Frédéric Herman[2], Shigeru Sueoka[1], Ryuji Yamada[3], Kentaro Omura[3]

1. Tono Geoscience Center, Japan Atomic Energy Agency, 2. Institute of Earth Surface Dynamics, University of Lausanne, 3. National Research Institute for Earth Science and Disaster Prevention

Constraining the denudation history is necessary for evaluating change of the Earth’s surface. Terrestrial cosmogenic nuclide (^{10}Be, ^{26}Al) dating is used to evaluate denudation rates averaged over a few meters at 10^2-10^4 year timescales, whereas low-temperature thermochronology, such as fission-track and (U-Th)/He methods, is applied to estimate denudation histories over a few to several kilometers in the last 10^6-10^8 years. However, the method of constraining the middle-term (10^4-10^5 years) denudation history remains challenging.
Recently, optically stimulated luminescence (OSL) thermochronometry has been proposed as a tool that offers potential for tight constraint of cooling histories in the low-temperature domain (30-100 ℃) over 10^4-10^5 year timescales. This method consists of determining the timing and rate at which electrons are trapped and thermally released in minerals, in response to in situ radiation and rock cooling. Luminescence signals can be converted into a rock cooling rate, or denudation history, by constraining the kinetic parameters that describe electron trapping and detrapping.

Application of OSL-thermochronometry is currently limited to regions that have experienced denudation rates higher than 5 mm/year (assuming a general geothermal gradient in Japan, which is ~0.03 ℃/m); luminescence signals saturate before the rocks are exhumed to the surface in slowly-denuding regions. However, constraining the slow cooling histories may be possible if unsaturated samples are obtained from within deep boreholes. Here we apply multi-OSL-thermochronometry to deep borehole cores drilled at the Tono and Rokko regions, southwest Japan, that have experienced slow (~0.1 mm/year) and moderate (~0.5 mm/year) denudation rates, respectively. We used the MIZ-1 core at Tono region, Gifu, and the Kabutyama core (National Research Institute for Earth Science and Disaster Resilience) at Rokko Mountains, Hyogo. In this presentation, we will present the preliminary results of the analyses.

This study was carried out under a contract with METI (Ministry of Economy, Trade and Industry) as part of its R&D supporting program for advanced research on long-term stability of geological environment.

Thin section etching of zircon for micro thermochronology by fission track method: A trial

Hiroaki Koyama[2], *Noriko Hasebe[1]

1. Institute of Nature and Environmental Technology, Kanazawa University, 2. Department of Earth Sciences, Kanazawa University

Zircon is a mineral commonly used for fission track dating. However, since it is an accessary mineral, it is generally used for analysis after the mineral separation. With the conventional methods, rocks are crushed and important information on the mineral occurrence is lost. If we could develop etching method of zircon in the thin sections, the interaction between coexisting minerals, the relationship between zircon occurrence and its age can be studied. Thin section dating could contribute micro thermochronology on samples with potential paleotemperature difference among a narrow zone, e.g., a fault gouge, an archeological vase, or archeological furnace sites, etc. The analyses without Teflon sheet mounting, which sometimes suffer electrostatic disturbance, may be useful for observation by, for example, AFM or SEM. To avoid the destruction of a thin section during the etching by high temperature alkali eutectic etchant, pinpoint etching only on zircon was tried. In order to perform pinpoint etching, a pipette tip made of polypropylene or Teflon was tried, but dropping of the etchant on the sample was impossible, because of the rapid solidification during the experiment. Dropping the etchant using a Teflon coated spoon on a sample was possible, but the control in amount of etchant was difficult. A photosetting resin was used as a material for bonding the rock and the slide glass. As a result of trial with several etchants, it was found that rocks came off with an etching solution at 160℃ or higher. The KOH:NaOH eutectic mixture used in the conventional zircon fission track method was found to be unsuitable because it had a melting point of about 170℃. On the other hand, the KOH:NaOH:LiOH eutectic mixture used as an alternative etchant has a melting point of about 140℃ and has higher etching efficiency than the KOH:NaOH eutectic mixture. Zircon in thin section was able to be etched using a KOH:NaOH:LiOH eutectic mixture at 150℃.

[S-CG60] Toward Discoveries in Solid Earth Sciences by Machine Learning

convener:Takahiko Uchide(Research Institute of Earthquake and Volcano Geology, Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST)), Yuki Kodera(Meteorological Research Institute, Japan Meteorological Agency), Hisahiko Kubo(National Research Institute for Earth Science and Disaster Resilience)

The recent development of the machine learning techniques including the deep learning is leading innovations in various fields. The applications of these techniques, for example, the classification, the pattern recognition, and the regression of data, to solid earth sciences are also now under development. On the other hand, there are concerns on the human-interpretability of the deep learning.
This session will provide an opportunity to share the application studies to various fields in solid earth science and inspire each other. In particular, we encourage contributions which made discoveries in solid earth sciences. We also look forward to studies addressing the black box issue of the deep learning.

Detection of seismic signals under low SNR condition using an artificial neural network: Toward development of dense low cost citizen seismic network in Yokohama

*Ahyi KIM[1], Hiroki UEMATSU[1], Gakuto NAKAO[1]

1. Yokohama City University

We have developed a community based low cost seismic network in Yokohama, Japan, called Citizen Seismic Network (CSN), to monitor local scale strong motion which is closely linked to community’ s life. Each sensor unit composed of 12 bit MEMS accelerometer and Raspberry Pi.

Since the units are supposed to be installed under high-noise condition such as inside of house where spiky noise made by human activities often misinterpreted as seismic signal, it is difficult to discriminate the seismic signals from other noises. In such condition, applying conventional detection method using amplitude ratio (e.g. STA/LTA) is problematic. To overcome the issue, we employed an artificial neural network (ANN) that utilizes pattern recognition to retrieve seismic signals. To make the ANN work, we trained it using numerical data set produced by seismic records obtained from conventional seismometer adding CSN sensor noise. As the network input, vector modulus of three component of accelerogram are used.

Firstly we explore the optimum number of input units and training data. Secondly, using the trained ANN, we tried to identify the numerical seismic signals which are not used in the training process. As a result, 95% of the P-wave is successfully detected. The comparison with the performance of STA/LTA using real data observed by our sensor indicates that our method reduce the false detection significantly.

Detection is further improved with multiple stages training: noise data detected as “seismic signal” is included in the next training process as “noise”. The ANN trained with multiple stages stably detects P-wave for Japan Meteorological Agency seismic intensity scale above 3. It indicates that our method can make low cost MEMS sensor not only as reasonable strong motion detector but also as P-wave detector for the intensity above 3. It means our sensor network can be used as a complementary of the conventional seismic network for earthquake early warning.

Earthquake detection based on deep learning

Junyu Yu[1,2], *Takahiko Uchide[2], Yuji Yagi[1]

1. Graduate School of Life and Environmental Sciences, University of Tsukuba, 2. Geological Survey of Japan, AIST

Earthquake detection, identifying the presence of an earthquake and determining its hypocenter, is challenging, because it requires the correct detection and association of seismic phases across different seismographs while also precisely picking the arrivals of P and S waves. Yet, this effort is essential for producing the earthquake catalog that provides important insights into many studies of observational seismology, such as the spatiotemporal distribution of Gutenberg-Richter's *b*-value, the geometry of faults, and foreshock behavior. Better catalog also enables us to use more event data for the determination of source parameters, such as focal mechanisms.

Despite several separating automatic methods are continuously developed to resolve each step of earthquake detection, seismic analysts still strive to identify earthquakes or calibrate the result proposed by automatic method manually for the superior accuracy and reliability of expert-made estimation. Accompanying with the explosion of seismic waveform data caused by the development of high sensitivity seismograph network, however, comprehensively identifying earthquakes from such massive data is becoming increasingly difficult, especially for earthquakes which are small yet dominate the overwhelming majority of earthquakes.

We integrate earthquake detection procedures into an efficient, sensitive, and coherently end-to-end framework. The framework extends Mask R-CNN, which is the de-facto standard method for instance segmentation in deep learning, by training it on multi- and single-seismograph waveform data separately to construct a detector branch in parallel with a picker branch, and afterwards both branches are concatenated together. The detector branch efficiently detects the time spans in which seismic phases originating from a common causative earthquake are included in a 120-second multi-seismograph waveform window while segmenting the preliminary tremors (waveforms from P- to S-arrivals) observed at each seismograph roughly. The picker branch subsequently generates high-quality segmentation masks that covers preliminary tremors further precisely to pick P- and S-wave arrival times. The framework, in addition, predicts confidence scores of distinguishing seismic phases from ambient noise for each earthquake and each preliminary tremor respectively, which can be used as the criterion of monitoring the quality of earthquake identification and phase picking.

We evaluate the framework on an unseen test dataset of 3,591 discrete earthquakes accompanying with the target labels of expert-picked P- and S-wave arrival time from Japan Meteorological Agency (JMA) earthquake catalog. After discarding some prediction scored with low confidence, the framework has successfully recalled and relocated 97.61% of the test earthquakes with small errors both in the phase arrival times and the hypocenter location, showing a near-human-level detection accuracy and great generality. We then apply the framework to a set of one-month continuous waveform data that have been

©2020. Japan Geoscience Union. All Right Reserved.

recorded by a temporary seismograph network operated by Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST) in northern Ibaraki, Japan. While trained on the seismic waveform data from a different seismic network, the framework generalizes well and has identified more microearthquakes beyond JMA earthquake catalog over the certain area around the temporary network, which allows us to demonstrate its robustness and detection sensitivity.

We hope our effective approach will serve as a general automatic method of earthquake detection to help ease monitoring earthquake activities and provide new information to facilitate further researches in seismology.

Large-scale matched-filter analysis with similarity search

*Naoto Mizuno[1], Satoshi Ide[1]

1. Department of Earth and Planetary Science, The University of Tokyo

The matched-filter analysis (Gibbons and Ringdal, 2006) is one of the essential tools in modern seismology. It detects events by calculating the cross-correlation between the template waveforms and the observed waveforms. In both ordinal and low-frequency earthquakes, this algorithm improves the number of detections of small events (e.g., Shelly et al., 2007a; Peng and Zhao, 2009; Kato et al., 2012; Ross et al., 2019). The matched-filter analysis is based on the assumption that the cross-correlation of two events should be high when their locations and mechanisms are similar. Because of this assumption, the detections are limited to similar events to the templates. To prevent missing events, we need to use a large number of templates to cover an analysis region. Ross et al. (2019) used nearly 284,000 earthquakes listed in the Southern California Seismic Network catalog as templates to detect small earthquakes and created a new catalog, which is almost complete for earthquakes of $M > 0.3$. Previous studies used parallel processing to manage massive computation, which is efficient to perform template matching (e.g., Chamberlain et al., 2018; Beaucé et al., 2018; Senobari et al., 2019; Zimmerman et al., 2019; Liu et al., 2020). Even with these improvements in algorithms, large-scale computation has been necessary.

In this study, we develop a new algorithm for the matched-filter analysis with a large number of template waveforms. Instead of using massive computational resources, our method improves the computation complexity with similarity search and efficiently handles over 100,000 templates by a single workstation. We reduce the formulation of the matched-filter analysis to the nearest neighbor search and introduce approximations to reduce the computational cost. Our algorithm is efficient for parallel processing on the graphics processing unit and manages the increase of templates using the approximations. The computation speed is remarkably improved and achieves over 100 times faster than the ordinary matched-filter analysis.

[S-CG61] The Japan Trench: Learning from the 2011 M=9 Tohoku-Oki earthquake, a decade later

convener:Takeshi Iinuma(National Research and Development Agency Japan Agency for Marine-Earth Science and Technology), Asuka Yamaguchi(Atomosphere and Ocean Research Institute, The University of Tokyo), Aitaro Kato(Earthquake Research Institute, the University of Tokyo), Tianhaozhe Sun(Pacific Geoscience Centre, Geological Survey of Canada)

The 2011 Tohoku-Oki earthquake (M=9) and its devastating tsunami triggered numerous new studies of earthquake processes in the northeast Japan subduction zone and worldwide. Multidisciplinary data in great quality and quantity have been collected across the shoreline during and since the earthquake. Important offshore observations include seafloor mapping, sub-seafloor geophysical imaging, coring, logging, and laboratory measurements associated with ocean drilling, GNSS-acoustic measurements of crustal deformation in and beyond the rupture area at an increasing number of sites, and multi-dataset geophysical observations by the newly established cabled seafloor monitoring network (the S-net) that covers the entire offshore area of the margin. Many geophysical and geological studies such as seismological and geodetic analyses, field surveys on fault-zone, regional and margin-wide structures, laboratory experiments on fault-zone and wall rock properties, and the associated numerical modeling have been conducted to investigate the preparation and generation of the M=9 rupture, its postseismic deformation, and its impacts on the general margin geodynamics. Today, approaching a decade from the earthquake, we need to synthesize these results to summarize what we have learned, what is still unknown, and what new studies should be conducted in the future. In this session, we welcome presentations on all aspects of the 2011 Tohoku-Oki earthquake and the seismogenic processes in the Japan Trench and other subduction margins based on, but not limited to, geophysical and geological field observations, laboratory experiments, and modeling studies.

Vertical deformation style along the Sanriku coast inferred from coastal geology examined after the Tohoku earthquake

*Yuichi Niwa[1], Toshihiko Sugai[2]

1. Faculty of Science and Engineering, Chuo University, 2. Department of Natural Environmental Studies, Graduate School of Frontier Sciences, The University of Tokyo

Along the Sanriku coast, northeast Japan, discrepancies in crustal movement have been reported between uplift on a timescale of 10^5 years estimated from presence of flat surface previously recognized as Pleistocene marine terrace (Koike and Machida, 2001) and subsidence on a timescale of 10^1 –10^2 years from geodetic record (Kato, 1983; Ozawa et al., 2011). Some hypothetical models, which explain these discrepancies, are proposed in relation to megathrust earthquake cycle (e.g., Nishimura, 2014). These models assume that crustal movement style is same within whole part of the Sanriku coast, and show that amount of accumulation of uplift exceeds that of subsidence during one earthquake cycle. However, because of lack of reliably identified MIS5 (ca. 125ka) marine terrace with age data along the Sanriku coast except for northernmost of the coast (Miyazaki and Ishimura, 2018), and of putative marine terrace along the southern part of the Sanriku coast (Koike and Machida, 2001), spatial distribution of crustal movement cannot be estimated on the basis of only feature of Pleistocene marine terrace.

After the 2011 earthquake, we have examined Holocene sedimentary successions of alluvial plains distributed along the Sanriku coast in order to obtain data on millennial-scale crustal movements, which help to solve the problem about the temporal inconsistency of crustal movement. Recent studies have reported millennial-scale subsidence in central to southern parts of the coast (e.g., Niwa et al., 2014; Niwa et al., 2017), but only one comparable dataset is available for the northern part of the coast (Niwa et al., 2019). To obtain a comprehensive understanding of millennial-scale crustal movements along the Sanriku coast, we obtained well-dated Holocene sediment cores from the Kuji plain in the northern part of the coast.

These cores record a transgressive barrier-lagoon system from ca. 9500 to 8000 cal BP, a regressive prodelta to delta front from ca. 8000 to 6500 cal BP, and a subsequent wave-influenced shallow marine and fluvial environment. Relative sea-levels in the Kuji plain are higher than −20.1 m, higher than −4.3 m, higher than −4.8 m, and higher than −5.9 m on the basis of sediments deposited under the sea-level dated to 9000 to 8730 cal BP, 7580 to 7470 cal BP, 6940 to 6740 cal BP, and 6400 to 6260 cal BP. These sea-levels are higher than that in the Tsugaruishi plain, central Sanriku coast, where millennial-scale subsidence was previously estimated (Niwa et al., 2017). This discrepancy indicates that the Kuji plain has uplifting trend relative to the Tsugaruishi plain on a millennial-scale. By the addition of relative uplifting trend of the Omoto plain (Niwa et al., 2019), millennial-scale crustal movements along the Sanriku coast are best characterized as subsidence along the central to southern parts and relative uplift along the northern Sanriku coast. Spatial distribution of millennial-scale crustal movements accords with marine terrace distribution that uplifting trend during the past 100ka is confirmed only in northernmost of the Sanriku coast (Miyazaki and Ishimura, 2019). This agreement suggests a continuous southward tilting trend along the Sanriku coast since ca. 100 ka.

Trial of the crustal deformation detection accompanied with the tremor activities in Fukushima-Oki deduced from the ocean bottom pressure gauge data

*Hideto Otsuka[1], Yusaku Ohta[1], Ryota Hino[1], Kazuaki Ohta[2]

1. Research Center for Prediction Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University, 2. National Research Institute for Earth Science and Disaster Resilience

Recently, various phenomena of the slow slip events (SSEs) were detected in the Japan Trench. For example, Ohta et al. (2019) have detected low-frequency tremor activities in the Fukushima-Oki deduced from the Ocean Bottom Seismometer (OBS). They found the five tremor episodes with recurrence intervals of ~60 days which slow migration behavior and shear mechanisms consistent with plate subduction. They estimated the slip amount caused by these episodes based on the cumulative apparent moment of the tremor events as proposed by Hiramatsu et al. (2008). The apparent moment of the tremor was calculated on the basis of the ground displacement of the tremor seismograms and then converted to the seismic moment of the SSEs with an empirical scaling factor (Hiramatsu et al., 2008). The cumulative slip amount was roughly 1.5cm to 2.0cm. During the OBS observation, Tohoku University also developed the five Ocean Bottom Pressure-gauge (OBP) to detect the crustal deformation phenomena. In this study, we try to detect the crustal deformation accompanied with the tremor activities in this region.

Firstly, we assess the expected vertical displacement amount in the OBP sites. We assumed the fault model based on the results from Ohta et al. (2019). The fault area covered the area of the tremor activity, and the fault slip amount was assumed as 2cm which was based on the result of Ohta et al. (2019). The expected vertical displacement was approximately less than 1cm. This amount, however, may have the uncertainty because the slip amount may be affected by the value of the scaling factor which control the relationship between the seismic amount and apparent moment.

The obtained OBP time series will contain not only the crustal deformation but also the other contribution such as tidal component, non-tidal component, and specific sensor drift. Ocean tides were accounted for by harmonic analysis using the BAYTAP-G model of Tamura et al. (1991) and removed from the OBP time series. The model by Inazu et al. (2012) were applied to remove the non-tidal component. We fitted the drift model (Watts and Kontoyiannis, 1990) to each of the observed time series to estimate the drift function of individual sensors and removed from the time series.

Based on the obtained time series, we tried to detect the crustal deformation accompanied with the tremor activities. However, no significant displacement was detected from the OBP time series. This suggests that no crustal deformation has occurred beyond the current detectable accuracy of OBP. The current detectable accuracy of OBP is approximately ~1cm. If the 1cm displacement occurred at the OBP sited, roughly 5.7cm interplate slip is required. This is about 3.5 times slip amount suggested by Ohta et al. (2019).

After the 11 March 2011 Tohoku-oki earthquake, we have conducted multibeam bathymetric surveys. The bathymetric data were collected along the same tracks obtained before the earthquake. These selected tracks were crossing the trench and extending from the landward to seaward trench slopes. We examined seafloor displacement on the landwardrelative to the seaward by means of the difference in multibeam bathymetry before and after theearthquake. Up until the present, we have evaluated several tracks from off-Fukushima to off-Sanriku, thus the seafloor displacement distributionalong the Japan Trench.

Along the off-Miyagi tracks near the epicenter, crossing the trench at 38˚05'N,the landward slope was largely elevated, the seafloor displacement extended to the trench, and there was sharp bathymetric changes at the trench axis [Fujiwara et al., Science 2011]. The conclusive result suggests fault rupture and slip extending to a shallow part of the subduction zone reached the trench axis. We estimated the coseismic horizontal displacement using the horizontal bathymetric offset. The horizontal displacement was very large about 50 m to the trenchward direction.

Notably, on the outermost landward slope, the 40 km wide area between the slope break and the trench axis, the seafloor was more than 10 m shallower on average. The observed seafloor elevation change on the outermost landward slope corresponds to a sum of vertical displacement and additional uplift for the sloping seafloor due to horizontal displacement. This uplift was likely an important factor contributing to the generation of the massive pulsating pattern of tsunami waves.

The method described in the Fujiwara et al. [2011] paper implicitly assumed the seafloor moved as a block unit. Sun et al. [Nat. Commun. 2017] evaluated the fault slip distribution over the most near-trench 40 km zone. The slip gently increased towards the trench and peaked at the trench axis. The slip was determined to be about 60 m.Quantitative information on the shallow slip is of critical importance to understand the rupture mechanism and the generation of the ensuring devastating tsunami.

Upward and downward changes in seafloor elevation of ±50 m are evident at the axial seafloorat 38˚05'N. Seismic data showed deformation of the sediment layer within the trench.The result is further evidence of the rupture propagation through the sediment layer [Kodaira et al., Nat. Geosci. 2012; Strasser et al., Geology 2013]. This bathymetric deformation is confined to an area extending 13 and 7 km along and across the trench directions, respectively. Currently, similar prominent bathymetric deformation is not found in any other places.

©2020. Japan Geoscience Union. All Right Reserved.

Large seafloor displacements suggesting coseismic slips to the trench were consistent in survey tracks in the off-Miyagi area, as far as the track at 38˚35'N. While, smaller seafloor displacements were observedalong the off-Fukushima track crossing the trench at 37˚25'N and along the off-Sanriku track crossing the trench at 39˚05'N, therefore the large coseismic slip to the trench is considered to be limited to the off-Miyagiarea near the epicenter.

We acquired three off-Sanriku survey trackscrossing the trench at 39˚10'N, 39˚20'N, and 39˚30'Nbecause maximum tsunami height caused by the earthquakewas observed at the coast of Sanriku.The evaluated seafloor displacements were relatively small, less than about 20 m in trenchward horizontal displacement and several meters in vertical displacement. Thus localized very large fault slip or very large submarine landslide is unlikely at least on the three survey tracks. There were coherent relative differences in the seafloor elevation on the landward trench slopes, which suggests the outermost lower slope was uplifted and the middle slope and the mid-slope terrace subsided along the trench axis [Fujiwara et al., GRL 2017].

Relatively small displacements less than 20 m in horizontal displacement and several meters in vertical displacement, these values are within ranges of error of the analysis [Fujiwara et al., MGR 2015]. Thus, quantitative discussion is rather difficult as values of the seafloor displacements are concerned about burying in the ranges of error. Additionally, in our analysis, data quality of the bathymetric data before the earthquake was major problem because the usage of repeated bathymetric survey for detection of seafloor displacement was not foreseen at that time. For the future, repeated acquisition of high resolution and accuracy bathymetric data using state-of-the-art technology at the present time of survey is important in the tectonically active regions.

Modelling of spontaneous and periodic slow slip in the northern part of the Japan Trench

*Ryoko Nakata[1,2], Takane Hori[1], Ryota Hino[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Graduate School of Science, Tohoku University

In our previous studies, we focused the afterslip of the 2011 Tohoku-Oki earthquake, and conducted numerical simulation of earthquake generation cycles along the Japan Trench. We reflected trench-parallel remarkable difference of fault structure between the central and southern part based on marine survey and observations to spatial distribution of friction parameters of M~9 coseismic and postseismic areas. As a result, we could explain longer duration of postseismic slip in the southern part of the Japan Trench. However, we did not modeled slips in the northern part of the Japan Trench, where large coseismic slip of the Tohoku-Oki earthquake did not propagated, and slow-slips and tsunami earthquakes occur. Here, we modeled spontaneous and periodic slow slip in the northern part of the Japan Trench by using the same method. We will discuss roles of these slow slip during interseismic periods of a massive earthquake to understand physical conditions for generating a massive earthquake.

Structural-morphological and sedimentary features of forearc slope off Miyagi, NE Japan: implications for development of forearc basins and plumbing systems

*Jih-Hsin Chang[1], Jin-Oh Park[2], Tzu-Ting Chen[3], Asuka Yamaguchi[2], Tetsuro Tsuru[4], Yuji Sano[2], Ho-Han Hsu[3], Kotaro Shirai[2], Takanori Kagoshima[2], Kentaro Tanaka[2], Chiori Tamura[2]

Multibeam (MB) and subbottom profile (SBP) data along the forearc slope off Miyagi, Japan, are combined to investigate structural-morphological and sedimentary structures along the forearc slope of the Japan Trench subduction zone. In addition to dip-oriented slope gullies, the MB data image a nearly dip-perpendicular slope trough bounded by a fault scarp landward of the trench-slope break. Seaward of the trench-slope break, the subbottom mostly contains normal faults that dip in opposite direc- tions. The SBP data show not only unconformity and sliding surfaces, but also underfilled (forearc trough) and filled structures that may reflect the most recent forearc subsidence and basin filling. We propose these forearc trough and associated filling structures may indicate the earliest developments of modern isolated basins. Thus, a model of forearc basin development from slope gully to slope trough, isolated basins and forearc basin, transferred by active structures, could be proposed. Observed seafloor liquefaction in the SBP data may represent a near-surface seep structure of a plumbing system that enables hydrosphere- mantle fluid migration plausibly activated by earthquake cycles.

Structural variation in the shallowest part of the Japan Trench subduction zone and its correlation with shallow megathrust slip and tsunamigenesis

*Yasuyuki Nakamura[1], Toshiya Fujiwara[1], Shuichi Kodaira[1], Seiichi Miura[1], Koichiro Obana[1]

1. Japan Agency for Marine Earth Science and Technology

The shallow megathrust slip to the vicinity of the trench is one of the key features of the 2011 Tohoku earthquake. Understanding the detailed structure in the shallowest portion of the Japan Trench subduction zone is indispensable to investigate the nature of the shallow slip. We have conducted seismic reflection surveys using a “compact” seismic system to map the seismic structural characters in the Japan trench axis region. Differential bathymetry estimation provided strong evidence with which to examine the shallow megathrust slip to the trench. Seismic sections in areas with large horizontal displacement estimated from differential bathymetry display folds and thrust faults, whereas ones in areas without large displacement display chaotic acoustic structures in the trench axis without any clearly imaged thrust faults or folding deformation. We suggest that the thrust faults clearly imaged in the trench axis acted as the shallowest plate boundary megathrust during the Tohoku earthquake and caused the displacement observed by the differential bathymetry. The trench axis around the 39.5˚N where the tsunami source was proposed, the seismic sections and bathymetric data indicate the past slope failures. The differential bathymetry estimates suggested no large trench-ward displacement during the Tohoku earthquake in this region. Taking into account the slope failures imaged in the seismic profiles in this region, we speculate that small-scale slope failure might have contributed to tsunamigenesis during the Tohoku earthquake. In the north of 40˚N where neither large displacement nor tsunami generation was supposed during the Tohoku earthquake. In this region, the seismic sections show a well-developed thrust-and-fold structure not only within the vicinity of the trench axis but beneath the lower landward slope 10 –20 km landward from the trench axis. This area is proposed as the tsunami source area of the 1896 Meiji Sanriku earthquake together with the area of slope failure around 39.5˚N. The Meiji Snariku earthquake and tsunami might be generated by a combination of the slope failure and thrust faults imaged.

[S-CG62] Investigation of inputs to subduction zones: Influence of tectonic processes on the incoming plate

convener:Makoto Yamano(Earthquake Research Institute, the University of Tokyo), Tomoaki Morishita(School of Geoscience and Civil Engineering, College of Science and Technology, Kanazawa University), Gou Fujie(Japan Agency for Marine-Earth Science and Technology)

Various tectonic processes occur on the seaward side of the trench associated with bending of the incoming oceanic plate, e.g., fracturing of oceanic crust, infiltration of water, and intraplate volcanism. Investigation of these processes and their influence on the incoming plate provides important information on the boundary condition at the trench, inputs to subduction zones. Variation in inputs should significantly affect geophysical/geological phenomena around the plate interface and geochemical cycles in subduction zones. We welcome contributions from a broad range of earth science (geophysics, geology, petrology, and so on) discussing topics related to inputs to subduction zones such as occurrence of tectonic processes due to bending of the incoming plate, modification of the incoming plate by the processes, relationship between the processes and the inherited structure of the incoming plate, and influence of the processes on the subduction plate interface. We hope discussions are made on studies of a variety of subduction zones, including the Japan Trench and the Nankai Trough, and comparative studies among different subduction zones.

Incoming Plate Faulting at the Outer Slope of the Middle America Trench offshore Mexico

*Emmanuel Soliman M Garcia[1], Yoshihiro Ito[1]

1. Disaster Prevention Research Institute, Kyoto University

At the northern segment of the Middle America subduction zone, the Cocos Plate subducts underneath the North America Plate. Seaward of the trench, the seafloor contains horsts and grabens. These structures are typically associated with normal faulting, but their orientation with respect to the trench are mostly parallel or sub-parallel, which suggests that they are reactivated abyssal hills faults. At other subduction zones, such as at the Kuril and the Alaska-Aleutian, the reactivation of these normal faults formed at the spreading ridge is typically attributed to bending of the incoming plate. However, compared with the outer rise at these other subduction zones, the flexural deformation of the incoming Cocos Plate offshore Mexico is less prominent. This is expected if the elastic thickness is dependent on age, since the seafloor age in this region is less than 30 Ma. Furthermore, the characteristics of the trench outer slope faults vary across the segments of the subduction zone offshore Mexico. At the northwest portion which is offshore Guerrero, the fault scarps are mostly lower than 100 meters and have strikes that tend to be parallel to the trench. Meanwhile, at the southeast portion which is offshore Chiapas, the fault scarps are a few hundred meters in height and have strikes that are slightly oblique to the trench. To better understand the connection between lithospheric flexure and the observed normal faulting at the trench outer slope, we calculated the stresses due to elastic bending, which is linearly related to the curvature of the plate. Deriving the curvature from bathymetry can be challenging because of the presence of rough seafloor topography such as seamounts. Thus, to minimize effects from the bathymetric noise, we set up a regularized parameter estimation problem to solve for the bending curvature. Our results suggest that the higher plate curvatures at the Chiapas segment compared with the Guerrero segment are consistent with the differences in observed faulting and seismicity between the two regions.

Analysis of the variations in topographic features around the outer-rise of Japan trench

*Tomoko Hanyu[1], Jin-Oh Park[2], YUE SUN[2], Ehsan Jamali Hondori[2], Yukari Kido[3]

1. Kobe Ocean-Bottom Exploration Center, Kobe University, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Japan Agency for Marine-Earth Science and Technology

The 1933 Showa-Sanriku earthquake which was caused by a shallow and near-trench earthquake-fault on the outer-rise of the northern part of Japan Trench occurred 37 years after the 1896 Meiji-Sanriku tsunami earthquake. Precise location of earthquake-fault of the 1933 earthquakes have not yet been obtained (e.g. Obana et al., 2018).
For identifying the earthquake-fault around the outer-rise of Japan trench, it is necessary to determine the mechanism by which the topographic features of the outer-rise are formed. Most of the previous studies about flexural modeling identify only the deformed shape of the subducting plate without considering the features unrelated to flexural bending, such as earthquake-faults, seamounts, and volcanic ridges. Sparse topographic and gravity data make it difficult to estimate the elastic thickness distribution of the local area adjacent to the faults. To solve this problem, we aim to calculate the "non-isostatically-compensated topography (non-isostatically topography)" by using the method of Zhang et al. (2014). The non-isostatically topography was calculated by removing from the observed bathymetry (1) the effects of sediment loading, (2) isostatically-compensated topography based on gravity modeling, (3) age-related lithospheric thermal subsidence, and (4) flexural model of the bending plate. Fine scale bathymetry data set, which was compiled and provided by JCG and JAMSTEC (after Kido et al., 2011), was used for the analysis. The Matlab toolbox TAFI (Jha et al., 2017) was applied for modeling flexural deformation of the bending plate. The plate flexural bending model was estimated by every 0.05 degrees for latitude perpendicular to the subduction.
We will discuss the non-isostatically topographic features and elastic thickness in the local area of the outer-rise of Japan Trench.

Drift sediments recording bottom current history in NW Pacific

*Kiichiro Kawamura[1], Tomoka Adachi[1], Maki Suzukawa[1]

1. Yamaguchi University

We reported in detail deep-sea drift sediments collected from on an abyssal plain in NW Pacific. Four sediment core samples were collected using a 4-m piston corer system during the cruise KH-18-5; HFPC01–04. The sediment samples are composed of mostly diatomaceous silty clay layers with sandy layers. The sediment layers are interbedded with a volcanic ash layer. There are two lines of evidence on drift sediments on the basis of sedimentological and magnetical analyses as follows.
First, we counted sedimentary grains of 63–128 μm in diameter in 2 cm intervals. The sedimentary grains consist of quarts, pumice, volcanic glass, diatom, radiolaria and so on. Two types of pumice grains could be observed as dirty grains with mud cover and clear grains. The clear pumice and volcanic glass would be associated with volcanic eruption, whereas the dirty pumice has no correlation with those grains. There were spike peaks of dirty pumice grains cyclically throughout the core sediments. We consider that the dirty pumice might be washed out of surface sediments and transported with long-term flows as re-sedimentation processes.
Second, we measured magnetic properties in the sediment core samples; anisotropy of magnetic susceptibility (AMS) and paleomagnetism. In general, the AMS demonstrates the alignment patterns of magnetic grains in specimens. These anisotropy can be represented by magnetic ellipsoids with three magnetic axes; maximum, intermediate and minimum susceptibilities (hereafter Kmax, Kint, Kmin, respectively). Kmax generally indicates the alignment direction of the magnetic grains. In this case, sediment core samples were rotated during sampling operation, so that we could not understand the north direction of the samples. In order to determine the north direction, we measured paleomagnetic directions in the core samples. We used remenent magnetization data under the 200G alternating field demagnetization conditions. Thus, we measured alignments of magnetic grains using two magnetic methods. As a result, the Kmax direction of these sediment core samples were mostly E-W indicating sub-parallel to the present bottom current directions as shown in Fujio and Yamamoto (2005).
As mentioned above, the the magnetic grains in the sediment core samples in NW Pacific were alinged sub-parallel to the present bottom current directions. This indicates that these sediments were transported and deposited by the bottom currents as drift sediments and/or contourite deposits. At least, the sediments were closely related to the bottom currents. These sediments contained dirty pumice grains indicating probably a re-working process.

Effects of lithology on the mechanical properties of the input materials at the Hikurangi margin

*Alexi Kristina Allen[1], Hiroko Kitajima[1]

1. Texas A and M University

Subduction zones are known to produce large, damaging earthquakes, but they can also experience slow-slip events which cannot be felt by humans. Understanding the mechanisms that influence this variation in slip rate is crucial for better assessing how the subduction zones will act in the future. While the seafloor sediments make up a small portion of the subducting oceanic plate, they can have a noticeable impact on its ability to produce both large earthquakes and slow-slip events. Here, we report the mechanical properties of sediments and rocks that are subducting in the Hikurangi Margin. The International Ocean Discovery Program (IODP) Expedition 375 recovered input sediments and basement rocks at Sites U1520 and U1526. We compared shipboard physical properties with the chemical composition determined using the X-ray fluorescence (XRF) scanner at the Gulf Coast Repository. We also analyzed drilling data and conducted deformation experiments on volcaniclastic materials from Site U1520. By integrating the XRF data with porosity, p-wave velocity, and drilling parameters, as well as lab tests to determine the strength of these rocks, we can evaluate how the composition of the sediments affects their physical and mechanical properties. The preliminary results show a strong correlation between calcium content, porosity, and p-wave velocity for the volcaniclastic cores. There is also evidence to suggest that the torque on bit during drilling is an indication of rock strength as it increases sharply when the calciferous-volcaniclastic boundary is reached. Triaxial compression tests in the lab should confirm and quantify the rock strength of the volcaniclastic materials. This investigation into the subducting sediments properties builds onto pre-existing studies into the effects of seamounts on subduction and the factors that influence the slip rate at subduction zones.

Subduction initiation at active spreading mid-ocean ridge indicated by ultrahigh temperature slab melting

*Chiou-ting Lin[1], Kuei-Chih Feng[2], Masaki Enami[3], Hou-Chun Liu[4], Ji-Hao Zhu[6], Ron Harris[5], Wei-Dong Sun[1]

1. Center of Deep Sea Research, Institute of Oceanology, Chinese Academy of Sciences, 2. Department of Mechanical Engineering, Ming Chi University of Technology, 3. Institute for Space–Earth Environmental Research, Nagoya University, 4. Department of Earth Science, National Cheng Kung University, 5. Department of Geology, Brigham Young University, 6. State Oceanic Administration, Second Institute of Oceanography, Ministry of Natural Resources

The initiation of plate subduction is the last piece of the jigsaw puzzle of the plate tectonic theory. How the subduction of small oceanic plates commenced, and the magmatism of the subduction initiation has been particularly controversial. Here we report a new type of calc-alkaline andesite/dacite associated with initiation of subduction. The *Lichi andesite/dacite (LAD)* has typical geochemical features of slab melting, but abnormally displays relative enrichments in Nb-Ta and depletion in Ti and Pb. The *LAD* mineral assemblage consists mostly of plagioclase and two-pyroxenes with rare hornblende and biotite. No quartz or K-feldspar phenocrysts are observed. The presence of cristobalite in the matrix of the dacite and geochemical relations indicate slab melting occurs at an ultrahigh temperature and relatively low pressure environment, which is consistent with subduction initiation of an active spreading ridge along a transform fault.

[S-CG63] Dynamics in mobile belts

convener:Yukitoshi Fukahata(Disaster Prevention Research Institute, Kyoto University), Ray Y Chuang(Department of Geography, National Taiwan University), Toru Takeshita(Department of Natural History Sciences, Graduate School of Science, Hokkaido University), Hikaru Iwamori(Earthquake Research Institute, The University of Tokyo)

The dynamic behaviors of mobile belts are expressed across a wide range of time scales, from the seismic and volcanic events that impact society during our lifetimes, to orogeny and the formation of large-scale fault systems which can take place over millions of years. Deformation occurs on length scales from microscopic fracture and flow to macroscopic deformation to plate-scale tectonics. To gain a physical understanding of the dynamics of mobile belts, we must determine the relationships between deformation and the driving stresses associated with plate motion and other causes, which are connected through the rheological properties of the materials. To understand the full physical system, an integration of geophysics, geomorphology, geology, petrology, and geochemistry is necessary, as is the integration of observational, theoretical and experimental approaches. In particular, rheological properties, which are physically affected by fluids in the crust and chemical reactions assisted by fluids, can be resolved only through such an interdisciplinary approach. After the 2011 great Tohoku-oki earthquake, large-scale changes in seismic activity and regional scale crustal deformation were observed, making present-day Japan a unique natural laboratory for the study of the dynamics of mobile belts. This session welcomes presentations from different disciplines, such as seismology, geodesy, tectonic geomorphology, structural geology, petrology, geochemistry and hydrology, as well as interdisciplinary studies, that relate to the dynamic behaviors of mobile belts.

Seismic potential along the Caribbean subduction zone northwestern Colombia revealed by GPS data

*Sindy Carolina Lizarazo[1], Takeshi Sagiya[2], Hector Mora-Paez[3]

1. Graduate School of Environmental Studies - Nagoya University, 2. Disaster Mitigation Research Center - Nagoya Univesity, 3. Geological Survey of Colombia - GeoRED Project

Colombia is characterized by the complex interaction among the Caribbean, Nazca and South American plates, as well as the North Andean and Panama blocks. This setting causes intense seismicity and faulting along the collision and subduction regions whose natures are not well understood. Under these conditions, the current GPS network becomes an important tool to study the regional kinematics, understand the observed crustal deformation and evaluate the seismic potential in the country.

We analyzed data from 87 continuous GPS stations during the period 2008-2017 obtained by the GeoRED project from the Geological Survey of Colombia and the COCONet project (Continuously Operating Caribbean GPS Observational Network).Daily coordinates of the GPS sites were calculated using the GAMIT/GLOBK software v.10.7 under the ITRF2014 reference frame. Then, average displacement rates were calculated by using HECTOR software considering seasonal components and offsets due to instrumental changes (Bos et al., 2013). Finally, a geodetic inversion analysis following Yoshioka et al. (1993) was performed in order to evaluate the interplate coupling and the seismic potential along the Caribbean subduction zone.

Along the Caribbean subduction zone, we identified an isolated fully locked patch south of the city of Cartagena extending from 5km to 20km depths. The origin of this asperity is enigmatic and it allows us to propose two possible interpretations. The first one is elastic deformation able to generate a Mw 8.2 earthquake. We obtained a seismic moment accumulation rate of assuming an average slip deficit rate of 9.9 mm/yr and consequently, we estimate an average recurrence interval of ~540 years. Although there is no record of giant earthquakes in this area, we cannot reject this scenario because the historical record is too short to register the past event. The second one is that the whole deformation is inelastic. Estimates of long-term shortening based on seismic cross sections do not support this hypothesis because it is too small compared with the geodetic rate. However, still this possibility holds since there is a possibility of an accelerated deformation during the last 1 Ma. To discern between both scenarios, it is essential to conduct a careful geological investigation to identify recent evidence of crustal shortening or paleotsunami along northwestern Colombia.

New Megathrust Locking Model for the Southern Kurile Subduction Zone Incorporating Viscoelastic Relaxation and Non-uniform Compliance of Upper Plate

*Yuji ITOH[1], Takuya NISHIMURA[2], Kelin WANG[3], Jiangheng HE[3]

1. Graduate School of Science, Kyoto University, 2. Disaster Prevention Research Institute, Kyoto University, 3. Pacific Geoscience Centre, Geological Survey of Canada

In the southern Kurile subduction zone, many megathrust earthquakes have occurred, including a M 9 tsunamigenic event in the 17th century. Current locking state of the megathrust has been inferred from land GNSS data before the 2003 M_w 8.0 Tokachi-oki earthquake in many previous studies using either elastic or viscoelastic models. The previous locking models exhibit physically unreasonable features such as slip deficit rates exceeding the plate convergence rate and/or high a degree of locking at large depths where stick-slip behavior is not expected. We think the cause of the problems is the assumption of a mechanically uniform upper plate. In order to improve the locking model, we have constructed a subduction zone model that includes variations in the elastic compliance of the upper plate in the margin-normal direction, consistent with the thermal regime of the subduction zone.
We construct a 3D viscoelastic model using the Finite Element Method. In our model, the rigidity values in the backarc, volcanic arc, and forearc regions are 48 GPa, 16 GPa, and 48 GPa, respectively. The elastic thicknesses of the three areas are 10 km, 7.5 km and 25 km, respectively, except for a portion of the forearc that has a greater thickness to account for the presence of a “cold nose” of the mantle wedge. For comparison, we also construct a model in which the upper plate rigidity and elastic thickness are uniformly 48 GPa and 25 km, respectively. We generate interseismic viscoelastic Green’s functions using these structures and derive megathrust locking distributions by inverting GNSS velocities prior to the 2003 earthquake.
In the model of non-uniform upper plate, full locking of the megathrust is limited to depths shallower than the downdip rupture limits of the 2003 mainshock and the 1973 M_w 7.8 Nemuro-oki earthquake in the northeastern neighbor region. Similar results in which parts of past megathrust rupture areas are not fully locked during the interseismic period have been reported for the Tohoku-oki and Kamchatka regions. It is consistent with the shrinking of megathrust locked zone during the interseismic period and/or the invasion of dynamic rupture into low-locking areas predicted by numerical simulations with a rate-and-state friction laws. However, sensitivity tests using forward modeling show that full locking covering the 2003 rupture area can also reasonably fit the horizontal GNSS data. To constrain spatiotemporal changes in megathrust locking during the interseismic period in future studies, we will need a much longer observational time window which requires additional conventional geodetic data prior to the GNSS era. In our preferred model, the near-trench part of the megathrust is fully locked. A model in which the near-trench part is forced to creep can fit the land GNSS velocities equally well. Therefore, even after incorporating the non-uniform compliance and interseismic viscoelastic relaxation, the locking state of the megathrust near the trench cannot be resolved by the land data only. Nevertheless, we infer locking near the trench axis of the Nemuro-oki region because no tremor is detected with the seafloor observation network S-net.

Occurrence of normal-type earthquakes and stress loading model under Boso Peninsula, Japan

*Akinori Hashima[1], Hiroshi Sato[1], Toshinori Sato[2]

1. Earthquake Research Institute, University of Tokyo, 2. Graduate School of Science, Chiba University

Boso Peninsula, Japan, was formed by the interaction of the Philippine Sea, Eurasian and Pacific plates around the trench-trench-trench Boso triple junction. Normal-type earthquakes are persistently observed in the subducting Philippine Sea slab under the peninsula at depth of ~30 km, including a recent (2019) Mw4.9 earthquake which caused shaking throughout the Kanto region (greater Tokyo). Such shallow intra-plate earthquakes are potentially hazardous to this heavily populated region, yet their mechanism is poorly understood, compared with the outer rise earthquakes or intermediate deep earthquakes within slabs. In the previous study, we modeled long-term deformation due to steady subduction of the Pacific and Philippine Sea plates (Hashima et al., Tectonophysics, 2016). Here, we calculate stress rates in the Philippine Sea slab and the surrounding area, using our subduction model, to explain the generation of the regional stress field and its effect on earthquake occurrence.

In our model, the subduction of the Pacific and Philippine Sea plate is expressed by the steady slip (dislocation) on the plate interfaces. The collision of the Izu Peninsula is expressed by slip-rate deficit. The area of the slip-rate deficit is determined to satisfy the long-term deformation data obtained by geological and geomorphological methods. Then, slip-rate deficit turned out to be distributed on the northwest side of the Izu Peninsula.

Using this optimum model, we obtained all-around horizontal extensional stress rates under Boso Peninsula both above and below the Eurasian-Philippine Sea plate interface. In broader view, the stress rates are northwest-southeast compression in the collision zone around Izu Peninsula, strike-slip type in the Philippine Sea plate to the south, and horizontal extension in the Eurasian plate north of Boso Peninsula.

We apply our calculated stress rates to the nodal planes of the observed earthquakes to calculate the Coulomb failure function (ΔCFF). These calculated ΔCFFs are generally positive on normal-type earthquakes under Boso. This result indicates that modeled intra-plate stress pattern is consistent with earthquake occurrence as the stress release process. The ΔCFFs are also consistent with earthquakes in adjacent seismically active areas: the Izu collision zone, the interior of the Philippine Sea plate, and in seismic swarms in the Eurasian plate northeast of Boso Peninsula, which further supports our stress loading model.

To reveal the individual contributions of the Philippine Sea and Pacific subduction and the Izu collision, we decomposed the calculated stress rates. The collision effect is negligible on Boso Peninsula. The subduction of the Pacific plate creates east-west extension, while that of the Philippine sea plate creates north-south extension. Both subduction together creates the characteristic all-around extension under Boso Peninsula.

3-D Numerical Simulation of Island Arc Deformation Due to Steady Plate Subduction

*Yutaro Mori[1], Yukitoshi Fukahata[2]

1. Graduate School of Science, Kyoto University, 2. Disaster Prevention Research Institute, Kyoto University

Island arc-trench system is characterized by a pair of anomalies in topography and free-air gravity, which is high in the island arc and low around the trench. Although this feature is observed without exception in the world, physical mechanism of the formation of this feature has not been well understood. Fukahata and Matsu'ura (2016) calculated deformation of the island-arc lithosphere due to steady plate subduction for a 2-D problem and explained the deformation mechanism based on the combination of lithospheric rotation and gravity. However, 3-D geometry of the plate interface may have an important effect on lithospheric deformation. For example, a large negative gravity anomaly is observed around a bend of a trench axis (Sandwell and Smith, 1997). This feature has been well reproduced by a numerical model (Hashimoto et.al., 2008), but the physical mechanism of the formation has not been clarified yet.

In this study, we develop a 3-D numerical model based on elastic-viscoelastic dislocation theory and compute lithospheric displacement rates in the island arc-trench system caused by steady slip on a plate interface, which has a convex bend toward the island arc along the trench axis. Computed results show that the island arc lithosphere significantly subsides around the bend, where horizontal extension parallel to the trench axis is observed. This result suggests that the slip vectors that have the direction away from the bend along the trench in the overriding plate results in mass deficit around the bend and subsidence of the island-arc lithosphere.

Cause of the horizontal deformation of the Philippine Sea plate subducting beneath southwestern Japan

*Kazuki Miyazaki[1], Junichi Nakajima[1]

1. Department of Earth and Planetary Sciences, Tokyo Institute of Technology

The Philippine Sea plate subducting in southwestern Japan shows an interesting feature that it undergoes horizontal deformation after subduction. However, the cause of the significant deformation remain poorly understood. Therefore, this study investigates the horizontal deformation of the Philippine Sea plate in terms of the geometrical interaction with the Pacific plate.

First, we confirm that the observed eastern limit of the Philippine Sea plate beneath Kanto can be well reproduced with the subduction of the Philippine Sea plate onto the Pacific plate at dip angles of 12º down to a depth of 40 km and 40º at greater depths. Next, we apply the method that can expand a deformed plane surface to an undeformed geometry using lattice points assigned on the subducted Philippine Sea plate. Based on the two analyses, we conclude that the deformation of Philippine Sea plate is controlled by the shape of Pacific plate.

Modeling strain concentration zones in Kyushu Island considering heterogeneous rheological structure

*Bunichiro Shibazaki[1]

1. International Institute of Seismology and Earthquake Engineering, Building Research Institute

Recent large intra-plate earthquakes in Japan have occurred in strain concentration zones which have been revealed by the analysis of dense GNSS data. For example, the 2016 Kumamoto earthquake occurred in a strain concentration zone in Kyushu Island (Nishimura et al., 2016) and the 2016 Central Tottori earthquake occurred in the Sanin strain concentration zone (Nishimura and Takada, 2017). It is thought that strain concentration zones are caused by heterogeneous rheological structures that are the result of heterogeneous thermal structures and distributions of water content and preexisting geological structures. This study models the Kyushu strain concentration zones to understand the generation processes of large intraplate earthquakes by considering the heterogeneous rheological structure.

Geothermal gradients according to data obtained from Hi-net (Matsumoto et al. 2007) and from the Geological Survey of Japan (Tanaka et al. 2004) indicate high geothermal anomalies in the Beppu–Shimabara graben zone, in particular, regions that include the Kujyu and Aso volcanoes and the Beppu region. Geothermal gradients are also high in the regions of the Kirishima and Sakurajima volcanoes. The distribution of the geothermal gradient is similar to that of the cut-off depth of the seismicity obtained by Matsumoto et al. (2016).

This study models strain concentration zones by considering the heterogeneous rheological structure using the finite element method (Shibazaki et al., 2007), with nonlinear viscoelasticity and Mohr–Coulomb plasticity. From the observed geothermal gradient distribution, we assume that temperature increases with depth. We set the boundary conditions as extensional in the N–S direction and compressional in the E–W direction. We reproduce the strain concentration zone along the Futagawa fault, where the 2016 Kumamoto earthquake occurred. However, we cannot reproduce the strain concentration zone along the Hinagu fault. Therefore, we include the low-strength region around the Hinagu fault zone considering the existence of an ancient accretional complex, and the low-strength region in the northern part of the Okinawa Trough. By considering these low-strength regions, we can reproduce the strain concentration zones along the Futagawa and Hinagu fault zones, the pattern of which is similar to the observed one.

Estimation of inelastic strain rate in the lower crust based on GNSS and seismic data and its implication for dynamics in Kyushu, southwest Japan

*Yuhei Yuasa[1], Satoshi Matsumoto[2]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2. Institute of Seismology and Volcanology, Faculty of Science, Kyushu University

It is considered that localization of inelastic deformation due to viscous inhomogeneity in the lower crust results strain concentration zone in island arc, and estimation of the inelastic strain rate in the lower crust is being performed. On the other hand, while the inelastic strain rate and the deviatoric stress are related by the flow rule, the information on the estimated deviatoric stress field has not been taken much care in the previous studies. In this study, we proposed a new method for estimating the inelastic strain rate in the lower crust, which incorporates the information of deviatoric stress field. Furthermore, since the subduction of the plate is an important factor for the crustal deformation process in island arc, we also attempted simultaneously to estimate the distribution of locking at the interface of the subducting slab with the inelastic strain rate in the lower crust.

We adopted back slip model (Savage, 1983) for the coupling of the interface and the box-shaped source (Barbot et al., 2017) for inelastic deformation in the lower crust. Using the ground surface strain rate estimated from GNSS observations as data, the inelastic strain rate in the lower crust and the slip deficit rate at the plate boundary were estimated. We applied two constrains in the scheme: 1) the smoothing of the slip deficit rate distribution and 2) the direction of the inelastic strain rate followed the deviatoric stress (flow rule). The strength of these constraints is determined by minimizing the Akaike Bayesian information criterion (Akaike, 1980).

The results showed that high inelastic strain rate (~1×10^{-6} /yr) were obtained around Central and southwestern Kyushu. These areas correspond to the areas with high seismic activity. We found that the seismicity was induced by the inelastic deformation in the lower crust by calculating the stress change due to the inelastic deformation in the lower crust. In addition, these areas have high geothermal gradients in Kyushu (Tanaka et al., 2004), and the seismic velocity at depth 20 km is low velocity anomalies (Saiga et al., 2010). The results suggest that the lower crust in these region is in a high temperature / wet environment, and that the viscosity of the rocks is low. Therefore, the estimated high inelastic strain rate can be interpreted as an inelastic deformation concentration zone in the low viscosity lower crust. Also, the estimated the distribution of slip deficit rate is 10 - 25 mm/yr around the Bungo Channel, while the Hyuga-Nada is hardly locked. The stress change due to locking between plates are smaller than one due to inelastic deformation in the lower crust. Therefore, it is considered that the inelastic deformation in the lower crust plays an important role in seismic activity and crustal deformation in inland Kyushu.

Tectonic development along the Hinagu fault zone, Kumamoto Prefecture, Japan

*Kenta Kobayashi[1], Keiji Ogashiwa[1]

1. Department of Geology, Faculty of Science, Niigata University

The Futagawa and the Hinagu fault zones were activated at the time of the 2016 Kumamo earthquake. To understand how fault zones have developed over a long period of time, it is necessary to observe fault zone structures at the macro to microscope scales. We carried out field surveys in the aftershock area of the earthquake, and analyzed the meso-structures of the brittle fault rock zones and porphyry dikes. Paleo-stress field and K-Ar age of the porphyry were determined.
NNE-SSW striking remarkable brittle shear zone was recognized in the Hinagu Formation (Early Cretaceous), indicated dextral-normal slip sense (2nd stage). On the other hand, outsides of the shear zone, indicated sinistral slip sense (1st stage). The shear zone was intruded by porphyry dikes, and cut by NNW striking sinistral and E-W striking dextral minor faults (3rd stage). Based on the slip sense of the 2nd stage faults and geometry of the dikes, paleo-stress field was determined as strike slip to normal type. The K-Ar age of the porphyry was dated as 21.78±0.56Ma.
Brittle fault rock zones were also distributed in the Higo metamorphic rocks. The macroscale fault zone in the aftershock area has a long history of deformation and complicated structure. Parts of them were selected, and activated at the time of the aftershocks.

Physical modeling of postseismic deformation following the 2008 Iwate-Miyagi Nairiku Earthquake

*Yoshiki Takei[1], Youichiro Takada[2], James Daniel Paul Moore[3], Mako Ohzono[4]

1. Department of Natural History Sciences, Hokkaido University, 2. Faculty of Science, Hokkaido University, 3. Earth Observatory of Singapore, Nanyang Technological University, 4. Institute of Seismology and Volcanology, Graduate School of Science, Hokkaido University

The Iwate-Miyagi Nairiku Earthquake (hereafter IMNE) occurred on June 14, 2008 (Mw 6.8). Fault models of the mainshock have been proposed from GNSS survey (Ohta et al., 2008; Iinuma et al., 2009), InSAR analysis (Takada et al., 2009; Abe et al., 2011), and seismographs (Suzuki et al., 2010). The fault models proposed from GNSS and seismographs consist of west-dipping reverse faults with maximum slip exceeding 6 meters. On the other hand, InSAR and offset measurement of SAR intensity images clearly indicate the existence of east-dipping fault along the western side of the hypocentral area.

Large postseismic deformation following the mainshock also have been detected by GNSS and InSAR (e.g., Iinuma et al., 2009; Ohzono et al., 2011; Takada et al., 2011). The interferograms taken from descending orbit (2008/7/16 - 2010/7/22) indicate the LOS displacements ~10 cm away from the satellite at hanging-wall side of the west-dipping faults, and ~15 cm toward the satellite around the northern part of Mt. Kurikoma.

Two physical models of the postseismic deformation of IMNE have been proposed previously. Iinuma et al. (2009) estimated the after-slip distribution from GNSS data near the fault traces for a month after the mainshock. They found cumulative afterslip on the coseismic faults as well as nearby active fault named the Dedana Fault (DF). The viscoelastic relaxation of this earthquake was calculated by Ohzono et al. (2011). They modeled crust-mantle system as an elastic layer overlying a viscoelastic substratum, and successfully explained the far-field displacements. In these studies, (1) only GNSS data were used, and (2) mutual interaction between the afterslip and viscoelastic relaxation has not been considered.

In this study, we construct a physical model of the postseismic deformation following IMNE on the basis of half analytic solution, named Unicycle (Barbot et al., 2017; Moore et al., 2017). With Unicycle, we consider (1) mutual interaction between the afterslip and the viscoelastic relaxation, (2) afterslip following the rate-and-state friction law (e.g., Dieterich, 1979; Ruina, 1983), and (3) horizontal heterogeneity of rock rheology with nonlinear power-law creep predicted from room experiments (e.g., Kirby, 1983). We started from simple model with the rheological structure proposed by Ohzono et al. (2011) and the coseismic slip distribution proposed by Iinuma et al. (2009).

In our calculation, large afterslip on DF is not triggered unlike Iinuma et al. (2009). The calculated postseismic displacement field well explains far-field GNSS data, which is consistent with Ohzono et al. (2011). In addition, our calculation explains the near-field GNSS data in the eastern side of the faults. Large discrepancies between the calculated and the observed displacements along the western side of hypocentral area are, possibly due to lack of the east-dipping fault in the current coseismic slip model. Thus, we have to consider the conjugate fault system proposed by Takada et al. (2009) and Abe et al. (2013) to explain both GNSS and InSAR data.

Spatial change of extension direction detected by paleostress analysis in the Miocene Tanabe Group, Southwest Japan

*Noriaki Abe[1], Katsushi Sato[1]

1. Division of Earth and Planetary Science, Graduate School of Science, Kyoto University

Stress state in forearc basin is considered to reflect deformations along the underlying plate boundary fault and of basement such as accretionary prism. Lin et al. (2010) reported spatial difference of stress in the Kumano Basin, present-day forearc basin offshore the Kii Peninsula (Lin et al., 2010). Extension direction is perpendicular to trench near outer-arc high, whereas it becomes perpendicular to subduction direction as distance from outer-arc high increases. The spatial resolution, however, is not enough to reveal whether the difference reflects local deformations or regional stress change related to plate subduction or deformation of basement. Onland paleoforearc basin sediments, as an analog to present basin, are suitable for bring out spatial variety of stress. This study performed a series of paleostress analyses by using outcrop-scale structures in the Miocene Tanabe Group, paleoforearc basin sediments. The study area extends roughly 10 km along the coastal area of the Shirahama Formation, the upper part of the Tanabe Group, the Kii Peninsula, southwest Japan. The measured structures consist of outcrop-scale faults and mineral veins. Fault displacements range from about several mm to 1 m. The thicknesses of veins are about several mm. In total, 159 faults and 245 veins have been observed. They have been analyzed by the stress inversion methods (Sato, 2006; Yamaji and Sato, 2011), which can detect multiple stress conditions from a dataset.
As the result, normal and strike-slip faulting stress regimes were detected. The horizontal extension direction was spatially variable. It trends roughly N-S in southern area, rotates clockwaise and trends E-W in northern area. The change of extension direction is not consistent with the frequency of map-scale faults. Extension normal to the outer-arc high at the southern end of the Kumano Basin can be considerd to reflect rising of outer-arc high. The change of extension direction in the Tanabe Group may be reflect the same tectonics at the pereiod.

Non-double-couple earthquake in the focal area of the 2000 Western Tottori earthquake by “0.1 manten” hyperdense seismic observation and spatial distribution of non-double-couple components

*Yuto Hayashida[1], Takumi Motokoshi[1], Satoshi Matsumoto[2], Yoshihisa Iio[3], Shin'ichi Sakai[4], Aitaro Kato[4], Group for "0.1 manten" hyperdense seismic observation Group registration

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2. Institute of Seismology and Volcanology, Faculty of Sciences, Kyushu University , 3. Disaster Prevention Research Institute, Kyoto University, 4. Earthquake Research Institute, University of Tokyo

Non-double-couple (NDC) earthquakes are defined as a faulting of ordinary double-couple (DC) earthquake on a fault associated with additional rupture at the hypocenter. They have been mainly observed in volcanic zones and interpreted as faulting related to fluid effects in the hypocentral region. Study on NDC earthquakes is important for understanding the faulting process and provides an opportunity to obtain new information on stress and strength of the Earth’s crust.

We had installed 1,000 temporary seismic stations in and around the source region of the 2000 Western Tottori Earthquake during the period from April 2017 to April 2018. This observation is called “0.1 manten” hyperdense seismic observation. We determined hypocenters using the data of the seismic network of both the “0.1 manten” and Hi-net by NIED. We manually picked the arrival times and P wave polarities. We found that the observational polarity distribution was slightly different from that expected by a DC source model at certain areas. Especially, we observed positive polarities at the stations where the DC model suggested to be negative polarities on and around the null-axis and nodal planes. In this study, we attempted to estimate the precise moment tensor solution to explain the observed polarity for the NDC event. We adopted the tensile-shear model and searched optimal model by performing a grid search and correlation analysis of S/P wave amplitude ratio.

We revealed that most of the events were modeled as DC earthquake or DC earthquake with an opening crack. In addition, we found the trend that the events with large NDC components were located around the large co-seismic slip zone and the northern part of the aftershock area where we observed a branched fault zone. These results suggest that pressurized fluid or a weak tensile crack might exist along the rupture zone of the Western Tottori earthquake.

Driving stress of the 2013 M_w5.8 Awaji Island earthquake, Japan, inferred from well-constrained focal mechanisms and its seismotectonic implication

*Kazutoshi Imanishi[1], Makiko Ohtani[2], Takahiko Uchide[1]

1. Geological Survey of Japan, AIST, 2. Earthquake Research Institute, The University of Tokyo

A driving stress of the 2013 M_w5.8 reverse-faulting Awaji Island earthquake was investigated using well-constrained focal mechanism solutions. The stress tensor inversion and the slip tendency analysis revealed that the stress field within the source region deviates from the surrounding area, in which the stress field locally contains a reverse-faulting component with NNW–SSE compression. This local fluctuation in the stress field is indispensable to produce the reverse-faulting earthquake. The existing knowledge on regional-scale stress (tens to hundreds of km) could not predict the occurrence of the Awaji Island earthquake, emphasizing the importance of estimating local-scale (< tens of km) stress information. We suggest that the local-scale stress heterogeneity has been formed by local tectonic movement, i.e., the formation of flexures in combination with recurring deep aseismic slips. The coseismic Coulomb stress change induced by the disastrous 1995 M_w6.9 Kobe earthquake increased along the fault plane of the Awaji Island earthquake, while the postseismic one was negative. We concluded that the gradual stress buildup due to the interseismic plate locking along the Nankai trough overcame the postseismic stress reduction in a few years, pushing the Awaji Island earthquake fault over its failure threshold in 2013. The observation that the earthquake occurred in response to the interseismic plate locking has an important implication in terms of seismotectonics in southwest Japan, facilitating further research on the causal relation between the inland earthquake activity and the Nankai trough earthquake. Furthermore, this study highlighted that the dataset before the mainshock may not have sufficient information to reflect the stress field in the source region due to the lack of earthquakes in that region, because the earthquake fault is generally locked prior to the mainshock. Further research is needed for estimating the stress field in the vicinity of an earthquake fault via pre-mainshock seismicity alone.

A systematic investigation of rupture directivity, stress drop, fault geometry, and radiation efficiency of small inland earthquakes in Japan

*Keisuke Yoshida[1]

1. Tohoku University

Stress drops of small earthquakes have been estimated under the priori assumption that the rupture propagates symmetrically within a circular fault. However, recent studies have observed directivity effects on seismic waves even for small earthquakes. In this study, the rupture directivity was investigated systematically for small to moderate-sized earthquakes (M 3.5-5.5) beneath inland Japan from 2004 to April 2019. The apparent moment rate functions were determined, and their corner frequencies were inverted using the rupture parameters of 1,463 earthquakes. The results indicate that most of the analyzed earthquakes (1,335 of 1,463) are characterized by a significantly asymmetrical rupture propagation. The rupture tends to propagate to the direction along the fault-strike both for dip-slip and strike-slip earthquakes. The stress drop for the earthquakes were estimated by considering the asymmetrical rupture propagation. The average value of the stress drop is 16.8 MPa, which is almost two times larger than that based on the commonly used symmetrical rupture model. Spatial distribution of stress drop correlates well with the maximum shear strain rate in central and eastern Japan where strain rate probably contributed to the accumulation in the background stress field. Estimated stress drop increases with depth. These observations are consistent with the hypothesis that stress drop reflects the absolute values of shear stress and fault strength.

Modeling Internal Deformation Due to Inelastic Sources Under Inhomogeneous Structures

*Daisuke Sato[1], James Daniel Paul Moore[2]

1. Disaster Prevention Research Institute, Kyoto University, 2. Earth Observatory of Singapore

Available geodetic/seismological data and inelastic crustal deformations such as fault motions, volcano deformation, and asthenospheric deformation have been tied by the modeling of the elastic deformations incurred in the crust (Yabuki & Matsu'ura, 1992; Ide & Takeo, 1997). However, theoretical Green's functions (observation equations) for the inversions of these inelastic sources are currently available only for the simple elastic properties of 1D or homogeneous structures. 3D modeling of the elastic inhomogeneity is already achieved with finite-element and finite-difference methods (e.g., Hashima et al., 2016) but still computationally expensive.

In this study, we present a suite of analytical and semianalytical solutions of Green's functions for the displacements, strains, and stress due to localized (faulting) and distributed (volumetric) inelastic deformation in an elastically inhomogeneous full- and half-space. Variations in elasticity are treated as piecewise constant elastically homogeneous regions. We prove the equivalence between the boundary traction integral equations with those for displacement or volumetric inelastic strain, which have known analytic forms. With this equivalence, we are able to express the traction balance on the boundaries between elastic regions with contrasting elastic parameters, by a corresponding virtual fault displacement or volumetric strain.

We demonstrate this approach with computer programs that evaluate these expressions free of major singular points. These expressions represent a powerful tool for the analysis of deformation data applicable to many primary geophysical applications.

Combined inversion technique to determine stress condition and friction coefficient from fault orientation

*Katsushi Sato[1]

1. Division of Earth and Planetary Sciences, Graduate School of Science, Kyoto University

Stress condition and friction coefficient of fault control the brittle deformation in earth's upper crust. Since shear zone materials cannot preserve their physical properties at the time of activation over the geological time scale, it is difficult to estimate the friction coefficients of ancient geological faults.
This study proposes to simultaneously estimate the friction coefficient of faults and the stress condition which activated them by the following procedure. Stress tensor inversion using fault-slip data can calculate principal stress axes and a stress ratio, which allows us to draw a normalized Mohr's circle. Assuming that the faults have a common value of friction coefficient, the frequency of fault orientation is expected to have a peak at the tangential point between the Mohr's circle and the friction envelope and to decrease according to the distance from the envelope. This model was combined with the Wallace-Bott hypothesis that a fault slips along the shear stress vector to compose the objective function of inversion to determine the stress condition and frictional coefficient.
The method was applied to some examples of natural outcrop-scale faults. The first example is from the Pleistocene Kazusa Group, central Japan, which filled a forearc basin of the Sagami Trough. Stress inversion analysis showed WNW-ENE trending tensional stress with a low stress ratio. The friction coefficient was calculated to be about 0.7, which is typical value for sandstone.
Another example is from an underplated tectonic mélange in the Cretaceous to Paleogene Shimanto accretionary complex in southwest Japan along the Nankai Trough. The stress condition was determined to be an axial compression perpendicular to the foliation of shale matrix. The friction coefficient ranges from 0.1 to 0.3, which is extremely low indicating a weak plate boundary under the accretionary wedge.

Correlation between physical and hydraulic properties of rock fractures constrained by surface geometry: Digital rock physics approach

*Kazuki Sawayama[1], Takuya ISHIBASHI[2], Fei Jiang[3], Takeshi Tsuji[4], Yasuhiro Fujimitsu[4]

1. Graduate school of engineering, Department of Earth Resources Engineering, Kyushu University, 2. Fukushima Renewable Energy Institute, National Institute of Advanced Industrial Science and Technology, 3. Department of Mechanical Engineering, Faculty of Engineering, Yamaguchi University, 4. Department of Earth Resources Engineering, Faculty of engineering, Kyushu University

Fracture flow and fracture aperture distribution are of great interest to evaluate the mechanism of earthquake and fractured reservoirs. To predict and image the subsurface fluid-flow behavior, geophysical observations, such as seismic and electromagnetic methods, and classical rock physical models have been broadly applied. However, there is no established rock physical model to estimate the fluid-flow behaviors (e.g., permeability) in the fracture from resistivity or elastic wave velocity, and thereby fluid-flow behavior in the fracture are difficult to be precisely interpreted by geophysical data. To reveal the fluid-flow behavior in the fractured zone, we need to establish the rock physical model for the fracture. In this study, to establish the rock physical model which can correlate fracture aperture, fracture permeability, elastic wave velocity and resistivity, we measured and calculated them by using real rock and digitalized rock fractures.

We conducted laboratory fluid-flow test by using fractured Inada granite (50 mm in a diameter, 80 mm in a length) which have single tensile fracture with different roughness. For the numerical model, we digitalized this real rock fracture (0.1 mm grid resolution) to calculate fluid-flow, resistivity and elastic wave velocity under the same condition with experiment. A series of 3D fracture flow simulations was revealed by using Lattice Boltzmann method and we applied finite element analysis to calculate resistivity and elastic wave velocity after this fluid-flow simulation.

As the results of experiments and simulations, we clarify the changes in fracture aperture, fracture permeability, elastic wave velocity and resistivity associated with increasing effective normal stress. Moreover, changes in the permeability and the resistivity were not affected by the roughness, whereas velocity change shows roughness dependency. This roughness dependence of velocity change can be explained by the distribution of asperities. We also correlate the changes in permeability, resistivity and elastic wave velocity. The relationship between permeability and resistivity can be modeled regardless of the roughness, while the relationship between permeability and elastic wave velocity change depend on the roughness. Our results suggest that the resistivity survey is effective for estimating the change in permeability, whereas elastic wave velocity may need to be modeled in consideration of the asperities. As the results of further studies using synthetic fracture, fracture geometry (e.g., asperity) affects these relationships.

The evolution of cataclastic rocks and their implication on the development of the Median Tectonic Line fault architecture, Japan

*Thomas Jing Yi Yeo[1], Toru Takeshita [1], Wencheng Huang[1]

1. Department of Natural History Sciences, Graduate School of Science, Hokkaido University

The Median Tectonic Line (MTL) is a long-lived crustal scale fault that experienced a long history of movement. Beginning from the Late-Cretaceous period, the MTL has been an active strike slip fault, directly related to the formation of the mylonites in the southern marginal shear zone of the Ryoke granitoid belt (e.g. Hara et al., 1980) and was later superposed by cataclasite at the core region during exhumation. During the early Paleocene (c.60Ma), large scale north dipping normal faulting occurred which led to the juxtaposition of the Ryoke granitoids against the Sanbagawa metamorphic rocks. (Kubota & Takeshita, 2008)

Field observations in the Ryoke granitoids of the MTL fault zone in Mie Prefecture, SW Japan, show that the mylonitic rocks originated from two main protoliths namely tonalite and granite located at the southern and northern part respectively, both of which are extended in the E-W direction (Bui, 2019). We for the first time found that the two bodies were separated by a north dipping normal fault which we named Akaiwadani fault. The granitic body are mainly mylonites with bands of ultramylonites at the proximal region of the Akaiwadani fault. The tonalitic body mainly consists of protomylonite with bands of mesomylonites and also utramylonites at the core region of the MTL.

The purpose of our study is to characterise the types of cataclasites found in the MTL region and relate them to their deformation mechanism and conditions. Methods applied include SEM-EBSD analysis for quartz CPOs, XRD analysis for bulk mineralogy, and image analysis of microstructures were preformed. Analysis done includes shaped preferred orientations (SPOs), clast sizes, orientations, etc.

The cataclasites overprint the core region of both fault zones, evidenced by the occurrence of ultramylonite clasts. The cataclasites can be roughly divided into foliated and non-foliated ones. Non-foliated cataclasites only exist near the fault core of the MTL, whereas foliated cataclasites are found in abundance. All foliated cataclasites have a various degree of alteration to phyllosilicates, potentially indicating the degree of maturity, coinciding with the phyllonites described by Jefferies et. al (2006). XRD results indicate a significant drop in the percentage of K-feldspars in the Akaiwadani fault cataclasites and also a reduction of plagioclase in cataclasites of the MTL core zone. This may be contributed by the enhancement of fluid flow during cataclasis causing albitisation and pressure solution. We also first observed that some of the phyllonites have undergone poly-cataclasis. The SPO of clasts within a poly-cataclasites suggests that the smaller older clast (G_1) is randomly orientated whereas the larger younger clast (G_2) shows a stronger preferred orientation. This implies that the rock experienced multiple cycles of brittle deformation and consolidation during the prolonged fault movement.

Such study holds significance in characterising the spatiotemporal strain distributions in the MTL fault zone in relation to the changes in slip rate of the MTL. Phyllonites are found to formed with the presence of phyllosilicates as a result of pressure solution or alteration associated with the aseismic slip of the MTL. Such mechanism was first described by Spry (1969) as phyllosilicate creep and Niemeijer & Spiers (2005)

©2020. Japan Geoscience Union. All Right Reserved.

stated that phyllosilicate creep occurs with slow slip velocity <0.5 μms^{-1}. Moreover, the poly-cataclasites may potentially indicate the evidences of both generation of earthquake and phyllosilicate creep, which are associated with their respective palaeo-seismic and aseismic slip periods.

Development history of the mylonite zone distributed along the Mie Prefecture Median Tectonic Line

*Huang Wencheng[1], toru Takeshita[1], Thomas Jing Yi Yeo [1], Jun-Ichi Ando[2]

1. Department of Natural History Sciences, Graduate School of Science, Hokkaido University, 2. Department of Earth and Planetary Systems Science, Graduate School of Science, Hiroshima University

The Median Tectonic Line (MTL) is the longest fault in Japan over 800 km and is an excellent place to study rock deformation. Both the brittle and plastic deformation associated with the fault zone is crucial for the understanding of fault development. A ductile shear zone with sinistral sense was first developed at the end of the Cretaceous period (74-67 Ma, Shimada, et al., 1998) at the north block of the Median Tectonic Line where the Ryoke granite is located. During Early Paleogene (63-58 Ma, Kubota and Takeshita, 2008), it joined together with the Sanbagawa belt located in the southwestern outer zone, forming the current of MTL. In this study, the localization of deformation was described for the plastically deformed Ryoke granites, and their development is also discussed.

In recent years, studies on the plastic deformation of mylonites at the Median tectonic line has been actively conducted. According to Dong (2019), based on the c-axis fabric of quartz microstructure, the mylonites could be categorized as tonalitic protomylonite zone (distance from Median tectonic line, 0-350m), granitic mylonite zone with S-type quartz texture (350-500m) and granitic mylonite zone with P-type quartz texture (500-800m). The definition of the S-type and P-type quartz microstructures are based on Masuda and Fujimura (1981). In the S-type mylonite zone, a Y-maxima c-axis fabric (estimated deformation temperature: 400-500 degrees, e.g. Takeshita, 1996) and a type II cross girdle c-axis fabric(300-400 degrees) was developed. By comparing the mylonite zone with P-type quartz microstructure with the mylonite zone with S-type quartz microstructure, the grain size of quartz grains has been reduced from 140 microns to 20-30 microns, where the quartz grains are becoming finer. In the mylonite zone with a P-type quartz microstructure, only the Y-maximum c-axis fabric develops as it experiences a relatively higher deformational temperature. Based on the above-mentioned results, first, a mylonite zone with a P-type quartz microstructure was formed, and then the deformation stopped at a distance of more than 500 m north of the MTL. The deformation continued at a distance of 350-500 m as the temperature decreased. Thus, a localization model for the deformation that forms the S-type mylonite zone was proposed (Dong, 2019).

In this study, we conducted field surveys and analyzed the microstructure of the Tsukide region over an area of 2km width and 1km north from the MTL. To analyze the deformational characteristics of K-feldspar, the K-feldspars are stained with sodium cobaltinitrite. The following new findings were obtained from the study. (1) The K-feldspar phenocrysts in the mylonite zone with S-type quartz microfabric located at 350-500 m are weakly deformed and not damaged. The K-feldspar is plastically deformed in the mylonite zone with P-type quartz microfabric located at 500-900 m. (2) The K-feldspar in the mylonite zone with S-type quartz microfabric has a smaller grain size, and it was observed to be associated with the development of the EW trending fault. Grain size reduction was seen at the northern block of the fault, but it was not observable in the southern block.

Based on the above results, the following considerations were made on the development of the MTL structure. In the mylonite zone with S-type quartz microfabric, K-feldspar is not altered and maintains the original phenocryst texture, therefore it cannot be fully interpreted by the progressive the deformational

process as proposed by Dong (2019). One of the possible explanations is that the mylonite zones with P-type and S-type quartz microfabric have different source rocks and are formed under different conditions, and they may have been juxtaposed together by the possible presence of faults.

Extensional stress conditions determined from the orientations of Middle Miocene dikes in the Kumano area

*Toshiki Haji[1,2], Atsushi Yamaji[1]

1. Graduate School of Science, Kyoto University, 2. Institute of Geology and Geoinformation, AIST

We deny the established theory about the compressional stress in the SW Japan arc in the Middle Miocene after 15 Ma that terminated the Japan Sea opening. The orientations of dikes with such ages in the Kumano area, southern Kii Peninsula, are considered to evidence the compression (e.g., Tsunakawa, 1986; Yamamoto, 1991). A few tens of dikes in the area were considered to make a NNW trending parallel dike swarm, and the E-W trending folds of the strata that hosted the dikes were thought of as the evidence for the compression during the dike intrusion. However, it is uncertain when the formation was folded. In addition, previous researchers assumed that dikes were formed more or less perpendicular to the axis of maximum horizontal compression. This is not always true: Overpressured magma can intrude into fractures with various orientations. Consequently, the arguments about the timing of folding and the stress condition for the dike intrusion has been circular.

In the Kumano area, we observed 14 felsic dikes in the Early to early Middle Miocene Kumano Group and 151 mafic dikes in the early Middle Miocene Shionomisaki Igneous Complex. The uppermost part of the group interfingers with the basal part of the complex. The orientations of the dikes were inverted by fitting mixed Bingham distributions (Yamaji and Sato, 2011) to reveal the stress regime during their intrusions. The method determines three principal stress axes, stress ratio and non-dimensional magma pressure only from dike orientations. The method can determine one or a few stresses from non-parallel dikes.

As a result, the normal faulting stress regime with the ENE-WSW trending σ_3-axis and a stress ratio of 0.14 was determined from the felsic dikes. The magma pressure was relatively low. The mafic ones had various trends, but those with NW trends were dominant. The normal faulting stress regime with NE-SW trending σ_3-axis and a stress ratio of 0.50 was determined from the mafic dikes. The magma pressure was relatively high. We obtained the zircon fission-track ages of 14.5 ±1.4 Ma and 13.9 ±1.4 Ma from two felsic dikes. The microfossil and fission-track ages (Ikebe et al., 1975; Hoshi et al., 2003) indicate that both types of dikes intruded from 14.5 to ~13 Ma. Therefore, the area was affected by NE-SW to ENE-WSW extensional stress after 15 Ma. The folding probably postdated the magmatism.

Syn-orogenic extrusion of HP-LT blueschists in the northern Tyrrhenian Sea (northern Apennines, Italy)

*Samuele Papeschi[1], Eric Ryan[2], Hans Joachim Massonne[3,4], Giovanni Musumeci[5,6], Francesco Mazzarini[6], Giulio Viola[7]

Dipartimento di Scienze Biologiche, Geologiche e Ambientali, Università di Bologna, Bologna, Italy

High pressure-low temperature (HP-LT) rocks, such as blueschists and eclogites, help us to understand deep processes that shape collisional zones during underplating, accretion, and exhumation. A key question in geoscience is which processes drive the exhumation of deep-seated, underplated rocks. To answer this question, we studied glaucophane- and lawsonite-bearing metabasites, calcschists, and marbles, which are exposed on the Island of Elba (Italy) in the northern Tyrrhenian Sea. These rocks record HP-LT metamorphism, which is related to the Oligocene –Early Miocene continental collision in the northern Apennines. The HP rocks on Elba are characterized by a top-to-the-west mylonitic deformation that is related to their exhumation within a pile of west-dipping and east-verging nappes. Detailed analyses of bulk rock and minerals and phase equilibria modeling of metabasites from Elba constrain peak metamorphic conditions to 1.5-1.8 GPa and 320-370 ˚C and indicate nearly isothermal exhumation to greenschist-facies conditions at 0.2 GPa. During exhumation, peak metamorphic assemblages were overprinted and partially obliterated by epidote-blueschist and, subsequently, albite-greenschist facies metamorphic assemblages. Geochronological data indicate that exhumation occurred over a period of time of 15 Ma between the early Miocene (20-19 Ma) and the late Miocene (6 Ma) with exhumation rates around 2.5-3.7 km/Ma.

Based on this study, we propose that continental units were brought to greater depths than previously reported for the northern Apennines. We show that syn-orogenic extrusion acted as the main exhumation mechanism for continental and oceanic units during early continental collision in this orogenic section.

Elastic wave velocities and electrical conductivity in a brine-saturated granitic rock with single fracture

*Tohru Watanabe[1], Arina Tomioka[1]

1. University of Toyama

Geophysical mapping of fluids is critical for understanding crustal processes. Interpretation of seismic velocity and electrical resistivity structures requires a thorough understanding of the pore structure that governs physical properties under high pressures. Watanabe et al. (2019) showed that wide aperture parts in cracks remain open to govern physical properties under high pressure. In the crust, there should be cracks with various sizes: from grain boundary to large faults. In order to understand the role of a fracture as a conduction path under high pressure, we have made measurements of elastic wave velocities and electrical conductivity in a brine-saturated granitic rock with single fracture. A cylindrical rock sample (D=26 mm, L=30 mm) with single fractures was cored from a block (20 cm x 20 cm x 20 cm) of Aji granite from Kagawa Prefecture, which was artificially fractured. The fracture goes through the sample from top to bottom. The sample was filled with 0.1 M KCl aqueous solution, and velocity and conductivity were simultaneously measured by using a 200 MPa hydrostatic pressure vessel. The pore-fluid was electrically insulated from the metal work by using plastic devices. Compressional and shear wave velocities were measured in the direction subperpendicular to the fracture, while electrical conductivity in the axial direction.

A preliminary experiment was conducted up to 40 MPa. Compressional and shear wave velocities increase with increasing confining pressure. At 40 MPa, the compressional wave velocity was almost the same as that in intact Aji granite samples, while the shear wave velocity was significantly lower than that in intact samples. The electrical conductivity at the atmospheric pressure was around one order of magnitude higher than that in intact samples. It greatly decreased from 0.1 MPa to 5 MPa, then showed a gradual decrease to 40 MPa. The conductivity at 40 MPa is also around one order of magnitude higher than that in intact samples. The average aperture of fracture at 40 MPa is estimated to be 2 micro meters. However, the fracture should be segmented under high pressure. X-ray CT observation will be conducted to understand the pore structure under high pressure.

Hydraulic monitoring results during SIMFIP injection experiments through Shionohira fault zones in Fukushima Prefecture, Japan

*Kazuhiro Aoki[1], Hiroshi Wakahama[2], Haruka Nojo[2], Etuo Iwasaki[2], Masao Kametaka[2], Yukumo Tanaka[1], Takumi Yoshida[1], Kazuyoshi Seshimo[1]

1. Japan Atomic Energy Agency, 2. Dia Consultants

The Shionohira fault caused the April 11, 2011 Fukushima ken Hamadori Earthquake of Mw 6.7 which occurred one month after the Tohoku-Oki earthquake of Mw 9.0. Co-seismic surface ruptures trending NNW-SSE allowed to estimate a normal slip faulting with a 2 m maximum displacement. The authors have been conducting a series of studies at the Shionohira fault and its southern extensions in order to develop a fault activity evaluation method.
The fault slip injection tests using a SIMFIP (Step-Rate Injection Method for Fracture In-situ Properties) probe have been performed at the Shionohira and Minakamikita sites (Aoki, et al., 2019 and Watanabe, et al., 2019). This report gives the hydraulic monitoring results obtained from a borehole located about 3m distance from the injection hole during the injection tests conducted at both sites.

In the fault slip injection tests, double packers were placed above and below the underground fracture and high pressure water was injected from the surface to artificially trigger a slip in the fracture in order to measure the three dimensional deformation in micrometer to millimeter units (Guglielmi et al., 2013). Pore pressure was monitored in a monitoring hole located about 3 meters from the injection hole in order to check the continuation of a fracture zone and to obtain hydro-mechanical data.

Significant increase in pore pressure was measured in the intervals of fault fracture zone corresponding to the increase of water inflow at both Shionohira and Minakamikita sites, suggesting that water flow pass had been created from the injection interval to the monitoring boreholes through fracture plane. Backflow of the injected water from the open fracture back into the interval was also observed. Permeability in fault plane will be discussed at the conference.

At Shionohira site, a vertical injection borehole of 30m length was drilled at 7.3m from the top of the fault escarpment (S70W) perpendicular to the strike of Shionohira fault (N20W). A vertical monitoring borehole of 30m length was drilled in the direction of S70W at 7.3m from the top of the fault escarpment perpendicular to the strike of the fault. The distance between the two boreholes was 3.3m running nearly parallel to the fault at N8W. Pore pressure was monitored with a single packer set at depths of GL.-12.20m to GL.-13.20m in the monitoring borehole. Test 1 was conducted between depths 7.0m and 11.5m isolated with upper and lower packers and pressurized above the recently activated fault zone in the unfaulted sandstone layers. Test 2 was conducted between depths 12.8m and 17.3m across the recently activated fault zone. Test 3 was held at depths between 17.0m and 21.4m to assess the ancient fault activation zones in the metamorphic green schist. A significant increase in pore pressure was measured in Test 2.

At Minakamikita site, the target fault has an N-S strike with a dip of 80 degrees to the west. Because of the limitation in study area, injection and monitoring boreholes were drilled at 50 degrees to the east from the surface, of 30m lengths each. The distance between the two boreholes was 3.5m. Pore pressure was monitored with double packers set at depths of GL.-17.0m to GL.-18.0m and GL.-25.0m to GL.-25.9m in the monitoring borehole.

©2020. Japan Geoscience Union. All Right Reserved.

Injection tests were performed at the following four intervals: (1) fracture zone 1 (G.L.-19.75 to -21.70m); (2) fracture zone 2(G.L.-21/65 to -23.60m); (3) sandstone layer G.L.-17.85 to -19.80m); and (4) greenschist (G.L.-23.29 to -25.24m). A significant increase in pore pressure was measured at interval (2).

Change in electrical conductivity in a brine-saturated granite under uni-axial compression

*Yui Aikawa[1], Tohru Watanabe[1]

1. University of Toyama

Geophysical observations have shown that fluids exist pervasively within the crust. Fluids fill intergrain cracks (open grain boundaries) and intra-grain cracks at the upper and middle crust conditions. Since the opening of cracks strongly depends on the stress state, electrical conductivity should be anisotropic under a stress state. We have conducted uni-axial compression tests on a brine-saturated granitic rock and studied the change in electrical conductivity in the directions parallel and perpendicular to the compression.

The loading system is composed of a hand press (Maximum load: 20 kN), a load cell and stainless steel end-pieces. A fine grained (100-500 mm) biotite granite (Aji, Kagawa Pref., Japan) was selected as a rock sample for its small grain size and textural uniformity. A cube sample with the edge length of 25 mm was filled with 0.1 M KCl aqueous solution and loaded up to 20 MPa. Electrical impedance was monitored during a compression test with two-electrode method (Ag-AgCl electrodes). Separate compression tests were made for measuring electrical impedance in two directions.

Electrical conductivity decreased with increasing axial stress in the directions parallel and perpendicular to the compression. When the axial stress was increased from 0 MPa to 10 MPa, the magnitude of decrease in conductivity was 5% both in the direction parallel and perpendicular to the compression. The decrease in conductivity was much smaller than that observed in hydrostatic compression tests (e.g., Watanabe and Higuchi, 2015). The decrease in conductivity must be caused by the closure of cracks, which were perpendicular or subperpendicular to the compression. Electrical conduction paths in the direction parallel and perpendicular to the compression are both composed of these cracks. Electrical conductivity in two directions thus shows similar changes. A differential stress will not lead to an anisotropy in electrical conductivity.

Grain shape and connevtivity of pores in granular materials

*Katazakai Haruka[1], Tohru Watanabe[1]

1. Toyama University

Connectivity of pores controls transport properties in granular materials and strongly depends on grain shape (Friedman, 2005). When the porosity is identical, electrical conductivity of a brine-filled granular material is significantly higher for spherical grains than for oblate spheroidal grains. However, connectivity of pores in granular materials has not been fully understood. In order to understand the influence of grain shape on the connectivity of pores, we conducted electrical conductivity measurements on brine-filled granular materials. Various types of sand were employed. The structure of pores and grain shape were characterized through analyses of X-ray CT images. Measurements were conducted on granular materials composed of spherical glass beads for comparison. The influence of grain shape on the connectivity of pore will be discussed in our presentation.

Grain shape and pressure sensitivity of transport properties in granular materials

*Maremichi Abe[1], Tohru Watanabe[1]

1. Toyama University

The connectivity of pores is a key factor in controlling transport properties of rocks. Even in porous rocks, it is sensitive to the confining pressure. Electrical conductivity in brine-saturated Berea sandstone (porosity~20%) decreased by ~22% as the confining pressure was increased to 40 MPa, while the pore-fluid pressure was kept at the atmospheric pressure. From the volumetric strain measurement, the change in porosity should be less than 1%. The observed relatively large decrease in conductivity must be caused by a significant reduction of the connectivity of pores under pressure. In order to understand the influence of pressure on the connectivity of pores, we conducted compression tests on granular materials: spherical glass beads and oblate quartz sand. Compressional wave velocity increases with increasing pressure similarly in both materials, while electrical conductivity decreases significantly only in quartz sand. This suggest the important role of grain shape in governing the pressure sensitivity of connectivity of pores. X-ray micro CT images of granular materials impregnated with epoxy resin were analyzed to study the structure of pores. Changes in electrical conductivity under pressure and the structure of pores will be presented for different grain shapes.

[E] Poster | S (Solid Earth Sciences)：S-CG Complex & General

[S-CG64] Crust-mantle connections

convener:Yoshihiko Tamura(Research Institute for Marine Geodynamics, Japan Agency for Maine-Earth Science and Technology), Osamu Ishizuka(Geological Survey of Japan, AIST)

The western portion of the Pacific Plate, the oldest oceanic plate in the world, has been drilled several times and, based on Ocean Drilling Program (ODP) Site 801, an understanding of its layers, from pelagic clay through chert to alkali basalts and tholeiitic mid-ocean ridge basalts (MORB), has been established. This oldest oceanic plate is experiencing a renaissance and we propose a strategy to drill the most suitable three sites to recover specific parts of the plate to continue its renaissance. This submitted IODP preproposal is entitled The Renaissance of the Oldest Oceanic Plate: REY (Rare Earth elements and Yttrium) rich Mud, Radiolarite of Jurassic-Cretaceous Boundary (JKB), and Jurassic Oceanic Crust without Moho. The drilling sites, MM, MAT, and MINA, target (1) the most complete sedimentary sequence of pelagic clay including REY-rich mud, (2) newly found outcrops of the Jurassic-Cretaceous boundary (JKB), and (3) MORB tholeiites without Moho, respectively. This session invite scientists who are interested in these exciting drillings.
It is common knowledge that the Moho is the boundary between the crust and the Earths mantle, discovered by and named after the Croatian seismologist Andrija Mohorovicic. The oceanic Moho is defined by seismic reflection images, but seismic profiles generally show that Moho reflections are not universal. Where the Moho can be detected clearly the crust is thicker. A good example is the profile from Kaneda et al. (2010) near Minami-Tori Shima, which is the main motivation for drilling at Site MINA. The session also seeks to explore the crust-mantle connections among ophiolites, at divergent and convergent plate boundaries and ocean island settings based on petrology, geochemistry, geophysics, geochronology, and geodynamics studies.

International Ocean Discovery Program (IODP) Expedition 351 “Izu–Bonin–Mariana (IBM) Arc Origins” drilled Site U1438, situated in the north-western region of the Philippine Sea. Here volcaniclastic sediments and the igneous basement of the proto-IBM volcanic arc were recovered. To gain a better understanding of the magmatic processes and evolution of the proto-IBM arc, we studied melt inclusions hosted in fresh igneous minerals and sampled from 30- to 40-Ma-old deposits, reflecting the maturation of arc volcanism following subduction initiation at 52 Ma. We performed a novel statistical analysis on the major element composition of 237 representative melt inclusions selected from a previously published dataset, covering the full age range between 30 and 40 Ma. In addition, we analysed volatiles (H_2O, S, F and Cl) and P_2O_5 by Secondary Ion Mass Spectrometry (SIMS) for a subset of 47 melt inclusions selected from the dataset. Based on statistical analysis of the major element composition of melt inclusions and by considering their trace and volatile element compositions, we distinguished five main clusters of melt inclusions, which can be further separated into a total of eight subclusters. Among the eight subclusters, we identified three major magma types: (1) enriched medium-K magmas, which form a tholeiitic trend (30–38 Ma); (2) enriched medium-K magmas, which form a calc-alkaline trend (30–39 Ma); and (3) depleted low-K magmas, which form a calc-alkaline trend (35–40 Ma). We demonstrate that (1) the eruption of depleted low-K calc-alkaline magmas occurred prior to 40 Ma and ceased sharply at 35 Ma; (2) the eruption of depleted low-K calc-alkaline magmas, enriched medium-K calc-alkaline magmas and enriched medium-K tholeiitic magmas overlapped between 35 and 38–39 Ma; and (3) the eruption of enriched medium-K tholeiitic and enriched medium-K calc-alkaline magmas became predominant thereafter at the proto-IBM arc. Identification of three major magma types are distinct from the previous work, in which enriched medium-K calc-alkaline magmas and depleted low-K calc-alkaline magmas were not identified. This indicates the usefulness of our statistical analysis as a powerful tool to partition a mixture of multivariable geochemical datasets, such as the composition of melt inclusions in this case. Our data suggest that a depleted mantle source had been replaced by an enriched mantle source due to convection beneath the proto-IBM arc from >40 to 35 Ma. Finally, thermodynamic modelling indicates that the overall geochemical variation of melt inclusions assigned to each cluster can be broadly reproduced either by crystallisation differentiation assuming P = 50 MPa (about 2-km deep) and 2 wt % H_2O (almost saturated H_2O content at 50 MPa) or P = 300 MPa (about 15-km deep) and ~6 wt % H_2O (almost saturated H_2O content at 300 MPa). Assuming oxygen fugacity (f_{O2}) of log f_{O2} equal to +1 relative to nickel-nickel oxide (NNO) buffer best reproduces the overall geochemical variation of melt inclusions, but assuming a more oxidising conditions (log f_{O2} = +1 to +2 NNO) likely reproduces the geochemical variation of enriched medium-K and calc-alkaline melt inclusions (30–39 Ma).

Evolution of Rear Arc Magmas following backarc basin formation behind the Izu arc: Site U1437, IODP Exp. 350

*Takashi Miyazaki[1], J B Gill[2], C Hamelin[3], S M DeBari[4], Tomoki Sato[1], Yoshihiko Tamura[1], Jun-Ichi Kimura[1], Bogdan Stefanov Vaglarov[1], Qing Chang[1], Ryoko Senda[5], Satoru Haraguchi[6]

1. Research Institute for Marine Geodynamics, Japan Agency for Marine-Earth Science and Technology, 2. University of California, Santa Cruz, 3. University of Bergen, 4. Western Washington University, 5. Kyushu University, 6. University of Tokyo

IODP Site U1437 is located in the Izu rear-arc region, at 31.790 N, 139.026 E. The recovered core consists of seven lithologic units. The oldest four (Units IV through Unit VII) that include volcaniclastics and hyaloclastites with coarse lava clasts as well as tuff and lapilli-tuff, and have ages of about 6–15 Ma [1, 2] is focused to investigate the evolution of that mantle soon after Shikoku back arc basin opened between 24-15 Ma. Recent geochemical studies clarified that the previous stage of N-Izu rear arc volcanism was not consistently same to current form [3, 4, 5]. To test and constrain these hypotheses in detail, we investigated the early N-Izu rear-arc magmatism using our new Sr-Nd-Hf-Pb isotope data and the Arc Basalt Simulator v. 4 (ABS4) coded by [6]. Like to the classification of [5], three types of volcaniclastic sediments characterized the Izu reararc at Site 1437 from 15 to 6 Ma, based on our new Sr-Pb-Nd-Hf isotope and trace element ratios. They are RASC (Rear Arc Seamount Chains), Rift, and VF (Volcanic Front)-types. Rift-type sediments dominate from 15 to 9 Ma, and RASC-type from 9 to 6 Ma. Both are from proximal sources. VF-derived sediments are less common and randomly distributed. The models of ABS4 for mafic Unit VII samples show the magma genesis that are similar to those for basalts in the modern rift environment indicating the addition of ~1% of a melt-rich slab component generated at ~125 km to a Philippine Sea Plate ambient mantle that was more depleted than DMM. The magma source and tectonic implications of this evolution will be discussed.

International Ocean Discovery Program Expedition 350 drilled between two Izu rear-arc seamount chains at Site U1437 and recovered the first complete succession of rear-arc rocks. The drilling reached 1,806.5 m below seafloor. In-situ hyaloclastites, which had erupted before the rear-arc seamounts came into existence at this site, were recovered in the deepest part of the hole (~15-16 Ma). Here we show that the composition of the oldest rocks recovered do not have rear-arc seamount chain geochemical signatures, but instead show affinities with volcanic front or some of the extensional zone basalts between the present volcanic front and the rear-arc seamount chains. We infer that following the opening of the Shikoku back-arc basin, Site U1437 was a volcanic front or a rifting zone just behind the volcanic front, and was followed at ~9 Ma by the start of rear-arc seamount chains volcanism. This geochemical change records variations in the subduction components with time, which might have followed eastward moving of hot fingers in the mantle wedge and deepening of the subducting slab below Site U1437after the cessation of Shikoku back-arc basin opening.

The origin of fertile plagioclase lherzolite in the Upper Zone of the Horoman peridotite complex

*Yumeto KOGURE[1], Eiichi TAKAZAWA[1,2]

1. Department of Geology, Faculty of Science, Niigata University, 2. VERC, IMG, JAMSTEC

The Horoman periodite complex is a 2,800m thick orogenic lherzolite complex inter-layered along the Hidaka Main Thrust. Although much research has been done on the Horoman complex, the origin of the layered structure is still being discussed. The Upper Zone structurally occupies the upper 800-meter-thick section and has recorded a thermal history about max 200˚C higher than the Lower Zone [1]. In the Horoman peridotite complex, small amounts of mafic layers of a centimeter to a meter thick are often found in peridotites. Relatively thick mafic layers (tens of centimeters to a meter) are thought to have formed as cumulates that crystallized from melts at various depths (i.e., garnet- or plagioclase-stability field) [2] [3]. On the other hand, the plagioclase lherzolite is often accompanied by a thin mafic layer of a few centimeters. Malaviarachchi et al. (2010) [4] concluded that the thin mafic layers alternated with thin peridotites in the Horoman river have been formed from a Pacific-type MORB melt of about 300 Ma. Investigating the origin of the other thin mafic layers is important in studying the layered structure of the Horoman complex. Therefore, we selected a continuous section in the Upper Zone (Fumo section) for this study and examined variations of whole rock major and trace element compositions along lithological sequences.

The Fumo section has a thickness of 263m, which is about one third of the thickness of the Upper Zone and consists of plagioclase lherzolite (51%) and harzburgite (49%) with minor amount of mafic rocks. The lower 190 meters are dominated by plagioclase lherzolite and locally form banding with harzburgites of several centimeters to several meters thick. The upper 73 meters consist of 70 m thick single harzburgite layer and become plagioclase lherzolite at the top. In the Fumo section, 1 to 3 centimeters-thick mafic layer appears locally concentrated in plagioclase lherzolite. Amphibole is included in the mafic layer and its surrounding plagioclase lherzolite, but not in plagioclase lherzolite and harzburgite far from the mafic layers. In many cases, plagioclase and spinel form fine-grained granular seams, whereas in the neighbor of the mafic layer, lenticular shaped plagioclase-rich pools with a thickness of several centimeters are also observed.

The plagioclase lherzolite and harzburgite show a linear trend in the whole rock major elements vs. MgO diagrams, and the mafic layer is plotted on this extension, suggesting the possibility of mixing two end members. Among the plagioclase lherzolites, those with lower MgO and enrichments in melt components such as Al, Ca, Na than DMM [5] are distributed near the mafic layer in the Fumo section. Thus, the melt infiltrated to peridotite to form both mafic layer and fertile plagioclase lherzolite. The presence of amphiboles only in the mafic layer and its surrounding plagioclase lherzolite suggests that the melt forming the mafic layer may have been a hydrous melt.

On the other hand, plagioclase lherzolites, which are located far from the mafic layer in the Fumo section, have composition similar to DMM or more depleted in melt components. They may have the original composition of peridotite before the intrusion of mafic layer-forming melt. The plagioclase lherzolites near the boundary with harzburgite is depleted in melt components relative to other plagioclace lherzolites, and their composition is comparable to that of the lower zone lherzolite. Since the Upper Zone has a higher temperature history than the Lower Zone, it indicates that the subsolidus reaction in which spinel,

©2020. Japan Geoscience Union. All Right Reserved.

Opx and Cpx become plagioclase and olivine was promoted in the Upper Zone even with the same composition. This suggests that there were two different origins of plagioclase in the Upper Zone.

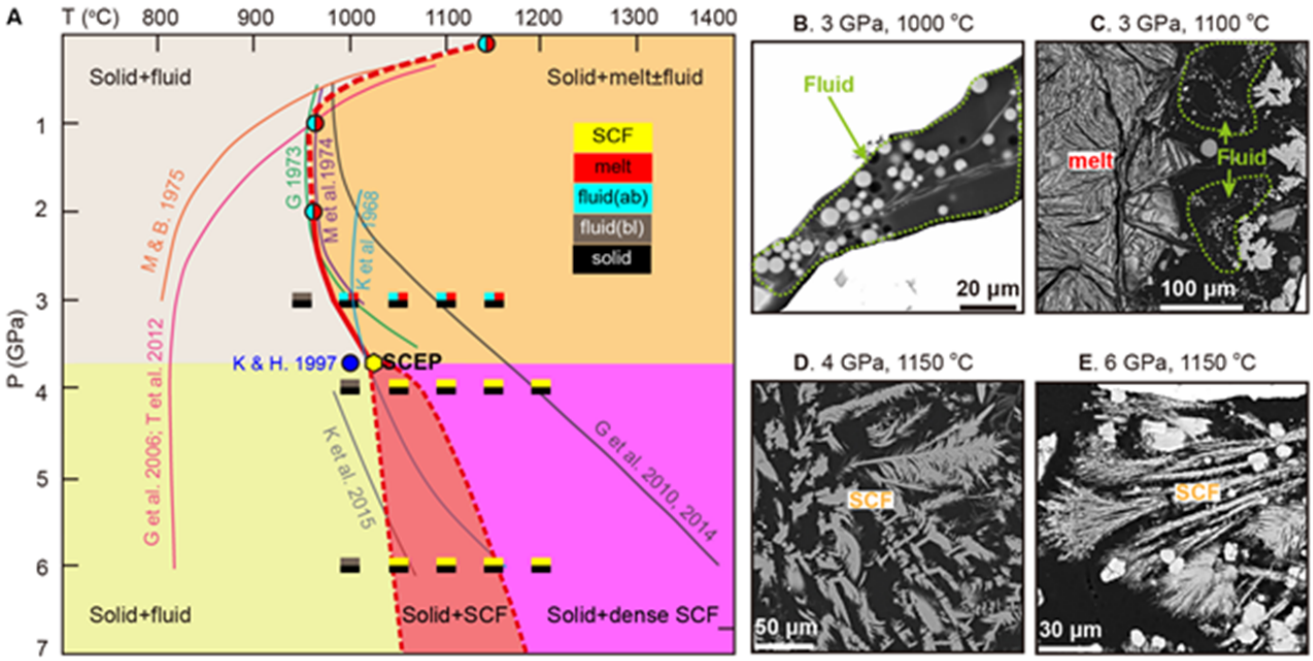
Water-saturated solidus and second critical endpoint of peridotite determined by textures and chemistry of the quenched liquid

*Jintuan Wang[1], Eiichi Takahashi[1]

1. Guangzhou Institute of Geochemistry, Chinese Academy of Sciences

Water-saturated (‘wet’) solidus of mantle peridotite defines the initial melting temperature of Earth’s mantle under water-saturated conditions and the second critical endpoint (SCEP) marks the end of the wet solidus. However, the location of the wet solidus remains an outstanding issue for over 50 years and the position of the SCEP is hotly debated. Published wet solidus shows a difference of 200–600˚C at given pressures, meanwhile, reported SCEP ranges from < 4 to > 6 GPa. Using a large-volume multi-anvil apparatus SAKURA-2500 at Guangzhou Institute of Geochemistry, we investigated the water-saturated melting behavior of a fertile peridotite (at 3–6 GPa, 950–1200 ˚C) and obtained well-preserved quenched liquid. Based on the texture and chemistry of the quenched liquid, we successfully determined the wet solidus and the SCEP of peridotite (Fig A, bold red curve). Experiments were carried out with 25mm edge MgO octahedron (25M) with $LaCrO_3$ heater of 9mm OD and 6mm ID. Staring material was a mixture of glass and $Mg(OH)_2$ with the bulk chemical composition equivalent to a fertile peridotite KLB-1 + 10 wt% H_2O.

At 3 GPa, the quenched fluids exhibit fragile fibres at 950 ℃ and spherule–fibre mixtures at > 1000 ℃ (Fig. B&C). While the quenched hydrous melt appears as a felt-like mass or as dendritic crystallites and coexists with the fluids (Fig. C). We interpreted the presence of spherule–fibre mixtures as evidence for aqueous fluid above the solidus and fragile fibres as evidence for aqueous fluid below the solidus. Thus, the occurrence of quenched melt and spherule–fibre mixtures indicate that the wet solidus lies between 950 and 1000 ℃ at 3 GPa and that 3 GPa is lower than the critical pressure. The most important textural difference between the run products at 3 GPa and those at other pressures (4 and 6 GPa) is the presence of aqueous fluids in the former (Fig. B&C) and the absence of which in the latter (Fig. D&E). The spherule–fibre mixtures were not found in the 4 and 6 GPa run products. Liquids quenched from 4 and 6 GPa run products are homogeneous (SCF supercritical fluid), suggesting that Pc is lower than 4 GPa.



Compositions of the liquids were analyzed by averaging broad area using EDS. We find that the liquid compositions become more deficient in silica and richer in olivine components with increasing pressures. In conjunction with previous studies, the compositions of silicate melts or SCFs change regularly with pressure: andesitic at 1 GPa, boninite-like at 3 GPa, picritic at 4 GPa, and kimberlite-like at pressures > 5 GPa. These results propose that ultra-basic magmas can be formed in subduction zones at low temperatures, high pressure, and H_2O rich conditions. On the basis of present experiments and detailed observation on the cross section of north Japan based on seismology and petrology, we propose a new magma genesis model in subduction zone (Takahashi & Wang, JpGU2020, S-CG64).

[B-BC03] Earth and Planetary Science Frontiers for Life and Global Environment

convener:Yoshinori Takano(Japan Agency for Marine-Earth Science and Technology (JAMSTEC)), Yohey Suzuki(Graduate School of Science, The University of Tokyo), Shingo Kato(RIKEN), Keisuke Fukushi(Institute of Nature & Environmental Technology, Kanazawa University)

Earth and planetary science is currently capable of sampling from three frontiers: space, deep ocean and deep underground for the study of the origin and evolution of life. Next generation sequencing technology of nucleic acids and nanotechnology driven innovation of solid characterizations are very powerful to expand our understanding of many fields of earth and planetary sciences. It is also important for us to be aware of global warming and climate change that dramatically affect biodiversity, biological activities and elemental cycling. The aim of this session is to cross the border of science sections to explore the frontiers of earth and planetary science.

Serpentinite-hosted systems attract more interest from the perspective of studying the origin of life. High concentrations of methane (CH_4) and higher hydrocarbons (C_{2+}) are commonly observed in serpentinite-hosted systems (e.g., Schrenk et al., 2013; Etiope and Sherwood-Lollar, 2013). Previous studies have suggested that stable hydrogen and carbon isotopic compositions of hydrocarbons are compatible with abiotic formation via polymerization process (Proskurowski et al., 2008; Suda et al., 2017). However, little is known about when and where the hydrocarbon synthesis occurs. Our purpose is to constrain both the time and place for methane production by analyzing radiocarbon isotope (^{14}C) and noble gas isotopes (^{3}He, ^{4}He, ^{20}Ne) in the serpentinite-hosted hot spring in Hakuba Happo, Japan. Hakuba Happo hot spring lies on a serpentinized ultramafic rock body in the Shiroumadake area, which belongs to the Hida Marginal Tectonic Belt in central Japan. Hyperalkaline hot spring water (ca. 50˚C, pH = 10.6) rich in H_2 and CH_4 gas is pumped from two borehole wells; Happo #1 and Happo #3 (Homma and Tsukahara, 2008; Suda et al., 2014). Sample collection was conducted between 2015 and 2018. In the same manner as Suda et al. (2017), gas and water samples were obtained from two borehole wells. Pipe-scale carbonate samples of the Happo #1 borehole well were collected at the timing of when the old water-pumping pipes were replaced with new pipes in 2016. For the ^{14}C measurements of CH_4, a sample preparation step of CH_4 combustion to CO_2 was conducted at JAMSTEC by using the custom-built flow-through vacuum line system, which was based on Pack et al. (2015). Radiocarbon contents of purified CO_2 samples were determined at the University of Tokyo by using the graphitization system (Yokoyama et al., 2007) and the Accelerator Mass Spectrometry (AMS). The sample preparation and ^{14}C-AMS measurement for carbonate samples were conducted at the University of Tokyo by using an automated sample preparation system, which is composed of an elemental analyzer and a glass vacuum line based on Kato et al. (2014). Noble gas isotope abundances were measured with a noble gas mass spectrometer at GSJ, AIST. The concentration of dissolved inorganic carbon (DIC) in spring water was measured by using GasBench/IRMS system at GSJ, AIST.

We found that ^{14}C contents in CH_4 were close to the detectable limit, whereas pipe-scale carbonates which precipitated from hot spring water contained the detectable ^{14}C. Radiocarbon evidence rules out a modern carbon (e.g., atmospheric CO_2, organics in surface soil) as the carbon source for CH_4, suggesting that Hakuba Happo CH_4 is derived from old carbon source in deep crust or mantle. In Hakuba Happo hot spring, CO and CO_2 were below detection limit (<0.0005 vol.%). DIC concentration was <28 μmol/L (upper values because of suspicion of air contamination during sampling), which was lower than dissolved CH_4 concentration (124-664 μmol/L; Suda et al., 2014). If CH_4 production occurs under on-site condition, the inorganic carbon compounds (CO, CO_2 and DIC) are not likely to be a carbon source for CH_4. The high helium isotope ratio ($^{3}He/^{4}He$) was observed in both well sites, indicating that a major portion of He is mantle derived. In Shiroumadake area, the $^{3}He/^{4}He$ ratios tend to decrease with distance from Norikura Volcanic Chain, suggesting volcanic gases are dissolved in groundwater and then brought to surrounding hot spring. The $CH_4/^{3}He$ ratios of Hakuba Happo samples were one order of magnitude higher than those of other hot springs which are not directly related to serpentinite rocks. Exceptionally

©2020. Japan Geoscience Union. All Right Reserved.

high $CH_4/^3He$ ratio can not be explained by simple influx of mantle-derived CH_4. Another CH_4 source different from mantle-CH_4 may be required. Based on the ^{14}C and noble gas results, we suggest that a major portion of CH_4 at Hakuba Happo is produced in deep crust rather than shallow and modern groundwater.

Deep Microbial Colonization in Saponite-Bearing Fractures in Aged Basaltic Crust: Implications for Subsurface Life on Mars

*Yuri Sueoka[1], Seiya Yamashita[1], Mariko Kouduka[1], Yohey Suzuki[1]

1. Graduate School of Science, The University of Tokyo

One of the most promising planetary bodies that might harbor extraterrestrial life is Mars, given the presence of liquid water in the deep subsurface. The upper crust of Mars is mainly composed of > 3.7-billion-year-old basaltic lava where heat-driven fluid circulation is negligible. Earth’ s oceanic crust composed of basaltic lava is recognized as the analogous crustal environment to the Martian subsurface. The basaltic crust tends to cool down for 10–20-million-years after formation. However, microbial life in old cold basaltic lava is unknown in large part even in the Earth’ s oceanic crust, because of the lack of vigorous circulation preventing sampling of pristine crustal fluid from boreholes. Alternatively, investigation of deep microbial life using pristine drill cores obtained from basaltic lava is important. We investigated a basaltic rock core sample with mineral-filled fractures drilled during Integral Ocean Drilling Project Expedition 329 that targeted 104-million-year-old oceanic crust. It was revealed that fractures/veins were filled with Mg-rich smectite called saponite and calcium carbonate by mineralogical characterizations of fracture-infilling minerals. The organic carbon content from the saponite-rich clay fraction in the core sample was 23 times higher than that from the bulk counterpart, which appears to be sufficient to supply energy and carbon sources to saponite-hosted life. Furthermore, our method developed newly to detect microbial cells in a thin-section of the saponite-bearing fracture revealed the dense colonization of SYBR-Green-I stained microbial cells spatially associated with saponite. These results imply that the presence of saponite in old cold basaltic crust is favorable for microbial life. In addition to carbonaceous chondrite, saponite is a common product of low-temperature reactions between water and mafic minerals on Earth and Mars. Therefore, it is expected that deep saponite-bearing fractures could host extant life and/or the past life on Mars.

Trace element chemistry of deep-sea corals from different oceanic regions

*Kazuko Saruwatari[1], Makoto Miura[1], Nozomu Iwasaki[2]

1. GIA Tokyo Godo Kaisha, 2. Rissho University

Deep-sea corals belong to Octocorallia subclass animal known to live up to 1500 meters depth, which is different from reef corals of Hexacorallia subclass living near shallow oceans. Mineralogically, these corals are high magnesium calcite containing about 10% magnesium. Red-pink-white corals among them are, especially, called as precious corals and organic gemstones. Its major habitats are the eastern Atlantic Ocean from the Mediterranean to Africa, the western Pacific Ocean from Japan and Vietnam, and the North Pacific Ocean from Midway to Hawaii. The trace element composition of these three deep sea corals is analyzed by Laser Ablation Inductively Coupled Plasma Mass Spectrometry (LA-ICP-MS). As a result similar to previous studies (1-2), differences in lead and barium concentrations were observed, suggesting that they correlate with the seawater composition of the habitat.

Alkaline lakes have functions of absorption of atmospheric CO_2 to natural water and fixation of dissolved carbonate by mineralization. Therefore, it has been considered that alkaline lakes located in arid area inside the continents play important roles in carbon cycle on the earth surface (Finley et al., 2015; Fukushi and Matsumiya, 2018). Generally, formation of carbonate minerals was caused by evaporation of lake water under dry environment. However, alkaline lakes in cold inland area are frozen in winter. Frozen lakes cannot evaporate because it is isolated from the air.

Freezing of lake water causes the increase of the ion concentrations because almost most of the ions are excluded from ice to solution. Inland closed lakes don’ t have inflow and outflow rivers of which situation is almost same with evaporation. Therefore, the mineralization can be also caused by freezing process.

In this study, we have examined “ice-mineralization” process in the alkaline lakes from the observations of water chemistry from summer to winter in Mongolia.

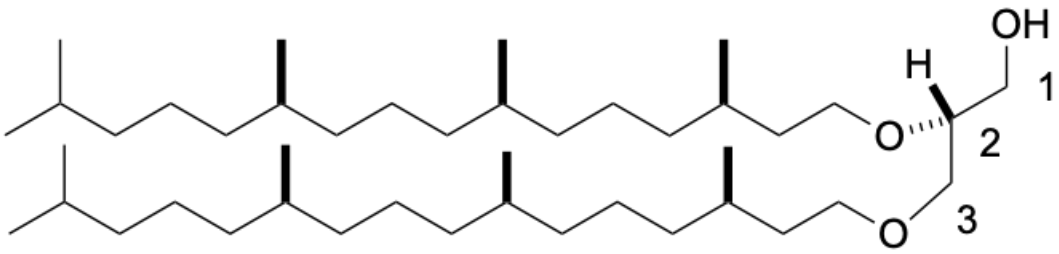
The rediscovery of diversity of archaeol derivative in halophilic archaea especially living in high salt concentration

*Noriaki YAMAUCHI[1]



1. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University

Archaea has a characteristic lipid-core, archaeol(**1**). Further, a characteristic diether lipid-core (C_{20}-C_{25} diether (**2**), extended archaeol) which is constructed from one C_{25} and one C_{20} isoprenoid is produced by halophilic archaea[1]. Recently, Dawson et al. showed the existence of several unsaturated isoprenoid diethers in the lipid-core of several halophilic archaea isolated from very high salt concentration[2]. On the other hands, existence of regioisomer **3** were shown in halite from Spain[3].
In my study, chemically synthesized unsaturated diether were different from those of Dawson’s unsaturated diether, the existence of the regioisomeric mixture were strongly suggested[4]. And the chemical synthesis of **2** and **3** revealed diether in halite is the mixture of **2** and **3**[5].
Until now, **2** have been the only isomer from a cultured microorganic origin. On the other hand, **2** and **3** were existed in halite. Further, the comparison of chemical synthetic unsaturated diether and microorganic samples, diversity of unsaturation in archaeol and extended archaeol were observed in perliminary study. The search of **3**, and the analysis of diversity of unsaturation of archaeol and extended archaeol were conducted in each microorganisms, the halophilic archaea especially living in a high salt concentration. The comprehensive analysis of lipid core obtained from the type cultures in Riken BRC, isolated from high salt concentration field, or from halite were incubated, and the lipid-core analysis were executed. The progress of this study is presented.
About the the preparation of lipid core, alkaline hydrolysis of polar head group used by the preparation ofhydroxyarchaeol[6] were adopted instead of acid hydrolysis usually performed. Thus, the divirsity of unsaturtion of archaeol derivative in each halophilic archaea species. And the exsitence of extended archaeol isomer **3** from the *Halorhabus utahensis* (JCM 11049) with its unsaturated derivative were proved. So far, the archaeol derivative were only discussed in **1**, **2** and its unsatutaed isomers. However, the relatively large diversity in each species in extremely halophilic archaea exists. Further studies from the comprehensive analysis is in progress.

China’s terrestrial ecosystem carbon balance during the 20th century: An analysis with a process-based biogeochemistry model

*Yanyu Lu[1], Wei Sun[2], Dongyan He[1], Hanqing Deng[1], Hong Tian[1], Biwen Wu[1]

1. Anhui Climate Center, Anhui Meteorological Administration, 2. Anhui Public Meteorological Service Center, Anhui Meteorological Administration

China’s terrestrial ecosystems play a pronounced role in the global carbon cycle. Here we combine spatially-explicit information on vegetation, soil, topography, climate and land use change with a process-based biogeochemistry model to quantify the responses of terrestrial carbon cycle in China during the 20th century. We find that that the regional soil thermal and moisture regimes have dramatically changed. Specifically, evapotranspiration increased due to rising temperature and soils were drying in the last two decades of the 20th century. At a century scale, China’s terrestrial ecosystems have acted as a carbon sink averaging at 0.09 Pg C yr^{-1}, with large inter-annual and decadal variabilities. The regional sink has been enhanced due to the rising temperature and CO_2 concentration, with a slight increase trend in carbon sink strength along with the enhanced net primary production in the century. Meanwhile, the heterotrophic respiration increased in response to warming. The spatial and temporal variabilities of carbon balance in China are due to multiple controlling factors including temperature and precipitation and changing atmospheric CO_2 concentrations. Land-use changes including reforestation and afforestation during the late 20th century partially contributed to the increase in carbon sink at the national scale.

Adsorption behavior of molybdenum on ferrihydrite :dynamics analysis of Mo in Erdenet river, Mongolia

*Akihiro Okuyama[1], Solongo Tsetsgee[1], Keisuke Fukushi[2]

1. Kanazawa University , 2. Institute of Nature and Environmental Technology

Changes of molybdenum concentration in rivers in the Erdenet region of Mongolia may be caused by the adsorption and desorption reactions of molybdenum on ferrihydrite. In this study, we conducted molybdenum adsorption experiments on ferrihydrite and constructed the predictive model which can predict the adsorption behaviors of molybdenum by surface complex modeling. The result of the adsorption experiment showed that the adsorption was almost complete up to pH 7 at acidic condition, but desorption over pH 7, and almost completely desorbed at pH 10. The adsorption data was parameterized using an extended triple layer model, a submodel of surface complex modeling. We used one outer sphere complex ($>SOH_2^+_HMoO_4^-$) and two inner sphere complexes ($>S(OH)_2MoO_3(H_2O)$, $>S(OH)_2MoO_3OH^-$). These complexes were consistent with spectroscopic results of molybdenum adsorption on ferrihydrite. The distribution coefficient K_d was calculated to compare with the measured value observed in the river-sediment system in Erdenet area. The comparison showed that the trends of the change of the observation can be captured by the theoretical model. This study suggests that the environmental behavior of molybdenum in rivers in the Erdenet region may be affected by the adsorption/desorption of molybdenum by ferrihydrite.

Keywords: molybdenum, ferrihydrite, surface complexation modeling

Genomic and geochemical characterization of antimony-reducing microbial consortium obtained from mine tailing soil

*Okubo Tomotaka[1], Daisuke Yamashita[1], Hiroyuki Kashima[2], Satoshi Mitsunobu[3], Natsuko Hamamura[1]

1. Kyushu University , 2. JAMSTEC, 3. Ehime University

Antimony (Sb) is a naturally occurring toxic element. Although the concentrations of Sb in soils are generally low, elevated levels of Sb have been released via mining and other anthropogenic activities. Antimony is commonly associated with arsenic (As) in the polluted environments, and both elements have similar chemistry and toxicity. Antimony and arsenic are mainly found in two oxidation states, trivalent (III) and pentavalent (V). The pentavalent form, Sb(V), is the stable species over a wide redox range and is often found to be strongly adsorbed with hydrous Fe(III) oxide in natural soils.
Although we have just began to unveil the full diversity of microbial-Sb interactions, microorganisms are likely to play important roles in Sb redox transformations in the environment. Recently, we have obtained various bacterial isolates and enrichment cultures capable of Sb transformations. In this study, we characterized Sb(V)-reducing anaerobic consortium by using physiological, geochemical, and genomic approaches. An anaerobic consortium was enriched from antimony mine tailing soil by its ability to reduce Sb(V) with lactate. As previously reported with a dissimilatory Sb(V)-reducing bacterium [1], the precipitation of Sb(III) as antimony trioxide was also confirmed in this consortium by X-ray absorption near-edge structure (XANES) analysis. In addition to Sb(V), other electron acceptors such as As(V), Fe(III) citrate, and anthraquinone-2,6-disulfonate (AQDS) were reduced in the presence of lactate. Microbial reduction of Fe(III) can release toxic metalloids bound to Fe(III) oxides, potentially influencing mobility of Sb and As in the contaminated soils. The ability of this consortium to utilize solid-state electrode as an electron donor was also indicated by using a bioelectrochemical system. Phylogenetic analysis of this consortium showed the predominant presence of Firmicutes and α-Proteobacteria-related populations. Draft genome sequence of this consortium was also determined. Majority of the sequences (>90%) were assigned to Firmicutes, and 79% of sequences belonged to the genus *Desulfitobacterium.* Functional genes associated with arsenic resistance, nitrate reduction, nitrogen fixation, polysulfide reductase, and putative reductive dehalogenase were found in the genome, indicating metabolic versatility of this consortium. Collectively, our study showed that the Sb(V)-reducing microbiota may influence mobility of Sb by direct reduction of Sb(V) and indirectly by the reduction of Fe(III), and its potential to facilitate bioremediation of other environmental pollutants indicated by the genomic content.

[B-PT04] Biomineralization and Geochemistry of Proxies

convener:Takashi Toyofuku(Japan Agency for Marine-Earth Science and Technology (JAMSTEC)), Jelle Bijma(Alfred-Wegener-Institut Helmholtz-Zentrum für Polar- und Meeresforschung), Hiroshi Kitazato(Tokyo University of Marine Science and Technology (TUMSAT)), Kotaro Hirose(Faculty of Science and Engineering, Waseda University)

In order to reconstruct the Earth climate system, marine paleoclimatologists resort to transfer functions or geochemical proxies, which are produced or affected by organisms. The relationships used for reconstructions are generally based on field calibrations or derived from laboratory experiments. The danger of these so-called empirical relationships is that they may be valid only within the restricted parameter space of their calibration. Application of proxy relationships to very different environmental settings (e.g. high vs. low latitude or glacial vs. interglacial) requires a mechanistic understanding of these relationships. Much progress can be expected by a better understanding of the biomineralization mechanisms and the incorporation of proxy signals.
In this session we facilitate contributions related to the biomineralization, calibration and validation of marine proxies from field study, laboratory culture experiment and paleo-environmental reconstruction.

Since the Industrial Revolution, ocean acidification (OA) is expected to adversely affect marine ecosystems, especially carbonate organisms. In this study, we investigate the effects of OA on the chemical composition and structure of the shell and spines of sea urchins, *Mesocentrotus nudus* and *Strongylocentrotus intermedius*, whose main components are calcite. In addition, the potential of sea urchins as paleoenvironmental proxies is also examined.
In this study, sea urchins were raised under the following five carbon dioxide partial pressures (pCO_2, μ atm): (i) 2000, (ii) 1000, (iii) 700, (iv) 350 (controlled setting), (v) 250. The conditions from (i) to (iii) were adjusted by addition of CO_2 and that of (v) was adjusted chemically. For the culture experiment, 5 to 7 sea urchins were placed in individual bottles at each setting. The shell length and the body weight were measured monthly, and one spine from individual sea urchin was also collected at this time. Oxygen and carbon isotope ratios ($\delta^{18}O$, $\delta^{13}C$) contained in the spines of *M. nudus* were measured with a stable isotope ratio mass spectrometer (IsoPrime). The Mg/Ca ratio contained in the spines of both sea urchins, the shell and the lantern (chewing part) of *S. intermedius* were measured with an inductivity coupled plasma optical emission spectrometer (Agilent 720). The observation of the surface structure of both sea urchins was performed by a scanning electron microscope (JEOL, JSM-5500G).
As the result of culture experiments, the shell length and the body weight decreased with increasing pCO_2. The spine Mg/Ca ratios of both sea urchins showed positive relations against pCO_2. Since it has been reported that calcites with higher Mg contents have higher solubility, spines of sea urchins would become vulnerable under the projected OA conditions. The SEM observations of surface structures of spines showed that spines reared under higher pCO_2 conditions were disordered compared to those reared at controlled setting. For the results of $\delta^{18}O$ and $\delta^{13}C$ measurements on the spines of *M. nudus*, variation of $\delta^{13}C$ showed a clear negative correlation without temperature effect. On the other hand, $\delta^{18}O$ in the spines showed a seasonal change which is probably related to variation of seawater temperature during the rearing period with negligible effects from differences of pCO_2. Therefore, $\delta^{18}O$ and $\delta^{13}C$ in the spines of *M. nudus* would have potential for environmental proxies of water temperature and seawater pCO_2, respectively.

Relationship between anthropogenic pollution and spatiotemporal change in element composition contained in the bottom sediments from Tokyo Bay, Japan.

*Sumika Yoneto[1], Kotaro Hirose[1], Hideo Yamazaki[2], Kazuo Kamura[1]

1. Faculty of creative science and engineering of the department of resources and environmental engineering, Waseda University, 2. Department of Life Science, School of Science and Engineering, Kindai University

Elucidating temporal variations using sediment records from the hydrosphere is an effective methodto evaluate the historical trends of environmental loads and the resulting effect to aqueous ecosystems.

The watershed of Tokyo Bay is widespread in Kanto Plain including large cities in capital district such as Tokyo and Yokohama, where approximately 30 million people live (1/4 of that of Japan). Especially, industrial and residential districts with urban infrastructures are located along the coasts, and 25,000 ha of water area are reclaimed. Therefore, history of the effects of such anthropogenic modifications are considered to be recorded in the bottom sediments in Tokyo bay as a temporal variations of element components.

Matsumoto (1983) investigated the elemental composition for the last 100 years up to 1981 in Tokyo Bay, and evaluated the manifestation and peak of artificial alteration. However, the spatiotemporal distribution after the peak, especially trace metal elements such as rare metals are not enough clarified. Therefore, we investigated the temporal distribution of each elements for the last 70 years in two surface cores TB12B-38 (c.l. 82 cm) and TB15-68 (c.l. 58.5 cm) recently drilled in Tokyo Bay by using ICP-MS. We also investigated surface sediments collected at 14 sites in Tokyo Bay to evaluate the horizontal distribution of each elements and the factor of the concentration to the bottom sediment.

Temporal distributions of many elements, including Cu, Pb, Zn which are the general indicators for industries, rapidly increased from 1950’s to 1970’s, then decreased to core surface (2010’s). These trends are considered to be the effects of the historical change of anthropogenic loads, such as the high economic growth after the World War II and later effluent control for the severe environmental problem. More specific trends in each element due to their emission source and sedimentation trend will be discussed on the presentation.

Morphologic changes of a calcareous nannofossil group, *Reticulofenestra* group, from Eocene to Miocene in the Atlantic Ocean

*Doi Nobuhiro[1], Koji Kameo[2]

1. Division of Earth and Environmental Sciences, School of Science and Engineering, Chiba University, 2. Department of Earth Sciences, Faculty of Sciences, Chiba University

Coccolithophores, uniceller marine phytoplankton, produce calcite plates called coccolith, consisting of two elliptical discs arranged a lot of tiny, tabular calcite plates (e.g., Young et al., 1992). The *Reticulofenestra* group, composed of a genus *Reticulofenstra* and its related taxa, is one of the major coccoliths during the Cenozoic. Specimens have been classified by their shape and central structures of a coccolith. Size variations during the Miocene and Pliocene have been studied (Young, 1990; Kameo and Bralower, 2000) because frequent size reductions can be considered to correlate globally. Changes in size and morphologic characters of *Reticulofenestra* group have been studied mainly in the Neogene and Quaternary, and a few in the Paleogene to the Early Miocene. So, we applied biometric measurements to *Reticulofenestra* group in the Paleogene to the Early Miocene in order to clarify evolutionary trend of this taxon.

In this study, we investigated morphologic characters and sequential size variations of *Reticulofenestra* group during the Eocene–Miocene based on the scanning electron microscope (SEM) observation. Samples from Ocean Drilling Program (ODP) Leg 208 in the South Atlantic Ocean were used. The ages of the core used here range from ~42 Ma to ~10 Ma. One hundred specimens of *Reticulofenestra* group were examined and morphometric analysis (measurements of diameters of overall coccolith and its central part) were done using a software ImageJ.
Specimens in the *Reticulofenestra* group can be divided into three genera, *Cyclicargolithus*, *Dictyococcites*, and *Reticulofenestra* based on their morphologic characters. Moreover, dominated ranges of larger forms of each genus were clearly different; *Reticulofenestra* in the Eocene–lower Oligocene, *Dictyococcites* in the Oligocene–lower Miocene, and *Cyclicargolithus* in the lower Oligocene–lower Miocene, respectively. The size of the central opening of *Cyclicargolithus* can be a good morphologic character to separate it from other forms of *Reticulofenestra* group. After the middle Miocene, another abundant occurrence of large forms of *Reticulofenestra* are observed with some morphologic changes. Detailed observations will enable us to clarify specific characters of each *Reticulofenestra*.

The formation process of axial internode skeletons in deep-sea isidid octocorals inferred from crystal orientation

*Yukiko Kozaka[1], Katsuyoshi Michibayashi[2], Yui Kouketsu[2], Yuki Tokuda[3], Hiroshi Sato[4]

1. Institute for Space-Earth Environmental Research, Nagoya University, 2. Department of Earth & Planetary Sciences, Graduate School of Environmental Studies, Nagoya University, 3. Faculty of Environmental Studies, Tottori University of Environmental Studies, 4. School of Business Administration, Senshu University

Isidid octocorals (Bamboo coral), which are cosmopolitan in distribution and occur to 4850 m in depth, have bamboo-like jointed axis consisting of elongated calcitic internodes with hollow structures in its center. These are joined by short nodes consisting of dark scleroprotains. The calcareous internode grows both vertically and horizontally, and show concentric growth layers in transverse section. To understand the formation process of their skeletons, previous studies have only focused the histology, cytology, and the observations using SEM. However, the hypotheses of the formation process are not consistent with each other.

The previous study suggested a rejuvenation near the center part of the calcareous internode by using radio carbon dating methods. The causes of the rejuvenation are considered (1) the changes of the age of water mass or (2) the secondary infilling of the hollow structure of internode (Farmer et al., 2015). On the other hand, the histological study of the precious red coral (*Corallium rubrum*) suggested that the formation of concentric layers of calcitic axial skeleton were secreted by skeletogenic epithelium on its outer surface (Grillo et al., 1993). Based on the histological study, the process of the infilling of the inner hollow part of axial skeleton may not be suitable for isidid octocorals.

To ascertain whether the infilling of the center part of internodes occurs in the isidid octocorals, we analyze the crystal orientation of the calcitic internodes. The different formation processes considered to makes different crystal structures. The isidid octocorals samples are collected by dredge during KH-10-7 from the Conrad Rise, Indian sector of the Southern Ocean. Our EBSD data of both the horizonal and vertical lines show that (1) the internodes are not composed by the fiber crystals but the very fine grains, (2) the directions of the c axis of the calcitic internodes are almost parallel to vertical growth line, (3) the crystal structure of the internodes is almost uniformed. These results support that the formation of the calcitic internodes occurs only on the outermost part of internodes by the skeletogenic epithelium. This clarification of the formation process makes the isidid octocorals available for paleoceanographic research.

The cell dynamics of sexual reproduction in foraminifera *Spirillina vivipara*

*Yukiko Nagai[1,2], Remi Tsubaki[3], Nanami Kishigami[2], Takashi Toyofuku[2,4]

1. National Museum of Nature and Science of Tokyo, 2. Japan Agency for Marine-earth Science and Technology , 3. The University Museum, The University of Tokyo, 4. Tokyo University of Marine Science and Technology

Foraminifera performs both asexual and sexual reproduction. In asexual reproduction, it has been reported that the cytoplasm of one foraminifer into 10 to more than 1000 individuals and proliferates. However, foraminifera proliferated many cases by only asexual reproduction in culture experiments. Therefore, information about sexual reproduction is limited. In sexual reproduction, many foraminifers form zoospores and release them to the outside. It has been reported that the released zoospores cross each other and become new individuals. In other benthic foraminifera, there are known species in which 2 to 3 foraminiferal cells are mixed and sexually reproduced.
In this study, we observed cell dynamics of sexual reproduction in the foraminifer *Spirillina vivipara*. This species grows a tubular spirally shell with cytoplasmic growth. It is known that *S. vivipara* grows rapidly and changes generation rapidly enough to divide from the mother cell and become reproductive in a few days (Myers, 1936). In our observations, it was observed that the generation changes while repeating asexual reproduction and sexual reproduction in about 5 to 14 days, so in this study, we described cell dynamics of the sexual reproduction of *S. vivipara* in detail.

Foraminifera: either biological organs or chemical factories

*Hiroshi Kitazato[1]

1. Tokyo University of Marine Science and Technology (TUMSAT)

Foraminifers are eukaryotic microorganisms that roots have been traced back to pre-Cambrian Era. The organism adapts to ambient environments with rapid evolutionary rates. Recently, foraminifers are used as quite sensitive proxy organisms for Earth's environments. But, why ? We need to know foraminifers both from biological organs and chemical factories. During my presentation, I would like to figure out natural history of foraminifers. the view points should make clear foraminifers as chemical factories.

Identification of factors affecting partitioning of rare arth elements between calcite and seawater

*Kana Fujimori[1], Hirotaka Nishino[1], Tasuku Akagi[1]

1. Department of Earth and Planetary Sciences, Faculty of Sciences, Kyushu University

[Introduction]

Concentrations of 14 rare earth elements (REEs) in carbonates are considered to reflect that of seawater via partitioning coefficients, which may be controlled by chemical conditions of seawater. Therefore, partitioning coefficients could be used as a proxy of either REE composition of seawater or chemical conditions. However, the reported partitioning coefficients of rare earth elements are inconsistent, and it has not been certain whether it could be applied to an actual seawater column. In the ocean, carbonate particles are supplied at the surface layer and absorb dissolved elements during settling through a column. In this study, we devised an experimental system mimicking a natural seawater column, where carbonate particles were introduced to carry out partitioning. We have identified several factors that affect the partitioning.

[Method]

Calcite particles of various sizes were added to seawater in a reaction vessel, and were left to partition REEs for a certain period under slightly saturated conditions with respect to calcite by modulating carbon dioxide partial pressure in bubbling air. The calcite particles in half of the seawater were size-separated by elutriation and analyzed for REEs and Ca using ICP-MS and ICP-OES (Stage 1). The calcite particles in another half the seawater were further subjected to the partitioning under an unsaturated condition with respect to calcite by increasing the carbon dioxide partial pressure in bubbling air (Stage 2). They were treated in the same manner as in Stage 1. The partitioning coefficient under each condition was determined by analyzing the relationship between particle size and Ln/Ca.

[Results]

Thermodynamic analysis of the system using pH and calcium concentration data revealed that the presence of REEs significantly inhibits the dissolution of calcium carbonate. REEs have been reported to inhibit calcium carbonate growth, but inhibition of dissolution has not been reported. The partitioning pattern was significantly affected by the addition of iron, but it was found that Mn in seawater had little effect. Also, iron appeared to form an independent hydroxide phase. In addition, it was found that the overall pattern sensitively changes depending on pH of seawater. We also conducted experiments with a fairly small amount of REEs added. Partitioning values higher than most of the reported values were obtaine.

[B-PT05] Biotic History

convener:Isao Motoyama(Faculty of Science, Yamagata University), Takao Ubukata(Division of Geology & Mineralogy, Department of Earth & Planetary Sciences, Kyoto University), Kazuyoshi Moriya(Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University)

The Biotic History session covers all aspects of ancient life and the history of biosphere through the geologic time. The study of ancient life is essential for unveiling mysteries of our planet earth. It also provides evidence for evolution of oceans, continents and island arcs. Modern progress in this field has been enhanced by interdisciplinary collaboration with allied sciences, such as paleoceanography and evolutionary biology. Our session intends to be a hub of communication amongst all earth scientists studying the biosphere; we welcome biological and biogeochemical approaches toward the understanding of the history of life.

According to the fossil record, the early evolution of multicellular animals occurred during the late Ediacaran and early Cambrian. However, detailed timing and process of the evolution are unclear partially due to the scarceness of fossil record and appropriate research site. Moreover, paleoenvironmental reconstruction of marine environment during the Ediacaran-Cambrian and its relationship with the early animal evolution are still unclear on the global scale. This study focuses on the Khubsugul Group in northern Mongolia as a prospective research site for paleontological and paleoenvironmental studies.

Ediacaran and Cambrian Khubsugul Group consists of three formations: Ongoluk, Khesen and Erkhelnur Formations in upward sequence. Recent fossil discovery of “Doushantuo-type” microfossils from the group as well as the occurrence of relatively large-sized trace fossils from the coeval formations of adjacent Dzabkhan terrane also implies that the Khubsugul Group is potentially important for future paleontological study. Nevertheless, very few geochronological or paleoenvironmental studies have been done for the Khubsugul Group. Therefore, carbon isotope and geochemical analyses of this group, the former for the correlation of the group, and the latter for the marine environmental study have been conducted.

New $\delta^{13}C$ data from the Ongoluk and Khesen Formations showed two negative excursions, one in the upper part of Ongoluk Formation and the other in the upper part of Khesen Formation. The Ediacaran-Cambrian boundary could be assigned to either of the two horizons in the group considering the world-wide existence of a conspicuous negative excursion (BACE excursion) at the boundary.

The results of total sulfur (TS) and total organic carbon (TOC) analysis both showed high concentrations in the calcareous shale in the lower part of the Khesen Formation. This result could be explained by either of the two scenarios: one is that the redox variation had driven the changes in TS and TOC, and the other is related to the biotic activity. The former, redox variation scenario stands on the understanding that carbonate rocks would record high TS and TOC values if the seawater is anoxic and record low values if oxic. The measured values may indicate that the seawater changed to relatively anoxic during the deposition of the Khesen Formation. The latter, biotic scenario is inferred from the result that increase of TS and TOC coincides with the increase of siliciclastic components and concentrations of metal elements (aluminium, iron, manganese, vanadium, thorium, and molybdenum). According to these increases, a scenario can be proposed that the terrestrial weathering and input of siliciclastics and other metal elements into the marine environment during this period promoted enhanced production by marine organisms.

Planktic foraminiferal biostratigraphy across the mid-Cretaceous Oceanic Anoxic Events

Soichi Shirakawa[3], Ryo Nakanishi[2], *Kazuyoshi Moriya[1]

1. Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University, 2. Department of Earth Sciences, School of Education, Waseda University, 3. Department of Earth Sciences,Resources and Environmental Engineering, Graduate School of Creative Science and Engineering, Waseda University

Massive deposition of carbon-rich black shales in the mid-Cretaceous is widely known as Oceanic Anoxic Event (OAE). OAE is identified as a negative feedback cooling mechanism at the Cretaceous thermal maximum. In fact, a sudden temperature drop and southward migration of Boreal fauna have been reported just after the beginning of the OAE at the Cenomanian/Turonian boundary (OAE2). Distinctive faunal turnovers in pelagic taxa, such as calcareous nannofossils, planktic foraminifers, radiolarians, etc., have also been found at OAE2. Among these taxa, planktic foraminifers show an interesting pattern in extinction. Deep dwelling species went extinct at the beginning of the OAE2, followed by the extinction of thermocline dwelling species. The rest of mixed layer dwelling species survived. These observations have been reported from rather expanded outcrops distributed around North Atlantic, and possibly indicate shoaling of the top depth of the oxygen minimum zone in a water column.

In this study, we report planktic foraminiferal biostratigraphy from the Cenomanian through the Campanian at Newfoundland margin to identify planktic foraminiferal diversity change against some environmental perturbations in this age. Samples were recovered by Integrated Ocean Drilling Program Expedition 342. Semi-glassy preserved individuals with open-aperture occurred throughout the sequences analyzed. We found two intervals showing faunal turnover in planktic foraminifers. The first, lower interval is correlated to the Cenomanian/Turonian boundary. Sediment of this interval is composed of black shale, which indicates that this faunal turnover represent the extinction event at OAE2. The second, upper interval can be correlated to the Santonian/Campanian boundary or lower Campanian. At this interval, fluxes of both benthic and planktic foraminiferal individuals become almost zero. Sediments trun into darker in color, but no sign of black shale. On the other hand, abundant foraminiferal test fragments have been found in smear slides. These facts indicate planktic foraminifers did inhabit within a water column, but their test were not well preserved in sediments, implying bottom water acidification at this interval. We possibly found two different types of biotic response against the environmental perturbations in the mid- to late Cretaceous.

Organic carbon isotope stratigraphy across the Cenomanian/Turonian boundary at northern Atlantic

Yasuko Miyakura[2], *Kazuyoshi Moriya[1], Akiko S. Goto[3], Takashi Hasegawa[3]

1. Department of Earth Sciences, Faculty of Education and Integrated Arts and Sciences, Waseda University, 2. Department of Earth Sciences,Resources and Environmental Engineering, Graduate School of Creative Science and Engineering, Waseda University, 3. Faculty of Earth Science and Civil Engineering, Institute of Science and Engineering, Kanazawa University

Carbon cycle is one of the important drivers/regulators of Earth's climate system. In the modern world, increasing atmospheric carbon dioxide concentration produces global warming which we should deal with. It is suspected that climate-carbon cycle feedback in near future would become positive feedback. As a result, obviously, global warming would be accelerated. On the other hand, in geological history, climate-carbon cycle feedback may act as negative feedback. One of those examples is Oceanic Anoxic Event (OAE) in the mid-Cretaceous. OAE is defined as stratigraphically restricted deposition of carbon-rich sediment in the world ocean. The deposition of massive amount of carbon on the global seafloor decreases atmospheric carbon dioxide, resulting in global cooling.

Since OAE is the global event, a carbon cycle perturbation at OAE can be found in global sediments. On the other hand, precise age, i.e. stratigraphic position, of carbon-rich black shale is significantly different from site to site. For example, black shale occurs throughout the Cenomanian/Turonian transition in the Equatorial Atlantic, while it is restricted to the upper Cenomanian in British coast. In this study, we present new records of organic carbon isotope stratigraphy at Newfoundland margin, mid-latitude western Atlantic. Samples were recovered by Integrated Ocean Drilling Program Expedition 342. Although upper half of the Cenomanian/Turonian transition were within a core gap and not recovered, the first buildup, trough, second buildup intervals of carbon isotope stratigraphy are clearly identified. Interestingly, black shale only occurs the trough and second buildup intervals, which can be correlated to the upper half of the Plenus Marls Member in British coast. This observation implies that productivity and ocean circulation in mid-latitude western Atlantic (Newfoundland) were different from those of mid-latitude eastern Atlantic (British coast).

The analysis of periostracum on Ammonoid shells from Cretaceous Yezo Group

*Hideharu Kohno[1], Haruyoshi Maeda[1]

1. Kyushu University

Molluscs are animals belonging to the phylum Mollusca in the taxonomic class of creature. Its features are (1) the body is bilaterally symmetric, (2) the mantle (membrane covering the internal organs) is maintained, and (3) the calcium carbonate shell is formed. Among them, the shells of molluscs that form shells are covered with an organic film called periostracum. Its thickness and fine shape differ depending on the species.

The periostracum surface of modern bivalves (e.g. Unionidae, Lternulidae) has been shown to retain microprojections, and the microprojections on the periostracum itself help protect the shell from friction between the water stream and the shell. It is suggested that it is possible. In addition, molluscan periostracum is known to contain pigments (mainly melanin, carotenoids, tetrapyrrole) and to exhibit various colors. Heretofore, it has been considered that the color of the periostracum is a complex one that varies greatly depending on the side chain of the pigment compound and the type of binding protein. However, recent spectroscopic studies suggest that the structure of the polyenes that make up the carotenoids can determine the color. The color and color band of the periostracum formed by polyenes play important ecological roles, such as identifying the same species and camouflaging the predator's eyes.

On the other hand, organic periostracum is easily decomposed and hardly remain in fossils. However, a closer examination reveals that even the fossil of Ammonoids may still have periostracum. For example, *Owenites* cf. *koeneni* from the Triassic has a dark color band on the periostracum. This band is considered to be the original pattern when it was alive because (1) it had a radial pattern and (2) the pattern was interrupted at the damaged part of the shell. Color bands and shells are also known from *Protexanites*, *Tetragonites*, and *Gaudryceras* from the Cretaceous Yezo Group. However, its substance (function, color of the time when Ammonoid alive, etc.) has not yet been clarified because it was difficult to extract the pigment. In this study, we clarify substance of the periostracum preserved in Ammonoid shells from the Cretaceous Yezo Group.

To clarify the substance of the periostracum, *Gaudryceras*, which is known to have a large number from the upper Albian to Maastrichtian and known to have a better periostracum quality of preservation than other individuals, was selected. The surface and cross-section microstructure of periostracum were observed by SEM. Observation of the surface confirmed a clear structural difference between the shell and the periostracum that was presumed to coat on it. The former has a structure in which the crystals constituting the shell are layered. The latter had many microprojections (1-5 μm in diameter) as seen in the shells of modern bivalves.

A functional-morphospace analysis of allometrically growing ammonoids

*Takao Ubukata[1]

1. Department of Geology & Mineralogy, Kyoto University

Theoretical morphology allows us to generalize the relationship between geometries and functional properties of biological form by constructing a functional landscape on a theoretical morphospace. Functional-morphospace analyses have been widely performed particularly for planispiral ammonoids using Raup’s theoretical morphologic model. However, such studies have largely omitted any exploration of the potential effects of allometry because Raup’s model is designed to simulate isometric growth. Here I propose a novel theoretical morphologic model which mimics allometric shell growth commonly observed in ammonoids to represent ontogenetic trajectories of morphological traits as well as shell shape itself. I tried to generalize the relationship between the shape change trajectories and hydrostatic and hydrodynamic properties using the newly introduced model.
The present model approximates shell shape by a planispiral conical tube with elliptic cross-section just as Raup’s model. However, the parameters are defined referring to a hypothetical spiral passing through the center of the elliptic generating curve unlike Raup’s parameters. They are defined using four dimensions, i.e., the lengths of a pair of radius vectors of the spiral parted by p (r_q, r_{q-p}), and radii of the elliptic generating curve in the radial and bilateral directions (h_q, b_q), that are functions of the revolving angle of the generating curve around coiling axis. The present model is based on the allometric relations of r_{q-p}, h_q, and b_q to r_q, and is defined by a total of six allometric coefficients (two for each allometry): degree of whorl involution, relative whorl height, relative whorl breadth, and their scaling exponents. A biometric analysis using more than 100 ammonoid species shows that ontogenetic change in shell shape can fairly be approximated by the present allometric model in most species examined.
A functional morphospace analysis was performed using the present allometric model. A time series of functional landscapes was constructed on a morphospace with reference axes representing the allometric coefficients. Hydrostatic inefficiency of shell shape was assessed by the specific surface area of the totally produced shell. Hydrodynamic inefficiency of shell shape at high Reynolds number was estimated by the projected area of the shell in the direction of movement per unit volume. Hydrodynamic inefficiency of shell shape at low Reynolds number was evaluated by the surface area of the exposed shell portion per unit volume. The results of the analyses revealed the followings: 1) Hydrostatic efficiency highly depends on allometry of whorl involution (or whorl expansion) rather than on allometry of whorl cross-sectional shape. 2) A positive allometry of whorl involution produces hydrostatically inefficient shell shape in a large individual. 3) Allometry of whorl cross-sectional shape dominantly influences hydrodynamic efficiency either at high or low Reynolds number. 4) When the whorl is depressed, a positive allometry of whorl height seems to compromise the three functional properties in a large individual, while a negative allometry of whorl height tends to minimize both hydrostatic and hydrodynamic efficiencies. The results suggest that a negative allometry of umbilical width commonly observed in many ammonoid lineages is advantageous for nektonic or nekton-benthic mode of life.

Phylogenetic aspect of ontogenetic trajectory of whorl shape in ammonoids

*Takao Ubukata[1], Fumitaka Katsuno[1]

1. Department of Geology & Mineralogy, Kyoto University

Ontogenetic changes in shell geometry commonly observed in ammonoids have long attracted much attention among paleontologists from both phylogenetic and functional morphologic points of view. Many authors have tried to extract phylogenetic information from their ontogenetic trajectories using traditional morphometrics or theoretical morphology. However, morphological variation in ammonoid shell form cannot be fully encompassed in a few ratios of dimensions. Geometric morphometrics developed in decades allows us to utilize thoroughly multidimensional information contained in morphological data. Here we use geometric morphometrics as an exploratory tool to compare ontogenetic trajectories of cross-sectional shape of ammonoid whorl. In order to assess phylogenetic signals in the whorl shape and its ontogeny, a relative warp analysis, a principal components analysis of partial warp scores, was performed after Procrustes superimposition of landmarks and semi-landmarks recorded along the outline of the whorl cross section.
As a result of the analysis using ten Cretaceous species, we found phylogenetic signals in morphometric data obtained from radial cross sections of ammonoid shells. The shape variation distinguishing each superfamily was summarized in three principal components that represent, respectively, relative whorl height, development of the ventrolateral shoulder, and shape of the lateral flanks. The shape change trajectories depicted in the size–shape space fairly separate higher taxa, even though many species commonly show a dorsoventral elongation of the whorl with growth. The rate of the dorsoventral elongation was different not only among superfamilies but also between genera within the same superfamilies. The results revealed that non-uniform morphological variation as well as the uniform component has important phylogenetic information in ammonoids. The ontogenetic trajectories of some non-uniform components tend to show complicated patterns in the size–shape space, and we found a diagnostic fluctuation pattern of the shape change trajectories characterizing desmoceratoid species. The present study indicates that relative warp analysis is useful for extracting phylogenetic signals from morphometric variables collected from ammonoid shells if we focus on ontogenetic variation. Further analyses using larger numbers of species are required to identify features in ontogenetic trajectories that characterize each phylogeny.

Evaluation of the metabolic status in extant Amniota based on nasal structures

*Seishiro Tada[1], Takanobu Tsuihiji[1,2]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2. Department of Geology and Paleontology, National Museum of Nature and Science

Dinosaurs are one of the best known, most intensively studied and most successful clades of tetrapods. Since they were recognized as a distinct lineage of vertebrates in the 19th Century, one of the main research focuses on dinosaurs has been their physiology, especially concerning the question “Were dinosaurs warm-blooded (endotherm) or cold-blooded (ectotherm)?” Endothermic animals regulate their body temperature by internal heat production, whereas ectotherms depend on external heat sources. Deciphering the metabolic status of dinosaurs would help improve our understanding of their ecology and evolutionary changes leading to extant birds.

One potential “Rosetta stone” for thermal physiology is the nasal turbinate. It is a scroll-like structure in the nasal cavity and is present only in endotherms (birds and mammals) among extant tetrapods. This structure increases the surface area and volume of the nasal cavity for efficient heat and water exchanges between the respiratory mucosa and inhaled- and exhaled-air, thus compensating for extra heat and water losses caused by efficient lung ventilation in endotherms. Because the degree of development of the nasal cavity is expected to be correlated with the form and size of the nasal cavity, characteristics of the latter are potentially informative in evaluating the metabolic status of amniote animals, especially fossil forms.

Before tackling the question on dinosaur metabolism, it is necessary to establish a quantitative relationship between the metabolic condition and size of the nasal structure in extant amniotes so that could be applied to extinct species.

In the present study, heads of more than 40 extant species were CT-scanned and their nasal cavities were digitally reconstructed three-dimensionally based on the scanned data. The surface area and volume of the nasal cavity were then measured as size parameters of this structure. These values were plotted against the skull volume for comparison between endotherms and ectotherms.

The result shows a clear difference in the slope of the regression lines between endotherms and ectotherms. As expected, endotherms have significantly larger nasal cavities than ectotherms, likely reflecting the existence of the nasal turbinates. In contrast, however, there is no significant difference detected in the slope of the regression lines between them when those size parameters of the nasal cavity was plotted against the whole body weight. One possible explanation for such a difference is that, because the head region houses the brain, an organ metabolically highly consumptive, and endotherms tend to have a relatively larger brain than ectotherms, so the skull volume may be more tightly correlated with metabolic conditions than the body weight. The body weight also tends to have a lager margin of the error than the skull volume because the former sometimes needs to be estimated rather than being directly measured (e.g., cases of alcohol-preserved specimens).

These results suggest that it may be possible to infer metabolic conditions of amniotes based on the size of the nasal cavity. Applying the above relationship to the fossil record of non-avian dinosaurs will

©2020. Japan Geoscience Union. All Right Reserved.

contribute to clarifying the evolutionary changes in metabolism toward fully endothermic extant birds.

[E] Poster | B (Biogeosciences)：B-CG Complex & General

[B-CG06] Decoding the history of Earth: From Hadean to the present

convener:Tsuyoshi Komiya(Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo), Yasuhiro Kato(Department of Systems Innovation, Graduate School of Engineering, University of Tokyo), Katsuhiko Suzuki(Submarine Resources Research Center, Japan Agency for Marine-Earth Science and Technology), Kentaro Nakamura(Department of Systems Innovation, School of Engineering, University of Tokyo)

The latest results of Earth's evolution and geological processes through 4.6 billion year
s from Hadean to Modern, based on various approaches including fieldworks, chemical
analyses, experiments and computer simulation, will be presented. In this session, we ai
m to discuss and understand causal relationships and interplay among the evolution of
Earth's deep interior, changes in the surface environments, and development and evolut
ion of life. Wide-ranging topics are accepted.

Ocean oxidation and microbial activity just after the Marinoan Snowball Earth

*Tsuyoshi Komiya[1], Miyuki Anzai[1], Teruyuki Maruoka[2], Yohei Matsui[3], Manabu Nishizawa[3], Yusuke Sawaki[1]

1. Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo, 2. Faculty of Life and Environmental Sciences, University of Tsukuba, 3. Japan Agency for Marine-Earth Science and Technology

The Marinoan Snowball Earth event is one of the most severe environmental changes, and occurred about 650 million years ago in the Cryogenian. It is widely considered that the Earth was completely covered with ice, and that bioactivity significantly collapsed during that event. On the other hand, many fossils including acritarchs, Metazoan eggs and embryos, and algae were found after the Marinoan Snowball Earth event, indicating the bioactivity was completely recovered and organisms quite rapidly evolved in the Ediacaran. However, recovery and extent of bioactivity just after the event is still obscure. Therefore, we tried to estimate the biological activity just after the Snowball Earth event based on geological and geochemical studies of the Cap Carbonate deposited right after the event.

We analyzed aggregate of organic matter, carbonate rocks and pyrites in the Cap Carbonate of the Siduping section, South China. The Cap Carbonate is subdivided into 3 parts: C1, C2 and C3 in an ascending order. The C1 part consists of a stromatactis structure, which forms network structures of many quartz veins, and contains many domains rich in organic materials and pyrite within cavities of the stromatactis structure. The rims of veins comprise quartz, which suggests that carbonate has been silicified and replaced by silica minerals simultaneously or immediately after deposition. Generally speaking, the silicification of carbonate is due to organic acid formed by heterotrophs. Most of the central parts of the veins or cavities of the stromatactis structures contain aggregate of organic matter and pyrite, suggesting active microbial activity within pore water of conduits and among minerals. We call the organic matter as stromatactis organic matter hereafter. The C2 and C3 parts comprise layered dolostone, and the C3 part contains more detrital materials than the C2 part. No stromatactis structure is present in the C2 and Ce parts. We examined the stromatactis organic matter and organic matter within carbonate parts of the carbonate rocks from the C1 to C3 parts in order to estimate the microbial activity in the ocean and sediment.

The isotope ratios of organic carbon within the carbonate parts in the C2 and C3 parts range from -28 to -24‰, corresponding to photosynthesis by cyanobacteria. The carbon isotope ratios of organic matter within the carbonate parts in the C1 part is characterized by a wide range of the values (-34~-22‰), possibly due to mixing between photosynthetic carbon fixation and methane-related processes. In addition, carbon isotope ratios of the stromatactis organic matter are significantly low, ranging from -35 to -30%, possibly due to the methane-related processes. Methanogen and anaerobic methanotrophic Archaea possibly produced the organic matter with the low carbon isotope values. In addition, there are many pyrite grains occur together with the stromatactis organic matter, which also suggests active sulfate reduction together with the anaerobic methanotrophic activity. We try to prove the microbial combination based on sulfur isotopes.

Nitrogen isotope ratios range from -2 to +7‰. The nitrogen isotope values of the stromatactis organic matter in the C1 part ranges from -1 to +1‰, whereas those of carbonate parts abruptly increase from -1~+1‰ in the lower part to +7‰ at the top of the C1 part. The low values around -1 to +1‰ indicate that

©2020. Japan Geoscience Union. All Right Reserved.

nitrogen fixation was dominant after the Snowball Earth event. On the other hand, the high nitrogen isotope values indicate that the nitrification and denitrification restarted at that time possibly because seawater became oxic enough to form nitrate. On the other hand, it is considered that nitrogen fixation by methanogen was also active within the sediment because nitrogen isotope values of organic matter formed in seawater increased to +7‰, but the nitrogen isotope values of the stromatactis organic matter formed within sediment were consistently around 0‰.
Carbon and nitrogen isotope values of the stromatactis organic matter and organic matter in the carbonate parts in the Cap Carbonate suggest that ocean and subseafloor environments shared common biological activity just after the Marinoan Snowball Earth event, and that the ocean was very quickly recovered to oxic and nitrate-rich environment. The rapid recovery probably became a prelude to biological evolution of emergence of the Metazoan.

Alkaline magmatism in a fore-arc region: igneous activity in relation to the Ashizuri igneous complex, SW Japan

Takumi Matsumoto[1], *Kazumasa Aoki[1]

1. Department of Applied Science Okayama University of Science

A-type granitic rocks are basically developed in anorogenic tectonic setting and relatively alkaline composition (e.g. Cremens et al., 1986; Bonin, 2007 and references therein). These rocks are volumetrically insignificance compared with the vast amounts of I- and S-type rocks exposed in various parts of the world, but their genesis plays one of important roles in understanding of evolution of granitic rocks through Earth’ s history because the granite rocks exist in only the Earth within the Solar system that may represent the specificity of the Earth.

Ring igneous complex exposed in Shikoku is called Ashizuri igneous complex (Murakami et al., 1983; 1989), and is composed mainly of felsic lithology with subordinate amount of alkaline gabbro and dolerite (Murakami et al., 1983; 1989; Stein et al., 1996). The felsic rocks are classified into the A-type granite. They are a close genetic relation with the opening of Japan Sea and the commencement of subduction of the young and hot Shikoku Basin of the Philippine Sea plate during the Neogene period (e.g. Kimura et al., 2005; Shinjoe et al., 2010; 2019). Thus, identifying the formation process of Ashizuri igneous complex leads to a greater understanding of the alkaline magmatism in arc-trench systems. A lot of studies for the genesis of the Ashizuri igneous rocks have been reported so far, however, there are no unified views on this issue (e.g. Kimura et al., 2005; Shinjoe et al., 2010; Yoshikura, 2012).

Igneous zircon is one of powerful tools to elucidate the origin of the parental magmas because the trace elements of zircons could vary depending on the parent melt compositions controlled by some physicochemical processes such as crystallization, differentiation and dehydration (e.g. Grimes et al., 2007; 2015; Yang et al., 2012). Moreover, U–Pb dating of igneous zircons can be used to constrain the timings of igneous activity. In this study, we report new U–Pb and geochemical data of the zircons separated from three granitic and two gabbroic rocks in the Ashizuri igneous complex by the using laser ablation ICP mass spectrometry. Moreover, zircon data from sandstone sample in the Paleogene Shimizu Formation intruded by the Ashizuri igneous complex is also reported. Finally, we would like to discuss the origin of the alkaline magmatism in fore-arc regions as illustrated by a case study of the Ashizuri igneous complex, based on our new data integrated with previous geological and geochemical data reported by other researchers.

Feedback mechanism of solid earth system on glacial-interglacial climate cycles: Constraints from osmium isotopic mass-balance in the ocean

*Yusuke Kuwahara[1], Kazutaka Yasukawa[2,1,3], Koichiro Fujinaga[3,2], Tatsuo Nozaki[4,2,5,3], Junichiro Ohta[2,3,6], Honami Sato[3,4], Jun-Ichi Kimura[6], Kentaro Nakamura[1], Yasuhiro Kato[2,1,3,4]

Solid earth has affected and responded to changes in the global carbon cycle and climate. Volcanic degassing of carbon dioxide (CO_2) and silicate chemical weathering consuming atmospheric CO_2 are believed to have regulated the carbon budget of Earth's surface system on a geologic timescale (>10^6 yr). However, characteristics of the solid earth response against shorter (<10^5 yr) fluctuations such as the Quaternary glacial-interglacial cycles, are still controversial. In order to constrain the response of the solid earth to glacial-interglacial climate changes, we employed the marine Os isotopic ratios ($^{187}Os/^{188}Os$) as a proxy of solid earth response. The marine Os isotopic ratio reflects the relative intensity of two dominant influxes to the ocean: radiogenic continental materials ($^{187}Os/^{188}Os$ = 1.0–1.4) and unradiogenic mantle-like materials (i.e. hydrothermal fluids and cosmic dust) ($^{187}Os/^{188}Os$ = ~0.12). Owing to the contrasting $^{187}Os/^{188}Os$ values between these two influxes, and short residence time of Os in the ocean (~10^4 yr), the variability in $^{187}Os/^{188}Os$ of seawater can constitute a sensitive tracer for mantle and continental inputs into the marine environment on a glacial-interglacial timescale. Here we show a high-resolution record of the marine osmium isotopic composition ($^{187}Os/^{188}Os$) as a proxy of solid earth's response during the past 300,000 years. We demonstrate that the seawater $^{187}Os/^{188}Os$ has varied associating with glacial-interglacial cycles. Based on a marine Os isotopic mass-balance simulation, the observed $^{187}Os/^{188}Os$ fluctuation cannot solely be explained by the change of global chemical weathering rate synchronized with glacial-interglacial climate changes. Instead, the fluctuation can be reproduced by a combination of two short-term processes: (1) inputs of radiogenic Os derived from the intense weathering of glacial-till during deglaciation, and (2) inputs of unradiogenic Os derived from enhanced seafloor hydrothermalism during glacials. Our results constitute the first evidence that the solid earth system involving chemical weathering of glacial-till and seafloor magmatism systematically and repetitively responded to the glacial-interglacial cycles on <10^5 yr timescales.

Geochemical constraints on the Earth environment after the Lomagundi Event; The Cape Smith belt, Canada

*Kento Motomura[1], Shoichi Kiyokawa[1], Minoru Ikehara[2], Takashi Sano[3], Kentaro Tanaka[4], Tsubasa Miki[4], Yuji Sano[4]

1. Kyushu Univ., 2. Kochi Univ., 3. National Museum of Nature and Science, 4. Univ. of Tokyo

The beginning of the Paleoproterozoic era (ca. 2.5–1.6 Ga) is characterized by Great Oxidation Event (GOE: ca. 2.5–2.3 Ga) and subsequent positive carbon isotope excursion event (Lomagundi Event: ca. 2.2–2.0 Ga). These events represent dynamic changes between the Archean and Proterozoic Earth environment including the primary production, oceanic sulfate level, and redox structure (e.g. Lyons et al., 2014). Last two decades, several studies have cleared the Earth environment during ca. 2.5–2.0 Ga, however, aftermath of the events is poorly constrained. In this study, we measured organic carbon isotope ($\delta^{13}C_{org}$) of black shales deposited ca. 1.96 Ga and estimated Earth environment after the Lomagundi Event.

Two core samples consisting of sandstone–black shale alternations were drilled at the Cape Smith belt, Canada (4G8069 and 718.3333). These two drilling points are 10 km off each other. Sedimentary sequences composing a part of 4G8069 and 718.3333 are regarded as Povungnituk Group sediments which were deposited on the continental margin of the Superior at about 1.96 Ga (St-Onge & Lucas, 1990). Komatiitic lava overlying the sandstone–black shale sequence is observed at the top of the 4G8069 core. 718.3333 core also contains komatiitic lava, but the lava is observed ~100 m above our sampling intervals. Microscopic observation revealed that the black shales are rich in organic matter and pyrrhotite which origin is likely to sedimentary pyrite generated by bacterial sulfate reduction.

$\delta^{13}C_{org}$ values of the 4G8069 core range from −32.0 ‰to −29.5 ‰and show systematic changes. Two carbon isotope excursions (CIEs) are identified from the 4G8069 core: CIE 1) the gradual increase from bottom of the sequence (−32.0 ‰) to 45 m point (−29.5 ‰), CIE 2) the gradual decrease between 45 m and 50 m (−32.1 ‰), and subsequent increase toward the top (−31.0 ‰). CIE is also observed in the 718.3333 core, which shows gradual decrease from −30.6 ‰to −33.2 ‰, and subsequent increase toward −31.9 ‰.

CIE 1 of the 4G8069 core could be comparable with CIE of the 718.3333 core based on ~100 m distance from the komatiitic lava. Therefore, it is plausible that CIEs occurred at least twice after the Lomagundi Event. There are two possibilities for the trigger of the CIEs: (1) volcanic activities or (2) oxidative weathering could cause CIEs.

Occurrence, petrography and chemical compositions of black shale in the Isua supracrustal belt: A potential to decode surface environmental conditions on the early Earth

*Suzuki Akiko[1], Yusuke Sawaki[2], Tsuyoshi Komiya[2]

1. The University of Tokyo , Graduate School of Science, 2. Department of Earth Science & Astronomy Graduate School of Arts and Sciences The University of Tokyo

The Earth is the only planet, which has been covered with H_2O-ocean throughout the geologic time, in the Solar System. Therefore, it is very important to understand the origin and evolution of the Earth's oceans. Generally speaking, there are two ways to decipher the Earth's early evolution. The first is numerical calculation, and the second is the analysis of geological samples. The numerical calculations provide general solutions that may have occurred on Earth, but may not provide specific events that have occurred only on Earth. Therefore, this study adopts the latter method. In particular, to estimate the surface environment of the early Earth, it is essential to examine sedimentary rocks formed on the early Earth, and it is important to find sedimentary rocks such as black shale, that are suitable for the estimation, from the Eoarchean geological terrains. There will be.

One of the significant events on the early Earth was the Late Heavy Bombardment (LHB). It is considered that the event occurred 4.2 to 3.8 Ga based on age-distribution of the moon's craters, and that the event caused significant impacts of a large number of meteorites on the earth. However, no evidence is, so far, found from terrestrial materials so that it is still controversial whether the event really took place. It is generally known that meteorite impacts leave anomalous signatures of a platinum element group in abyssal sedimentary rocks. However, the concentration of Ir in the banded iron formations (BIFs) in the Isua supracrustal belt has been analyzed, but no significant anomaly has been found. Generally speaking, it is regarded that the BIFs was slowly deposited, analogous to modern deep-sea pelagic sediments such as chert. On the other hand, it is widely known that the banded iron formation is derived from intermittent hydrothermal activity. It is more important to study sedimentary rocks with a low sedimentation rate, such as black shale.

Relatively, less metamorphosed supracrustal rocks, under the amphibolite facies or less conditions, are present in the Isua area in southern West Greenland. In 2016, we conducted a geological survey of the Isua Supracrustal Belt, and discovered new black shale outcrops. Black shale, rich in organic matter, has been reported in the western part of the Isua Superficial Rock Zone (Rosing, 1999), but no black shale has been reported in the northeastern part In addition, the previous report did not show detailed description of the geological occurrence such as accompanied lithology and detailed lithostratigraphy. This presentation reports the geological occurrence, mineralogical description, major and minor chemical compositions of the black shale, and discusses its significance.

The Isua Supracrustal Belt (ISB) is located approximately 150 km northeast of Nuuk, and has an arcuate shape. The ISB is composed of ultramafic rocks, basalts with pillow structures, BIFs, chert, carbonate, and clastic sedimentary rocks such as conglomerate, sandstone and pelitic rocks. It is intruded by the Eoarchean (3.7 to 3.8 Ga) granitic gneiss (Itsaq gneiss). Although they have undergone metamorphism under the greenschist to amphibolite facies conditions, we mention the rocks as rock names of the estimated precursors hereafter. The northeastern part consists of piles of about 10 fault-bounded

©2020. Japan Geoscience Union. All Right Reserved.

subunits, which have similar lithostratigraphy of basaltic layer, chert and clastic sedimentary rocks in an ascending order to each other. The lithostratigraphy is similar to modern ocean plate stratigraphy. The existence of the imbricate structure and oceanic plate stratigraphy suggests that the belt was an accretionary complex.

Black shale occurs mainly in two regions of the northeastern part of the ISB; the northern black shale has been previously described as mafic sedimentary rocks (Komiya et al., 1999) or chert (Nutman & Friend, 2009). The black shale stratigraphically underlies the BIFs. It is considered that the BIFs in the ISB belong to the Algoma-type because it is regarded that all of them occur on basaltic lava so far. However, this work presents another occurrence of the BIFs, which were deposited on black shale. In addition, the discovery may allow us to detect the LHB signatures from the Eoarchean sedimentary rocks because black shale, generally speaking, is deposited quietly slowly in open ocean.

In this study, microscopic observation and chemical analysis were performed in addition to the geological observation. The northern black shale contains quartz, calcite and chlorite, whereas the southern black shale consists of quartz, amphibolite and biotite. We will also discuss the results of chemical analysis.

U-Pb chronology and geochemistry of detrital monazites from major North American rivers

*Kazumi Yoshiya[1], Keita Itano[2], Tsuyoshi Iizuka[1], Shigenori Maruyama[3]

1. The University of Tokyo, Department of Earth and Planetary Science, 2. Kanazawa University, 3. Tokyo Institute of Technology, Earth-Life Science Institute

The North American continent formed through collisions of Archean cratons which surrounded by Proterozoic orogenic belts, and the outermost parts are enclosed by Phanerozoic orogens. Detrital minerals in river sands have been eroded from basement rocks along rivers, and transported to the river mouth areas. Monazite, one of the robust minerals, is a light rare-earth element phosphate which can be precisely dated by the uranium-thorium-lead method. Monazite occurs as an igneous mineral in low-Ca peraluminous felsic rocks and as a metamorphic mineral in a wide range of metamorphic rocks. Previous monazite chronology and geochemistry revealed that detrital monazites from the African rivers recorded orogenic metamorphic events more accurately than detrital zircons (Itano et al., 2016). In this study, we extend the application of monazite chronology and geochemistry to large rivers of the North American continent in order to better understand orogenic metamorphic events in the continent. To constrain the timing and nature of major orogenic events that formed the continent, we analyzed U-Pb ages and geochemical compositions of 178 detrital monazite grains from the Mississippi (83 grains) and Mackenzie Rivers (95 grains). The U-Pb age distribution of detrital monazite from the Mackenzie River shows large four peaks at 0.15-0.2, 1.8-1.9, 2.0, 2.6 Ga and small peaks at 0.45 and 2.5 Ga. On the other hand, that from the Mississippi River shows large three peaks at 1.45, 1.7, 2.65 Ga and small peaks at 0.4, 1.1, 1.65, 1.85 Ga. Some of the monazite age peaks are not observed in the U-Pb age histograms of detrital zircons from the same rivers (Iizuka et al., 2005; Rino etal., 2004; 2008), suggesting that the age peaks reflect the timing of major metamorphic events. Comparison with geological events, 0.15-0.2 Ga peak of the Mackenzie River reflects contributions from the Cordilleran orogen (Gehrels et al., 2002). Other large peaks around 1.8-2.0 Ga of the Mackenzie River may reflect contributions from the Thelon, Wopmay and Trans-Hudson orogens. The largest peak for monazite from the Mississippi River is observed around 1.4 Ga. It may reflect contributions from anorogenic magmatism (Nyman et al., 1994) or early stage of the Grenville Orogeny (Windley, 1993). The second large peak around 1.7 Ga of the Mississippi River may reflect contributions from the Penoken, Trans-Hudson, and Yavapai-Mazatzal orogens.

Variations of burial rates of organic carbon in terrestrial and marine environments during the Phanerozoic

*Kazuhiro Aoyama[1], Eiichi Tajika[1], Kazumi Ozaki[2]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2. Toho University

Emergence and evolution of land plants had a large effect on atmospheric O_2 and CO_2 levels through carbon geochemical cycle, especially an increase in an efficiency of chemical weathering of soils, and an increase in a rate of organic carbon burial on land. However, there are few studies which evaluate influence of the rise of land plant and relative contribution of organic carbon burial in terrestrial and marine environments to the carbon geochemical cycle and to the climate through geologic time.

In this research, we modified a model for combined cycles of carbon and sulfur (GEOCARBSULF) to consider this problem. We estimated ratios of global organic carbon and pyrite burial rates (C/S ratio) from the model with marine carbon and sulfur isotopic records. We used compiled data of C/S ratio from sediments deposited in freshwater, oxygenated and euxinic seawater environments to distinguish the burial rates of organic carbon in terrestrial and marine environment.

As a result, it was indicated that, as inferred from the previous studies of carbon cycle by Robert Berner, the burial rate of organic carbon in terrestrial environment had increased greatly in the Late Paleozoic (Carboniferous) owing to advent of vascular plants which produces microbially resistant organic matters such as lignin. In contrast, it was also shown that terrestrial burial rate had been virtually zero before the Silurian when there were no vascular plants on land, and decreased largely at the Devonian/Carboniferous, Permian/Triassic and Triassic/Jurassic mass extinction boundaries. We will discuss influence of Ocean Anoxic Events (OAEs) on the burial rate of organic carbon and pyrite through the Phanerozoic time.

New morphotypes, cell-wall structures, and elemental distribution of the Gunflint microfossils

*Kouhei Sasaki[1], Akizumi Ishida[1], Naoto Takahata[2], Yuji Sano[2], Takeshi Kakegawa[1]

1. Department of Earth Science, Graduate school of Science, Tohoku University, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Precambrian microfossils have been studied by previous investigators for decades to constrain their microbial activity, while their ultrastructure and chemical composition have been poorly understood. Since microbial metabolism is performed on the cell surface, the elemental compositions, ultrastructure and coexisting minerals of microfossils can be a strong clue to understand their microbial metabolisms. In the present study, in situ analysis on individual microfossils by high spatial resolution Secondary Ion Mass Spectrometry (NanoSIMS) was performed together with other standard geochemical and mineralogical methods on the Gunflint microfossils, well known as great preservation, occurred in the 1.9 Ga Gunflint Formation, Canada.

Morphological observation revealed that some new morphotypes of microfossils having morphological affinities to cyanobacterial akinete (*archeaoellipsoides*), eukaryotes and fungi, which had not been reported in this age. Bilayered cell-wall structures were also newly discovered in thick-wall spherical microfossils. Having multi-layered wall structure are essential for modern-style microbial life, such as cyanobacteria, to promote complex metabolism and the storage of organelles. These findings indicate that advanced microbes and modern-style cell wall structures had already evolved in the Paleoproterozoic ocean, earlier than thought in previous studies.

Secondary ion mapping for 12C-, 12C14N-, and 32S- were newly obtained on 30 individual Gunflint microfossils with 10 morpho-types. They showed mostly similar elemental distribution patterns among different morpho-types. A unique elemental distribution was observed in globular type microfossils, showing that heterogeneous N and S distribution between the cell wall and inner structure. This indicates that this type of microfossil possibly had a special function, such as production of baeocytes during cell differentiation like modern cyanobacteria (e.g., Pleurocapsales).

Outer parts (i.e., walls) and inner parts of examined microfossils often showed contrast chemistries. Inside organic matter contained microcrystals of iron-bearing minerals and trace amounts of Ca or Mo. They imply that successful detection of minerals and elements, which are possibly related to cyanobacterial enzyme. Outer parts were generally depleted in N and enriched in S. In addition, Na, K, and Cl were often detected from cell wall indicating deposition of chloride crystals with organic matter of microfossils, which were suggested that the Gunflint microbiota were active in the evaporitic environment.

This research does not only constrain the microbial activities indicating the early rise of advanced microbes and modern like biological functions in the Gunflint ocean, but also provides new keys to understand the evolution of early life and their living environments in the Paleoproterozoic era.

Modelling the behaviors of marine carbon isotopic composition after Neoproterozoic snowball Earth event

*Akari Miki[1], Eiichi Tajika[1], Kazumi Ozaki[2]

1. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo, 2. Toho University

The atmospheric oxygen level is thought to have increased soon after the snowball Earth events in the early and late Proterozoic, leading to the modern oxygen-rich environment from a completely anoxic environment [e.g. 1-5]. A biogeochemical cycle model [6] predicts that an extremely hot climate immediately after the snowball Earth event should cause intense continental weathering and supply a large amount of nutrients into the ocean, leading to increases of primary productivity in the surface ocean and global organic carbon burial, which, in turn, results in an inevitable rise of the atmospheric oxygen level. However, since the massive organic carbon burial removes a large amount of light carbon isotopes from the environment, a positive excursion of marine carbon isotope ratio is predicted, which contradicts the marine carbon isotope record in the snowball Earth events in the Neoproterozoic. Here, we report an investigation of the behavior of marine carbon isotope ratio just after the snowball Earth event. We propose a possible scenario for explaining the negative excursion of carbon isotope ratio with a new idea that a temperature dependence of a rate of microbial decomposition of organic matter may explain an apparent negative anomaly of the carbon isotope ratio in seawater. We will compare this new scenario with various other scenarios proposed so far and discuss the possible scenario, with a marine biogeochemical carbon cycle model coupled with an atmospheric photochemical model.

Paleoecological variations reconstructed by organic matter derived from lichens and fungi across the Cenomanian/Turonian boundary in the Tomamae area, northern Hokkaido, Japan

*Masashi A. Ikeda[1], Ken Sawada[2], Takuto Ando[3], Hideto Nakamura[4], Reishi Takashima[5], Hiroshi Nishi[5]

1. Graduate School of Science, Hokkaido University, 2. Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, 3. Estuary Research Center, Shimane University, 4. Faculty of Science, Osaka City University, 5. The Center for Academic Resources and Archives, The Tohoku University Museum, Tohoku University

The Cretaceous period is known as the extreme greenhouse period due to active magmatism caused by superplume. Especially in the mid-Cretaceous, the Oceanic Anoxic Events (OAEs) occurred in several times, and had a great impact on marine and terrestrial ecosystems. Moreover, many animals and plants in the terrestrial ecosystem likely have undergone rapid diversification since the mid-Cretaceous (e.g. Dilcher, 2000; Meredith et al., 2011). Noticeably, the lichens have acquired strong light tolerance and undergone rapid diversification, and fungi have gained new symbiotic relations with trees through the appearance of ectomycorrhizal fungi since the mid-Cretaceous (e.g. Gaya et al., 2015; Taylor et al., 2011). However, these researches are limited to molecular phylogenetic analysis and numerical simulations, and few fossil records have been reported. In the present study, we analyzed biomarkers and organic fossils (palynomorph) derived from the lichen and fungi in the sediments deposited across the Cenomanian/Turonian boundary (CTB) from the northern Hokkaido, Japan to evaluate paleoecology during environmental disturbance event.

We analyzed sedimentary rocks across the CTB in the Saku Formation, Yezo Group, were collected from the Omagari-zawa sections of the Tomamae area, northern Hokkaido, Japan. The sediments used correspond to the OAE2 intervals (1st build-up, Trough, 2nd build-up and Plateau phases), determined by $\delta^{13}C$ stratigraphy (Omatsu et al., 2014). For the biomarker analysis, lipids were extracted from freeze-dried sediments, subsequently fractionated using silicagel column, and analyzed by GC-MS. For palynomorph analysis, kerogens were separated by HCl and HF from the extraction residue, and observed under a fluorescent light microscope.

Based on sterane and hopane ratios, we confirmed the high contribution of terrigenous matter input and low maturity of organic matter (vitrinite reflectance ca. 0.4% level; lignite to subbituminous coal rank) in the Omagari-zawa section. Recently, a perylene is thought to be fungal biomarker. In our study, we tentatively defined that the ratio of perylene to plant-derived aromatic terpenoids is useful as indicator of fungal biomass in terrestrial flora i.e. fungal activity. On the other hand, it has known that the lichens produce dibenzofuran (DBF). In particular, we suggested that specific isomers of alkyl DBF such as 1-methyl DBF are useful for the lichen biomarkers. Here, we established the ratio of 1-methyl DBF to plant wax *n*-alkanes (C_{27}-C_{31}), and it assumed to reflect relative contribution of lichens among terrestrial plants. These results implied that the fungi constantly flourished, and their activities declined during environmental disturbances such as before and after the 1st build-up and before the 2nd build-up stages. On the other hand, the variations in lichen-derived biomarker index are synchronous with those of the angiosperm/gymnosperm ratio (ar-AGI), indicating that the lichen increased during the angiosperm expansion period. The coniferous vegetation index such as Higher Plant Parameter (HPP) increased during the 1st build-up and 2nd build-up stages, implying that the conifer has expanded under arid

©2020. Japan Geoscience Union. All Right Reserved.

condition. However, the HPP values declined during the Trough and Plateau stages. These results suggest that, in the eastern margin of the Asian continent during the CTB, fungal activity was affected by arid/humid fluctuation, while lichen contribution on terrestrial ecosystem was greatly affected by angiosperm/gymnosperm vegetation changes.

Petrography of magnesite-orthopyroxene-olivine veins in the Ujaragssuit Nunât layered ultramafic body terrane, southern West Greenland

*Toma Takahashi[1], Tomoaki Morishita[1], Tomoyuki Mizukami[1], Akihiro Tamura[1], Keita Itano[1], Juan Miguel Guotana[1], Ikuya Nishio[1], Kanta Takahashi[1], Kristoffer Szilas[2]

1. Kanazawa university, 2. University of Copenhagen

Researches on Hadean-Archean terranes are essential to reconstruct the geologic past of the early Earth, which is believed to be different from the present plate tectonics. Southern West Greenland preserves a wide exposure of Archean geologic units. This study reports magnesite-bearing veins in the Ujaragssuit Nunât layered ultramafic body, southern West Greenland.

Ultramafic rocks are transformed into serpentinite and carbonated rocks when they react with H_2O-CO_2 fluids under low temperature conditions. Carbonated ultramafic rocks from the Archean geological unit might provide information on impact of carbonatization of peridotite on atmospheric and water chemistry in Archean.

The studied magnesite-bearing veins occur in amphibole harzburgite. The magnesite-bearing veins contain coarse grained olivine and orthopyroxene, anthophyllite and talc, with minor amounts of phlogopite, chlorite, Cr-spinel and Fe-Ni sulfide. Magnesite contain anthophyllite and olivine. Anthophyllite is radial in shape. The Mg# (Mg/(Mg+Fe) atomic ratio) is 0.927-0.941 for magnesite, 0.862-0.882 for anthophyllite, 0.893-0.901 for coarse-grained orthopyroxene, 0.974-0.984 for talc, respectively. Orthopyroxene sometimes contains magnesite as inclusion, and micro-veins mainly composed of talc. Fine-grained olivine with minor amount of magnetite occurs in the micro-veins. The Mg# is 0.893-0.901 for coarse-grained orthopyroxene, 0.974-0.984 for talc, and 0.872-0.889 for fine-grained olivine. The Mg# of fine-grained olivine in talc micro-veins (0.872-0.889) are distinctively lower than coarse-grained olivine and olivine inclusions in magnesite (0.882-0.905).

The carbonate veins were formed as follows: 1) coarse-grained orthopyroxene was formed by the reaction between olivine in the host and CO2-bearing fluid

Mg_2SiO_4 (P1) + CO_2 (fluid) = $MgCO_3$ + $MgSiO_3$ (1),
whereas coarse-grained olivine and anthophyllite were formed by reaction with low-CO_2 activity fluids, such as

$5MgSiO_3 + H_2O = Mg_2SiO_4$ (secondary) + $Mg_3Si_4O_{10}(OH)_2$ (2),
and the fine-grained olivine in talc veins in large grained orthopyroxene was formed by the reaction
$9MgSiO_3 + H_2O$ (fluid) = $Mg_7Si_8O_{22}(OH)_2 + Mg_2SiO_4$ (3).

Palynomorph assemblage in sedimentary rocks of the Mesoproterozoic Qaanaaq Formation from northwestern Greenland.

*Yuki Hara[1], Takuto Ando[3], Ken Sawada[2]

1. Graduate School of Science, Hokkaido University, 2. Department of Earth and Planetary Science, Faculty of Science, Hokkaido University, 3. Estuary Research Center, Shimane University

The evolutions of cyanobacteria and eukaryotic algae have been thought to be promoted by expansion of shallow ocean environment under long-term climatic warming by volcanic activity during the Mesoproterozoic, which is reconstructed by the analyses of sedimentary rocks deposited the delta-submarine fan system formed during the Grenville orogeny (Taira, 2007). Molecular biological researches supported that the pronounced promotion of eukaryote evolution was possibly occurred during the Mesoproterozoic (Philippe and Adoutte, 1998). In paleontological studies of the Mesoproterozoic fossils, organic microfossils such as acritarchs were used as strong indicators for reconstructing the marine organisms. The acritarchs is one of organic microfossils (palynomorphs) that are insoluble by acid and alkali treatments, and cannot be assigned to known group of organisms while they are thought to be cysts and sporangia of eukaryotic organisms. Morphology of the acritarchs became various and complicated after the Phanerozoic, especially during the Paleozoic, so that the acritarch fossils were used for paleontological and paleoenvironmental reconstructions after the Paleozoic. However, there are few studies for evolutional history and paleoecology including the biological response against environmental changes of the acritarchs during the Precambrian. In the present study, we performed the morphological observation of the acritarch fossils in the Mesoproterozoic sediments from northwestern Greenland to identify and examine their species (kinds) and to reconstruct the paleoecology of the marine organism during the Mesoproterozoic.

The samples used were greyish shales of the Qaanaaq Formation belonging to the Dundas Group, collected from the Thule Basin in northwestern Greenland during July-August 2018 and 2019. These expeditions were supported by MEXT (Japanese Ministry of Education, Culture, Sports, Science and Technology) through Arctic Challenge for Sustainability (ArCS) the Arctic region research project. The kerogens were separated by HCl and HF treatments of the sediments, and observed under a fluorescent light microscope.
We could identify 8 kinds of acritarchs such as *Leiosphaeridia* sp., *Synsphaeridium* sp., *Satka* sp., *Navifusa majensi*, *Simia* sp., *Lophosphaeridium* sp., *Schizofusa* sp., *Tasmanites* sp. and filamental microfossils. *Leiosphaeridia* sp. is the most abundant in all horizons of the Qaanaaq Formation in our study, and their diameters tend to increase upwards of the horizons. The *Leiosphaeridia* sp. fossils include several species and cannot distinguish with the broken and isolated colonial cells because their cells have simple structure (Samuelsson et al., 1999). From this fact, the increasing of the fossil sizes observed in our study was presumably affected by the mixture and shift of the several species morphologically identified as *Leiosphaeridia*. *Synsphaeridium* sp. and *Satka* sp. are distinctive features in the aggregates of cellular structures (colonial species), and the relative abundances of these two acritarchs in all assemblage tend to increase in total acritarchs assemblages in the upper horizons. These results indicate that such acritarchs were important for increasing cell size of the eukaryotic algae, and moreover, these evolved to multicellular organisms.

Pb-Pb chronology of Fe-Ti oxides

*Ito Kengo[1], Tsuyoshi Iizuka[1]

1. The University of Tokyo

Fe-Ti oxides appear in a wide range of igneous and metamorphic rocks. These minerals have been widely used for investigating the temperature and oxidation state of igneous and metamorphic processes. In addition, their potential as a U–Pb chronometer was demonstrated: Burton and O’ Nions (1990) reported Pb isotope compositions of Fe-Ti oxides in amphibolite- and granulite-facies orthogneisses in Sri Lanka, whereas Noyes et al. (2011) presented Fe-Ti oxide Pb isotope analysis of the Monastery kimberlite in South Africa. The results of these previous studies illustrated that the potential utility of Fe-Ti oxides as a reliable U-Pb chronometer due to having high U/Pb value and high closure temperature of Pb (~ 800 ℃). Nevertheless, the application of Fe-Ti oxide chronology remains highly limited. This is mainly because Fe-Ti oxides generally have only moderately high U contents (~0.1 ppm) so that the presence of small amounts of contaminant Pb degrades the age precision and accuracy. In this study, we utilized the acid leaching technique to improve the precision and accuracy of Fe-Ti oxide chronometer.

We analyzed Fe- Ti oxides from the anorthosite FC1 in the Duluth complex, which yields the widely used zircon U-Pb standard (1,099 ±0.6 Ma : Paces & Miller. (1993)). We evaluated the resistance of Fe-Ti oxides to acid leaching using SEM observation. In addition, we analyzed acid washed Fe-Ti oxides for Pb isotopes by MC-ICPMS. The results show that Fe-Ti oxides have high U/Pb ratio (> 189) compared with the whole rock fraction (3.29) and yield a reliable Pb–Pb age (1107 ±102 Ma: MSWD = 15).

Recently, we have applied Fe-Ti oxide Pb-Pb chronology to an amphibolite in the Acasta Gneiss Complex, Canada. The Acasta Gneiss Complex is an Archean terrane containing the oldest known rocks (Bowring & Williams. (1999)) and is composed of felsic orthogneisses and amphibolites. Although the formation and metamorphic ages of the felsic gneisses have been extensively investigated, no reliable chronological data have been obtained from the amphibolites. We are in the process of determining Pb–Pb ages of Fe-Ti oxides from the amphibolites in an attempt to get the reliable chronological information.

Investigation on the internal texture of demospongiae fossil in meta-tuff from the Cambrian Akazawa Formation, Hitachi district

*Michio Tagiri[1], Katsutoshi Hanawa[2], Akira Oikawa[2], Noriaki Watanabe[3]

1. Hitachi City Museum, 2. Geonet Hitachi, 3. Graduate School of Environmental Studies, Tohoku Univ.

We already reported the occurrence of demospongiae fossil from Cambrian meta-tuffs in the Hitachi Paleozoic formation, the southmost Abukuma Mountains. We investigate the internal texture of these sponges by means of stereoscopic microscope, polarized microscope and X-ray CT scan instrument. Deformed bubble-shaped globe of 1mm diameter are packed in the fossil, and those link with each other by fine tube. These globes consist of internal and external walls with reticulation. The globe with these walls may be a choanocyte of sponge. In the poster presentation, we will show this internal texture of sponge fossil by means of the animation of CT scan photographs and of the 3D shaping,

The stromal tissue of sponge fossil is occupied by very fine-grained silicate material, in which the sponge spicule-like texture develops, but this texture is completely replaced by fine acicular amphiboles. The sponge spicule did not remain in these fossils. However, whitish siliceous and micro-bubble bearing sponge texture still remains. Demospongiae fossil was formed by silicification in tuff.

Re-evaluating acid digestion for the analysis of organic carbon and nitrogen contents and stable isotope ratios in geological reference materials

*Wataru Fujisaki[1], Yohei Matui[1]

1. Japan Agency for Marine-Earth Science and Technology

The accurate and precise determination of the total nitrogen (TN) and organic carbon (TOC) abundances and its isotopic compositions ($\delta^{15}N_{TN}$ and $\delta^{13}C_{org}$) in sedimentary rocks have been considered as important proxies for our interpretation of paleoenvironmental and paleoclimate processes. For the carbon and nitrogen analyses, the following acid digestion techniques have conventionally been employed: (1) acidification followed by sequentially rinsing with deionized water (rinse method), (2) acidification by exposure to an acid vapor (fumigation method), and (3) acidification in silver capsules (capsule method). Among these methods, acidification by the rinse method using hydrochloric acid has been widely used and is the standard treatment method for the elemental and isotopic analyses of both nitrogen and carbon in sedimentary rocks. However, some researchers have reported that the acid strength and heating during the decalcification in the rinse method could lead to a change in the TN and TOC contents and its isotopic compositions. Additionally, previous works showed that the TN and $\delta^{15}N_{TN}$ values of HCl acidified samples had changed compared with that of untreated samples. In this study, we systematically compared the effect of acidified and non-acidified samples (in rinse method) on the reliability of TN and TOC abundances and $\delta^{15}N_{TN}$ and $\delta^{13}C_{org}$ values by using geological reference materials (GRMs) issued by the GSJ and USGS: marine sediments (JMs-1, JMs-2, and SBC-1), stream sediments (JSd-3 and JSd-4), and lake sediment (JLk-1).

The TN and TOC concentrations and $\delta^{15}N_{TN}$ and $\delta^{13}C_{org}$ values were measured with a Flash EA1112 elemental analyzer coupled to a Thermo-Finnigan DELTA plus advantage isotope ratio mass spectrometer interfaced with a ConFlo IV at JAMSTEC. Acidified and untreated samples were prepared in three batches to ensure accuracy and precision in the analytical data and evaluate the procedural error. Approximately 200–500 mg of powdered samples was weighted in a 15mL glass tube and acidified in 8 mL 2M or 6M HCl at room temperature or at 70 ℃ in a thermostatic bath for 24 hours, respectively. Subsequent to acidification, the residue was sequentially rinsed three times with Milli-Q water, and dried at 80 ℃ for 48 hours in a closed oven with a light Al foil cover. Aliquots of the acid-treated and untreated samples were weighted into a tin capsule (9 ×10 mm, Lüdi) for the carbon and nitrogen analyses. The analytical reproducibility of the TN and TOC concentrations was evaluated by repeated analyses of reference materials (USGS40 and USGS41); the reproducibilities were better than ±1.8 % and ±1.0 %, respectively. The $\delta^{15}N_{TN}$ and $\delta^{13}C_{org}$ values are represented in ‰relative to atmospheric N_2 and the Vienna Peedee Belemnite (V-PDB) standard, respectively. The uncertainties in the $\delta^{15}N_{TN}$ and $\delta^{13}C_{org}$ values were within ±0.13‰ and ±0.09‰, respectively, as determined by the repeated analyses of reference materials.

Our results show that the average values of TN contents in the rinse method of all GMR samples are lower than that of untreated samples by up to 70 %. Additionally, the $\delta^{15}N_{TN}$ ratios of acid-treated samples, except for SBC-1, were decreased to 2.1‰ in maximum as compared with untreated samples. The magnitudes of the negative shift of TN and $\delta^{15}N_{TN}$ values were larger when the samples were acidified in 6M HCl and heated at 70 ℃. Loss of ^{15}N has previously reported during the acidification and was attributed to small losses of acid-soluble proteins and amino acids via the volatilization of oxidized

©2020. Japan Geoscience Union. All Right Reserved.

nitrogenous organic compounds. However, the $\delta^{15}N_{TN}$ values of SBC-1 are almost stable under the acidified and non-acidified conditions, probably indicating that the organic matter composition in SBC-1 was significantly different from the other GMS samples. On the other hand, as similarly to the nitrogen analysis, the magnitudes of the negative shift of TOC and $\delta^{13}C_{org}$ values were larger when acidification by 6M HCl and heating at 70 ℃ of GMR samples. It suggests that the decalcification with 2M HCl was unsatisfied with obtaining accurate results probably because of the poorly-soluble minerals, such as siderite and dolomite that were retained during the acidification. Overall, we propose that the analysis of nitrogen and carbon contents and its isotopic compositions should be separately measured, i.e., non-acidified sample for nitrogen analysis and 6M HCl acidified and heated samples for carbon analysis.

Taxonomy of Silurian conodonts from the Yokokurayama Group, Kurosegawa tectonic zone, distributed in Kochi Prefecture

*Akifumi Ito[1], Sachiko Agematsu[1], Yuichi Fukushima[1]

1. University of Tsukuba

Paleozoic sedimentary rocks distributed around Mt. Yokokurayama, Kochi Prefecture, are classified into the Yokokurayama Group consisting of the Gomi, Fukata, Ichiyama, Joryu, Nakahata, and Ochi formations, in ascending order. Although there have been sporadic reports and descriptions on trilobites, corals, and others macrofossils, the area is one of the best known Paleozoic fossil localities in Japan. Based on these paleontological studies, the depositional age of the Yokokurayama Group has been thought to be Silurian to Devonian. The authors are recently conducting reviews and taxonomic reexaminations of Paleozoic conodonts in Japan. In this presentation, we show a result of the study on the Yokokurayama Group.

The group is mainly made up of clastic sedimentary rocks, except for the Fukata Formation composed of carbonate rocks. The Fukata Formation, which is about 200 m in thickness, consists of light grey, massive limestones and limestone conglomerates. Kuwano (1974) reported several Ordovician and Silurian conodonts from the formation (The Ordovician specimens are thought to be a reworked assemblage). The massive limestone comprises lime mudstone an wackestone, under a microscope, and contains macrofossil fragments and very fine-sized quartz grains. Three conodont species belonging to three genera are identified from the formation: *Ozarkodina* sp., *Panderodus unicostatus*, and *Wurmiella excavata*. These species indicate that the Fukata Formation was deposited during middle to late Silurian.

Devonian ostracods from the Fukuji area, Takayama City, Gifu Prefecture, central Japan

*Mai Harashima[1], Sachiko Agematsu[1]

1. University of Tsukuba

Ostracods are one of the most long-ranging group of crustaceans from the Ordovician to present day. Ostracods occur in every aquatic environment and their fossils are important indicator as a palaeoenvironment. In addition, most of the Palaeozoic ostracods are benthonic or nektobenthonic. Thus, Palaeozoic ostracods have been used for analysis of palaeogeography. In Japan, while Cenozoic ostracods are well known, much less work has been done on Paleozoic ostracods. This study focuses on ostracods from the Lower Carbonate Member of the Lower Devonian Fukuji Formation, and discusses their palaeobiogeogpahy.
The Fukuji Formation located in the Fukuji area, Takayama city, Gifu Prefecture, central Japan. Fossiliferous black bedded limestone and gray massive limestone are mainly distributed in this area. These limestones are divided into four lithofacies; coral rudstone, bioclastic pack/wackestone, micrite and peloidal grainstone. Quartz grains are also included in limestones, consequently the Fukuji Formation was deposited under sallow marine near coral reefs along a continental magin. Using the method called Hot-acetolysis, 11 ostracod species belonging to 15 genera are obtained from limestone of the Lower Carbonate Member. Most of the ostracods are classified into Palaeocopida or Podocopida, thus relevant to shallower-water ostracod assemblage. In addition, the ostracods from the Fukuji Formation share species-level links with those of South China and Russia, indicating palaeogeographical relationships with those areas.

[G-01] Amazing technologies and capabilities that contribute to STEAM

convener:Day Brian Hamilton(NASA Ames Research Center), Emily Law(Jet Propulsion Laboratory), Go Murakami(Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency), Kristen J Erickson(NASA Headquarters)

NASA, JAXA, and other agencies play an essential role in Education and Communication to inspire, engage and educate in the disciplines of Science, Technology, Engineering, Art, and Math (STEAM). The remarkable science discoveries, knowledge, and research are shared with audiences through a variety of technologies such as web portals, mobile apps, VR/AR applications, citizen science/crowdsourcing applications, and the serving of data as commodities for use by advanced visualization facilities including planetariums. This contributes to improving teaching and learning, increasing scientific literacy of the general public, and enriching STEAM efforts. This session seeks talks and demonstrations that: describe existing capabilities, technologies, tools and facilities that contribute to Education, Engagement and Communication; exciting projects and programs in development; and what other awesome technology ideas that will greatly benefit Education, Engagement and Communication, and STEAM. This has been an ongoing, successful session at the AGU Fall Meeting for the past 5 years and we look forward to expanding it to JpGU.

Dagik Earth is a project to utilize a portable 3-D digital globe for STEAM education in schools and museums. 3-D digital globe is an attractive device to present scientific data of the Earth and planets, and now widely used in science museums. Geo-cosmos is a large one with 6-m diameter in Mirai-kan, Japan. Science On a Sphere (SOS) is developed by NOAA, and installed in more than 150 science museums all over the world. Dagik Earth is much simpler than these systems with much lower cost. It consists of a spherical screen, a PC projector and a PC or tablet. No special equipment is required. The software is freely available for education and science. It is used in classroom from elementary schools to universities, science museums, and science events. The flexibility of the system enables to use the 3-D digital globe in various occasions even outdoors. A join event with music concert was held in Kyoto national museum in August, 2019. The outline of the system, its usage examples and the future plan of the development will be introduced in the presentation.

Increasing the understanding of abstract chemical concepts using VR programming

Garrison Penzo[1], Dante H Delgado[1], *Colleen M Knight[1]

1. College of Coastal Georgia

Chemical concepts such as the structure of the atom or the inner workings of nuclear chemistry are often difficult to convey to students. The main setback for students is the inability to visualize structures at the subatomic level. In a true interdisciplinary project, undergraduate mathematics majors teamed up with a chemistry professor to develop two programs within the Oculus platform. One program allows students to visualize the actual behavior of electrons in an atom. The other program allows users to create a theoretical nucleus and watch that nucleus undergo nuclear decay to reach the next stable nucleus. The output to the user identifies the new nucleus, and a list of decays allows the user to follow the path of decay to a stable nucleus. Both of these programs increased the understanding of chemical concepts to the undergraduate students who programmed the applications and can also serve as valuable tools to make abstract concepts more accessible in the classroom and beyond.

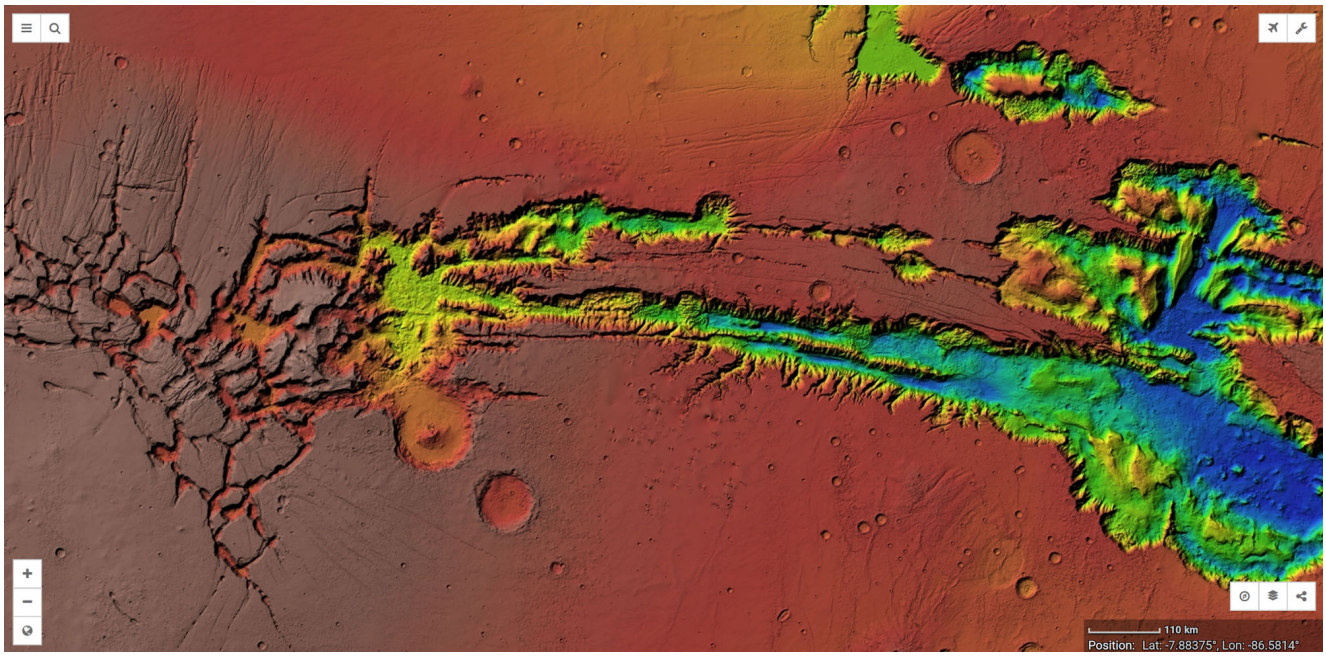
STEAM Engagement with NASA’s Solar System Treks

*Brian Hamilton Day[1], Emily Law[2], NASA Solar System Treks Team -[2]

1. NASA Ames Research Center, 2. NASA Jet Propulsion Laboratory

NASA's Solar System Treks (https://trek.nasa.gov) online portals provide web-based suites of interactive visualization and analysis tools to enable mission planners, planetary scientists, students, and the general public to access mapped data products from past and current missions for a growing number of planetary bodies. These portals are being used for site selection and analysis by NASA and its international and commercial partners supporting upcoming missions. The portals offer great benefits for science, technology, engineering, art, and math (STEAM) education and public outreach, providing access to data from a wide range of instruments aboard a variety of past and current missions. As a component of NASA's Science Activation Infrastructure, they are available as resources for NASA STEAM programs, and to the greater STEAM community. As new missions are planned to a variety of planetary bodies, these tools facilitate public understanding of the missions and engage the public in the process of identifying and selecting where these missions will land.

During the past year, significant changes have been made to The Solar System Treks suite. New portals have been added and portals for a range of additional bodies are now in development. New visualization and analysis tools are being integrated. New data products have been ingested and new means of generating specific data products including image mosaics and DEMs have been implemented.



As of early 2020, there are seven web portals in the program available to the public. This expanded list includes portals for the Moon, Mars, Vesta, Ceres, and Titan. Icy Moons Trek features seven of Saturn’s smaller icy moons. The latest addition is the new Mercury Trek portal, developed in collaboration with JAXA in support of its role in the BepiColombo mission. Two new portals are scheduled for release this spring and will be showcased at JpGU: Ryugu Trek supports JAXA’s Hayabusa2 mission and Bennu Trek supports NASA’s OSIRIS-REx mission. In addition, Phobos Trek, focusing on Mars’ larger moon, is currently under development in support of JAXA’s planned MMX mission. Interfaces for the Mercury, Ryugu, and Phobos portals are being internationalized with main interface controls offered in both English and Japanese. All of the portals are unified under a new project home site with supporting content. As web-based toolsets, the portals do not require users to purchase or install any software beyond current web browsers.

The portals provide analysis tools for measurement and study of planetary terrain, allowing data to be layered and adjusted to optimize visualization. Visualizations are easily stored and shared. The portals provide interactive 3D visualization capabilities, allowing users to fly over the terrains of other worlds. Users have the ability to select terrain for generation of STL/OBJ files that can be directed to 3D printers. Such 3D prints are valuable tools in museums, public exhibits, and classrooms - especially for the visually impaired. Particularly popular is the ability for users to draw any path they want across a planetary surface using the browser interface. The system returns a QR code which the user scans into their smartphone, places their phone in an inexpensive pair of Cardboard-compatible goggles, and flies whatever path they drew in virtual reality. The program supports additional clients, web services, and APIs facilitating dissemination of planetary data to external applications and venues such as planetariums. NASA challenges and hackathons also provide members of the software development community opportunities to participate in tool development and leverage data from the portals.

©2020. Japan Geoscience Union. All Right Reserved.

While we are expanding the number of worlds covered by the project, we are paying special attention to the Moon and enhancing Moon Trek’ s capabilities supporting upcoming human and robotic missions to the Moon.

[M-IS01] Tsunami deposit

convener:Daisuke Ishimura(Department of Geography, Tokyo Metropolitan University), Takashi Chiba(Faculty of Bioresource Sciences, Akita Prefectural University), Masaki Yamada(Department of Geology, Faculty of Science, Shinshu University), Takashi Ishizawa(International Research Institute of Disaster Science, Tohoku University)

The 2011 off the Pacific coast of Tohoku Earthquake and tsunami have an influence on the development of tsunami deposit research. After the tsunami, a lot of findings have been reported on various research fields. However, it is still uncertain how to use the tsunami deposit in the estimation of tsunami size and source and the risk assessment. In this session, we welcome researches from all aspect of sedimentary records of modern and paleo tsunamis both onshore and offshore, and numerical and experimental modeling studies for risk assessment. In addition, we also welcome other event deposits, such as flooding and storm surge, that they are considered to be important for discrimination of tsunami deposit.

The National Institute of Advanced Industrial Science and Technology

Historical and prehistorical tsunami deposits in Shikotan Island, the Northern Territories, were studied as parts of visa-free exchange programs of Japan and Russia. The reconnaissance survey was conducted from July 5th to 15th in 2019 in Horobetsu, Anama, Matakotan, Chiboi, and Inemoshiri. And candidates of tsunami deposits and volcanic tephra were examined at 32 sites by using a handy geoslicer and a peat sampler. As a result, In Inemoshiri, 6 candidates of tsunami deposit and 4 tephras were traced inland up to 530m from the coast. In Horobetsu, 1 candidate of tsunami deposit and 3 tephras were traced inland up to 350m from the coast. In Shikotan Island, it is reported that tephra from volcanoes of Hokkaido, such as Ko-c1 (1856), Ta-a (1739), Ko-c2 (1694), Ta-b (1667), Ma-b (10th Century) and Ta-c (2,700 BP) are deposited (Razzhigaeva et al., 2016). With these volcanic deposits as the key layer, we can estimate the age of the candidates of tsunami deposits. Our study was mainly conducted in the peatland developed in a valley facing the sea, as there are no wide and flat wetlands on the island. We needed to distinguish sandy layers caused by slope collapse and river flood from tsunami deposits based on a detailed survey of their distribution and sedimentary facies at each site.

Facies description of 15 valley-filled tsunami deposits observed in Lake Tokachi-Chobushi for the past 2500 years and evaluation of their recurrence intervals

*Kiyoyuki Shigeno[1], Futoshi Nanayama[2,5], Kazuaki Watanabe[2], Masayuki Ishii[3], Keita Fukatsu[4]

1. Meiji consultant co.,Ltd., 2. Geological Survey of Japan, AIST, 3. Ishii Professional Engineer Office, 4. Notsuke Peninsula Nature Center, 5. CWMD,Kumamoto Univ.

It is known that M8-class trench-type earthquakes occur every 100 to several decades in the eastern Pacific coast of Hokkaido. In addition to this, it has been clarified that interlocking giant earthquakes of Mw 8.5-9 class with the epicenters off Tokachi and Nemuro offshore occur repeatedly at intervals of 300 to 500 years (Nanayama et al., 2003; Nanayama, 2020). It can be considered that the giant tsunami trace stratigraphy between Tokachi coast and Nemuro coast has been almost established by the research results of the past 20 years. However, the estimated tsunami size and recurrence period are not clear because the number of tsunami deposits differs depending on the area, even if the interval between giant tsunamis is about 300 to 500 years. In particular, the number of tsunami deposits recorded is regulated by topography and sedimentary environment. In previous studies, tsunami deposits were found to occur more frequently in sediments filling the valley topography than in the surrounding marsh environment.

Lake Tokachi-Chobushi is a brackish lake with a width of about 1.8 km and a maximum depth of about 1.5 km. It is known that a tidal inlet emerges at the southwestern edge of the lake due to the seasonal break of the sand bar. On the southern shore of this tidal inlet, large cliffs of sea cliffs of about 9 m in height appear continuously. Here, there are two fissured valleys with a width of about 50 to 100 m that erode the Upper Pliocene to Pleistocene long nodule (diatomaceous silt deposit). This valley is filled with a Holocene peat layer of about 3.5 m thickness. The fifteen tsunami-originated event sand layers are sandwiched in this peat layer. The fifteen event sand layers consist mainly of fine-grained sand to silty sand, with a thickness of several centimeters to several tens of centimeters. The base may have a sub-round to sub-angular gravels and these diameters are 1 to 2 cm. From the degree of sorting, sand particles are assumed to originate from marine sand.

Four clear Holocene tephras were interposed in the peat layer, and the top tephra was found to be Ta-b (AD 1667 eruption from Tarumai Volcano), the tephra at the bottom is assumed to be Ta-c (2.5 cal kyr BP eruption from Tarumai Volcano). Using the ages obtained from these tephras, the recurrence interval of the event sand layer for the last 2500 years is estimated to be about 150 years. This value is significantly lower than the 300-500 years thought to have been caused by the tsunami associated with the giant earthquake. In this case, it is suggested that the tsunami caused by the M8 class interplate earthquake that occurred every 100 to tens of years in the Kuril Trench is also preserved. However, it is difficult to determine the magnitude of the earthquake or tsunami that caused each event deposit by at least outcrop observation alone.

Relationship between facies of tsunami deposits and paleo sedimentary environment which were reconstructed from plant macro fossils in peat

*Takashi Ishizawa[1], Yuichi Nishimura[2]

1. International Research Institute of Disaster Science, Tohoku University, 2. Institute of Seismology and Volcanology, Hokkaido University

Correlation of tsunami deposits is important to assess inundation area by paleotsunami. In general, correlation of tsunami deposits is conducted using facies of tsunami deposits and age marker (tephra or ^{14}C dating). However, even though some tsunami deposits were formed by same tsunami, the facies of tsunami deposits often vary due to paleo sedimentary environment. Herein, we show facies variations of tsunami deposit which were formed by same tsunami but were preserved in different sedimentary environment. Our study area is Kiritappu wetland, Hokkaido. We surveyed about 40 m^2 area of the wetland and focused on 17th and 12-13th century tsunami deposits which were already correlated in the wetland by tephrochronology. Sedimentary environment was reconstructed by analysis of plant macro fossils in peat. Our results showed that tsunami deposits formed at water place (characterized by reeds within peat) were thicker than the tsunami deposits formed at relatively dried wetland. Moreover, tsunami deposits formed at water place showed bluish color and had clear sedimentary structures such as lamina and grading. Our results indicate that correlation by tsunami deposit facies is not preferable unless sedimentary environment is discussed. Such findings were important to discuss correlation of tsunami deposits at wetland.

Ages and distribution of paleo-tsunami deposits since 6 ka at Koyadori, Yamada Town, Iwate Prefecture, northeast Japan

*Daisuke Ishimura[1], Keitaro Yamada[2]

1. Department of Geography, Tokyo Metropolitan University, 2. Research Organization of Science and Technology, Ritsumeikan University

Long-term paleo-seismic history is significant for the understanding of earthquake mechanisms and the assessment of earthquake and related hazards (e.g., tsunami). Especially, tsunami deposits research progressed after the devastating large tsunamis (e.g., the 2004 Indian Ocean earthquake and 2011 Tohoku-oki earthquake) and paleo-tsunami deposits have been identified all over the world. In the terrestrial environment, it is generally difficult to find an appropriate site for revealing the long-term paleo-tsunami history and such appropriate sites were limited due to landform development and artificial modification. It is true along the Pacific coast area in the Tohoku region, northeast Japan. However, the authors found the most appropriate site for the reconstruction of long-term paleo-tsunami history on the Sanriku Coast. This is the Koyadori site, where organic fine sediments accumulated continuously since Towada-Chuseri (To-Cu) tephra (ca. 6 ka; Mclean et al., 2018) and sediments supply from surrounding are small except for tsunami deposits. In this study, we show the ages of paleo-tsunami deposits since 6 ka and their subsurface distribution in Koyadori lowland based on dense and many excavation and drilling surveys.

From 2012 to 2015, we conducted trench excavation survey (Ishimura and Miyauchi, 2015), outcrop survey (Ishimura and Miyauchi, 2015), drilling survey (Ishimura et al., 2014), short Geoslicer survey (Ishimura et al., 2015), and long Geoslicer survey from 200 m to 400 m distance from the coastline and used these samples to this study. In the laboratory, we conducted the radiocarbon dating, tephra analysis, μXRF analysis, and gravel roundness analysis for lateral correlations of sediments. In this study, we mainly used five long Geoslicer samples. All samples reached To-Cu tephra and, that is, they record a continuous 6 thousand years history. From these samples, we confirmed that there are 14 tsunami deposits including the 2011 event after To-Cu tephra and the average recurrence interval is estimated to be 300-400 years.

Subsurface distribution of them was revealed by sedimentary facies, geochemical signature, gravel roundness, and radiocarbon dates of long Geoslicer, short Geoslicer, and drilling cores. As a result, the most appropriate site in Koyadori for tsunami deposits research is limited only 300 m to 350 m area distance from the coastline. On the other hand, in the seaside area behind the 5-m-high beach ridge (200 m to 300 m distance from the coastline), large erosion occurred a few times after To-Cu tephra and these erosions were not expected from the present topography. This indicates that we need to care buried topography and to conduct a multi drilling survey. Takeda et al. (2018) pointed out a similar thing.

This study gives us clues for tsunami deposits identification and accurate lateral correlation of sediments. Dense drilling surveys and/or continuous outcrops tell us an accurate number of tsunami deposits. Tephra layers give us robust ages and correlative layers in sediments. A geochemical signature can be used to correlate background sediments and gravel roundness is useful to identify tsunami deposits and correlate them. Radiocarbon dating gives us confirmation of the lateral correlation of sediments. We thought that this is an efficient procedure for paleo-tsunami deposits research.

Machine-learning for correlation of tsunami deposits using geochemical proxy

*Kamiya Tomohisa[1], Kazuhisa Goto[2], Takashi Ishizawa[1], Hiroshi Tetsuka[1], Erick Velasco R.[1], Daisuke Ishimura[3], Kenta Satoh[1]

1. Tohoku University, 2. University of Tokyo, 3. Tokyo Metropolitan University

Correlation of tsunami deposits is very important to assess local tsunami size and frequency. In general, paleotsunami researchers conduct coring at several sites and correlate tsunami deposits in each core based on lithology and chronology. However, it is difficult to correlate tsunami deposits based only on lithology if the coring points are separated. Also, measuring numerous ^{14}C age is costly. Herein, we propose a methodology to correlate tsunami deposits based on geochemical features together with machine learning technique. As geochemical proxy, we measured elements of tsunami deposits by using a core scanner that can conduct non-destructive and high-resolution XRF analysis. To correlate tsunami deposits based on elemental data quantitatively, we used SVM (support vector machine), machine learning technique for classification. We compare the results of correlations by machine learning and that by conventional approach based on lithology and chronology. As a result, we found that machine learning is useful to find the possible way of correlation while it is difficult to correlate tsunami deposits based only on machine learning. Therefore, machine learning is useful for correlation of tsunami deposits as a supplementary tool of other methods, and it is beneficial for us to decrease the number of samples for dating and to enhance reliability of correlation.

Numerical study of the formation process of sandy deposit formed by the 2011 Tohoku-oki tsunami

*wataru nakamura[1], Kazuhisa Goto[2], MASASHI WATANABE[3]

1. Tohoku University, 2. The University of Tokyo, 3. Chuo University

For modeling of tsunami sediment transport, grain size is generally assumed as single grain size or multiple grain size. Although there are some studies that conducted modeling under the multiple grain size condition, most studies have been performed under the single grain size. However, in the single grain size condition, we cannot calculate lateral and horizontal variations of grain size distribution of tsunami deposits, so we cannot confirm whether the model can reproduce landward and upward fining features that are commonly observed in the tsunami deposits. In this study, we simulated the sediment transport during the 2011 Tohoku-oki tsunami in order to evaluate the reproducibility of the modeling and to clarify the sedimentation process of the tsunami deposit.

Our study area is around the right bank of the Nanakita River mouth in Sendai, Japan. In this area, a detailed field survey was carried out by Abe et al. (2012), and we set a transect along their transect B. Delft3D, which is developed by deltales, was used in this study. Based on the 2011 Tohoku-oki tsunami modeling results using a source model proposed by Imamura et al. (2012), we extracted a wave profile at 2 km offshore of the transect. Then, this wave pattern was set as an incident wave for the calculation. We assumed 5 m thick movable bed uniformly from the bottom of the sea to the Teizan canal as in Watanabe et al. (2018), while landward from the canal was assumed as fixed bed. Normal distribution was assumed as grain size distribution at the movable bed based on Takashimizu et al. (2012) and Szczuciński et al. (2012); then four particle size was chosen for the multiple grain size modeling. We carried out calculations under multiple and single grain conditions (sediment 1 to 4) plus single grain size at mode diameter (354 μm) and compared each result. Manning's roughness coefficient was assumed based on a distribution map of Sugawara et al. (2014). Modeling results showed that inundation distance, flow depth and distribution of the tsunami deposit were generally consistent with those measured by Abe et al. (2012), although there were some discrepancy in the flow depth near the shoreline. Fining landward trend was not changed to the coarsening trend through the calculation. Although landward coarsening trend was locally and temporally formed, it was then changed to the fining trend through time. As a whole, our modeling results reproduced landward thinning and fining trends. Actually, the modeling results using both single mode diameter and the multiple grain size were almost similar. This is probably because normal distribution of grain size was assumed in this study and the percentage of around mode diameter is high.

Reduction Effect of Tsunami Sediment Transport by Coastal Forest: Numerical Simulation of the 2011 Tohoku Tsunami on Sendai Plain, Japan

*Satoshi Kusumoto[1], Kentaro Imai[1], Aditya Gusman[2], Kenji Satake[3]

1. JAMSTEC, 2. GNS Science, 3. ERI, The University of Tokyo

The reduction effect of the energy of tsunami waves during their passage through coastal forest has been recognized since the 1998 Papua New Guinea tsunami and the 2004 Indian Ocean tsunami (e.g., Dengler and Preuss, 2003, PAGEOPH; Nandasena et al., 2008, JSCE). Numerical simulations conducted to investigate the effects of coastal forest on tsunamis (e.g., Shuto, 1987, Coastal Engineering in Japan; Harada and Imamura, 2005, Advances in Natural and Technological Hazards Research) have showed that tsunami height, inundation distance and flow velocity are markedly reduced by the presence of coastal forest. However, the reduction effect of coastal forest on the transport of tsunami sediments has not been evaluated. In this study, we examined the contribution of coastal forest to tsunami sediment movement by using the numerical simulation of tsunami sediment transport on Sendai plain, Japan, during the 2011 Tohoku tsunami.

To account for varying roughness coefficient in areas of coastal forest, the composite equivalent roughness coefficient was used (e.g., Aburaya and Imamura, 2002, JSCE; Imai et al., 2013, JSCE). Tree occupancy and trunk width are given as 1 %, and 0.15 m, respectively, on the basis of the previous studies (e.g., Harada et al., 2000, JSCE; Imai et al., 2009, JSCE). The area of coastal forest was determined from aerial photographs and land use maps compiled before the 2011 Tohoku earthquake.

Our results revealed that the simulated mean sediment concentration, wave height, flow velocity, and inundation limit were abruptly reduced by the presence of coastal forest. The volumes of net deposition and erosion were reduced to 52-85% of those in the simulation without coastal forest; these reductions were particularly remarkable for fine sand. The maximum extent and thickness of sand layer are also reduced. This evidence of the inhibition of sediment transport by coastal forest suggests that land use conditions and the vegetation environment at the time of a tsunami should be considered in evaluations of historical tsunamis on the basis of geological evidences.

Temporal change in sedimentological and geochemical characteristics of the 2011 Tohoku-oki tsunami deposits in the northeastern region of Fukushima Prefecture

*Kentaro Izumi[1], Ikuro Narayama[1], Tomoya Abe[2]

1. Faculty & Graduate School of Education, Chiba University, 2. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

To evaluate how sedimentological and geochemical characteristics of tsunami deposits temporally change, we collected samples of the 2011 Tohoku-oki tsunami deposits and the underlying and overlying deposits at several sites in northeastern region of Fukushima Prefecture. In this study, thickness, grain size, sedimentary structures and organic-matter content of the tsunami deposits were observed and analyzed. As a result, thicknesses of the tsunami deposits do not show significant temporal change from at least 2014 to 2019. In addition, soft-X observations show that laminae are observed in tsunami deposits at several sites, suggesting that original sedimentary structures have been preserved in the past nearly 8 years. On the other hand, grain-size and organic-matter analyses of the tsunami and underlying deposits revealed that at least some portions of the tsunami deposits have been transported into the underlying deposits, resulting in sediment homogenization. It is assumed that this sediment homogenization has been caused by bioturbation mainly of meiobenthos whose body size is similar to sediment grain size.

Flow reflection of onshore tsunami and features of the deposits

*Yasuhiro Takashimizu[1], Hibiki Saito[1]

1. Niigata University

This study aims to obtain features of the onshore tsunami deposit indicated-flow reflections based on the analyses of a block sample of the 2011 Tohoku-oki tsunami deposits in the Odaka region of Minami-Soma city, Japan. Sampling site U-07 was located 1.75 km from coastline and surrounded by artificial embankments of an approximately 3 to 4 m height in the southern and western parts. In previous studies, the flow direction of the tsunami inverted and the inflow tsunami was changed to outflow after the collision of the runup tsunami with the embankments.
According to the results of the analyses, the U-07 sample was composed of three units, namely, Units 1, 2, and 3 in ascending order. Unit 2 was further subdivided to 6 units, namely, a, b, c, d, e, and f in ascending order. Unit 1 was composed of coarse-grained sandy sediments with mud clasts by runup flow, Unit 2 of alternating beds of sand (Units 2b, d, and e) and mud (Units 2a, d, and f) from the flow inversion and outflow, and Unit 3 of the mud accumulated from suspended loads in stagnating seawater after the tsunami. Mud layers in Unit 2 were interpreted as mud drapes under water stagnation by the tsunami collision with the artificial embankments. On the other hand, sand layers in Unit 2 were the deposits from complicated flow by the tsunami collisions and outflow after the collisions.

Numerical estimation of paleotsunami size at southern part of Japan Trench based on geological records

*Hokuto Higaki[1], Kazuhisa Goto[2], Hideaki Yanagisawa[3], Daisuke Sugawara[4]

1. Tohoku University, 2. Department of Earth and Planetary Science, The University of Tokyo, 3. Department of regional Management, Faculty of Liberal Arts, Tohoku Gakuin University, 4. Museum of Natural and Environmental History, Shizuoka

In the coastal area facing to the northern and central Japan Trench, many researchers have conducted paleotsunami surveys to estimate the size and frequency of tsunamis in the past several thousand years. In contrast, the area facing to the southern part of Japan Trench has poorly been studied due to the coastal urbanization. Therefore, the elucidation of tsunami size and frequency in the southern part of Japan Trench has not been well understood in comparison with the northern and central Japan Trench. It is reported that deposits in Kobatake-ike pond in Choshi City, Chiba Prefecture, record three large tsunami events during past three thousand years; tsunami were probably triggered by the subduction zone earthquakes at southern part of Japan Trench (Yanagisawa et al., 2016). The thickness and grain size of these tsunami deposits have different in characteristics and may be important factors for constraining the tsunami size in the southern part of Japan Trench. This study applies coupled tsunami hydrodynamic and sediment transport modeling to paleotsunami deposits at Kobatake-ike pond in order to estimate the fault parameters of earthquakes and tsunamis in the southern part of Japan Trench. Source parameters of each paleotsunami events were investigated by comparing numerical simulations with thicknesses of tsunami deposits in the Kobatake-ike pond in addition to historical records of tsunami inundation, if available. Numerical simulation results revealed that the tsunami caused by the earthquake with the fault slip of 11 to 16 m and Mw of 8.34 to 8.43 repeatedly and constantly occurred in the southern part of Japan Trench. Sediment transport modeling results suggest that modeled thicknesses of the tsunami deposits in the Kobatake-ike pond sensitively reflect changes of the grain size of deposit and the fault slips. Therefore, the thickness and grain size of the tsunami deposits may provide the effective constraints for estimating fault parameters of the historic/prehistoric tsunami which has no detailed historical records.

Detailed analysis of tsunami deposits made by large-scale laboratory experiments

*Takumi Yoshii[1], Shiro Tanaka[1], Masafumi Matsuyama[1]

1. Central Research Institute of Electric Power Industry

The characteristics of tsunami deposits can reflect the hydraulic parameters of tsunami which made the tsunami deposits. However, considerable variation of tsunami deposits in the field makes it difficult to estimate the scale of tsunami from the resulting deposits. Thus, the authors have conducted the large-scale laboratory experiment on tsunami deposits and succeeded in reproducing the deposits (Yoshii et al., 2017, 2018). In these previous studies, the hydrodynamic conditions and the resulting deposits were investigated by using bulk samples.

In this presentation, we will present detailed analysis of tsunami deposits made by these flume experiments and discuss the reproducibility of the deposits in the flume. Okazaki et al.,(2017a,b) have already indicated that the se flume tsunami deposits has the complex structures and Okazaki el al.,(2018) have discussed the similarity to the tsunami deposits in the field. Based on these results, we analyzed the structure of these flume deposits by using core samples and peer samples. The result will provide useful information for future field investigation and interpretation of tsunami deposits.

[M-IS02] Environmental, socio-economic and climatic changes in Northern Eurasia

convener:Pavel Groisman(NC State University Research Scholar at NOAA National Centers for Environmental Information, Asheville, North Carolina, USA), Shamil Maksyutov(National Institute for Environmental Studies), Evgeny P Gordov(Institute of Monitoring of Climatic and Ecological Systems SB RAS), Akiyo Yatagai(Hirosaki University)

We invite presentations on the biogeochemical cycles, the surface energy budget and water cycle, and climate and ecosystem interactions in Northern Eurasia (land-cover/land-use change, atmospheric aerosols, soil, and permafrost changes that affect and are being affected by climate and ecosystem change), human dimension, and tools to address the Northern Eurasia studies.

In environmental studies, our Session foci are on the permafrost changes in Siberia, Asian Mountains, and the Arctic coastal regions and on the carbon cycle of Northern Eurasia.

In the regional water cycle studies, our Session foci are on the changing distribution of precipitation intensity, frequency, form (solid versus liquid) and on the pattern and seasonal cycle changes of runoff.

In the human dimension studies, our Session foci are on assessments of impact of the ongoing environmental changes in Northern Eurasia on the human well-being and on mitigation strategies development in response to harmful consequences of these changes.

The particular foci of this Session will be the studies of changes that impacts regional sustainable development in Eurasian Arctic and the Drylands of Northern Eurasia.

We invite also early career scientists associated with (or interested in) the Northern Eurasia Earth Science Partnership Initiative and its continuation, Northern Eurasia Future Initiative (http://nefi-neespi.org/NEFI-WhitePaper.pdf).

BIOAVAILABILITY OF METALS DEPENDING ON THEIR SPECIATION IN NORTHERN LOW-SALINE WATER

*Tatyana I Moiseenko[1], Marina I Dinu[1]

1. Russian

The bioavailability and ecotoxicity of metals are determined by their speciation, which in their turn depend on the parameters of the aqueous environment: the content of calcium, humic acids, pH, temperature and a combination with other metals. The paper highlights metal speciation calculating model which is based on mathematical modeling of the chemical reactions in natural waters. Metal concentrations (Hg, Cd, Pb, Ni, Cu, Al, Sr) were determined and their speciation in water was calculated for 22 research areas in the Kola region. At these same points, the accumulation of metals in various systems of the fish was studied (as exemplified by whitefish). It is shown that the biogeochemical activity of metals determines the ratio of labile and unlabele speciation in water. In the zones of distribution of the non-ferrous industry effluents, metal aqua-ions of the studied metals prevail; during the distribution, the ratio changes in accordance with the metals activity. The bioavailability of metal speciation is estimated depending on the aqueous geochemical conditions and, accordingly, the speciation of metals (*in situ)* based on the results of original studies in the lakes of the Kola North of Russia. The connection between the metal contents in fish and metal content in water have been identified using multidimensional scaling and RDA-techniques.

Divergent responses of ecosystem water-use efficiency to extreme droughts over Northern Eurasia

*Mengtian Huang[1], Panmao Zhai[1]

1. Chinese Academy of Meteorological Science

Water, as one of the most basic environmental factors of terrestrial ecosystems, is of significant importance for the thermal acclimation and metabolism of terrestrial vegetation. Water availability is a major limitation to the distribution and productivity of terrestrial vegetation. At the ecosystem scale, water-use efficiency (WUE) is generally defined as the ratio of annual gross primary productivity (GPP) and annual evapotranspiration (ET). It indicates the coupling of the carbon and water gross fluxes exchanged between ecosystem and the atmosphere, and monitors the adaptability of an ecosystem to variable climate conditions. Previous researches have concluded a significant positive trend in WUE in most areas of terrestrial ecosystems over the globe, as a result of the increasing CO_2 concentration and climate change during the past several decades. At the same time, extreme climatic events, such as heat waves, drought etc., occurred across the globe. These changes have likely altered the ecological functioning of terrestrial ecosystems, as well as the structure of plant communities. Nevertheless, how terrestrial ecosystem WUE responds to extreme climatic events is still poorly understood.

In this study, we examine the impacts of extreme drought events on ecosystem WUE during 1948-2008, with a particular focus on distinguishing response of different biomes over Northern Eurasia. The responses of ecosystem WUE to extreme droughts differed among different regions. For northern high latitudes (north of 50˚N), hot days and increasing solar radiation were usually concurrent with droughts, which to some extent eliminate the limitations of low temperature and insufficient light on photosynthesis. In this case, vegetation productivity was potentially enhanced, with higher ecosystem WUE during drought years than during normal years. By contrast, for biomes in relatively arid climate conditions, extreme drought years tended to aggravate the water stress for vegetation growth. Consequently, in these regions, vegetation photosynthesis was largely suppressed with significantly lower ecosystem WUE observed. Our results, therefore, highlight that background climate is a crucial factor determining drought impacts on terrestrial carbon-water interactions. Further increases in baseline aridity could therefore exacerbate the impact of punctuated droughts on terrestrial ecosystems.

Homogeneity analysis of air temperature and wind speed records of the Azov-Black sea region

*Natalia Alexandrovna Lemeshko[1], Vladislav P. Evstigneev[2,3], Maxim P. Evstigneev[2], Pavel Ya. Groisman[4]

1. SPBU, 2. IPTS, 3. SevSU, 4. IORAS

In the study a homogeneity of long-term hydrometeorological data series of monthly air temperature and wind speed was tested using routine observations at thirteen sea coast stations of the Azov-Black Sea region for the whole period. Test for time-series homogeneity was carried out by method introduced by Wang et al. who used penalized maximal t - and F-tests to detect mean value shifts in the data with lag-1 autocorrelation. The method is implemented as a recursive testing algorithm within RHtestsV3 package for R software environment for statistical computing and graphics. Detection of inhomogeneity by means of RHtestsV3 was carried out in the mode “with a reference series” for monthly air temperature and in the mode “without a reference series” for monthly wind speed. As a result, inhomogeneity shifts supported by metadata were detected and adjusted. The main sources of heterogeneity of meteorological observations are as follows: meteorological site relocation, changes in instrument exposure due to urbanization, changes in instrument mounting and sheltering, changes in type of the instrument and terms of observations. Only 3 among 13 stations have homogeneous data series both for air temperature and wind speed. For all the rest stations, only homogeneous data series more accurately reflect climate change dynamics general for the Azov-Black Sea region. Therefore, application of adjusted climatic data series instead of initial one is reasonable for inference making about climatic tendencies in the region under study and is necessary stage of climate treatment. The validity of ready-to-use algorithm was confirmed enabling RHtestsV3 introduction into climatological datasets processing.

This work was supported by the RFBR project No. 18-05-01073

Soil response to sub centennial climate change

*Natalia Alexandrovna Lemeshko[1], Vladislav P. Evstigneev[2,3], Alexey V. Rusakov[1], Pavel Groisman[4]

1. SPBU , 2. IPTS , 3. SevSU, 4. IORAS

The most inertial object of the climate system is the lithosphere, including soil. To study the impact of modern climate change on agricultural soils, which are currently under wild cenoses, a special technique is being developed. For its development, the vast territory of the Yaroslavl Volga region was selected, for which we have data on the morphological and genetic properties of agricultural soils for more than 40 years. In order to obtain a climate-dependent response of soils to the current scale of global warming, data on the evolution of soils, parent rocks, vegetation, and also the intensity of anthropogenic impact are used. The methodology is based on a comparison of the climatic component for two periods - 1961-1990 and 1991-2018. The analysis of the variability of air temperature, precipitation, temperature totals of more than 10 ˚C and agroclimatic indices for these periods. A joint analysis of changes in soil properties and climatic indicators will allow us to evaluate the speed of soil processes and soil fertility and become the basis for modeling soil climate for the future.

This work was supported by the RFBR project No. 19-29-05243.

Climate change impacts on seed quality and distribution of light-needled *Pinus sylvestris* and *Larix* spp. in Northern Eurasia in a warming climate

*Nadezhda Tchebakova[1], Elena I. Parfenova[1], Elena V. Bazhina[1], Nina A. Kuzmina[1], Pavel Y. Groisman[2]

1. Institute of Forests, Siberian Branch, Russian Academy of Sciences, 2. NC State University Research Scholar

Global simulations have demonstrated the potential for profound effects of climate change on the distribution of terrestrial ecosystems and individual species at all hierarchical levels. We modeled progressions of potential forest types, dominant tree species and their seed zones (climatypes) in Siberia during the 21st century. We developed and used large-scale bioclimatic models and statistical seed models to predict forest types and seed crops in a warming climate. All simulations were run for the baseline period 1961-1990 and for the mid- and end of the century. We ran twenty global circulation models from CMIP5 (AR5) and used two climate change scenarios RCP 2.6 (less warming) and RCP 8.5 (greater warming) to provide a range of warming. Ecological-bioclimatic modeling projects substantial vegetation changes: biomes shift northwards; area of conifer forest decreases and grasslands increases. The zone at risk of forest loss in Siberia would extend northwards. To minimize negative consequences and benefit from climate change in Siberian forests potential adaptive measures may be introduced depending on management goals. A genetic approach is to assist trees and forests to adapt to new climates by transferring seed to locations that are suitable to the seed zones of future climates. A bioclimatic model of *Pinus sylvestris* seed quality and productivity that relates seed weight and climates ($R^2 = 0.74$) was used to map the seed weight distributions in new CMIP5 RCP 2.6 and RCP 8.5 climates. Seed weight isolines would shift northwards in a warming climate: as far as 500 km in the moderate scenario and up to 1000 km in the extreme scenario. In the cold climate of Siberia pine and larch seed production may benefit from climate warming and would favor to expanding areas of productive forests.

The study was supported by RFBR grant # 20-05-00540.

Northern Eurasia Future Initiative (NEFI), Update

*Pavel Groisman[1,2,3]

1. NC State University Research Scholar at NOAA National Centers for Environmental Information, Asheville, North Carolina, USA, 2. Shirshov Institute of Oceanology, Russian Academy of Sciences, Moscow, Russia , 3. Hydrology Science and Services Corporation, Asheville, North Carolina, USA

NEFI was conceived in 2015 as a successor of the Northern Eurasia Earth Science Partnership Initiative (NEESPI; ***http://neespi.org***). In 2016, a NEFI White Paper was posted at ***http://nefi-neespi.org/***. This White Paper was converted and expanded into two peer-reviewed programmatic NEFI Science Plan papers (Monier et al. 2017; Groisman et al. 2017). Being focused on the same region, the difference between two Initiatives stems from their major Science Questions: (1) NEESPI: How do Northern Eurasia' s terrestrial ecosystems dynamics interact with and alter the biosphere, atmosphere, cryosphere, and hydrosphere of the Earth? (2) NEFI: How to provide in Northern Eurasia a sustainable societal development (economy well-being, activities, health, and strategic planning) in changing climate, ecosystems, and societies? In other words, while NEESPI foci were on understanding of the processes that have and will be occurred over Northern Eurasia, NEFI foci are to answer questions about what should be done for the human well-being in the changing natural and social environments of the region. Currently, NEFI includes 30 international projects devoted to the Arctic, Eurasian boreal forest zone, and the Dry Land Belt of Northern Eurasia. Each year, the NEFI active organizes three or more dedicated NEFI Sessions at the AGU, JpGU and SCERT Conferences. NEFI Special Issue of the *Environ. Res. Lett.* is being published (currently, the Issue has 35 papers accepted and 23 manuscripts are in the review process). The deadline for the article submissions is June 30, 2020. Incomplete list of NEFI publications in 2018-2019 includes about 50 per-reviewed papers and book chapters. NEFI is open for joining of other research groups.

[M-IS03] Structure and deformation in the overlying plate due to subduction and related feedbacks

convener:Hiroshi Sato(Earthquake Prediction Research Center, Earthquake Research Institute, The University of Tokyo), David A Okaya(University of Southern California), Eh Tan(Institute of Earth Sciences, Academia Sinica), Masahiro Ishikawa(Graduate School of Environment and Information Sciences Yokohama National University)

Subduction over time modifies the overriding plate by fractionation, accretion, and tectonic deformation. This can lead to processes such as tectonic shortening (orogeny), regional uplift, weakening by back-arc spreading and volcanism, basin formation, and/or destabilization of the lithosphere. In turn, the composition, strength, and morphology of the overlying plate, which may be the product of a long geological history and have significant along-strike variations, can affect current large-scale subduction dynamics such as slab dip, and ultimately broad-scale plate kinematics in two and three dimensions. Examples of geological settings that bear witness to these processes are found along the Pacific Rim, including Japanese arcs, Taiwan, Hikurangi, northwestern North America, and Tethys margin, including Himalaya and the Mediterranean mobile belt. We seek contributions from all geoscience disciplines that document the structure and tectonic evolution of overlying plate deformation and their feedbacks onto subduction processes. We welcome studies on topics such as: geologic and tectonic geomorphological deformation of the overlying plate and its relation to the subduction; geodetic deformation of the overlying plate; active and passive imaging of the overlying plate and crustal structure; rheological features obtained by laboratory and earthquake seismology; basin development and mountain building processes; numerical geodynamical modeling of overlying plate deformation; and backarc opening proceses. Comparisons of the Nankai and Japan Trench subduction systems to other global subduction zones are of particular interest. This session is supported by ILP (International Lithosphere Program).

Three-dimensional seismic velocity model must be necessary for forecasting earthquakes and tsunami events more reliably as well as determination of hypocenters with high-resolution around the Nankai Trough. Although Nakanishi et al. (2018) first constructed the three-dimensional seismic velocity model, it was mainly based on results of marine seismic refraction survey. To construct more realistic model, results of marine seismic reflection surveys must be also considered into the three-dimensional model that will be able to explain the seismic reflection data. In this study, we try to upgrade the three-dimensional model by integrating the results of marine seismic reflection surveys. In particular, seismic interfaces interpreted by both seismic refraction and reflection surveys are all adjusted in the time domain. Precise velocity structure of the shallow sediments estimated by using seismic reflection data are preferentially used to construct the three-dimensional model. Geometry of the plate interface beneath the Shikoku island estimated by receiver function analysis by using onshore seismic observation give more well-determined and reliable information for deep structure. In this presentation, we show an upgraded three-dimensional model considering marine seismic reflection and onshore seismic data.
This study is part of 'Research project for compound disaster mitigation on the great earthquakes and tsunamis around the Nankai trough region' and the project 'Comprehensive evaluation of faults information on offshore Japan' funded by Ministry of Education, Culture, Sports, Science and Technology, Japan.

Deformation of the seismogenic zone in the northeastern part of the Izu Peninsula, Japan, inferred from GNSS observations

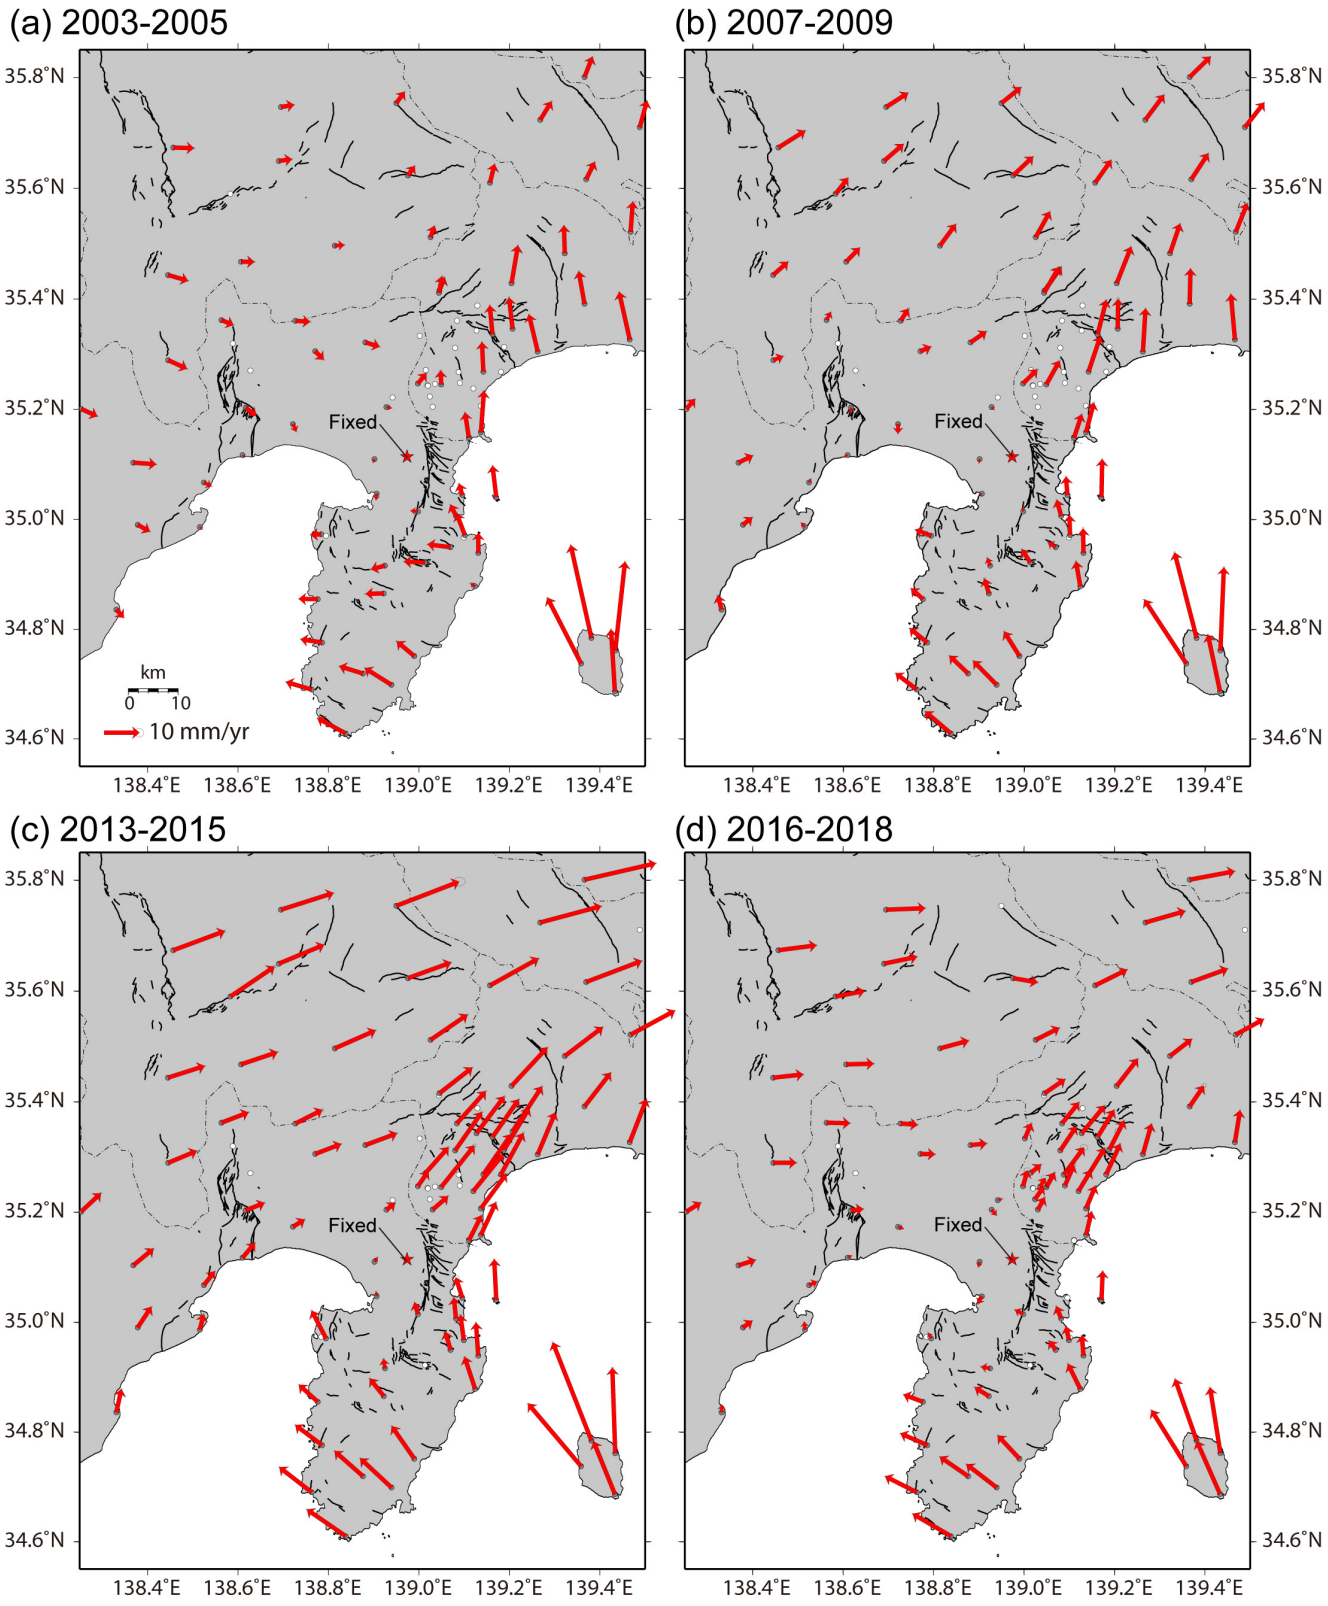
The Izu collision zone, which is characterized by the collision between the Izu-Bonin arc and the Honshu arc, is located in the northernmost part of the Philippine Sea Plate. Particularly in the northeastern margin of the zone, numerous large earthquakes have occurred throughout history. To clarify the convergent tectonics of this zone related to the occurrence of these large earthquakes, in this study we collected and analyzed Global Navigation Satellite System (GNSS) observation data from the Izu collision zone.



We used observation data from our GNSS sites, as well as other sites, to calculate the velocity vectors and strain rate fields of the region in and around the Izu Peninsula in central Japan. Our calculations provided the following results:
•The GNSS velocity vectors in the eastern and western parts of the Kita-Izu Fault Zone are different; in particular, the sites located farther east have larger northward velocities in the area between the fault zone and the Ashigara Plain.
•There is a shear deformation zone in the area extending from the northeastern part of the Izu Peninsula to south of the Tanzawa Mountains, with maximum shear directions that agree with the left-lateral slip direction of the Kita-Izu Fault Zone.
•Seismic activities in the Tanzawa Mountains and the northeastern part of the Izu Peninsula were correlated. This might suggest that both areas are affected by temporal changes in stress accumulation due to the subduction of the Philippine Sea Plate.
•The deformation rate obtained by GNSS data is almost the same as or twice the geologically determined deformation rate. This fact is important when considering the relationship between the accumulation process of deformation in the shear zone and the occurrence of large earthquakes at the West Sagami Bay Fracture or the Sagami Trough.
•The shear zone can be regarded as the transition zone between plate collision and subduction zones: that is, the northeastern part of the Izu Peninsula is being dragged by the relative motion between the separated Izu Peninsula and the North American Plate, which is coupled to the rigid portion of the Philippine Sea Plate.
•We assumed the existence of a weakly coupled detachment zone beneath the shear deformation zone. This can explain both the northward velocities in the shear zone and the divergent displacement and dyke intrusion in the Higashi-Izu Monogenetic Volcano Group.

Shift in provenance composition of Cretaceous Japan arc: from Jurassic granitoids/accretionary complex to Cretaceous granitoids

*Ryo Hasegawa[1], Yukio Isozaki[1], Atsushi Yamamoto[3], Yukiyasu Tsutsumi[2]

1. The University of Tokyo, 2. National Museum of Nature and Science, 3. Kindai University

U-Pb dating of detrital zircons in shallow marine/fluvial sandstones is effective in reconstructing distributary pattern of terrigenous clastics within ancient active continental margins, e.g., the differentiation of fore-arc, intra-arc, and back-arc basins. The Japan segment of Cretaceous arc-trench system in East Asia experienced an episodic formation of crustal rocks, such as arc granitoids, accretionary complexes, and blueschists; nonetheless, details in secular change of arc-related sedimentary basins and their provenance were not fully clarified. This study investigated detrital zircon chronology of the Late Jurassic and Early Cretaceous fore-arc sandstones (18 samples) in SW Japan from Kyushu to Kii peninsula, central Japan. We obtained the following results. 1) During the Late Jurassic to Valanginian (163-133 Ma), pre-Cretaceous (with Proterozoic) zircons were supplied steadily to the fore-arc domain, 2) after the Hauterivian, their abundance started to decrease, and 3) after the Albian, Cretaceous zircons predominated in the fore-arc, whereas pre-Cretaceous ones became almost absent throughout the Late Cretaceous. In contrast, in intra-arc and back-arc domains, older zircons were constantly supplied till the end-Cretaceous. This major change in provenance likely reflected the emergence of a major topographic relief composed of Cretaceous arc granitoids that performed as a significant barrier for older grain flux to the fore-arc domain. The significant arc magmatism and emplacement of voluminous arc-granitoids during the Cretaceous may have first induced surface erosion of the overlying Jurassic accretionary complexes (sandstones with abundant Proterozoic and Paleozoic detrital zircons) that were intruded by the Cretaceous granitoids primarily in mid-shallow crustal levels, and then the erosion of arc granitoids *per se*.

Understanding the relationship between active fault and seismic source fault with more detailed structural data on source faults is crucial to estimate seismic hazards, . For this purpose, we carried out seismic reflection profiling to illuminate geometry of blind thrusts in the Shonai plain and Yamagata basin, Northeast Japan. Three seismic lines (Yuza, Nakanomata and Amarume) are located across the central to eastern margin of the Shonai plain to image underlying blind thrust structures, and Sagae line crosscuts the western margin of Yamagata plain to image fault-related folds above a west-dipping thrust. The length of seismic line is 6-12 km. In seismic data collection, we used vibrator trucks as a seismic source and deployed 10 Hz geophones at 10 m interval covering whole seismic line. Seismic shots with sweep frequencies of 5-100Hz were provided at all midpoints of receivers and corresponding seismic signals were recorded by fixed 600-1000 channels of seismic recorders. The obtained seismic data were processed using conventional common midpoint (CMP) reflection methods. All of seismic sections successfully illuminate subsurface images down to 2 seconds in two-way travel time, and depth converted seismic sections show detailed structures of fault-related folds above blind thrust faults and east-dipping reflectors in 1.5km depth in the Amarume and Nakanomata seismic line.

Northern Honshu, Japan, is known as a classic example of compressive island arc forming a trench-arc-backarc basin. To understand the crustal deformation and the mechanisms devastative earthquakes in the overriding plate, construction of numerical model is needed. To construct an advanced numerical model, the information of lithospheric structure is essential. We conducted a seismic profiling across the central part of Northern Honshu using controlled sources in summer of 2019. The seismic line crosses the epicentral area of the 2011 Tohoku-oki earthquake (M9). For constructing a numerical model on crustal deformation the structural investigation whole lithosphere is required. We aimed two step approach to obtain total lithospheric structure; one is using a controlled source and the other is by passive recording. Here we describe the results of onshore seismic reflection profile the crustal structure obtained by deep seismic reflection profiling. The length of onshore seismic line is 160 km within the total 850-km-long seismic line from Japan trench to the Yamato bank. The air-gun shots in the forearc and backarc sides were recorded by onshore seismic line using 1616 fixed channels. Onshore seismic sources were four vibroseis trucks and three dynamite shots. To obtain the deep crustal image, we used low-frequency signals. The produced sweep frequency by vibroseis trucks was 3 to 40 Hz and seismic signals were recorded by 4.5 and 5 Hz geophones. Sets of 150 stationary vibroseis sweeps were produced at about 10 km interval along the seismic line. Conventional CMP reflection processing and refraction tomography revealed the crustal structure down to 10 km. Together with the velocity structure obtained by earthquake tomography (Matsubara et al., 2019). Lithospheric structure is estimated by velocity structure obtained from active and passive sources, and geological data. With seismic reflection profiles in the forearc (Miura et al., 2005) and backarc (No et al., 2014), the onshore seismic section portrays the first image of the seismic reflection profile across the Northern Honshu arc from the trench to the backarc basin. The basic structure of the overlying plate were formed by the rifting of backarc opening stage. Most of the active faults inherited from the Miocene normal faults. The formation of backarc basins were achieved by the development of multi-rift systems. An axial part of failed rift within a continental crust is marked by a higher P-wave velocity lower crust, thick post-rift sediments underlaid by thick basalts. The failed rift is bounded by faults dipping to the outward of rift axis associated with mafic intrusion in a rift axis. The reverse faulting of the rift-bounding faults produced a fold-and-thrust belt in the post-rift Neogene basin fill. Judging from the tectonic geomorphological and geological features, these faulting and fault-related folding are active in late Quaternary. Detachment in this fold-and-thrust belt commonly accommodates in over pressured mudstone units in the rift basin. The major style of deformation of backarc is basement involved normal faults. Reactivation as reverse fault concentrated along the backarc continental failed rift.

[M-IS04] An asteroid impact in SE Asia at 0.8 Ma and its effect on the environment and biota

convener:Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo), Paul A Carling(University of Southampton), Wickanet Songtham(Nakhon Ratchasima Rajabhat University, Thailand), Kerry Sieh(Nanyang Technological University)

The impact of a small celestial body in Indochina Peninsula at 0.79 Ma, known as Australasia Tektite event (AATE), has been known for more than half a century due to the wide-spread distribution of tektite. Yet, the source crater of the tektite is not yet found inspite of the probable large size (>30 km in diameter) of crater, its relatively young age, and intensive search by many researchers. However, the situation is changing rapidly during the last several years and the area for the location of the crater is gradually narrowed down. Also, the evidence of environmental perturbation and possible relation with local extinction and migration of hominid and animals has been suggested recently.
In addition, because its timing is close to the Matsuyama/Brunhes paleomagnetic reversal event and in the middle of glacial lowstand during MIS 20, precise age of AATE and its relation with glacio-eustatic sea level changes should have a significant implication to Quaternary chronostratigraphy.
For these reasons, we propose a special interdisciplinary session on the location, mode, magnitude, and exact timing of the AATE impact and its possible effect on the environment and biota
The topic should be of major interest to geologists, sedimentologists, planetary scientists, paleontologists, paleoclimatologists, anthropologists, and so on, especially to those working in SE Asia. Thus adequate topic for JpGU-AGU joint meeting.

Tektite is a glass material formed from terrestrial debris ejected during a meteorite impact. (Sub)millimeter-scale tektites are called microtektites. Tektites occur in four strewn fields and Australasian strewn field is the youngest (ca. 0.8 Ma) and the largest (>10% of the Earth surface) of them. Previous studies revealed asymmetric distribution of the Australasian microtektites with the most distant distribution toward the southeast from southeast Asia to Antarctica. Although the exact location of the impact has not yet been identified, recent studies suggest the location as in southern Laos. Because location and magnitude of the impact can be estimated based on distribution of microtektites, to precisely define the distribution of microtektites is important.

During IODP Expedition 346, Tada et al. (2015) found possible microtektites at site U1422 in the northern part of the Japan Sea from the horizon immediately below the Matsuyama-Brunhes boundary. Here we report the occurrence of microtektites from this horizon at site U1422 and the equivalent horizon at U1426. Microtektites are mostly spherical with some teardrop and dumbbell forms of ca. 100 mm in diameter, transparent and pale olive green in color. Major element composition of microtektite agree well with that of Australasian microtektites reported in previous literatures. The Quaternary hemipelagic sediments of the Japan Sea are characterized with millennial-scale alternations of dark and light layers that can be traced throughout the deeper part of the sea, and the microtektite horizons at the two sites shows parallel relationship with dark layers immediately above and below it, suggesting they are synchronous, supporting primary ejecta origin.

Discovery of Australasian microtektite at site U1422 extends northeastward distribution of Australasian microtektite by ca. 2500 km, almost double the extent in northeastward direction. Microtektite flux to site U1426 is >500 particles/cm^2, which is much larger than expected. It is possible that previous studies overlooked microtektites of less than 125 mm because they used >125 mm fraction to look for microtektites. The result of this study suggests that distribution of Australasian microtektites could be much larger than previously suggested. It is possible that Australasian microtektite horizon can be distributed widely in northwest Pacific.

Ejection behavior after hypervelocity oblique impacts in an atmosphere

*Kosuke Kurosawa[1], Ryota Moriwaki[1], Kojiro Suzuki[2], Takafumi Matsui[1]

1. Planetary Exploration Research Center, Chiba Institute of Technology, 2. Department of Advanced Energy, Graduate School of Frontier Sciences, The University of Tokyo

It is believed that the Australasian strewn field is an outcome after an hypervelocity oblique impact. The impact must occur in a thick Earth’ s atmosphere, resulting in an intense interaction between ejected materials and the surrounding atmosphere. Here, we report about a new experimental apparatus to investigate the impact outcomes after hypervelocity impacts under an atmosphere. The system has been installed to a hypervelocity impact laboratory at Planetary Exploration Research Center of Chiba Institute of Technology. The system is consist of a two-stage light gas gun, a vacuum chamber with a gas inlet and with two glass view ports that face each other, a high-speed video camera, and a pulsed-diode laser-light source. In addition, we constructed a Schlieren imaging optics between the light source and the camera to visualize the flow field driven by an downrange moving ejecta plume. We could capture Schlieren images with the time resolution of 0.2 microsecond. By using the system, we conducted a series of hypervelocity oblique-impact experiments with polycarbonate projectiles 4.8 mm in diameter. The impact velocity was ranged from 2.7 km/s to 6.9 km/s. The impact angle was fixed at 45 degrees measured from the target surface. Three different targets, which are made of polycarbonate, aluminum, and copper, were used to examine the effects of the shock impedance of the target materials on the ejection behavior. After the air in the chamber was evacuated, we introduced N_2 or Ar gas into the chamber up to 6.0 kPa. We observed a downrange moving ejecta plume and an intense atmospheric interaction with the surrounding gas as a strong self-emission in the visible range. We found that the morphology of the ejecta plume depends on both impact velocity and the target materials. In the poster presentation, we will discuss about possible environmental perturbations after the hypervelocity oblique impact.

Impact cratering is a ubiquitous process on terrestrial planets and asteroidal bodies in the solar system. Many researches focus on impact craters on the Earth to reveal details of planetary-scale shock metamorphism. In particular, quantification of shock pressure that minerals in meteorites and impactites have experienced leads to a clue to understanding a partition of the impact energy and cratering mechanism on Earth as well as terrestrial planet and asteroids. Quartz, which is one of the most abundant and widely distributed rock-forming minerals on the Earth’ s crust, has been widely used to evaluate shock pressure on the impactite. However, the conventional shock barometer based on the mineralogical features of quartz, such as observation of planer deformation features (PDFs), are no more than a qualitative approach. Hence, it is required for a more detailed and accurate evaluation of shock pressure to develop a new advanced method using quartz.

Recently, we clarified the drastic change of cathodoluminescence (CL) features of quartz due to shock metamorphism [1]. The blue CL emission intensity (450-460 nm) of quartz increases drastically with the experimentally shock-induced pressure and reaches up to 100 times as large as that of the starting materials. The mechanism for the increase in the blue CL intensity can be explained by a combination of Dauphine twin generation and shock-induced vitrification. Because of the monotonical response to shock pressure, the blue CL intensity of the shocked quartz could be used as a new shock barometer [1]. In this study, we measured natural samples of quartz in impactite from the Chicxulub Crater drill core (YAX-1) in order to verify its application as shock barometer using CL for the natural crater samples.

The two core samples named Unit 1 (ejecta from impact-produced tsunami deposit) and Unit 5 (impact melts) were extracted from the YAX-1 core and selected for CL analyses. The extracted quartz grains form these samples were measured by microphotography of the PDFs orientation and the qualitatively estimated shock pressures of the quartz grains are < 15 Gpa for Unit 1, and 25 - 40 GPa for Unit 5 [2].

Quartz samples from Chicxulub crater exhibit similar CL profile to shock experimental quartz samples. Both natural samples show two peaks; CL spectra of Unit 1 samples consist of a pronounced peak at ~440 nm and a broad peak at ~630 nm. On the other hand, Unit 5 samples have a weak peak at ~440 nm and the peak at ~630 nm with relatively high CL intensity. As Unit 5 samples originate from impact melt which have experienced a high-temperature effect, post-impact annealing could affect the original blue CL emission of the quartz samples. Unit 1 samples, ejecta from the tsunami deposit, would have experienced lower degree of post-impact annealing than Unit 5 samples. These facts suggest that blue CL emission could be used as a shock barometer for natural impact samples which were not strongly affected by post-shock annealing. The quantitative pressure estimation and applicable scope of CL to natural impact samples will be also discussed.

Geography and Environmental Science, University of Southampton, 8. Northeastern Research Institute of Petrified Wood & Mineral Resources, Nakhon Ratchasima Rajabhat University

Shocked quartz has been the most commonly used mineral as a barometer of shock metamorphism in the terrestrial impact structures, because of its abundance, durability, and tendency to develop striking and unique deformation features depending on the degree of shock pressure. Various methods have been developed to evaluate the shock pressure that the minerals experienced, such as optical and electron microscope, Raman and cathodoluminescence spectroscopy, and X-ray diffraction (XRD) analyses. However, it is still difficult to quantitatively evaluate the degree of shock metamorphism under the lower range (5–15 GPa) of shock pressure.

Quartz powder samples highly compressed above 25 GPa by shock experiments are known to exhibit lattice expansion that is detected by laboratory powder XRD analyses. However, the lattice expansion of quartz shocked below 25 GPa could not be monitored by a laboratory X-ray diffractometer, resulting in the impossibility of determination of shock pressure in the lower range. In this study, we applied synchrotron XRD analysis, with quite higher energy resolution and X-ray beam intensity than the laboratory instrument, in order to detect a change of lattice constants of quartz in the wide range of shock pressure from 5 to 40 GPa. The experimentally shocked quartz samples, not grinded, were subject to the synchrotron XRD analysis using a high-resolution diffractometer with a multidetector system on beamline BL4B2 at the Photon Factory in the High Energy Accelerator Research Organization (KEK PF). Synthetic Si powder was selected for a standard material for wave energy calibration, leading to monitoring a change of lattice constants at $0.001^\circ\theta$ resolution.

The result of the synchrotron XRD analysis revealed that with increasing shock pressure, the lattice constants of quartz slightly increase in the low shock pressure range of 5–15 GPa and drastically in the high range of 20–30 GPa. Quartz samples shocked above 35 GPa show no XRD signals, indicating that the amorphization has been completed. Similar drastic changes of the lattice constants in the pressure range of 20–30 GPa and absence of XRD signals above 35 GPa have been reported in the previous laboratory XRD analyses. The lattice expansion recognized in the low shock pressure range of 5–15 GPa is up to 0.00059(6) Å (0.01%) for the constant *a*, 0.0003(1) Å (0.006%) for the constant *c* and 0.034(6) $Å^2$ (0.03%) for the cell volume *V*. All of the values cannot be explained by the above-mentioned sample and analytical errors. As this pressure range is corresponding to appearances of mechanical twins and planar deformation features (PDFs), this slight lattice expansion might be caused by a change of quartz structure due to these low-grade shock-induced microtextures. This result indicates that the measurement of lattice constants of quartz by synchrotron XRD analysis is useful to evaluate lower (5–15 GPa) range of shock deformation.

Then we applied this technique to the basement Mesozoic sandstones around the probable impact site of Australasian Tektite Event. The basement sandstone samples were taken from 18 sites in northeastern Thailand and southern Laos. The synchrotron XRD analysis of quartz extracted from the sandstone samples by chemical treatments was conducted to determine the values and distribution of shock pressure around the probable impact site.
The result of the synchrotron XRD analysis demonstrated that the lattice constants of quartz increase eastward, from northeastern Thailand to the southern part of the Thailand-Laos border. The lattice expansion is up to 0.00028(6) Å (0.006%) for the constant *a*, 0.0003(1) Å (0.005%) for the constant *c* and 0.018(6) $Å^2$ (0.02%) for the cell volume *V*. This spatial variation of the lattice constants of quartz in the basement Mesozoic sandstone indicates that the degree of shock deformation increase to the Thailand-Laos bordar and that the impact took place somewhere in the area around the border.

Quaternary stratigraphy and occurrence of the Australasian tektites in Thailand, Laos PDR, and Cambodia: implication of the impact location

*Wickanet Songtham[1], Ryuji Tada[2], Paul A Carling[3], Toshihiro Tada[2], Praphas Chansom[1]

1. Nakhon Ratchasima Rajabhat University, Thailand , 2. The University of Tokyo, Japan, 3. The University of Southampton, United Kingdom

Quaternary sediments and stratigraphy in northeastern Thailand, southern Laos PDR, and northeastern Cambodia have been investigated and studied. A 0.8 Ma tektite-bearing sedimentary layer was recognized in association with basal breccia sediments ranging in sizes from pebbles to granules regarding as a key bed layer representing a 0.8 Ma marker. The tektites were mainly splash-form with some Muong Nong-type, layered, at some places. They were mainly discovered as floated specimens on ground surface but some tektites were on site as in situ occurrence at a certain stratigraphic position mostly along the interface between the basement and the key bed layer generally coated by iron oxide as ferricreted layers. These in situ tektites were widely discovered in Thailand, Laos PDR, and Cambodia. The basements supporting the key bed layer are gravel and sand deposits with petrified woods in general as well as the Mesozoic sandstone bedrocks. Some gravel deposits overlay the Cenozoic basalt flows whereas some basalt gravels are also of constitution of the gravel deposits. Whereas, the sediments over the tektite-bearing key bed are widely distributed over the region characterized by structureless reddish orange fine-sand deposits with basal breccia granules and pebbles in association with some in situ tektites regarding as ejecta materials. The stratigraphic succession over the key bed were vertically and laterally varied over the region. In Thailand and Cambodia, they were characterized as tektite-bearing fine sand deposits that is clearly visible in northeastern Thailand designated as some soil series by the Land Development Department with thickness ranging from 3 to 5 meters. The basal part of the ejecta deposits varied into pebbles of sandstone fragments in Laos clearly visible in some areas of Salavan Province. This type of sediments is probably hidden under the younger basalt flows in the areas of the Bolaven Plateau. This Quaternary stratigraphic succession and the occurrence of the Australasian tektites can be speculated that the impact location is highly reliable that it is at a location within the southern Laos PDR around 0.8 Ma.

Assessment for BPCA method as biomass burning proxies and their application to meteorite impact event

*Song Lu[1], Youhei Yamashita[2], Tomohisa Irino[2], Toshihiro Tada[3], Ryuji Tada[3]

1. Graduate School of Environmental Science, Hokkaido University , 2. Faculty of Environmental Earth Science, Hokkaido University, 3. Department of Earth and Planetary Science , Graduate School of Science, The University, of Tokyo

Behavior of black carbon (BC) is crucial for the earth surface environment because it could cause global warming by absorbing sunlight in the atmosphere. BC is originated from incomplete combustion of biomass or fossil fuels. Combustion in natural processes is incomplete due to local limitation of oxygen during the fire, which leads to the formation of organic fire residues. Robustness of BC to degradation in the natural environment enables us to use BC as a proxy to study the driving force of frequency and burning temperatures of past wildfire events. But the previous fire researches did not discuss the BC archives of fire remnants caused by meteorite impact.

Objective of this study is to reconstruct the thermal field during Australasian Tektite Event (AATE) and its impact on climate change. For these purposes, the burning temperatures were estimated for ejecta deposits and charcoal samples through measurement of composition of benzene polycarboxylic acids (BPCAs), molecular markers of fire residues, determined with High Performance Liquid Chromatography (HPLC).

It has been suggested that the location of the impact crater is in eastern part of Indochina peninsula. Surge and air-fall deposits were sampled from the outcrop at Huai Om section site (HO), in NE Thailand. HO section consists of Units1, 2, and 3 in ascending order. Unit1 consists of alternating beds of granular fine-medium sand and silt with red shale fragment. Unit2 is characterized by inversely graded granular to pebbly sand. Unit3 is homogenous fine-medium sand with granules. Plant debris were also collected in Ban Tha Chang, which may have undergone pyrolysis during the AATE event.

The concentration of BPCA in Units2 and 3 sediments are 5 times higher than sediments from Unit1 in HO site. The fire temperature estimated from B6CA (%) indicate that the charcoal in Units2 and 3 sediments experienced a fire above 500 ˚C, while those in Unit1 were burnt by a fire of only 400 ˚C. We speculate that the charcoal in sediments formed by surge and air-fall contains charcoals from different environments of burning temperature.

The concentration of BPCA in plant debris samples are about 10 mg/g, all of them from low temperature fires (< 400℃). The estimated burning temperature for two plant debris samples from Ban Tha Chang show higher BPCA concentrations and higher fire temperatures than one sample from Ban tha Chang and the other from NR1 site. Although all the sampling sites are closely located, the BPCA compositions showed that the bark and core of these plant debris experienced different pyrolysis temperatures.

Department of Geology, Chulalongkorn University, Khet Pathumwan, 10330 Bangkok, Thailand

Physical and chemical characteristics of the Australasian tektites suggest that they originated within the Thai-Lao Khorat Plateau, and more specifically within the 100,000 km^2 inner strewnfield of Muong Nong-type tektites. The lack of an obvious crater and very low rates of erosion in this region imply that the crater must lay buried. Several converging lines of evidence imply that indeed the 0.8-Ma impact crater is buried beneath the 350-m thick summit flows of the 5,000-km^2 Bolaven volcanic field in southern Laos. Chemical compositions of the tektites indicate the presence of a weathered basaltic component that had accumulated mostly during the few million years before the impact. Accordingly, ^{40}Ar-^{39}Ar dates from distal lava flows can be traced uphill to weathered pre-impact basalts now buried beneath younger flows of the summit impact region. Also as predicted by the hypothesis, all ^{40}Ar-^{39}Ar dates from exposed flows at and near the impact region post-date the impact. Moreover, a gravity anomaly there may reflect the presence of a buried ~15 km wide elliptical crater with low-density fill. We interpret a thick deposit of crudely layered, bouldery sandstone and mudstone breccia in two outcrops 10–20 km from the center of the impact crater to be part of the proximal ejecta blanket. Fractured quartz grains within these boulder clasts lend support to this interpretation of an impact origin of these peculiar deposits. A pebbly, cobbly layer that extends and thins for more than 100 km from the impact site, almost everywhere containing angular muong nong tektites, comprises the more distal part of the ejecta blanket. Commonly, atop this layer is a massive, meters-thick coarse-silty to fine-sandy layer that we interpret to be partially or largely comprised of fallout of fine debris driven and convected into the atmosphere during and immediately following the impact. In this talk, we will present available physical and geochronologic evidence for the Bolaven impact as the source for the Australasian tektite strewnfield. In an accompanying contribution, we will present correlative geochemical evidence.

[M-IS05] Cenozoic Evolution of the Asian Monsoon and the Indo-Pacific Paleoclimates

convener:Masanobu Yamamoto(Faculty of Environmental Earth Science, Hokkaido University), Steven C Clemens(Brown University), Hongbo Zheng(Research Center for Earth System Science, Yunnan University), Ryuji Tada(Department of Earth and Planetary Science, Graduate School of Science, The Univeristy of Tokyo)

The Asian monsoon (AM) and the El Nino-Southern Oscillation (ENSO) are dominant atmospheric-ocean phenomena on the Earth and affect the climates of Asia, Oceania and circum-Pacific regions. During the Cenozoic, the climate of these areas changed drastically, but the behaviors of the Asian monsoon and the tropical ocean-atmosphere interactions like the ENSO were not fully understood. From July 2013 to December 2016, IODP conducted a series of expeditions such as 346 (Asian Monsoon), 353 (Indian Monsoon Rainfall), 354 (Bengal Fan), 355 (Arabian Sea Monsoon), 356 (Indonesian Throughflow), 359 (Maldives Monsoon and Sea Level), 361 (Southern African Climate), and 363 (Western Pacific Warm Pool) that are related to the AM and tropical Pacific climate evolution and its interaction with global climate system in NW and tropical Pacific and Indian Ocean regions, and exciting results are coming out. We believe it is timely to start synthesizing the results of these cruises and update and exchange information and ideas to promote our understanding of the AM and tropical Pacific evolution, variability, their controlling factors, and their interaction with global climate system during the Cenozoic. On orbital and millennial timescales, studies on the response of the AM and the ENSO to climate forcing are intensively studied using various archives such as sediments, speleothems, corals, etc., during the last decade. Presentations and discussions on the above topics from various backgrounds (proxy and modeling studies) are highly welcome.

Isotope analysis of Neogene marine sediment from Maldives

*Yuka Tatera[1], Katsuyuki Yamashita[1], Tsuyoshi Ishikawa[2], Mayuri Inoue[1]

1. Okayama University, 2. Kochi Institute for Core Sample Research, JAMSTEC

The South Asian Monsoon (SAM) is one of the most intense climatic elements mainly affecting around India. Betzler et al. (2016) suggested that the SAM was established around 12 Ma from the presence of drift sediment, but it has not yet been clarified in detail when and how it developed. In this study, we analyzed Pb and Sr isotope ratios in marine sediments from the Maldives in order to understand the variation of wind direction and its relation to the development of the SAM. Lead has four naturally occurring stable isotopes, and when the lead mineral is formed, the lead isotope is sequestered from the parent nuclide, at which point the change in the lead isotope ratio stops. Lead is not subject to significant physical and chemical isotope fractionation, making lead isotope a potential tool to determine the origin of lead bearing minerals. In addition, since the ocean tends to have a uniform Sr isotope composition in terms of dissolved Sr, it is possible to estimate the input balance of the region such as inflow of Sr from the continent based on the measurements of Sr isotope ratios.
In this study, the core of Site U-1468 (4 ˚56′N, 73 ˚4′E) drilled during the cruise of the International Ocean Discovery Program Exp.359, which has an age from ~25 to 10 Ma, was used for the analysis of Pb and Sr isotope ratios. The core is characterized by coral reefs around it with dead bodies piled up and rich in carbonate components. Therefore, the sample was chemically separated into carbonate and non-carbonate components and Pb and Sr were purified on each type of sample. The isotope ratios were analyzed using TIMS (Finnigan MAT262) for both Pb and Sr and MC-ICP-MS (NEPTUNE) for Pb, and the contents of Pb and Sr in 5% of the sample were measured by ICP-MS (Aglient 7700x).
As a result of the measurement of Pb isotope ratio of Maldives sediment, both carbonate component and non-carbonate component show a trend in which the ^{206}Pb / ^{204}Pb increases from around 13 Ma when the drift sediment was developed. In this study, the carbonate component has a systematically higher Pb isotope ratio than that of the non-carbonate component which is similar to that reported from the Himalayas (Wilson et al., 2015). For the Sr isotope ratios, $^{87}Sr/^{86}Sr$ in the carbonate components has a value close to that of seawater, that may reflect the influence of the surrounding seawater. On the other hand, variation of $^{87}Sr/^{86}Sr$ in the non-carbonate components behaves differently from that in seawater before 13 Ma, suggesting another input of Sr around this age.

Human activities during last 700 years as recorded in the concentrations of polycyclic aromatic hydrocarbons and pentacyclic triterpene methyl ethers in sediment cores from Lake Suigetsu

*Masaya Inagaki[1], Hideto Nakamura[2], Masanobu Yamamoto[1], Takeshi Nakagawa[3]

1. Graduate School of Environmental Science, Hokkaido University, 2. Faculty of Science, Osaka City University, 3. Research Center for Palaeoclimatorogy, Ritsumeikan University

Polycyclic aromatic hydrocarbons (PAHs) are formed by burning of biomass or fossil fuel. Pentacyclic triterpene methyl ethers (PTMEs) are biomarkers that typically derive from graminoid plants. The presence of these compounds indicates human activities, for example, industrial burning, agriculture, and so on. In this study, we analyzed PAHs and PTMEs in sediment cores (SG06 and SG17 LIMNOS cores) from Lake Suigetsu in Fukui Prefecture. The concentration of PAHs peaks around 1945 C.E., indicating intense biomass burning near the study site. We suppose that this reflects the structural fires caused by air-attacks in the neighboring cities such as Tsuruga and Maizuru. The ratio of specific PAHs changed during the studied period, suggesting changes in the usage of biomass and fossil fuels. The relative amount of PTMEs, i.e., Sawamilletin and Miliacin, changed in 1320 C.E. and 1530 C.E. This suggests a change in graminoid vegetation around the study site, which might be related to historical shifts in cropping system.

Reconstruction of paleoclimate changes in the region where the Okhotsk culture flourished over the past 2,700 year

*Ryuichi Seto[1], Osamu Seki[2], Masanobu Yamamoto[3], Takuya Itaki[4]

1. Graduate School of Environmental Science, Hokkaido University, 2. Institute of Low Temperature Science, Hokkaido University, 3. Facility of Environmental Earth Science, Hokkaido University, 4. Geological Survey of Japan, AIST

The Okhotsk Culture, which is characterized by marine hunting lifestyle, is different from the culture peculiar to other regions of Japan, and thus is wrapped in many mysteries. Okhotsk culture was transformed into Tobinitai Culture around A.D. 10 century and ended. Climate change has been proposed to be one of the reasons for the demise of the culture (Onishi, 1996). However, the relationship between climate change and Okhotsk culture is not well understood because of the lack of detailed paleoclimate records in the region where Okhotsk culture prospered. In this study, we generate high-resolution paleoclimate records in the northern Hokkaido and south Okhotsk Sea over the past 2,700 years based on organic and isotope geochemical techniques in order to better understand the causal relationship between the regional climate and Okhotsk culture.

Terrestrial paleoclimate is reconstructed from a peat core collected from Sarufutsu wetland in northern Hokkaido while a paleoceanographic change in the Okhotsk Sea is derived from a marine sediment core taken from off the coast of Shari, Okhotsk Sea. We apply the hydrogen isotope ratio of plant leaf wax, as well as the mineral content to estimate the change in the hydrological cycle in terrestrial realm where the Okhotsk culture has flourished. On the other hand, SST is reconstructed from TEX_{86} temperature proxy, while sea ice change is reconstructed from the stable carbon isotope ratio of phytoplankton derived C_{16} fatty acid. TEX_{86} based SST record shows that long-term cooling trend over the past 2,700 years with the rapid cooling around 800 years ago, which corresponds to the late stage of Medieval Climate Anomaly. In this presentation, we discuss the regional climatic impact on Okhotsk culture based on multiple paleoclimate records obtained from terrestrial and marine paleoclimate achieves.

Fluvio-sedimentary response to late Quaternary climate at the Himalayan frontal thrust, central Nepal

*Mari Hamahashi[1], Judith Hubbard[1], Samuel Haines[1], Rafael Almeida[2], Edgardo Latrubesse[1], Sanjita Mishra[3], Lewis Owen[4], Soma Nath Sapkota[3]

1. Earth Observatory of Singapore, Nanyang Technological University, 2. Yachay Technical University, Ecuador, 3. Department of Mines and Geology, National Seismological Center, Nepal, 4. North Carolina State University, USA

Indo-Asian monsoonal fluctuations throughout the late Quaternary have likely altered the depositional environment in the frontal Himalaya. The Indian summer monsoon is responsible for more than 80% of the annual rainfall in the subtropical regions of the Himalayan foreland to the Indo-Gangetic-Bengal basin, significantly impacting river discharge and sediment flux in the system. The effect of monsoon on sedimentation (deposition vs incision), however, exhibit regional variabilities. While downstream variations may be explained by sediment supply tapering off downstream and increased effect of sea-levels on rivers, variations among other areas in the frontal foreland are not well understood, and are likely due to the differences in the size of the river/catchment, the distance downstream, and the amount of tectonic activity.

To reconstruct the late Quaternary evolution of the fluvio-sedimentary environment at the frontal foreland of central Nepal, we study the sedimentary facies and chrono-stratigraphy over the last 50 ky from ten boreholes across the Main Frontal Thrust there, using optically stimulated luminescence and radiocarbon dating. Previous seismic survey along the riverbed imaged ~100 m thick sediments above the incised bedrock, and onlap of strata onto folded strata, implying recent enhanced effect of sedimentation and changes in river base-levels (Almeida et al. 2018). Drilling penetrated 50-100 m of these sediments below the surface. We observe three types of facies along the depth: (a) poorly-sorted gravels with silt to sand, interpreted to be coarse-grained braided channel facies, (b) moderately-sorted silt to sand with gravels sandwiched by thin floodplain silts, interpreted to be fine-grained braided channel facies, and (c) massive, well-sorted clayey silt with bioturbation, alternating redox state and occasional sand beds, interpreted to be fluvio-lacustrine facies. Facies (c) likely deposited in a depocenter formed by the damming of the river due to the uplift on the thrust anticline. A major transition from facies (b) and (c) to facies (a) occurred at the early Holocene to latest Pleistocene (~12-13 ka, or slightly younger), inferred from preliminary age results, in which sediments were finer prior to this period, and coarser afterwards.

Given the sediment age range and the observed variations in <~40 ky timescales, the most relevant features comparable are likely to be monsoonal climate variations. The observed facies transition around the early Holocene likely coincide with the strengthened monsoon that is reported at ~15-12 ka and ~10-6.5 ka from cave speleothems in northern India (Sinha et al. 2005; Dutt et al. 2015), correlating with the time the northern hemisphere summer solar insolation increased towards the peak, around the Bolling-Allerod interstadial and/or across the last glacial to interglacial boundary. We interpret that strengthened monsoon have led to increased river discharge and advance of coarse bedload-dominant braided channels. Weak monsoon periods, in contrast, decreased river discharge and formed finer-grained channel environment with high lateral mobility.

Further age results from the samples will enable to constrain the variations in deposition rates, and the timing of incision and on-lap surfaces imaged in the seismic section. Deposition rates infer rates of aggradation and/or progradation, reflecting sediment supply, which is not necessarily dependent on river

©2020. Japan Geoscience Union. All Right Reserved.

discharge. Monsoon have likely affected the base-levels through varying river discharge and sediment supply.

Understanding the large-scale processes that govern sediment supply and base-levels in the foreland will allow us to generalize the processes elsewhere and help in interpreting various rates from sediment age including tectonic deformation. Study of sedimentary processes and the effect of climate in these depositional fan systems will impact our overall understanding of sediment fluxes within this large system.

Tropical western Pacific hydrology during the last 6000 years based on charcoal records from Borneo

*Masanobu Yamamoto[1], Takafumi Kikuchi[1], Hiromichi Sakurai[1], Ryoma Hayashi[2], Osamu Seki[1], Takafumi Omori[3], Abdullah Sulaiman[4], Hasrizal Shaari[5], Lulie Melling[6]

1. Faculty of Environmental Earth Science, Hokkaido University, 2. Lake Biwa Museum, 3. The University of Tokyo, 4. Minerals and Geoscience Department Malaysia, 5. Universiti Malaysia Terengganu, 6. Tropical Peat Research Institute

Borneo is one of the islands between the tropical Pacific and Indian Oceans. The climate is tropical, and both temperature and precipitation are high year-round. The precipitation is influenced by both the Asian winter monsoon the El Niño-Southern Oscillation (ENSO). Today, the ENSO regulates the frequency of forest fires in Borneo. In El Nino years, the frequency of forest fires is significantly higher, due to low precipitation and dry environments.
In this study, we generated 6200-year long charcoal records from Borneo peats to understand changes in hydrology in the western Pacific region on centennial and millennial timescales and what regulated precipitation in Borneo. Charcoal in sediments is a good proxy of forest fires. We retrieved peat cores from five different sites in northwestern Borneo.
In each site, charcoal abundance show large fluctuation. The peaks are correlated between five different locations. This correspondence suggests that charcoal abundance reflect regional environmental changes rather than local factors. The abundance peak of charcoal in Borneo peats appeared every several hundred years, showing a 560-year periodicity, reflecting regional dry-wet cycles in Borneo. Higher charcoal abundance corresponded to higher solar irradiance and El Niño (Moy et al., 2002) from about 4000 to 1000 years BP, but the relationship was not clear and even reverse in other periods. The variation is consistent with stalagmite δ18O records from inland China and central India. This suggests a linkage of tropical climatic dynamics and the Asian summer monsoon on multi-centennial timescale.

[M-IS06] Dust

convener:Ishizuka Masahide(Kagawa University), Yasunori Kurosaki(Arid Land Research Center, Tottori University), Thomas Sekiyama(Meteorological Research Institute), Kana Nagashima(Japan Agency for Marine-Earth Science and Technology, Research and Development Center for Global Change)

Mineral dust is generated from the ground surface by strong winds, and it transports long distance over the earth. In the process, cloud formation and absorption and scattering of solar radiation cause weather and climate changes. Also, when deposited in the ocean, feeding nutrients to phytoplankton, promoting photosynthesis, and when deposited on snow and ice causes albedo change. This is known as the yellow dust (Asian dust) phenomenon in Asia region including Japan. In order to understand this, integration in a wide range of academic areas is necessary.
 In the emission process, the amount of dust changes greatly depending on the surface conditions in dryland area, and in order to know the effect, it is necessary to deal with broad areas such as soil, topography, vegetation, precipitation, desertification and soil deterioration. In the transport process, we deal with areas such as weather, atmospheric aerosol, radiation. In the deposition process, we deal with areas such as ocean, snow ice, health to people and livestock. Drying and changes in vegetation also have social scientific aspects such as national policies, management of livestock, and population increase. In addition, dust and sand dunes are common phenomena not only in the Earth but also in other planets such as Mars and Saturn. In this way, it is impossible to understand the dust phenomenon only from one field, it is important for researchers in many areas to discuss and share information through this session, and advance exchange of researchers.

Detection of aeolian dust in a sedimentary sequence at Tsujita Site

*Haranosono Daichi[1], Shin Toyoda[1], Kenji Nagai[2], Toshirou Naruse

1. Okayama Univesity of Science, 2. Aichi Gakuin University

The Tsujita site is located in Yahata Nishi-ku, Kitakyuushu City, Fukuoka. This site was excavated to clarify the historical dynamics of human migration to Japanese Islands during the late Pleistocene. Total of 9 sedimentary layers have been recognized by the conducted excavations. The observations that Layer 4 is underlaid by the primary Aso-4 pyroclastic flow deposition (Layer 5) and AT was found in the middle of Layer 2 would indicate that Layers 2 to 4 correspond to the last interglacial to glacial climate change. If this is the case, Layer 2 should be composed of loess, Layer 3 of paleosol, and Layer 4 of loess. Burnt rock fragments was found from the lowest part of the Layer 3 to the uppermost part of Layer 4.
The number of oxygen vacancies in quartz measured by ESR (electron spin resonance) correlate with the ages of granitic rocks. Using this feature, there are several works that discussed the origin of the aeolian dust brought to the Japanese Islands from China. The present study aimed to find the change of the amount of aeolian dust from China deposited in the sedimentary sequence of Tsujita site.
From Layers 2 to 5 at the Babayama part of Tsujita site, 22 sediment samples were collected with every 5 cm interval. The sediment samples were treated with hydrochloric acid and hydrogen peroxide followed by grain size separation with the Stokes method into 2 to 20, 20 to 50, and 50 to 125 μm. The samples were then treated with hexafluorosilicic acid to extract quartz. By XRD analysis with calibration with silicon, the quartz content in the sample was estimated. After giving γ rays to a dose of 2.5 kGy, the extracted quartz was heated at 300 ˚C for 15 minutes before ESR measurement.
The number of oxygen vacancies was obtained as the signal intensity of the E_1' center in a unit of 1.3×10^{15} spins/g for the 2~20μm grain size fractions. As the first order approximation, it was assumed that the number of oxygen vacancies in aeolian dust from China is 20 unit and the local dust is 0 in order to estimate the fraction of the aeolian component in the measured sample, from the obtained number of oxygen vacancies. Finally using that, we calculated the mass of quartz of the aeolian dust component from China and the mass was divided by the initial mass of the sediment to obtain the concentration ranging from 0 to 1800 ppm. The concentration of aeolian dust quartz component from China was found to be higher in Layer 1 and 3 while lower in Layer 2 and 4 confirming the correlation with the estimated climate change.

Effect of stone on threshold friction velocity in Tsogt-Ovoo, Mongolia: Observation and Model simulation

*Batjargal Buyantogtokh[1], Yasunori Kurosaki[1], Masahide Ishizuka[3], Tsuyoshi T Sekimaya[2], Taichu Y Tanaka[2], Atsushi Tsunekawa[1], Mitsuru Tsubo[1]

1. Arid Land Research Center, Tottori University, 2. Japan Meteorological Agency, Meteorological Research Institute, 3. Faculty of Engineering and Design, Kagawa University, Japan

In arid areas, surface roughness is mainly controlled by inert non-erodible elements such as rocks, stone, gravel, and green and senescent vegetation. They affect the erosion threshold in two ways. First, the elements cover part of the surface and thus protect it from the Aeolian erosion. Secondly, they consume part of the wind momentum that will not be available to initiate particle motion (Marticorena et al., 1997). Although the effect of stone and gravel on sand flux is studied by mainly a field wind tunnel measurement, there are few reports on the simulation of threshold friction velocity and field observation with the stone effect of the Gobi Desert. We will show the results of the threshold friction velocity and sand flux by observation and simulation around Tsogt-Ovoo located in the northern part of the Gobi Desert, Mongolia. Simulations were conducted with two conditions which are with and without stone effects. We made measurements of stone coverage, sand saltation count, and meteorological parameters at 11 sites during 31 April –5 May 2018 and 25 April –10 May 2019. Threshold friction velocities were estimated from sand saltation count data observed at 30-seconds intervals. Vertically integrated sand saltation flux for each dust event was estimated from saltation amount data observed by passive samplers installed at 10 cm, 30 cm, 50 cm, and 100 cm heights. We used the dust emission scheme of Shao (2004). Figure 1 shows that simulation results are improved very well at sites by an installation of stone effects except for the Main site and the site of 2019Sub14A in 2019. Regarding the Main site and the site of 2019Sub14A, we are thinking the senescent vegetation and soil crust suppressed the sand saltation, but we don’ t have quantitative data about them.

Monitoring dry-season vegetation mass at a dust hotspot (Tsogt-Ovoo) in the northern Gobi Desert

*Jing Wu[1], Yasunori Kurosaki[1], Ganatsetseg Batdelger[2], Adrian Chappell[3], Ishizuka Masahide[4], Batjargal Buyantogtokh[1]

Accurate prediction of dust emission is of significance to prevent its eco-environmental and social-economic damaging effects on not only source regions but also down-wind regions. However, due to insufficient observation data of erodibility factors (especially at source regions) and a lack of understanding of how and to what extent they affect dust emission, the model simulation of dust is not behaving well. As one of the important erodibility components, effects of vegetation on dust emission have been widely investigated. Most previous studies analyzed green vegetation during growing season, while the period for green vegetation is short in the Gobi Desert. Early studies pointed out green vegetation in summer remained as dead leaves till next spring, and suppresses dust emission. However, few studies have dealt with monitoring of dry-season vegetation mass in the northern Gobi Desert. The present study aims to estimate dry-season vegetation mass by using remote sensing data (e.g., MODIS) at Tsogt-Ovoo (TsO), Mongolia.

Soil Tillage Index (STI), which is the ratio of band 6 (1.6 μm) and band 7 (2.1 μm) derived from MODIS Nadir BRDF-Adjusted Reflectance products, is a potential index to estimate dry-season vegetation mass. STI in September 2019 around TsO was tested against field measurement of aboveground biomass (AGB). We found a significant correlation between STI and AGB (R^2=0.49, $p<0.05$). In addition, STI in April was compared with an estimated shear stress (U_s*) scaled by the freestream wind speed (U_h) during the period of 2001-2018. The estimated U_s^*/U_h reflects the aerodynamic roughness and shelter based on albedo. We also found a highly negative relationship between STI and U_s^*/U_h (R^2=0.59, $p<0.01$). Abundant dead leaves result in high values of STI, as well as increase roughness and decrease wind momentum at the soil surface, thus resulting low values of U_s^*/U_h.

The results imply that STI can be applied to monitor dry-season vegetation mass in the Gobi Desert and potentially in large-scale dust simulation models.

Saltation is one of the process for sand and dust transportations. Sand movement makes geomorphological changes in not only desert and coastal area but other planets. In this study, we focus on the saltation splash. When saltation sand particles hit grounds, not only dust but other sands are newly emitted to the atmosphere. The new sand emission from grounds induced by saltation is known as ″ splash″. The splash particles receive energy from impacting saltation particles and can move as creeping or new saltation. The emitted new sand particles (splash particles) directly get energy from wind and accelerate the particle velocity. Then, they might behave as new impacting (saltation) particles. By repeating saltation and splash, large amount of sand and dust are supplied to the atmosphere more and more.
In order to clarify the mechanism of splash, wind tunnel experiments are conducted in Forestry and Forest Products Research Institute, Tsukuba, Japan. Toyoura sand is used as saltation particle and three soils are used as a target soil, 1) Mongol soil which has both finer and larger particles (Loam) sampled at Tsogt-Ovoo in the northern Gobi Desert, Mongolia, 2) Toyoura sand, and 3) Kasaoka clay. Sand splash is measured by using a high-speed camera. The frame rate is set to 30000 fps in order to capture particles as clearly as possible. PTV (Particle Tracking Velocimetry) method is used to analyze the particles motion. As a result, when the velocity of saltation particle is about 7.0 m s^{-1}, the mean velocity of splashing particles is 2.8 m s^{-1}. A reduction of kinetic energy of saltation particle is evaluated after hitting the ground surface. These findings are fundamental for elucidating the process of saltation and will link to improve dust forecasting accuracy of atmospheric dust transport models.

Isotopic fractionation of methane gas with clathrate hydrate formation under the condition of ice crust / internal ocean boundary in icy satellite

*Kushi Kudo[1], Atsushi Tani[1], Keita Yamada[2], Naohiro Yoshida[2,3]

1. Department of Human Environmental Science, Graduate School of Human Development and Environment, Kobe University, 2. Department of Chemical Science and Engineering, School of Materials and Chemical Technology, Tokyo Institute of Technology, 3. Earth–Life Science Institute, Tokyo Institute of Technology

Icy satellites have capability of having extra biota due to eruption of plume, which is consisted by sea ice particles including organic matter. The observation using Cassini clarified that this plume included hydrogen molecule (H_2), CO_2, methane (CH_4) and organic matter (e.g. Porco et al. 2006; Waite et al. 2006, 2009, 2017). Especially in plume gas species, methane (CH_4) is regarded as one of the candidate of signature of biological activity due to CH_4 formation reaction by methanogen. However CH_4 gas in plume is consisted of not only microbial origin but also primitive and/or hydrothermal origin and this fact does not let CH_4 detection is sufficient for conclusion for existence of biological activity by microbe. Therefore, we consider that evaluation of the elementary process of CH_4 isotopic fractionation ($\delta^{13}C$ and δD of CH_4) via room experiment is important for isotopic observation of icy satellite in nearly future.

In this study, we focus on CH_4 hydrate which is reservoir to produce the plume (Kieffer et al. 2006) and plan to evaluate isotopic fractionation with its formation. Isotopic fractionation with hydrate formation has been found at only δD of CH_4 (~10‰) at the Earth condition (P: ~6 MPa) (e.g. Hachikubo et al. 2007, 2015; Lapham et al. 2012). In the case of condition of icy satellites and icy planets, the pressure range is wider than of the Earth, and therefore we need to estimate isotopic fractionation (P: 5–50 MPa).

We formed clathrate hydrate samples using hydrate formation equipment under the extreme environments, which can hold until 50 MPa. We lowered cell temperature from room temperature to 276 K, and then stirred CH_4 gas and pure water at 85 or 400 RPM stirring rotation speed to form hydrate sample. We inserted CH_4 gas at slightly higher pressure than the previous studies (5, 10 MPa). We collected gas samples of primitive gas from CH_4 gas cylinder and remained gas samples from the high pressure cell after hydrate formation, and then we measured stable isotopic ratio ($\delta^{13}C$ and δD of CH_4) using GC-IRMS equipment at Tokyo Tech.
Results in isotopic measurements show that the $\delta^{13}C$ value of remained gas phase was slight lower (less than 1‰) than of primitive gas phases and became lower at higher pressure. This suggest that 1) $^{13}CH_4$ and $^{12}CH_4$ easily condensed into gas phase in hydrate and remained gas phase (plume) with clathrate hydrate formation, respectively, and 2) this condensation became stronger at higher pressure. Furthermore, the $\delta^{13}C$ value of remained gas phase became lower at faster stirring rotation speed. Since Wijayanti (2018) reported that hydrate formation rate, stability and storage capacity became higher at higher stirring rotation speed, the above tendency of stronger isotopic fractionation at higher stirring rotation speed is acceptable. We found slight isotopic fractionation unlike in the previous reports. As the isotopic fractionation easily occurs by pressure, we plan to proceed the experiment at higher pressure. These tendencies indicate that isotopic fractionation of CH_4 with clathrate hydrate formation in icy satellites may depend on pressure and stirring rotation speed in internal ocean water–CH_4 gas mixing.

Observation of the interface between ice and water under high pressure with gas as a simulation of the bottom of ice crust in icy bodies

*Kenshiro Moriyama[1], Atsushi Tani[1]

1. Department of Human Environmental Science, Graduate School of Human Development and Environment, Kobe University

Gas hydrates are clathrate compounds where hydrogen-bonded water cages include a guest gas molecule. Methane hydrate is one of famous gas hydrates because it is naturally found in deep-sea and permafrost sediments on the Earth. Gas hydrates would exist in icy bodies as well. One of the candidates is Pluto where the presence of subsurface ocean is suggested. Gas hydrates may exist between the ice shell and the subsurface ocean and play an important role as insulator to keep warm inside. The presence of subsurface ocean is also suggested in some icy satellites like Enceladus. INMS (Ion and Neutral Mass Spectrometer) aboard the Cassini orbiter has investigated composition of the plumes there that includes H2O (< 90 %), CH4, CO2, NH3, and other various organic materials. These results could reflect the composition of the subsurface ocean and imply the presence of clathrate hydrates in the ocean. Density of gas hydrates depends on guest gas molecules. For example, methane hydrate is lighter than the water, whereas CO2 hydrate is heavier. If CO2 hydrate forms at the bottom of the icy shell, the average density may become large and the ice (water ice + CO2 hydrate) may start to sink locally. If the size of each gas hydrate become small and granular gas hydrates exist in subsurface ocean, heat can be transferred by not only thermal conduction but also convection. This means that icy bodies may be cooled faster. To elucidate how gas hydrates form in the subsurface ocean in icy bodies, we developed the observation system of gas hydrate formation and dissociation below the ice sheet. The observation system was set in the thermostatic cooling bath after it was filled with water. As temperature in the cell degreased, water ice was formed in the lower part of the cell and high pressure gas was supplied. In this study, we used CF4 gas to increase the pressure in the system to form CF4 hydrate. It is heavier than water and should sink in the water cell, if it is formed. After several experiments, we found that the surface of water ice slightly changed to hold CF4 gas on the ice surface.

H_2-rich hydrothermal environment in the Enceladus' subsurface ocean

*Takazo Shibuya[1], Sota Numaho[1,2], Hisahiro Ueda[1], Sakiko Kikuchi[1], Yutaro Takaya[3], Takuya Saito[1], Mariko Abe[1], Masaru Tomita[2], Ken Takai[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Keio University, 3. Waseda University

Saturn's icy moon Enceladus has a global ocean beneath the icy crust and is presently discharging water-vapor plume from its south pole. The discovery of silica nanoparticles derived from the plume strongly suggested the presence of ongoing seafloor hydrothermal activities hosted by chondritic rocky core (Hsu et al., 2015; Sekine et al., 2015). Furthermore, the Cassini spacecraft detected molecular hydrogen (H_2) from the plume, which pointed to the energetic habitability of H_2-utilizing living forms sustained by the hydrothermal serpentinization of the rocky core (Waite et al., 2017). In this work, we conducted a hydrothermal experiment using synthetic metal-free chondrite and alkaline fluids at 200 ˚C, 200 bars to assess (1) whether the serpentinization of rocky core has the potential to satisfy the observed hydrogen flux from the subsurface ocean to the space and (2) the habitability of H_2-utilizing living forms based on the H_2 concentration of potential hydrothermal fluid generated in the seafloor hydrothermal systems.

The results show that the H_2 concentration in the fluid increased up to 14.6 mmol/kg 5,760 hours after the beginning of the experiment, which indicates that water-chondrite reactions likely generate H_2-rich hydrothermal fluid. 3D tidal heating simulations indicates that more than 10 GW of heat can be generated by tidal friction and that water transport in the tidally heated permeable core can also generate hotspots (1–5 GW) at the seafloor in the south pole region (Choblet et al., 2017). If it is assumed that the heat flux of hotspots is totally carried by 200-degree C hydrothermal venting, the H_2 flux at the south pole seafloor is estimated to be 5.2×10^8–2.6×10^9 mol/year, corresponding to 10–260 % of the H_2 flux (1–5×10^9 mol/year) observed by Cassini spacecraft. Therefore, the observed H_2 flux can be partially or completely explained by hydrothermal activities near the south pole hotspots. Of course, if lower-temperature but global hydrothermal activities are present, the seafloor water-chondrite reactions would sufficiently account for the observed H_2 flux.

The high H_2 concentration of fluid in the experiment corresponds to those of peridotite-hosted seafloor hydrothermal systems on Earth. Considering that hydrogenotrophic methanogens certainly exist in most of the terrestrial peridotite-hosted hydrothermal systems, the results suggest that the hydrothermal systems on Enceladus are capable of sustaining hydrogenotrophic methanogenesis if temperature of venting hydrothermal fluids is close to 200 degrees C. Further water-chondrite experiments at temperatures lower than 200 degrees C would provide more constraints on the temperature of hydrothermal systems and the habitability of H_2-utilizing living forms within Enceladus.

Abiotic nitrate reduction in hydrothermal environments and nitrogen cycle in early earth

*Manabu Nishizawa[1], Takuya Saito[1], Akiko Makabe[1], Takazo Shibuya[1], Ken Takai[1]

1. Japan Agency for Marine-Earth Science and Technology

Nitrogen is an essential element for life as a major component of biomolecules and a substance for energy metabolism. Currently, nitrogen cycle in surface environments is mainly driven by biological processes including nitrogen fixation, nitrification and denitrification. In contrast, little is known about nitrogen cycle in the pre-biotic Earth and its relation to chemical evolution. This study focuses on nitrate chemistry during water-rock interaction in deep-sea hydrothermal environments to understand the fate of atmospherically-derived nitrate in the Hadean ocean. In this study, artificial seawater with nitrate was reacted with synthetic komatiite at i) 250°C and 500 bar or ii) 350°C and 500 bar, using a closed system hydrothermal reactor reaction cell. To unravel the pathway and kinetics of nitrate reduction, time course measurements of chemical and nitrogen isotopic composition of fluid samples were conducted during the ongoing experiments. Our experiments show multi-step reduction of nitrate to ammonium and dinitrogen and temperature-dependence on the molar ratio of final products (NH_4^+/N_2). The experimental results imply that the Hadean deep-sea hydrothermal vents may have been favorable for chemical evolution in that both electron acceptor for energy metabolism (nitrate) and reduced nitrogen for organic synthesis (ammonium) were continuously supplied to the hydrothermal fluid-seawater mixing zone.

Experimental study of phosphorus dissolution from hydroxyapatite in liquid CO_2

*Kaito Seo[1,2,3], Takazo Shibuya[3], Fujishima Kosuke[4], Ken Takai[3], Masaru Tomita[1,2]

1. Graduate School of Media & Governance, Keio Univ., 2. Inst. Adv. Biosci., Keio Univ., 3. X-Star, JAMSTEC, 4. ELSI, Tokyo Tech

Phosphorus (P) is known as one of the essential elements for life. It is incorporated in various macromolecules like DNA and RNA, phospholipids that forms cell membrane, as well as the energy currency and cofactors including but not limited to ATP, Acetyl-CoA and NADPH [1]. In the biogeochemical P cycle, oceanic content is far less than that on land, due to low solubility of phosphate minerals in seawater [2]. On Earth, major mineral that contains P is apatite [$Ca_5(PO_4)_3$-(F,Cl,OH)] in which, over 95% of P in the crust is included [3]. Few studies suggest additional supply sources of P through meteorites or other terrestrial minerals but their contribution to early chemical evolution is still under debate[4]. Under the ocean floor near hydrothermal vent sites, pool of liquid carbon dioxide (CO_2) was found [5,6]. Liquid CO_2 has unique property as a solvent, which can dissolve various hydrophobic chemical compounds including alcohols, carboxylic acids, phenol, esters, amides, etc., that are in many cases insoluble in water [7,8]. It is plausible that such liquid CO_2 reservoirs likely existed on hadean Earth, due to higher CO_2 concentration in the atmosphere [9] and deeper ocean compared to today. Apatite is known for their insoluble nature in seawater, however it has been shown to dissolve in CO_2 rich brines [10]. Hence, in this study, we performed dissolution of P from the powder of hydroxyapatite in liquid CO_2 saturated system with aqueous solution and analyzed the P concentration in both liquids.

Effects of minerals on the formose reaction: implication for the potential ribose formation on ancient Mars

*Chinatsu Ono[1], Takeshi Kakegawa[1], Yoshihiro Furukawa[1]

1. Graduate School of Science, Tohoku University

DNA, RNA, and proteins work together to support the essential system of the present life. RNAs catalyze biological reactions as well as have nucleotide sequence transcribed from DNA. Therefore, abiotic RNA formation has been regarded as an essential step of the origin of life. Ribose is an essential constituent of RNA and is known to form in the formose reaction in which a series of condensation and polymerization of formaldehyde under alkaline condition forms many sugar molecules. Thus, formose reaction on prebiotic Earth has been investigated intensively. On the other hand, chemical evolution might have happened on the other planets in some extent. Mars, one of the candidates of past habitable planet, is shown to have liquid water on the surface and/or subsurface and had CO_2-rich atmosphere. Thus, photochemical formaldehyde formation would have been possible on ancient Mars. However, ribose formation on ancient Mars has not been investigated. Therefore, this study investigates effects of ancient Martian environments to the formose reaction and evaluated potential ribose synthesis on ancient Mars. In particular, this study investigates effects of minerals potentially presented on ancient Mars. Phyllosilicates such as saponite distribute widely in Noachian sediments. Carbonates such as magnesite, siderite, and calcite have been found from sediments close to the Noachian phyllosilicate-rich sediment. The Gale crater sediments suggests a neutral pH of the lake water on Noachian Mars. On the other hand, sulfides such as jarosite and gypsum were known to present in Hesperian sediments and suggest the presence of acidic aquatic environments on Hesperian Mars.

The formose reaction experiments were conducted with formaldehyde and glycolaldehyde with minerals. Ribose formation was accelerated in neutral solution with several minerals. The residual amount of formaldehyde was decreased with increasing reaction. Ribose formation was not seen in acidic solution (pH: ~4) with/without minerals, although tetroses were formed.

These results suggest that ribose was spontaneously formed from formaldehyde and glycolaldehyde in neutral aquatic environments implying that ancient Mars promoted sugar-forming chemical evolution.

Hydrogen generation by water-rock reactions on the early Mars

*Hisahiro Ueda[1], Takazo Shibuya[1]

1. JAMSTEC

Clay minerals such as serpentine and chlorite was observed in Mars' s Noachian terrains, which are interpreted as evidence for early weathering, hydrothermal activity, and diagenetic aqueous environments (Ehlmann et al., 2011; Mcsween et al., 2016). This indicates that serpentinization occurred and possibly hydrogen was generated. The H_2 is an important molecule as one of energy sources for hydrogenotrophic chemotrophs and as a reducing agent in the Mars' surface environment.

Olivine is commonly exposed in Mars' s crustal rocks such as Gusev basalt and meteorite and its Fe content is higher than that in the Earth (Ehlmann and Edwards, 2014; Morris et al., 2010). Because thermodynamic calculations suggest that potential for the H_2 generation by olivine hydration becomes higher with increasing Fe content in olivine (Klein et al., 2013b), a larger amount of H_2 production via water-rock interactions is expected on the early Mars. However, it has not revealed how SiO_2 and Al_2O_3 contents affect H_2 generation during reactions between Gusev basalt and fluid, as discussed for terrestrial equivalents by reported Frost and Beard., (2007) and Shibuya et al., (2015). Furthermore, since in addition to presence of Mg-Fe-Ca carbonate minerals in the surface (Niles et al., 2013), atmospheric CO_2 level on the early Mars could be high (Kurokawa et al., 2018; Ramirez et al., 2014), the serpentinization and H_2 generation on the early Mars is also possibly limited by incorporation of Fe into carbonate minerals during alteration (Ueda et al., 2016).

In this study, we conducted two hydrothermal experiments to examine the amount of H_2 generated by reactions between synthetic Gusev basalt and CO_2-free and -rich fluids at 300 ˚C, 200 bars, respectively. The synthetic Gusev basalt includes olivine, Cr-spine and glass, and shows spinifex texture as observed for terrestrial komatiites.

The results of the experiment under the CO_2-rich condition show that ΣCO_2 concentration in the fluid decreased from about 400 mmol/g to 90-100 mmol/kg, which suggests formation of carbonate minerals. The H_2 concentration in the fluid increased up to ~2 mmol/kg under the CO_2-rich condition and up to about 1.4 mmol/kg under the CO_2-free condition, approximately 2500 hours after the beginning of the experiment. The observed trend that H_2 concentration in the fluid generated under CO_2-rich condition is higher than that under CO_2-free condition is inconsistent with the previous experiments using terrestrial komatiites (Ueda et al., 2016). This is possibly because the experiments have not yet reached a steady state and /or because the precipitated carbonate minerals have not included Fe as ferrous iron. The results suggest that H_2 generation potential of hydrothermal alteration of Gusev basalt, regardless of CO_2 -free or -rich condition, is greater than normal basalts and less than ultramafic rocks (peridotite) in the Earth (e.g., Seyfried et al., 2007). Thus, the results imply that the water-rock reactions on the ancient Mars provide the amount of H_2 enough to maintain life' s ecosystem.

Impact-generated hydrothermal systems that can promote organic synthesis: Implications for the origin of life

*Kazumu Kaneko[1], Yasuhito Sekine[2], Takazo Shibuya[3], Hisahiro Ueda[3], Natsumi Noda[2,4]

1. Department of Earth and Planetary sciences, School of science, Tokyo Institute of Technology, 2. Earth-Life Science Institute, Tokyo Institute of Technology, 3. Japan Agency foe Marine-Earth Science and Technology, 4. Department of Earth and Planetary science, Graduate School of science, The University of Tokyo

Understanding of geological processes responsible for prebiotic organic synthesis on Hadean Earth is critical for the origin of life. Hydrothermal systems are suggested to be a promising emergence place of life given both of the presences of early chemoautotrophs in current hydrothermal vents and chemical gradients (e.g., Martin et al., 2008). However, organic synthesis, such as CH_4 formation, through reduction of CO_2 are considered to be inhibited even high abundances of H_2 without metallic catalysts (e.g., Shibuya et al., 2013, McCollom, 2016). On the other hand, life would have emerged on Earth at least in 3.95 billion years ago, which is coincident with the end of the late heavy bombardment period. Recent studies suggest that impacts of differentiated bodies (e.g., metallic small bodies) would have provided Fe-Ni alloy into the impact craters (e.g., Kendall and Melosh, 2016), where hydrothermal systems could have been subsequently induced due to impact heating (e.g., Osinski et al., 2013). Here, we perform both hydrological modelling and hydrothermal experiments to examine the possibilities of prebiotic organic synthesis within an impact crater of differentiated bodies on early Earth.

Using the hydrological model, we reproduce hydrothermal groundwater circulations emerged within an impact crater with diameter of ~200 km. Our model results show that a large-scale hydrothermal circulation occurs within whole of the crater when the heat source is 200ºC beneath the crater. In this large-scale circulation, upwelling of hydrothermal groundwater occurs mainly at the crater floors where the altitudes are lowest. In contrast, our results also indicate that multiple circulation cells appear within the crater when the heat source is 300ºC. In the small-scale circulations, groundwater experiences temperatures up to ~200ºC and, then, rapidly upwells into the crater cavity. Our results suggest that hydrothermal circulations would be closed within the crater cavity if the heat source is 200ºC or greater. The experienced temperature would be ~200ºC in the hydrothermal circulations.

We conducted hydrothermal experiments using a $^{13}CO_2$-containing (99.99 % ^{13}C), NaCl solution and a powder mixture of synthesized basaltic rocks and Fe-Ni alloy at temperatures of 200ºC and 300ºC and a pressure of 300 bars. Although almost initial CO_2 (~ 90 %) is fixed as carbonate mineral, we find the formation of $^{13}CH_4$, $^{13}C_2H_6$, and HCOOH (or $HCOO^-$) from CO_2 in fluid samples collected during the experiments. C_3H_8 is also found in the experiment of temperature of 200ºC. Hydrothermal alterations of basaltic rocks control fluid pH as alkaline (pH ~8–9) (Shibuya et al., 2013), where reactive HCO_3^- is stable and is reduced to form $HCOO^-$ using H_2 in fluids. Metallic Fe-Ni alloy would be a catalyst to hydrogenate $HCOO^-$ to CH_4. Based on the low H_2 concentrations in the fluids, the rate limiting reaction of CH_4 formation is highly likely H_2 production due to oxidation of metallic Fe. Given the low activation energy of oxidation of metallic Fe (30 kJ/mol: Grosvenor et al., 2005), CH_4 formation proceeds effectively even at low temperatures, such as 200ºC.

Combining these results, we suggest that impacts of differentiated bodies would have provided hydrothermal environments, where reduced organic molecules are effectively provided. Produced CH_4 and other hydrocarbons could be converted to prebiotic organics, such as HCN or HCHO, through

©2020. Japan Geoscience Union. All Right Reserved.

photochemical reactions. The formation process of CH_4 from CO_2 is similar to the carbon fixation of anaerobic chemoautotrophs, such as methanogen; namely, methyl branch of acetyl CoA pathway. Our results imply that impact-generated hydrothermal systems could provide a promising place where early life could have acquired metabolic pathways on Earth.

Clumped isotope signatures of abiotic methane formed via Fischer-Tropsch catalysis and their implications

*ZHANG NAIZHONG[1], YASUHITO SEKINE[1], MAYUKO NAKAGAWA[1], NAOHIRO YOSHIDA[1]

1. Earth-Life Science Institute, Tokyo Institute of Technology

The isotopic compositions of CH_4, such as $^{13}C/^{12}C$ and D/H ratios ($\delta^{13}C$ and δD, respectively), are widely used as a tracer for identifying the CH_4 formation processes. However, obvious defects are existent, such as partly overlapping of isotopic signatures for different CH_4 sources, difficulty in constraining CH_4 generated from two or more sources, and so on (Douglas et al., 2017). Very recently, CH_4 clumped isotope signatures has been considered as a helpful constraint to provide more information on origins of natural CH_4 (e.g. Douglas et al., 2017; Young et al., 2017).

The clumped isotope refers to molecules substituted by two or more rare stable isotopes, e.g. $^{13}CH_3D$ and $^{12}CH_2D_2$, whose abundance relative to a random distribution is temperature dependent (Stolper et al., 2014). Therefore, the formation temperatures of CH_4 can be obtained if the reactions are in isotopic equilibrium. On the other hand, kinetic effect will introduce disequilibrium clumped isotope values, which can be used in identifying specific process/mechanism (Stolper et al., 2015). Overviewing the literature of CH_4 clumped isotope, almost all of the studies focused on the microbial and thermogenic CH_4 samples so far, while limited abiotic data has been reported by Young et al. (2017) and Wang et al. (2018) only. Two preliminary results of low-temperature Fischer-Tropsch Type (FTT) reaction (Sabatier reaction) using ruthenium (Ru) as catalyst presented strongly disequlibrated clumped isotope signals, which was considered to be caused by quantum tunneling effect (Young et al., 2017). On the other hand, lack of clumped isotope data from other FTT reaction with different catalyst and reactant, limiting this technique as a tool to identify the pathways of natural abiotic CH_4 formation.

In this study, we will present the clumped isotopic signatures of laboratory produced abiotic CH_4 via gaseous FTT reactions, using various experimental parameters and catalysts, such as Ni, Fe, Ru and Co. Both $\Delta^{13}CH_3D$ and $\Delta^{12}CH_2D_2$ values are analyzed using a 253 Ultra High Resolution Isotope Ratio Mass Spectrometer established in Earth-Life Science Institute (ELSI), Tokyo Institute of Technology, following the similar procedures described in Eldridge et al. (2019). We will discuss the controlling factors of clumped isotopic signatures in laboratory produced abiotic CH_4, and try to apply these results in clarifying the producing mechanism of natural abiotic CH_4 gases, which might provide more information to illustrate the early earth environment and life origin, as well as other planet with abiotic CH_4 existent.

Development of novel characterization method for extraterrestrial clay mineral

*Kosuke Inoue[1], Keisuke Fukushi[2], Koki Morida[3], Hiroki Suga[4], Yoshio Takahashi[4]

1. Kanazawa University , 2. Institute of Nature and Environmental Technology, 3. Graduate School of Science, The University of Kanazawa, 4. Graduate School of Science, The University of Tokyo

Clay minerals, a kind of hydrous minerals that may be included in meteorites, are generated in the presence of liquid water. There are a wide variety of clay mineral species depending on their mineral content and coordination positions. The mineral species of clay minerals are related to their formation environment (e.g., the cation compositions and/or the Eh-pH condition). Therefore, the characterization of clay mineral species can reveal the water environment of extraterrestrial material such as meteorite when they were formed. In this study, we focused on the “scanning transmission X-ray microscope (STXM)” as a new tool for analyzing meteorite samples containing clay mineral species. The purpose of this study is to collect X-ray absorption spectra of the major elements from various standard clay minerals on the earth for the construction of a database for the identification of clay minerals species in the actual meteorite samples such as Martian meteorite.

Evolution of aqueous environment on Early Mars inferred from reconstructed water chemistry at Gale

*Keisuke Fukushi[1], Yasuhito Sekine[2,1]

1. Institute of Nature & Environmental Technology, Kanazawa University, 2. Earth-Life Science Institute, Tokyo Institute of Technology

There is a wealth of geomorphological and mineralogical evidence indicating the presence of liquid water on early Mars. The NASA rover Curiosity has conducted a geological survey of the successive lacustrine and eolian sediments from Gale crater, a former lake on Mars, and provided mineralogical and geochemical data of the sediments. We developed a methodology for quantitative estimation of the water chemistry of the pore water in the sediments based on exchangeable cation compositions in the smectite and the salt mineralogy (Fukushi et al 2019). We applied the methodology to the lacustrine sediments from Yellowknife Bay formation, the lowermost layer of Gale crater observed by Curiosity, and found that the water chemistry was of Na-Cl type with moderate salinity (0.1-0.5 mol/kg) and circumneutral pH (Fukushi et al 2019). The Curiosity has obtained the mineralogical and geochemical data from the several lacustrine sediments from Murray formation, the upper layer of Gale crater, and showed the presence of smectite and some authigenic minerals in the sediments. In present study, we applied the methodology to the sediments from the Murray formation. The environmental condition to produce the water chemistry in the Murray formation and the evolution of water environment at Gale will be discussed in this presentation.

Effective formation of Al-rich surface clays through acidic water activity on early Mars

*Mitsuteru Sugiuchi[1], Yasuhito Sekine[2], Shuya Tan[2,3], Natsumi Noda[2,3], Yoshio Takahashi[3], Ramses M Ramirez[2]

1. Department of Earth and Planetary Science, School of Science, Tokyo Institute of Technology, 2. Earth-Life Science Institute, Tokyo Institute of Technology, 3. Department of Earth and Planetary Science, Graduate School of Science, The University of Tokyo

Remote sensing observations have revealed a widespread occurrence of weathering profiles in the low-latitude regions of Mars (e.g., Bishop et al., 2008, Murchie et al., 2009). The weathering profiles consist of Al-rich clays and sulfate minerals in the upper part and Mg/Fe-rich clay minerals in the lower part (Murchie et al., 2009; Bishop et al., 2008). These secondary minerals would have been formed through water-rock reactions between basement rocks and infused surface water on early Mars (Zolotov and Mironenko, 2016, Bishop et al., 2018). The previous geochemical model suggests that Al-rich clays may have formed due to water-rock reactions near pH 8 in a prolonged warm period (~10^6 years) (Bishop et al., 2018). Although the timescale may be consistent with a proposed formation time of valley networks, the spatial distribution of the weathering profiles on Mars does not always agree with that of valley networks. This may imply that the formation of Al-rich clays may not be simply formed as a result of the same water activity that formed valley networks.

In the present study, we perform laboratory experiments of chemical weathering using a newly-developed flow-through type reactor, in which solution is continuously infused into Martian soil analogues. We used two types of solution: One is pure water in dissolution equilibrium with 1 bar of CO_2 (pH ~ 4) and the other is sulfuric acid solution in dissolution equilibrium with 1 bar of CO_2 (pH ~ 1). Our experimental results using pure water in equilibrium with CO_2 show that pH values near the top of the reaction vessel are 4–5 owing to high levels of dissolved CO_2; whereas, in the lower part of the reaction vessel, pH are 6–7 owing to pH buffer by carbonate mineral. Under this weakly acid to circumneutral pH conditions, a supply of Al and Si into pore water is limited owing to slow dissolution of plagioclase. Since olivine dissolves effectively in this pH range, Mg carbonate forms in the reaction vessel. On the other hand, our experimental results using acidic sulfuric solution show that pH at the top of the reaction vessel becomes 2–3 owing to pH buffer by sulfate mineral. In the lower part of the reaction vessel, pH becomes 5–6 owing to cation supply by dissolution of primary minerals. At the top of the reaction vessel with pH 2–3, Al, Si and Mg are effectively supplied to the pore water owing to rapid dissolution of both plagioclase and olivine. Since the pore water including these ions is infused into the lower part with pH 5–6, Al-rich clay mineral, montmorillonite, precipitates in the reaction vessel. After consumption of Al and Si in pore water due to deposition of Al-rich clays, Mg-rich clay mineral, Mg saponite, forms subsequently in the lower part of the reaction vessel. The formation order of the secondary minerals in the experiment using acidic sulfuric solution is consistent with the weathering profiles observed on Mars. Based on the measured Al contents in the pore water, we suggest that Al-rich clay deposits of the weathering profiles can be generated rapidly (~10^3 years) by infusion of acidic surface water enriched in sulfuric acid. The weathering profiles may have formed upon transient warming at locations where sulfuric acids accumulated on early Mars; whereas, valley networks would have formed at locations where precipitation rates were high.

The Preparation for Return Sample from Asteroid Ryugu by STXM at KEK-PF

*Hiroki Suga[1,2], Sakiko Kikuchi[3], Shuya Tan[1,4], Shohei Yamashita[2], Yasuo Takeichi[2], Daisuke Wakabayashi[2], Masao Kimura[2], Yoshio Takahashi[1,2], Yasuhito Sekine[4]

1. Graduate School of Science, The University of Tokyo., 2. Institute of Materials Structure Science, High Energy Accelerator Research Organization (KEK)., 3. Institute for Extra-cutting-edge Science and Technology Avant-garde Research (X-star), Japan Agency for Marine-Earth Science and Technology (JAMSTEC)., 4. Earth-Life Science Institute (ELSI), Tokyo Institute of Technology.

Hayabusa2 mission aimed at conducting sample return from a C-type asteroid named Ryugu, which is considered to be the parent body of the carbonaceous chondrite. As for the formation process of the Ryugu, the following hypotheses have been considered (i) internal heating case by short-lived radionuclide, (ii) impact heating case, (iii) incipient aqueous alteration case, and (iv) masking case by darker organic matter contributing to the low reflectance of Ryugu. If we can extract the information about the past collision and the water environment from the organic matter and secondary minerals in the actual Ryugu return sample, the scenarios above can be determined. In 2019, we analyzed the organic and inorganic simulated samples using a new Scanning Transmission X-ray Microscope (STXM) installed at BL-19A of Photon Factory.

As for the analog of the extraterrestrial organic matter, recovered samples of organic simulants of planetary bodies (OSPBs) from impact experiment described in [Sekine et al., 2018, MAPS] was used. STXM measurement was performed for the shock experienced OSPBs which recovered from shock wave with 0, 2, 5, 10, and 12 GPa. On the other hand, synthesized secondary saponite which was described in [Kikuchi and Shibuya, 2019, Asteroid Science 2019, #2049] was used. After the 100 days synthesized experiment, the newly formed fibrous minerals were notably observed at the surface of the original olivine, these minerals were identified as a saponite by the lattice fringes using TEM. Both of these samples were dropped on the Formvar-membrane supported Cu-mesh grid before the STXM measurement. The exposure time of clay sample to the atmosphere was less than 3 min before it was mounted on the STXM to prevent oxidation of Fe(II) in saponite. STXM stack measurement was conducted to C K-edge of OSPBs and Fe L_{III}-edge of synthesized saponite. Several grains were measured to guarantee the reproducibility. In addition, repeated stack measurement (9 times) was conducted to confirm the X-ray irradiation damage.

The C-XANES feature of shock-recovered OSPBs above about 7 GPa and 400 ˚C, which would be achieved in a typical asteroid belt collision, showed that the aromatic and graphite peaks are dominant with broad shape. From these results, we can summarize that (i) the aromatic and graphite peaks were not remarkable in the unheated sample, (ii) the aromatic and graphite peaks were confirmed but broad in the collision experienced sample, and (iii) the aromatic and graphite peaks become sharp and remarkable in the long-term heating sample. It is indicated that to distinguish between short-term heat event by collision and long-term heating event by radioactive elements is possible by C-XANES features.

Even if saponite is a common product of the low-temperature water-rock reaction between water and mafic minerals on Earth, Fe(II)-saponite is easily oxidized to Fe(III)-saponite under the atmospheric condition. In this study, the Fe(II) in the saponite is obviously detected by the minimized oxidation. Besides, we checked the beam damage on the Fe(II)-saponite oxidation by repeating measurements in the same field of view, the peak intensity of Fe(III) did not increase clearly shown. These results suggested that

©2020. Japan Geoscience Union. All Right Reserved.

STXM is better enough to identify the Fe(II)-saponite, and the best measurement condition of the extraterrestrial secondary minerals is an air-isolated system throughout the sample preparation to the analysis.

Throughout this study, the C-XANES analysis results of OSPBs gave us the evaluation criteria to determine the Ryugu formation scenarios. The synthesized redox-sensitive clay minerals analysis by STXM-XANES also contribute to the detailed identification of clay mineral species and its related water redox condition, which is also useful to determine scenarios of Ryugu alteration.

Clustering analysis of Ryugu spectral data obtained by NIRS3 infrared spectrometer onboard Hayabusa2 spacecraft

*Moe Matsuoka[1], Hikaru Iwamori[2], Deborah Lolin Domingue[3], Tomohiro Usui[1], Kohei Kitazato[4], Takahiro Iwata[1]

1. ISAS/JAXA, 2. Earthquake Research Institute, the University of Tokyo, 3. Planetary Science Institute, 4. University of Aizu

The Near-infrared Spectrometer (NIRS3) onboard the Hayabusa2 spacecraft obtained near-infrared (NIR) reflectance spectra of C-type asteroid 162173 Ryugu at an altitude of ~20 km from July 10-12 2018 with a spatial resolution of ~40 m (Box-A). The NIRS3 data, ranging from 1.8–3.2 μm with a spectral sampling resolution of 18 nm [1], show a 2.72-μm OH stretching absorption and a low reflectance which are globally homogeneous and similar to moderately-heated or shocked carbonaceous chondrite spectra [2, 3].

This study performs cluster analysis of Ryugu's NIR spectral data using a new statistical method [4] based on combinations of k-means cluster analysis (KCA), principal component analysis (PCA), and independent component analysis (ICA) for the seven channels ranging from 1.8 to 3.0 μm with ~200 nm interval and one channel at 2.72 μm of NIRS3 Box-A data. We performed three-step cluster analysis: (1) standardization and whitening of the original data using PCA, (2) dimension reduction of the data by selecting principal components (PCs) with significant eigenvalues and the corresponding scores of the individual data, and (3) performing KCA (and ICA) [4]. Whitening is essential to extract the independent features hidden in the data, which is not possible only by standardization.

The preliminary result of KCA and PCA using photometric-corrected Box-A global data obtained on July 11th 2018 shows that the data variation can be characterized with three significant PCs. We performed KCA using the values of these three PCs as the whitened and dimension-reduced data. To find the optimal number of clusters (k), k was varied from five to eight. The case with k = 6 (Fig.1) best captures the spectral properties. Regional heterogeneity is observed, even in the northern equatorial region which displays homogeneous morphologies in the Optical Navigation Camera Telescope (ONC-T) images [3].

All the clusters have a common OH-absorption at 2.72 μm with similar depths, yet they have differences in albedo and slope. The brightest average spectra are distributed around the equatorial ridge and in the Southern hemisphere around 150 to 300 degrees in longitude. The reddest spectra are located in the Southern region around 90 to 150 degrees in longitude. Interestingly, the spectra of the pole regions are grouped into the same clusters as those distributed in other areas. In addition to global thermal alteration, more plausible causes producing this NIR feature differences possibly reflecting variations in; (a) carbon content, (b) opaque material abundance, (c) grain size and porosity, and (d) space weathering maturation across the surface of Ryugu. A previous clustering study [5] suggest that NIR clusters indicate hydrous mineral contents variation. Our study further proposes a possible grain size and porosity variation to explain the spectral reddening.
In this study we found that the clustering results indicate NIR spectra would have a heterogeneity depending on location. For further study, we will perform KCA, PCA, and ICA analyses using photometric-corrected NIR data of lower altitude observations.

Figure 1. A NIRS3 spectral cluster map using data obtained on July 11th 2018 at ~20 km altitude. The six

clusters are separately distributed possibly reflecting the geomorphology and/or surface mineralogical/physical properties.

Recognition and classification of Martian chaos terrains using imagery machine learning

*Hiroki Shozaki[1], Yasuhito Sekine[2], Nicholas Guttenberg[2,3]

1. Tokyo Institute of Technology, School of Science, Dept. of Earth and Planetary Sciences, 2. Earth-Life Science Insitute, Tokyo Institute of Technology, 3. Cross Compass Ltd.

Chaos terrains on Mars are irregular to circular fractured areas that consist of jumbled knobs and polygonal flat-topped blocks (e.g. Pedersen et al., 2014) . The blocks of the chaos terrains vary in size (kilometers to tens of kilometers) and shape depending on locations (e.g. Pedersen et al., 2014) . The blocks are surrounded by depressions with altitude difference of typically 1–2 km (e.g. Warner et al., 2011) . Chaos terrains locate primarily in Valles Marineris, with the numbers of ~470 individual terrains, on Mars. Based on the preservation of the original surface structures on the fractured blocks, some chaos terrains are interpreted to be collapsed terrains due to discharge of groundwater upon melting of ice (e.g. Zegers et al., 2010) . This can be supported by the fact that chaotic terrains are often associated with outflow channels (e.g. Pedersen et al., 2014) . On the other hand, others propose that based on the geomorphologic features, other chaos terrains may have been formed through different formation processes, including magma excavation (Sharp, 1973) , degradation of ground ice (e.g. Zegers et al., 2010) , and clathrate destabilization (e.g. Rodriguez et al., 2006) . Owing to high resolution images on Mars, a number of chaos terrains have been found thus far. However, only limited numbers of chaos terrains are investigated to interpret the formation mechanisms. In addition, the interpretations of the observations vary depending on the locations. This implies that there are significant differences in the morphology and possibly formation mechanisms among the chaos terrains.

In the present study, we perform imagery machine learning for the chaos terrains on Mars with aims at for recognition and classification. We used the fine-tuning VGG19 model, which was constructed by Visual Geometry Group with convolutional layer depth of 19. We prepare total 3300 images of chaotic terrains on Mars, including 1100 visible images taken with the Context Camera, CTX, in grayscale, 1100 images of thermal inertia map taken with the Thermal Emission Imaging System, THEMIS, and colored 1100 images of Mars Orbiter Laser Altimeter (MOLA) High-Resolution Stereo Camera (HRSC) blended digital elevation model (DEM) taken by Mars Global Surveyor, MGS and Mars Express, MEX. Among the chaos terrains, we define two types of chaos terrains: Ones were probably formed through the discharge of groundwater based on the previous studies (e.g. Zegers et al., 2010; Roda et al., 2014; Rodriguez et al., 2005) (221 images) , and the others were probably generated in association with magma excavation and tectonic tiles based on the previous studies (Sharp, 1973; Bamberg et al., 2014) (151 images) . We also collect 200 images of non-chaotic features, such as valley networks and impact craters, on Mars to construct the classifier.

Our preliminary results show that using THEMIS images, we can classify chaotic terrains with 83% accuracy. The constructed classifier is useful to find new chaos terrains on Mars and other planets, such as Earth. However, the accuracy to recognize whether they formed through discharge of groundwater or magma excavation is low. This means that the formation mechanisms may not be able to suggest based on only the morphology.

Reactive iron supply control dominant sulfur species in the limestones of Ediacaran Doushantuo and Dengying Formations

*Fumihiro Matsuura[1], Ryoichi Nakada[2], Yuichiro Ueno[3,2], Yusuke Sawaki[4], Masafumi Saitoh[5], Kajitani Iori[4], Tomohiro Usui[1]

1. JAXA, 2. JAMSTEC, 3. Tokyo Tech, 4. The University of Tokyo, 5. University of Lausanne

C-S-Fe systematics in modern and ancient sedimentary systems have been intensively investigated from 1970s. The availability of reactive iron limits pyrite formation in both euxinic and non-euxinic marine sediments where sufficient metabolizable organic matter is supplied. The dominant sulfur species in the most sedimentary carbonate rocks is pyrite, though organic sulfur, a second significant sink for sulfur during early diagenesis, can be a major sulfur species exceeding the content of pyrite. Relative contribution of organic sulfur on total sulfur is controlled by the supply of reactive iron. The limestones in the Ediacaran Dengying Formation, South China have minor amount of carbonate associated iron (Fe_{carb}) concomitant with low pyrite concentration compared to the limestones and dolostones in the preceding Ediacaran Doushantuo Fm.. Given the adequate TOC content in the limestones of the Dengying Fm., pyrite content is controlled by sulfate concentration or reactive iron supply. Here we investigated species and concentration of sulfur distributed within the matrix of the limestones of the Shibantan Member in the Dengying Fm. and the Member 3 of Doushantuo Fm. by μ-XRF and S K-edge X-ray absorption near edge structure (XANES) analyses. The XANES spectra of Dengying limestone show peaks corresponding to the organic sulfur and carbonate associated sulfate (CAS), whereas the XRF analyses suggests that the organic sulfur occurs in the matrix of limestones with concentrations exceeding 100 ppm. In contrast, the XANES spectra of Doushuntuo limestone indicate that the S dominantly occurs as CAS. The different characteristics observed in XANES spectra of samples collected from two Fms. suggest that sulfur cycle during the deposition of Doushantuo and Dengying Fms. were dominated by different mechanism. The abundant organic sulfur preserved in the Dengying limestone may be resulted from intense sulfurization of organic matter owing to the iron limitation during deposition. The speciation μ-XRF mapping showed that the distribution of CAS in the matrix of limestone is different between Doushntuo and Dengying limestones. The average CAS concentrations within the matrix of the two Dengying limestones are 199 ± 153 ppm and118 ±112 ppm with eliminating the outlier to make normal distribution. On the other hand, the average CAS concentrations within the matrix of the two Doushantuo limestones are 173 ±37 ppm and 199 ±53 ppm. The standard deviation of CAS concentration within the matrix of limestone in Doushantuo Fm. is much smaller than that of Dengying Fm, which shows the CAS in the limestone of the Doushantuo Fm. are distributed with small heterogeneity compared to that of the Dengying Fm. We suggest isotopic composition of a fluid possibly ocean water can be reconstructed from the limestone, in which CAS is distributed with relatively small heterogeneity, with dodging secondary vein and intense elimination of soluble sulfate.

New sulfur isotopes 1-D photochemical model for revealing early earth's atmosphere

*Yoshiaki Endo[1,2], Mark W. Claire[2], Chester E. Harman[2,3], Laura Crick[2]

1. Tokyo Institute of Technology, 2. University of St Andrews, 3. NASA Ames Research Center

Constraining the atmospheric composition of planets is essential to understanding habitability. However, the chemical composition of the early Earth's atmosphere is poorly understood. Here, mass-independent fractionation of sulfur isotopes (MIF-S) in pre-2.4 Ga sedimentary rocks provide a hint of atmospheric composition at that time. For the early Earth, it is believed that partial pressure of O_2 was very low and atmosphere was reducing. Recently, our sulfur dioxide (SO_2) photochemical experiments under carbon monoxide (CO) atmosphere reproduced the $\Delta^{36}S/\Delta^{33}S$ slope from the Archean (~−1), which is the most basic character of Archean MIF-S (Endo et al. 2016). Moreover, it was found that the MIF-S trend depends on total pressure, indicating that MIF-S is sensitive to absorption spectral shape of SO_2 via SO_2' s own UV absorption (Endo et al. 2019). We synthesized SO_2 isotopologues absorption spectra which reproduce the MIF-S of photochemical experiments (Endo et al. 2019). Therefore, we can predict MIF-S produced in various atmospheric compositions using the SO_2 isotopologues absorption spectra and irradiative UV spectra, and the resulting MIF-S depends on altitude. Here, we develop a 1-D (vertical) photochemical model including 4 sulfur isotopes (^{32}S, ^{33}S, ^{34}S, and ^{36}S) and very high resolution SO_2 absorption spectra (~0.0004 nm). This new model is based on previous models including sulfur isotopes and low wavelength resolution SO_2 absorption spectra (Claire et al. 2014; Izon et al. 2017). We will present preliminary results and discuss the meaning of MIF-S in Early Earth rocks and modern atmospheric sulfates, if possible, Martian meteorites.

Retrieval of vertical structure in the Martian atmosphere during 2007 global dust storm by OMEGA/MEx limb observation

*Risei Kogure[1], Arnaud Mahieux[2,3], Hiromu Nakagawa[1], Shohei Aoki[2], Yasumasa Kasaba[1], Nao Yoshida[1]

1. TOHOKU University, 2. Belgian Institute for Space Aeronomy (BIRA-IASB), 3. University of Texas at Austin, USA

Recent studies have revealed an unexpected high abundance of water vapor in the middle atmosphere that supposedly drives the enhancement of the atomic hydrogen escape (Chaffin et al., 2017; Fedorova et al., 2018, 2020, Heavens et al., 2018; Vandaele et al., 2019; Aoki et al., 2019). However, it is unclear how to extract water vapor from the lower atmosphere and place it in the middle atmosphere since water vapor is limited in its vertical propagation by the cold trap of its condensation level. The cold trap leads to water freezing out, confining water in the lower atmosphere. It has been proposed that an inflation of the lower atmosphere due to the sunlight absorbed by the upsurge of dust associated with intensified meridional circulation can transport water vapor effectively into the middle atmosphere (Aoki et al., 2019; Neary et al., 2019). A comprehensive picture of the water transport and the background atmospheric condition in the middle atmosphere is yet to be established. Two-dimensional local distribution of physical parameters can contribute to clarify the transient phenomena, such as rocket dust storm (Spiga et al., 2013).

In this study, we aim to present the 2D vertical structures of water vapor, dust opacity, and CO_2 non-LTE emission in the periods of 2007 global dust storm (Ls = 265-305) using the OMEGA limb observation onboard Mars Express. The indexes of water-vapor, dust opacity are obtained from the wavelength ratio between 2.50 and 2.64 micron (Maltaliati et al., 2011), and the radiance at 2.70 micron (Fouchet et al., DPS, 2004), respectively. CO_2 non-local thermal equilibrium (LTE) emission is detected at 4.3 micron (Piccialli et al., 2016). From the slope of the observed spectrum between 0.5 and 3.0 micron, the effective radius of aerosol particles can be estimated. As the reference, observations during the global dust storm in orbit#4483 (Ls = 268) and orbit#4621 (Ls = 292) is compared with that at clear-sky season in orbit#291 (Ls = 17) and orbit#685 (Ls = 68).

We show a significant increase of water vapor up to ~60 km altitude during the global dust storm, as reported by recent studies (Vandaele et al., 2019; Aoki et al., 2019; Fedorova et al., 2020). Our result suggests the concentration of water vapor in 40-60 km altitudes. This is totally different from that at orbit#685 at clear-sky season, which shows the confined water vapor up to ~40 km altitude.

The slopes of observed spectra suggest larger particle size during the global dust storm at orbit#4483 (~1.0 micron) than that in the clear-sky at orbit#291 (~0.4 micron). This is comparable with previous studies (Oliva et al., 2018; Clancy et al., 2019). We find that such large aerosols reach into the mesosphere.

We confirmed that the CO_2 non-LTE emission peaks at higher altitudes (100-120 km) during the global dust storm in orbit#4483 (The statistical analysis can be found in Piccialli et al. (2016)). This result basically suggests about 20 km increase of peak altitudes comparing with that in the clear-sky at orbit#291. This can be explained by the heating by absorption of incoming sunlight via suspended dust particles.

We intend to discuss the physical parameters, such as water vapor amount, dust opacity etc by using JACOSPAR (Iwabuchi and Yang, 2011; Iwabuchi et al., 2016), which is a multiple scattering radiative transfer code that uses the backward-propagating Monte Carlo method, and the dependent sampling approach in order to reduce the computation time.

Numerical experiments of climate of early Mars by the use of DCPAM

*Masaki Ishiwatari[1], Yoshiyuki O. Takahashi[2], George L. Hashimoto[3], Kiyoshi Kuramoto[1], Yoshi-Yuki Hayashi[2]

1. Department of Cosmosciences, Graduate school of Science, Hokkaido University, 2. Department of Planetology, Graduate School of Science, Kobe University, 3. Department of Earth Sciences, Faculty of Science, Okayama University

We have been performing one- and three-dimensional numerical experiments of early Mars. In order to do those, we have developed a radiation model for a thick CO_2 atmosphere, and implemented that into our general circulation model, DCPAM. The radiation model includes advances on radiative transfer calculations which were reported by our groups. The DCPAM is an atmospheric GCM, which uses primitive equation system, and a number of parameterizations, such as radiation, turbulent diffusion, surface energy budget, and condensation processes.

Numerical experiments of one-dimensional radiative convective equilibrium of pure CO_2 atmosphere without radiative effects of cloud shows surface pressure dependence of surface temperature which is similar to that reported by a previous study. That is, surface temperature is highest at a surface pressure of several bars. But, the highest surface temperature is far below the freezing point.

Three-dimensional numerical experiments are also performed by the use of the general circulation model, DCPAM, with the radiation model. In the experiments, we assumed both cases with and without radiative effects of cloud. In experiments without radiative effects of cloud, global mean surface temperatures are similar to those obtained by one dimensional radiative convective equilibrium experiments. But, surface temperature increases with increasing the surface pressure. Further, in experiments with radiative effects of cloud, surface temperature is higher than freezing point. The behavior is different from that reported by previous study.

We will check the energy budget, circulation structures, and atmospheric structures obtained by the models in order to consider the difference of results between ours and previous study's.

Habitable zone for a planet with a small amount of water on its surface

*Takanori Kodama[1], Hidenori Genda[2], Ryouta O'ishi[3], Ayako Abe-Ouchi[3]

1. University of Bordeaux, 2. Earth-Life Science Institute, Tokyo Institute of Technology, 3. Atmosphere and Ocean Research Institute, University of Tokyo

Some of the detected exoplanets are expected to be Earth-sized rocky planets. Habitable exoplanets seem to be significant targets for observation of exo-terrestrial planet and exo-life. Liquid water evaporates entirely when planets receive the insolation above a certain critical value, which is called the runaway greenhouse threshold. If planets receive very weak insolation, on the other hand, such planets lapse into the snowball state where the insolation is called the complete freezing threshold. Most of studies for habitable exo-terrstrial planet have been discussed introducing the habitable zone, in which planets can maintain liquid water on their surface for a long term.

We call a planet with a small amount of water on its surface, a land planet. Land planets have less water amount in its atmosphere and can radiate stronger planetary radiation than that for aqua planets, which have a large amount of water on its surface. Thus, a planet with a small amount of water on its surface has a wider habitable zone than that for a planet with a large amount of water on its surface [Abe et al., 2011; Kodama et al., 2018; 2019]. Here, we investigate the relationship between the width of the habitable zone and the surface water distribution using 3D GCM(General Circulation Model). We confirm that the habitable zone strongly depends on the surface environment. In this presentation, we summarize the climates and habitability for exo-land planets.

Formation region of volatile-rich asteroids inferred from nucleosynthetic isotope variations in carbonaceous chondrites

*Ryota Fukai[1], Sota Arakawa[2]

1. Japan Aerospace Exploration Agency, 2. National Astronomical Observatory of Japan

Describing the comprehensive evolutionary scenario for asteroids (i.e., meteorite parent bodies) is the key issue to explain the various physical processes of the Solar System, such as migration of giant planets and late accretion of volatile elements to rocky planets. In this study, we tried to determine the formation region of asteroids by utilizing the nucleosynthetic Cr isotopic variation ($^{54}Cr/^{52}Cr$) in bulk-scale carbonaceous chondrites (CCs) that possibly record the information of the protoplanetary disk. Numerical calculations are conducted to track the temporal evolution of isotopically different (solar and presolar) dusts and $^{54}Cr/^{52}Cr$ values for mixed materials with disk radius. Our results suggest that nucleosynthetic isotopic variations in CCs were predominantly caused by the spatial heterogeneities of dusts. The formation region of B-, Ch-, D-, and K-type asteroids could be determined using the profile of $^{54}Cr/^{52}Cr$ and the accretional ages of CCs. Among these asteroids, B-type asteroids formed in the outermost region, which is apparently inconsistent with the present population of asteroids showing that D-type asteroids are generally located beyond most of the C-complex asteroids. Both the initial and present orbits of asteroids can be explained by the scatter attributed to the inward–outward gas-drag migration of Jupiter and Saturn.

[M-IS08] Paleoclimatology and paleoceanography

convener:Yusuke Okazaki(Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University), Benoit Thibodeau(University of Hong Kong), Akitomo Yamamoto(Japan Agency for Marine-Earth Science and TechnologyAtmosphere and Ocean Research Institute), Hitoshi Hasegawa(Faculty of Science and Technology, Kochi University)

Past environmental changes and events at multi-decadal to tectonic timescale toward an understanding of Earth climate system by an integration of terrestrial and marine proxy studies and numerical modeling will be discussed. This session includes a special series of presentations on the ocean circulation under climate change in the past, present and future relating to MOC, ventilation and hypoxia. We welcome a variety of paleo-environmental studies from a wide range of background. We hope that this session will provide an opportunity to promote communication between participants from multidisciplinary field.

Reconstruction of the climate condition in the Carnian from bedded chert by using a new index of chemical weathering

*Tenichi Cho[1]

1. Waseda University

Reconstruction of paleoclimate during the Triassic Period is important for the understanding of the Earth system operated during the super-continent and super-ocean, polarized surface landform condition. In the early Late Triassic, an abrupt warming/humidification event, so-called Carnian Pluvial Episode emerged, which was considered to be triggered by the eruption of LIP and increasing atmospheric CO_2. Previous studies regarding the Carnian Pluvial Episode were mainly performed in the western Tethys realm, while the global impact of the Carnian Pluvial Episode is not well understood. This study newly presents the reconstruction of continental chemical weathering intensity through the Carnian from the pelagic deep-sea sediment, which is preserved as bedded chert in the accretionary complex in Japan. In this study, to unravel the hinterland chemical weathering variation from bedded chert, a new weathering index was introduced. The new index was derived from the multivariate statistical analysis (Independent component analysis) using major element compositions of fresh igneous rock and their weathering profiles. The concentrations (wt. %) of TiO_2, Al_2O_3, Fe_2O_3, MgO, Na_2O, K_2O were used to extract the chemical weathering variation which should be independent from the source rock composition. The newly developed index has two features; (1) It retains the advantage of W index (e.g., applicable to a wide range of rock types; less sensitive to specific element concentrations; Ohta and Arai, 2007). (2) It does not require the SiO_2 and CaO concentration data, and thus applicable to samples with contamination of silica, apatite, or calcite. This new index enables the quantitative reconstruction of chemical weathering not only in bedded chert but also in shallow sea or terrestrial sediments that contain diagenetically derived calcite or biogenic apatite fragment. To investigate the climate of the continental region in the Carnian, more than 80 mudstone samples were successively collected from the bedded chert sequence of Section R, Q, Inuyama area, Mino terrain, which cover the whole Carnian Stage (Sugiyama, 1997, Nakada et al., 2014, Yamashita et al., 2018). After washing in an ultrasonic bath to remove the weathered part of the rock surface, major elements were analyzed by XRF (ZSX Primus II , Rigaku Co., Ltd.). The new chemical weathering index demonstrates a clear increase at the Lower Carnian/Upper Carnian boundary, and this high weathering condition continues about 1.3 million years. Then, the weathering intensity decrease suddenly at the boundary of TR5A and TR5B radiolarian biozones (Tuvalian substage). The onset timing of this high weathering period matches with that of the Carnian Pluvial Episode in Tethys. This result suggests that, in the middle of the Carnian, the prolonged warming/humid period lasted for about 1.3 million years in the broad area of the continental region related to the Carnian Pluvial Episode. This increasing of continental weathering intensity and the changes in fossil assemblage suggest that the Carnian Pluvial Episode was a global phenomenon and this environmental disturbance affected biological evolution not only in the Tethys realm but also in the whole Panthalassa. Thanks go to Prof. Tohru Ohta of Waseda University for kind advice and fruitful discussions. Dr. Kazutaka Yasukawa of the University of Tokyo is thanked for his guidance of Independent component analysis. This study was supported by the National Science Foundation of China (Grant No. 41888101; D. Kemp).

Response of Climate and Water Cycle to Atmospheric CO2; Cretaceous vs. Modern

*Taro Higuchi[1], Ayako Abe-Ouchi[1], Wing-Le Chan[1]

1. Atmospheric and Ocean Research Institute, the University of Tokyo

The study of paleoclimate during warm periods using climate models is important for the understanding of the Earth system under greenhouse conditions and for verifying model performance.
The Cretaceous is known as one of the warmest periods in the Phanerozoic due to intense volcanic activity and increased levels of greenhouse gases. In particular, the mid-Cretaceous is the warmest during that period, and terrestrial proxy data (e.g., climatically sensitive sediment) from that time show a marked change in the water cycle. For example, mid-Cretaceous strata distributed throughout the low latitudes of Asia include desert deposits or evaporites, indicating aridification during the mid-Cretaceous. It is thought that the cause of the change in the water cycle is the result of increased atmospheric CO2, because within the Cretaceous, mid-Cretaceous CO2 concentration in the atmosphere was especially high. If the water cycle change during the mid-Cretaceous is due to increased atmospheric CO2, then it should be comparable with that associated with global warming predictions as suggested by climate models. However, the water cycle changes in the Asian region are quite different. Thus, it is not obvious whether the change in the water cycle during the mid-Cretaceous can be attributed to increased atmospheric CO2. Even if it can be, it is still not clear why the responses of the water cycle to increased CO2 differ during present day and the Cretaceous.
To resolve this issue, simulations of the Cretaceous climate with different CO2 levels are carried out in this study using the atmosphere-ocean general circulation model MIROC4m. The aim is to investigate the response of the climate and water cycle to increased atmospheric CO2 for a Cretaceous paleogeography and to compare results with Cretaceous proxy data and a present-day warming experiment.
The precipitation change due to increased CO2 in the Cretaceous experiment is consistent with the water cycle change during the mid-Cretaceous, as indicated by geological evidence. With increased atmospheric CO2, the precipitation in the low latitude regions of Asia decreases in the Cretaceous experiment, while it increases in the present-day experiment. The precipitation decreases in southern Europe, but increases in the mid-latitude regions of Asia and North America. This result implies that the water cycle change during the mid-Cretaceous can be explained as a response to increased atmospheric CO2.
Water budget analysis indicates that the difference in the water cycle changes is attributed to the different summer atmospheric circulation responses in Asia. In the Cretaceous experiment, the updraft in the continental interior weakens due to increased atmospheric stability with global warming, resulting in a decrease in the precipitation. On the other hand, in the present-day experiment, it does not fully weaken because diabatic heating over the Tibetan plateau enhances the atmospheric circulation. As a result, the increase in moisture flux due to increased atmospheric moisture overcomes the effect of the atmospheric circulation weakening, resulting in increased precipitation with increased atmospheric CO2.
Additionally, ‘No-Tibet’ experiments, eliminating the Tibetan plateau, are carried out in order to investigate the role of the Tibetan plateau on the water cycle change due to increased atmospheric CO2. In the No-Tibet experiments, the precipitation decreases in low latitude regions of Asia with global warming, which is comparable to the results of the Cretaceous experiment. The summer updraft in Asia becomes weaker than that in the present-day experiment, resulting in decreased precipitation. These results indicate that, in the low latitude regions of Asia, the difference between the precipitation changes of the present day and the Cretaceous is attributed to the Tibetan plateau. This study shows that the

Enhanced dinoflagellate productivity by ocean stratification and eutrophication in the Anthropocene, Miocene, and Cretaceous

*Takuto Ando[1], Ken Sawada[2]

1. Estuary Research Center, Shimane University, 2. Faculty of Science, Hokkaido University

Dinoflagellate is one of the main marine organisms causing red-tide near coastal region. Red-tide, especially harmful algal bloom (HAB), impact on not only fishery but also human health, and therefore, the prediction of red-tide/HAB are important for understanding variability in marine ecosystem in the future. Red-tide events are also related to the expansion of nutrient-rich water. For example, dinoflagellate bloom caused by eutrophication near the coastal area of Japan during high economic growth period (~Anthropocene). Summer stratification is the other factor to enhance occurrence of red-tide. A large number of marine organisms near the coast of Florida are actually killed by the blooming of toxic dinoflagellate (*Karenia brevis*) owing to oceanic stratification during summer in 2018 (Weisberg et al., 2019, *JGR Oceans*). These obvious changes in marine ecosystem in the present gain on importance to reveal relationship between dinoflagellate bloom and climate change. Dinosterol is biosynthesized by dinoflagellate and used as dinoflagellate biomarker in the sediments/sedimentary rocks. Triaromatic dinosteroid is applicable dinoflagellate biomarker for mature sedimentary rocks. In this presentation, we focus on the Anthropocene, late Miocene and mid-Cretaceous OAEs, and compare the variation in dinosteroid percentage with the paleoclimatological /paleoceanological proxies.
We collected the sediment/sedimentary rock samples from Seto Inland Sea (Japan, Anthropocene), Andaman Sea (IODP Exp.353, site U1447, late Miocene), Hokkaido (Yezo Group, Japan, the mid-Cretaceous OAE2) and Vocontian Basin (south eastern France, the mid-Cretaceous OAEs).
Dinosterol are main dinosteroid among the samples collected from Seto Inland Sea and Andaman Sea. We defined DSIP (Dinosteroid index for polar fraction; %) as the percentage of dinosterol/dinostanol among the sterols without C_{29} sterols mostly originated from terrestrial plants. The values of DSIP are higher in the surface sediments deposited near the coast in Seto Inland Sea compared with the samples collected from Pacific Ocean and Yodo River flowing into Osaka Bay. Especially, DSIP is the highest value in the Sea of Harima which is characterized by stratified and eutrophic water in summer season. On the other hand, DSIP values increased from ~7 Ma in the sediment core samples collected from Andaman Sea. Holbourn et al (2018, *Nature Commun.*) suggested that the cooling event in Andaman Sea after 7 Ma was related to strengthening of the dry and cold East Asian winter monsoon. Winter monsoon enhance the North Equatorial Current and the East Indian Current which transport nutrient-rich water from the Strait of Malacca into the Andaman Sea (Brewer et al., 2015, *CSIRO Oceans and Atmosphere*). It is likely that dinoflagellate productivity is also higher under eutrophic condition during the late Miocene.
Triaromatic dinosteroids are main identifiable dinosteroids in the Cretaceous sedimentary rocks collected from Hokkaido and SE France. TADS (Triaromatic dinosteroid index %; Ando et al., 2017a, *Org. Geochem.*), which indicates the productivity of dinoflagellate, were higher in the samples from the mid-Cretaceous OAE1b and 2 levels in Vocontian Basin, SE France. The marine environment in Vocontian Basin during OAE1b and 2 were characterized by eutrophic and stratified condition due to wet and warm climate (Herrle 2003, *Mar. Micropaleontol.*; van Helmond et al., 2014, *Geology*). However, there is no obvious change in TADS values in the samples of OAE2 level collected from the Yezo Group, Hokkaido. The biomarker-based redox indicated the timing of oceanic anoxia in Hokkaido are different from OAE2 in the Tethys and Atlantic regions (Ando et al., 2017b, *Island Arc*). These results imply that dinoflagellate bloom was mainly related to ocean stratification and eutrophication during the Anthropocene, Miocene, and Cretaceous.

Study on productivity feedback during the recovery phases of early Eocene hyperthermals: Comparison between the central North Pacific Ocean and southern Indian Ocean

Koshiro Sato[1], *Kazutaka Yasukawa[1,2], Junichiro Ohta[1,2], Keishiro Azami[1], Kentaro Nakamura[1], Koichiro Fujinaga[2,1], Minoru Ikehara[3], Yasuhiro Kato[1,2]

1. School of Engineering, The University of Tokyo, 2. ORCeNG, Chiba Institute of Technology, 3. Center for Advanced Marine Core Research, Kochi University

The Paleocene-Eocene Thermal Maximum (PETM) at 56 Ma was the most serious and well-studied hothouse in the Cenozoic era, characterized by a rapid global warming by 5 to 8˚C, severe ocean acidification, and a distinct negative carbon isotope ($\delta^{13}C$) excursion both in the marine and terrestrial realms [1]. These features suggest a massive injection of ^{13}C-depleted greenhouse gas(es) to the ocean-atmosphere system. Moreover, during the early Eocene period (ca. 56-52 Ma), multiple PETM-like transient global warming episodes, called hyperthermals, have also been recognized over the past dozen years [2].

A previous study using the ODP legacy cores drilled in the southern Indian Ocean indicated that an enhanced biological pump efficiently sequestered the excess carbon in the recovery phases of the PETM and other modest hyperthermals, regardless of the magnitude of the events [3]. However, it remains uncertain whether this productivity feedback is a globally general response of the Earth system to a rapid warming.

Here we newly analyzed deep-sea sediment samples collected from ODP Site 1215A in the central North Pacific Ocean, in which multiple hyperthermal events including the PETM, Eocene Thermal Maximum (ETM) 2 and ETM3 are recorded [4]. We constructed a multi-elemental dataset of major- and trace-element contents, $\delta^{13}C$, $\delta^{18}O$, and $CaCO_3$ content for bulk sediment. Based on the dataset, we estimated the abundance of Ba associated with the biological productivity. In the presentation, we will compare the results in the central North Pacific Ocean and southern Indian Ocean, and discuss their relationships with the multiple hyperthermal events.

Sulfur isotope ratios in co-occuring barite and carbonate from Eocene sediments: A comparison study

*Kotaro Toyama[1], Adina Paytan[2], Ken Sawada[3], Takashi Hasegawa[4]

1. The University of Tokyo, 2. UCSC, 3. Hokkaido Univ., 4. Kanazawa Univ.

The marine sulfur cycle over geologic timescales is closely linked to the redox state of the Earth's surface environments due to the burial of redox-sensitive sulfur species. Fluctuations in the $\delta^{34}S_{sw}$ record have been related to a wide range of global environmental changes, such as oxygenation of the biosphere, bacterial evolution, and mass extinctions. In order to investigate the utility of bulk carbonate as a recorder of seawater sulfate sulfur isotope ratios ($\delta^{34}S_{sw}$), co-existing pelagic barite and bulk carbonate in Eocene sediments from the Equatorial Pacific Ocean (IODP Exp. 320/321 Sites U1331 to U1333) were analyzed for their sulfur isotope ratios ($\delta^{34}S$). The $\delta^{34}S$ from both minerals showed parallel fluctuation throughout the Eocene with carbonate associated sulfate (CAS) values about 0.8‰ heavier than those of barite. A similar offset was observed in CAS $\delta^{34}S$ obtained using species-specific cleaned planktonic foraminifers (Rennie et al., 2018). The consistent results from two distinct minerals suggest that the original $\delta^{34}S_{sw}$ can be derived from bulk CAS analysis, if post deposition carbonate recrystallization is minimal.
Our $\delta^{34}S_{barite}$ data added an important data set in middle Eocene (Lutetian, 47.8 to 41.2 Ma). The data set combined with previous studies showed a ~5‰ increase of $\delta^{34}S_{sw}$ during the Eocene (from 53 Ma to 36 Ma) with the majority of the shift within 7 myr between 53 and 46 Ma. This change is more gradual than previously reported. The timing of this $\delta^{34}S_{sw}$ shift coincides with extensive pyrite burial in the Arctic Ocean, supporting the hypothesis that the 5‰ increase in Eocene $\delta^{34}S_{sw}$ has been caused by ^{34}S-enriched water outflow from the Arctic Ocean as suggested in the previous study.

Late Eocene travertine in the SE Tibet and cyclical change in its isotopic composition implying the monsoon climate

*Aki Sakuma[1], Hirokazu Kato[1], Yoshihiro Kakizaki[1], Akihiro Kano[1], Ryuji Tada[2,3], Hongbo Zheng[2]

1. Department of Earth and Planetary Science, School of Science, the University of Tokyo, 2. Yunnan University, 3. Chiba Institute of Technology

The Asian monsoon is the most dominant monsoon system in the world but when and how it was established is still under the debate. Recently, its onset during the late Eocene was suggested (Licht et al., 2014) but little geological evidence in the low-latitude region hinder the reliable evaluation of the past climate pattern. In this study, we investigated the sedimentary environment of the late Eocene limestone in the Jianchuan basin by the microfacies and carbon and oxygen isotope analyses. We identified six lithofacies (laminated bindstone, oncoidal grainstone, calcareous conglomerate, wackestone, lime-mudstone, and bafflestone) and the limestone appears regular lamination and encrusted waterweed, which are unique features of travertine. The high $\delta^{13}C$ and low $\delta^{18}O$ values strongly support the travertine origin and disagree with the previous interpretation of lacustrine carbonate. The high $\delta^{13}C$ values resulted from a large proportion of isotopically depleted fraction from endogenic CO_2. Furthermore, high-resolution isotopic analysis for the laminated travertine confirms a seasonal pattern that is consistent with the laminated texture observed in the modern travertine. The isotopic pattern of the travertine also indicates humid summer and dry winter in the late Eocene, which are the same as the modern monsoonal climate regime.

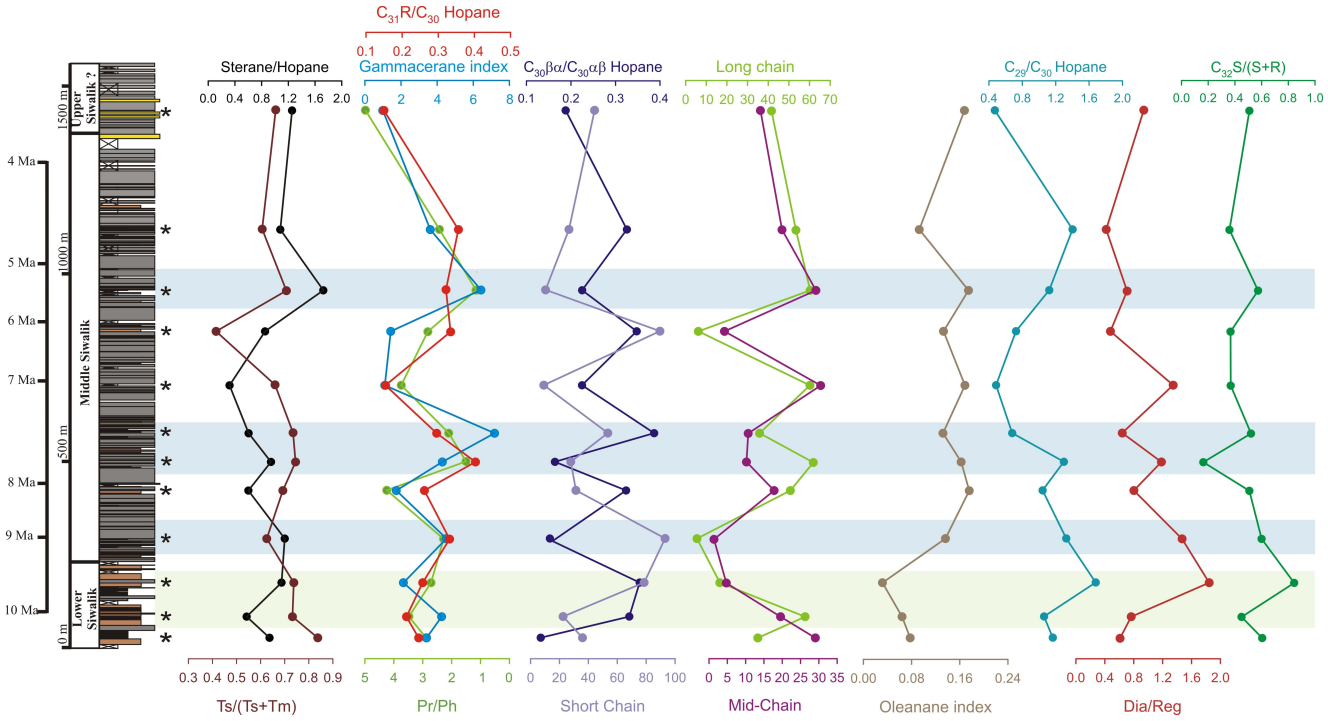
Reconciling marine influences in the Eastern Siwaliks through the use of biomarkers and reconstructing the Miocene-Pliocene closure of Himalayan Foreland Basin



*Biswajit Roy[1], Sohom Roy[1], Sambit Ghosh[1], Prasanta Sanyal[1]

1. Indian Institute of Science Education Research Kolkata

The Siwalik group of rocks archives an essential part of the Himalayan foreland basin evolution. These east-west laterally extended foreland sedimentary packages were previously thought to have been deposited by fluvial alluvial fan settings. However, recent studies on ichnofossils, leaf macrofossils, pollens, and sedimentary architectures provided contradicting evidence from the Miocene-Pliocene Eastern Siwalik suggesting a depositional exclusively of marine dominated environment setting. The marine signatures suggest openness of the foreland basin to marine influences that were supposed to have closed after the retreating of Eocene sea. However, most of these signatures are qualitatively known from the Eastern Siwalik. To validate the marine influences more quantitatively, an alternate perspective, molecular-level characterization of these Eastern Siwalik sedimentary sequences has been attempted to re-evaluate the organic matter (OM) origin and paleo-depositional conditions. The *n*-alkane profiles show a bimodal distribution, with a relatively higher abundance of long-chain *n*-alkanes, Pristane/*n*-C_{17} and Phytane/*n*-C_{18} cross-plot, and relative abundance of C_{27}-C_{28}-C_{29} steranes suggesting major OM contributions from the terrigenous source. The temporal increase in the oleanane index also demarcates an increase in contribution from higher-plants with age. Redox-sensitive parameters like Pristane/Phytane and C_{30}-norhopane/C_{30}-hopane ratios indicate fluctuations between highly oxic to suboxic conditions typical for the terrestrial dominated environment. Interestingly, an increased abundance of gammacerane, high regular sterane/17a-hopane ratios, and high $d^{13}C$ values of bulk OM during the suboxic phases suggests water-column stratification and deposition in hyper-saline/brackish water or marine conditions. Our data, therefore, indicate a mixture of the terrestrial, lacustrine and open bay/estuarine type, suggesting a fluctuating near-shore depositional condition during Siwalik deposition. Throughout the depositional period of the Eastern Siwaliks, marine influences (high $C_{31}R/C_{30}$ hopane and Gammacerane index) were observed mostly during the deposition of the older deposits, which then subsided and allowed the domination of the fluvial signatures (higher Oleanane and long-chain n-alkane abundance) with minor marine influx during forced transgression stage. However, Late Miocene-Pliocene tectonics in the hinterland areas subsequently uplifted the foreland basin and drove back the paleo-Bay of Bengal Sea leading to complete closure of the Himalayan foreland basin and allowed the deposition of fluvial sedimentary packages.

The paleo ocean temperature recorded in carbonate clumped isotope of early Pleistocene fish otolith fossils from the Dainichi Formation of the Kakegawa Group, Shizuoka

*Hirokazu Kato[1], Shota Amekawa[1], Akihiro Kano[1]

1. Department of Earth and Planetary Science, The University of Tokyo

The Dainichi Formation of Kakegawa Group distributed in southwestern Shizuoka Prefecture is shallow sea sediment of early Pleistocene (~2 Ma) and contains various marine fish otoliths. Otolith is calcium carbonate structure in the inner ear of vertebrates and used as balance indicator. Otolith of teleost fish especially grows large and many of them weigh over ~10 milligrams. They often keep firm structure in stratums. We analyzed the bulk and clumped isotopes of fossil and modern otoliths of several species including *Sillago* sp. *Nibea* sp. *Apogonichthys* sp. in order to examine their potential for the ancient temperature archive.

The carbonate clumped isotopes thermometry is a technique to reconstruct the temperature of mineral precipitation without the isotopic information of the parent water. The abundance anomaly of $^{47}CO_2$ (Δ_{47}) generated by acid digestion of calcite is an index of temperature (Ghosh *et al.* 2006). There are few studies about otolith Δ_{47} value although its rigid microstructure is tolerant against diagenetic alternation. The temperature calibration of fish otolith Δ_{47} value by Ghosh et al. (2007) is marginally different from the original calibration of Ghosh et al. (2006). The small discrepancy might reflect a vital effect, or systematic error in temperature estimation of fish growth (Eiler, 2011). We used temperature calibration depending on synthetic calcites developed by Kato et al. (2019).

The Δ_{47} values were 0.709–0.723‰ (13.0–17.4˚C) for fossil *Sillago*, 0.717–0.719‰ (14.0–14.7˚C) for fossil *Nibea* and 0.724‰ (12.4˚C) for fossil *Apogonichthys* with typical measurement error of ±0.01‰. While the modern otoliths yield Δ_{47} temperatures well reproducing the modern ocean temperature. The result of paleo temperature reconstruction is ~5˚C colder than Δ_{47} temperatures from modern otoliths. The paleo water $\delta^{18}O$ value reconstructed from fossil otolith $\delta^{18}O$ corrected by Δ_{47} temperature was –1–−2‰VSMOW. This value is significantly lower than present ocean $\delta^{18}O$ and may indicate strong influence of fresh water in the depositional setting of the lower Pleistocene Dainichi Formation.

Orbital-scale paleoceanographic changes around the Pacific side of Japan in Early Pleistocene based on calcareous nannofossil records

*Daisuke Kuwano[1], Koji Kameo[1], Yoshimi Kubota[2], Kanako Mantoku[2], Masayuki Utsunomiya[3], Makoto Okada[4]

1. Chiba University, 2. National Museum of Nature and Science, 3. Geological Survey of Japan, AIST, 4. Ibaraki Uviversity

The Mid-Pleistocene Transition (MPT) is the well-known interval that the dominant periodicity of earth's climate cycles shifted from 41 to 100 ky rhythms (e.g., Elderfield et al., 2012). This study will discuss paleoceanographic changes during the Early Pleistocene before the MPT around the central part of the Pacific side of Japan based on calcareous nannofossil assemblages. We studied the Kiwada Formation in the Kazusa Group, distributed the Boso Peninsula. Two different counting techniques were used to clarify biostratigraphic and paleoceanographic events based on calcareous nannofossils. The age model for this section was proposed by Kuwano et al. (2019a, b). Investigaed ages is Marine Isotope Stage (MIS) 41 to 36. Spectral analyses using the PAST3 software were also applied in order to extract paleocanographic signals from nannofossils.
At least 13 species and 13 genera of calcareous nannofossils were identified in the examined section. *Umbilicosphaera sibogae*(Kuroshio water index) increased at the glacial-interglacial boundaries, *Florisphaera profunda* (stratified, warm offshore water index) and *Helicosphaera* spp. (freshwater inflow index) increased in the interglacial period. On the other hand, *Calcidiscus leptoporus* (cool offshore water index) and very small *Gephyrocapsa* spp. (eutrophic freshwater index) increased during the glacial period. In particular, *Coccolithus pelagicus* (eutrophic cool water index) abundant at the end of the glacial period. The power spectra of *F. profunda*, *U. sibogae*, very small *Gephyrocapsa* spp., and *C. leptoporus* show 55-57 kyr periodicity, which also appeared in benthic foraminiferal $\delta^{18}O$. The periodicity of 22-23 kyr was recognized from relative abundances of *F. profunda*, *U. sibogae*, and *Helicosphaera* spp. Those sequential fluctuations of nannofossils indicate that northward/southward of the Kuroshio and Subarctic Front around the Pacific side of Japan. It can be presumed that oceanic front movements linked East Asian monsoon variations because paleoceanographic records in this study corresponded with Chinese loess-paleosol records (Sun et al., 2010).

Sea-ice history in the central Okhotsk Sea based on diatom assemblages during the Middle Pleistocene Transition

Araki Eisuke[1], *Yusuke Okazaki[1], Lo Li[2]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 2. Department of Geosciences, National Taiwan University

The Okhotsk Sea is the second largest marginal sea in Pacific Ocean. One of the most notable features of the Okhotsk Sea is the seasonal sea-ice cover from late autumn to early spring, constituting the southernmost sea-ice covered area in the northern hemisphere. Recent climate changes have significantly impact in the sea-ice covered area in Okhotsk Sea, however, geological timescale sea-ice evolution histories is still unknown in this region due to the lack of long paleoclimatic records. During the period between 1.25 and 0.75 Ma known as the Mid-Pleistocene Transition (MPT), the glacial/interglacial (G/IG) cycles has modulated from 41-kyr to 100-kyr. The first deep glaciation appeared in the Marine Isotope Stage (MIS) 16, between 0.68 and 0.62 Ma. To reveal sea-ice history in the Okhotsk Sea during the MPT period, diatom floral assemblages in a giant piston core obtained from the central Okhotsk Sea (MD01-2414; 53°11.77’ N; 149°34.80’ E; water depth 1123 m) were investigated. Age model of MD01-2414 was established based on magneto-stratigraphy as well as orbital-tunings of element concentrations and sediment color, yielding the bottom age as ~1.6 Ma. Diatom abundance (No. valves g-1 dry sediment) between 1.2 and 0.6 Ma showed cyclic patterns along with G/IG cycles: increased (decreased) abundances by 1 or 2 orders of magnitude during cold (warm) periods, vice versa. A total of 18 genus 21 species were identified in MD01-2414 core. Main diatom species were Actinocyclus curvatulus, Paralia marina/sulcata, Rhizosolenia hebetata forma hiemalis, Shionodiscus trifultus, and S. oestrupii. Sea-ice related species such as Bacterosira bathyomphala, Fragilariopsis cylindrus, F. oceanica were less than 10% throughout the MPT except for MIS 26, 18, and 16. The MIS 26 peak was temporal whereas the MIS 18 to MIS 16 peaks continued for tens of thousands years. This suggests that the onset of major sea-ice cover was since MIS 18, ~0.75 Ma in the central Okhotsk Sea.

Millennial-scale hydrographic changes in the northwestern Pacific during marine isotope stage 19: Teleconnections with ice melt in the North Atlantic

*Yuki Haneda[1], Makoto Okada[2], Yoshimi Kubota[3], Yusuke Suganuma[1]

1. National Institute of Polar Research, 2. Department of Earth Science, College of Science, Ibaraki University, 3. National Museum of Nature and Science

Marine isotope stage (MIS) 19 has been suggested as one of the best orbital analogs for present interglacial, because of the similarity of the orbital configurations between both interglacial periods. Therefore, paleoenvironmental reconstructions of MIS 19 will provide valuable knowledge to evaluate the anthropogenic impacts for present and future climate changes. Additionally, the abrupt climate changes associated with the iceberg melting in the North Atlantic are globally documented in the paleoceanographic and paleoclimatic records during the MIS 20–19 transition and late MIS 19, suggesting global climatic teleconnection during the periods. The Kuroshio Current, the largest western boundary current of the North Pacific ocean, transports a large amount of heat and water poleward strongly influences the East Asian climate, however, responses of the Kuroshio Current to the ice melting in the North Atlantic remains unknown. Here, we reconstruct detailed paleoceanographic variations in the northwestern Pacific during MIS 19 using stable oxygen isotope ($\delta^{18}O$) records from the Chiba composite section (CbCS), central Japan. Spectral and wavelet analyses were conducted in order to assess periodicity of our new $\delta^{18}O$ records. Vertical water temperature structure and their gradient (ΔT) exhibit latitudinal displacements of the Kuroshio Extension Front (KEF) on multi-millennial scale across the MIS 20–19 transition and during late MIS 19 (MIS 19b to 19a). Results of the spectral and wavelet analyses for the $\delta^{18}O$ records show periodicities of approximately 3,000–6,000 year during late MIS 19. Similarities of timing and periodicity between paleoceanographic records from the CbCS and North Atlantic indicate that disruption of the Atlantic meridional overturning circulation due to freshwater discharge into the North Atlantic caused the southward displacements of the KEF via atmospheric dynamic. A power of the 9,700 year-periodicity in surface planktonic $\delta^{18}O$ and ΔT is stronger during MIS 19c, which probably originates from tropics caused by equatorial insolation at equinoxes with the orbital perihelion. This result indicates the seasonality of the insolation at low-latitudes paced the sea surface condition at the CbCS throughout MIS 19 and this low-latitude influence became larger especially when the North Atlantic forcing by freshwater discharges and AMOC variability was low.

Influence of Southern Ocean Intermediate water on the South Pacific’ s thermocline during the last ~500 Ka

*RAUL TAPIA[1,3], Sze Ling Ho[1], Nele Meckler[2], Dirk Nürnberg[3]

1. Institute of Oceanography, National Taiwan University, Taipei, Taiwan, 2. Bjerknes Centre for Climate Research and Department of Earth Science, University of Bergen, Norway, 3. GEOMAR –Helmholtz Centre for Ocean Research Kiel, Kiel, Germany

The Southern Ocean Intermediate Waters (SOIWs), such as Subantarctic Mode Water and Antarctic Intermediate Water, transport climatic signals from high to low latitudes and ventilate the thermocline in the Southern Hemisphere Gyres. Reconstructions of the SAMW-AAIW in the South Pacific suggest substantial spatial variability in their advection to lower latitudes during the last glacial, but the SOIWs’ impact on the South Pacific Gyre’ s thermocline beyond the last glacial cycle is largely unknown.

Here, we present ~500 ka multiproxy records of Mg/Ca ratios, clumped isotopes and stable oxygen isotope, measured on sea surface and thermocline-dwelling planktic foraminifera from the center of the SPG. The local salinity and Mg/Ca-temperature at the sea surface is relatively stable (~10 ºC) throughout the record. However, the dual proxy-based thermocline temperature records show two distinct climatic intervals. Prior to 300 ka, the conditions were cold and fresh, with average temperatures of ~4 ºC. Thereafter (<300 ka), the thermocline of the SPG became warmer and saltier, with average temperatures of ~8 ºC.

The SOIWs variability in the Pacific basin have been traditionally linked to the Southern Westerlies Winds. However, the evolution of the subsurface-temperature and -salinity substantially differs from the glacial-interglacial variability (position and/or intensity) of the Southern Westerlies Winds. We discuss several possible mechanisms that could lead to this enigmatic shift in our thermocline temperature and salinity records.

Simulating selected time intervals during the Quaternary using MIROC-ES2L earth system model in comparison with paleo-proxy data

*Rumi Ohgaito[1], Akitomo Yamamoto[1], Tomohiro Hajima[1], Manabu Abe[1], Hiroaki Tatebe[1], Michio Kawamiya[1], Ayako Abe-Ouchi[2,3,1]

1. Japan Agency for Marine-Earth Science and Technology, 2. U. Tokyo, AORI, 3. NIPR

Simulating paleoclimate is a valuable opportunity to evaluate climate models on simulating climate change significantly different from the present day. We performed numerical experiments targeting several time periods during the Quaternary, Last Glacial Maximum (LGM, 21,000 years before present), mid-Holocene (6ka) and the last millennium (LM) using an earth system model, MIROC-ES2L.
MIROC-ES2L is an earth system model (ESM) (Hajima et al. 2019) which was developed to simulate future climate projection and to contribute Coupled Model Intercomparison Project phase 6 (CMIP6).
In this presentation, we describe how we simulated the paleoclimate experiments, compare the output with paleo-proxy data and discuss the agreements and discrepancies between them. The reference experiment is pre-industrial control (PI), which was submitted to CMIP6 as “piControl”.
We performed the experiments following protocol of Paleoclimate Modelling Intercomparison Project (PMIP) phase 4 (PMIP4, Kageyama et al. 2017). For LGM, we began a spin-up experiment using the physical core of MIROC-ES2L. An experiment is branched from PI and the greenhouse gas levels (GHGs) are changed to the LGM values. After integration for 2,640 years, the other LGM conditions are applied step by step manner and the total spin-up reached 6,760 model years. The initial conditions at the 6,760th year of the spin-up experiment were used to initiate an experiment using MIROC-ES2L. Finally, the length of the integration reached 9,060 years from the beginning of the spin-up and the last 100 year climatology was submitted to PMIP4/CMIP6. Tropical temperature cooling of LGM relative to PI is -2.0 degree Celsius. This is comparable with paleo-proxy archives (Bartlein et al. 2011, MARGO project members 2009). The temperature anomaly over the mid to high latitudes varies more than in the tropics. For the central Greenland, the cooling of the LGM experiment resulted -11.1 degree Celsius relative to PI, which is about the half of the estimate by ice core data (Johnsen et al. 1995, Dahl-Jensen et al. 1998). The large discrepancy would be attributed to the difficulty of the realization of ocean thermohaline state in the model experiment.
6ka is known from the warming of the northern hemisphere and from associated strengthen of the boreal summer monsoons. We branched the simulation from PI and gave the orbit and GHGs of 6ka condition (Otto-Bliesner et al. 2017), and extended 1500 model years. The climatology of the last 100 year was used for the analyses and was submitted to CMIP6/PMIP4. The temperature anomaly during boreal summer showed the warming as expected from the radiation anomaly. Strengthen of boreal summer monsoons were simulated in the experiment, consistent with proxy data qualitatively, but quantitatively underestimated. This is persistent tendency of modelling studies under PMIP model configurations. We would either need further components of model or improve experimental conditions.
The initial state of LM is obtained by an experiment forced with 850 CE condition constantly for 200 model years. LM was started from the end of this experiment. LM is a time varying experiment for 1000 years from 850 CE until 1850 CE, conducted in the same manner with historical experiments following Jungcluas et al. (2017). The resulting time series of the northern hemisphere mean temperature revealed repeating clear cooling responses to huge volcanic eruptions. The responses to the other forcing were not clear. Further investigations and sensitivity experiments would be necessary but the other forcing supposed to be too weak compared to the internal variabilities. The LM is followed by a historical experiment (HIST) until 2014 CE. HIST experiment represented multi-decadal climate variabilities during

Fossil diatom records from IODP Exp. 382 Sites U1536 and U1538 (preliminary results)

*Yuji Kato[1], Michael E. Weber[2], Maureen E. Raymo[3], Trevor Williams[4], - The IODP Expedition 382 Scientists

1. Center for Advanced Marine Core Research, Kochi University, 2. University of Bonn, Germany, 3. Lamont-Doherty Earth Observatory of Columbia University, USA, 4. International Ocean Discovery Program, Texas A&M University, College Station, USA

As the Southern Ocean plays a significant role in global climate system, there has been a great discussion about paleoceanographic changes in the Southern Ocean. Of these, fossil diatoms preserved in sediments have been treated as useful paleoenvironmental indicators for reconstructing past ocean conditions over geological timescales.

International Ocean Discovery Program (IODP) Expedition 382 (from March to May 2019) obtained several high-resolution sediment cores from Scotia Sea (Atlantic sector of the Southern Ocean), which covers Plio-Pleistocene ages. Of these, Site U1536 (59.44ºS, 41.06ºW, water depth 3220 m, Dove Basin) and Site U1538 (57.44ºS, 43.36ºW, water depth 3131 m, Pirie Basin), which are located in the vicinity of modern winter sea-ice limit, are likely to contain robust paleoceanographic information such as sea-ice history and SST changes. In the current presentation, we will present preliminary results of diatom assemblage analysis extending past ca. 0.5 myrs and discuss their paleoceanographic and biostratigraphic significance.

Variations of the North and South Pacific Subtropical Gyres over the past 400 kyrs

*Furukawa Keisuke[1], Osamu Seki[2]

1. Graduate School of Environmental Science, Hokkaido University, 2. Institute of Low Temperature Science, Hokkaido University

The gyre in the ocean is thought to play an important role in the climate system as meridional heat and material transports between low and high latitudes. In late Pleistocene paleoceanographic study, previous study revealed that the large variation of intensity of North Pacific Subtropical Gyre (NPSG) associated with glacial-interglacial cycles with 23 kyr cycle (Yamamoto et al., 2008), suggesting a precession control on intensity of NPSG circulation. However, the mechanism driving the long-term variability of the subtropical gyre and its role in global climate change are still remains uncertain.
In this study, we reconstructed and analyze mid sea surface temperature (SST) records in the western and eastern sides in the NPSG and South Pacific Subtropical Gyre (SPSG) for the past 400 kyrs to investigate evolution of those gyres. We reconstructed intensity of the gyre circulation from ΔSST difference between west and eastern sides of the gyres. The west-east ΔSST record in SPSG show orbital scale variations over the past 400 kyrs. Spectral analysis suggests predominance of 23 and 41 kyr cycles, suggesting precession and obliquity control on SPSG.

Paleovegetation and paleoenvironmental changes in the northern Mongolia since MIS 3 (preliminary results)

*Ryosuke Imaoka[1], Koji Shichi[2], Hitoshi Hasegawa[1], Niiden Ichinnorov[3], Nagayoshi Katsuta[4], Davaasuren Davaadorj[5], Masafumi Murayama[1], Miho Sasaoka[1], Masao Iwai[1]

1. Kochi University, 2. Forestry and Forest Products Research Institute, 3. Mongolian Academy of Sciences, 4. Gifu University, 5. National University of Mongolia

We present results of paleovegetation and paleoenvironmental analysis for new lake sediment record of Sangiin Dalai lake in the northern Mongolia. We took a surface sediment core in August 2016 (16SD02; 84 cm length), and five boring cores in March 2019 (19SD01~05; totally ca. 16 m length) from Sangiin Dalai lake, a large permanent hard water lake. The studied lake is located in the southern margin of Siberian continuous permafrost zone, and surrounded by forest-steppe vegetation dominated by Larix Sibirica. In order to reconstruct paleoenvironmental and paleovegetation change, we conducted palynological analysis and high-resolution elemental composition analysis using μXRF core scanner (Cox, Itrax) at Center for Advanced Marine Core Research, Kochi University. We also performed ^{14}C and OSL age dating. On the basis of palynological analysis and biome reconstruction (Tarasov et al., 2000), marked vegetation changes from steppe-desert in last glacial to steppe-taiga in the Holocene were reconstructed. We also note the periodic lithological change indicating drastic lake environmental change during MIS 3. Further palynological analysis for reconstructing variations in paleovegetation and paleoenvironment in the northern Mongolia since MIS 3, and comparison with palynological record in surrounding area (e.g., Kotokel lake in southern Siberia: Shichi et al., 2009; and Orog lake in southern Mongolia: Yu et al., 2019) are now ongoing.

Upper ocean (0–200 m) temperature reflects large scale ocean circulations and the atmospheric-ocean heat exchange. It is therefore a useful metric in characterizing paleoclimate, including the roles played by the East Asian Monsoon and the Indo-Pacific Warm Pool in driving the hydroclimate of East Asia. Geochemical proxies are widely used to reconstruct past ocean temperature, but may yield discrepant estimates due to chemical and ecological differences. This uncertainty in reconstructions can be constrained by a multiproxy approach. However, most existing paleoclimate studies in East Asia are inferred from single paleotemperature proxy. Consequently, the multiproxy discussion in this region is in fact based largely on different proxies from different sites, rendering it challenging to disentangle the effect of local climate from proxy discrepancy. In this study, we aim to characterize the magnitude and spatial pattern of the upper ocean temperature change in the western Pacific using an integrative multiproxy, multisite approach. Our sediment core sites span the South China Sea, Indo-Pacific Warm Pool and Kuroshio region. We generate a multiproxy paleotemperature database by combining newly generated data with published data. For all these sites, we obtain paleotemperature records inferred from three proxies, each based on vastly different source organisms, namely planktic foraminifera-based Mg/Ca, haptophyte-based UK’ 37, and archaea-based TEX86. As all proxies have their own pros and cons, this approach allows us to take advantage of the strengths of proxies to constrain the uncertainty of the others, thereby improving the robustness of paleoclimate reconstructions. As well as providing a constraint to the magnitude and spatial pattern of temperature change, this multiproxy database allows mapping of the ocean temperature change between distinct climate periods such as the Holocene and Last Glacial, which are often used to benchmark climate models. We envisage that this systematic multiproxy approach will refine our understanding of past changes in the oceans surrounding East Asia.

Changes in oceanic carbon and oxygen cycle during Heinrich event

*Akitomo Yamamoto[1], Ayako Abe-Ouchi[2]

1. Japan Agency for Marine-Earth Science and TechnologyAtmosphere and Ocean Research Institute, 2. Atmosphere and Ocean Research Institute, The University of Tokyo

Weakening of the Atlantic Meridional Overturning Circulation (AMOC) during Heinrich events was often accompanied by the atmospheric CO_2 increase of 10-20 ppm over 1000 years. Previous modeling studies display conflicting atmospheric CO_2 response to an AMOC shut down. On the other hand, recent paleoproxy records suggest that dwindling iron fertilization by dust in the Southern Ocean can contribute millennial-scale CO_2 oscilations (Martínez-García et al., 2014). However, the effect of changes in iron cycle has not been considered in the previous modeling studies.
In this study, we investigate the response of atmospheric CO_2 to changes in ocean circulation and dust-bone iron supply using numerical models. In associate with the AMOC weakening from 26 Sv to 6 Sv, the atmospheric CO_2 decreases by 2 ppm over 1000 years. Combining AMOC weakening and decrease in dust-bone iron supply, the atmospheric CO_2 increases more than 10 ppm. Reduction in export production associated with dwindling iron supply in the Southern Ocean release carbon from the deep sea, contributing to the increase in the atmospheric CO_2. Reduction in export production simultaneously increases dissolved oxygen in the Antarctic Bottomo Water, which is consistent with proxy records. Our results show the significant contribution of changes in dust-bone iron supply to the millennial CO_2 change in the glacial periods.

Stalagmite evidence for ^{18}O-depleted surface water of Japan Sea during the last glacial

*Shota Amekawa[1], Kenji Kashiwagi[2], Masako Hori[3], Tomomi Sone[4], Hirokazu Kato[1], Tomoyo Okumura[5], Tsai-Luen Yu[6], Chuan-Chou Shen[6,7,8], Akihiro Kano[1]

High-precision Mass Spectrometry and Environment Change Laboratory (HISPEC), Department of Geosciences, National Taiwan University, 7. Global Change Research Center, National Taiwan University, 8. Research Center for Future Earth, National Taiwan University

In East Asia monsoonal realm, stalagmites generally record lower $\delta^{18}O$ during warm humid interglacials and higher $\delta^{18}O$ in the cold dry glacials. Here, we present an unusual trend in stalagmite $\delta^{18}O$ between the last glacial interval and Holocene from Fukugaguchi Cave, Niigata Prefecture, where a major moisture source is the East Asian winter monsoon (EAWM) carrying vapor from the warm surface of the Japan Sea. The $\delta^{18}O$ profile of this stalagmite overall exhibits low $\delta^{18}O$ values; the mean sampled glacial $\delta^{18}O$ is distinctly lower than the mid-Holocene mean of another stalagmite (Sone et al., 2013) from the same cave. An interpretation assuming greater vapor transportation than mid-Holocene from the intensified EAWM during the last glacial contradicts marine carbonate records indicating that the entrance of the Tsushima Warm Current into the Japan Sea was interrupted because of lowered sea level. Additionally, our model indicates that the amount effect of winter meteoric water was insignificant. Low $\delta^{18}O$ in the stalagmite dated to glacial intervals in Fukugaguchi Cave most likely resulted from low-salinity and ^{18}O-depleted surface water, which developed in the isolated Japan Sea. This is the first terrestrial evidence indicating ^{18}O depletion and salinity of the Japan Sea surface water during the last glacial.

Biogenic opal changes at the Kamchatka Strait in the Bering Sea since the last glaciation

*Koshiro Matsuo[1]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University

The subarctic Pacific is known as a high biological productivity region mainly by diatoms. Particularly the central and eastern parts of the subarctic Pacific are high nutrient low chlorophyll (HNLC) regions. In the HNLC regions, lack of micronutrients such as iron regulate phytoplankton productivity despite of macronutrient availability such as nitrate, phosphate and silicate. Modern oceanographic observation has revealed dissolved iron transportation from the Okhotsk Sea to the western subarctic Pacific thorough intermediate water. Biological productivity in the subarctic Pacific was markedly low during the last glacial. Since the last glacial termination, the productivity in the subarctic Pacific increased but considerable regional differences were observed. In this study, biogenic opal content in KST-2A-PC obtained from the Kamchatka Strait was measured to understand changes in diatom production in the western Bering Sea. The biological opal content in KST-2A-PC showed gradual increase since the last glaciation without deglacial peak. This pattern was not similar to the central and eastern Bering Sea but similar to the Okhotsk Sea. The peaks of biological productivity at the southern, eastern, and northern Bering Sea and north open Pacific during the last deglaciation were influenced by increasing of supply in macronutrients which came from deep water and/or from continental shelves following the rise of sea level. However, Macronutrients had been consumed completely before reaching the western Bering Sea, so, in the last deglaciation, there were no peak of biological productivity at the western Bering Sea and in the Okhotsk Sea. Since Holocene, supply of macronutrients from deep sea and dissolved Fe from the Okhotsk Sea transported by intermediate water was increased, which caused increasing of biological productivity in the north Pacific marginal seas. Changes of utilization efficiency in macronutrients indicate that it was in the period from the last deglaciation to Holocene that macronutrients as regulatory factor of biological productivity were replaced with dissolved Fe, thus HNLC regions ware formed.

Intermediate water formation in the Bering Sea since the last glacial maximum based on *Cycladophora davisiana* abundances.

*Kento Ogata[1], Yusuke Okazaki[1]

1. Kyushu university Earth and Planetary sciences

Radiolarians are marine zooplankton with biogenic opal skeleton living in surface to deep ocean. Radiolarian microfossil assemblages in deep-sea sediments are used as paleoceanographic indicators and stratigraphic markers. Cycladophora davisiana is a radiolarian species dwelling in intermediate water with low temperature, high oxygen concentration, and rich in organic carbon. Therefore, increase and decrease in C. davisiana abundance in marine sediments suggests the presence of ventilated intermediate water. The Bering Sea, a marginal sea located in the North Pacific, is to be a source region of well-ventilated intermediate water in the glacial North Pacific. Here we show changes of C. davisiana abundances in sediment core obtained from the Kamchatka Strait, the largest strait in the Bering Sea, to reconstruct intermediate water formation change since last glaciation. KST-2A piston core sample was obtained from the Kamchatka Strait during Mu18 cruise by R/V Prof. Multanovskiy (56°11’ N;165°1’ E; water depth 3545 m; core long 454 cm). KST-2A-PC recorded past 20 kyrs (since the last glacial maximum, LGM) based on radiocarbon dating of planktic foraminifera and calcium concentration patterns. Two types of microslides were prepared for light microscopic observation by sieved through screens with different mesh opening sizes (>63 μm and >45 μm). Total radiolarian abundances (No. skeleton g-1) have gradually increased for the past 20 kyrs. Cycladophora davisiana abundances (No. skeleton g-1) fluctuated with peaks during deglacial warming periods. Although the total radiolarian and C. davisiana abundances (No. skeleton g-1) were significantly low during LGM, relative abundances (%) of C. davisiana were high during LGM as well as the deglacial warming periods. These C. davisiana abundance patterns suggest that intermediate water formation was active in the Bering Sea during the deglaciation. Total radiolarian abundances (No. skeleton g-1) estimated by using >45 μm were much higher than those of >63 μm. However, there was no significant difference in %C. davisiana patterns between >45 μm and >63 μm samples.

Analysis from Benthic foraminifera populations of expansion and intensify of the northwestern Pacific oxygen minimum zone during the last deglaciation

*Keisuke Sakai[1], Ken'ichi Ohkushi[1], Akihiko Shibahara[2]

1. Graduate School of Human Development and Environment, Kobe University, 2. Fukui Prefectural University Institute of Dinosaur Research

During the last deglaciation, the oxygen minimum zone (OMZ) at 1 km water depth in the northwestern Pacific Ocean intensified. However, time-series fluctuations of the upper layer of the OMZ are poorly understood. Fossil benthic foraminifera are useful indicators of historic deoxygenation at the seafloor due to their specific patterns of adaptation to dysoxic environments. Thus, we studied benthic foraminifera assemblages in a sediment core taken from a water depth of 777 m off of Hokkaido, North Japan, to reconstruct changes in the upper layer of the OMZ during the last deglaciation. The results suggested that dysoxic species such as Brizalina seminuda and Buliminella tenuata increased rapidly during the Bølling/Ållerød warming event, implying severe oxygen depletion. Similar dysoxic assemblages were recorded at 1 km water depth in this region. We concluded that the upper limit of the OMZ in the northwestern Pacific expanded during the last deglaciation, due to an increase in biological production and decrease in intermediate water ventilation.

Keywords: Benthic foraminifera, last deglaciation, oxygen minimum zone, northwestern Pacific, Bølling/Ållerød

Changes in carbon and oxygen isotopes of benthic foraminifera in the East China Sea since the last glacial maximum

*Miki Muranaka[1], Yusuke Okazaki[2], Yoshimi Kubota[3]

1. Department of Earth and Planetary Sciences, Kyushu University, 2. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University, 3. National Museum of Nature and Science

The continental shelves shallower than 200 m water depths occupies more than 70 % of the area of East China Sea (ECS). During the last glacial maximum (LGM), sea-level dropped by 120 m. Therefore, vast area of the ECS continental shelves were aerially exposed. Here we present carbon and oxygen isotopes of benthic foraminifera in sediment core from the Danjo Basin, northern ECS (KY07-04-PC01, 31˚38.35’ N, 128˚56.64’ E, 758 m water depth). Foraminiferal shells are composed of calcite ($CaCO_3$). Carbon isotope ratio ($\delta^{13}C$) of benthic foraminifera is used as a proxy for nutrient concentrations Therefore, benthic foraminiferal $\delta^{13}C$ is useful for reconstructing past water mass structures. Oxygen isotope ratio ($\delta^{18}O$) of benthic foraminifera is used as a proxy for ice volume and water temperature. Two benthic foraminiferal taxa *Uvigerina* spp. and *Hyalinea balthica* were picked up from KY07-04-PC01 sample and were used for $\delta^{13}C$ and $\delta^{18}O$ measurements. The $\delta^{13}C$ of *Uvigerina* spp. during LGM was ~2 ‰heavier than those of Holocene. This offset can be explained by oscillation of two water masses in ECS: cold and nutrient-rich Chinese coastal water was prevailing in glacial semi-closed ECS; warm and nutrient-depleted Kuroshio water increased since deglaciation with sea-level rise. The $\delta^{18}O$ of *Uvigerina* spp. gradually decreased from 3.76 ‰during LGM to 2.39 ‰during late Holocene. The 1.36 ‰ $\delta^{18}O$ offset is caused by ice volume and water temperature. Because the ice volume effect for benthic $\delta^{18}O$ between LGM and present is estimated to be 1.1 ‰, the residual 0.27 ‰is equivalent to water temperature change of 1 ℃. This suggests intermediate water temperature in northern ECS has risen by 1 ℃ since LGM. There are two morphology in *Uvigerina* spp., with more spiny and less spiny. Because offsets of $\delta^{13}C$ and $\delta^{18}O$ between the two morphologic types, it is desirable to measure separately. *Hyalinea balthica* showed ~1 ‰lighter $\delta^{13}C$ and $\delta^{18}O$ values than those of *Uvigerina* spp. In addition, it was time-consuming for cleaning *Hyalinea balthica* shells. Thus, *H. balthica* is not a proper benthic foraminiferal species for $\delta^{13}C$ and $\delta^{18}O$ measurements.

Southward Migration of Inter-Tropical Convergence Zone (ITCZ) during Mid-Late Holocene: New Evidence from Sri Lanka

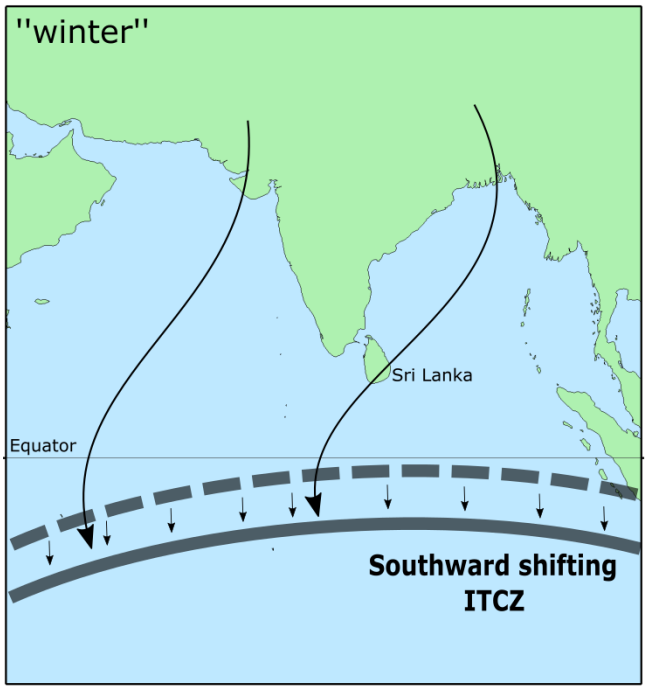
*Kasun Gayantha[1], Patrick Roberts[2], Joyanto Routh[3], Achim Brauer[4], Rohana Chandrajith[5], Oshan Wedage[2], Florian Ott[2], Gerd Gleixner[1]

1. Max Planck Institute for Biogeochemistry, Jena, Germany, 2. Max Planck Institute for the Science of Human History, Jena, Germany, 3. TEMA-M, Linköping University, Linköping, Sweden, 4. GFZ, Potsdam, Germany, 5. Department of Geology, University of Peradeniya, Sri Lanka

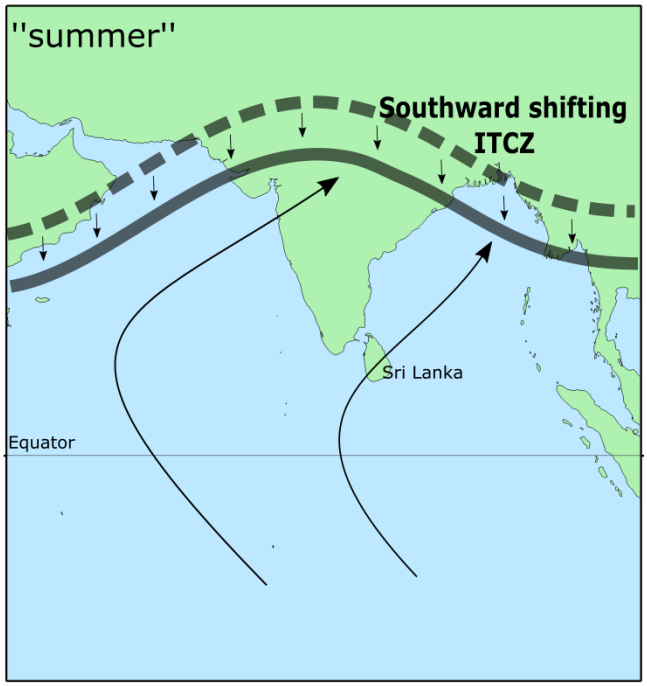
Southward migration of the mean latitudinal position of the Inter-Tropical Convergence Zone (ITCZ) as a response to decreasing solar insolation in the Northern hemisphere during the Mid and Late Holocene is discussed widely (Haug et al. 2001; Broccoli et al. 2006; Fleitmann et al. 2007). This hypothesis is supported by the millennial-scale continuous weakening trend of the Indian summer monsoon (ISM) and Asian summer monsoon (ASM) within the core monsoon domains in the Indian sub-continent (Gupta et al. 2003), East Asia (Wang and Tsonis 2008), Middle East (Fleitmann 2003) and South America (Maslin and Burns 2000). However, in contrast to this hypothesis, some studies suggest an abrupt weakening of the ISM and ASM between ~ 4.5 and 5.0 ka BP (Morrill et al. 2003 and references therein). This forms a question of whether the ISM and ASM weakening occurred gradually related to orbital forcing or abruptly due to variations in other components of the climatic system, that is important to know for developing general and regional climate models that help to predict future climate trends.

The South Asian region is directly impacted by the ISM and retreating Indian winter monsoon (IWM) and the agriculture-based economy in this region is strongly dependent on the seasonal precipitation. However, very limited well-dated and continuous paleoclimate archives, especially in the southern parts of the Indian sub-continent that is fed by both summer and winter monsoon rainfalls creates a significant knowledge gap to understand the behavior of Indian monsoon system. So far, our understanding of millennial-scale ITCZ fluctuations depends on the ISM records and evidence from the retreating IWM are still scarce.

The geographical location of Sri Lanka, lying in the center of the seasonal ITCZ migration path and the rain shadow effect due to the central highlands, allows us to study the summer and winter monsoon rainfall variations separately. The position of ITCZ is directly impacting the duration of both monsoon seasons (Fig 1). Therefore, a multi-proxy analysis was conducted on three sediment cores retrieved from the summer monsoon-fed wet zone (South Bolgoda Lake and Horton Plains) and winter monsoon-fed dry zone (Panama lagoon) of Sri Lanka. Together with ^{14}C based age models, rainfall variations in the regions were traced based on compound-specific carbon and hydrogen isotopes of leaf wax *n*-alkane (*n*-C_{33} and C_{31}) and detrital elemental ratios (Zr/Rb and Zr/Al) related to grain size variation.



The increasing trend of δD and $\delta^{13}C$ values of leaf wax *n*-alkane of ISM influenced South Bolgoda Lake and Horton Plains showed a gradually decreasing trend of the rainfall over last ~6 ka BP despite few short-term abrupt events. This trend is also supported by the gradual decreasing trend of detrital element ratios (Zr/Rb and Zr/Al) supporting less continental erosion from declining rainfall. In contrast to these trends observed in the wet zone, retreating IWM influenced Panama lagoon located in the dry zone showed inverse results indicating a more gradual increase in winter precipitation during the same period. This inverse relationship between ISM and IWM rainfall can be explained by the concept of southward migration of the mean latitudinal position of ITCZ during the mid and late Holocene that occurred as a



©2020. Japan Geoscience Union. All Right Reserved.

response of solar insolation variations in the Northern and Southern

Hemispheres. When the southern and northernmost positions of ITCZ gradually shift southward, the duration of IWM rainfall can increase resulting in relatively higher rainfall in the dry zone of Sri Lanka. Meantime, the inverse effect on the ISM can be expected in the wet zone. Our results indicate that the annual precipitation of Sri Lanka shifting towards a winter monsoon dominant system from summer monsoon dominant system over last ~ 6 ka BP, as a result of the solar-induced shift of ITCZ.

Diatom and Chrysophyceae Assemblages from the Holocene Alluvial Core Sediments at Southern and Western Coasts of Korea Peninsula

*Kaoru Kashima[1], Yu Fukumoto[3], Sangheon Yi[2], Dong-Yoon Yang[2], Min Han[2]

1. Department of Earth and Planetary Sciences, Kyushu University, 2. Korea Institute of Geoscience & Mineral Resources (KIGAM) , 3. Ritsumeikan University

The Holocene alluvial sediments kept traces of the abrupt Holocene climatic events in coastal area. Park et al (2019) presumed at 8.2 ka, 4.2ka and 2.8 ka BP events using drilling cores at south and west coast of Korea Peninsula by Pollen analysis, C14 dating and chemical analyses.

We selected the three cores along the western and southern coasts of Korea Peninsula for the analysis of diatom and Chyrysophyceae assemblages. All cores presumed to insert marine clay within the core by their lithological observation. The diatom assemblages showed the marine transgressive process at the lowland according to the Holocene marine transgression, the closing bay and lagoon forming processes, marine regressions and land forming processes clearly. Diatoms also showed the erosional stages by the sudden changes of their assemblage compositions when we could not find the erosional structures in the deltaic sediment. For discussing of the ancient sailing rout, to detect the erosional surface by tidal currents was necessary to presume the ancient water depth.

Chrysophyceae is one of the single cell algae, generally called as Golden Algae. It forms hard silicate cist (Statospore) at the resting period of its life cycle. Although soft bodies of Chrysophyceae were not able to be kept in the sediments, their statospores were well kept in the sediments. They were reported not only from freshwater lake and pond sediments, but also from oceanic drilling cores. The Statospores taken from the cores of this paper might be freshwater alkaline favorite ones by their shapes and size. The possibility for the tools of paleo-environmental reconstructions has been under discussing.

In this presentation, we will discuss the Diatom and Chrysophyceae Assemblages from STP17-13 core, southern coast of Korea Peninsula, STP16-01 core, south-western coast of Korea Peninsula and DSE18-06 core at western coast of Korea Peninsula. All of them were taken undisturbed core samples until the base of the Holocene, and lithological and microfossil assemblages (Pollen) presumed the Holocene climatic events at 8.2 ka, 4.2ka and 2.8ka in the cores. Diatom and Chrysophyceae Assemblages shifted to be corresponded to those climatic events.

Correlation between stable isotope ratio of pollen and climate, as well as its possible application for paleoclimatology

*Yamasaki Akiteru[1], Keitaro Yamada[2], Takayuki Omori[3], Ikuko Kitaba[2], Takeshi Nakagawa[2]

1. Fukui Prefectural Satoyama-Satoumi Reserch Institute, 2. Research Centre for Palaeoclimatology, Ritsumeikan University, 3. The University museum, The University of Tokyo

Introduction

Obtaining detailed paleoclimate information on terrestrial realms is essential for understanding the interaction between the atmosphere and the ocean. In particular, climate in mid- latitudinal land is closely related to the human’ s life.
Fossil pollen analysis in lacustrine sediments is a widely used method for examining the paleoclimate on land (e.g. Tarasov et al., 2011; Kigoshi et al., 2014).
Quantitative reconstruction of paleoclimate using pollen data has also been attempted (Guiot, 1991; Nakagawa et al. 2002). However, direct correlation between pollen records and other high-quality data sets, such as ice core and ocean records, is not straightforward because of the response time of vegetation (Williams et al., 2002).
To solve this problem, the possibility of reconstructing paleoclimate using pollen isotope data has been pointed out (Loader and Hemming, 2004). Recently developed method of efficient high purity pollen extraction (Yamada et al.,2019, INQUA) made it realistic.
We aim at quantitative reconstruction of paleoclimate based on pollen isotope data. In this study, we evaluated the response of pollen isotope to climate using live arboreal pollen.

Method

Studies on the relationship between pollen stable isotope ratios and climate in Europe suggests a correlation between hydrogen isotope ratio and precipitation. However, the data size is too small to use the results for application. In this study, we measured oxygen isotope ratio of cedar pollen that were collected from 125 sites across Japan. The measurement was made using TC/EA (thermo Scientific Co., Ltd.) of the University Museum, the University of Tokyo.
As the meteorological observation data, we used mesh agricultural meteorological data from National Agriculture and Food Research Organization (NARO). he mesh dataset has 1km resolution and was generated from AMeDAS weather observation records, taking into account temperature lapse rate, topography and other relevant factors (Kiyono, 1993; Ono et al., 2016).

Results and discussion

The 125 sites that we could include in this study covered an area with an average annual temperature of 12-17 ˚C, precipitation of 1600-4000mm, altitude of 0-1000m, and latitude of 32-39 ˚.A strong correlation between pollen oxygen isotope ratio the mean annual temperature was found (r = 0.66).On the other hand, there was a systematic drift in isotope ratio according to the altitude of the pollen sampling point.
This study confirms that the oxygen isotope ratio of pollen responds to temperature.
In the future, although we still have to understand the isotope fractionation process of pollen and apply correction against altitude, it is possible to use the pollen oxygen isotope data for quantitatively reconstructing temperature.

Uncertainty of tree-ring based temperature reconstruction: Effects of soil moisture environment and air pollution on reconstruction records

*Shunsuke Tei[1], Shinya Takano[1], Teppei J Yasunari[1]

1. Arctic Research Center, Hokkaido University

Since global observation records only cover for the last 120 years, the paleoclimate reconstruction using proxy records is indispensable to fully understand past climate change on a multi-decadal/century time scale. Tree rings have long been used to be an excellent proxy for temperature. However, since the latter half of the 20th century, the correlation between the tree ring parameters (width and density) and temperature has been significantly weakened in several areas in the northern high latitudes, which likely reduces credibility of the reported tree-ring based temperature reconstructions. While the temperature records indicate a substantial warming trend in the late 20th century, tree rings in such areas do not display a corresponding change. Although some hypotheses on explaining the inconsistency have been suggested, the best mechanism for fully understand it has not been obtained yet.

The purpose of our study is to identify the environmental factors responsible for the influencing the relationship between tree-ring parameters and temperature in the northern high latitudes by using available datasets for tree ring parameters and environmental variables. We focus on two environmental factors: 1) soil moisture environment; 2) air pollution, both of which might affect plant carbon uptake processes through adjustment of stomatal openness. We clarify the effects of these environmental factors on tree ring parameters. In this presentation, we intend to show the preliminary results on this, especially for the possible impact of the air pollution on the tree ring parameters.

Horizontal distribution of diatoms in the western Bering Sea surface waters

*Aika Yamamoto[1], Yusuke Okazaki[2]

1. Department of Earth and Planetary Sciences, Kyushu University, 2. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University

Diatoms are phytoplankton with biogenic opal ($SiO_2 \cdot nH_2O$) frustules. A variety of diatom species live in various aquatic environments sensitively responding to environmental change. Diatom’ s reproduction rate is notably rapid due to their reproductive cycle by combining asexual cell division and sexual reproduction to restore the cell size. Diatoms are major primary producer in the present hydrosphere. The Bering Sea is a margin sea of North Pacific with northern continental shelves and southern basin. The Bering Sea is characterized by high productivity mainly by diatoms. In particular, pronounced high productivity area called the Bering Sea Green Belt is distributed along the edge of the continental shelves. Productivity in the Bering Sea has strong seasonality with primary spring peak and secondary fall peak due to insolation and nutrient availability in the euphotic zone. Purpose of this study is to clarify the horizontal distribution of diatom assemblages in western Bering Sea. Surface water samples were collected at 30 stations in the western Bering Sea during Mu18 cruise by *R/V Multanovskiy* in summer 2018. The seawater samples were filtered onboard. After disembarking, scanning electron microscopic observation for diatom assemblages was performed using the filter samples. A total of 15 genus 9 species were identified. Clear differences of diatom assemblages were found between basin and continental shelf stations. Major diatom taxa in basin stations were *Nitzschia* spp., *Fragilariopsis* spp., and *Neodenticula seminae.* On the other hand, major diatom taxa in continental shelf stations were *Nitzschia* spp., *Thalassiosira* spp., and *Arcocellulus* spp. Most of *Fragilariopsis* spp. encountered in this study were markedly small probably proliferated by asexual reproduction. Among *Thalassiosira* spp., *T.* cf. *oceanica* were commonly found at most of the shelf stations except for stations with low temperature and high salinity where *T. nordenskioeldii* and *T. pacifica* were abundant.

Spatio-temporal variations in fossil coral assemblages in late Middle Pleistocene limestones of the Minatogawa Formation, southern Okinawa-jima, Japan

*Riho Tomatsu[1], Marc Humblet[1], Kazuhiko Fujita[2], Yui Kouketsu[1], Yasufumi Iryu[3]

1. Graduate School of Environmental Studies, Nagoya University, 2. Department of Physics and Earth Sciences, University of the Ryukyus, 3. Institute of Geology and Paleontology Graduate School of Science Tohoku University

Quaternary reef-complex deposits crop out extensively in the Ryukyu Islands, southwestern Japan, providing a unique record of reef growth history close to the northern limit of modern coral reef distribution. The late Middle Pleistocene Minatogawa Formation (<0.4 Ma) is exposed along the coast of southern Okinawa Island and on nearby islets. The Minatogawa Formation is 20 m thick in the study area and is composed of four units (in ascending order: Unit 1–4) separated by unconformities. The main lithologies are coral-rich limestone (coral boundstone and rudstone) and well-sorted detrital limestone (mainly foraminifer-rich grainstone). In this study, we examine the taxonomic compositions and the spatio-temporal distribution of fossil coral assemblages in the Minatogawa Formation to achieve the following goals: (1) to clarify the depositional history of the Minatogawa Formation and (2) to reconstruct relative sea-level changes and their impact on coral communities. To reach these objectives, field work was carried out in a large quarry in southern Okinawa Island. Results reveal six distinct coral assemblages in Unit 2 and 3, each indicating a particular reef environment, from shallow (<5 m) exposed and protected settings to deeper (up to 25–30 m) reef-slope settings. The coral assemblage found in Unit 2 suggests that the coral boundstone and well-sorted detrital limestone in this unit formed concomitantly in a lower reef slope setting, or perhaps, a shallower but turbid environment. In contrast, the analysis of coral assemblages of Unit 3 and of the boundary between the coral boundstone and adjacent well-sorted detrital limestone in this unit suggest a relative sea-level history more complex than previously thought, as attested by the occurrence of a subaerial exposure surface between the coral boundstone and adjacent well-sorted detrital limestone. Temporal (vertical) variations in coral assemblages within Unit 3 reflect the various stages of reef growth, from reef initiation at the base of the unit to reef demise at the top due to exposure during relative sea-level fall. In addition, crustal movements have influenced reef growth during the deposition of the Minatogawa Formation. A syn-depositional fault intersecting the boundary between Unit 2 and 3 attests of small-amplitude sea-level changes caused by tectonic activity. Ongoing efforts are being made to constrain the age of the Minatogawa Formation in order to clarify the relationship between its depositional history and global eustatic sea-level changes.

[M-IS09] Interdisciplinary studies on pre-earthquake processes

convener:Katsumi Hattori(Department of Earth Sciences, Graduate School of Science, Chiba University), Dimitar Ouzounov(Center of Excellence in Earth Systems Modeling & Observations (CEESMO) , Schmid College of Science & Technology Chapman University, Orange, California, USA), Jann-Yenq LIU(Department of Space Science and Engineering, National Central University, Taiwan), Qinghua Huang(Peking University)

This session expands the interdisciplinary discussions on preparation process of earthquake and earthquake predictability by presenting the latest progress in studying the physically based pre-earthquake phenomena. New observations from space and ground have provided evidences, which may enhance better understanding of tectonic activity. The session anticipates talks that include but not limited to observations and analyses of seismic, electrical, electromagnetic, electro-chemical and thermodynamic processes related to stress changes in the lithosphere along with their statistical and physical validation. Presentations on the latest observational results associated with major earthquakes obtained by different methodologies are welcomed. The topics of the session are as follows but not limited.

 -General discussion on earthquake preparation process and the physics of pre-earthquake signals
 - Theory, modeling, laboratory experiments, computational simulation for generation and propagation of pre-earthquake signals and their connection with seismic cycle
 - Multi-parameter observations, detection, and validation of pre-earthquake signals
 - Cross-disciplinary studies, practical and technical approaches for better understanding of earthquake preparation processes and their connection with seismicity

FORMOSAT-7/COSMIC-2 observing seismo-ionospheric precursors of the 14 November 2019 M7.1 Indonesia Earthquake

*JANN-YENQ Liu[1,2], CHIYEN LIN[1,2], FU-YUAN CHANG[1,2], Yuh-Ing Chen[3]

1. Center for Astronautical Physics and Engineering, National Central University, Taiwan, 2. Department of Space Science and Engineering, National Central University, Taiwan, 3. Graduate Institute of Statistics, National Central University, Taiwan

FORMOSAT-7/COSMIC-2 (F7/C2), with the mission orbit of 550 km altitude, 24-deg inclination, and a period of 97 minutes, was launched on 25 June 2019. Tri-GNSS Radio occultation System (TGRS), Ion Velocity Meter (IVM), and RF beacon onboard F7/C2 six small satellites allow scientists to observe the plasma structure and dynamics in the mid-latitude, low-latitude, and equatorial ionosphere in detail. F7/C2 TGRS sounds ionospheric RO (radio occultation) electron density profiles, while F7/C2 IVM probes the ion density, ion temperature, and ion velocity at the satellite altitude. The F7/C2 electron density profiles and the ion density, ion temperature, and ion velocity, as well as the global ionospheric map (GIM) of the total electron content (TEC) derived from global ground-based GPS receivers are used to detect seismo-ionospheric precursors (SIPs) of the 14 November 2019 M7.1 Indonesia Earthquake. The GIM TEC and F7/C2 RO NmF2 significantly increase specifically over the epicenter on 25-26 October, which indicates SIPs of the 14 November 2019 M7.1 Indonesia Earthquake being detected. The F7/C2 RO electron density profiles upward motions suggest that the eastward electric fields have been enhanced during the SIP days of the 2019 M7.1 Indonesia earthquake. The seismo-generated electric fields of the 2019 M7.1 Indonesia earthquake are 0.34-0.64 mV/m eastward. The results demonstrate that F7/C2 can be employed to detect SIPs in the ionospheric plasma, which shall shed some light on earthquake prediction/forecast.

Statistical Analysis of Pre-Seismic Ionospheric Anomalies and their Characteristic

*Sanaka Saito[1], Chie Yoshino[1], Katsumi Hattori[1]

1. Chiba University

Recently, many papers show various electromagnetic phenomena preceding earthquakes. For example, anomalous changes in ionospheric electrons observed by GNSS satellites (GNSS-TEC) have been reported worldwide. [Kon et al., 2011] performed statistical analysis on pre-seismic anomalies of the total electron contents (TEC) over Japan. Their results showed that significant positive anomalies appear 1-5 days before the earthquake.
On the other hand, GNSS-TEC data exist after the late 1990s. In this study, we focused on the ionosonde which is a ground-based ionosphere monitoring instrument that has long-term data (1958-) over Japan. We performed statistical correlation analysis between a sizeable earthquake and an anomaly in the ionospheric maximum electron density (NmF2) and its altitude (hmF2). The method of statistical analysis is Superposed Epoch Analysis (SEA). From the results of SEA.

We take 15 days backward median and its IQR for the definition of anomalies. If the observed data exceeds median+1.5IQR or median-1.5IQR, we define it shows anomaly.

Since ionospheric disturbances are also caused by geomagnetic storms, it is necessary to remove these effects. We checked the characteristics of ionospheric anomalies caused by geomagnetic storms in statistically and removed those effects based on the magnitude of storm and its generation time in local time.
We select earthquakes occurred within 1000 km and 350 km radius from the ionosonde station, and M >= 6 and D <= 40 km.

The results of SEA show that there are significant positive anomalies in NmF2 for 6-10 days before the earthquake within a radius of 1000 km and for 1-10 days within a radius of 350 km. On the other hand, no clear anomalies were found for hmF2.

Further, Molchan's Error Diagram (MED) analysis was performed to assess the precursory of NmF2. We applied MED analysis for the most significant anomalies such as 6-10 days in 5-day count and 7 days in 1-day count before the earthquake. As a result, MED showed a precursor to the earthquake in both cases.

Pre-earthquake early-warning signals of ULF geoelectric data and their earthquake forecasting probability: A case of Kakioka, Japan

*Hong-Jia Chen[1], Katsumi Hattori[1], Ryo Takahira[1]

1. Chiba University

As laboratory rock experiments and field data analyses show, electromagnetic phenomena are believed to be candidates for the short-term prediction of large earthquakes. Moreover, among previous studies for the field data analyses, ULF electromagnetic signals are one of the most promising precursor methods due to deep skin depth observation. However, the previous studies were carried on through case-study analyses or one-phase optimizations (i.e., a training phase). Before the earthquake forecasting, the first intermediate step is to test relationships between the prescribed anomalies and an earthquake catalog. This is what machine learning scientists refer to as "the training phase". Once detecting anomalies of any earth science data, we have to define a specific algorithm relying on a limited set of unambiguous parameters, which associates those anomalies within a target space-time-magnitude window relative to an impending earthquake. This is the only way to quantify the skill of the tested model and its sensitivity to input parameters. After the training phase, true forecasts can be proposed, which consist in selecting the optimal model parameters and applying them to an independent dataset (i.e., a testing phase). In this study, we verify the relationship between electromagnetic anomalies and earthquakes through the two-phase optimization (i.e., a training phase and a testing phase). First, we analyze ULF geoelectric data at Kakioka, Japan each day and calculate three statistical moments (i.e., variance, skewness, and kurtosis) based on the early-warning signal theory (Scheffer, 2009). Second, we estimate the thresholds for variance, skewness, and kurtosis for the N- and E-components of the geoelectric data and define the anomalies for the three statistical moments of both components. Third, we set up a predictive model and optimize this model within a training phase. Fourth, we select the optimal model parameters and test those parameters within a forecasting phase following the training phase. Results show that the model performance for the forecasting phase has significance, implying that the pre-earthquake electromagnetic anomalies are true earthquake precursors, although the mechanism remains unclear. The present study is therefore intended to make contributions to the establishment of correctly examining correlations between anomalies of earth science data and earthquake catalogs.

Keywords: ULF geoelectric data, statistical moment, earthquake forecast

Numerical simulation of ULF electromagnetic wave propagation in the lithosphere associated with earthquakes by using the WLP-FDTD method

*Ryota Kimura[1], Yoshiaki Ando[1], Katsumi Hattori[2]

1. The University of Electro-Communications, 2. Chiba University

For decades, many papers reported that the Ultra Low Frequency (ULF) radiations associated with earthquakes were observed by magnetometers installed at the Earth’ s surface. Those mainly focused on detection of anomalies exceeding noises, or anomalous characteristics extracted from noises via signal processing. However, observed signals involve information of not only their source intensity, but also losses of media in which the ULF waves propagate, which should be taken into account. For this reason, numerical simulation of ULF propagation in the lithosphere is of importance.

In this study, we develop numerical simulation of the ULF propagation by using the weighted Laguerre polynomial finite-difference time-domain (WLP-FDTD) method with considering electrical properties of lithosphere, and investigate correlation between magnitude of earthquakes and the source current intensity of ULF radiation which is deduced from the numerical simulation.

The WLP-FDTD method solves electromagnetic fields by expanding solutions into weighted Laguerre polynomial series, discretizing computational region in space, and reducing the Maxwell equations into linear equations. This method is not a marching-on-time, but a marching-on-degree scheme, so that we can obtain more precise solutions by iteration even for responses over long time duration. The WLP-FDTD method showed several ten times less computational time than the conventional FDTD method.

We adopt Loma Prieta earthquake as a standard because the observation was performed over wide range of frequency bands so that frequency characteristics of the source current can be deduced. The conductivity distribution around the epicenter was obtained by the magnetotelluric measurement and it is implemented in the WLP-FDTD simulation.

Next, we calculate the source current intensity of earthquakes, such as Spitak EQ (1988), Biak EQ (1996), and Alum Rock EQ (2007), under the assumption that the frequency dependence of the source current is the same as one of Loma Prieta EQ. Especially, in Biak EQ the ULF signals are not detected directly, but the polarization analysis showed an anomaly associated with EQ. Therefore, we deduce that the Signal-to-Noise ratio of Biak EQ is approximately -3dB because the ULF wave at the observation point is less than noises, but is not much less. The conductivity is also taken into consideration in the simulation in each EQ, using MT measuments and bathymetry data.

From the above analyses, it is found that the relative intensity of source currents grows exponentially with the magnitude of EQs.

Geomagnetic *S*q equivalent currents variation characters in the 210° mm meridian region

*Xiaocan Liu[1], Katsumi Hattori[2,3], Huaran Chen[1], Peng Han[4], Chie Yoshino[2], Xudong Zhao[1]

1. Institute of geophysics China Earthquake Administrition, 2. Graduate School of Science, Chiba University, Chiba, Japan, 3. Center for Environmental Remote Sensing, Chiba University, Chiba, Japan, 4. Department of Earth and Space Sciences, Southern University of Science and Technology, ShenZhen, China

Abstract When solar-terrestrial disturbances are absent, daily variations of the geomagnetic field are called *S*q (solar quiet) [Campbell, 1989; Yamazaki, 2009]. It is well known that the amplitude of *S*q variation shows annual changes [Chapman and Bartels, 1940; Chapman, 1951, Kane, 1976], well as the intensity and morphology of the equivalent *S*q current system, and the position of the vortex centers of the current system have an annual variation in the local time and latitude [Matsushita and Maeda, 1965; Takeda, 1999,2002; Olsen, 1997; Yamashita and Iyemori,2002; Xu W.Y., 1992, 1993,2003,2004; Zhao X.D. et.al, 2008, 2010,2014]. Most of these studies are based on global geomagnetic observations, so there is lack of researches on regional *S*q variation changes, Yamazaki (2009) analyzed the spatial distribution of the annual and semiannual *S*q variations by using 19 stations along 210°mm during 1996 to 2007, but the external and inner parts of Sq equivalent current system were not be separated in his work. So, in present work, we use different stations along 210° mm to investigate the variation characteristics of the external and inner two parts of *S*q equivalent current systems respectively during 2009 to 2013 in Japan- Australia region.

We use 20 geomagnetic observatories distributing at both the Northern hemisphere and the Southern hemisphere along with the 210°magnetic meridian(mm) from 2009 to 2013, which include 10 observatories in Japan, and investigate the variation characters of *S*q equivalent external and inner currents in D season(January, February, October, December, namely winter season) E season(March, April, September, November namely equinox season) and J season (May, June, July, August, namely summer season), here we use three currents parameters to analyze, as the local time (LT), latitude (Lat) and current intensity(J) of current vortexes center, as the result, both external and inner current parameters demonstrate significant seasonal variation respectively. There are also special case, as each hemisphere have one vortex in northern and southern, we find Lat parameter in northern vortex of external current and southern vortex of inner current almost have non-seasonal variations. Then, we analysis more detail variation characters in each season, like J parameter in D season is lowest, have values about 50kA to 100kA, however the values are about 100kA to 150kA in other seasons of external currents. And we also get some asymmetric variation characters for northern and southern hemisphere, for example, in J season, LT of Southern hemisphere vortex center is about 1400LT, but in northern hemisphere vortex center is about 1030LT at the same time, here, obvious LT time shift and asymmetric activity between two hemispheres appear.

Measurement of vertical distribution of environmental radiation using a drone at Choshi

*Tohru Okabayashi[1], Kiyotaka Ninagawa[2], Isao Yamamoto[2], Nobuhiro Maeda

1. Chiba Institute of Science, 2. Okayama University of Science

Increases of radon density in atmosphere [1] and in groundwater [2] at the southern part of Hyogo Prefecture Earthquake in 1995 were reported, respectively. In the case of Tohoku Region Pacific Coast Earthquake, the data obtained the exhaust air monitor that peak duration was long and the peak decreased rapidly before earthquake has been reported at the radiation facility of Fukushima Medical College in Fukushima [3]. An anomalous increase in radon concentration was measured at the Nakaizu observatory on the Izu Peninsula prior to the 2011 Thohoku earthquake [4].

We have reported continuous measurements of atmospheric radon density on the ground at Okayama for three years, Kochi, Choshi and Kiyosumi for two years, to predict earthquakes. In these measurements, we usually measured daily variations of the radon density. A model of the daily variations was proposed by Yoshioka [5].

This time, we tried to measure the vertical distribution of environmental radiation in atmosphere by using a drone (DJI MAVIC2 PRO) with a gamma ray detector, Radi (PA-1100, HORIBA). Preliminary measurement was done at Choshi (N35.71˚, E140.84˚), inside Chiba Institute of Science (CIS) from 12:06 to 12:17 on Feb. 15, 2020. We observed radiations of 0.056 micro-Sv/h (43m of altitude), 0.05 (56.6m), 0.054 (60.5m), 0.043 (79.5m), 0.036 (101.5m), 0.032 (112.5m), 0.033 (124m), 0.034 (141m) and 0.022 (151.2m). Environmental radiation dose trended to decrease in increase of altitude. Further measurements of vertical distribution of environmental radiation around CIS will be presented.

Ground Rn flux anomaly and crustal activity around Asahi station, Boso Peninsula, Japan

*Haruna Kojima[1], Chie Yoshino[1], Katsumi Hattori[1], Michikuni Shimo[2], Toshiharu Konishi[3], Ryuichi Furuya[4]

1. Chiba University, 2. Fujita Health University, 3. OHYO KOKEN KOGYO Co.,Ltd, 4. COM SYSTEM Inc.

In recent years, there are many studies reported on electromagnetic phenomena preceding earthquakes such as geomagnetic, ionospheric, and atmospheric anomalous changes. Ionospheric anomalies preceding large earthquakes are most of the promising phenomena. Lithosphere-Atmosphere-Ionosphere Coupling (LAIC) model has been proposed to explain earthquake-related atmospheric and ionospheric phenomena. In this study, to evaluate the possibility of chemical channel of LAIC by observation, we have installed sensors for atmospheric electric field (AEF), atmospheric ion concentration (AIC), atmospheric Rn concentration (ARC), ground Rn concentration (GRC), and weather elements at Asahi station, Boso Peninsula, Japan. Because the atmospheric electricity parameters could be mainly influenced by weather factors, it is necessary to remove these influences as much as possible. In this sense, we apply the MSSA (Multi-channel Singular Spectral Analysis) to remove these influences from the GRC variation and estimate the ground Rn flux (GRF). We investigated the correlations between GRF and crustal activity such as earthquakes and deformation.

For earthquakes within an epicenter distance of 50 km from the station, it is found that the correlation between Rn flux and regional cumulative seismic moment and/or Es index, which indicates the daily local seismic energy received at the station. These earthquakes had the characteristics they occurred directly underneath the station in the boundary of the Pacific Plate and the North American Plate and they are reverse fault type components.

We investigated the relationship between stress change and GRF to consider the model of fluctuation of the GRF. In this study, we calculated the dilatation using the F3 solution published by the Geospatial Information Authority of Japan. As a result, the GRF increased with compression and decreased with expansion. The result suggests that GRF has the sensitivity to stress changes and can be an indicator of large earthquakes that have pre-slip and slow slip events.

The Study of Sq Equivalent Current during the Solar Cycle

*Xudong Zhao[1]

1. Institute of Geophysics, China Earthquake Administration

The Sq current relates to the solar very closely. The activities of solar directly affect the Sq current. In this paper, the geomagnetic data from INTERMAGNET and Geomagnetic Network Center of China Earthquake Administration in 23rd solar cycle (1996~2006) have been used to analyze the variation of external and internal source Sq equivalent current. The method we adopted is the spherical harmonics analysis. The strength of the Sq equivalent current has a good correlation to the spot number of the sun. The intensity of the current is larger during the solar maximum years than that during the solar minimum years. The latitude of the current focus is not affected significantly by the solar activities. There is an evident difference between the seasonal change of current intensity during the solar maximum years and solar minimum years. During the solar maximum years, the peak value of current intensity occurs near the equinoxes, while during the solar minimum years, the peak value of current intensity occurs near the solstices.

Keywords: external and internal Sq current, the spherical harmonics analysis, solar activity

Development of 3D self-potential tomography and electro-kinetic effects

*ayaka ishikawa[1], Katsumi Hattori[1]

1. chiba university

Visualization of the dynamics of underground fluid is important to investigate geothermal resources and study earthquake generation physics. Conventionally, potential as a resource and physical characteristics of the epicenter have been estimated and interpreted using snapshots from MT and electrical exploration. If a dynamic image of underground flow could be visualized, its understanding would be further advanced. Therefore, in this paper, we tried to visualize underground flow by constructing three-dimensional self-potential tomography using sandbox experiments. Specifically, we have constructed a three-dimensional self-potential tomography algorithm for numerical simulation of self-potential generation due to groundwater flow (electro-kinetic effect) and for estimation of groundwater dynamics (pressure head and direction of water flow) using self-potentials. It was also verified by actual experiments of water injection. In the water injection experiment, the box was filled with homogeneous sand and water was injected from the lower part of the tank on the one side, which is simulating the groundwater flow. The parameters of the sand in the box, such as the permeability coefficient and the interface conductivity coefficient, were measured in another experiment, and are constant in the box. So, realistic values are used.
First, the reconstruction results of pore water pressure (pressure head) and water flow from the self-potential changes by the numerical simulation of the injection experiment and those by the reconstruction using the developed tomography are consistent. It suggests that the developed tomographic algorithm are confirmed effective. Furthermore, the dynamics of underground flow were investigated by applying the developed algorithm to the actual experimental data. Details will be shown in the presentation.

Application of Multi-channel Spectrum Analysis (MSSA) in noise reduction to MT data observed at Boso Peninsula in Japan

*Shu Kaneko[1], Katsumi Hattori[2], Toru Mogi[2], Chie Yoshino[2]

1. Chiba University Graduate School of Science and Engineering, 2. Chiba University Graduate School of Science

Near the Boso Peninsula, there are triple junctions where the Pacific Plate, the Philippine Sea Plate, and the North American Plate gather, and crustal deformation is very active. Off the coast of Boso is the epicenter of the Enpo earthquake, and the southern Boso area is the epicenters of the 1702 Genroku Kanto earthquake and the 1923 Taisho Kanto earthquake. Recently, slow slip events have been confirmed off Katsuura every 5-6 years. In 2014-2016, Chiba University conducted a wide-area MT survey in the Boso Peninsula to investigate the source structure of the past major earthquake and the resistivity structure of the plate boundary. The observations were made at 12 long-term observation points at 1 Hz sampling using U43 and 41 short-term observation points at 2400, 150 and 15 Hz using MTU-5 and MTU-5A. However, in the Boso Peninsula, the influence of artificial noise included in the acquired MT data is extremely large due to leakage current from a DC train, factories, or power lines running around/in the peninsula. A conventional remote reference method using geomagnetic 1 Hz data at Memambetsu station operated by Japan Meteorological Agency was applied to the Boso MT data, but the effect of noise reduction was insufficient. Therefore, in this study, we applied the noise removal of time series data using Multi-channel Singular Spectrum Analysis (MSSA) as preprocessing of MT analysis. MSSA parameters include window length, data length, and principal component grouping. By changing these parameters, the effect of noise removal on Boso MT data was investigated in detail. This time, we will report mainly on the effect of noise removal by parameters.

Keywords: noise reduction, Multi-channel Singular Spectrum Analysis, MT method

Development of Ionospheric Electron density tomography using linear regularization.

*Sanaka Saito[1], Rui Song[1], Katsumi Hattori[1]

1. Chiba University

The physical mechanisms of pre-seismic ionospheric anomalies are still not wel-known. In order to clarify the physical mechanism, it is essential to understand the three-dimensional distribution of ionospheric electrons. [Hirooka et al., 2012] developed and operated ionospheric tomography by using GEONET data. However, their method has a drawback that the estimation of the ionospheric structure becomes unstable because the SN ratio falls during the night. Therefore, it is necessary to continuously reconstruct the three-dimensional structure of the ionospheric electron density. We tried to develop ionospheric tomography which can be applied in the nighttime. In this study, we developed a 3D tomography using the Phillips-Tikhonov regularization. In order to evaluate the performance, we used simulated data with International Reference Ionosphere (IRI) model for reconstruction. The results are not so bad and will be shown in the presentation.

[M-IS10] Coupling between the atmosphere, ionosphere and magnetosphere above thunderstorms

convener:Pasko Victor P(Pennsylvania State University Main Campus), Yukihiro Takahashi(Department of Cosmosciences, Graduate School of Science, Hokkaido University), Mitsuteru Sato(Department of Cosmoscience, Hokkaido University), Teruaki Enoto(RIKEN)

This session will cover all aspects of coupling between lightning, sprites, jets, elves and the atmosphere/ionosphere/magnetosphere system. This includes observations of transient luminous events, associated radio and electromagnetic effects (ULF-VHF), energetic radiation (X ray and gamma ray) effects, and theoretical results on these topics. This includes also studies about the impact of these phenomena at a local or global scale.

[MIS10-P01] Thunder Cloud Project : Ground-based multipoint radiation measurement campaign of high-energy atmospheric phenomena

In winter, we frequently observe low-altitude thunderstorms and powerful lightning discharges in the coastal area along the Sea of Japan. Since 2006, the Gamma-Ray Observation of Winter THunderclouds (GROWTH) collaboration has been measuring gamma-ray glows, high-energy radiation from thunderstorms, in this area. Recently, we are expanding this project to a multi-point radiation measurement network at the Kabazawa city, which was named ‘Thunder Cloud Project’, and being collaborated with ground-based radio monitoring of lightning discharges. We also developed several versions of handy radiation detectors. Every winter, this new observation campaign has been detecting not only many gamma-ray glows from thunderstorms but also photonuclear reactions triggered by lightning discharges. In 2020, we are working to make our observation network a new citizen-supporting program, in which citizen supporters will deploy our handy detectors in their home. Here we summarize our recent progress and future prospect of the Thunder Cloud Project.

The Contribution of Lightning and Precipitation Currents to the Global Atmospheric Electric Circuit

Bandholnopparat Kittanapat[1], *Mitsuteru Sato[1], Yukihiro Takahashi[1], Kamogawa Masashi[2]

1. Department of Cosmoscience, Hokkaido University, 2. Global Center for Asian and Regional Research, Univ. of Shizuoka

Thunderstorms and electrified rain/shower clouds are the main current sources in the global atmospheric electric circuit (GEC). These current sources generate the upward current to the ionosphere and maintain the electrical potential gap of ~250 kV between the ionosphere and the Earth' s surface. However, the contribution of the global lightning and precipitation activities to the GEC is still poorly understood due to the difficulty of estimating the occurrence number of cloud-to-ground (CG) and intracloud (IC) discharges. In addition, it is difficult to quantitatively estimate the contribution of the global precipitation current to the GEC due to the difficulty of identifying the precipitation volume and its global distribution. This study aims to investigate the contribution of lightning and precipitation currents to the GEC. First, the global map of the IC/CG ratio (Z-ratio) estimated by the JEM-GLIMS data and the CG lightning data obtained by the WWLLN were combined to estimate the global occurrence number of the IC discharges with the time resolution of 5 minutes and with the spatial resolution of 0.2º×0.2º. Then, the estimated occurrence number of the IC and CG discharges and the precipitation data provided by the global precipitation measurement (GPM) project and the tropical rainfall measuring mission (TRMM) were used as the input parameters in the 3-dimensional model of the GEC, which we have newly developed. In this model, the average column resistance including the influence of the cloud coverage was assumed. Using this model, we estimated the fair weather electric field at the Syowa station in Antarctica, Reading station in UK, and Kakioka station in Japan. It was found that the lightning and precipitation currents in the GEC were ~80 A and ~1200 A, respectively. It was also found that the average fair weather electric field is ~ 70 V/m. The absolute value of the estimated fair weather electric field is almost consistent with the observational data. From these results, the role of lightning and precipitation current in the GEC is quantitatively evaluated, and we found that the upward current to the ionosphere generated by lightning discharges is only 6% while that induced by the precipitation is 94%.

Photodetachment of electrons at sprite altitudes by molecular nitrogen emissions as a mechanism of initiation of sprite streamers

*Victor P Pasko[1], Reza Janalizadeh[1]

1. Pennsylvania State University Main Campus

Modeling and experimental findings indicate that the presence of plasma irregularities is a necessary condition for initiation of sprite streamers [e.g., Lang et al., JGR, 116, A10306, 2011; Qin et al., JGR, 116, A06305, 2011; GRL, 40, 4777, 2013; Nat. Comm., 5, 3740, 2014]. Sprite streamers are often preceded by a relatively low intensity diffuse glow discharge referred to as sprite halo [Barrington-Leigh et al., JGR, 106, 1741, 2001]. Janalizadeh and Pasko [Abstracts AE21A-08; AE21B-3132; presented at 2018 Fall Meeting, AGU, Washington DC, 10-14 Dec., 2018] introduced a framework allowing investigation of sprite streamer initiation as a result of electron impact ionization (due to lightning induced electric field) and photoionization (due to halo emissions) of small traces of metallic species deposited by meteoric trails. Furthermore, Janalizadeh and Pasko [Abstract AE31B-3105; presented at 2019 Fall Meeting, AGU, San Francisco CA, 9-13 Dec., 2019] have recently expanded this framework to studies of photodetachment of electrons from O-, O2-, OH- and NO3- ions. In the present work we expand on initial results reported at 2019 Fall AGU Meeting. In particular, we investigate streamer initiation from O2- ions, which possess the lowest electron affinity (i.e., 0.45 eV) among negative ions mentioned above [e.g., Phelps, Can. J. Chem., 47, 1783,1969; Pavlov, Surv. Geophys., 35, 259, 2014]. We also consider sequential sprite streamer initiation as a result of photodetachment from O- ions in more detail. Note that O- is the most abundantly produced negative ion in sprite streamers [Sentman et al., JGR, 113, D11112, 2008; Gordillo-Vazquez, J. Phys. D: Appl. Phys., 41, 234016, 2008] and may provide relatively long-lasting seeds for sequential initiation of sprite streamers. In addition to the first positive N2, second positive N2, first negative N2+, and Lyman-Birge-Hopfield (LBH) N2 band systems that have already been documented in sprites [e.g., Liu et al., GRL, 33, L01101, 2006, and references therein] and for which photodetachment has already been modeled [Janalizadeh and Pasko, Abstract AE31B-3105; presented at 2019 Fall Meeting, AGU, San Francisco CA, 9-13 Dec., 2019], we also consider photodetachment from aforementioned negative ions due to N2 band systems in the extreme ultraviolet spectral region, that has previously been discussed in the context of O2 photoionization in air [e.g., Zheleznyak et al., High Temp. 20, 357, 1982; Janalizadeh and Pasko, PSST, 28, 10, 105006, 2019].

[M-IS11] Expedition Earth: discovering our planet's past and future through scientific drilling

convener:Junichiro Kuroda(Department of Ocean Floor Geoscience, Atmosphere and Ocean Research Institute, the University of Tokyo), Katsuyoshi Michibayashi(Department of Earth and Planetary Sciences, Nagoya University), Kohtaro Ujiie(Graduate School of Life and Environmental Sciences, University of Tsukuba), Clive Robert Neal(University of Notre Dame)

This multidisciplinary session encourages presentations of various scientific researches that uses samples and data obtained through scientific drilling projects such as the International Ocean Discovery Program (IODP) and the International Continental Scientific Drilling Project (ICDP). We organize several subsessions on the basis of scientific themes to effectively convey achievements and information to the audiences. These scientific themes include "Resilient and Dynamic Earth" (geohazard, climate change and natural resources), "Terrestrial to Extraterrestrial" (plate tectonics, planetary structure, asteroid impacts, and deep biosphere/astrobiology), and "Innovative Science and Technology" (subseafloor observatories, drilling technology development and data science). This session will invite lectures that summarize recent achievements and highlights in each field, and encourages presentations on recently implemented ICDP projects and IODP expeditions. We also aim to provide information on upcoming ICDP projects or IODP expeditions, and we welcome contributions on state-of-the art technological developments related to scientific drilling. The principal goal of this session is to provide a place where participants can efficiently acquire substantial information related to scientific drilling.
Also please visit the J-DESC event page for more details on this session;

To enhance understanding of the forcing factors of marine biological community structure in the Bay of Bengal, we studied proxies for biogenic carbonate and silicate production in the western Bay of Bengal and compared them with proxies for upper-ocean stratification and strength of the Indian summer monsoon (ISM). Specifically, we investigated the record in a sediment core in the western Bay of Bengal that extended to approximately 80 kyr before the present. The records of Globigerinoides ruber sensu stricto $\delta^{18}O$ minus Neogloboquadrina dutertrei $\delta^{18}O$($\Delta\delta^{18}O_{r-d}$) were used to investigate changes in upper-ocean stratification. In addition, mass accumulation rates (MARs) of $CaCO_3$ and biogenic silica were used as proxies of calcareous and siliceous productivities. Greater difference between Globigerinoides ruber sensu stricto $\delta^{18}O$ and Neogloboquadrina dutertrei $\delta^{18}O$ during the marine isotope stage (MIS) 1 and 5a indicate intervals with less saline and more stratified conditions. In contrast, the relatively small difference between both planktic foraminiferal $\delta^{18}O$ during MIS 2 and 4 indicates diminished stratification during these periods. Elevated carbonate production during MIS 2 and 4, demonstrated by the increase in $CaCO_3$ MAR, could have been driven by lower freshwater influx to the western Bay of Bengal resulting from lower ISM precipitation, and thus the increased mixing and upwelling of deep nitrate into the photic zone. The relative increase in BSi MAR during periods of high ISM precipitation and decreased salinity of surface waters suggests a limited recovery in biological siliceous production under interglacial conditions, possibly due to enhanced fluvial SiO_4 delivery to the ocean. Fluctuations of $\Delta\delta^{18}O_{r-d}$ during MIS 3 indicate that freshwater stratification was moderate and insufficient to restrict upwelling. This might have induced moderate biogenic silica and carbonate productions during this period.

Preliminary results of IODP Exp. 382: Iceberg Alley and Subantarctic Ice and Ocean Dynamics

*Yuji Kato[1], Osamu Seki[2], Mutsumi Iizuka[2], Masanobu Yamamoto[3], Michael E. Weber[4], Maureen E. Raymo[5], Victoria L. Peck[6], Trevor Williams[7], - The IODP Expedition 382 Scientists

1. Center for Advanced Marine Core Research, Kochi University, 2. Institute of Low Temperature Science, Hokkaido University, 3. Faculty of Environmental Earth Science, Hokkaido University, 4. University of Bonn, Germany, 5. Lamont-Doherty Earth Observatory of Columbia University, USA, 6. British Antarctic Survey, UK, 7. International Ocean Discovery Program, Texas A&M University, College Station, USA

We collected sediment cores from five sites in Atlantic sector of the Southern Ocean during International Ocean Discovery Program (IODP) Expedition 382, which took place from March to May 2019. The recovered material includes continuously deposited Plio–Pleistocene sediments. Our primary aim is to reconstruct the past history and variability in Antarctic Ice Sheet (AIS) mass loss and associated paleoceanographic changes. The drilling sites include two sites (Site U1534 and U1535) at the northern edge of the Scotia Sea and three sites (Sites U1536–U1538) in the southern Scotia Sea. The materials from Sites U1534 and U1535, which are located in the vicinity of Subantarctic Front, will be used to reconstruct how ocean circulation responds to climate changes. The principal object of Sites U1536–U1538 is to study the flux of icebergs through “Iceberg Alley,” the main pathway along which icebergs calved from the margin of the AIS travel. In the current presentation, we will present an overview of the expedition with a special focus on biostratigraphic results and preliminary results of TEX86 derived sea surface temperature records in Sites U1537 and U1538 during the Plio-Pleistocene.

Osmium isotopic composition and platinum group element abundances of Cretaceous-Paleogene boundary section at Site U1514C on the Mentelle Basin, SW Australia

Hayu Ota[1], *Junichiro Kuroda[2,3], Maria Luisa Tejada[3], IOPD Exp 369 Shipboard Science Party

1. University of Tsukuba, 2. AORI, University of Tokyo, 3. JAMSTEC

During IODP Expedition 369, Cretaceous and Paleogene sediments were recovered at Site U1514 in the Mentelle Basin, off SW Australia. Shipboard micropaleontological investigation revealed that Cretaceous–Paleogene boundary (K–Pg boundary, 66.0 Ma) is located at 369-U1514C-23R-2, 2-3 cm interval, at 393.52 m depth (core depth from seafloor, CSF-A). Here, uppermost Maastrichtian light gray chalk is overlain by Paleocene greenish gray claystone with a heavily bioturbated contact. In this study, we analyzed abundances of platinum group elements (PGEs)—including Ru, Pd, Os, Ir and Pt—and the radiogenic isotopic composition of Os ($^{187}Os/^{188}Os$) for the sediments across the K–Pg boundary section. According to the shipboard studies on bio- and magnetostratigraphy, applying ages from the Geologic Time Scale 2012, our samples cover a time interval from 68.1 Ma (Maastrichtian) to 65.9 Ma (Danian). Our data show a clear peak in Ru (4.8 ng g^{-1}), Os (1.4 ng g^{-1}) and Ir (5.3 ng g^{-1}) concentrations at 393.52 m CSF-A, with values two orders of magnitude higher than background concentrations during the Maastrichtian. Abundances of PGEs of the sample from 393.52 m CSF-A show a flat pattern when normalized to CI chondrite values, while the other samples show patterns similar with the upper continental crust. The sample from 393.52 m CSF-A also marks a clear drop in the $^{187}Os/^{188}Os$ value of 0.18. Our data on the PGE abundances and Os isotopes clearly shows that the sediment at 393.52 m CSF-A contains PGEs from an extraterrestrial source, most likely associated with the well-known bolide impact at the K–Pg boundary.

The $^{187}Os/^{188}Os$ values in the uppermost Maastrichtian interval show two [LKO1] gradual decreases from 0.6 to 0.4 and 0.4 to 0.2, while those in the lowermost Danian interval show a gradual increase from 0.2 to 0.4. The gradual variation in Os isotopic composition suggests that sediment was deposited continuously without significant hiatus. The decreasing trends of $^{187}Os/^{188}Os$ values in the Maastrichtian interval is slightly different from those reported from other sites previously, which may be attributed to either 1) heavy bioturbation or 2) some local or regional volcanic events at this site.

Keywords: Os isotope, PGE, K-Pg boundary

Short-term environmental disturbance of early Turonian (Cretaceous) in southern high latitude : Insights from organic geochemistry

*Yusuke Takagi[1], Yukina Takeda, Kengo Sadami, Akiko S. Goto[2], Takashi Hasegawa[2]

1. Earth Science Course School of Natural System, College of Science and Engineering, Kanazawa University, 2. Faculty of Geoscience and Engineering, Institute of Science and Engineering, Kanazawa University

An environmental change of the Early Turanian, Cretaceous was investigated using the samples from IODP Exp. 369, U1512. A stable carbon isotope stratigraphy based on bulk rock analysis showed a positive 3 ‰ carbon isotope excursion (CIE) within the lower Turonian. Based on this high isotopic value and the biomarker composition, phytoplankton blooming is interpreted to be a factor that caused the CIE.

During Turonian (93.9-89.8±0.3Ma), which is the target of this study, temperature as warm as ~30℃ was suggested by some previous studies and physical simulation even in the high latitude regions. Turonian is an age of recovery from major environmental changes after the disturbance of the carbon cycle by Oceanic Anoxic Event 2 (OAE2: Cenomanian/Turonian boundary event). Site U1512, in Great Australia Bight, was located around the paleolatitude about 60 ˚S during Early Turonian. The site is expected to provide new paleoenvironmental information and add important geologic records of paleoenvironments. In this study, a positive 3‰ carbon isotope excursion (CIE) in the lower Turonian is investigated as it should be a signal of paleoenvironmental change and perturbation.
Additional denser samples were taken across the CIE to obtain the exact magnitude and duration of the CIE. It emerged that the time interval of the CIE was about 4-20 thousand years. Compound-specific carbon isotope analyses were also performed on selected samples across the CIE. The carbon-isotopic profile of *n*-alkanes did not replicate that of the bulk organic carbon indicating the CIE observed with the bulk analyses is not comparable to that of OAE2, and rather ascribed to a change in origin of organic matters and their mixing rate. Biomarker analysis at the CIE horizon revealed that compounds from marine plankton (C_{27}diacholentenes, ≦ *n*-C_{18} *n*-alkane) dominated relative to the terrestrial ones. Higher isotopic value of bulk organic carbon in the CIE horizon can be ascribed to smaller carbon isotopic fractionation of phytoplankton during blooming. Based on these results, phytoplankton blooming is interpreted to be a most plausible factor for the CIE.

Neogene Kuroshio variability and evolution of the North Pacific subtropical gyre

*Yusuke Okazaki[1]

1. Department of Earth and Planetary Sciences, Graduate School of Science, Kyushu University

The Kuroshio Current is a western boundary current located on the western edge of the North Pacific subtropical circulation. It transports numerous amounts of heat and materials from the equatorial Pacific to the mid-latitudes of the North Pacific. Changes in the Kuroshio Current flow path and strength under different climate must had a pronounced impact on the climate and environments in the North Pacific and surrounding regions. The Mid-Miocene Climatic Optimum (MMCO) is the one of the most remarkable Neogene warming event prolonged from 16 to 14 Ma. During MMCO, The Kuroshio Current flowed much more northward, which leaded marked expansion of subtropical circulation in the North Pacific, evidenced by terrestrial geologic records from the NW Pacific margin. Unfortunately, complete sedimentary sequence of MMCO in the western North Pacific has not yet obtained due to hiatuses distributed widely in the western North Pacific. We have re-established DSDP 296 biostratigraphy (calcareous nannofossils, planktic foraminifera, and radiolaria) and chemostratigraphy (strontium isotope ratios, and stable carbon and oxygen isotope ratrios) from the northern Kyushu-Palau Ridge near the Kuroshio Current flow path to reveal almost continuous sedimentation for the past 20 Myrs although the several drilling gaps. Re-drilling at site DSDP 296 will provide us a chance to recover complete sedimentary sequence including MMCO. Since late Miocene, earth’s climate has cooled down, intensification of the glaciation in the Northern Hemisphere during Pliocene, and leaded to an initiation of glacial-interglacial cycles. However, long-term Kuroshio Current variability responding to the above major climatic events are still poorly understood mainly due to lack of appropriate marine sediment samples. We would like to fill the gap by drilling new sediment cores along the western North Pacific margin such as the Benham Rise, Okinawa Trough besides the DSDP 296 site.

SCORE Drilling: Preliminary results of Expedition 912-Leg 1 at Tokai, Nankai Trough, southwest Japan

*KanHsi Hsiung[1], Toshiya Kanamatsu[1], Ken Ikehara[2], Io Miura[3], Juichiro Ashi[3], Shuichi Kodaira[1], Kohsaku Arai[2], Natsumi Okutsu[1], Kan Aoike[1]

1. Japan Agency for Marine-Earth Science and Technology, 2. Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology, 3. The Atmosphere and Ocean Research Institute, The University of Tokyo

Chikyu Shallow Core Program (SCORE) is a short and shallow ocean drilling program, providing opportunities for scientific ocean drilling test and project which can complete in a short period of time by using the ocean drilling vessel (D/V) Chikyu except for IODP expedition period. The title of Expedition 912-Leg 1 is “Enigmatic recurrence pattern of Tokai earthquake in the Nankai Trough, southwest Japan: the link between great earthquakes and ridge subduction”. The objective of our program is to investigate the past earthquake occurrence from a continuous sedimentary sequence at a local tectonic basin (i.e., Kanasunose Trough) in the Nankai Trough. The target of this drilling program is to find an enigmatic recurrence pattern of Tokai earthquake in the Nankai Trough, southwest Japan. Hydraulic Piston Coring System (HPCS) of the D/V Chikyu can provide an opportunity to obtain an excellent long and continuous sedimentary record to unravel the earthquake recurrence pattern of this study area.

Expedition 912 was conducted by D/V Chikyu sailing from Shimizu to Sasebo, Japan from 4 January - 15 January 2020. The Leg 1 of Expedition 912 was cored Hole A and B in Site C9035. The penetration depth at site C9035 is 80.19 meters with HPCS drilled from 5 January to 8 January 2020. The site of Hole A is at 34°5.7000’ N, 138°8.0300’ E with 2413.5 meters of water depth in the Kanasunose Trough, the Nankai Trough. Because mud line cannot be identified in Hole A, Hole B was drilled in 10-m southeast to Hole A. Hole B is at 34°5. 6962’ N, 138°8.0346’ E with 2414.0 meters of water depth. The cores including 9.5 m thick of Hole A and 80.0 m thick of Hole B was retrieved. Core recoveries are 105.3% and 104.7% of Hole A and Hole B, respectively. The shipboard measurements of whole-round cores involved X-ray CT scan and multisensory core logger (MSCL). After splitting, we conduct measurements including visual core description, smear slides, split surface image, paleomagnetic measurement by superconducting rock magnetometer, penetration strength, and moisture and density measurements, and Vane shear test.

The sedimentary succession is dominated by silty sediments with numerous coarse-grained (coarse silt–very fine sand) layers and some volcanic ash layers and spots. Two lithological units (Unit I and II) can be distinguished based on sedimentary facies. Unit I (0 –42.1 m) consists of bioturbated silt and layered coarse silt–very fine sand with massive silt. Three ashes were founded in Unit I and will provide good age control. Layered coarse silt–very fine sand beds with fining upward pattern can be regarded as turbidite beds. Unit II (42.1 m –80.19 m) is characterized by matrix-supported gravelly mud–muddy gravel and angular mudstone gravel. In the downhole variation changes in around 42 m also can be observed in the GRA density, Natural Gamma radiation, and Electric resistivity. The future work will focus on the significant turbidite beds which could be related to earthquakes, and to evaluate the recurrence intervals of earthquakes in Unit I. After integration of post-cruise measurements, the relationship between great earthquakes and ridge subduction of Tokai earthquake in the Nankai Trough will be expected.

Analytical method of noble gases using cuttings to understand distribution and origin of noble gases in accretionary prism in precise -

*Tomohiro Toki[1], Shugo Kurahashi[1], Naoto Takahata[2], Yuji Sano[2,3]

1. Faculty of Science, University of the Ryukyus, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Institute of Surface-Earth System Science, Tianjin University

In this study, we measured noble gases from cuttings crushed in a vacuum, and obtained a data set of noble gases free from air contamination. As a result, the contribution rate of air-saturated interstitial water could be determined, and the helium isotope ratio released from the slab of the Philippine Sea Plate could be determined accurately. In addition, mantle-derived helium laterally would be supplied from wedge mantle around 1503 mbsf. Based on the lithology and hydrocarbons distribution, the sandstone layer distributed between 1000 and 1500 mbsf could play a role as flow path of deep-rooted gas from great depths. To obtain more accurate in-situ information than gas analysis using mud gas, we propose gas analysis using cuttings as an international standard for exploration of noble gas distribution during drilling.

Variation of pore water geochemistry across the mass transport deposits off Cape Erimo, Hokkaido, Japan

*Sara Fujiwara[1], Hitoshi Tomaru[1]

1. Chiba University

Marine pore water geochemistry is often constrained by the redox potential and microbial activities in shallow sediment and also receives dissolved elements from minerals under high temperature/pressure environment in deep sediment. The concentration gradients of these elements therefore reflect the gradual change of physicochemical environment in the sediment column, which characterize basic material migration system in surface area. However, the sediment environment is disturbed and becomes discontinuous when a drastic environmental change such as submarine landslide occurs. The pore water in the mass transport deposit (MTD) can be also disturbed and changes thereafter to stabilize again under the given new condition. This may significantly disrupt the material circulation system via pore water at the Earth's surface, however, the relationship between these phenomena and the distribution of MTD has not been sufficiently discussed. In this study, we analyzed geochemical composition of pore waters collected across the MTD and investigated how the pore water geochemistry responded to the disturbance of sediment environment.

Pore waters were collected from sedimentary sequences intercalated with MTDs down to ~100 mbsf off Cape Erimo, Hokkaido, Japan during the Chikyu Shallow Core Program (SCORE) by D/V Chikyu in 2017. The pore water geochemistry shallower than sulfate-methane interface (SMI) rapidly changes due to anaerobic methane oxidation, decomposition of organic matter, methane production from organic matter, precipitation of carbonates etc. On the other hand, below the SMI, the pore water composition was changed mainly by the mineral alterations in high temperature environments and the diffusion of components which released into or removed from the pore water due to decomposition of biogenic sedimentary rocks and organic matter. In particular, the concentration gradients of iodine and magnesium become smaller around the upper boundary of the MTD, unlike the gradual changes in concentration through the entire drilling depth. In addition, barium and lithium showed a curve-like concentration change with minimum values at the upper boundary of the MTD. The radioisotopic analysis of iodine showed significantly high value in the MTD, reflecting seawater component dominates in the interval. These changes were caused by trapping, migrating, and accumulating shallow pore water in the deeper sediments, pore water geochemistry can be modified along with the development of the MTD.

3.1Ga Banded Iron Formation drilling: DXCL drilling project in the coastal Pilbara terrane in Australia

*Shoichi Kiyokawa[1], Takashi Ito[2], Minoru Ikehara[3], Kosei E. Yamaguchi[4], Kohei Ishikawa[1], Mami Takehara[5], Kenji Horie[5]

1. Department of Earth and Planetary Sciences Faculty of sciences, Kyuushu University, 2. Faculty of Education, Ibaraki University , 3. Center for Advanced Marine Core Research, Kochi University, 4. Toho University and NASA Astrobiology Institute, 5. National Institute of Polar Research

The Dixon Island –Cleaverville Drilling Project (DXCL) was successfully completed at Cleaverville Beach, northwestern Pilbara Craton, at August 2007, 2012. The drilling provided ‘fresh’ samples (free of recent, near-surface weathering effects) of Archean banded iron-formation (BIF) and black carbonaceous shale. The formations drilled were the Cleaverville Formation, Dixon Island Formation, and Port Robinson Basalt (new name), all interpreted as belonging to a Mesoarchean immature island-arc succession at three drilling site, DX, CL1, CL2 and CL3. Drilling revealed that although modern weathering at Cleaverville Beach extends to depths of 50 m and the drill core is suitable for petrologic, geochemical, and isotopic investigations. Here we focus CL3 core (200m long) which focus the Cleaverville Formation with BIF. The BIF in this area is well exposed along the coast area.

The Cleaverville Formation was subdivided by the Black Shale and BIF members. The Black Shale Member formed organic rich black shale which formed 10-20 cm thick beds and with thin silt- very fine sandstone lamination. The fine grain is mostly related volcanic origin plagioclase. These volcaniclastic laminations have well preserved cross laminations and identified as younging direction. The thin very fine sandstone laminations are increase to the top. The BIF Member formed three units, 1) Siderite BIF unit which formed fine laminated greenish shale/white chert and massive chlorite rich greenish shale, 2) Magnetite BIF unit which formed fine lamina of magnetite/white chert and massive chlorite rich greenish shale, and 3) Black shale-siderite unit which formed fine laminated black shale and greenish siderite.

In detail observation, the BIF Member not contains detrital grains such as volcaniclastics origin fine sandstone. Bedded thickness in Siderite BIF and Magnetite BIF is resembles about 10-20 cm in each bed, also massive greenish shale beds are resembled each unit. The greenish massive greenish shale is very homogenous. These beds are corelated red and white beds in outcrop, which have lateral variation of thickness from 50 –100m wide. Some these beds are more than 80 cm in thickness to change 10 cm in thickness.

In addition, magnetite laminations are only formed in fine lamina of greenish shale portion in the Siderite BIF. The most BIF Member contains overgrowth siderite crystals especially in white chert lamination. Most place of Siderite BIF and Magnetite BIF are not containing early stage sedimentation evidence. Only black shale-siderite unit contains organic rich wavy laminations. It might be preserved primary sedimentation evidence during deposition of iron material. These very thin wavy laminations suggest that the microbial (Iron oxidized bacteria) activity might be occurred on the ocean floor surface. However, it is still unknown of the origin of homogenous greenish shales as sedimentary muds or diagenetic beds.

In-situ crustal stress measurement in inland Japan - Applications of DCDA method to rock core samples from NIED seismic observation wells -

*Kentaro Omura[1], Akio Funato[2], Takatoshi Ito[3]

1. National Research Institute for Earth Science and Disaster Resilience, 2. Fukada Geological Institute, 3. Institute of Fluid Science, Tohoku University

In-situ crustal stress is an important factor to understand earthquake mechanism and tectonic activities. However, the reliable in-situ crustal stress data seems to still be poor, because complicated procedures are necessary for measure the in-situ crustal stress in a borehole. We tried to apply DCDA (Diametrical Core Deformation Analysis) method for in-situ crustal stress measurement using boring core rock samples. DCDA method measures the circumferential diameter variation and elastic constants of core sample if we have recovered the core sample from the borehole. We expect the method can be applied to old-time boring core samples from NIED (National Research Institute for Earth Science and Disaster Resilience) seismic observation wells, and we may collect global in-situ crustal stress data in Japan island.
We used recovered hard rock core samples from 7 Hi-net observation wells of NIED (more than 10 years ago) from the depth about 100m - 200m (one is from the depth of 2000m). The circumferential core diameter variation was measured by an especially designed apparatus that consists of an optical micrometer, a pair of motor-driven rollers and a data processing system (Funato and Ito, 2017, IJRMMS). We got the sine curves of circumferential diameter variation of some of the core samples associated with stress relief. The data suggest that the DCDA method is applicable to boring core samples from shallow seismic observation wells.
To decide the value of stress, we need elastic constants of the core samples; Young's modulus and Poisson's ratio. We tried to use the data of rock mass P and S wave velocities by means of P-S logging at the time of boring. Assuming the value of densities, we calculated the elastic constants of the core samples. Assuming 2.5 g/cm3 as a representative value of various kind of rocks composing the crust, the differential stresses are around 10 MPa. Those results suggest the in-situ crustal stresses are measured by DCDA method in global area of inland Japan with existing core rock samples. In the next step, we will apply laboratory rock tests to measure the elastic constants of core samples directly.

Rock magnetic properties, grain size, and layer thickness of turbidites at the northern Hikurangi margin, New Zealand: Results from IODP Exp. 375, Site U1520

*Atsushi Noda[1], Annika Greve[2]

1. National Institute of Advanced Industrial Science and Technology, 2. Department of Earth Sciences, Utrecht University, The Netherlands

Environmental magnetism is the study of the fine magnetic minerals in sediments. Differences in type, abundance, magnetic grain-size, and diagenetic state allow to draw conclusions about the sediment source regions, transport and depositional conditions. Here we present the results of detailed rock magnetic investigations conducted on turbidites deposited within the trough sediments at IODP site U1520, Exp. 375, northern Hikurangi Margin, New Zealand. The study encompassed the measurement of rock magnetic properties and grain size on a total 67 turbidites in the upper part (Lithological Units 1–3, 0–510 mbsf) of the hole U1520D.

Discrete paleomagnetic samples were collected from cores by pushing standard 7-cm^3 plastic cubes into the sediment near the basal part of turbidites. The cubes were subjected to magnetic analysis at JAMSTEC. Low-field, mass-dependent magnetic susceptibility (χ) and AMS were measured using an AGICO Kappabridge KLY-4S. AFD and ARM acquisition experiments were conducted using a horizontal 2G cryogenic passthrough magnetometer with an in-build degausser. ARM was imparted in a peak alternating field of 80 mT (AF), and a 100-μT biasing field along +z. Subsequently we imparted an IRM along +z using an ASC Impulse Magnetizer and a field of 1.2 T. Remanence was subsequently measured and the same procedure repeated by applying reverse fields of 0.1 and 0.3 T. Magnetic hysteresis parameters (B_c, B_{cr}, M_s, M_{rs}) were measured using a MicroMag Vibrating Sample Magnetometer. As final step, grain-size analyses were conducted using a laser diffraction/scattering particle size distribution analyzer.

The magnetic susceptibility (χ), SIRM (here: $IRM_{1.2T}$), NRM and M_s are sensitive to the concentration of magnetic minerals within the turbidites. and are parameters to indicate the magnetic grain-size. The S-ratios are calculated using and , respectively. S-ratios help to distinguish between the contributions of magnetically hard and soft remanence carriers (e.g. magnetite vs. hematite). The ratios of the hysteresis parameters M_{rs}/M_s and $B_{cr}/B_c$are indicative for the magnetic domain and thus grainsize. We applied the K-means cluster analysis for these magnetic properties to characterize the turbidites into the three units which have distinct magnetic properties.

Samples in cluster 1 have relatively low values of χ, SIRM, S-ratios and SIRM/χ, and intermediate values of M_{rs}/M_s and B_{cr}/B_c. The majority of the turbidites sampled in Unit 2 and parts of Unit 3 were classified into cluster 1. Samples from cluster 2 show low values of B_{cr}/B_c, intermediate values of χ, and high values of SIRM, S-ratios and SIRM/χ, and high values of M_{rs}/M_s. These samples can be found throughout Units 1–3. Cluster 3 is represented by high χ, S-ratios, intermediate SIRM and B_{cr}/B_c, and low M_{rs}/M_s and SIRM/χ values. This cluster was recognized only in Unit 1. Most of the thick and coarse-grained turbidites belong into Cluster 3. One of the major differences between cluster 3 and the other clusters is that the SIRM is weaker than in cluster 2, while χ is higher than cluster 2. The other difference is a very low M_{rs}/M_s and high B_{cr}/B_c ratios, indicating cluster 3 is dominated by multidomain (MD)-sized grains.

©2020. Japan Geoscience Union. All Right Reserved.

There are two viable interpretations for this dataset: The distribution of the clusters may reflect on different source regions of the turbidity currents. A major difference exists between the rock magnetic properties of lithological units 1 and 2. This may indicate a major change in the dominant sediment provenance and transport direction. Alternatively, the differences in the rock magnetic properties may also be caused by differing diagenetic state through the sequence (e.g. magnetite–greigite–pyrite). These differences may be affected by depositional conditions such as submarine landslides or turbidity currents.

An attempt to integrate 3D seismic and borehole datasets: construction of a 3D geomechanical model at the Nankai Trough, SW Japan.

*Yasuhiro Yamada[1,2,3], Adam Wspanialy[1], Kazuya Shiraishi[1]

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Kochi University, 3. Royal Holloway University of London

Data integration is vital to explore subsurface. One of the reasons is that a variety of different geophysical methods are used to acquire data from subsurface and the reality can hardly be expressed by a single data source. The sparsity of the subsurface data and limited quality, because of the indirect measurement, may also be included in the reasons as well. Once we can drill a borehole, then we could get much more data. Such borehole data, however, have a huge scale gap to the exploration geophysics data and the integration is a key technique to fill the gap by all means.

As one of such initiatives, we used 3D seismic data and well data acquired at the Nankai Trough offshore Kii Peninsula, Japan, where extensive scientific drilling and geophysical surveys performed by the International Ocean Drilling Programme (IODP) and JAMSTEC, to construct a geomechanical model. The technique has been utilized for commercial purpose by the oil and gas industry to optimize production / well placement in the existing fields and to avoid borehole failure, but rarely used for scientific purposes. In this presentation, we are going to report some updates of the modelling, and discuss how such approach is useful for future scientific drilling.

A Perspective of the Mantle Drilling and Observatory Initiative

*Nan XIAO[1], Natsue Abe[1], Yasuhiro Yamada[1], Fumio Inagaki[1]

1. Japan Agency for Marine Earth Science and Technology

Over the past half century, there has been a desire in geoscience to explore the entire sequence of Earth’s oceanic crust and to reach the upper mantle beneath the Mohorovičić discontinuity (also termed the “Moho”). Scientists have common knowledge that the mantle as the largest layer of Earth’s interior, makes up to about 83% in volume and 67% in weight of our planet; however, nobody has ever seen the pristine mantle. To comprehensively understand the plate tectonics, earth dynamics, and evolution of the our planet, drilling through the “Moho” to the mantle, offers an unprecedented opportunity to all the science community of truly integrated scientific approaches toward a better understanding of the ocean, atmosphere, and biosphere on Earth.
The mantle beneath the oceanic crust can ONLY be accessed through scientific ocean drilling. Over the past 50 years, scientific ocean drilling has been a great success to expand our knowledge of the ocean-Earth-life system and provided new insights into the essence of planetary habitability. After years from the first try of mantle drilling in 1950s, the *Chikyu* was built in 2005 as a new generation of scientific ocean drilling vessel. *Chikyu* was born to meet the strong demand that human can know better about our planet by penetrating the oceanic crust down to Earth’s upper mantle where is the deepest accessible limit for today’s drilling technology.
The challenge into the upper mantle will also provide an excellent opportunity of and potential for the long-term observatory of the mantle and the crustal behaviors. To date, large gaps in our understanding of the Earth’s dynamism and the interactions between multi-spheres remain to be filled. Continued international and transdisciplinary collaborations among the scientific ocean drilling community will help all scientists to illuminate the Earth’s activities of the planetary system, from deep time to the present, and to the future. NOW is the time to build up the mantle-dedicated scientific ocean drilling program and its initiative for future observatory. In this presentation, the Mantle Drilling Promotion office (MDP), newly established in JAMSTEC in April 2019, will share the concept and perspective of the mantle drilling and observatory initiative.

Learning Lessons is Key to the Success in Future Scientific Ocean Drilling

*KYAW MOE[1]

1. Japan Agency for Marine-Earth Science and Technology

Most of scientific ocean drilling (IODP, ODP) expeditions fall in deep (>300 m water depth) and ultra deepwater (>1500 m) environments which are designated in oil and gas industry as most complex and high risk areas to operate and cost three times more than shallower water depths. Three key factors play in deepwater project management- time, cost and quality and hence those programs drill fewer wells while maximizing well information extraction.

Over five decades of deepwater drilling experience, scientific ocean drilling pioneered in offshore drilling technology ahead of oil industry at the beginning, however industry progressed later in offshore exploration and production with bigger rewards from higher oil prices and long term production. In 2005, D/V Chikyu was built in hope of overcoming seismogenic zone drilling challenges with riserless drilling. Key lessons learnt from the 12 years of operations include deep seismic imaging, operation under high current, borehole instability and geomechanics, operation efficiency with best use of technology, coring in faster rate and better quality, clean sampling for microbiology analysis.

While IODP operators are struggling with drillship maintenance and operating cost, oil and gas industry has been transforming in speed into digitalization and developing new technologies to maximize efficiency in time and cost as well as for safety. Within the limits, IODP operators developed and tested new or better tools and techniques in imaging, sampling, measurement and analyses and drilling optimization. To continue challenging into the ultra deepwater targets, IODP needs to work closely not only with International Continental Drilling Program but also with industry R&D portfolio in exchange of deepwater experience.

The upcoming IODP Japan Trench Paleoseismology Expedition: New perspectives from tracking past earthquakes in the sedimentary record

*Michael Strasser[1], Ken Ikehara[2], Carol J. Cotterill[3], Lena Maeda[4]

1. University of Innsbruck, Austria, 2. Institute of Geology and Geoinformation, National Institute of Advanced Industrial Science and Technology, Japan, 3. British Geological Survey, U.K., 4. JAMSTEC Japan Agency for Marine-Earth Science and Technology

Short historical and even shorter instrumental records limit our perspective of earthquake maximum magnitude and recurrence and thus are inadequate to fully characterize Earth’s complex and multiscale seismic behavior and its consequences. Examining prehistoric events preserved in the geological record is essential to reconstruct the long-term history of earthquakes and to deliver observational data that help to reduce epistemic uncertainties in seismic hazard assessment for long return periods. “Submarine paleoseismology” is a promising approach to investigate deposits from the deep sea, where earthquakes leave traces preserved in the stratigraphic succession. However, at present we lack the comprehensive data sets and long-term records that allow for conclusive distinctions between quality and completeness of the paleoseismic archives.

Motivated by the mission to fill the gap in long-term records of giant (Mw 9 class) earthquakes, International Ocean Discovery Program (IODP) Expedition 386, Japan Trench Paleoseismology, aims at testing and developing submarine paleoseismology in the Japan Trench. We will implement a multicoring approach by Mission Specific Platform shallow subsurface (40 m) giant piston coring to recover the continuous upper Pleistocene to Holocene stratigraphic successions of trench-fill basins along an axis-parallel transect of the 7–8 km deep trench. The cores from 18 proposed primary (and/or 13 alternate) sites will be used for multimethod applications to characterize event deposits for which the detailed stratigraphic expressions and spatiotemporal distribution will be analyzed for proxy evidence of earthquakes.

Sediment remobilization related to the 2011 Mw 9.0 Tohoku-Oki earthquake and the respective deposits are preserved in trench basins formed by flexural bending of the subducting Pacific plate. These basins are ideal study areas for testing event deposits for earthquake triggering because they are poorly connected for sediment transport from the shelf and experience high sedimentation rates and low benthos activity (and thus high preservation potential) in the hadal environment. Results from conventional coring covering the last ~1,500 y reveal good agreement between the sedimentary record and historical documents. Subbottom profile images are consistent with basin-fill successions of episodic muddy turbidite deposition and thus define clear targets for paleoseismologic investigations on longer timescales accessible only by IODP coring.

We will apply, further refine, and implement new methods for establishing event stratigraphy in the deep sea and for recognizing giant versus smaller earthquakes versus other driving mechanisms. Our results can potentially produce a fascinating record that unravels an earthquake history that is 10–100 times longer than currently available information. This would contribute to a tremendous advance in the understanding of the recurrence pattern of giant earthquakes and earthquake-induced geohazards globally and provide new constraints on sediment and carbon flux of event-triggered sediment mobilization to a deep-sea trench and its influence on the hadal environment.

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS12] Developments and applications of XRF-core scanning techniques in natural archives

convener:Huang Jyh-Jaan Steven(Institute of Geology, University of Innsbruck), Atsuko Amano(National institute of Advanced Industrial Science and Technology), Masafumi MURAYAMA(Faculty of Agriculture and Marine Science, Kochi University), Liang-Chi Wang(National Chung Cheng University)

X-ray fluorescence (XRF) core scanning techniques have revolutionized element proxy-based paleo-researches over the last decade and now becomes an indispensable tool for many research area. However, despite being fast, non-destructive and providing records of elemental variations at submillimeter resolution, science applications of XRF-core scanning results also encounter numerous challenges due to its intrinsically semi-quantitative and ultra-high resolution nature, such as the influences of down-core physical and organic variations, parameter optimizations of machinery, as well as quantitative calibrations and evaluations of the voluminous and complex scanning data. Therefore, the implications of shifts and trends in the elemental data remain difficult to interpret in many settings.
It is therefore considered timely to bring together international specialists using high-resolution XRF-core scanners in all fields of science to present new research, to stimulate new collaborations and discussions, as well as to propose new technological developments.

We present results of XRF core scanner analysis on a marine sediment core (MR16-09 PC02) obtained from coastal southern Chile (46S, 76W, 2793 m depth). The study site is located near the boundary of present-day South Pacific summer and winter westerly jet path. Thus, the compositional change of studied core thought to record latitudinal changes of Southern westerly that influence rainfall patterns and water discharges of southern Chile. XRF core scanner (Cox, Itrax) were conducted at Center for Advanced Marine Core Research, Kochi University. Using method of Katsuta et al. (2019), water content-corrected X-ray fluorescence intensities of wet sediment cores were converted to elemental concentrations. Based on the obtained elemental composition, we reconstructed multi-millennial-scale variations in terrestrial detrital inputs, that likely record variations in westerly jet path during the last glacial.

1. National Institute of Advanced Industrial Science and Technology, 2. Ehime Univ., 3. Kochi Univ.

In Beppu Bay, Pref. Oita (central Japan), we aimed to reveal the way to record events such as anthropogenic activities and hazards into the sediment. For this purpose, we obtained several surface sediment cores using G.S.-type surface sediment sampler (Ashura) and gravity core sampler in 2017 and 2019. These sediment cores were CT-scanned and analyzed by the micro XRF scanner (ITRAX). We also measured radioactivities of ^{137}Cs and excess ^{210}Pb by 4cm intervals for age determination.

We investigated 4 points in the bay and checked the depth distribution of the sediment in 2017. At the deepest part of Beppu Bay, 70m depth, we found laminated semi-pelagic sediment with clear lamination with 6-7mm thickness. In the shallower area of the bay, we cannot find lamination. Based on the result of ITRAX measurement and Soft-X images, it is revealed that lamination is caused by the change in the amount of detrital material. The amount and composition of detrital material also show several positive spikes. Some of them can be observed by naked eyes as light gray or reddish-brown colored thin layers (minor event layers), suggesting that they were supplied from different provenance than usual. These layers are considered to be caused by the occurrence of floods, earthquakes, or eruption. The results of Pb and Cs measurements agree with the age of Ev-1a, which is considered to be caused by the Hyuga-Nada earthquake in 1968 (Kuwae et al., 2013). Counting of lamination also agrees with Pb and Cs based age model when unclear lamination is interpolated by the average thickness of laminations.

In the survey on Sep. 2019, we aimed to verify newly deposit sediments in the last two years. We also aimed to obtain the core with sufficient length from the sediment-water interface to the horizon below the ^{210}Pb would be attenuated. Using Ashura sediment sampler with 120 cm-long acrylic pipes, we could obtain the cores with 90cm length. Based on the correlation of the cores of 2019 and 2017, we found newly deposited sediment with 2 cm thickness at the top part of the 2019 core. This accumulation rate agrees with the thickness of laminations found in both cores. These results strongly suggest that lamination at the bottom of Beppu Bay is annual lamination, varve. The inflow of detrital material by heavy seasonal rain could be the generation factor of varve. Lamina preservation becomes clear gradually after around 1960. there is a possibility that the submarine stratified structure has been strengthened by the change of a marine environment with economic growth. We are conducting the measurement of Cs and Pb isotopes of the 2019 core.

Keywords: Beppu Bay, annual lamination, varves, event layers

Change of depositional environment in Lake Tazawa estimated by X-ray fluorescence core scanner

*Yoko Ishiyama[1], Daizo Ishiyama[1], Kazuyoshi Yamada[2], Masafumi MURAYAMA[3], Takeshi Hayashi[4]

1. Graduate School of International Resource Sciences, Akita University, 2. Museum of Natural and Environmental History, Shizuoka, 3. Center for Advanced Marine Core Research, Kochi University, 4. Faculty of Education and Human Studies, Akita University

Lake Tazawa, located in eastern part of Akita Prefecture, is caldera lake formed at 1.7 Ma (Kano et al., 2008 & 2020). The lake is the deepest lake in Japan (432 m in depth). Researches on sediments of Lake Tazawa are few because of difficulty of sampling caused by the depth. Four sediment cores were collected from Lake Tazawa in 2015. The age of sediments at the bottom of the cores is estimated to be 7,000 years ago (Matsuoka, 2016). In this study, TZW15-4 core sample, which is located at the point near caldera wall in southwest part in Lake Tazawa, was investigated. The distance between edge of Lake Tazawa and sampling point of TZW15-4 is 1.0 km. This study presents results of variation of facies of sediments, grain size distribution, density, mineral assemblage and chemical composition determined by X-ray fluorescence (XRF) core scanner, Itrax regarding TZW15-4 core sample and estimates events in Lake Tazawa from 7000 years ago to present.

Total length of TZW15-4 core is 340 cm. The sediment core is composed of silt, sandy silt, diatom earth and tephra. The dominant sediment is silt in the core. Thirty-eight (38) sandy silt layers, 9 diatom earth layers and 2 tephra layers are intercalated in the silt. The tephra layers are Towada Chuseri and Towada-a tephra (Matsuoka, 2016). The sediment is classified into three parts from lower to upper parts from 340 to 185 cm, 185 to 13 cm and 13 to 0 cm by observation by naked eyes. The lower part is characterized by presence of lamina of sandy silt. The part from 185 to 13 cm is characterized by dominance of silt. The part from 13 to 0 cm is also characterized by discolored silt. The relative density of sediments of the core samples was measured by Computed Tomography (CT) scan. The part of silt and sandy silt correspond to low density and high density, respectively.

Fe, As, Ca, Sr, Cu, Pb and Zn concentrations of the core samples were measured by XRF core scanner. The positions having high intensity of Ca and Sr (peaks of Ca and Sr) in the Ca and Sr spectra correspond to sandy silt. Based on the number of peaks of Ca in the core sample, number of emplacements of sandy silt in silt can be clarified clearly.

Age of sediments of TZW15-4 was estimated by ^{14}C radiometric method (Matsuoka, 2016). Based on the age data and number of peaks of Ca (number of sandy silt layers), frequency of emplacement of sandy silt layers was estimated. The frequency is different in the part from 340 to 185 cm and the part from 185 to 13 cm. The frequency of sandy silt layers in the part from 340 to 185 cm is 6.1 times/1000 years, on the other hand, the frequency of sandy silt layers in the part from 185 to 13 cm is 1.7 times/1000 years. Particle size distribution also shows that sandy silt layers in the parts from 340 to 185 cm and 185 to 13 cm is rich and poor in sand component, respectively. Lake Tazawa does not have large river flowing into Lake Tazawa. Source of sediment materials is thought to be derived from the somma of lake Tazawa. Under the warmer condition, amount of precipitation at catchment area of Lake Tazawa is thought to be increased. Amount and frequency of inflow of sediment materials was increased due to the increase of amount of precipitation. This mechanism corresponds to bottom part (340 to 185 cm). On the other hand, the upper part was estimated to be sediments that was formed under small precipitation in colder period because the low frequency of inflow of sandy silt layer and low abundance of sand in sandy silt layers. Based on the ^{14}C radiometric age data (Matsuoka, 2016, Fukumoto et al., 2019), the boundary between the part from 340 to 185 cm and part from 185 to 13 cm corresponds to the age of climate

change around 4,700 BP. The age accord with the age of the starting of climate cooling in Japan around 5,000 BP (Komoto, 2008; Fukumoto et al., 2019).

Institute of Geology and Geoinformation, Geological Survey of Japan, AIST, Japan

Lake Kitaura is located in the northeast area of Tokyo, facing the Pacific Ocean. We pay more attention to the natural disaster records of this lagoon. Previous studies indicate that the Lake Kitaura recorded twice volcano eruption events, one is A.D. 1707 (Fuji-Hoei), and the other is A.D. 1783 (Asama-a). We drilled two sediment cores here in A.D. 2017 to use multiproxies for interpreting the environmental changes and natural disaster events. First, according to the magnetic susceptibility scan by MSCL, we defined volcanic eruption events in the position of peaking magnetic susceptibility. Our results reveal 6 layers of the volcanic eruption in the lake based on historical records. Those are eruptions from Mt. Fuji in A.D. 1707 and Mt. Asama in A.D. 1783, 1973, 1983, 2004, 2009. The composition of volcanic glass was determined by EDS and LA-ICP-MS for analyzing the SiO_2 content and ratio of Rb/Y and Rb/Sr.

We found that the grain size of sediments was influenced by the volcanic eruption, typhoon, and tsunami events. Br/Ti and S/Ti ratio from Itrax core scanner gives us the information of environmental changes between marine and freshwater, and also indicate that the lagoon formed after about A.D. 1200. After the Mt. Fuji eruption in A.D. 1707, the river brought a lot of sediment accumulation at that time to cause the Br/Ti and S/Ti signals decreasing and forming a more closed brackish environment. We also can judge the duration of salt damage before the Hitachi River locks in A.D. 1975. The sediment cores may record the tsunami event of A.D. 1707, and frequent storm tides between A.D.1275-1340 closed to the time of Kamikaze typhoon in historical records.

Detecting the seismo-turbidites of off Kumano, the Nankai Trough using ITRAX profile

*Natsumi Okutsu[1], Juichiro Ashi[2], Rina Fukuchi[3], Asuka Yamaguchi[2]

1. Japan Agency for Marine-Earth Science and Technology, 2. Atmosphere and Ocean Research Institute, The University of Tokyo, 3. Dia consultants Ltd.

Paleoseismic studies using turbidite have been performed in various sea regions including off the west coast of North America. The characteristics and sedimentation process of turbidite may vary depending on the composition of sediments, the scale of seismic motion, and the seafloor topography. Therefore, for estimating the seismic history using turbidite, it is important to compile characteristics on sedimentary structures, physical properties, chemical compositions, etc. and extract features in each sea region. This study focuses on obtaining the fundamental data of fine-grained turbidites, and apply it to reconstruct the seismic history in the off Kumano, the Nankai subduction zone.

We analyzed multi-cores and piston cores collected from off Kumano, the Nankai Trough. Main samples are obtained from small slope-basins with pin-point accuracy. Based on its sedimentary structure and magnetic susceptibility, fine-grained turbidites are identified. We will mainly report its chemical characteristics based on XRF core scanner, ITRAX.

The first feature of fine-grained turbidite off Kumano is the stratigraphic change of Mn content. McHugh et al. (2016) show a sharp positive peak in Mn just below turbidite, which is different from the trend observed in this study. They suggest that it is due to the shift of the redox boundary just below turbidite. On the other hand, in this study Mn shows the minimum in the mud layer just below the turbidite and starts increasing from the base of the turbidite. High Mn value continues to the high CT value horizon. In the low CT value horizon above it, Mn decreases upward to the base of the next turbidite. The possible scenario for this Mn variation is as follows: when turbidite is deposited, the lower layers below turbidite are separated from the sea floor. This makes deposits reductive and decrease of Mn. On the other hand, the turbidite upper surface must be in contact with oxic seawater for a long time.

The second feature is the stratigraphic change of Ca and Fe. Coarse silt layer (hereinafter, this is called KLa unit), silt layer (KLb) and a thick homogeneous clay layer from the bottom to the top of the upper unit can be identified as fine-grained turbidites. More specifically, KLa unit shows low CT value, which cannot be shown in X-ray CT image and has Fe peak in ITRAX profile. KLb unit shows high CT value and has Ca positive peak in XRF core scanner profile. Although X-ray CT image can be useful tool to identify the fine-grained turbidites, it may lead to misunderstanding the basement of fine-grained turbidites. C-14 radiocarbon dating of the foraminifera, the individual sediment layer interval is 160 years, which is almost consistent with past earthquake recurrence intervals. Moreover, some C-14 ages agree with historical earthquake ages.

Multivariate statistical and multi-proxy constraints on earthquake-triggered sediment remobilization processes in the central Japan Trench

Tobias Schwestermann[1], *Jyh-Jaan Steven Huang[1,5], J. Konzett[2], A. Kioka[3], G. Wefer[4], Ken Ikehara[5], J. Moernaut[1], T.I. Eglinton[6], M. Strasser[1,4]

MARUM –Center for Marine Environmental Sciences, University of Bremen, 5. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology (AIST), 6. Geological Institute, ETH Zürich

Understanding the impact of earthquakes on subaqueous environments is key for submarine paleoseismological investigations seeking to provide long-term records of past earthquakes that allow assessing seismic and tsunami hazards on relevant time scales. In the central Japan Trench, three event deposits (i.e., turbidites) linked to past major earthquakes over the last 1,500 years have been identified and stratigraphically correlated across several isolated basins along the trench. However, their spatio-temporal petrographic and geochemical fingerprints have not yet been established, limiting our knowledge about sediment source and the underlying remobilization processes induced by these past earthquakes. In this study, we show that the existing event-stratigraphic correlation can be significantly enhanced by employing a multivariate statistical correlation of X-ray fluorescence core scanning, magnetic susceptibility, and wet bulk density data from cores taken along the central Japan Trench. Such statistical correlation is confirmed by heavy mineral analysis of the turbidite sands and further combined with new erosion model based on previously reported bulk organic carbon ^{14}C dates. We find that surficial sediment remobilization, a process where strong seismic shaking remobilizes just the upper few centimeters of slope sediment, is the predominant remobilization process during strong earthquakes at the Japan Trench. This finding sheds light on source-to-sink processes in hadal trenches during earthquakes and helps to assess the completeness of the turbidite paleoseismic record. We further suggest that shallow-buried tephra on the slope might significantly influence the volume and the geochemical and petrographic fingerprints of remobilized sediment.

Comparison of element profiles obtained from Itrax-XRF core scanner in evaluating data quality among laboratories used by geological reference material.

*Atsuko Amano[1], Jyh-Jaan Steven Huang[2], Ken Ikehara[1], Masafumi MURAYAMA[3], Takuya Matsuzaki[3]

1. National institute of Advanced Industrial Science and Technology, 2. University of Innsbruck, 3. Kochi University

The non-destructively and high-resolution X-ray fluorescence (XRF) core scanner have become a useful tool for paleoenvironmental research as well as in many other fields. In Japan, two Itrax-XRF core scanner (Itrax) produced by Cox Analytical Systems, equipping different generations of XRF detectors, were set up at Center for Advanced Marine Core Research in Kochi University (CMCR, CS-38, first generation) at 2014 and National Institute of Advanced Industrial Science and Technology (AIST, CS-49, third generation) in 2019, respectively. In order to understand data quality of these two Itrax, six geological reference materials from different sedimentary environments (lake, marine and fluvial sediments produced in Geological Survey of Japan) were measured.
The reference materials were firstly filled in 2.2×2.2 cm sample cube and covered by a thickness of 1.4 μm PET film. These samples were measured in 100, 30, 15, 5, 1 seconds of exposure times using Molybdenum (Mo) and Chromium (Cr) X-ray tubes at 0.2 mm intervals, respectively. All the XRF spectra were reevaluated by the Q-Spec software (Cox Analytical Systems, version 15.1) to obtain individual element peak area. The continuous 50 measurements in the central part of scanning were selected and averaged to avoid possible edge error. These results (Al, Si, S, K, Ca, Ti, Mn, Fe, Ni, Cu, Zn, Rb, Sr, Ba, Pb) were further compared with the absolute concentrations of six reference materials and calculated the correlation coefficients (R^2) with each exposure times and X-ray tubes.
Beside the results using Mo X-ray tube at AIST (failed to measure due to the machine failure), we compare our results with the data using first generation XRF detector in National Taiwan University (NTU, CS-16 in 2009) that reported by Huang et al. (2016). The correlation coefficients of Si, S, K, Ca, Ti, Mn, Fe, Ni, Cu, Zn, Rb and Ba show high (R^2>0.90) among all the laboratories in all machine setting, while Al shows low (R^2<0.80). Therefore, we confirm that (1) the influence of different exposure times is insignificant for the accuracy of the scanning results; (2) Al is difficult to measure by Itrax due to its low detectability, even advanced XRF detectors in CMCR and AIST were used. More detailed discussion will be made once we obtain the Mo tube data of AIST.

[M-IS13] Integrated Analysis of Geoscience Observations from the Floor to Surface of the Ocean

convener:Keisuke Ariyoshi(Japan Agency for Marine-Earth Science and Technology), Joan S Gomberg(USGS Earthquake Science Center), Narumi Takahashi(National Research Institute for Earth Science and Disaster Resilience), Motoyuki Kido(International Research Institute for Disaster Science, Tohoku University)

Sea bottom pressure data contains various components such as crustal deformation, ocean oscillation, tidal variability, atmospheric change, and instrumental drift. So far, seismologists have treated the ocean oscillation as noise, and ocean physicists have done vice versa (considering crustal deformation as noise). Such problems apply to ongoing undersea acoustic distance measuring and other types of ocean observations. In this session, wewelcome contribution on various topics focusing on the complementary relationship between seismology, ocean physics, meteorology, tsunami technology, and other related fields.

Launch of GNSS-Acoustic observation for horizontal and vertical movements off Nemuro using a triangular PXP array with an optional centered-PXP.

*Yukiho Kimura[1], Motoyuki Kido[2], Yusaku Ohta[1], Chie Honsho[1], Fumiaki Tomita[3]

1. Graduate School of Science, Tohoku University , 2. International Research Institute of Disaster Science, Tohoku University, 3. JAMSTEC

Recent studies on tsunami deposit revealed that M9-class huge earthquakes repeatedly occur along the Kuril trench. This suggests that the seismicity gap found in the shallow portion of the off-Nemuro subduction zone shall not be a stably sliding area but an interseismic locking area, which causes destructive tsunamis at the time of a huge earthquake like as the off-Miyagi region. Then the research groups in Tohoku and Hokkaido universities and JAMSTEC have started integrated geodetic and seismic surveys on July 2019 to reveal the interplate locking condition off Nemuro. In this talk, we focus on GNSS-Acoustic (GNSS-A) observation among the whole surveys.

Three GNSS-A sites were newly constructed along the survey line nearly perpendicular to the trench axis off Nemuro. They are G21 (four PXPs (Precision Transponders), ~100 km from the trench, 2920 m in depth) and G22 (four PXPs, ~35 km from the trench, 6242 m in depth) on the land-side slope, and G23 (three PXPs, ~30 km from the trench, 6700 m in depth) on the Pacific plate. The layout of G21 and G22 has a unique feature with a centered-PXP in the triangular PXP array, which can “resolve vertical motions even only by point survey” as well as horizontal motion. Thus, this layout will be useful for employing autonomous surface platforms which are not suited for moving survey. Different emission angles to PXPs are required to distinguish vertical motions from sound speed variation. The DOP (Dilution of Precision) based evaluation in geometrical strength [e.g., Imano, 2020] showed that putting a centered-PXP produced sufficiently different angles when dimension of the array (circumradius) to the site depth is larger than 0.7; in the viewpoint of detecting vertical motions, this four-PXP layout results in favorable geometry than our pre-existing six-PXP sites (consisting of large and small concentric triangles) which are specialized to solve horizontal gradients of sound speed structure.

In this campaign cruise, both moving and point surveys were conducted at each site for determination of array geometry and position of the array. In this talk, we firstly report on the positioning of the individual PXPs to determine the array geometries because of the first campaign survey. Reference sound velocity profile was calculated from concurrently-measured CTD or XCTD cast. We expressed temporal variation of the sound velocity by NTD (Nadir Total Delay) that consists of B-spline curves every 250 s. Then, we simultaneously solved NTDs and the 3-D position of three or four PXPs in a single array. The positions were successfully determined with accuracies of 4.9–13.8 cm in horizontal and 9.9–13.2 cm in vertical with RMSs in traveltime residuals of 0.070–0.085 ms. Significant positive bias in NTD by ~3.0 ms was obtained at the time of CTD casts, which should be zero in definition because of the reference velocity. This bias indicates that the true sound velocity is ~0.9996 of that calculated using our employed formula by Chen & Millero (1977).

The next survey is scheduled in May 2020 and tentative array displacements will be obtained after that. Now we try to analyze time variation of apparent vertical motions of the array during the point survey of this campaign, which can be a rough indication of the accuracy in the estimate of inter-campaign vertical

A study on the effects of sea surface height and density of sea water on bottom pressure off the southeastern coast of Hokkaido, Japan after El Nino events using a high-spatial-resolution ocean assimilation data

*Takuya Hasegawa[1,2], Akira Nagano[1], Keisuke Ariyoshi[1], Toru Miyama[1], Hiroyuki Matsumoto[1], Masahide Wakita[1]

1. JAMSTEC, 2. Tohoku University

To investigate the effects of sea surface height (SSH) and sea water density on bottom pressure (BP) off the southeastern coast of Hokkaido, Japan after El Nino events, a state-of-the-art high-spatial-resolution (1/12 degree) ocean assimilation data of the JCOPE2M for the period of 2001-2018 are analyzed. On year-to-year timescale, after the weak El Nino events occurring in 2004/05, 2006/07 and 2009/10, positive SSH anomalies less than 0.15 m appear off the southeastern coast of Hokkaido, while stronger SSH anomalies greater than 0.2 m exist after the very strong El Nino event of 2015/16. The result shows that although such positive SSH anomalies have effect of increase of BP, density changes of sea water from the sea surface to the ocean bottom (i.e., steric effect), in general, cancel out the effect of SSH anomalies on BP change. In offshore area (i.e., area with bottom depth of deeper than 1000 m), roughly 90 % of the effect of the SSH anomaly is cancelled out by the density change of sea water, and roughly 80 % in near-coastal area with bottom depth from 500 m to 1000 m. In the area very close to the coast with bottom depth less than 500 m, density change of sea water cannot cancel adequately the SSH anomalies as compared to the offshore area; for example, from 20 % to 50 % in the area with bottom depth of around 100 ~ 200 m. Thus, it can be said that oceanic isostasy is generally well established especially in the offshore area, as contrast to the shallow area.To check further the strength of the oceanic isostasy, oceanic isostasy anomaly (OIA) is newly introduced in this study. The OIA is defined as a sum of SSH anomalies and geopotential distance (GPD) anomalies from bottom to sea surface. If value of OIA is zero, it means that oceanic isostasy is perfectly established; if OIA is positive (negative), oceanic fluid can lead increase (decrease) of BP. The value of OIA ranges from -0.025 to +0.025 m for both weak and strong El Nino events. For example, at PG1, OAI shows 0.003 m in July 2015, then becomes to 0.015 m in July 2016, showing a change rate of roughly +0.01 m/year during this period. OIA again becomes to be a small value (0.003 m) in July 2017, showing roughly -0.01 m/year change rate of OIA from July 2016 to July 2017. It is also shown that spatial pattern of OIA is not same for each El Nino event. This means that effect of oceanic fluid on BP change shows a spatio-temporal change in association with El Nino events at year-to-year timescale. The present results indicate that effect of oceanic fluid due to both SSH and sea water density changes on BP change cannot be neglected when BP change (or change rate of BP) should be evaluated with order of 1 cm (or 1 cm/year) at year-to-year scale. Therefore, to better take the year-to-year scale BP changes due to crustal deformation related to such as long-term slow slip events (SSEs) or plate convergence, OIA should be removed from the total value of BP.

Bottom Pressure Variation in Association with the 2017-Present Large-meander of the Kuroshio South of Japan

*Akira Nagano[1], Yusuke Yamashita[2], Keisuke Ariyoshi[1], Takuya Hasegawa[1,4], Hiroyuki Matsumoto[1], Masanao Shinohara[3]

1. JAMSTEC Japan Agency for Marine-Earth Science and Technology, 2. Kyoto University, 3. The University of Tokyo, 4. Tohoku University

In the region off the southern coast of Japan, the Kuroshio alternatively takes large-meander (LM) and non-large-meander (NLM) paths on interannual to decadal time scales. An LM path is greatly displaced southward associated with a large cyclonic eddy off the southern coast of Japan. Meanwhile, an NLM path flows near the coast. Further, there are two types of LM path in terms of the stability of the current path. An LM path formed in August 2004 and continued until July 2005 is an example of the stable type. The LM path was formed from a nearshore NLM path, which flows through the channel north of Miyake-jima Island. Meanwhile, another LM path occurred in September 2017 and continued at present is an example of the unstable type. The LM path changed from an offshore NLM path, which passes through the channel south of Hachijo-jima Island. In addition, the meandering trough of the LM was observed to be more shifted to the east and to be frequently located on the Izu-Ogasawara Ridge. To obtain the mechanisms of the two types of LM path, we performed a detailed comparison between the 2004-2005 and 2017-present LM paths using hydrographic, acoustic surface-bottom round-trip time, sea surface height (SSH), and bottom pressure (BP) data. While, associated with the formation of the stable type (2004-2005 LM) , BP varies vigorously owing to the passage of a deep cyclonic eddy, BP before the formation of the unstable type (2017-present LM) is invariable. In this study, using bottom pressure data collected in the area east of Hyuga-nada, Kyushu, from March 2014 to April 2019, we examine the variation during the LM period.

[M-IS14] Evolution of Pelagic Realm

convener:Atsushi Matsuoka(Department of Geology, Faculty of Science, Niigata University), Toshiyuki Kurihara(Graduate School of Science and Technology, Niigata University), Tetsuji Onoue(Department of Earth and Planetary Sciences, Faculty of Science, Kyushu University), XIN LI(State Key Laboratory of Palaeobiology and Stratigraphy, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences)

This session focuses on the evolution of ecosystem in the pelagic realm,
including discussions on all aspects of pelagic biota covering biostratigraphy,
biochronology, evolution, and biogeography, which are important to the
reconstruction of the spatio-temporal framework in the pelagic realm.
Reconstructions of plate configuration through time are included in the scope of
 this session. Biological, geochemical, sedimentological approaches to the
pelagic environments are welcomed.

Preservation of Permian–Triassic boundary section in the Jurassic accretionary complex of the Lake Hamana, Central Japan

*Wang Ding[1], Kohtaro Ujiie[1], Katsuo Sashida[1]

1. University of Tsukuba

The Permian-Triassic (P–T) boundary has been received extensive attention, because it recorded the largest mass extinction event in Earth’ s history. However, the entire P-T section has been rarely preserved in the pelagic sedimentary rocks. We examined the lithostratigraphy and deformation structures of the accreted pelagic rocks in Lake Hamana, Central Japan, based on a detailed field mapping and the radiolarian ages. The constructed lithostratigraphy is composed of Late Permian gray chert, black chert, black claystone with a high carbon content of 4.86%–6.78%, siliceous claystone, black chert, and middle Triassic gray chert, in the ascending order. The symmetry in the lithostratigraphy and the change in the radiolarian ages with respect to black carbonaceous claystone are presumed to represent a deep-sea anoxic event that occurred across the P–T boundary. The P–T boundary black carbonaceous claystone suffered from an intense shear, resulting in blocks of siliceous claystone in the scaly black claystone matrix. In places, the sheared terrigenous rocks composed of sandstone blocks in the mudstone matrix are intercalated into the pelagic rocks, possibly representing complex mélange forming processes during the development of the Jurassic accretionary complex.

1. Department of Geology, Faculty of Science, Niigata University

Calendars for the year of 2019 and 2020 were produced for enhancing a degree of social recognition of radiolarians. Images for the 2019 calendar come from radiolarian specimens taken from a single rock sample of earliest Cretaceous (Berriasian) tuffaceous clayey radiolarite collected during a dive of the submersible "Shinkai 6500" along the outer slope of the Mariana Trench. Color images of living radiolarians for the 2020 calendar come from radiolarian specimens in the surface water of the East China Sea near Okinawa Island.

A set of playing cards using scanning electron microscope (SEM) images of radiolarian specimens in the same sample as that for the 2019 calendar. The sample contains more than 400 radiolarian species. Candidates of marker taxa defining the Jurassic-Cretaceous boundary can be found in the fauna.

A picture book including SEM images of the above-mentioned Maria radiolarians was published in collaboration with a writer and a book producer. Photo exhibitions were organized in relation to this publication in Tokyo, Osaka, Niigata and other cities in Japan.

Phyletic evolution and paleogeographic distribution of the Early Cretaceous radiolarian *Turbocapsula*

*XIN LI[1], Matsuoka Atsushi[2]

1. State Key Laboratory of Palaeobiology and Stratigraphy, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences, 2. Department of Geology, Faculty of Science, Niigata University

A radiolarian biostratigraphic study ranging from the latest Barremian to the Aptian of a pelagic sequence (section BB1) near Babazhadong in southern Tibet revealed phyletic relationships of species belonging to the genus *Turbocapsula*. Three species and two subspecies are included in this genus: *Turbocapsula tetras* LI & MATSUOKA, *T. fugitiva* O'DOGHERTY, and *T. costata* (*T. costata* (WU) *multicostata* LI & MATSUOKA, and *T. costata* (WU) *costata*). *Turbocapsula fugitiva* appears to have arisen from *T. tetras* by losing the septa between the third and the fourth segments. *Turbocapsula fugitiva* seems to have given rise to *T. costata* multicostata following the development of thicker costae between its two to five rows of pores. With the decrease in the number of the costae and the development in the costae, *T. costata multicostata* evolved into *T. costata costata*. The phyletic evolution of the genus *Turbocapsula* has a high stratigraphic value.An overview of localities where *Turbocapsula costata* (Wu) has been reported and lithology, depositional setting, associated fossil records, Paleomagnetic data from these localities are summarized. All these data lead to the conclusion that locations of known *T. costata*-bearing strata are restricted to the low to mid-latitude Mediterranean and eastern Tethys. This indicate that the zonation established by the phyletic evolution of the genus *Turbocapsula* cannot be utilized for Early Cretaceous zonal correlations between the Pacific, the Atlantic and other regions.

New tectonostratigraphic unit of the Ashio terrane in the Ashio Mountains, central Japan

*Tsuyoshi Ito[1]

1. Geological Survey of Japan, National Institute of Advanced Industrial Science and Technology

The Ashio terrane, a Jurassic accretionary complex, is distributed over the Ashio Mountains of Gunma and Tochigi prefectures, central Japan. Previously, the Ashio terrane is divided into three tectonostratigraphic unit, namely the Kurohone–Kiryu, Omama and Kuzu complexes. The author has recognized new tectonostratigraphic unit (tentative name: Complex A) from the Ashio terrane. The characteristics of Complex A are described here.

Complex A is distributed over mainly the Hachioji hills and Mt. Gyodosan in Tochigi and Gunma prefectures. This complex overlies tectonically the Kuzu Complex and consisits mainly of muddy mixed rock and chert with minor amounts of blocks of sandstone and siliceous mudstone. Early–middle Permian, Triassic and Middle Jurassic radiolarians were obtained from chert. Middle Jurassic radiolarians were extracted from siliceous mudstone and mudstone.

The presence of the Permian chert without basalt and carbonate is the notable characteristic for the comparison with other terrane such as the Tamba and Mino terranes. Although some tectonostratigraphic units of the Tamba and Mino terranes possess Permian chert, these generally include abundant basalt and carbonate as well. Meanwhile, Complex A has no basalt nor carbonate. The comparison indicates the uniqueness of Complex A, suggesting that the complex has unusual geologic history.

[M-IS15] Global climate change driven by the Southern Ocean and the Antarctic Ice Sheet

convener:Osamu Seki(Institute of Low Temperature Science, Hokkaido University), Akira Oka(Atmosphere and Ocean Research Institute, The University of Tokyo), Yoshifumi Nogi(National Institute of Polar Research), Robin Elizabeth Bell(Lamont Doherty Earth Observatory)

The Southern Ocean and Antarctic ice sheet, which are the giant reservoirs of heat, water, and materials, have a potential to play central roles in long-term global climate change. This system is composed of the following sub-systems; ice shelf which is a place of the interaction of ice sheet and ocean, flowing iceberg, seasonal sea ice zone, Antarctic bottom water which drives the thermohaline circulation, active biological production and Antarctic Circumpolar Current. These sub-systems are interacted with each other and have significant impact on changes in the global environmental system. This session aim to summarize recent observational and simulation studies from various fields relating to the past and present changes in the Antarctic Ice sheet and Southern Ocean, which are essential elements for unraveling the changes in the global climate system. Further, future science plans for understanding of the environmental changes of the Antarctic Cryosphere is also discussed.

The Antarctic ice sheet is the largest freshwater reservoir on the Earth surface. Mass loss from the Antarctic ice sheet results directly in global sea-level rise and Southern Ocean freshening. Recent observational and modeling studies have demonstrated that ice shelf basal melting, resulting from the inflow of warm water onto the Antarctic continental shelf, plays a key role in the ice sheet’s mass balance. In recent decades, warm ocean-cryosphere interaction in the Amundsen and Bellingshausen Seas (ABS) has received a great deal of attention. In contrast, East Antarctic continental shelves are primarily occupied by “cold waters” (Schmidtko et al., 2014), with ice shelves typically having cold ice cavities. An exception is Totten Ice Shelf (TIS) which experiences the highest basal melt rates in East Antarctica (>10 m/yr) comparable with those for the ABS ice shelves. Although comprehensive hydrographic observations from ice front to continental shelf and slope regions are indispensable for understanding ice-ocean interaction beneath the TIS, so far, the observations in these regions are quite sparse. The only one observation has been done by Australia in January 2015 and has revealed relatively warm, modified CDW inflows into TIS cavity (Rintoul et al., 2016; Silvano et al., 2017).

In this presentation, we show the characteristics of offshore-origin warm water distribution at the TIS ice front and continental slope regions, using the hydrographic data obtained by Icebreaker *Shirase* in March 2018 (59th Japanese Antarctic Research Expedition) and R/V *Kaiyo-maru* in February 2019 (multidisciplinary ecosystem survey in the eastern Indian sector of the Antarctic with a focus on Antarctic krill, Fisheries Agency). The offshore-origin modified Circumpolar Deep Water (mCDW, up to 0.3°C) is found in deep glacial troughs near the TIS ice front, which is ~0.7°C warmer than that observed at the almost same position in January 2015 (Rintoul et al., 2016). This suggests a seasonal or interannual variation in inflowing ocean heat flux into TIS cavity. Along the continental slope, warmer mCDW (>1°C) lies at subsurface layer (~300-500 dbar), and particularly warm cores (1.2-1.4°C) is found around the eastern limb of cyclonic eddies, indicating a possible role of cyclonic eddies on a poleward transport of offshore warm water. Various processes from offshore to ice front regions would consequently result in the variations in the ocean heat flux into TIS cavity (i.e., the magnitude of basal melting) with various time scales.

Changes of Antarctic Bottom Water off the Wilks Land coast of the Australia-Antarctic Basin

*Taiyo Kobayashi[1]

1. Japan Agency for Marine-Earth Science and Technology

Changes of Antarctic Bottom Water (AABW) off teh Wilks Land coast (near 115˚E) of the Australia-Antarctic Basin were examined mainly with historical hydrographic datasets and recent observations of reasearch vessels and deep floats. From climatological views, AABW (denser than γ^n = 28.30) has decreased its thickness since around 1970 by the rate of about 15 m yr^{-1} at the “hypothetical” station of 60˚S 115˚E. The freshening of AABW began before 1960 in the region and it was accelerated in time. These climatological features are fairly consistent with those that had been reported on the AABW changes in the other regions in the Australia-Antarctic Basin.

After around 2010, however, the changes in AABW seemed to have modulated from these climatological trends. The thickenss of AABW was kept at almost the same level until around 2015, and then it has decreased rapidly (by about 50-100 m yr^{-1}). The isothermal salinity decreased rapidly by more than -1.0×10^{-3} yr^{-1} for the period of 2010-2015, and then the freshening seemed to be halted.

The recent modulations of the AABW changes off the Wilks Land coast are similar to the recent changes in AABW off the Adélie/George V Land coast (around 140˚E) (Kobayashi, 2018) at many points. Meanwhile they have several differences; the former modulations probebly began about 4 years later of the latter occureances, and and the former changes were more gradual than the latters. These feasures would suggest that the recent modulations of the AABW changes off the Wilkes Land coast were derived from the arrival of the modified AABW from the east and ultimately attributed to the collapse of Mertz Glacier Tongue in February 2010.

Preliminarily results from numerical modeling of chlorofluorocarbons (CFCs) and sulfur hexafluoride (SF_6) in the Southern Ocean

*Yoshihiko Ohashi[1], Michiyo Yamamoto-Kawai[1], Kazuya Kusahara[2]

1. Tokyo University of Marine Science and Technology, 2. Japan Agency for Marine Earth Science and Technology

Antarctic Bottom Water (AABW) forms in the Southern Ocean and spreads throughout the global ocean. The time scale of AABW spreading has not been understood in detail. To quantitatively understand its time scale, it is effective to use transient tracers such as chlorofluorocarbons (CFCs) and sulfur hexafluoride (SF_6). We carry out numerical experiments of CFCs and SF_6 in the Southern Ocean using a coupled ocean-sea ice-ice shelf model and investigate the relationship between partial pressure of CFC-12 (pCFC-12) and partial pressure of SF_6 (pSF_6) in AABW. The concentrations of pCFCs in the model are significantly high near formation regions of the AABW (Ross Sea, Weddell Sea, off the Cape Darnley, and off the Adelie Land). This horizontal distribution is consistent with observational results. The linear relationship between pCFC-12 and pSF_6 are found near formation regions of the AABW, indicating that a strong mixing of waters with different ages. The transit time distribution (TTD) method using pCFC-12 and pSF_6 provides information about mean age and age distribution of a water parcel. In the presentation, we will reveal the TTD in the model and estimate the water mass age using the TTD and observed multi-transient tracers.

Dense water production and downslope flow off Cape Darnley reproduced by a realistic numerical model

*Vigan Mensah[1], Yoshihiro Nakayama[1], Masakazu Fujii[2], Yoshifumi Nogi[2], Kay I. Ohshima[1]

1. Institute of Low Temperature Science, 2. National Institute of Polar Research

The ability of the Massachusetts Institute of Technology general circulation model (MITgcm) to reproduce dense water production and its downslope outflow through a complex topography is evaluated through a series of simulations at different horizontal and vertical resolutions. The study domain is the region off Cape Darnley in East Antarctica, where intense sea ice production from March to October leads to the formation of Dense Shelf Water, previously observed to outflow periodically as a downslope current. Our experiments are based on a hydrostatic parametrization, using a coupled ocean-ice-atmosphere model for realistic forcing and sea ice production. Different vertical and horizontal resolutions are used to evaluate the relative importance of the model vertical grid and of the topography on the production of dense water and its outflow, and the model output is compared with the mooring observation data for evaluation purposes. The bottom topography data around the main canyon (Wild Canyon) are based on multibeam echo-sounder observations. While the outflow of dense shelf water is seen in the model outputs at the mooring location for each vertical and horizontal resolution, increasing the horizontal resolution leads to a start of the outflow and a periodicity more consistent with the observations. This suggest the dominant role of horizontal resolution for the accurate reproduction of dense shelf water production and outflow. We then proceed to determine the optimal setting allowing for reproduction of these phenomena at the lowest possible computational cost.

Modeling Ice-shelf ocean interactions of West Antarctic and East Antarctic ice shelves

*Yoshihiro Nakayama[1], Hong Zhang[2], Vigan Mensah[1], Shigeru Aoki[1], Dimitris Menemenlis[2]

1. Institute of Low Temperature Science, Hokkaido University, 2. NASA Jet Propulsion Laboratory, California Institute of Technology

In the Amundsen and Bellingshausen Seas (ABS), modified Circumpolar Deep Water (mCDW) intrudes into ice shelf cavities of West Antarctic Ice Sheet (WAIS), causing high ice shelf melting near the ice sheet grounding lines, accelerating ice flow, and controlling the pace of future Antarctic contributions to global sea level (~0.3mm/y). On the other side of Antarctica, recent studies are pointing out that the ice shelves of East Antarctic Ice Sheet (EAIS) may be beginning to shrink, which is crucial as the EAIS contains marine-based ice equivalent to 19 m of global sea-level rise. Recent oceanographic observations evidenced the inflow of mCDW (~-0.4ºC) into the Totten ice shelf cavity.

Using MITgcm, we have conducted various regional ocean simulations for ice shelves in the ABS and off Sabrina coast with a focus on Pine Island,/Thwaites ice shelves and Totten ice shelf, respectively. Our ABS domain extends from the Antarctic Continent to 65ºS and from 140ºW to 65ºW and our East Antarctic domain extends from the Antarctic Continent to 60ºS and from 90ºE to 150ºE. Detailed comparison between model and observations are conducted. Pathways of mCDW towards grounding lines, temporal and spatial variabilities of ice shelf melt rates, mechanisms of simulated and observed interannual variabilities, etc., have been investigated.

In this presentation, we will summarize key findings and model capabilities from available ocean configurations. We introduce our various existing model outputs focusing on the eastern Amundsen Sea as an example, and demonstrate how to access these outputs and plot basic variables. We hope that these model outputs can be utilized for different aspects of oceanographic researches including observational planning, boundary conditions for ocean and ice sheet models, and data analysis for physical, biological and biogeochemical oceanography.

Geological evidences for Cape Darnley Bottom Water in the Wild Canyon, Antarctica: Preliminary results of R/V Hakuho-maru KH-20-1 cruise

*Minoru Ikehara[1], Hiroshi Sato[2], Masakazu Fujii[3], Keiko Takehara[4]

1. Center for Advanced Marine Core Research, Kochi University, 2. Senshu University, 3. National Institute of Polar Research, 4. Soka University

The Cape Darnley Bottom Water (CDBW) produced in the Cape Darnley polynya (CDP) descends down Wild Canyon (Ohshima et al., 2013). According to the mooring observations (Ohshima et al., 2013), significant signals of CDBW was found at the center of Wild Canyon just off the CDP. Two months after the onset of active sea-ice production, a colder, less saline, and denser signal appeared and became dominant after June. However, there are no direct evidence for sedimentary processes in the Wild Canyon. We have conducted marine geological survey in Wild Canyon during the KH-20-1 cruise by R/V Hakuho-maru in 2020 austral summer. We obtained sediment samples at two sites using multiple corer with deep-sea camera at the bottom of the Wild Canyon. For site CAD-5 (2660m water depth), small amount of sands was recovered. Based on deep-sea camera observation, sea-floor is covered by sand and rocks. Short sediment cores were recovered at the site St16 (3347 m water depth), which is located at downstream area from CAD-5. Sediments were composed of sandy silt in the canyon, and current ripple are observed on the seafloor in the canyon, which is main stream of the CDBW.

Boulder, cobble, pebble, and granule of continental crust rocksfrom the Wild Canyon, off Cape Darnley, East Antarctica: Preliminary results of dredged samples during KH-20-1 cruise, R/V Hakuho-maru

*Hiroshi Sato[1], Masakazu Fujii[2], Minoru Ikehara[3], Keiko Takehara[4]

1. School of Business Administration, Senshu University, 2. National Institute of Polar Research and SOKENDAI, 3. Center for Advanced Marine Core Research, Kochi University, 4. SOKA University

The Cape Darnley Bottom Water (CDBW), which is produced in the Cape Darnley polynya (CDP), descends down the Wild Canyon (Ohshima et al., 2013). According to the mooring observations by Ohshima et al. (2013), significant signals of CDBW were found at the center of the Wild Canyon just off the CDP. Two months after the onset of active sea-ice production, a colder, less saline, and denser signal appeared and became dominant after June. However, there is no direct evidence for the transportation processes of geological materials in the Wild Canyon.

Dredge operation was performed during KH-20-1 cruise at the bottom of Wild Canyon. Approximately 170 kg of granitoid and metamorphic rocks that are consist of continental crust were recovered. They contain boulder, cobble, pebble, and granule size of granitoid and metamorphic rocks. Furthermore, they show subangular to subrounded shape. Based on deep-sea camera observation, sea-floor is covered with soft sediments and scattered boulders.

Lithology and petrological characteristics of continental crust rocks will reveal not only transportation and sedimentary processes at the Wild Canyon but also (tectonic) development history of both the Wild Canyon and East Antarctica.

Revising the Dome Fuji ice core chronology

*Ikumi Oyabu[1], Kenji Kawamura[1,2,3], Kyotaro Kitamura[1], Frédéric Parrenin[4], Anais Orsi[5], Christo Buizert[6]

1. National Institute of Polar Research, Research Organization of Information and Systems, 2. The Graduate University of Advanced Studies (SOKENDAI), 3. Japan Agency for Marine Science and Technology (JAMSTEC), 4. Institut des Gé osciences de l'Environnement, 5. Laboratoire des sciences du climat et de l'environnement, 6. Oregon State University

Precise chronology is essential for paleoclimate proxies to examine the sequences, durations and phasing of the climate records, as well as for numerical simulations, both for their input and validation data to better understand the transient behaviors of climate and ice sheet. The chronology of the Dome Fuji ice core over the last 340 kyr was constructed by synchronizing variations in the O_2/N_2 ratio of occluded air with local summer insolation (Kawamura et al., 2007) with stated uncertainty of less than ~2.5 kyr in general. The accuracy of the chronology is generally supported by the comparison with a radiometric (U-Th) dating of Chinese speleothem records (Cheng et al., 2009), but relatively large errors were recently found around the last interglacial period (Fujita et al., 2015). Here, we revise the Dome Fuji chronology using newly acquired O_2/N_2 ratio (summer insolation proxies), new densification models and 1-D ice flow model (PaleoChrono), and discuss the timing of penultimate deglaciation from atmospheric records of CH_4 concentrations and $\delta^{18}O$ of O_2 in the Dome Fuji ice core.

Carbonaceous aerosol records in Domu Fuji ice core over the past 160 kyrs

Haruki Honda[2], *Osamu Seki[1], Kaori Ono[1], Yoshinori Iizuka[1]

1. Institute of Low Temperature Science, Hokkaido University, 2. Graduate School of Environmental Science, Hokkaido University

Carbonaceous aerosols influence climate via direct and indirect effects on radiative balance and are thought to have a potential to substantially affect global climate. Although numerous studies have been conducted to better understand chemical and physical properties, source, transport and fate of carbonaceous aerosols in the atmosphere, significance of carbonaceous aerosol for global scale climate still remains uncertain. This is mainly due to difficulty to evaluate net radiative effects of carbonaceous aerosol. In this study, we reconstructed changes in terrestrial and marine derived biogenic carbonaceous aerosols during the glacial-interglacial cycle (over the past 160 kyrs) based on analysis of organic molecular tracers in Antarctic ice core, Dome Fuji, in order to evaluate substantial role and impact of biogenic carbonaceous aerosol on glacial-interglacial scale climate. The fluxes of both terrestrial and marine derived organic molecular tracers show large variations over the past 160 kyrs with low and high during the glacial and deglacial to interglacial periods, respectively. Their variation patterns are consistent with biomass changes in the aerosol source regions; high latitude regions of the South America and South Atlantic Ocean. This correspondence suggests emissions of the biogenic carbonaceous aerosols are primary controlled by biomass of aerosol sources. Comparison of the organic molecular tracers and surface air temperature records in the Dome Fuji ice core and sea surface temperature in the water vapor source revealed that the emission of biogenic carbonaceous aerosol does not correlate with Antarctic and Southern Ocean temperatures. The observed decoupling of high latitude temperature in the southern hemisphere and biogenic carbonaceous aerosol indicates that carbonaceous aerosol does not play an important role in affecting large scale climate change and thus, that net radiative effect of carbonaceous aerosols is almost negligible.

CO_2 sensitivity experiments to study the climate of the mid-Pliocene Warm Period: results from Antarctica and the Southern Ocean

*Wing-Le Chan[1], Ayako Abe-Ouchi[1,2]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. National Institute for Polar Research

The mid-Pliocene Warm Period (mPWP), 3.3-3 million years ago, was a period of sustained warmth before global cooling occurred and a shift to repeated glacial cycles. It was also the most recent time in the history of Earth when atmospheric carbon dioxide levels were similar to those of present day. The study of this period is thus of much importance, given the growing concerns over future climate change associated with anthropogenic emissions of greenhouse gases. Recently, an increasing number of climate models have been used to investigate the mPWP climate, most contributing to the Pliocene Model Intercomparison Project (PlioMIP), while a large collection of proxy data from both terrestrial and marine sources have been made available. Reconciling model results and proxy data remains an important issue.

In our study, we use the mid-resolution MIROC4m coupled atmosphere-ocean general circulation model and apply ice sheet configuration, land-sea mask, orography and biome distribution from PRISM data sets, as set forth in the second phase of PlioMIP. We conduct a series of experiments which include a range of atmospheric carbon dioxide levels given the spread in values suggested by different sources of proxy data and show how various aspects of the climate in the southern polar region respond. We also compare sea surface temperature anomalies with proxy values derived from PRISM data sets.

Glacial ocean carbon cycle changes caused by enhanced stratification in the Southern Ocean and iron fertilization from glaciogenic dust

*Hidetaka Kobayashi[1], Akira Oka[1], Akitomo Yamamoto[2], Ayako Abe-Ouchi[1]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. Japan Agency for Marine-Earth Science and Technology

The glacial-interglacial variation of atmospheric carbon dioxide concentration (pCO_2) is recognized to mainly arise from changes in the ocean carbon cycle, but the detailed mechanism behind this change is not clarified. This study conducts an ocean carbon cycle simulation using a global-scale three-dimensional ocean general circulation model considering the enhanced stratification in the Southern Ocean and the iron fertilization from glaciogenic dust during the glacial periods and shows the glacial change of atmospheric pCO_2 by about 80 ppm. Considering these processes also improves simulating the ocean inventory and distribution of dissolved oxygen, carbonate ion, $\delta^{13}C$, and radiocarbon ages. We show that the effective biological pump under the enhanced stratification and increased ocean alkalinity inventory due to carbonate compensation, which are not appropriately considered in previous OGCM studies, are important to sequester carbon to the deep ocean under the constraints of proxy data during glacial periods.

Incorporation of grounding line parameterizations in the three-dimensional ice sheet model SICOPOLIS

*Takashi Obase[1], Ayako Abe-Ouchi[1,2], Fuyuki SAITO[3], Ralf Greve[4]

1. Atmosphere and Ocean Research Institute, the University of Tokyo, 2. National Institute of Polar Research, 3. Japan Agency for Marine-Earth Science and Technology, 4. Institute of Low Temperature Science, Hokkaido University

Understanding the nature, stability and climatic thresholds of the Antarctic ice sheet is important for projecting future sea level change. Flow of Antarctic ice sheet is commonly represented with Shallow Ice Approximation (SIA) and Shallow Shelf Approximation (SSA). However, under coarse horizontal resolution (~10km) that is feasible for long-term simulation of Antarctic ice sheet of glacial cicyles, combined SIA/SSA model has limited utility in the migration of grounding lines (Pattyn et al. 2012). Recent Antarctic Ice Sheet models utilize sub-grid parameterization of grounding line migrations to represent large-scale grounding line migration of Antarctic marine ice sheets during glacial cycles. Here, a sub-grid grounding line parameterization is incorporated to the 3-dimensional ice sheet model SICOPOLIS. We present the results of model evaluations under both of idealized topography and realistic Antarctic topography.

Modeling the evolution of the Antarctic ice sheet driven by basal melting using the three-dimensional ice sheet model SICOPOLIS

*Kaho Harada[1], Ayako Abe-Ouchi[1,2], Takashi Obase[1], Fuyuki SAITO[3], Ralf Greve[4]

1. Atmosphere and Ocean Research Institute, The University of Tokyo, 2. National Institute of Polar Research, 3. Japan Agency for Marine-Earth Science and Technology, 4. Institute of Low Temperature Science, Hokkaido University

The Antarctic ice sheet is the largest fresh-water storage at present, whose geometry and volume have changed in response to climate changes like glacial-interglacial cycles. These changes are controlled by the surface and basal mass balance of the Antarctic ice sheet, which also affect grounding line migration. The basal melting beneath ice shelves is one of the dominant drivers for mass loss from the Antarctic ice sheet as it causes ice shelves to thin and reduce their buttressing effect on the upstream grounded ice, which leads to accelerated ice drainage and thus mass loss. However, the relative importance of basal melting on the response of the Antarctic ice sheet to climate change is still not clear.

In this study, we use the three-dimensional ice sheet model SICOPOLIS to investigate steady states of the Antarctic ice sheet with various basal melting rates beneath ice shelves, starting from the present-day ice sheet as initial condition. We analyze the response of the whole Antarctic ice sheet as well as that of specific areas, namely the Siple Coast, Wilkes, Aurora and Recovery subglacial basins. Siple Coast is located in West Antarctica, at the east side of the Ross Ice Shelf, while the other basins are located in East Antarctica. All areas have large ice shelves, so that they are highly sensitive to the basal melting beneath ice shelves. We also investigate steady states of the Antarctic ice sheet at various sea levels relative to the present to take into account the influence of glacial-interglacial cycles.

Antarctic ozone and precipitation variability in the Southern Hemisphere

*Alessandro Damiani[1], Raul Cordero[2], Pedro Llanillo[3], Sarah Feron[4], Hitoshi Irie[1], Shingo Watanabe[5]

1. Chiba University, Japan, 2. Santiago University, Chile, 3. AWI, Germany, 4. Stanford University, USA, 5. JAMSTEC, Japan

Although Antarctic ozone depletion occurs mostly in spring, the consequent reduction in shortwave heating lasts long into the summer, accelerating the stratospheric zonal winds and causing negative geopotential height anomalies at high latitudes. Such changes propagate from the stratosphere to the troposphere, affecting winds, precipitation, pressure, and temperature and result in a modulation of the trend of the Southern Annular Mode (SAM), especially during the austral summer. Nevertheless, Antarctic ozone can also potentially affect the climate at an interannual timescale due to its significant interannual springtime variability. On the other hand, ozone anomalies can be considered a proxy for variability in polar vortex strength. In this study, we investigated the interannual connection among ozone, SAM, and precipitation, exploring the possibility of using springtime Antarctic ozone as a predictor of summertime precipitation. Observations were compared with simulations of the present and future climate from a coupled climate model with interactive atmospheric chemistry. Then, in an attempt to identify the regions where ozone variations could improve seasonal predictions, we focused on areas where previous studies found a connection between surface climate and the ozone hole. Overall, we suggest that including ozone variations in models could enhance seasonal predictions.

Position of grounding line at outlet glacier.

*Chiyuki Narama[1], Tsutomu Yamanokuchi[2], Shin Sugiyama[3]

1. Program of Field Research in the Environmental Sciences, Niigata University, , 2. RESTEC, 3. Institute of Low Temperature Science, Hokkaido University

To identify a grounding line at the Langhovde Glacier in East Antarctica, "double differential interferometric SAR (DDInSAR) analysis" is performed using ALOS-2 / PALSAR-2 microwave data. By comparing the vertical component obtained by DDInSAR with the field survey data, we estimated position of a grounding line at the Langhovde Glacier.

Acceleration and retreat of Langhovde Glacier, East Antarctica, after the breakup of land-fast sea ice in 2016

*Ken Kondo[1,2], Shin Sugiyama[2]

1. Graduate School of Environmental Science, Hokkaido University, 2. Institute of Low Temperature Science, Hokkaido University

The Antarctic ice sheet drains ice into the ocean through floating ice shelves and outlet glaciers, which play key roles in the mass balance of the Antarctic ice sheet. Since iceberg calving and ice shelf basal melting are major ablation processes of the ice sheet, understanging the dynamics of floating ice is important. Land-fast sea ice affects the stability of ice shelves by exerting battressing force on the ice front. For example, previous studies reported glacier front retreat, disintegration of ice shelves and ice flow acceleration after breakup of sea ice in front of glaciers (e.g. Miles et al., 2017). Lützow-Holm Bay located in East Antarctica is usually covered with land-fast sea ice all year round, but a large portion of sea ice broke up in April 2016 (Aoki et al., 2017). In order to investigate the impact of the sea ice break up on outlet glaciers in the region, we carried out satellite observations on Langhovde Glacier, one of the outlet glaciers terminating in Lützow-Holm Bay. Glacier terminus position was deliniated from 2000 to 2020, using Landsat 7 Enhanced Thematic Mapper Plus (ETM+) and Landsat 8 Operational Land Imager (OLI) imagery. Changes in glacier surface area near the calving front were devided by the width of the calving front to obtain mean retreat/advance distance. Ice flow velocity field from 2014 to 2020 was measured, by applying a feature tracking method (Sakakibara and Sugiyama, 2014) to Landsat 8 OLI image pairs.

Terminus position has been relatively stable from 2000 to 2012, with only small fluctuations within a range of 200 m. The glacier then advanced by 400 m from 2012 to 2016. After 2016, the year of the land-fast sea ice break up, the terminus retreated rapidly by 720 m by 2020 as a result of large calving events in 2016 and 2019. The glacier front reached the most retreated position since 2000. After the sea ice breakup, ice speed increased from 110 m a^{-1} in 2017 to 135 m a^{-1} in 2019. The results of this study suggest the glacier had been stabilized by the land-fast sea ice by 2016. Rapid retreat and acceleration after the breakeup indicate significant influence of sea ice on the dynamics of outlet glaciers in Antarctica.

Flow velocity and ice sheet elevation of Shirase Glacier and Totten Glacier from SAR and Laser altimetry

*Shotaro Ohkawa[1], Koichiro Doi[2], Kazuki Nakamura[3], Hiroto Nagai[1]

1. WASEDA University, 2. National Institute of Polar Research, 3. Nihon University

The whole area of Antarctica ice mass balance has already calculated by previous studies (eg. Rignot et al., 2019). However, Antarctic glaciers have various flow rates, which might be related to their responses to climate change, therefore present flow dynamics observation at high spatial and temporal resolutions is necessary.

This study estimates two glaciers' ice flow velocity and ice elevation profiles in available parts. Two glaciers which are Totten Glacier and Shirase Glacier in the East Antarctica were chosen in this study. Previous studies found out that Totten Glacier has been melted rapidly (Li et al., 2016; Rignot et al., 2013), whereas Shirase Glacier is one of the fastest ice streams in Antarctica (Nakamura et al., 2010; Rignot et al., 2011). We estimated the ice flow velocities using Synthetic Aperture Radar (SAR) images corrected by C-band SAR onboard Sentinel-1A/-1B in 2018 to 2019 and the Phased Array L-band SAR-2 (PALSAR-2) onboard Advanced Land Observing Satellite-2 (ALOS-2) in 2017 to 2018.

The Geoscience Laser Altimeter System (GLAS) on the Ice, Cloud, and land Elevation Satellite (ICESat) and the Advanced Topographic Laser Altimeter System (ATLAS) instrument onboard ICESat-2 provide accurate global elevation data. ICESat-2 was launched on September 15, 2018, which is the newest laser altimeter satellite at this time. ICESat data is available from 2003 to 2009 and ICESat-2 data are available from 2018 to 2019. Laser altimetry data are combined with the existing digital surface models (DSM) like the Reference Elevation Model of Antarctica (REMA) and ALOS World 3D-30m (AW3D30) which have some data missing. Laser altimetry data was used to fill some data missing of DSM.

In the presentation, we will estimate ice volume change and ice flux from glacier to compare with the past results using flow velocity data and elevation data. We will also try to cover some data missing in the DSMs using the elevation data. DSMs are necessary for using estimating flow velocities from other SAR data processing techniques like InSAR.

This study was partially supported by JSPS KAKENHI Grant No. 17H06321.

Summary of the 3rd Year Activities of the Project on the Interaction of the solid Earth and the Antarctic Ice Sheet

*Yoichi Fukuda[1], Jun Nishijima[2], Takahito Kazama[1], Kazuki Nakamura[3], Koichiro Doi[4], Yusuke Suganuma[4], Jun'ichi Okuno[4], Akito Araya[5], Heitaro Kaneda[6], Yuichi Aoyama[4], Hideki Miura[4]

1. Department of Geophysics, Graduate School of Science, Kyoto University, 2. Graduate School of Engineering, Kyushu University, 3. Faculty of Engineering, Nihon University, 4. National Institute of Polar Research, 5. ERI, University of Tokyo, 6. Graduate School of Science, Chiba University

A five years research project funded by JSPS (Japan Society for the Promotion of Science) has been started in July 2017. The title of the project is "Giant reservoirs of heat/water/material: Global environmental changes driven by Southern Ocean and Antarctic Ice Sheet" and is aiming to establish a new research area for Antarctic environmental system science. The project consists of 7 research topics, including Antarctic ice sheet and Southern ocean sciences, new observation methodology, modeling and other interdisciplinary topics, and we are involved in the topic, "Interaction of the solid Earth and the Antarctic Ice Sheet".

The Antarctic ice sheet is an essential element of the Earth system for predicting the future environment changes. Thus many studies have been conducted by means of geomorphological, geological, geodetic surveys, as well as satellite observations. For these studies, one of the largest uncertainties is the effects of GIA and the main reason of the uncertainties come from insufficient in-site observations. Thus we planned to conduct geomorphological, geological and geodetic surveys in the outcrop areas and the coastal areas in East Antarctica. Combining these new observations with other in-site data, various satellite data and numerical modeling, we aim to estimating a precise GIA model, constructing a reliable ice melting history after the last glacial maximum and obtaining the viscoelastic structure of the Earth's interior.

As the third year activities, we conducted absolute gravity measurements in Korean Jang Bogo station and Itarian Marrio Zucchelli station, boring core sampling and geomorphological surveys near Indian Maitri Station as well as several data analyses, numerical modeling, and other related studies.

In this presentation, we report these activities and the results so far obtained, and the observation/research plans in 2020 as well.

This study was partially supported by JSPS KAKENHI Grant No. 17H06321.

Dependences of GIA model parameters on the geodetic data in East Antarctica

*Jun'ichi Okuno[1,2], Koichiro Doi[1,2], Akihisa Hattori[2], Yoichi Fukuda[3]

1. National Institute of Polar Research, 2. The Graduate University for Advanced Studies, 3. Kyoto Univ.

Recent global warming has accelerated the melting of both the Greenland and Antarctic ice sheets and has resulted in global sea-level rise, which has become a social concern. The recent melting of the Antarctic Ice Sheet (AIS), the largest freshwater reservoir on Earth, has been detected by various observations. In particular, time series of gravity changes by GRACE, which launched in 2002, described in detail the movement and change of mass in Antarctica. However, the observation of gravity fields such as GRACE includes not only the change of ice mass but also the change of mass caused by the deformation of the solid Earth called Glacial Isostatic Adjustment (GIA). For this reason, an accurate estimate of the solid Earth deformation is required to prescribe the recent ice mass balance by gravity observations.
Furthermore, the current deformation rate of the solid Earth also includes the component induced by the melting of the AIS since the Last Glacial Maximum (ca. 20kyr before present). Therefore, the estimates of the deglaciation history of the AIS on a time scale over 10,000 years derived from geomorphic and geological observations are also required. In the GIA modeling study, the development of numerical methods simulating the Earth's response due to surface load has been continued with the inference of the melting history of the continental ice sheets simultaneously. At present, several scenarios of the AIS deglaciation history based on geomorphic and geological data have been proposed and are still being debated. In this study, we discuss the GIA-derived gravity change and crustal deformation in the East Antarctic region using the previously published AIS deglaciation models and the GIA modeling code currently under development. GIA is highly dependent not only on surface load variations such as the changes of ice and seawater volume but also on the structure of the Earth's interior (mainly viscosity structure of the mantle). Therefore, to discuss the recent ice mass change in detail, we will conduct the numerical experiments with the extensive GIA model parameters and show the effects of the GIA-induced geodetic signals on the estimates of current ice mass fluctuations quantitatively.

Antarctic ice sheet dynamics during the Last Interglacial

*Mutsumi Iizuka[1], Osamu Seki[1], Keiji Horikawa[3], Tina van de Flierdt[2], Tomohisa Irino[1], Masanobu Yamamoto[1], Takuya Itaki[4], Saiko Sugisaki[4], Minoru Ikehara[5], Yusuke Suganuma[6]

1. Hokkaido university, 2. Imperial College London, 3. University of Toyama, 4. Geological Survey of Japan, 5. Center for Advanced Marine Core Research, Kochi University, 6. National Institute of Polar Research

Ongoing global warming could cause various problems in the future. One of the serious concerns potentially caused by the global warming is a sea level rise due to the melting of ice sheet. Antarctic ice sheet, which hold a massive amount of fresh water, was considered to be stable even if global warming progresses in a future. However, recent studies have shown that Antarctic ice sheet is more sensitive to global warming than previously thought. Therefore, it is an important to better understand extent to which Antarctic ice sheet sensitive to global warming.

Study of past warm period provides a useful insight into the prediction of sea level rise in a future. In particular, the last interglacial (MIS 5e), which was ~1˚C warmer than that of the preindustrial, is receiving increased attention, since sea level in the period is estimated to be several meters higher than that of the present. This suggests substantial loss of Antarctic ice sheet during MIS 5e. However, variability of Antarctic ice sheet during MIS 5e has been poorly understood. In this study, we generate high resolution records of mineral composition, Nd isotope and iceberg rafted debris (IBRD) in GC1407 collected from near the Wilkes Basin, East Antarctica (130.518˚E, 63.74˚S) in order to better understand Antarctic ice sheet dynamics during the warmer than the present climate condition.

The two episodic IBRD increase events are found to be recognized during MIS 5e in GC1407, suggesting that increases in icebergs transport occurred during MIS 5e. Nd isotope and mineral composition records in GC1407 suggest that icebergs originated from area with relatively higher eNd, possibly either Wilkes Land Basin or West Antarctica ice sheets. The iceberg discharge events happened when Antarctic air temperature was warmer than that of preindustrial era, suggesting a link between Antarctic warming and increase in iceberg discharge. Furthermore, the timings of iceberg

©2020. Japan Geoscience Union. All Right Reserved.

discharge events are simultaneous with the onsets of sea level rises estimated from geological record in Western Australia. The correspondence between the sea level and Antarctic ice sheet records suggests substantial contribution of Antarctic ice mass loss to the sea level rises during MIS 5e.

The West Antarctic Ice Sheet (WAIS) and East Antarctic Ice Sheet (EAIS) contain an amount of ice equivalent to 3-5 m and 53 m sea level rise, respectively (1). The WAIS, as a largely marine-based ice sheet, is susceptible to changes in ocean temperatures and prone to retreat. Recent research has revealed that areas of the EAIS situated below sea level are also very sensitive to atmospheric and oceanic temperature changes and vulnerable to retreat (2, 3). The two largest subglacial basins in East Antarctica, the Wilkes and Aurora subglacial basins, hold a total ice mass equivalent to 28 m sea level rise (4), demonstrating that even a partial collapse of the EAIS would have a major effect on global sea level.

To investigate the response of these vulnerable areas to a warming ocean and atmosphere, we have evaluated beryllium isotope concentrations from Adélie Basin, located on the continental shelf offshore the Wilkes Subglacial Basin. Our record covers the most recent period of major Holocene ice sheet retreat, sea level rise, and increased atmospheric CO_2since the Last Glacial Maximum ice sheet retreat (5). The beryllium isotope data suggest oceanic or climatic changes occurred at ca. 9.8 ka, ca. 6.3 ka, and from ca. 4.1 ka. From prior research, we can conclude our high meteoric ^{10}Be values at ~9.8 ka and ~6.3 ka are attributed to an open marine environment created by the retreat of grounded ice along with an increased influx of meltwater (6-8). The elevated concentration and frequency variation of meteoric ^{10}Be values starting from ~4.1 ka indicates a change in regime, possibly linked to changes in climate.

Geophysical and geological signatures of submarine canyons off Cape Darnley, Antarctica

*Masakazu Fujii[1,2], Minoru Ikehara[3], Hiroshi Sato[4], Keiko Takehara[5], Takuya Itaki[6], Yoshifumi Nogi[1,2], Yasuyuki Nakamura[7]

1. National Institute of Polar Research, 2. The Graduate University for Advanced Studies, SOKENDAI , 3. Center for Advanced Marine Core Research, Kochi University, 4. Senshu University, 5. SOKA University, 6. Geological Survey of Japan, AIST, 7. Japan Agency for Marine Earth Science and Technology

The Antarctica continental slope off Cape Darnley is known as a major pathway of colder, less saline, and denser bottom water, which is produced in the Cape Darnley polynya and known as the Cape Darnley Bottom Water (CDBW). The mooring observations showed that significant signals of CDBW occurs at the center of the Wild Canyon (Ohshima et al., 2013). Intensive erosion and material transports from shallow regions to deep ocean can be expected here, but the relationship between submarine canyons and bottom water is still debated. Here we present new observations from large networks of submarine canyons off Cape Darnley. We conducted underway geophysical mapping, multichannel reflection seismic survey, bottom rock samplings and bottom sediment coring in this region during the R/V Hakuho-maru KH-19-1 and KH-20-1 cruises. Underway geophysical mapping was widely conducted in the area 60 ×90 miles. Multibeam bathymetry, sub-bottom profiler, total and vector magnetic fields, and gravity data were acquired. New bathymetric map compiled with previous survey data (e.g., Japanese Antarctic Research Expedition 51–55) clearly reveals that a large channel network of submarine canyons exists in the pathway of the CDBW. Sub-bottom and multichannel seismic reflection profile clearly show sub-seafloor structure of submarine canyons and surrounding sedimentary layers. Based on collected rocks, cored sediments, and deep-sea camera observations, it is shown that seafloor surface is covered with angular clast and sand in the shallower part of the channel. Furthermore, it is observed that sandy silt with current ripple morphology is deposited in the deeper part of the channel. These results imply that a main stream of the CDBW strongly contribute to erosion, transportation, and sedimentation at the submarine canyons, shaping the seafloor off Cape Darnley continental slope. This finding provides new insight into the ice-ocean-seafloor connection and indicates the distribution of the Cape Darnley Bottom Water, which is potentially linked to material transports from continent and/or continental margin into the deep ocean.

Structure across the South Shetland Trench from the incoming plate to the back-arc basin

*Hiroaki Koge[1], Masakazu Fujii[2], Jinyu ZHOU[3], Kyoko Okino[3], Minoru Ikehara[4], Asuka Yamaguchi[3], Taichi Sato[1]

1. GSJ, AIST, 2. NIPR, 3. AORI, UTokyo, 4. Kochi University

How are back-arc basins (BABs) formed in the continental crust? It is little known because active BABs are rare. Bransfield Strait in the South Shetland Trench system, Antarctica, and Okinawa Trough in Ryukyu Island Arc are considered the limited active continental back-arc basins which going on opening without a large strike-slip. Therefore, the researches of both areas are the key to the question. The formation of BABs is also expected to affect the formation of accretionary prisms through the changes in convergence rate and/or the sediment supply system from the continent.

We conducted the geophysical observations in the Antarctic Sea using R/V Hakuho-maru in December 2019 (KH-19-6 leg4 cruise)., We successfully obtained the data along the lines across the South Shetland Trench from the incoming plate to the back-arc basin. The collected data include; multi-narrow beam echo sounder (MBES) bathymetry data, shipborne vector magnetic fields data, shipboard gravimeter data, sub-bottom profiles (SBP), and XCTD profiles.

We describe the area of the South Shetland Islands in 65°W / 55°W / 62°40’ S / 58°S and show the preliminary report of these data on the point of the structures.

In this area, we had three XCTD casts to obtain the seawater sound velocity profile in which seawater conductivity (equivalent to salinity), temperature, and depth. The profile of XCTD #1 (58°20.974’ S, 65° 18.237’ W) showed higher velocity near sea surface than those of the profiles of XCTD #2 (61° 03.815’ S, 57°56.977’ W) and XCTD #3 (61°58.998’ S, 62°19.352’ W). XCTD #2 and #3 showed the almost similar sound velocity profile. All of the data was used for the sound velocity correction of the MBES data.

The bathymetric grid is created with noise removal processing using Caris HIPS and SIPS. The slope angle map is also created from the bathymetric map. We described the geomorphological features across the lines of the South Shetland Trench from the incoming plate to the back-arc basin with respect to the seafloor morphology, slope angle map, and SBP profiles.

On the incoming plate of the South Shetland Trench, the lineaments trending NE-SW direction are well-developed on the seafloor. Most of these lineaments are considered to be formed during seafloor spreading process of the former Phoenix-Antarctic Spreading Ridge, because they are almost parallel to the direction of the ridge. In addition, several dome-shaped structures can be seen near 58°40’ S, 64° 20’ W on the incoming plate. Based on the SBP profiles, the relative height was approximately 700 m, however, any internal structures were not recognized due to the strong reflection at the surface of the structure.

In the South Shetland Trench, there is a depth difference between the east and west ("west in King George island ", "strait between Smith Island and Snow Island"); the depth of the east side is approximately -5300m, on the west side the depth is approximately -4700m. The bottom of the trench is relatively flat, therefore it can be expected to fill with sediments. In the operation of the piston core, we could recover the samples with almost full recovery. However, SBP profiles do not have enough resolution to confirm a clear sedimentary structure.

In the landward slope in the arc-trench system, on the east side, the motif of the slope looks uniform angle from the bottom to the 500m below the sea surface, and gradually rises to a depth of 300m from there. In the western slope, at our bathymetry data, the sedimentary environment may be different from that on the

The mass loss of the Antarctic Ice Sheet due to the global climate changes will largely contribute to global sea-level rise. The information of present ice-sheet mass balance is required to achieve an accurate projection of Antarctic Ice Sheet changes. The timing and amplitude of Antarctic Ice Sheet change during the Last Deglaciation is essential to assess a glacial isostatic adjustments effect on the present ice-sheet mass balance. However, the difficulty of access to Antarctica makes it challenging to obtain field-based evidence of ice-sheet and sea-level change during the Last Deglaciation. In the 61st Japanese Antarctic Research Expedition (JARE61), the geomorphological survey was carried out in Langhovde and West Ongul Island in Lutzow Holm Bay, East Antarctica. We will report the preliminary results of JARE 61 such as the bathymetry data, CTD profiles, and sampling locations in shallow water and Lake Nurume of Langhovde. These data will be used to obtain the geological evidence of paleoenvironmental changes due to sea-level and ice-sheet fluctuation in future studies.

Changes in oxygen and CFC concentrations in AABW along 115°E from 1990s to 2010s

*Michiyo Yamamoto-Kawai[1], Narimi Baba[1], Yoshihiko Ohashi[1]

1. Graduate School of Marine Science and Technology, Tokyo University of Marine Science and Technology

Antarctic Bottom Water (AABW) is formed by a mixing of old deep water with newerly ventilated shelf water. This process has important implications for the transport of heat, freshwater, oxygen and carbon into deep ocean. Recent studies suggest reduction of AABW formation due to surface warming and freshening. In order to investigate changes in ventilation rate and properties of AABW, we have compared CFCs, oxygen and other water properties between observations made in 2016/2017 and 1995/1996 in the Australian sector of the Southern Ocean. Results showed increases in apparent oxygen utilization (AOU) and CFC age, indicating reduced ventilation of AABW in 20 years. We compare results with model simulation to discuss possible mechanisms of the reduction as well as quantitative implication of the reduction.

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS16] Rift-related tectonics, magmatism, mineralization, and paleoceanographic effects

convener:Luisa Tejada Maria(Volcano and Earth Interior Research Center, Institute for Marine Geodynamics, Japan Agency for Marine-Earth Science and Technology), Eun Young Lee(Chonnam National University), Erik Wolfgring

The session will focus on various types of rift-related magmatism and associated mineralization that forms during different stages of development from rifting to breakup. It will focus on various tectonic mechanisms resulting in either passive or active margins, effusion of both mafic and felsic volcanic rocks or their intrusive equivalents, and paleoceanographic perturbations. The session may include various topics relating to tectonic models and interpretations, magma generation and evolution, lithospheric interaction, intrusive mechanism, eruption mechanisms, and associated mineralization. In addition, contributions regarding the possible link of hotspots or mantle plumes with continental rifting and contemporaneous paleoceanographic perturbations are most welcome. Both oral and poster presentations are desired.

Rift-related volcanism at Naturaliste Plateau, Indian Ocean

*Maria Luisa Tejada[1], Eun Young Lee[2], Hans-Jurgen Brumsack[3], Bernhard Schnetger[3], Dennis Harry[4], Seong Soo Chun[2], Jun-Ichi Kimura[1]

1. Volcano and Earth Interior Research Center, Institute for Marine Geodynamics, Japan Agency for Marine-Earth Science and Technology, 2. Institut für Chemie und Biologie des Meeres (ICBM), Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany, 4. Department of Geosciences, Colorado State University, Fort Collins, CO, USA

Seismic reflection and dredging data indicate that extensive volcanism on and around the Naturaliste Plateau accompanied Early Cretaceous rifting between Australia-Antarctica and Greater India during the breakup of Eastern Gondwana. However, no direct stratigraphic evidence for this was available until International Ocean Discovery Program drilled into the volcanic sequence at Site U1513. We report petrological, petrophysical, paleomagnetic, and geochemical data from this volcanic sequence and discuss their: (1) petrogenesis and emplacement history; (2) lithostratigraphy; and (3) relationship with onshore and previously dredged basalts in Australia and the Naturaliste Plateau, respectively. The volcanic sequence consists of interlayered lava flows and volcaniclastic flows, cut by multiple intrusions. Baked and depositional contacts suggest that at least five phases of eruption took place, possibly in response to episodic rifting events. Petrological and textural evidence suggest subaerial to shallow water eruption. Primary magma composition derived from the most primitive basalts (high MgO, Ni, and Cr) could be parental to most of the flows and, by extension, to dredged basalts and onshore Bunbury Basalt based on geochemical similarity. Petrogenetic modeling indicates origin from magmas generated by ~20% partial melting at 1.5 GPa and a mantle potential temperature of 1398℃, indicating a more fertile than normal ocean ridge mantle source, which corroborates chemical affinities with basalts generated by the Kerguelen plume. Magnetrostratigraphy of overlying volcaniclastic-rich sedimentary unit indicates contemporaneous emplacement of Site U1513 basalts with the oldest Bunbury Basalt flows and the reported age of the earliest seafloor magnetic anomalies in the Perth Abyssal Plain. Available evidence indicates that Site U1513 were erupted near sea level during the last stages of extension on this part of the southwest Australian margin, after seafloor spreading had begun on the Perth Abyssal Plain but before the onset of seafloor spreading west of Naturaliste Plateau. The timing of emplacement and the relatively fertile source derived from petrogenetic modeling suggest an influence of a thermal anomaly during rifting.

Qualitative Assessment of the Transition and Noble Metal Enrichment in Hydrothermally Altered Volcanic Sequence Using a Portable X-ray Fluorescence Spectrometer

*Xandr Neal Borja Uboan[1], Maria Luisa Tejada[2], Eun Young Lee[3], Wataru Tanikawa[4]

1. National Institute of Geological Sciences, University of the Philippines Diliman, Philippines, 2. Institute for Marine Geodynamics (IMG), Japan Agency for Marine-Earth Science and Technology, Yokosuka, Kanagawa 237-0061 Japan, 3. Faculty of Earth and Environmental Science, Chonnam National University, Gwangju, Republic of Korea, 4. Kochi Institute for Core Sample Research, Japan Agency for Marine-Earth Science and Technology, Nankoku 783-8502 Japan

IODP Expedition 369 recovered the first stratigraphically constrained volcanic sequence at Site U1513 on the Naturaliste Plateau, comprising basalt flows interlayered with volcaniclastic beds and intruded by dikes. Dike intrusions may be responsible for the widespread hydrothermal alteration. We used portable X-ray fluorescence (pXRF) to measure the elemental composition and assess any metal enrichment trends associated with hydrothermal alteration. Most major elements (Si, Ti, Fe, Mg, Ca, P) and some trace elements (Sr, Y, Cr, Zn, Cu, Ru, Pd, Ag) measured by pXRF have ≦10% precision. Concentrations measured by both pXRF and XRF plotted with depth show a similar trend for most elements but with some discrepancies. The matches and differences can be explained by the type of material measured by pXRF (i.e., clast/vein/matrix/groundmass vs. whole rock). Concentration plots of transition metals with depth show a notable enrichment at ~688, ~695, and ~697 meters below seafloor (mbsf) for Hole U1513E and ~700, ~710, and ~750 mbsf for Hole U1513D. Enrichment of Fe concentration coincides with the presence of hematite, goethite, and dickite associated with the alteration of the glassy matrix, groundmass, and Fe-Ti oxides during hydrothermal alteration. Spikes in the concentration of Cu reflect the occurrence of native copper as vein or dissemination near the dike intrusions or within the volcaniclastic units. For the noble metals, apparent depletion of Ru and Pd is notable at ~700 and ~750 mbsf, and enrichment of Ag at ~700 and ~750 mbsf. Apparent depletion or enrichment of the elements may be associated with their mobility and immobility during hydrothermal alteration. The pXRF measurement can be used for qualitative assessment of the enrichment or depletion of elements during hydrothermal alteration and as a preliminary tool to identify sample points for further studies of alteration and mineralization associated with the volcanic sequence.

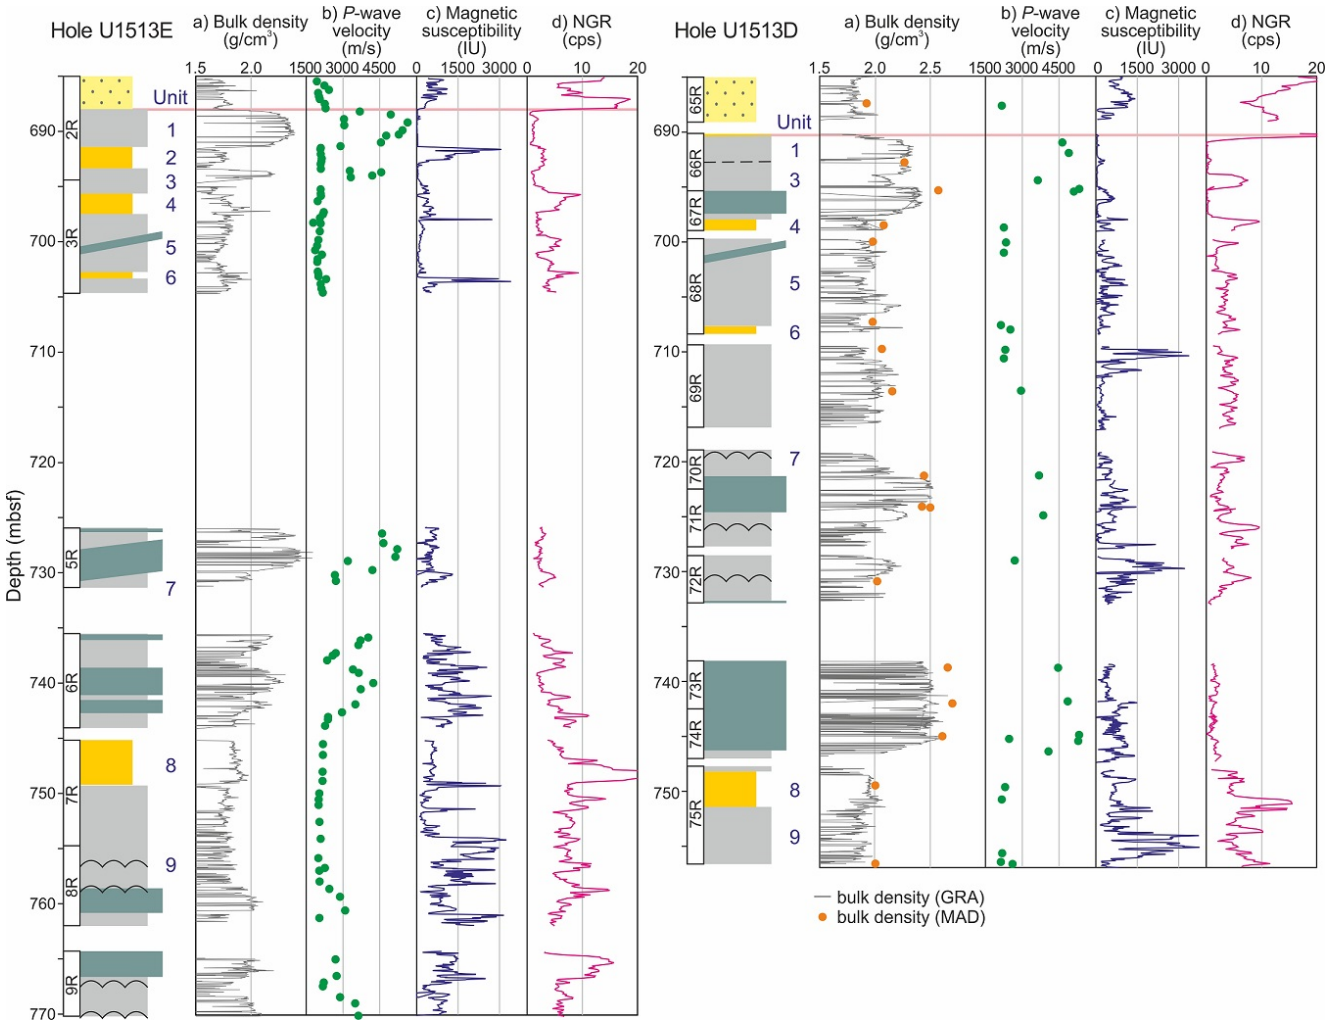
Petrophysical characteristics of the volcanic succession at IODP Site U1513: Implications for stratigraphy and alteration

*Eun Young Lee[1], Maria Luisa Tejada[2], Seung Soo Chun[1], Insun Song[3], Erik Wolfgring [4]



1. Faculty of Earth Systems and Environmental Sciences, Chonnam National University, Gwangju, Rep. Korea, 2. Institute for Marine Geodynamics (IMG), Japan Agency for Marine-Earth Science and Technology, Yokosuka, Kanagawa, Japan, 3. Korea Institute of Geoscience and Mineral resources, Daejeon, Rep. Korea, 4. Department of Geodynamics and Sedimentology, University of Vienna, Vienna, Austria

International Ocean Discovery Program (IODP) Expedition 369 recovered the volcanic rocks at Site U1513 on the eastern flank of the Naturaliste Plateau, offshore southwest Australia. The volcanic succession (Lithostratigraphic Unit VI) is defined as the syn-rift volcanic rocks emplaced during the Valanginian breakup between Greater India and Australia-Antarctica. Based on a total cored thickness of 82.2 m, it is subdivided into nine lithologic units: Units 1, 3, 5, 7 and 9 are classified as basaltic flows, and Units 2, 4, 6 and 8 as volcaniclastic flows. Dolerite dikes and hydrothermal veins intruded the whole volcanic succession. During the expedition, the excellent correlation between physical properties and the lithologic units in Hole U1513D was used as a guide to correlate the lithologic boundaries in Hole U1513E. We define that the variation in the petrophysical datasets correspond to the lithologic boundaries and mineralogical composition of/within the units in Holes U1513D and U1513E. We present the physical properties, lithologic descriptions as well as XRF data, acquired during and after the expedition, and demonstrate the good correspondence between lithologic/mineralogical and petrophysical characteristics. In both holes, the top of the volcanic succession is characterized by sharp increases in bulk density and *P*-wave velocity and a drop in Natural Gamma Ray (NGR) values. Within the succession, intervals of low bulk density, low *P*-wave velocity and high porosity, with coinciding spikes in NGR, define the volcaniclastic units, and correspond well to highly altered basalts. The increase of alteration degree in basaltic units contributes to a decrease in bulk density, *P*-wave velocity and an increase in porosity, NGR values. Comparatively high bulk density, high *P*-wave velocity and low porosity are associated with dikes. Magnetic susceptibility in the succession is high, and varies downhole with occasional sharp increases that are attributed to alteration by iron-bearing minerals and paramagnetic clay minerals. Our results show that systematic acquisition and assessment of physical properties in the volcanic succession can be used to discriminate lithologic boundaries, mineralogical composition, and alteration type and degree. Such correlation can be a useful tool for drilling and core description strategies in future ocean drilling expeditions.

Paleoenvironments of a Cretaceous marginal ocean basin - the Turonian to Santonian of the Australo-Antarctic Gulf, IODP Site U1512

*Erik Wolfgring [1], Michael Anthony Kaminski[2], Anna Waśkowska[3]

1. University of Vienna, Geodynamics and Sedimentology, Althanstrasse 9, 1090 Vienna, Austria, 2. King Fahd University of Petroleum and Minerals (KFUPM), Earth Sciences Department, Geosciences, Dhahran, SaudiArabia, 3. Faculty of Geology, Geophysics and Environmental Protection, AGH University of Science and Technology, Mickiewicza St. 50, Cracow, Poland

IODP Expedition 369 (Australia Cretaceous Climate and Tectonics) drilled an approximately 700 m thick Santonian to Turonian succession (nannofossil zones CC 17-CC 10) at Site U1512 in the Great Australian Bight (Fig. 1). Site U1512 was drilled aiming at understanding the paleoceanographic evolution of the Southern Australian realm during the final stages of the breakup of Eastern Gondwana and to help document the Late Cretaceous climate evolution in the Southern High Latitudes (SHL).

The formation of the Australo-Antarctic gulf is characterized by rapid subsidence from the Albian onwards. Restricted accommodation space and a marginal marine setting that is affected by the discharge of a vast continental river system to the North are factors that seriously influenced the paleoecologic setting recovered in the Great Australian Bight.

Material recovered at IODP Site U1512 presents an unique record of a deep water agglutinated foraminifera community from the Southern High Latitudes. The highly diverse assemblages yield many new taxa that are yet to be described.

Calcareous benthic foraminifera are generally rare or absent, as well as planktonic taxa. Calcareous benthic foraminifera are frequently recovered from the early to mid-Turonian as well as Santonian strata. Hole U1512A yields highly abundant radiolaria from the mid Turonian onwards - the share of radiolarian of the total microfossil assemblage often exceeds 50% in the younger strata of U1512. The stratigraphic framework is based on calcareous nannofossil biostratigraphy and assigns the succession to calcareous nannofossil zones CC16/17-CC10c.

Preliminary results show a diverse foraminiferal assemblage: 180 taxa were identified (126 agglutinated and 54 calcareous). The most common elements of the deep-water agglutinated foraminifera assemblage are tubular (i.e., *Kalamopsis grzybowski*, *Bathysiphon* spp, *Ammodiscus* spp…) and planispiral forms (i.e., *Haplophragmoides* spp., *Buzasina* sp., *Labrospira* spp…). The Turonian strata yield highly abundant *Bulbobacculites problematicus* and *Spiroplectammina navarroana*. The presence of *Uvigerinammina* provides a tie-point to the Tethyan deep-water agglutinated foraminifera biozonation of Geroch & Nowak (1984).

The total abundance of tubular agglutinated taxa that show an epifaunal habitat preference in relation to the entire assemblage peaks just before we record an increase in the abundance of radiolaria in the mid Turonian. Generally, the abundance of tubular agglutinated foraminifera and radiolaria correlates negatively through Hole U1512A.

The assessment of foraminiferal assemblages together with the evolution of other fossil groups (Radiolaria in particular) indicates unstable conditions at Site U1512 during the early Turonian-Santonian.

©2020. Japan Geoscience Union. All Right Reserved.

Preliminary results from the quantitative analysis of the benthic foraminiferal assemblages could indicate either changes in paleobathymetry or instable patterns in ocean circulation creating a restricted paleoenvironmental regime during Late Cretaceous times. The prominent increase in the abundance of radiolaria during the mid-Turonian coincides with a previous peak in the abundance of tubular epifaunal foraminifera. This could either indicate an increase in bathymetry (and associated changes in ocean chemistry) that would roughly correspond to the Turonian sea level highstand. As high latitudes reflect climatic change more directly, changes in the microfossil assemblage could furthermore reflect a subtle recovery of the mid Turonian SHL temperature regime after the Cretaceous thermal maximum.

The facies architecture of felsic subaqueous volcanoes in “Green Tuff” Formation in the Katakai field, Niigata, Japan

*Miyuki Nonaka[1,2], Masahiko Yagi[1], Yasuo Yamada[1], Susumu Umino[3]

1. Japan Petroleum Exploration Co.,Ltd., 2. Graduate School of Natural Science & Technology, Kanazawa University, 3. Department of Earth Sciences, Kanazawa University

Interpretation of the mechanism of subaqueous volcanic activity related to “Green Tuff” is important since it greatly contributes to clarifying the formation process of the island arc and active subaqueous volcanoes all over the world. Also, “Green Tuff” is necessary from the viewpoint of energy resources because it is bearing and producing a large amount of gas especially in the Northeast part of Japan. In this study, we constructed a facies model of the subaqueous basin in which a variety of volcanic facies are intercalated with sedimentary facies to clarify a series of volcanic activity styles in the unrevealed “Green Tuff” field located in the Niigata Chuetsu district.

The Katakai field is located 10km southwest of Nagaoka-city and consists of an anticline 5km long and 1.5km wide extending in the NNE - SSW direction. “Green Tuff” was produced by subaqueous volcanic activity during back-arc rifting in early to middle Miocene. After the activity, Nanatani and Teradomari Mudstone as source rock overly the “Green Tuff” formation in late Miocene. Finally, the compressive tectonic movement created the current anticline in the field. The top of “Green Tuff” Formation is deeper than 4,000m, its thickness is more than 1,000m and its lower limit is unidentified.

We observed cuttings and core samples from more than a dozen wells in the field analyzed major elements in the cutting samples and trace elements of the core samples with the information of electricity well logging and FMI image data.

The Formation is the succession of volcanic materials which consist mainly of felsic rocks (from rhyolite to dacite) and accompanied with mafic rocks (from basalt to basaltic andesite). The stratigraphic classification characterized by rock types, textures, occurrences, and distribution is below:

The lower part of the formation at least several tens meters thick is distributed only in the south of the field. It is dominated by pumice clasts and glassy rhyolite lava. They are considered as carapace pumice breccia which surrounds lava dome. The middle part several hundred meters thick is distributed over the whole area in the field. It has a wide variety of rhyolite, including massive lava, breccia, tuff breccia, tuff, and perlite. They are considered as the complexes of lava domes which consist of coherent lava facies, block lava facies and resediment facies one to several hundred meters thick and several hundred to one thousand meters wide. The complex in the north of the field is dominated by glassy rhyolite lava with flow band and breccia. The upper part about several hundred meters thick is distributed over the whole area of the field. It consists of dacite pumice, tuff breccia, and tuff. The uppermost part is distributed from the central area to the south area of the field and consists of massive lava, breccia, and tuff breccia.
From the bottom to upper part, massive basalt lavas several tens to a hundred meters thick bearing intersertal textures are observed. They are considered to the succession of sheet flows during the bimodal volcanic activity.

From their distribution, the transition of the eruption style throughout the subaqueous volcanic activity is

©2020. Japan Geoscience Union. All Right Reserved.

indicated. The formation was composed of the successions of felsic the lava domes and mafic sheet flows by the bimodal volcanic activity. In the early stage, the lava domes associated with carapace pumice breccia formed under the deep marine environment. As the increment of the supply rate of magma, large-scale volcanic complexes were created from south to central part of the field. On the other hand, the north of the field had the source of lava which formed the complex(es) of relatively glassy lava domes. In the late stage, after the dacite pyroclastic material was provided over the whole area under the shallow marine environment, the magma changed its composition to rhyolite and provided a volcanic complex.

[E] Poster | M (Multidisciplinary and Interdisciplinary)：M-IS Intersection

[M-IS17] Astrobiology

convener:Hikaru Yabuta(Hiroshima University, Department of Earth and Planetary Systems Science), Seiji Sugita(Department of Earth and Planetary Science, Graduate School of Science Sciece, The University of Tokyo), Misato Fukagawa(National Astronomical Observatory of Japan), Fujishima Kosuke(Tokyo Institute of Technology, Earth-Life Science Institute)

Twenty years have passed since when the field of Astrobiology, which aims to unveil the origins, evolution, and habitability of life by integrating multidisciplinary fields, was established. Individual themes related to Astrobiology, such as chemical evolution in the early Solar System, formation of planetary system, prebiotic chemistry in the early Earth, evolution of life in the Earth's history, extremophile, and habitable planetary environments, has been studied by the knowledge and methods from the multiple fields, which has enabled us to explain "Where we came from" in some ways. However, despite an overwhelming number of investigations and discussions through gathering of the scientists from different fields, there has remained the long-standing unsolved question: How did abiotic materials gain biological function in the Earth and elsewhere in universe? There is still a large gap between prebiotic organic chemistry and biochemistry toward Origins of Life and planetary habitability. Therefore, the JpGU Astrobiology session focuses on pathfinding of "integration of astronomy, geoscience, and biochemistry", which will face an increasing need for the future Astrobiology. In order to enhance our understanding of "What is life", we propose to discuss the biochemical events linked with planetary systems, which is beyond the knowledge in a test tube, by an integration of exoplanets and molecular biology, etc. Through this approach, we will lead the discussions and developments of life-detection strategies for the future exploration of life in universe.

Amino acids have been detected in water extracts of carbonaceous chondrites (CCs) [1], which suggests that extraterrestrial organics could be sources for the first life on the Earth. The fact that amino acids extracted from CCs increased after acid-hydrolysis [1] showed that not only free amino acids but also amino acid *precursors* were present in them. Experiments simulating interstellar environments showed that amino acid *precursors*, rather than free amino acids, were formed [2]. Though extraterrestrial *amino acid precursors* have not been well-identified, aminonitriles and hydantoins could be candidates. Beside such *simple* amino acid precursors, *complex* amino acid precursors were found in the product after proton irradiation of interstellar media analogue [3]. If extraterrestrial amino acids were delivered to the primitive Earth, they should survived in space environments against various types of energetic particles and photons. We investigated the stability of amino acids and their precursors against heavy ions, gamma-rays, UV, soft X-rays, etc. In addition to these laboratory simulations, we exposed amino acids and their precursors in the Exposed Facility of Kibo, ISS in the Tanpopo mission (2015-2019) [4] and the Tanpopo 2 mission (2019-2020).

Ground Experiments: Samples used were glycine (Gly), aminoacetonitrile (AAN), hydantoin (Hyd) and CAW (products of proton irradiation of a mixture of CO, NH_3 and H_2O [3]). *Heavy ions irradiation*: Aqueous solution of each molecule, frozen in liquid nitrogen, was irradiated with 290 MeV/u carbon ions from HIMAC (NIRS, Japan). *γ -Rays irradiation*: Aqueous solution of each target molecule was irradiated with γ -rays (5-15 kGy) from a ^{60}Co source (Tokyo Tech, Japan). *UV irradiation*: Each sample was UV irradiated from a xenon (Ushio), a deuterium (Hamamatsu Photonics) or an eximer lamp (Ushio) after dried in pits of an aluminum plate. *Soft X-rays irradiation*: Each sample was on the Al plate was irradiated with soft X-rays from a BL-6 of NewSUBARU. *Hydrothermal reaction*: Aquous solution of each sample was heated at 150℃ for 6-24 hours in an ETTAS Hightemp oven. Amino acid analysis: all the target materials were acid-hydrolyzed (6 M HCl, 110℃, 24 h), and were determined with an amino acid analyzer (Shimadzu UHPLC NEXERA).

The Tanpopo Mission: Alminum exposure panels with small pits were used. Gly, Hyd and CAW were put in the pits and covered with hexatriacontane (HTC). Five plates were prepaired: (i) The space-exposed with a MgF_2 window, (ii) the space-exposed with a SiO_2window, (iii) the dark control that was space-exposed behind other panels, (iv) the cabin control, stored in the ISS cabin and (v) stored in a ground laboratory (the ground control). Three sets of the plates were launched in 2015, and each set of the plates returned to the Earth in 2016, 2017 or 2018.

The Tanpopo 2 Mission: Gly, Hyd and CAW with different thickness of HTC were prepaird by using the

©2020. Japan Geoscience Union. All Right Reserved.

same kind of aluminum plate. Besides them, Gly and CA (products of proton irradiation of a mixture of CO and NH_3) were directly evaporated onto silicon plates. The silicon plates with and without windows were prepared. Space exposure of the aluminum and the silicone plates with the target organics started in August 2019, and will returned to the Earth in 2020.

RESULTS AND DISCUSSION Recovery was discussed by glycine amount since glycine was major compound after acid-hydrolysis of the products (with the exception of Ival and EMHyd). Among Gly, Hyd, AAN and CAW, Gly showed the lowest recovery against gamma-rays, and AAN showed the lowest recovery in hydrothemal reaction, while Hyd showed the lowest recovery after space exposure of the Tanpopo Mission. In the case of UV irradiation, relative stability differed by the kinds of light sources: Gly was more stable than CAW in the Xe-lamp experiment, but CAW showed higher recovery than Gly in the D_2-lamp experiment and the soft X-ray experiment. Thus space experiments are importance to test stability in actual space environment. Overall, space UV would be fatal to all the organics tested, so that they should be protected by shielding with minerals or other materials to survive in space for a long period. CAW, complex precursor of amino acids, showed to be more stable against charged particles, soft X-rays, VUV and heat than free amino acids and simple precursors. The Tanpopo 2 would give further information on stability of organics in space.

Radiation transfer simulation of circular polarization at the NIR/UV wavelengths

*Hajime Fukushima[1], Hidenobu Yajima[1], Masayuki Umemura[1]

1. Center for Computer Sciences, University of Tsukuba

Circular polarization (CP) at the ultraviolet (UV) wavelength induces the enantiomeric excesses. It is suggested that they initially cause the biomolecular chirality of amino acids. The excesses of L-acids are also discovered in meteorites, and it is proposed that the CP light in the interstellar medium is related to biologically homochirality. In the star-forming regions, the high degree of CP (>20%) at the near-infrared (NIR) wavelength induced by aligned dust grains is observed, but it is not known that it exists at the UV wavelength. In this study, we develop the radiative transfer code with the Monte Carlo technic, which follows a change of Stokes parameters in scattering/absorption processes by dust grains. We find that the high degree of the CP at the NIR wavelength is realized when the micron-size dust grains exist in the interstellar medium, and the CP degree of the UV light reaches 20% with sub-micron sized dust grains. We will discuss the relations of the CP degree between the NIR and UV wavelength.

Analysis of nucleic acid bases formed from simulated interstellar media

*Kotomi Sugaya[1], Kensei Kobayashi[1], Yoko Kebukawa[1], Yoshiyuki Oguri[2], Hitoshi Fukuda[2]

1. Yokohama National University, 2. Tokyo Institute of Technology

1. Introduction
In the course of chemical evolution, it is necessary to supply nucleic acid bases which are major constituents of DNA and RNA. Since nucleic acid bases are detected in the meteorite, it is considered to be generated in space environments such as in molecular clouds.
In this study, first, we considered analytical methods for nucleic acid bases in mixtures with complicated compositions. Second, in order to verify the generation of nucleic acid bases in interstellar media, proton beam simulating cosmic ray was irradiated to the interstellar media analogs, and we investigated possible generation of nucleic acid bases and related compounds. From these experiments, we considered the possibility that nucleic acid bases essential for the generation of life could be supplied from out of the Earth.
2. Experimental
(1)Nucleic acid bases analysis
Twelve nucleic acid bases standard reagents [adenine (Ade), guanine(Gua), cytosine(Cyt), uracil (Ura), thymine(Thy), pirimidine(Pyr), hypoxanthine(Hyp), xanthine(Xan), purine(Pu), barbituric acid(BA), isoguanine(Iso-Gua), isocytsine(Iso-Cyt)] were first fractionated by gel filtration chromatography (GFC) and then each fraction was analyzed by reversed-phase HPLC (RP-HPLC), where a novel core-shell column (SunShell RP-AQUA) was used.
(2)Proton irradiation experiment
As a simulated interstellar media, a mixed gas of CO and NH_3 (350 Torr each) and 5 mL of ultrapure water were enclosed in a Pyrex glass tube, and 2 mC of 2.5 MeV proton beam was irradiated to the gas mixture by using Tandem accelerator at Tokyo Institute of Technology. The resulting product is hereafter referred to as “CAW.”
Irradiated products were injected into GFC and sorted in three compartments of retention time 15-30min (CAW1), 30-45min (CAW2), 45-60min (CAW3).
Each fractionated CAW was injected to RP-HPLC, and the nucleic acid bases were identified. For the comparison, the products were analyzed directly by RP-HPLC without fractionation by GFC.
3. Results and Discussion
(1)Nucleic acid bases analysis
In RP-HPLC, comparing the standards separation with the SunShell RP-AQUA column with a previously-used Capcell Pak C18 column, it was found that separation with SunShell RP-AQUA superior separation for each base to conventional reversed-phase columns. Therefore, in the separation / analysis of nucleic acid bases by using RP-HPLC, it was found that more accurate analysis can be performed by using SunShell RP-AQUA column.
(2)Proton irradiation experiment
BA, Cyt, Ade were detected from CAW1, Iso-Cyt was detected from CAW2, and Gua was detected from CAW3. Since Ura and Cyt were predominant in past experiments, it was suggested that Cyt and Ura are easily generated from interstellar media. In addition, BA that are considered as a candidate for non-canonical proto-RNA system, was clearly detected. It was suggested that BA is a molecule that is likely to be produced in the interstellar environment.
Compared with the RP-HPLC chromatograms of without pre-fractionation with GFC, RP-HPLC

©2020. Japan Geoscience Union. All Right Reserved.

chromatograms after fractionated with GFC looked better since huge peak of polymer-like products appeared at 1-4 min are removed, and it facilitated the identification of nucleic acid bases whose retention time was 1-4 min. In addition, it was found that nucleic acid bases with less yields could be more clearly detected. It was found that pre-fractionation of the nucleic acid bases by GFC made it possible to loaded less amount of samples on the column of RP-HPLC and the analysis of nucleic acid bases could be performed more accurately.

4. Conclusions

In this experiment, it was found that the separation using the SunShell RP-AQUA column is useful for analysis of nucleic acid bases in RP-HPLC, compared with conventional Capcell Pak C18 column. In addition, it was found that in complex mixtures, nucleic acid bases can be more accurately by pre-fractionation with GFC in the separation of nucleic acid bases.

In proton beam irradiation experiments, Ade, Gua, Cyt, Ura, which are components of RNA, were generated from simulated interstellar media, together with non-canonical bases such as Iso-Cyt and BA, which are considered to be components of proto-RNA.

From these facts, it was suggested that various nucleic acid bases and analogs whose structures were similar to them could be generated in interstellar environments.

Astronomical detections of prebiotic molecules with the next generation Very Large Array

*Misato Fukagawa[1], Daisuke Iono[1], Munetake Momose[2]

1. National Astronomical Observatory of Japan, 2. Ibaraki University

The next generation Very Large Array (ngVLA) is the ground-based cm/mm-wave radio telescope, and one of the future astronomy projects led by US for the next decade. The dedicated study group for ngVLA has recently been launched in the National Astronomical Observatory of Japan to seek for the eventual Japanese participation in this project. The telescope will be composed of 214 18-m antennas with the baselines up to 9000 km (extending from Hawaii to the US Virgin Islands), providing the unprecedented sensitivity and angular resolution. The ngVLA will cover the cm/mm-wave range, which will become a great advantage to detect complex prebiotic molecules that are free from line blending. In fact, one of the key science goals of ngVLA is "Probing the Initial Conditions for Planetary Systems and Life with Astrochemistry". The simulations on biogenic molecules such as Glycine and Glyceraldehyde (McGuire et al. 2018) show that the lines from those molecules are below the detectability of the existing telescopes but will be discovered with ngVLA, enabling transformational science on the chemical building blocks of life.

Evaluation of the aldononitrile acetate ester derivatization method for aldose analysis in products from chemical evolution experiments

*Shunpei Abe[1], Yoko Kebukawa[1], Kensei Kobayashi[1]

1. Yokohama National University

Introduction

Sugars and sugar derivatives play important roles in biological processes on the Earth. Sugars such as ribose, a component of RNA, are essential compounds for the origin of life. Since some sugars have been found in meteorites [1, 2], there is a possibility that some sugars made in space brought to the early Earth by meteorites. As a prebiotic sugar formation reaction, “formose reaction” have been attacked attention [3].

Since there are so many kinds of sugars and sugar derivatives, GC/MS is a promising technique to identify them, but a suitable derivatization technique is required for it. One of the derivatization methods for sugars is aldononitrile acetate ester derivatization. This method is very effective for aldoses [4]. However, previous studies have mainly focused on pentoses [2], and other sugars have not been widely discussed. In this research, we verified the usefulness of the aldononitrile acetate ester derivatization for aldoses other than pentose. In addition, verification of whether sugars were formed or not in products by “formose-like reaction” simulating the interior of meteorite parent bodies.

Experimental

Standard reagents of aldose (C3-C6: glyceraldehyde, erythrose, threose, ribose, lyxose, arabinose, xylose, allose, glucose, galactose) were derivatized by aldononitrile acetate ester derivatization. Then resulting sugar derivatives were analyzed by GC/MS. Limits of detection of all the aldoses were examined.

In order to simulate reactions in the meteorite parent bodies, a mixture of H2O, HCHO and NH3 (molar ratios were 100:5:5, 100:5:1, 100:5:0 and 100:10:0) were prepaird. 200 mL each of the mixture was heated at 150℃ for 3 days. An aliquot of each product was derivatized by the present method, and analyzed by GC/MS.

Result and Discussion

Retention time and major m/z of each aldose were obtained with authentic standards: The retention time (major m/z’s) were as follows. Triose: 9.7 min (m/z 86, 103), tetroses: 17.7-18.0 min (m/z 103, 145), pentoses: 24.8-26.0 min (m/z 103, 115, 145), and hexoses : 31.0-33.0 min (m/z 103, 115, 145).There is a correlation between the carbon number and the retention time. The carbon number increases by 1, then the retention time increases by about 7 minutes.

Although varied by the number of carbon, limits of detection of the aldoses were about 2~50 mM.

By comparing the analysis results of aldose standard reagents and the products of the “formose-like reaction” simulating the interior of meteorite parent bodies, peaks similar to those of tetroses and hexoses were detected in all the products. In the 100:5:1 product, pentoses were tentatively detected in addition to tetroses and hexoses. It was suggested that, in the products of 100:5:5, 100:5:0 and 100:10:0, glyceraldehyde (C3) generated in the initial stage of formose-like reaction reacted with unreacted formaldehyde (C1) to form tetroses (C4), or reacted with other glyceraldehyde to form hexoses (C6). The other possibility is that the glycolaldehyde (C2) generated in the initial stage of formose-like reaction reacts with other glycolaldehyde to form tetroses, and this tetroses reacts with glycolaldehyde to form hexoses. In the sample of 100:5:1, slightly added ammonia might act as a catalyst, which promoted

©2020. Japan Geoscience Union. All Right Reserved.

the formation of pentoses. Further experiments are required to verify such hypotheses.

Polycyclic aromatic hydrocarbons in Jbilet Winselwan carbonaceous CM chondrite: Novel molecular proxies for thermal metamorphism of asteroids

Hiroki Kato[1], *Hikaru Yabuta[1]

1. Hiroshima University, Department of Earth and Planetary Systems Science

Introduction: On June 27, 2018, Hayabusa2 spacecraft arrived at the C-type asteroid Ryugu (Watanabe et al. 2019). The surface of Ryugu is thought to have experienced thermal metamorphism, according to the remote sensing observations (Kitazato et al. 2019). Therefore, it is important to investigate the chemical compositions of thermally metamorphosed CM chondrites for understanding the surface process of asteroid Ryugu. Although the extents of thermal metamorphism of CM chondrites have been evaluated by elemental and molecular compositions of insoluble organic matter (IOM) (Naraoka et al. 2004; Yabuta et al. 2005), molecular-level evolution of IOM is still unknown. Soluble organic molecules from the thermally metamorphosed CM chondrites have not been quantified (Shimoyama et al. 1989). Therefore, in this study, we analyzed polycyclic aromatic hydrocarbons (PAHs) in Jbilet Winselwan CM chondrite, which is a thermally metamorphosed CM chondrite and show similar reflectance spectrum to that of asteroid Ryugu (Sugita et al. 2019), for precise evaluation of parent body thermal metamorphism. The relative abundances of the hydrocarbons were compared with those of Murray CM chondrite and Allende CV3 chondrite.

Samples and Methods: Powdered samples of Jbilet Winselwan (CM2), Murray (CM2), and Allende (CV3) meteorites (0.2-0.4g) were extracted with dichloromethane/methanol (9:1) by sonication. The extracts were applied to a silica gel column. From the column, aliphatic hydrocarbons were eluated with hexane and then PAHs were eluated with dichloromethane. The hexane and dichloromethane eluates were concentrated to 100 μl individually under a nitrogen flow for analysis by a GC-MS. Identification and quantification of compounds were made by comparison of peak retention times on mass chromatograms and mass spectra, and peak areas, respectively, with those of standard compounds. For compounds without standard compounds, identification was made by comparison of mass spectra with library data.

Results and discussion: Total concentration of PAHs from Jbilet Winselwan meteorite (0.22 μg/g meteorite) was 350 times lower than those from Murray meteorite (74.0 μg/g meteorite). Di- and trimethylnaphthalenes, fluorene, phenanthrene, pyrene, fluoranthene, methylbiphenyl (0.002-0.036 μg/g meteorite) were identified from Jbilet Winselwan, while low molecular weight PAHs, such as naphthalene, methylnaphthalene, and acenaphthene, and cata-condensed PAHs, such as anthracene, benz[a]anthracene, chrysene, were not detected. Thus, highly volatile and/or structurally unstable PAHs in Jbilet Winselwan meteorite were preferentially lost during thermal metamorphism. On the other hand, biphenyl-type PAHs, such as biphenyl (BIP), methylbiphenyls (MBP), diphenylamine, benzophenone, fluorenone, dinenzofuran, oxibisbenzene, are relatively abundant in Jbilet Winselwan compared to those in Murray and Allende. In order to evaluate the thermal metamorphism on the parent body of Jbilet Winselwan meteorite, we have applied several organic geochemical molecular thermal indicators: (i) a

©2020. Japan Geoscience Union. All Right Reserved.

ratio of fluorene to 2-methylbiphenyl (FLU/2-MBP) and (ii) methylphenanthrene (MP) isomer ratio ([2-MP+3-MP]/[1-MP+4-MP+9-MP]). The ratio of FLU/2-MBP for Jbilet Winselwan was one order of magnitude higher than Murray, indicating that cyclisation reaction of 2-MBP to give FLU prpbably occured during thermal metamorphism of the Jbilet Winselwan parent body. Also the MP isomer ratio for Jbilet Winselwan was three times higher than Murray, indicating that methyl rearrangement of methylphenanthrene isomers probabaly occured during thermal metamorphism of the Jbilet Winselwan parent body. Applying the ratios to the kinetic parameters of these two reactions obtained by organic geochemical studies (Alexander et al. 1988; Sanpei et al. 2004), it was estimated that Jbilet Winselwan meteorite experienced 410 –428 degrees Celcius for one week, or 387-397 degrees Celcius for one month.

Relationship between visible reflectance at 550 nm and carbon contents in carbonaceous chondrites: At-tempt to estimate the bulk carbon contents of asteroid Ryugu’ s surface

*Hikaru Yabuta[1]

1. Hiroshima University, Department of Earth and Planetary Systems Science

Remote sensing observations of asteroid Ryugu by Hayabusa2 mission has revealed that Ryugu is one of the darkest bodies in the Solar System (Watanabe et al. 2019). It is of great interest to identify the darkening agent of Ryugu’ s surface. In the preliminary investigation, it was reported that there was a correlation between the reflectance at 550 nm of primitive carbonaceous chondrites and the insoluble organic matter (IOM) contents of the meteorites. Their result suggests that the bulk carbon contents of asteroid Ryugu are potentially estimated by the visible re-flecntance acquired by optical navigation camera (ONC) of Hayabusa2 spacecraft. On the other hand, it is challeng-ing to estimate IOM contents from meteorites, due to the mass loss during the purification process by acid treat-ment and/or due to its static electricity. In this regard, total carbon contents can be estimated more accurately rather than IOM contents. Therefore, in this study, the reflectance spectra and total carbon contents of the same meteorite samples were measured in this study for increasing the accuracy of correlation.
As the samples, three primitive carbonaceous CM/CI chondrites (Murchison, Murray, and Yamato 980115), five thermally metamorphosed CM/CI chondrites (Jbilet Winselwan, Yamato 982086, Yamato 793321, Belgica 7904, and Yamato 86720), and three carbonaceous chondrites (Murchison, LAP 04721, and Tagish Lake) experimentally heated at different temperatures (300, 400, 500, 600 and 900˚C) for 50 hrs, and a simulant of Phobos were used. Their grain sizes and/or porosity were made constant. Reflectance spectra of the meteorites were analyzed by VERTEX 70v, Bruker (Tohoku Univ.). Total carbon contents of the meteorites were analyzed by a CHN elemental analyzer (Flash EA1112) (Kochi Univ.).
For the primitive CM/CI chondrites and thermally metamorphosed CM/CI chondrites, roughly linear correla-tions were observed between total carbon contents and reflectance at 550 nm (R(550)) and 390 nm (R(390)). Thus, the meteorites with higher carbon contents show lower reflectance. However, some meteorites (Murchison, Murray, Y-982086, Jbilet Winselwan, Y-793321) with similar carbon contents showed variations in reflectance. This is probably due to the difference in chemical compositions between primitive CM/CI chondrites and thermally meta-morphosed CM/CI chondrites. The thermally metamorphosed CM/CI chondrites containing IOM with higher aro-maticity (Yabuta et al. 2005) show lower reflectance compared to the primitive CM/CI chondrites. Based on the relationship, asteroid Ryugu, whose mean R(550) is 0.019, may contain higher than 3% of carbon.
In the correlation plots between total carbon contents and R(550) and R(390) for the experimentally heated car-bonaceous chondrites, overall, meteorites with higher carbon contents show lower reflectance. However, individual meteorites showed different behaviors during heating. For instance, the reflectance values of Murchison were low-ered while the total carbon contents of Murchison did not change during heating up to 400˚C. During heating at 500 - 600˚C, the reflectance values of Murchison were raised again while the total carbon contents of Murchison decreased only slightly. At 900˚C, the total carbon contents of Murchison suddenly decreased with increasing reflec-tance. These variations in reflectance are related to not only total carbon contents but also chemical change of IOM with increasing temperature, such as aromatization, pyrolytic degradation, and gasification. LAP 04721 and Tagish Lake showed similar trends, but their variations in reflectance differed depending on their original carbon contents and compositions. Based on the relationship, R(550) of Ryugu is the most similar to those of the

heated Tagish Lake at 400-600˚C or heated Murchison at 400˚C. The result appears to be consistent with the conclusion obtained by the near infrared spectral pattern of the surface of Ryugu (Kitazato et al. 2019).

Minerals and their catalytic effects on amino acid formations in environments simulating asteroids

*Walaa Elmasry[1], Yoko Kebukawa[1], Kensei Kobayashi[1]

1. Yokohama national university, graduate school of Engineering Science

Extraterrestrial delivery of organic compounds including amino acids to the early Earth during the late heavy bombardment (3.8-4.5 billion years ago) may have been important for the origin of life. Recently, it is suggested that chondritic organic matter was produced through reactions of interstellar formaldehyde, followed by condensation, and carbonization probably during hydrothermal alteration on chondritic asteroids (Cody et al 2011). Furthermore, Kebukawa et al. (2013, 2015) illustrated that the presence of ammonia significantly enhances the yields of IOM from formaldehyde via formose reaction at 150 ˚C, producing amino acids. Meteorites serve as delivery systems for extraterrestrial phyllosilicate minerals to Earth. Phyllosilicates may act as absorbents and catalysts for the reactions of organic precursor molecules in the early solar system (Pearson et.al 2002). In the current research, we are studying formations of amino acid at 150 ˚C and reveal the expected role of minerals, namely, montmorillonite, olivine and serpentine for amino acid productions in water-bearing planetesimals.

We synthesized organic compounds using a mixture of water, formaldehyde and ammonia (H2O, H2CO, NH3) in a ratio of 100:7:1 with adding minerals (10 g/ L) by simulating primordial materials in comets and asteroids. Aqueous solutions were heated at 150 ˚C for 24, and 72 hours. The resulted products were divided into two parts, the first part analyzed using a FT/IR, and GFC, while the other one was acid hydrolyzed, desalted, and subjected to amino acid analysis using an HPLC.

In HPLC analysis, considerable amounts of various amino acids including glycine and alanine were detected. Moreover, presence of non-protein amino acids (β-Ala, γ-ABA) is considered as an evidence for extraterrestrial origin and against terrestrial contamination. Our preliminary results showed that the obtained amount of amino acids was elevated with the presence of minerals. FT/IR spectra of samples with minerals showed more spectral intensities than samples without minerals due to synthesis of more organic compounds. GFC showed that high molecular weight organic compounds were formed which may be characterized as amino acid precursors that maintain stable at high temperature and longer durations giving various kinds of amino acids after acid hydrolysis. These results suggested that various amino acids could be formed abiotically via a mixture of formaldehyde, ammonia, and water, as well as, the associated minerals act as catalysts to produce amino acid precursors during aqueous activities in the planetesimals.

The Surviving Rate of Organic Materials after the Cometary Impacts

*Taiki Suzuki[1,2], Takashi Shibata[2], Natsuki Hosono[3]

1. Astrobiology Center, 2. National Astronomical Observatory of Japan, 3. Japan Agency for Marine-Earth Science and Technology

While it is widely accepted that the first life has emerged through the chemical evolution with simple organic materials on the early Earth, the origin of organic materials is still controversial. On the early Earth, a large amount of material is believed to have been delivered by comets/meteorites, providing the starting materials for the origin of life. Despite the importance, the large objects would not have been decelerated by the atmosphere and subjected to compression heating. The numerical studies discussed the possibility of molecular surviving during the cometary impact (e.g., Chyba et al. 1990; Blank et al. 1997; Pierazzo & Chyba 1999). These studies suggested that the extreme pressure and the obliqueness of the impact may increase the surviving rate of the organic molecules.

However, the previous numerical studies employed the simple method by reducing the dimension to 2D, or by assuming the relationship between the obliqueness and the temperature. In the poster, we present the latest result of the 3D simulation of oblique impacts utilizing DISPH (Density Independent Smoothed Particle Hydrodynamics) code. A supercomputer named XC50 and the Framework for Developing Particle Simulators (FDPS) enabled us to solve the three-dimensional impacts without any assumption for the obliqueness. The comet and the sea are composed of the 8200 and eight million particles, respectively. The cometary radius is fixed to be 1 km, and the dependency of the temperature on the obliqueness and the initial velocity are investigated. During the simulation, the physical parameters of all particles are traced through five seconds after the impacts. We name the particles with the peak temperature less than 1200 K as the low-temperature particles, where the organic materials may survive. As the results of our calculation, the percentage of the low-temperature particles is almost zero if the obliqueness is more than 70 degrees. Still, it increases along with the increase of the obliqueness.

In addition to the percentage of low-temperature particles for the different obliqueness, we consider the probability of impacts with different obliqueness to obtain the surviving rate for the organic materials. Then, we estimated the surviving rate of the organic materials to be 2 percent. If this is the case, comets could have provided organic materials more efficiently than the interstellar dust particles and other formation processes on the early Earth. Our result suggests that cometary impact may have been the primary source to provide organic materials to the early Earth.

Supercritical fluids in the search for origins-of-life in Earth and beyond

*CANER AKIL[1], Kosuke Fujishima[1]

1. Earth-Life Science Institute

The origins of life is unresolved. The path leading to a self-sustainable complexed chemical system is yet unknown, and at the core of this system exists a two-biopolymer (nucleic acids and proteins) system conserved in all life forms on Earth. This system is supported by an aqueous condition maintained by water. In this context, water has been considered as a sign for habitable environment on Earth and beyond where life can emerge. However, the abiotic synthesis of biopolymers is thermodynamically unfavorable in water. The paradox behind the water prone biopolymer and the water as a biosolvent bring into question whether alternative solvents existed on early Earth to drive chemical reactions leading to more complexed molecules including biopolymers.

In this study, we aim to investigate the effect of supercritical carbon dioxide ($scCO_2$) upon chemical reactions that are difficult to occur in aqueous conditions. $scCO_2$ has been known for its use in the industry as a ‘green’ solvent, however it has also found in deep-sea environments in modern ocean and more likely to be present in Hadean Earth which could have served as the key matrix to promote other different chemistry from aqueous chemical reactions. We will focus on two fundamental steps towards the formation of biopolymers 1) Non-enzymatic synthesis of nucleotides (from nucleobase, sugar and phosphate), 2) Condensation of nucleotides and amino acids towards abiotic synthesis of the two-biopolymer architecture.

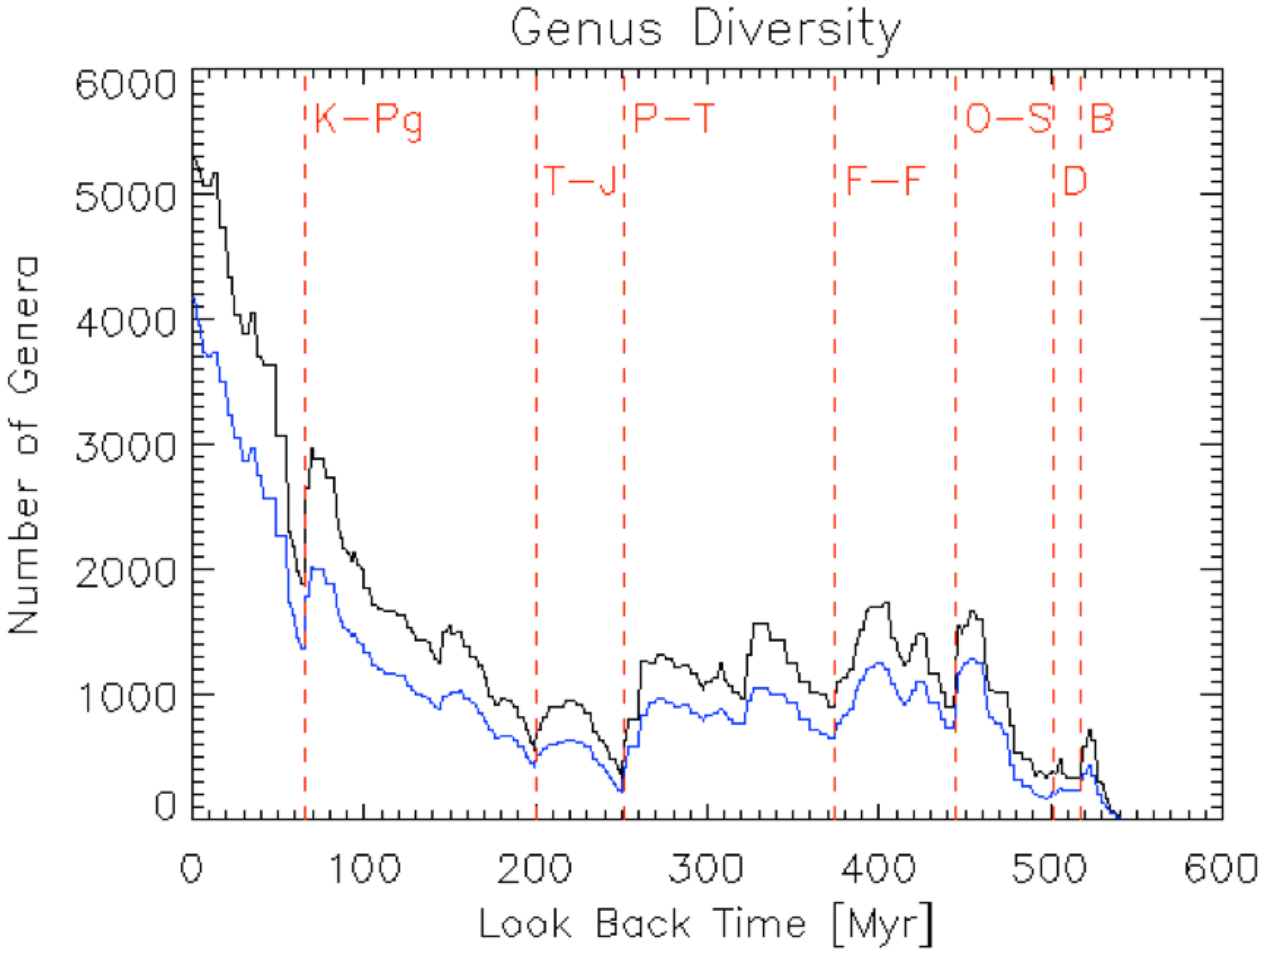
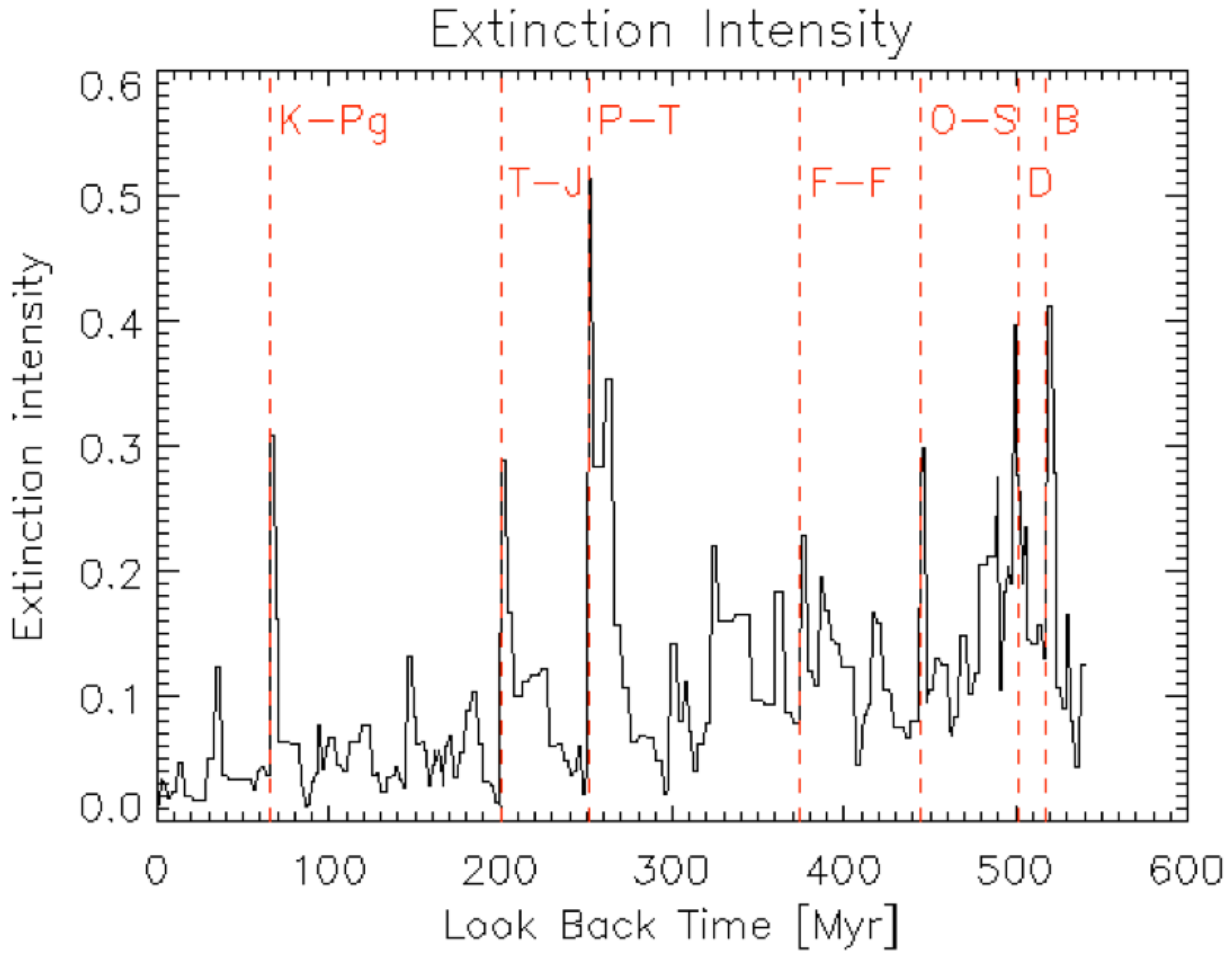
Estimation of the fraction of life-bearing planets that evolve intelligence f_i in the Drake equation by the terrestrial extinction history

*KOHJI TSUMURA[1]

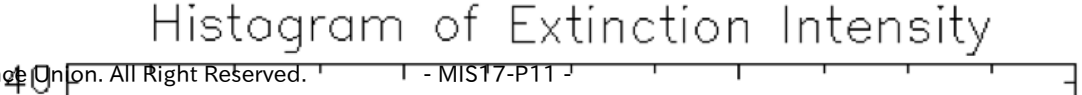
1. Department of Natural Science, Faculty of Science and Engineering, Tokyo City University



The Drake equation is a simple algebraic expression for quantifying the number of communicative civilizations in our Galaxy. Although some factors in the Drake equation can be reliably estimated by recent astronomical observations, remaining other factors are largely or entirely based on conjecture. One of such conjectural factors in the Drake equation is f_i, which is the fraction of planets with life on which an intelligent civilization emerges. The previous estimates of f_i range from pessimistic (f_i ~0) to optimistic (f_i ~1).



In this presentation, a new approach to estimate f_i is introduced based on the terrestrial extinction history, which is our only available data. Since its birth, life on the Earth has gone through any magnitudes of extinction due to various external factors such as the changes in the environment or the impacts of meteorites. In this study, f_i was calculated as a probability that we have continued to "win the lottery of extinction" since the birth of life, assuming that the intensity of extinction is determined by a probability density function, and also assuming that complex life essentially always becomes intelligent if it does not become extinct first like the terrestrial evolution history. The probability density function of extinction was deduced from the histogram of extinctions in the Phanerozoic eon of the Earth, covering from 540 Myr ago to present with 3 Myr resolution (Rohde & Muller 2005).



The histogram of the extinction intensity in the Phanerozoic eon was fitted by a log-normal function very well (reduced chi-squared of the fitting is ~1). The choice of the log-normal distribution function is supported by the statistical principle that a random multiplicative process converges to a log-normal distribution owing to the Central Limit Theorem. Because the terrestrial extinctions were basically caused by random events such as volcanic activities of the Earth or asteroid impacts, it can be justified that the terrestrial extinction intensity is expressed by the log-normal probability distribution as a result of the random multiplicative process. Assuming that the fitted log-normal function is a probability density function of the extinction intensity of terrestrial life, the survival probability for a unit time (3 Myr), p, is calculated as $p = 0.9985^{+0.0012}_{-0.0058}$. The factor f_i in the Drake equation can be expressed as $f_i = p^{T/\Delta T}$, where T is the evolution time of intelligent life and ΔT is the time resolution of the probability distribution function (ΔT = 3 Myr in this case). Recent geological evidences suggest that the first life on the Earth occurred 3.7-4.1 Gyr ago. Assuming that the obtained probability distribution function of extinction can be extended to this era, the evolution factor f_i can be calculated as $f_i = 0.13^{+0.52}_{-0.13}$ (99% confidence level) for 4.1 Gyr. This is the first data-based estimation of f_i. Because f_i is the two-parameter function of p and T, this method can be extended to the other life-bearing exoplanets by estimating these two parameters in some way, although this estimation is still based on the one-sample statistic of the Earth.

The safety assessments of reaction vessels used for the space exposure experiments in order to synthesize nucleotide by UV irradiation

*Madoka Shiromizu[1], Kazumichi Nakagawa[2], Yoshitaka Bessho[3], Hajime Mita[1]

1. Fukuoka Institute of Technology, 2. Osaka University, 3. Academia Sinica, Institute of Biological Chemistry

1. Introduction

Nucleotides are constituents of DNA and RNA, the process of nucleotide synthesis in the primitive Earth is one of the most important processes in the origin of life.
In the previous studies, nucleobases and sugars have been found in the carbonaceous chondrites and the simulated primitive Earth experiments. Thereby, source materials of nucleotides would be existed in the primitive ocean. And, molecular oxygen and ozone didn’t exist in the atmosphere of the primitive Earth. This suggests that the short wavelength (≦280 nm) UV lights, which is interrupted at the surface of the present Earth, reached to the surface and worked as an important energy source for the chemical reactions at that time. Therefore, we proposed a hypothesis that nucleotides would be synthesized by the UV irradiation in the primitive ocean.
In order to verify this hypothesis, nucleotide synthesis experiments using the Japanese exposure facility on the International Space Station (ISS) as a similar UV environment to the primitive Earth are proposed in the part of the “TANPOPO 4” mission. “TANPOPO” is series name of the astrobiology experiments in Japan using the ISS. In the previous "TANPOPO" mission, films or powdered organic compounds were exposed to the space environment. But this nucleotide synthesis would be performed under aqueous solution. Then, new apparatus those are able to used in the space exposure experiment should be required. The exposure facility on the ISS is in environment of ultra-high vacuum and rapid temperature changes. The reaction vessel containing the aqueous solution should be sealed completely and the seal should withstand the drastic temperature changes in ultrahigh vacuum. Therefore, we developed vessels that can expose the aqueous solution to UV rays by improving the cells used in the TANPOPO experiments.
In this paper, nucleotide synthesis experiments by UV irradiation and the preliminary safety assessments of new developed reaction vessels those are based on the previous TANPOPO mission were performed.

2. Experimental method

Equimolar solution of nucleobases and ribose-5-phosphate (R5P) were mixed and irradiated with UV light (172 nm) for 4 days. This irradiation is equivalent to approximately one year of irradiation on the ISS orbit. After irradiation, irradiated solutions were analyzed by high-resolution LC/MS in order to confirm the synthesized nucleotides.
The reaction vessel was placed in ultra-high vacuum environment where the temperature changes drastically and left for several months. The changes in degree of vacuum and mass were observed, and it was tested whether the solution leaked from the reaction vessel.

3. Result

Five kind of nucleotides were synthesized by UV irradiation. Adenylic acid was the highest yield and thymidylic acid was not found after irradiation. Furthermore, it was found that the addition of Ni^{2+} ions increased the yield of adenylic acid. The conformational analysis of the synthesized nucleotide will be performed.

©2020. Japan Geoscience Union. All Right Reserved.

We improved the structure-assessed cells used in the TANPOPO experiments and construced the reaction vessels for UV exposure that can seal the aqueous solution (Figure). Since the surface temperature of the ISS changes from 30 to -40 ℃, the solution freezes and melts repeatedly. A little air was admitted into the reaction vessel to prevent the MgF_2 glass from breaking due to volume expansion when water was frozen. The sealing test under ultra high vacuum and repeatedly temperature change conditions showed that the reaction vessel did not break and did not leak solution. In addition, this reaction vessels withstood the maximum vibration at launch and landing on water in the random vibration test. In the future, we will investigate the strength change of the O-ring inside the reaction vessel by UV irradiation and temperature change.

[M-IS19] Conservation of geoparks, natural geosites, and cultural heritage: weathering and damage assessment

convener:Luigi Germinario(Saitama University), Celine Schneider(University of Reims-Champagne-Ardenne), Chiaki T. Oguchi(Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University), Tetsuya Waragai(Graduate School of Science and Engineering, Nihon University), Miguel Gomez-Heras(Universidad Autonoma de Madrid), Patricia Vazquez(GEGENAA EA 3795 University of Reims Champagne-Ardenne), Magdalini Theodoridou(Cardiff University), Wonsuh Song(Waseda University)

Geoparks, geosites, World Heritage Sites, and historical structures represent an important natural and/or cultural heritage. They have been exposed to weathering in the geological and human time scale, so that the rocks and other geological materials they are made of, may often face severe deterioration. In order to preserve those sites, conservation measures should be considered. Several studies were carried out on this topic, involving a wide range of research fields: geomorphology, engineering geology, geoarchaeology, conservation science, geoconservation, materials science, petrophysics, geochemistry, geotechnical engineering, etc. However, our knowledge on many aspects is still limited. This session welcomes contributions presenting original research, discussions, as well as case studies, on documentation, measurement and monitoring techniques, experimental procedures, predictive models, damage assessment, etc. Papers from all the research fields dealing with the broad topic of geosites and cultural heritage are invited.

Development of magnetic resonance surface scanners for the nondestructive in-situ measurement of water fractions in cultural heritages

*Yoshito Nakashima[1]

1. National Institute of Advanced Industrial Science and Technology

Nondestructive measurement techniques are essential for the maintenance and investigation of cultural heritages. Water is often responsible for the degradation of the outdoor cultural heritages, such as walls and pavements made of stones, plasters, clays, and bricks. Portable scanners that allow the nondestructive quantification of water contents are needed for the in-situ investigation of porous wet walls and pavements. I am developing such scanners to measure the water volume fraction of outdoor cultural heritages. The principle of the scanners is based on the low-field time-domain proton magnetic resonance (i.e. NMR) relaxometry employing a single-sided magnetic circuit [1]. Water protons in a static magnetic field produced by the single-sided permanent magnets are excited by the radio-frequency coil, and the resultant proton transverse relaxation signals are acquired as raw data, which can be translated into water volume fractions, and pore-size distributions and permeabilities of the wet porous media. The investigation depth (distance from the coil to the sensed region) is several to several tens of millimeters, depending on the magnet size. A surface scanner with an investigation depth of 30mm constructed for a different purpose [2] was as heavy as 50 kg, which is not a hand-held type. Thus I am constructing a new scanner employing a smaller magnet (4 kg in weight) as shown in the figure, which allows hand-held use and increase the operationability. The current status and future perspective of the new scanner being developed would be presented.

Effect of temperature and humidity changes on salt weathering: Verification by rock surface moisture content and color measurements

Masaki Oi[1], *Masato Sato[2], Tsuyoshi Hattanji[3]

1. Graduate School of Life and environmental Sciences, University of Tsukuba, 2. National Research Institute for Earth Science and Disaster Resilience, 3. Faculty of Life and Environmental Sciences, University of Tsukuba

This study investigates weathering processes using porous rocks with three types of salts in field environments where water supply is limited to vapor in air. The experiments were performed using three types of rocks (Oya tuff, Ubara sandstone and Kominato mudstone). Each rock sample was cut into a cylinder having a diameter of 5 cm and a height of 5 cm. The shaped rock was immersed in a saturated salt solution of NaCl, Na_2SO_4, or $MgSO_4$ for 48 hours, then oven-dried at 110˚C. After these treatments, the rock cylinders were placed in a box on a field for 51 days in winter or summer season. The two types of boxes were used in the experiment; one has a transparent roof penetrating solar radiation and another has a roof shielding solar radiation. The roofs prevent rainwater into the two boxes, then water supply is limited to water vapor in air.

The experimental results are summarized as follows: (1) Rocks containing salt weathered during the daytime with low humidity. (2) Rock weathering in summer were greater than those in winter. (3) Weathering rates of rocks with sodium chloride were largest when exposed to solar radiation, while they were smallest without solar radiation.

Moisture content and color of rock surface indicated that the salt deliquesced and turned into a solution during high-humidity term at night, and recrystallized during the daytime with low humidity. As a result, detachment progressed during the daytime. Temperature and humidity observation suggested that the deliquescence in summer was longer and more frequent than that in winter. In actual field environments such as stone heritage, cave wall and tafone, the seasonal contrast in weathering rates would be occurred by the difference in temperature and humidity conditions for deliquescence.

Study on relationship between water content, NIR absorbance and colour values of various stones and cement mortars

*Chiaki T. Oguchi[1], Keni'chiro Tanaka[2]

1. Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University, 2. Department of Engineering, Saitama University

This study examined the relationships between water content, absorbance, and color values in various building stones and mortar cements. The rocks used are; Shirahama sandstone, Oya tuff, Savonnierre limestone, Shirakawa welded tuff, Tago sandstone, while cement mortars used are sulfate resistant Portland cement (SRPC) and normal Prtland cement (NPC), NPC mixed with silica fume (SF) and fly ash (FA). Those rocks and mortars are cut into rectangle with the size of 5 cm-5 cm-15 cm. Firstly, the specimens were dried at 110 degrees for 24 hours, and then, they were immersed in distilled water in 24 hours. Then, they were taken from the distilled water and weighed to calculate water content and porosity. By using moisture measurement apparatus (JE-130, JE Engineering Co. Ltd.) with near infrared ray (NIR), absorbance values were measured and weight with elapsed time. In the same way, L* values were also measured by using colorimeter (CM-700d, Minolta Co. Ltd.) with elapsed time. The relationship among water content, absorbance values, L* was compared for each specimen. As a result, it is turned out that the values of absorbance increase with increasing water content, whereas the values of L* increase with decreasing water content.

Surface morphology representations at different scales for rock art characterisationSurface morphology representations at different scales for rock art characterisation

Mohammad Hafez Seada[1,3], *Miguel Gomez-Heras[1], Laura Lopez-Gonzalez[2], Ayman Hamed[3]

1. Universidad Autonoma de Madrid, 2. Art Fabrik, 3. Suez University

Rock art is one of the oldest evidences of cultural transmission and probably one of the most sensitive to decay. Rock art is often found in shelters and outcropping rocks in areas where they are difficult to protect both again natural weathering agents and vandalism. In this scenario, surface morphology representations serve for the quantification of rock weathering or any change caused by human hands. Surface morphology is also an excellent tool for archaeological studies, particularly in rock art in the form of engravings, as micro-topographic measurements may be of substantial importance for the interpretation of the tools used for engraving. This communication deals with a set of Palaeolithic petroglyphs in Domingo Garcia (Segovia, Spain). This set of petroglyphs, which includes a variety of engraving techniques, is found across a wide area in a very rural setting that makes it very difficult to manage in terms of conservation. This communication explores different techniques for surface morphology acquisition at different scales, discussing their use for conservation and site management.
[This work was supported by Top Heritage (P2018/NMT-4372) programmes from the Regional Government of Madrid (Spain)].

Life on stones as microbial communities colonized substrates freshly exposed to the atmosphere where climatic conditions as sunlight, temperature and water availability are the key factors to the micro-organisms growth. The micro-organisms colonization is a widely recurring phenomenon which can lead to irreparable damage and the loss of unique cultural monuments. Besides the biological weathering, biofilms induce fouling that changes the visual aspect of monuments and statues. Biocolonisation is a major concern for conservators who face the endless maintenance of buildings which reach a notable economic costs.

Microbial communities composing biofilms spread thanks to nutritive elements found in the components of stone, and favour the anchorage of other micro-organisms such as fungi, algae, moss and lichen which deteriorate the materials by minerals dissolution and penetration of hyphae and roots driving to chemical and mechanical damage. In this respect, the early biofilm growth on stone walls must be taken into account to limit stones damage and financial costs. The colour measurement is currently used in cultural heritage as a non-destructive technique (NDT) to assess the biofilm spreading on a stone wall through its colour change. Nevertheless, other factors inducing colour variations are not driven by micro-organisms such as urban pollution, humidity degree and natural ageing of patina over time. Accordingly, the tracking of pioneer micro-organisms on stones is not always easy by this method and an earlier detection of biocolonisation should be more profitable than a visual one. In this study, infrared thermography (IRT) has been investigated in first assays in order to assess the sensitivity of this NDT to track down the biocolonisation earlier than colourimetry. It is an evaluation tool commonly used in monitoring and maintenance of buildings. The stone surfaces and subsurfaces are tested by analysis of thermal emissions. It is a powerful technique for art analysis thanks to its non-contact imaging application. This work analyzed thermal responses of biocolonised stones after a stimulation by a heating pulse (active IRT). Two natural limestones have been selected for their use in many buildings in Eastern France (Courville and Savonnières stones). Samples have been previously exposed six months in a garden where biofilms grew, then compared to non-exposed samples. The experiment has been set up in laboratory condition in order to avoid external artefacts. Recorded thermograms have been analysed by using post-processing calculations as SVD (Singular Value Decomposition) thanks to IR Explorer software and temperature variation of surfaces have been measured from them. First results displayed that SVD highlighted a net variation between stones without biofilm and stones with biofilm. Moreover, after a flash stimulation the maximum temperature was higher on the stone surface with biofilm than without it in dry and damp conditions for both types of stones. This study showed that active IRT could detect thermal variations on stones due to the biofilm settlement. This technique is thus able to highlight weak variations of energy for the detection of early biofilm.

Effectiveness of waterproofing protection coating on salt weathering experiment using building stones

*Chiaki T. Oguchi[1], Akimune Sasaki[2]

1. Institute for Environmental Science and Technology, Graduate School of Science and Engineering, Saitama University, 2. Department of Engineering, Saitama University

Salt damage impact on buildings and cultural properties and developing various coating materials on waterproofing protection were obtain investigated recently. However, there are few studies on its effectiveness under severe condition of saline solution immersion to building stones. In the present study, continuous partial immersion experiment were performed by using 4 types of specimens of Oya tuff and Savonierre sandstone blocks to be found the effectiveness of waterproofing protection coat. From the experiment, the following findings were obtained regarding the effectiveness of the protection coating for salt weathering: 1) preventing salt solution from absorbing water; 2) suppression of rock surface degradation by filling gaps in rock surface; 3) increase the strength of rock surface; and 4) causeing a certain damage under conditions that allow water absorption.

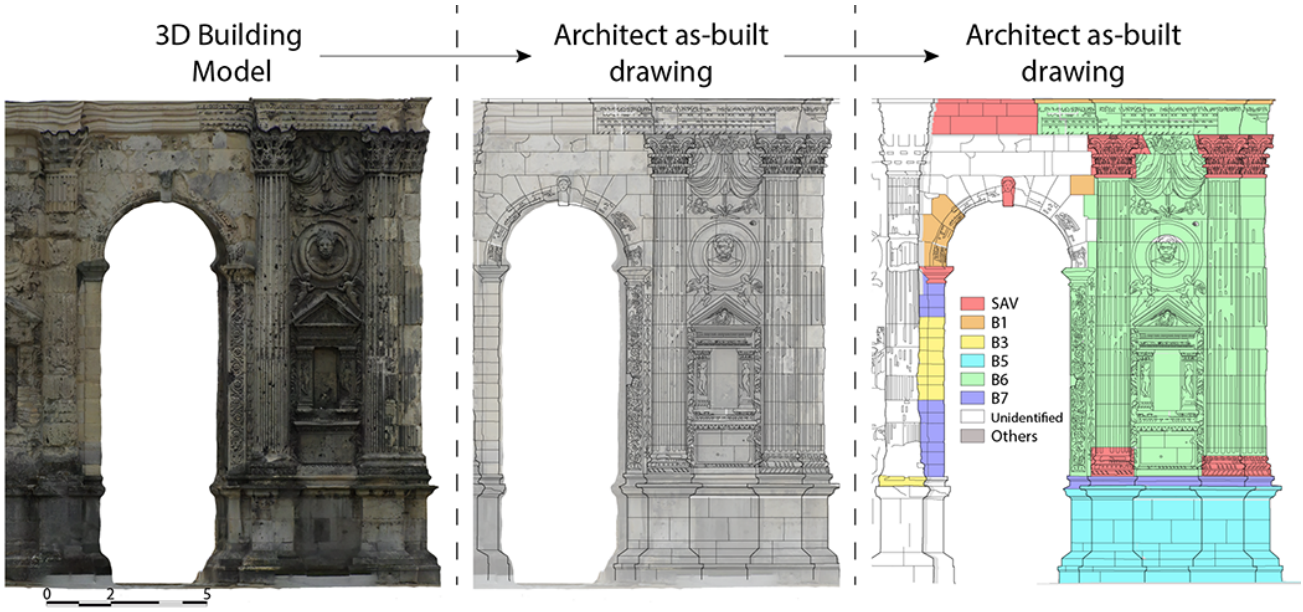
Integration of durability parameters of cultural heritage building stones using by integrated geomatic methodologies

*Sebastien LARATTE[1], Céline THOMACHOT-SCHNEIDER[1], Gilles FRONTEAU[1], Alexandra GUILLANEUF [1], Patricia VAZQUEZ[1]

1. University of Reims-Champagne-Ardenne



The “Porte de Mars”, is one of the most emblematic ancient monuments of the city of Rheims. This three-bay roman arch rises at the northern end of former *Durocortorum,* capital of *Gallia Belgica* province. Its construction dates from the mid 2nd to early 3rd c. AD. It was then integrated into the Late Roman rampart of the city. Encased, from 1162 to 1856, in the medieval city wall and then in the castle of the city's archbishops, it was completely cleared and restored during the 19th century. During this period, it was barely saved from being dismantled after the ruin of the archbishops' castle and its complete dismantling by the town's population. It is considered the largest "arch" of the Roman Empire north of Roma. It is 32.35 m long, 6.45 m wide and 12 m high today. Since its rediscovery and until today, the “Porte de Mars” is located in the centre of Rheims, at the crossroads of major traffic axis.

A photogrammetric survey was carried out using a total of 370 high-resolution photos. For this, a camera with a 20.3 Megapixel sensor was used, taking care to work with a single focal length. The upper part of the monument was treated in a second step thanks to the presence of an aerial lift. Part of the photos were taken by fixing the camera on a pole and using a tablet as a means of preview, georeferencing and remote control. After a quality control; the photographs were processed with the Agisoft Metashape software which allows to carry out all the operations of the photogrammetry calculation chain (Structure fFrom Motion - SfM method). This method allows the reconstruction of 3D objects from 2D data. The technique is based on an algorithm that automatically matches points in a set of photos. These points are then treated as remarkable points and repositioned in space in the manner of the perception of volumes by biological eyes. The spatial coordinates of the points are on the one hand calculated by the software and on the other hand provided by the georeferencing data of the images. The distances between 125 key points on the monument are measured with a laser range distance meter (Leica Disto D2) in order to scale the model to its final dimensions. The software allows the extraction of orthophotographs from the 3D mesh according to the chosen orientations.

The modelled datas and orthophotos are injected into a geographic information system (GIS) implemented under QGis 3.4 because of the interoperability of the formats considered. Its data is then used as the basis for plan and volume plots on the one hand and an attribute database on the other. These data are both qualitative (nature of the stone, petrography, assumed origin, restoration phase, etc.) and quantitative (chemical composition, mineralogy, porosity, capilarity, etc.). The methodology will also make it possible to discretize continuous information such as thermal data at the stone scale.
This non-destructive approach to the monument built from an integrated geomatics chain of operations allows the cross-referencing of data of various origins (geological, environmental, archaeological...). Interoperability of the database is essential so that this tool can represent a transversal interest and be used in the framework of building conservation. This approach allows the construction of thematic maps of the monument, such as material maps, stone compatibility maps or prospective parameter maps such as the durability of materials. In addition, the use of photogrammetry has considerably lightened the process of acquisition and calculation of the model, making the construction of the information system much easier.

[M-GI33] Data assimilation: A fundamental approach in geosciences

convener:Shin ya Nakano(The Institute of Statistical Mathematics), Yosuke Fujii(Meteorological Research Institute, Japan Meteorological Agency), Takemasa Miyoshi(RIKEN), SHINICHI MIYAZAKI(Graduate School of Science, Kyoto University)

Data assimilation is an inversion approach to estimate the evolution of a system by utilizing a constraint given by a dynamical simulation model. Data assimilation is now widely used not only in meteorology and oceanography but also other fields of geosciences such as hydrology, solid earth science, and space science. This session aims at providing
an opportunity for discussion on data assimilation studies among researchers of various field of geosciences. We encourage contributions addressing novel methods and theoretical developments of data assimilation. Contributions dealing with useful applications of data assimilation are also welcome.

Information on the distribution of dissolved iron (*dFe*) concentrations in many parts of the ocean has been provided by recent ocean observation programs. However, a knowledge is still limited concerning the rates of processes that control the concentrations and cycling of *dFe* in the ocean. In this study, we constructed a three-dimensional gridded dataset of oceanic *dFe* concentrations by using both observations and a simple model of the iron cycle. The fluxes of *dFe* from the sea surface associated with the falling aeolian dust and from the dissolution of sediments on the seafloor of the continental shelves were set as the external flux. We used a Green's function approach to integrate the observations and a simple model. The control variables, in addition to model parameters, were the flux of *dFe* from the dissolution of sediments on the seafloor of the continental shelves. The three-dimensional distribution of *dFe* that we obtained was in basic agreement with observations. These estimates imply large differences in the cycling of *dFe* between the two basins that would need to be taken into consideration in projections of future scenarios. Although there is some uncertainty in our estimates, global estimates of iron cycle characteristics based on this approach can be expected to enhance understanding of the iron cycle process in the ocean.

Enhanced correlations between SST and precipitation in the weather time scale represented by a coupled atmosphere-ocean data assimilation system

*Yosuke Fujii[1], Chiaki Kobayashi[1], Ichiro Ishikawa[1], Takaya Yuhei[1]

1. Meteorological Research Institute, Japan Meteorological Agency

The Meteorological Research Institute (MRI) of the Japan Meteorological Agency has developed a weakly-coupled atmosphere-ocean data assimilation system, MRI-CDA1, and coupled reanalysis experiments based on MRI-CDA1 are conducted for the period from November 2013 to December 2015. Then we examined the relationship between sea surface temperature (SST) and atmospheric elements in the one-to-ten-day time scale which is the typical time scale for weather variation. In the coupled reanalysis, the variation of SST is positively correlated with the variation of precipitation with one-day lag, and the variation of precipitation is negatively correlated with the variation of SST with one-day lag, particularly in the tropics. High SST, thus, induces atmospheric convection and the convection induces low SST in turn. These lagged correlations mostly disappear between precipitation and prescribed SST data in an uncoupled atmospheric reanalysis. When the prescribed SST is replaced by the SST in the ocean data assimilation system forced by the atmospheric reanalysis, the lagged correlations are recovered but weaker than those in the coupled reanalysis. Thus, the lagged correlations are enhanced with coupled data assimilation. In addition, correlations become weaker also when the prescribed SST is replaced by the SST in the coupled reanalysis, which means that the precipitation field in the coupled reanalysis is changed in order to adjust to the SST field driven by the coupled model. This is contrastive to the longer (intraseasonal) time scale in which the atmospheric field in the coupled reanalysis is mostly unchanged from the conventional atmospheric reanalysis but SST filed is adjusted to the atmospheric fields. This effect of coupled data assimilation enhancing the correlations between SST and precipitation may cause improvement of the precipitation field over the uncoupled atmospheric analysis.

Non-Gaussian statistics in global atmospheric dynamics with a 10240-member ensemble Kalman filter experiment using an intermediate AGCM

*Keiichi Kondo[1,2], Takemasa Miyoshi[2]

1. Meteorological Research Institute, 2. RIKEN Center for Computational Science

In our previous work, we performed local ensemble transform Kalman filter (LETKF) experiments with 10240 ensemble members using an intermediate atmospheric general circulation model (AGCM) known as the SPEEDY (T30/L7) model. The previous study reported that the improvement in the tropics was relatively small by increasing the ensemble size up to 10240. We hypothesize that these small improvements be related to convectively dominated tropical dynamics. In this study, we found that the non-Gaussian probability density functions (PDFs) appeared in the regions with large analysis error, mainly in the tropics and storm track regions. The non-Gaussian PDFs are mainly generated by convective parametrization in the tropics and by the instability associated with advection in the storm track regions.

Acknowledgements: This study was partly supported by JST CREST (JPMJCR1312), JST AIP (JPMJCR19U2), JSPS KAKENHI (JP16K17806), and Post-K priority issue 4 of Japan Agency for Marine-Earth Science and Technology, which was promoted by the Ministry of Education, Culture, Sports, Science and Technology, Japan. Part of the results was obtained using the K computer at the RIKEN R-CCS through proposal numbers ra000015 and hp150019.

Data assimilation of lightning observation data for global numerical weather prediction

*Toshiyuki Ishibashi[1]

1. Meteorological Research Institute/Japan Meteorological Agency

To improve the accuracy of global numerical weather prediction (NWP), it is necessary to assimilate more observation data with a data assimilation system (DAS). Lightning observation data is new valuable observation data including information on the deep part of cumulonimbus clouds. Lightning observation from satellites has been ongoing since the 1990s. The third generation geostationary meteorological satellites are equipped with lightning sensors and have high spatiotemporal resolution and wide observation coverage. However, to assimilate the lightning observation data adequately, there are some basic difficulties, which are the nonlinearity of the lightning observation operator, shortage of forecast accuracy for water substances, and water substance error statistics. In this research, we first summarize lightning observations and observation operators, and then describe our initial results such as forward calculation of lightning. We also consider next steps of the data assimilation of lightning observations.

Development of a "multilingual" data assimilation library

*Shin ya Nakano[1], Genta Ueno[1], Shunichi Nomura[1], Daisuke Murakami[1]

1. The Institute of Statistical Mathematics

Data assimilation is now applied in various fields not limited to geophysical researches. There are several documents and textbooks for data assimilation methods, and some free data assimilation codes are also available. These materials have been helping researchers of various research areas who want to use data assimilation techniques. However, it is sometimes time-consuming to implement a data assimilation method for a practical simulation code after reading the documents and the public assimilation codes. In particular, if one can not find any data assimilation codes written in his/her familiar language, it would take trouble to development a data assimilation code. We aim to provide a data assimilation program library in a variety of programming language which is easy for various researches to try to apply. As a pilot work, we developed a library of the particle filter based on Python which was reported last year, and it have been provided for several researchers. Now we are developing a similar framework in different languages such as R and Matlab which help researchers to develop a data assimilation system with the ensemble Kalman filter or the particle filter. We will introduce our data assimilation library and discuss future prospects.

Observation impact study in global numerical weather prediction

*Toshiyuki Ishibashi[1]

1. Meteorological Research Institute/Japan Meteorological Agency

To improve the accuracy of global numerical weather prediction (NWP), it is necessary to assimilate more observation information with a data assimilation system (DAS). To know impact of each assimilated observation on analyses and forecasts is essential for this. In this study, we estimate observation impacts using the adjoint based impact estimation method, which used an adjoint operators of a DAS and a NWP model. Various properties of observation impact such as nonlinearity, probabilistic nature, system dependency are also considered.

[M-GI34] Near Surface Investigation and Modeling for Groundwater Resources Assessment and Conservation

convener:Jui-Pin Tsai(National Taiwan University, Taiwan), Hwa-Lung Yu(National Taiwan University), Makoto Taniguchi(Research Institute for Humanity and Nature), Ping-Yu Chang(National Central University)

Groundwater resources serve as a vital source for regional water supply under the climate change condition. However, improper use of the available groundwater resources leads to serious environmental disasters such as land subsidence or seawater intrusion. Therefore, groundwater management is a key issue for groundwater resources conservation. Before applying any management practice, it is essential to accurately assess the groundwater system in multi-scales. In this session, we focus on the issues associated with the application of near-surface investigation and modeling on groundwater resources assessment. We welcome studies related to numerical modeling, spatiotemporal modeling, data fusion, and field investigation using hydrogeological approaches, geophysical approaches, geochemical approaches, and remote sensing. We also welcome the studies associated with groundwater contamination transport and remediation, geothermal energy exchange, groundwater microorganisms, hot spring, volcanic hydrology, and environmental disasters evaluation and prevention. We especially encourage the pilot groundwater management studies that solve multi-scale and interdisciplinary problems.

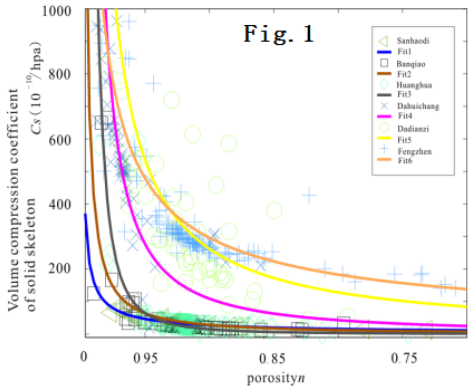
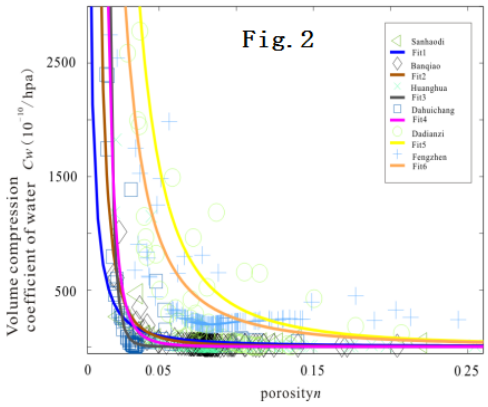
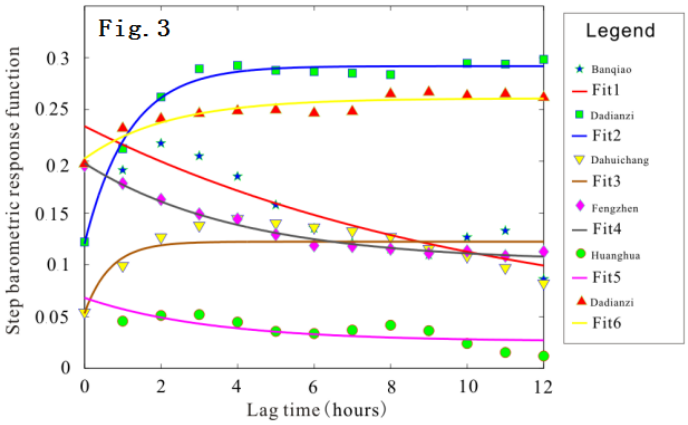
Digital water level analysis based on well tide and air pressure effect



*feng he ding[1]



1. Earthquake Administration of Ningxia Hui Autonomous Region



In this paper, the porosity, the volume compression coefficient of solid skeleton and the volume compression coefficient of water in the aquifer are studied by using the air pressure coefficient and tide factor from Dahuichang Well, Banqiao Well, Huanghua Well, Dadianzi Well, Fengzhen Well and Sanhaodi Well in the north of North China.
The results show that there is an obvious power function relationship between porosity and volume compression coefficient of solid skeleton and that of water in aquifer.(1)In the first quadrant, the volume compression coefficient of aquifer solid skeleton increases with the increase of porosity.This is due to the fact that when the pore pressure increases, the volume of water decreases. When the external stress remains unchanged, the skeleton stress decreases, the skeleton volume increases, and the pore volume increases together.Therefore, with the decrease of skeleton stress and the increase of skeleton volume (expansion), the volume change (or rate of change) is also larger (easy to compress). The compression coefficient of skeleton volume increases with the increase of porosity.(2)When the pore pressure increases, the volume of water decreases, and the smaller the volume change (or change rate), the smaller the volume compression coefficient of water. At the same time, this process is the process of porosity increase. Therefore, the volume compression coefficient of water decreases with the increase of porosity.(3)The elastic deformation of water decreases with the increase of porosity. This is because the compression coefficient of water is smaller and smaller, and the volume change is smaller and smaller, so the water is more difficult to compress. At the same time, the solid skeleton is easy to compress and elastic deformation becomes stronger.(4)The relationship between the volume compression coefficient of the water in the aquifer and the solid skeleton satisfies the quadratic polynomial of one variable, and the volume compression coefficient of the water in the aquifer is larger than the volume compression coefficient of the solid skeleton, so the water is easier to be compressed.
In addition, combined with the step response function of water level to air pressure in convolution regression method, the results of groundwater type determination of the aquifer system of these six Wells show that there is an obvious exponential function form with e as the bottom between the lag time of water level to air pressure and the step response function of water level to air pressure in each of the six Wells. The positive and negative coefficient a before the base number e determines the underground water of the Well aquifer system Type of water. For pressure Wells, the step response function of water level to air pressure increases with the increase of lag time of water level to air pressure, while for non pressure Wells and semi pressure Wells, it is the opposite.

Applying Independent Component Analysis and Wavelets Analysis to Explore the Response of Groundwater Level to Surface Hydrology

*Chin Wei Huang[1], Liang Cheng Chang[1], Chin Tsai Hsiao[2], Wan Chung Lu[3], Tzu Hua Lai[3]

1. Department of Civil Engineering, National Chiao-Tung University, Hsinchu, Taiwan 30010, R.O.C., 2. Department of Landscape Architecture, Chung Chou University of Science and Technology, Changhua County, Taiwan, 510, R.O.C, 3. Central Geological Survey, MOEA, Taiwan 235, R.O.C

The groundwater is a component of the global hydrology cycle. For an aquifer system, the responses of the external forces such as rainfall, river flow, groundwater pumping and earth tide etc. were mixed in the groundwater level. This study applies the Independent Component Analysis (ICA) and the Wavelets Analysis to decompose the signals of groundwater level, rainfall and river water-level in time and frequency domain. The decomposition facilitates exploring the response of groundwater level to the surface hydrology. The independent components (ICs) of groundwater level and external forces are examined by their cross-correlations and the associated wavlets transform. The proposed method was applied to the Taichung Basin based on the data collected during 2009-2017. The study identified a pair of groundwater level ICs to rainfall ICs with a high correlation coefficient value (0.85) and a similar pattern of wavelets transform. A river water-level ICs with correlation coefficient 0.69 to groundwater level ICs was also identified. The result demonstrates that the rainfall has a significant influence on the groundwater level, and the river water-level has a moderate impact on the groundwater system in Taichung Basin. Besides examing the impact of surface hydrology to groundwater level, the proposed methodology can obtain a clean signal pair of impact-to-response and that is valuable to more advanced study.

Optimal Artificial-Recharge Planning to Raise the Groundwater Level of Land Subsidence Area

*Ming-Sheng Wang[1], Liang Cheng Chang[1], Wan Chun Lu[2], Yun Shuen Wang[2]

1. Department of Civil Engineering, National Chiao-Tung University, Hsinchu, Taiwan, 30010, R.O.C, 2. Central Geological Survey, MOEA, Taiwan 235, R.O.C

The alluvial fan of the Zhuoshui River in Taiwan has rich groundwater resources. However, the groundwater over-pumping to supply the agricultural and aquaculture water demand in early year induced drawdown of groundwater level significantly, and caused land subsidence problems. To mitigate the land subsidence problem, raising the groundwater level is the most effective method.
Therefore, this study develops an optimal planning model for regional groundwater recharge planning and applies the model to the Zhuoshui River alluvial fan. The optimal planning model integrated a genetic algorithm with a surface water allocation model and a groundwater simulation model. To reduce the computational complexity, the optimal planning model is formulated as a sequential optimization model instead of a global optimal one. The model computes the optimal recharge plan step by step. For each step, three consecutive time steps optimal was considered. To further increase the computational efficiency, a response matrix model is used to surrogate the groundwater numerical simulation model, MODFLOW. However, before creating a response matrix, a groundwater simulation model (MODFLOW) needs to be built. The optimal planning model was applied to compute the optimal recharge plain in the Zhuoshui River alluvial fan. The retired water treatment plants are the candidate sides to be selected as injection sites. The simulation results demonstrated that the optimal recharge plan can indeed raise the groundwater level significantly. The principle of the proposed methodology can be applied to other land subsidence areas, and the result is a valuable reference for mitigating the land subsidence problem

[M-GI36] Open Science in Progress: Data Sharing, e-Infrastructure, and Transparency in International Contexts

convener:Yasuhisa Kondo(Research Institute for Humanity and Nature), Baptiste Cecconi(LESIA, Observatoire de Paris, CNRS, PSL Research University), Yasuhiro Murayama(Strategic Program Produce Office, National Institute of Information and Communications Technology), Shelley Stall(American Geophysical Union)

Open Science is widely accepted as a new research paradigm to accelerate scientific innovation. Deployed by ICSU-WDS (2008), G8 Open Data Charter (2013), deployment of Research Data Alliance (2013), OECD Global Science Forum's research projects (2016), and G7 Science Ministers' Communique (2017), it commonly refers to the top-down policies making results of publicly-funded research freely available and accessible. Open Science also refers to the participatory bottom-up approaches such as citizen science, crowdfunding, and transdisciplinary research (Kitamoto 2016). It is noted that both approaches envision the transformation of research process to more findable, accessible, interoperable, and reusable one (Wilkinson et al. 2016).
Followed by the JpGU-AGU Great Debate "Role of open data and open science in Geoscience" at JpGU Annual Meeting 2018, follow-up sessions at the AGU Fall Meetings 2018 and 2019, and JpGU 2019, this session reviews the current broad spectrum of Open Science in international contexts. The session welcomes a wide range of papers and posters covering (but not limited to) open research data, open source licenses, data papers and journals, data repository, e-infrastructures and platforms for sharing data, citizen science, crowdsourcing, crowdfunding, transdisciplinary research, capacity building, international networking, and deployment in earth and planetary sciences.

Research Data: Emerging Challenges and Opportunities in International Research Collaborations

*Kamata Takehito[1]

1. Sophia University

Researchers and professionals from different academic backgrounds share diverse types of information, knowledge, and data to study interconnected complex global issues. Their collaborations yield new knowledge that can create innovations around the world, and interdisciplinary teams of specialists work together to conduct flexible research collaborations in analyzing large amounts of data, information, and samples.

Research data governance policies regarding international research vary across academic disciplines, professions, and nations. Researchers, professionals, and all related stakeholders need to understand emerging challenges and opportunities in integrating research data with their collaborators across nations. This study introduces emerging challenges and opportunities in integrating data across nations.

Anderson (2010) identified the four dimensions of national research system, the organization of the research system, the legal and regulatory systems, the oversight related to research integrity, and the training of graduate students and postdoctoral fellows as potential challenges when promoting research and support in international research collaboration. Dealing with challenges at the appropriate organizational levels is key to pursuing successful international research collaboration.

There are many education and research systems around the world, and the affiliated systems influence researchers' engagement and involvement differently. In addition, each individual's academic, professional, and cultural experience determines and reflects the attitudes, behaviors, characteristics, objectives, and values of an organization or institution. It is crucial to recognize differences in trained individuals' knowledge, skills, research integrity and ethics, as well as other research-related training (National Research Council, 2011).

Different legal and regulatory systems pose challenges for international research collaboration. Some government agencies and international organizations have more complex hierarchies than others, and some nations are strict on spending their public funds in particular research fields. Recognizing differences among organizations, sectors, and nations will be significant to establish effective collaboration and communication platforms to deal with emerging challenges in international research collaborations.

The increase of data storage capacity and the development of information technology infrastructure have enabled researchers and professionals to integrate data and samples through international research collaborations. Although each academic discipline has different data sharing principles and practices, it is the shared responsibility among the stakeholders to improve data integration infrastructure in data management and governance in international research collaborations.

National funding agencies or oversight organizations do not have the clear authority and function to assess the various risks and threats associated with data sharing in international research collaboration. Elsevier started offering to store the research data that underlie the papers published in its journals;

©2020. Japan Geoscience Union. All Right Reserved.

however, it did not consider the cost of doing so (National Research Council, 2018). Researchers must work with their collaborators to recognize research integrity principles, understand government regulations, follow legal guidelines, spend allocated funds appropriately, satisfy other requirements, and ensure public trust in research (Kaye, 2015).

Incorporating multiple data integration perspectives and practices will be significant to eliminate potential challenges and create responsible research data governance policies in international research collaborations. Based on the definitions of internationalization, this study examines the organizational responsibilities and functions of the research data governance at the institutional, sector, national, and international levels.

NenuFAR is a new radioastronomy instrument located in Nançay (France) operating in the 10–85 MHz frequency band. It is a SKA (Square Kilometre Array) Pathfinder at low frequency at the last stages of its construction, currently in early science phase. The instrument will produce up to 2 PB of data per year in its standalone imager mode. We are now setting up a local data center in order to pre-process the raw data. An e- or physical infrastructure is under development and will allow for, e.g., data transfer/storage/archive, user access and computing time allocation management, scientific analysis platform deployment with preconfigured radio astronomy software suites.

Open data action to publish the GNSS-A seafloor geodetic data

*Tadashi Ishikawa[1], Yusuke Yokota[2], Shun-ichi Watanabe[1]

1. Hydrographic and Oceanographic Department, Japan Coast Guard, 2. Institute of Industrial Science, the University of Tokyo

Seafloor geodetic data are particularly important for monitoring the behavior of undersea inter-plate boundary regions. Since the mid-1990s, Japan Coast Guard have been developing the combined Global Navigation Satellite System-Acoustic ranging (GNSS-A) technique for realizing seafloor geodesy. This technique allows us to collect time series of seafloor crustal deformation. The datasets of time series can be used to investigate several seismological phenomena along the subduction zones around Japan, such as the Nankai Trough and Japan Trench. These regions are globally important places in geodesy and seismology and are also suitable for comparison with other geophysical datasets. Therefore, sharing the datasets in an appropriate way, it is expected to promote further understanding of megathrust zones.

First, we published our datasets on our web site (https://www1.kaiho.mlit.go.jp/KOHO/chikaku/kaitei/sgs/datalist_e.html). However, this is not an appropriate way because the description of the datasets in not sufficient for other researches to use. In addition, our site has not a function to mint DOIs for datasets. To solve this problem, we published our datasets as data paper (Yokota et al. 2018). Data paper is a peer-reviewed paper for descriptions of datasets that advances reuse of the data. Our intention is for data paper to widely share the GNSS-A datasets to promote further advances of seismology and geodesy.

Sample management in JAMSTEC: Cooperation-based management of diverse samples

*Takayuki Tomiyama[1], Tohru Iseto[1], Yasumi Toyoda[1], Miki Morioka[1], Makoto Ito[1]

1. Japan Agency for Marine-Earth Science and Technology

JAMSTEC[*1] publicly distributes samples and data obtained by JAMSTEC-AORI[*2]-JURCAOS[*3] Cooperative Research Cruises [1], as well as those by JAMSTEC private/open-call cruises, through online database (DB) websites, for additional uses with research/educational purposes. These online DBs are, from a long-term perspective, under a process of reorganization and integration: Public-level information systems for rock and sediment core samples were integrated into DARWIN DB [1] in FY2017. As for marine biological samples, whose information has been mainly distributed through “Marine Biological Sample DB [3], a part of information is already shared with DARWIN to utilize its search/map functions.

DB integration is in progress for not only public-level but also management-level information system, which are operated by sample holders responsible for storage of physical samples. In FY2018, JSDB (JAMSTEC Sample Management Database) is installed for the management of JAMSTEC rock, sediment core and biological samples, and actual data was transferred into this new system in FY2019. For rock and sediment core samples, information forwarding from management-level system (JSDB) to public-level system (DARWIN) is planned to be established in the near future.

JSDB consists of data tables for sample matadata information for onboard sampling activities, sample archive information for status and storage of physical samples, associate data information for various data obtained for samples, literature information for published documents, sample distribution information for service logs for sample requests. User authorization includes group setting, enabling individual sample holders outside Data Management Office to read, create and modify the information in an appropriate manner, although the DB is only accessible from inside JAMSTEC because of security reasons. Associate data information is supposed to include various data types, such as photos/images, text-based descriptions, spread-sheets and URLs etc., and open/close status control and group-setting are available for individual entries. Information for research proposals/projects or other data management issues, which should be associated with multiple samples, can also be managed as associated data information. For the future possibility of involvement with IGSN, sample metadata entries and their vocabulary are reorganized to follow the IGSN Descriptive Metadata [4], as much as possible.

Peoples involved in sample and data management tend to spend much effort for dealing with unusual conditions/situations which are not originally expected. Robustness is important for design/operation of information systems, because lack of flexibility and too much complexity of information systems are frequent causes of such kind of problems.

Improving the Reusability of Data and Sample Obtained JAMSTEC's Research Vessels and Submersibles

*Kazuyo Fukuda[1], Hajime Kawakami[1], Hiroki Horikawa[1], Tomoki Sasaki[1], Takako Sato[1], Takayuki Tomiyama[1], Makoto Ito[1], Yasumi Toyoda[1], Hideaki Saito[1], Chizuru Saito[1]

1. Japan Agency for Marine-Earth Science and Technology

Japan Agency for Marine-Earth Science and Technology (JAMSTEC) has been disseminated information of data and samples obtained by JAMSTEC's research vessels and submersibles via some databases. The core database is the Data and Sample Research System for Whole Cruise Information (DARWIN, http://www.godac.jamstec.go.jp/darwin/e). DARWIN provides information of more than 2000 cruises and 6500 dives, and its related observation data and geological sample. Each cruise or dive information page of DARWIN has links to related contents such as biological sample, deep-sea image, cruise report and data book provided by another databases.

In this poster, we will introduce some examples of efforts to improve the reusability of data and sample described above.

- Assignment of Digital Object Identifier (DOI): DOIs have been assigned to more than 2000 research cruises information from the early 1980s onward to promote data citation. A granularity of DOI is a research cruise information page defined as a cruise ID at this time.

- Specification of Data Policy: DARWIN has been treated data and samples based on only JAMSTEC data policy until FY2018’s research cruises. Currently, the applicable policy is dependent on type of cruise because the cooperative research cruises have been started since FY2019. DARWIN has been updated to display of an applicable policy on each information page clearly. The function is also available to add to another policy in the future.

- Data Rescue: A cruise report is a prompt report that includes the purpose of the cruise, information about what kind of observation was done, how it was done and the results. Cruise reports for past research cruises have been found when moving laboratory and submitted to the Data Management Group. The reports have been scanned and saved as individual PDF to store for long-term and prepare for publication. A part of them with Principle Investigators' consent have been disseminated step by step.

Activities toward research data management at NIES/CGER

*Yoko Fukuda[1], Chisato Wada[1], Yasuhiro Tsukada[1], Jiye Zeng[1], Tomoko Shirai[1]

1. National Institute for Environmental Studies

The Center for Global Environmental Research (CGER), National Institute for Environmental Studies (NIES), has been managing and operating the Global Environmental Database (GED) since May 2014 as a platform for publication and search of data focusing on global environmental research including global warming. DOIs have been assigned to research data sets since 2016, and data have been regularly updated. Nowadays, more and more academic publishers ask authors to publish data used in papers online. Inquiries regarding the publication and DOI minting of evidential data and submissions to data journals are increasing at NIES/CGER. In addition, funding agencies are starting to request researchers to submit a research data management plan that contains policies for storing, managing, and sharing of research data and where to store them when they will be opened. There is an increasing demand to develop a persistent system to store and manage research data.
NIES/CGER has developed a research data management system (RDMS) as a data management platform so that researchers and research assistants can efficiently perform routine research data management and preparation for data publication. The RDMS mainly provides functions to support creating metadata which are essential to search and utilize datasets, versioning, DOI minting and licensing. Research data and metadata registered in the RDMS can be promptly released through GED using a back-end database shared by the RDMS and GED. “Public” or “private” can be set for each data file so that users can also manage private datasets in the RDMS. Access users can also be set for each dataset so that multiple members involved in a project can cooperatively manage their datasets and share update histories. When a user logs in to the RDMS, a list of datasets that the user can access is displayed, and the status indicating the work progress is displayed for each dataset. Moreover, users can visualize research data on a quick plot tool, with which they can set graph types, display parameters, display ranges, and axis titles. In this presentation, we introduce the RDMS and GED currently under development.

[M-GI37] Integration of Earth Observations and Multiple Use for Earth Science and Benefits to Societies - GEO

convener:Hiroyuki Muraoka(River Basin Research Center), Kentaro Ando(Japan Agency for Marine and Earth Science and Technology), Osamu Ochiai(Japan Aerospace Exploration Agency), Shinichi Sobue(Japan Aerospace Exploration Agency)

Earthquakes and tsunamis, floods and drought, environment deterioration and pollution, global warming and island losing, and ecosystem degradation endanger the security of water, food, energy, health and ecosystem services. To confront these challenges, there is a demand to foster its application capacity and to develop integrated, sharable, and sustained observation systems. Group on Earth Observations (GEO) is a partnership of 107 national governments including Japan and 132 Participating Organizations that envisions a future where decisions and actions for the benefit of humankind are informed by coordinated, comprehensive and sustained Earth observations. There is a unique regional activity focusing on the Asia-Oceania (AO) region which poses big challenges to the society with its large population, various and fast environmental changes and frequent natural disasters. To develop such capacity, it is necessary to promote a regional cooperation on earth observation with various communities. AOGEO aims to foster regional application activities focusing on water security, biodiversity, carbon and greenhouse gas, ocean and islands, and food security, etc. It is also seeking data sharing, Open Data Cube for AO region and user engagement and communication.
This session aims to 1) introduce the current status of data integration efforts in GEO and AOGEO, 2) engage any contributions of similar activities from outside of GEO and AOGEO, and 3) activate GEO and AOGEO activities and its related activities via any submissions and contributions of analysis of earth observations both from integrated data and single unique data on the earth science and societal applications. We seek submissions which include a) scientific researches by use of earth observation data from various platforms including satellite and in-situ, b) development of new data sets for national, regional and global analyses, and c) development of data integration platform and its broad application.

Biodiversity and ecosystem observations by Asia Pacific Biodiversity Observation Network (APBON)

*Hiroyuki Muraoka[1], Yayoi Takeuchi[2], Takehisa Yamakita[3], Yuichi Kano[4], Shin Nagai[3], Sheila Vergara[5], Eun-Shik Kim[6], Tetsukazu Yahara[4,7]

1. Gifu University, 2. National Institute for Environmental Studies, 3. Japan Agency for Marin-Earth Science and Technology, 4. Kyusyu University, 5. ASEAN Centre for Biodiversity, 6. Kookmin University, 7. Kyusyu Open University

The Asia-Pacific (AP) Region encompasses 28 million square kilometers of land area, which is approximately 22 percent of the total global land area, across over different climatic conditions, rich natural resources, and diverse culture. Also, the region contains some of the longest rivers and extensive deltas in the World, the majority of continental and oceanic islands, various coastal ecosystems including mangroves and coral reefs, and large portions of the Pacific Ocean and the Indian Ocean (IPBES 2018). The region account for approximately 54% of global population (UNEP 2016) and hosts 13 of the total 35 biodiversity hotspots and accounts for nearly one third of all the threatened species in the world (CEPF 2015). Having entered the “Asian Millennium,” many countries in AP region are now rapidly growing their economies and social infrastructures. This development is causing the rapid loss of Asian biodiversity, and thus prompting work toward achieving a more sustainable balance between development and conservation is a highly urgent task in the region (IPBES 2018). These circumstances call for interactions and partnerships that will integrate available information, appropriately document those that are being discovered and promote the exchange and use of such information in biodiversity conservation and policy development. Asia is now regarded by many scientists as the most biotically threatened part of the planet, yet to mediate this loss further data is needed to develop baselines on biodiversity and assay patterns of diversity and threat. Science is expected to play a leading role in the area of biodiversity, including characterizing the biodiversity of various areas, clarifying ecosystem services supplied to society, quantifying how rapidly biodiversity is being lost, and justifying needs and identifying possibilities for conservation and sustainable use of biodiversity.

The AP Biodiversity Observation Network (APBON) was established in order to network institutions and research groups in AP region that contribute to and utilize a knowledge resource base for decision making and policy for the conservation of biodiversity and ecosystems. It was launched in 2009, by responding to Biodiversity Observation Network under the Group on Earth Observations (GEO BON) in 2008. Since then, APBON aimed at promoting biodiversity monitoring and contribution to sound decision-making based on scientific knowledge. To do so, APBON facilitates the organization of and periodically convenes a regional network of biodiversity observation institutions to maintain a knowledge base that will support biodiversity conservation. APBON focuses on terrestrial, freshwater and marine systems to develop the observations and ecosystem service assessment.

In this paper we review how APBON has achieved developing networks; we have facilitated the communication and interaction opportunities inter-/intra- researchers and stakeholders through workshops and publications. APBON successfully developed as a network of biodiversity scientists belonging to many institutes of AP region (Yahara et al. 2014). APBON has also contributed to networking biodiversity-related bodies and programs including CBD, GBIF, IUCN, International Long-Term Ecological Research–East Asia–Pacific Regional Network (ILTER-EAP) and Asia Oceania GEO (AOGEO). The multidisciplinary efforts in APBON also contributed to develop a strategy for the Earth observation for biodiversity monitoring by connecting in-situ and satellite observations. We also developed tools for data

©2020. Japan Geoscience Union. All Right Reserved.

collection, sharing, analysis, and synthesis for further observations and capacity building. Contributions to carrying out assessments such as IPBES, which contributed to improving ecosystem management and sustainable use of biodiversity, are also highlighted.

Ocean data networks and its utilization in Asia-Oceania region - challenges in AOGEO

*Kentaro Ando[1], Andy Steven[2], Aidy Mohamed Shawal M Muslim[3], Danling Tang[4], Fumihiko Akazawa[1]

1. Japan Agency for Marine and Earth Science and Technology, 2. Commonwealth Scientific and Industrial Research Organisation, 3. University Malaysian Terenganu, 4. South China Sea Institute of Oceanography

Ranging from the mountaintops of the Himalaya to small atoll nations in the Pacific Ocean, the Asia-Oceania (AO) region encompasses two-thirds of the world's population, that live in more than 60 countries that vary in size, economy, development status and environmental condition. With continuing development, particularly urbanization, the AO region is subject to rapid and widespread environmental changes that result in environmental deterioration, habitat and biodiversity loss and pollution that even reaches to the farthest waters for the Pacific. Sustainable development must therefore be based on a comprehensive assessment of disaster and environmental risks, along with their potential ramifications for environmental security and human well-being.

Thus, the Group of Earth Observation (GEO) has developed a new regional initiative, Asia Ocean GEO (AOGEO), that seeks to exploit coordinated access to earth observations to support sound decision-making at local, national and regional scales.

Under the AOGEO, the “Ocean, Coasts and Islands Task” promotes better access to marine data through: interoperability of data such as catalogues of state owned-data; standardization of in situ and satellite data through the development and application of standards including Analysis Ready Data (ARD), that provide confidence and consistency, and to better validate satellite based marine and coastal products by applying in-situ observation for calibration, validation and algorithm processing. OCI continues to build upon its user-engagement activities with Oceania states to provide capacity building and training, develop regionally-specific best-practice EO methods and products that are useful to these communities in addressing climate, environment and livelihood issues.

Multidisciplinary efforts towards regional to global scale CO_2 budget estimation

*Kazuhito Ichii[1], Masayuki Kondo[1], Prabir Patra[2], Nobuko Saigusa[3], Josep Canadell[4]

1. Chiba University, 2. Japan Agency for Marine-Earth Science and Technology, 3. National Institute for Environmental Studies, 4. Commonwealth Scientific and Industrial Research Organisation

The estimation of greenhouse gas (GHG) emissions and removals from the country to the global scales is essential to assess progress towards the goals of the Paris Agreement. The “global stocktake”, specifically aiming to track such progress, provides an important opportunity for the scientific community to contribute towards the development of key indices and measures. The development of country-scale CO2 budgets are one of such measures. In the Asia-Oceania GEO (AO-GEO) framework, Taskgroup-3: Carbon and GHG Monitoring is expected to contribute to the development of greenhouse gases budgets.

In this presentation, we will show the current activities on this Task group. In particular, we will report on the refinements of both top-down and bottom-up estimate approaches, high-level syntheses , and application of recently available new observation datasets to better understand and constrain carbon budgets at the country, continental, and global scales.

Keywords: Carbon cycle, Synthesis, Paris Agreement

[M-AG42] CTBT IMS Technologies for Detecting Nuclear Explosion and Their Applications to Earth Science

convener:Ozel Nurcan Meral(Comprehensive Nuclear-Test-Ban Treaty Organization), Hiroyuki Matsumoto(Japan Agency for Marine-Earth Science and Technology), Noriko Kamaya(Earthquake Research Institute, The University of Tokyo), Yosuke Naoi(Japan Atomic Energy Agency)

The Comprehensive Nuclear-Test-Ban Treaty Organization (CTBTO) was founded in 1996 in response to the adaption of the Treaty in 1996 by the United Nations General Assembly, which bans nuclear explosions on the Earth's surface, in the atmosphere, underwater and underground. The Treaty has a unique and comprehensive verification regime to make sure that nuclear explosion goes detected. The regime is supported by International Monitoring System (IMS) composed of the four state-of-the-art technologies; 1) Seismic, 2) Hydroacoustic, 3) Infrasound, and 4) Radionuclide, by the International Data Centre (IDC), and by the On-Site Inspections (OSI).
IMS will, when complete, consists of 337 facilities worldwide to monitor the planet for signs of nuclear explosion. Around 90 % of the facilities are operational and sending the data to the IDC in Vienna, Austria.
The huge amount of data collected by the IMS network can be used for other purposes such as civil and scientific applications in addition to detecting nuclear explosions. For example, they can provide Tsunami Warning centers with near real-time information about an underwater earthquake. The data could also help better understand of earthquakes, volcanoes, oceans, climate change, and other issues on our planet.
This session will provide the overview of the IMS, the scientific discussion on each technology, and its outcomes. The session strongly welcomes young scientists and engineers who are interested in four IMS technologies.

Overview of Integrated Operational Exercise conducted under CTBT national operational system in Japan.

*RYOHEI EMURA[1], Takayuki Otsu[1], Masashi Motohashi[1], Toyomi Sakamoto[1], Soshi Iwata[1], Takanari Fujii[1], Mami Nogami[1], Makiko Iwakuni[1]

1. Japan Weather Association

Japan Weather Association (JWA) is working as the Comprehensive Nuclear-Test-Ban Treaty (CTBT) National Data Centre-1 (NDC-1) of Japan. JWA is in charge of analysis on waveform data, operation and maintenance of seismic and infrasound stations in Japan as for Station Operator (SO).
NDC-1 has two main roles of 1: Collect and analyze waveform data related to seismic and infrasound waves and provide advice from a technical perspective and 2: Operation and maintenance of monitoring facilities of the International Monitoring System (IMS) (8 sites in Japan)
As a part of the provisional operation at NDC-1, in cooperation with the Secretariat and NDC-2, integrated operation exercises with continuous monitoring for one week are conducted a few times per a year. The purpose of these exercises is to contribute to the training of analysts, as well as to catch up issues and problems in automatic seismic wave monitoring system operation and manual analysis operation. It also aims to verify the analysis results by an automatic system and by analysts.
Assuming a nuclear test monitoring activity during the full operation of NDC-1, the test operation of the automatic seismic wave monitoring system is performed, and if the occurrence of an event is suggested within the preset monitoring target areas, the analyst conducts a detailed analysis and closely examines the location and characteristics of the event (whether or not it is an explosion event). In addition, we summarize exercises results, verify analysis results, and extract issues after ending integrated operational exercise.
Furthermore, in order to address the issues and problems that became apparent through the integrated operation exercises, monitoring techniques and analysis methods have been improved. The results of studies on improvement and advancement of monitoring technology and analysis methods will be reflected in the various systems in operation. It will be verified through the next integrated operation exercise.
In this presentation, we will also introduce the approaches including cooperation with the Secretariat and NDC-2.

Keywords: CTBT, National Data Centre, seismic, waveform analysis, event discrimination analysis

Contribution of the hydroacoustic hydrophone stations of the International Monitoring System to natural disaster mitigation

*Hiroyuki Matsumoto[1], Mario Zampolli[2], Georgios Haralabus[2], Jerry Stanley[2], Nurcan Meral Özel[2]

1. Japan Agency for Marine-Earth Science and Technology (JAMSTEC), 2. Comprehensive Nuclear-Test-Ban Treaty Organization (CTBTO)

In-situ data recorded by the water-column hydrophones of the hydroacoustic (HA) stations of the International Monitoring System (IMS) of the Comprehensive Nuclear-Test-Ban Treaty (CTBT) are examined. The main objective of this study is to share the knowledges and understand how the IMS HA facilities contribute to natural disaster mitigation through the examination of in-situ data of the IMS hydrophones. The first part of the presentation is focusing on the detectability of tsunami by the IMS hydrophones. Data of the IMS hydrophones station HA11, Wake Island (U.S. Territory) at the Tohoku, Japan earthquake in 2011 are examined. The HA11 station which is about 3100 km southeast from the source area could detect tsunami signals in addition to T-phase associated with the main shock. It is evidenced that the theoretical dispersion curve of surface gravity wave follows the dispersive feature recorded at the frequency range less than 10^{-2} Hz. The similar result could be obtained at HA03, Juan Fernandez Islands during the Chile earthquake in 2015. These instances suggest that the tsunami signals can be identified by the water-column hydrophones at the time when tsunami propagates over the IMS hydrophone stations. The second part of the study is focusing on the hydroacoustic signals originated from the submarine eruptions of Ioto, a volcanic island of Japan. Cross-correlation analysis is applied to the hydrophone triplet data of HA11, about 2700 km away from the volcano to estimate the direction-of-arrival (DOA) of hydroacoustic signals of the entire period of September in 2018. Volcanic seismicity based on the on-site observation had become higher than usual, and discolored waters and a splash were observed nearshore by a local flyover during this period. Although hydroacoustic signals associated with seismic activities in the Pacific region are usually apparent, it is possible to discriminate between Ioto volcanic activity and other seismic activities based on the DOA. Our analysis suggests that about three-fourth of detectable hydroacoustic signals were associated with the submarine eruptions of Ioto. The analysis of hydroacoustic data recorded at the IMS hydrophone station HA11 shows that the remote hydrophones appear to be capable of detecting and identifying signals from submarine volcanic eruptions at distances of 1000’s of kilometers.

Detection of hydroacoustic signals associated with the 2015 Torishima volcanic tsunami earthquake

*Hiroko Sugioka[1], Natsuo Nemoto[1]

1. Kobe University

On 2015 May 2, a submarine earthquake occurred underneath the Smith Caldera near Torishima on the Izo-Bonin arc, Japan. The occurrence of such earthquakes is quasi-regular, approximately every 10 years, always accompanying anomalously large tsunamis. The focal mechanism is always a type of non–double couple known as compensated linear vector dipole (CLVD) with the vertical T axis. The moment magnitude is always 5.6 to 5.7. Most CLVD earthquakes with a vertical T (or P) axis have been reported at active volcanoes on land or on an island but not under the sea. The Torishima earthquakes are unique in that they are submarine CLVD events accompanying anomalously large tsunamis (Satake and Kanamori, 1991; Kanamori et al., 1993) and successive T-wave trains (Sugioka et al., 2000). Its mechanism of the 2015 earthquake was estimated as a CLVD with vertical opening of the shallow horizontal tensile fault (Fukao et al., 2018).

We calculated the autocorrelation function of data recorded on hydrophones of the Dense Oceanfloor Network system for Earthquakes and Tsunamis system (DONET) to improve the noise to signal ratios. We extracted significant hydroacoustic signals at the frequency of around 1.3 Hz associated with the 2015 Torishima volcanic tsunami earthquake.

[M-AG43] The Application Usability Level (AUL): A Standard Measure of Progress to Benefit Space Research

convener:Jeffrey Klenzing(NASA Goddard Space Flight Center), Adam C Kellerman(University of California Los Angeles), Brett A Carter(RMIT University), Tam Dao(Geospatial Center, RMIT University)

As space physics becomes both more interdisciplinary and more intertwined with commercial and government operations, there has risen a need for improved communication between different groups, and a system for tracking the progress of a project towards the specific application for a given user. The Application Usability Level (AUL) framework was developed precisely for this task, and in addition, encourages publication of instrument-like papers for delivering and publicizing AULs to help the community quantify the progress of successful applications, metrics, and validation efforts.

In a given project within the AUL framework, there is typically a diverse eco-system of individuals necessary to ultimately produce a useful space weather product or productive research collaboration. For example, in the case of non-academic fields, users and researchers alike may benefit from a translator, i.e. a broker, who may help with the effective transition from research to operations. Independent validators are another essential player for validation efforts and comparing like products for a specified application. In many cases the different players throughout the process will act in multiple roles as well as act in different roles for different projects and AUL pathways.

We invite papers to this session that show projects which are using the AUL framework, have found new research and applications through transdisciplinary interactions, or describe how a project moves through this eco-system and the players involved.

To improve communication between space weather research groups and radio propagation users, the radio propagation subgroup was started in the A01 group (Space Weather Forecast System) under the PSTEP (Project for Solar-Terrestrial Environment Prediction) umbrella in early 2016. Day-to-day bottom side variation of ionosphere has great influence on availability and integrity of radio waves in high frequency (HF, 3-30 MHz) band. We, therefore, developed the HF propagation simulator that is capable with the realtime realistic ionospheric information. The simulator name is HF-START (HF Simulator Targeting for All-users' Regional Telecommunications).

Recently, the HF-START web tool has been being prepared for public users. We have been working toward a development of a near realtime service. No prerequisite on space weather knowledge is required to use the HF-START web tool. The HF-START web tool will have a closed test service within NICT from March 2020. Its service will be opened to the public later. We open for international collaboration to gain global competitiveness on the service.

The prediction of Equatorial Plasma Bubbles (EPBs) on a daily basis is an ongoing scientific challenge, despite decades of observations and research. Various methods for predicting the onset of EPBs have now been developed, however the research community is yet to investigate the methods for which these prediction models and techniques can be meaningfully evaluated and compared. Various assessment metrics, including percentage correct (PC), the Heidke Skill Score (HSS) and the True Skill Statistic (TSS), have been reported for space weather predictions, but the validity of their use for the purpose of EPB prediction assessment has yet to be investigated. In this study, 12 months of co-located GPS and UHF scintillation observations from locations spanning South America, Atlantic/Western Africa, Southeast Asia and Pacific sectors is used to evaluate the Generalized Rayleigh-Taylor (R-T) plasma instability growth rates calculated from the Thermosphere Ionosphere Electrodynamics General Circulation Model (TIEGCM). As part of this analysis, the limitations and caveats in using various assessment metrics are explored. In particular, the impact of employing significance testing on skill scores as a means of selecting thresholds is demonstrated. The sensitivity of the HSS, TSS and the Odds Ratio Skill Score (ORSS) to dataset type (i.e., GPS versus UHF) and dataset size (30, 50, 60 and 90 days/events) is also investigated, and it is shown that when a minimum of 50 days is used then the resulting TSS and ORSS values are similar. Further, it is shown in this analysis that to achieve statistically significant TSS and ORSS values 50 days/events are required. To investigate methods for conducting model-model comparisons, the TIEGCM R-T growth rate is compared to the ‘persistence’ forecast using the ORSS, but it is shown that the levels of 95% significance do not clearly indicate which model/method is higher quality. To that end, the concept of forecast ‘sufficiency’ is used as a direct comparison between the TIEGCM R-T growth rate the persistence forecast, and the results were found to be mixed across the different stations and EPB seasons. Importantly, throughout most of the datasets, these EPB prediction techniques were found to be of comparable quality (i.e., ‘insufficient for each other’). In this analysis, a valuable lesson learned is that it is important that the observation dataset exhibits an appropriate level of daily EPB variability in order to be used as a valid model/technique evaluation. The UHF observations from South America tended to show little daily variability in this analysis, therefore preventing any conclusive model-model comparison. Recommendations for how to meaningfully use skill scores and ‘sufficiency’ to track EPB forecast model/technique progress are given.

Sami2py is a python module that runs the SAMI2 ionospheric model, as well as archives, loads and plots the resulting modeled values. SAMI2 is a model developed by the Naval Research Laboratory to simulate the motions of plasma in a 2D ionospheric environment along a dipole magnetic field [Huba et al, 2000]. SAMI2 solves for the chemical and dynamical evolution of seven ion species in this environment (H^+, He^+, N^+, O^+, N_2^+, NO^+, and O_2^+). The python implementation allows for additional modifications to the empirical models within SAMI2, including reduction of the exospheric temperature in the NRLMSIS thermosphere and the input of custom ExB ion drifts.

The code is open source and available to the community on github. As part of the Application Usability Level (AUL) framework, we will discuss the usability of this code in terms of simple ionospheric applications, including as a core dependence of the “growin” project.

[M-AG45] Satellite Land Physical Processes Monitoring at Medium/High/Very High Resolution

convener:Jean-Claude Roger(University of Maryland College Park), Shinichi Sobue(Japan Aerospace Exploration Agency), Eric Vermote(NASA Goddard Space Flight Center), Ferran Gascon(European Space Agency)

We solicit papers on the land physical processes monitoring. In particular, it will include the inversion and use of land products from medium, high, and very high spatial resolution. For the last years, medium, high, and very high resolutions became a useful and a powerful toll for Earth studies. Topics of interest mainly include (not limited to):- New developments for data processing, including atmospheric correction and cloud screening;- Analysis and correction of directional effects in land surface reflectances;- Use of time series of surface reflectances for land monitoring, including land cover classification and crop yield prediction (including data integration and data harmonization);- Development and use of new vegetation indices (i.e. red edge) and other products for agriculture applications;- Theoretical studies for sensors capabilities enhancements to future sensors at high/medium resolutions;- Use of products in agricultural monitoring applications (such as crop area, crop type, crop growing, yield estimation and prediction, damage assessment);- Agriculture monitoring algorithm description;- Evaluation or validation of potential products with ground measurements, official statistics;- International initiative to enhance Earth-Observing-based agricultural information.Depending on outcome, we think about a special issue.

1. NASA Goddard Space Flight Center, 2. University of Maryland, Dept. of Geographical Sciences

Surface reflectance is one of the key products used in developing several higher-order land products, such as Vegetation Indices, Albedo and LAI/FPAR, it is therefore seminal to detecting trends in the biosphere and land surface and has been classed by NOAA as a “Fundamental Climate Data Record (FDCR) for Land”. Building a long-term surface reflectance data record of climate quality implies combining different instruments, sensors and satellites, accounting for different spatial resolutions and spectral characteristics, assuring consistent calibration, and correcting for atmospheric and directional effects. As the spatial resolution issue is addressed by aggregating the original data to a resolution still suitable for climate studies (e.g. 0.05 degree latitude, longitude), the instrument calibration becomes the first major hurdle one has to go through before being able to proceed any further.

In this work, we are using robust reflectance data records and inter-comparison methods that we have developed over the past several years (consisting of atmospheric correction, directional effect correction and spectral normalization) to establish and verify the inter-consistency of the reflectance products from the AVHRR sensors on-board NOAA 7, 9, 11, 14, 16, 17 and 18, the MODIS sensors on-board Aqua and Terra and the VIIRS sensors on-board Suomi-NPP and JPSS1 as well as OLCI/SLSTR from Sentinel 3. These approaches are also applied to high spatial resolution dataset from Sentinel 2A and 2B and Planet Lab.

Mapping and analysis of irrigation water quality index of Hisar district Haryana, India by using Surfer Software

*shilpa singh[1], Amit Kumar[1], Yogesh Pandey[1], JAHANGEER -[2]

1. SKUAST- Kashmir, 2. University of Nebraska

An investigation is carried out to analyze the underground water quality of 26 villages in Hisar for their quality parameters and comprehensively arriving at a single water quality index. The irrigation water samples were collected manually from the bore wells which are approximately equally distributed all over 26 villages of Hisar. The samples were analyzed using standard procedures in the laboratory (APHA, 1985). The parameters analyzed during the analysis are pH, EC, Chlorides, Calcium, Magnesium representation of irrigation water quality attributes using SURFER 7.0 for individual as well as weighted water quality index. From the investigation, it is clearly evident that the groundwater of the area needs some degree of treatment before consumption. Based on the investigations carried out, it is observed that Saharwa, Kanwari, Lakhpul, Kinala, Adampur, Chanotl and Bhaganal villages contain water quality very poor for irrigation purpose due to over salt accumulation. Necessary measures are to be taken to gain safe irrigation and drinking water to the people living in the villages. Total hardness was found to be very high in Kanwari and Lakhpul villages. Very high concentrations of chloride, calcium and magnesium were found in Mangali, Sisai , Salemgarh and Balaws villages. The water quality is good in Lawda, Bagla, Madha, Parba, Sarsod, Rajli, Siswal, and Dahima villages based on water quality index. The qater quality was found moderately food in Sundawas, Moth Rangran, Parbhuwala, Lohari Ragho and Masudpur villages.

The land surface reflectance is a fundamental climate data record at the basis of the derivation of other climate data records (Albedo, LAI/Fpar, Vegetation indices) and has been recognized as a key parameter in the understanding of the land-surface-climate processes.

This work relies on a generic approach developed to derive surface reflectance over land from a variety of sensors. The approach is based on the inversion of the radiative transfer equation in the Lambertian case, with no adjacency effects, that account for a simplified coupling of the absorption by atmospheric gases and scattering by molecules and aerosols as implemented in the 6SV radiative transfer code. The processing code relies on look-up tables generated by 6SV, for which the accuracy (~1%) has been well documented in several papers. The LaSRC code uses ancillary data such as pressure and gas concentrations but relies on a per pixel inversion of the aerosol properties to assure the best possible accuracy for the surface reflectance, as aerosols can be highly variable both in space and time. This new aerosol inversion builds on the extensive dataset acquired by the Terra platform, combining MODIS and MISR to derive an explicit and dynamic map of band ratio’s between blue and red channels and is a refinement of the operational approach used for MODIS and LANDSAT over the past 15 years. The aerosol inversion is generic and applicable to a variety of sensors. We use this basic approach to derive Landsat 8 and Sentinel 2 surface reflectance products for medium, high and very high spatial resolution (MODIS, VIIRS, LANDSAT, SENTINEL-2, WORLD VIEW 3…). The validation scheme is based on using aerosol models developed for each AERONET sites. We will present here the methodology to get these models. We will also show comparison of surface reflectance products with field measurements done by an instrument developed by us.

Finally, we will presents performances of LaSRC inter-compared with other operational approaches in the framework of the CEOS-ACIX (Atmospheric Correction Intercomparison eXercise) Calibration Validation Task co-Lead by ESA and NASA.

AVHRR LTDR product cloud and snow mask using Support Vector Machines

*Jose Luis Villaescusa[1,2], Eric Vermote[2], Jean-Claude Roger[1,2], Belen Franch[3,1], Sergii Skakun[1,2]

1. University of Maryland College Park, 2. NASA Goddard Space Flight Center, 3. Universitat de Valencia

The Advanced Very High Resolution Radiometer (AVHRR) sensors aboard the different NOAA satellites provide a unique global remote sensing dataset that ranges from the 1980s to the present. Using these data, the NASA funded Long Term Data Record (LTDR) project aims to develop a quality and consistent Climate Data Record (CDR) of AVHRR data with the use of the Moderate Resolution Imaging Spectrometer (MODIS) instrument as a reference. The current product uses a simple climatology approach using the red band to mask clouds from land and has no internal algorithm to discern cloud from snow. Previous studies using AVHRR data make use of MODIS climatology or multispectral threshold techniques. In this study we aim to use both approaches to better detect clouds and snow. We do this by assigning a probability of belonging to each class according to the distance of each pixel to the average climatology MODIS pixel, and to the multispectral clusters obtained using MODIS bands analogous to AVHRR. These distances are then treated as independent variables in an SVM classification that best selects the threshold to increase the separability of the classes. First, this approach is tested on MODIS data, and then applied to AVHRR. The main objective is to increase the overall accuracy of the classification, since errors in the cloud/snow mask have a significant impact on accurately determining global long-term trends of level-2 parameters such as surface albedo and have a direct impact on the Earth’ s radiative forcing.

Winter wheat yield assessment from Landsat 8 and Sentinel-2 data

*Sergii Skakun[1,2], Eric Vermote[2], Belen Franch[1,3], Jean-Claude Roger[1,2]

1. University of Maryland College Park, 2. NASA Goddard Space Flight Center, 3. University of Valencia

Combination of data acquired by Landsat 8 and Sentinel-2 remote sensing satellites can provide high temporal resolution globally (3-5 days) (Li & Roy, 2017), which is critical for various applications requiring dense data time series. Previously, such (or better) high temporal resolution at global scale was available mainly for remote sensing sensors, which acquire daily data over Earth’ s surface, but at coarser spatial resolution (> 250 m) (Justice et al., 1998, 2013). The latter, for example, includes space-borne remote sensing sensors, such as MODIS, VIIRS, AVHRR, SPOT-VEGETATION. Taking into account an increased frequency of observations at moderate spatial resolution (<30 m), the assumption is that methods and models developed for generating products for coarse spatial resolution sensors can be ported to moderate spatial resolution sensors (Landsat 8/OLI, Sentinel-2/MSI). However, the practice shows that such transition is not always straightforward due to larger data gaps because of clouds and uneven coverage, sensor characteristics and increased spatial resolution (at least at the order of 10, when going from 250 m to 30 m).

Consider a crop yield assessment/forecasting application (Becker-Reshef et al., 2010a). The hypothesis is that satellite-based features, such as vegetation indices (VIs) or biophysical parameters derived at a single date or accumulated over some time period, can be correlated to crop yields (Johnson 2016, Meroni et al., 2016). Since the reference data on crop yields are mainly available at regional scale, the corresponding empirical models are built by averaging satellite-based features over those regions and correlating these derived variables to crop yields (Becker-Reshef et al. 2010b, Franch et al., 2015; Kogan et al., 2013). It is assumed that there is a homogeneity within the region in terms of crops grown and agricultural practices applied and, therefore, the averaging should be performed for satellite data acquired at the same (or approximately the same) stages of crop growth, meaning that the data are normalized. This is usually the case for coarse spatial resolution remote sensing sensors, which enable high likelihood of obtaining cloud-free data over the Earth’ s surface (Whitcraft et al., 2015a, 2015b). This is also evidenced by multiple successful applications of applying coarse spatial resolution satellite data to crop yield assessment and forecasting (Becker-Reshef et al. 2010b, Franch et al., 2015; Johnson 2016; Kogan et al., 2013; Kolotii et al., 2015; López-Lozano et al., 2015; Mkhabela et al., 2011).

However, this is not the case for moderate spatial resolution satellite data (<30 m). Irregular spatial coverage, when the area in question is covered by several “stripes” sensed at different times, and high revisit cycles lead to discrepancies in dates of cloud-free observations. Therefore, satellite data should be normalized for the further processing. Though a combination of Landsat 8 and Sentinel-2 offers high frequency of observations, discrepancies in available cloud-free data, however, will still exist. With more and more applications transitioning to a higher spatial resolution, it is important to explore and analyze the effect of those discrepancies on the quality of the resulting products. In the case of crop yield assessment, one of the important questions is as follows: How do discrepancies in dates of satellite observations influence the performance of empirical crop yield models at regional scale? The present study aims to address this question by documenting results of the study on building empirical models for winter wheat yield assessment with Landsat 8 and Sentinel-2 data in Ukraine. Through simulation modelling and analysis of real datasets, we show that satellite data normalization is critical in building robust crop yield models. Not performing satellite data normalization may lead to poorer performance of

©2020. Japan Geoscience Union. All Right Reserved.

the empirical crop yield model, which would be attributed not to the lack of correlation with satellite-derived variables, but rather to observation irregularities.

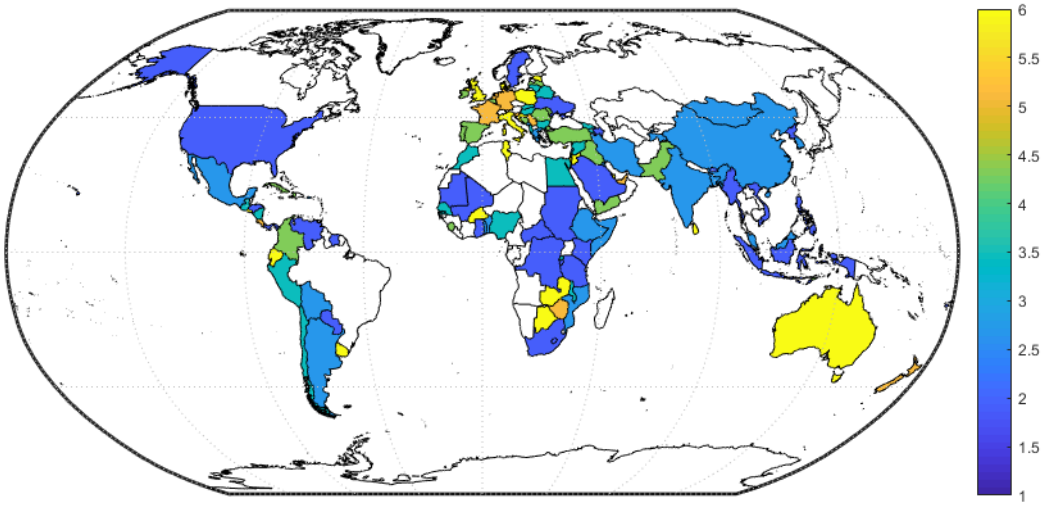
INDICATORS OF HIGH VARIABILITY COVER LAND with Landsat-8 and Sentinel-2

*Natacha kalecinski[1,2], Sergii Skakun[1,2], Jean-Claude Roger[1,2], Eric Vermote[2]

1. Department of Geographical Sciences, University of Maryland College Park, USA, 2. NASA Goddard Space Flight Center, Greenbelt, USA

In the actual context of constant increase in human population and climate warming, the land use is more than ever important for agriculture with issues like food production, irrigation, crop yield and fertilization. It is also important for forestry including various issues such as parasites spread, long term CO_2 storage or natural spaces near or inside large towns. The use of active and passive remote sensing from space allows us to have a better understanding of what is going on. The increase in satellite’s spatial and temporal resolutions offers an incredible tool which can be of great interest to study parameters at a national or continental scale.



The aim of this study is to find indicators of drastic change of agriculture land cover over the globe in the first step and for particular countries in a second step.

We propose a study to link key parameters of agriculture land cover modifications from human activity and meteorological events. Even if it is difficult to quantify the quantity of earth change in land use, different database were developed like the one from Food and Agriculture Organization (FAO). We defined significant proxies and parameters to identify drastic changes as a marker of social changes for different countries during these 10 past years. The proxies used are trend, ramp rate, ramp amplitude of area, production, yield and importation/exportation. We can define a number of drastic events in agricultural cover for each country. The study is concentrated around the grass feet for a part and the crop land in the other part with the 6 majors crop: Soybean, Wheat, Maize, Rice, Millet, Sunflower.

To study high variability at the country’s scale, we combined the use of Sentinel-2 and Landsat-8 normalized difference vegetation index (NDVI). In complement to satellites dataset, ground base dataset such as meteorological stations helps us to better understand key parameters which can be related to actual land cover. Several approaches as high urbanization area, stability versus conflicts, deforestation and meteorological hazards are explored to provide a wide field of vision of actual and future agricultural practice.

CAMSIS: An Automated System for the Validation of Surface Reflectance from High Spatial Resolution Sensors

Eric Vermote[2], Joel McCorkel[3], *Andrés Eduardo Santamaría-Artigas[1,2], William Henry Rountree[1,2], Sergii Skakun[1,2], Belen Franch[4,1], Jean-Claude Roger[1,2]

1. University of Maryland, College Park, 2. NASA Goddard Space Flight Center Code 619, 3. NASA Goddard Space Flight Center Code 618, 4. Universitat de Valencia, Spain

We present CAMSIS, an automated system for the validation of satellite surface reflectance products. The system is currently installed 120 meters above ground on a TV tower at the Chequamegon National Forest, WI, USA, and captures imagery in Blue (470nm), Green (550nm), Red (650nm) and Near-Infrared (850nm) wavelengths every 15 minutes. Raw imagery from the camera is calibrated to surface reflectance values using a 50% reflectance calibration target mounted on a motorized arm, which permits to protect the reference target while not in use. The calibrated imagery is georeferenced using very-high spatial resolution imagery from an aerial sensor and resampled to match the satellite data spatial resolution and grid. In this work, we present the comparison between CAMSIS calibrated data and 10 meter Sentinel-2 atmospherically corrected reflectance, derived by the LaSRC (Land Surface Reflectance Code) processor. Results for the Blue, Green, and Red bands show Coefficient of Determination (R2) values higher than 0.90 and Root Mean Square Error (RMSE) values close to 0.01. However, the NIR band show worse results with an R2 of 0.18 and an RMSE of 0.11, which suggests stronger Bidirectional Reflectance (BRDF) effects for this band that still need to be fully accounted for, especially for the pixel of forest areas. Results for the NDVI also show good agreement between S2 and CAMSIS, with an R2 of 0.86 and RMSE of 0.05. These initial results show that CAMSIS provides valuable information for continuous validation of high spatial resolution surface reflectance. Future research will focus on developing and implementing BRDF correction methods based on CAMSIS data.

[M-SD46] Effects of lightning, severe weather and tropical storms

convener:Mitsuteru Sato(Department of Cosmoscience, Hokkaido University), Yoav Yair(Interdisciplinary Center Herzliya), Xiushu Qie(Institute of Atmospheric Physics, Chinese Academy of Sciences), Yukihiro Takahashi(Department of Cosmosciences, Graduate School of Science, Hokkaido University)

Thunderstorms are markers of deep convection and severe weather, producing heavy precipitation, hail and strong winds that lead to significant natural hazards, especially in coastal and urban areas. Huge economic damages and loss of human lives often result from such events. As the intensity and frequency of thunderstorms is projected to increase in the future - when the atmosphere and oceans become warmer - the need for detecting and nowcasting thunderstorms and lightning on local and regional scales becomes crucial.
We invite contributions dealing with thunderstorms and lightning and their atmospheric effects. We seek contributions focusing on convective storm evolution, forecasting of thunderstorms and lightning using regional and global detection networks as well as other sensors. Also, works on global lightning patterns in an era of climate change, satellite-based studies of thunderstorms and other remote-sensing technologies, as well as urban effects on lightning and public safety from lightning danger.

Modelling of streamer ignition and propagation in the system of two approaching hydrometeors

*Victor P Pasko[1], Jaroslav Jansky[2]

1. Pennsylvania State University Main Campus, 2. Department of Mathematics and Physics, University of Defense, Brno, Czechia

The lightning initiation in low thundercloud fields represents an unsolved problem in lightning discharge physics. One of the initial conditions required for formation of a hot leader channel is initiation of non-thermal streamer discharges. Streamers can be initiated from electron avalanches, however, the problem of existence of an electric field strong enough for streamer initiation in thunderclouds is still open. The maximum electric field in thunderstorms measured by balloons is typically ~3-4 kV/cm/atm, that is significantly smaller than the breakdown electric field needed for avalanche multiplication of electrons Ek=28.7 kV/cm/atm. One of the possible explanations for the streamer corona initiation is that hydrometeors greatly intensify the local electric field by at least an order of magnitude to initiate an electron avalanche. It was suggested that a particle pair or chain create more favorable conditions for initiation of lightning discharge than a single precipitation particle in low electric fields. Recently, Cai et al. [GRL, 44, 5758-5765, 2017] and Cai et al. [JGR, 123, 7050-7064, 2018] analyzed the ignition conditions for two hydrometeors of same and different radii. In the present work we use first principles plasma fluid model to study streamer initiation scenarios in a system of two hydrometeors with typical radii on the order of several millimeters under thunderstorm conditions (i.e., at an elevated location in the Earth's atmosphere corresponding to half of air density at ground level and at applied electric field approximately half of that required for avalanche multiplication of electrons in air). It is demonstrated that UV photons produced by the electrical discharges developing due to the electric field enhancement in the gap between two hydrometeors and resultant photoionization in the discharge volume lead to much less stringent conditions for conversion of these discharges to a filamentary streamer form than in the case not accounting for the effects of photoionization. It is also demonstrated that this photoionization feedback [Naidis, JPD, 38, 2211-2214, 2005; Liu et al., JASTP, 80, 179-186, 2012] is critical for understanding and correct description of the subsequent streamer discharges developing on the outer periphery of two hydrometeors whose potential is equalized due to the electrical connection established by the initial streamer discharge between them. The initial streamer ignition between the hydrometeors can be preceded by the corona development, that can have detrimental effect on the ignition. However, it is demonstrated that for hydrometeors approaching with a speed of 10 m/s the effect of this onset corona is small.

Estimation of cloud base altitude using cloud images captured by all-sky camera

*Atsuya Nemoto[1], Hiroyo Ohya[2], Alessandro Damiani[3], Tamio Takamura[3], Toshiaki Takano[2], Hiroyuki Nakata[2]

1. Graduate School of Science and Engineering, Chiba University, 2. Graduate School of Engineering, Chiba University, 3. Center for Environmental Remote Sensing, Chiba University

Clouds may significantly affect the radiation budget and water cycles of the Earth by altering their various properties. Besides the cloud microphysical properties, the cloud base height, which is one of the important cloud macrophysical structures, is of particular significance for the infrared radiation at the surface. The cloud base height is also extremely important for air safety, airborne military activities, and surveillance operations [Vislocky and Fritsch, 1997]. Thus, an accurate method for estimating cloud base height may further improve our understanding for the impact of clouds on the Earth's radiation budget and provide useful information for improvement of aviation safety. Ground-based instruments, such as radars and lidars, can help obtain relatively accurate the cloud base height locally [Takano and Takamura, 2014]. However, they cannot provide the cloud base height information in wide area. The advantage of satellites is that high-resolution, two-dimensional distributions of the microphysical and macrophysical properties of clouds may be retrieved on a global scale [Huang et al., 2006]. However, the retrieval of the cloud base height is considerably complex and not directly available from satellite observations. Wilheit and Hutchison [2000] also proposed a method to retrieve the cloud base height by combining passive microwave brightness temperature and infrared cloud top temperature. However, these methods work mainly for special cloud types (e.g., relatively thin, stratiform, or convective clouds). In this study, we propose an estimation method of the cloud base height using a pair of cloud images observed by all-sky imagers at two sites. The advantage of all-sky imagers is to be cheaper than radars and lidars. The two all-sky imagers were installed on the roofs of Engineering Research Building 1 (35.6246N, 140.1037E) and 2 (35.6266N, 140.1040E) in Nishi-Chiba campus in Chiba University, Japan. The distance between the two all-sky imagers is 216 m. The all-sky imagers have equisolid angle projection method that cloud amount can be estimated with high accuracy. The estimation method of the cloud base height is described below. When the cloud base height is assumed in the range of 500-3000 m with step of 10 m, the two cloud images are projected to each map. Then we calculate cross-correlation between the two maps. When the cross-correlation coefficients take the maximum in the all cases, the cloud base height is determined. As a result, the cloud base heights were estimated to be 1330 m and 1370 m at 13:03:12 LT and 13:06:12 LT on 27 August, 2018, respectively. The cloud base height was observed to be 1830 m by a lidar installed by the National Institute for Environmental Studies (NIES) in the same campus in Chiba University at 12:45:00 LT. The difference of the cloud base height (about 500 m) could be caused by the time difference of observations (18-21 minutes). In addition, we estimated the cloud base height for two isolated clouds at 13:29:53 LT on 16 November, 2018. The cloud base heights were estimated to be 1950 m and 1850 m, respectively. The lidar measured a reflection altitude of 2160 m at 13:30:00 LT on the same day. There was a difference of about 200-300 m between them, because the cloud themselves observed by the all-sky imagers might be different from those observed by the lidar. In the session, we will compare between the cloud base height estimated by cloud images and that observed by the 95-GHz FMCW cloud radar FALCON-I that was originally developed by our group.

Variation of Phase Relation Between OLR in Western Pacific Warm Pool and the Equator

*Kambiz Torabi[1], Yukihiro Takahashi

1. Department of Cosmosciences, Hokkaido University

Linkage between the 11-year solar activity based on sunspot number and climate change of the Earth has been suggested by monthly or yearly averaged data, even though short periodic variation could modulate longer periodic phenomena. In pervious study, 27-day variation of Outgoing Longwave Radiation (OLR) during solar maximum year was found by Takahashi et al. (2010). Moreover, anti-phase relation between lightning around Marine Continent and OLR around Western Pacific Warm Pool region was found by Sanmiya et al. (2013).

Motivation of this study is that clarifying the phase relation of about one-month periodic variation of OLR in Western Pacific Warm Pool and the equator. We have performed cross correlation analysis between OLR in Western Pacific Warm Pool and the equator by using interpolated OLR data from NOAA. Western Pacific Warm Pool is known as correlating negatively with lightning around Marine Continent and typhoon-rich area. The equator is known as correlating positively with lightning around Marine Continent and typhoon-pool area. We will discuss about characteristics of variation of phase relation from 1974 to 2018 which includes 21st to 24th of solar cycle.

An observational study on thunder cloud activities over Tama, Tokyo based on atmospheric electrostatic field measurements - Case study for the hail storm event in May 4, 2019 -

*Jun-Ichi Hamada[1], Jun Matsumoto[1], Tomoshige Inoue[1], Masashi Kamogawa[2], Yukihiro Takahashi[3]

1. Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, 2. Global Center for Asian and Regional Study, University of Shizuoka, 3. Department of Cosmosciences, Graduate School of Science, Hokkaido University

In order to monitor lightning activities and development of thunder clouds, we have established an observational network with electromagnetic and electrostatic field measurements over the Tokyo metropolitan area since 2016. In the early summer and summer seasons of 2019, we observed atmospheric electrostatic field with the electric field monitor (BOLTEK ELF-100) at Hachioji campus of Tokyo Metropolitan University and the surrounding area. In the afternoon of May 4, 2019, hail and heavy rainfall were observed in a wide area including the observational sites. Form the X-band Multi-Parameter radar observation, thunder clouds had developed with the height of 10 km or more near the observational site at around the time of hail was observed. The electrostatic field measurement detected frequent lightning around the peak of hail events and the electrostatic field fluctuations due to developing/approaching of the thunder clouds. At the meeting, we will discuss the relationship between atmospheric electrostatic field variations and thundercloud development processes more detail.

This study was supported by TMU Strategic Research Fund (President Selected) of Tokyo Metropolitan University and Japan Science and Technology Agency (JST) and Japan International Cooperation Agency (JICA) under SATREPS.

Relation between Lightning Activities Measured by the V-POTEKA Network and Intensity Development of Western North Pacific Typhoons

*Mitsuteru Sato[1], Loren Joy Estrebillo[1], Yukihiro Takahashi[1], Hisayuki Kubota[1], Shunsuke Niwa[1], Glenn Vincent Lopez[2], Joel Marciano[2]

1. Department of Cosmoscience, Hokkaido University, 2. ASTI, DOST

Lightning activity is a good proxy representing the precipitation and updraft intensities in thunderclouds. Recent studies suggest that the monitoring of the lightning activities has a high potential to predict the maximum wind speed and minimum sea-level pressure of the tropical cyclone by one or two days before, though the prediction error of typhoon intensities by the recent meteorological model is getting worse in the past 30 years. Many countries in the western north Pacific region suffer from the attack of tropical cyclone (typhoon) and have a strong demand to predict the intensity development of typhoons by means of a cost-effective way. Thus, we have developed a new automatic lightning observation system (V-POTEKA) and installed this system in the Philippines, Guam, Palau, Jakarta, Okinawa, and Sapporo since September 2017. Using the V-POTEKA data, lightning locations are estimated by using the time-of-arrival geolocation software. We have compared the relation between the lightning activities measured by the V-POTEKA network and the intensity variation of the western north Pacific typhoons in 2018 and 2019. In 2018 and 2019, a total of 29 and typhoons occurred, respectively. As for the 2018 typhoons, we selected 11 of 29 typhoon events and conducted cross-correlation analysis between lightning activities and typhoon intensities. We confirmed that the time variations of the detected lightning event numbers and typhoon intensities (maximum wind speed and center pressure) are highly correlated. Especially, there is clear time lag (~1.5 days) between lightning activities and typhoon intensities in the category 1-3 typhoons, that is, the peak of lightning activity comes first, then the peak of the typhoon intensity comes next. However, as for the super typhoons (category 5 typhoons), this relation is not always clear. At the presentation, we will also show the detailed results derived from this cross-correlation analysis between lightning activities and intensity development of the 2019 typhoons.

[M-TT48] Cryoseismology - A new proxy for detecting surface environmental variations of the Earth -

convener:Masaki Kanao(National Institute of Polar Research), Seiji Tsuboi(JAMSTEC, Center for Earth Information Science and Technology), Genti Toyokuni(Research Center for Prediction of Earthquakes and Volcanic Eruptions, Graduate School of Science, Tohoku University), Yoshihiro Hiramatsu(School of Geosciences and Civil Engineering, College of Science and Engineering, Kanazawa University)

In high latitude and elevation regions, the Earth's glaciers, ice sheets, sea ice, permafrost, and snowpacks are undergoing rapid change. Fortunately, many of the cryospheric processes of interest produce ground vibrations. Analysis of these seismic signals can yield insight into the relationship between environmental forcing and the response of ocean-cryosphere-solid earth system.
Ice-related seismic motions for small magnitude events are generally named ice-quakes and can be generated by glacially related dynamics. Such kinds of cryoseismic sources are classified into the movements of ice sheets, sea-ice, oceanic tide-cracks, icebergs and the calving fronts of ice caps. Cryoseismic waves are likely to be influenced by variations in environmental conditions, and the continuous study of their time-space variability provides indirect evidence of climate change. As glacial earthquakes are the most prominent phenomena found recently in polar regions particularly around Greenland, the new innovative studies from seismology are expected by long-term monitoring under extreme conditions in the Earth's environment.
Taking these issues into account, the conveners are willing to invite many contributions to a special session on "Cryoseismology", which cover recent topics on glacial related seismic events and associated phenomenon. It is particularly encouraged to have contributions based on seismic signals involving the dynamics of ice sheets, sea-ice, icebergs and glaciers. Although the glacial earthquakes are the most prominent evidence found recently in polar regions, all related topics involving polar seismology are welcome, such as studies of crust and mantle structure, comparison of tectonic and glacier-related seismicity, recent triggered earthquakes and active volcanoes, glacial isostatic adjustment (GIA), harmonic tremor associated with cryoseismic events.

The Greenland Ice Sheet (GrIS) is a huge storehouse of water on Earth, and has the potential to raise the global sea level by approximately 7 m if completely melted. Although researchers have been mainly studying the GrIS surface snowmelt as a response to climate warming, recent progress in ice-core drilling, remote sensing, and theoretical analyses has turned a spotlight on its basal conditions. However, the traditional observation techniques, such as ice-core drilling and ice-penetrating radar, provide only discontinuous information in both time and space.

Seismic observation is now drawing widespread attention as an alternative method for monitoring the GrIS. The Greenland Ice Sheet Monitoring Network (GLISN), an international project between 11 countries that began in 2009, now provides broadband, continuous, and real-time seismic data from 35 stations in and around Greenland. Japan is a partner country from when the GLISN project was launched, and has been sending an expedition team every year since 2011. In 2011, a joint USA and Japanese GLISN team installed the dual seismic–GPS station ICESG-GLS2 in the middle of the GrIS. During 2012–2018, we conducted maintenance of three stations on the GrIS (station codes: ICESG-GLS2, DY2G-GLS1, and NEEM-GLS3), and three stations on bedrock in coastal areas (NUUK, DBG, and SOEG). We had succeeded in real-time transmission of broad-band and continuous seismic waveform data from the three ice stations. It was the first time in the world that the seismic data with such a high sampling rate are transferred from the ice sheet. The data is now open to public and available from the IRIS Data Management Center (http://www.iris.edu/ds/nodes/dmc/). This presentation will summarize our field activities for 2011–2019, and introduce the future field plans.

Acknowledgments: The Japanese GLISN team has been supported by research grants from JSPS (24403006, 18K03794).

Estimation of seismic source location around East Ongul Island, East Antarctica, by using two seismic arrays

*Manami Nakamoto[1], Masaki Kanao[2]

1. Association for the Development of Earthquake Prediction, 2. National Institute of Polar Research

In the polar region, various vibration phenomena are exited in association with physical interactions between the solid earth, atmosphere, ocean, and cryosphere systems. These phenomena can be observed as seismic and infrasonic waves, and the relationship between their occurrence and environmental variations was pointed out in the Lützow-Holm Bay region, East Antarctica (e.g., Murayama et al. 2017; Tanaka et al. 2019). To monitor environmental changes, it is important to reveal their characteristics and generation processes. Although several seismic and infrasound stations have been deployed in and around East Ongul Island, East Antarctica, it is not sufficient to detect small seismic events such as local icequakes and tremors because of the sparsity of the stations in the existing seismic network. One of the useful methods for estimating source locations is the array analysis, which uses data obtained by a dense seismic network. Hence, we carried out a special experiment using two seismic arrays in East Ongul Island during the summer of 2017-2018. These two arrays consisted of seven three-component seismometers and six vertical seismometers, respectively, with a spacing of about 100m. First, we picked 93 short-duration seismic events based on the short-term-average to long-term-average (STA/LTA) ratio from continuous waveforms with a high signal-to-noise ratio (SNR). Contamination caused by strong winds, as well as long-duration signals from the ice-breaker ship and helicopters, were carefully filtered out. Then, we estimated the direction of arrival of these signals by applying semblance analysis. As a result, we found that some of their epicenters existed around East Ongul Island. These events can be considered as icequakes because the sea-ice condition around the Lützow-Holm Bay had been changing dramatically during the observation period. We further investigate the relationship between these signals and the sea-ice distribution in this area.

Progress in Cryoseismology –A review of Japanese contribution -

*Masaki Kanao[1]

1. National Institute of Polar Research

Majority areas of Antarctica and Greenland are under the thick ice sheet and characterized by evolving cryosphere surroundings. In the polar region, associated with the recent trend on climate change such as global warming, glacier relating earthquakes are increasing during this 21st century. In this paper, a decade of progress in “Cryoseismology” at bi-polar regions will be demonstrated by focusing on the contribution from Japanese researches. In particular, specific cryoseismic events are treated, which occurred in the coastal area of East Antarctica, around the Lutzow-Holm Bay, together with the coast and whole inland area of Greenland. Harmonically frequency-overtone signals are explained by a constant source, suggesting inter-glacial asperities that generate characteristic cryoseismic tremors.

Characteristic multi-sphere interaction in the coastal and marine environment inferred from infrasound observation at Terra Nova Bay, Antarctica

*Takahiko Murayama[1], Masaki Kanao[2]

1. Japan Weather Association, 2. National Institute of Polar Research

Characteristic features of infrasound waves observed in the Antarctic reveal physical interaction involving surface environments around the continent and Southern Ocean. An infrasound array (100 m spacing) by using three sensors (Chaparral Physics Model 25, with a detectable frequency range of 0.1-200 Hz), together with a broadband barometer (Digiquartz Nano-Resolution Model 6000-16B Barometer, with a detectable frequency range of 0-22 Hz) were installed at Jang Bogo Staion, Tera Nova Bay, West Antarctica in December 2015 by the Korea Arctic and Antarctic Research Program (KAARP). The initial data recorded by the broadband barometer include several signals originated surrounding surface environment, in addition to the local wind noises such as katabatic signals. Clear signals from background oceanic origin (the "microbaroms") are continuously recorded at the austral summer on mid-December with predominant frequency around 5 s. Variations of their frequency context and strength appeared in Power Spectral Density are affected by evolution of the sea-ice surrounding the Tera Nova Bay.

[M-TT49] GEOSCIENTIFIC APPLICATIONS OF HIGH-DEFINITION TOPOGRAPHY AND GEOPHYSICAL DATA IN THE ANTHROPOCENE

convener:Yuichi S. Hayakawa(Faculty of Environmental Earth Science, Hokkaido University), Shigekazu Kusumoto(Graduate School of Science and Engineering for Research, University of Toyama), Christopher A Gomez(Kobe University Faculty of Maritime Sciences Volcanic Risk at Sea Research Group)

Recent technical developments have enabled us to acquire high-definition topographic and geophysical data for geoscientific research, including land surface processes, subsurface structures, submarine and aerial environments, and geo-ecological interactions. Such high-definition or high-resolution data are particularly useful for studies on relatively short-term, i.e., decadal to millennial time scales, and for future predictions using numerical modelings. In this session, we expect submissions on topics challenging the issues in the Anthropocene, the most recent geological era of the Earth considerably affected by human activities. A range of topics would fit the session framework, such as theoretical works, improvements in the data acquisition, extensive data preservation and archiving, pre- and post-processing, statistical analysis, physical modeling, and numerical simulation for any kind of geoscientific research in the Anthropocene. The methodological approaches may include, but not limited to, laser scanning, SfM-MVS photogrammetry, GNSS precise positioning, SAR interferometry, multi-beam sonar, ground-penetrating radar, geomagnetic and electromagnetic sensors, based on terrestrial (fixed or mobile) and aerial (UAV or manned airborne) platforms.

A Study of Slope Displacement Monitoring with PSInSAR Technique

*Chin-jen Lin[1], Shen Yu Hsiao[1]

1. National Chung Hsing University

This research is aimed at slope displacement monitoring on Taiwan mountainous areas in 2019 using Persistent Scatterer Interferometric Synthetic Aperture Radar (PSInSAR) technique. The radar satellite images used in this study are from Sentinel-1 mission developed by the European Space Agency (ESA). The software for data processing is based on Stanford Method for Persistent Scatterers (StaMPS). The surface displacement of each observation ground point is computed by six satellite images with different observation times. The weather and atmosphere conditions affecting observations are precisely corrected in the procedure of data processing. The results from PSInSAR will be well compared to those from the optical images and the GPS stations. With this research, the slope activities on Taiwan mountainous areas can be monitored. This research also can provide effective information on disaster risk assessment.

Monitoring Soil Erosion Changes by SBAS-InSAR Technology

*Yu-Chi Hsieh[1], Shen Yu Hsiao[1]

1. National Chung Hsing University

This study uses the Synthetic Aperture Radar (InSAR) technique to analyze the soil erosion mass changes in the past 7 years at four major reservoir areas in Taiwan. Four major reservoirs include Shimen, Tseng-Wen, Techi, and Nanhua reservoirs where are averagely distributed in northern, central, and southern Taiwan. The method for deriving soil erosion changes is based on Small Baseline Set Algorithm (SBAS). The radar satellite data used in this study is from the missions of Sentinel and ALOS PALSAR. The software for data processing is GMTSAR. The changes of the soil erosion monitored by SBAS-InSAR will be mutually verified with those measured by the erosion pins. It is expected that with this study, the erosion degree of the slopes of the four reservoir areas can be accurately calculated to provide important references in the fields of hydraulic engineering, and soil and water conservation.

Spatiotemporal analysis of topography and vegetation in check dams using RTK-UAV and SfM-MVS photogrammetry

*Masato Hayamizu[1], Yasutaka Nakata[1], Satoshi Hasui[1], Hajime Sato[1], Yu Nagasaka[1], Akiko Nagasaka[1]

1. Hokkaido Research Organization Forestry Research Institute

In the world mountain and forest streams, the construction of soil erosion control dams (also called check dams or Chisan-dams; hereinafter called “Chisan-dam”) has been widely applied to stabilize the sediment movement of the river basin. Despite the number of constructed Chisan-dam more than 35000 in Hokkaido (Tamate & Hayajiri 2008), there are few reports of quantitative evaluation of whether the topography changed as planned or how the forest vegetation changed after the establishment. Therefore, it is needed to conduct an efficient survey of many Chisan-dams and assess whether the topography and vegetation are changing as planned.

Unmanned Aerial Vehicle (UAV) photogrammetry and structure-from-motion multi-view stereo (SfM-MVS) photogrammetry are widely applied due to the advantage of obtaining Digital Surface Model (DSM) at relatively low cost. Whereas, the accuracy of the model varies because it is difficult to set Ground Control Points (GCPs) uniformly such as small forest basin. In October 2018, the DJI Phantom 4 RTK unmanned aerial vehicle (RTK-UAV) was launched with direct integration of the Real Time Kinematic - Global Navigation Satellite System (RTK-GNSS). The aerial images of RTK-UAV records highly accurate position information via RTK-GNSS, and it is possible to acquire high-precision DSM without installing GCPs even in forest areas with many undulations and obstruction (Nakata et al. in press).

The aim of this study was to measure the change of longitudinal gradient before and after the construction of a Chisan-dam constructed in 1985. After restoring the vertical slope before construction from the design drawing of 1985, a vertical survey using a total station was conducted at the same site in August 2019. In addition, we verified the possibility of construction of a high-resolution DSM model without GCPs using the RTK-UAV.

As a field survey using total station, the riverbed 34 years after the Chisan-dam construction was equal to the height of the sedimentary surface, and it was achieved the planned gradient. On the other hand, the riverbed below the Chisan-dam was scoured by about 1 m more than before its construction. Result of investigating the flight conditions of the RTK-UAV, a DSM model with a resolution of 2.67 cm / pix was constructed without using GCP. In the presentation, the validity of the RTK-UAV survey will be discussed by comparing the data obtained from the field survey with the data extracted from the DSM.

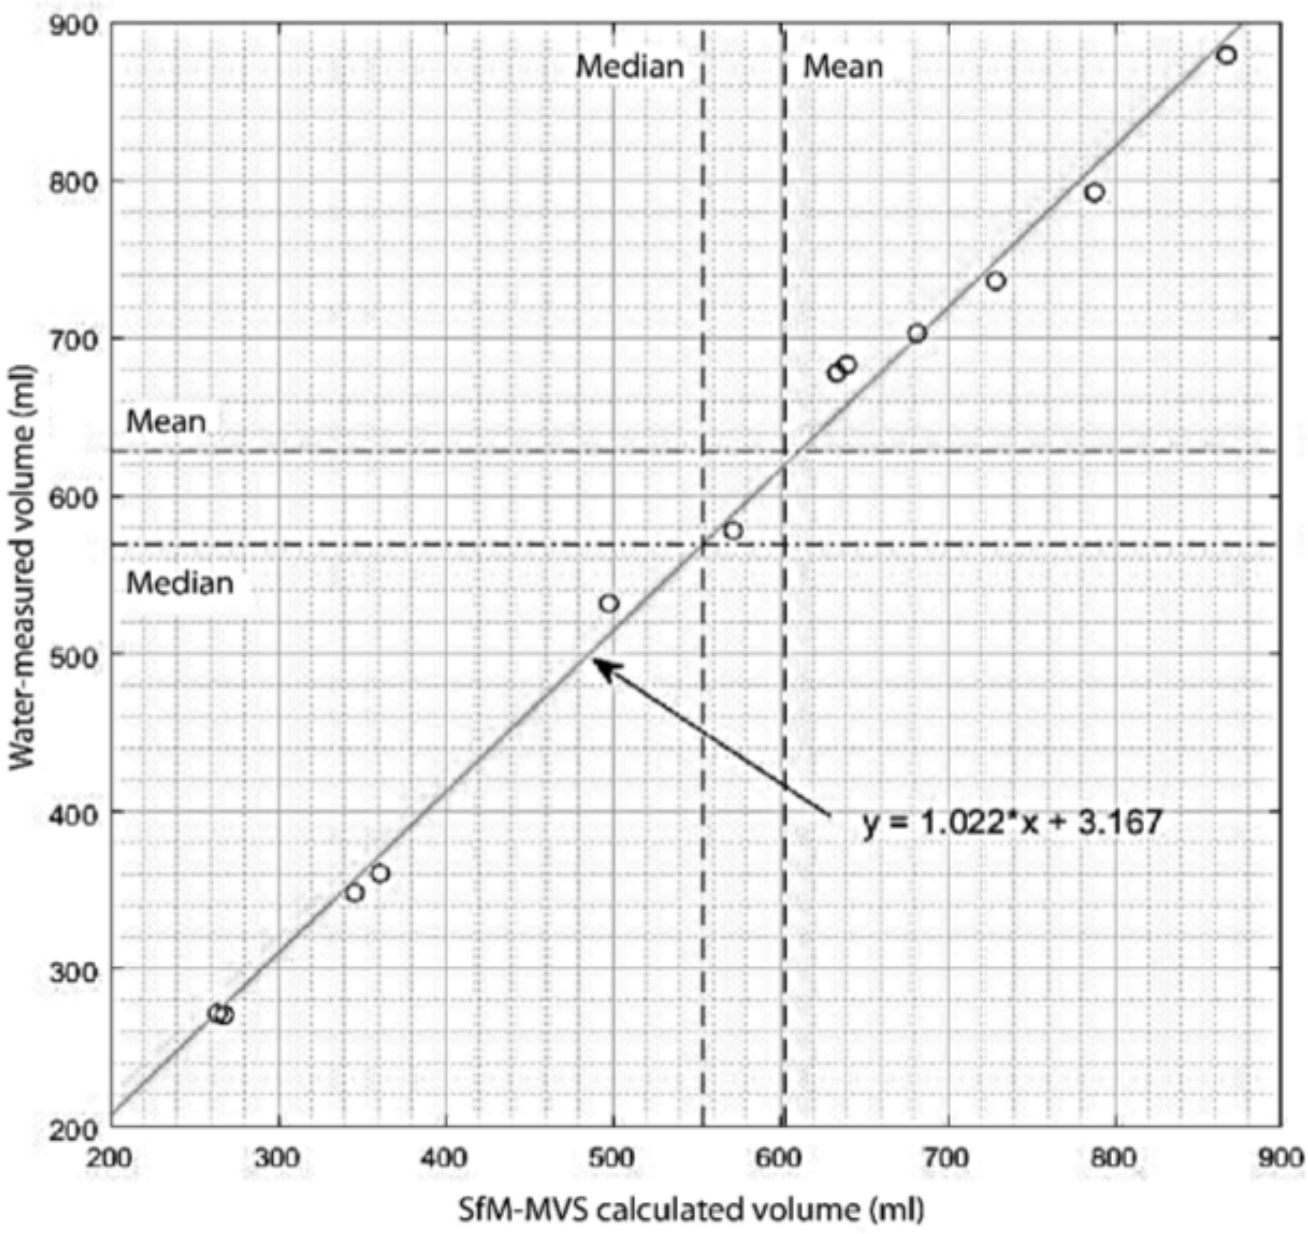
A new method to measure in situ soil density using SfM-MVS photogrammetry



*Christopher A Gomez[1]

1. Kobe University Faculty of Maritime Sciences Volcanic Risk at Sea Research Group

The measure of soil density in the field has been relying traditionally on the sand-cone method, the balloon method or the radioactive method. All those methods require heavy equipment, are not appropriate for non-horizontal surfaces, and do not provide control over the methodological error in the field, that is very site-dependent.
To solve this issue, the author has developed a new (or adapted other methods from different fields) method to measure the soil density using photogrammetry based on SfM-MVS, so that the method can be used in irregular soils that are coarse grains, and with limited equipment transported in the field. Furthermore, the method the author proposes can be used along outcrops vertically and on horizontal surfaces, whereas a perfectly horizontal surface was necessary up to present.
Results show good agreement between the water-measured hole volume and the SfM-MVS data, with the best linear fit correlation line of y=1.022*x+3.167, where x is the SfM-MVS calculation and y represents the water measurement. The water-measures are thus slightly higher than the volumes calculated using SfM-MVS. The RMSE of the upper 50% of the data is ~5 and the lower 50% displays an RMSE of 2.6 (about half of the top 50%). The author interpreted this result as being a function of the small crannies that are filled with water and that can’ t be calculated from SfM-MVS, which had a millimeter-scale infra-millimeter (after software calculation). Therefore the discrepancy between the two datasets can be potentially linked to the size of the surface of the hole walls and the roughness of the grains.
The photogrammetric-based method to measure field density proves to be a reliable method with a control on the potential error (error control from the photogrammetric method), providing a more reliable method of field density measure and calculation. At present, the author is preparing further result presentation with full-scale field data, showing the usability and reducing the weight of the equipment carried in the field.

Frequent acquisition of topographic data for a wide area is fundamental for studies on volcanoes because volcanic activities often cause changes in topography, and other properties, including gravitational anomalies, needs to be calibrated based on the topographic data. Airborne laser scanning (ALS) by a crewed aircraft is a standardized approach to acquire topographic data in a wide area, but its high cost limits its frequent applications. Measurements using an unmanned aerial vehicle (UAV)-based structure-from-motion (SfM) photogrammetry is becoming more popular in recent years for geoscientific studies, but its accuracy is often found to be relatively low particularly if ground control points (GCPs) are unable to be set in the areas of interest. However, the use of low-accuracy data can still be beneficial for some specific research purposes such as geomorphological mapping and gravity mapping. To validate the usefulness of low-accuracy data, we compare ALS-derived and UAV-SfM-derived topographic data of the island of the Taal volcano in the Philippines. Although the UAV-based data shows significant inaccuracies and errors, the data can be instantly obtained at a low cost and is found to be enough for a rough geomorphological mapping and calibration of gravitational data for the wide area. Further assessments and compilation of acceptable resolution and accuracy of various topographic data are encouraged.

[M-TT50] Distributed Fiber Optic Sensing for Geophysical Applications

convener:Matthew Becker(California State University Long Beach), Xiangfang Zeng(Institute of Geodesy and Geophysics, Chinese Academy of Sciences), Ziqiu Xue(Research Institute of Innovative Tech for the Earth), Herbert F Wang(University of Wisconsin Madison)

Distributed fiber optic sensing has generated tremendous excitement with applications including seismology, seismic imaging, hydrology, petroleum development, carbon dioxide sequestration, and geothermal energy. Distributed Temperature Sensing (DTS) became widely accessible about a decade ago. DTS can measure temperature along a fiber optic cable at sub-meter intervals, over distances of kilometers, and at sampling frequencies of 0.1 Hz or less. Distributed Acoustic Sensing (DAS) is a more nascent technology that is only now being tested for geophysical applications. DAS can acquire dynamic strain at sub-meter intervals, over distances of kilometers, and at sampling frequencies of 100 kHz or less. Both technologies can use standard telecommunication fiber optic cables for measurement. DAS, for example, has been used to sense earthquake movements in unused (dark) buried fiber optic communication networks. We invite presentations that discuss novel applications of distributed fiber optic sensing, interpretation of results of monitoring, and advancements in processing of data streams. This session will bring together practitioners from many disciplines to discuss opportunities, share experience, and suggest solutions to technical challenges.

1. Silixa Ltd.

Over the past decade, distributed acoustic sensing (DAS) has evolved from a novel to established tool in the earth sciences with still ever-expanding applications. The adoption of DAS for geophysical investigations has been facilitated by advanced optoelectronic architectures with amplitude and phase coherent, broadband measurement capability over a few tens of kilometers. The development of high precision engineered sensing fiber and associated DAS systems has allowed DAS system noise for an individual sensing channel to match that of point sensors. The inherent capabilities of DAS for monitoring and characterization of earth processes have generated an increasing level of interest in retrofitting DAS to existing optical fiber infrastructure to create vast terrestrial sensing arrays. A suite of methods has been recently developed that further expand sensor range and coverage, offering a significant capability and economic improvement for both retrofit and new infrastructure installations. The application of range extending methods for interrogation of dark fiber networks is discussed. Based on these developments, the next few years are expected to mark an era of rapidly expanding adoption of DAS, with exciting opportunities and challenges on the horizon for maximizing value from spatially and temporally expansive data.

Lessons learned from dark fiber distributed arrays in a large urban campus

*Dante Fratta[1], Herbert F Wang[1], Neal Lord[1], Shreeshrita Patnaik[1], Agatha Podrasky[2], Alexander Malamet[1], Paul Barford[1]

1. University of Wisconsin Madison, 2. Silixa Ltd.

We have deployed a distributed acoustic sensing (DAS) array using dark fiber across the urban campus of the University of Wisconsin-Madison. During two weeks, a Silixa iDAS interrogator was used to target campus traffic, railway activity, commercial movements across busy thoroughfares, sporting events, and a carillon concert. These events were captured on the DAS array and used to assess the performance of dark fiber for the deployment in city-wide and regional monitoring systems. This deployment faced challenges related to the mapping of the cable, the coupling of the optic fiber to conduits and near-surface ground, and multiple sources from different locations acting simultaneously. The lessons learned from these studies can be used to develop a better sensing array and make greater use of existing communication infrastructure.

Combining DAS and air-gun: a cost-effective medium change monitoring system

*Xiangfang Zeng[1], Baoshan Wang[2], Jun Yang[3], Yuansheng Zhang[4], Zhenghong Song[2,1], Xiaobin Li[4], Rongbin Lin[1], Manzhong Qin[4], Congxin Wei[4]

1. State Key Laboratory of Geodesy and Earth's Dynamics, Innovation Academy for Precision Measurement Science and Technology, Chinese Academy of Sciences, 2. School of Earth and Space Sciences, University of Science and Technology of China, 3. Earthquake Agency of Yunnan Province, 4. Earthquake Agency of Gansu Province

The large-volume air-gun systems have been installed in serval water reservoirs to excite high similar signal. The air-gun signal can be detected up to 150 km that make it possible to monitor medium change at large scale. The deployment cost of monitoring system can be significantly reduced with the low-cost DAS system. Two DAS air-gun experiments were conducted at two sites with different settings. A telecommunication fiber-optic cable in urban area was used in the first experiment. After stacking, the air-gun signal emerges on the 30-km DAS array at about 9 km epicentral distance. A 5-km cable was deployed starting from the air-gun source to about 2 km away. About 800-m cable was frozen into the ice above the air-gun and provided clear single-shot signals. The rest cable was lay on the road and the part across a fault is cemented. On the stacking multiple shots' records, the wavefield in fault zone emerges too. These two experiments demonstrate the feasibility of using various fiber-optic cables as dense array to acquire air-gun signal in different environments.

DAS Research Coordination Network in Geosciences and Engineering

*Herbert F Wang[1], Robert Woodward[3], Robert Detrich[3], Scott Tyler[2]

1. University of Wisconsin Madison, 2. University of Nevada, Reno, 3. Incorporated Research Inst Seismology

A DAS Research Coordination Network (RCN) is being formed under a National Science Foundataion award to advance the applications of Distributed Acoustic Sensing (DAS) in geosciences and engineering. The RCN will also strive to bring together DAS researchers and users from a diverse international base of research organizations, industry, technology companies, and government agencies to exploit synergies and enhance efficient utilization of resources in DAS development and applications. The RCN activities will be focused around multi-day workshops and short courses, and topical webinars. Working Groups will be formed in major areas of DAS applications, data management, and technology. Guidance and direction for the community activities will be by the principal investigators and a multidisciplinary steering committee. Early-career scientists and graduate students are the target audience for activities.

Distributed Acoustic Sensing (DAS) as a Distributed Hydraulic Sensor

*Matthew Becker[1], Thomas I Coleman[2], Christopher Ciervo[1]

1. California State University Long Beach, Long Beach California, 2. Silixa LLC, Houston, USA

Distributed Acoustic Sensing (DAS) instruments were originally intended to measure oscillatory strain (vibration) at frequencies of 1 Hertz or more. Recently, the ability to measure much lower frequencies has opened the possibility of using DAS as a strain sensor in boreholes. A fiber optic cable that is mechanically coupled to a geologic formation will strain in response to hydraulic stresses in pores and fractures. Because DAS measures dynamic strain along the entire length of a fiber optic cable, it is capable of both locating hydraulically active features and quantifying the hydraulic stress in the formation. We present field experiments in which a fiber optic cable was mechanically coupled to a crystalline rock borehole. The formation was stressed hydraulically at a second well using alternating injection and pumping. The DAS instrument measured oscillating strain at the location of a fracture zone known to be hydraulically active. The experiment was repeated in two wells using multiple periods of hydraulic stressing. Nanostrain was measured in response to head changes as small as 2 mm of water. These results suggest that fiber optic cable embedded in geologic formations may be used to map hydraulic connections in three dimensions. A great advantage of this approach is that strain and, therefore, hydraulic stress can be measured without beforehand knowledge of the fracture network. The technology has obvious applications in oil and gas, geothermal energy, and remediation of groundwater in fractured bedrock.

[M-ZZ53] Availability of earth science data in renewable energy field

convener:Hideaki Ohtake(National Institute of Advanced Industrial Science and Technology), Fumichika Uno(Nihon University, College of Humanities and Sciences), Teruhisa Shimada(Graduate School of Science and Technology, Hirosaki University), Daisuke Nohara(Central Research Institute of Electric Power Industry)

Renewable energy penetration is increasing dramatically in the world. Renewable energy power generations have become a strong presence in grid operations. However, it is a challenge for renewable energy to be stable power sources due in part to natural variability of renewable energy and its uneven distribution. For effective use of renewable energy, a combinational use of various power resources and energy storage technologies (e.g., pumped-storage power generation, storage battery system, electric vehicles) should be desired. Therefore, we need to understand the amount of renewable resources, causes of variation, and the predictability of power output. Then, observation and forecast information from earth science field should be analyzed and applied to power energy field to achieve easy use of earth science databases.
 Recently, observation databases from remote sensing technology and/or forecasts from numerical models have become essential for both renewable energy and electric power system fields. Impacts of both earth science data and optimization are essential to economic evaluation of grid operations.
This proposed session needs your presentation from the whole of renewable energy fields (such as, wind power, solar power, geothermal power, tidal power, wave power and biomass power generations). Our goal of this session is to exchange views with various researchers between renewable energy field and earth science field (e.g., usage-trends of earth science datasets for renewable energy field, earth science datasets availability, integrated studies, renewable energy resources in future climate system, and a request from renewable energy field to earth science field).
The proposed session features contribution of general interest within earth sciences community.

Promising geothermal resource exploration areas in the vicinity of the Iwaki Volcano include the area around Dake and Hyakuzawa. Since 2011, three geothermal resource exploration drillings have been conducted around the Dake area. However, no promising geothermal power site has been found. Therefore, this study attempts to identify signs of such a site from the Br/Cl ratio of river, spring, and hot spring water samples collected from various locations around the entire area of the Iwaki Volcano.

We used 10 spring water, 18 stream water, and 27 hot spring water (Onsen) samples. We analyzed sample for Li^{+}, Na^{+}, NH_4^{+}, K^{+}, Mg^{2+}, Ca^{2+}, F^{-}, Cl^{-}, Br^{-}, NO_3^{-}, SO_4^{2-}, Fe, Mn, Sr, Ba, B, Si, alkalinity, $\delta^{18}O$, and δD.

The analysis of Br/Cl in the hot spring water samples using the Cl vs. Br concentration diagram from Angcoy and Arnórsson (2015) revealed that they were relatively clearly divided into having seawater or magmatic (geothermal signature) origins. From the Br/Cl ratio of the hot spring water samples, it was determined that any geothermal signature in the river and spring waters would be detected by the Br/Cl ratio of those samples.

The results of the analysis of the Br/Cl ratio of these river and spring water samples indicated that they were not magmatic in origin with the exception of two rivers flowing around the Dake and Hyakuzawa areas. However, hot spring water flows into these. Thus, no promising geothermal resource exploration areas were found outside the Dake and Hyakuzawa areas.

Machine learning based prediction of solar power generation by utilizing all-sky camera

*Masataka Imai[1], Toru Kouyama[1], Hideaki Ohtake[1], Takashi Oozeki[1], Mitsuteru Sato[2]

1. National Institute of Advanced Industrial Science and Technology, 2. Hokkaido University

In recent years, the installed capacity of the global solar photovoltaic (PV) represents exceeds 500 GW and that meets 2.6% of world electricity demand at the end of 2018 (the new 2019 Edition of the IEA PVPS report: 2019 Snapshot of Global PV Markets). Because of the awareness of climate change rises, increasing the renewable energy sources must be crucial and solar PV is regarded as the largest component of the renewable energy source. The cost of solar panels continues to decline, and the growth of PV is expected to continue as their strongest increase in five years.

The long-term average power output of solar PV is well characterized by diurnal and seasonal changes in solar insolation. However, short-term (minutes and hours) PV output is much harder to predict due to meteorological volatility, especially cloud coverage. At the current stage, the electric demands still depend on the other sources (e.g. fossil fuels). Therefore, it is desired to control the production and distribution of electricity more efficiently (smart grid), and the precise prediction of solar PV power generation is one of the important tasks to minimize the waste of other resources and to establish the efficient energy system as well as increasing the total capacity of solar PV. The state-of-the-art short-term predictions of PV output are poor, with a root mean square error (RMSE) of order 200–400 W m^{-2} for ~10 minute level predictions in partly cloudy conditions. Recently, the machine learning technique becomes popular prediction methods for the solar PV power generation. Several studies utilized all-sky images to predict the power generation assessing images correlate with contemporaneous PV output. One of the issues to develop such kind of machine-based prediction model is preparing the dataset. Ideally, the all-sky camera should be installed at the close place of PV panels located, and the data was collected for several years considering the seasonal weather change.

In this study, we used over 5 years of all-sky images obtained at Nayoro Observatory, Faculty of Science, Hokkaido University. Solar irradiance and other meteorological measurements (e.g. temperature, humidity, wind speed and direction, and precipitation) are recorded every 1 minute at the same time of image acquisition. We developed a multi-layered 3D convolutional network model with fully connected layers, where we input five sequent images with reduced size of 100 x 100 pixels and tested to predict solar irradiance at the next time step (1 minute later). Our model can predict the solar irradiance within the RMSE of 10% when the weather is fine. As for the partially cloudy condition, our model results showed spiky variations of the irradiance Although the absolute precision is worse in such sky condition, large variability in the solar irradiance (PV power generation) could be predicted by our model. In order to increase the total performance of our model we now developing other RNN (Recurrent Neural Network) based model to enable to learn the temporal feature in the sequent sky condition change. Additionally, we are preparing additional input information of other weather information. In this presentation, we will demonstrate our latest results for predicting the solar power generation by utilizing the all-sky images obtained at an astronomical observatory.

Probabilistic Wind Power Prediction Based on Ensemble Weather Forecasting

*Daisuke Nohara[1], Masamichi Ohba[1], Takeshi Watanabe[1], Shinji Kadokura[1]

1. Central Research Institute of Electric Power Industry

Despite the growing popularity of renewable (e.g., wind and solar) energy usage, the volatility of the corresponding sources, partially due to the natural variability of weather conditions, hinders their further commercialization and necessitates the development of cost-effective and easily implementable predictive models such as those simulating power generation. Despite the recent increase in the accuracy of numerical weather prediction models, most of them still face problems such as the poor predictability of wind ramp event intensity, location, and timing, which can be addressed through the use of probabilistic modeling. Herein, we present a probabilistic wind power prediction method based on a numerical weather prediction model, using a power curve empirically estimated from the relationship between area-averaged wind speed and area-integrated wind power generation to project wind power and accounting for the inherent uncertainty associated with the above curve. The established probabilistic prediction method exhibits high statistical consistency and reliably captures the confidence interval of wind power variability, thus being well suited for ramp event prediction.

Improvement of prediction of wind power generation output for an area and its sub-area by using monitoring data

*Shinji Kadokura[1], Daisuke Nohara[1], Masamichi Ohba[1], Atsushi Hashimoto[1], Hiromaru Hirakuchi[1]

1. Central Research Institute of Electric Power Industry

Introduction of power generation by renewable energy such as photovoltaics(PV) and wind power (WT) is worldwidely progressing. Since PV and WT power generation are markedly fluctuated due to the change of the wheather, there is concern about the stability of the electric power system. Therefore, we have been developing a prediction method of wind power generation output to contribute for the stabilization of electric power system.
In this method, the numerical forecast value provided by the Japan Meteorological Agency is downscaled using the weather model WRF and CFD model to predict the wind speed at the wind turbine, and the power output is predicted using the power curve. By adding the generated power output for each wind turbine obtained, the total output of the area is obtained.
In this study, we evaluated the accuracy by simulating the power generation output for each sub-area divided into eight in the Tohoku area and the total. It was confirmed that the accuracy was improved by performing the correction using the relationship between the past observational and prediction power generation output data. However, when the correction is performed on the basis of the observational data of the wind speed and the power output of each windmill, it is suggested that the accuracy is further improved, therefoe the more detailed measurement is still important.

Detectability of large forecast error on surface solar radiation using grand ensemble method considering atmospheric circulation patterns

*Fumichika Uno[1,4], Mio Matsueda[2], Takashi Oozeki[3], Hideaki Ohtake[3,4], Yoshinori Yamada[4]

1. Atmoshere and Ocean Research Institute, The University of Tokyo, 2. University of Tsukuba, 3. National Institute of Advanced Industrial Science and Technology, 4. Japan Meteorological Agency, Meteorological Research Institute

Forecasting of surface solar radiation (SSR) using numerical weather prediction (NWP) models usually use at several hours to several days forecast. Large forecast errors (forecast busts) for SSR and therefore photovoltaic power generation may lead to either a shortage of power supply or production of excessive surplus power. This study assessed the hit rate and false alarm rate of forecast busts event using lognormal ensemble spread (standard deviation of ensemble forecast). This study used the lognormal ensemble spread on the four NWP centers (Japan Meteorological Agency: JMA, European Centre for Medium-Range Weather Forecasts: ECMWF, National Centers for Environmental Prediction: NCEP, United Kingdom Met Office: UKMO). Also, we evaluated the a multi-center grand ensemble (MCGE), which calculated weighted average of the esemble forecast on 4 NWP center.
The study period is January 2014 to May 2017 in five winter months (January, February, May, November, December), and forecast lead time is from 24 to 144 hour every 24hours. The forecast busts were defined as the top 5, 10, 15, 20 absolute forecast error. The atmospheric circulation patterns are categorized Winter monsoon (WM), Winter Pacific (WP), High Pressure (HP), Low Pressure (LP), Southerly Flow (SF) using 500hPa height. As the results, the proposed method in this study indicate higher detectability of forecast bust than the non-categorized detection (previous study) method. The values of Youden index improved of considering the flow patterns. Moreover, the improvement assessed by the false alarm rate under perfect hit rate (FPR) was indicated in all cases. The FPR is smallest when top 5% forecast busts cases, The FPRs of MCEG in 6 forecast lead time are 0.52, 0.44, 0.50, 0.44, 0.41, 0.53 respectively. The improvement not only the detection method using MCGE but also the method using single NWP center ensemble forecast.

[M-ZZ54] Communicating Hazard and Risk: What do we know about how to make this information understandable?

convener:Danijel Schorlemmer(GFZ German Research Centre for Geosciences), Alexandra Freeman(Winton Centre for Risk and Evidence Communication, University of Cambridge), Sarah Dryhurst(University of Cambridge), Naoshi Hirata(National Research Institute for Earth Science and Disaster Resilience)

There is no point modelling hazards and risks if that information is of no use to decision makers (at individual and policy levels including the scientific community, the public, governmental institutions, engineers, policy makers, emergency and resilience managers). We therefore have to ensure that we are providing the information focusing on the needs of these stakeholders, in a format and time frame that is of use to them, minimizing the possibility of misunderstanding or misperception.

In this session we aim at addressing the problems surrounding communicating hazard and risk of natural catastrophes. Important questions include: who are the key stakeholders for each kind of information? What information does each require? How do we balance the trade-off between restricting the information provided to improve comprehension versus the ethics of withholding information? How do we approach the boundary between providing information and providing advice? How do we communicate the different uncertainties (both epistemic and aleatory)? What can be learned about the communication of geospatially- and temporally-dynamic data from other fields (such as meteorology, military defence etc.) and how should we communicate in ongoing crises, in particular during unexpected changes in the development of catastrophic events? How do we ensure our communications are trustworthy? What are the metrics of success in such communications?

We will be considering all time frames and stages of hazard assessment from long-term maps and planning to emergency warning and rapid loss assessment when an event occurs. This includes all possible communication channels (e.g. scientific publications, public or press announcements, social networks, TV, radio, newsletters) and/or content types (e.g. text, video, graphics).

We solicit contributions from all fields with the aim of bringing together a variety of researchers to share their experiences from their respective fields.

An Integrated GIS and Big Data Platform for Meteorological Disaster Risk Management and its Application

*YING LI[1]

1. Beijing Climate Center

Under the background of global changes, the frequency and intensity of various meteorological disasters are increasing, which poses a great challenge to the risk management worldwide. The Sendai Framework was put forward by the third world conference on disaster reduction, providing a roadmap for the international community to respond to disaster risks. In recent years, China has stepped up its implementation of disaster risk reduction actions, but there has been no systematic platform to supply professional services of meteorological disaster risk reduction for decision makers. In order to effectively reduce the risk of meteorological disasters and meet the urgent need in service, Beijing Climate Center of China developed a Meteorological disaster risk management platform (MDRMP), which integrates the technology of big data management, scientific achievements transformation and spatiotemporal multidimensional visualization, under a unified highly intensified framework. Through three years of hard work, MDRMP was initially built and has been put into operation, providing professional services for decision makers and other stakeholders with realtime disaster monitoring, early warning, impact analysis and risk assessment. The main functions of MDRIMP include hazard identification, risk prediction, risk regionalization, warning service, information inquiry, online analysis, etc.

MDRMP contains four subsystems, namely, Big Data Application Center, Model and Algorithm Center, Online Analysis Center and Operation Center. Big Data Application Center include 12 major categories, more than 600 million various pieces of information. Based on the Cloud-terminal and GIS technology, the multisource and heterogeneous data is jointed in horizontal direction and correlated in vertical direction with its spatial attributes, forming the core database of the whole system. Model and Algorithm Center integrated more than 100 models of the algorithm related to disaster risk analysis. The algorithm library realizes the unified scheduling, management and real-time monitoring through registration, classification and execution monitoring technologies. MDRMP has already been applied nationwide based on a Cloud terminal, and support unified access, personalized configuration and service customization of users in provinces, cities and counties in China. This paper provides an overview, functions and the current status of the MDRMP. It will also describe how services are made available to the end user via various channels in addition to the productions of MDRMP in routine operations.

Emergency flood detection using multiple information: Integrated analysis of natural hazard monitoring and social media data

*Kikuko Shoyama[1]

1. National Research Institute for Earth Science and Disaster Resilience

Nowadays the extreme weather events occur more frequently due to climate change. In October of 2019, the eastern japan was hit by a large and high-speed typhoon, Hagibis (no.19). This unprecedented typhoon caused the evacuation of 237 thousand people, the casualties of over 300 people, and the house damage of over 94,000 households throughout the affected area. Flood is one of the most devastating natural disasters thus providing effective early warning is critical to reducing disaster impacts as preparing for such extreme weather events. Current warning against rainfall-induced disasters is issued based on the rainfall threshold, which varies depending on the disaster type. For example, the amount of 1.5 hours-effective rainfall and the river water level have been used as relevant criteria for flood hazards. However, warning based on only natural hazard monitoring is not enough to detect areas subject to disaster. Integrated analysis natural hazard monitoring and social media data could improve the warning system to enhance awareness for disaster managers and citizens about the emergency event. We analyzed time-series data including rainfall, effective rainfall, river water level monitoring data, and Twitter data relating to disaster events during 5 days from 11 to 15 October, focusing on the most affected area around the watershed of Abukuma-river and Chikuma river in Japan. The analysis using 47,520 tweet samples revealed that spatial and temporal resolution and extent of these monitoring data influence to detect the emerging change and spatial deviation relate to the flood events. Thus, the design of monitoring system should meet the criteria for emergency detection.

Global Dynamic Exposure and the OpenBuildingMap - Communicating Risk and Involving Communities

*Danijel Schorlemmer[1], Naoshi Hirata[2], Kuo-Fong Ma[3], Karsten Prehn[1], Cecilia Nievas[1], Thomas Beutin[1], Fabrice Cotton[1], Max Wyss[4]

Earthquake-Disaster & Risk Evaluation and Management (E-DREaM) Center, National Central University, Taiwan, 4. International Centre for Earth Simulation Foundation, Geneva, Switzerland

The substantial reduction of disaster risk and live losses, a major goal of the Sendai Framework by the United Nations Office for Disaster Risk Reduction (UNISDR) requires a clear understanding of the dynamics of the built environment and how it affects, in case of natural disasters, the life of communities, represented by local governments and individuals. These dynamics are best understood and captured by local communities, following two of the guiding principles UNISDR formulated: "empowerment of local authorities and communities" and "engagement from all of society". Moreover, communities that participate in risk assessments increase their understanding of efficient risk mitigation measures.

Our Global Dynamic Exposure model and its technical infrastructure build on the involvement of communities in a citizen-science approach. We are employing a crowd-sourced exposure capturing based on OpenStreetMap (OSM), an ideal foundation with already more than 375 million building footprints (growing daily by ~150,000), and a plethora of information about school, hospital, and other critical facilities. We are harvesting this dataset with our OpenBuildingMap system by processing the information associated with every building in near-real-time. We are enriching this dataset in a truly big-data approach by including built-up area detection from remote sensing with satellite and radar imagery combined with different sources of road networks, as well as various open datasets and aggregated exposure models that provide relevant additional information on buildings and land use. With this approach, we increase the resolution of existing exposure models from aggregated exposure information to building-by-building vulnerability. Additionally, we include available open datasets to further improve our indicator assessment.

We expect the quality of near-real-time estimates of the extent of natural disasters to increase by an order of magnitude, based on the data we are collecting. We envision authorities and first responders greatly benefitting form maps pinpointing the greatest trouble spots in disasters and from detailed quantitative estimates of the likely damage and human losses. With our tools, interested communities can capture their exposure and analyze how natural disaster may affect them. It helps communicating risks down to the community level and helps educating community members in the risks they are facing, how they can mitigate risks, and how they can prevent losses of lives.

Tokyo Metropolitan Resilience Project, from CSR to CSV

*Takashi Furuya[1], Keiko Tamura[2], Danijel Schorlemmer[3], Naoshi Hirata[1]

The Tokyo metropolitan area will likely be hit in the future by a major earthquake of magnitude 7 or larger. Such an earthquake will create a serious disaster due to the extraordinary exposure and a population of more than 35M. To reduce potential losses, it is necessary to improve the disaster resilience of Tokyo, its building stock, economy and society. For this purpose, in April 2017 the “Tokyo Metropolitan Resilience Project” started to integrate multi-disciplinary research of social sciences, seismology, and earthquake engineering. Furthermore, to improve disaster management capabilities, we founded a Data Use and Application Council for Resilience (named DEKATSU) among four Japan-wide sectors; industry, government, NPO/NGOs, and academia. They are intended to collaborate to contribute improved resilience capabilities, currently mainly in the Tokyo metropolitan area by following the strategy of holding public symposia, organizing private thematic panels, and implementing data disclosure policies. We develop activities from CSR(Corporate Social Responsibility) to CSV(Creating Shared Value).

DEKATSU has members from 53 private companies, 3 municipalities, 9 NPO/NGOs (as of 11 February, 2020). Eight thematic panels*, consisting of the consortium members with common interests and issues, were established within DEKATSU. "Academics" is providing research results for solving problems of companies and organizations in the field of disaster/disaster prevention techniques and measures. "Industries" is providing information and data. "Government" is providing guidance, regulation, and information. "NPO/NGOs" is providing information about local needs and connecting the consortium to the public.

The National Research Institute for Earth Science and Disaster Resilience (NIED), Japan, is the core institute of the project. And we aim to gather and consolidate data effective for the overall business continuity and disaster response capabilities of government and private sector, as well as for disaster resilience activities of individuals.
